Alternating Current Electrolysis

Results of Further Experiments on the Generation of Explosive Gases in Electrical Heating Equipment of the Water-Resistor Type

J. W. Shipley,
Assistant Professor of Chemistry, University of Manitoba, Winnipeg, Manitoba,
and
Chas. F. Goodeve,
Research Student in Chemistry, University of Manitoba, Winnipeg, Manitoba.

Paper to be presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Quebec, Que., February 15th to 17th, 1927

It was observed, early in the history of electrochemistry, that an alternating current, when passed by means of electrodes through an electrolyte, would, under certain conditions, decompose the water and under other conditions cause no visible decomposition. The dangers of experimentation were complained of by De la Rive as early as 1837. In all cases the gases produced, (hydrogen and oxygen), were less than that required by Faraday's law. Attention was drawn to this by Maneuvrier and Chappuis[1], who give empirical laws drawn from their observations. These laws led to the theoretical considerations of Mengarini[2] and Malagoli[3], to whom further reference will be made. The work of Hopkinson, Wilson and Lydall[4] and of Marsh[5] on certain phases of the subject are also of importance.

The comparatively new application of electric power in which it is transformed into heat by passing, by means of iron electrodes, an alternating current directly through natural water, has brought up again the subject of electrolysis by alternating currents. The recent experimental work of Shipley and Blackie[6] has shown conclusively that the products of electrolysis are found in electric heaters of the water-resistor type. An extensive series of experiments was begun some time ago in the chemical laboratory of the University of Manitoba to determine the factors which affect the decomposition of water by alternating currents, with the object in view of discovering what conditions, if any, would reduce the production of explosive gases to a minimum or completely eliminate them.

Preliminary Experiments

In order to arrive at the underlying principles, experiments were first performed with platinum electrodes. The apparatus used was a miniature heating system, in which the electrodes were rectangular pieces of platinum foil of dimensions 1 by 2.5 by 0.0063 centimetre, and the electrolyte was tap water. At currents below 0.2 amperes no gas was evolved, but above this current evolution took place, at first on the sharp corners, and at higher currents along the edges of the electrodes. Only at currents of 3 or 4 amperes was gas evolved from the flat surfaces. The gases were found to contain two volumes of hydrogen to one volume of oxygen mixed with a little air.

Similarly, miniature heaters using carbon electrodes and circular rods of iron gave large quantities of gas from the exposed edges or ends. In the case of carbon, the gases produced contained a quantity of carbon dioxide as well as hydrogen.

The Importance of Current Density

If one draws or imagines the equipotential surfaces about electrodes immersed in a uniform conducting medium, it is readily seen that the current density will be greatest on any projecting points or edges. The sharper the projecting point or edge the greater will be the current density on this point or edge, and it may amount to many hundred times that on the flat surface. The exact value of this local current density may be obtained with difficulty by complicated integrations, but will undoubtedly be found to be related to the curvature. The greater the curvature the greater the current density, and the current density will be

a minimum when the curvature is zero, that is, on a flat surface.

This variation of current density has been totally neglected by early experimenters, and but briefly mentioned by Marsh (loc. cit.). The preliminary experiments of this research, having shown that gas is first produced at the places of high current density, showed also that no progress could be made without a design of electrode in which the current density is as nearly as possible uniform over the surface. Current density is the primary factor in the production of gas by alternating current electrolysis. In the remainder of this paper all references will be to current density in amperes per square centimetre.

Methods of Obtaining Uniform Current Density

The theoretical method of obtaining uniform current density would be to use two perfect spheres, separated by a distance, great as compared with their diameters, the boundary of the conducting liquid being also at a distance from the spheres, which is great as compared with their diameters. This, of course, is not practical.

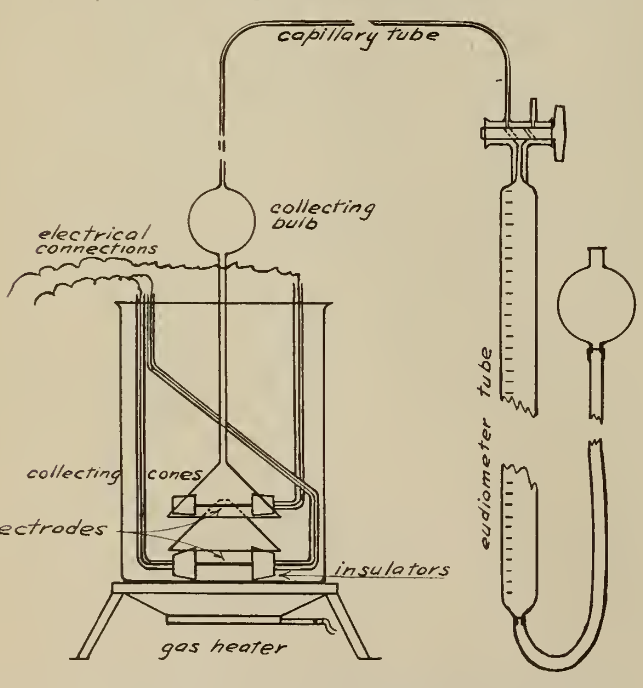

Figure No. 2.—Apparatus for Determining Rate of Electrolysis by Alternating Currents, showing Electrodes and Gas Collecting Apparatus. The Temperature Controlling Apparatus is not Included in the Diagram.

A second method which was tried with some success was to use two circular discs fitting tightly into the ends of a glass cylinder. The electrodes were parallel and the current density was shown to be fairly uniform by the uniform evolution of gas over the surface. The difficulty of taking care of the heat developed makes this arrangement generally impracticable and its experimental usefulness was limited.

The final method by which, as was shown later in the research, a current density of a high degree of uniformity was obtained, was as follows:—

Shielded Electrodes to Obtain Uniform Current Density

The cause of the high current density on projecting points is, that from such points the current may travel through a larger body of liquid, and therefore by this path the resistance will be less. It does not matter in which direction the point is, for the current will pass through all possible paths from one electrode to the other. Equipotential surfaces will be closer together, and closer to the point than they will be on the flat surface. It therefore occurred to the authors to shield the ends of the electrodes to make the resistance in all directions equal.

A combination of the two above theoretical methods was designed in which two identical cylindrical rods or tube electrodes were projected from one flat insulator to another, separated by a distance, great as compared with their diameter. The cylinders were of a convenient diameter, and were parallel to one another. The insulating plates were also parallel and their boundaries were at a great distance, as compared with the diameter of the electrodes. No part of the electrodes except that between the insulating plates was in contact with the liquid. This design is shown in figure No. 1-b.

Thus the equipotential surfaces were nearly concentric cylinders, as shown in the figure. A cross-section of these is shown in figure No. 1-c.

The position of the equipotential surfaces about the electrodes with one insulating plate removed is shown in figure No. 1-a. The current at any point varies inversely as the distance to the nearest equipotential surface.

Proof of the uniformity of current density, using this type of electrode, was obtained in later experiments. It was found that the rate of corrosion of the electrode was roughly proportional to the current density. When one part of the rod electrodes for some reason corroded away more than other parts, the current density was increased on this narrower part, causing greater corrosion and eventually cutting it in two. In the experiments, the results of which are given in this paper, the corrosion was uniform, and in one case the electrode, although 86 per cent corroded away, did not vary in diameter more than two-thousandths of a centimetre over its entire surface.

In the latter part of this research the above method of obtaining uniform current density was slightly varied by placing the electrodes between separate pairs of insulators, as shown in figure No. 2. The electrodes were placed further apart and observations were made on each separately.

Experiments at Low-Current Densities

The apparatus used was again in its essentials a miniature hot water heating system. The electrode chamber was a glass bulb and contained six electrodes of mild steel, (carbon content, 0.174 per cent), the exposed length of each was 9 centimetres, and the diameter was 0.68 centimetre. The ends of the electrodes were protected by a large rubber stopper at the top and bottom. A suitable inlet and outlet for the water were provided. The electrodes were connected to a distributing board, by which any combination could be connected through the ammeters and resistances to the switchboard.

Above the electrode chamber was placed a specially-designed gas trap by which the water was rotated, forcing

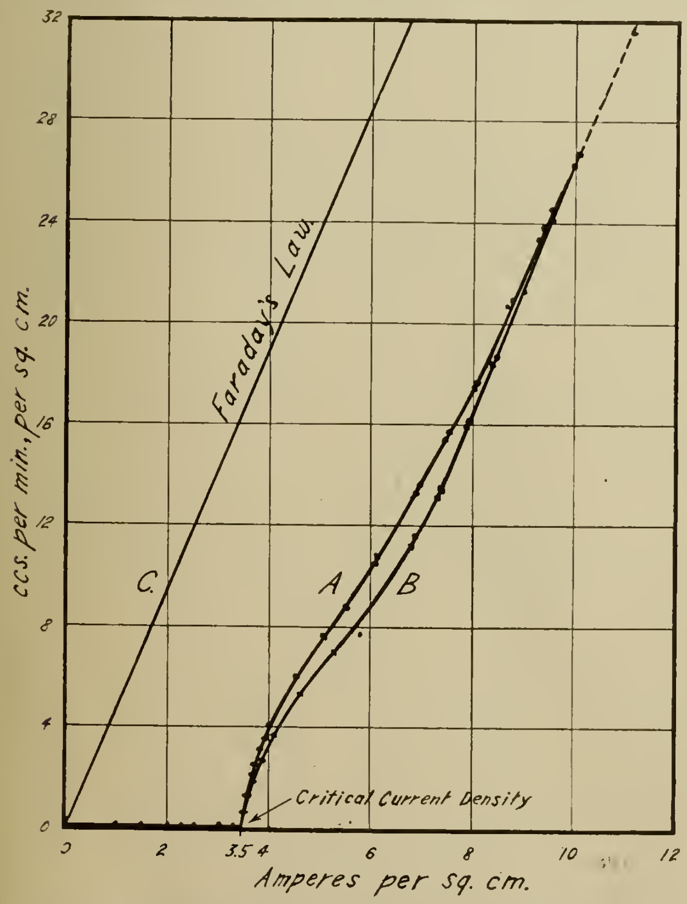

Figure No. 3.—Relation of Rate of Generation of Electrolytic Gases to Current Density. The Change in the Rate Agrees with Faraday's Law above the Critical Current Density.

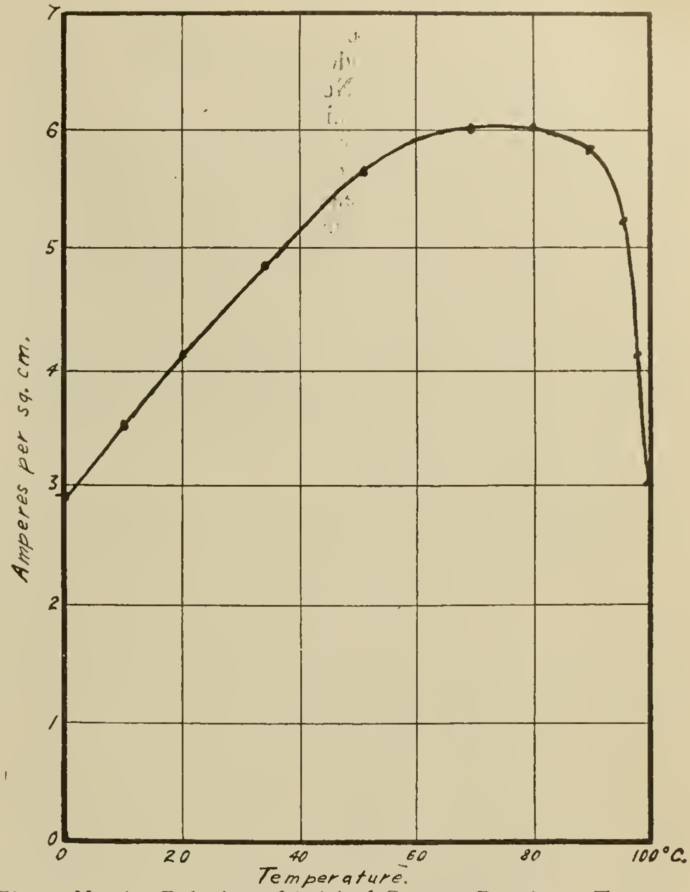

Figure No. 4.—Relation of Critical Current Density to Temperature at Atmospheric Pressure and with Iron Electrodes.

the gas away from the water outlet to the collecting apparatus. The remainder of the apparatus consisted of controlled cooling jackets, reservoir, thermometers, etc. To prevent accidents due to a possible explosion, a control was designed to cut off the circuit if the electrolyte did not completely fill the electrode chamber, or if the reservoir level varied to a dangerous extent. The gases that collected were analyzed for hydrogen by the copper oxide method to an accuracy of one-tenth of one per cent.

Using a dilute solution of sodium hydroxide, (approximately 0.005 normal), as electrolyte and operating at the boiling point, readings were taken at gradually-increasing current densities. The fresh electrodes with a polished surface produced traces of electrolytic gases for a few minutes, but the electrodes darkened and the evolution of gas ceased. Fifteen readings were taken, each being for an average period of twenty hours at current densities starting from 0.037 amperes per square centimetre and taken at intervals of approximately 0.01 amperes current density. The highest value was 0.2 amperes current density. The gases that collected were residues from the steam *and in no case was hydrogen detected.* The analyses averaged about 90 per cent nitrogen and 10 per cent oxygen. This is evidently due to air having been brought into the system and part of the oxygen having been combined with the iron.

These experiments indicate that an electric boiler can operate under the conditions given above at a current density of 0.2 amperes per square centimetre, (1.3 amperes per square inch), without producing explosive gases.

Experiments at Higher Current Densities

The above apparatus, although capable of high accuracy in collecting gases, had a limited range of current densities, and the temperature, an important factor in the production of gas, was difficult to control. An apparatus was developed in which the electrodes were on separate pairs of insulators, as shown in figure No. 2.

A four-litre beaker contained the electrolyte. The gases, when evolved, were collected by a pair of cones and a bulb, and were drawn off into a eudiometer tube situated at some distance from the heater. The temperature was controlled by a mercury thermostat control operating electric relays, which, in turn, controlled the water supply from a constant pressure reservoir to a copper cooling coil in the electrolyte. The reservoir was replaced by an ice-brine bath for low-temperature experiments. A motor stirrer kept the whole at a constant temperature. Auxiliary gas and electric heaters were fitted. Certain accessories, such as thermometers, ammeters, resistances, etc., were included. The design had the advantage of allowing ready removal of the electrodes for examination.

A series of experiments was again carried out, at the boiling point, in which the current density was raised in successive readings from 0.2 amperes per square centimetre to 2.0 amperes, (13.0 amperes per square inch). The same mild steel was used for the electrodes. In no case was hydrogen detected in the residual gas. The last experiment of this series operated for a period of twenty hours at a current density of 2.0, without the production of electrolytic gases. The electrodes became black.

On raising the current density to 2.5 the first traces of hydrogen were discovered. The rate of evolution, which was very low, increased slowly up to a current density of 3.5, above which it rose rapidly. The gases produced were violently explosive, and on analysis they were found to contain, by volume, two parts of hydrogen to one part of oxygen. At a current density of 5.0 and above, arcing took place and the current became irregular. The highest value was 7.0 amperes per square centimetre, at which the rate

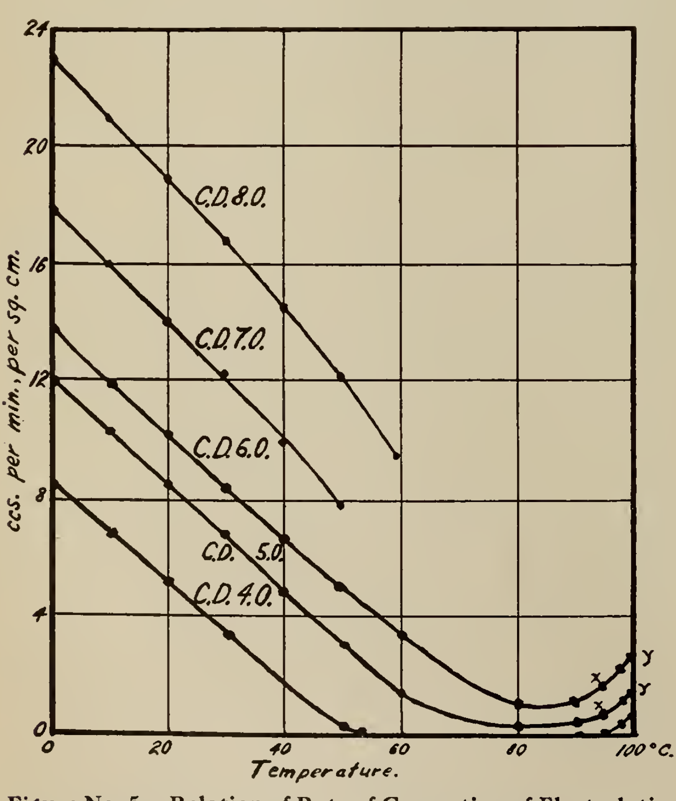

Figure No. 5.—Relation of Rate of Generation of Electrolytic Gases to Temperature, with Iron Electrodes.

was 6.8 cubic centimetres of electrolytic gas per minute per square centimetre of electrode surface. This measurement was made from one electrode only.

Critical Current Density

The existence of a "critical current density," below which no decomposition takes place and above which there is rapid decomposition, has been definitely established in the course of this research. Over thirty series of experiments of from ten to fifty observations in each, using steel electrodes under varying conditions, gave a value of current density above which electrolytic decomposition suddenly commences. In the preliminary experiments, in which the current density was not uniform, the critical point was gradual, while in later experiments its position could be found to one-tenth of an ampere. This position was found to vary as conditions were varied, such as corrosion, temperature, etc. These factors will be discussed presently.

Twelve series of experiments, similar to the above, indicated a very definite critical current density with platinum electrodes. The position of the critical current density for platinum was lower than iron and depended on such factors as temperature and coating of the electrodes.

Experiments at Lower Temperatures

Operating at a temperature of 30° Centigrade, the current density was successively increased from zero to 10.0 amperes per square centimetre. Piano wire steel was used for the electrodes and half-normal sodium hydroxide for the electrolyte. No decomposition took place until a current density of 3.5 was reached. The rate at which electrolytic gases were produced from one electrode in cubic centimetres per minute per square centimetre, corrected to standard conditions, is shown, plotted against the current density by the curves *A* and *B*, (taken under the same conditions but at different times), in figure No. 3. Readings were taken at half-ampere intervals above a current density of 4.0 and at one-tenth-ampere intervals near the critical point, and each reading was verified by three to four duplicates. These duplicates are not shown in the graph.

Similar curves were obtained at different temperatures and different states of corrosion. These were of the same slope as *A* and *B*, but were displaced to one side or the other.

Relation of A. C. Electrolysis to Faraday's Law

One ampere of direct current in one minute would produce, in accordance with Faraday's Law, 10.4 cubic centimetres of electrolytic gas at standard conditions. As the ammeter reading of an alternating current is 1.11 times the average current for each wave, and as the average current is the electrochemical current, one ampere of alternating current should theoretically produce 9.42 cubic centimetres per minute. One electrode should produce 4.71 cubic centimetres of electrolytic gas per minute. This is shown by curve *C* in figure No. 3.

It was found that above the critical point an increase of one ampere increased the rate of gas production by 4.71 cubic centimetres per minute, within the limits of experimental error. (There is a small discrepancy close to the critical point.) This is shown in the graph by the curves *A*, *B* and *C*, the upper part of A and B having the same slope as that of C. *Above the critical current density alternating current electrolysis follows the law of direct current electrolysis, provided that the critical current density is subtracted from the current density used.* When the critical current density is reached, all the current above that point generated electrolytic gases, which are freed from the electrode. This law for alternating current electrolysis was developed from over one thousand observations on the rate of gas production with iron and platinum electrodes.

Influence of Temperature on Critical Current Density

The initial point at which gas is evolved was determined over the range of temperature 0°C to 100°C. It was found that the critical point rose rapidly to a maximum at about 80°C and fell off to a value of 3.0 amperes at the boiling point. This is shown in figure No. 4.

The rise in the first part of this curve indicates that gas was first evolved at a continuously-increasing current density, as the temperature was raised. On the formation of steam on the electrodes the critical current density was lowered, the extent of the lowering increasing with the increase of steam formation. The rise is due, we believe, to an increase in the velocity of the secondary reactions with a rise in temperature. The catalytic activity of the surface, which, it seems probable, is largely responsible for the secondary reactions, evidently increases with the temperature. Further reference to these secondary reactions will be made later. The formation of steam on the electrodes probably has a washing effect whereby recombination is partly prevented by the removal of some of the products of electrolysis. The part played by temperature in this phenomenon is being further investigated.

All of the experiments of this research were carried out at atmospheric pressure. Increasing the pressure would increase the temperature at which boiling takes place, and the drop in the curve would take place near the new boiling point.

Other Factors Which Affect Critical Current Density

Fresh metallic electrodes produce gas at a lower current density than corroded electrodes. The extent of the corrosion is very important. At constant temperature moderately corroded electrodes gave a critical point at 3.5 amperes per square centimetre, whereas heavily corroded electrodes were found to produce no decomposition at a current density of as high as 9.5 amperes. It is to be remembered in this connection that the current densities given are the apparent current densities. No allowance can be made for pitting of the electrodes, which would thereby increase the actual surface. Apparent current density is all that is necessary for practical considerations.

No marked difference in the position of the critical current density was observed when the electrolyte was prepared from an acid or a salt. The corrosion of the iron in the normal salt solution and the acid solution was much greater than in the sodium hydroxide solution. Alkaline solutions have thus a practical advantage.

Mild steel was found to have normally a higher value for its critical current density than hard steel, such as piano wire. This will be investigated further. The critical current density using platinum electrodes was very sharp at 0.75 amperes per square centimetre at 30°C.

Effect of Temperature on the Rate of Electrolysis

Typical curves for steel electrodes, in which the rates of evolution of gas at constant current densities are plotted against the temperature, are shown in figure No. 5. Numerous curves representing different states of corrosion to that of those shown were obtained. They were all of the same form, but were above and below the position of those in the figure. The rate drops rapidly with rising temperature to a minimum at 80°C and rises again at the boiling point. These curves are related to the critical current density curves by the relation to Faraday's Law given above.

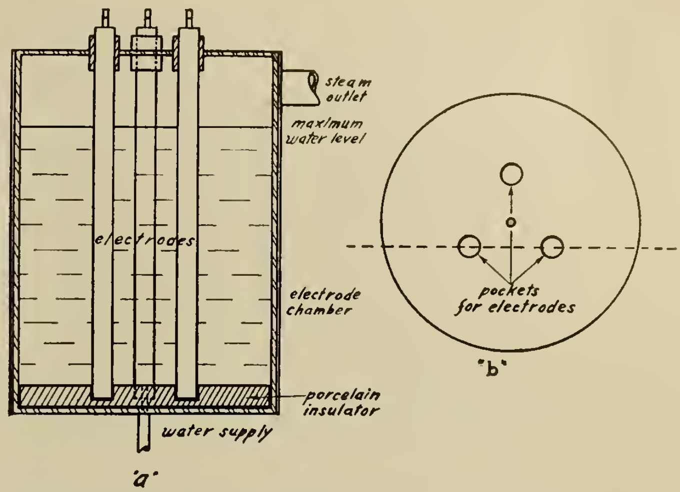

Figure No. 6.—Proposed Design (1) of Electrode Chamber in Electric Boilers for the Prevention of Generation of Explosive Gases. (a) Cross-Section of Insulator and Boiler. (b) Insulating Plate.

Effect of Arcing

Arcing took place to some considerable extent at high current densities and temperatures, and was associated with vigorous boiling. A slight increase in the rate occurred along with the arcing, but this increase was no greater than the normal increase at the boiling point without arcing. In figure No. 5 the parts of the curves for current densities 5.0 and 6.0 marked "*xy*" indicate where arcing took place. The rise in these parts is no greater than the rise in the curve below, in which there was no arcing.

A large number of experiments were performed in which arcing took place, and in no case was it found that arcing made any appreciable difference in the rate of electrolysis. Actual observations showed a decided drop in the rate with arcing, but when the rate was corrected for the change in area due to steam coating, (calculated from the change of resistance), the curve shows the normal rise.

These results are not in agreement with the statement made by Kaelin and Matheson[7], who assume that no decomposition takes place except thermal decomposition in arcs on the electrode surface.

Other Factors Affecting the Rate of Electrolysis

All of the above experiments were carried out using 60-cycle alternating current. The effect of changing the frequency has been experimented with by Maneuvrier and Chappuis, (loc. cit.), who found that increasing the frequency decreases the rate of gas formation. The relation is not simple.

Our experiments were carried out at voltages below 110. Electrostatic effects and an increase in arcing might be expected at high voltages. Whether these factors have any appreciable effect or not on the evolution of gas is being investigated.

Theoretical Considerations

Before proceeding with the theoretical considerations, it must be understood that the primary question is, "Why does an alternating current not bring about electrolysis according to Faraday's Law?" An alternating current is only a series of equal and opposite direct currents each of which must liberate its equivalent of electrolytic gases according to Faraday's Law. Why, then, does not the sum

7. F. T. Kaelin and H. W. Matheson, Eng. Jour. IX, No. 2, p. 198, 1926.

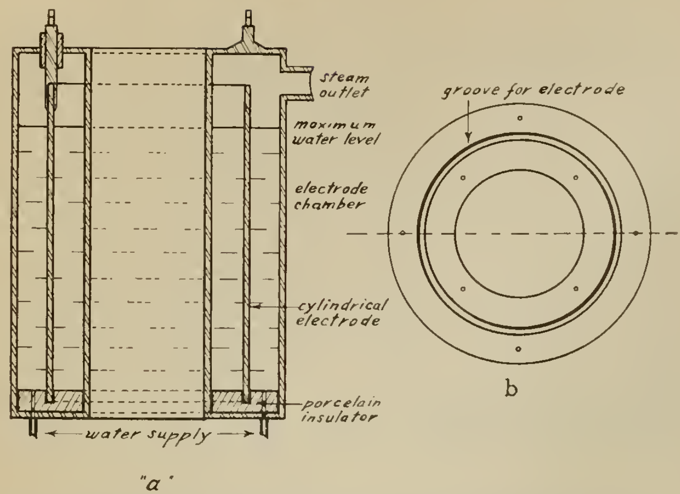

Figure No. 7.—Proposed Design (2) of Electrode Chamber in Electric Boilers for the Prevention of Generation of Explosive Gases. (a) Cross-section of Insulator and Boiler. (b) Insulating Ring.

total also obey the law? The answer probably lies in secondary reactions which remove all or part of the electrolytic products by recombining them to form water. The extent of these secondary reactions determines the critical current density. The surface of the electrode plays an important part in these secondary reactions by storing up part or all of the products from the second half of one half-wave to allow them to react with the products of the first half of the second half-wave. Catalytic action is undoubtedly involved. The capacity of the electrodes is limited, and if the current is such that the individual quarter-wave produces more gas than can be stored the excess will be liberated.

If other variables, such as frequency, temperature, etc., are constant this "electrolytic capacity,"[8] as it may be called, is constant over the range of current densities used in the experiments of this research. This accounts for the constant difference between the rate of alternating current electrolysis and direct current electrolysis, as shown in figure No. 3.

Malagoli, (loc. cit.), made an important contribution to the theory of alternating current electrolysis, in which he treated the subject with mathematical precision, but gave no experimental evidence in support of his equations.

Practical Considerations

The first principle to be observed in preventing alternating current electrolysis is the obtaining of uniform current densities. Pipe or rod electrodes with exposed, rounded ends, as at present used, will produce high current densities on these ends. The current density used commercially in steam-producing electric boilers is about 0.75 amperes per square inch, as calculated on the assumption of uniform current density. Above this density, decomposition of the electrolyte becomes serious. From the above experimental work, it is seen that electrodes producing steam can be operated at a current density of 13 amperes per square inch without decomposition of the electrolyte, which density is some distance from the critical point of 19 amperes per square inch. Such a high current density as 13 is impracticable due to difficulties in handling the steam, but the present-day boiler can be made safe and its heating capacity increased to a considerable extent if the electrode chamber is designed to obtain as far as practicable the conditions of uniform current density.

Two suggested designs of such electrode chambers are shown in figures Nos. 6 and 7. In one the three electrodes are placed symmetrically and vertically in a metallic cylindrical tank, as shown in figure No. 6. No special arrangement at the top is necessary as long as the water level remains below the steam outlet. The essential feature is the large porcelain insulator at the bottom. This is a circular plate which fits the bottom of the chamber with three shallow pockets for the ends of the electrodes, (figure No. 6-b). No great thickness of the porcelain is necessary, as there is no strain upon it. A hole is provided through the centre of the porcelain and the electrode chamber for the water supply. The above arrangement with electrodes of two inches diameter, separated from one another and the walls of the chamber by ten inches, gives a high uniformity of current density.

Concentric cylinders might also be employed, as shown by figure No. 7. In this design the electrode chamber is built from two cylindrical walls and acts as one electrode. The other cylindrical electrode is inside. The porcelain insulator is a flat ring with a circular groove, as shown in figure No. 7-b. Numerous small holes give access to the water supply. This design is advantageous because of its compactness, but is limited in this form to single-phase current. A shamrock group of three such chambers, or an arrangement of three cylindrical and concentric cylinders in the same way as above is adaptable to three-phase current. In the second case the diameters of the cylinders would be such as to equalize the load. The limitation of the compactness of such a design would not be in the current density but in the handling of the steam. This is a problem for the electrical heating engineer.

Summary

(*1.*) The primary factor in alternating current electrolysis is current density.

(*2.*) For a given set of conditions, i.e., frequency, temperature, pressure, voltage and electrolyte, there is a critical current density for the electrode, below which no gas is evolved.

(*3.*) Above the critical current density gas is evolved per square centimetre according to Faraday's Law, provided that the critical current density is subtracted from the current density used. In other words, when the critical current density is reached, all the current above that point generates electrolytic gases, which are given off from the electrode.

(*4.*) The critical current density with iron electrodes varies with temperature, rising from 0°C to about 80°C and falling to the boiling point.

(*5.*) The rate of gas evolution with iron electrodes likewise varies with temperature, falling from 0°C to about 80°C and rising to the boiling point.

(*6.*) Arcing in itself makes no appreciable difference in voltages below 110.

(*7.*) The generation of explosive gases in the water-resistor type of electric heater can be prevented by a design of electrode chamber that would secure and retain under operating conditions uniform current density.

(*8.*) The current density in such a heater can be considerably increased over present usage without danger of the generation of explosive gases.

The research is being continued under a financial grant from the National Research Council of Canada.

8. "Electrolytic capacity," as used here, is measured, as distinct from electrostatic capacity or polarization capacity, in coulombs.

Rack Structure and Penstock Intake of the Isle Maligne Hydro-Electric Power Station

Features of Design and Construction of the Rack Structure and Penstock Intake of the Plant of the Duke-Price Power Company, Ltd., at Isle Maligne, on the Saguenay River

W. S. Lee, M.E.I.C.
Consulting Engineer, New York, N.Y.

Paper to be presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Quebec, Que., February 15th to 17th, 1927

The Isle Maligne station is a typical design in which the power house and water intakes are made part of the dam or impounding structure located as far downstream as possible so as to obtain the maximum possible head for the development.

This type of design is economical for heads between 60 and 120 feet, since it enables the designer to lay out short waterways, thereby reducing the friction losses and obtaining better regulating conditions for the turbines. In addition, it permits a downward sloping of the top of the water-

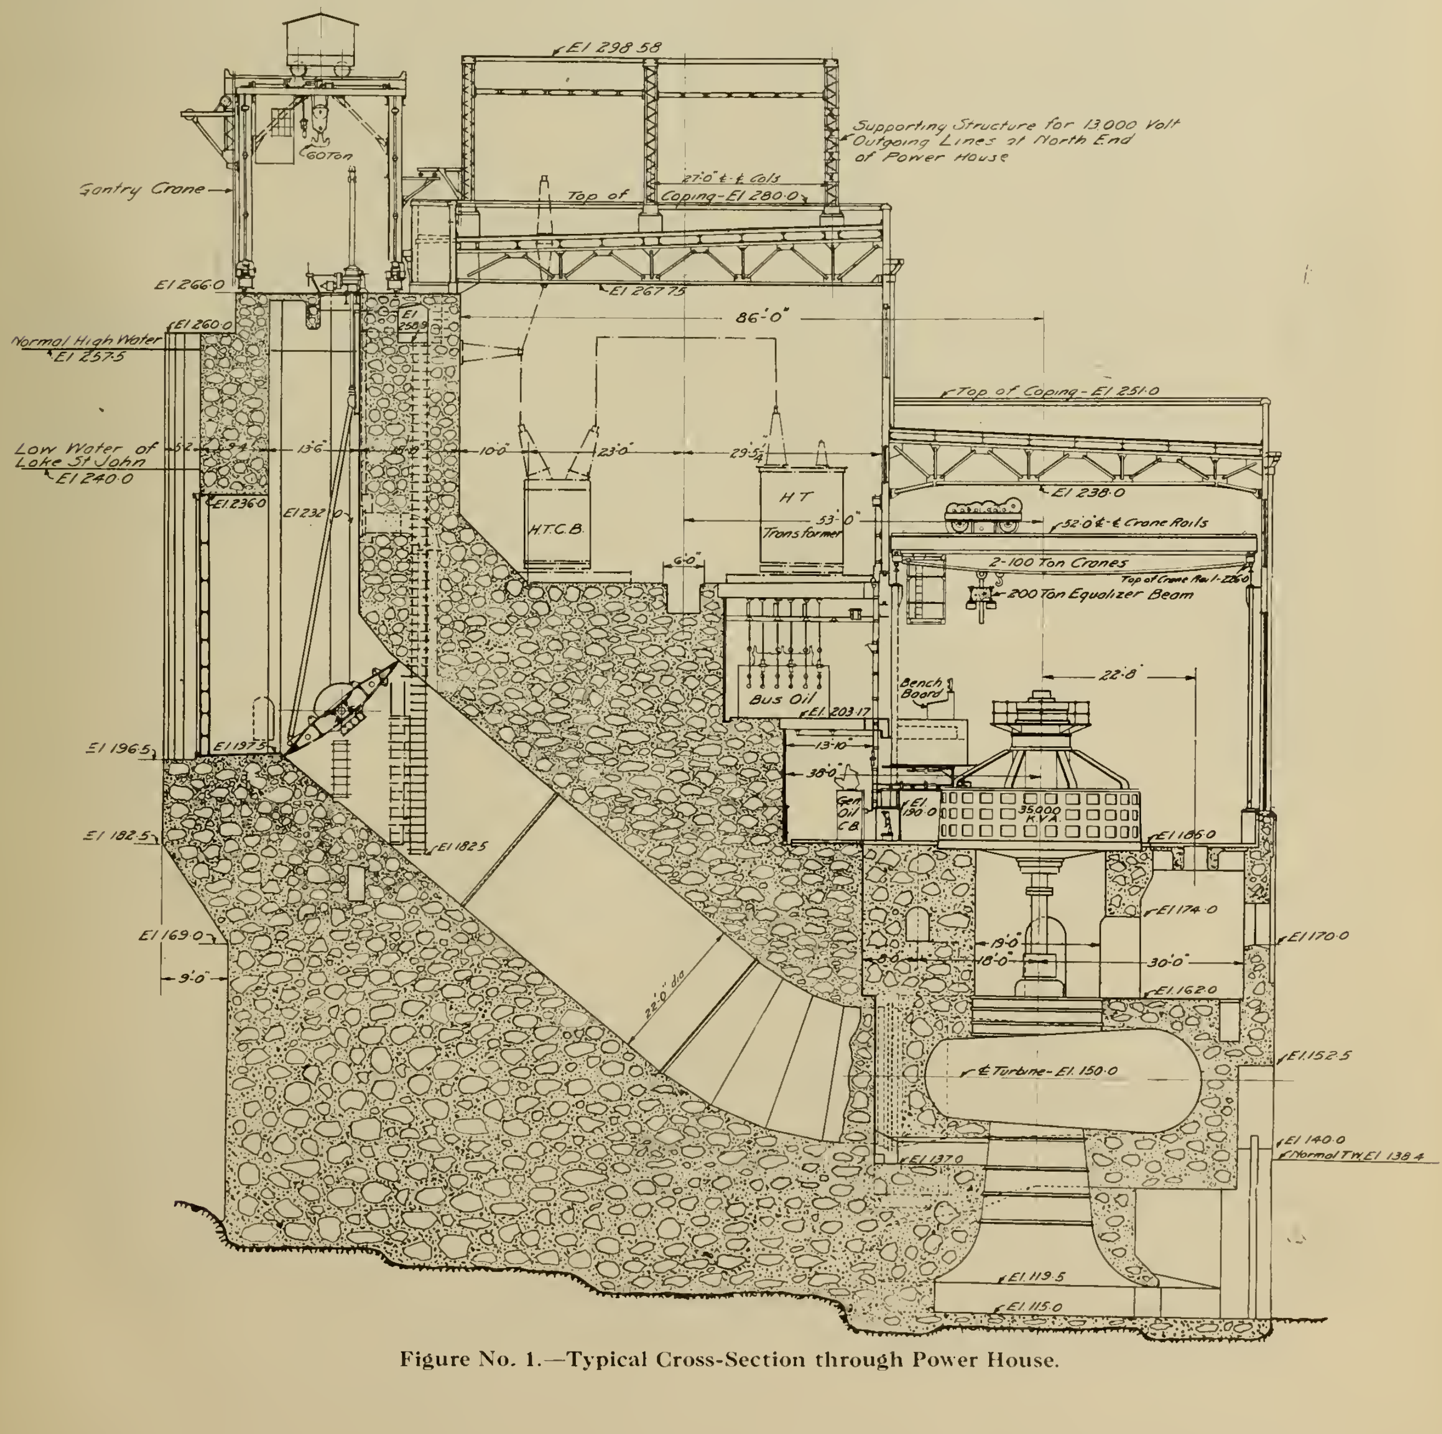

Figure No. 1.—Typical Cross-Section through Power House.

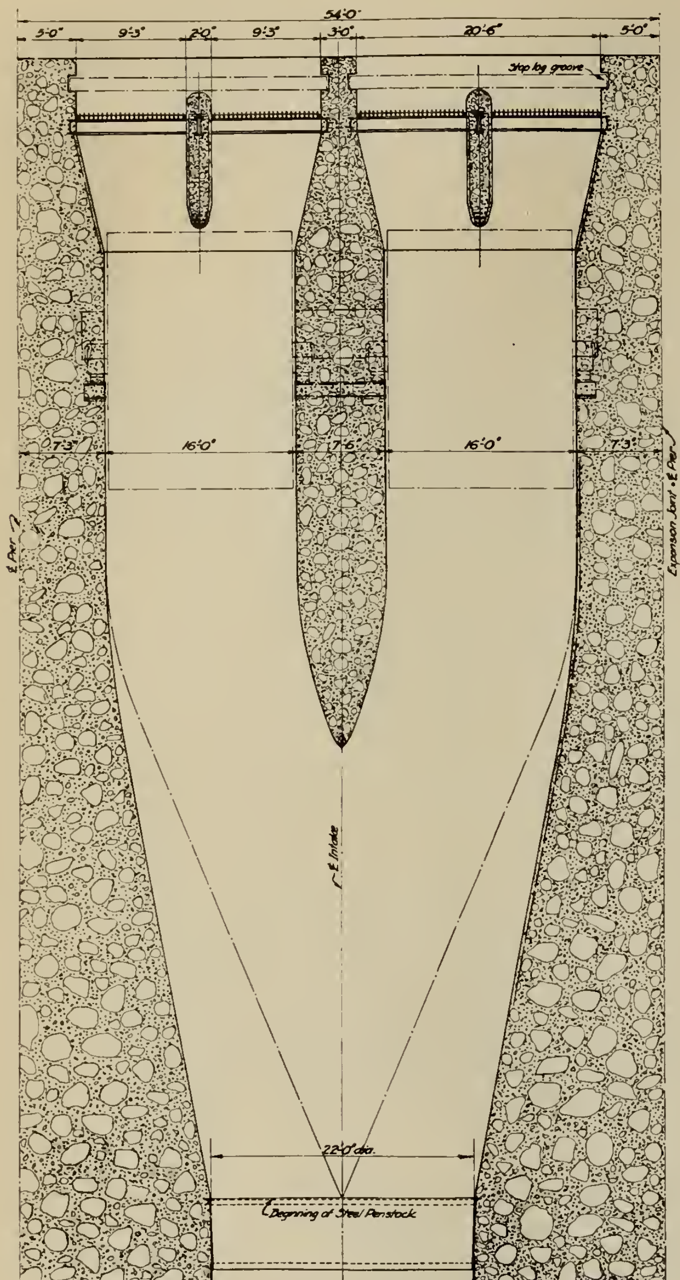

Figure No. 2.—Sectional Plan of Intake.

ways toward the turbine wheel case, so that no pockets of air can be formed.

By use of the modern single-runner vertical turbine, waterways of ample size may be formed in the impounding structure, leaving enough space for division walls to keep the stresses in the bulkhead and power house substructure within safe limits.

The 722 feet long power station at the foot of Isle Maligne, the last of the many islands in the Grand Discharge of the Saguenay river, is designed for twelve 45,000-horse power hydro-electric units, the operating head ranging between 100 and 117.5 feet, depending on the stage of lake St. John.

Power House Forebay

The power house forebay is an extension of lake St. John. At low water stage the depth of water in the forebay is more than 75 feet, and the velocity of approach of the water to the rack structure is negligible, even if all twelve turbines are operated.

The water is drawn into the intakes at an average depth of 30 feet below its surface, the top of the intake being always submerged, as shown in figure No. 1. It is not expected that anchor or frazil ice will be formed in winter time tending to clog up the racks. In general, the ice cover on lake St. John is from two to three feet thick.

Rack Structure

The rack structure forming the upstream portion of the power house bulkhead is built of reinforced concrete and structural steel with the top of the rack bars at elevation 236.0, leaving a margin of 4 feet below the ordinary low water level of lake St. John. Referring to the sectional plan and elevation of the rack structure and penstock intake, figure No. 2, there are four steel rack sections of 39 feet height and 9 feet 3 inches width each per unit. This subdivision of the rack structure permits, first, the placing of reinforced concrete baffle piers anchored to the masonry base at the bottom and to the 24 feet high masonry block on top, thus cutting in half the unsupported length of the horizontal steel beams to which the rack bars are attached, and, second, the fabrication of rack frames which can be shipped assembled to the power house site and quickly set in place.

The 6 inches by ⅜-inch thick steel rack bars of 39 feet 6 inches length each are spaced 4½ inches on centres, and the method of connecting same to the slotted angle irons and plates, which are riveted to the horizontal beams of the frames, is shown in detail in figure No. 3. It will be noticed that, with the exception of the cutting to the required length, the rack bars do not require any shop work. There are 24 rack bars per frame, and each set of bars was shipped in a bundle weighing 7,250 pounds. An upstream view of the rack structure nearing completion is shown in figure No. 4.

The rack structure is designed to withstand hydrostatic pressure against its covered upstream face due to ordinary high water of lake St. John and considering the penstock

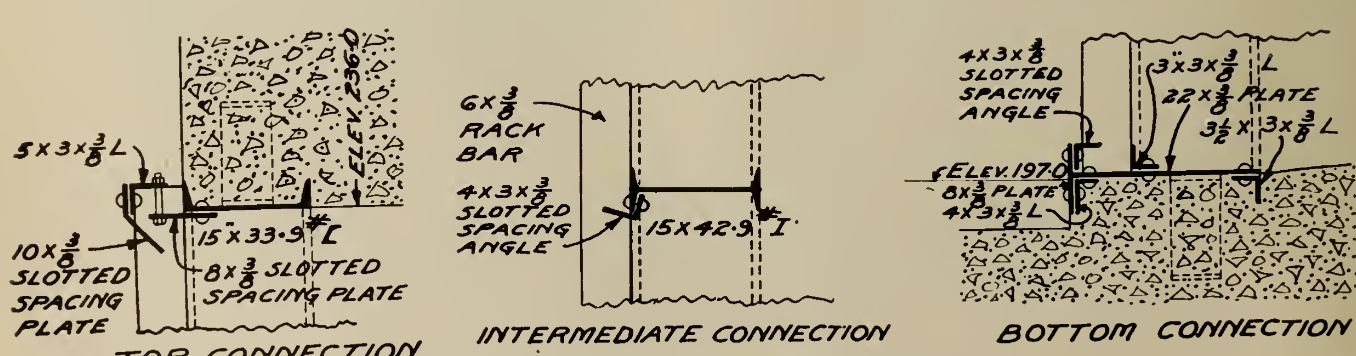

Figure No. 3.—Details of Racks and Frame Connections.

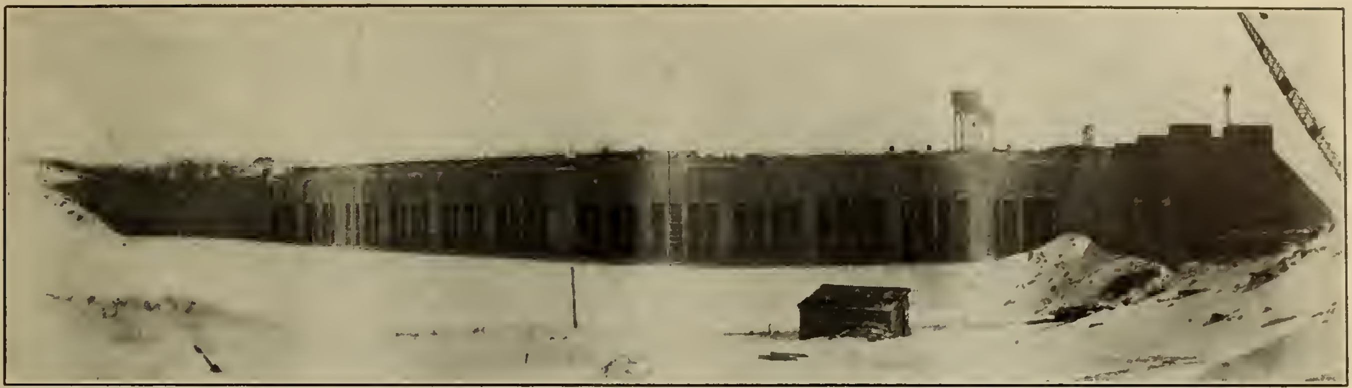

Figure No. 4.—Upstream View of Rack Structure During Construction.

intake unwatered. In this case the steel work will be stressed to its elastic limit. The grooves provided in the main piers extending further upstream from the face of the rack sections are for the insertion of stop logs, allowing an inspection of the racks. Under normal operating conditions there is no steel exposed to the action of the air, even if the lake is at its low water stage.

Penstock Intake

The waterway formed in the rack structure converges into the twelve bell-shaped penstock intakes, each of which is divided into two openings by a 7 feet 6 inches thick partition of concrete masonry. Each opening is controlled by a 16 feet wide by 22 feet high rectangular gate of the butterfly type, having in the centre a cast steel girder of 2 feet 8 inches depth and of 2 feet 6 inches width, with bronze bushed trunnions of 18 inches outside diameter and 24 inches length at each end. The wings of the gate are of cast iron, and are firmly attached to the girder by machine bolts and shrink links. The general design of the gate and frame, including its sealing devices, is shown on figures Nos. 5 and 6.

Each gate is operated by an individual, completely enclosed hoist located on top of the power house bulkhead, as outlined in figure No. 1.

Direct-current, 230-volt electric power is supplied for the operation of the hoists. Each headgate motor is completely enclosed, and has a starting torque of 275 foot-pounds and a running torque of 140 foot-pounds, based on six minutes service, with a temperature rise not exceeding 55 degrees centigrade. Under the most severe operating

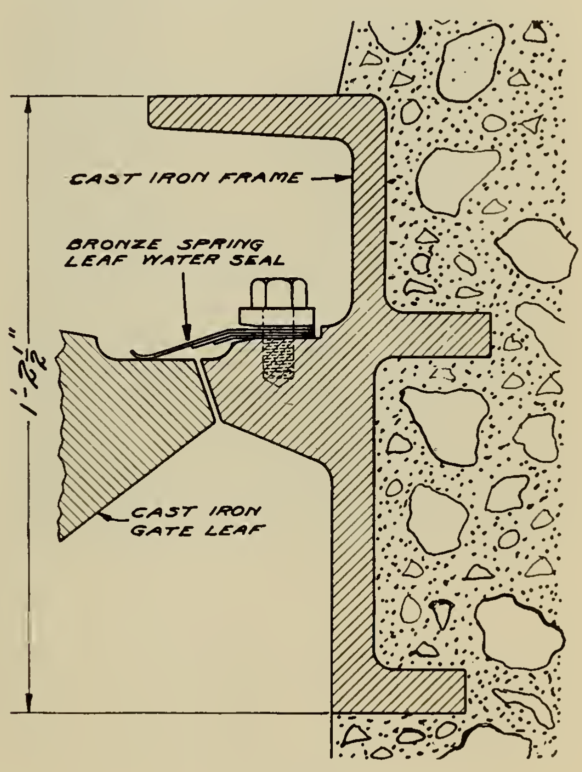

Figure No. 5.—Detail of Water Seal.

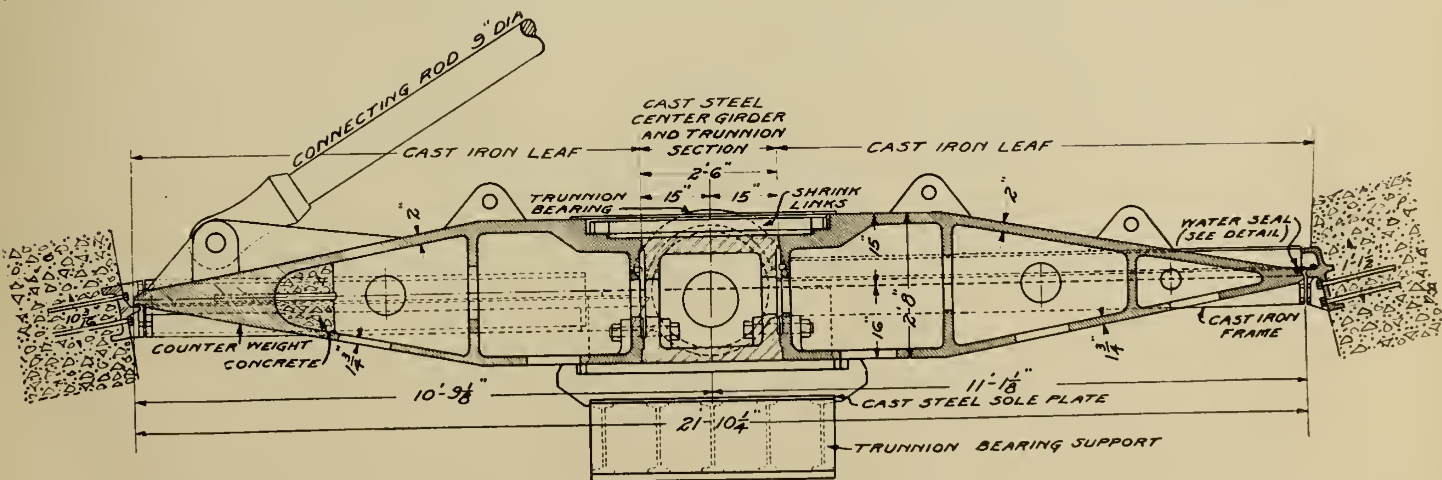

Figure No. 6.—Section Through Headgate.

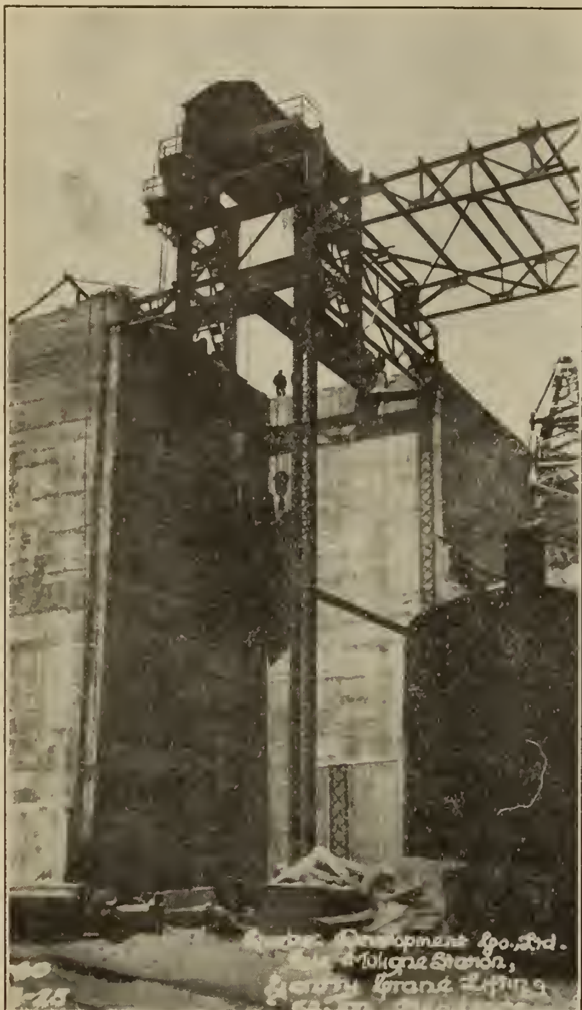

Figure No. 7.—Gantry Crane, Lifting 54-ton Headgate.

conditions the gate may be completely closed or opened in five minutes. A weather-proof push-button control station is provided for each hoisting mechanism on top of the bulkhead and a non-weather-proof control station on the power house benchboard for distant closing of each gate. The emergency push-button control on the benchboard is for use in case of accidents only, as the intake gates can be readily closed when the generator is operating under full load.

A 36-inch diameter by-pass is provided in each intake for filling the penstocks before the headgates are opened and the turbines started. By means of vents leading to a passageway near the top of the bulkhead the air will escape from or be admitted to the turbine flumes. This passageway has a number of side openings to both the space between the rack structure and the intake and to the transformer and circuit breaker room of the power house. In cold weather the warm air from the generators is passed through these side openings into the space below the headgate hoists, the object being to prevent freezing of the water surface above the headgates.

Each headgate weighs 108,000 pounds, excluding the weight of the frame, and railroad clearances permitted the gates to be shipped assembled in special cars. The travelling gantry crane on top of the bulkhead is provided with two hoists, the main hoist having a capacity of 60 tons and the auxiliary hoist of 5 tons, and it was used for unloading and lifting each headgate on top of the bulkhead and for transferring and lowering same to its respective position. In addition, the gantry crane has two bracket hoists of five tons capacity each, for lowering and raising stoplogs in front of the rack structure.

A view of the gantry crane lifting a headgate is shown in figure No. 7.

Logways

At each end of the intake structure provision is made for the removal of logs or floating matter from the forebay by means of a logway. Each logway opening is 5 feet wide by 12 feet high; it is controlled by a concrete-filled steel sliding gate which is in its raised position when closed. When it is desired to remove logs or debris, the gate is lowered a sufficient distance below the existing water level to allow the logs or debris to pass over the top of the gate.

The logs and debris taken through the opening at the north end of the intake pass through a tunnel formed in the power house bulkhead and substructure and finally discharge into the tailrace. The logway at the south end of the intake is formed in a section of the spillway adjoining the power house bulkhead.

Electrical Characteristics of the Quebec-Isle Maligne Transmission Line

Location, Construction and Electrical Features of the Transmission Line at Present under Construction between Isle Maligne and Quebec City

Clarence V. Christie, M.E.I.C.
Professor of Electrical Engineering, McGill University, Montreal.

Paper to be represented at the Annual General Professional Meeting of The Engineering Institute of Canada. at Quebec, Que., February 15th to 17th, 1927

The harnessing of the great water powers of the Saguenay river in Quebec has been delayed for many years waiting for men who could combine the visions to see sufficient industrial development to utilize at least the main part of the power and who had the initiative and influence to carry out the project. The late J. B. Duke and the late Sir William Price saw the vision, and during 1925 and 1926, through the construction of the plant of the Quebec Devel-

Figure No. 1.—Transmission System of the Shawinigan Water and Power Company.

Transmission Line Quebec to Isle Maligne Standard Light Tower.

Figure No. 2.—Standard Transmission Towers.

opment Company at Isle Maligne, 350,000 horse power of electrical power has been made available; of this, about 150,000 horse power is used in the paper mills at Port Alfred, Kenogami and River Bend; 100,000 horse power in the new plant of the Aluminum Company of Canada at Arvida, leaving about 100,000 horse power which has been purchased by The Shawinigan Water and Power Company to supply the future demand for power in the Quebec district.

Choice of Location

To transmit this 100,000 horse power to Quebec, two routes were available; the direct route running straight across the Laurentide National Park, which surveys have shown to be 135 miles in length, and a second route extending down the Saguenay river to Ha Ha Bay, then across country to Baie St. Paul, and from thence direct to Quebec, a total distance of about 170 miles. The cost of high voltage lines is too great to unnecessarily increase their lengths, and the decision was made to follow the shorter route.

Surveys were completed in September 1926. Through the greater part of its length the line crosses virgin country, and it was necessary to build roads both for construction purposes and for patrolling. Shortly after leaving Isle Maligne the country rises to an elevation of about 2,000 feet above sea level and it returns to the lower level about 25 miles from Quebec. The maximum elevation reached by the lines is about 2,900 feet, near its centre.

Voltage and Number of Circuits

After extensive studies of the relative cost of transmission at 200,000 volts and 150,000 volts, a delivery voltage of 150,000 volts was adopted for Quebec, requiring approximately 165,000 volts at Isle Maligne on the line side of the step-up transformers. Provision has, however, been made for an increase of the delivery voltage to 160,000 volts if future load conditions warrant it.

Although, from the point of view of continuity of service and freedom from interruptions, it was desirable to use two single circuit lines on separate rights-of-way, the necessity of keeping down the capital cost of the line forced the decision to use a double circuit steel tower line. When the load to be transmitted to Quebec increases beyond 150,000 horse power, a second double circuit line will be constructed.

It is the purpose of this paper to discuss the electrical features entering into the design of this line and to make a comparison with the present 100,000-volt line of The Shawinigan Water and Power Company from Shawinigan Falls to Montreal.

The map (figure No. 1) shows the main transmission lines of The Shawinigan Water and Power Company, and shows the relation of the new line to that system.

The Quebec-Isle Maligne line is now in process of construction and will be ready for service in July 1927. It is a double circuit line with conductors of 397,500 circular mils aluminum cable, steel reinforced, is carried on steel towers with concrete foundations, and the normal span is about 900 feet.

Towers

The standard light tower is shown in figure No. 2, and beside it for comparison is the standard light tower used on the Montreal line. The light tower is designed to take angles up to 4°. Its weight is 10,400 pounds and the weight of the footing for each leg is 8,100 pounds, consisting of 2 cubic yards of concrete with reinforcing bars. The over-all height of the tower is 84 feet, and the cross-arms are spaced 12 feet vertically with an extension of 5 feet on the centre arm.

Conductors

The conductor used is 397,500 circular mils A.C.S.R. with an outside diameter of 0.806 inch. It is made up of 30 strands of aluminum of 0.1151 inch diameter over 7 strands of steel of the same diameter. The elastic limit of the cable is 13,800 pounds and its ultimate strength is 19,170 pounds. The calculated maximum operating stress is 10,000 pounds per conductor when operating with ¾-inch of ice and a 10-pound wind.

The conductors are spaced 12 feet apart vertically and the centre conductor has an off-set of 5 feet, giving actual conductor spacings of 13 feet, 13 feet and 24 feet, and the equivalent spacing used in the calculation of inductance and capacity is $\sqrt[3]{13 \times 13 \times 24} = 16$ feet.

Insulator Strings

Ten 10-inch discs are used for suspension and twelve for strain. The latter are high-strength units.

The complete string of insulators is shown in figure No. 3, with an arcing horn at the lower end. The over-all length of the string is 56⅜ inches. This compares with seven units and an over-all length of 42 inches for the 100,000-volt line.

Clearances to Steel

The towers are designed for the following clearances to steel:—

(1) 1/3 inch for each kilovolt in excess of 22 plus 12 inches for normal conditions. (Minimum for 154,000 volts = 56 inches.)

(2) ¼ inch for each kilovolt in excess of 7 plus 6 inches for intermittent condition. (Minimum for 154,000 volts = 43 inches.)

Hangers are designed for angles so that the minimum clearance to steel is 44 inches.

Tests have shown that at 60 cycles the flashover voltage from conductor to steel is about 9,000 volts per inch and to jump across the minimum clearance of 44 inches would require 400,000 volts.

Two ground wires will be installed, 7/16-inch seven-strand steel.

Table No. 1 gives comparative characteristics for the 150,000-volt and 100,000-volt lines.

Table No. 1:—Comparative Characteristics for the 150,000-Volt and 100,000-Volt Lines.

(All figures refer to light towers)

Item	Isle Maligne Line	Montreal Line
Conductor	397,500 CM. A.C.S.R. { 30 alum. 7 steel	266,800 CM. A.C.S.R. } 6 alum. 7 steel
Spacing	13 ft. 13 ft. 24 ft.	11.2 ft. 11.2 ft. 20 ft.
Span	900 ft.	550 ft.

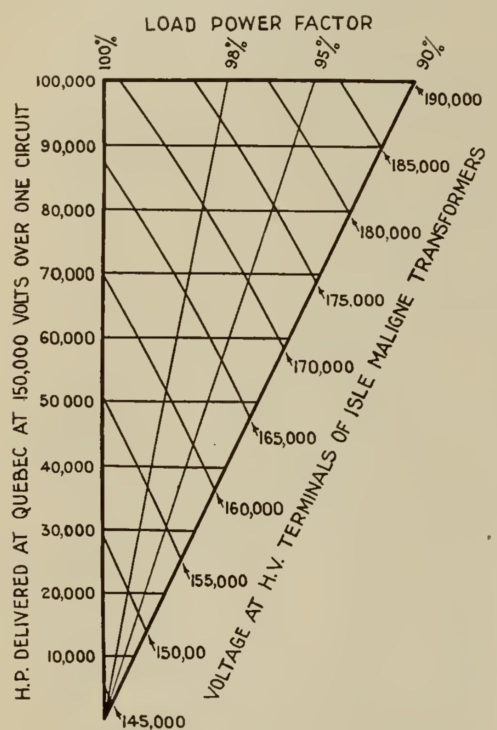
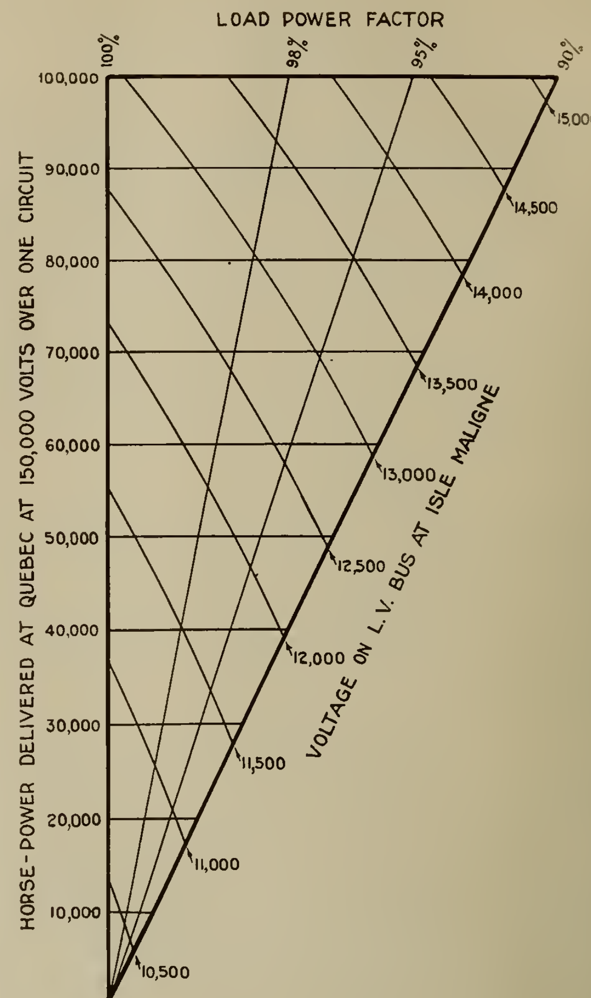
Figure No. 3.—Standard Suspension Insulator Strings.

Electrical Constants of the Line

The electrical constants of the line are as follows:—
Resistance per circuit at 40° C. = 34 ohms.
Reactance per circuit at 60 cycles = 102 ohms.
Capacity susceptance per circuit = 7.35 × 10^{-4} mhos.
Charging current per line at 150,000 volts = 63.5 amp.
Charging kv.a. per line at 150,000 volts = 16,400.
Charging kv.a. per line at 165,000 volts = 20,000.
The resistance of one bank of step-up transformers referred to the high-voltage side = 2.9 ohms.
Reactance of one bank of transformers = 51.25 ohms.



4a—Regulation Chart for Line Only—One Circuit.



4b—Regulation Chart, Line and Step-up Transformers—One Circuit.

Figures Nos. 4a and 4b.—Regulation Charts for the Isle Maligne Line.

Thus the reactance of the step-up transformers is half as much as the line reactance.

There will not be any corona loss on this line below 180,000 volts in fine weather. In stormy weather, corona loss will begin about 155,000 volts but will not be excessive.

Step-Up Transformers at Isle Maligne

The transformers at Isle Maligne are rated, single-phase, sixty-cycle, 25,000-kv.a., to be connected delta on the low-voltage side and star on the high-voltage side with permanently grounded neutral.

The ratio of voltages is 13,200 volts delta to 187,000 volts star with taps on the high-voltage side to give voltages 178,750, 170,500, 162,250 and 154,000 volts and the normal operating ratio will be 13,200 to 178,750 volts, and this is the ratio on which the regulation chart in figure No. 4-b has been constructed.

The efficiency at full load is 99.0 per cent; ¾-load, 99.1 per cent; ½-load, 99.0 per cent, and ¼-load, 98.6 per cent. The iron loss is 0.31 per cent at normal voltage, and 0.40 per cent at 110 per cent voltage; the copper loss, 0.64 per cent at full load; and the approximate reactance is 12 per cent.

The equivalent impedance of the transformer bank referred to the high-voltage side at the operating voltage ratio is $Z_{tr} = 2.9 + 51.3j$ ohms.

Regulation Charts

Regulation charts giving the operating characteristics of the line alone and of the line with step-up transformers are shown in figures Nos. 4a and 4b.

These diagrams were constructed using the most exact methods of calculation, but only the essential parts of the diagram have been retained in order to make them as convenient for use as possible.

When delivering 50,000 horse power per circuit to Quebec at 150,000 volts, 95 per cent power factor, the voltage required at the high-voltage side of the step-up transformers at Isle Maligne is 162,500 volts, figure No. 4-a, while the voltage on the generator bus is 12,200 volts, figure No. 4-b.

When delivering 100,000 horse power at 150,000 volts, 98 per cent power factor over one circuit, the voltage on the line at Isle Maligne is 177,500 volts and on the generator bus is 13,800 volts.

The capacity of this system of two lines will be about 150,000 horse power at 95 to 98 per cent power factor. When the demand at Quebec has increased beyond 150,000 horse power, further lines will be required.

The Water Power Developments of The Alouette-Stave-Ruskin Group of the British Columbia Electric Railway Company, Limited

E. E. Carpenter, M.E.I.C.
Consulting Engineer, British Columbia Electric Railway Company, Ltd.

Paper to be presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Quebec, Que., February 15th to 17th, 1927

The southwest coast of British Columbia is especially favoured by nature in the matter of water power resources. The heavy precipitation, varying from 100 to 200 inches at watershed elevations, falls largely in the form of snow upon the lofty peaks and rugged flanks of the Coast Range mountains, at altitudes that retain it in this form or in the form of glacial ice for a large part of the year. The lower watersheds are clothed with a dense forest cover that effectively retards the run-off. These conditions, coupled with the close proximity of the elevated Coast Range to the populous coastal districts, where the agricultural, commercial and industrial needs for electric energy are centred, tend to simplify water power problems in many ways.

The Company

The British Columbia Electric Railway Company, Ltd., owns and operates all power, light, gas and traction utilities serving the Pacific coast districts of British Columbia and the southerly districts of Vancouver Island.

The populous centres are the city of Vancouver on the mainland and the city of Victoria on the island. The former, with its suburban municipalities of Point Grey, South Vancouver, Burnaby, North Vancouver and West Vancouver, has a population of approximately 225,000; the adjacent communities, of which New Westminster is the principal one, raise this figure to 275,000. Victoria has a population of 60,000, to which its suburban districts add about 25,000.

There is no interconnection between the mainland and the island systems, nor is any practicable on account of the intervening water distance.

The records of power usage on the mainland point unmistakably to vigorous and sound future growth. Close study of the situation warrants the prediction of an annual incremental increase in total load approximating 10 per cent; a doubling of energy output for each period of 7 to 8 years in the future.

A glance at the past record shows that this rate of load growth has persisted in spite of the vicissitudes of the abnormally rapid expansions from 1910 to 1913, the recession period immediately following from 1913 to 1915, and

Figure No. 1.—Topographic Panoramic View of Alouette- Stave-Ruskin Power Developments.

the war period immediately following that. The mainland substation outputs for the year 1925 exceeded that of 1924 by 11 per cent. The power generated in 1925 amounted to 332,000,000 kw. hrs.

The doubling of the load during each 7 to 8 years means the doubling of the facilities for producing power in each similar period. The present hydro-electric generating capacity of all the plants of the mainland system,—including plants under construction,—is 123,325 kv.a. The doubling of this capacity by 1934 will mean an expenditure of some $25,000,000 in new plants, transmission lines, substations, etc., an annual expenditure in increasing power facilities of some $3,000,000 per year.

A summary of the company's plants and their respective capacities follows:—

Mainland Plants		*Capacity kv.a.*	
Buntzen No. 1	hydro	21,000	
Buntzen No. 2	"	26,700	
Stave Falls	"	65,625	
Alouette	"	10,000	
Vancouver	steam	12,500	
Total			135,825
Vancouver Island Plants			
Jordan River	hydro	16,000	
Goldstream	"	2,700	
Brentwood Bay	steam	4,000	
Total			22,700
Grand total			158,525

With the above outline of the company and the scope of its system as a basis of general acquaintance, the real subject of the discussion, the developments of the Alouette-Stave-Ruskin group, will be proceeded with. A glance at the topographic panorama, in figure No. 1, will disclose the relation of the three projects in a better way than descriptive text. The three plants utilize progressively the head available from the watersheds feeding the Alouette lakes and Stave lake. The developments existing and proposed will be discussed in the order of their place in the chain or series, beginning with the Alouette project, which lies at the highest elevation.

Alouette Development

The Alouette lakes lie in a narrow valley about eight miles north of the Fraser river and about twenty-five miles due east from Vancouver. They are drained by the Alouette river, which, after flowing southwesterly about fifteen miles, discharges into the Pitt river at tidal elevation.

At low water there are really two lakes separated by a short stretch of running stream, but, with the water level raised, the two merge into one. The lakes lie at an elevation about 140 feet above Stave lake and about 370 feet above mean sea level.

The raising of the level of the Alouette lakes by building a dam at their outlet, thereby affording storage to regulate their waters; the piercing of the narrow granite rim with a tunnel to divert the waters into Stave lake; and the installation of a generating plant at the outlet of the tunnel to recover the energy of the falling waters on their way to the lower levels of Stave lake, are the essential features of the Alouette project.

The waters thus diverted not only yield their energy at the new plant at the tunnel outlet, but, mingled with the waters of Stave lake, successively pass through the wheels at the Stave Falls plant, and, at a later date, through the proposed plant at Ruskin, thereby eventually yielding practically all the energy due to their drop from lakes to sea.

The watershed is in the main steep and rugged, barren and rocky in its higher elevations, but timber-clothed on its lower slopes. The region comprising it is unmapped, but its area is approximately eighty square miles; and the combined area of the lakes is about five square miles.

The flow of the Alouette river has been carefully measured since 1911. Studies of the mass diagrams compiled from the stream flow records extending from August 1st, 1911, to September 15th, 1924, indicate that with the storage of 170,000 acre-feet afforded by the Alouette dam there would have been available, during the thirteen years covered by the record, possible regulated drafts varying from 692 to 910 cubic feet per second.

As a basis of power development, it was assumed that there may be appropriated for power uses an average annual flow of 700 cubic feet per second, 90.2 per cent of the mean discharge, which may be drawn at varying rates to best suit the operating requirements.

Dam and Spillway

The dam consists of an earth fill of the semi-hydraulic type, with an exceptionally broad base and separate concrete-lined spillway. It is 65 feet high from the lowest point of the river bed and 1,030 feet long on the crest. Figures Nos. 2 and 3 show the general plan, section, and some of the details of the structure.

Strictly speaking, the site of the dam possessed few conditions to recommend it as a dam site. A profile along the axis reveals a trough-like depression some 150 feet wide and 35 feet deep, through which the river had its channel. The banks rise abruptly from the river and the trough is flanked on either side with gently rising terraces which merge into the steeper slopes of the adjoining hills. The entire area was covered with an exceedingly heavy forest growth. The west terrace is plentifully scattered with odd boulders, but these are rare on the east side.

The formation has the usual characteristics of the glacial outwash. Clays, intermingled with lesser or minor strata of silts, sands, gravels and boulders predominate in the river bed and the adjoining terraces.

This clay formation is remarkable for its resistance to erosion; in fact, it is the sole barrier that has held the lakes in being. Extensive borings were made of the sites of both dam and spillway. The clay blanket or barrier is eroded deeply in the channel, particularly at the downstream toe, where barely 10 feet of it remain in place. Under it lies a stratum of fine sands, silts and gravels, extending to a depth of over 100 feet.

To best meet the conditions imposed by the site, a dam of the earth fill type with exceptionally broad base and separate spillway was determined upon. The slopes of the dam are exceptionally flat, thus providing the broad base to reinforce and blanket the none-too-generous layer of underlying clay and affording conservative slopes for placing the clay fill, the behaviour of which, under the construction methods used, could not be definitely predicted.

The area occupied by the dam was cleared of timber and stumps and the thick forest floor removed. In addition, the central area, occupied by the core, was thoroughly stripped of top soil, so as to expose the surface of the underlying clay. Cut-off trenches were excavated in the clay to afford a better bonding between the underlying clay and the core material deposited upon it.

Practically all the material for the embankment was obtained from the spillway excavation. According to preliminary exploration and analysis, it would all be clay and would carry a very large proportion of fines. With these conditions in mind, the semi-hydraulic method of placing the fill was determined upon, in preference to the straight hydraulic method. The method used affords a much better control of the amount of water used and of the character of the material as deposited on the dam. If excavated hydraulically and pumped into the fill, an excess of fines was to be feared that would possibly have endangered the stability of the fill. The rate at which the embankment had to be placed to bring it to completion before the flood season left no margin for possible shut downs for draining out an unconsolidated fill.

All the material was excavated with steam shovels and drag lines, brought to the dam in dump car trains drawn by locomotives and dumped at or near the outer slopes. Hydraulic giants mounted at the top of the slopes attacked the dumps and washed the material inward toward the central pond. At the same time, a similar hydraulic monitor mounted upon a float in the central pool played upon the inner faces of the clay slopes, washing the finer materials down into the pool and leaving the coarser lumps lying on the slopes. The clay lumps proved remarkably resistent and did not break up to any great degree under the action of the nozzle streams. The benefit obtained was twofold; the limiting of the quantity of fines going into the puddle, and the affording of drainage for the central puddle core.

The employment of monitors for spreading the dump material proved most effective and economical, and had the distinct advantage of thoroughly working over with water all the materials going into the dam. Under the ordinary methods of semi-hydraulic filling by dumping from trestles or dry spreading, and with the hydraulic action on the inside slopes only, a considerable portion of the resultant fill is placed dry and remains so throughout the work, generally resulting in settlements and possible cracking of the slopes. By the method used at Alouette, this condition was entirely avoided. The settlements observed during the construction period and after completion were remarkably small.

Check elevations taken June 15th, 1925, on thirteen iron rods embedded in the fill before its final completion in January 1926 show a maximum settlement of 0.04 foot. Some difficulty was experienced, particularly at the higher levels, in holding the core pond to the limits of the specified width, which was, at any level, to be equal to the distance below the crest of the dam to that point plus 10 feet. The perfect control of pond level afforded by the method was of material assistance in regulating the width and consistency of the puddle mass.

The sluicing pond level was regulated closely to the requirements by pumping in through the dump monitors and pumping out with the floating pond monitor supplemented as required with a second floating pump employed exclusively for this purpose. A relatively deep pond was carried, generally 7 to 8 feet. All the material in the core area was thus deposited under water and the voids in the coarser materials forming the slopes at the edges of the core were well filled with fines.

When the core reached elevation 482, the normal high water level of the reservoir, the pond was abandoned and the side embankments were brought on up by dumping and sluicing in with the dump monitors, all collected water being drained out continuously. The final topping of the crest to a depth of about 3 feet was made entirely of gravel dumped from a track laid along the centre of the crest.

As the dam reached the higher levels and the pond narrowed, some difficulty developed from the action of the nozzle streams in throwing large fragments of the broken-up clay over into the body of the puddle. The difficulty was entirely overcome by placing large vertical screens mounted on floats along the edges of the pond and directly in front of the dump monitors. These so effectively checked the streams that whatever burden of coarse materials they carried was dropped at the edge of the pond. The screens were cheap and simply constructed and easily moved from place to place. They were built in units about 40 feet long by 10 feet high and consisted of one-inch mesh chicken wire backed with 6- by 6-inch reinforcing mesh mounted upon a light timber framework supported and floated by two cedar logs. A screen was provided on either side of each float to permit its use on either side of the pond simply by moving it laterally across the pool.

Samples of core material for analysis and penetration tests with 6-inch cast iron ball were taken weekly. Two typical analyses of samples of core material are given below:—

	Sampled Aug. 9th Elevation 444 Ball penetration 10 feet per cent.	Sampled Sept. 7th Elevation 461 Ball penetration 0.8 feet per cent.
On 100 mesh	6.84	3.62
200 mesh	4.72	3.05
Diameter of particles, mm....		
0.075 to 0.050	18.50	28.67
0.050 to 0.025	13.75	14.16
0.025 to 0.010	23.65	20.71
0.010 to 0.005	20.04	25.92
Less than 0.005	12.50	3.87

The diversion of the Alouette river during the construction of the dam was made through the Alouette tunnel, which was not sufficiently completed for this purpose until June 17th, 1925. The coffer dam was closed on June 21st, but the stripping of the foundation in the river bed delayed the major filling operations until July 13th. On October 30th, the embankment had reached elevation 485 and the spillway had progressed sufficiently to remove the danger of damage from flood. Progress thereafter was slower, due to trimming and finishing both the embankment and the spillway.

The maximum progress was made in September, when 35,070 cubic yards of embankment were placed in 25 days of two 8-hour shifts. On the best two-shift day, 1,954 cubic yards were placed. All the excavated material had to be loosened with powder for efficient digging with the excavating machines.

The quantities involved in dam are:—

Clay from spillway excavation	93,000	cubic yards
Clay from borrow pit	15,000	" "
Gravel facing	29,770	" "
Cofferdam embodied in main dam	1,850	" "
Rock paving	3,380	" "
Total	143,000	" "

Owing to a tendency of the clay material to disintegrate if allowed to dry and subjected later to wetting. a gravel cover 2 feet in thickness was laid on both slopes and the crest of the dam. This cover acts as a mulch to keep the underlying clay constantly moist. The entire upstream slope was paved with hand-placed rock obtained from quarries up the lakes and transported in scows to the dam. The specifications called for rock paving varying from 11 to 16 inches in thickness with an average thickness of 12 inches, but the paving as placed averaged considerably thicker.

A separate concrete-lined spillway with control gates and overflow weir carries the flood waters around the westerly end of the dam and conducts and discharges them into the river some 200 feet below the downstream toe.

The dimensions, slope and hydraulic characteristics of the spillway structure afford a safe outlet for 30,000 cubic feet per second of flood water. The greatest recorded flood of the river occurred in October 1921, when the peak discharge, of short duration, amounted to 15,000 cubic feet per second. The normal maximum yearly flood discharge is 6,000 to 7,000 cubic feet per second.

The design of the spillway was influenced by necessity of meeting the requirements of timber interests operating or owning timber above the dam, for passing logs, shingle bolts and other forest products through the spillway and splashing or floating them on down the river.

The approach is of ample proportions to insure low velocities which will not damage by erosion the unlined portions. As these velocities build up, a concrete lining of sides and bottom is provided for both the entrance apron and the spillway proper; the side linings average 14 feet in height and extend well up the sides to an elevation 2 feet above the highest water level.

The drop of the water from the spillway level down to the stream bed, a distance of about 38 feet, was accomplished by an ogee section at the end of the spillway. The excavation was shaped to the required form and a reinforced-concrete covering, consisting of longitudinal and transverse ribs with a 15-inch slab, was placed directly on the excavated surface of the clay.

The safeguarding of the foot of the ogee structure against erosion was something of a problem, since, at the lower levels, the capping of hard clay had been cut through and the material encountered below was a mixture of fine sand and clay,—a material very susceptible to erosion. The flat discharge section at the end of the ogee structure is depressed below the river bed so that at all stages of discharge the backwater forms a pool of sufficient depth to induce an hydraulic jump. This was relied upon to dissipate to a considerable extent destructive water velocities. At the lower end a concrete cut-off toe wall 5 to 7 feet in thickness was carried to depths of 12 to 15 feet below the ogee floor. This toe wall was also carried back under each side of the ogee a distance of 19 feet, thus forming a deeply-founded, U-shaped spigot protecting the entire end of the ogee structure.

As a further protective measure, a flexible mattress, 40 feet in length and flaring from 120 to 145 feet in width, was placed beyond the toe wall. This mattress was formed of very large boulders, specified to have a minimum diameter of 3 feet. Eyebolts were anchored in the top of each boulder and all were securely tied together with longitudinal and transverse cables intersecting at the eyebolts and securely clamped to them. Over the tops of the boulders a 12-inch slab of concrete, encasing the cables and eyebolts, was poured. Beyond the mattress a loose riprap of heavy boulders was placed along the rising slope leading to the stream-bed level. At the sides steel sheetpiling was driven to afford in emergency, temporary protection against undercutting.

When discharging its full capacity of 30,000 cubic feet per second, the water in the spillway will be approximately 12 feet deep and will flow at the rate of 20 feet per second.

The control of the spillway is effected by three crest gates and one shingle bolt or log bay, supplemented by a free weir having an effective crest length of 348 feet, into which are introduced thirteen under-sluices to permit the increase of flow of water for log splashing at lower lake levels. A flood of the proportions of the maximum accorded flood of 1921 would be amply taken care of by the free weir, which will be topped by 5 feet of water at extreme high lake level at elevation 487. With lake level at 487, the combined discharging capacity of the log-way, crest gates and weir section is approximately 30,000 cubic feet per second.

The three crest gates, of the Stoney Roller type, 20 feet 6 inches in width by 18 feet in height, are set between massive concrete piers. A steel superstructure supports the operating hoists by which the gates are raised or lowered, normally by motor-driven winches, but, in emergency, by hand power. The sills of the spillway crest gates are at elevation 466, 16 feet below the normal high lake level.

The log chute bay, 10 feet in width, is adjacent to the east abutment of the spillway and is closed with heavy timber stop logs. Its V-shaped bottom is 2 feet lower than the sills of the adjacent roller crest gates, and is extended upstream through the entrance apron to afford greater facility for passing shingle bolts at low water stages. On the downstream side of the log bay and extending the full length of the spillway, the log chute is formed by setting a heavy concrete wall parallel to the easterly side of the spillway, thus forming a V-shaped channel 11 feet wide at top and 6 feet deep between the wall and the side lining of the spillway, through which timber products may be passed from lake to river.

The under-sluices are designed to interfere to the least extent possible with the flow of water over the weir crest. They are of the sliding face cast iron type, 6 by 7 feet opening, and are provided with short stems which do not extend above the weir crest level. There will be no occasion to open these sluices when the water level is topping the weir, hence the operating head will never exceed 16 feet above their sills. The sluices are raised and lowered by a moving capstan hoist travelling upon rails set in the concrete weir crest. The capstan is removed from the crest and stored during the high water season.

A 36-inch steel outlet pipe, set in concrete and with valve and structural steel operating tower, is provided to release water for domestic and agricultural purposes at the lowest stages of the lake.

About 8,000 cubic yards of concrete were used in the construction of the dam, the greater part of this being in linings 6 to 15 inches thick in the spillway cut. The concrete aggregate was obtained from the gravel bank that supplied material for the gravel facing of the dam.

The side linings of the spillway lie on a 1:1 slope and average about 14 feet high. As a means of holding down

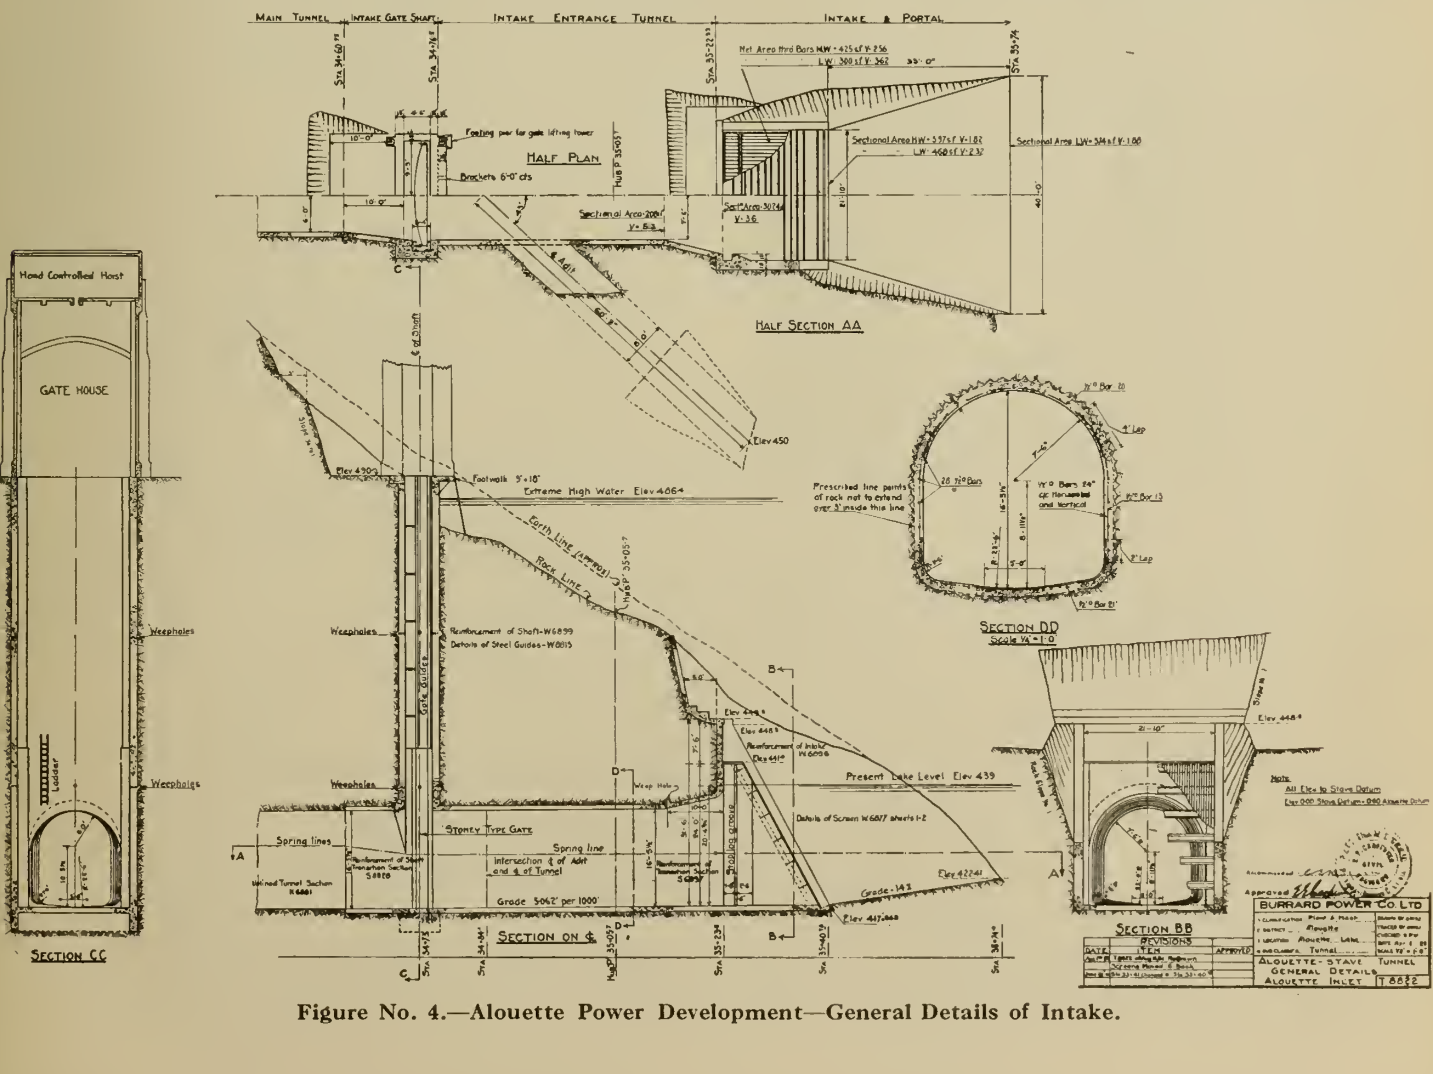

Figure No. 4.—Alouette Power Development—General Details of Intake.

Figure No. 5.—Alouette Tunnel Intake—View from Lake.

the forms against the uplift of the concrete on this slope, concrete ribs spaced 14 feet 3 inches, centre to centre, were first poured and allowed to set and then the forms for the lining were anchored to them. The ribs were of inverted T-section, 12 inches deep and 14 inches wide, including a 2-inch shoulder on either side to receive the slab forming the lining. The lining slab was 12 inches thick at the bottom, decreasing to 9 inches at the top, while the rib was 12 inches deep throughout. Expansion joints were placed at alternate ribs.

The spillway floor, 9 inches thick, was poured in alternate blocks about 20 by 30 feet in size. Expansion joints consisting of ¼-inch sheets of asphalt and asbestos fibre compound were placed between blocks. Both side and bottom linings were reinforced with 6- by 6-inch No. 5 welded wire mesh, the reinforcement being carried through the expansion joints.

Alouette Tunnel

From Alouette portal and intake, on the westerly shore near the upper end of the upper lake, the tunnel extends in an easterly direction for 3,539 feet before reaching the head gate of the short penstock leading to the power house.

The intake, which is depressed 19 feet below the low water level of the lake to afford full draft at this stage, is provided with screens and stop logs set in a heavy concrete structure. A short section of tunnel, 46 feet long, leads to the intake gate shaft, which extends upward through solid rock to the surface of the mountain side. The shaft head is at elevation 490, and is 3 feet above extreme high water level. A heavy control gate of the Stoney Roller type, 18 feet wide by 15 feet high, closes the tunnel at the bottom of the shaft, its operation being accomplished by means of a powerful hand-operated hoist set in a gate tower at the shaft head. The shaft, entrance tunnel and intake are lined with reinforced concrete 9 to 15 inches in thickness. For general arrangement and details, see figure No. 4. A photographic view of the intake and gate tower is shown in figure No. 5.

The main tunnel, exclusive of entrance section and adits, is 3,485 feet in length; straight in alignment and has a uniform grade of 5.062 feet in 1,000 feet. In section, it is an arched rectangle 12 by 16 feet. The data for the normal unlined section are:—

Area inside prescribed line	178.5	sq. ft.
Excavation inside prescribed line (per lin. ft.)	6.61	cu. yds.
Hydraulic radius	3.58	ft.
Co-efficient of roughness—Kutter formula (n)	.032	
Discharge $Q =$ 700 c.f.s., velocity	3.92	ft. per sec.
hydraulic slope	.00128	
Discharge $Q =$ 1080 c.f.s. velocity	6.09	ft. per sec.
hydraulic slope	.00308	

The tunnel bore traversed in the main a solid granitic formation affording excellent stability of section and good drilling and breaking qualities. At frequent intervals, fractures or seams, heavily water bearing, were encountered but these were of little consequence except as a matter of the minor delay and inconvenience attending them. Only one major break in the formation was encountered. Approximately 700 feet from the Stave portal an extensive and troublesome mud seam or fault zone was encountered which necessitated the setting of nearly 100 feet of heavy permanent timbering before it was traversed. The progress of the work was delayed some three weeks on this account. The timbered section and an equal length of rock section adjoining it were lined with a heavy lining of concrete before water was turned in.

The tunnel proper terminates at the penstock gate shaft, 14 by 15 feet in size, which rises 85 feet through solid rock from the surge chamber floor to the surface of the hillside.

In order to gain access to the main tunnel at the Stave portal, an adit tunnel 8 by 10 feet in section was driven from the hillside somewhat south of the line of the main tunnel, to the gate shaft. In addition to its function as a construction agency, the adit serves as a by-pass for draining the main tunnel and for drawing water from Alouette lake into Stave lake in case the Alouette plant is shut down. A 6 by 8 feet sliding cast iron Coffin type gate with bronze facings is set in the gate shaft at the head of the adit for controlling its flow.

The penstock head gate is of the caterpillar self-closing type, 13 by 14 feet clear opening, with motor hoist and remote control. The maximum head is 88 feet above its sill.

A concrete gate tower conforming in architecture to the power house surmounts the shaft and houses the hoisting equipment for the two gates and for the screens. The structure is carried on high columns to afford headroom for hoisting the gates and screens clear and to allow the surge overflow to discharge freely. The arrangement of penstock shaft and gates is shown in figure No. 6.

Immediately back of the penstock gate shaft a tapering vertical enlargement of the tunnel was excavated in the rock. This, in combination with the penstock gate shaft, forms the surge chamber designed to meet the hydraulic conditions imposed by variations of load on the turbine and the consequent variations in rates of flow in the tunnel.

The combination of shaft and enlarged tunnel form of chamber results in something of a differential action, in that the area of the chamber increases with the falling water levels, with the result that, when there is an increased demand for water to supply the penstock, the water level

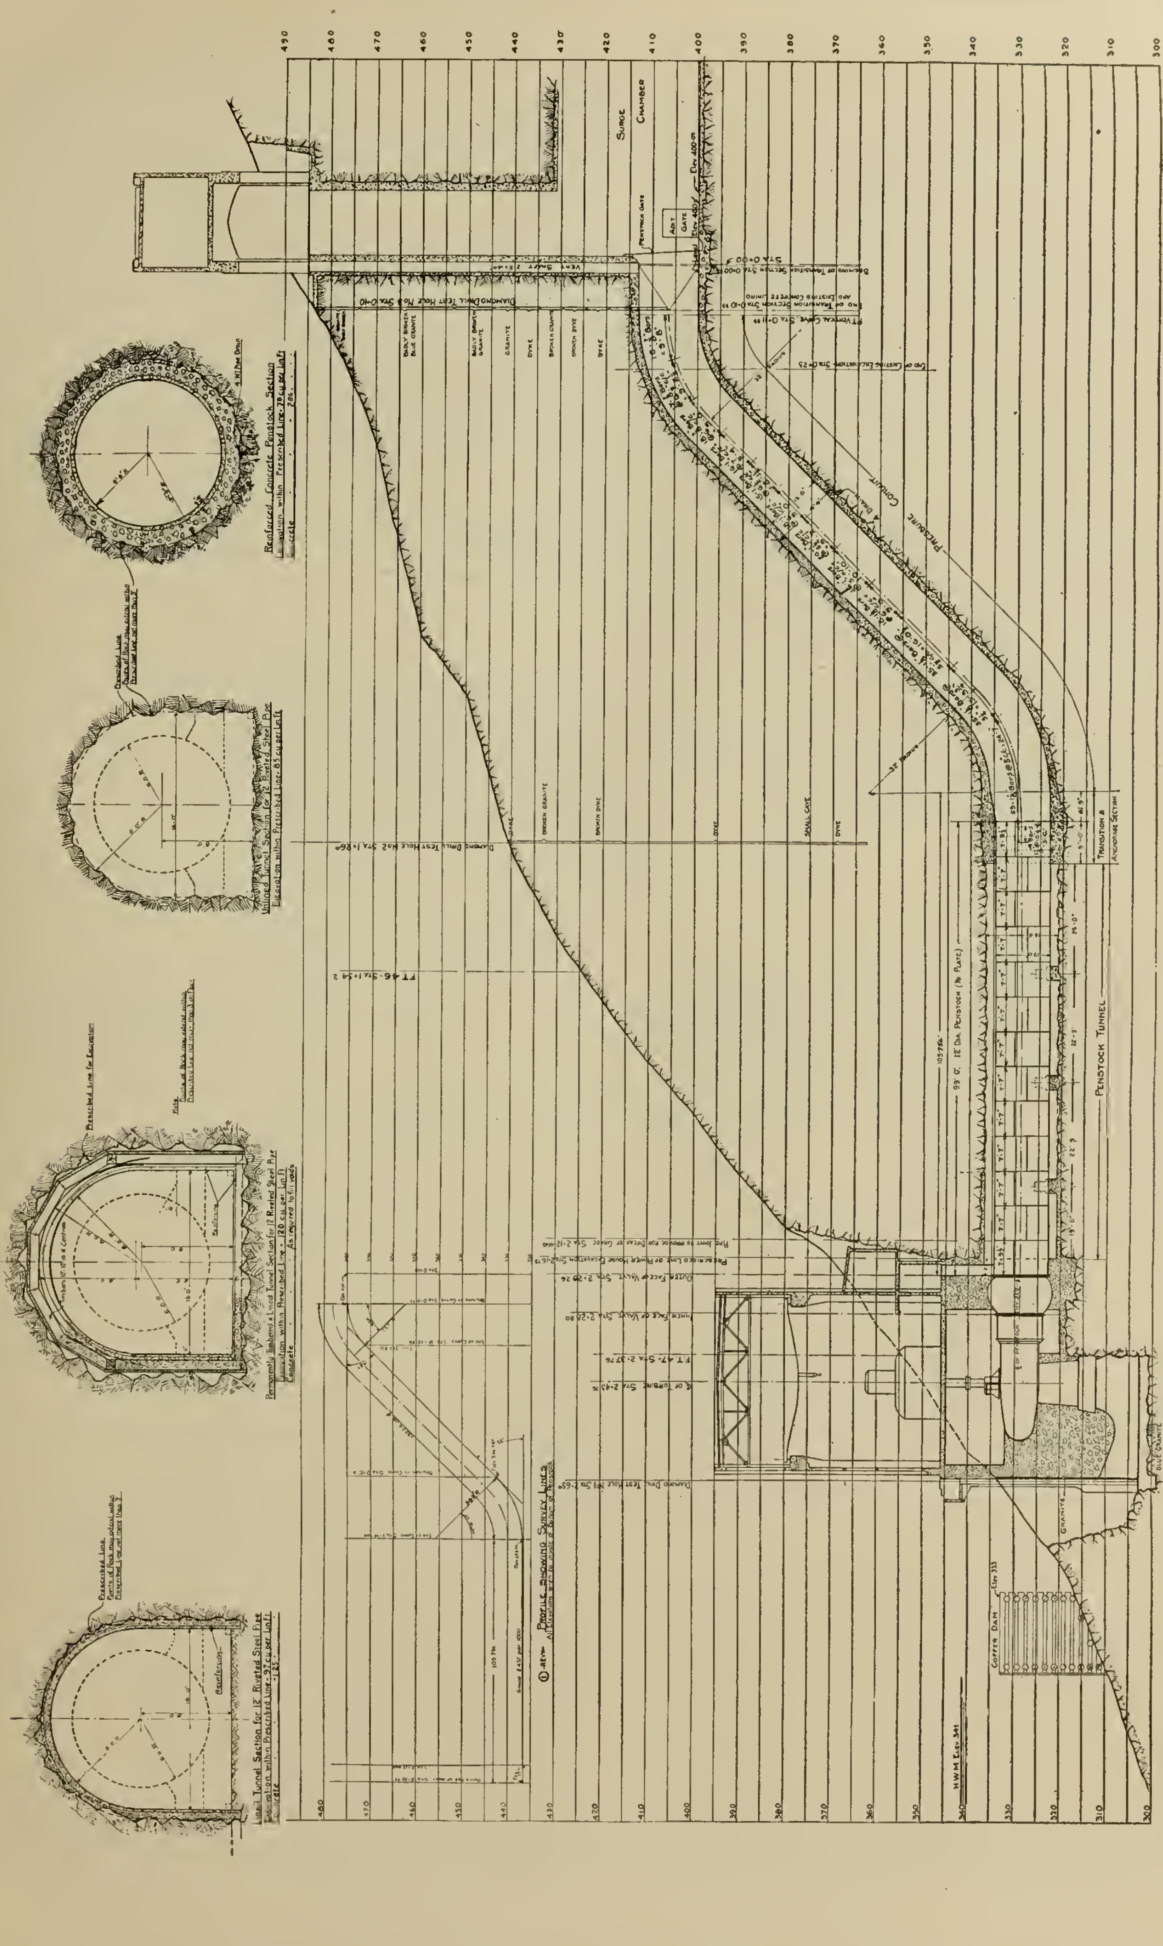

Figure No. 6.—Alouette Power Development—Section of Tunnel Outlet, Penstock and Generating Station.

in the surge chamber drops rapidly at first, thus quickly accelerating the flow in the tunnel and at the same time providing in its lower levels a proportionately greater storage of water to supply the deficiency in the penstock. The necessity of meeting the condition of low level in the surge chamber due to the Alouette storage being drawn down to 437 was an important influence in the design. This latter condition requires the effective storage capacity of the surge chamber to be concentrated at elevations below 437.

The design, as shown in figure No. 7, is calculated to permit the rejection of full load and the consequent shutting off of all the water at the turbine in 2½ seconds without damage or disturbance other than a waste of water for half a minute's time from the overflow basin at the top of the shaft; similarly, the turbine may be started from dead stop and brought to full steady load in 75 seconds, and from half to full steady load in 10 seconds without drawing the water in the chamber to a dangerous level or causing surge fluctuations of a dangerous nature.

While these conditions would probably not afford the best commercial regulation under rapidly fluctuating loads, if the plant were operating alone, this is not essential as the Alouette plant is small in comparison with the remainder of the system and will operate in parallel with the other plants amply capable of taking care of the situation.

Work of driving the adit on the Stave side was started July 9th, 1924, and work from the Alouette side was started October 10th. The two headings met May 26th, 1925, at a point 2,522 feet in from the Stave shaft.

In excavating for the Alouette portal and intake, a rim of rock was left between the excavation and the water line of the lake. This was drilled from the excavated face with holes inclined downward and also with a row of 20-foot holes from the top at the water's edge, inclined out toward the lake. Before shooting this rock rim, stop log timbers were put in place across the entrance to the tunnel and the steel trash racks were set, then covered with a barrier of hemlock logs, 12 to 18 inches in diameter, placed side by side vertically. Outside of the logs a layer of baled straw was placed as a cushion. The holes were loaded with a total of about 800 pounds of powder, there being some 500 cubic yards of rock to break up. In spite of all these precautions the shot, kicking back directly toward the tunnel, broke through the barrier and destroyed the screens, supporting beams and stop logs and admitted the water to the tunnel some four or five days before it was planned to do so. No other damage of consequence was done, but some considerable difficulty was experienced in closing off the water again to replace the damaged members and complete the concrete work.

Penstock

The tunnel proper terminates at the penstock gate shaft where the caterpillar gate controlling the flow through the penstock is set. The penstock continues on in tunnel some 250 feet further to the power house. As a consequence of its short length, loss of head had little influence on its design, the limiting conditions being rather the choice of a

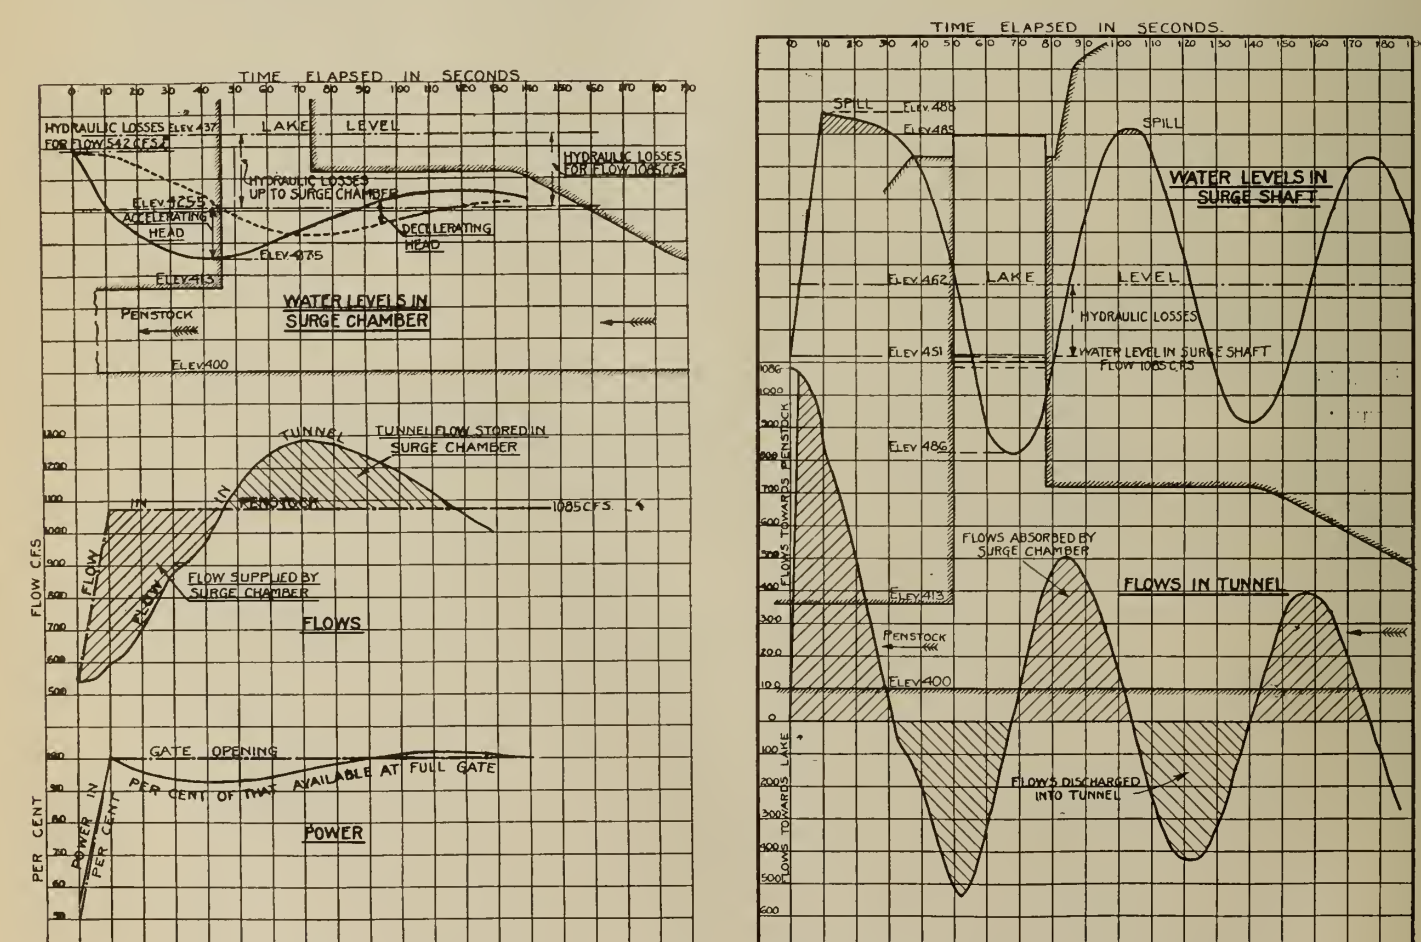

Figure No. 7.—Alouette Power Development—Surge Temperature Graphs of Surge Conditions. (1) Surge conditions with gate open half to full in ten seconds. (2) Surge conditions with flow of 1085 c.f.s. and gate closing in two and-a-half seconds.

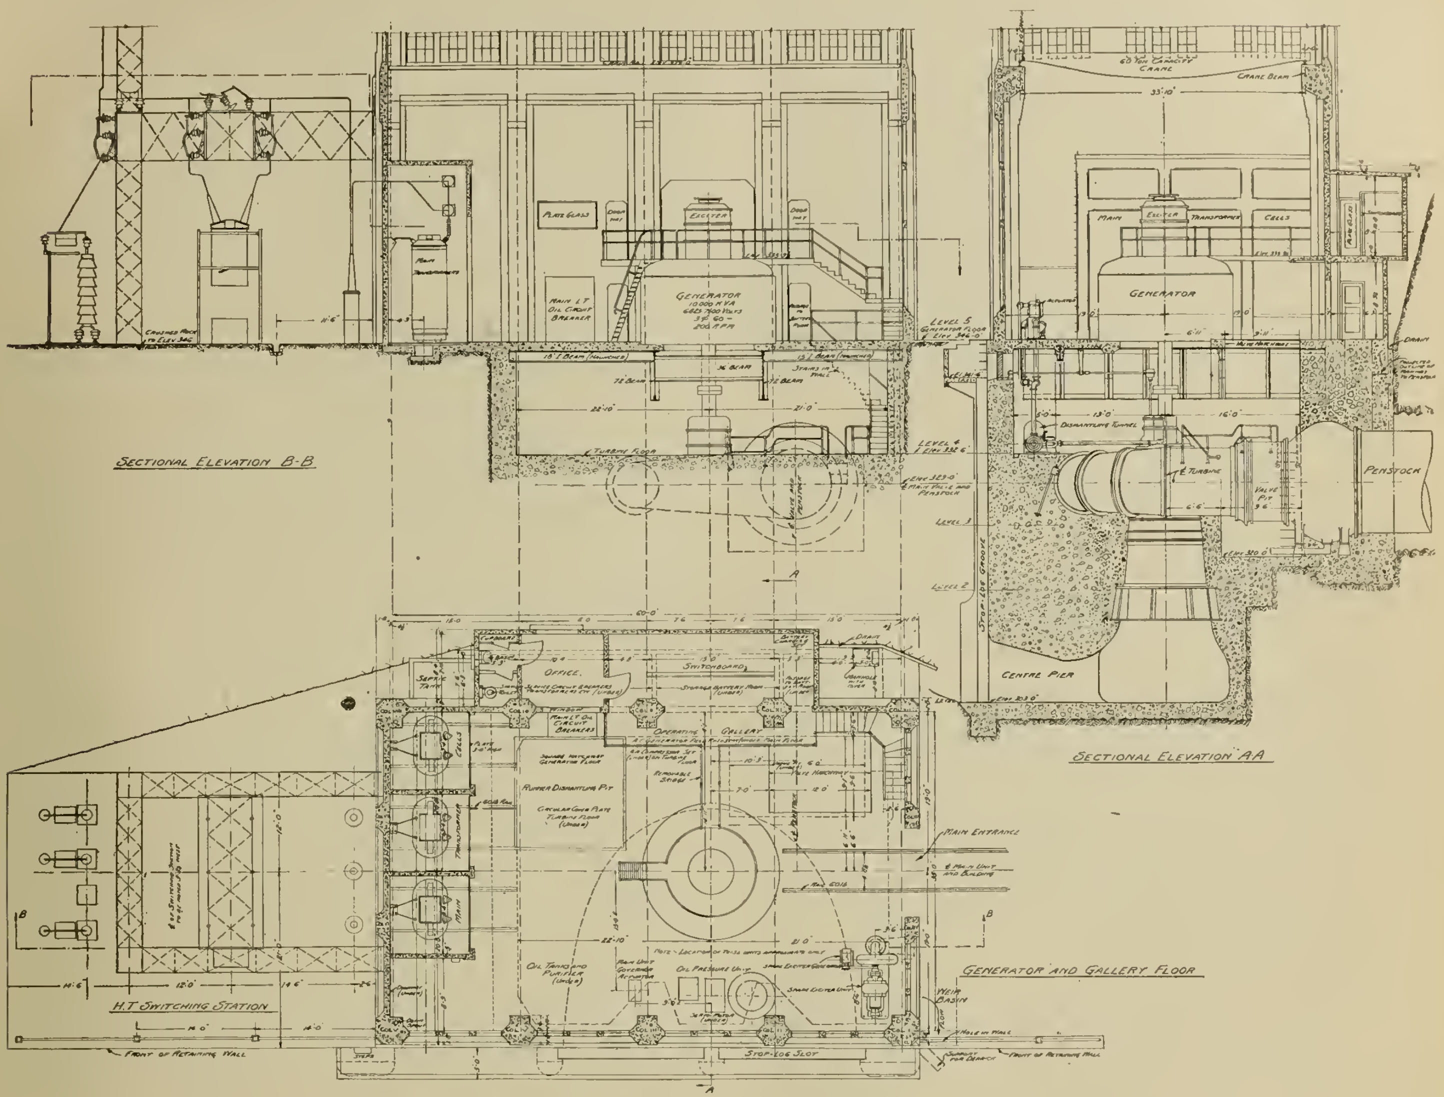

Figure No. 8.—Alouette Power Development—General Layout of Generating Station.

diameter to afford permissible velocities in terms of pressure rise under consistent regulation.

A sectional view of the penstock and its relation to the tunnel, surge chamber and turbine is shown in figure No. 6.

The upper portion is designed as a pressure conduit or pressure tunnel 13 feet inside diameter, lined with concrete 15 inches thick and reinforced to withstand the total head, including pressure rise, without stressing the steel reinforcement beyond its elastic limit. The rock cover theoretically and under ideal conditions affords sufficient backing to take up the thrust due to water pressure, but after due consideration and taking into account the actual conditions of rock structure and the probability of not being able by the best workmanship and inspection to actually meet ideal conditions, it was decided to provide the reinforcement.

At the lower end of the pressure conduit the change in diameter from 13 to 12 feet is accomplished in the transition section heavily lined with concrete similarly reinforced.

The lower section, 99 feet in length, is a steel pipe line 12 feet in diameter, laid in an open tunnel and supported and anchored in concrete piers. The tunnel is unlined except where rock structures may require lining.

The entire pipe line is of $\frac{5}{8}$-inch steel plates in parallel courses with lap joints triple riveted on the longitudinal and double riveted on the roundabout seams.

Power Station

The power house is set in the steep rocky hillside adjoining the west shore of Stave lake, some $10\frac{1}{2}$ miles north of Stave falls, the only approach to it being by water from Stave falls. The station, in section, is shown in figure No. 8. The building, as designed, is of reinforced concrete construction, massive but pleasing in appearance. On the south side adjoining the building, a level space 40 by 40 feet is provided as a switch yard and at the north end a similar space 30 by 100 feet forms a material yard. Both spaces are formed at the expense of considerable rock excavation and concrete retaining walls along the lake shore.

The main building covers an area 64 by 41 feet, is 50 feet in height, and contains the single vertical 12,500-h.p. hydraulic turbine direct-connected to a 10,000-kv.a. alternator, with direct-connected exciter, a turbine-driven spare exciter, low tension oil circuit breakers, and the step-up transformers. The usual auxiliaries including governors, governor oil pumps, field rheostat for the alternator, oil-purifying and handling outfit for lubricating, transformer, and circuit-breaker oils, and general service equipment, sump pumps and air compressor, are also housed in the building. A leanto adjoins the main building and lies between it and the hillside. The leanto houses the main switchboard, control storage battery, low tension disconnecting switches, and other auxiliary electrical equipment. The main floor elevation of the power house is at elevation 346; the leanto floor at elevation 355.75, and the turbine floor at elevation 332.

Beyond minor soil stripping, all the excavation for the building and machinery foundations is in solid rock. The draft tube and tail race excavation extends down to elevation 301, some 39 feet below the high water level of Stave lake. Some 6,000 cubic yards of rock are involved in preparing the foundations.

A concrete weir, 100 feet long, with crest elevation at 314, will control the tail water, the normal low level of which is 316.

To hold out the waters of the lake, which will rarely drop as low as 316, during the construction of the foundations a heavy cofferdam of rock-filled log cribs with timber sheet piling facing and completely enveloping the front of the building and the weir, has been constructed. The top of the coffer dam is at elevation 333, below which level the waters of the lake are being held until the front wall of the building shall have been poured to floor level. The tail race bays will then be closed with stop logs and the coffer dam will no longer be required.

An electrically operated bridge crane of 60 tons capacity will be provided for service inside the building. A 30-ton steel derrick is provided for handling heavy parts and materials from scows to station yard. The derrick has a special setting at the building corner, the walls being specially designed to function as stiff legs for its support.

In the switch yard adjoining the building on the south will be mounted the 60,000-volt line oil circuit breaker, disconnecting switches, and lightning arrester equipment. A simple steel structure is provided for mounting disconnecting switches, and terminating the transmission line that connects this station with Stave falls.

The station building and appurtenant works are now under contract and the work is proceeding satisfactorily. The major part of the rock excavation both for the building and machinery foundations and for the pipe line tunnel and pressure conduit is completed.

To control the supply of water to the main turbine from the penstock, there is provided a main valve of the balanced cylindrical type. It is 15 feet long, has a maximum body diameter of 17 feet, with inlet and outlet diameters of 12 and 8 feet respectively. It is hydraulically operated, designed for remote automatic control, actuation being accomplished electrically or in emergency by hand.

The main turbine is a vertical shaft unit of the Francis type, developing 12,500 h.p., effective rated output under 125.5 net effective head, running at 200 r.p.m. The spare exciter turbine is a horizontal shaft reaction unit of 150 h.p., running at 900 r.p.m.

Governing equipment for the main unit consists in general of actuator, servo-motor, and oil pumping unit. The oil pumping unit is driven by both hydraulic turbine and electric motor, a constant pressure of oil for operation of turbine gates being thus assured. The governor is arranged for both electric and hand control.

The alternator is a vertical shaft unit with revolving field rated at 10,000 kv.a., and designed to operate at 80 per cent power factor, 6,827-7,500 volts, 3-phase, 60-cycle, 36 poles, 200 r.p.m. The rotor is designed to withstand 100 per cent overspeed. Brakes operated by air pressure are provided to bring the rotor quickly to rest on all occasions of shut-down.

Both main and spare exciters are of 119 kw. capacity, with nominal voltage rating of 250. The former is of vertical shaft type with its armature mounted on an extension of the alternator shaft; the latter is a horizontal unit direct connected to a hydraulic turbine mentioned previously.

Three transformers now on hand, which are conservatively rated at 3,000 kv.a., will be used to step up from alternator voltage of 6,827-7,500 to transmission voltage of 60,000-66,000. They are indoor type, water-cooled and consequently have been given an inside setting. A spare unit will be available.

While the last details of the switching and control equipment are not yet decided upon, the plant as designed may be termed a *full-automatic* station, with, however, the single reservation that the manually operated starting and stopping indications will be given at Stave falls generating station.

The starting indication is given when the station operator at Stave falls closes, at that station, the oil circuit breaker in the transmission circuit connecting Alouette and Stave falls. Energy is thus made available at Alouette and a master starting device is energized and commences to function and, providing correct starting conditions exist, the penstock valve is opened, the turbine gates start to open and the rotor is set in motion; as the speed increases the exciter voltage is built up, and when this voltage reaches the proper point a contactor closes, applying exciting current to the alternator field; as synchronous speed approaches, an automatic synchronizing device takes hold, and when the required conditions of speed, voltage and phase relation are reached it closes the low tension oil circuit breaker, thus connecting the alternator to the transmission system. The machine then assumes load in accordance with the governor setting.

When a stopping indication is given at Stave falls by opening the line oil circuit breaker, loss of load causes certain devices to function and the penstock valve closes; at the same time the governor closes the turbine gates; at the running light position the alternator is disconnected from the line, field excitation is removed, and the brakes are applied and the machine comes to rest.

Complete provision, as in all automatic stations, will be made to prevent starting or shutting down if abnormal conditions develop. Provision will also be made for full manual operation of the station if desired.

All the hydraulic equipment and the main generator, exciters and their auxiliaries are in the course of manufacture by the English Electric Company, Limited, of London, England. Deliveries are expected in the early spring of 1926.

The switching and control equipment is being designed and manufactured by the Canadian General Electric Company, Limited. Particular study and attention is being given to the automatic features.

Transmission Line

The current from the Alouette station is transmitted to Stave falls, where it is fed into the high tension buses for transmission to system load centres. The line was built in 1924 to furnish construction power for the tunnel work. It is 10½ miles long, of the single cedar pole type, carrying one 3-phase, 66,000-volt power circuit, and one telephone circuit.

The Stave Falls Development

The initial development of the Stave falls project was undertaken and carried to completion in 1911 by the Western Power Company of Canada, Ltd., then, and until 1921, a competitor of the British Columbia Electric Railway Company. At the latter date the control of the Western Power Company of Canada was acquired by the British Columbia Electric Railway Company, which has since improved and added to the plant the features described in some detail in this paper.

The initial installation consisted of the intake dam, the sluice dam and the Blind Slough dam,—all raised to a height to permit storage in the lake to elevation of 318,—control works and penstocks for four 8,825-kv.a. generating units, three of which were installed.

The improvements and additions undertaken in 1922 and completed in 1925, included as a first step the installation of the fourth generating unit, followed by the raising of the intake dam, the construction of the west wing wall, the Blind Slough dam, and the filling in and raising of the sluice dam, all to a level to permit storage to be carried to elevation 340,—a net raise of 22 feet in the former storage level,—and the installation of a fifth generating unit with the necessary penstock, extensions in power house building, tail race, etc.

Stave lake as it stands today, with its water level at elevation 340, (269 feet above mean sea level), is a beautiful body of water some 17 miles in length and 1½ miles in width, lying 35 miles east of Vancouver and, with the upper river feeding it and the lower river joining it to the Fraser river at Ruskin, forming a drainage system some 60 miles in length. The original lake terminated about 7 miles above the falls, where the plant is built. The river at this point separated into two channels forming an island between them and dropped over a series of falls some 80 feet.

The intake dam, power house and tailrace occupy the westerly channel, and the sluice dam or main dam the easterly or main channel. A quarter of a mile further east and separated from the main channel by a high rocky hill, is a third channel known as the Blind Slough. This latter channel is some 20 feet higher than the others and did not function as an outlet, but was closed by ancient log jams and beaver dams, hence its name. The Blind Slough dam now closes this old channel, which is used to carry away the flood overflow from the lake. Figure No. 9 shows the general location of the plant with reference to the topographic and surface features.

The watershed of the Stave river, like that of the Alouette, is largely unsurveyed and unmapped, hence its area can only be given in approximate figures as 450 square miles.

The watershed lies on the westerly slope of the Coast Range mountains; the lower part, extending from the dam half way up the lake, rises to a maximum altitude of 4,000 feet, and is, in the main, heavily timbered. Beyond this point the mountains rise more abruptly to heights above the timber line, the topography becomes more broken and rugged, and perpetual snow fields and small glaciers occupy a considerable part of the area. The principal peak of the watershed, Mount Baldy, stands near the head of the lake and rises to an altitude of over 6,000 feet.

The Stave lake basin is clearly of glacial origin, the receding glacier having formed a series of morainal dams, the remnants of which, combined with occasional spurs of bedrock, form the barrier that holds the lake in place. These dams have been eroded away by stages, and the present river valley, with its terraced flanks and occasional gorges, has been cut deeply into the stranded remnants of the bedrock that withstood the grinding glacier but have proved a futile barrier to the gentler but persisting action of the stream.

The average annual precipitation for the 15-year

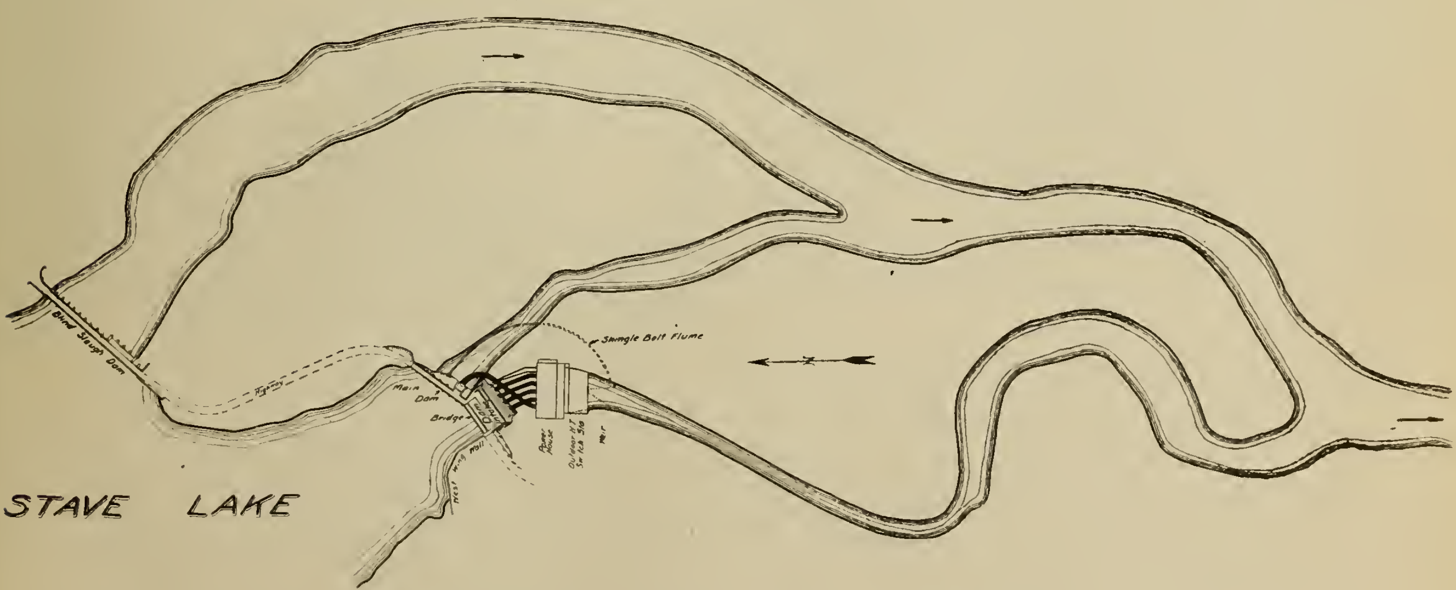

Figure No. 9.—Stave Falls Power Development—General Layout.

period 1910 to 1924 inclusive, as recorded at the observing station at Stave falls, is 78.3 inches, which is made up of monthly averages as follows:—

Jan.	10.4 inches	May	4.21 inches	Sept.	5.24 inches
Feb.	6.64 "	June	3.69 "	Oct.	8.22 "
Mar.	7.66 "	July	1.82 "	Nov.	11.39 "
Apl.	5.27 "	Aug.	2.87 "	Dec.	10.89 "

During January, February and a part of March, the greater part of the watershed is snow-covered, and from October to May the precipitation over the greater part is in the form of snow.

The relation between mean annual run-off and mean annual precipitation is interesting. Assuming the watershed area to be 450 square miles, the ratio of run-off to precipitation is 1.4, which indicates that much heavier precipitation occurs over the whole watershed than at the observing station.

The records of run-off of the Stave river are based upon a long period of observation and are fairly well and firmly established. From 1905 to 1911, when the initial plant was put into operation, excellent and continuous records were kept. Since the latter date run-offs have been computed from electrical output records and spill. The mean annual run-off of the watershed for the 18-year period 1906 to 1923 inclusive, was 3,880 cubic feet per second. Studies of the mass diagrams for this period point to the conclusion that, with the regulation afforded by the raised impounding works which afford the storage of 471,000 acre-feet, the dependable flow for power purposes may be taken as 3,500 cubic feet per second. This, augmented by the supply of 700 cubic feet per second contributed by the Alouette tunnel, makes 4,200 cubic feet per second continuously available for power at Stave falls station.

The tailwater elevation of the Stave falls plant is 210. The high water elevation of the lake is 340. The intake gate sills are set at elevation 285, which permits full draft for power at a low level elevation of 306. The static heads available are:—

Maximum head	130 ft.
Average head	115 ft.
Minimum head	96 ft.

With plant efficiency of 78 per cent, allowing for all machine and penstock losses, the 4,200 cubic feet per second is capable of generating 32,000 kw. continuously, and the annual energy output is estimated at 280,000,000 kw.hrs. When the fifth unit is put in operation the installed capacity of the plant will be 65,625 kv.a. At 0.9 power factor the plant will have a peak load capacity of 59,000 kw. Owing to the limit of turbine capacity, however, it is believed that a peak capacity greater than 54,000 kw. cannot be depended upon under conditions of average head. The plant can therefore operate on an average annual load factor of 59.1 per cent. The system load factor approximates 50 per cent.

Intake Dam

The intake dam which closes the westerly channel of the river lies about 200 feet upstream from the power house and in it are set the intake gates, screens and other control structures for the proper supplying of four of the main penstocks and the two exciter penstocks. The original dam, constructed by the Western Power Company in 1911, was a full gravity section concrete structure about 55 feet maximum height, 160 feet long, and was designed to accommodate high lake level of 318 feet with a free board of 7 feet.

Provision was made in its design and construction details for raising its height at some later time. Four radial Tainter gates 19 feet wide by 20 feet high controlled the flow of the penstocks. Timber stop logs were set in the bays upstream from the gates as a means of emergency control. The raising of the intake dam entailed the placing of about 8,800 cubic yards of concrete.

In raising and reconstructing the dam to elevation 345 the Tainter gates were removed and the large wells required for their proper setting and operation were filled with concrete to give the necessary weight to the new structure. Four structural steel gates of the fixed roller type, 20 feet wide by 21 feet high clear opening, were installed in their places.

The four hoisting winches operating the gates are set upon the deck of steel structure extending over the entire length of the four gate openings. The winches are operated through separate clutches by a cross shaft driven by a 15-h.p., 125-volt, direct current motor set about mid-length of the shaft.

Emergency control of the gate openings is provided by one set of five new steel stop logs, replacing the former timber ones, and which may be dropped into checks upstream from each of the roller gates. Each stop log is formed of two I-beams connected with channels and plates rivetted on and all filled with concrete to give sufficient weight to permit placing. The stop logs are placed and removed by a travelling hoist moving along the deck on a 9-foot gauge track extending the length of the gate openings. The arrangement permits the closing of any of the openings safely and rapidly with the one set of logs provided. The engaging and lifting of the logs is accomplished by means of a steel master log with catches at either end. Figures Nos. 10 and 11 show plan and sections of the intake dam.

West Wing Dam

At the west end of the intake dam the bedrock dips sharply westward and plunges beneath the overlying strata of glacial clays, gravels and boulders. Explorations indicated that a foundation for cut-off walls on bedrock could not be reached. In order to cut off the danger of seepage in this zone a heavy retaining wall about 280 feet in length connecting with the west end of the intake dam and extending upstream some 150 feet, and then curving west into the rising shore, was constructed. The wall has its base at elevation 295, is about 50 feet in height and is founded on bedrock for about 160 feet from the intake dam and upon clay and hard pan for the remainder of its length. It contains about 3,900 cubic yards of concrete. The space back of the wall was filled with earth, the lower portions of which were hydraulic filling, and the upper portion placed with cars, but the toe of the dump was constantly kept under water, and thus a good water settling of the whole fill was obtained. About 20,000 cubic yards of filling were placed behind the wall.

Main Dam

The new main dam was formerly the sluice dam of the first builders, and as such was designed to discharge the entire flood of the river. With the raising of lake level the Blind Slough became available for this purpose, and the sluice dam was consequently filled in and raised to the proportions of a solid gravity section concrete structure with crest level at elevation 345. The old sluiceways, five in number, were 22 feet in width and were separated by concrete piers 8 feet thick. The sluiceways were closed with timber stop logs.

In the new structure a roadway 16 feet wide is provided on the crest; this road is connected with the west wing dam by a steel truss span 135 feet long bridging the intake bay in front of the penstock gates.

The intake of the penstock for the fifth unit is set in the main dam in the second bay from the east abutment of the intake dam. A fixed roller gate with hoisting winch similar to the intake gates for the other penstocks is provided for control. A vertical screen in sections is set in the old stop log checks for protecting the gate and the penstock entrance.

One of the most ingenious features of the main dam is the shingle bolt chute for the passage of bolts, which are produced in large quantities on the lake, through the dam and into the tailrace below the power house at all stages of lake water level. This feature has proved most efficient in its operation. With a water supply of 25 cubic feet per second, 10,000 bolts have been put through the chute, flume and tunnel and discharged into the tailrace in eight hours' time.

Approximately 9,500 cubic yards of concrete were placed in raising and reconstructing the main dam.

Blind Slough Dam

Before the improvement, this channel was closed with a small rock-filled timber crib structure with ten sluices, 6 by 14 feet, which served as an auxiliary spillway. With the raising of the reservoir level the former dam was discarded and replaced by a concrete dam 640 feet long consisting of a series of heavy piers with fourteen spillway bays between them and surmounted with a heavy deck slab carrying the roadway. Ten of the bays are closed with stop logs, the openings being 20 by 28 feet with sills at elevation 320. Four of the bays at the west of the stop log section are closed with the Tainter gates removed from the intake dam. These gate openings are 19 feet 6 inches high by 19 feet ½ inch wide with sills at elevation 294, some 16 feet below the sills of the stop log bays.

With the water level at 340 the combined discharging capacity of the fourteen spillway openings is 96,000 cubic feet per second. The largest recorded flood of the river occurred in 1921, when it was estimated that 60,000 cubic

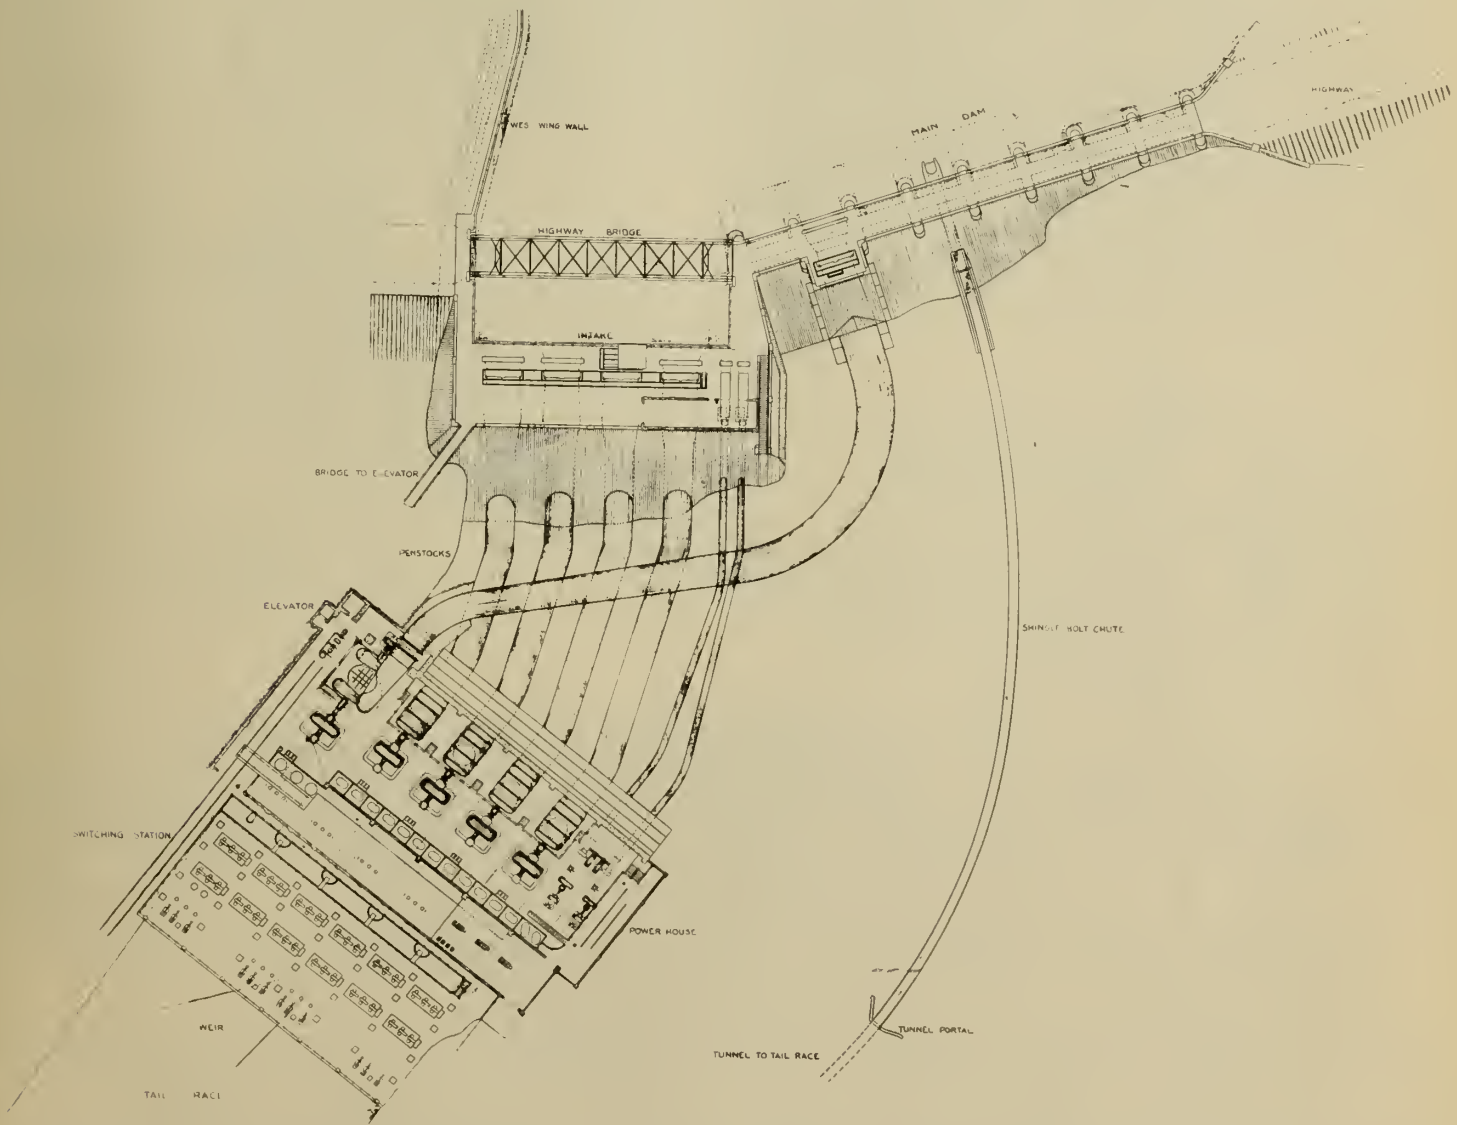

Figure No. 10.—Stave Falls Power Development—General Plan of Intake Dam, Main Dam, Penstocks and Generating Station.

feet per second were discharged by the old sluice dam and the Blind Slough auxiliary spillway dam.

The operating winches for the Tainter gates and a motor-generator set for supplying current for all purposes are set in a gate house erected upon the deck of the dam. Each winch is operated by an 8-h.p., 125-volt, direct current motor.

Upstream from each of the gates, slots are provided for the travelling emergency gate which may be placed in any of the openings to relieve the gate for repair or adjustment. This emergency gate is of the fixed roller type quite similar in design to the penstock intake gates previously described. When not in use, the gate is lifted clear of the roadway slab and moved to the end of the dam for convenient storage.

The stop logs are of timber, two pieces being bolted together with a steel stiffening plate between. The stop log machine formerly used at the sluice dam is employed for lifting and placing them. Figures Nos. 12 and 13 show the general construction and details of the Blind Slough dam. The dam contains 20,000 cubic yards of concrete.

Penstocks

The four penstocks for the original units are 14 feet 6 inches inside diameter and 190 feet in average length. The upper ends, which are embedded in the concrete of the intake dam, are belled out to a diameter of 19 feet. The plates at the upper end are ½-inch thick, and at the lower end ¾-inch thick. Roundabout seams are double riveted and longitudinal seams triple riveted; every alternate roundabout seam is stiffened with a heavy angle ring riveted on. The penstocks are supported up to their centre lines in concrete for the greater part of their lengths. A heavy continuous concrete anchor block encases all of them at the power house wall. There are two separate 46-inch steel penstocks provided for the exciter turbines.

The penstock for the new fifth unit has its intake in the main dam and hence must cross the other four main penstocks and the two exciter penstocks to reach the location of the unit at the westerly end of the power house.

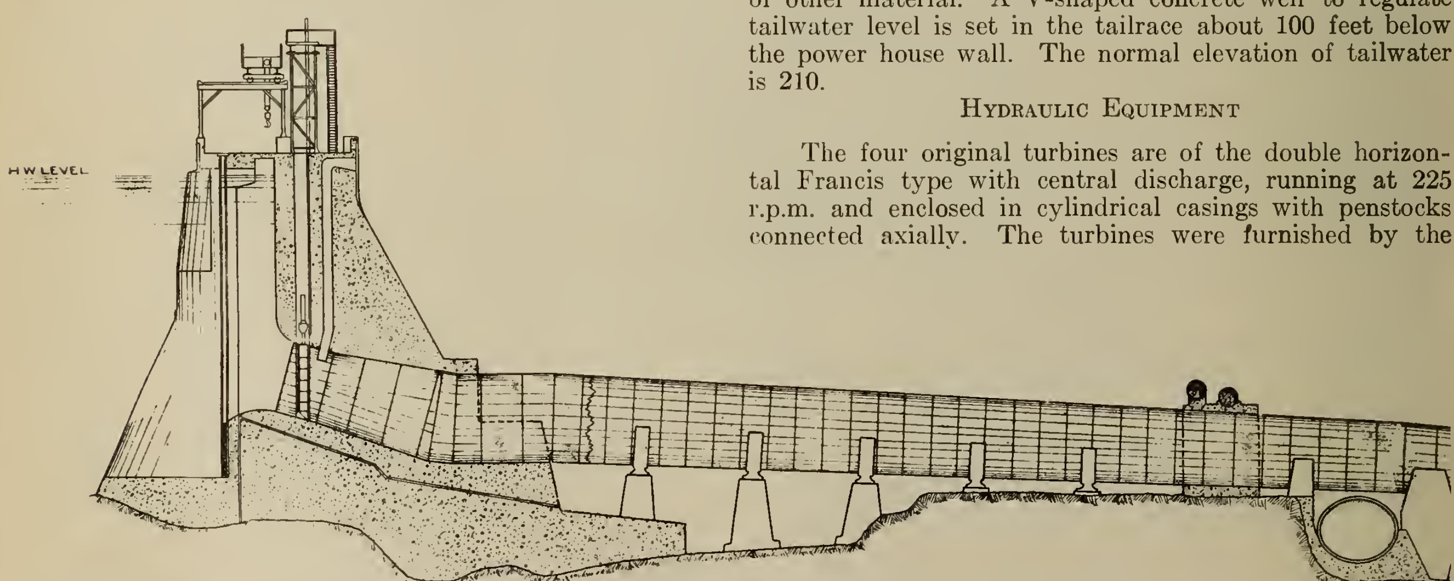

Figure No. 11.—Stave Falls Power Development—Cross-sections of Intake Dam, Main Dam, Penstocks, Generating Station.

It is 20 feet in diameter at the intake and tapers uniformly to 13 feet diameter at the butterfly valve at the power house wall.

The total length of the penstock is 324 feet. It is supported on heavy concrete piers between the existing penstocks. The profile and plan of the penstock are shown in figures Nos. 10 and 11.

Power House

The power house building is of reinforced concrete 100 feet wide, and, with the addition for the fifth unit, 215 feet long. It is set in the bed of the westerly channel some 200 feet downstream from the intake dam. The foundations rest on bedrock. Some 58,000 cubic yards of rock excavation was required in preparing foundations for the building and the machinery.

The switchboard bay extends along the east end of the building with its floor elevated some 21 feet above the generator floor. The plan and section of the building are shown in figures Nos. 10 and 11.

Switching Station

Immediately in front of the station building, on the downstream side, is located the new 60-kv. outdoor switching station. The substructure consists of a reinforced concrete slab 160 feet long by 68 feet wide supported on twelve concrete piers set in the tailrace. The superstructure of latticed steel towers and girders is 153 feet long and 50 feet wide, the maximum height being 62 feet.

Tailrace

The tailrace, 70 feet wide, is excavated in the old channel for a distance of 1,500 feet to its junction with the main river. Its construction entailed the excavation of some 22,000 cubic yards of rock and 75,000 cubic yards of other material. A V-shaped concrete weir to regulate tailwater level is set in the tailrace about 100 feet below the power house wall. The normal elevation of tailwater is 210.

Hydraulic Equipment

The four original turbines are of the double horizontal Francis type with central discharge, running at 225 r.p.m. and enclosed in cylindrical casings with penstocks connected axially. The turbines were furnished by the Escher Wyss Company of Switzerland. The casings are 18 feet in diameter, of ¾-inch steel plate with heavy forged steel flanges. The end plate is of cast steel designed to take the full hydraulic thrust. The runners are 63 inches in diameter, built of steel plates cast into their steel hubs. The bearings are water-cooled, the larger one being 15¾ inches in diameter. Draft tubes are moulded into the concrete in carefully expanding section, beginning with a circular form 8 feet in diameter and ending with a rectangular form 9 feet 5 inches by 21 feet 9 inches. The turbines are rated to develop 13,000 b.h.p. under average head of 110 feet.

The governors are of Escher Wyss hydraulic type operating under oil pressure of 300 pounds per square inch, the oil being supplied from a central pumping station equipped with two high-pressure pumps driven by impulse wheels through pipe connections from the exciter penstocks. Each pump is capable of supplying all four governor sets.

The two 250-kw. exciters are separately driven by 500-h.p. single-runner Francis type turbines, each fed by a 46-inch steel penstock.

Electrical Equipment

The four original generators were supplied by the Canadian General Electric Company. They are 3-phase, 60-cycle, 4,400-volt, 225 r.p.m. alternators rated at 8,825 kv.a. at 85 per cent power factor.

The two exciters are 250 kw. rated capacity, 125-volt, 500 r.p.m., direct-current, direct-connected to their driving turbines.

One bank of three single-phase, 4,400-kv.a., 4,000/60,000-volt, oil-insulated, water-cooled transformers is provided for each generating unit.

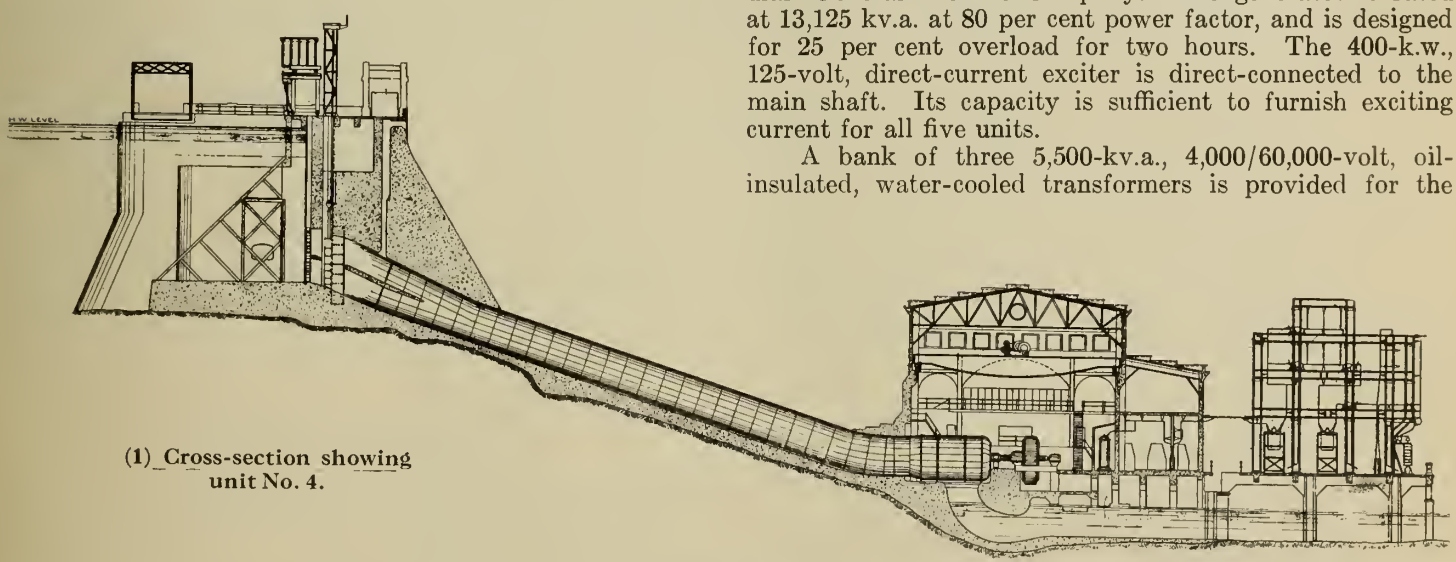
With the added water supply from the Alouette development, the continuous water energy capacity at Stave Falls could not be used with the four machines, and a fifth unit was accordingly planned, in addition to which certain changes in the four original units were undertaken. One of the four original machines was given a test run, which demonstrated that its turbines are capable, at mean head, of developing 10,800 k.w. of generated energy. Upon the undertaking of the Canadian General Electric Company that the mechanical strength of the old units would safely withstand the higher load, a contract was let to that company for rewinding and rebuilding the four original units to bring their capacity up to that of the new fifth unit, i.e., 13,125 kv.a.

The rewinding of the last of the four machines was completed in September 1925, since which time they have operated under full load satisfactorily. While no formal tests have been made, observed temperature rises indicate that their performance is in accordance with the guarantee of the manufacturer.

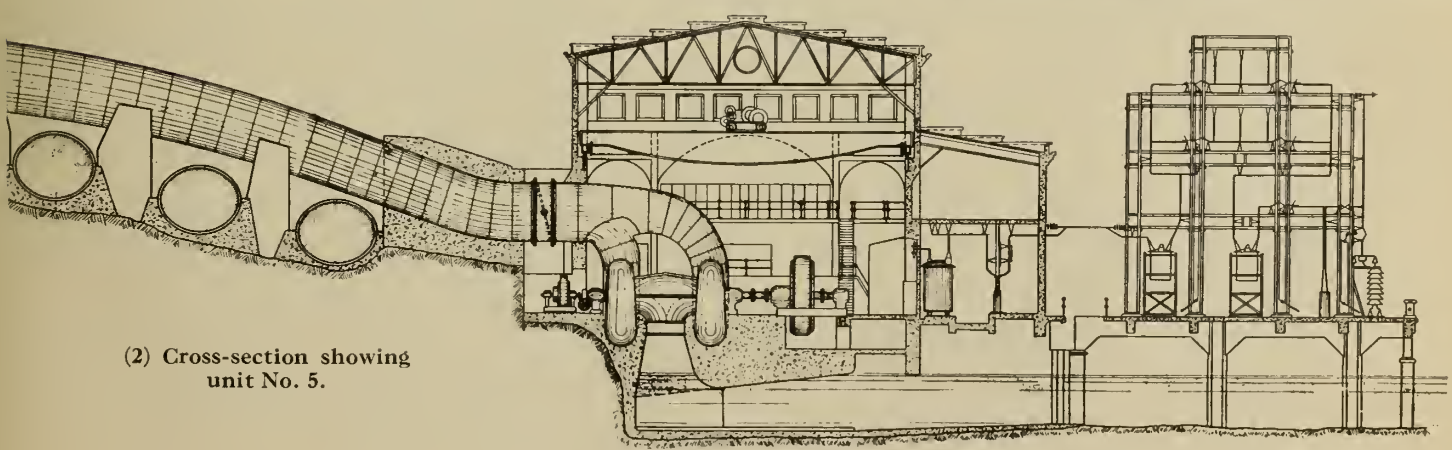
The fifth unit turbine and governor were supplied by the Canadian Allis Chalmers Company. The turbine is of the double-runner, spiral-casing, single-discharge, horizontal type, 225 r.p.m.; normal rating 15,000 b.h.p. at mean operating head.

The generator, exciter, transformers, switches and other electrical equipment were furnished by the Canadian General Electric Company. The generator is rated at 13,125 kv.a. at 80 per cent power factor, and is designed for 25 per cent overload for two hours. The 400-k.w., 125-volt, direct-current exciter is direct-connected to the main shaft. Its capacity is sufficient to furnish exciting current for all five units.

A bank of three 5,500-kv.a., 4,000/60,000-volt, oil-insulated, water-cooled transformers is provided for the



(1) Cross-section showing unit No. 4.



(2) Cross-section showing unit No. 5.

unit. The transformers are designed to operate in parallel with the existing transformers, either singly or in banks. One spare transformer is provided.

The switching equipment layout conforms in the main with standard practice, and embodies no unusual features. Figure No. 14 is a one-line wiring diagram of main circuits; the apparatus within the dotted enclosure is housed in the station building, while that outside is installed in the outdoor station.

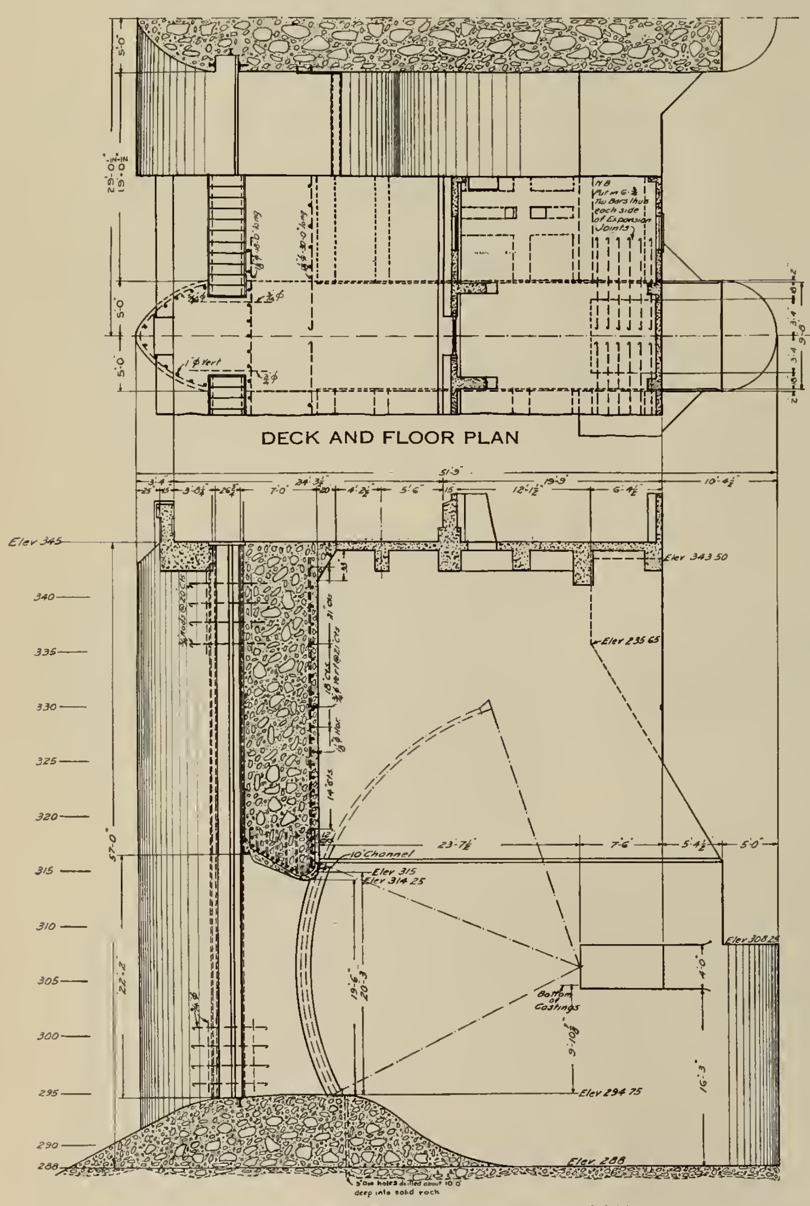
Each generator with its step-up transformer bank is considered as a unit,—the five units being tied together on the high tension buses. Between each generator and its transformers is an oil circuit breaker, (H-206), 3,000 amperes, 7,500 volts, which serves for synchronizing and for isolating the generator in case of transformer trouble. Between each step-up transformer bank and the high tension buses is an oil circuit breaker, (F.H.K. 0.136), 600 amperes, 73,000 volts, and two sets of bus selector disconnecting switches, (Pac. Elec.), 600 amperes, 73,000 volts. The disconnecting switches are of the gang-operated type connected by rods to operating levers at floor level.

Generators are star-connected with the neutral leads brought out to provide for installation of current transformers for differential relay protection, after which they are solidly grounded. The generators are protected against excessive overspeed by means of an overspeed device on the end of the shaft and by an overfrequency relay. The step-up transformers are protected by differential relays. The generator units are further protected by overload relays.

In addition to the equipment for controlling the generating units just described, provision is made for handling the output of the Alouette station. As described elsewhere in this paper, it is proposed to make this plant automatic, and it will be treated at Stave Falls as a generating unit and tied in accordingly on the high tension buses.

Two high tension, 60-kv. buses are installed to provide for the required flexibility of operation.

Feeding off the high tension buses are three transmission circuits. Two of these, the *North* and *South*, carry the greater portion of the output of the Stave Falls and Alouette stations. They are equipped with balanced differential and induction-type overload relays. The third circuit, the "Bellingham," at present feeds into the Puget Sound Power and Light Company's system at Bellingham, Washington, but provision is made for its ultimate use as one of two tie lines to the Ruskin station, when that portion of the Alouette-Stave development is undertaken. The line is equipped with induction-type overload relays. On account of the importance of the North and South lines and the desirability of



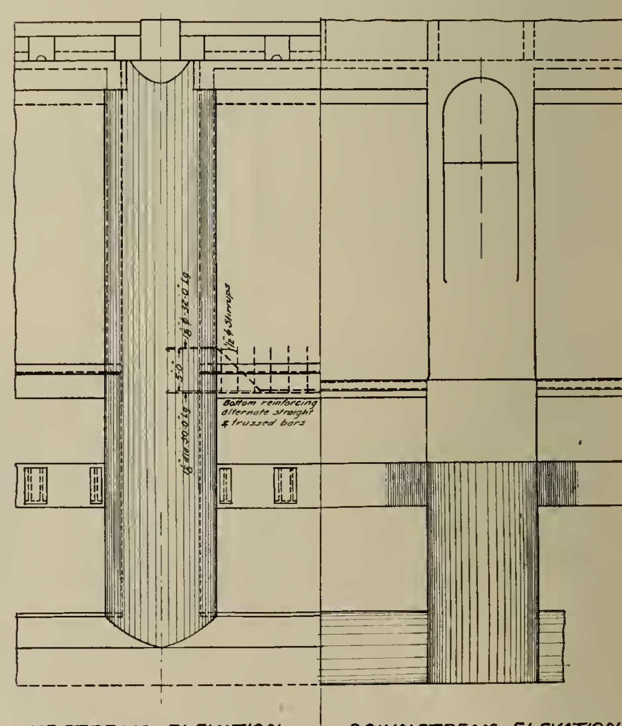


Figure No. 12.—Stave Falls Power Development—Typical Plan and Elevations of Tainter Gate Section of Blind Slough Dam.

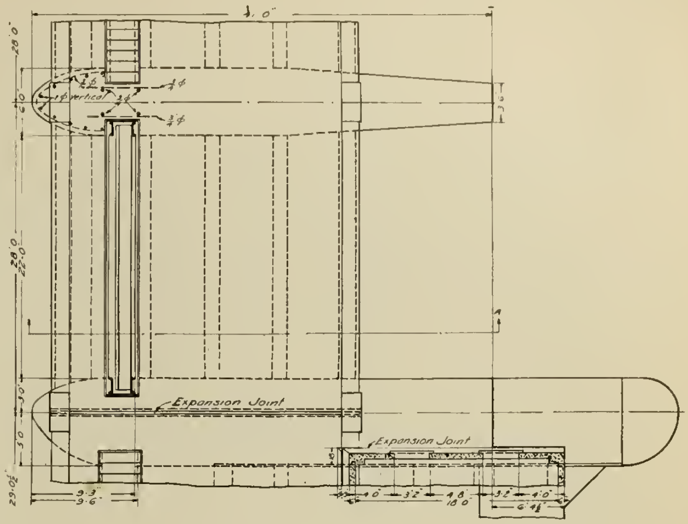
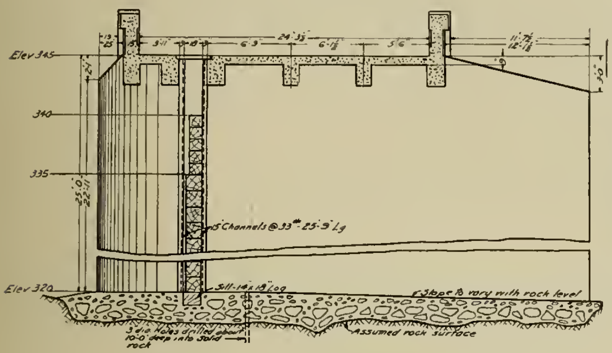
maintaining the maximum continuity of service, two oil circuit breakers are installed on each of these circuits, one on each high tension bus. The Bellingham line has one circuit breaker, bus selection being made with disconnecting switches. Transmission line oil circuit breakers and disconnecting switches are of the same type and capacity as those mentioned previously. Transmission and tie lines are equipped with choke coils and lightning arresters of the oxide film type.

Feeding off the high tension buses, a circuit leads back into the station building to a bank of 60/12 kv. transformers for supplying 12 kv. current for local use.

The switchboard gallery affords an unobstructed view of turbines, generators and low tension oil circuit breakers.

Facing the front of the gallery is the main switchboard which contains the control switches and instruments. In addition to the usual indicating and recording instruments, there are provided five 8-point graphic temperature recorders. These are arranged to indicate and record generator stator winding and step-up transformer oil temperatures. Behind the main switchboard is an auxiliary upon which are mounted all relays and the station service control equipment. Directly under the switchboard gallery is the direct current room, where exciter current is centralized and distributed. In this room are also located the generator field rheostats.





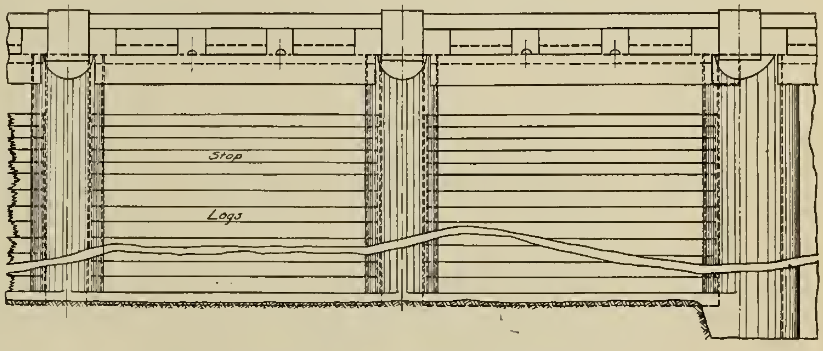


Figure No. 13.—Stave Falls Power Development Stop Log Section, Typical Plan and Elevations of Blind Slough Dam.

The Ruskin Development

The site of the Ruskin development, the last of the group under discussion, lies at a point on the Stave river, about 3½ miles downstream from Stave Falls, and near the junction of the Stave river with the Fraser river.

After meandering through the terraced valley below Stave falls, the river has cut its way deeply through a rock barrier that once blocked its course and from which it debouches into the flood plain of the Fraser at little above tidal level. The lower section of the gorge thus formed affords the site for the development.

While the water rights for the project have been held and maintained by the company for many years, no particular or detailed study of the structures required for its development nor their cost had been made until recently. The site has now been thoroughly surveyed, explored by test borings and preliminary plans for a scheme of development have been made. These will furnish the basis for this discussion. The site will not be developed, under any circumstances, until the power needs of the company shall warrant it.

Strange as it may seem, the river, in cutting its way through a morainal barrier which crossed the site, ignored the softer zones of glacial outwash that flanked, and probably covered, a spur of bedrock and started to form its new channel by cutting in a quartering direction into the solid rock barrier. Once started it continued its erosion and the formation of the Ruskin gorge, some 160 feet deep, with abrupt walls rising on either side, has resulted from its action. Borings have developed the fact that the exposed bedrock at the rims of the gorge are the highest points and that the bedrock drops away on either side from these exposures. The drawing in figure No. 15 shows plainly the relationship of surface topography to bedrock topography as closely as the borings reveal it.

The plan of development has been conceived to meet the conditions imposed by the subsurface topography of the bedrock, which, in a general way, have controlled the major elements of the design.

The site has no contributing watershed as such, its water being drawn from the tailwater of the Stave Falls plant, 3½ miles upstream. Its reservoir will function only as a forebay to regulate these waters; only daily regulation will be possible. The average water supply is therefore taken as 4,200 cubic feet per second.

The head available will be limited to that created by the dam. No falls or rapids of any consequence exist at the site. The high water level of the Ruskin reservoir will nominally conform to the tail water level of the Stave Falls plant, which is 210.

The elevation of the tailwater is variable owing to the fluctuations of flood level of the Fraser, which vary from possible extreme elevation of 100 during the summer

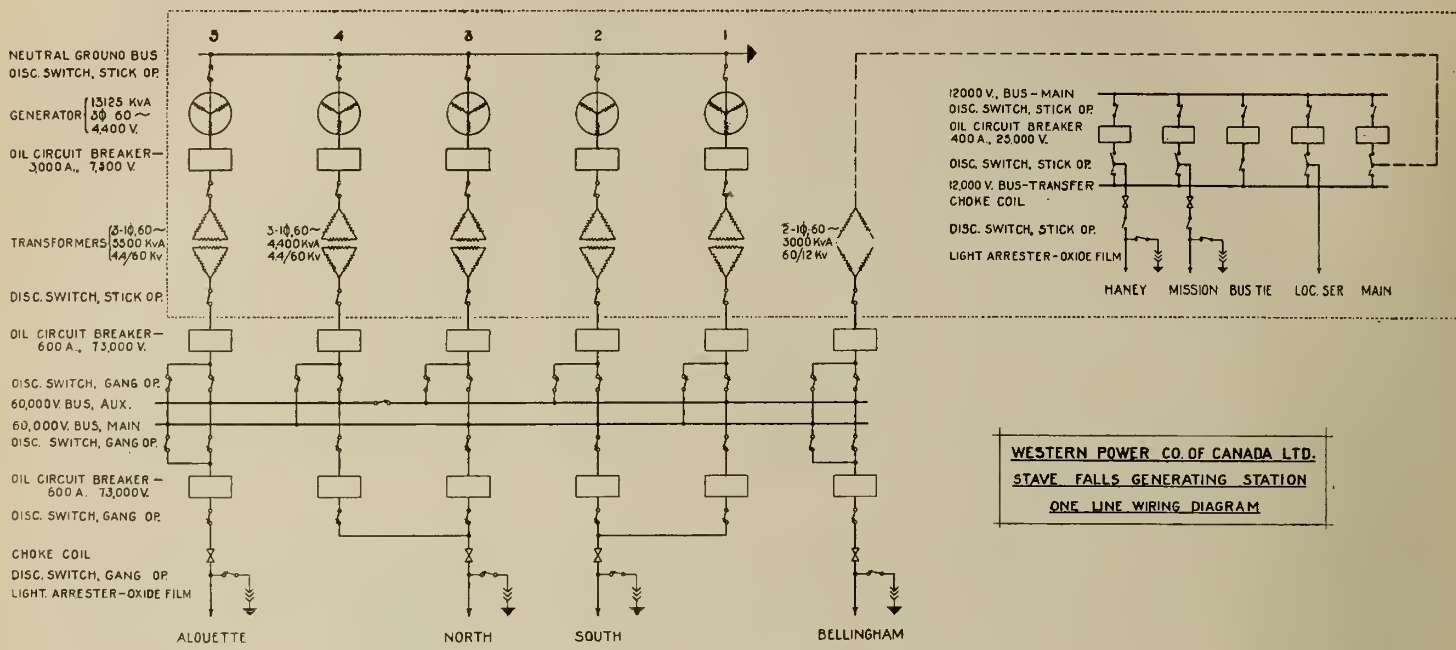

Figure No. 14.—Stave Falls Power Development Generating Station—One-line Wiring Diagram of Main Circuits.

freshet season to 76 at the low water winter flow. Daily variations of level will also occur at certain stages owing to tidal influence. A study of all conditions leads to the conclusion that 83 may be taken as the average elevation of tailwater.

The following heads were taken as a basis of the investigation:—

	Static head.
Average	126 feet
Normal low	119 "
Normal high	131 "
Extreme high	139 "
Extreme low	100 "

The forebay storage lake formed above the dam will be about 700 acres in extent. The Stave Falls plant under full load will discharge into the forebay at the rate of about 7,100 cubic feet per second. The four Ruskin units will draw under full load at the rate of about 9,100 cubic feet per second. The excess of draft over input will result in drawing down the forebay level at peak load periods at a maximum rate of about 3 inches per hour. Under normal operation of 2-hour peak load period, the variation in forebay level will be slight; a 12-hour peak operation would not lower the water more than 3 feet.

If the Stave Falls plant were fully shut down the Ruskin plant could operate at full capacity for 9 hours without drawing the forebay level more than 10 feet.

With assumed over-all plant efficiency of 84 per cent, the 4,200 cubic feet per second available at Ruskin is capable of generating 37,000 kw. continuously and the annual energy output is estimated at 328,000,000 kw. hrs.

The proposed development as preliminary determined is a simple one. A dam closes the gorge, raising the water level of the river from elevation 80 to 215; a headrace on the west bank admits and conveys the water to the penstock headgates, from which the penstocks conduct it to the station on the east bank of the river below the gorge.

The perspective study shown in figure No. 16 gives the essential features of the development.

Main Dam

The main dam as planned is a concrete structure, gravity section, crest overflow type with ten bays of regulating gates set between piers supporting a deck 31 feet wide which carries the gate-operating gear and a roadway. The dimensions of the dam are:—

Length of crest	325 feet
Maximum height	183 "
Elevation of deck	220 "
Elevation of overflow crest	190 "

The foundations will rest on the granite bedrock of the gorge. Some 35,000 cubic yards of boulders, loose rock and top bedrock will be excavated to prepare the foundation for the reception of concrete. The excavation will have a maximum depth of 35 feet.

The diversion of the river to permit the excavation of the foundations will be costly. The cofferdams, one at the upstream face and one at the downstream toe to hold out the back water, will be required. A diversion tunnel or an extensive timber flume will be necessary to carry the 7,000 cubic feet per second of tailwater from the Stave Falls plant. Probably the flume method will prove the most economical, although the tunnel method is shown on the plan. The seasonal floods will not be a particular menace as the preparation of the lower parts of the foundation and the pouring of the base of the dam up to a safe level can easily be accomplished during the normal dry season extended by the controlling agency of the Stave Falls dam.

The dam proper is estimated to contain approximately 87,000 cubic yards of concrete. The aggregates will be obtained by dredging and pumping from the foreshore in front of the power house and distant about 1,500 feet from the dam.

Owing to the conformation of the bedrock the west abutment of the dam is founded at elevation 160, some 30 feet below the crest and 55 feet below extreme high water level. In order to insure a cut-off to the bedrock to prevent leakage and erosion in the sandy formation traversed, a curtain of steel sheet piling 600 feet long and averaging 50 feet in depth will be necessary. As an alternative, a plan of blanketing the hillside with hydraulic fill has been considered. The sheet piling method seems the more practicable, provided the formation proves favourable for driving.

Ten crest gates with 25 feet clear opening and 21 feet in depth are planned to control the flood overflow. The gates will be of the Stoney Roller type with head frames and operating gear set upon the main deck.

A shingle bolt flume for the passing of bolts will extend from the west abutment to the river opposite the tailrace. As the variation in the reservoir water level will be comparatively slight, the head works for the flume are much simpler than at Stave Falls plant. The flume as planned is entirely of concrete.

Headrace

The headrace is planned as an excavated basin extending from the reservoir to the penstock headworks. The curved intake, 300 feet long with sill at elevation of 182.5, will rest entirely on bedrock, and will consist of two abutments and eleven concrete piers supporting the primary screens. No gates will be provided at the intake, but the piers will be designed for the setting of emergency stop logs to permit shutting the water out of the basin at lower stages of the reservoir.

An extensive excavation will be required to form the headrace. About 160,000 cubic yards will be removed, of which 100,000 cubic yards are estimated as earth and 60,000 cubic yards as rock. Much of the earth may be removed by sluicing. About 80,000 cubic yards will be deposited hydraulically on the slope above the intake to reinforce the bank against possible seepage through the ridge west of the headrace, which is composed of gravel

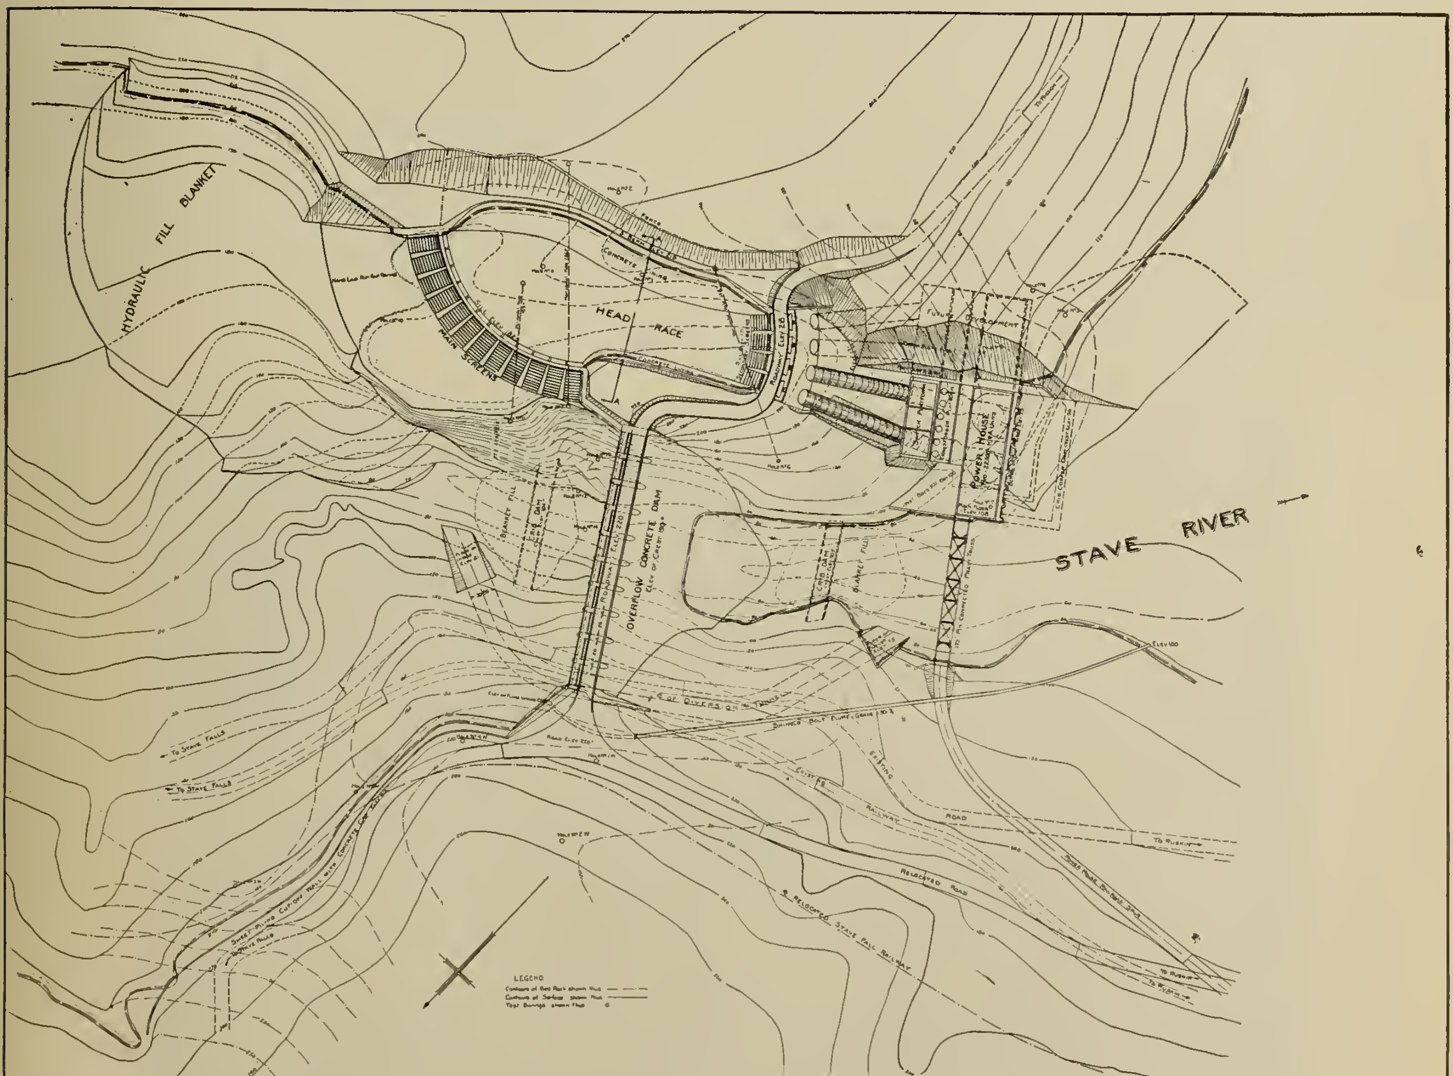

Figure No. 15.—Ruskin Power Development—General Plan of Proposed Plant.

and boulders carrying little clay. The remainder of the excavated material will be wasted in the tidal flat south of the power station, where an area for use as station grounds and operators' quarters will be built up.

The entrance apron to the intake will be paved with rock for a width of 100 feet. Approximately 15,000 cubic yards of concrete will be required in the construction of the headrace, including the penstock headworks.

The headrace will be lined with concrete throughout. Bottom linings will be 12 inches thick, and side linings 3 feet to 18 inches thick with nominal reinforcement. Where bottom lining is placed on earth or gravel, the foundation will be thoroughly settled with water before concreting.

Primary screens, with 4-inch clear openings between bars, will be set in the panels between piers at the headrace intake. Secondary screens with 1½-inch clear opening are provided in front of the penstock intakes.

Stop-log slots are provided for closing the penstock intake openings in front of the headgates. One set of steel stop-logs with operating machine will be provided for emergency use in clearing the gates and penstocks for inspection and repair.

Four penstock headgates of the Stoney roller type or the caterpillar self-closing type will be installed. The gates as planned are 19 by 19 feet clear opening and the maximum head to sills will be 44 feet.

Penstocks

The four penstocks for the ultimate plant as planned will be riveted steel pipes with an average length of 225 feet, and inside diameter of 19 feet and will be 9/16 to 13/16 inch plate, butt jointed and provided with stiffening rings of angle iron as required. The hillside will be excavated to an extent which will permit the placing of the pipes on bedrock. Some 9,000 cubic yards of rock and 15,000 cubic yards of earth excavation will be necessary for this purpose. The pipes will be supported on concrete piers and anchor blocks.

Balanced valves of some type will be provided for control at the lower end of the penstocks.

Power House

Only a rough preliminary design of the station building, sufficient for close estimating purposes, has been prepared. It is planned as a combination steel frame and reinforced concrete building of sufficient size to house the four proposed units. It will consist of a generator room 48 by 265 feet, with floor level at elevation 103, fronting the tailrace. Immediately back of the generator room, a two-storey bay 18 feet wide extends the full length of the building. The lower storey is designed for low tension use and the upper for switchboard purposes. Back again of this bay the transformer bay, 25 feet wide, extends the length of the building. The outdoor type transformers are placed on the upper deck of the bay, the space beneath being intended for storage. The rear bay, 34 by 265 feet, will be used for high tension switching, buses and supporting steel structures. The transformer and switching bays are not enclosed.

Owing to the bedrock topography and the relation of tailwater level, an extensive and costly excavation job is entailed in preparing for the power house foundations. Since the lowest foundations extend some 50 feet below the tailwater level, a coffer dam barrier surrounding the entire work will be necessary. This is planned as a timber crib to be filled and sunk in place fronted with a cut-off of steel sheet piling extending to bedrock. It is estimated that some 8,500 cubic yards of earth and gravel

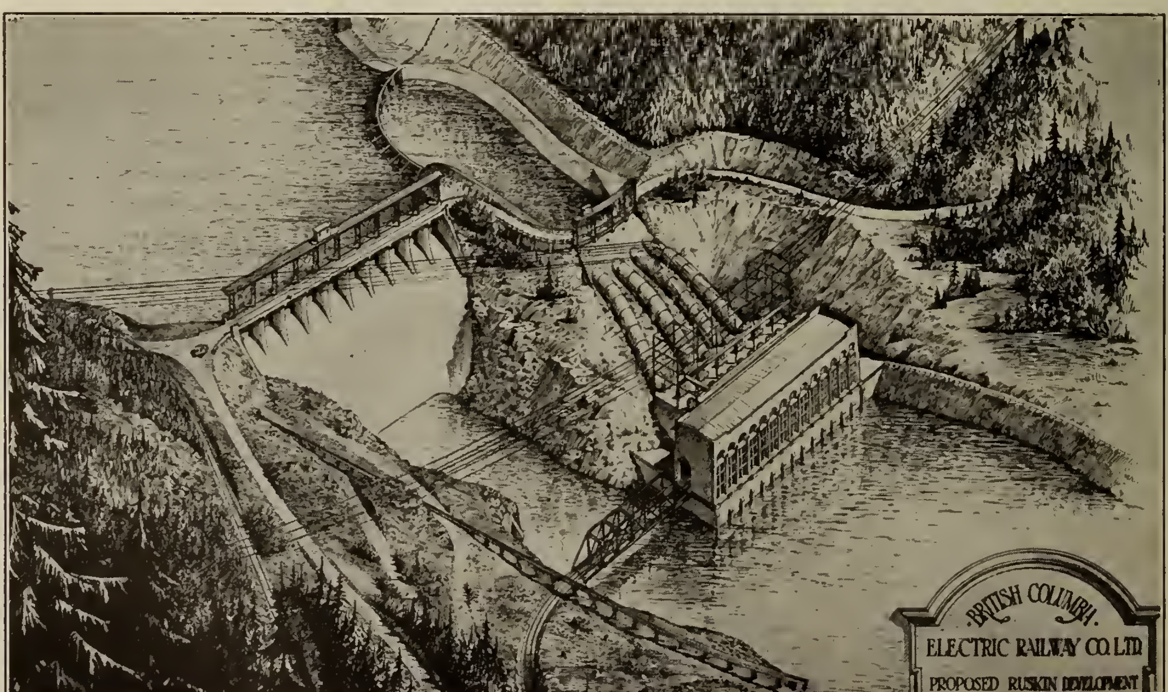

Figure No. 16.—Perspective Study of Proposed Ruskin Development.

and 11,500 cubic yards of rock will be removed to provide a setting for the foundations. In addition, some 5,000 to 10,000 cubic yards of material outside the coffer dam will be removed by dredging to provide space for the tailwater discharge.

Estimates call for the placing of some 11,000 cubic yards of concrete in the building and its foundations.

Hydraulic and Electrical Equipment

The plant as conceived will consist of four 30,000-b.h.p., reaction turbine units, direct-connected to four 22,500-kv.a. generators, all with vertical settings. Two units will be installed in the initial undertaking; the installation of the remaining two to be deferred until required. This installation will just about balance the whole system for load factor requirements. A review of these conditions may be interesting:—

Comparison of Plant Load Factors

(Ratios of Continuous to Installed Capacities at 0.9 Power Factor)

Plant.	Continuous kw.	Installed kv.a.	Installed kw.	Load factor per cent.
Buntzen Nos. 1 and 2...	16,650	47,700	43,030	38.7
Stave Falls	31,950	65,620	54,000	59.1
Alouette	6,550	10,000	9,000	72.9
Ruskin (proposed)	37,400	90,000	81,000	46.2
System total and mean.	92,550	213,320	187,030	49.5

At normal low head, the four 30,000-h.p. wheels will require nearly 10,000 cubic feet per second to drive the generators.

A spur track about a quarter of a mile long connects the site with the main line of the Stave Falls Railway, thus affording rail transportation to storage and construction yards. The river south of the power house is spanned with a permanent steel bridge which brings the tracks inside the station building and under the crane.

Acknowledgment

The data for the paper have been drawn from many sources. In this respect, the writer wishes to acknowledge as particularly valuable two most excellent technical papers previously prepared and presented.

The first, by the late R. F. Hayward, M.E.I.C., having for its subject "The Stave Falls Power Development of the Western Canada Power Company, Limited," was read by its author at the monthly meeting of the Canadian Society of Civil Engineers at Montreal on October 7th, 1915, and is printed in Vol. XXIX, Part II of the Transactions of the Society.

The second paper, by J. I. Newell, electrical superintendent, and A. F. Tredcroft, A.M.E.I.C., resident engineer for the British Columbia Electric Railway Company, Limited, has for its subject "Stave Falls Power Development of the British Columbia Electric Railway Company, Limited," and was read by Mr. Newell before the Vancouver section of the American Institute of Electrical Engineers on August 30th, 1924.

The general plans involved in the raising of the dams and the installing of the fifth unit at Stave Falls were prepared by R. S. Kelsch, M.E.I.C., consulting engineer. Details of electrical features, specifications and working drawings were prepared, and the work carried out by the electrical department of the company under the direction of Mr. Newell, assisted by R. M. Skinner, superintendent of construction, and Mr. Tredcroft.

The Alouette project was designed and is being installed by the construction department of the company, under the direction of the writer, assisted by C. E. Blee, assistant engineer, S. P. Wing, designing engineer, James Gilbert, construction engineer, and the other members of the staff whose valued co-operation is acknowledged.

The valuable assistance of Mr. Blee and C. W. Colvin, assistant electrical engineer, in preparing the paper is especially acknowledged.

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME X JANUARY 1927 No. 1

Amendments to By-Laws

The following circular letter regarding the proposed amendments to the By-laws has been mailed to all corporate members of The Institute, in accordance with By-law Section No. 76:—

To Corporate Members,
The Engineering Institute of Canada.

AMENDMENTS TO BY-LAWS

In accordance with Section 76 of the By-laws, Council has approved the following proposals for amendments to the By-laws of The Institute; these, having been drawn up by the Committee on Legislation and By-laws, are here given for the information of members, and will be presented for discussion at the forthcoming Annual General Meeting, after which they will be submitted by letter ballot to the Corporate Membership of The Institute.

The proposed amendments are as follows:—

Section 13, Paragraph 3, lines 2 and 3.

The words "priority of election to the office of Vice-President" to read "priority of election as a Vice-President."

Section 38, last line of Paragraph 1.

Delete all words after "vote" and substitute the following: "Council may take action in the case of a member who is in arrears by:—

(a) Directing that he shall not receive the publications of The Institute
and/or
(b) Removing his name from the register of members."

R. J. DURLEY,
Secretary.

Meeting of Council

Meeting of December 14th, 1926

A meeting of Council was held at eight p.m. on Tuesday, December 14th, Mr. Geo. R. MacLeod in the chair, and four members of Council being present.

The report of the Finance Committee with the financial statement to November 30th was approved, and nine special cases were given consideration. Two requests for reinstatement were considered and approved, and six resignations were accepted.

Life memberships were granted to Mr. R. Armour, Toronto, who has been a member since 1887, and to Baron Gustave de Coriolis, of Paris, France, on account of their advanced age.

The revised programme for the forthcoming Annual Meeting at Quebec, embodying the suggestions of the Executive Committee of the Quebec Branch, was submitted and approved.

The annual reports of the following Committees of The Institute were considered and approved:—

Publication Committee,
Papers Committee,
International Co-operation,
Code of Ethics,
Legislation and By-laws.

The membership of the Leonard Medal Committee for the year 1926 was submitted and approved as follows:—

J. C. Kemp, A.M.E.I.C., *Chairman.*
Dr. A. Stansfield, M.E.I.C.
G. D. Macdougall, M.E.I.C.
J. F. Robertson, M.E.I.C.
A. B. Ritchie, A.M.E.I.C.

The list of officers of the St. Maurice Valley Branch was submitted and unanimously approved as follows:—

Ellwood Wilson, M.E.I.C., *Chairman.*
R. Morrissette, A.M.E.I.C., *Secretary-Treasurer.*
H. Dessaulles, A.M.E.I.C. }
B. Grand Mont, A.M.E.I.C. } *Executive Committee.*
S. W. Slater, A.M.E.I.C. }

The gift of a number of old engineering books from Colonel E. B. Worthington, of Sherbrooke, Que., was announced, and the donor was thanked for his generosity.

The following elections and transfers were effected:—

Elections

Members	1
Associate Members	1
Juniors	2
Affiliates	1
Students	24

Transfers

Associate Member to Member	1
Junior to Associate Member	2
Student to Associate Member	2
Student to Junior	4

Twenty-two applications for admission and transfer were scrutinized and classified for the ballot returnable January 17th, 1927.

Four special cases were considered in connection with applications for admission.

The Council rose at eleven-thirty o'clock p.m.

See page 42 for Programme of the Annual General Professional Meeting and page 58 for Railway and Hotel Arrangements for the Meeting

The Need of a Forest Policy

The proper conservation and utilization of our forest resources is not only of vital importance to every Canadian, but has a special and personal interest for engineers of all branches of the profession. This fact is not always realized, but a little reflection will be convincing. A very large proportion of all present engineering and industrial activities in Canada is either directly or indirectly dependent on forest products and forest industries, as these require the services of engineers in so many fields of work; for example: the manufacture of logging, pulp making and paper making machinery; the provision of electrical equipment and turbines; the construction of power houses and dams; the measurement and regulation of streams; transportation and shipping; the provision of aeronautical equipment for fire protection and photography. Many other items might be added to this list. Proper and practical methods for forest conservation, for the maintenance of our supply of timber and wood, and for their economical transportation and manufacture are therefore the concern of all engineers, and members of the engineering profession should be fully informed as to the present situation.

The average man is somewhat bewildered by the mass of statistics which appear from time to time in the public press regarding the denudation of our forests and the toll which fire takes from our timber resources, and he knows little or nothing about the existing stand of timber, whether it is being cut wisely or wastefully, or the rate at which cut-over areas can recuperate under natural and artificial reforestation.

In 1923, the annual drain on the soft-wood forest resources of the Dominion from all causes was estimated at about 4,000 million cubic feet, and since that time the consumption has largely increased. It seems evident that with a total estimated stand of, say, 200,000 million cubic feet, (of which half is inaccessible at present prices), it will not be long before the industry as a whole will have to depend for its supply on areas already cut-over and on what virgin timber is left in the more inaccessible regions. In this connection, it may be noted that in Canada there are many areas of virgin forest in which a large proportion of the trees have passed the age of maximum production, so that their annual contribution to our stock of available timber is less than is generally supposed. Such areas can only be rendered fully productive through proper forest management. There is little reliable information as to the length of time required for natural reforestation, varying as it does in accordance with locality, climate, seasonal conditions, nature of soil, and so on.

The last few years have witnessed a phenomenal increase in the number of Canadian pulp and paper mills, operating and projected, and their consumption of pulp wood, particularly for newsprint, is advancing by leaps and bounds. Some idea of the call now being made on our forest resources by the pulp and paper industry can be obtained when it is remembered that the requirements of a single large modern newsprint mill may involve the clearing of about one square mile of timber per week.

Passing to the question of conservation, the appalling extent of our fire losses is well known, and the disastrous economic consequences that will result from their continuance must be so obvious to all thinking persons as to make it unnecessary to lay stress on the fire danger here. But while fire damage is the best known sign that all is not well with our forests, it is by no means the only one. Another disquieting symptom is the fact that in so many districts land has been thrown open to colonization, has been settled, the forest has been removed or burned off, and the settlers have abandoned their farms, in many cases leaving the land useless either for agriculture or timber. The expansion of agriculture is, of course, a necessary and desirable thing, and there can be no question as to the propriety of clearing the forest from land on which real farms can be made, but colonization should not involve taking land which cannot support real farms, allowing it to be stripped of its timber, and then to be abandoned.

The gravity of this situation is not altogether to be measured by the actual quantities of wood concerned, although these are large, but by such considerations as the following: in the first place, such colonization contributes in a marked degree to the fire risk, in that settlers' brush has to be burned in close proximity to the green forest, and that it is frequently burned carelessly. Secondly, the possibility of losing their limits through colonization, or by suffering heavy losses of green timber through settlers' fires, discourages limit holders from making the heavy expenditures on their forests that are entailed by the preparation of comprehensive inventories and working plans and the adoption of the most modern methods of management.

It is true that the various provincial governments make forest laws and regulations from time to time, but these are as a rule concerned rather with individual points than with general policy, and do not grapple with underlying causes. A constructive forest policy should be in force everywhere, and should be based on two things, namely, adequate fire protection and an immediate and wholesale classification of the Crown lands, leading up to the formation of permanent forest reserves, that is to say, areas devoted to wood production in perpetuity.

This is not a new or revolutionary policy, it is merely common sense applied to the regulation of the forests.

Adequate fire protection, which means such legal, educational or practical measures as are found actually to stop the fires, is an absolutely necessary preliminary condition, without which all other effort towards conservation must be wasted; and the institution of permanent forest reserves based on land classification would immediately stop the losses now caused by mistaken colonization and its attendant fires, and would make possible the introduction of improved methods of forest management such as would not only ensure the perpetuation of the forest but would increase the future yield of wood per unit of area.

It seems evident that if the fire risk were reduced to a minimum, and if security were guaranteed to limit holders in the tenure of their timber lands, improvements and reforms on the part of the limit holders would either follow automatically or would be demanded by public opinion, and that a superstructure of forest laws to deal with matters of detail could gradually be built up.

Following on the effective and universal adoption of such a policy, limit holders could be required more effectively to take such measures as reforestation of logged areas, proper disposal of slash, adoption of improved methods of logging, and the like, while wasteful and uneconomical methods of transportation and manufacture would be discouraged.

The foregoing are only a few of the factors that must be considered when discussing the future of the forest industries in Canada which deserve far more attention on the part of the general public than they now receive.

With the hope of forming a correct and instructed body of opinion regarding these matters among the members of the Engineering Institute of Canada, a series of papers on subjects connected with forest preservation and forest utilization has been arranged for the forthcoming Annual Professional Meeting of The Institute at Quebec in February next, and it is expected that the discussions on these will throw light, not only on the nature of the problems which are pressing upon us, but also on the means to be adopted for their solution.

Genuine reform in a democratic state must come from the force of public opinion, and at the present time the members of The Institute can render no greater public service than in aiding to bring about this result by familiarizing themselves with the present conditions, drawing attention to the fact that our forest resources are not boundless, but are lessening day by day, and impressing on the laymen with whom they come in contact the defects of the present methods of operation, and the necessity and practicability of better ones.

Annual General and General Professional Meeting

The Annual General Meeting will be convened at Headquarters, 176 Mansfield Street, Montreal, on Thursday, January 27th, 1927, at 8.00 p.m.; after the reading of the minutes of the last Annual General Meeting, the appointment of Scrutineers to count the Officers' Ballot, and the appointment of the Auditors for the ensuing year, the meeting will be adjourned to reconvene at the Chateau Frontenac, Quebec City, February 15th to 17th, 1927.

Meeting at Quebec City

Chateau Frontenac—February 15th, 16th and 17th, 1927

PROGRAMME

(*Subject to Revision*)

Tuesday, February 15th.

9.00 a.m. Registration.

10.00 a.m. Reception and discussion of reports from Council, Committees and Branches. Scrutineers' report and election of officers. Retiring President's address. Induction of new President.

1.00 p.m. Lunch—complimentary to visitors. Welcome to members by Chairman of the Quebec Branch, who will preside. Brief address by the Mayor of Quebec.

1.00 p.m. Lunch for ladies.

3.00 p.m. Continuation of Annual General Meeting—unfinished and new business.

9.00 p.m. Smoker or special entertainment. (Admission by ticket.)

9.00 p.m. Theatre party for ladies.

Wednesday, February 16th.

10.00 a.m. First technical session.

Room A—

Notes on the Forests of Quebec—G. C. Piché, A.M.E.I.C. Deals with questions of forest administration.

The Wood Consuming Industries of Canada—John Stadler, M.E.I.C. Has special reference to pulp and paper manufacture.

Woodlands Management and Operation—S. L. de Carteret, A.M.E.I.C.

Transportation in Pulpwood Operations—G. E. La Mothe, A.M.E.I.C. Outlines modern methods of handling wood from the forest to the mill.

Room B—

Electrical Characteristics of Quebec-Isle Maligne Transmission Line—Professor C. V. Christie, M.E.I.C. Deals with the most recent large transmission line in Eastern Canada.

Alternating Current Electrolysis—Professor J. W. Shipley. Further experimental work in this interesting field.

Building an Industrial Plant in the Saguenay District—John L. Guest. Covers the construction problems encountered in building the works of the Aluminum Company of Canada at Arvida, Que.

Protection Against Seepage at Lake Kenogami—O. O. Lefebvre, M.E.I.C. The methods adopted to cope with a difficult situation.

2.00 p.m. Visit to Quebec Bridge or St. Malo Shops.

7.30 p.m. Annual Dinner of Institute. (Admission by ticket.) President in the Chair.

7.30 p.m. Dinner for ladies.

Thursday, February 17th.

10.00 a.m. Second technical session.

Design and Construction Features of Rack Structure and Penstock Intake for Isle Maligne Station of Duke-Price Power Company, Limited, on Saguenay River, Province of Quebec, Canada—W. S. Lee, M.E.I.C. Data regarding a vital portion of this important development.

The Water Power Developments of the Alouette-Stave-Ruskin Group—E. E. Carpenter, M.E.I.C. Describes an interesting group of hydro-electric plants in British Columbia.

Developments of the Gatineau Power Company on the Gatineau River—A. H. White, M.E.I.C. Data regarding the three installations at Farmers, Chelsea and Paugan, with notes on some special features of design.

2.00 p.m. Third technical session.

Notes on the Ore Deposits of Western Quebec—Theo C. Denis. Deals with the geological relations of the new goldfields.

The Metal Mining Industry of Northern Ontario—W. R. Rogers, A.M.E.I.C.

Discussion of papers previously presented.

5 p.m. to 7 p.m. Ladies will be entertained at tea.

8.30 p.m. Supper-dance and Bridge in Ball Room. (Admission by ticket.)

OBITUARIES

Francis Clarke Gamble, M.E.I.C.

From coast to coast in Canada members of The Institute have learned with the greatest regret of the passing of Francis Clarke Gamble, M.E.I.C., one of Canada's pioneer railway builders and one who, within the profession and in all walks of life, was held in the highest esteem by all who were privileged to know him.

A staunch supporter of The Institute ever since its incorporation as the Canadian Society of Civil Engineers, Mr. Gamble took a very active part in its affairs. He joined as Member on January 20th, 1887. He was elected a member of Council in 1892 and again in 1898. In 1913 and 1914 he was vice-president and in 1915 became president.

Born in Toronto on October 23rd, 1848, he attended Upper Canada College, where he received his primary education, later continuing his studies under private tuition and subsequently at the Rensselaer Polytechnic Institute of Troy, N.Y.

FRANCIS CLARKE GAMBLE, M.E.I.C.

Choosing the engineering profession as his life work as far back as 1869, he entered the employ of the Intercolonial Railway, serving in various junior capacities until 1870. Subsequently he became assistant engineer with the Great Western Railway; resident engineer for contracts of the Prince Edward Island Railway; assistant engineer on the Intercolonial Railway during the years 1876-1877 and for the Q. M. and O. R. the following year.

In 1879, Mr. Gamble was engaged in private practice. The following year he was first assistant engineer on contract No. 42, of the Canadian Pacific Railway, and the next year in the same capacity in British Columbia. From 1881 until 1887, he was assistant engineer with the Department of Public Works, British Columbia, and for the following ten years was government agent and resident engineer for that department. In the year 1897 he was again engaged in private practice and in 1898 was appointed public works engineer for the provincial government of British Columbia, becoming chief engineer of the Department of Railways for the province in 1910.

He was recognized as a high authority on the various professional works to which he devoted his time, and after retiring from active practice in 1918 he continued to take a great interest in the affairs of The Institute and of the profession in general.

Noel Edgell Brooks, M.E.I.C.

Noel Edgell Brooks, M.E.I.C., of Sherbrooke, Que., one of The Institute's earliest members, passed away following a sudden attack of heart trouble on May 12th, 1926.

The late Mr. Brooks was born at Sherbrooke on December 25th, 1866, and at the age of eighteen commenced his first engineering work as assistant on surveys and preliminary work with the Pecos Valley Irrigation Company in New Mexico. He was engaged on this work for two years, and returning to Canada he spent the next two years with the Canadian Pacific Railway Company as rodman, first on the Smith Falls branch and later on the Atlantic and Northwest branch. In connection with the latter work, he was appointed resident engineer on construction in 1888. This was his first important engineering work, and throughout the remainder of his life he continued to be engaged in railway engineering work.

NOEL EDGELL BROOKS, M.E.I.C.

From August 1889 to September 1890 he was resident engineer on the construction of the Qu'Appelle-Lake Long and Saskatchewan Railway. During the next year he was resident engineer on the construction of the Calgary and Edmonton Railway, following which he was engaged on the construction of the Crow's Nest Pass Railway. In June 1892 he returned as resident engineer to the Calgary and Edmonton Railway, and in the fall of the same year occupied the same position on construction at the Crow's Nest Pass. In 1894 he was appointed assistant on construction to the chief engineer of the Montreal Electrical Street Railway, and two years later was appointed inspector on the Calgary and Edmonton and other railways in western Canada. From this position he became inspector for the bondholders of these railways, and in 1903 he was superintendent of maintenance-of-way and structures while these railways were operated by the Canadian Pacific Railway Company. In November 1903 he became division engineer on the western division of the Canadian Pacific Railway, with headquarters at Calgary, and during 1912-13 he was acting general superintendent of the Alberta division of the same company. He was then moved to Winnipeg, occupying the position of engineer maintenance-of-way of western lines, and 1915 retired on account of his health.

The late Mr. Brooks joined The Institute as Student on April 28th, 1887, transferred to Associate Member on November 20th, 1890, and to Member on December 9th, 1897.

Edward Thornbrough Parker Shewen, M.E.I.C.

In the death of Edward Thornbrough Parker Shewen, M.E.I.C., which occurred at St. John, N.B., on December 9th, 1926, The Institute has lost another of its first members; one who was enrolled in the membership list of the Canadian Society of Civil Engineers on January 20th, 1887, prior to its incorporation.

The late Mr. Shewen was born at Brockhurst, Hants, England, in 1849, and was educated at the Royal Naval School and by private tuition. He was one of the English army engineers who came to Canada about 1870 and settled in Nova Scotia. His first work in Canada was as assistant engineer on the Louisbourg Railway. Later he was engaged on railways, surveys and construction in various parts of Nova Scotia. In May 1879 he was appointed resident engineer on the Halifax and Cape Breton Railway. In 1883 he was employed by the Nova Scotia Government as assistant engineer with the bridge department, and in the same year joined the staff of the Department of Public Works of the Nova Scotia Government.

He moved to St. John in 1895, becoming resident engineer with the federal Department of Public Works and continuing in that position until 1911, when he retired on account of ill health. Since that time he has been acting in the capacity of consulting engineer. As resident engineer in St. John he was responsible for many of the original projects and harbour construction schemes and river improvements throughout the maritime provinces.

William Robert Pilsworth, M.E.I.C.

In the death of William Robert Pilsworth, M.E.I.C., which occurred at his home in Vancouver, B.C., on November 13th, 1926, The Institute has lost one of its early members, whose election as Associate Member of the Canadian Society of Civil Engineers took place on May 18th, 1888.

The late Mr. Pilsworth was born at Willsgrove, County Kildare, Ireland, on July 26th, 1849, and came to Canada at a very early age. His first engineering work was with the Canadian Pacific Railway Company in the junior capacity of rodman and leveller for four years, from 1879-1882. For the following two years he was engaged as assistant engineer with a firm of contractors in Toronto on harbour improvement work in that city. Subsequently he was engaged with contractors on the enlargement of the Welland Canal until the end of 1886. The following year he returned to Toronto, where he was first connected with the Gravitation Survey in connection with the water supply to the city from lake Simcoe, then as assistant engineer on the staff of the chief city engineer, during which period he was in charge of the Ashbridges Bay improvement works, later being engaged on the survey of Toronto island and harbour.

In 1898, he was appointed division engineer in charge of construction on the Columbia and Kootenay Railway, following which he was chief engineer of the Thompson Valley Power and Irrigation Company. In 1901, he was appointed engineer in charge of the construction of the Thompson river bridge for the British Columbia government. In 1902, he was in charge of the party on the survey of structures for the mountain division of the Canadian Pacific Railway Company, later being engaged on surveys and plans for proposed irrigation scheme in British Columbia. From 1903-06, he was with the Canadian Pacific Railway Company and was engaged in irrigation work in Alberta. He joined the British Columbia Electric Railway Company in 1906, during which time he located the Burnaby lake line and the extension of the Capilano line. He entered private practice at Kamloops in 1909, and in 1911 was appointed district engineer of the Kamloops district for the Water Branch of the Lands Department of the British Columbia Government. During the Riel Rebellion in 1885 he was Captain of the Winnipeg Light Infantry.

The late Mr. Pilsworth remained an Associate Member of the Canadian Society of Civil Engineers until October 8th, 1903, when he was transferred to Member.

Benjamin James Forrest, M.E.I.C.

Benjamin James Forrest, M.E.I.C., died at his home in Montreal on November 19th, 1926.

A native of Scotland, Mr. Forrest was born at Begbie, Scotland, on November 24th, 1860. He received his early engineering training as apprentice to Messrs. Higson and Francis, civil engineers, and later with Messrs. Fawcett Preston and Company, mechanical engineers. His apprenticeship covered a period of six years. He then was appointed assistant engineer to the chief engineer of the Bilboa Railway and Iron Mining Company in Spain, where he was engaged for five years on the construction of railway projects, harbour works and other general construction work for the company. Subsequently he was engaged on similar works in Argentina and Brazil, and later on railway and preliminary work in Costa Rica.

On coming to Canada, he first went to Toronto, where he was engaged on mine surveys and reports. He then joined the staff of the Dominion Iron and Steel Company at Cape Breton, being engaged on prospecting and surveys. His next work was in connection with railways and mines on the construction of plant and harbour facilities at Port Hastings. From 1904-06 he was with Messrs. Mackenzie and Mann, Limited, on railway and harbour construction for the Inverness Railway and Coal Mines. Later he was with the Public Works Department at St. John on inspection work. In 1906 he was appointed division engineer on the construction of the Guelph and Goderich branch of the Canadian Pacific Railway Company, and in 1909 became resident engineer for the same company on the main line in the vicinity of Winchester, Ont. The following year he occupied a similar position on the inspection of the Quebec Central Railway.

Subsequently he was engaged on electric railway and power development work at Berlin and Guelph, Ont., and in the latter part of 1911 was on the staff of the Canadian Inspection Company in Montreal. His later work included construction and inspection with the Canadian Pacific Railway Company, the Canada Steel Corporation at Windsor, Ont., the Asbestos Corporation at Thetford Mines, the Montreal Harbour Commission and the Hollinger Mining Company.

Mr. Forrest was a member of the Canadian Institute of Mining and Metallurgy and was at one time an Associate Member of the Institution of Civil Engineers of Great Britain and of the Mining Society of London, England. He was admitted to the Engineering Institute of Canada as Member on January 14th, 1904.

ELECTIONS AND TRANSFERS

At the meeting of Council held on December 14th, 1926, the following elections and transfers were effected:—

Member

LeROY, William Lindsey, with H.E.P.C. of Ont., superintending power house constrn. at the Queenston-Chippawa Power Development, Queenston, Ont.

Associate Member

MOUNTFORD, George Colledge, mech. supervisor, Ont. Power Plant, Niagara Falls Hydro-Electric Power Co., Chippawa, Ont.

Juniors

COOIL, Thomas Reginald, B.Sc., (Univ. of Sask.), instrumentman with City of Saskatoon, Saskatoon, Sask.

PARKER, Charles Alexander, B.Sc., (McGill Univ.), English Electric Co. of Canada, Montreal, Que.

Affiliate

PALMER, Leonard Charles Dunlop, 1st vice-president Wm. Hamilton Ltd., Montreal mgr. in charge Eastern Canada, Montreal, Que.

Transferred from class of Associate Member to that of Member

WOLFF, A. Oscar, resident and division engr., C.P.R., Brownville Jct., Maine, U.S.A.

Transferred from class of Junior to that of Associate Member

BOWMAN, Charles McCawley, commercial engr. with Mar. Tel. and Tel. Co., Halifax, N.S.

McPHAIL, Donald Stuart, B.Sc., (McGill Univ.), executive engr. i/c hydraulic project division of the Mandi hydro-electric scheme, Lahore, India.

Transferred from class of Student to that of Associate Member

GREENWOOD, William, B.Sc., (Queen's Univ.), New Liskeard, Ont.

MILLS, Arthur McTavish, B.Sc., (Queen's Univ.), asst. to res. engr., Dept. of North. Development, Ont., Cochrane, Ont.

Transferred from class of Student to that of Junior

MacNAUGHTON, Moray Fraser, B.Sc., (McGill Univ.), ch. inspector on constrn. of sub-structure Mtl. South Shore bridge for Milton Hersey, Westmount, Que.

SPRIGGS, William, B.Sc., (McGill Univ.), on relay protection with Shawinigan Engineering Co., Montreal, Que.

VALIQUETTE, Charles, C.E. and B.A.Sc., (Univ. of Mtl.), asst. road engr. constrn. and mtce., Road Dept. of Prov. of Que., Outremont, Que.

VARDON, Lester Milton, B.A.Sc., (Univ. of Toronto), engr. on traffic statistics with Toronto Transportation Commission, Toronto, Ont.

New Construction Tendencies

An interesting article by James Govan, R.A.I.C., consulting architect, Toronto, entitled "New Construction Tendencies and their Probable Effect Upon Canadian Architecture," has been issued in reprint form following its publication in the Journal of the Royal Architectural Institute of Canada.

The General Supply Company of Canada, Limited, have entered into an agreement with the Automatic Transportation Company, Inc., of Buffalo, N.Y., to control the basic patents relative to the manufacture and production of storage battery electric truck and tractor equipment, whereby they become the exclusive Canadian distributors for that company. The Canadian sales of this equipment were previously handled by Mr. H. S. Powley, of Toronto, Ont., who has now entered the services of the General Supply Company.

CORRESPONDENCE

Engineering Features in Breaking the Allegheny Ice Gorge

Ottawa, December 9th, 1926.

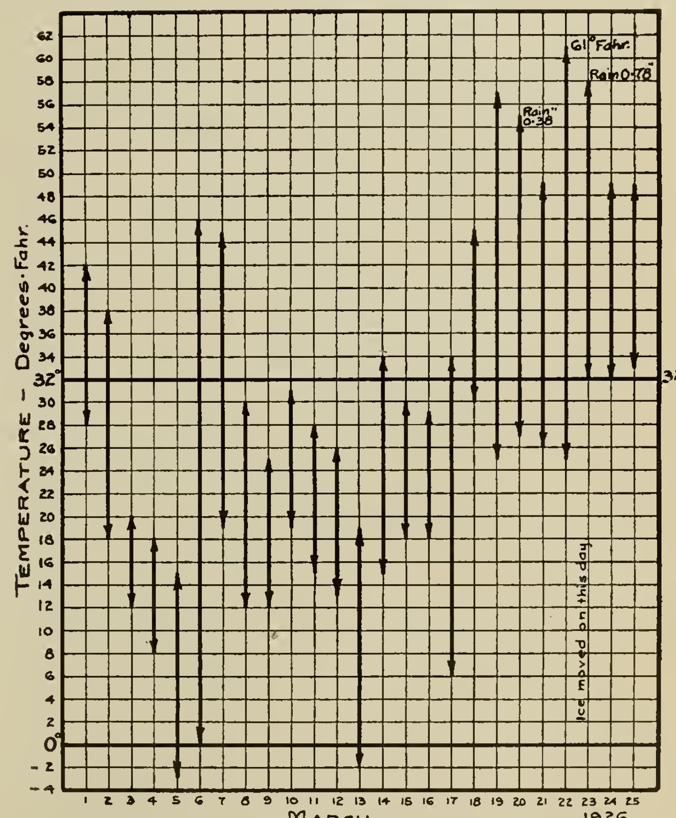
The Editor (*The Engineering Journal*)—

Dear Sir:—

Referring to Dr. Howard T. Barnes' address entitled "Engineering Features in Breaking the Allegheny Ice Gorge," I beg leave to present the following statements:

The excellent ice work which Dr. Barnes has accomplished needs no word of praise from me at this moment. I have praised it wholeheartedly all over the country at more than two score meetings of engineers, scientists and hydraulic power plant operators. His work has been more help to me in my own ice problems than any other work of which I have ever heard.

In his address on the use of thermit in the Allegheny river, he makes mention of the ice-melting action of the sun and rain,—but does he give enough credit to those enemies of ice? He found the river gorged with ice for 25 miles, and reading the Engineering Journal's report of his work, with a copy of the accompanying weather chart, which I have prepared alongside of that report, it seems that only about 5,000 feet of river-length, (out of 25 miles of ice), was cleared of ice with dynamite and with thermit up to the middle of March, simply because the weather remained very cold.



The Allegheny Basin—Temperature Records.

Figures taken from the U. S. Dept. of Agriculture's "Climatological Data." Only four clear days in February, 1926. Snow = 19.6 inches.

Co-incident with the arrival of warm weather, about March 18th, (see the diagram), the weakening of the ice gorge proceeded at a great pace and on the 20th, to the accompaniment of 0.38-inch of rain, the whole upper pack moved.

With air temperatures ranging from 49° to 61° Fahrenheit in the next three days, and with a rainfall of 0.78-inch on the 23rd, the whole gorge was released.

I regret that Dr. Barnes was not so aided in his stupendous task on the Allegheny river that he could have secured water-temperature measurements with his micro-thermometer, because I feel he would have secured very valuable data.

While not disparaging what he did accomplish with thermit, I am compelled to ask: Does he give sufficient credit to the ice-melting work done by the sun, air and rain in the Allegheny basin?

JOHN MURPHY, M.E.I.C.

The Work of the Canadian Engineering Standards Association

During the first six years of its existence, this association established a record of satisfactory achievement, but its activities were unfortunately somewhat checked in 1925, owing to the withdrawal at that time of the grant hitherto received from the Dominion Government. The National Research Council, however, recognizing the importance of the association's work, has been able to furnish means for the complete resumption of its activities, upon the understanding that additional support will be obtained from Canadian industry. A programme of increased usefulness and further development is thus rendered possible, and is now being carried on. Particulars of the work already accomplished and the projects now in hand will be contained in the report to council which is furnished annually by the three members nominated on the main committee of the C.E.S.A. by the council of the Institute.

The following extracts from the forthcoming Year Book of the Canadian Engineering Standards Association set forth in concise form so many pertinent features of standardization work that no apology is needed for their presentation to readers of the Engineering Journal at this time.

Industrial Standardization

Industrial standardization has been classified under the following heads:

1. Selection of standard terms, nomenclature and definitions.
2. Agreement on standards of quality, resulting in uniformity of specifications and requirements of purchase, and in methods of testing and rating.
3. Selection of suitable standard dimensions and tolerances, thus insuring interchangeability of parts, economy of manufacture or assembling, and satisfactory operation.
4. Elimination of unnecessary sizes, grades and types of product, making for simplicity of manufacture, economy in stock carried and the lessening of sales costs.
5. Selection of standard rules or requirements necessary for the safety of employees and the public.

The purpose of the Canadian Engineering Standards Association is to provide the facilities by which manufacturers and users of engineering materials can get together and formulate mutually satisfactory standards. It has had the support of the Government from the beginning, and also a considerable measure of assistance from the industries, and as a result of its activities a number of important standards have already been nationally adopted. It is as yet only at the commencement of its work, and a vast field is open in which further standardization can be undertaken with the greatest advantage to the manufacturers and users in Canadian industry.

Success in manufacture is becoming more and more a question of the ability to employ mass production as against specialized production in any article. It may be objected that conditions in Canada do not lend themselves to mass production as practised in the United States or other large manufacturing countries where the demand for any one product is many times greater than with us, and there is no doubt that in many respects this is true. The economies effected by mass production are, however, largely those attendant on the continual production of similar articles as contrasted with the production of a constantly changing series of articles, and, by industrial standardization, many of these advantages may be obtained even though the aggregate output is comparatively small.

In the production of a standardized article, economies are effected through the avoidance of new designs and drawings, by the simplicity in making out orders, by the familiarity of everyone in the plant with the article required, by the ability to produce large quantities as one set-up, and by the reduction in the stock required to fill orders.

As far as the standardized article is concerned, both manufacturers and users are benefited by avoidance of varieties in design and qualities that are not of vital importance but largely demanded by personal ideas or the lack of a definitely established standard to determine the choice between one article and another.

Even in the case of railroad bridges and steel structures where mass production in any sense of the word would be an impossibility, the establishment of the C.E.S.A. standard has been of decided advantage in those bridges and structures that are not of extraordinary design or highly specialized. The user, by ordering in accordance with C.E.S.A. standard, is assured of a thoroughly well-considered and satisfactory specification without the work and expense of preparing it, and as it has been agreed on by the manufacturers, one in which there are no extra charges or annoying complications. The manufacturer benefits by the work not only in regard to methods of estimating, calculating and design with which his staff is thoroughly familiar, but by the use of standard material, and by his workmen becoming accustomed to the established practice.

To consider a widely different class of standardization, the case of stove bolts may be instanced, for which the C.E.S.A. standard has defined seven standard sizes, uniform threads, and uniform tolerances, in place of the great variety that formerly existed. In selecting a bolt for any desired purpose, the user has a choice of a definite number of agreed on sizes, in place of the entire range quoted in a typical trade catalogue. If a special bolt is necessary, it can still be obtained by special arrangement, but if, on the other hand, one of the standards adopted will suit his purpose, he will be using an article that will be more cheaply produced, more promptly delivered and obtainable at any time.

These are only two examples of the benefits obtainable by industrial standardization, but they serve to illustrate the field of activity that is available in this line of work.

Method of Work

The C.E.S.A. standards are not originated by the association or its staff, but by working committees which the association organizes on which manufacturers and users nominate the majority of the members. These representatives take part in the actual discussion of the problem, and handle the technical work. The results, on which all interests concerned are therefore in agreement, thus carry with them no idea of compulsion, and are adopted and used by reason of their inherent suitability and advantage. The standard as proposed is finally submitted to the main committee of the association, which satisfies itself that full consideration has been given to the subject and that all interests have been adequately represented before it authorizes publication by the association.

The services of the committee are also available for the periodical revision of their reports, and when it appears advisable to revise any standard, the procedure adopted in the preparation of the original standard is adopted. If necessary, however, the membership of the committee may be augmented to include interests not previously represented, but whose co-operation would assist the committee in its deliberations. This obviates any risk of retaining a standard in use after improvements or changes of practice have rendered it obsolete in any respect. The association does not assume the rôle of a director, but rather of a co-operative body, and therefore must be guided in its operations by the requirements of the manufacturing or industrial interests represented on its committee.

Co-operation with Foreign Standardizing Bodies

Standards as published, tentative specifications, and progress reports on standardization projects are freely exchanged with the other national standardizing bodies. These reports are prepared semi-annually and are made on a form adopted as standard by all the bodies. The various secretaries are in continual communication with each other and many matters of mutual interest are discussed. Two international conferences of secretaries have been held, the first in London in 1921, and the second in Zurich in 1923. An international conference was held in New York in 1926 in connection with the meeting of the International Electrotechnical Commission, and many of the foreign secretaries were present. The secretary of the Canadian Engineering Standards Association attended all three of these conferences.

Co-operation with the British Engineering Standards Association and with the American Engineering Standards Committee is naturally much closer than with other bodies. In the case of the B.E.S.A. tentative specifications are published, standards are received and submitted to interested members of the C.E.S.A. for criticism. Comments received are sent to the secretary of the B.E.S.A. for transmission to the various committees concerned. It has been found that in many cases these have been very helpful. A small stock of the publications issued by the B.E.S.A. is kept on file and copies are on sale by the secretary.

With the A.E.S.C., co-operation is carried on by the exchange of minutes of committee meetings in some cases, by the appointment of representatives who act as observers on committees, and by correspondence between the secretaries. Copies of any standard issued by the A.E.S.C. can be obtained through the secretary of the C.E.S.A., but no stock is kept.

Field Open to Operation

Conditions in Canada are peculiarly favourable to an organization such as the Canadian Engineering Standards Association, for the reason that industrial standardization is in its infancy and the development of simplified practice has never been seriously attempted.

In the United States the work of national standardization is handled by the American Engineering Standards Committee, but simplified practice comes under the jurisdiction of the Federal Department of Commerce. In Canada, however, both these matters can be handled by one organization, namely, the C.E.S.A. In Great Britain the work of the British Engineering Standards Association is being extended more and more into the field of simplified practice and the benefit to industry has been remarkable.

Work Accomplished

The Canadian Engineering Standards Association has published nineteen standard specifications to date, which have been largely adopted, and in many cases are Dominion Government standard.

ABSTRACT OF PAPER

The Okanagan and Its Problems

Major J. C. MacDonald, Comptroller of Water Rights, Victoria, B.C.
Victoria Branch, November 3rd, 1926

Major MacDonald remarked that while he had been in close touch with the irrigation affairs of the interior for the last seven years, covering developments in the Lillooet district, the Okanagan, and the Princeton and Grand Forks districts, the engineering features had not included structures of any great cost or interest, but were interwoven with the other economic features. As affecting the returns from orchards in the Okanagan he would place marketing, production, and irrigation water costs, in the order of precedence given.

At its very best, the marketing of the crop was an extremely difficult affair, and if from any cause, such as surplus supply at any point, or independent shipping, the price was cut, it was practically impossible to bring it up to a fair level again. Potatoes, as a necessity, would be purchased at any price within range, but apples, as a luxury, could be done without. This year, for instance, the prairie market fell to pieces, owing to the unfortunate weather that occurred in September, which held up the threshing, reduced the quality of the grain, and left the roads in such condition that only necessary transport took place.

An outline was given of the efforts that had been made to overcome these marketing troubles, and it was pointed out that assuming an irrigation cost of five cents per 40-pound box of apples, it was easily seen that the range of the market price was of vastly more importance than the cost of irrigation water.

Similarly in regard to production, returns might vary from 100 boxes to 600 boxes per acre, with a general average of perhaps 300 boxes. Assuming the cost of irrigation water at 20 boxes per acre, it was evident that the productivity of the orchard was of the greater importance.

A brief history of the development and growth of the fruit industry was given, and the circumstances that led up to the call for assistance by the growers under several systems, and the establishment by the government of the Conservation Fund, were outlined.

The detail allocation of money received from this fund had been placed in the hands of the districts themselves, but the expenditure had to be checked by the speaker as superintendent of construction, to insure that there was no waste or extravagance. This method of dealing with the moneys insured that the government had not built costly works and then charged them to the water users.

The poor returns from the crops of 1922 started a crusade for relief from some portion of the repayment charges, and a two-year moratorium was granted the payment of interest, and the payments on account of permanent (30-year) structures being carried over, to be funded afterwards. This was of considerable assistance; but a further difficulty arose later. The repayments from any particular district were spread over a certain number of irrigable acres. Where land reverted to the district for non-payment of water taxes, the amount due from the reverted lands had to be added to the paying lands, with a resultant increase in irrigation water cost; and it soon became evident that this added burden might become unbearable.

It has therefore been devised that on land becoming delinquent, if it is not sold within a reasonable time, the title is transferred to the government, and the government accepts responsibility for the charges assessed against that area. These lands are dealt with by the lands department, as reverted Crown Lands, and sold at such price as may be determined, the purchaser assuming the responsibility for further repayments to the Conservation Fund.

In this way, no owner can be called upon to pay more than the actual cost of delivery of water to his own land.

The latest returns show:—

Irrigation districts	18
Water users communities	10
Companies	6
Under municipalities	2
Government project	1
Total	37

And the estimated irrigable areas under present works are as follows:—

	Irrigable areas. (acres)
Co-operative irrigation organizations, assisted financially by the Government	34,800
Co-operative irrigation organizations not assisted by Government	4,700
Under company control	17,500
Under municipal control	8,600
Government project	10,000
Total	75,600

ANNOUNCEMENT OF MEETINGS

CALGARY BRANCH

Secretary-Treasurer, H. R. Carscallen, A.M.E.I.C.

Jan. 6th: Annual Dinner.
Jan. 20th: Address on "Kimberley Mines, B.C.," by B. L. Thorne, M.E.I.C.
Feb. 4th: Address by R. W. Boyle, M.E.I.C. (Subject not yet available.)
Feb. 17th: Address on "Oil Situation in Alberta," by C. C. Ross, M.E.I.C.
Mar. 4th: Address on "The Development of the Art of Communication," by A. M. Mitchell.
Mar. 12th: Annual Meeting.

LETHBRIDGE BRANCH

Secretary-Treasurer, N. H. Bradley, A.M.E.I.C.

Jan. 8th: Address by Mr. K. McKenzie. (Subject not yet available.)
Jan. 22nd: Address on "The Water Power Sites of the Crow's Nest Pass," by A. L. Ford, M.E.I.C.
Feb. 5th: Address on "The Irrigation Possibilities of South Eastern Alberta," by B. Russell, M.E.I.C.
Feb. 19th: Address on "Artillery Development in the Great War," by Brig.-Gen. J. S. Stewart.
Mar. 5th: Address by Prof. R. S. L. Wilson, M.E.I.C. (Subject not yet available.)
Mar. 19th: Annual Meeting.

MONCTON BRANCH

Secretary-Treasurer, V. C. Blackett, A.M.E.I.C.

January: Address on "Concrete in Sea Water," by A. G. Tapley, A.M.E.I.C.
February: Address on "Various Phases of the Official Life of a Public Works Engineer," by T. J. Locke.
Mar. 29th: Address on "Gunnery," by John Stephens, M.E.I.C.
Apr. 26th: Address on "Modern Tendencies in Highway Construction," by E. O. Turner, A.M.E.I.C.

VANCOUVER BRANCH

Secretary-Treasurer, F. P. V. Cowley, A.M.E.I.C.

Feb. 2nd: Address on "Education and the Mining Engineer," by J. M. Turnbull, B.A.Sc.
Feb. 9th: Address on "Coast Range of British Columbia," by Dr. V. Dolmage, B.A.Sc., Ph.D.
Feb. 16th: Open date.
Feb. 23rd: Open date.
Mar. 2nd: Address on "Education and the Legal Profession." (Speaker not yet definitely arranged.)
Mar. 9th: Address on "Recent Advances in Metallurgy," by Prof. H. N. Thomson, B.Sc.
Mar. 16th: Open date.
Mar. 23rd: Address on "The Work of the Vancouver and District Joint Sewerage and Drainage Board," by J. M. Begg, A.M.E.I.C.
Mar. 30th: Open date.

BRANCH NEWS

Border Cities Branch

C. G. R. Armstrong, A.M.E.I.C., Secretary-Treasurer.

Annual Meeting

The annual meeting of the Border Cities Branch was held Friday, December 10th, 1926, at 6.30 p.m., in the Prince Edward hotel, Chairman A. J. M. Bowman, A.M.E.I.C., presiding.

The minutes of the previous meeting were read and adopted, and the annual reports of the following committees were then presented and accepted:—Membership, by A. E. West, A.M.E.I.C.; Papers and Entertainment, by W. B. Pennock, Jr.E.I.C.; By-laws, by H. Thorne, M.E.I.C., and the reports of the Secretary and Treasurer, by Will H. Baltzell, M.E.I.C. Chairman A. J. M. Bowman, A.M.E.I.C., then reviewed the activities of the branch during the past year, giving many valuable suggestions for the ensuing year.

The election of officers for the year 1927 was then proceeded with, resulting in the following being elected:—L. McGill Allan, A.M.E.I.C., chairman; Harvey Thorne, M.E.I.C., vice-chairman; C. G. R. Armstrong, A.M.E.I.C., secretary-treasurer. O. Rolfson, A.M.E.I.C., A. E. West, A.M.E.I.C., and E. G. Ryley, A.M.E.I.C., were elected members of the executive committee. The ex-officio members for the year are A. J. M. Bowman, A.M.E.I.C., and Will H. Baltzell, M.E.I.C.

Mr. Pennock recommended that two committees be formed instead of the present Papers and Entertainment Committee, i.e., a Papers Committee and an Entertainment Committee.

Hamilton Branch

W. F. McLaren, M.E.I.C., Secretary-Treasurer.
J. R. Dunbar, Jr.E.I.C., Branch News Editor.

Executive Meeting, November 23rd

A meeting of the executive of the Hamilton Branch was held on November 23rd in the office of W. L. McFaul, M.E.I.C., city engineer, eight members of the executive being present. The meeting was mainly devoted to routine matters. It was decided to make the meeting to be held on November 25th open to the public on account of the general nature of the subject. An expenditure of about $12.00 was authorized to advertise the meeting in the local papers.

A communication from the general secretary of the Institute regarding a revision of the conditions under which students' prizes are awarded was referred to a committee composed of H. B. Stuart, A.M.E.I.C., and J. R. Dunbar, Jr.E.I.C.

The Geology of the Hamilton District

A meeting of the Hamilton Branch was held in the auditorium of the Hamilton Technical Institute on Friday, November 25th, 1926. The speaker of the evening was Professor A. P. Coleman, M.A., Ph.D., F.R.S., who had been for thirty-one years head of the geological department, University of Toronto. Dr. Coleman is now retired but keeps up an active interest in geology.

On account of the general interest of Dr. Coleman's subject, "The Geology of the Hamilton District," the meeting was thrown open to the public and when the meeting was called to order there were 180 present, including several ladies and the representatives of the local press.

Before the address a vocal solo was rendered by Mr. J. C. Hodges, a teacher at the Hamilton Technical Institute, who was accompanied by Miss Doris Stock.

L. W. Gill, M.E.I.C., chairman of the branch, introduced Dr. Coleman, who commenced his address by congratulating the city on its magnificent technical school. He declared that Hamilton should be proud of the institution.

The history of the deepest layer of the foundations of Hamilton dates back one thousand millions of years. This has been ascertained by drilling which was carried out for gas in the vicinity of Toronto near lake Erie. Under Toronto, granite was found at a depth of 1,200 feet and under lake Erie at a much greater depth. Drilling has not been actually carried out in Hamilton, but there is no doubt that granite is there, since Hamilton lies between Toronto and lake Erie. The drilling has greatly aided the study of the geological history of the region. The granite was originally the mountain surface. Then a change came, and where Hamilton now is there was a shallow sea with mud at the bottom, which is now changed to shale. That was, say, 500 millions of years ago, which Dr. Coleman referred to as comparatively recent times. Sometimes the water was clearer, when limestone was formed from plants and small animals. Sandstone showed where rivers had rolled down and ground rocks to fragments. There is not much sandstone in the neighbourhood of Hamilton. The sea that covered this region appears to have had a bottom that was slowly settling down. Near Hamilton material was deposited to a depth of 300 feet in layers which turned into various kinds of rock. This can be studied by a visit to the Hamilton mountain, which is called an "escarpment" by geologists.

Dr. Coleman showed pictures, on the screen, of the creatures that inhabited this region billions of years ago when the world was young.

Coming forward to a period only two or three million years ago, he showed a map on which was marked a river flowing from Barrie through Newmarket and Richmond Hill, across Ontario and on down to the sea. It actually existed once and had a tributary that flowed between Dundas and Hamilton. Sounding showed that in those days there really was a mountain here around 2,500 feet high. There were no great lakes then. This river was known as the Laurentian and flowed well out into the gulf of St. Lawrence.

The cliffs of the Hamilton escarpment are very useful in tracing the history of the region. Ice 3,000 feet thick once covered this district. For thousands of years it remained so. Showing a picture in the moraines in the Dundas valley, the speaker said that only ice in the form of glaciers could produce that hummocky landscape. Boulder clay and striated stones, such as are found in this district, are evidence of the passing of a glacier. Hamilton was well within the boundaries of the immense glaciers.

Finally the ice retreated, and as it retreated it blocked the river valleys. The Kingston region was left buried after the ice had retreated from the local district. During this period, two great lakes were formed; lake Algonquin, which approximately covered the area now occupied by the upper lakes, and lake Iroquois, which approximately covered the area at present occupied by lake Ontario.

The ice wall at Kingston blocked the outlets of these down the old Laurentian valley, and of course new outlets were found. At different times during this period the water of the upper lakes found outlets down the Mississippi, down the Ottawa, flowing out through the present Georgian bay into lake Ontario, past Trenton and down the present Hudson river through lake Ontario. Practically all these original water courses had been advocated from time to time by various engineers for canal routes.

The gravel bar over which the high level bridge out of Hamilton is built and Dundas bay above the bar, corresponded exactly in the old lake Iroquois to Burlington beach and Burlington bay in the present lake Ontario. This gravel bar is one of the wonders of lake Ontario and Dr. Coleman hoped that it would not all be used up for building material.

From the excavations for the old Desjardins canal, traces have been found of the cariboo and the reindeer. Bones of elephants, (mammoth or mastadon), and the musk-ox, have also been found.

Then the level of the country was lowered and the sea came in, and Hamilton was nearly a seaport, the sea being only five or ten miles away. The gulf of St. Lawrence reached almost to Hamilton. Sea shells were found as far up as Brockville, but the fresh water nearer here was at the same level.

After the sea withdrew, Niagara falls began its work. The falls began at the escarpment. It had cut its way back seven miles. He showed a slide of the first picture of Niagara falls, taken 350 years ago. There was no horseshoe then, and the horseshoe has now changed into a point. Unless some engineering effort is made, the time will rapidly come when the plunge will be replaced by rapids. The horseshoe falls are cutting the land away at the rate of four and a half feet a year. By this calculation it was figured that the falls began 7,000 to 8,000 years ago. That was when the ice age ended. The American falls are wearing away at the rate of only two inches a year.

In concluding, Dr. Coleman expressed a hope that the water of the Great Lakes would not be diverted past Chicago and that engineers would find a means of preventing Niagara falls from becoming a rapids.

At the conclusion of Dr. Coleman's remarks, Mr. John Wallace, a local geologist, stated that steps were being taken to preserve the gravel bank which formed the gravel bar in lake Iroquois.

A hearty vote of thanks was accorded the speaker on the motion of H. A. Lumsden, M.E.I.C., county roads engineer, seconded by W. L. McFaul, M.E.I.C., city engineer. The meeting closed with the singing of "God Save the King," with E. M. Coles, A.M.E.I.C., at the piano.

Executive Meeting, December 6th

A short meeting of the executive of the branch was held in the office of W. L. McFaul, M.E.I.C., to discuss final arrangements for the meeting to be held on December 14th.

Reports on three applicants for admission or transfer for higher grade in the Institute were received from the membership committee and were approved.

A letter from the general secretary of the Institute regarding co-operation between the Engineering Institute of Canada and the local Board of Trade was read and considerable discussion followed. It was finally decided to forward a copy of the letter to the local Chamber of Commerce stating that the Hamilton Branch were willing to co-operate and asking what action they wished to take.

Regular Meeting, December 14th

A meeting of the Hamilton Branch was held in the cafeteria of the Hamilton Technical Institute on Tuesday, December 14th, with L. W. Gill, M.E.I.C., presiding. During the evening musical numbers were provided by different students. These included a vocal solo by Leslie Emery accompanied by his sister, and several selections from the school jazz orchestra, led by Mr. J. Sloan.

The Manufacture of Carbon Products

The subject for the evening was "The Manufacture of Carbon Products," which was presented in a very interesting and instructive address by J. C. Webster, now sales engineer for the Canadian National Carbon Company in Toronto, and formerly connected for several years with the Carbide and Carbon Research Laboratories of Cleveland, U.S.A.

The address was comparatively brief, but it was made very interesting by means of a film entitled "Behind the Pyramids," which showed the various stages in the manufacture of carbon brushes, from the raw materials to the finished product. The list of the principal raw materials used in the manufacture of the various carbon products includes lamp-black, petroleum coke, artificial and natural graphite, and the various pitch and tar binders, a group which is apt to appear small in variety to the uses of carbon, but the process of manufacture, the mixing, forming and baking of the carbon, gives to it the many variations which make it so useful electrically.

The specific resistance can be varied from 0.0004 to 0.004 ohms per inch cube, or a range of 10 to 1. This range can be still further increased by the use of metals such as copper. The hardness as measured by scleroscope can be varied from approximately 10 to 85, or a range of 8½ to 1. The contact drop can be varied from approximately 1¼ volts per brush to below 1/10 volt per brush. The co-efficient of friction can also be controlled, although not to so great an extent.

These changes in physical and electrical properties are accomplished by variations in the raw materials, in the methods of forming the carbon, and by the heat treatment after forming. By properly controlling the final temperature, identical raw materials will produce entirely dissimilar finished products.

Carbons are formed by two methods: first, a moulding process under hydraulic pressure, and secondly, an extrusion process by which the carbon-binder mixture is extruded from an hydraulic ram through dies of various sizes and shapes.

Two types of furnaces are used for the baking, known as the muffle type and the regenerative ring type respectively. The muffle type requires thirty-five days to complete the baking, whereas the regenerative ring type completes its cycle in about two weeks, and carries the carbon to a much higher temperature.

The film showed all the above operations, and in addition the inspection and finishing processes. The number of inspections and tests to which a carbon brush is subjected is astounding. Carbon can be worked to very close tolerances. In the case of round carbons, the minimum tolerance can be less than one mil, and in rectangular carbons less than two mils.

On the motion of J. J. MacKay, M.E.I.C., seconded by E. H. Darling, M.E.I.C., a hearty vote of thanks was tendered Mr. Webster.

After the technical part of the meeting was over, refreshments were served and all present joined in community singing, led by Mr. F. J. Evans, accompanied by E. M. Coles, A.M.E.I.C.

Lethbridge Branch

N. H. Bradley, A.M.E.I.C., Secretary-Treasurer.

If Sherlock Holmes had turned his talents as a sleuth toward an engineering career, he would undoubtedly have become a geologist. This must have been the impression of some at least who heard Dr. John A. Allan in his address on the evening of December 4th, before the Lethbridge Branch.

Geological Aspects of Spray Lakes Project

As professor of geology at the University of Alberta, it is the doctor's duty to know every rock in the province, know each intimately and by name. That he does know rocks and can paint a vivid picture of what they imply historically and in terms of practical utility, was evident to all who followed his discourse when he delved into the geological aspects of the Spray lakes power development near Banff.

Known, perhaps, more familiarly as an authority on our oil and gas resources, it is not generally known that for the past two years he has been doing the geological work on the big Spray lakes project, a power plant that will develop 40,000 horse power and estimated to cost over thirteen millions of dollars.

Dr. Allan's investigations have been devoted entirely to the geological features, ascertaining definitely the foundation material on which the huge dam will stand. The dam will be 170 feet high and 395 feet long and its stability will depend largely on its underlying bed. He has had to discover and define the class of material through which a tunnel two miles long will be driven. He has had to analyze the various soils that will be used in filling the dam. This work required much diamond drilling and in addition thirty hand-dug test holes, the samples secured being later subjected to careful laboratory experiments.

Speaking to an audience of engineers, his address was naturally of a highly technical nature. To the ordinary individual, such terms as mesozoic, jurassic, triassic, paleozoic, mean little, but to the doctor these words came glibly. They suggested profound problems that must be understood and determined before the tunnel could be driven, before the dam could be started and, in the final analysis, before the tired business man is enabled to snap a switch in his well ordered home, a switch that will bring to his elbow electrical current generated from water coursing through some mountain gorge hundreds of miles away.

Not showy work, this geology. The public sees little of it and understands less. After the doctor has completed his task, the construction engineer begins. Structural designs are made, and away off in Montreal or Toronto, steel is fabricated into great trusses and beams and these are shipped to the site of the work, a site that lies over rough trails in the midst of a mountain wilderness. Hundreds of men will labour for months as the dam takes shape. Other hundreds will bore through a mountain the tunnel that will be two miles long and twelve feet in diameter. There will be the great power houses to be built and a thousand miles or so of copper wire to transmit the power.

Such is engineering. After all these things are done, it is a simple matter to snap on a switch and get light.

His address was illustrated with slides, and among these were two showing the class of country that would be inundated by the 18-mile reservoir. It appeared to be desolate and barren. Covered with water, it will be a lake, a useful body of water that will add much toward progress in Alberta.

In the information given on a subject that is little understood by the public at large, Dr. Allan's address on the work of a geologist was intensely interesting. He was greeted by a large audience, and during the dinner which preceded the lecture the local engineers entertained with music by the Rainbow Orchestra, community singing, and songs by Chris Gibson and a violin selection from Mr. Vallance. In the absence of J. T. Watson, A.M.E.I.C., G. N. Houston, M.E.I.C., presided.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

"The Richibucto Cape Breakwater" was the subject of an address by Geoffrey Stead, M.E.I.C., at the regular monthly supper meeting of the branch, held in the Y.M.C.A. on November 30th. Mr. Stead, who is district engineer of the Dominion Public Works Department, was responsible for the design of this work, and was also engineer-in-charge of construction.

A. S. Gunn, A.M.E.I.C., chairman of the branch, presided, and there was a large attendance of members present.

During the course of the supper, the gathering was pleasantly entertained with vocal solos by Mr. Alonzo Johnson, of Dumbells, and banjo selections by Mr. G. H. MacQuarrie.

Richibucto Cape Breakwater

The speaker described, in detail, the progress of the work, his remarks being illustrated by maps and lantern slides. Special reference was made to shifting sand bars, which at times threatened to block the entrance to, and even fill the basin.

On being questioned as to the economic aspect of the work, Mr. Stead declared that expenditures for such projects were considered justifiable when the resulting annual increase in business was equal to the capital cost of the work. In the case of Richibucto cape, the value of fish products passing through that port had risen from $25,000 to $75,000 per annum. This increase was considerably in excess of the cost of the breakwater.

On the conclusion of the address, a vote of thanks was tendered the speaker, moved by H. W. McKiel, M.E.I.C., and seconded by C.

S. G. Rogers, A.M.E.I.C. The latter expressed the opinion that it should be a matter of pride to engineers that the profession included men who could plan so wisely and execute so admirably public works of great and lasting benefit to our Dominion.

THE SHAWINIGAN POWER FILM

Through the courtesy of Fraser S. Keith, M.E.I.C., of the Shawinigan Water and Power Company, the branch secured the loan of an historical four-reel film dealing with the development of power from the early days up until the present time. It was our intention to show this film immediately following Mr. Stead's address, but unexpected difficulties in obtaining a moving picture machine resulted in our being disappointed. For the information of branches that may have the good fortune to secure the film we might mention that there are two types of moving picture projectors in general use,—the Standard and the Pathe,—and it is the Standard machine that must be used when showing the Shawinigan film. Pathe machines we could get a-plenty, but only one Standard, and that one sadly in need of repair. Although strenuous efforts were made up to the very last to put the machine in order, the projector, with the proverbial cussedness of inanimate objects, stubbornly refused to "project." The film was later sent to Sackville and shown at one of the moving picture houses of that town for the benefit of the engineering students of Mount Allison. Unfortunately, similar arrangements could not be made in Moncton without interfering with the regular theatre programmes.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
H. W. B. Swabey, M.E.I.C., Branch News Editor.

USE OF DURALUMIN IN THE MANUFACTURE OF ALL-METAL ARTIFICIAL LIMBS

On Thursday evening, November the 18th, the branch was fortunate in having a paper on the subject of Duralumin, by N. F. Parkinson, A.M.E.I.C., deputy minister of the Department of Soldiers' Civil Re-establishment.

The author dealt in a general way with the development of artificial limbs, referring to wooden limbs, and giving a comparison in weight and durability between these and the latest all-metal artificial limbs manufactured of duralumin.

He gave particulars of physical tests, chemical composition, and heat-treatment of duralumin, together with a comparison with other metals, and mentioned that tests and experiments were originally carried out on this alloy by Professor Allan Polard, technical adviser to the British Ministry of Pensions. Reference was made to further experiments which are proceeding with other alloys, which may result in even greater improvements.

Samples of artificial limbs made of both wood and duralumin were exhibited, and which are now being manufactured at the Canadian Government's factory in Toronto.

Mr. Parkinson gave some particulars as to the number of amputation cases in the C.E.F. resulting from the war, and referred to some of the difficulties encountered in supplying suitable artificial limbs in the more complicated cases.

The paper was illustrated with lantern slides. Dr. H. T. Barnes, M.E.I.C., and F. P. Shearwood, M.E.I.C., took part in the discussion, and a vote of thanks to the speaker was proposed by J. A. McCrory, M.E.I.C. The chairman was J. L. Busfield, M.E.I.C.

HYDRO-ELECTRIC DEVELOPMENT OF BRYSON

An interesting paper was read on November 25th by H. E. Pawson, M.E.I.C., describing the development of the power on the Calumet channel of the Ottawa river near Bryson by the Ottawa River and Power Company. The ultimate capacity of this power was given as 75,000 h.p., with present operating capacity of 25,000 h.p.

It was constructed on the site of an old dam built by the government for logging purposes, and facilities were provided in the present dam by means of a log chute for the passage of logs. A full description was given of the construction of the dam and power house, illustrated by lantern slides. A useful feature of the construction was the provision of a gantry crane from the wharf-landing to the power house to facilitate the handling of heavy machinery. A large steel scow was specially built to transport construction material, machinery and equipment in cars from the nearest railway point on the river to the site of the power plant.

Mr. Pawson gave full details as to the construction costs of dam and power house, including camp and administration buildings used during construction operations.

D. C. Tennant, M.E.I.C., proposed a vote of thanks. Prof. C. V. Christie, M.E.I.C., was the chairman during the first part of the evening, but as he had to leave early, the chair was later taken by E. G. Burr, A.M.E.I.C.

RAILWAY SUPPLIES

"What is the Supply Department of the Railway Doing to Keep Pace With Other Prospective Units?" was the full title of a paper read on Thursday evening, December 2nd, by Mr. L. C. Thomson, director of stores, Canadian National Railways.

The writer stated that Canadian railways have to pay 30 to 35 per cent more for their supplies than railways in the United States, due, to a great extent, to taxes and import duties. Large quantities of material which run into high figures, such as coal, steel plates, boiler tubes, tires, etc., have to be purchased in the United States.

In referring particularly to the Canadian National Railways, he mentioned that they were somewhat handicapped owing to the fact that in the consolidation of these railways they had to maintain more repair shops than would otherwise have been necessary. It is the policy of the railway executive to maintain a three-months' supply of coal on hand, and large quantities of ties have to be stocked each year so that there may be plenty on hand in the spring to start work as soon as the weather permits. Large quantities of ties are also creosoted and have to be thoroughly seasoned before treatment. Mr. Thomson mentioned that fuel and ties were the largest individual items on their material balances. He described the modern methods of stock-keeping which had been instituted, resulting in considerable economy, whereby the stock balance on the railways, comprising the Canadian National Railways, was reduced from $25,000,000 before consolidation to $12,000,000 in October this year.

The paper was illustrated by moving pictures of railway stores and shops, showing methods of handling and issuing supplies, etc., which had been taken by the publicity department of the Canadian National Railways. A picture was also shown of a trip along the coast of Alaska.

Col. D. Hillman, M.E.I.C., chairman of the railway section of the branch, presided, and C. K. McLeod, A.M.E.I.C., proposed a vote of thanks to the speaker.

BUILDING FOUNDATIONS IN RELATION TO STREET LEVELS

On Thursday evening, December 9th, Geo. R. MacLeod, M.E.I.C., engineer-in-charge of technical service for the city of Montreal, read a paper on the above subject, illustrated by lantern slides.

The author, in referring to the many difficulties that the engineering department of the city has to overcome, stated that these would be largely obviated if owners would consult the department before starting on a project. In many cases, it is intended to change the existing levels of streets and sidewalks when re-paving the streets, so as to improve the grade or cross-section of the street. Under such conditions, if building plans in these localities are laid out to the existing elevations, they will not fit in with the proposed improvements.

It was pointed out that the by-laws allow the construction of foundations to proceed before a permit is obtainable from the city authorities. However, in the near future, it is expected that legislation will be secured to force the obtaining of a permit before ground is broken.

As instances of difficulties arising through failure to consult the city engineers, several of the larger structures of the city were mentioned.

SNOW REMOVAL

Following Mr. MacLeod's paper, J. LeBlanc, A.M.E.I.C., assistant engineer of the Montreal road department, gave a short paper on "Snow Removal," which was illustrated by lantern slides depicting the various types of equipment used by the city for this purpose.

Since the advent of motor cars and their use throughout the winter, the speaker mentioned that the task of snow removal had been enormously increased. In consequence, the machinery and equipment required for this purpose had been improving rapidly every year.

Mr. LeBlanc gave statistics of snowfall and cost of removal in recent years; the largest fall in the past four winters being 131 inches in 1923-24 and cost $1,231,124 for removal. Last winter, with a fall of 117.8 inches of snow, it cost $1,404,292 for removal. In the discussion which followed the paper, it was pointed out by Mr. LeBlanc that the cost of removal of snow is not always in proportion to the amount of the fall, due to the amount of ice which formed and general weather conditions.

The meeting was presided over by J. G. Caron, A.M.E.I.C., chairman of the municipal section of the branch, and a vote of thanks to the two speakers was proposed by Dr. Frigon.

ANNUAL MEETING

The annual meeting of the Montreal Branch was held on Thursday evening, December 16th.

After the meeting was called to order by C. J. Desbaillets, M.E.I.C., the retiring chairman, the secretary, C. K. McLeod, A.M.E.I.C., read the minutes of the last meeting.

In his address, Mr. Desbaillets called attention to the number of engineers that were leaving the profession to take up other more lucrative employment. He stated that the number of engineers at this meeting was a repudiation of this policy. He advised the students and young engineers who may be tempted to give up their profession to look back at the development of Canada in the past one hundred years, during which time there had been built extensive railways, vast hydro-electric installations, and water-storage systems, canals, bridges, industrial plants, etc. He also referred to the big development of the mines, steel and paper industries, and stated that in all this development the largest part was due to the efforts of the engineer.

Mr. Desbaillets referred to the Institute as the home of big ideas and wonderful conceptions, in which many engineers had delivered lectures describing great enterprises so that others might benefit from their experience.

In closing his address, Mr. Desbaillets expressed a vote of thanks to Mr. McLeod, the secretary of the branch, for his help and co-operation during his term of office.

The financial statement for the year was read by the secretary, in which he compared various items with those in last year's financial report. The statement showed a total revenue of $3,258 and a surplus of $1,637.

William C. Adams, M.E.I.C., chairman of the nominating committee, announced the results of the ballot for officers for the coming year as follows:—

C. V. Christie, M.E.I.C., chairman; F. C. Laberge, M.E.I.C., vice-chairman; J. G. Caron, A.M.E.I.C., D. C. Tennant, M.E.I.C., and D. Hillman, M.E.I.C., members of the executive committee.

In a short address, Mr. Christie thanked the members for electing him chairman of the branch. J. G. Caron, A.M.E.I.C., also expressed his thanks for his election as a member of the executive committee. The other members elected were not present at the meeting.

A vote of thanks to the retiring chairman and members of the executive was proposed by J. H. Hunter, M.E.I.C., and seconded by R. E. MacAfee, A.M.E.I.C.

J. A. Burnett, M.E.I.C., proposed a vote of thanks to the Papers and Meetings Committee, and read a list of papers to be read at the meetings during the first half of the coming year.

A vote of thanks to the Publicity Committee was proposed by P. L. Pratley, M.E.I.C. In his remarks he referred to the satisfactory way in which the press had reported the meetings, making particular mention of the French papers.

After a vote of thanks to the Reception Committee had been proposed by Geo. R. MacLeod, M.E.I.C., the meeting adjourned.

Refreshments were served after the meeting.

Programme of Meetings for the Spring Term

The Papers and Meetings Committee have been successful in arranging a very satisfactory programme for the spring term, the list of papers being as follows:—

Date	Subject	Author
Jan. 6	Water Cooled Furnaces	B. N. Broido
" 13	Mercury Arc Rectifiers	O. K. Marti
" 20	Vacuum Process for Paper Manufacturing	Ogden Minton
" 27	Railway Lands—Titles, Surveys, Leases and Taxes	F. Taylor
Feb. 3	Traffic Regulations by Automatic Signals	K. W. Mackall
" 10	Radium	Dr. Gendreau
" 17	Annual Meeting	
" 24	Student Papers	
Mar. 3	The Scientific Method in Industry	G. P. Cole, M.E.I.C.
" 10	Developments in Steam Boiler Design	F. A. Combe, M.E.I.C.
" 17	Locomotive Feed Water Heating	W. C. Hamm
" 24	Geology of Island of Montreal	A. Mailhot
" 31	Tele Vision	Dr. L. E. Pariseau
Apr. 7	Recent Development in Aviation	Mr. Reid
" 14	Manufacture and Uses of Carbon Dioxide	J. R. Donald, A.M.E.I.C.
" 21	Vallee Street Sub-Station	H. Milliken, M.E.I.C.
" 28	Gatineau Developments	A. H. White, M.E.I.C.

The members will note, amongst others, our old friend Dr. Pariseau, who is always very popular.

There are six out-of-town speakers who are all coming to Montreal specially to deliver papers before the branch. As the subjects are all of prime interest, it is hoped that large meetings will result.

Peterborough Branch

W. E. Ross, A.M.E.I.C., Secretary.
B. Ottewell, A.M.E.I.C., Branch News Editor.

Annual Banquet

With a general air of jollity, with happy speeches and with hearty singing and enjoyable musical numbers, the annual banquet of the Peterborough Branch,—the night-of-nights for the local engineers,—was held at the Empress hotel on the night of November 23rd.

The branch has had the pleasure of entertaining many officers and past-officers of the Institute on the occasion of previous annual banquets. This year, among the guests, the branch welcomed a goodly representation of the council of the Association of Professional Engineers of Ontario, and the function might very properly be labelled "Professional Engineers' Night." Not only were the members of the branch afforded an opportunity of meeting some of the leaders who are working for the improvement of conditions within the profession, but also, in many cases, they heard for the first time some details of that great work, and so have a greater appreciation of what is being done for them.

About eighty members of the branch and guests were in attendance, the latter including many leaders of the profession from other branches of the Institute, and a number of prominent citizens of Peterborough. Throughout the evening, the members joined in singing well-known songs and parodies under the leadership of Paul Manning, A.M.E.I.C., past secretary of the branch, while a feature of the evening was the banjo selections given by Messrs. Wickwire, Ryan and Gore, while Ian MacKenzie presided at the piano.

The chairman of the branch, B. L. Barns, A.M.E.I.C., presided, and after welcoming the guests he referred to the value of such functions in bringing the members together. He then called attention to the objects of the Institute as set forth in the by-laws, pointing out the importance of each and responsibility resting upon each member in the fulfilment of these objects.

The secretary, W. E. Ross, A.M.E.I.C., read messages of felicitations and regrets at being unable to attend the banquet from Fraser S. Keith, M.E.I.C., Frederick B. Brown, M.E.I.C., Lt.-Col. Le Pan, A.M.E.I.C., Professor Peter Gillespie, M.E.I.C., and others. He then introduced N. E. D. Sheppard, A.M.E.I.C., assistant secretary of the Institute, welcoming him on the occasion of his first visit to the branch.

Mr. Sheppard brought greetings from headquarters and from a number of past officers of the Institute, and in his introductory remarks referred to the enviable reputation that the Peterborough Branch has made for itself, particularly in connection with its annual banquet. He pointed out that members of the branch should be proud of this reputation, explaining that, "Our Institute cannot be expected to thrive, or we cannot hope to carry out its objects unless there is that bond of good-fellowship, mutual esteem and confidence among its members which has its genesis in such functions as this."

Mr. Sheppard then gave a short résumé of Institute affairs and dealt with the problems being faced by the Institute, outlining the methods being used to solve some of them.

In closing, the speaker drew attention to the need for improvement in the status of the engineer, saying: "The question is persistently raised: why can't something be done to improve the status of the engineer? The question is pertinent,—the engineer is not recognized as he should be,—he does not get the credit that is due him for the important part he plays in the development of our country,—he should be the executive head of practically all our industries,—he should occupy the executive positions in all our works,—and he should be the leading factor in the administration of our country's affairs, in the direction of our municipal, provincial and federal governments. Why? Because his training qualifies him for these positions. But why does he not occupy these positions? Where does the fault lie? Not with our educational institutions, for their function is to teach him the fundamentals of science and how to apply them. Not with the general public or financiers or politicians, for they are all very much engrossed with matters of their own aggrandisement. Not with any of the factors outside of the profession, at whose feet the blame is often laid. The fault lies with the engineer himself, with each one of you gentlemen. Before the engineer can hope to be appreciated by those outside of the profession, he must appreciate himself and the engineers under him. He must place a higher value on himself. He must realize that this is the engineering age, the age of industrial development, and that with his training, his power to grasp a situation, analyze it and arrive at a sound decision, he has a tremendous advantage over others who have not that training. Now where does this lead? Once he realizes this advantage the field for the engineer becomes almost unlimited. He may enter any of our numerous industries, any of our financial and business houses, with the feeling that he is best equipped to learn that business and to ultimately direct its affairs.

"Then there is a component part of this thought,—the necessity for the engineer to take a far more active part in public affairs. As long as the engineer is so engrossed in his own work that he cannot give thought to or take part in affairs of a public nature, he will remain the very essential technical detailer for his own specialized line of work and he will be little known outside of his own small circle. How then can he hope for recognition,—what chance will he have for the appointment to an important post when, if by chance his name is mentioned, those making the choice can only say we never heard of him?"

Lt.-Col. H. J. Lamb, D.S.O., M.E.I.C., superintending engineer of the Ontario Department of Public Works, and president of the Association of Professional Engineers of Ontario, was introduced by A. L. Killaly, A.M.E.I.C., and brought greetings from the association, and in his opening remarks said: "The activities of this branch and the energy displayed by its members, has for many years stamped it as one of the most progressive branches of the Institute."

Before outlining the efforts being made by the Professional Engineers' Association to secure legislation in the province of Ontario, similar to that in force in practically all the other provinces, Col. Lamb paid tribute to the Engineering Institute, saying: "It is only right that, on behalf of the Association, I first pay tribute to the Engineering Institute of Canada for the prominent part which the Institute took, at the instigation of a few of its far-seeing members, in the initial work which eventuated in the passing of the Act in 1922 under which the Association of Professional Engineers of Ontario now functions. We would indeed be ungrateful if we forgot this fact, but the co-operation and valuable assistance of the Institute by no means stopped there; on the contrary, its branches throughout the province have continued to be one of our main sources of support in co-operating with us in the intensive organization work which we are carrying on throughout the province."

Col. Lamb went on to explain that in March, 1925, the Association, for certain reasons, considered it advisable to withdraw its proposed amendments to the Act, and undertook an intensive organization along the broadest possible lines of the whole engineering profession in this province. He then outlined the work which has been done by the Association towards organization, which has as its prime object the education of the engineer along the lines of working together for the betterment of the profession.

Councillor Ross L. Dobbin, M.E.I.C., introduced the next speaker, Mr. George H. Mickle, formerly head of the Department of Mining Engineering in the University of Toronto, and now with the Department of Mines of Ontario. Mr. Mickle outlined the present status of the mining industry in Ontario. Gold and nickel he placed as most important, and said that both these industries had recovered from very poor business conditions which existed a few years ago.

In introducing Mr. R. B. Wolsey, secretary and registrar of the Association of Professional Engineers of Ontario, Professor H. E. T. Haultain, M.E.I.C., of Toronto, told of Mr. Wolsey's work in connection with the various engineering bodies in Toronto. Mr. Wolsey in a few words, thanked the Peterborough Branch for the invitation to be present at such an enjoyable function.

A. B. Cooper, M.E.I.C., formerly of the Canadian General Electric Company, Peterborough, and now of the Ferranti Electric, Ltd., Toronto, was introduced by W. M. Cruthers, A.M.E.I.C. Mr. Cooper referred to the large number of applications he had been receiving from young Canadian engineers at present located in the United States, who wish to return to this country, and urged that everything possible should be done by the Institute to secure satisfactory positions for these men in Canada.

Replying to Mr. Cooper, Mr. Sheppard stated that similar requests were constantly being received at headquarters, and outlined the efforts which were being made to place such men.

Max Sauer, M.E.I.C., of the William Hamilton Limited, Peterborough, introduced Mr. Arthur Hull, of the Hydro-Electric Power Commission, who, in a few well-chosen words, advised the engineers to study the constitution and by-laws of their associations, and to take an active part in assisting their officers by making constructive suggestions and by supporting them in their work.

George Clark, M.E.I.C., who was introduced by Claude Rogers, M.E.I.C., dealt with the possibilities of the engineer with his technically trained mind occupying executive positions not purely engineering in character. Mr. Clark has recently been appointed manager of the contract department of the Robert Simpson Company.

Mayor Holloway, of Peterborough, spoke in humorous vein, welcoming the visitors to Peterborough and, becoming more serious, referred in terms of praise to the work of the engineer in the advancement of science.

Mr. E. A. Peck, M.P., referred to the lack of engineers in both the federal and provincial parliaments, and urged those present to consider seriously the remarks made by Mr. Sheppard with a view of taking a greater part in national affairs.

Mr. F. H. Dobbin, who was greeted with cheers, spoke encouragingly to the younger men, urging them to do their best in their daily duties and assuring them that their progress was watched and that they would receive recognition for their work.

Illumination

At the regular meeting of the branch, held on December 9th, 1926, the speaker was Mr. H. D. Burnett, formerly manager of several of the lamp factories of the Canadian General Electric Company and now manager of the Lighting Service Department. The chairman for the evening, Paul Manning, A.M.E.I.C., in introducing the speaker, referred to the fact that this is an age of rapid progress, and especially so in the matter of illumination.

Mr. Burnett prefaced his remarks with the statement that as one-quarter of our lives was spent under artificial light and sight is the most valued of the senses, there was ample reason for giving the subject due consideration. Statistics showed that there was a progressive increase in defective vision with age, from 15 per cent in young children, to 50 or 60 per cent in middle age and so on, and the speaker claimed that this was largely due to insufficient or incorrect lighting.

He outlined the requirements of good illumination as being:—ample light on the work and sufficient on the surroundings, freedom from glare, avoidance of heavy shadows, suitable colour of light, convenience for cleaning, and, last and least, reasonable cost.

The modern scientific methods of designing lighting schemes were next described, as opposed to the rule of thumb methods formerly used. The first thing to be decided is the intensity of illumination, and for this purpose standards have been set up by the Illuminating Engineering Society, giving intensities in foot-candles for every conceivable class of work and kind of building.

At this point the speaker defined very clearly the more common terms used in illuminating engineering—candlepower, foot candle, lumen, coefficient of utilization, factor of depreciation, etc.

Emphasizing most strongly the necessity for avoiding glare, Mr. Burnett urged the use of reflectors or globes to hide the lamps, especially those of the gas filled type. This led to consideration of the three general types of luminaries, the direct, semi-direct and wholly indirect, and the characteristics, advantages and disadvantages of each.

Having determined the intensity desired and the most suitable type of unit the speaker showed how, by a knowledge of the output in lumens of different lamps and of utilization factors for different colours of walls and ceilings and sizes of room, the total wattage or the watts per square foot was obtained.

It was then only necessary to decide on the number of units, paying due regard to the fact that, though the larger lamps are more efficient in lumens per watt, enough units must be used to give even illumination and avoid shadows.

Mr. Burnett showed a large number of slides of lighting installations, good and bad, also giving in graphical form the effects of good lighting in better discrimination, reduced fatigue of the eyes, reduction of accidents and increased production. He also, by the use of an ingenious "box of tricks," gave an interesting demonstration of varying effects obtainable by light from different directions, and of the great changes in appearance of coloured fabrics under lights of different colours,—here the "daylight lamp" with bluish glass bulb is most useful.

At the conclusion Mr. Burnett answered a number of questions and was given a hearty vote of thanks, proposed by George Burchill, Jr.E.I.C.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Thermit in Ice Control

At the first evening lecture of the present season, arranged by the Ottawa Branch, Dr. Howard T. Barnes, D.Sc., F.R.S.C., M.E.I.C., F.R.S., professor of physics at McGill University, was the lecturer. That his subject, "Use of Thermit in Ice Control Work," was of great interest, not only to engineers, but to the general public, was attested by the large crowd which gathered in the Palm Room of the Chateau Laurier on December 9th.

Dr. Barnes first reviewed the history of ice investigations, in which he had been more or less engaged since 1895. Ice, he said, commenced to form when the temperature of water had been lowered a very small fraction of a degree, say a few thousandths below 32 degrees Fahrenheit, and melting commenced at a correspondingly small variation above 32 degrees. A very small change in temperature therefore had a great effect in preventing the formation of ice, and Dr. Barnes at this point paid high tribute to John Murphy, M.E.I.C., of Ottawa, electrical engineer of the Department of Railways and Canals, and of the Railway Commission, whom he termed the first "ice engineer." Away back in 1904, Mr. Murphy had, in spite of the derision of many people, courageously applied the results of physical experiments to the solution of a practical problem. It was generally recognized as being absurd to try to heat a river or other large body of water to prevent ice formation, and yet Mr. Murphy, by the introduction of steam into turbines, prevented the troublesome frazil ice, which had been the cause of great worry to the power-house superintendent, from sticking to the turbines and shutting them down.

The action of the early morning rays of the sun on icebergs furnished another example of the effect of a small amount of heat. The sun's rays at daybreak penetrate to considerable depths and the infinitesimal amount of heat sets up forces which cause the berg to crack. Ice control then, according to the speaker, depended on the proper use of a small amount of heat in such form that it would penetrate to great distances. Thermit, he said, possessed this property, and with slow motion pictures, Dr. Barnes demonstrated the explosives or shattering effect of charges of two pounds of thermit placed in blocks of ice weighing 400 pounds. The thermit used consisted of a mixture of metallic aluminum and iron oxide, which was placed in a metal container in the ice and ignited. The aluminum takes the oxygen from the iron oxide, forming an oxide of aluminum with the generation of 5,000 degrees Fahrenheit of heat. When burning has proceeded to a certain degree, the bottom is melted out of the metal container and the thermit comes in contact with the ice. The iron has an affinity for the oxygen molecules of the ice and great quantities of hydrogen are released. There is a great disruptive force and the experimental blocks were virtually burned up, Dr. Barnes stated. The moving pictures showed the burning column of liberated hydrogen.

The lecturer then proceeded, with the aid of lantern slides and moving pictures, to show the help which he had given with thermit in March of this year to Oil City and Franklin, Pennsylvania, in lowering the flood waters of the Allegheny river, and how, with the coming of warmer weather and rain, the ice jam, which blocked the river for a distance of twenty-five miles, had eventually moved out in orderly fashion without serious damage to property. He stressed the part which thermit had played in clearing a channel under the ice and in saving the Reno traction bridge at Oil City. This bridge had been lifted 18 inches off its piers by the ice. Following thermit treatment, it had settled back into place without damage and was immediately re-opened to traffic.

Dr. Barnes also spoke of the experiments conducted on icebergs off the coasts of Newfoundland last summer. Following treatment with a thermit mine, a large berg had split asunder within a few hours and had turned over. Thermit had also been used effectively in an experimental way on the St. Lawrence river in the spring of 1925. The judicious use of a small amount of thermit at key positions had caused a heaving of the ice and the jams had moved out in each case within twenty-four hours.

At the conclusion of the lecture, Mr. Murphy gracefully returned the compliment which Dr. Barnes had paid him. He had known Dr. Barnes for many years and had followed with great interest the important work which the latter was doing in his ice research work. Mr. Murphy then had a slide thrown on the screen which gave the United States Government record of maximum and minimum temperatures at the nearest point of record on each of the days during which Dr. Barnes had been engaged in the Allegheny river relief work. In friendly fashion he pointed to the rising temperatures and the rain which fell, and wondered whether Dr. Barnes had given sufficient credit to "old sol" and the rain. Dr. Barnes reiterated that he had not been trying to work against nature but with it and had kept close watch for favourable weather. He emphasized the fact that the jam had been loosened from the lower end and had gone out in orderly fashion, the reverse of what would have been expected had nature alone been allowed to take its course.

D. W. McLachlan, M.E.I.C., engineer-in-charge, St. Lawrence Waterways, Department of Railways and Canals, also had a word to say about the thermit experiments on the St. Lawrence river. Referring to the Chimney Island jam, he found that the records of the temperature of the water showed that the jam might be expected to move within twenty-four hours of the time when thermit was used, and in fact he had a report to this effect from one of the officers stationed at the river. Dr. Barnes again pointed out that there were similar results in three cases, which, however, he admitted might have been coincidences.

J. D. Craig, M.E.I.C., chairman of the Ottawa Branch, presided and thanked Dr. Barnes for the delightful entertainment afforded by his most interesting lecture.

Pre-treatment of Fuels

At the luncheon meeting held in the Chateau Laurier on Friday, December 3rd, the Ottawa Branch was particularly favoured in having as its guest and speaker C. H. Lander, D.S., director of the British Fuel Research Board. Dr. Lander attended the International Conference on Bituminous Coal at Pittsburgh, Pa., and came on to Ottawa especially to address the Ottawa Branch.

The subject of Dr. Lander's talk was "The Pre-treatment of Fuels," and the speaker traced the progress made in research since the Fuel Research Board was formed in 1917 for the dual purposes of making "a survey of the fuels of Great Britain from the chemical and physical point of view," and "of investigating problems of pre-treatment to make fuels with greater availability of heat." The fuel research station at Greenwich cost about $1,000,000. The survey had an immediate beneficial result for the operators, since close examination of vertical and horizontal samples from the coal seams disclosed the characteristics of the coal, particularly the sulphur bands. The survey will take many years to complete.

Dealing with the pre-treatment of coal, Dr. Lander said that its object, generally speaking, was to raise the availability of heat units and that this was always accompanied with the loss of some units.

The problem of greatest importance in Great Britain was to get a smokeless fuel, which would better atmospheric conditions in the great cities. On account of there being practically no natural oil and no natural gas in the British Isles, a solution which would yield oil as a by-product would be very attractive.

Three methods of producing coke were mentioned:—The high temperature (1,200°) gas-house process with gas the main object; the metallurgical process; and the low-temperature carbonization (600°) or coke-house process. The coke produced in the gas-house is not popular and neither is the hard metallurgical coke. The low-temperature carbonization yielded a more free-burning fuel which was suited to the English use in open grates, and it produces fuel oil as a by-product.

Dr. Lander said there were many processes for low-temperature carbonization. He personally knew of 200. The mere designing of a system of treatment did not make it a commercial success and the Fuel Research Board had started at the bottom with bench tests of a few grams of coal in test tubes, after which they had entered the second stage with tests of 50 or 100 pounds. The third stage was the development of a unit plan. This stage had been reached and the research station plant was capable of handling eight tons of coal per day on low-temperature carbonization. The remaining stage in the development of low-temperature carbonization was its utilization in industry as a commercial paying proposition and the multiplication of the unit plant into great batteries of coke producers.

The board is also investigating the production of synthetic gasoline, and there is no question, the speaker said, of the feasibility of producing a synthetic gasoline or a product very nearly akin to natural petroleum.

Dr. Lander was optimistic as to the outcome of the experiments being undertaken and implied that the time would come when the utilization in industry of the successful results of low-temperature carbonization would be an accomplished fact.

J. D. Craig, M.E.I.C., chairman of the Ottawa Branch, presided, and expressed the highest appreciation of Dr. Lander's address, which was of very great interest to Canadians on account of the great deposits of bituminous coal in Canada.

Canadian Coal for Canadian Consumers

"Canadian Coal for Canadian Consumers," was the subject of an able and eloquent after-luncheon address by Mr. E. J. Garland, M.P., to the members of the Ottawa Branch at the Chateau Laurier on December 16th.

Mr. Garland, who represents the constituency of Bow river, Alberta, in parliament, has given a great deal of thought to this subject, which is of exceedingly great interest to all Canadian engineers. A national subject of ranking importance with any others before Canadians today, the speaker tackled it along broad economic lines.

"Of what use are natural resources if you do not use them?" asked Mr. Garland. The coal in Alberta alone represented 15 per cent of the world's supply. Of the total reserves of coal in the British Empire 72 per cent is in Alberta, and again, 87 per cent of all Canada's coal is in the same province. But the mere presence of coal did not constitute wealth. A bank would not loan a dollar on it except as a development proposition with a market for the product.

"The coal purchases which Canadians have made in the United States would have paid off the national debt," said Mr. Garland, and $100,000,000 was being expended annually for coal and the transportation of it from fields outside of Canada, an amount equal at least to $300,000,000 in purchasing power, if spent at home, since money, according to the speaker, turns over from three and one-half to five times annually. This would maintain a population of one million people. The turn-over of this money would benefit all classes, not merely miners, for only one-third of the cost of coal goes to the mines. Another third is expended for transportation, and the remaining third for distribution. All provinces of Canada, not merely those with coal mines, would therefore benefit through the mining of Canadian coal.

Mr. Garland stressed the point that $100,000,000 a year of Canadian money is being spent to maintain a non-Canadian industry, and that as the population of Canada increases, unless the problem of using Canadian coal is solved, this export of wealth would increase in proportion. Solution of the problem meant, like the growing of wheat, more new wealth; it meant more miners, more machinery, more transportation tonnage, more clothes, more food, more homes, more railway work, more factory work and greater national purchasing power.

Coming to the solution of the problem of "Canadian Coal for Canadian Consumers," Mr. Garland did not think that the coking of coal presented a solution. It was only commercially feasible, in his opinion, where there was a nearby market for the by-products, especially gas. Such situations existed in the United States, where there were great centralizations of industry with large populations. He had visited the large modern coking plant at Troy, N.Y., and found it operating under ideal conditions for commercial success. This plant cost $6,000,000, and produced 1,000 tons of coke and 18,000,000 cubic feet of gas per day. The company controlled coal mines and had cheap transportation, with its plant located on the Hudson river. Great industrial concentration with large cities and towns nearby furnished a market for its products. In Canada there were few such opportunities, Montreal, Toronto and Hamilton representing the nearest approach to parallel conditions.

Could Canadian mines supply Canada's coal needs in a hurry? Mr. Garland found that they could, at least insofar as domestic and steam requirements were concerned. Canadians consumed at present 33,000,000 tons annually, of which 18,000,000 tons are imported. But the capacity of the existing mines is double the present output and with very little additional overhead the demand could be met.

The solution, Mr. Garland found, lay in cheaper transportation. At present the market for British Columbia's coal was limited to the Pacific coast, while the Maritimes were confronted with high rail rates, which, if satisfactorily adjusted, would permit of eastern coal moving further into central Canada. The freight rate on Alberta coal to Toronto is $12.50 per ton, though a limited amount had been brought down under a special concession at $9.00 per ton. The cost of bringing Alberta coal to Ontario, the speaker said, had been grossly over-estimated, and he went into details of costs presented by the Canadian National Railways to show this. After paring down items, which he found ridiculously high, he arrived at an out-of-pocket cost of $5.25 per ton. If the Railway Commission found the cost not to exceed $7.00 per ton, he thought the problem was solved.

There was no need of bounties or subsidies. Rates had, in the past, been set to the level at which a commodity would move. This was the governing factor and he believed an out-of-pocket cost rate was justified and would in time yield a profit.

Alberta coal, the speaker said, is practically ashless and smokeless. For domestic use no sifting is required. It can be easily and satisfactorily managed. Mere B.t.u. content is not a measure of the value of a coal to the householder. It is what you can get out of it, said Mr. Garland, and Alberta coal is just as satisfactory as anthracite. He had yet to learn of any criticism of it which would hold good. He appealed to the members of the Institute as Canadians to get behind the movement for "Canadian Coal for Canadian Consumers," and said it was an opportunity for everyone to serve his country. He thought every branch of the Institute should take up the matter and the committee formed in Alberta to further this project would, he knew, gladly send speakers.

J. D. Craig, M.E.I.C., chairman of the Ottawa Branch, presided and thanked the speaker for his interesting address.

Niagara Peninsula Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

One of the preliminary steps in bridge construction is to plot a curve of traffic expectation. This curve for the Niagara Peace bridge was more than likely revised on or about December 1st to a considerably steeper angle. As a commercial proposition, this revision will probably put it in Class A-1.

Mr. Lupfer, however, tells us that it is not a commercial proposition and upon the paying off and retirement of two bond issues the bridge is to become the property of the adjoining countries and all stock is to be cancelled.

The Niagara Branch had the honour of inspecting this Peace bridge on October 4th; meeting some engineering confreres from Buffalo, and afterwards being addressed by Chief Engineer Edward P. Lupfer at a dinner meeting. The weather was inclement; an east wind with snow made travelling anything but pleasant and thinned the ranks of those who went out on the bridge and had their picture taken for the Buffalo papers, but the dinner at Niagara falls was well attended.

The bridge spans the Niagara river between Buffalo and Fort Erie. It consists of five deck steel arch spans and a through truss span over the entrance to the Erie canal. The arches vary in length from 346 feet to 423 feet and the total length, including approaches, is 5,800 feet.

Remarkably quick time was made by contractors J. P. and R. B. Porter, who had the substructure, the west approach and the concrete decking, and also by the Bethlehem Steel Company, which had the steel superstructure. A little more than fifteen months since the actual construction started and now this $4,500,000 bridge is practically complete. Mr. James Kelly, who was in charge of the steel erection, also received great praise.

Mr. Lupfer, however, did not dwell very strongly upon constructional problems. He spoke of the approaches or terminals and stressed the fact that in these days of rapid transportation they controlled the whole situation, particularly where an international boundary is crossed and examination by the customs and immigration authorities is necessary. The terminals of this bridge are in the shape of a fan, allowing seven lanes of entrance at each end, eleven lanes of exit on the Canadian shore and nine on the American. It is calculated that this arrangement will allow a peak of 3,000 automobiles an hour to be handled in one direction.

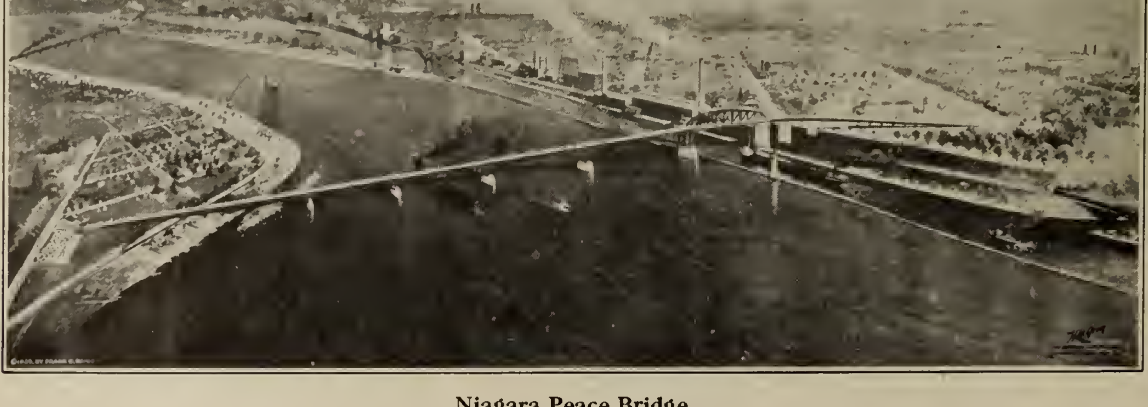
As an indication of what might be expected in the way of traffic, Mr. Lupfer quoted the following figures from the present ferry reports:

	1919	1920	1921	1922	1923	1924	1925
Autos—	134,000	156,000	209,000	293,000	354,000	475,000	550,000
Passengers—	......		1,110,000	......	......	......	3,600,000

The bridge is to be an emblem of peace; of the goodwill which has existed between Canada and the United States ever since the treaty of Ghent in 1814. As Mr. Lupfer expressed it, "The spiritual side of this project cannot be overemphasized. The bridge is designed to be a monument to the method of settling disputed questions by means of arbitration rather than by war."

A tactful compliment was paid to the Victoria Parks Commission by Mr. Lupfer when he referred to the great beauty of the driveway and parks along the Canadian side of the river.

S. R. Frost, A.M.E.I.C., was in the chair. Colonel J. MacDonald moved a vote of thanks and this was seconded by J. R. Bond, A.M.E.I.C., and heartily approved by the meeting.



Niagara Peace Bridge.

Saint John Branch

W. J. Johnston, A.M.E.I.C., Secretary-Treasurer.

Architectural Design of Buildings

A meeting of the St. John Branch, at which A. R. Crookshank, M.E.I.C., presided, was addressed by W. W. Alward, A.R.I.B.A., of Alward and Gillies, architects, St. John, on November 18th, 1926. The subject of the address was "The Architectural Design of Buildings."

The first section of the address dealt with an historical sketch of the different forms of ancient architecture. The first known forms of architecture existed in the early tombs on the banks of the Nile, and were followed by the Chaldean types. Architecture received greatest attention and made its greatest progress during the early Greek civilization. The various features of the Parthenon of Athens were described as an example of the splendid style of architecture developed by the Greeks. It was shown that the Greeks were familiar with tricks to overcome the effects of optical illusions so that the completed structure was not only structurally sound but also pleasing to the eye. The speaker also mentioned the Graeco-Roman type of architecture prevailing in Great Britain at the beginning of the last century, and the mid-Victorian type of fifty years ago.

The present types of industrial buildings were touched on, and it was shown that a plain office building with every detail properly proportioned to bear its share of load, was architecturally correct on account of its simplicity of outline.

Various forms of architecture on different buildings in St. John were mentioned. The point was brought out that some good examples of architecture exist on buildings in this city.

By using a blackboard the speaker showed how architectural drawings were made. In particular, the method of making perspective drawings was shown at some length. Following a discussion on the address, a vote of thanks to the speaker was moved by G. N. Hatfield, A.M.E.I.C., and J. D. Garey, A.M.E.I.C.

Industrial Lighting

On December 9th, 1926, the members of the St. John Branch were addressed by S. C. Webb, A.M.E.I.C., on the subject "Industrial Lighting." The meeting was held in the New Brunswick Telephone Company building, with A. R. Crookshank, M.E.I.C., presiding.

The crude early forms of lighting were briefly mentioned,—the fire brands thrown into the caves in early days, torches, oil-lamps, and finally to the incandescent electric lamp developed by Edison in the latter part of the nineteenth century. The carbonized filament of Edison's lamp was later replaced by the tungsten filament lamp of the present day. The application of the "Lumen" method was described in arriving at sizes and numbers of electric lights to use in lighting given areas under certain conditions. Such details as the style of reflector, location of the fixture, and the later necessary maintenance by removal of dust and dirt from electric globe were stressed.

The speaker showed by demonstrations of several classes of lights and fixtures, specially installed in the room for this meeting, the different lighting effects obtained. A moving picture reel entitled "Yesterday and Today," contrasted the difference between electricity and other forms of lighting. Two reels were shown of the manufacturing processes of an electric light bulb. A vote of thanks to the speaker was moved by Geoffrey Stead, M.E.I.C., and G. N. Hatfield, A.M.E.I.C.

A moving picture describing the electrical developments of the Shawinigan Water and Power Company was shown. A vote of thanks to Fraser S. Keith, M.E.I.C., for courtesy in sending this film was passed by the meeting.

A resolution of regret at the death of E. T. P. Shewen, M.E.I.C., which occurred the afternoon of the day of the meeting, was passed by the branch.

Saskatchewan Branch

R. W. E. Loucks, A.M.E.I.C., Secretary-Treasurer.

A regular meeting was held in the Kitchener hotel on November 19th, preceded by a banquet. Vice-chairman M. B. Weekes, M.E.I.C., presided. Guests included Mayor Taisey and Alderman Mathison of Estevan, Sask., both of whom are well known to the members of this branch by reason of their participation in the two summer meetings which this branch has held at Estevan. H. S. Bare, A.M.E.I.C., and S. Wright, of the engineering staff of the new Canadian Pacific Railway hotel under construction in Regina, were also guests at this meeting.

Recent Advance in the Engineering Side of Building Construction

J. H. Puntin's, A.M.E.I.C., paper on "Recent Advances in the Engineering Side of Building Construction," was well received. Mr. Puntin laid particular stress on the feasibility and advisability of winter construction in Canada, or, what may be termed "all year" construction. The extra direct cost of construction in winter over similar work in summer does not amount to more than from 1 to 3 per cent, and this extra direct cost is more than compensated for in other ways. There is a saving in transportation charges, labour, overhead, etc. Authorities all over the continent are agreed that winter construction is the solution of many of the problems of the builder and contractor. Mr. Puntin pointed out that concrete can be poured in the coldest of weather without reducing its strength if the materials are heated before mixing and the concrete when poured is not subject to alternate thawing and freezing.

H. S. Bare, A.M.E.I.C., engineer with the Canadian Pacific Railway hotel, Regina, stated that he has just completed three years of continuous winter construction of concrete and his experience has been that the concrete is not injured in the least with the exposure to frost. His practice is to add four pounds of calcium chloride to each bag of cement, which gives the concrete a seven days' set in twenty-four hours. Salamanders are used to keep the concrete warm until it has attained its initial set. Mr. Bare has recently been engaged on the construction of the Canadian Pacific Railway hotels at Quebec, Lake Louise and Banff. He mentioned the advantages of the Massillon bar joists in floor construction, which is the type used in the Regina hotel.

Mineral Deposits of Southern Saskatchewan

Mr. W. H. Hastings, engineer with the Bureau of Labour and Industries, read a paper on "Mineral Deposits of Southern Saskatchewan, Their Location, Uses and the Possibilities for Development." Mr. Hastings stressed in particular the coal and clay deposits. He also made reference to the deposits of sodium sulphate, volcanic ash and bentonite. He pointed out that Saskatchewan now consumes about 1,500,000 tons of coal annually and mines about 500,000 tons of lignite coal. He predicted that some day Saskatchewan's clays will be as noted as are her agricultural products.

The discussion on Mr. Hastings' paper brought out the possibilities of using the sulphate deposits as a preservative for timber. Messrs. Perry, Lewis and Campbell testified to the fact that railway piles and ties laid in areas covered by sulphates have a considerably extended life over similar timbers laid in ordinary soil.

Mr. Hastings' paper was illustrated by several slides showing the extent and development of the mineral deposits of Saskatchewan.

Outdoor Signs

Stewart Young, A.M.E.I.C., director of town planning with the government of Saskatchewan, read a paper on "Outdoor Signs." Mr. Young described the practice of erecting objectionable bill-board signs on streets and public highways, and the movement towards reduction or elimination or regulation of such signs. Mr. Young's paper was illustrated with a number of suitable slides.

H. S. Carpenter, M.E.I.C., in discussing Mr. Young's paper, spoke of the decision of the Department of Highways to erect traffic signs on all provincial highways, and this will necessitate the removal of many unsightly signs at present located in objectionable locations. He suggested that the erection of "danger signs" may be overdone and lose much of their intended purpose. R. N. Blackburn, M.E.I.C., was of the opinion that signs on private property could not be prohibited. H. R. Mackenzie, A.M.E.I.C., stated that in Ontario the provincial government control and charge fees for the erection of signs on or adjacent to provincial highways.

A vote of thanks to the speakers and pleasure at having such distinguished guests present at the meeting was moved by A. C. Garner, M.E.I.C., and seconded by H. R. Mackenzie, A.M.E.I.C.

Round the World

The meeting on December 10th, 1926, took the form of a "Round the World" night, and consisted of addresses on the outstanding engineering achievements of several selected countries with special reference to the influence of such engineering achievements on world progress.

"Africa" was described by J. C. Meade, A.M.E.I.C., who spent some three years on railway construction in Nigeria. He described the Ju Ju's, consisting of egg shells fastened to sticks stuck in the ground, which the natives regarded as sacred and would not touch. Railway construction is done by hand labour and the materials transported in baskets carried on the heads of the natives. When wheel barrows were supplied the natives carried the loaded wheel barrows on their heads, so the barrows were discarded as being unnecessary. A 3½-foot gauge was used, and sharp curves introduced to reduce the cost of construction. It was necessary to use steel ties, as insects destroy wooden ties very quickly. A number of slides were shown illustrating the remarks of the speaker.

"China" was dealt with by J. G. Schaeffer, S.E.I.C. The Chinese were the earliest of races to use science. As far back as 2900 B.C., we find records of arch design. Gunpowder was used by them long before its use by any other race. One of the earliest and greatest achievements was the building of the great wall, started in the third century B.C. The total length of the wall is about 1,500 miles. It varies in height from 20 to 30 feet. The thickness at the base is from 15 to 25 feet, while the top width is 12 feet. For the most part it was built of round boulders and earth. Masonry construction was used only in the valleys and mountain passes. Another engineering project commenced about 486 B.C. was the construction of the grand canal, portions of which are still being used today. This canal extends from Hang Chow in the south to Peking in the north, a total distance of 1,200 miles. Railway construction, commenced in China in 1875, has gradually increased until in 1923 they had a total mileage of 7,513. China is rich in coal, iron, copper and tin, but owing to lack of capital these mineral deposits have not been extensively developed.

"Germany" was described by P. R. Genders, A.M.E.I.C. He traced the history of the German Empire, and referred to the great advances made in modern industries in that country.

"India," D. D. Low, Jr.E.I.C., described as being divided into three distinct regions, the northern or mountainous region, the central or great plains region and the southern or plateau region. One of the most important engineering achievements of India has been the construction of the great system of canals for irrigation purposes in the Punjab river basin. This has been the means of turning great swamp areas into productive territory. With over 32,000 miles of railway in operation in 1910 the great cities of Calcutta and Bombay had flourished. Bombay is now one of the largest manufacturing centres in the world and derives its energy from the hydro-electric development in the hills of southern India. At one point electricity is developed from a water power with a head of 1,725 feet.

"Italy" was described by G. G. Fitzgerald, A.M.E.I.C., and he confined his remarks mainly to the "Roman roads." Great roads were undoubtedly built long before the beginning of authentic history leading to the pyramids of Egypt and in the vicinity of Babylon. The Persians, Assyrians, Carthaginians, Chinese and Peruvians were all great road builders, but the Romans were the first road builders of whom we have definite knowledge.

The Appian Way and the Flaminian Way were great military highways leading from Rome, and in the height of her glory Rome had twenty-nine great roads radiating from her gates leading to all parts of the great empire. The entire system of main or military roads at that time is estimated to have amounted to 50,000 miles.

The construction of the main Roman roads was extremely massive, consisting of four courses having a total thickness of about three feet and generally a width of from sixteen to thirty-two feet and slightly crowned to permit of drainage. The road was constructed upon a solid foundation of rock or piles and the four courses laid in order as follows:—

1. The foundation course, (statumen), which was composed of large flat stones, bedded in mortar.
2. The rudus, a layer nine inches thick of hand rock, laid in a form of lime or cement mortar.
3. The nucleus, six inches thick, consisting of small stones, gravel, or pieces of broken brick and tile, also laid in mortar or cement, and the top made smooth.
4. The summa crusta, or wearing surface, of large flat blocks of the hardest stone to be found, closely fitted to each other, with the greatest nicety, so as to present a perfectly smooth surface.

The Roman roads usually were located in a direct line from point to point, avoiding deviations which would have reduced the cost of construction materially. That they were substantial is evidenced by the fact that some of them have borne the traffic of 2,000 years without material injury.

The majority of these great highways were built by contract at the public expense. A few were built from the spoils of war, the private wealth of emperors or great personages ambitious for public approval. They were maintained by the enforced labour of soldiers and slaves. The highway legislation of the Romans forms the basis of many of our present road laws. By the Roman law, the right to the use of the roads was inherent in the public.

"Japan" was described by J. B. Parker, A.M.E.I.C., who dealt with the great engineering feat of restoring the telephonic and telegraphic communication in Tokio following the recent earthquake and fire in that country on September 1st, 1923.

The earthquake disrupted and broke all telegraph circuits radiating from Tokio, including cables, etc., and many of the central offices were burned. However, a temporary telegraph office was opened in the Tokio central post office and on the second day,—thirty-five hours after the earthquake,—communication regarding relief business was successfully opened to three neighbouring cities. By repairing underground cables, communication was re-established in eight days to six adjacent cities and a circuit established between the central telegraph office and the telegraph corps radio station in one of Tokio's suburbs, which acted as a link for other radio stations and the warships in the harbour. Sixteen faults were located in the Guam cable to the United States, and these were repaired by October 27th, under great difficulties owing to the depth of the water. Of the twenty telephone exchanges fifteen were burned, one was unavailable and only four capable of renewing business. Sixty per cent of the subscribers' stations were burned and practically half the outside plant was destroyed. By November 10th sufficient circuits were opened so that all restrictions were removed.

"Norway and Sweden" were covered by Edwin Markham, A.M.E.I.C. The outstanding engineering achievement of the Norwegians is the development of water power. There are in Norway twelve million horsepower of electrical energy under development or consideration. About 75 per cent of the population are already supplied with electrical energy. The cost to the consumer varies from $25 to $65 per kilowatt per annum. Of the power developed in Norway, 42 per cent is used in electro-chemical and electro-metallurgical industries. Included in the twelve million horsepower is provision for the electrification of the railways of that country.

Sweden has available six million horsepower of electrical energy and only about 50 per cent of this can be economically developed. In that country electricity is used extensively to operate farm machinery.

Bessemer's process in making steel was introduced into Sweden in 1858 and at that time it was almost essential to use the Swedish iron ore being low in silicon content.

"Russia," according to W. T. E. Smith, BRANCH AFFILIATE, owes her chief claim to greatness to her agricultural resources. Her steppes have raised more grain in a single year than any other country. In 1913 this amounted to 1,027,000,000 bushels.

Industrially, Russia is very weak, most of her wealth is in raw products and her trade consists largely of exporting this instead of manufacturing it at home. One very vital need of Russia is the railroad. Even in 1913 a much greater proportion of her freight traffic was carried on her rivers than on her railroads. In 1860 she had less than 1,000 miles of railway and in 1905 about 40,500 miles.

Since the war there has been a slowing up of many of the industries of Russia and this situation is due to the lack of foreign capital for investment in that country.

At the conclusion of these addresses a ballot was taken for the purpose of selecting the best and the one most nearly conforming to the instructions governing their preparation. The vote was in favour of Mr. Fitzgerald's address on Italy, and he was presented with a suitable gift.

Amongst the visitors was F. K. Beach, A.M.E.I.C., from Calgary. He conveyed the greetings of the Calgary Branch, of which he is a prominent member.

A vote of thanks to the speakers was moved by A. P. Linton, A.M.E.I.C., and seconded by S. Young, A.M.E.I.C.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer.

The regular monthly meeting was held in the Y.W.C.A., Queen street east, on November 26th. A dinner for the members and guests was held previous to the meeting.

Chairman C. H. Speer, M.E.I.C., called the meeting to order and disposed of the business. Mr. Speer then briefly gave a report of the Great Lakes Harbour Commission convention held at Buffalo on November 15th and 16th. This meeting was one of protest against the existing conditions at Chicago in regards to the Chicago drainage canal and the taking of 10,000 feet of water from lake Michigan. Mr. Speer was one of the delegates representing Sault Ste. Marie, Ontario, at the convention.

Mr. H. B. Greenstead, engineer of tests of the Algoma Steel Corporation, was introduced by the chairman and gave a most interesting paper on "The Manufacture and Composition of Alloy Steel."

A hearty vote of thanks was tendered to Mr. Greenstead by Messrs. A. E. Pickering, M.E.I.C., and W. J. Fuller, M.E.I.C.

Toronto Branch

J. W. Falkner, A.M.E.I.C., Secretary-Treasurer.
J. Hyslop, M.E.I.C., Branch News Editor.

Construction and Maintenance of Equipment on a Modern Electric Railway

On November 25th, Mr. W. R. McRae, superintendent of rolling stock, Toronto Transportation Commission, read a paper on "Construction and Maintenance of Equipment on a Modern Electric Railway."

When the Toronto Transportation Commission took over the Toronto Street Railway system a thorough analysis determined that complete modernization of rolling stock and shops was necessary for economical operation; the results have shown the wisdom of this decision.

All new cars purchased were of the Witt type of steel construction with wood interior trim; the motor cars having front entrance and centre exit and the trailers with centre entrance and exit. All cars retained from the Toronto Railway system were rebuilt; part to front-entrance rear exit types; part to one-man operated with front entrance and front and rear exit, and part for two-car train operation, the front car being fitted with motors on all axles and the rear car with motors on two front axles only. All car heaters are of Peter Smith type coal fired, the ventilation is well cared for, the air being changed every three minutes.

The one-man operated cars have been used on certain routes, proving economical in operation, the cost of conversion being absorbed by eleven months' operating economies.

The commission's repair shops are entirely new, of fire-proof construction, occupying an area of 10.4 acres. They are the result of very careful study, containing the following sections: car body erection, machine shop, wood working shop, blacksmith shop, motor shop, paint shop, and stores. All tools are modern. Car movement inside the shop is handled by an electrically operated transfer table and the handling of car parts by means of an overhead electric monorail system.

One specially interesting piece of equipment is the car straightening equipment, whereby cars distorted in collision are straightened. This work is done in most cases without the necessity of dismantling the parts affected.

Painting is done by the spray method, which proves economical both in time and paint, striping and lettering being done by hand.

All cars are given a general overhaul every 60,000 miles. Its various parts are removed or overhauled, repaired and tested trucks are fitted to body, which has all dents removed, and is then scrubbed, dried and sent to paint room. After being painted the car and equipment is thoroughly tested; the car being in the shop for a period of six days.

Story of Compressed Air

On November 25th, Mr. G. R. Southee, of Canadian Ingersoll Rand Company Limited, addressed the members of the branch on the "Story of Compressed Air."

Mr. Southee's paper was well illustrated by moving pictures. After showing the principle of the air compression, the moving pictures showed its application to various fields, including mining, quarrying, stone cutting, moulding in foundries, riveting, chipping in iron work, wood working, hoisting, water lifts, hat and sausage manufacture. After the paper an animated discussion took place.

Victoria Branch

K. M. Chadwick, M.E.I.C., Secretary-Treasurer.

A business meeting was held on November 3rd, with J. N. Anderson, A.M.E.I.C., branch chairman, presiding.

A vote of sympathy was passed to J. Hunter, M.E.I.C., who was injured in an unfortunate motor accident recently.

Nominations for the 1926-27 executive were made and other branch business attended to.

On the completion of business the chairman called on Major J. C. MacDonald, comptroller of water rights, for his paper on "The Okanagan and Its Problems." An abstract of this paper appears in this issue of the Journal.

The chairman expressed the thanks of the meeting for this interesting paper, and after Major MacDonald had answered a number of questions in regard to markets, orchards and irrigation, the meeting adjourned.

On November 16th Major Geo. Walkem, M.E.I.C., president of the Institute, and also of the British Columbia Association of Professional Engineers, was a guest at a joint luncheon of Victoria members of the two societies, some thirty-three sitting down to lunch.

The branch chairman, J. N. Anderson, A.M.E.I.C., in calling on Major Walkem to speak, remarked that the West was rarely honoured with the selection of the president of the Institute, and that besides his dual presidential office Major Walkem was also member in the provincial legislature for Richmond-Point Grey.

The president gave a rapid sketch of the progress of many of the branches he had visited from the east to the west of the Dominion, outlining the industrial, or educational, or governmental conditions at each centre that made the continuance of a branch possible at that place.

While the address, unfortunately, does not lend itself to detailed report, it was of great interest to members of the Institute, and afforded a large amount of information on industrial progress in many parts of the Dominion, particularly in the east.

The thanks of those present for the favour of a visit were suitably expressed by the chairman.

Listening to such an interesting recital of the difficulties, successes and progress of other branches, gave a realization of the unity of the Institute throughout Canada, encouragement for the future, and suggested that this contribution of Branch News was an opportune one in which to say:—

Best wishes to all for an enjoyable and prosperous New Year from Members of the Victoria Branch.

Annual Meeting

The annual meeting of the branch was held on December 1st, and after the election of the officers for the coming year, F. C. Green, M.E.I.C., gave a lecture on "Some Experiences of a Surveyor."

Under British Columbia law the same piece of land might be subject to the following leases and rights, (1) timber lease, (2) apex mineral rights under the 1891 Act, (3) ordinary mineral rights, (4) placer rights, (5) coal lease, and (6) a pre-emption. All these might conceivably occupy the same area, all with well defined rights and all yielding revenue to the government.

The speaker proceeded to describe incidents from his own experience. The most striking was a case where during railway construction a fire did extensive damage to logging operations and standing timber in the Fernie district. A suit for damages was tried at Nelson and as a hopeless conflict of evidence developed, the trial was adjourned to the ground, and the judge, jury, sheriff, witnesses and council travelled two hundred miles to Fernie, where the trial was carried on amid the old stumps of timber. The judgment as finally given probably differed widely from what it would have been had it been based solely on the evidence given at Nelson. This precedent if followed might aid justice in other engineering disputes.

Travel on the Cariboo road, in stage coach days, and the hundred-mile snowshoe trip over the trail to Fort George, a distance now covered by a good motor road, were next described. It then took five or six days to travel what can now be done in the same number of hours by motor. The speaker closed with some anecdotes of the trail and a reference to an axe-made cantilever bridge for streams where the timber is too small to span.

Winnipeg Branch

James Quail, A.M.E.I.C., Secretary-Treasurer.

Meeting of October 21st

The meeting of the branch, held on October 21st, took place in the plant of the Canada Malting Company, Winnipeg. It convened in the laboratory with thirty members and visitors present. The chairman, N. M. Hall, M.E.I.C., occupied the chair. He introduced Mr. Geo. Bailey, manager, who addressed the meeting, describing the processes of malting, and the various uses of malt, with details of the market for it,—as a preliminary to conducting those present through the plant.

The meeting was divided into two parties, one of which was conducted through the plant by Mr. Bailey, and the other by Mr. K. E. Grant. The vote of thanks was moved by E. P. Fetherstonhaugh, M.E.I.C., who expressed regret that the weather and a conflict with other meetings should have conspired to make the attendance at an unordinary and most enjoyable meeting smaller than it would otherwise have been.

Meeting of November 4th

The meeting of the branch of November 4th was held regularly. N. M. Hall, M.E.I.C., chairman, occupied the chair. There were some eighty members and visitors present.

Under "new business" the chairman reported the proposed meeting of the Empire Mining and Metallurgical Congress, which would convene in Canada in August, 1927. Preliminary steps in the arrangements for the congress, insofar as Winnipeg Branch would co-operate in them, were left in the hands of the executive.

The attention of the meeting was drawn to the provincial Public Utility Board Act. In this connection the secretary was instructed to communicate with the provincial government to the effect that, in the opinion of the branch, a member of it as a member of the board, would be advantageous in the administration of the act.

Dr. J. W. Shipley and C. F. Goodeve were the speakers of the evening. The subject was "The Formation of Explosive Gases in Electrically Operated Steam and Hot Water Boilers." In introduction Dr. Shipley said that the subject would be presented in the form of a paper that would cover the consideration of the effect of the gases formed, the nature of electrode materials, and the variation in current densities; and that suggestions would be made as to the direction which investigation should take to find solutions for the problems involved. A demonstration with the apparatus used in the research would be attempted.

Dr. Shipley gave Mr. Goodeve credit for the development of experiments into important research.

Mr. Goodeve outlined the history of the investigation of the subject. He followed that by presenting in detail theoretical and practical analyses of the reactions taking place.

E. V. Caton, M.E.I.C., moved the vote of thanks.

Kamloops Area Mapped

An area of about 400 square miles in the interior plateau of British Columbia, in the vicinity of Kamloops, is shown upon a new map sheet just issued by the Topographical Survey, Department of the Interior. The sheet is known as the Kamloops sheet of the National Topographic series. It is issued on the scale of one mile to the inch, and was compiled from surveys by the above named organization during the past two years, together with information supplied by the Surveys Branch, Department of Lands, British Columbia, and by the Geological Survey of Canada.

Railway and Hotel Arrangements for Annual Meeting

In connection with the forthcoming Annual Meeting to be held in Quebec on February 15th, 16th and 17th, please note that round trip tickets will be issued to groups or parties by both the Canadian National and the Canadian Pacific Railways on the following basis:—

Number of party—not less than *ten* adults.

Going	—must all travel together on the same train and from the same station.
Returning	—may travel individually if desired.
Rate	—Fare and one-half for the round trip from the Branch headquarters City to Quebec and return.
Time limit	—Points East of Fort William—ten days—(From Western Canada a longer limit is given).

If you propose attending the meeting in Quebec, please communicate *at once* with your Branch Secretary so that a party may be organized, and that as soon as he has received the necessary number of names he may arrange for the group rate with the local Passenger Agent of the railway selected.

If a sufficient number offer, a through car can be arranged for from the concentration point to Quebec.

Members are reminded that they must make their own hotel reservations at Quebec, and, owing to the popularity of that city as a winter sports centre, early action is needed to avoid disappointment.

The following special rates have been arranged at the Chateau Frontenac:—

Single room without bath	$3.00
Single room with bath	4.00
Double room with bath	7.00

Engineering Institute of Canada Headquarters and Registration Bureau will be at the Chateau Frontenac.

Preliminary Notice

of Applications for Admission and for Transfer

December 18th, 1926

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in January, 1927.

R. J. Durley, Secretary.

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council shall be required to pass an examination before a board of examiners appointed by the council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ANNETT—FRED. A., of Flushing, N.Y., Born at Lakeville, N.B., Aug. 26th, 1879; Educ., mech. elect'l engrg course, Am. School of Correspondence; grad. from N. Y. Volume X — Montreal, February, 1927 — Number 2

The Mineral Deposits of the Rouyn-Harricana Region in Western Quebec

The Physiography and Geology of Western Quebec, the Occurrence of Mineral Deposits and Present Extent of Development

Theo C. Denis.

Director, Quebec Bureau of Mines, Quebec, Que.

Paper to be presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Quebec, Que., February 15th to 17th, 1927

Quebec, the largest province of Canada, comprises an area of 706,834 square miles, or 452,000,000 acres, to use the figures given by the federal government authorities. Of this large area, the physiographic feature which stands out most prominently is the Laurentian plateau, which occupies in Quebec 95 per cent of the entire superficies of the province. In fact, if you join the cities of Quebec and Ottawa by a straight line, then follow up the Ottawa river to Mattawa on the west and down the north shore of the St. Lawrence to the east of Quebec city, the whole of the area of 670,000 square miles to the north is occupied by the Laurentian plateau, leaving only 36,000 square miles for the two other physiographic regions of the province, viz., the flat plain of the St. Lawrence lowlands, in the St. Lawrence valley, and the sharply-folded and mountainous Appalachian region, which latter extends from lake Champlain to the eastern end of Gaspé peninsula.

The 670,000 square miles of the Laurentian plateau in the province of Quebec are occupied by the oldest rocks known, classified collectively under the name of pre-Cambrian rocks. That they are the oldest, few will doubt who read the last presidential address of the Royal Society of Canada, in which Dr. Parks, of the University of Toronto, assigns to the youngest of the pre-Cambrian rocks the venerable age of 550,000,000 years. To the oldest he gives a tentative age of one and one-half billion years. Such are the ages of the rocks which constitute the banks of the Saguenay river, and of those over which fall the waters of the Montmorency river at its mouth, and of the Laurentian hills which constitute the background of the landscape to the northeast of the city of Quebec.

The great majority of these pre-Cambrian rocks consist of light coloured, usually reddish, rocks coarsely crystalline in texture, of the granite family. They often present a banded or striped structure, called gneissic structure. These granites, massive as well as gneissic, to which the term Laurentian was formerly applied are, as a rule, barren of metallic minerals. On the sketch map figure No. 1 they are designated by "A." But associated with them are patches, (*1*) of fine-grained dark green to black rocks of the Keewatin formation, the oldest known, consisting of volcanic rocks mostly thick lava flows, sheets of basalts, andesites, porphyries, usually deeply altered and metamorphosed; (*2*) of sedimentary rocks, conglomerates, sandstones, limestone altered into quartzites, slates, crystalline limestone and other metamorphosed rocks designated as Grenville and Temiscamingue formations; (*3*) of dark coloured coarse-grained igneous rocks, diabases, diorites, gabbros, norites; (*4*) sedimentary rocks, conglomerates, quartzites, slates of the Cobalt series.

These patches of dark grey to dark green igneous rocks, fine- or coarse-grained, and of sedimentaries, are of all sizes from a few square feet to thousands of square miles. They are indicated by A1, A2, A3 on the map figure No. 1. Contrary to the lighter coloured granites and gneisses, they usually carry metallic constituents which are liable to be segregated, collected together, in sufficient concentrations to give rise to workable metalliferous deposits. These may be looked upon as mineralized islands, dotting, so to speak, a sea of lighter colored granites and gneisses, which for the most part are unmineralized, or in which the metalliferous elements are too scattered or disseminated to be worked economically. It is in these mineralized islands, or patches, of dark rocks, that we find the silver deposits of Cobalt; the gold deposits of Porcupine and of Kirkland lake; the nickel deposits of Sudbury; the copper and zinc deposits of Flin-Flon; the copper of Bruce mines; the lead and zinc ores of Portneuf county and of the Chelmsford region; the old

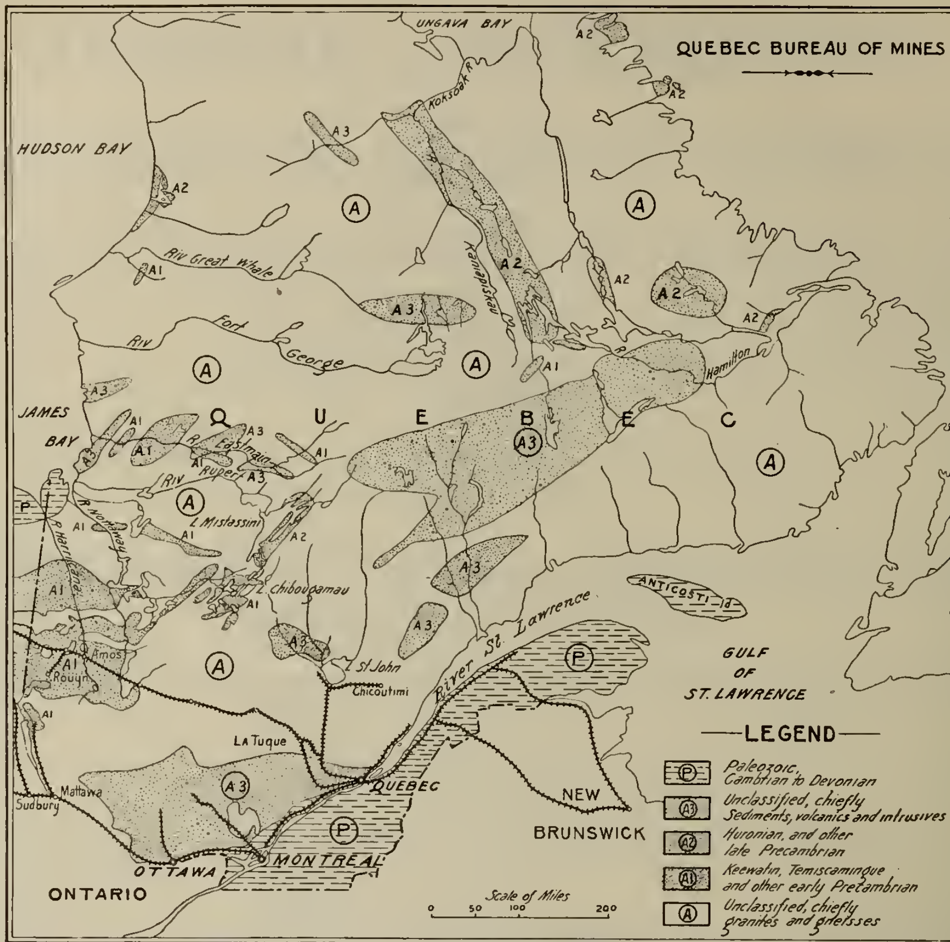

Figure No. 1—Geological Sketch Map of the Province of Quebec, Showing Relative Distribution of Pre-Cambrian Rocks (*A*, *A1*, *A2*, *A3*) and of Paleozoic Rocks (*P*).

silver deposits of the lake Superior district; the large iron deposits of Michigan, Minnesota and Wisconsin; the copper-gold-zinc deposits and the gold ores of the Rouyn-Harricana district of western Quebec.

The chronological geological table of the pre-Cambrian while still a controversial matter among geologists, might probably be constituted somewhat like the following, in descending order, the Keewatin being the oldest and the Keweenawan basic intrusions the youngest.

Keweenawan basic eruptives.
Iron series of lake Superior.
Sudbury nickel eruptives.
Basic dykes and sills (diabase).
Cobalt sediments.
Algoman granites, diorites, syenites, porphyries.
Gabbros and basic dykes.
Temiscamingue sediments.
Laurentian granites and gneisses intrusives.
Grenville crystalline limestone, quartzites and slates.
Keewatin volcanic flows and sheets, and a few sediments.

The above table of geological sequence is more or less conventionalized, for geologists have not yet reached perfect agreement as regards the nomenclature of the pre-Cambrian. The pre-Cambrian epoch was eminently characterized by great igneous and eruptive activities, disturbances and invasions. Periods of sedimentation were followed by periods of intrusion, invasions and flows of molten, pasty, rock magmas, which, on cooling, formed massifs, dykes, flows, sheets of igneous rocks, such as basalts, andesites, rhyolites, granites, gabbros, porphyries, according to their composition, the way in which they invaded and penetrated the pre-existing rocks and the rate of cooling.

Modes of Occurrence of Mineral Deposits

These high temperature igneous magmas, or molten rock-matrix, coming from sources below the earth's crust, are all metal-bearing, to a more or less degree, according to their composition. They are the mineralizing agents which form the mineral deposits. With the metals these magmas also carry large quantities of sulphur. Mineral deposits, therefore, formed under high temperature or medium temperature conditions, are generally sulphides, such as iron pyrites, (FeS_2); chalcopyrite, ($CuFeS_2$); galena, (PbS); zinc blende, (ZnS); molybdenite, (MoS_2); argentite, (Ag_2S). Gold, however, does not combine with sulphur and is found native even when it is mixed with the sulphides, as it often happens.

The metalliferous sulphides only constitute a very small proportion of the igneous molten mass, and if the latter cooled quickly in a solid mass the metallic minerals would be too thinly disseminated to constitute workable ore bodies. To give rise to such deposits there must be present certain conditions which cause a concentration of the sulphides, and dispose them into masses large enough and rich enough to be economically mined. In a crude way, it may be said that there are two main processes of concentration of the metallic contents of igneous magmas into ore bodies, viz.: (*1*) filling of fissures and spaces in the rocks of the earth's crust; (*2*) replacements, by chemical action, of parts of the invaded rock-beds by the metallic elements of the eruptive magma.

Igneous magmas, when deep down below the surface, miles down, are under tremendous pressure and high temperature. When such masses find their way upwards, towards the surface of the earth's crust, conditions of pressure and temperature change, the equilibrium of the magma is disturbed. Under such circumstances, certain phenomena of breaking up of the molten mass take place. Emanations, fluid and gaseous, are produced which find their way upwards through any small fissure, crack, opening and zone of weakness. These magmatic emanations carry gold, silver, sulphides of metals and gangue materials of various nature, silica, carbonates, alcaline salts. When these solutions reach wider open fissures, under conditions of lower temperature and greatly diminished pressure, they abandon, by precipitation and evaporation, their less soluble elements, effecting thereby a sort of natural concentration of their constituents, and forming, by filling of the open fissures, the mineral deposits designated as "fissure veins."

In the replacement process of mineral deposits formation, the action takes place in depth, under conditions of high pressure and high temperature. In many cases, as may be imagined, the molten magmas issuing from deep-seated reservoirs and invading the rocks which form the solid crust of the earth do not always find their way to the upper levels, to break up into solutions and other emanations which fill up pre-existing fissures and cracks. They may remain at great depths where they would retain their temperature and pressure for a long time. They cool very slowly, and the contact zone presents extensive alterations, the magma having attacked, eaten into, digested, absorbed the invaded rocks, more especially when an acid magma, rich in silicic acid, is injected through basic rocks, that is, carbonates and silicates of iron, calcium, aluminium, setting up chemical reaction between them. In such zones, metallic deposits are formed, the rock having been slowly transferred and replaced by the precipitation of sulphides and gangue contained in the magma. The most common sulphides thus precipitated and concentrated by replacement processes are pyrrhotite, pyrite, chalcopyrite, zinc-blende, galena, which carry down with them the gold and the silver when the mineralizing magma contains them. The shape of such deposits is not as regular and continuous as those formed by the filling of fissures, the width, length and depth of the latter being much more even and persistent than the bunchy, pockety, lenticular replacement deposits. Replacement deposits have given rise to some of the largest mines in the world.

These two modes of formation of mineral deposits are, in nature, seldom clean cut and definite. In most cases both processes have had some part in the genesis of the ore-deposit. Given a metal bearing molten mass, injected into the rocks forming the crust of the earth, the replacement mode predominates in the formation of metallic deposits in the immediate neighbourhood of the magma, while fissure-filling becomes more and more prevalent and definite as we recede from it. The two processes merge and grade into one another, depending on the composition and the physical condition of the invaded rocks.

General Geology

In the western Quebec new mineral field, which spreads out from the interprovincial boundary to the Bell river and from 10 to 15 miles north of the Transcontinental Railway to 40 or 50 miles south of it, the rocks consist of Keewatin lava flows, both basic and acid; tuff beds of volcanic ash and dust; Temiskaming sedimentary beds; all of these having been intruded, penetrated, and cut by masses, necks and dykes of igneous rocks, granite, diabase, gabbro, diorite-porphyry, syenite porphyry, lamprophyre.

Keewatin

In the rocks of the Keewatin period, the lava flows predominate. They consist mainly of basic dark-green to black fine-grained rocks such as basalts and andesites, interbedded with, and grading into, more acid flows of trachyte, rhyolite and dacite, with occasional intercalations of tuff beds, all of which are dark grey to creamy in colour.

According to Dr. H. C. Cooke, from whose reports on the geology of the region the data for the following notes have been taken and condensed, the Keewatin period was one of active vulcanism during which thick flows of lava, following each other with considerable rapidity, poured out and piled up in layers on top of one another, to such an extent that at Dasserat lake a total thickness of four miles of lava beds has been observed, without any sign of the bottom nor the top beds. These extrusions were submarine, as indicated by "pillow" structure in the lavas.

With the end of the extrusion period began a regional uplift movement of the earth's crust, which raised the consolidated lava flows above the sea level and folded them. Once thus raised and folded the surface was subjected to

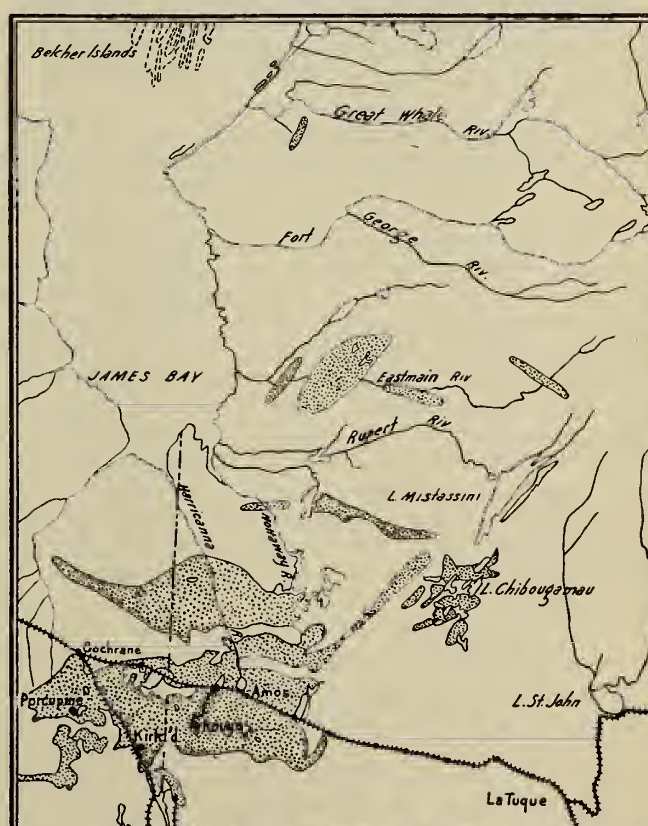

Figure No. 2—Sketch Map of Keewatin Volcanics and Schist Complex in Western Quebec, Showing Geological Relation with Porcupine and Kirkland Lake Districts.

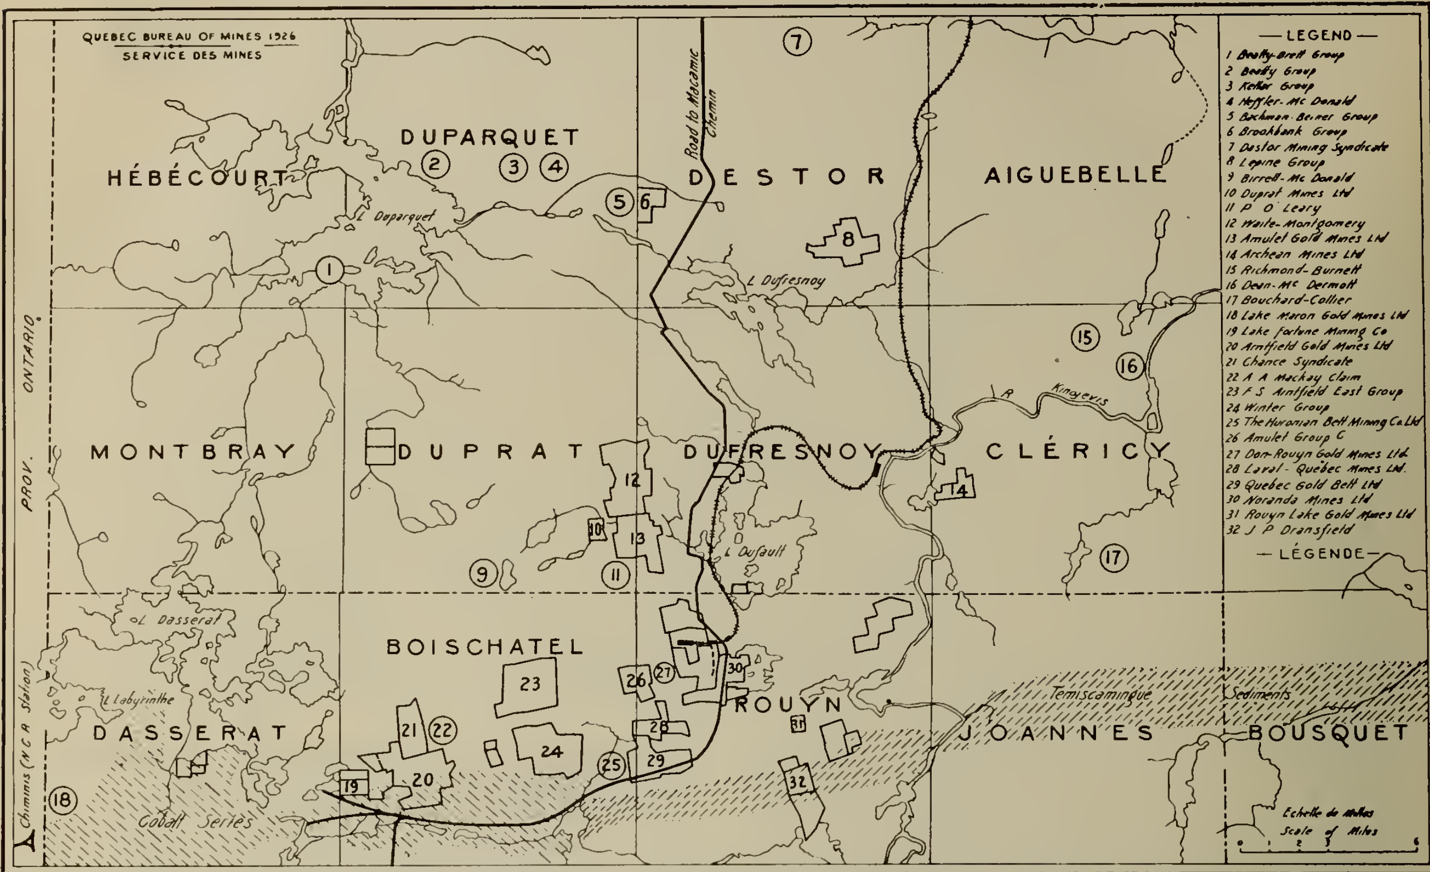

Figure No. 3—Western Quebec—Sketch Map of Western Part of Mineral District Showing Railroad from Taschereau to Rouyn, and Waggon Road from Macamic to Angliers.

violent erosion, which was all the more rapid for the entire lack of vegetation. "The land," says Dr. Cooke, "at that time must have been a scene of unimaginable desolation; black lava everywhere, carved no doubt by the weather into cliffs, spires, and an infinite variety of weird shapes; with the gloomy tints of basalts relieved here and there, it is true, by the lighter colours of rhyolite or dacite, but without a trace of the soft green of vegetation; with the surface everywhere piled high with blocks, boulders and masses of rock, from between which almost every particle of soil had been swept by running water. From the mountains rushed torrential streams, black with lava mud, and rolling quantities of gravel and boulders along their beds to the plains below."*

Temiskaming Sedimentation and Subsequent Earth Movements

It was during that period of violent erosion that the deposition of the Temiskaming sedimentary beds took place. After the formation of this series came intense horizontal thrusts which sharply folded the Keewatin lava flows and the overlying Temiskaming sedimentary beds, turning them on edge, from the original horizontal position. This was followed by the intrusion and invasion of various igneous rocks, gabbros, granites, syenites, porphyries and lamprophyres. The intrusions of granite were specially vast and widespread. Enormous volumes of molten magma slowly ate their way upwards through the overlying Keewatin and Temiskaming rocks. In fact in the region south of the remaining band of Temiskaming sediments the granite magma ate up and digested the whole of the lava flows, and of the 7,000 feet of Temiskaming beds resting on the lavas. This period must have been a very active one of metallization of the pre-existing rocks.

The period of intense folding which preceded the magmatic invasions, had converted that part of northern Canada into a mountainous country, with peaks and ranges equal to the Alpine and the Himalayan regions, for according to Dr. Cooke the subsequent erosion, which wore down and reduced the level of the country to a plateau near sea-level, must have removed a thickness of rocks which he estimates at 14,000 feet as minimum and 30,000 feet as maximum. This new plain-like surface therefore, uncovered and exposed outcrops of remnants of Keewatin, of Temiskaming formation and massifs of intrusive rocks which formerly were covered by several thousand feet of overlying rocks.

Mineralization and Ore Bodies

Apparently the period of mineralization of the Keewatin lava beds and of the Temiskaming sediments followed immediately the violent thrusts and earth movements which folded sharply and turned on edge these formations. The axes of the folds in the region were east and west, for the edges of the lava flows and of the Temiskaming beds which formed the surface after the intense planing off of the ridges, domes and mountains by erosion, are oriented east and west.

The ore-bodies in the new mineral district of western Quebec are partly true fissure veins, partly true replacement lenses and partly deposits which owe their origin to a combination of the two processes. The beds of the tougher, hard lavas such as the grey lavas, rhyolite and

* H. C. Cooke.—Geological Survey of Canada, Summary Report 1922, p. 59D.

trachyte, as well as the grauwacke beds which constitute the majority of the Temiskaming sedimentaries, were fissured without much shearing or shattering. Their composition is not such that they would be attacked and replaced by an acid magma, so that the deposits which formed in them are more of the true fissure vein type. Such are most of the deposits in Dubuisson township, in Bourlamaque, in Barraute, in Fournière, in Cadillac, as well as some of the deposits in Rouyn and Boischatel, the ore, or vein filling, consisting of quartz gangue, mineralized with free-gold, pyrite, pyrrhotite, chalcopyrite, sometimes tellurides, occasionally arsenopyrite, and often accompanied by carbonates, tourmaline needles in the quartz, and hornblende. Good examples of such deposits are the Stabell, the Unison, the Siscoe in Dubuisson township; the claims of the Fournière Gold Mines, Ltd., and of the Malartic Mining Company in Fournière township; the O'Brien mine and the Thompson claims in Cadillac township; the Powell vein and the Chadbourne claim in Rouyn township; the Lake Fortune mine in Boischatel and many others.

Among the outstanding examples of ore bodies formed by replacement of the rock, may be cited the Horne mine in Rouyn township; the Waite-Montgomery claims and the Amulet property in Dufresnoy and Duprat townships; the Alderson-Mackay claims in Boischatel township, which all show lenses of solid sulphides, consisting of pyrrhotite, pyrite, chalcopyrite and zinc blende, many of them gold-bearing. These lenses, or series of lenses, affect all shapes and sizes, the ones of the Horne mine (Noranda Mines, Ltd.) have so far been developed sufficiently to show ore-bodies containing one million tons of ore of an average content of $5.50 in gold and $19 in copper. Some parts of these lenses, as exposed in underground workings of the mine are of solid chalcopyrite, which contain copper to the value of $90 per ton, apart from the gold which would probably add $2 to $5 a ton. The Horne is here cited because it is the pioneer successful property in Rouyn and its development is the most advanced in the region. It has two shafts, one of which is down 330 feet, and the underground drifts and cross-cuts total a length of nearly two miles. But the other ore bodies of this type have a very promising appearance from the comparatively little work done on them.

Other deposits partake of the characteristics of both replacement and fissure vein type, such as the Arntfield claims; the Francœur claim in Boischatel; the McMillan claim in Rouyn.

The prospectors were attracted to the district in 1922 by the possibilities offered by the quartz veins of the fissure type, along the extension into Quebec of the mineralized zone in which are situated the gold-quartz veins of Metachewan, Kirkland Lake and Larder Lake in Ontario, and for nearly two years the sulphide bodies were neglected. It was in the fall of 1923 that work was started in earnest on the Horne claim, with such results that the gold-quartz ore bodies have lost much of their importance in the eyes of prospectors, and that the lenses of solid sulphides of copper and zinc, accompanied by gold, are now sought for as being of greater promise of economic importance. It is quite probable that eventually the gold-quartz deposits will regain some of the ground that they lost in the esteem of the interested public, but at present the solid sulphide bodies of the Horne, of the Waite-Montgomery, of the Amulet, of the Alderson-McKay are greatly in the limelight, and with very good reason.

The claim on which is situated the Horne mine was

Figure No. 4.—Provincial Government Road from Macamic to Rouyn.

staked by an experienced prospector Mr. Edw. Horne as early as 1920. The story goes that Mr. Horne and his partner Ed. Miller were " grubstaked " by a syndicate of northern Ontario men, who comprised ten members, eight of whom put up in the vicinity of $500 each, and Messrs. Horne and Miller put in their experience and their work. In 1922 the claims were optioned to the Noranda Mines, Ltd., for $320,000 in cash, payable in various payments, the last one in 1928, and a tenth interest in any company formed to exploit the deposit. In February, 1926, by an agreement between the parties, $250,000 was paid to the syndicate, who received in addition for their one-tenth interest, 125,000 shares of Noranda Mines, Ltd., now selling in the vicinity of $20, or altogether a value of some $2,750,000. Needless to say, not all prospecting ventures are thus rewarded.

It is now assured beyond a doubt, that the Rouyn district, helped in all probability by other camps which will eventually develop in the mineralized region outlined between the Ontario boundary and the Bell river, will in a near future put Quebec in the ranks of the important producers of metals, copper, zinc and gold. At present the annual mineral production of our province, $24,000,000, is constituted by 95 per cent of non-metallic substances such as asbestos, mica, feldspar and building materials, and 5 per cent of ores of metals. But with the discoveries of the last three years in western Quebec, as well as with the development of the promising lead and zinc deposits of the Gaspé peninsula, the future of our metal mining industry is of the brightest and permits us to presage that before long the metalliferous products will equal in value the non-metallics and that the annual output of our mines and quarries will reach a value of fifty million dollars.

If we look further into the future the mineral possibilities of Quebec are even greater. The Rouyn-Harricana district constitutes only the southern fringe of a vast area

Figure No. 5.—Town of Rouyn in July, 1926.

of 10,000 square miles of Keewatin rocks which extends for fifty miles north and south of the Transcontinental Railway. Other vast patches of rocks known favourably as possible mineral bearers, designated on the geological sketch map as A_1, A_2 and A_3 occupied mainly by the Keewatin, Grenville, Temiscamingue, Huronian, Keweenawan formations have been roughly outlined by our Canadian geologists. These areas of mineral possibilities occupy 75,000 square miles of the Laurentian plateau, and it is not an exaggeration to state that they offer to the hardy prospector a field unequalled anywhere else in the world.

The effects of promising mineral discoveries and of the establishment of a mining camp on the development of a region have been vividly demonstrated in the case of the Rouyn district. In 1923 it was a wilderness, remote from means of communications, bush covered, uninhabited and frequented only by prospectors. Tents, and a few log cabins sparsely scattered over an area of hundreds of square miles, were the only shelters. The first active development work in the region was started on the Horne claim in the fall of 1923, and in 1926, three years later, a 45-mile railway spur was in operation from the Transcontinental Railway to the centre of Rouyn township; a waggon road was opened from Macamic, on the Transcontinental, to Angliers, the terminus of the Canadian Pacific Railway in Temiscamingue, a distance of one hundred miles; a town has sprung up, which now has 450 buildings and a population of 2,500; a neighbouring site has been subdivided according to modern principles of town planning; water-works and sewerage systems are being put in; an electric-power line, sixty miles long, delivers power and light; a smelter to treat 1,000 tons of ore a day is under construction and is expected to be in operation within a year; a telephone service gives speaking connection with all the centres in Ontario and Quebec.

The Rouyn district is just now experiencing a period of boom, and, as in all such cases, along with the promising, healthy mineral discoveries there are, unfortunately, a multitude of parasitic ventures, whose main object is to mine money out of the excited public rather than ore from the ground. This cannot be avoided; it is very difficult to prevent fools from parting with their money. For, history repeats itself, and the ultimate result of the Rouyn boom will be a few good outstanding producing mines and a healthy smelting industry, which will prove a national asset, and a multitude of claims which will never produce ore, but will have been used to exploit the public. As in all victories there will be individual casualties, but the establishment of the mining and smelting industry will, of course, be a source of prosperity to the country.

As a rule the promising mineral discoveries and likely claims, in the Rouyn district, do not have to resort to making appeals to the public for funds to explore and develop them. The Rouyn camp is not "a poor man's camp," like the Klondike, or even the Cobalt camp. It requires very large sums of money and the best technical knowledge available, to do exploration work on these copper-zinc-gold deposits. Fortunately there are several powerful companies interested in the field. These can procure the best technical help obtainable, both geological and operating, and such organizations do not publish full-page advertisements, advising the public to get in on the ground-floor at 10, 15 or 25 cents a share, nor do they send peddlers from door to door, selling beautifully-engraved certificates of mining companies with alluring sounding names. One may be sure that very little of the money obtained by such means is put into honest, effective work on the claims.

In concluding, the author wishes to pay a cordial tribute of appreciation to the work of geological and topographical mapping which has been carried on for the last four years by the Geological Survey of Canada in the new western Quebec mineral region.

The general planning of this work is under the direction of Dr. W. H. Collins, director of the Geological Survey, with Dr. H. C. Cooke as senior geologist. During the field-season of 1926 this federal service had five distinct field-parties, geological and topographical, working in western Quebec, with the object of mapping the whole region in a series of detailed sheets, on a scale of one mile to the inch. Several of these geological sheets, with accompanying reports, have already been issued, and have proved an inestimable help to the public interested in the development of our mineral resources.

This series of maps and reports was preceded, several years before its inception, by excellent general descriptions and maps of the country, by Dr. M. E. Wilson for the Geological Survey of Canada, and Dr. J. A. Bancroft for the Quebec Bureau of Mines.

The Metal Mining Industry of Northern Ontario

An Historical Review of the Development of the Industry

W. R. Rogers, A.M.E.I.C.
Director of Publications and Statistics Branch, Department of Mines, Province of Ontario.

Paper to be presented at the Annual General Professional Meeting of the Engineering Institute of Canada, at Quebec, Que., February 15th to 17th, 1927

Introduction

The mineral industry of the province of Ontario has been marked by steady growth, with some fluctuations owing to the general state of business, and in late years, to war and post-war abnormal conditions. The following table, beginning with production for the year in which the Ontario Department of Mines was established, records the facts on a valuation basis:—

Mineral Production of Ontario by Five-Year Periods

Year	Metals	Non-metals	Total
1891	$ 388,715	$ 4,316,958	$ 4,705,673
1896	963,288	4,271,715	5,235,003
1901	5,016,734	6,814,352	11,831,086
1906	13,353,080	9,035,303	22,388,383
1911	29,102,867	12,873,930	41,976,797
1916	55,002,918	10,300,904	65,303,822
*1921	28,777,581	25,786,728	54,564,209
**1926	61,000,000	26,000,000	87,000,000

As to variety of mineral products, it may be stated that Ontario possesses practically all the economic metals with the exception of tin and most non-metals with the important exception of coal. It is not the purpose of this paper to discuss non-metallic minerals, other than to point out that in recent years these have had a valuation of approximately $25,000,000 per annum, and that it was not until the year 1905 that the output of metals exceeded in value that of non-metals.

Ontario holds first place among the provinces of Canada as regards mineral production, having taken the lead from British Columbia in 1907. In the year 1925, Ontario produced 39 per cent of the total mineral output of Canada, British Columbia 29, Alberta 11 and Quebec 10 per cent. As to individual metals, Ontario leads at the present time in output of gold, nickel, platinum metals and cobalt, while supremacy in silver has been won, for 1926 at least, by British Columbia.

The following data, abstracted from the Canada Year Book for 1925, shows the relative monetary importance of the main sources of primary production for the year 1923 in Canada:—

Agriculture	Forests	Mines	Fish and Game
$1,107,571,858	$313,748,937	$214,079,331	$58,730,104

Compared with agriculture, mining may appear a small industry, but it is a pioneer industry, searching out our unexplored areas, and development in other lines follows in its wake. The search for metals in northern Ontario, following the finding of silver at Cobalt in 1903, has resulted in important mineral discoveries in South Lorrain, Gowganda, Porcupine, Kirkland Lake and many lesser camps.

* Year of post-war depression. ** Estimated.

Railway construction has kept pace with the needs of these new mining communities, and in this connection the Temiskaming and Northern Ontario Railway, belonging to the Ontario government, has played an important part.

Historical Sketch

No discussion of metalliferous mining in Ontario would be complete without a brief historical review touching the early days of the industry.

Iron

Metal mining in Ontario had its beginning on the Gananoque river at Furnace Falls, (now Lyndhurst), in the county of Leeds, where an iron furnace was erected about the year 1800*. An attempt was made, with ore of inferior quality, to make cast hollow ware, such as pots and kettles, for the use of settlers, but the enterprise proved a complete failure. A second venture was made in 1813 to utilize the bog iron ores of Norfolk county, and for this purpose a crude plant was erected at the mouth of Potter's creek, in the township of Charlotteville, where waterpower was available and lake transport convenient. Only a few tons of pig iron were smelted when the furnace lining gave way, and the project was abandoned, to be taken up later, however, by Joseph Van Norman and his associates, who repaired the furnace and re-started smelting in the year 1822. This furnace was operated until 1847, when it was shut down owing to scarcity of ore and fuel. The enterprise latterly was conducted by J. Van Norman and Son, the name Normandale being given to the locality where business was carried on. The furnace was in blast for 8 or 9 months each year, producing 700 to 800 tons of pig iron annually, which required charcoal fuel from 4,000 cords of hardwood. Ore hauled by wagons, came from within a range of 12 miles. Daily ore consumption was about 9 tons, and the yield 3 tons daily on the average of an excellent quality of pig iron. Various castings were made on the spot, such as stoves, sugar and potash kettles, and these were distributed to settlers along the north shore of lake Erie and taken to the interior by teams. Some export business with Buffalo and Chicago was developed when the home market became overstocked.

An unsuccessful attempt to treat magnetic iron ore at Blairton, on Crow lake, in the township of Marmora, was made about 1820. Van Norman was induced to buy the property and furnace in 1847, after closing down at Normandale. The purchase price was $21,000. After a further large expenditure in furnace fittings, blowing apparatus and general repairs he got the furnace started in 1848. But the iron output was small relative to fuel consumption, and transport for 32 miles over rough roads to Belleville was difficult. Another transport route was tried, via the Trent river to Rice lake, and then by road 12 miles to the dock at Cobourg. The product sold at $30 to $35 per ton. Un-

*Some records say 1810.

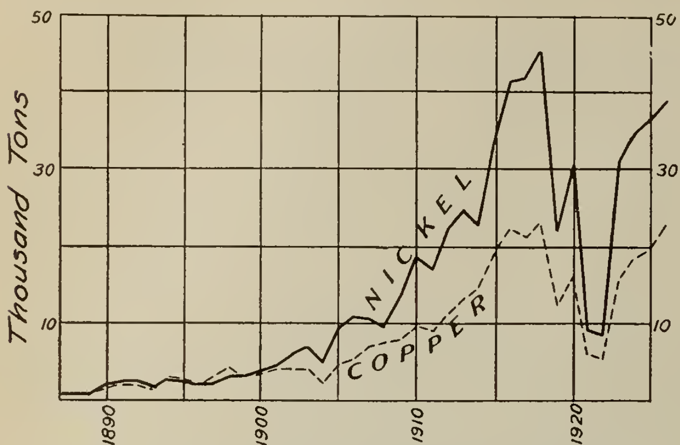

Figure No. 1.—Graph Showing Nickel and Copper Content of Matte Produced from the Inception of Smelting at Copper Cliff in 1887.

fortunately for the enterprise, foreign pig iron was soon available at Cobourg and Belleville at $16 per ton, as a result of the completion of the St. Lawrence canals. The Marmora plant was forced to close down, with a total loss to Van Norman. Subsequent efforts by other companies up to about 1875 resulted in failure, due principally to poor transport and antiquated methods which made costs prohibitive.

In 1837 a charcoal blast furnace for smelting magnetic iron ore was erected at Madoc, in Hastings county, as a result of successful experiments conducted at Wolcott, in New York state, on sample lots of ore from the Seymour mine in Madoc township. Some good cast iron was produced, and also pig iron which sold at $27 per ton in Belleville. Primitive methods and experimental work, complicated by litigation, made costs prohibitive and resulted in abandonment of the enterprise. In fact, Ontario's early iron mining was a series of failures, demonstrating that someone must pay for experience. Commenting on the failure of the Steel Company of Canada in 1885, the editor of the Charcoal Iron Workers' Journal said: " It is seldom that pioneers in iron manufacture in any region are successful, and almost every iron-producing district in the United States has a graveyard of buried hopes and expectations." Such was the beginning of the iron industry in Ontario. Space will not permit reference to later successful blast furnace operation and steel production at Sault Ste. Marie and Hamilton.

Copper

Turning to the early days of copper mining, it appears that although the presence of copper on both sides of lake Superior was mentioned in narratives of Jesuit missionaries over a century prior to the abandonment of the first mining operations near Mica bay in 1773, no further attempt was made to find copper ore in Ontario until 1845. This effort was stimulated by the rich copper deposits of the Keweenaw peninsula in northern Michigan being developed, immediately following the extinguishing of Indian title in 1843.

In 1847 the Montreal Mining Company acquired the Bruce Mines location, on the north shore of lake Huron, and vigorously prosecuted mine development until 1850. Concentrating and smelting equipment was unsatisfactory, also the grade of ore proved to be lower than expected owing to the miners excavating more wall rock than necessary. After E. B. Borron was appointed manager in 1852, results were more satisfactory and profits were made in 1853-54, followed by losses in the two following years under old methods re-employed to speed production. Concentrates running about 15 per cent copper were shipped to England, and production continued on a limited scale until 1865, when the property passed to the West Canada Mining Company, after 20 years of unsuccessful effort at Bruce Mines, due principally to the deterioration of the veins at depth.

Silver

Silver Islet,—a tiny speck in lake Superior near Thunder cape,—belonged to the Montreal Mining Company in 1868 when the now famous discovery of silver was made. Some rich specimens were taken out that year and the vein prospected in 1869, but in 1870 the property was sold along with all their other mining locations to the Ontario Mineral Lands Company. Between 1870 and 1884 the Silver Islet deposit was worked to a depth of 1,230 feet and silver extracted to the value of $3,250,000. Again, silver was discovered in 1882 at Rabbit and Silver mountains, some 50 miles west of Fort William. Production continued until 1903, the gross output from the Port Arthur area, including Silver Islet, being 4¾ million dollars. Silver Islet was again worked in 1920 and 1922, some 16,879 ounces of silver being removed, chiefly from the roof of the old workings.

Coincident with the cessation of production from the Silver mountain area in 1903, another discovery was made which time has proved to be one of major importance. During the construction of the Temiskaming and Northern Ontario Railway from North Bay to tap timber areas and serve a small farming community at the head of lake Temiskaming, La Rose, a French-Canadian blacksmith who worked for a railway contractor, picked up a heavy piece of mineral with a coppery appearance in a rock cut at Long lake, later renamed Cobalt lake. This was examined in Haileybury by Thos. W. Gibson, director of the Bureau of Mines, in October, and forwarded to Willet G. Miller, late provincial geologist of Ontario, who identified the specimen as niccolite. Miller made a hurried trip, along with Wm. Nicol, professor of mineralogy at Queen's University, Kingston, to the new discovery in the late autumn of 1903, by way of Mattawa and lake Temiskaming. Meantime, some silver veins had been uncovered. Production from this famous silver and cobalt area, (one of the richest in the world), was rapid, and will be discussed in another part of this

Figure No. 2.—Sketch Map showing Wide Distribution of Gold in Pre-Cambrian Rocks.

Some twenty-seven distinct areas are shown where gold has been discovered, indicating wide distribution in pre-Cambrian formations.

paper. Silver mining at Cobalt was well established when finds were reported in 1906 from Maple mountain, Silver lake and Elk lake, to the northwest of Cobalt. Late in 1907, silver finds were reported from Gowganda lake, and also from Miller and Leroy lakes. The Miller lake section has since proved to be the backbone of the Gowganda silver area. Meantime, from South Lorrain, some 18 miles south of Cobalt, silver was found in identical geological conditions to those obtaining at Cobalt. Actual production from South Lorrain and Casey township began in 1908, while Gowganda developed more slowly,—not making shipments of moment until 1910. Both the South Lorrain and Gowganda camps have had checkered careers, the former taking on a new lease of life in 1921 and the latter in 1924.

Nickel

During construction of the Canadian Pacific Railway in 1883, in a railway cut near Sudbury, a find was made of mineral at first thought to be copper but later ascertained to contain nickel as well. This discovery, which became known as the Murray mine, proved a momentous one in the mineral history of the province, paving the way for other important discoveries in what is known as the Sudbury nickel basin, covering an area 20 by 50 miles. In 1886 the Canadian Copper Company was organized and the mining of copper ore actually commenced, but it was not until 1887 that the nickel content of the ore was recognized. At that time world consumption of nickel was about 1,000 tons per annum, supplied largely from New Caledonia ores refined in France. No process was then known for refining the Sudbury copper-nickel ores, but soon the Orford and Mond processes of separation and refining were in operation. Uphill work marked the early years of the nickel industry, both as regards metallurgical treatment and finding a market for the product.

Ontario's chief competitor in nickel production has been New Caledonia, an island 40 by 250 miles in size, belonging to France, and lying about 1,000 miles northeast of Sydney, Australia. Before the discovery of Sudbury ores, New Caledonia controlled the world's nickel market, and the same was true in respect of the metal cobalt prior to the finding of cobalt-silver deposits at Cobalt in 1903. Nickel was found to occur in economic quantities in New Caledonia in the year 1874, and shipments of ore were first made in 1875. Production from New Caledonia and Ontario was about equal between 1890 and 1904. Since then Ontario's output has grown steadily in importance, and for the past decade has represented from 80 to 90 per cent of the world's production. Since 1920, New Caledonia's production has been about 4,000 tons per annum.

Nickel steel used for armour-plate and ordnance absorbed about 50 per cent of the output prior to the Great War, and the year 1918 marked the peak of production when 45,886 tons of nickel were contained in ore smelted. Following the war, new peace-time uses for the metal had to be found and new markets developed. World production slumped to less than 10,000 tons in 1921, as a direct result of the Disarmament Conference, but has since risen

Figure No. 3.—Map Showing Pre-Cambrian Areas.

steadily to 40,000 tons in 1925. Now nickel steel for automobile manufacture and purposes other than war uses makes up 50 per cent of the total consumption. This wonderful come-back in four years is a tribute to splendid effort, engineering ability and scientific research applied to a problem that meant life or death for the nickel producers.

Gold

In 1866 gold was discovered in Madoc township, in Hastings county, on the farm of J. Richardson. This property and others along a narrow belt about 70 miles long have been worked spasmodically since that date, but with indifferent success. The ores are largely of the arsenical-gold type. Next, a find was made by Peter McKellar in 1871 in the township of Moss, some 75 miles west of Fort William. This became known as the Huronian mine, where a 10-stamp mill was erected in 1883 at great expense. Some milling of a good grade of ore was done in 1884, but a shut-down was forced in 1885 owing to difficulties of transportation. It is of interest to note that this property, lying idle all these years, was again being developed in 1926. This is a case where modern milling methods may make a success of a mine which failed in its early days of development.

Gold was discovered in the Lake of the Woods region in 1878 or earlier. Some mining was done near the north end of the lake during the next five years, but owing to the dispute between the federal and provincial governments over the ownership of this territory, it was impossible to secure title to property or money to finance development. This region attracted considerable attention in the late nineties, and the boom reached its peak in 1897, coinciding with the discovery of the Klondike placer deposits.

Ontario produced gold to the value of $424,568 in 1899, after which the output slumped off to $32,445 in 1909, the lowest ebb in the history of gold mining, in the same year in which Porcupine was discovered. It should be said in passing that some of these old gold properties should have a chance to make good since cyanide treatment, making better recovery possible, has been introduced in recent years. Prejudice, however, in view of past failures, is a difficult thing to overcome. For this very reason, many said we would never have important gold production from Ontario, and consequently the rich silver finds at Cobalt in 1903 distracted attention temporarily from gold.

The auriferous schist of the Hollinger mine had been tramped over for years by Hudson Bay officers and Indians in portaging across the route connecting the Mattagami and Frederickhouse rivers. In 1908 a gold find had been made on Porcupine lake, and this was followed in 1909 with the discovery by J. S. Wilson of the quartz dome from which the Dome mine took its name. In the same year, Benny Hollinger, Jack Miller and Alex. Gilles staked the property already referred to which later became known to the world as the Hollinger mine. To the end of 1925, the Hollinger produced over 99 million dollars and paid dividends in excess of 30½ million dollars. Sandy McIntyre staked the mine which bears his name.

Ore deposits in the Hollinger-McIntyre section occur in basic volcanic schists and at the Dome in a metamorphosed greywacke-conglomerate. In both cases ore is found near the contact of a schisted quartz porphyry of younger age which has intruded the older rocks. According to A. G. Burrows, provincial geologist of Ontario, who has made an intimate study of Ontario gold deposits, the intrusions have in some way influenced the deposition of gold, but probably have not been the source of gold-bearing solutions. Quartz veins serve as avenues of gold mineralization for both themselves and the schists, and are regarded as genetically connected with Algoman (young) granites and associated rocks of the region.

The most intense mineralization is usually along fracture planes in the quartz. The deposits are found in pronounced shear zones. One stock of quartz-porphyry, known as the Pearl Lake mass, is 5,000 feet long and 1,400 feet wide and it is around this that most of the veins are found in the lode system of the Hollinger-McIntyre area. Stopes have been carried half a mile along certain connecting veins at the Hollinger. At the Dome mine the ore deposits are more lens-like in shape, 15 to 150 feet wide, up to 600 feet in length and 800 feet in depth. In fact, the ore may be likened to plums in a pudding. The great irregularity of these ore shoots has made mining a difficult problem for both the mine geologist and mine manager. Faulting in ore bodies is not so marked as might be expected in such ancient rocks, movements usually taking place over a few feet only.

Gold at Kirkland Lake was discovered in 1912. Next to Porcupine, this is the most important gold area so far discovered in Ontario. Here the main fracture is distinctly marked and has been productive from the Kirkland Lake mine on the west to the Tough-Oakes Burnside on the east, a distance of 2¼ miles. Lying in between from west to east are the Teck-Hughes, Lake Shore, Wright-Hargreaves and Sylvanite mines, the latter not having reached the point of production as yet. At Kirkland an assemblage of intrusive rocks, (porphyries, syenites and lamprophyres in the

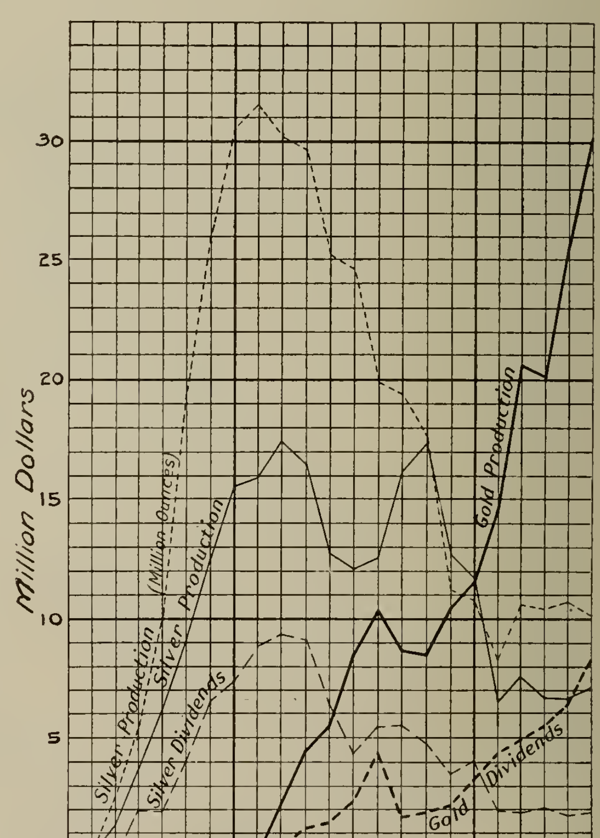

Figure No. 4.—Graph Showing Silver and Gold Production, and Dividends from Ontario's Mines since the Discovery of Silver at Cobalt in 1903.

form of stocks and dykes), have cut the Temiskaming sediments. Much faulting occurs along this ore zone, and through the fractures gold-bearing solutions were deposited. Subsequent faulting also has taken place. The fault walls of the main fracture are from a few feet to 40 feet apart, and ore is found near one or other of the walls or across the whole zone. In places the porphyry or syenite gangue is much brecciated and the ore, apart from the quartz, is reddish in colour as distinct from the Porcupine ores, which are generally of a greyish-black colour. Kirkland ore is rich in tellurides, some of them gold bearing, but the most common is altaite or lead telluride.

To show the average grade of ore at present being mined, production figures for the first nine months of 1926 show values of $14.53 per ton for Kirkland Lake and $7.66 for Porcupine, where larger tonnages are milled. The gross output for the same period was 18 million dollars for Porcupine and over 5 millions for Kirkland Lake.

General Geological Conditions

Canada has one distinct physiographical and geological feature which, coupled with its location in northern latitudes, has had a profound effect on the development of the country. The Laurentian Highland, Archean Protaxis or pre-Cambrian Shield, as it has been variously called, covers an immense U-shaped region surrounding Hudson and James bays and occupying over half of the entire area of the Dominion. It is made up of the most ancient rocks in the world. These have been glaciated for the most part and are covered with only a thin mantle of soil. The south boundary of this famous belt extends south of lake Superior, embracing the northern parts of Minnesota, Wisconsin and Michigan, and then cuts across Ontario from Penetanguishene to Gananoque, where a narrow neck crosses into New York state. Hudson and James bays form the centre of the letter " U," and on the southwest side there is a basin of Paleozoic (sedimentary) rocks similar in age to those underlying southern Ontario. Canada possesses the largest pre-Cambrian areas on the North American continent. Similar rocks occur in volume in Africa, South America, Australia and India, and have been productive of gold, but for the most part in these countries the pre-Cambrian is located in tropical or semi-tropical regions. Reference to the accompanying sketch maps, (figures Nos. 2 and 3), of pre-Cambrian regions will indicate the widespread occurrence of these rocks in Ontario,—in fact, 70 per cent of the province's area is so classified.

Ontario's vast pre-Cambrian area, larger than India, has been a barrier separating east from west, dividing Canada's agricultural communities and necessitating the construction of expensive transcontinental railway systems to cement Canada politically. Many have looked upon this region of comparatively low relief, not exceeding an altitude of 2,000 feet in Ontario, as an immense waste land. It is lake-studded and has an imperfect drainage system. Few have realized until recent years that it contains " vast stores of mineral wealth," as stated by Sir William Logan, the first director of the Geological Survey of Canada. Water powers are numerous for the development of forest and mineral resources.

Before passing on to a discussion of mineral resources, it should be mentioned that the pre-Cambrian contains many small isolated but fertile agricultural areas. In addition, one large region, known as the " clay-belt," in northeastern Ontario and northwestern Quebec, is traversed by the National Transcontinental Railway, and is estimated to occupy 20,000 square miles in Ontario, an area equal to half the agricultural section of southern Ontario. The fertile soil of the " clay-belt " is due to silt deposition in the basin of glacial lake Ojibway during the period when the northward retreating ice sheet blocked drainage in that direction. This " clay-belt " in the same latitude as the international boundary west of Lake of the Woods is proving to be excellent agricultural land as it is gradually cleared and cultivated, and the products are finding a market in adjacent mining centres.

Hydro-Electric Power

In the early stages of new mining developments, wood is the usual fuel supply. Of late years, Diesel oil-burning engines have been much used until such time as development warrants hydro-electric power. Nickel companies in the Sudbury area have power plants with turbine capacity as follows:—International, 21,700, and Mond, 11,800 horse power. Nickel-copper, gold and silver mines of northern Ontario are using about 83,000 horse power, divided as follows:—Nickel-copper 28,850 h.p., gold 46,350 h.p., and silver 7,800 h.p., all of this coming from Ontario power plants except that from the Quinze development of 10,000 horse power,—the first of four units. The total turbine capacity of Ontario plants is 112,720 horse power.

Deep Mine Workings

With the completion of the McIntyre 4,000-foot shaft in March, metal mining in Ontario will have reached its greatest depth to date. The Hollinger sub-shaft has been sunk to 3,151 feet. In the Sudbury area the Frood Extension, (Mond Nickel Co.), has reached a depth of 2,030 feet, and at the Frood the International Nickel Company of Canada expects to sink to 2,300 feet. The Kirkland Lake mine shaft is 2,265 feet deep. In South Africa " rock bursts " and earth tremors have been experienced at depths of 3,000 feet and greater. The " Village Deep " mine in the Transvaal is 6,980 feet deep and the rock temperature at the bottom is 94°F. Fortunately no high temperature problem exists in Ontario, but we are now confronted with problems peculiar to deep mining, and the McIntyre mine has announced a change from " shrinkage " stoping to the " cut and fill " method as standard practice on the new levels. The Hollinger is using sand for back filling stopes below the 2,000-foot level.

Wealth of the Pre-Cambrian

Ontario, it has been pointed out, possesses immense pre-Cambrian regions. What follows will demonstrate that within the pre-Cambrian certain geological sub-divisions are favourable for the occurrence of economic minerals, metals in particular. The world-famous copper mines of the Keweenaw peninsula, which juts north into lake Superior, have been regularly worked for 80 years and in normal years produce 100,000 tons of copper. These noted copper deposits on the south side of lake Superior occur in pre-Cambrian rocks, as do also the iron deposits of northern Michigan, Wisconsin and Minnesota. This " lake " region has produced enormous tonnages of iron ore. Last year some 60,000,000 tons of " lake " ore were shipped, by boat for the most part, chiefly to iron centres of the United States. Large reserves, estimated at 70,000 million tons, still lie untouched. Although high-grade ore is diminishing, the technical problem of beneficiation is meeting with success, and lower-grade ores will be used in larger volume in future than at present. As that day approaches, Ontario's siliceous ores,—magnetites and siderites,—will be utilized. During the past year, not a ton of Ontario iron ore has been mined or charged to Ontario blast furnaces. Ontario's iron deposits are extensive and will prove valuable ultimately.

Sudbury, Cobalt and Porcupine, all situated within the pre-Cambrian, have poured out their wealth of nickel-copper, silver-cobalt and gold. Sudbury has in reserve more than 100 million tons of ore, enough to last seventy-five years at the present rate of production. Although silver output from Cobalt is declining the life of the camp has been long (24 years) as mining camps go, and outlying areas, such as South Lorrain and Gowganda, are coming to the fore. Production from Porcupine, Kirkland Lake and lesser camps has placed Ontario in third position among the gold-producing countries of the world, exceeded only by South Africa and the United States, and the prospects for overtaking the United States before 1930 are good.

The following table presents the value of output in 1925 and also the total to the end of 1925 for the three major metal mining industries of the province:—

ONTARIO METAL PRODUCTION AND DIVIDENDS

Industry	1925	Total to end of 1925		
		Value	Dividends	Per Cent
Nickel-Copper.	$22,361,551	$296,631,764	....	....
Silver-Cobalt...	9,312,100	244,758,432	$ 91,951,725	37.9
Gold..........	30,206,432	184,492,033	48,338,005	26.2
Others........	616,389	97,170,367	....	....
Total......	$62,495,472	$823,052,596	....	....

Incidentally it may be mentioned that Ontario in 1925 passed the Yukon in the gross output of gold. Maximum production in the Yukon was in 1900 when gold to the value of $22,275,000 was produced.

Ontario's mineral production in 1925, the last year for which statistics are complete, was $87,583,306. Of this total, $62,495,472 was credited to metals, $7,488,034 to non-metallic minerals, $12,451,174 to construction materials and $5,148,626 to clay products. Employees numbering 20,409 received $24,836,744 in wages. The nationality of men employed by twenty-seven metal mining companies of Ontario as of February 1st, 1923,—the officers of all these being members of the Ontario Mining Association,—shows that out of 7,317 employees, 39 per cent were Canadians, 25 per cent from the British Isles, 11 per cent Italians, 6 per cent Finnish, 5 per cent Poles, 4 per cent Austrians, 3 per cent Slavs, 2 per cent American, 2 per cent Roumanian and 3 per cent from other countries. Speaking roughly, it may be stated that two-thirds the value of our mineral production is expended in wages, equipment and supplies of all kinds, and eventually filters down to all classes of society. Dividends go to the investor and in turn are expended in the same way or are re-invested in new enterprises.

Northern Ontario undoubtedly has before her a bright future. Metals are widespread and segregations in centres other than those where profitable operation already has taken place will be discovered. Large virgin areas, particularly in Patricia district, still remain to be prospected. Most of the economic areas so far discovered have been mapped by geologists of either the Ontario Department of Mines or the Geological Survey of Canada, but pre-Cambrian geology is so complex that many years must elapse before detailed maps of the whole can be prepared. This leads us to a conclusion of human interest, namely, that our mineral wealth in the pre-Cambrian offers great inducements for red-blooded young men of our generation to turn their faces north rather than south and devote their energies to the development of our yet undiscovered mineral resources. The miner is a pathfinder, paving the way for development of other branches of industry.

Notes on the Forests of Quebec

A Review of Problems of Forest Administration

G. C. Piché, A.M.E.I.C.
Chief of Forest Service, Department of Lands and Forests, Quebec, Que.

Paper to be presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Quebec, Que., February 15th to 17th, 1927

Having had occasion to deal, somewhat at length, with the question of our forest resources at your annual meeting, held in Montreal in 1920, it is not intended in this paper to cover exactly the same ground, but rather to make a summary of our situation and of our methods of administration, and to answer some of the questions raised by an article on "The Need of a Forest Policy" which appeared in the January issue of "The Engineering Journal."

First, the writer wishes to say that he agrees with the statement in that article to the effect that every engineer should keep in close touch with the forest policy of our country. In the past, this was not so evident as it is to-day, but as the industrialization of our forest products is becoming more and more intense, as the difficulties of transportation from our forests increase on account of the distance and of other factors, it is necessary to employ more efficient means and more mechanical devices than heretofore.

The necessity of making rapidly the reconnaissance of our northern territories has compelled us to employ aeroplanes. The wireless telegraph and telephone are now used for the protection of our forests and to improve means of communication with the remote sections of our province.

The enormous hydraulic development which is now taking place in Canada, and especially in this province, through the harnessing of our waterfalls, the power being stabilized by the construction of huge storage dams, has also a direct connection with the protection of the forest cover of these watersheds, as it regulates the flow of the streams.

It is obvious that engineers are deeply interested in a national forest policy. It is also natural that a certain group of young men, finding a new field of activity in the treatment of our forests, in the handling of our lumbering problems and of the methods of utilizing forest products, have begun to specialize in the studies required for this important task. Forest engineers should form part of The Institute, and they desire that those working in other fields of engineering should support them in the work which they have at heart.

Extent of Forest Resources

On account of the gradual opening up of colonization areas, of the building of large and small towns and of villages, and also owing to disastrous fires and lumbering methods, the forest resources of this country, as well as those of other countries of the world, have been greatly diminished to a point such that many people are wondering whether the remainder is really in a safe position to supply us with the amount of timber which is now removed every year from them. Although the timber situation is generally bad, there are a few countries like Canada, Sweden and Russia which are still in a position to produce enough timber to meet their legitimate requirements, and also to export a certain quantity for their neighbours in dire need.

It must not be forgotten that Canada still possesses over 700,000,000 acres of timberlands, (see Appendix Note No. 1), and that the province of Quebec controls for her share about 130,000,000 acres of territory which may produce, in the course of a sylvicultural rotation varying from 80 to 150 years, wood-goods that can be used with profit by the trade or the industry.

Some people forget that the cut-over lands, and even the burnt-over sectors, will yield eventually a new crop of timber if they do not suffer repeated damages from other fires. In fact, we are now cutting pulpwood in some sectors of the lake St. John district where the fire of 1870 had completely destroyed the forest, and the same is true with other sectors of the province. But it must be admitted that, in too many cases, where fires have followed fires the result has been that the bare rock is the only thing left, and in such places one cannot expect a merchantable crop until several centuries have passed. One must not forget also that we have in Old Quebec an area of 225,000,000 acres and as many acres in New Quebec. Therefore, when the statement is made that our merchantable forests cover less than 30 per cent of all the territories in this province, which runs from the 45th parallel north to the 62nd and which extends from the 56th degree of longitude west to the 79th, the writer claims that the estimate is moderate. But, in order to avoid being misquoted or misunderstood, the writer wishes you to realize that the whole of this area of 130,000,000 acres is not fully covered with forests that could be cut immediately, but contains a succession of age classes which assure us of a continuous timber production, *provided this immense domain is duly protected against fires and that it is properly improved by the sylvicultural methods advocated by foresters.*

Ownership of the Forests

Thanks to the foresight of our predecessors, the government of this province still remains proprietor of the bulk of our forest wealth, as not more than 5 per cent is held in fee simple.

The private forests, covering about 7,000,000 acres, are found within our old seigniories and in the territories granted as railway subsidies; in the same group we include the numerous woodlots of farmers and settlers.

The so-called timber limits are forests leased at public auction from time to time by the government, after several notices in the Official Gazette. These timber limits are not sold, but simply leased to the lumbermen for a period of twelve months. The lease contract, which is called license or lumbering permit, can be renewed on the first of May of every year, provided the limit holder has duly observed the law and regulations. Presently, more than 50,000,000 acres in the province of Quebec are thus held under license to cut. These timber limits extend in the St. Lawrence watershed from the boundaries of our villages to the Height of Land. The major part of the Ottawa valley and of the

St. Maurice watersheds and a good proportion of the lake St. John and Saguenay districts are under license to cut. On the south shore of the St. Lawrence, only 30 per cent of the land is in timber limits, the rest being occupied by farmers and private forests.

The great reserves of the Crown, that is, the vacant forest lands, are situated partly in the upper lake St. John district, partly in the Saguenay country, between Bersimis and Blanc-Sablon, and the balance is found in the basins of James bay and of the Hamilton river. Thus, the leased forests comprise the bulk of the accessible forest lands, whereas most of vacant Crown forests are located outside of present means of communication, except for Saguenay county, where conditions are improving very fast and where much activity is to be expected in a near future.

Therefore, in calculating to what extent we can allow our licensees to cut, we cannot and do not yet take into account the forests of James bay, of Hamilton river or other sections of New Quebec, but must and do base our calculations exclusively on the actual resources of the St. Lawrence watershed.

Timber License Requirements

You will be interested to learn what our limit holders are required to do, remembering that the provincial government is often accused of favouring unduly the influential and wealthy lumberman. Each limit holder, in order to obtain the right to cut, has to pay immediately, if he is the successful bidder at auction, a certain amount per square mile, called the "*bonus of adjudication.*"

Every year he is required to pay a rental fixed, until 1930, at $8.00 per square mile. This *ground rent* alone produces a revenue of more than $600,000 a year. The limit holder is also compelled to defray all the expenses of preventing forest fires, trespassers, etc., which means an annual expense of about $10.00 per square mile.

When he cuts timber on his limits, he must then pay royalty or *stumpage dues* on every log made. Stumpage dues are liable to change from time to time. Until 1910, they were only 65 cents per thousand feet B.M. for spruce, but since 1920 they have been increased to $2.70. The Hon. Mr. Taschereau has refused to fix them for any definite period, reserving the liberty to adjust the royalties according to conditions of the market. Should the lumber trade or the pulp and paper business flourish, the government wishes to get its legitimate share during any such prosperous period by increasing the royalty; but should there come a commercial depression, the government is also willing to adjust dues accordingly. Stumpage dues now give us a revenue of about $3,000,000 a year.

The government has allowed timber licenses to be given as collateral security for loans made by banks to our lumbermen. These titles can also be sold or exchanged, but in each case a transfer premium of $20.00 per square mile is exacted, so that again we may share a little in the profits obtained through these transactions.

All these sources of income enable us to transmit to the treasurer of the province about $5,000,000 per year. Since Confederation, our timber limits have given a total revenue of $71,341,435.96; more than a half of this large amount has been collected since 1910, when Sir Lomer Gouin inaugurated important changes in our stumpage rates, in the amounts imposed for ground rent, etc.

This annual income of $5,000,000 may appear substantial, but it is small compared to what our forests will give us in the future, *provided we take the means to protect and improve them efficiently.*

Improvement in Forest Protection

In connection with the possibilities of utilizing our forest resources, let us consider what has taken place in Sweden, a country where conditions of the forest, of the soil, of climate and of the species are not altogether as good as ours.

The area of the Swedish forests is almost equivalent to that now under license in this province. (See Appendix Note No. 2.) Yet Sweden draws from her forests one and one-half billion cubic feet per annum, whereas the present production of our Quebec timber limits is only one-fourth of that quantity. It is true that the area of burnt-over tracts in Sweden is insignificant compared to the millions of acres which have been devastated here by fires until recent years, but we can hope to do as well as the Swedes are now doing if we follow their example. Fifty years ago they had fires as bad and as numerous as we have had here until late, but they did not hesitate to entrust the full management of their forests to engineers, with the result that to-day the Swedish forests are greatly improved, and they are now really fireproof, so much so that they do not now spend one-twentieth of the sum we have to disburse every year for fire protection.

The progress made here during the last two decades enables us to hope that we may, before long, reach the same stage as our competitors. In less than ten years the protection of our forests has been so improved that during the last three years the damages suffered therefrom have been very small. Public opinion is now so interested in our forest policy that the government is fully supported whenever energetic laws and measures have to be imposed to safeguard or improve our forests. Allow me to recall also that from the Forest School, opened in Quebec in 1910, seventy-two engineers have graduated up to this date.

Four years ago a Rangers' School was established at Berthierville, and already two classes, of twenty men each, have received their diplomas, and every one of these is working either for a company or for the government.

Forest Inventories

Though it was only in 1922 that the law of Forest Inventories was passed by Hon. Mr. Mercier, we have now over 11,000 square miles, or about one-seventh of the total area of our leased forests, inventoried, and, further, working plans have been passed and approved for these areas by the Lieutenant-Governor-in-Council. A quantity of timber,—which we consider equal to the annual increment of these forests,—is set as the maximum yield which the limit holder can cut thereon every year. Before allowing the licensee to operate, an inspection is made by officers of the Forest Service in order to decide upon the best methods of treatment to be employed so as to insure the proper regeneration of the forest. Therefore, on these 11,000 square miles of timber limits the yearly cut is virtually limited to the annual growth of the forest.

You will be agreeably surprised to learn that on these 11,000 square miles there were found 45,000,000 cords of softwoods, and this, though this group which comprises cut-over lands, burned-over tracts and virgin forests, was not specially selected. In fact, it includes limits from every part of the province. While not in position to affirm that this is an exact average of our present forest conditions, yet if it were, and the chances are it may be so, there would be left at least 300,000,000 cords of pulpwood within the areas under license, and it would mean that we could draw six million cords every year from our timber limits alone. This would be very encouraging. Therefore, it is essential that the forest inventories of all timber limits, as well as of a good part of our vacant Crown lands, should be carried on energetically. In fact, we expect that by 1930 all the timber limits will have been inventoried and the same work on unallotted Crown lands and township reserves will not be far behind.

The thing which may delay forest inventories is the difficulty of making definite land classification. In many places it is possible to create immediately permanent forest reserves, but in several regions the question presents numerous difficulties and it requires a succession of adjustments before being finally decided.

The question has also been raised about the encroachments of settlers on our public domain. Without any doubt, many errors have thus been made in the past and many other errors will still be made hereafter, but this is human, and, furthermore, it must be expected in the building up of such an enormous country as ours. However, the writer feels confident that these errors will never be duplicated on a large scale, as our people now realize the necessity of making permanent reserves to supply the needs of large wood-working establishments. For example, a seventy-five year reserve was created last year for the benefit of the Singer Manufacturing Company, who wanted this guarantee before building, at Thurso, a huge furniture plant. This mill, employing hundreds of men, will certainly bring to that region far greater advantages than could be derived from a few settlers toiling on lots of doubtful character located in isolated places, and thus deprived of chances to make a success, notwithstanding their great efforts.

Several similar permanent reserves could be established with advantage, but it would not be a good policy to organize these reserves in favour of any lumbering company without exacting as a compensation the quick completion of their forest inventories and the building of adequate wood-working plants to finish the products here.

The important progress made during the last decade in the prevention and fighting of forest fires through the organization of efficient protective services by the government and among limit holders and through an active and incessant propaganda has already been mentioned. The results obtained are really encouraging, but we must not stop there. The problem of forest débris is yet an important one to solve. Active and complete patrolling of our forests must be maintained, notwithstanding the apparent reduction in danger. The government control of the burning of clearings on settlers' lots has indeed brought much relief and satisfaction but this burning is such a great cause of fires that it must always be followed closely. Railways have improved wonderfully their control of bush fires along their rights-of-way, so much so that they now cause but little damage. The travel permit system has been a real blessing, as it has forced the various travellers in our woods, such as fishermen, hunters, etc., to become more careful with their fires. Five years have elapsed since the big mining boom started in the Rouyn district, and yet no big fire has occurred there since 1923; this shows that co-operation between prospectors, miners and protective organizations has not been inoperative. Much work remains to be done, but it is being accomplished as fast as possible. The quicker our forests are being made fireproof the greater hopes can we place upon them.

Reduction of Logging Waste

Coming now to the question of reducing waste in logging operations, it is found that in that field much progress has also been made during the last twenty years. In several pulpwood operations we are now cutting stumps as low as one foot above the ground, tops are reduced to two or three inches; fire-killed timber as well as insect-killed or blown-down material are removed as promptly and completely as possible. Hardwoods, which formerly were not utilized on our limits, are now being exploited to a greater degree every year. This is welcome, as it allows more room for the reproduction of softwoods and it increases the productivity of our woodlands. It may be necessary to build and operate railways to reach inaccessible stands in order to remove a larger proportion of the stock per acre; these reforms are to be expected, but they will become more general as the market conditions improve. For example, when newsprint was selling for $32 per ton, we could not expect or compel our lumbermen to practice sylviculture or to adopt lumbering methods similar to those which they themselves have introduced now that their product is selling at $65. Should paper reach $100 per ton, we might expect and should exact from them a more intense application of forestry.

Our forest policy should not neglect the various means of increasing the productivity of our forests, and this requires extensive researches in the field. As these studies must be conducted by expert foresters, a bureau of forest research will very soon be organized to handle this very important work, in co-operation with the owners and lessees of forest lands.

Reforestation will also be very beneficial in the oldest sectors of this province. In the Eastern Townships alone, there are close to one million acres of waste lands which, if planted, could produce every year enough timber to meet the requirements of two big pulp and paper mills. Should the natural means of regeneration be found insufficient to bring back some of our forests to normal condition, it will be advisable to complete the stand by planting good trees.

A sound forest policy is one that aims to utilize all possible forest products with the maximum of advantage to all interested. In Sweden, for example, in the majority of operations, we find that the débris of logging, such as tops, refuse, etc., are converted into charcoal, but they do this only where it pays to do so. When this operation is not profitable, they simply leave their tops and other débris on the ground, just as we do now.

Therefore, close to manufacturing establishments, to railways, to waterways, you can practice better forestry than in the remote sections where there is no facility to remove all the products. In other words, forestry follows closely the development of a country and is dependable on adequate markets.

Present State of Our Lumber Industry

During the French régime our lumber industry assumed no great importance, as it only consisted in the export of small quantities of deals, boards, masts and spars to French ports and in the supply of oak timber for the few ships built in the vicinity of Quebec city. It was only during the Continental Blockade that England began to draw upon her colony of North America for the lumber which she could not obtain, as before, from the Continent. Our export business rapidly became considerable and the wooden ship industry meant much to us, as more than 2,500 wooden ships were built in this country between 1797 and 1880. About 1840, the depletion of the American forests in the New England states enabled us also to export lumber to our neighbours, and this new field soon acquired great importance, and it still remains our best export market.

About 1895 the first large pulpwood operations began to supply our mills and those of the United States. The growth of this industry, which is now by far the most important of Canada, having even eclipsed that of flour, has been very remarkable in the last twenty years. Pulpmills are mentioned for the first time in the census of 1881, although there was one established at Windsor Mills about 1870. In 1925 there were 114 pulp and paper mills in Canada; the capitalization of the industry being $460,397,-772 and the total value of their manufactured products $240,896,560. The total quantity of pulpwood produced in that year was 5,092,461 cords, of which 3,668,959 cords were manufactured in Canada and 1,423,502 were exported. This question is being covered in another paper, but it is interesting to note that to-day the pulp and paper industry has almost displaced and replaced the lumber industry in eastern Canada. Except where pine, hemlock or hardwoods can be manufactured into lumber, our large sawmills are closing down one after the other. Pulp and paper manufacturers acquire each year more and more of the pulpwood timber limits, so much so that in Quebec 75 per cent of our timber limits are now controlled by this industry.

This transformation should not be regretted, because the pulp and paper industry is a very stable and interesting one. So much capital is invested in it that the industrials naturally take a greater interest in the preservation of the forests than the majority of the old lumbermen, who considered their industry as being of a more transient character. Pulp and paper companies are all disposed to employ foresters, to organize systematic lumbering and to place their forests under intensive management. It must not be thought that the writer has no word of praise for the old lumbermen, for it is impossible to forget what they have done for this country, how they led our pioneers to open up our remote districts, how they supported new settlements, how they fought battles royal to dispose of their products in the markets of England and the United States. A great debt is owing to them, but it cannot be helped that a new industry has replaced theirs, and that sawmills will only thrive in rural districts to take care of the local trade.

The instances already mentioned regarding the protection and utilization of our forests are the concern of the forest engineer, lumberman and manufacturer, but it should be noted that chemical, mechanical and electrical engineers are also occupied with this subject and are developing new lines of investigation, the results of which will aid in economy by utilizing the waste products from wood and by opening up new avenues of usefulness. There is space only for one or two illustrations of this department of progress.

New discoveries made in late years in France have shown that gas from charcoal may replace gasoline for internal combustion engines, and that wood gas may be used for the propulsion of autos, tractors and other vehicles. Should this process be developed for general use, it will mean very much to us, as it will allow the cleaning of the forest floor, thus minimizing the danger of fire and also permitting us to use more of the hardwoods, which, as you know, produce better charcoal than softwoods.

Among the by-products which wood may furnish through distillation may be named wood alcohol, turpentine, lampblack, acetate of lime, wood gas, wood tar, etc., and also the potash and pearlash which were produced in the old days by washing the ashes of hardwoods. From sawdust one can obtain either oxalic acid or glucose, the last will, if fermented, produce ethyl alcohol or real sugar. It is also claimed that one can extract from the rosin of wood or from the needles of spruce various products which can be transformed into artificial camphor.

To-day there is being manufactured a new chemical pulp called *alpha pulp,* which contains almost 100 per cent of fibre, which is equal to, if not better than, that of cotton and which is used for conversion into rayon or artificial silk. Therefore, the products which wood may give under chemical treatment are almost unlimited, and one feels sure that the by-products which can be produced or recovered from the mill's wastes have also a very promising future.

All this shows that it is possible in the near future, by the co-operation of all those who have an interest in the welfare of our forests, to obtain a larger number of products and by-products than before, and the more useful and remunerative our forest products become the more it will be possible to give to our forests an intensive treatment which will increase their value to the community.

APPENDIX

Note No. 1

The total area covered by existing forests in Canada has been estimated at approximately 1,227,000 square miles. The estimated stand of timber of merchantable size, (disregarding present accessibility), is approximately 482,075,500,000 feet board measure for saw timber and 1,279,705,000 cords of pulpwood, cordwood and other merchantable products. Of the total for saw timber, 72 per cent is located in British Columbia; 22 per cent in the eastern provinces, and about 6 per cent in the prairie provinces. About 91 per cent of hardwoods being found chiefly in the eastern provinces. The total for merchantable material of all kinds has been estimated at 246,826 million cubic feet.

Lumber Industry in 1924.
Bulletin, Statistics Bureau.

Note No. 2

The productive forests of Sweden are estimated at 55,000,000 acres, of which public or state forests constitute 13,000,000 acres and private forests 42,000,000 acres.

Woodlands Management and Operation

The Conditions Governing Forest Development with Exploitation

S. L. de Carteret, M.E.I.C.
Hammermill Paper Company, Quebec, Que.

Paper to be presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Quebec, Que., February 15th to 17th, 1927

About one-quarter of the total area of Canada, or 950,000 square miles, is forest area, of which 460,000 square miles carries timber of merchantable size.

In 1924 the total estimated stand of timber of merchantable size was placed at 246 billion cubic feet. Of this amount, over 80 per cent, or 198 billion cubic feet, consists of the softwood species, from which comes 95 per cent of our sawn lumber production and practically 100 per cent of our pulpwood production.

Canada's forest industries are second only to agriculture in value of production. In 1923 our wood and paper products had a gross value of over $550,000,000.

Our principal forest products are lumber, pulpwood, ties, poles, firewood and various minor products and biproducts.

Methods of forest operation vary materially in different parts of the Dominion.

In the east, climatic conditions limit cutting and hauling largely to the fall and winter months. Cutting is commenced in the late summer or early fall and continues until the snow becomes too deep for cutting and skidding. Logs are assembled in skidways and pulpwood in piles, near the point of felling, and are hauled on snow and iced roads with horses or tractors to adjacent drivable streams during the winter, to be driven to the mills or shipping points on the flood water of the following spring.

In the west, operations are carried on in most cases throughout the entire year. There logs are assembled by slides and various cable systems, while logging railways are used extensively to carry the timber direct to the mills or to the larger rivers, or to tide water, from whence it is towed to the mills.

Past and Present Attitudes in Regard to Forest Operations

The increasing consumption of forest products, accompanied by lessening supplies and enhanced values of standing timber, as well as higher operating costs, have resulted in an entirely different attitude towards the treatment of the forest in recent years.

Not very long ago it was the general custom to instruct the woods boss to cut a certain number of logs in a specified region, and if he got the requisite quantity at a seemingly reasonable cost the operation was considered a success.

No attention was paid to the fact that only the best of the timber adjacent to the streams was being cut; that more mature timber was being left to decay or blow down than was taken; that waste in high stumps and large tops was equivalent to a considerable percentage of timber actually utilized; and that the future cost of cutting the merchantable timber then left would be all out of proportion with reasonable logging costs.

However, before censuring the policy then followed, consideration should be given to the business conditions which existed previously. What is commercially profitable to-day was not so then. Twenty years ago there was no profit in logs produced for lumber, unless they were large, clear and entirely sound. To-day logs 3 inches in diameter at the small end can be used to advantage in the manufacture of pulp and paper, and those containing a considerable amount of rot can also be utilized in some classes of pulp.

A few years ago spruce was considered the only species from which really good pulp could be made; balsam was frowned upon for various reasons and the mills tried to limit the quantity used to a low percentage. In consequence, operators restricted their cut in the forest to spruce as much as possible, and the greater part of the merchantable balsam was left standing and allowed to become a total loss. At the same time this less desirable species, being more prolific than the spruce, soon seeded in large areas, with the result that almost pure stands of balsam now replace the previously mixed stands of greater value. Some pulp and paper makers still object to high percentages of balsam, but it is no longer customary to discriminate against it to any great extent in present-day logging operations.

As a result of the changed conditions previously referred to, the wood-using industries now appreciate that their forest capital merits as much care and attention as their other invested capital. They are fully aware of the limitations of supply and are actively engaged in providing for the future through operating plans based on sustained yield, improved logging methods, closer utilization, more efficient forest production and by further acquisitions of timber lands.

They realize that while utilizing the present merchantable material in the forest they must at the same time provide for the continuance of the forest and for the production of timber in the future. They appreciate that the condition of the forest must be improved and its productivity increased, that waste must be eliminated, and that losses from decay, fungi, insects, windfall and fire must be prevented insofar as is humanly possible.

How the Desired Results May be Obtained

The attainment of these results calls for a detailed classification of the forest. This is the first requisite, for without it a rational cutting programme and suitable silvicultural system cannot be evolved.

Time does not permit going into extended details as to silvicultural systems. Briefly, the result desired is to secure quick reproduction of the more valuable species in fully-stocked stands; to produce trees of good form and quality and to accomplish rapid growth.

Quick reproduction is secured by careful cutting, avoiding injury to young growth as much as possible and by keeping out fire. Increase in quantity of desirable species is obtained by cutting the less desirable species to a lower diameter limit.

Fully-stocked stands are dependent on an abundant distribution of seed and conditions favourable to germination and early growth. Good form and quality are obtained in mixed rather than pure stands.

General Conditions Pertaining to Standing Timber in the East and Present-Day Methods of Handling

In the east the timber with which we have to deal may be divided into three general classes, viz.:—

Mature and over-mature stands of merchantable timber;

Immature stands containing stock of merchantable size; and

Areas of reproduction and young growth.

A very large portion of our timber falls into the first class. A small annual increment may be observed in individual trees, but this is often balanced by decay in others, and the stand as a whole may be either at a standstill or going backward. Our greatest problem, and the one which will take the most time, is to place such areas on a profitable producing basis.

It has been found that cutting such stands to a fixed diameter is useless and wasteful. There are many small trees which are as old as the largest in the stand, which, if left, will produce but little growth and may not survive until the next cutting period. In such stands clear cutting is resorted to, which involves the removal of all the merchantable timber in one operation.

To provide for sufficient natural reproduction where this does not already exist in the form of numerous seedlings and young growth, thrifty, full-crowned, wind-firm seed trees are left. For this purpose small trees are as satisfactory as large trees, provided they are thrifty and full-crowned, and many of those which are left because they are not of merchantable size fulfill this purpose.

Immature stands containing stock of merchantable size constitute our second line of defence in regard to future supply, and should not be cut into beyond what is necessary to improve their condition and to stimulate maximum production of merchantable wood of high quality. Selective cuttings are applicable to these growing stands where the trees are wind-firm, and where the volume of merchantable timber per acre is sufficient to permit a partial cut on an economic basis.

In actual practice certain diameter limits are adopted, but before a diameter limit can be successfully applied it is necessary to determine what the forest can produce and at what diameter further growth is no longer sufficiently profitable. Also, any particular diameter limit does not take into consideration the condition of trees as to health and growth. Defective trees should be removed, while others above the diameter limit may be making such rapid growth that it is good policy to leave them. Then again, it is sometimes necessary to cut whole groups of trees under the diameter limit to save them from loss by windfall.

The advantages of selective cutting are several. A large number of seed trees, comparatively close together, are distributing seed at regular intervals. The shade of the standing trees retards the growth of brush, weeds and grass and the seedlings are protected from drying out and from frost. A new stand is established during the period in which the remaining old stand is gaining its maximum growth.

The third class, namely, areas of reproduction and young growth, are a fertile field for future efforts, but, in the meantime, if fire can be kept out of them, nature will go a long way in carrying them along until it is economically practical for us to attempt to improve their condition.

Woodlands Management and Operation in Eastern Canada

The Forest Inventory

It has been stated or inferred in the foregoing that a detailed classification of the forest is the first requisite for intelligent and successful operation of the forest. This classification, more familiarly known as a *forest inventory*, comprises:—

Maps, preferably topographic, showing natural features, such as the drainage system, with the drivable streams specially indicated, and watershed lines; distribution of timber by types, species, amount and size; existing improvements, such as roads, trails, camps, dams, etc.; subsequent changes in the forest, such as cuttings, burns, windfalls, etc.; division of the area into suitable logging units based on the natural features of the land; relation of the tract to other properties; means of access by railways, summer and winter roads and navigable waters.

Tabulations, showing classification of the total area.

Estimates of merchantable timber in total, and subdivided by watersheds and logging units and classified according to type, species, diameter and age.

Reports covering condition of timber, rate of growth and reproduction; aspects relative to operating; condition of existing improvements; further improvements, property and rights necessary for efficient operation; opportunity for co-operation with other companies in the vicinity; sources of danger from fire and necessary facilities for protection; suitability of land for agriculture if cleared; extent of operation possible, estimates of operating costs and carrying charges.

The General Working Plan

The forest inventory is the basis on which a *general working plan* is formulated, which, to be of real value, must be made for several years in advance in order that necessary improvements may be anticipated and constructed on a predetermined time schedule and to permit cutting operations to be regulated so that logs and pulpwood may be produced over a period at a uniform cost.

Working plans should be made for periods of from five to ten years in advance, subject, of course, to changes and modifications in detail from time to time as unforeseen conditions warrant. The ideal working plan aims at maximum production at a uniform cost over a period of years, with uniform expenditures from year to year for operating improvements rather than heavy capital additions at irregular intervals.

The forest inventory shows the distribution and amount of available timber in any watershed, and the cost of improvements necessary for its removal is figured and later written off on a cord or thousand-foot basis over the total amount of timber served during the useful life of the various improvements.

The maps and estimates show the amount of timber directly tributary to any particular stream, section of river or road, and improvements are extended gradually in advance of cutting requirements.

In formulating a working plan, after the quantity to be cut annually has been decided upon, the accessibility of the property from the operating viewpoint has to be considered. If winter roads are to be relied upon, it becomes necessary to put in sufficient provisions and supplies during one winter to carry the following season's operations along until snow hauling is again possible.

This method of operation has various disadvantages, among which are: initial cost and maintenance charges of large storehouses; working capital tied up in provisions and supplies for from eight to twelve months before they are used; interest, insurance and handling charges; losses from shrinkage and spoiling; inability to purchase at opportune times; poor means of communication and transportation during spring, summer and fall; attendant difficulties to obtain and transport labour because of inconvenience and time element involved; all contributing to the demand for higher prices by contractors.

A system of summer roads suitable for wagons, trucks or tractors permits transporting provisions and supplies as needed, thereby eliminating to a large extent many of the charges mentioned in the previous paragraph.

If the operations are at a considerable distance from the source of supply it may still be advantageous to put in the heavier supplies during the winter, but the greater the distances to be overcome the better the means of ingress and egress required, particularly from the standpoint of obtaining and keeping the necessary labour.

With summer roads, the current season's field crops can be utilized, fresh meat can be obtained as required, improvement crews can be moved about and handled with greater efficiency, and early cutting can be commenced when desired, with greater ease.

Improvements

A study of the maps and reports forming part of the forest inventory aids in locating the most suitable routes for main roads and sites for operating headquarters and storehouses in the woods.

Roads

Surveys are made for road locations previous to construction so that the best possible grades may be obtained, and are built in a manner permitting gradual improvement and reasonable maintenance charges in the future.

A good bottom, completely freed from stumps and roots, adequate drainage and sufficient clearing on either side to permit drying out by wind and sun are the primary requisites for a satisfactory woods road. Such a road may be rough in the beginning, but with reasonable annual expenditure for maintenance and improvement it can be made suitable for the use of light weight motor vehicles in a comparatively short space of time.

Camps and Storehouses

Headquarters and scalers' camps are constructed in central locations which will permit maximum supervision with the minimum amount of travel. Unless lumber is immediately available, such camps are built preferably of peeled logs.

Storehouses are located where they will serve the greatest territory economically for the longest time, and are designed to expedite the handling of supplies with the least amount of labour.

Driving Dams and Other River Improvements

Studies are made as to precipitation, run-off and available storage capacity before dams are built. They are then designed and constructed according to specifications and dimensions which provide for stability and safety under the most adverse conditions to be expected, and with facilities permitting operation and control of the water stored to the best advantage during the course of driving operations.

Driving dams of low heads of ten to twelve feet are built of round timbers, preferably sap peeled, and are most frequently of the rafter or self-loading type, the use of stone filling being limited to the " pockets " adjacent to the gate openings and to the reinforcing cribwork on the sides of the sluiceways. The upstream face is covered with two thicknesses of plank with broken joints, or with hewn poles caulked with moss or shingle rip. Brush mats are placed at the toe and the whole is covered with a bed of clay, gravel or earth for a considerable distance in front of the toe and well up the slope of the face.

Frequently it is necessary to construct wooden dams for heads in excess of fifteen feet, or it may be desired to provide for longer life than can be figured on in dams of the rafter type. In such cases, crib structures filled with stone are built. Timbers are hewn or sawn on two faces and the bark is removed from the balance. Sawing to uniform thicknessses is preferable, as labour in erection is then greatly lessened, fitting is reduced to a minimum and a much better job throughout is obtained than in the use of hewn or round timber. Also, with a small sawmill at the site for facing the main timbers, it is then easy to saw the necessary lumber for sheathing, sheet piling, lining, etc., and the time and expense of " chinking " and caulking is eliminated.

Other river improvements consist of side piers and abutments, removal of obstacles by blasting, removal of fallen trees, etc., in stream beds, clearing flowage areas through which wood is driven or in which wood is stored, shear and guide booms.

Flumes

There is no cheaper method of transporting softwoods than by floating, but the natural watercourses do not always suit requirements. They may not run in the desired directions or they may be too small or too rough to carry the necessary quantities. Under such conditions, flumes can frequently be used to advantage in diverting wood from one watershed into another and in increasing the output of a particular region over what could be carried by the streams in their natural condition.

Flumes may also be used to concentrate the output of several streams at one central point; also in loading vessels and cars.

Flumes have been used extensively in some of the western states for many years. Their use has been chiefly where stream transportation was not available and where topography rendered railway cosntruction costly. Such flumes have been built in lengths up to 65 miles, with grades varying from 5 to 18 per cent and curvature up to 20°.

In the east, flumes have come into more frequent use during recent years in connection with the development of some of the more inaccessible and difficult pulpwood properties, particularly for the purpose of transporting logs and pulpwood from one watershed to another and in bringing pulpwood to points where it can be loaded on board vessels and railway cars. These eastern flumes do not have the high grades of those referred to in the west; in fact, the low grades of some of the eastern flumes are rather worthy of note, viz., varying from 0.1 to 0.2 per cent and having a capacity of from 40 to 60 cords per hour.

Annual Logging Plans

Any cutting policy, to be a success, must, in its final analysis, show a commercial profit or at least a definite promise of one in the near future. In consequence, it must be elastic enough to conform to current conditions. When labour and supplies are reasonable in price, scattered and difficult timber may be made at a profit, but under reverse conditions easier timber must be taken in order to keep the cost of raw materials at a reasonable figure.

Operating Maps

Previous to the commencement of each logging season, operating maps are prepared, based on the general working plan, showing the boundaries of each logging unit which is to be cut, these units being further subdivided into suitable logging chances where necessary. These subdivisions are numbered on the maps and the estimated amount of timber thereon is also shown. These operating maps are accompanied by sheets showing the area of each subdivision, stand per acre, amount to be contracted, point of delivery, average length of haul, proposed contract price, totals and averages.

This information is obtained from the maps and estimates and from further travel of the territory, and is used as a basis of letting contracts. As the contracts are let, the contractors' names are inserted on the operating maps on the areas assigned, for future reference.

Contracts are not let for exact amounts, *but to remove all the timber covered by the specifications* of the contract, which may be *found on the areas assigned,* estimated at so many cords or thousand feet, *more or less.*

It is usually found that a contractor demands a much larger area than necessary to cut a specified amount. If such concessions are made the usual result is that the easiest and best timber is cut first, and, after the contracted amount is made, scattered bunches remain on the area for which a much higher price is demanded at some later date.

From the standpoint of economy in operation, it is therefore preferable that contracts be made for the removal of all the timber conforming to specifications from a certain area rather than for definite amounts.

Contracting Policies

Contracting policies vary materially in different places. Some companies give out their entire cuts to one or more main contractors, who in turn sub-let all or part to sub-contractors. Other companies let a sufficient number of comparatively small contracts direct to total their requirements.

Not infrequently the large main contracts include the building of roads and storehouses, making river improvements and driving the timber cut under the contract to some specified point of delivery.

From the standpoint of producing large quantities of logs and pulpwood, there are certain advantages in such an arrangement with a responsible contractor; he has his own organization and makes his own arrangements for provisions, supplies, labour, equipment, buildings and transportation, and the company avoids initial expenditures of time and money on these items to a large extent. Responsibility for production and delivery at a certain point is assumed by the contractor, and the company is freed from the details of same up to a certain point.

However, there are many uncontrollable variables which may affect the carrying-out of the transaction before it is completed. The contractor, in anticipating his costs, must necessarily make adequate allowances for risks assumed and contingencies, and in consequence his total charge per cord or per thousand feet is increased accordingly.

Furthermore, while the company may supervise his cutting operations closely, it is much more difficult to get the desired results from the standpoint of utilization and careful preparation of wood, etc., in dealing with the numerous sub-contractors of a large contractor than is the case where the various contractors are dealing directly with the company.

Adequate control of logging operations is easiest obtained where individual contracts are limited in amount to, say, from 2,000 to 5,000 cords.

Logging Contracts

Some of the more important items usually covered in a logging contract are the following:—

Description and boundaries of the territory assigned.

Species to be utilized and estimated quantity, more or less, of same on the area, according to cutting specifications and place of delivery.

Specifications as to how the timber is to be cut and prepared, i.e., trees to be saw-felled, all logs to be cut with the saw, at both ends, in specified lengths; all branches and knots to be entirely removed, all sound wood in the tree to be utilized up to a specified top diameter; specifications as to quality of wood which is acceptable.

Manner of delivery, such as wood to be delivered on the banks of the rivers or lakes at places specified, or, at the option of the company, on the ice; landings to be entirely cleared of brush, stumps, etc.; wood to be piled evenly; space to be left between piles to permit inspection and scaling; back end of piles not to exceed a certain distance from the river or lake.

Measurement to be made at place of delivery only, by scalers named by the company; scalers may refuse to measure wood which is not properly piled or wood which is piled on landings improperly cleared.

Miscellaneous Regulations: The throwing or leaving of branches, trees or other debris in the rivers or lakes is prohibited; dates for commencing and completing cutting as well as minimum weekly production; dates for commencing and completing hauling as well as minimum amount to be hauled weekly; camps to be built of the dimensions and according to plans furnished by the company and in locations approved by the company.

Penalties: Covering trees left which should have been cut; trees cut outside boundaries of territory assigned; high stumps and large tops; wood cut but not hauled.

Contract Price: Schedule of advances.

Control of Logging Operations

Forest inventories and working plans are made by forest engineers, and it is logical that they should supervise and control the forest operations.

After seeing that the cutting areas have been marked out on the ground to correspond to the season's operating maps, the forest engineer co-operates in placing the contractors, selecting sites for logging camps and in marking out the main hauling roads.

Inspection

With the commencement of cutting operations, inspectors follow the cutting crews and see that they work in accordance with the conditions of the logging contract, paying particular attention to utilization, the way the wood is made and the production of the various crews. In addition to seeing that waste does not occur in high stumps, large tops, lodged trees, etc., the more important phases of inspection are to prevent scattered cutting, to keep the contractor within his boundaries and to see that he has sufficient labour and equipment at all times to make and deliver all the wood on his territory according to schedule of minimum production mentioned in his contract.

The latter cannot be followed successfully unless frequent inspections are made, as well as weekly reports showing number of men and horses engaged on each job and their average production. Also, good work and a small percentage of waste cannot be expected unless sufficient men and equipment are gotten in early enough to complete cutting before the deep snow.

These inspections are continued throughout the logging season. The closest inspection is necessary at the start, when additional assistance is received from the scalers who are on the staff and who are later changed to their regular work of measuring at points of delivery when sufficient wood has been hauled to occupy their time.

Each inspection is reported on a loose leaf *field inspection sheet*, filled in as the inspection is made, a separate sheet being used for each contractor and sub-contractor. This report shows date inspection is made; number of merchantable trees and tops left; number of high stumps, trees felled with the axe, logs or bolts under-length or over-length, culls and infractions; general conduct of the operation; sanitary condition of camps; number of men cutting, hauling, on roads and other work; number of horses hauling and on other work.

During the course of their inspections the inspectors draw the attention of the cutting crews to faulty work and infractions, and usually a marked improvement results immediately. In cases where the cutting crews are not amenable to reason, the woods superintendent follows up the contractor and induces him to exercise closer supervision over the work of his employees in order that the results desired may be obtained.

As cutting progresses, estimates are made of the quantities cut and piled in the woods and same are recorded on loose leaf *field estimate sheets*, a separate sheet being used for each inspection and for each contractor and sub-contractor. Each pile is numbered to correspond with numbering on the estimate sheets, and, in the case of logs, their number and average diameter is recorded; in the case of pulpwood, the approximate dimensions of the piles are given and the estimated percentage of cull.

Progress Reports

These field inspection and field estimate sheets are compiled weekly into a *logging inspection and progress report*, which, in addition to giving a summary of the items mentioned above, shows: number of weeks in cutting season; cutting schedule per week; previous total cut; amount cut during week; total cut to date; previous surplus or deficit on schedule; week's surplus or deficit; total surplus or deficit.

Similarly in regard to the hauling, this weekly report shows: number of weeks in hauling season; hauling schedule per week; previous total hauled; amount hauled during week; total hauled to date; previous surplus or deficit on schedule; week's surplus or deficit; total surplus or deficit.

These logging inspection and progress reports, which are made weekly for each contractor, permit a frequent review of the operations. They show what parts of the work need the closest watching as to improper methods, insufficient crews and production below schedule. They also show quite accurately progress to date, and form the basis for computing amounts earned and advances due up to the time of scaling at points of delivery.

Scaling

It has been well said, as far as logging is concerned, that the scaler is the most important accountant on the job, for upon the accuracy of his figures the company is dependent in making proper payments and in computing production costs all down the line. In consequence, the uttermost care should be exercised in the choice and training of scalers, in systematizing their work and in checking their accuracy.

Rollways and piles are marked and numbered as scaled at place of final delivery, in such a manner as to permit identification of any particular pile for the purpose of check scaling. It is a simple matter to scale straight, sound logs, but where defects occur, haphazard deductions usually result in loss to the company. A definite schedule of deductions for defects should be used and track kept of the deductions made. Similarly, losses occur in the measuring of pulpwood where proper allowances are not made for rot, knots, loose piling, short sticks, etc.

Where wood is driven it is difficult to check the amounts made in the woods by measurements at the mills because of the quantities left back on the drive each year and driven during following seasons with other cuts. In such cases, shortages are not detected until a clean-up is made on the river, which usually occurs only once every few years, and then it frequently becomes necessary to write off large amounts to profit and loss. It is safe to say that a large part of the losses attributed to sinkage in driving is actually due to improper and loose scaling methods in the woods.

Where large quantities of wood are being made it is a paying proposition to have a *scaling inspector*, whose duties comprise checking the methods and measurements of both the regular scalers and check scalers. This scaling inspector should be engaged by and report directly to the manager or some other executive outside the actual logging organization, and should be supplied with an adequate staff to carry out his work. This constitutes an *outside audit* of the scaling done by the logging organization.

Measurements made at points of delivery form the basis of settlement with the contractor for wood delivered, and in consequence each group of logs or pile of pulpwood scaled should be so marked and recorded that check measurements may be made and compared, for the company's satisfaction, and also to satisfy the contractor in cases of dispute.

All logs should be stamped as scaled and the piles numbered and marked with the date of the scale and the scaler's initials. Pulpwood piles should be similarly numbered, dated and initialled and all bolts stamped at the time of measurement.

Some contracts provide that the stamping be done by the contractor, but it is felt preferable that it be done by the scalers and their assistants at the time of measurement. It is then assumed that logs and pulpwood bearing stamp marks have been previously scaled. Also, where the company's employees do the stamping there is greater assurance that every piece will be clearly marked, which is of prime importance for future identification in later sorting operations during the drive.

The original scaling record is made on *field scale sheets*, which show the contractor's and sub-contractor's names, contract number, cutting area number, date, name of scaler and pile numbers. In the case of logs, they are tallied according to species, lengths and diameters, culls and cull deductions being recorded separately. In the case of pulpwood, the dimensions of each pile are recorded, and all deductions for rot, long sticks, short sticks, loose piling, knotty wood, etc., are listed separately under these various headings.

From these field scale sheets, *official scale slips* are made in triplicate in the woods office, for distribution as follows: one copy for the contractor, one for the accounting office, the third being retained in the scalers' office. Appropriate forms are used for check scalings and audit scalings, on which previous measurements can be listed for comparison, and for scaling summaries.

The transportation of logs on land and by water is being covered in a separate paper, so reference herein to those phases of logging operations will be limited to the following in respect to driving.

Driving

With adequate water supply and river improvements, successful driving then depends on the prompt and efficient handling of labour and water. The greatest aid in this connection is a telephone system along the streams being driven, with instruments at all dams and points where trouble may be anticipated.

Based on each year's experience, data should be compiled showing the periods of flood water on the various streams, the time required to fill dams, the time taken to draw them down with varied gate openings, the time required to drive various sections of the rivers and streams under normal conditions, time required to sluice known quantities of wood through dams and slides, driving capacity of streams, height of water necessary to give an adequate driving pitch at critical points, etc.

In order to follow and report the progress of drives, it has been found advantageous to place mile posts on the banks of the streams being driven. These are usually numbered boards nailed up in conspicuous places, the mileage being measured from the mouth of the main river, and a new count being used on each tributary, starting from its mouth.

Wood Handling Plants

Unless all the timber on a particular river is controlled under one ownership, the question of adequate holding and sorting space is of great importance. The layout should be planned so that facilities at first installed can still be utilized in the future when more space and additional facilities are required due to increased quantities of wood being driven and used.

In sorting, the current is taken advantage of, and wherever possible the hauling-out plant should be so placed that the tendency is for the wood to float on to the chains.

Cutting-up plants, barking plants and loading apparatus should be so arranged that they can be run independently. There should also be space for a large reserve of wood, available at all times for rapid loading, the reserve being replenished between loading periods. At the same time, it should be possible for the wood which is cut up and barked during the period of loading to pass directly into the cars or vessels being loaded, thereby saving rehandling of that portion.

Any layout is, of course, limited by the natural features of the location to a large extent, but frequently the wood can be delivered to the cutting-up plant, barking plant, reserve piles, cars or vessels by the use of flumes and gravity, or one or the other in combination with some other form of power, with a resultant saving in the total amount of power which would otherwise be required.

Labour is the largest item entering into the cost of pulpwood and logs, and any mechanical device which eliminates a handling or lessens the amount of manual labour usually saves both time and money.

Visualization of Operating Progress

Where large quantities of wood are being cut, and operations are being conducted in several different districts or regions, it is extremely difficult for company executives to visualize the progress being made, in detail, from the tabulated progress reports. This obstacle is overcome to a large extent by the use of copies of the operating maps referred to under the heading "Annual Logging Plans."

As stated therein, the contractor's name has been placed on the map on the area assigned to him. To this is added the approximate quantity of wood covered by his contract, the dates he is expected to be up to schedule production on cutting and hauling, and the schedule amount he is supposed to cut and haul per week.

When the weekly logging inspection and progress report for each contractor is received, pins with coloured heads of different sizes, each size representing a certain quantity of wood, are inserted in his area, corresponding to the amount of wood cut as shown by the report, and where there is a deficit according to schedule "danger signal" pins of another colour are also inserted for the amount of the deficit.

From week to week additional pins are added as further reports are received, and, if desired, each week's cut can be separated from that of the preceding one by smaller pins of another colour.

Similarly in regard to the hauling, pins of other colours are inserted in the map near the approximate locations of the landings, representing the quantity of wood hauled; one colour being used for that landed on the ice as the place of final delivery and another colour for that delivered on the bank. "Danger signal" pins are also used where hauling is behind schedule.

This method of procedure shows at a glance how cutting and hauling is progressing, and permits comparisons between districts, and contractors, and indicates which ones are behind on their schedules and need pushing.

The visual presentation constantly emphasizes such points in detail, where in the tabulated reports they may be obscured or lost sight of, at least temporarily if not entirely, or until it may be too late to prescribe a remedy.

The amount of wood remaining to be hauled at any report date is readily seen by comparing the "cut" pins with the "landed" pins. When the final hauling report has been received, all the "cut" pins are removed except those representing the amounts cut but not hauled.

At the time of the drive, pins representing "wood landed on the ice" then correspond to the quantity already delivered in the water, and, as the balance of the wood is rolled, pins are changed to the corresponding colour. As reports are received showing the progress of the drive to various known points, pins are advanced down the streams accordingly.

Pins of distinctive colours are used to indicate the head and tail of the drive on each stream. Wood left back, and its approximate quantity and location, is so indicated by pins remaining back of the "tail" pins.

With mile posts marked on the maps to correspond with those placed along the streams, as mentioned under the heading "Driving," the progress being made can be readily followed and conclusions reached as to what drives should be pushed harder or perhaps abandoned for the time being, how the output of the various tributaries is coming into the main river, and plans for moving crews from one place to another can be made in advance more intelligently when the whole operation is in clear view.

Records of Forest Operations

In making the maps accompanying the forest inventory, as well as other maps of record, a legend is used which permits showing subsequent changes, such as cuttings, burns, windfalls, etc., by additions thereto in the form of cross-hatching in distinctive colours.

In order that the maps may be of the greatest value in future operations, as well as constituting an up-to-date record of what has happened in the past, surveys of cuttings, burns, etc., are made promptly after they occur, and their extent is shown on the maps. Tabular statements are kept for each district, watershed and logging unit. The original entries show the merchantable areas in acres and the quantities of timber found therein at the time of the forest inventory.

Where cuttings have been made previous to the forest inventory and the amounts removed are known, these figures are entered ahead of the inventory data to arrive as nearly as possible at the quantity of the original stand. At the end of each logging season, the merchantable area cut over and the amount of timber removed is deducted and the balance remaining shown.

Similar deductions are made to cover losses resulting from fire, insect depredations, etc., and from time to time adjustments have to be made to take care of over-runs, shortages and differences found as cuttings proceed and when subsequent timber estimates are made. This part of the record is referred to as the *timber cut and standing* statement, and is particularly valuable in showing original quantities of timber, amounts removed by seasons, the balance remaining and its distribution.

Statements are also compiled showing the amount of timber removed per acre of merchantable area, from each area contracted, logging unit and watershed, for each season's operation. Graphs are made for individual logging units and watersheds, showing contract price variations and differences in length of haul, and are carried along from season to season to indicate trend and for comparative purposes.

Comparative statements for successive operating seasons are compiled showing in detail the individual items contributing to the total cost per cord or per thousand feet delivered in the mill pond or at shipping point, the principal items and their subdivisions being as follows:—

Woods expenses:
- Superintendence,
- Surveying and exploring,
- Logging plans,
- Inspection, scaling and stamping,
- Forest protection,
- Woods office expenses,
- Maintenance and repairs of buildings, roads and telephone lines,
- Equipment consumption,
- Depreciation on woods improvements,
- Insurance,
- Miscellaneous woods expenses.

Contract cost of landed wood:

Stumpage and depletion:

Total landed cost

Driving expenses:
- Superintendence,
- Rolling wood,
- Driving, rafting, booming and sluicing,
  - (a) On tributary streams,
  - (b) On main river,
- Sorting,
- Shore rentals and land damages,
- Maintenance and repairs of driving improvements,
- Equipment consumption,
- Depreciation on driving improvements,
- Insurance,
- Miscellaneous driving expenses,
- Drive shrinkage.

Total driven cost

General expenses:
- Head Office:
  - Salaries,
  - Supplies and expenses,
  - Telephones and telegrams,
  - Travelling expense,
- Maintenance and repairs of buildings, furniture and fixtures,
- Depreciation,
- Insurance,
- Taxes,
- Legal expense,
- Charities and donations,
- Audit fees,
- Miscellaneous general charges.

Total delivered cost

While accounting procedures vary materially, the end in view should always be to present *cost facts* promptly, at frequent intervals, in a clear-cut manner, permitting easy analysis of the costs of each part or step in the operation whenever desired, and these statements form the basis from which future budgets and cost estimates are derived.

Forest Protection

The protection of the forest from fire is of prime importance, for without adequate preventive measures and proper facilities for extinguishing fires when they occur, all other plans for the perpetuation of the forest through efficient management and operation are of little use.

Each provincial government has its protection service which affords protection principally to unoccupied Crown lands and settled districts and co-operates with the Board of Railway Commissioners, the Forest Protective Associations, and individual owners.

In the province of Quebec, in 1925, the government fire protection staff included 1,745 inspectors, fire-rangers and auxiliary rangers, whose sphere of activity covered approximately 100,000 square miles of unoccupied Crown lands and settled districts, while the five co-operative associations had under their supervision and control some 71,000 square miles of licensed Crown lands and private holdings, on which they employed a staff of 1,434 men.

Private owners employed 235 more, making a grand total of over 3,400 engaged in the various fire protective services during the fire season, as compared with a total of about 400 ten years ago.

The general fire protection system has been improved in recent years by the extension of telephone lines through the forest and in linking up the look-out stations, by increasing the number of observation towers and railway speeder patrols, by the use of air craft, portable fire pumps and other modern fire-fighting equipment, by special legislation requiring the use of burning and travel permits, and by educational campaigns conducted throughout the country.

However, great difficulty is encountered in attempting to build up efficient field organizations for apprehending and combating fires. The work is seasonal and men of the type best fitted for these duties hesitate to take them up, as they desire year-round employment. To engage themselves for the period of the fire season often prevents them from completing spring work, such as the drives or may prevent them from obtaining the fall and winter jobs they desire, as they are not available when the work commences. In consequence, a large part of the ranging force is often composed of young men seeking summer jobs, who lack experience, and, while they may develop during the season, most of them do not return the following year, with the result that another green crew has to be taken on.

Until forest protection is recognized to be of sufficient importance to guarantee the men engaged in it year-round employment, just so long will it be impossible to obtain sufficient men of the right type and experience, and the results obtained will continue to be far below the standard desired.

Recognition of this fact is gradually becoming more widespread, and some of the organizations engaged in woodlands operation are now providing steady employment for the fire protection staff. Men who are scalers, stampers, logging inspectors, woods clerks and storekeepers during the fall and winter months are transferred to forest protective work as required, and are again placed in their former positions when the fire season is over. It is sometimes inconvenient to transfer a man just when he is needed, but if the principle is admitted that protection comes first there is no room for argument.

Where a number of men are engaged in protecting the same lands that they assist in operating, and vice versa, thereby receiving year-round employment, their work develops into more than a job for them; they see opportunities to display their ability and for advancement, and, with a reasonable amount of encouragement, become personally interested in the whole undertaking.

Personnel in Forest Operations

The methods outlined in the foregoing are the result of endeavours to co-ordinate the knowledge of the experienced operator with that of the engineer. Fundamental methods and practices have not been changed but rather have been amplified and systematized.

The training of the engineer has been brought into play to obtain and record information pertaining to the forest and its operation, the use of which increases the efficiency of the logging organization, and to collect and keep up-to-date such information as the executive heads of the controlling organization may require from time to time, relative to immediate and future wood supply, operating plans for the future, improvement and operating budgets, wood-handling plants, transportation facilities, depreciation charges, depletion and replacements, etc. Accordingly, a well-balanced personnel necessarily includes one or more persons of technical and engineering training, their number depending on the magnitude of the undertaking.

The value of the operator who has had to rely on the hard school of practical experience for all his knowledge should not be underestimated. However, men of higher education and technical training who are willing to apply themselves conscientiously to securing first-hand knowledge of logging methods in actual operations can and do become able woodlands managers and executives within a comparatively short space of time and without the excessive tedium often undergone by those of limited education.

Trend of Forest Utilization in Canada

In the Lumber Industry

While the lumber industry of Canada is of great magnitude, still the average amount produced annually during the last eighteen years has fluctuated up and down rather than showing any steady increase in production, as has occurred in the pulp and paper industry.

The lumber industry reached its peak in 1911 with a production of 4.92 billion F.B.M. In 1908, 3.35 billion F.B.M. were produced and in 1922, 3.14 billion F.B.M., the intervening years coming within the range quoted.

In the Pulp and Paper Industry

Compare with the above figures the consumption of forest products in the Canadian pulp and paper mills:—

In 1908	483,000 cords
In 1915	1,406,000 cords
In 1920	2,777,000 cords
In 1925	3,669,000 cords

This shows an *increase* in consumption of over 650 per cent in the seventeen years mentioned. During the same period the quantity of pulpwood converted into pulp and paper in mills situated in the province of Quebec has increased from 256,000 cords in 1908 to 1,765,000 cords in 1925.

The pulp and paper industry now controls the greater part of the timber lands situated in the eastern provinces. In consequence, pulpwood production and the perpetuation of the forest as a source of adequate supply for future requirements are the main problems in woodlands management in the east to-day.

Note:—Various statistical figures quoted are from the Canada Year Book, and publications of the Forestry Branch, Department of the Interior, Canada.

Transportation in Pulpwood Operations

Some Features Entering into the Transportation of Men and Supplies to Operating Areas and Pulpwood from the Stumps to the Mill

G. E. LaMothe, A.M.E.I.C.
Engineer, Saguenay Division, Woodlands Department, Price Brothers and Company, Limited.

Paper to be presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Quebec, Que., February 15th to 17th, 1927

The pulpwood transportation problems which arise in eastern Canada may be classed under two headings:—(1) Transportation of men, provisions, equipment, etc., to the operating areas; (2) Transportation of the pulpwood from the stump to the mill.

Transportation of Men, Provisions and Equipment

Allowing 4 pounds of food per man and 50 pounds per horse, some 40 pounds of freight are sometimes required for each cord of wood cut, and, with such restless labour as is employed in logging operations to-day, it may be assumed that the labour turnover on 100 cords from stump to mill is approximately 3 men. To take a concrete example, let us assume an operation of which the centre is located at 50 miles from the railway and cutting 225,000 cords to supply a 500-ton-a-day paper mill. The total transport for such an operation would be 9,000,000 pounds of freight and 7,000 men. The cutting season would start in August and finish in March. The drive and river improvement season, starting in late April, would last until November.

Very few companies are so located as to be able to transport all of this by water, and many companies, therefore, are adopting a "good road" policy, using mechanical transport. The capital expenditure of such a policy is large but the maintenance is less, and there are many other advantages, such as:—

(*a*) The lumberjack can be transported to the cutting area in one day, whereas three days are taken by horse transport. In some cases they are paid and given their board while going to the cutting area, and on a labour turnover as shown above the saving with mechanical transport is substantial.

(*b*) It can be conservatively stated that mechanical transport in the woods costs less than half of horse transport.

(*c*) Loss of interest, depreciation and insurance on stocks carried during the previous winter on snow roads is lessened.

(*d*) Forest fires can be much more easily fought when good roads exist, as men can be transported quickly to the scene of the fire. One forest fire quickly stopped will result in a saving sufficient to pay for many miles of road.

The general specifications for these roads include the provision of a wide clearing to help the ditches to receive full benefit of the sun and wind and to give sufficient room to deposit the ploughed snow during winter. The distance between ditches should not be more than 15 feet, and the road proper, generally gravel, not more than 8 feet wide.

The grades should not be more than 10 per cent, so as to use tractors to their full advantage, while the alignment should be as good as possible so as to permit use of one or more trailers. Bridges and culverts should be built of peeled logs, and all other requirements should be in accordance with ordinary highway practice.

In ordinary country, $5,000 a mile will go a long way towards making a good road. With medium tractors, loads of 20,000 to 30,000 pounds in summer and 60,000 to 70,000 pounds in winter can be hauled.

Accommodation and Communication Service

To lodge men and beasts passing along these roads, and also at distributing centres, provision of stopping places must be made.

The usual practice followed in construction camps is employed, i.e., 30 to 40 square feet per man, with ample provision for heating, as most of the transients have been in cold open vehicles all day.

Stabling is a problem in itself, each horse requiring 800 cubic feet of space, one window and 15 square inches of ventilation. The stables also have to be made warm, as they are empty all day.

All buildings are made of sawn lumber, this being an economy over the old style log cabin. To supply this, gas-driven or water-driven portable saw mills are used, equipped with carriage, edger and planer.

Telephones are essential to logging operations, and, except where transmission lines exist, are ground return, with No. 9 wire looped through porcelain knobs attached to the trees. These wires are not very liable to damage if a tree falls on them. The reason why few metallic circuits are used is not only to avoid the comparatively small cost of the pole line, itself carrying the two wires on solid insulators, but also to avoid the more expensive clearing of a right-of-way wide enough to prevent line breakage by falling trees.

Transportation of Pulpwood from the Stump to the Mill

Timber in pulpwood forests in eastern Canada is, as a rule, small and scattered. It is therefore improbable that

Figure No. 1.—A Typical Bridge as Used on Bush Roads.

Figure No. 2.—A Log Jam.

overhead or ground mechanical skidding from the stump to the yarding areas, as practised in the west, will be practicable here for a long time to come. Horses will continue to be used for hauls up to 3 miles.

It is not intended to enter into the details of hauling with horses from the stump to the yards or landings, but rather to deal now with the transportation of the wood from the landings to the mill.

This transportation may be by water, by land, or by a combination of the two.

Transportation of pulpwood by water can be carried out in the following ways, separately or combined:—(1) driving streams and lakes; (2) towing rafts; (3) fluming; (4) barging.

Driving Streams and Lakes

Driving streams and lakes is simply a matter of placing logs in the river and allowing them to float down with the current. Theoretically, driving operations will be cheaper if carried out in low water. The reason is obvious. High water will strand the logs high and dry, and to bring them back into the channel is one of the big expenses of the drive and is called the "sweep." Another axiom is that the longer the log, the more expensive the drive. For this reason, creeks of but two or three square miles' drainage area are driven in four-foot lengths very economically.

River Improvements

In order to attain the ideal of driving, that is, at low water, the stream must be improved. The object of these improvements is to keep the logs floating down in the deepest part of the river channel, and to achieve this the following are necessary:—

Remove from the sides all brush, etc., which would hold up the floating logs.

Remove from the channel all rocks which might stop the logs, care being taken not to remove rocks near the shore which protect the bank from scouring.

Build wing dams, so as to confine all possible water to the main channel and to keep logs out of high water channels and off shoals.

A wing dam is generally built in the form of a rock-filled crib, with a width equal to its height, the minimum being 6 feet. The life of these dams is about ten years, but to increase this on regular driving rivers where foundations of solid rock may be secured, concrete quays have been built. Some experimenting has been done towards using precast reinforced concrete cribs. (See figure No. 3.)

Dams

To facilitate driving, flushes of water are required as a general rule; and to impound water two kinds of dams, storage and flush, are used. In estimating the required storage, a depth of one foot of water over the drainage area gives good results.

Flush dams are generally so located as to permit the relay of water to pass over difficult stretches of river. Frequently long wide dead waters have rapids below them, and to float logs down these a certain depth of water is required. Flush water coming from above takes a long time to fill these dead waters to a point where they will discharge enough to float logs through the stretches referred to; and as logs travel more quickly than water a delay and a loss of water will occur. Flush dams are therefore built to remedy this by relaying the necessary water.

These dams are generally built of wood either as rock- or earth-filled crib dams, or hollow dams with inclined upstream face. The foundations of these dams very often present difficulties, as rock bottom is generally too expensive to reach. The sheeting of the face of the dam is used as a cut-off wall, and is placed in the ground to the required depth, depending on the soil.

As these dams are seldom more than 15 feet high, the cut-off wall is never sunk more than the height of the dam. However, as a further precaution against percolation, the excavation in front of the dam is carried to a width of sometimes two or three times the height of the dam opposite the particular section. The excavated part is then filled with moss and woven balsam branches, over which is placed sand, gravel and clay, which, when well compacted, becomes hard and the coefficient of percolation is therefore increased. The dam, if properly built, will give very good service under these conditions, even with very poor foundations.

Lakes

Generally speaking, lakes are a hindrance to the drive, except for the storage of water. The ice on them thaws later than on the streams and delays progress. When the drive can be operated with the wind they are improved by booming off deep bays and parts covered at high water only.

Figure No. 3.—A Wing Dam with Skeleton Made of Precast Reinforced Concrete Timbers.

Figure No. 4.—Typical Section—Hollow or Beaver Type Driving Dam.

When the prevailing winds do not agree with the direction of the drive it is necessary to resort to towing.

Towing of Rafts

Logs, floating loosely in a floating enclosure, consisting of long pieces of timber joined together with chains and called booms, are towed to their destination by tugs of various kinds. There is no other operation in pulpwood handling in which good or poor equipment will influence the cost as much as in rafting.

Shallow Towing

As it is impossible to use high-powered tugs economically when rafting in shallow bodies of water, warping craft are used.

A drum, around which a mile or so of cable is wound, is geared to the engine of the boat. An anchor is attached to the end of the cable. The tug goes ahead of the raft, drops the anchor, and, paying out the cable, returns to connect up with the raft. By winding up the cable on the drum, both tug and raft are pulled forward to the anchor. This type of craft is economical for shallow bodies of water and for short tows, and is very handy for making up rafts, closing, opening and manoeuvring.

The engines used vary from the Ford marine engine equipped with a small drum or nigger-head and placed in an 18-foot punt to the high-powered 30- to 100-h.p. steam or Diesel engine placed on boats with steel hulls 70 to 80 feet long. On account of the cheapness, this type of craft is sometimes used on deep water long tows, but the cost of operation and the risk are then high, since the time to cover the tow is much greater than in the case of a straight pull, and in high winds the tug is in difficulties, being held down at one end by the raft and at the other end by the cable, so that unless the boat has a lot of free board and is very seaworthy it will have to abandon its tow to seek protection.

The following will give an idea of the performance of this type of boat:—

(1) Tow of 60 miles takes ten days, a 60-h.p. steam warping tug being used; a crew of ten men for day and night; wood used for fuel at the rate of 5 cords per 24 hours. Average tow is 2,500 cords. Lake shallow but offers good protection against wind. Draft 36 inches, punt style 70 by 18 feet.

(2) Tow of 12½ miles taking 24 hours, a 100-h.p. Diesel warping tug being used; a crew of 7 men for day and night; crude oil used at the rate of 4 gallons per hour warping and 6 gallons per hour on the screw. Average tow 1,500 cords. Lake deep and offering no protection from the wind. Draft 4 to 5 feet; length 60 feet.

It may be said that in the second case the boat's raft is limited by the wind, but otherwise it could tow 3,000 cords under same conditions as the first example.

Deep Water Towing

It may be stated, roughly, that wherever a tug can swing a 6-foot propeller the ordinary high-power tug will tow more economically than the warping tug. It is faster, and in high winds it can tow more easily and with less risk.

The following performances will give an idea of the different capacities of this type of tug:—

(1) Tow of 28 miles takes 26 hours; 450-h.p. steam tug being used; crew of 8 men for day and night; bunker oil fuel used at rate of 60 to 70 gallons per hour. Average tow 4,500 cords. No protection from wind, boat and rafts weathering practically any weather. Draft 10 feet, length 105 feet.

(2) Tow of 40 miles takes 60 hours; steam tug about 300-h.p.; coal fuel used at rate of 15 tons for the trip. Average tow 2,000 cords. Good wind protection. Length 90 feet, draft 11 feet.

(3) Tow of 20 miles takes day and night for return trip; 350-h.p. Diesel tug used; crew of 8 men for day and night; fuel oil used at rate of 300 gallons per trip of 24 hours. Average tow 2,000 cords, restricted by narrowness of river; could probably tow 3,000 to 3,500 cords without difficulty under better conditions. Very good wind protection. Draft about 9 feet, length 90 feet.

These figures must be taken with certain restrictions. The efficiencies of the engines were not measured; the above figures being those at which the engines were bought. The range of the different performances is also wide. The figures, however, are sufficiently accurate to show the economy of the Diesel type over the steam engine for this class of work. The former type has also the following advantages over the latter:—

Lighter fuel and engine for the same power, therefore reduction of draft and more space for crew in same sized boats.

The initial cost is about the same in each type.

The main disadvantages of the Diesel type are:—

Difficulty of using power for auxiliary purposes, such as for anchor winches, pumps for water ballast, etc.

Heat for late fall and early spring not available.

A little more difficulty in manoeuvring, as the ranges of speed are not so pronounced as in steam.

One other point brought out by these figures is the small capital cost of the warping tug as compared with the ordinary tug; and the high operating cost of the warping tug compared to the ordinary tug.

Booms

In a towing operation, booms are a very important part of the equipment. They must be large enough to prevent the logs from passing either under or over them while on the tow or in high winds.

The accompanying sketch, (figure No. 5), shows a type of spool boom which gives very good satisfaction at a low cost. The one-strand chain is lighter than the usual belt and the swivel keeps the chain from corking and breaking. It often happens that booms of logs are stranded in a tow, and the swivel will permit the boom to roll over on itself and not break when the boom is in movement. The

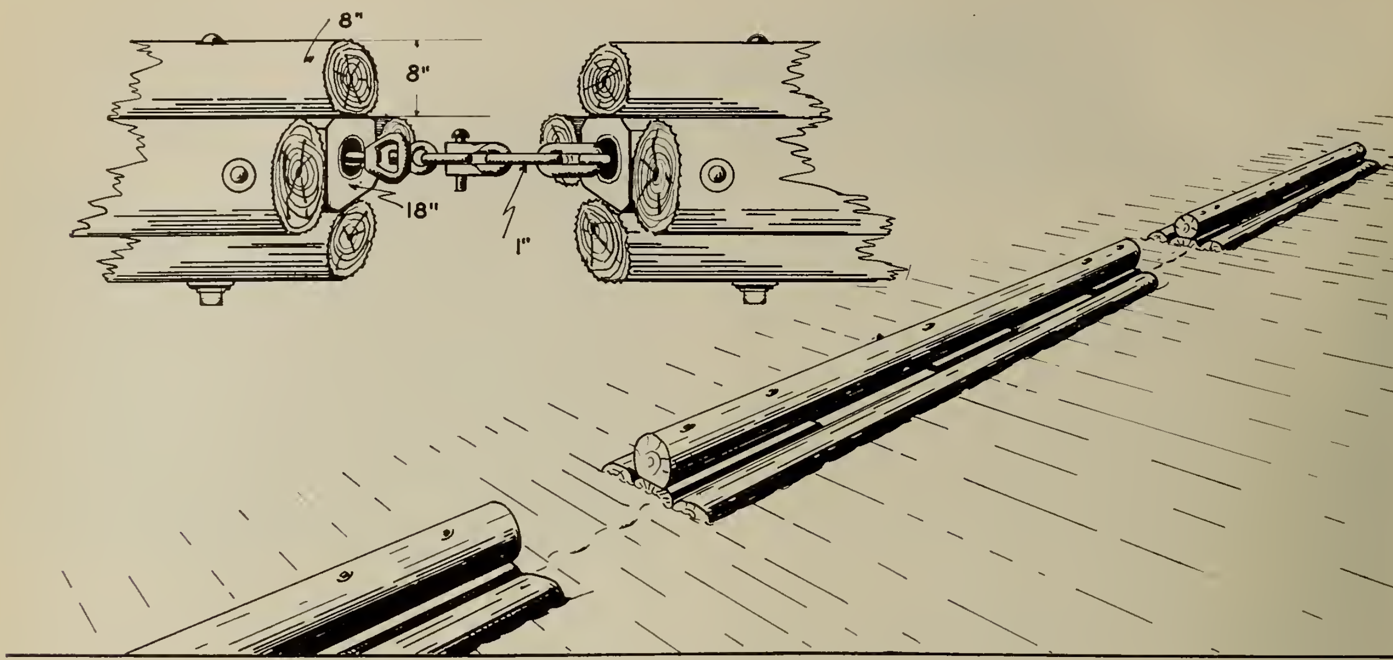

Figure No. 5.—Towing Spool Boom.

wear of the chain on the boom is very slight as compared with the other types, due to the nipple inserted in the end.

It is often required to stop large amounts of pulpwood on large rivers. On account of the big loss involved should failure occur, the holding must be secure.

In choosing a place for holding logs, two kinds of site are generally sought, or a combination of the two. The first, which is generally the cheapest, is a wide deep section of river where the water velocity is low, a boom is then stretched with guys attached to anchors or submerged piers, the booms and guys taking all the strain. Sometimes it is difficult to find such a site, and a shallow site is then chosen. Big piers are built and a boom stretched below the piers. Guys called " top " are placed above the water; and " bottom " guys are placed in the water as in the preceding case.

The logs come down and jam between the boom and the piers, forming a solid mass above the piers. The strain is taken mostly by the piers, and, as the logs sometimes jam to the bottom of the river, the piers are sometimes relieved of some of the strain. The boom is held in place by the top and bottom guys and should not have too great a strain if well stretched and if the piers are properly distributed. In both these cases the site is preferable at a bend in the river. The line of greatest resistance of the boom and piers starts from the apex of the convex side and finishes near the downstream point of tangent on the concave side. In this fashion the concave side takes a part of the strain, and the swifter water on this side has but a short length of boom against which to act. The bulk of the logs strain the boom where there is less current, i.e., near the convex side.

Flumes

Flumes have many practical applications in the pulpwood industry, the principal of which are:—

Transferring logs from one watershed to another, thereby avoiding some expensive operation, such as rafting, railing, etc.

Passing rapids, falls, dams, etc., which is an expensive operation.

Loading barges, etc., for deep sea transportation.

Operation

Their operation is simple and the cost depends greatly on uniformity of grade, reasonable curvature, easy entrance to flume and a good emptying point. More men will be necessary to operate a flume if the various grades and curves accelerate or diminish the velocity of water, and so cause the logs to bunch and jam.

Water and logs are as a general rule admitted into the flume by gravity, although in some cases pumps and jack-ladders are used. The ponds should be large enough to hold a good reserve of logs, as delay is more apt to occur in fluming if the pond has to be continuously refilled from the river above. The intake should be placed in that part of the river where the current has most velocity. This will diminish the crew sluicing and feeding the flume. For the same reason the flume intake should be placed near enough to the ordinary sluice gates to profit by their drawing effect.

If the intake is in an hydro-electric development dam, it should be placed near the penstock intakes, in order to get full possible benefit of the current drawing in this direction. To increase the current velocity, various expedients are resorted to, such as filling the forebay entrance level with the sills or placing semi-floating troughs, with the general idea of diminishing the area of the section and so increasing the velocity to draw logs to the flume intake. Stationary winches, operated by gas engines or some other type of engine, are also used to draw the logs to the flume intake.

The location of the emptying point is also important. The flume should fall into deep running water, otherwise the logs will pile up and block the flume.

Operating Personnel and Flume Capacity

The personnel depends mainly on the quantity of logs to be flumed in a certain time and on the grades and alignment, while the capacity also depends on these factors plus personnel and size of box. The following concrete examples, taken from actual practice, with logs averaging 12 feet in length and 6 inches at small end, will illustrate these points more clearly.

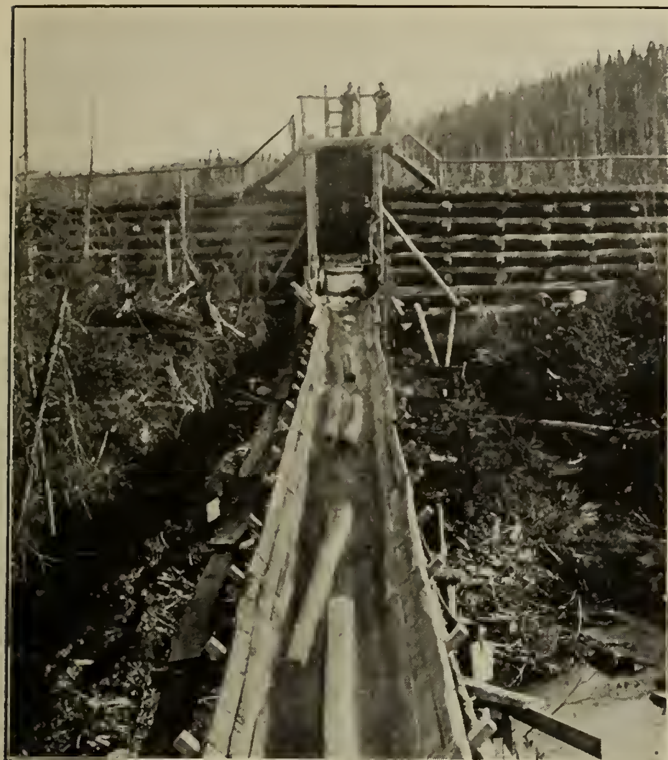

Figure No. 6.—Typical Flume Intake.

No. 1 flume, 11 miles long, practically uniform grade 0.2 per cent; a 48-inch V-box, using about 35 second-feet, with a crew of 50 men, will pass throughout a season an average of 2,000 logs per hour, curves being no hindrance.

The same flume operated with 25 men will pass, on an average, through a season 1,200 logs per hour with less mishaps than with the 50 men passing more logs.

No. 2 flume, 3 miles long, first 1.5 mile with a grade of 0.2 per cent, the remainder varying from 1 to 5 per cent; using about 25 second-feet, passes on an average 1,000 logs per hour with a crew of 12 men. One curve of 28° in the 0.2 per cent grade requires a guardian continually.

No. 3 flume, 2 miles long, with a practically uniform grade of 0.24 per cent; a 40-inch V-box, using about 25 second-feet, with a crew of 20 men, passes on an average 1,600 logs an hour, with bad curves all guarded.

No. 4 flume, 2 miles long, the grade varying from 0.4 to 4 per cent, with frequent changes; a 30-inch V-box, using about 20 second-feet; crew of 11 men, passes, on an average, 1,000 logs per hour; curves no hindrance.

No. 5 flume, 1½ miles long, with a grade average about 11 per cent and maximum 20 per cent; a 28-inch V-box, using about 15 second-feet; a crew of 5 men could pass an average of 2,000 to 3,000 logs per hour without difficulty, but on account of restricted banks at the pond this cannot be attained as an average, but only on trials. The average of this flume is 1,500 logs per hour.

A review of these figures will show that there are no hard and fast rules for the cost of operation of flumes, but that each case must be studied individually, having regard to grade, alignments, water, time allowed and quantity of logs to be flumed. If you have a large number of logs to flume in a short time, your unit cost will probably be higher than if you had the same quantity to flume over a longer period. The length and size of log, of course, influence your price per cord.

Design

The V-section with a 90° angle seems to be the most practical for our bush operations. It is easy to construct; it is generally built by common labour, with very few carpenters; it requires less water to float a log; and it is not apt to jam so much as other types of section.

Grades from 0.2 to 20 per cent have been built and successfully operated by the writer, and there is no doubt that the flatter or steeper grades can be employed provided the hydraulic functions of Kutter's formula $V = c\sqrt{rs}$ are adhered to.

A greater velocity will be obtained in the flat grades by an increase of the quantity of water, or a diminution of the coefficient of friction, but the foundations will have to be good, as the least settling will cause the flume to overflow. The problem in the case of steep grades is to get enough water in the box to prevent the logs wearing it out; and the solution of this problem depends to a large extent upon the amount of money you can afford to spend.

The curve is influenced mainly by the length of log. Sharp curves should not be placed on steep grades or at the foot of such grades. With 12-foot logs 30° curves can be negotiated on slight grades, but in operation these curves will require a guardian.

The quantity of water and the size of box are governed by grades, drainage area available, size of log and the capacity required.

No. 5 flume, described above, has only one square mile of drainage area above it, and is employed during fifteen days each May to pass 150,000 to 200,000 logs without any shortage of water.

Type of Construction

Steel or concrete constructions should not be used for permanent flumes unless very good foundations are available. Jams and consequent overflow of water or breakages are possible on the best of flumes, and the necessary repairs to steel or concrete constructions in such events would cause serious delays. Wood is more suitable in these circum-

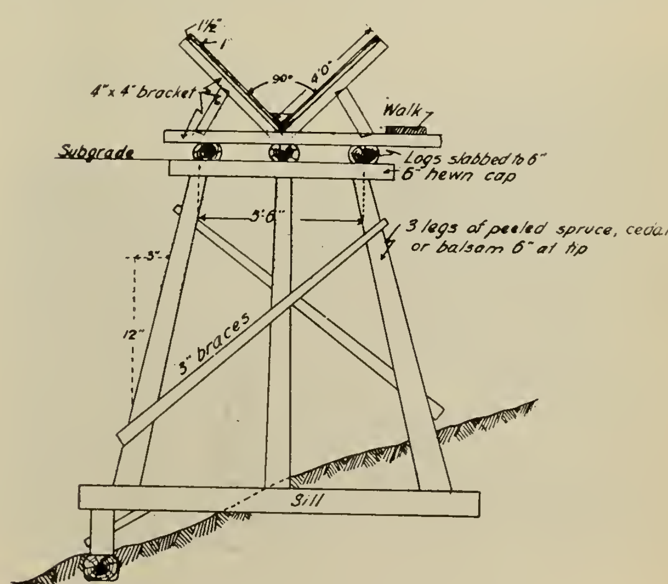

Figure No. 7.—Typical Flume Section.

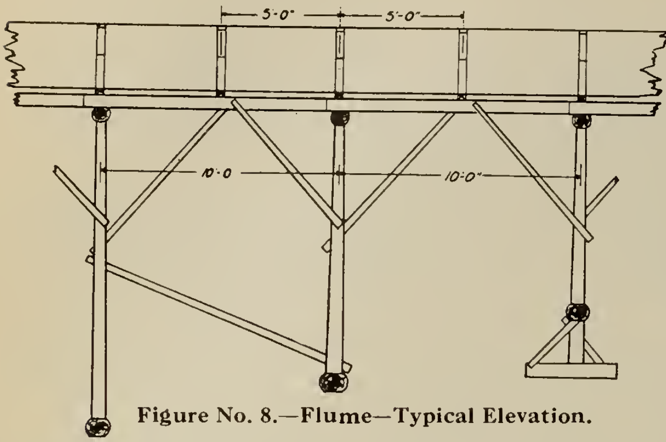

Figure No. 8.—Flume—Typical Elevation.

stances, and substructures of cedar are cheap and last a long time.

The box is of two thicknesses of spruce. The bottom layer should be thick enough to receive the nailing, while the top layer may be inferior 1-inch boards. Top sheeting should be placed at break joint to give more rigidity.

Usual practice is followed with regard to stringers, allowing a good safety factor on account of fatigue.

If for a permanent flume the saddles or brackets should not be less than 4 by 4 feet notched, as they are subjected to great strain when a jam occurs, tending to wedge the box open.

All other details are in accordance with the usual practice in timber construction. Creosoting all joints lengthens the life of the flume, and there is no objection to the use of green timber as water and dirt tightens the joints.

Location and Construction

The operation of the flume is influenced by its location, and many features governing the location of railways apply in the case of flumes. Side hills with soil that is easily washed should be avoided, as an overflow will wash away the foundations.

For a short flume, it is sometimes economical to instal a portable sawmill at the head of the flume and to float the sawn lumber down the flume as the building progresses. For a long flume, it seems more economical to spread out the work and to operate your sawmill at two or three centres, as it is only very rarely that a good road runs parallel to the whole length of the flume. Wire nails can be used freely, in preference to iron. Given handy wood and a gas-driven portable sawmill, the inclusive cost of building, including the lumber from the stump and nails, would be about $40 per 1,000 feet. Only a few carpenters need be employed, the balance being good bush labour.

Flume System

Feeding their Kenogami mill, Messrs. Price Bros. have the following flume system, which is illustrated in figure No. 11.

Logs cut on Valin and Shipshaw, to be used in Kenogami paper mills, would normally have to be driven down the Valin and the Shipshaw, towed to Chicoutimi wharf, loaded on cars and railed to Kenogami. With the flume system shown in figure No. 11, Valin river logs, which are all above the flume intake, are flumed to the Shipshaw and floated down with the Shipshaw logs to another flume intake on the same river, and from there flumed to one of the Kenogami mill slashers.

The system with due consideration for depreciation, etc., operates at about one-half the cost of the usual method, *i.e.* towing and railing, as above mentioned.

Barges

On large bodies of water, such as the St. Lawrence river, where the pulpwood has to be transported over long distances, it is sometimes impracticable to tow in open rafts. The wood is then loaded on to barges or freighters, which have a capacity varying from 40 to 1,500 cords. The pulpwood is cut into 4-foot and 2-foot lengths, and is loaded into the boats by means of a flume or a jackladder. The boats are either towed or travel under their own power to their destinations.

At the destination the wood is unloaded by various means; by hand labour, grapples, conveyors, etc. Some boats have been so designed as to enable them to be partly sunk, the pulpwood cargo then floating off by itself.

Although less risky than towing in open rafts, this method of transportation is more expensive on account of requiring loading equipment and operation, towing and towing equipment, and unloading equipment and operation.

In Sweden certain devices are used which might have application in this country. The pulpwood is loaded into

Figure No. 9.—Typical Scene on a Flume, Showing Guardian and Logs Going Down.

Figure No. 10.—A High Trestle Flume—Subgrade 80 feet above Sills.

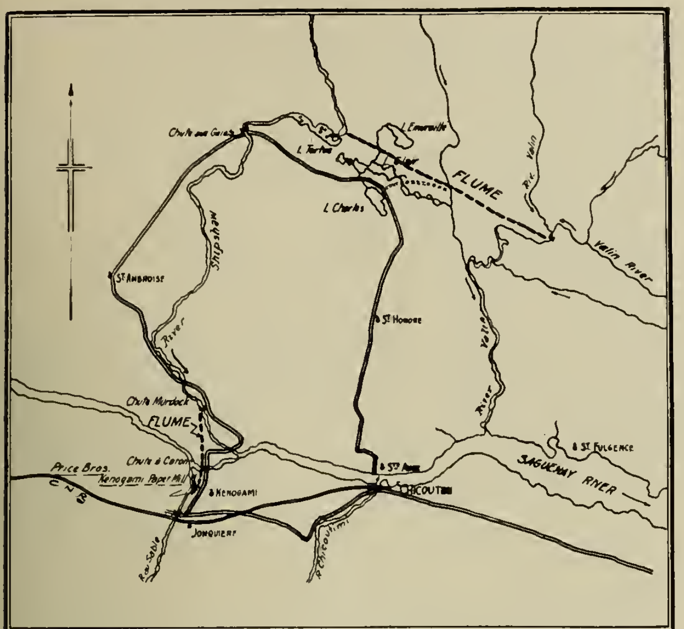

Figure No. 11.—Plan Showing Flume System to Avoid Towing and Railroad Operations.

floating racks, at a much lower cost per cord, both as to capital cost and maintenance, than any type of boat. These racks, of course, tow harder, but on the other hand they can be very easily unloaded when at the mill boom. One side of the rack is so arranged that it can be lowered easily, the rack then pulled forward so that the pulpwood comes out by itself. The author understands that in British Columbia shingle bolts are transported in this same manner.

Land Transportation of Pulpwood

Horse transportation from the stump will not be discussed in this paper, although it can sometimes compete satisfactorily with mechanical transport for hauls up to three or, as is sometimes claimed, five miles. The other methods of land transportation will be outlined under three headings:—by tractor, by railway, by bush railway.

Transportation by Tractor

Under this heading it is intended to consider transportation over snow roads only. These roads should be cut with a right-of-way 30 to 50 feet to allow ample space for the snow when it is removed by the snow plow. The roads should be well stumped and grubbed, and up grades should be avoided as much as possible. The ideal condition is to have a down hill road, even at the expense of distance. They should be kept as free from snow as possible, and generally iced, in order to increase the traction and to give a solid foundation.

The pulpwood, which is piled at the sides of the road, is loaded on to sleighs by jammers, operated by horses or power. The sleighs are made of wood with steel shod runners and are of the ordinary bob sleigh type, as used by horses, except that the timbers are much heavier and 12-foot bunks are usually used. Trains are sometimes made with smaller tractors and hauled to the landing. Extra sets of sleighs are often used to avoid delaying the tractor. At the landing, which must be prepared to receive the logs, the sleighs are unloaded by jammers, operated by a gas or steam engine.

The following performance will give some idea of the work that can be done with a tractor.

A 60-h.p. tractor of the semi-heavy type, weighing 10,000 pounds, with caterpillars on tractor part only and the front on runners; operating for 71 days, which can be considered a maximum for snow roads, even in northern Quebec.

Average length of haul, 5.5 miles.
Average number of trips per day, 3.1.
Miles per day loaded, 17.2.
Average sleighs per load, 3.87.
Average feet per sleigh Quebec scale 2,400 spruce and balsam.
Average feet per load Quebec scale 9,310 spruce and balsam.
Approximate weight of average load 90,000 to 100,000 pounds, in addition to weight of the sleighs.

The tractor was operated with one driver, one trainman and one garage man, and on an average used each day 40 gallons of gasoline and one gallon of motor oil.

Transportation by Railway

Pulpwood is very often transported by railway. Long logs are loaded on flat cars, while the short 2- and 4-foot pieces are loaded in boxed cars with open tops. The capacity of the car depends, of course, on its size. Of the ordinary run of empties furnished by the railway companies, it may be said that for 4-foot wood the capacity is about 16 cords and for 12-foot logs about 10 cords, allowing 500 feet Quebec scale to a cord.

Transporting pulpwood by rail is, of course, a question of weight. If the operation can be arranged so that the logs are not floated to the railway, the pulpwood will be lighter; but, on the other hand, it will be very expensive to bark, as economical barking requires thoroughly wet wood. If the logs have the bark removed and are dried before loading on the cars, the transportation cost will again be lowered; but the expense of equipment and operation will be very high and seldom warranted. In the block pile, moreover, pulpwood does not dry very much.

As a rule, the heaviest pulpwood is that cut in winter and placed in the water in the following spring. The lightest will be that cut in early spring and summer and not placed in water until the spring, or later, of the following year. The latter wood will have a chance to dry, and will be lighter than the former, provided it remains in the water for only a short time.

As there is no hard and fast rule for pulpwood weights, the following figures are given as a guide only:—

Figure No. 12.—A Flume During Construction.
Water-driven saw mill at dam and lumber ready to be flumed to where required.

Figure No. 13.—A Logging Tractor and Part of its Load.

	Spruce and Balsam weight per cord
Bone dry	2,150 pounds
Barked in some block piles	3,330 "
Partially barked by drive, just drawn out of water	3,900 "

The following were weighed in cars:—

Wood cut in winter; driven in May; in salt water for June and July; loaded into boats; unloaded in water and loaded on cars; and weighed almost at once. Average weight per cord was 4,690 pounds. Practically no bark was off. Wood mostly diseased balsam.

Wood cut in May, June and July; driven the following May, drive taking about two weeks; wood conveyed on shore and placed in block pile; loaded through the year from the block pile on to cars and weighed at destination. Average weight per cord was 3,481 pounds. Practically no bark was off the wood, which was mostly sound balsam.

As will be judged, the fluctuation of weights is an important factor in the planning of railway transport.

Short length pulpwood seems to be easiest to handle, but in a large operation special cars, open at the top, are required. Loading and unloading becomes a big item in large operations, if ordinary cars are used, and, in addition to this, box cars are sometimes hard to get if one has a long haul and wishes to fit in with the general traffic.

If the length of the cars is previously known, so that the logs can be cut to fit the cars, the long lengths can be better handled. However, this part of the problem is solved when the operator has his own cars. It will be seen that the problem of economical rail transport is one of reducing cord weights, coupled with the cutting of lengths to fit the cars.

Loading and unloading are separate problems which can be solved by the use of various devices, depending on the conditions under which the work has to be performed.

Railroad transportation of pulpwood may be said to be expensive, and, in most cases, more expensive than water transportation. If the wood is brought direct to the mill from the stump, it also incurs greater expense in barking, unless the wood can be placed in water before being barked. The advantages of this means of transportation are:—

Wood can be brought direct from stump to mill in any season and at very short notice. This reduces inventories and idle capital.

The loss of logs, which occurs during water transportation, is avoided.

Bush Railways

Of the many kinds of bush railways, there is one, of Swedish design, that has not yet been used in Canada, but which seems to merit consideration. It is known as the "Widegren," patented by a consulting engineer of that name in Sweden.

The road bed is built on timber trestles, high enough above ground, say, five feet, to avoid snow trouble. The rails are the stringers, placed to the gauge required and built of logs flattened on two sides for one rail, and on the four sides for the other rail.

The wheels have no flanges, but are broad and cylindrical and equipped with solid rubber tires. They are connected to the axles in the same way as the front wheels of automobiles. To keep the wheels on the rails, one of each pair is equipped with an automatic guiding device, attached to the axle and terminating in flat plates which fit against the flattened sides of the rail. It is for this reason that one rail is flattened on its four sides.

Any type of motive power can be used. The power from the engine can be transmitted through a universal joint shaft to the wheels of one or more of the trailers.

In wooded areas, where heavy transportation is necessary, this type of railway would seem to have the following applications:—

For hauling provisions, cement and material for distant hydro-electric or storage dams.

For transporting pulpwood, equipment and men.

For opening up new mining or agricultural areas, where the cost of a regular railway is not warranted.

Its advantages are:—

(1) All year operation.

(2) Low capital cost if through wooded areas, probably not exceeding $4,000 a mile where logs can be secured for 7 or 8 cents a running foot.

(3) Low operation and maintenance costs; probably less than truck or tractor hauling the same weight.

Its disadvantages for hauling pulpwood are:—

(1) As pulpwood can usually be taken out more cheaply in winter, a winter tractor road hauls as much as the Widegren and costs less, with no appreciable difference in operation.

(2) Owing to the greater difficulty of loading Widegren cars than tractor sleighs, because of the sidings, more mileage of the railway is required per square mile of timber lands than of tractor loads.

It may be said, however, that a Widegren railway would prove economical in transporting logs from one watercourse to another if a flume cannot be operated; and also in the transportation of hardwoods.

An enquiry made, at the request of the author, through The Engineering Institute of Canada to the secretary of the Svenska Teknologforeningen at Stockholm, (a technical society in Sweden), reveals the following:—

The officers of a company using the Widegren railway say that they are satisfied with the system and recommend the same as simple, inexpensive and reliable. The company has built two railroads, one of them being used for five years, both winter and summer. The cars load six to seven tons and the speed of the train can be as high as 25 to 30 kilometres per hour. The motor has 60 h.p. The track after five years is in good state and the solid rubber tires used on the wheels are only insignificantly worn. Snow is stated not to hamper the operation in any noteworthy degree. In conclusion, the company states that special conditions are necessary for the practicability of the road.

Other enquiries have given about the same information.

The Wood Consuming Industries of Canada

With Special Reference to the Pulp and Paper Industry

John Stadler, M.E.I.C.
General Manager, Lake St. John Pulp and Paper Company.

Paper to be presented at the Annual General Professional Meeting of the Engineering Institute of Canada, at Quebec, Que., February 15th to 17th, 1927

Until about fifteen years ago, Canada's forests were considered inexhaustible, and, as a consequence of such an impression, insufficient attention was given to one of Canada's most valuable natural resources and a very large percentage was allowed to be destroyed by fire. Fortunately, times have changed and we now know more about the extent of our forests and have learned to appreciate and protect them.

According to published data on wood consumption in Canada, we find the following:—

THE PRINCIPAL USES

		*Units of Wood used	Value of product in Canada	Relative value per unit of wood used
1.	Lumber and timber in all forms except pulp wood..	1,036,037	$134,378,778	$130
2.	Firewood	866,179	39,366,771	45
3.	Pulp and paper...	388,083	232,032,227	598
4.	Railway ties......	192,459	14,251,450	74
5.	Pulpwood exported	155,639	15,536,058	100
6.	Logs exported.....	63,156	4,855,298	77
7.	**Miscellaneous ..	106,961	9,269,924	87
	Total.........	2,808,514	$449,690,506	——

Analyzing the above tabulation, it will be noted, and it seems rather a coincidence, that the pulpwood which we export gives a relative value of 100 per unit, and that the manufactured lumber gives us a value of 130; hence it would suggest itself that we should make all such pulpwood into lumber as is suitable; but statistics show that the lumber industry has declined in Canada since 1911, and in particular in eastern Canada. It seems rather peculiar that wood made into ties should yield a product of less value than pulpwood, but this is to be accounted for by the fact that woods of lower value are used in the production of ties than are suitable for pulpwood. The lowest value is obtained, as would be expected, from firewood, but the quantity used is amazing. This fact is pointed out as part of this supply might possibly be used for pulp-making purposes by replacing it with other fuels obtainable in Canada. This suggestion is made in order to relieve somewhat the minds of those who have studied the chart prepared by the Royal Commission on Pulpwood, showing that Canada's possible consumption of pulpwood, which chart is reproduced, for reference, as figure No. 1.

Whether or not this chart is correct, we might as well face the situation now; a serious problem will present itself in the near future to supply our requirements of wood for fibre-making purposes.

Although this paper is intended to cover Canada only, the writer is taking the liberty of recommending, for those who may have hopes that large quantities of pulpwood are available in northern countries located closely to Canada, a very careful study of any reports that may exist, for it is well known that the growth and reproduction diminishes as we go north, and in some northern locations soil conditions are such that timber production is out of the question.

It is not the object of this paper to go into resources of wood in Canada, but to bring before you the question of the most profitable and economical use of Canada's wood supply.

From the preceding table, it is shown that converting

* One unit is the equivalent of 1,000 cubic feet of standing timber.

** The item "Miscellaneous" covers seven classifications, such as telephone and telegraph poles, round mining timber, fence posts, wood for distillation, etc.

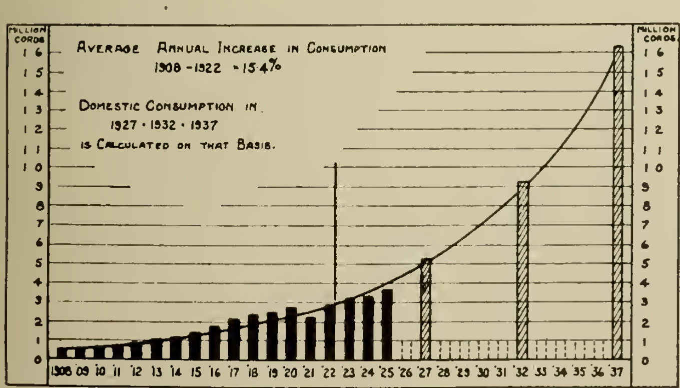

Figure No. 1.—Canada's Possible Consumption of Pulpwood for the Next Fifteen Years, from 1922, with Figures Added for 1923-4-5 Consumption.

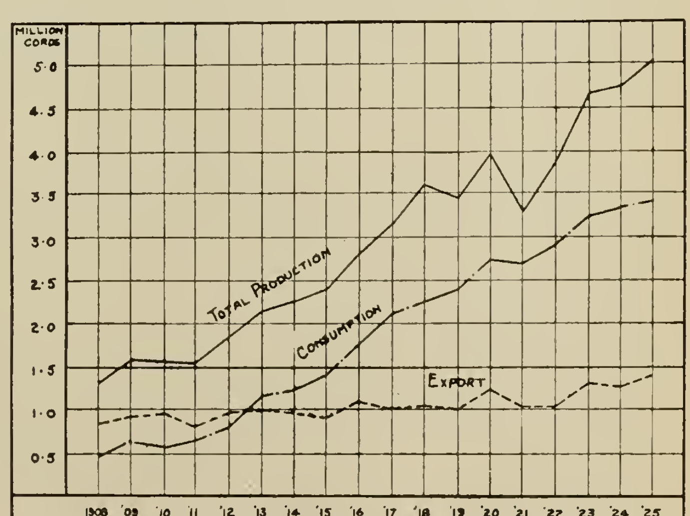

Figure No. 2.—Canadian Pulpwood Production, Manufacture and Export—1908-25.

	CANADA	U S A		CANADA	U S A		CANADA	U S A
1913	350 000	1 305 000	1918	734 783	1 260 285	1923	1 266 000	1 485 000
1914	415 000	1 283 000	1919	794 567	1 374 517	1924	1 352 994	1 470 881
1915	489 000	1 239 000	1920	883 215	1 511 968	1925	1 522 217	1 530 318
1916	608 000	1 315 000	1921	812 787	1 226 183	1926	1 874 021	1 683 600
1917	689 847	1 359 012	1922	1 086 551	1 447 688	1927		

Figure No. 3.—Newsprint Production in Canada and United States.

our wood into pulp and paper gives us eight times as much value as we would get if we used it for railroad ties; naturally, we must keep our railways supplied with ties, but the railway can do with a smaller quantity if all ties are properly treated before being used, and the quantity of wood thus saved can be more profitably utilized.

Someone connected with the paper industry will probably say that such wood as is used for ties and firewood is not suitable for pulp-making purposes. In answer to such a statement, it may be pointed out that less than twenty years ago it was not considered possible to make newsprint with more than 10 per cent balsam, whereas to-day in at least one of the large mills in North America newsprint paper of standard quality is manufactured with over 70 per cent balsam. Needless to say, the more inferior the raw material the more carefully the manufacturing process has to be controlled, but there is no apparent reason why, with adequate research and practical application of information obtained, we should not, within the very near future, utilize commercially such Canadian woods in the manufacture of fibre as are to-day considered unsuitable.

Before it is really necessary to resort to the use of inferior raw material, we could help a good deal in the profitable utilization of our wood by converting most of it into a finished product instead of exporting it in unmanufactured form.

It is pleasing to note, from the chart, (figure No. 2), showing pulpwood production, manufacture and export, that the export of pulpwood has remained relatively constant for a number of years past, and it is hoped that an effort will be made to utilize more wood in our own country so as to bring the curve to its former level.

It must not be overlooked, however, that for conversion, and especially for the manufacture of paper, power in large quantities is required. Where power and wood at reasonable prices are available, in locations which permit easy access to the markets for the finished product, undoubtedly the development for the manufacture of the finished product will continue, and thus our export of raw material will diminish by the creation of a home market for same.

During the recent past, in one of our daily papers has appeared a prominent article that the government of the province of Quebec is taking steps to restrict the construction of new paper mills in Quebec. Considerable attention was given to that article, and those who considered that the construction of paper mills was going on at too rapid a pace approved of it. Others, however, did not share the same opinion. Fortunately, however, a few lines in the papers at a later date contradicted the original article, and everyone appeared happy, but nevertheless there was left an undercurrent which may need rectification.

The engineering profession is much interested in the welfare of the Canadian paper industry, and since the province of Quebec is one of the largest producers of pulp and paper products, and, further, since the writer is more conversant with the natural resources of Quebec, (wood and power), than those of any other province in Canada, it may be appropriate to refer briefly to the article mentioned above.

From observation of the past, the policy of the province of Quebec has been to encourage the development of manufacturing within the province and to discourage the export of raw materials; since our forests contain a large amount of mature crop, it must be harvested, and since we have no desire to export the wood as raw material we must provide further manufacturing facilities.

On the assumption that the government will not restrict the construction of new mills, the further development will then be left as heretofore to the commercial requirements; and, to go a step further, the writer is of the firm belief that no government should financially assist a competitive manufacturing industry in order to have same located within its borders.

The most active development in Canada in the pulp and paper industry has been the manufacture of newsprint paper. This branch has now in Canada a daily capacity of 7,400 tons; this is 1,800 tons more per day than the United States, which until recently was the largest producer of newsprint paper in the world.

The rapid development of the newsprint industry in Canada is attributable to its favourable location to the market, and the continued and relatively steady increase in consumption of newsprint paper is shown by the chart giving production of newsprint in the United States and Canada, which shows an average increase of around 7 per cent over a long period of years.

In the past, the Engineering Institute of Canada probably has not sufficiently realized the large possibilities there

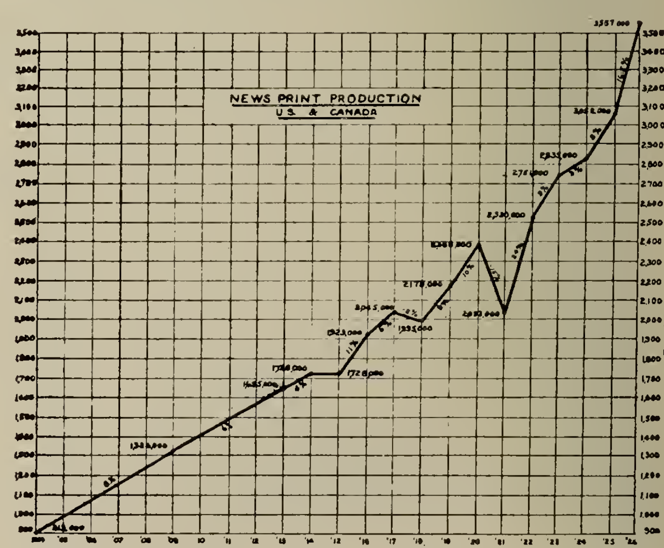

Figure No. 4.—Newsprint Production in Canada and United States.

are for its members in the pulp and paper industry of Canada, and, although some may view the future with apprehension, yet the writer is of the opinion that with some change in our methods of operations the industry will become more prosperous. However, it is essential that, as raw material becomes more expensive and competition more keen, different methods be used, and who is more qualified to develop and introduce more economical methods than the man with a scientific and practical mind, or, in other words, the engineer?

During a conversation some time ago with one of our Canadian paper mill men, who had just returned from Europe, he was very enthusiastic regarding the European methods of manufacture, and especially the economical use of raw material and utilization of by-products.

Permit me to refer to the paper on "Power Consumption in the Manufacture of Newsprint Paper," which was delivered by the writer at the monthly meeting of the Montreal Branch of The Institute held at Montreal on March 5th, 1914. During the discussion of that paper, the writer said:—

> "Paper mill machinery as constructed in Europe is of a higher grade as far as constructive details and finish are concerned, but quite often the machinery is not designed to suit American conditions, and therefore great caution is necessary in the adoption of European machinery."

It is not intended to make any comments on machinery of European origin which has been introduced into Canada since that time; the results are well known to those who are closely associated with the industry; but it will suffice to say that Canada is now producing machinery for the pulp and paper industry equally as good as made anywhere in the world, and, what is still more important, most of the machinery made in Canada is suitable for our conditions.

Our social conditions differ materially from other paper-making countries, and the writter cannot admit that our modern mills are not as economical as those located anywhere else. We produce more per man-hour, and as far as newsprint is concerned make the best and most uniform product. It is true we are not recovering by-products to the extent we should, but this is largely due to local conditions. We would have no market for such by-products as can be disposed of at a profit in Europe.

Manufacturing is largely a matter of transportation. This applies from the initial handling of the raw material through the entire manufacturing process up to the production of the finished article and its delivery; and in this we must endeavour to obtain the best results by the adoption of simple methods which require the minimum of effort, are reasonably low in first cost, and, above all, low in maintenance.

In converting our wood into fibre, whether it is done by mechanical or chemical means, we must give consideration to quality and yield of the grade of fibre which produces the best finished product. We must not measure power used in producing mechanical pulp, or chemicals used in making cellulose on the basis of wood consumed, but on the unit of acceptable fibre produced.

We may and must study processes and methods of other countries, but we cannot adopt them wholesale, as our own requirements differ for almost each individual plant. Engineers and chemists should combine more closely in the paper industry to produce the quickest, most practical and economical solution of our problems, of which there are still many.

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME X FEBRUARY 1927 No. 2

The Problem of the Young Engineer

The Annual General Meeting of a body like the Engineering Institute of Canada, affording, as it does, a common meeting ground for engineers of all branches of the profession from all parts of the country, gives a favourable opportunity for discussing The Institute's policies and questions of the day, and reference to the programme printed elsewhere in this issue will show that time has been set apart for this purpose during the morning and afternoon sessions of the opening day of the forthcoming meeting in Quebec.

As a live question which might well occupy the attention of members at this time, the problem of the young graduate has been suggested. Much has been written, and much discussion has taken place, on the vast subject of engineering education; but the educational period of the young engineer is usually thought of as terminating when he takes his degree at the university. The fact is not always recognized that at this stage he is just beginning the most important period of his training, that he is entering the hard school of experience, and that his further development will depend very largely on the treatment he receives and the opportunities afforded to him during the first years of his employment in practical work.

It is not sufficient for the young graduate merely to succeed in obtaining some kind of employment, more or less remunerative; in his best interests, his duties should be such as to give him opportunity for useful experience and for development in the art of dealing not only with materials but also with men.

During the past year, on the proposal of Professor H. E. T. Haultain, M.E.I.C., this matter has received the attention of Council, and a brief communication regarding it is printed among the reports of the various committees to Council. So far as investigation has gone, it has shown very definitely that while engineering graduates are needed in every department of construction, production and distribution, they have much to learn on leaving the university, and are not necessarily fitted to perform in the most effective manner the work assigned to them by their first employers. This is no reproach to the graduates or engineering schools of the universities, whose province it is to lay the foundation of their students' training, a training which is continued after leaving the university by years of experience; the task of moulding the still plastic material to its most efficient form must therefore lie very largely in the hands of the employers themselves.

This gives rise to several questions; for instance, what is the attitude of the average Canadian employer towards the technical graduate? What does he do towards developing young graduates with a view of obtaining the supply of competent men necessary for his future requirements? What opportunities for further training and development does the young engineering graduate get on his entry into industrial life? Is there anything that the graduates themselves can do to help in this matter? Finally, what are the duties and powers of a body like the Engineering Institute of Canada in this connection?

The problem of the further training and development of the young technical graduate is at least as difficult as that which confronts the engineering schools of the universities, but whereas his college education has for many years received intensive study at the hands of university faculties and committees, and such bodies as the Society for the Promotion of Engineering Education, there appears to have been comparatively little organized study or investigation directed towards the difficulties of his post graduate career.

It is true that in many cases the university authorities have taken action locally to interest employers, and attention has been given to the question by branches of The Institute and by certain of the Provincial Associations of Professional Engineers, for example, in British Columbia and in Ontario. In the latter province, a very interesting attempt is now being made to bring about collective action in this matter, and to provide funds for the commencement of a campaign designed to interest the manufacturer, industrialist and prospective employer in the young technically-trained men who are being provided by the engineering schools of the province.

The importance of the subject warrants a far more general activity and interest than has so far been displayed. We are accustomed to lay stress, and rightly so, on the part played by the engineer in the development of our country, but do not think so often of the necessity of a supply of properly trained, resoureeful and experienced engineers for this work in the future.

As a first step, and as regards The Institute itself, should we not initiate discussion on this subject, first in the Annual General Meeting, and later at branch meetings throughout the country? To aid in a correct understanding of the problem, information and data will have to be studied, not only as to the attitude of the employers of the young engineers, but also as to the activities of the engineering schools in following up their graduates' careers.

A frank discussion and statement of members' opinions on this important question might well form part of the proceedings of the 1927 Annual General Meeting.

Forty-first Annual General and General Professional Meeting

Quebec City, February 15th, 16th and 17th, 1927. — Headquarters: Chateau Frontenac.

The Annual Meeting which was convened at Headquarters in Montreal on January 27th, 1927, was adjourned to reconvene at the Chateau Frontenac, Quebec City, on Tuesday, February 15th, 1927, with sessions of the Professional Meeting continuing on the two succeeding days.

The committee of the Quebec Branch, under whose auspices this meeting is being held, have done everything possible to assure the success of the meeting and a very elaborate and intensely interesting programme has been provided. A copy of the tentative programme was published on page 42 of the January issue of the Journal.

The papers to be presented at the Technical Sessions are being printed in advance, and copies are being sent to prominent engineers throughout Canada, with the result that the discussion on each of these papers will, undoubtedly, be very interesting and instructive.

Four of these papers were published in the January issue of the Journal, as follows:—"Alternating Current Electrolysis," by J. W. Shipley and Chas. F. Goodeve; "Rack Structure and Penstock Intake of the Isle Maligne Hydro-Electric Power Station," by W. S. Lee, M.E.I.C.; "Electrical Characteristics of the Quebec-Isle Maligne Transmission Line," by Clarence V. Christie, M.E.I.C., and "Water Power Developments of the Alouette-Stave-Ruskin Group of the B.C. Electric Railway Company," by E. E. Carpenter, M.E.I.C.

In the present issue of the Journal, six more of the papers are published, two dealing with the mining industry in the provinces of Ontario and Quebec and four treating of various phases of forestry. The three remaining papers scheduled to be presented are:—"Building an Industrial Plant in the Saguenay District," by John L. Guest; "Developments of the Gatineau Power Company on the Gatineau River," by J. A. McCrory, M.E.I.C., and "Protection Against Seepage at Lake Kenogami," by O. O. Lefebvre, M.E.I.C.

It will be seen from the above that the Technical Sessions have much of interest, particularly as there will be ample time for a full discussion of each paper, since the papers will be presented in abstract only.

Provision has been made throughout the programme for visits to points of interest, and included in the social events are Luncheons, the Annual Dinner, a Smoker and a Supper-dance and Bridge, with special entertainment for the visiting ladies.

Railway and Hotel Arrangements

An announcement appears on Page 58 of the January Journal regarding the special transportation arrangement and hotel rates, and a similar notice was mailed to all members of The Institute. Those expecting to attend the meeting should communicate with their Branch Secretary as soon as possible in order that transportation arrangements may be made.

Programme Revised to Date

Tuesday, February 15th.

9.00 a.m. Registration.

10.00 a.m. Reception and discussion of reports from Council, Committees and Branches. Scrutineers' report and election of officers. Retiring President's address. Induction of new President.

1.00 p.m. Lunch—complimentary to visitors. Welcome to members by Chairman of the Quebec Branch, who will preside. Brief address by the Mayor of Quebec.

1.00 p.m. Lunch for ladies.

3.00 p.m. Continuation of Annual General Meeting—unfinished and new business.

8.30 p.m. Smoker or special entertainment. (Admission by ticket.)

9.00 p.m. Theatre party for ladies.

Wednesday, February 16th.

10.00 a.m. First technical session.

Brief introductory address by the Hon. H. Mercier, Minister of Lands and Forests, Province of Quebec.

A—(Jacques Cartier Room)

Notes on the Forests of Quebec—G. C. Piché, A.M.E.I.C. Deals with questions of forest administration.

The Wood Consuming Industries of Canada—John Stadler, M.E.I.C. Has special reference to pulp and paper manufacture.

(Wednesday morning session, continued)

Woodlands Management and Operation—S. L. de Carteret, M.E.I.C.

Transportation in Pulpwood Operations—G. E. La Mothe, A.M.E.I.C. Outlines modern methods of handling wood from the forest to the mill.

B—(Private Dining Rooms 3-4-5)

Electrical Characteristics of Quebec-Isle Maligne Transmission Line — Professor C. V. Christie, M.E.I.C. Deals with the most recent large transmission line in Eastern Canada.

Alternating Current Electrolysis — Professor J. W. Shipley. Further experimental work in this interesting field.

Building an Industrial Plant in the Saguenay District—John L. Guest, A.M.E.I.C. Covers the construction problems encountered in building the works of the Aluminum Company of Canada at Arvida, Que.

Protection Against Seepage at Lake Kenogami—O. O. Lefebvre, M.E.I.C. The methods adopted to cope with a difficult situation.

2.00 p.m. Visit to Quebec Bridge or St. Malo Shops.

7.30 p.m. Annual Dinner of Institute. (Admission by ticket.) President in the Chair. Addresses by Sir Henry Thornton, M.E.I.C., and other prominent speakers.

7.30 p.m. Dinner for ladies.

(Programme continued on next page)

Thursday, February 17th.

10.00 a.m. Second technical session.
(Jacques Cartier Room)

Design and Construction Features of Rack Structure and Penstock Intake for Isle Maligne Station of Duke-Price Power Company, Limited, on Saguenay River, Province of Quebec, Canada—W. S. Lee, M.E.I.C. Data regarding a vital portion of this important development.

The Water Power Developments of the Alouette-Stave-Ruskin Group—E. E. Carpenter, M.E.I.C. Describes an interesting group of hydro-electric plants in British Columbia.

Developments of the Gatineau Power Company on the Gatineau River—J. A. McCrory, M.E.I.C. Data regarding the three installations at Farmers, Chelsea and Paugan, with notes on some special features of design.

2.00 p.m. Third technical session.

Brief introductory address by the Hon. J. E. Perrault, Minister of Colonization, Mines and Fisheries, Province of Quebec.

Notes on the Ore Deposits of Western Quebec—Theo C. Denis. Deals with the geological relations of the new goldfields.

The Metal Mining Industry of Northern Ontario—W. R. Rogers, A.M.E.I.C.

Discussion of papers previously presented.

5 p.m. to 7 p.m. Ladies will be entertained at tea.

8.30 p.m. Supper-dance and Bridge in Ball Room. (Admission by ticket.)

Meeting of Council

Meeting of January 18th, 1927

A meeting of Council was held at eight p.m. on Tuesday, January 18th, 1927, Vice-President K. B. Thornton, M.E.I.C., in the chair and four members of Council being present.

The draft report of Council for the year 1926 and the annual reports of the various committees of The Institute were considered and approved.

The reports of the various branches were received and approved for presentation at the Annual Meeting.

The list of representatives of the various branches on the Nominating Committee for the year 1927 was noted and approved.

A report from the Legislation and By-laws Committee on the proposed by-laws for the Winnipeg Branch was submitted and approved.

The list of officers of the Victoria Branch for the year 1927 was submitted and approved.

The secretary reported that in accordance with the directions of a previous meeting of Council a letter had been addressed to Mr. F. B. Brown, secretary of the Corporation of Professional Engineers of the province of Quebec, requesting him to communicate with the governing bodies of the various provincial associations of Professional Engineers, with a view of initiating discussion as to the best method to be adopted to bring about substantial uniformity in the requirements for admission by examination to the several provincial associations and to The Institute; that Council's request would be complied with.

Mr. C. A. Price, assistant chief engineer of the Canadian Westinghouse Company, Limited, Hamilton, was appointed a member of the Canadian National Committee of the International Electrotechnical Commission.

Ten special cases were given consideration; three requests for reinstatement were considered and approved, and thirty resignations were accepted.

The following elections and transfers were effected:—

Elections		Transfers	
Member	1	Associate Member to Member	4
Associate Member	1	Junior to Associate Member	2
Juniors	2	Student to Associate Member	4
Students	5	Student to Junior	1

Sixteen applications for admission and transfer were scrutinized and classified for the ballot returnable March 21st, 1927.

Ten special cases were considered in connection with applications for admission.

The Council rose at ten-thirty o'clock p.m.

Publications of Other Engineering Societies

As previously announced in the Journal, an exchange arrangement exists between the Engineering Institute of Canada and the American Institute of Electrical Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Civil Engineers and the American Society of Mechanical Engineers.

Subscriptions may be sent either directly to New York or through Headquarters. The following list of rates gives in the first column the amounts payable by members of the Engineering Institute for the various publications:—

	Rate to Members	Rate to Non-Members
American Institute of Electrical Engineers		
Journal, single copies	$0.50	$ 1.00
" per year	5.50	10.50
Transactions, per year, paper	5.00	10.00
" " " cloth	5.00	10.00
Year Book	1.00	2.00
Pamphlets	.25	.50
American Institute of Mining and Metallurgical Engineers		
Magazine, single copies	0.50	1.00
" per year	5.00	10.00
Transactions, per volume, with pamphlets, paper	2.50	5.00
(Other publications, same rate E.I.C. members as to A.I.M.M.E. members.)		
American Society of Civil Engineers		
Proceedings, single copies	0.50	1.00
" per year	4.00	8.00*

American Society of Mechanical Engineers		
Journal, single copies	0.50	0.60
" per year	4.00	5.00
Transactions, per year	6.00	8.00
Year Book	1.00	2.00
(Other publications, same rate to E.I.C. members as to A.S.M.E. members.)		

**If subscription is received before January 1st, otherwise $10.00.*

†If received before February 1st, otherwise price $16.00.

OBITUARIES

William Russell Russell, M.E.I.C.

In the death of William Russell Russell, M.E.I.C., which occurred at Quebec, Que., on October 5th, 1926, the civil engineering profession in Canada has lost one of its widely known and highly esteemed members.

The late Mr. Russell was a native of Peterborough, Ont., where he was born on February 16th, 1859. His early education was received at the public schools of Kirkfield and Toronto and at the Toronto Model School. He was later an articled pupil of the late Mr. John C. Bailey, civil engineer of Toronto.

With the exception of four years, from 1904-08, when he was in Arizona, his entire engineering work has been in connection with railway construction, operation and maintenance. As early as 1879 he was assistant engineer on what was then known as the Victoria Railway, and between that time and 1883 he occupied the same position with the Credit Valley Railway and Midland Railway, all of which were in the province of Ontario. In 1883 he was appointed to the same position with the Quebec and Lake St. John Railway and six years later was made chief engineer and general superintendent of the Quebec, Montmorency and Charlevoix Railway. In 1901 he became general superintendent of the Great Northern Railway of Canada, later the Canadian Northern Railway, and three years later was engaged in the construction of the Ottawa and Gatineau Valley Railway. From 1904 to 1908 he was located in Arizona as chief engineer and general superintendent in connection with a number of mining companies in that country. Returning to Canada in 1908, he became engaged as divisional engineer on the National Transcontinental Railway. At the time of his death he was a member of the engineering staff of the Quebec Harbour Commission.

The late Mr. Russell joined The Institute in the first year of its incorporation, being elected Member on October 6th, 1887. Subsequently he discontinued his membership and was re-elected Member on April 9th, 1910.

Eric Charles Hutchinson, A.M.E.I.C.

It is with regret that we record the death of Eric Charles Hutchinson, A.M.E.I.C., which occurred at Ottawa, Ont., on December 17th, 1926, following a short sickness from typhoid fever.

At the time of his death, Mr. Hutchinson was on the staff of the Fraser-Brace Engineering Company, Limited, and had been engaged in connection with the power development on the Gatineau river.

The late Mr. Hutchinson was born at Vevey, Switzerland, on October 11th, 1896, and was a graduate in civil engineering of Ecole Polytechnique Fedorale Suisse, Zurich, of the year 1920, and coming to Canada he became connected with the Duke Price Power Company in August, 1924, in a junior engineering capacity, and in October of the same year joined the staff of the Wm. I. Bishop Limited, in connection with the construction of the Riverbend mill for Price Brothers and Company, Limited. In October, 1925, he entered the employ of the Fraser-Brace Engineering Company, Limited, as designing engineer on the Chelsea power development, subsequently becoming chief of an engineering party on the Farmers development of the Gatineau Power Company with the Fraser-Brace Engineering Company, Limited.

The late Mr. Hutchinson was elected Associate Member of The Institute on June 15th, 1926.

Heber William Dawson, A.M.E.I.C.

Sincere regret is expressed at the death of Heber William Dawson, A.M.E.I.C., which occurred at Ste. Anne de Bellevue hospital, Ste. Anne de Bellevue, Que., on January 4th, 1927.

Mr. Dawson was born in Montreal on December 6th, 1892, and was the son of Dr. W. Bell Dawson, M.E.I.C., of Ottawa. He received his early education at Trinity College school, Port Hope, and the Ottawa Collegiate Institute, and entered the engineering course at McGill University in 1911, but owing to the War he did not complete his course until after his return from overseas, receiving his degree of B.Sc. in 1920.

Shortly after the outbreak of war he proceeded overseas with the Canadian Engineers as lieutenant and due to

HEBER WILLIAM DAWSON, A.M.E.I.C.

his knowledge of wireless telegraphy he was attached to the Signal Corps.

Throughout the war he was with the Canadian Expeditionary Force in the Somme and Armentieres regions, and attained the rank of captain. On his return to civilian life, he joined the engineering staff of the Shawinigan Engineering Company, Limited, in May, 1920, and was still connected with that company at the time of his death. During that time he was engaged on electrical design in connection with some of the most important developments, among which were the 41,000-h.p. unit installed at Shawinigan Falls, the Great Falls development of the Manitoba Power Company, the La Gabelle development of the St. Maurice Power Company and the St. Narcisse development of the North Shore Power Company.

While the late Mr. Dawson had not been in good health for some two months prior to his death, the news of his death came as a great shock to his many friends both in the profession and private life. He was an active member of the Engineering Institute of Canada, having been elected Student on December 21st, 1920, and transferred to Associate Member on June 15th, 1926.

PERSONALS

E. Gray-Donald, S.E.I.C., who graduated from McGill University in 1926, is at present with the Quebec Power Company and is located in Quebec city.

C. R. Davis, S.E.I.C., who graduated from the University of Toronto in 1923, has accepted a position with the Massey-Harris Company, Limited, in Toronto, Ont.

H. W. Perkins, A.M.E.I.C., is resident engineer with the State of Minnesota, Department of Highways, and has been transferred from Ada to Detroit Lakes, Minnesota.

J. M. Campbell, S.E.I.C., of Vancouver, B.C., who has recently completed the graduate students' course with the Westinghouse Electric and Manufacturing Company, has accepted the position as assistant district manager with the Central Mexico Light and Power Company at Irapuato.

F. H. Job, Jr.E.I.C., formerly with the Koppers Construction Company at Pittsburgh, Pa., has resigned to accept a position with the Blaw Knox Company, Blawknox, Pa. Mr. Job was on the staff of the Hamilton Bridge Works Company, Limited, for a number of years prior to going to Pittsburgh.

Alphonse Bleau, S.E.I.C., has been appointed instructor in chemistry and French at the Royal Military College of Canada, Kingston, Ont. Mr. Bleau received his degree of B.Sc. from McGill University in 1923, and was for a time engaged in building construction, following which he was inspector of construction for the Montreal Water Board.

Lt.-Col. W. G. Tyrrell, M.E.I.C., is proceeding to Bombay, India, where he has been appointed in command of the Royal Engineers, his address being C.R.E. Office, Bombay, India. Colonel Tyrrell served with distinction through the great war with the Railway Branch of the Royal Engineers, and in addition to receiving the D.S.O., was mentioned twice in despatches. Col. Tyrrell was born at Port Rowan, Ont., on June 6th, 1882.

J. Henri Valiquette, A.M.E.I.C., city manager of Shawinigan Falls, Que., has resigned to accept the position of assistant to the managing director of the Anticosti Corporation. Mr. Valiquette is a graduate of Ecole Polytechnique, from which he received the degree of B.A.Sc. in 1907. Prior to his appointment as city manager of Shawinigan Falls in 1920, he was assistant engineer in charge of the Department of Surveys and Design of the city of Montreal.

D. E. O'Brien, M.E.I.C., senior assistant engineer in charge of section 2 of Welland ship canal, has been transferred to section 6 at Welland, Ont., in the same capacity. Mr. O'Brien is a graduate of the University of Toronto of the year 1905 and first joined the staff of the Welland ship canal in 1913, where for five years he was assistant engineer on section 2. In 1918 he became chief engineer of the Halifax Ship Yards at Halifax, N.S., where he remained until 1921, when he was appointed to the position which he now holds.

Edgar V. Gilbert, Jr.E.I.C., who has for some time been located at Hemming's Falls, Que., on the engineering staff in connection with the hydro-electric power development of the Southern Canada Power Company, Limited, has moved to Maniwaki, where he is with the Foundation Company of Canada, Limited, on the construction work which that company is doing on the development of the Gatineau river for the International Paper Company. Mr. Gilbert graduated in civil engineering from McGill University in 1923 and following graduation was for one year with the Robert W. Hunt and Company in Montreal.

J. H. Summerskill, A.M.E.I.C., is at present on the engineering staff under the director of engineering of the B. F. Goodrich Company at Akron, Ohio. Prior to accepting this position, Mr. Summerskill was connected with the E. G. Woolfolk Company of New York city, with which company he was associated with D. D. Kimball, heating and ventilating engineer, representing the former in Columbus, Ohio. Mr. Summerskill is a graduate of McGill University, having received his degree in electrical engineering in 1914 and in mechanical engineering in 1915, and was for a number of years with the Riordon Company, Limited, first in Mattawa and later at the head office in Montreal.

C. B. R. Macdonald, A.M.E.I.C., has written advising he is moving from Peru to Brazil and that his future address will be c/o San Paulo Railway Survey, Caixa "C," Sao Paulo, Brazil. Mr. Macdonald was engaged on the construction of a narrow gauge railway at Lobitos in the northern part of Peru, and on the completion of that work in July last, he was moved to Arequipa, Peru, on the location survey of a branch of the existing Southern Railway of Peru to the Borax deposits of the Borax Consolidated. His new work in Brazil will be in connection with railways. Mr. Macdonald received his diploma with honours from the Royal Military College of Canada in 1914, and after serving overseas he returned to Canada and was engaged on construction work at Niagara Falls, Ont., for the Hydro-Electric Power Commission of Ontario.

Vice-President of Ontario Professional Engineers

Lt.-Col. A. D. Le Pan, A.M.E.I.C., superintendent, University of Toronto, has been elected vice-president of the Association of Professional Engineers of Ontario.

Col. Le Pan is a native of Owen Sound, Ont., and is a graduate of the University of Toronto, from which he received the degree of B.A.Sc. in 1908. His first work after graduation was as assistant on the filtration plant and reservoir for the town of Owen Sound. Subsequently he was engaged on various works at the University of Toronto. He was appointed assistant superintendent of the university in 1910; general superintendent in 1915; and superintendent in 1920, which latter position he still holds.

President of Professional Engineers of Ontario

A. B. Cooper, M.E.I.C., general manager, Ferranti Electric, Limited, Toronto, has been elected president of the Association of Professional Engineers of Ontario.

Mr. Cooper is a graduate of Tufts College, from which he received the degree of B.S. in electrical engineering in 1903. Following graduation he spent two years with the General Electric Company at Schenectady, N.Y., in the testing department, and two years with the Westinghouse Electric and Manufacturing Company, Pittsburgh, Pa. In 1907 he was appointed assistant electrical engineer in charge of power house electrical construction with the Rio de Janeiro Light and Power Company, and in 1909 he was appointed engineer of the transformer sales department of the General Electric Company at Schenectady, N.Y. In 1913 he moved to Toronto as transformer engineer with the Canadian General Electric Company, which position he held until joining the Ferranti Electric, Limited, formerly the Ferranti Meter and Transformer Manufacturing Company.

J. E. Underwood, A.M.E.I.C., Elected Alderman

J. E. Underwood, A.M.E.I.C., of J. E. Underwood and Associate Engineers, Saskatoon, Sask., has recently been elected alderman of the city of Saskatoon. Mr. Underwood's decision to enter the political arena is said to have been the result of his having attended a meeting of the local branch of The Institute, at which President Geo. A. Walkem, M.E.I.C., addressed the members and dealt at some length with the necessity of having engineers take a more prominent part in municipal, provincial and federal affairs.

In this election, which was keenly contested, Mr. Underwood, who was practically unknown to the general public, headed the poll, and in a letter to President Walkem, Dean C. J. Mackenzie, M.E.I.C., of the University of Saskatchewan, says that during the campaign he was amazed at the evidence of esteem with which the engineer is regarded by the general public, and quotes numerous people as having said, "I don't know who this man Underwood is, but if he is a successful engineer he certainly will be a more valuable man on our council than most of those other candidates."

Mr. Underwood was born at Wroxeter, Ont., on November 3rd, 1882. He received his primary education at the high school in Hamilton and later graduated from the Faculty of Applied Science of the University of Toronto. Following graduation he was engaged on survey work for a number of years and was commissioned a Dominion Land Surveyor.

A. T. Spencer, A.M.E.I.C., joins Montreal Tramways

A. T. Spencer, A.M.E.I.C., has been appointed general superintendent of construction and maintenance for the Montreal Tramways Company. Previous to his present appointment he was assistant to the general manager of the Toronto Transportation Commission, of Toronto.

He was born at Port Morien, N.S., on February 18th, 1876, and received his primary and technical education in that province. He commenced his engineering work in 1901 with the Dominion Coal Company and the Sydney and Louisburg Railway, Glace Bay, N.S., in various capacities in connection with surveys, construction and mining work for these companies. From 1905 to 1907 he was transitman and chief of party for the Canadian Pacific Railway on grade revision surveys in New Brunswick, Quebec and Ontario.

In 1907 he joined the Montreal Park and Island Railway as special engineer in charge of surveys, and later the construction of certain suburban electric railway extensions. From the following year he was assistant engineer with the Montreal Street Railway and its successor the Montreal Tramways Company in the way and structures department until February 1921, when he joined the staff of the Railway Department of the Hydro-Electric Power Commission of Ontario as assistant engineer. In May of the same year he was appointed engineer of way for the Toronto Transportation Commission, and was in charge of the extensive rehabilitation and extension programme of trackwork done on the Toronto system from 1921 to 1923, and from April 1924 until accepting his present appointment he held this position from which he has recently resigned.

Brig.-General C. H. Mitchell heads Toronto Board of Trade

Brig.-General C. H. Mitchell, C.B., C.M.G., D.S.O., C.E., LL.D., D.Eng., M.E.I.C., Dean of the Faculty of Applied Science, University of Toronto, and consulting engineer, was recently elected by acclamation to the presidency of the Toronto Board of Trade. The Toronto Board of Trade, which at present has a membership of 3,000, has been in existence for eighty years. The election of General Mitchell to the presidency marks the first occasion on which the Board has chosen an engineer for its highest office.

General Mitchell was born at Petrolia, Ont., on February 18th, 1872. He graduated from the University of Toronto with the degree of B.A.Sc. in 1892, and received his degree of C.E. from the same university in 1898, and the honorary degrees of LL.D. (Tor.) in 1919, and D.Eng., (N.Y.) in 1922.

His engineering practice has been largely in hydraulic and hydro-electric power work and in addition to being retained as consulting engineer in design and construction of plants in various provinces in Canada and in an advisory capacity by the federal government, he has been engaged as arbitrator and expert witness in various technical and legal cases and as consultant in industrial and development undertakings. He was appointed dean of the Faculty of Applied Science of the University of Toronto in July, 1919. In 1920 he was appointed by the government of Ontario on the Royal Commission to report on the radial railways. In 1924 he was appointed by the Dominion Government on the Joint Board of Engineers to study and report on the St. Lawrence waterway project.

General Mitchell is a member and has had the office of president and vice-president in a large number of clubs

BRIG.-GENERAL C. H. MITCHELL, M.E.I.C.

and societies. He served as councillor on the Council of The Institute during the years 1908-1909 and as vice-president from 1920-1923 inclusive.

W. Nelson Smith, M.E.I.C., engaged on Valuation in Philadelphia

W. Nelson Smith, M.E.I.C., who for more than eight years has been actively engaged in engineering work in Winnipeg and Vancouver, has returned to the United States and is now temporarily engaged on a valuation of the Philadelphia Electric Company's property at Philadelphia, Pa.

While in Winnipeg, Mr. Smith was consulting electrical engineer of the Winnipeg Electric Company, and assumed the technical responsibility involved in the settlement of a long-standing electrolysis controversy between that company and the city of Winnipeg. He utilized the three-wire system of trolley distribution to reduce average track-potentials to negligible values, and subsequently (in collaboration with Dr. J. W. Shipley of the University of Manitoba) carried on research work with a view to establishing the fact that underground pipes of cast iron and lead are inevitably liable to external corrosive attack by solutions of alkaline salts of various kinds which permeate the soils in which they are buried, whether stray currents are present or not. A report of this work was presented to The Institute in 1921 and 1922, published in the Journal, for which the authors were awarded the Plummer Medal in 1923.

Besides the foregoing, Mr. Smith conducted several valuations for the Winnipeg Electric Company, also designed two substations, several improvements in the standby steam plant, salvaged over $200,000 worth of supposedly obsolete machinery and worked out various other special economic problems for the company. In 1923 he presented two more papers to The Institute, one on the three-wire trolley distribution above mentioned and the other on the economics of the Hudson Bay Railway project from the viewpoint of the Canadian taxpayer.

His work in Vancouver comprised several engagements with the Sydney E. Junkins Company, Limited, on the determination of power sites and general economics, in the course of studies and reports made by that company, for the project of electrifying the mountain subdivision of the Canadian Pacific Railway, further supplemented in 1926 by an economic study of the Diesel-electric locomotive.

J. L. Allison, m.e.i.c., joins Messrs. H. G. Acres and Company

J. L. Allison, m.e.i.c., has recently become associated with H. G. Acres and Company, Limited, consulting engineers, of Niagara Falls, Ontario, as hydraulic engineer.

Mr. Allison is well known among the engineers in Canada, and has been for many years a member of The Institute. He is also a member of the Corporation of Professional Engineers of Quebec, and an associate member of the Institution of Civil Engineers of Great Britain. As hydraulic and designing engineer for Messrs. Ross and Holgate, and later for Henry Holgate, m.e.i.c., he prepared the plans and supervised the construction of many of the larger hydro-electric projects in the Dominion, including such works as those of the Canadian International Nickel Company in Ontario, the West Kootenay Power Company in British Columbia, as well as several important installations in the province of Quebec.

During this period Mr. Allison also carried out the original studies for the great Cedars Rapids development on the St. Lawrence river, and in connection with this study prepared the original plans for the single runner vertical unit scheme of installation which was ultimately adopted.

As designing engineer for Wm. I. Bishop, Limited, Mr. Allison handled a considerable range of engineering work, including such items as the large reinforced concrete dam constructed by the Bishop Company on the Junction river for the Newfoundland Pulp and Paper Company, and the wood-handling plant of the St. Regis Paper Company at Godbout, Quebec.

Previous to becoming associated with H. G. Acres and Company, Limited, Mr. Allison was for eighteen months specially retained as a designing engineer by the Department of Railways and Canals of Ottawa to assist D. W. McLachlan, m.e.i.c., chairman of the Canadian section of the International Board of Engineers investigating the improvement of St. Lawrence river for navigation and power. In this capacity Mr. Allison prepared studies and designs for power installations on the St. Lawrence river between

J. L. ALLISON, M.E.I.C.

lake Ontario and Montreal, aggregating about 4,000,000 horse power of installed capacity.

Mr. Allison will make his permanent headquarters in Montreal as resident manager of the newly established branch office of H. G. Acres and Company, Limited, in the Canadian Pacific Express building.

CORRESPONDENCE

Allegheny Ice Gorge

Montreal, January 14th, 1927.

The Editor (*The Engineering Journal*)

Dear Sir:—

In reference to my work on the Allegheny ice gorge last March, on which John Murphy, m.e.i.c., comments in the January issue of this Journal, I am surprised to find that Mr. Murphy has apparently completely missed the point of my plan of work in the Allegheny valley.

Ice fighting is a military campaign and must be carried out as such to achieve success. My whole work was preparing for the oncoming of mild weather to obtain as much assistance from the sun as possible without allowing the sun to take the gorge out in the usual way with high levels and floods from the upper end first. Hence during the cold weather I was busy clearing out the channels under the ice and getting enough water down to the lower end of the gorge to float it successfully.

I had, therefore, to plan the entire work so that the ice would not be set in motion until conditions were such that it would pass easily through the restricted channels downstream. This was accomplished successfully and I had the entire gorge moving slowly downstream in a week's time, even during the cold weather, but I had to be careful to restrict the work to the lower end, for much damage could have resulted from the possible oncoming of mild weather and rain. Always, I stood by with my ear turned to the weather committee ready to change the plan of action at the slightest warning.

Far from not assigning due credit to the sun and rain, as Mr. Murphy suggests, I give abundant credit to these agencies, as I tried to make clear in my paper. What I had to watch was that the sun and rain did not get ahead of me and cause tremendous floods and damage in the valley before the lower end of the gorge was weakened and in a condition to move.

My operations were entirely guided by the reports of my weather committee from whom I received frequent advice and forecasts. The chart published by Mr. Murphy contains nothing that I had not already on file at the time.

Howard T. Barnes, m.e.i.c.

Art de l'Ingénieur et Métallurgie

Tables Annuelles de Constantes et Données Numériques

Gauthier Villars et Cie, Paris, 1926. Edited by L. Descroix, 8½ x 10¾; pages 1660 to 1908. Price, 75 frs. paper; 90 frs. bound, plus 40% in each case.

The tables of annual constants prepared under the auspices of the Conseil International des Recherches are of importance, and this volume of engineering and metallurgical data amply maintains the reputation of the previous issue published in 1922.

The committee responsible for the preparation of the work is under the patronage of the Iron and Steel Institute, the Institute of Metals, the Council of Scientific and Industrial Research, the American Society of Mechanical Engineers, the Comité des Forges, and the Société d'Encouragement pour l'Industrie Nationale. The information presented is of great service to scientific and practical workers, and includes, as regards engineering, the several mechanical constants for a great variety of materials in common use for structural and other purposes, also the thermal constants of refactory materials and fuels. In the section devoted to metallurgy, various technical data concerning metals and alloys, their mechanical constants, and electrical and magnetic properties are included.

Such a compilation as this involves the collection of fundamental data from all sources, and places in readily accessible form those new or improved measurements and determinations of the physical qualities of the materials we use, which are constantly being made by research workers in all parts of the world. Such data are originally published in various countries and in various forms, and are in many cases apt to escape the notice of those who could really benefit by them.

The kind of information contained in the volume under review will be indicated by naming a few of the items, taken at random, such as: the strength of high silica Portland cement, the wear of concrete road aggregates, the strength of artificial and natural silk, the influence of increasing temperatures of vulcanization on preparation of rubber, the effect of fittings on flow of fluids through pipe lines, the carbonization of coals at low temperatures, the thermal and electrical conductivity of iron-cobalt alloys, the melting points of tungsten steels, the corrosion of steel containing copper, and many electric and magnetic constants.

The whole forms a valuable work of reference.

Transmission Line Theory and Some Related Topics

By William S. Franklin and Frederick E. Terman. Franklin & Charles, Lancaster, Penn., 1926. Cloth, 5¾ x 8½ in., 312 pp., diagrs.

The recently published book "Transmission Line Theory," by Franklin and Terman, is a valuable addition to the rapidly growing number of works of reference on this important branch of electrical engineering. The authors throughout the work have not contented themselves with the mere statement of formulae and the methods of applying them but, as the name implies, have gone right back to the basic underlying mathematical and physical theory. This they have developed in a lucid and logical way into the form in which it may be put to practical use. No one but an experienced teacher could have written as clearly on the many intricate subjects involved in such a work.

Commencing with the discussion of the solution of the types of differential equations involved, the first chapter deals with the subject of non-periodic waves, their travel along the line and reflection from the open and short circuited ends as well as from the end when closed by an impedence. The distortionless line is also discussed.

The following chapter deals with the harmonic wave in a similar manner.

The equations for the long line in the steady state are developed in the third chapter and the three-phase line is discussed in the chapter following, which includes also an exposition of the circle diagrams of both generator and receiver ends of the line and the various loci which they may include.

Artificial lines and wave filters and their design are discussed in chapter V, which completes the first part of the book.

The two chapters of the second part are devoted to the Fourier series and to non-harmonic waves of electromotive force and current.

In each chapter there is included a series of well thought out examples with answers to illustrate the principles which have been discussed, and appendices are added at the end of the volume on subjects which include corona loss, simple transients, the algebra of complex quantities, hyperbolic charts and their use in solving the problems of long transmission lines, etc.

The book is not designed as a hasty reference for the busy engineer, but rather as an exposition of the why and the wherefore of the methods and formulae which are in common use.

E. P. Fetherstonhaugh, M.E.I.C.

ELECTIONS AND TRANSFERS

At the meeting of Council held on January 18th, 1927, the following elections and transfers were effected:—

Member

BRIDGLAND, Morrison Parsons, B.A., (Univ. of Toronto), i/c Calgary Office, Topographical Survey of Canada, Calgary, Alta.

Associate Member

GUEST, John Laurence, B.Sc., (Va. Military Institute), C.E., (Cornell), Office engr. Aluminum Co. of Canada, Ltd., Arvida, Que.

Juniors

CRAIG, Shirley Abbott, B.Sc., (McGill Univ.), student engrg. course, Can. Westinghouse Co. Ltd., Hamilton, Ont.

PATTERSON, Elmer Goodwin, B.Sc., (Queen's Univ.), asst. to res. engr., Can. Int. Paper Co., Gatineau, Que.

Transferred from class of Associate Member to Member

FOSNESS, Arthur Williams, E.M., (Univ. of Minn.), ch. engr. for Carter-Halls-Aldinger Co., Winnipeg, Man.

McNAUGHTON, Andrew George Latta, B.Sc., M.Sc., (McGill Univ.), Deputy Chief of the General Staff, Ottawa, Ont.

SHERMAN, Norman Clarence, ordnance mech. engr., mech'l. engrg. branch, Dept. of Nat. Defence in Inspection Dept., Esquimalt, B.C.

YUILL, Alexander Claude Roy, consulting engr., Vancouver, B.C.

Transferred from class of Junior to that of Associate Member

BOWMAN, Nelson, B.A.Sc., (Univ. of Toronto), ch. engr., Dom. Linseed Oil Co., Baden, Ont.

CUNNINGHAM, Adam, B.Sc., (Univ. of Edinburgh), asst. to mech. supt. at Riverbend Paper mill of Price Bros. & Co. Ltd., Riverbend, Que.

Transferred from class of Student to that of Associate Member

FENWICK, James Reid, B.Sc., (Univ. of Toronto), i/c design work on radio receiving equipment for Northern Electric Co., Montreal, Que.

LAURENDEAU, Camille Thomas Joseph, C.E., B.A.Sc., (Univ. of Montreal), valuator and supervisor of tech. dept., Title Guarantee and Trust Corp. of Canada, Montreal, Que.

VALLIERES, Irenee A., B.Sc., (Ecole Polytechnique), asst. engr. grade 1 with tech. service, city of Montreal, Que.

Transferred from class of Student to that of Junior

SIMPKIN, Douglas Benjamin, B.Sc., (Univ. of Alta.), struct'l dftsman, Braden Copper Co., Rancagua, Chile, S.A.

Winter in Canada

The Natural Resources Intelligence Service of the Department of the Interior, Canada, has issued an interesting booklet entitled "Winter in Canada," which is one of the series of tourist booklets being issued by that service.

Map of Sullivan Lake Area

The Topographical Survey, Department of the Interior, Ottawa, has issued another of the series of topographic maps forming part of the sectional map of Canada. The new map is known as the Sullivan Lake sheet and covers an area of about four thousand square miles, extending to the eastern boundary of Alberta to range 14 inclusive, west of the fourth meridian and from township 33 northerly to township 40.

ABSTRACTS OF PAPER

Mercury Mines of Almaden, Spain

Dr. E. L. Bruce, Mineralogy Department, Queen's University. Kingston Branch, December 10th, 1926.

Mercury is unique among metals in that it is the only one which is liquid at ordinary temperatures. This characteristic prevents its use as a constituent of alloys, and hence, it is the only metal the use of which is not increasing. It is possible that a large demand could be created were mercury less expensive but it ranks as one of the rarer elements and the cost of production will probably always render it unavailable for purposes such as the mercury turbine. Not only are new uses for any large amount not being developed but the mining industry, formerly the largest consumer, has, by the development of the more efficient cyanide method for gold extraction, largely ceased to use mercury. Once again the largest single use has become the ancient one as a pigment.

In spite, however, of a stationary or decreasing demand the price of the metal remains practically constant. This is due to the fact that most mercury deposits carry only a small percentage of the element, that the output of the one known rich deposit is under government control.

By far the largest and richest known occurrence of cinnabar, the one ore of mercury, is at Almaden in the province of Cuidad Real in the southern part of Spain. The history of mining at that locality goes back at least to 332 B.C., when the mines were operated by the Carthaginians. During the early part of the Christian Era cinnabar was exported to Greece and Rome to produce the vermilion reds for the artists of those cities. The labour involved in mining the material by the means then available, in transporting it a considerable distance by land and then by sea, shows the value placed upon it in ancient times.

Following the fall of the Roman Empire, it is unlikely that the mercury mines were worked during the three centuries of Gothic dominance of Spain, but with the conquest of Spain in 712 by the Moors, the Almaden mines were again exploited and the working methods improved. Moorish occupation of New Castille was ended in 1151 by the victories of Alfonso VII, but the provinces to the south were held for much longer. The mercury mines were entrusted first to the Templars, who were not able to protect them from the Moors, and later to the order of Calatrava. In 1348 they were proclaimed state property but were leased to the order of Calatrava until 1525 when Emperor Charles I ceded the mines to James and Marcos Fuggar to whom he was indebted, a royalty being paid the Crown. In 1647 this arrangement was terminated and Don Juan Bustamente, an engineer of great ability, was made superintendent. Under his management both mines and retorting plant were put on an efficient basis. Production continued steadily until the latter part of the 18th century, when German engineers, who had been placed in charge of mining operations, failed to maintain a proper reserve of ore and production was severely curtailed.

Normal conditions were again reached only about the beginning of the Napoleonic wars, and, due to disturbances following them, the mines were entirely closed from 1817 to 1825. Again during the Carlist disturbances of 1835 to 1838 production was interfered with, conditions becoming stable again about 1868.

In 1904 a period of modernization began. At present, installation of new equipment is not complete and in the retorting of the cinnabar the ancient furnaces of Bustamente are being used side by side with a very modern plant for volatilization.

The geological history of this part of Spain contains several lost intervals, so that the period of ore formation cannot be fixed with accuracy. The earliest rocks are a series of sandstones, shales and limestones found in early Paleozoic times, during the submergence of most of the Iberian peninsula. Later, probably in the carboniferous, powerful north-south thrusts threw the sediments into east-west trending folds and metamorphosed the sandstones to quartzites. At the same time came intrusions of granites along the axes of some of the folds. The area then became a land surface, and normal erosion truncated the folded beds, leaving the granite cores standing out as mountain ranges. Sedimentation during the Tertiary period covered all the early rocks with marls and sands. These are still practically flat lying in central and southern Spain but are closely folded and intruded by granites in the Pyrnees mountains, which are uplifted by the south-west north-east compression of the Alpine revolution. It is thought possible that the ore deposits belong to this period.

The cinnabar is believed to have been given off from some intrusive body during cooling and to have impregnated the porous quartzite beds lying above the igneous mass. Since the Alpine period of mountain building the peninsula has been mostly a land area undergoing continuous weathering and removal of its surface formations.

The topography of the southern and central part of Spain depends upon the stage which the removal of the flat-lying Tertiary beds has reached. The ancient mountains formed by the east-west masses of granite are again exposed. The Guadarrama mountains lie north of Madrid, the mountains of Toledo south of Toledo and the Sierra Morena still further south. Between the first two ranges the Tagus river flows westward. The Guadiana river follows a parallel course between the two southern ranges. The character of these two river valleys is decidedly different. In the valley of the Tagus the flat-lying Tertiary beds have not been removed to a depth sufficient to expose the underlying folded rocks. Hence the country is comparatively flat with mesa-like elevations where some harder bed has resisted erosion and has protected the soft beds beneath it. This is the high plain of Old Castille below which the rivers have cut broad valleys.

South of the mountains of Toledo the younger rocks have been practically completely removed and the old folded rocks exposed. Steep-sided parallel ridges have developed on the hard quartzites and the softer rocks form the intervening valleys. The main streams do not occupy these valleys but in general cut across the formations quite without regard to the structure, excepting that the stream valleys are narrow gorges where they pass through the quartzite ridges. Evidently the streams were formed originally on the flat-lying beds that once covered the whole region and, as these were gradually removed, the streams held their courses and cut down through the ridges to their present level. The net result is a monotonous mesa topography in Old Castille and a rugged and diversified topography with steep-sided ridges and many narrow gorges in New Castille.

The deposits of cinnabar at present being mined average about 7 per cent of mercury, which is much higher than the grade of any other known deposit. Three main lodes are being mined. They consist of portions of quartzite beds in which cinnabar has filled the cracks in the rock and the interstices between the grains of quartz. Widths as great as 36 feet have been mined and, in places, ore of extremely high grade has a width of 20 feet. In this ore the impregnation has been so complete that the whole mass of the rock looks like solid cinnabar.

Most of the ore at the present time is coming from the eleventh level (about 850 feet). Development has been carried to the thirteenth level at a depth of approximately 1,100 feet.

Drilling is done entirely by hand. As timber is scarce, underground supports are masonry, the older workings being supported by brick arches and part of the shaft being lined with brick. In the process of modernization electric hoists have been installed but the cables used in some of the shafts are still the multiple flat hempen rope of the old type.

In the retorting of the ore the mixture of old and new methods is even more noticeable. The cinnabar is trammed from the mine to a sorting floor, piled in heaps, and the high grade is sorted out. This is carried in small baskets to chutes, dumped down into ox-drawn carts and taken to the old furnaces that were installed in the middle ages. The ore is piled into the furnaces on supports made of pieces of already retorted rock, so that there is a large proportion of open space. The furnaces are fired without passing the fumes through this mass until the whole furnace is thoroughly heated. Connections are then opened and the heated air drawn through the ore. The mercury is votatilized and passing off at the top of the furnace is carried down through inclined pottery tubes, made of sections of about 1½ feet in length, each of which has the form of a bottomless jar with a neck diameter of 4 inches and a body diameter of about 8 inches. These are fastened together with clay. The metal collects in the bulging body of the jar. When the retorting is finished the jars are separated and the mercury runs down into a trough at the bottom of the incline and thence to the bottling room. The retorted rock has the same volume that the ore had before treatment and the labour of discharging the furnaces is practically the same as that of charging. The modern plant treats the lower grade ore in huge retorts from which the vapours are carried in goose-neck down-comers and condensed continuously.

One of the difficulties of mining and treating the ore is the danger of mercury poisoning. The cinnabar breaks down naturally into mercury so that even underground there is a considerable proportion of native metal in the ore. In retorting it is almost impossible to escape the evil effects of the fumes. As a result men work only part of each month and even at that are forced in a comparatively short time to give up work at Almaden and go to the copper mines of Rio Tinto, or to take up other occupations. Costs are therefore high and labour turnover excessive even in spite of the establishment of dental clinics and other preventive measures.

From even a hurried examination of the Almaden mines it is clear that the deposits are so high in grade that no other known deposits can compete with them in the matter of production. Modernization will probably reduce the costs, but owing to the peculiar conditions of the demand for the metal and to the rare occurrence of mercury deposits the market price will be so controlled that there will be no corresponding fall in selling prices. Market prices will be fixed by the costs of operation of lower grade deposits, such as those of Italy and California, and the Spanish government will reap the benefit of the large margin of profit possible in working the high grade ores of Almaden.

The Gas Scrubbing Plant in Turner Valley

S. G. Coultis, M.E.I.C., Superintendent, Royalite Oil Company. Calgary Branch, November 15th, 1926.

During his address Mr. Coultis stated that the gas, saturated with gasoline, is throttled at the well to a pressure which balances the rate of gas cleaning in the scrubbing plant and of use by the consumers in Calgary, Lethbridge and other cities. On the way to the scrubbing plant it passes through several separators in series which remove the moisture (gasoline) content.

In the scrubbing plant the gas is passed into the bottom of a series of absorbers and out at the top, passing on the way through a spray of sodium carbonate solution which enters at the top and is atomized by falling over a series of wood grids.

He pointed out that a special problem of this plant was to find a reagent for removing the sulphur. The reagent should be cheap and such that it may be used continuously because of the small local market available for the use of any by-products that might be produced.

Referring to the absorber, he stated that hydrogen sulphide is removed from the gas by being passed through a solution of sodium carbonate in water, the resulting sodium bicarbonate and sodium sulphide in solution being then taken to the top of an actifier down which it flows through a current of air, the main reaction in the actifier being the reversal of the process in the absorber, the hydrogen sulphide liberated being allowed to escape by a chimney and the sodium carbonate is reclaimed. But there are secondary reactions in which a certain amount of sodium thiosulphate (hypo) and free sulphur are produced, and the special problem here is that if hypo is formed in excess fixed salts are formed and loss of the soda solution ensues. The following absorber reactions were mentioned:—

Absorber Reaction—

$$H_2S + Na_2CO_3 = NaHS + NaHCO_3$$
$$CO_2 + H_2O + Na_2CO_3 = NaHCO_3$$

Actifier Reaction—

$$NaHCO_3 + NaHS = Na_2\,CO_3 + H_2S$$
$$2NaHCO_3 = Na_2\,CO_3 + H_2O + CO_2$$

The sodium carbonate solution is continuously circulated and if care is taken in maintaining the proper constant temperature little of the solution is lost.

Another special feature mentioned as peculiar to this plant is the high pressure at which the process must be worked on account of the high pressures at the well casing head and in the delivery pipe lines. The pressure in the absorbers varies between 100 and 300 pounds per square inch, depending on the "pull" on the line, and at these high pressures the temperatures must be maintained constant within very narrow limits for continuous successful operation. The actifier pressure varies from 4 to 6 inches water pressure. The pressure on the plant depends on several factors: the pressure at the casing head, the temperature, and the "pull" of the consumers on the line. It is kept constant by putting more or less absorbers in series according as the demand increases or diminishes, increasing the velocity of the gas flow as the number in series is increased.

The speaker described how the gas may be received at the absorber at temperatures considerably below zero, and that it has been found that maximum absorption is obtained at just above the freezing point of water, also that the gas is steam heated, but if its temperature is allowed to rise to a temperature much over 150° F. the sodium carbonate breaks down and is lost. The diameter of the absorbers is small because of the high pressure and velocity of the gas, being 36 inches by 60 feet high.

The actifier is in the open air and also has to be heated in winter to prevent freezing, and here also, care is necessary to prevent too high a temperature. He explained that it is necessary to circulate about 60,000,000 cubic feet of air in twenty-four hours during normal weather, but that this may be doubled in hard weather when the demand for domestic gas is heavy.

He further described the mechanical part of the plant as consisting of eight 80-h.p. gas engines which were originally direct coupled to compressors for boosting low pressure gas into the delivery mains; four of these now driving triplex pumps which circulate about 15,000 gallons per hour of sodium carbonate solution and two driving fans and auxiliaries, leaving two as spares for cleaning and emergencies.

There are eight absorbers, in two banks of four in series, under normal weather conditions four or six handling the load, whereas in hard weather a whole series of eight is necessary.

Another problem, he stated, which must be faced is the possibility of rapid corrosion of the parts coming in contact with the hydrogen sulphide in solution and of erosion by suspended matter in the gas, the chimney being made extra heavy on this account. Careful record is being made of the useful life of valves and seats which are of iron, while some experimenting is being done with the newer Monel metal and stainless steel.

Continuing, he explained that the plant requires 200 b.h.p. in cold weather to supply steam for heating the buildings, heating the gas from the well and the air to the actifier, and for heating some traps, valves, etc., that are liable to become frozen because of the physical changes consequent on the process and the severe climate.

EMPLOYMENT BUREAU

Situations Vacant

Pulp and Paper Mill Engineer

Pulp and paper mill engineer wanted, about March 1st, with several years' experience in pulp and paper mill layout and operation. Should be thoroughly familiar with design of pulp and paper making machinery and be able to re-design and re-model existing machinery where necessary. Should be able to take charge of draughting end of the engineering department. Applications should draughting end of the engineering department. Applicants should state salary acceptable, experience, technical training and date available. All applications will be treated strictly confidential in the first instance. Apply, box No. 160-V, Engineering Journal.

Mining Engineer

A mining company in eastern Quebec wishes to obtain the services of a young mining engineer capable of handling underground survey work, and also some knowledge of mechanical engineering which would serve in the laying out of plant equipment. Apply, box No. 161-V, Engineering Journal.

Mechanical Draughtsmen

Two mechanical draughtsmen required by an industrial organization in Montreal. Preferably young men with shop experience. Apply box No. 162-V, Engineering Journal.

Electrical Engineer

Recent graduate required by a large electrical manufacturing concern for sales engineering and statistical work. Please state in first instance, education, full qualifications, references, salary required, age and when available. Apply box 163-V, Engineering Journal.

Situations Wanted

Mechanical Engineer

Graduate mechanical engineer of McGill University desires new connection in Quebec or Ontario. Five years' experience in draughting, plant layouts, factory maintenance, tools, materials, and methods, standardization, estimating, etc. Twenty-seven years of age. Married. Apply box 218-W, Engineering Journal.

Civil Engineer

Available at thirty days' notice after April first. Member of Association of Professional Engineers of Nova Scotia, and licensed Nova Scotia Land Surveyor. Twenty years' experience in eastern, central and western Canada and the United States, including railway location and construction, water power development surveys, construction of dams, factory and office buildings, general steel plant construction, coal mine development, including construction of bankheads, yard tracks, underground surveys, and mechanical installations. Apply box No. 219-W, Engineering Journal.

Prizes Offered for Best Papers on Greatest Improvement in Arc Welding

In the December 22nd, 1926, issue of the American Society of Mechanical Engineers' News appears an announcement that the society has accepted the custody of $17,500, to be awarded by the society in a world competition for the papers descriptive of the greatest improvement in the art of arc welding during 1927.

This fund is provided by the Lincoln Electric Company and will be bestowed in three prizes: the first award is $10,000; the second $5,000, and the third $2,500. The prizes are to be administered by the Council of the American Society of Mechanical Engineers, who will invite qualified experts to assist. Complete information can be obtained by applying to the secretary of the society, and while a more extended statement of conditions of award of the prizes is being prepared, the following is published for the guidance of prospective contestants:—

(1) The award to be made for the year 1927 as soon after January 1, 1928, as practicable.

(2) Any one in any country of the world may try for these prizes, but papers must be submitted in the English language.

(3) The papers in competition are to be supplied in duplicate to the council of the A.S.M.E., addressed to its secretary, Calvin W. Rice, 29 West 39th street, New York, before January 1, 1928. Any delay thereafter will exclude a paper from the competition.

(4) To assist authors in the preparation of papers for this competition, the following conditions are added:—

(a) The paper should include drawings of the design and careful description of apparatus needed to carry out ideas of the writer.

(b) The utility of the suggestions must be shown not only for the application, but also for possible use in connection with other designs and for their purposes.

(c) The economic saving to the industry—and therefore to mankind—by the use of the methods suggested should be pointed out.

(d) A demonstration of the practicability of the process and design is necessary. It is not necessary, however, that the actual application of this suggestion be fully shown, if a clear statement is made of possible uses.

(e) Originality of design is preferable either in the method of applying the weld or in the design of the welding parts for their arrangement. Designs which are of no practical use will only be considered in case they include suggestions which could self-evidently be applied in other ways than those suggested.

(f) Methods of applying the arc or the welding art which will improve existing machines or make commercially possible machines which in the light of previous engineering have been regarded as impractical, are specially desired.

(g) It is not necessary that all parts of the structure should be made of welded metal. It is only necessary that one or more parts be so made.

(h) Although it is stated that the limit of time will be January 1, 1928, it will be well to submit papers in competition as soon as they are prepared, that is, as early as possible in the year. In case two or more identical suggestions are received, the one arriving in the hands of the secretary of the American Society of Mechanical Engineers first will have precedence over those following.

(i) It is recommended that the small amount of literature available be studied to get the fundamental principles which govern re-design. Numerous articles have appeared in the trade journals which will be valuable, and certain companies have done much work that will be helpful in getting out a paper.

(5) The council of the American Society of Mechanical Engineers may withhold any or all awards.

(6) To facilitate filing and transmitting, it will be necessary that the paper be typewritten on one side of paper 8½ x 11 inches, bound at the top with covers that will protect it. The name and address of the sender should appear on the front cover, and if possible a brief statement of his qualifications should be included with the letter of transmittal.

The Canadian S.K.F. Company, Limited, Toronto, has issued the first volume of a publication entitled "The Ball Bearing Journal." This publication contains considerable information regarding the subject of bearings and describes the nature of rolling resistance, the carrying capacity of ball and roller bearings and various uses of the products of the company.

BRANCH NEWS

Calgary Branch

H. R. Carscallen, A.M.E.I.C., Secretary-Treasurer.
W. St. J. Miller, A.M.E.I.C., Branch News Editor.

The Gas Scrubbing Plant in Turner Valley

An interesting and instructive address by S. G. Coultis, M.E.I.C., superintendent of the gasoline absorption and gas scrubbing plant of the Royalite Oil Company in the Turner Valley, was delivered to a large gathering of members and visitors at the general meeting held on November 15th, 1926. An abstract of this paper appears on another page of this issue.

The speaker, who assisted in designing and installing the plant, and has since been in charge of its operation, thought it was still too early to give any reliable cost data until more is known regarding the life of the various parts of the plant under the peculiar pressure and climatic conditions which it has to deal with.

An animated discussion ensued in which Dr. Atack of Kingston, Ont., and S. J. Davies, A.M.E.I.C., petroleum technologist of Calgary, took an active part.

The Head Hunters of Formosa

This was the formidable title of an address delivered before the branch by J. W. Davidson, F.R.G.S., on December 6th, 1926. This being the postponed opening meeting of the winter season was open to ladies, and a very pleasant evening was spent. Mr. Davidson proved a most interesting speaker and his address was listened to by all present with much pleasure. Many beautiful slides were presented and also several of a somewhat gruesome nature as was inevitable from the subject of the paper. It may be mentioned here that the speaker was a member of the party accompanying Peary on one of his North Polar expeditions, which goes to show that he is a much travelled man. Refreshments were served, at which Mrs. J. H. Ross, the wife of the chairman, and Mrs. G. P. F. Boese, wife of the past secretary, acted as hostesses.

Annual Dinner

The following verse appeared on the invitation card to the annual dinner, which took place on January 6th, in the Tapestry room of the Hudson's Bay Company:—

A little meet where we can greet a brother we hold dear;
A little seat where we can eat and sip the cup of cheer;
A little song to help along in case we get too sad;
A little smoke, a little joke, to make the heart strings glad;
A little plan to chase away that miserable gloom;
Don't that sound grand? Then be on hand at the Eliz'bethan room.

The chairman, J. H. Ross, A.M.E.I.C., acted also as toastmaster. Toasts were proposed and responded to as follows: "The Institute," S. J. Davies, A.M.E.I.C., and R. S. Trowsdale, A.M.E.I.C.; "Our Guests," F. K. Beach, A.M.E.I.C., and Lt.-Col. D. W. B. Spry, O.B.E., president of the Alberta Military Institute. G. N. Houston, M.E.I.C., speaking as a guest, conveyed the greetings of the Lethbridge Branch to the members present. Major D. G. L. Cunnington, M.C., also spoke in reply to the toast to the guests.

An excellent programme followed the dinner, which was conceded to surpass anything put on so far by the branch. Members of the branch taking part were G. H. Patrick, A.M.E.I.C., R. H. Goodchild, A.M.E.I.C., and W. St. J. Miller, A.M.E.I.C. Other artists on the programme rendered some splendid selections, which were enjoyed to the limit. A hearty vote of thanks was tendered by P. J. Jennings, M.E.I.C., to all those who had helped to make this evening such a success, both as entertainers, speakers and committee of arrangements, which arrangements were mainly in the hands of Secretary H. R. Carscallen, A.M.E.I.C., and Affiliate J. Cawthorne.

Halifax Branch

K. L. Dawson, A.M.E.I.C., Secretary-Treasurer.

A regular monthly meeting of the Halifax Branch was held as a supper-meeting in the Green Lantern on January 6th. C. A. Fowler, M.E.I.C., the newly elected chairman, presided, and over forty members and guests were present.

Among the guests present was I. P. MacNab, M.E.I.C., a former member and vice-chairman of the branch. Mr. MacNab, who always took an active interest in Institute affairs, was warmly welcomed by his many friends and in a brief address gave an interesting account of the people, customs and general conditions in Venezuela, where he is now stationed as general manager of the Venezuela Power Company.

The principal speaker of the evening was Captain the Hon. J. F. Cahan, A.M.E.I.C., who delivered an address on the life of Sir Sandford Fleming.

Capt. Cahan prefaced the main subject matter of his address with a discourse on the general characteristics, interests and tendencies of engineers as professional men.

The essentials of an engineering education and training tend toward a more or less specialized mathematical course, to the extent that the engineer is in danger of losing sight of the broader fields, for which, from the very nature of this education and training, he is especially well equipped. "The mathematics in which an engineer has to attain efficiency, in the course of his study, equip him to solve problems far removed from the subject in which he is trained. If science has a fault, it aims at being too definite; if mathematics have a fault, it is that the solution of a mathematical problem depends upon a definite answer." So the engineer, having solved his problem or completed his investigation, is too apt to consider his accomplishment in the light of finality and to ignore the many phases, in the broader field, which lie beyond or round about the scope of his immediate interest.

Thus it is that the engineer has not evinced the interest nor taken the prominent part in the solution of the great general public problems for which his education, training and experience have especially fitted him. His intimate relations and close contact with men in all walks of life have given him a better understanding of humanity and its problems than is enjoyed perhaps by any other class or profession, yet, "There is no question that medical men of equal personality and brain power, that lawyers no better equipped and no more aggressive, that clergymen of the same stamp, and journalists and business men, class for class, ability for ability, aggression for aggression, occupy far more outstanding positions in the country, acquire more credit and more material remuneration than does the engineer."

For such a state of affairs we, as an engineering profession, must shoulder a large share of the blame or responsibility, and with us rests the power to provide the remedy. We must not permit our immediate, technical, professional problems to narrow our vision. We must not confine our attention and activity to the special phase of a question, in which, because of our professional duty, we are directly interested. In our engineering meetings we should deal with questions of a broad public interest and guard against our papers and discussions becoming too detailed and restricted. We should take a more active part in the affairs of the country at large. In problems of development, and on economic questions of public interest, the engineering profession should have very definite ideas which would be of great value to the public bodies having to deal with such questions.

The Life of Sir Sandford Fleming

The speaker proceeded to give a sketch of the life and work of Sir Sandford Fleming, citing him as not only the foremost Canadian engineer of his time, but as occupying a position of equal prominence to that held by any professional contemporary on the North American continent.

Mr. Fleming, while engaged in the greatest engineering works of his time, necessitating arduous personal effort, found time to engage in many and varied pursuits outside the specific engineering projects directly in his charge. "He made contributions to the public welfare of this Dominion which entitle him to be forever classed as one of our first citizens," said Mr. Cahan. "He is perhaps the most outstanding engineer in our engineering records. A glance at his bibliography shows that he wrote one hundred and forty-two documents on a great variety of subjects. He wrote of railway inventions, railway termini and pleasure grounds, harbour improvements, oil wells, time, submarine telegraph, parliamentary government, postage stamps, colour blindness, post office reform, imperial intelligence service, a system of empire cables, Nova Scotia and the Empire, and the world girdling cable. Some of his contributions to The Royal Society dealing with the establishment of transcontinental railways have a breadth of view and an international scope which makes them historical documents bearing the stamp of a great mind."

Sir Sandford Fleming was born in Kirkcaldy, Fifeshire, Scotland, on January 7th, 1827, and by a strange coincidence the meeting at which Capt. Cahan's address was delivered was held within a few hours of the one hundredth anniversary of his birth. After attending the local parish school, he was apprenticed in his early teens to John Sang, an engineer and surveyor. He came to Canada in 1845. Among his early works in Canada was the compiling and publishing of a map of the town of Peterborough. He obtained the stones and lithographed the map with his own hands. At later dates he made maps of Newcastle and Toronto. In 1849 he was one of a small number of men who established the Canadian Institute and for fifty years he took an important part in its proceedings.

From 1853 to 1863, Fleming was on the staff of the Ontario, Simcoe and Huron Railroad, first as assistant engineer and afterwards as chief engineer. Subsequently he made surveys of Toronto harbour and lake Huron. In 1863 he was made chief engineer of the Intercolonial Railway, which position he held until the completion of the road in 1876. From 1871 to 1880 he was chief engineer of the Canadian Pacific Railway. It will be noted that he held these two important positions concurrently, nevertheless he found time to take an active part in public questions, notable among which was the establishment of Confederation. While some of the methods employed by Mr. Fleming were criticized by the Railway Commission and others, and there is no doubt that in the performance of his almost herculean tasks, he, being human, made mistakes, "No shadow of doubt as to his integrity ever existed."

Mr. Fleming was an ardent advocate of a state-owned cable, and "The ideas which for a time he held alone have been subsequently adopted by the whole British Empire."

"He was an engineer who did not confine himself to the mechanics of his profession, but permitted his mind to view the whole world as might one of the greater British statesmen. He was a man of prodigious energy and dominant perseverance and possessed almost a limitless capacity for arduous work. He was interested in everything from the design in lithographing and printing of a postage stamp, which he did at one time, to the construction of a national railway from the Atlantic to the Pacific. He was interested in popular representation in politics and at the same time interested in an 'All Red Cable Route,' which would embrace other British possessions. He was a great man of whom we may all be proud."

Capt. Cahan's address was supplemented by a number of lantern slides, illustrating many interesting features in connection with Mr. Fleming's life and works.

At the conclusion of this address, four reels of motion pictures were shown of the water power developments and kindred industries of the Shawinigan Water and Power Company. For these films, together with beautifully illustrated descriptive booklets, the branch is indebted to Fraser S. Keith, M.E.I.C., former general secretary of The Institute.

The thanks of the meeting was tendered to Capt. Cahan for his interesting and instructive address and to Mr. Keith for the booklets and the use of the films.

During the evening an amusing and enjoyable solo was rendered by Mr. H. F. Glass, city auditor, as well as several choruses by the members.

Hamilton Branch

W. F. McLaren, M.E.I.C., Secretary-Treasurer.
J. R. Dunbar, Jr.E.I.C., Branch News Editor.

A meeting of the Hamilton Branch of The Institute was held in the Westinghouse auditorium on Friday, January 7th, 1927. L. W. Gill, M.E.I.C., chairman of the branch, presided. There were two hundred present. After the minutes of the previous meeting were read and approved, Mr. Gill introduced Mr. A. M. Candy of the Westinghouse Electric and Manufacturing Company, East Pittsburgh, who gave an address on the "Arc Welding of Structural Steel Buildings," illustrated with lantern slides.

Arc Welding of Structural Steel Buildings

In introducing his subject, Mr. Candy stated that welding compared most favourably with riveting. He did not pretend that riveting did not give satisfactory results, since very good work has been done by riveting, but he considered that welding gives better results.

The company's welding engineers had long been of the opinion that arc welding could be applied to structural steel construction with advantage, and when a new building was to be erected at Sharon, Pa., they persuaded the management to use the welded construction in the fabrication of this building instead of rivets.

The factory at Sharon is 70 feet wide by 220 feet long and five storeys (80 feet) in height. Not a single rivet was used in the building. All connections were made by arc welding, erection bolts being used to hold the members in position until the welding could be done. A total of 900 tons of steel were used, which amounts to a saving of 12 to 15 per cent over the estimated amount of steel required for a riveted structure. The total cost, however, was as great or greater than the cost of a riveted building owing to the novelty of the work and the greater inspection required. Erection of steel was commenced October 27th, and completed December 3rd.

One of the desirable features of the welded construction is that it is more rigid than riveted work, thereby requiring less wind bracing. Corrosion is also relieved to a certain extent. In certain localities the elimination of noise is very important, such as in the case of hospitals. In one case which Mr. Candy cited, the proprietor of a hotel near a large structural steel building which was being erected by the riveted process stated that he would lose approximately two and one-half million dollars of business due to the noise of the riveters.

Mr. Candy showed several lantern slides of structural steel shapes made of the all welded construction which had been tested at the Carnegie Institute of Technology in Pittsburgh. A complete description of these tests is given in the Engineering Journal for December, 1926. The welded construction shows up very favourably in comparison with the riveted construction.

A hearty vote of thanks was tendered Mr. Candy, on the motion of R. K. Palmer, M.E.I.C., chief engineer, Hamilton Bridge Works, seconded by A. M. Jackson, A.M.E.I.C., county engineer, Brantford.

The next meeting was announced for January 26th, when Lieut.-Col. H. J. Lamb, D.S.O., M.E.I.C., will speak on the "Harbours of the Great Lakes."

In closing the meeting Mr. Gill expressed appreciation of the generosity of the Westinghouse Company in allowing the use of their auditorium.

Executive Meeting, January 18th

A meeting of the executive of the Hamilton Branch was held in the office of the city engineer, W. F. McFaul, M.E.I.C., on January 18th, five members being present. The details for the meeting on January 26th were finally determined and several routine matters were disposed of.

The report of the committee appointed to consider the awarding of prizes for papers was presented. Several recommendations regarding The Institute paper prizes and the awarding of Institute Students' prizes were adopted.

Hamilton Branch Prizes

It was also decided to offer a prize for papers presented by members of the Hamilton Branch, prizes for Students of The Institute who are members of the Hamilton Branch and a prize for students in the Hamilton Technical Institute. Since it is so late in the year, no prizes will be awarded for the year ending May 31st, 1927. The first award of prizes in 1928 will include papers presented from the present time until May 31st, 1928.

Conditions Governing Award of Branch Prizes

The conditions governing the awarding of branch prizes are as follows:—

A prize consisting of a certificate and $25.00 will be offered for the best paper presented by a member of the Hamilton Branch, Engineering Institute of Canada, at a branch meeting. The prize will be awarded annually if three or more papers are presented in any year ending May 31st. If less than three papers are presented such papers will be carried over into the competition of the following year. The rules governing the award of the Gzowski Medal, wherever applicable, shall govern the award of Hamilton Branch prizes. The papers entered for competition shall be judged by a committee of five corporate members of The Institute, to be called the Hamilton Branch Prize Committee.

Students' Prizes

Prizes will be offered to members of the Hamilton Branch who are eligible for Institute Students' prizes as follows:—

First prize—Certificate and $25.00.
Second prize—Certificate and $15.00.
Third prize—Certificate and $5.00.

Providing sufficient papers are presented in any year ending May 31st, all three prizes will be awarded annually. If less than five papers are presented in the competition year, the number of prizes awarded will be as follows:—

One paper only—One prize, provided it comes up to a standard of 5 per cent better than the minimum standard mentioned below.
Two papers—One prize.
Three or four papers—Two prizes.

Papers are to be delivered to the branch secretary, in duplicate, prior to the meeting at which the paper is to be presented.

One copy of the papers will be forwarded by the secretary to The Institute headquarters for The Institute Students' prize competition.

Papers ineligible for Institute Students' prizes are also ineligible for Hamilton Branch Students' prizes.

Each competitor will deliver an oral summary of his paper before a regular meeting of the branch, and will be allowed fifteen minutes for the oral presentation.

Points will be awarded as follows:—

Subject matter of paper	30 points
Arrangement and literary style	40 points
Oral presentation	20 points
Time of oral presentation	10 points

The examiners shall be the Hamilton Branch Prize Committee. In the case of the oral presentation, the actual points shall be awarded by the committee, but the order of merit shall be determined by a vote of the members present.

Regardless of the number of papers presented, no paper will be awarded a prize unless it comes up to the following minimum standard:—

For first prize—85 per cent.
For second prize—80 per cent.
For third prize—70 per cent.

If the first prize is not awarded, two second prizes may be awarded, and if first or second prizes are not awarded, two or three third prizes may be awarded.

Technical Institute Prize

An annual prize not exceeding $25.00 in value will be offered for competition by the Hamilton Branch to students of the Hamilton Technical Institute, (day or night), for the best essay between one thousand and three thousand words on any engineering subject, the award to be made by the Hamilton Branch Prize Committee and the prize to be of such nature as the branch executive considers advisable.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
H. W. B. Swabey, M.E.I.C., Branch News Editor.

Recent Developments in Boiler Furnaces

The first meeting of the year took place on January 6th, when a paper was read on the above subject by B. N. Broido, consulting engineer of the Superheater Company of New York.

The author commenced by referring to the development of boiler furnaces with the old hand-fired grates through various stages to the modern automatic stokers and the introduction of the use of powdered fuel. This development necessitated a considerable increase in the size of boiler furnaces and radical changes in their design, resulting in an exorbitant cost for construction and maintenance, as no refractories would long withstand the high temperatures.

In order to prevent the erosion of furnace walls, various means of cooling the furnaces have been developed, in some cases by the use of air-cooled blocks or hollow air-cooled walls and with boilers of high ratings by means of water-cooled furnace walls which has eliminated most of the brick work.

The question of radiation in boiler furnaces was fully discussed and how the water-cooled furnace walls affect the capacity and operation of the present large sized boilers, designed for high ratings. By use of tables and curves it was shown what furnace temperatures could be effected in a furnace with water-cooled walls burning pulverized fuels, and how this was influenced by the rate of heat liberation per cubic foot of furnace volume and also by the amount of water-cooled surface in the furnace. The benefit from pre-heated air on furnace temperatures was also demonstrated.

Some of the most modern boiler installations with water-cooled walls and equipped with superheaters were described by the speaker. He referred to the great heat losses from boiler and furnace walls which had only become generally recognized in recent years, and attempts made to minimize this loss by the use of various insulating materials, which was simplified to a great extent by the development of the water-cooled furnace. The latest designs of air-cooled brick walls were also referred to by Mr. Broido, as their use may be advantageous in some cases.

Reference was made to the new steam generator, which was described as practically a boiler built around a furnace. One of these generators has been in operation for about a year at Manchester, England, and several are now being installed in the United States.

In discussing the question of furnace control the author referred to the two serious sources of waste as incomplete combustion and hot flue gases. An illustration was shown of a recorder which records automatically both CO_2 and CO at the same time.

Following Mr. Broido, C. W. Burrows, A.M.E.I.C., gave a brief description of his new steam generator. He explained that the reasons prompting the new design were the desire to use Dominion coal and a desire to design a water wall and tube in one. After considerable study of different plants in the United States, the generator was designed and a glass model made to study the circulation of the water in the boiler.

He then described the construction of the generator and illustrated it with slides. The generator consists of sixty-four vertical tubes, arranged in a circle, the tubes being bent in at the top and bottom into headers. The water coming from the preheater enters the bottom of the tubes, passes upward through them and out at the top. The pulverized coal is the fuel which enters at the top of the cylinder and passes out through the bottom to the preheater.

Mr. Burrows stated that after six months' operation the boiler had proved entirely satisfactory, no clinkers being formed or scaling of the tubes taking place.

To illustrate the efficiency, he mentioned that when operating at 240 per cent rating, 48,000 pounds of steam per hour was generated, while when the rating was dropped to 120 per cent, 25,000 pounds per hour were generated.

Following Mr. Burrows, S. J. Fisher, M.E.I.C., referred to an installation that was made fifteen years ago in Nova Scotia of three water-tube boilers operating at 300 per cent rating, and stated that the efficiency of this boiler plant was very remarkable for its time, and in fact was practically equivalent to present day efficiency.

F. A. Combe, M.E.I.C., and R. E. MacAfee, A.M.E.I.C., also took part in the discussion, which was later answered by Mr. Broido. Mr. Durley extended the thanks of the branch to Mr. Broido and also to Mr. Burrows for his interesting contribution. F. S. B. Heward, A.M.E.I.C., was in the chair.

Modern Mercury Arc Power Rectifiers

On Thursday evening, January 13th, a paper was read by Mr. Othmar K. Marti, research engineer of the American Brown Boveri, on "Mercury Arc Rectifiers."

After explaining the necessity, from an economical standpoint, of transmitting electrical power from a long distance by means of high voltage, a.c., lines and converting it as near as possible to the site of application into direct current, where it was required to be used for such purposes as railways, the author described the various types of converters used for this purpose.

The most recent device used for converting alternating into direct current is an outgrowth of the glass bulb rectifier, which latter was not suitable for large power outputs. Many difficulties had to be overcome before the metal enclosed mercury arc rectifier was developed, and installations on a commercial scale began in Europe in 1912. From that time development went on steadily, though somewhat delayed by the war, and several large installations have been completed in Europe for railways and rolling mills, while the rectifier, with the highest d.c. voltage in the world of 4,000 v. at 1,000 k.w. has been installed in Italy.

The two factors which are responsible for the ready acceptance of the rectifier are high efficiency at all loads and the minimum attendance required.

Mr. Marti then went on to explain the elementary theory of alternating current rectification, leading up to the reason why this rectifier was a very high efficiency at high voltages. The simple and quick process of starting was given as another outstanding advantage.

Comparison was made by the author between mercury arc rectifiers and rotary converters, although he stated it was difficult to put both types of apparatus on a strictly comparative basis in regard to load, space required and price. He also described the special advantages of rectifiers for railway service and finally stated that he was convinced that in the not far distant future the rectifier, with its entrance adaptability to higher voltages, will revolutionize the electrification programmes long discussed in every country.

The paper was fully illustrated by lantern slides, and considerable discussion followed, to which it is hoped that Mr. Marti will later send a written reply. The chairman of the meeting was Professor C. V. Christie, M.E.I.C.

Kingston Branch

Gordon J. Smith, A.M.E.I.C., Secretary-Treasurer.

Annual Meeting

The annual meeting of the Kingston Branch was held in Carruthers hall, Queen's University, on December 10th, with the chairman of the branch, R. J. McClelland, A.M.E.I.C., presiding.

The customary reports were presented by the secretary-treasurer and the chairman of the Programme Committee. The branch was shown to be in a satisfactory financial position and, though the meetings held during the year had been fewer than usual, the average attendance had been considerably larger and the interest shown had been most encouraging.

The officers for the ensuing year were elected as follows:—

Chairman	Prof. L. T. Rutledge, M.E.I.C.
Vice-Chairman	Prof. D. S. Ellis, A.M.E.I.C.
Secretary-Treasurer	G. J. Smith, A.M.E.I.C.
Executive Committee	J. M. Campbell, M.E.I.C.
	Dr. L. F. Goodwin, M.E.I.C.
	Prof. A. Jackson, A.M.E.I.C.
Ex-officio	R. J. McClelland, A.M.E.I.C.
	Prof. L. M. Arkley, M.E.I.C.

After a short address by R. J. McClelland, A.M.E.I.C., the retiring chairman, in which he expressed his thanks to the members of the branch for their co-operation and help during his term of office and his appreciation of the honour of having been chairman of one of the branches of the E.I.C., the new officers were installed and the chairman-elect, Prof. L. T. Rutledge, M.E.I.C., took the chair. Prof. Rutledge in a few words stated that, though the activities of the branch had been very late in commencing this year due to the Queen's endowment campaign in Kingston, he expected that it would be possible to arrange a series of meetings for the second half of the season that would prove of more than customary interest.

At the close of the business meeting the members present had the pleasure of hearing an address by Dr. E. L. Bruce of the Mineralogy Department of Queen's on the "Mercury Mines of Spain." Dr. Bruce was in attendance at the International Geological Congress held in Spain during the past summer and while there made a close study of the mining of cinnabar, the ore of mercury. A number of slides were shown illustrating the methods of mining the ore and the distilling of the liquid metal as well as the general nature of the country surrounding the mines.

The lecture proved most enjoyable and instructive, and the appreciation of the members present was most ably presented in a vote of thanks moved and seconded by J. M. Campbell, M.E.I.C., and D. Wright. An abstract of Dr. Bruce's address appears on another page of this issue.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

At a largely attended luncheon held in the main dining room of the Chateau Laurier on December 29th, Ottawa members of The Institute had the pleasure of welcoming to Canada Frederick Palmer, president of the Institution of Civil Engineers of Great Britain. Mr. Palmer has been retained by the Dominion government to investigate and report on the ports of Hudson bay.

Welcome was extended on behalf of the Ottawa Branch by J. D. Craig, M.E.I.C., chairman, and on behalf of the council and The Institute by the general secretary, R. J. Durley, M.E.I.C., who is also a member of the British Institution. At the head table the government was represented by Hon. C. A. Dunning, minister of railways; Hon. W. R. Motherwell, minister of agriculture, and Hon. Robert Forke, minister of immigration.

Mr. Palmer's Address

Mr. Palmer said that after nearly fifty years of work he found himself in the proudest position to which any British engineer could possibly attain,—that of being president of the Institution of Civil Engineers. His real life work began in India forty-three years ago as a railroad engineer and after eighteen years of railroad building he had switched into harbour work. During recent years as consulting engineer for the government of India he has been associated with harbour, railroad and irrigation projects in that country.

The nightmare of famine in India, which previously caused millions of deaths, has been completely dispelled through the work of British engineers who brought to India the science of irrigation, Mr. Palmer said. He described two of the great irrigation works of that country,—the triple canal system of the Punjab, where the waters of the river Jhelum are led along the foothills of the Himalayas, crossing under and over huge mountain torrents to be dumped into the Chenab river and again picked up by the Chenab canals to be carried to the Ravi river where the canal crosses the river on a level crossing. There is a weir here 1,650 feet long with gates which pass the flood waters of the Ravi, (150,000 cubic feet per second). The canal restarts at the opposite bank and irrigates the former barren wilderness called the Lower Bari Doab. The immensity of the project is indicated by the distance from the Jhelum to the Lower Bari Doab, which is 500 miles, and by the capacity of the canals, which carry 10,000 cubic feet per second from the Jhelum. The system includes 433 miles of main canals, over 3,000 miles of distributaries and nearly 20,000 miles of water courses, commanding four million acres, of which two million acres are irrigated annually. Some one and a half million acres were absolutely barren wilderness. The country also had to be colonized and transportation provided. In one desert area, where there had been a population of 8,000, there were 800,000 people in ten years.

The second great work outlined was that of the river Periyar, where waters rising in impenetrable malaria stricken jungle and destined by nature to flow to the Arabian sea are now carried across the peninsula and led into the bay of Bengal. An irrigation work now in progress in Sind eclipses in magnitude any previous work. The canals will carry 50,000 cubic feet per second, (25 per cent more than the Ottawa river), from the river Indus and will command an area of seven and a half million acres.

The need for irrigation in India was stressed by Mr. Palmer with figures on rainfall. It varied from nil in Sind to a maximum of 900 inches at a place in Assam. In Sind there were thousands of square miles in which the rainfall was so insignificant that nothing grew thereon. From barren deserts devoid even of animal and bird life these huge territories have been transformed into veritable gardens by irrigation.

British rule has also brought to India a transportation system of 41,000 miles of railway and well equipped ports, notably Bombay and Calcutta. In these two ports alone, the shipping entering approaches fifteen million tons per year, while the value of the seaborne trade is in the neighbourhood of two thousand million dollars per year. Transportation is comparatively cheap in India at one cent per ton mile on goods and one-half cent for coal, while passengers are carried for two-thirds cent per mile.

Mr. Palmer did not discuss in any way his mission to Hudson bay, except to remark that a few weeks ago he was looking over harbour works on the equatorial gold coast and now was assigned to the Arctic region. He urged that closer relations should exist among the engineering associations of the world and particularly those of the British Empire.

Celestial Engineering

At the first luncheon of the new year, held at the Chateau Luarier on January 13th, a well-known member of the Ottawa Branch, R. Meldrum Stewart, M.E.I.C., director of the Dominion Observatory, was the speaker. Mr. Stewart chose as the subject of his address "Celestial Engineering."

The measurement of distances to the stars was in its inception that of the problem of the engineer or surveyor in measuring distances to an inaccessible object, Mr. Stewart explained. It was a matter of measuring the base of a triangle and the opposite angle, or the parallax, then solving the triangle. For instance, to get the distance to the moon it was a simple matter to observe its zenith distance at say Greenwich and Cape Town, but as distances increased the parallax angle became much smaller and sufficient accuracy could not be obtained with this simple method. The parallax of the sun is only about nine seconds, so observations were taken on an astroid called Eros, which gave a better object to observe on, and from the relationship existing between the periods of revolution of the earth and Eros around the sun and then distances therefrom it was easy to calculate the distance to the sun.

The nearest star is at a distance of four light years, Mr. Stewart said, and the parallax angle, using the distance from earth to sun as a base, was less than one second. Distances to over 1,000 stars had been determined by this method, but it became inaccurate for distances of over 100 light years, and only our nearest neighbours were within this radius. The average distance of all stars we can see with the naked eye is 300 to 400 light years. Mr. Stewart then sketched the methods used in obtaining the distances to stars further away, using relative motion, periods of revolution of binary stars and the relation between apparent and actual brightness. Actual brightness is determined from photographs of the spectrum of stars. This relationship was the means of determining the distances of 3,000 stars.

Still Mr. Stewart carried his audience off into space, past the milky way, which is the earth's galaxy of stars arranged in a circular band with a diameter of 300,000 light years, and on to other galaxies. The great Andromeda, he said, is the only one of the spiral nebulæ visible to the naked eye, and appears in very clear weather as a star cloud. Means had been found to measure its distance from the earth, and it had been determined that the great Andromeda nebula was 1,000,000 light years away. This galactic system had a diameter of 50,000 light years. It is our nearest neighbour among the nebulæ, of which there are thousands further away, some of which form galactic systems greater than our "Milky Way." Mr. Stewart dwelt in terms which, he said, admittedly "meant nothing,"—the distances are beyond the comprehension of man and, "It is laughable, to say the least of it," he concluded, "that mere man, under these circumstances, should sometimes imagine that he is of some importance."

J. D. Craig, M.E.I.C., chairman of the Ottawa Branch, presided at the luncheon, which was very well attended, about one hundred members listening to Mr. Stewart's address with the greatest interest.

Annual Meeting

Noulan Cauchon, A.M.E.I.C., town-planning expert and consulting engineer, was honoured with the chairmanship of the Ottawa Branch for the ensuing year, at the annual meeting which took place on the evening of January 13th, at the Daffodil, succeeding J. D. Craig, M.E.I.C. F. C. C. Lynch, A.M.E.I.C., was re-elected secretary-treasurer. New members elected to the Managing Committee for a period of two years were: Walter Blue, A.M.E.I.C., Alan K. Hay, A.M.E.I.C., and F. H. Peters, M.E.I.C. Members of the 1926 committee who continue in office for another year are: Col. A. E. Dubuc, M.E.I.C., and W. A. Rush, A.M.E.I.C.

The new chairman is prominent in town-planning, and for eighteen years has endeavoured to bring about a federal district planned along scientific lines. He is at present chairman of the Town-Planning Commission of Ottawa, and is an honorary member of the Ontario Association of Architects. Mr. Cauchon was with the Canadian Pacific Railway for twenty years, and filled the post of assistant engineer to the Board of Railway Commissioners for two years.

The report of the retiring chairman, J. D. Craig, M.E.I.C., indicated that the year had been one of varied activity. Mr. Craig particularly stressed the necessity of the engineer taking a greater interest in community affairs, and expressed his keen appreciation of the co-operation of the Management Committee and the members of the various sub-committees.

The chairman regretted having to record the loss through death of seven valued members: Dr. Martin Murphy, M.E.I.C., F. A. Wise, M.E.I.C., Le Roy T. Bowes, A.M.E.I.C., Col. Georges Roy, M.E.I.C., A. A. Dion, M.E.I.C., Thomas Shanks, BRANCH AFFILIATE, and E. C. Hutchinson, A.M.E.I.C.

Other reports were presented by the secretary-treasurer; W. A. Rush, A.M.E.I.C., chairman, proceedings committee; Col. A. E. Dubuc, M.E.I.C., chairman, membership committee; M. F. Cochrane, M.E.I.C., branch librarian, and Alan K. Hay, A.M.E.I.C., sub-committee on advertising. The reports of committees indicated that the Ottawa Branch had experienced an active and very satisfactory year. Mr. Lynch's report indicated that the branch finances are in very satisfactory condition.

Through the courtesy of B. E. Norrish, A.M.E.I.C., Associated Screen News of Canada, a film of "Felix the Cat" was screened, to the amusement of the engineers. The Canadian National Parks also contributed an interesting movie of wild life in New Brunswick, in addition supplying an operator. Community singing was also held, Mr. Charles O'Reilly officiating at the piano.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer.

The annual meeting was held in the Y.W.C.A. rooms on December 17th, 1926, following a dinner at which Mr. J. W. Curran, editor of the Sault Daily Star, was a guest.

Chairman C. H. Speer, M.E.I.C., called the meeting to order and the various standing committees reported on their share of the year's activities. The Paper Committee, under C. Stenbol, M.E.I.C., is to be commended upon the year's programme. The secretary-treasurer's report showed the branch in good standing and the average attendance at the meetings for the year was 27, which is fifty per cent of the resident members. The Nominating Committee reported the result of the election for 1927 as follows:—

Chairman	Geo. H. Kohl, A.M.E.I.C.
Vice-Chairman	R. S. McCormick, M.E.I.C.
Secretary-Treasurer	A. H. Russell, A.M.E.I.C.
Executive	R. A. Campbell, A.M.E.I.C.
	W. S. Wilson, A.M.E.I.C.
	J. G. Dickinson, M.E.I.C.
	C. R. Murdock, A.M.E.I.C.
Ex-officio	C. H. E. Rounthwaite, A.M.E.I.C.
	C. H. Speer, M.E.I.C.

The auditors appointed for the year were C. H. E. Rounthwaite, A.M.E.I.C., and W. S. Wilson, A.M.E.I.C.

The retiring chairman, C. H. Speer, M.E.I.C., gave a short review of the year's activities. He expressed his appreciation for the assistance and co-operation of the members and committees during the past year and he felt sure that the new executive would still improve the standing of the branch, and he would give all the assistance that he could.

Geo. H. Kohl, A.M.E.I.C., the new chairman, thanked the members for the confidence that they had expressed in him by electing him for 1927 to carry on after such an able chairman as Mr. Speer. Mr. Kohl has been working on a programme and it looks as if there will be a treat in store for the members the coming year.

Visit to Plant of Sault Daily Star

At 8.30 under the guidance of Mr. J. W. Curran, editor of the Sault Daily Star, the members visited the offices and plant of our enterprising daily and there we saw everything. The offices of the various departments, the job printing department, the linotypes, the large press, etc., and even the telegraph instrument tucked away in the corner, were all inspected.

The inspection started in the business office, where we were given an opportunity to examine the Star's cabinet of Algoma curios, including Indian relics, etc., and the cabinet of samples of Algoma minerals and other products. The exhibit of the handiwork of the

Technical School students was much admired. The editorial and reporters' rooms were next visited, which had been specially cleaned up for the occasion, (as one of the staff admitted). The mechanical department came next and the members were more at home, and the machinery and operation of same underwent a close inspection, especially from those who follow the mechanical branch of our profession. There we saw the linotypes in action setting up the day's news, and each of our members received a linotype slug with his name cast on it as a souvenir. There are six operators and they turn out fifty columns of type per day. The assembling of the galleys of type as taken from the linotypes into pages on the makeup table was most interesting. The page form was run through the matrix machine and the cardboard thus made was taken to the stereotyping room, where a cylindrical plate was cast from it. This plate was trimmed and trued and then placed in the big press, which was started up and ran off copies of a special edition of the Star, with the large headline across the top of the front page "Special Edition for Engineering Institute," which were given to the members as another souvenir of our visit. This large press turns out 25,000 copies of a 24-page paper every hour, it weighs forty tons, and the papers come out folded and counted.

The efficiency of the whole organization shows a capable manager at the head of a thoroughly well organized staff of skilled office workers and mechanics.

As a fitting finish to a most pleasant evening, Mr. and Mrs. J. W. Curran, as hosts, assisted by the girls of the staff, served coffee and cake to the visiting members in the large business office.

A hearty vote of thanks was moved by J. Hayes Jenkinson, A.M.E.I.C., to Mr. and Mrs. Curran and the staff of the Sault Daily Star for the royal manner in which they had entertained the members of our branch. Mr. Curran replied, expressing his pleasure in being able to have the members of the Sault Branch as guests and he cordially invited them all back some other time, and mildly suggested (amid cheers) that it would be after May 1st.

Vancouver Branch

F. P. V. Cowley, A.M.E.I.C., Secretary-Treasurer.

The annual meeting of the Vancouver Branch was held in the auditorium of the Vancouver Board of Trade on Wednesday, December 15th, 1926, at 8 o'clock p.m.

After the reading of the minutes of the previous annual meeting and the appointment of scrutineers to count the ballot for the election of officers, the secretary presented his annual report, the details of which are embodied in the Vancouver Branch report to Council, which is to be presented at the annual meeting of The Institute.

Following the transaction of general business, the retiring chairman, W. H. Powell, M.E.I.C., addressed the members as follows:—

The Retiring Chairman's Address

There are two periods of gratification to every person who undertakes the chairmanship or presidency of any organization: first, when assuming the office he realizes the confidence the members have placed in him; second, when leaving the office he breathes easily, as he feels that he is relieved of the duties that the position demanded.

One year ago this branch honoured me by electing me chairman, and I felt at the time and do still that the Nominating Committee played me a trick when they failed to place a second name on the ballot. It was unconstitutional. But never during the year was it necessary for your chairman to vote, accordingly your own unanimity of purpose has eliminated all doubt as to the legality and regularity of the appointment.

My year as chairman has been marked by considerable activity in the institution, and for this highly gratifying result I take absolutely no credit. The programme of visits to works and the excellent series of addresses which are now being held are the result of a great deal of work on the part of the Executive Committee, and particularly on the part of our secretary, E. A. Wheatley, A.M.E.I.C. Words cannot express my appreciation of his efforts to make this year a success. Probably no branch ever undertook a more pretentious programme, and I trust that those booked for the future will have your wholehearted support. I am sorry to say that in the past the attendance of Institute members at these meetings has not been all that your chairman desired, nor all that the study and preparation by the speaker merited. The only boast I make is that during my time as chairman I attended every trip and every meeting and I can truthfully say that each was enjoyable and profitable.

In connection with our trips, I would here like to speak a word of appreciation of the kindness of the British Columbia Electric Railway, the Britannia and the harbour board officials, who made our trips to Alouette, Britannia and around our harbour so pleasant that those who went will always have memories of unexcelled arrangements, unparalleled courtesy and unlimited hospitality.

Continually we are asked if it is worth while obtaining membership in The Engineering Institute, and I think that every engineer should be able and willing to point out the advantages of that connection.

A Dominion-wide organization working along the lines of facilitating professional knowledge, promoting professional interests, encouraging education and research and enhancing the usefulness of the engineers to the profession, must eventually bring to engineers proper recognition of their own worth to the community and then, aided by due scrutiny, examination and selection of those authorized to call themselves engineers, which can only be done at present by provincial legislation, we will finally arrive at the stage where the title, "Member of Engineering Institute of Canada," is the hall mark of superior education, highest professional ideals and the absolute confidence of the public in those essential engineering requirements.

The branch this year was fortunate in that we had as one of our most active driving forces the president of The Institute, Major Geo. A. Walkem, M.E.I.C. At the Professional Engineers' dinner forecasts were made of what we may expect from this highly talented engineer, and I'm sure that this branch will give to Major Walkem its unqualified support in the administration of any position to which he may be selected, for we know he is liberal with his assistance, conservative in his attitude, progressive in his ideas and not at all provincial in his views. His services to the branch this year as in the past should not be forgotten.

I cannot close without mentioning P. H. Buchan, A.M.E.I.C., who for many years served this branch as secretary, but pressure of work last spring forced him to ask to be relieved of those duties. We all truly appreciated his quiet attention to duty, the perfection and simplicity of his system and the accuracy of his records and accounts. He continues as one of the faithful of the Executive Committee.

Mr. Powell's address was received with continued applause, and when this had subsided the chairman called for the report of the scrutineers, which shows the following branch officers elected for the year 1927: F. W. Alexander, M.E.I.C., chairman of the branch for 1927, by acclamation; W. Brand Young, A.M.E.I.C., as vice-chairman, by election; F. P. V. Cowley, A.M.E.I.C., secretary-treasurer, by acclamation, and P. H. Buchan, A.M.E.I.C., H. W. Frith, M.E.I.C., A. C. R. Yuill, A.M.E.I.C., members of the Executive Committee, by election. These, together with those elected for the two-year period, in 1926, namely, W. B. Greig, A.M.E.I.C., E. A. Wheatley, A.M.E.I.C., J. R. Grant, M.E.I.C., together with ex-officio members, namely, Major Geo. A. Walkem, M.E.I.C., W. H. Powell, M.E.I.C., constituted the Executive Committee of the branch for the year 1927.

Mr. Powell then handed over the chair to his successor, Mr. Alexander, who, in a short address, expressed his appreciation of the honour accorded to him, stating his admiration for the high standing set by his predecessor and his determination to live up to that standard.

Mr. Young then thanked the members for electing him vice-chairman of the branch, and in conclusion asked the members to accept, through him, the regrets of Mr. Cowley, the newly elected secretary-treasurer, who was unable to be present on account of ill health.

After transacting other necessary items of business, a general discussion was held as to ways and means of improving the attendance at meetings and in this connection W. H. Powell, M.E.I.C., paid a tribute to Major H. B. Muckleston, M.E.I.C., whose attendance was one hundred per cent. He submitted to the elected executive that they act as an attendance committee, and by personal effort see that individually they bring some two or three to attend each meeting.

Victoria Branch

K. M. Chadwick, M.E.I.C., Secretary-Treasurer.

A very interesting paper on the manufacture of wood pulp was presented before the Victoria Branch by W. L. Ketchen, M.E.I.C., of the British Columbia Pulp and Paper Company, Limited, on December 15th, 1926.

Mr. Ketchen introduced his subject with an outline of the early history of the manufacture of sulphite pulp, and before entering into the details of its present manufacture, he pointed out the importance of the wood pulp industry in Canada. In 1925, 227,465 tons of bleached sulphite, and 615,320 tons of unbleached sulphite were manufactured in this country. The wood consumed in the production of this was approximately 1,686,000 cords.

Mr. Ketchen quoted from the United States Department of Agriculture Bulletin, which in 1924 stated: "A recent study of the world's timber supply shows that coniferous species supply nearly one-half of the timber cut in the entire world. They occupy little more than one-third of the world's area of forest lands. Furthermore, the current growth of coniferous is less than four-fifths of the cut. The critical timber supply problem of the next half century at least will centre in the coniferous forests. The speaker then referred to the forest conditions in some of the European countries. He then explained that it required in capital between $30,000 and $40,000 per ton to build a bleached sulphite mill, exclusive of the cost of an hydro-electric plant and timber limits, the cost depending to a large extent on the location of the mill.

Mr. Ketchen then went into considerable detail in describing the manufacturing processes, explaining the various stages of manufacture under three principal headings: the preparation of the wood; the preparation of the acid and the cooking process; and the preparation and bleaching of the pulp after cooking.

Towards the close of his address the speaker devoted some time to describing various articles into which sulphite pulp can be manufactured, dealing particularly with the several methods of making artificial silk. The lecture was illustrated by many instructive lantern slides and at the end of Mr. Ketchen's address a hearty vote of thanks was extended to him.

Maximum Spans for Dwelling House Floor Joists with a Plastered Ceiling on Underside

The following span table is based on actual sizes of joists, according to United States standards for lumber and on the working stresses approved by the Division of Building and Housing of the United States Department of Commerce.

SPECIES OF LUMBER	Joist Spacing Center To Center	These spans are limited by the stiffness of the piece and calculated so the maximum deflection when supporting the full live and dead load shall not exceed 1/360 of the span length. Live load assumed as 40 pounds per square foot of floor area. Dead load includes a lath and plaster ceiling estimated to weigh 10 pounds per square foot and double flooring at 5 pounds per square foot plus the weight of the joist itself. These span lengths apply to all grades in each species indicated. Utilizing the full bending strength of the joists and disregarding deflection would allow greater spans but the plaster ceiling would then be likely to crack. Calculations based on the actual sizes of joists according to American Standards for Lumber.									
		MAXIMUM SPANS FOR JOISTS (FOR ALL GRADES)

*Prepared by Richard G. Kimbell, architectural engineer, National Lumber Manufacturers Association.

Preliminary Notice

of Applications for Admission and for Transfer

January 18th, 1927.

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in February 1927.

R. J. Durley, Secretary.

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council shall be required to pass an examination before a board of examiners appointed by the council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ASHBY—REGINALD BEALE, of Montreal, Que., Born at York, England, Nov. 8th, 1902; Educ., B.Sc., McGill Univ., 1924; 1921 (summer), shop work, Dom. Engrg Co.; spring 1923, demonstrator, McGill survey school; 1924-25, student engrg. course with Westinghouse Electric & Mfg. Co., Pittsburgh, Pa.; 1925-26, supervising splicing and loading of Quebec toll entrance cable and testing for transmission, engrg. staff, Bell Tel. Co., Eastn. div.; at present, engrg staff, Foundation Co. of Can. Ltd.

WICKWIRE—JAMES LEANDER, of Port Arthur, Ont., Born at Kentville, N.S., Mch. 14th, 1902; Educ., B.Sc. McGill Univ., 1924; 1922 and 1923 (summers), instrument work on highway engrg. and town surveying with N. S. Highway Board, and 1924 (summer), same work with Seth W. Crowell; 1924-25, plant layout with Bell Telephone Co. of Canada, Montreal Div.; 1926 to date, grain elevator design work with C. D. Howe & Co., Port Arthur, Ont.

References: H. M. MacKay, E. Brown, R. deL. French, S. Crowell. C. D. Howe, R. B. Chandler.

FOR TRANSFER FROM ASSOCIATE MEMBER TO MEMBER

GRANT—LeROY FRASER, of Kingston, Ont., Born at Toronto, Nov. 7th, 1884; Educ., Diploma R.M.C., 1905, B.Sc. Queen's Univ., 1926; 1904, rodman, Guelph and Goderich Ry.; 1907-08, dftsman and levelman, G.T.P. Ry., Prince Rupert, B.C.; 1908-09, res. engr., G.T.P. Ry., Prince Rupert; 1909-10, on land surveys with F. S. Clements; 1911-14, land surveys, irrigation and power projects, municipal work, etc., with Dutcher, Maxwell & Co.; 1915-16, capt. overseas with Ry. Constrn. Corps, 1917-18, major, 2nd in command, 5th Brig. Can. Ry. troops; 1919 (summer), i/c party, Southern Okanagan irrigation project; 1920, i/c of party on surveys for B. C. Govt.; 1921-22, instructor in engineering, R.M.C.; 1923 to date, associate prof. of engrg., R.M.C.

References: H. K. Dutcher, W. P. Wilgar, D. Hillman, E. C. Goldie, A. MacPhail, N. M. Hall.

FOR TRANSFER FROM JUNIOR TO A HIGHER GRADE

ALDOUS—HERBERT, of Hamilton, Ont., Born at Watford, England, Sept. 15th, 1893; Educ., I.C.S. diploma concrete engineering; 1915-19, overseas with Sanitary Corps; 1919-21, deputy engr. i/c large public works contract, Norwich, England, extensive factory extensions, boiler house and plant, water softening plant, roads, drains and sewers; 1921, Gov't. inspector, Ont. Dept. of Public Highways; 1922-25, estimating engineer on heavy constrn. work, reinforced concrete, factories, warehouses, foundations, sewerage disposal works; 1925-26, temporary engr. large extension to pulp and paper mill, Powell River, B.C., responsible for field work re boiler house extension; at present, designer and estimator, W. H. Cooper, gen. contractor, i/c estimating dept. and responsible for design of all classes of construction work.

References: J. A. McFarlane, A. R. Holmes, A. L. P. S. Clifford, F. T. Nichol, N. L. Crosby.

BAYNE—BLAIR EDMONSTON, of Moncton, N.B., Born at Halifax, N.S., Nov. 26th, 1893; 3 yrs. engineering Dalhousie, N.S. Tech., E.E., 1922; N. B. Electric Power Commn., roadman and instrumentman on bldg. of St. John-Moncton transmission line, looked after installing of sub-stations during latter part of time at Moncton and Sussex, work finished May 30th, 1923; on survey party as transitman to locate a spur from Hardwood Ridge to Minto, on preliminary survey work between Lockeport station and town, work finished end of Aug. 1923; Jan. 15th to May 1924, levelman on Kingsclear-Vanceboro survey, tsfrd. to hbr. engr's office, remaining there until end of year looking after dredging at Cape Tormentine and Port Borden; July 1925 to present, with C.N.R.; maintainer on storage battery car at Halifax for two months, and since that time has been on the road doing wiring jobs for the electrical supervisor; war service; 13 months in munition factory at Moncton, 1916-17; Nov. 1917, passed for Air Force and trained, receiving commission of 2nd lieut., June 1918, in August going to Netheravon Camp, England.

References: F. O. Condon, A. S. Gunn, F. B. Fripp, C. S. G. Rogers, H. J. Crudge, G. L. Dickson.

DUNBAR—JOHN ROBERT, of Hamilton, Ont., Born at Toronto, Mch. 11th, 1900; Educ., B.Sc. McGill Univ., 1920; 1 yr. post-graduate study Mass. Inst. Tech.; summers of 1918-19 and 20, Geodetic Survey of Canada; Nov. 1920 to Sept. 1921, transformer design, Can. Westinghouse Co. Ltd., Sept. 1921 to Sept. 1922 and June 1923 to Sept. 1925 with same Co., generator and motor design; Sept. 1925 to date, i/c A.C. generator and synchronous motor design, Can. Westinghouse Co.

References: H. E. Hart, W. F. McLaren, H. B. Dwight, C. V. Christie, E. G. Burr, J. C. Nash, C. F. Medbury.

FOR TRANSFER FROM STUDENT TO A HIGHER GRADE

BOISMENU—ROMEO, of Montreal, Que., Born at Montreal, June 22nd, 1899; Educ., 2 yrs. Univ. of Montreal, for four years chainman, City of Montreal.

References: N. J. A. Vermette, J. E. Gill, W. T. Jamieson, W. Dickson, C. Godin, J. G. Caron, G. R. MacLeod.

KINGSTON—THOMAS MARTYN SIBBALD, of Buffalo, N.Y., Born at Penetangueshene, Ont., Oct. 11th, 1900; Educ., B.A.Sc. Univ. of Toronto, 1924; 1921 and 1922, summers, worked with res. engr. on constrn. work of Toronto Harbour Commn.; 1925, acted as office engr., E. P. Muntz Inc., Buffalo, N.Y., handled layout work and a portion of engrg. work for Seneca Iron & Steel Co. plant and coal trestle for Delaware Lackawanna and Western Co.; March 1926, in office of division engr. of Lehigh Valley Railroad; June 1926, field engr., Fed. Portland Cement Co.

References: T. R. London, C. R. Young, J. R. Cockburn, C. L. Hays, E. P. Muntz, P. Gillespie.

MILLS—CHARLES PERKINS, of Albany, Ga., Born at Ottawa, Ont., Mch. 19th, 1899; Educ., B.Sc. McGill Univ., 1923; 1920 (summer), rodman, G.T.R. survey; 1921 (summer), clerk, Central Experimental Farm, Ottawa; 1922 (summer), student engr., management div., Stone & Webster, Boston; June to Jan. 1923, student engr. with same company; 1923-24, secretary to gen. mg., Columbus Electric & Power Co., Columbus, Ga.; 1924-25, student industrial engr., Columbus Electric & Power Co.; 1925 to date, sales manager of S. Georgia Power Company, a subsidiary of Columbus Electric & Power Co., and under executive management of Stone & Webster Inc.

THE

ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

Published monthly at 176 Mansfield Street, Montreal, by The Engineering Institute of Canada, Incorporated in 1887 as The Canadian Society of Civil Engineers.

Entered at the Post Office, Montreal, as Second Class Matter

The Institute as a body is not responsible either for the statements made or for the opinions expressed in the following pages.

Volume X | Montreal, March, 1927 | Number 3

Hydro-Electric Power Developments on the Gatineau River

The Important Features of the Farmers, Chelsea, and Paugan Power Developments of the Gatineau Power Company

J. A. McCrory, M.E.I.C.

Office Engineer, Power Engineering Company, Montreal.

Paper presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Quebec Que., February 15th to 17th, 1927

The Gatineau river rises in the Laurentian mountains at the height of land near the headwaters of the St. Maurice and the Bell rivers, and flows in a southerly direction through a rugged and generally well wooded country to its junction with the Ottawa river at Hull, opposite the city of Ottawa.

The drainage basin of the river has an area of 9,600 square miles, which is about one-sixth of the total area drained by the Ottawa river. In its length of 275 miles it falls about 1,200 feet, half of this fall occurring in the last 135 miles, below the mouth of the Gens-de-Terre river, one of the principal tributaries of the Gatineau. The mean annual precipitation over the watershed is approximately 34 inches, and from one-half to three-quarters of which reaches the river as run-off.

The Department of Public Works of Canada has taken gauge readings at Chelsea since 1900, and at Alcove, fifteen miles above Chelsea, since 1917. Mr. S. S. Scovil, M.E.I.C., has correlated the readings of these gauges and has worked up dependable flow records for the last fourteen years. These records show a minimum flow during this period of 1,900 c.f.s., in February 1918, and a maximum of 72,300 c.f.s. in May 1924. The maximum flow of which there is any record is about 76,000 c.f.s.

Lumbering operations have been conducted along the Gatineau and its tributaries for many years, and in order to facilitate the floating of logs, timber dams have been built on a number of the tributaries. Until recently this has constituted the only attempt at regulation and has been used solely for log driving. At present, however, a large concrete dam is being built under the direction of the Quebec Streams Commission on the Gatineau river about thirty miles above Maniwaki. The reservoir formed by this dam will have an estimated storage capacity of 90,000,000,000 cubic feet, and will afford a minimum regulated flow of 8,000 c.f.s. in the dryest years. The ultimate regulated flow of the river has been estimated to be between 10,000 and 11,000 c.f.s.

Location of the Three Developments

Very little engineering investigation has been made along the river above the mouth of the Gens-de-Terre. Below that point there are a number of sites where the development of power is practicable, three of the more important of which, at Farmers rapids, Chelsea and Paugan falls, are at present being developed by the Gatineau Power Company.

The Farmers development is located four and one-half miles above the mouth of the Gatineau. One fall is being utilized in this development giving a head of 66 feet. The dam at Farmers will back the water up to the tailrace at Chelsea, a distance of one and one-quarter miles.

Work on the Chelsea development was begun about two months before that at Farmers. By drowning out four falls above Chelsea rapids and backing the water up to the Paugan tailrace, a head of 93 feet is obtained at this point.

The third of this group of developments, Paugan, is situated twenty-six miles above Chelsea or thirty-two miles above the mouth of the river. The high dam that is being built below the falls will back the water up to Chute Calumet, a distance of thirty miles, drowning out nine falls and rapids and creating a head of 136 feet.

By combining the operation of these three developments into one system it will be possible to utilize to the best

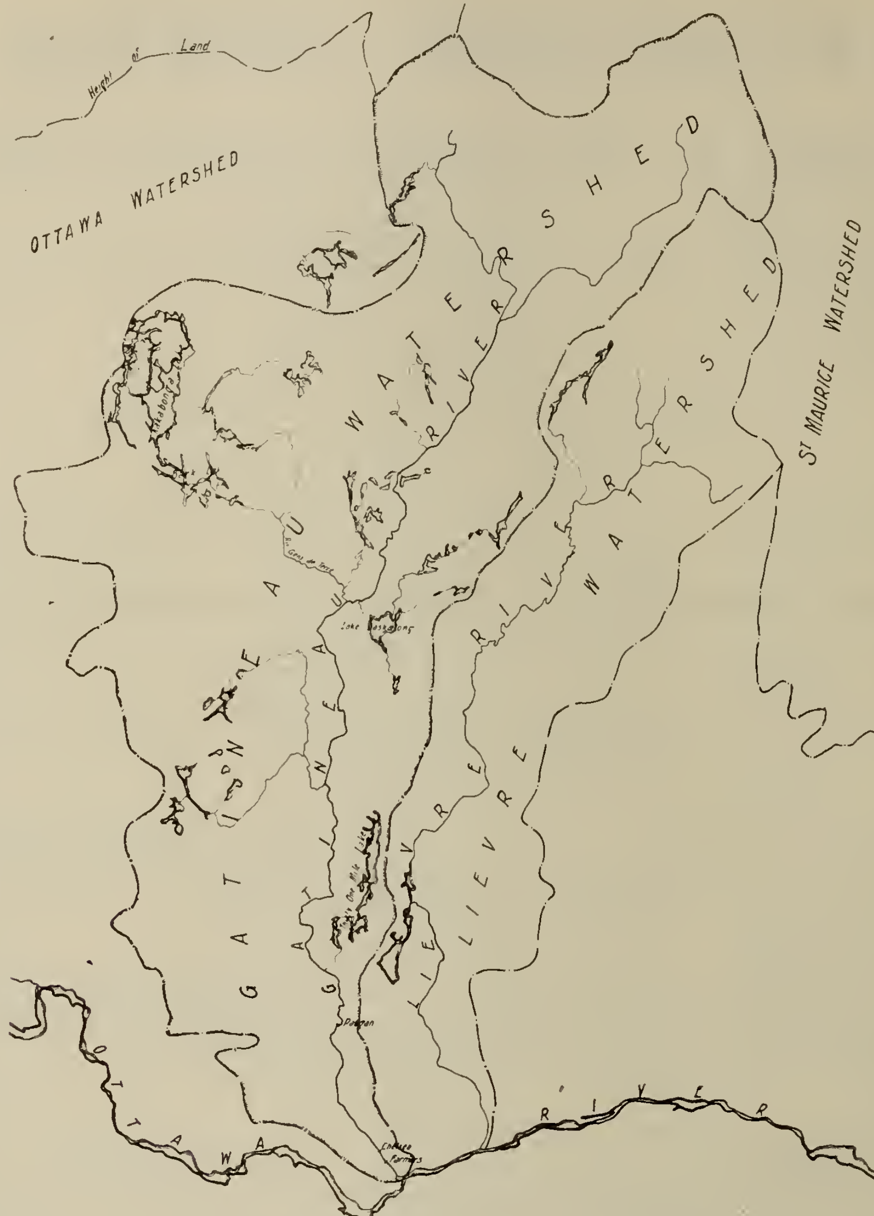

Figure No 1.—Gatineau Watershed Showing Location of Farmers, Chelsea and Paugan Power Developments.

advantage the total fall in the river from Chute Calumet to its mouth, a distance of sixty-two miles, and to develop at least two-thirds of the available power in the whole river. The storage provided by the ponds created above the Chelsea and Paugan plants will assist materially in the regulation of the system and should eliminate all possibility of trouble from ice.

Available Market for Power to Be Developed

The principal customers of the Gatineau Power Company are the Canadian International Paper Company, whose plant at Gatineau will take a large block of power, the Hydro-Electric Power Commission of Ontario, which will take power for distribution in Ontario, and the Hull Electric Company.

Owing to the fact that the Hydro-Electric Power Commission's system is operated at 25 cycles while the Canadian International Paper Company's mill and the system of the Hull Electric Company are at 60 cycles, the three developments will supply two independent distribution systems.

Although Paugan will be the principal source of 25-cycle power, one 25-cycle generator is being installed at Chelsea and one at Farmers in order to equalize the hydraulic demand of the three developments.

The Chelsea generators are being supplied by the Canadian Westinghouse Company and have a rating of 36,000 kv.a. for the 60-cycle machines, and of 32,000 kv.a. for the 25-cycle machine, all at 100 r.p.m. The Canadian General Electric Company is supplying the Farmers generators. The 60-cycle machines in this plant have a rating of 25,000 kv.a. at 90 r.p.m., while the rating of the 25-cycle machine is 22,500 kv.a. at 88.3 r.p.m. The generator in all cases is 6,600 volts.

Each generator will be connected to its respective bank of transformers, which will step the voltage up from 6,600 to 110,000 volts for transmission to Hull, to the paper mill at Gatineau and to the Paugan system.

The 60-cycle lines from Chelsea and Farmers will feed into a central switching station, which will be so arranged that excess power can be transmitted to the paper mill for use in electric boilers.

General Features of the Power Stations and Hydraulic Works

Chelsea and Farmers Developments

The Chelsea and Farmers power houses have a good many points of similarity. Both are of the type which has become practically a standard for low and moderate head developments, in which the substructure of the power house forms a part of the dam and contains the turbine intakes with their headgates and racks, as well as the turbine casings and draft-tubes. They are both laid out for five units, three of which are being installed in each power house at present.

The turbines are vertical machines, manufactured by the Dominion Engineering Works, with single Francis type runners. Those at Chelsea have a rated capacity of 34,000 h.p. each, at 93 feet head and a speed of 100 r.p.m. The rated capacity of the Farmers turbines is 24,000 h.p. at 66 feet head.

The regulation of the turbines is obtained by hydraulic governors. The water from the operating cylinders is dis-

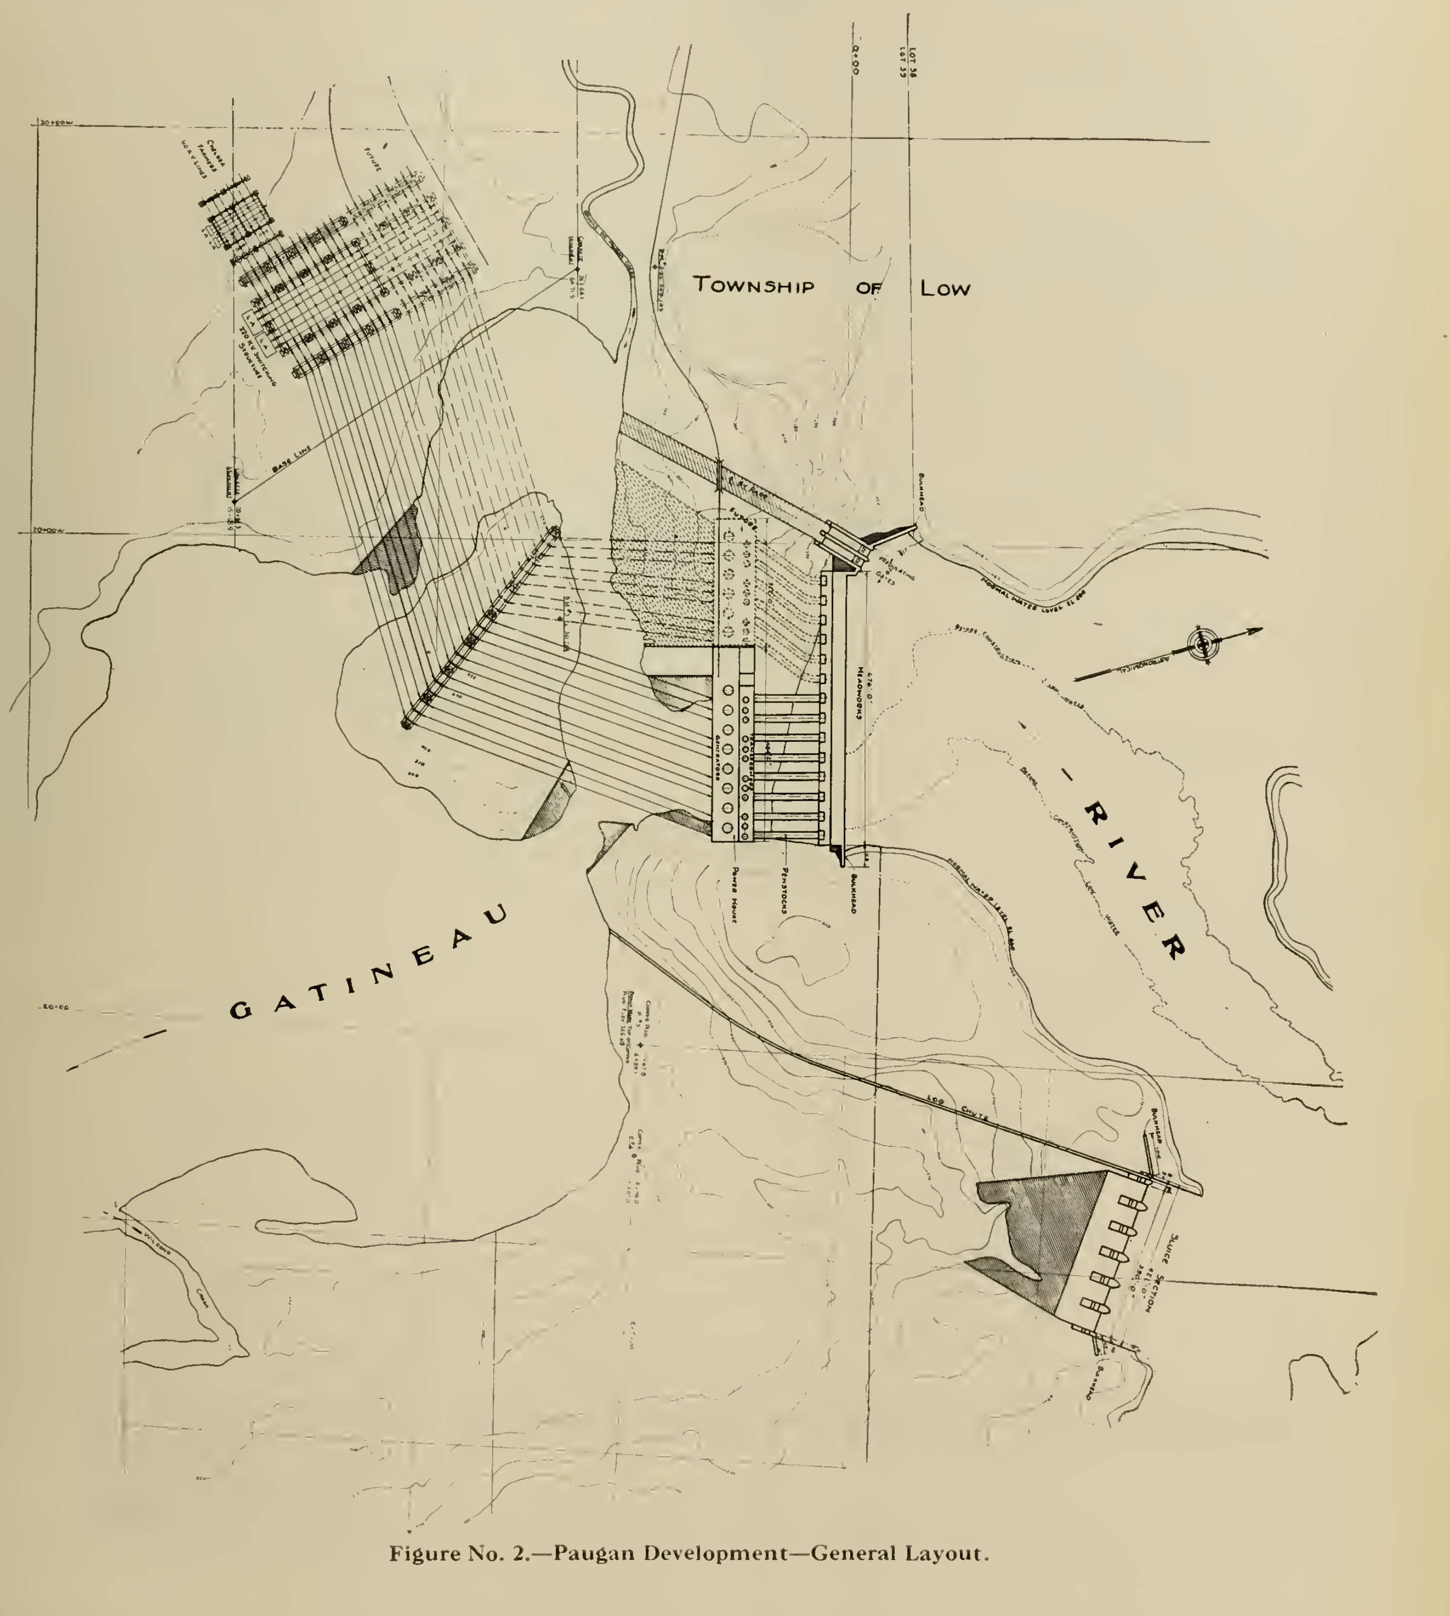

Figure No. 2.—Paugan Development—General Layout.

charged into a concrete sump tank which runs the full length of the building in the pipe tunnel on the upstream side of the generator room. From the sump tank the water is returned to the high-pressure system by three pumps, two of which are motor-driven and one turbine-driven, which are located, together with the air compressors for the governor system and the station service pumps, in the pump pit between units Nos. 2 and 3.

Each turbine intake consists of three water passages, those at Chelsea being eleven feet wide and those at Farmers twelve feet wide. The water passages are each provided with a set of steel trash racks with rack bars spaced about 3½ inches apart and a Stoney headgate. The headgates are motor-operated through a line shaft which runs the full length of the gate house and which can be connected by means of clutches to each hoist. Three sets of steel emergency gates have been provided to facilitate the unwatering of the intakes.

The power house superstructures are, of course, fireproof throughout and the various banks of transformers, oil switches, disconnecting switches and the high tension bus rooms have been so separated and isolated by means of partitions, barriers and fire doors that a serious flash-over or fire originating in one part of the power house cannot be communicated to other parts. The building walls and main partitions are of plastic brick. Auxiliary partitions and barriers are of metal lath and cement plaster. In the transformer rooms and oil-switch rooms the steel members of the structure have been encased with brick or concrete, while all floors and roofs are of reinforced concrete. Metal sash have been used throughout the buildings and all doors to switch rooms, bus rooms, control room, offices, etc., are kalameined.

The generator rooms, pump pits, corridors, lavatories and mess rooms are floored with red quarry tile with a tile cove around the walls. The walls of these rooms and of the offices are plastered. All walls and ceilings throughout the building are painted in light buff or white, kalameined doors and trim are dark brown and all exposed steel and steel sash are dark olive green.

The generator rooms are served with 150-ton travelling cranes. The crane in the gate house at Chelsea has a capacity of 30 tons and that at Farmers 50 tons. The reason for this difference is that at Farmers the railroad siding comes in at the upper level so that transformers and turbine parts are handled from the cars by the gatehouse crane and lowered through a transfer well to the transformer room level, while the siding at Chelsea enters on the generator room floor and this equipment is handled by the generator room crane.

Paugan Development

Above Paugan a mile of fast water, in which the river drops thirty feet, terminates in a small rocky pool. From this pool the river flows over Paugan falls, a sheer drop of twenty-eight feet, into a short, narrow gorge, at the foot of which it divides into two channels which empty into a large shallow basin. The walls of the gorge are very steep, on the east side rising almost perpendicularly for more than one hundred feet, and are flanked by high, rocky hills.

The main dam will be built in the gorge a short distance below the falls and will run across the hill on the west side to the higher ground beyond. This dam will contain two regulating sluices, each twenty feet wide, and the intakes for fourteen turbines. The maximum height of the dam, from the bottom of the gorge to its crest, will be 165 feet.

Some distance above the falls, a sluice dam will be built in a natural depression in the hill flanking the river. This dam will contain a log chute and six sluiceways each fifty feet wide provided with Stoney sluice gates and will discharge into the basin below the gorge. The dam has been designed for a discharge capacity of 120,000 c.f.s. at high water.

The power house will be located at the foot of the gorge; the turbines being connected to the intakes with steel penstocks seventeen feet in diameter. The substructure will contain the settings for eight units at present, each unit having a rated capacity of 34,000 h.p. at 132 feet net head and 125 r.p.m.

In order to take care of the flow of the river during

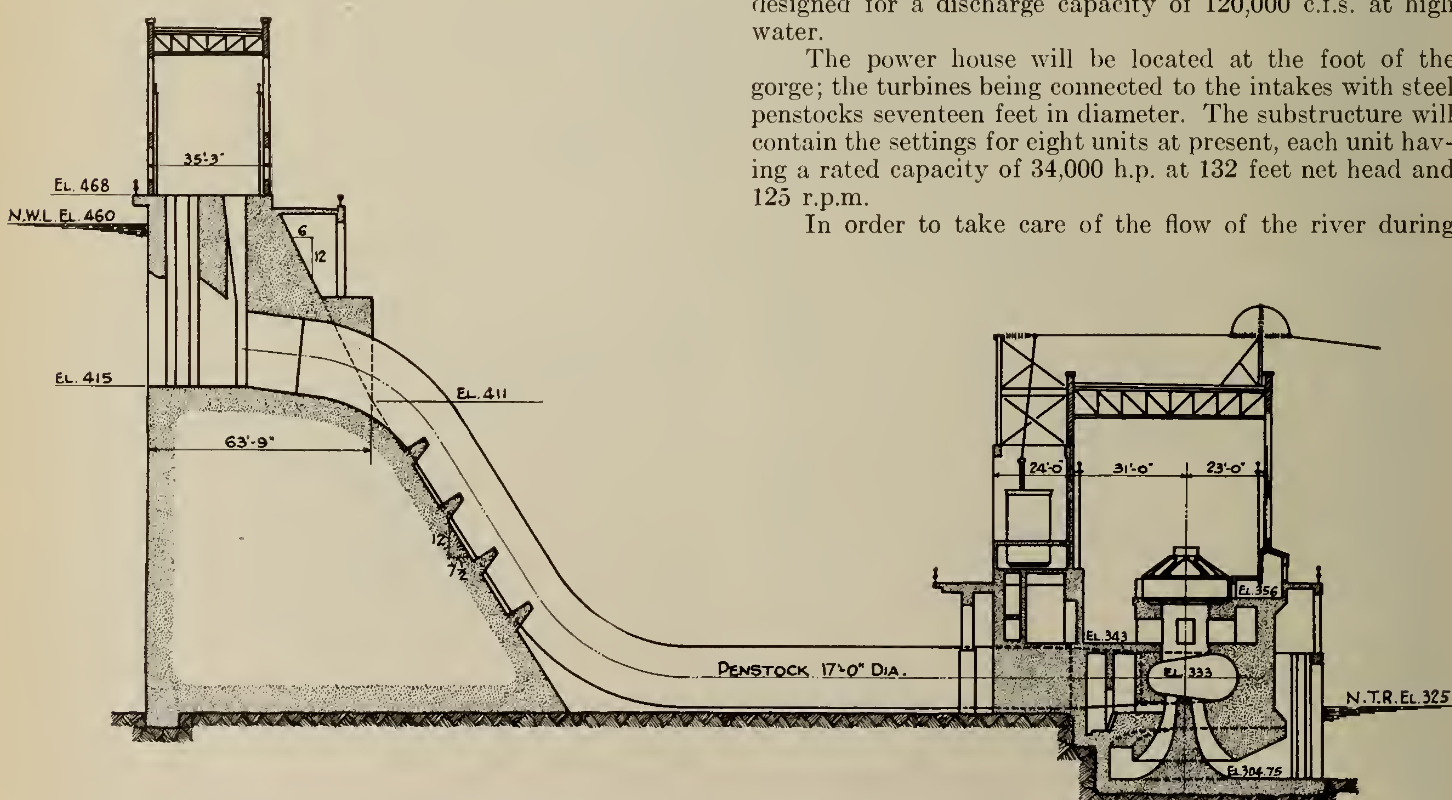

Figure No. 3.—Paugan Development—Typical Section Through Headworks and Power House.

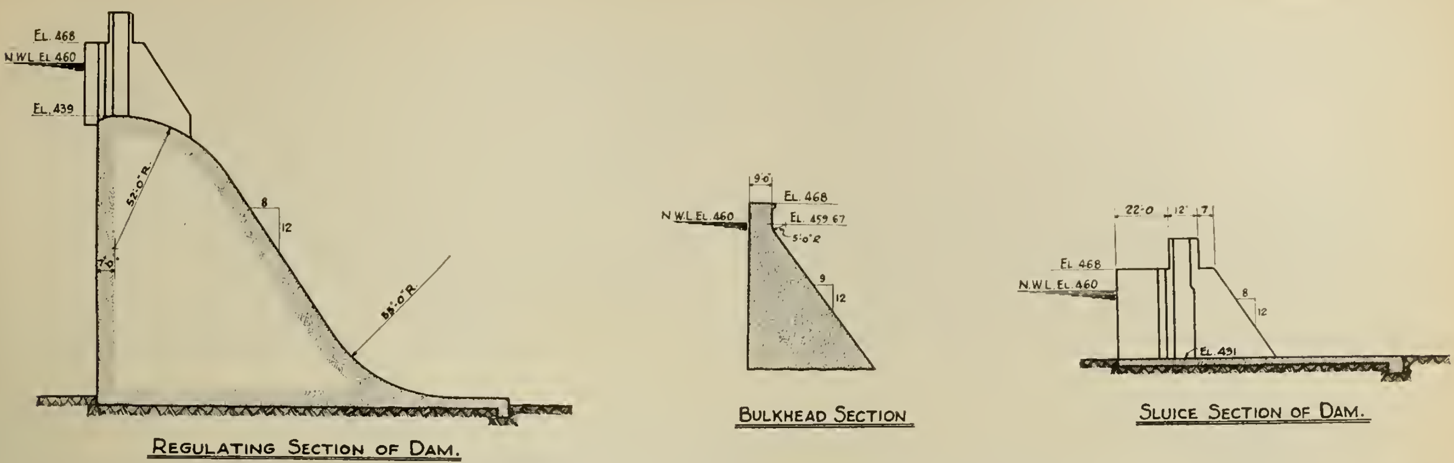

Figure No. 4.—Paugan Development—Typical Sections Through Dam.

construction of the intake dam and the power house, a deep channel which will be capable of taking care of the full flow of the river up to 30,000 c.f.s. is being excavated from the pool above the falls to the west channel below the gorge. The bottom of this by-pass channel will be about twenty feet below the present level of the pool. Upon the completion of the development this channel will take the discharge from the regulating sluices.

Details in the Design of the Chelsea Development

At Chelsea, the river is divided into two channels by a small, rocky island. The dam, which is 1,600 feet long, runs almost due east and west across this island. Beginning at the west side, the dam consists of about eighty feet of bulkhead section, the power house substructure 303 feet long, another 95 feet of bulkhead section, the west spillway section 300 feet long, the sluice section 325 feet long, the east spillway section 480 feet long, and about 50 feet of bulkhead which contains the log chute adjoining the east bank. The dam carries a reinforced concrete bridge with a twelve-foot roadway supported on concrete piers on the spillway section, which gives access to the power house from the east bank.

The discharge at Chelsea during maximum known flood was about 76,000 c.f.s. At normal high water, the dam, with five feet of freeboard, has a discharge capacity equal to one and one-half times this flood.

The sluice section of the dam contains five sluiceways each fifty feet wide. These sluiceways are provided with Stoney gates which are raised and lowered by a motor-driven travelling hoist on a steel bridge above the sluice dam.

The lowest point of the dam is in the main channel at about el. 215, sea level datum. All sections of the dam are of the gravity type and have been so designed that with the full static head against the upstream face of the dam with water at el. 320 acting together with an assumed upward pressure on the base of the dam equivalent to the full head at the heel and decreasing uniformly to zero at the toe the resultant will fall within the middle third.

The power house was located in the western channel in order to permit the railroad siding to enter at the generator room floor level. This channel was widened and deepened to form the tailrace canal which joins the main channel at the foot of the island.

The Power House

In designing a structure of this type it is necessary first of all to determine the general characteristics of the development, such as capacity and number of units, line voltage and arrangement of low-tension and high-tension busses, switching equipment and transformers, the character of the load and the relation of the development to other power plants on the same system.

After these characteristics have been determined, certain preliminary data must be obtained with regard to the dimensions and weights of generators and turbines, the amount of the hydraulic thrust and the layout of turbine casings and draft-tubes. With this information at hand a preliminary layout is made to determine the spacing and arrangement of the units. This layout is checked by means of the stability diagram.

The forces which must be taken into consideration in the design are the external forces, consisting of the hydrostatic pressure against the upstream face of the structure, the uplift that may develop due to seepage along the base and the weight of the structure itself and of the generators and turbines, together with the hydraulic thrust, and the internal forces, which consist of hydrostatic and surge pressures in the intakes, water passages and turbine casings.

In low head developments the intake and scroll-case blocks can usually be so constructed and reinforced that they will act together in resisting hydrostatic pressure and uplift. In the case of the Chelsea development this was found to be impracticable, and consequently the intake block was made sufficiently heavy to take care of these forces without assistance from the scroll-case blocks. It was also found necessary to limit the amount of uplift that might develop by building a cutoff wall at the heel of the structure and providing an 18- by 18-inch box drain 18 feet from the heel.

The units at Chelsea are spaced 48 feet centre to centre. Referring to the stability diagram, it will be noted that the hydrostatic pressure per unit is 5,400,000 pounds, with a moment arm of 60 feet, and the assumed maximum uplift is 1,620,000 pounds with a moment arm of 79 feet. The overturning moment therefore will be the sum of the moments of these two forces or 452,000,000 foot-pounds.

The water passages in the intake structure have been reinforced to take care of the internal pressure, so that the most unfavourable condition for stability is with the emergency gates closed and the water passages empty. This is the condition for which the diagram has been drawn. The weight of the structure and of the water above the emergency gates is 24,630,000 pounds, with a moment arm of 45 feet. The resisting moment therefore is 1,111,000,000 foot-pounds. This gives a factor of safety against overturning of about 2.5. The sliding coefficient of the structure, being the quotient of the pressure divided by the weight minus uplift is low, $\frac{23{,}010{,}000}{5{,}400{,}000} = 0.24$.

Intake Structure

In the detailed design the maximum unit stresses allowed were 12,000 pounds per square inch tension in the steel and 500 pounds per square inch compression and 50 pounds per square inch shear in the concrete. Reinforcing bars which are under full tension are embedded or lapped at least 60 diameters.

The various members of the intake structure are reinforced as follows:—

(1) Main Walls Between Units. These walls are seven feet thick. The main system of reinforcement is vertical and takes care of bending tension due to hydrostatic pressure with one intake empty and adjacent intake full and of direct tension due to the water pressure on the floor of the intake. A secondary system of horizontal bars is used to take the reaction from the vertical members at the emergency gate and rack slot and the headgate slot and to tie the head wall to the intake walls.

The vertical members are designed as slabs fixed at the upper end and supported at the lower. Taking as a typical

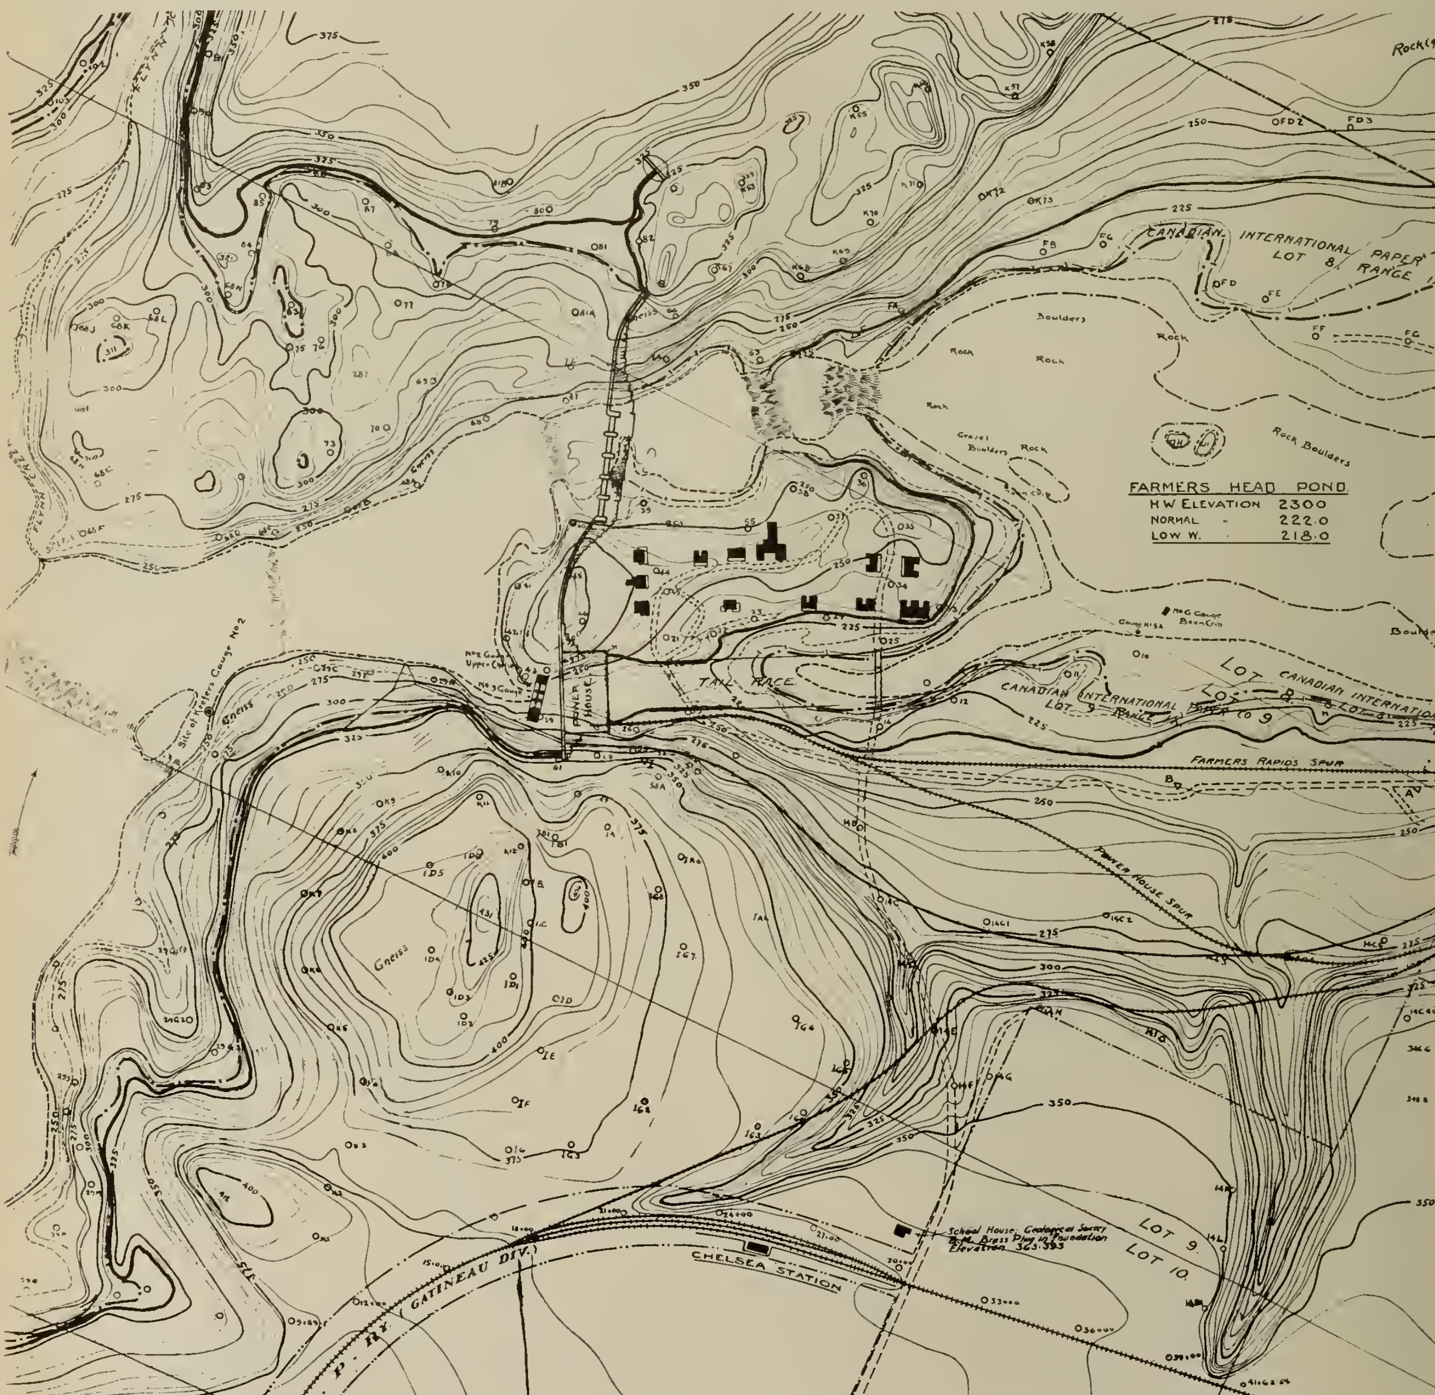

Figure No. 5.—Farmers and Chelsea

case the section of wall between emergency gates and racks the area of reinforcement required is found as follows:—

The span is 32 feet and the pressure diagram is a trapezoid with the lower base equal to 3,125 pounds per square foot.

The bending moment at any point X above the base will be

$$M = R_1x - \frac{wx^2}{2} + \frac{bx^3}{6}$$

in which R_1 = the bottom reaction,
w = the pressure per square foot at the bottom,
and b = the increment of pressure = 62.5 pounds per square foot.

The bottom reaction equals

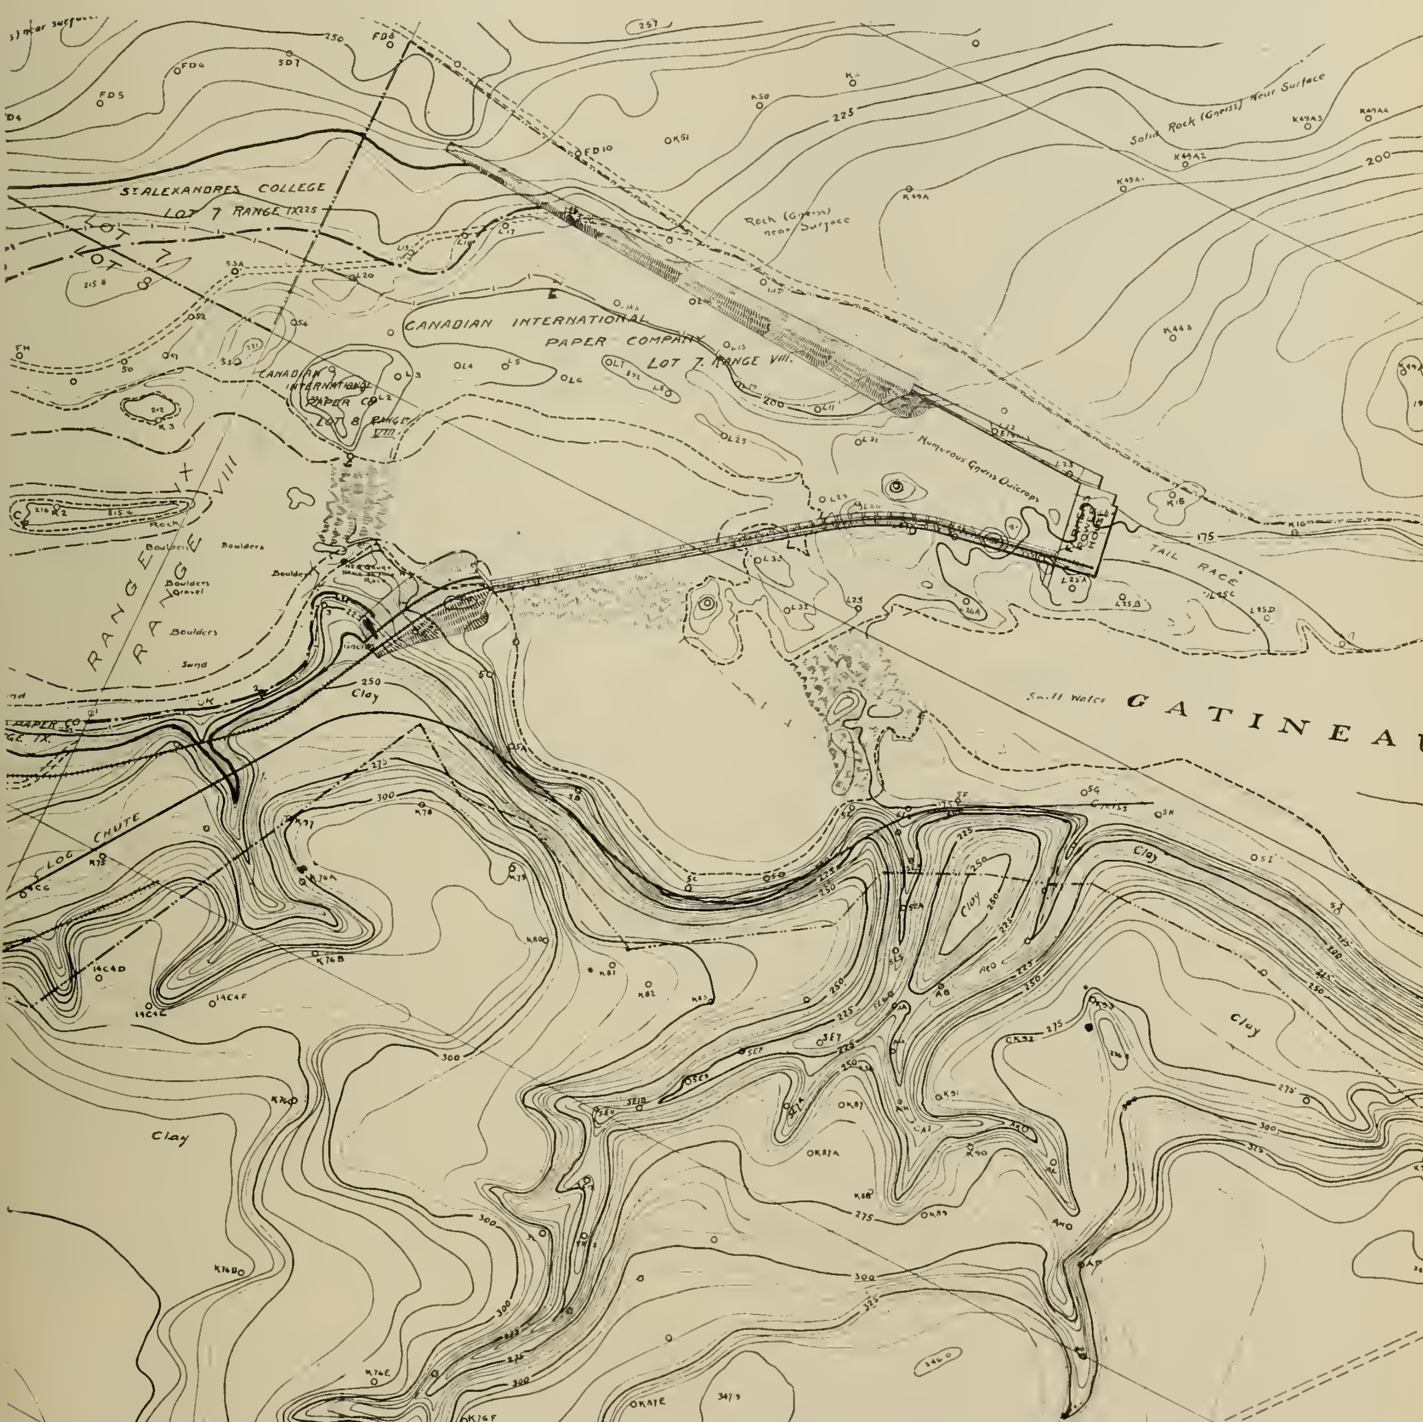
$$R_1 = \frac{3}{8} \times 3125 \times 32 - \frac{62.5 \times 32^2}{10} = 37500 - 6400 = 31100 \text{ pounds}$$

and the maximum moment equals

$$M_{max} = 31100 \times 32 - \frac{3125 \times 32^2}{2} + \frac{62.5 \times 32^3}{6} = -264000 \text{ foot-pounds}$$

$$A_s = \frac{264000 \times 12}{11000 \times 6.5 \times 12} = 3.7 \text{ square inches per foot.}$$

(2) Intermediate Walls. These walls are 4 feet thick, and have been designed for a difference in head between one side and the other of 27 feet. This difference in head may be brought about by having the emergency gates closed and the headgates open in the two outside passages of any unit and the headgate in the centre passage closed, while the machine is full open. It would be possible under this condition for 3,000 c.f.s. to flow from the central intake to the



Developments—General Layout.

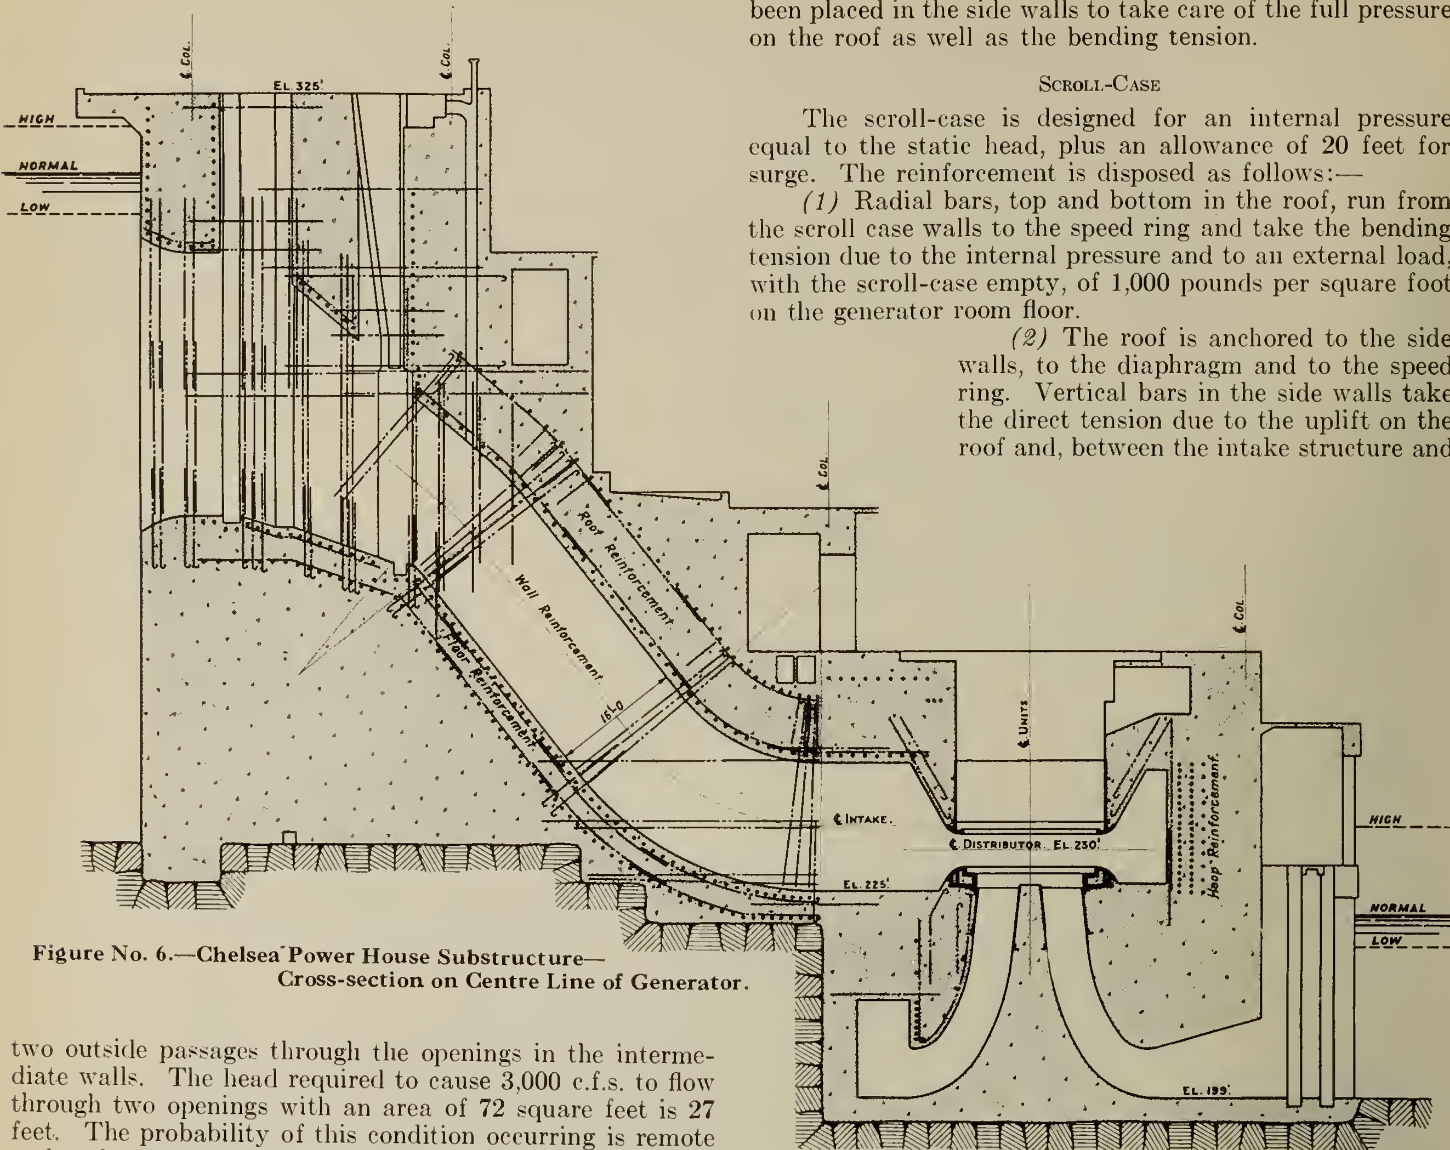


Figure No. 6.—Chelsea Power House Substructure—Cross-section on Centre Line of Generator.

two outside passages through the openings in the intermediate walls. The head required to cause 3,000 c.f.s. to flow through two openings with an area of 72 square feet is 27 feet. The probability of this condition occurring is remote and we have therefore increased the unit stresses in this wall to 18,000 pounds per square inch in the steel and 750 pounds per square inch in the concrete.

(3) Headwall. The headwall is 12 feet 4 inches thick, and has clear spans between bottoms of headgate gains of 14 feet 2 inches. The reinforcement required for bending is negligible. Three-quarter inch bars have been put in horizontally on 12-inch centres, near each face, to prevent the formation of shrinkage cracks. Sufficient reinforcement has been run from this wall into the main and intermediate intake walls to take care of the reaction from the water pressure.

(4) Floors of Intakes. The floors of the intakes are reinforced at the top between the emergency gates and the box drain to take bending due to uplift and at the bottom for the water pressure and the dead weight of the floor. Dowels from the floor project upward into the intake walls to take the reactions due to this pressure.

(5) Curtain Wall. Horizontal reinforcement has been placed in the curtain wall, which is 10 feet thick, sufficient to take an ice pressure of 50,000 pounds per lineal foot.

(6) Water Passages. Below the headgates the water passages down to the entrance to the scroll-case are designed all around for internal pressure equal to the full static head, plus an allowance of 10 feet for surge. Sufficient steel has been placed in the side walls to take care of the full pressure on the roof as well as the bending tension.

Scroll-Case

The scroll-case is designed for an internal pressure equal to the static head, plus an allowance of 20 feet for surge. The reinforcement is disposed as follows:—

(1) Radial bars, top and bottom in the roof, run from the scroll case walls to the speed ring and take the bending tension due to the internal pressure and to an external load, with the scroll-case empty, of 1,000 pounds per square foot on the generator room floor.

(2) The roof is anchored to the side walls, to the diaphragm and to the speed ring. Vertical bars in the side walls take the direct tension due to the uplift on the roof and, between the intake structure and the longitudinal centre line of the scroll-case, take the bending tension due to the internal pressure.

(3) Between the longitudinal centre line and the down stream side of the scroll-case the tension due to internal pressure on the walls is taken by three rows of hoops. Owing to the fact that the scroll-case and draft-tube block is not stable by itself, these hoops project into and anchor the scroll-case to the intake structure.

In determining the bending and direct stresses in roof and walls, the scroll-case is divided into a number of sectors and each sector calculated separately. Taking as a typical example the sector on the longitudinal centre line we have:—

(1) Roof

Scroll-case empty — Span = 8 feet 0 ins. Eff. depth = 8 ft. 0 ins.
Dead and live loads = 2100 lbs + 1000 lbs. = 3100 lbs. per sq. ft.

$$M = \frac{3100 \times 8^2}{8} = 24800 \text{ ft.-lbs.}$$

$$A_s = \frac{24800 \times 12}{10760 \times 8 \times 12} = 0.3 \text{ sq. in. per ft.}$$

Scroll-case full — Span	= 9 ft. 0 ins.
Pressure	= 6250 lbs. per sq. ft.
Weight of Roof	= 1500 lbs. per sq. ft.
Net uplift	= 4750 lbs. per sq. ft.

$$M = \frac{4750 \times 9^2}{8} = 48100 \text{ ft.-lbs.}$$

$$A_s = \frac{48100 \times 12}{10760 \times 8 \times 12} = 0.56 \text{ sq. in. per ft.}$$

(2) Side Wall

Span = 11 ft. 0 in. Eff. depth = 7 ft. 8 ins.

$$R_1 \text{ (at bottom)} = \frac{7060 \times 11}{2} - \frac{3 \times 62.5 \times 11^2}{20} = 37700 \text{ lbs.}$$

$$M_1 \text{ (at bottom)} = -\frac{2 \times 37700 \times 11}{3} + \frac{7060 \times 11^2}{4} - \frac{62.5 \times 11^3}{15}$$

$$= -68450 \text{ ft.-lbs.}$$

$$M_2 \text{ (at top)} = -68450 + 37700 \times 11 - \frac{7060 \times 11^2}{2} + \frac{62.5 \times 11^3}{6}$$

$$= -66550 \text{ ft.-lbs.}$$

$$A_s \text{ (at bottom)} = \frac{68450 \times 12}{10760 \times 7.5 \times 12} = 0.85 \text{ sq. in. per ft.}$$

$$A_s \text{ (at top)} = \frac{66550 \times 12}{10760 \times 7.5 \times 12} = 0.83 \text{ sq. in. per ft.}$$

Direct tension. Pressure on roof = (80 + 20 (surge)) × 62.5
=6250 lbs. per sq. ft.

Upward pressure...........6250 × 4.5........= 28150 lbs.
Weight of concrete in roof = (4.5+4)×12×140...= 14300 "
Net uplift at top...........................= 13850 "
Weight of concrete in wall = 4 × 16 × 77.5....= 4960 "
Net uplift at bottom........................= 8890 "

$$A_s \text{ (at top)} = \frac{13850}{12000} = 1.16 \text{ sq. in. per ft.}$$

$$A_s \text{ (at bottom)} = \frac{8890}{12000} = 0.74 \text{ sq. in. per ft.}$$

Total reinforcement in side wall per foot,
At top 0.83 + 1.16 = 1.99 sq. in.
At bottom 0.85 + 0.74 = 1.59 sq. in.

(3) Diaphragm

Upward pressure.........................= 6250 × 7.5 = 46900 lbs.
Weight of concrete in roof............= 7.5 × 12 × 140 = 12600 "
Net uplift at top..................................= 34300 "
Weight of concrete in diaphragm.......= 3 × 16 × 77.5 = 3700 "
Net uplift at bottom...............................= 30600 "

$$A_s \text{ (at top)} = \frac{34300}{12000} = 2.86 \text{ sq. in. per ft.}$$

$$A_s \text{ (at bottom)} = \frac{30600}{12000} = 2.55 \text{ sq. in. per ft.}$$

(4) Hoops

To determine the sectional area of the hoops required in the walls the scroll-case is assumed to be split on the longitudinal centre line.
Area of section = 609 sq. ft.
C.G. = 20.2 ft. from right hand side looking toward intake.
Total pressure = 6750 × 609 = 4,110,000 lbs.

$$A_s \text{ (right hand side)} = \frac{4{,}110{,}000 \times 23.8}{44 \times 16000} = 139 \text{ sq. in.}$$

$$A_s \text{ (left hand side)} = \frac{4{,}110{,}000 \times 20.2}{44 \times 16000} = 118 \text{ sq. in.}$$

The hoops project into the intake structure far enough to provide adequate anchorage for the scroll-case.

Draft-Tube

The weight of the generator, exciter and turbine runner and the hydraulic thrust are carried to the foundation through the stator frame, speed ring and draft-tube cone and cast steel vanes.

The reinforcement of the draft-tube is simple, consisting of radial bars near the bottom of the roof to take the bending tension due to water pressure in the scroll-case,

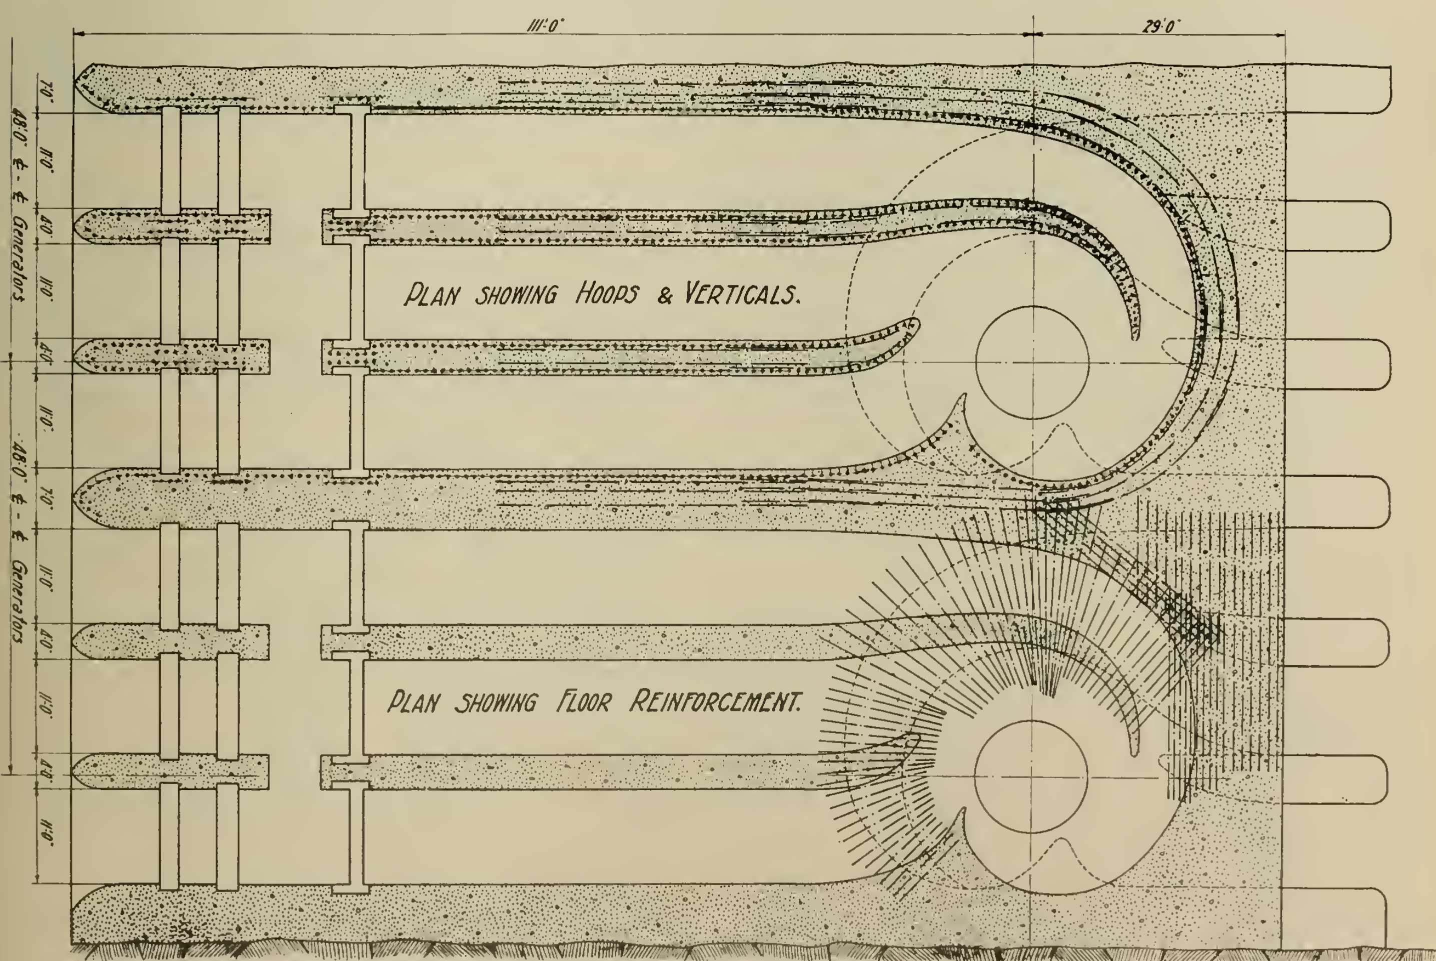

Figure No. 7.—Chelsea Power House Substructure—Cross-section Through Intake and Scroll-case.

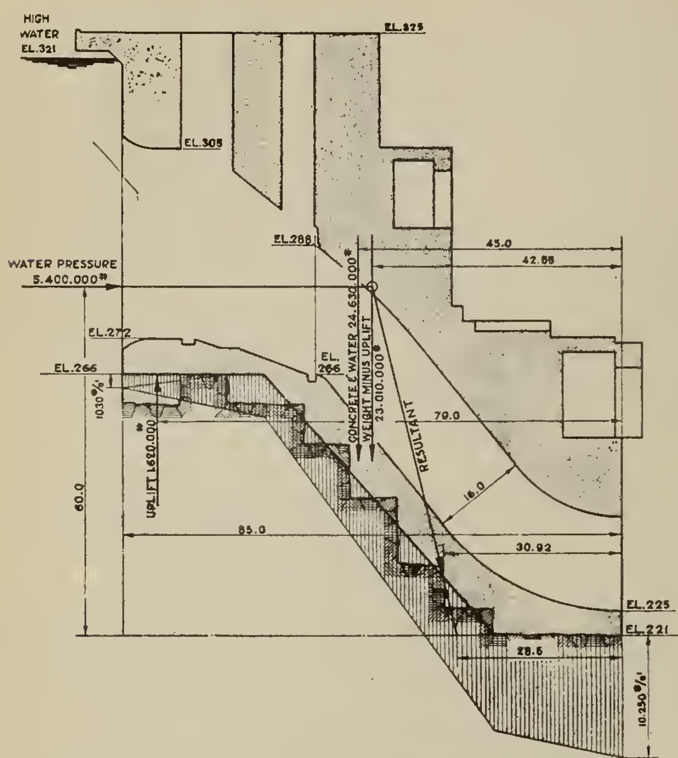

Figure No. 8.—Chelsea Power House—Intake Block.

vertical bars in the dividing walls between draft-tubes to take bending tension due to hydrostatic pressure in case one draft-tube is unwatered, and some hoops near the outside of the draft-tube bell. These hoops are necessitated by the fact that a slight eccentricity exists between the centre of the draft-tube vanes and the centre of the load.

The use of cast steel vanes to support the bell of the draft-tube has considerably simplified the reinforcement of the Moody draft-tube, especially in large units. The diagram shows a comparison between the reinforcement of the Chelsea draft-tubes and that for the 41,000 h.p. turbine at Shawinigan Falls. The dimensions of the Chelsea draft-tube are slightly smaller, but the amount of reinforcement required is negligible in comparison with that required for the Shawinigan draft-tube. At the time the Shawinigan installation was being designed the engineers suggested the use of supports under the draft-tube bell, but the turbine manufacturer would not sanction their use owing to lack of information as to the effect that the supports would have on the efficiency of the machine. Subsequent tests on models showed that the efficiency of the draft-tube was not impaired by the use of these supports.

In passing, it may be interesting to note another development in the Moody draft-tube that was suggested by the operation of the Shawinigan unit. It will be noted by reference to the diagram that the baffle in the Shawinigan draft-tube is at the back on the transverse centre line. After the machine was placed in operation it was noticed that most of the water was discharged from the right-hand opening. This is due to the fact that the water in the draft-tube has a clockwise whirl and tends to pile up against the baffle in the left-hand passage. In undertaking, shortly afterward, the design of the Manitoba Power Company's plant at Great Falls, the Shawinigan Engineering Company suggested the placing of the baffle at the left-hand side of the draft-tube, and tests conducted by the manufacturer showed improvement in its performance.

Areas of Water Passages

It is the aim of the designer to so proportion the water passages that the water entering the intakes at a low velocity will be speeded up gradually to the turbine runner and then the velocity gradually reduced to the draft-tube exit. At the entrance to Chelsea intakes the water has a velocity of 3 feet per second; through the racks about 4.5 feet per second, and at the head gates a little over 5 feet per second. From the headgates the velocity gradually increases to the

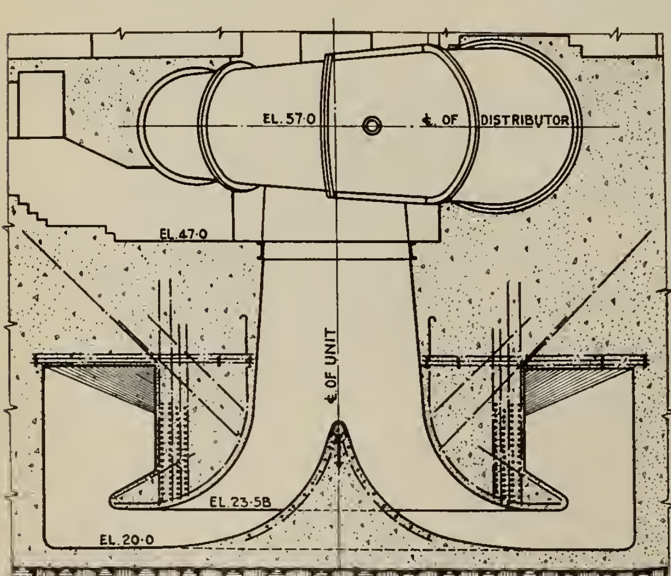

Figure No. 9.—Longitudinal Section—Scroll-case and Draft-tube, No. 6 Unit at Shawinigan Falls.

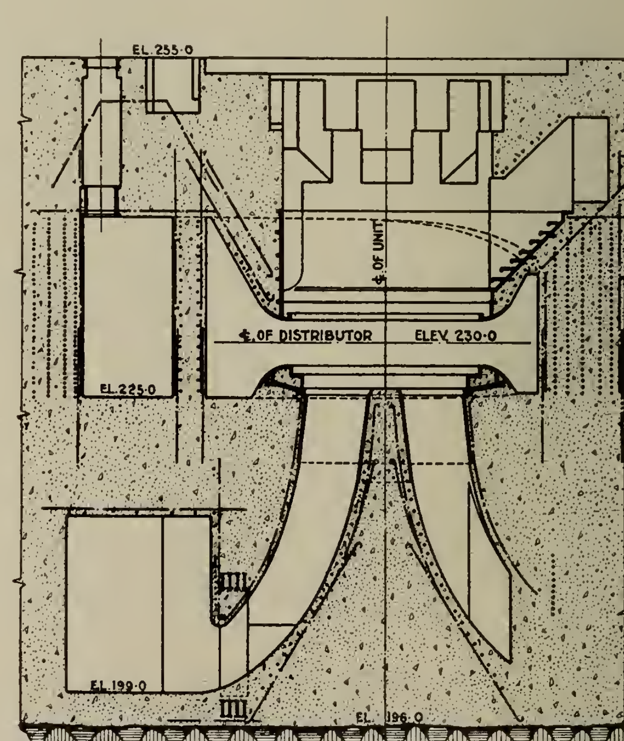

Figure No. 10—Longitudinal Section—Scroll-case and Draft-tube at Chelsea Development.

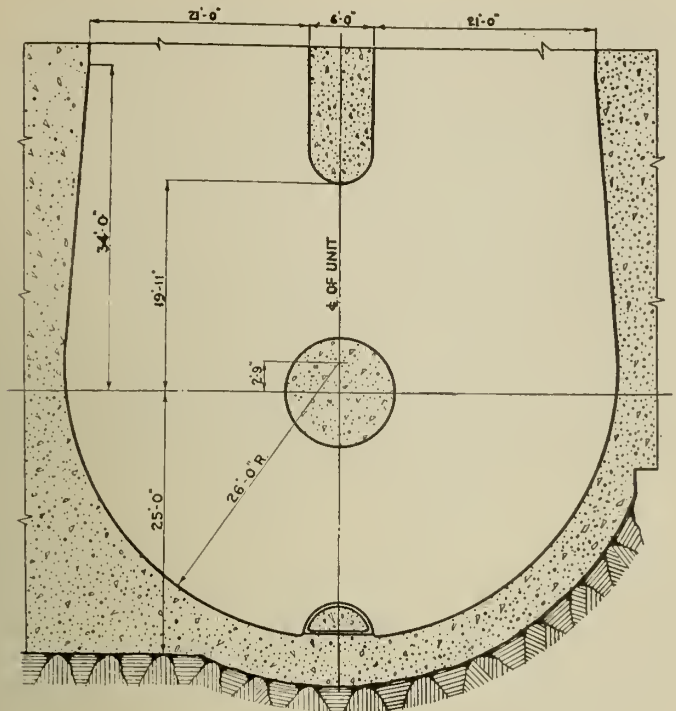

Figure No. 11.—Plan of Draft-tube, No. 6 Unit at Shawinigan Falls.

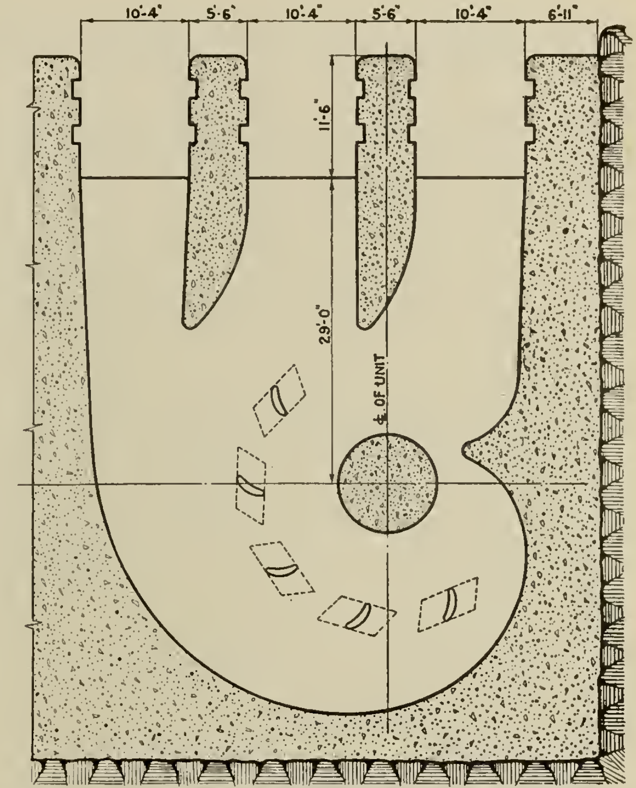

Figure No. 12.—Plan of Draft-tube at Chelsea Development.

scroll-case, where it is 7.3 feet per second. In the scroll-case the velocity is still further increased to about 18 feet per second at the speed ring. Below the turbine runner the speed of the water is gradually reduced until it emerges from the draft-tube at a velocity of 4 feet per second.

Conclusion

In the foregoing, the writer has endeavoured to give a general description covering the important features of the three power developments of the Gatineau Power Company, together with an outline of the steps taken in the reinforced concrete design of the Chelsea power house. He has also indicated the relation of the three plants to each other in a system, the importance of which to the district in which it is located is evidenced by the fact that it will be capable of delivering continuously 300,000 h.p. of electrical energy, and when the final units have been installed will have a peak load capacity of more than twice this amount.

The ground covered is so extensive that each of the four more important phases of the design, hydraulic, mechanical, electrical and structural, could be amplified into a fairly extensive paper, so that this paper must be considered as merely a summary of the important phases of these developments.

The writer is indebted to Messrs. S. S. Scovil, M.E.I.C., F. B. Brown, M.E.I.C., and O. O. Lefebvre, M.E.I.C., and to the Fraser-Brace Engineering Company for information and data which they have very kindly given him and which has assisted materially in the preparation of the paper.

Building an Industrial Plant in the Saguenay District

Preliminary Investigations, Design and Layout of Buildings and Construction Features of the New Plant of the Aluminum Company of Canada, Limited, at Arvida, Que.

John L. Guest, A.M.E.I.C.
Office Engineer, Aluminum Company of Canada, Limited, Arvida, Que.

Paper presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Quebec, Que., February 15th to 17th, 1927

During the past five years the development of the Saguenay and Lake St. John districts has attracted the attention of the entire province of Quebec as well as a large part of the eastern sections of Canada and the United States. The pulp and paper industry in this district has made rapid strides. The development of hydro-electric power has advanced even more rapidly. A few years ago the question arose in the minds of many, "How is this enormous amount of power to be absorbed?" This question was answered slightly over a year ago when the Aluminum Company of Canada, Limited, commenced the construction of its new plant at Arvida, which will absorb the surplus power that is now developed and is destined to form the basis for even larger water power developments in the future.

Arvida is located on the Canadian National Railway, about six miles west of its terminus at Chicoutimi. Fifteen months ago it consisted of a name and a considerable number of red painted stakes driven in the ground by survey parties. At that time the site now occupied by the plant and the two hundred and seventy employees' houses was partly under cultivation and partly wooded. At the time of this writing the plant is nearing completion and over half of the two hundred and seventy houses, comprising the new town, are occupied by the plant employees and their families.

Preliminary Operations

During the summer of 1925 an extensive topographic survey was made, covering a tract of about nine square miles at and around the plant site. In addition to this, numerous test pits were dug in order to determine the depth from the surface of the ground to solid rock. These tests proved conclusively that to attempt to secure a rock foundation for any of the plant buildings would be out of the question. It was therefore necessary to provide a sufficient bearing area for all foundations, so that a uniform pressure on the yielding soil would be provided throughout, in order to prevent unequal settlement. Obviously the next step was to determine the nature of the soil and the unit pressure that it would withstand without excessive settlement.

This soil consists of a very fine, dense, blue clay. The percolation of water through the soil in its natural state is extremely slow. This is evidenced by the fact that in several cases two pits were excavated within a few feet of each

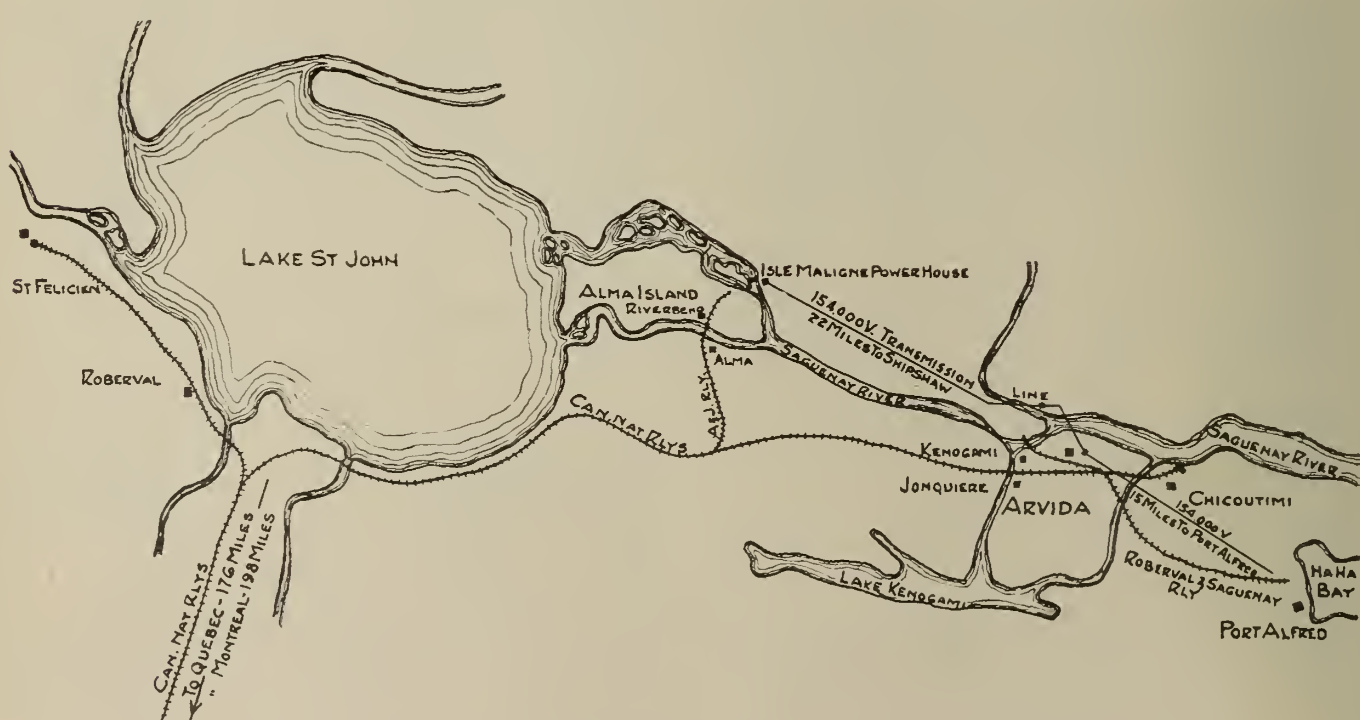

Figure No. 1.—Saguenay and Lake St. John District.

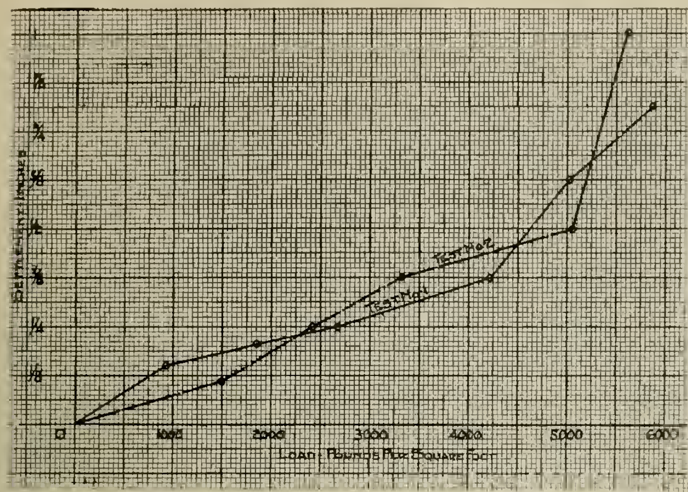

Figure No. 2.—Typical Load Settlement Chart for Soil Bearing Tests at Arvida, Que.

other and allowed to fill up with ground water. One pit was then pumped dry and kept in that state with a small hand pump. The lowering of the water in the adjacent pit was barely perceptible even over a period of several days. It was also noted that in its natural state this material has a very high moisture content. Samples were taken from a few feet below the surface and dried out. A shrinkage of about 20 per cent by volume and a loss of over 50 per cent by weight was noted in some cases. On account of the slow percolation of water through the soil it was decided that it would be useless to attempt to eliminate the moisture by means of sub-drainage prior to the construction of building foundations. It was also evident that any attempt to do so after the foundations were built would only result in a high shrinkage and consequent settlement.

The determination of the safe bearing power of the soil was accomplished by excavating a number of shallow pits at various points around the proposed plant site, loading the soil at the bottom of the pit, and measuring the settlement as the loading progressed. These pits were about fifteen feet square by three feet deep. In the centre of the pit a pedestal having a bearing area of sixteen square feet was built of 12- by 12-inch timbers, placed in four layers, running in alternate directions. This placed the top of the pedestal approximately one foot above the original ground surface. This elevation was carefully noted, and a wooden bin having a capacity of 1,000 cubic feet was then built on top of the pedestal and gradually filled with clay. The weight of the bin as well as the weight per cubic foot of the clay were predetermined, and the settlement was measured at frequent intervals throughout the process of loading. These tests were made when the soil was very wet after heavy rains, and also under comparatively dry conditions. The time element was also considered, the structure being allowed several days to settle under various loadings before taking final measurements. Some of the typical load settlement curves are shown in figure No. 2. After a careful study of these charts, it was decided that a unit bearing pressure of 3,500 pounds per square foot could be used without danger of unequal or excessive settlement, and this figure was used as a basis for the design of foundations.

Description of Plant

The layout of the plant buildings now under construction as well as proposed future extensions is shown in figure No. 3. The Arvida works consist essentially of an aluminum plant and a carbon plant. In addition to this there are the following auxiliary buildings:—

A high-tension transformer building, containing six 25,000-kv.a. transformers with a stepdown from 154,000 to 13,200 volts.

A rotary station, containing eighteen synchronous rotary converters for converting from alternating to direct current, and also nine 7,500-kv.a. transformers on the alternating current side with a stepdown from 13,000 to 440 volts. Direct current at 600 volts is taken from this building to the aluminum plant.

A pumping station and spray pond for circulating water for cooling the transformers.

An office building with 27,000 square feet of floor

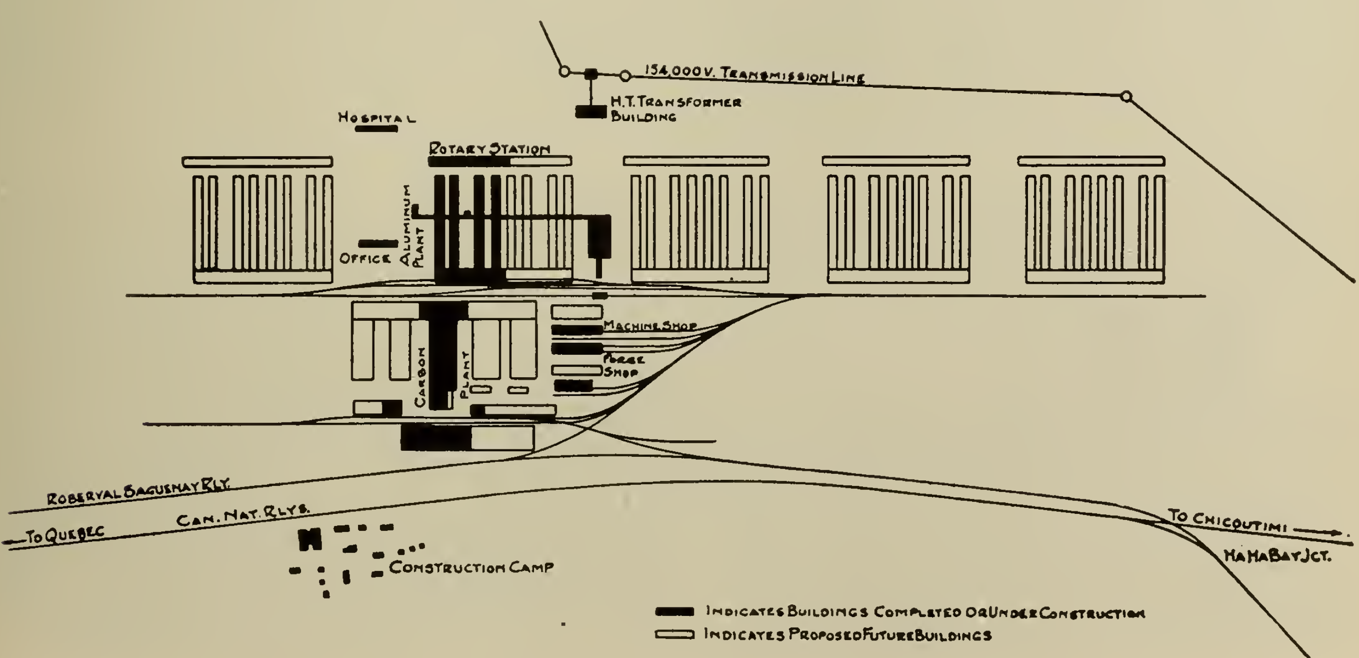

Figure No. 3.—Layout of Plant.

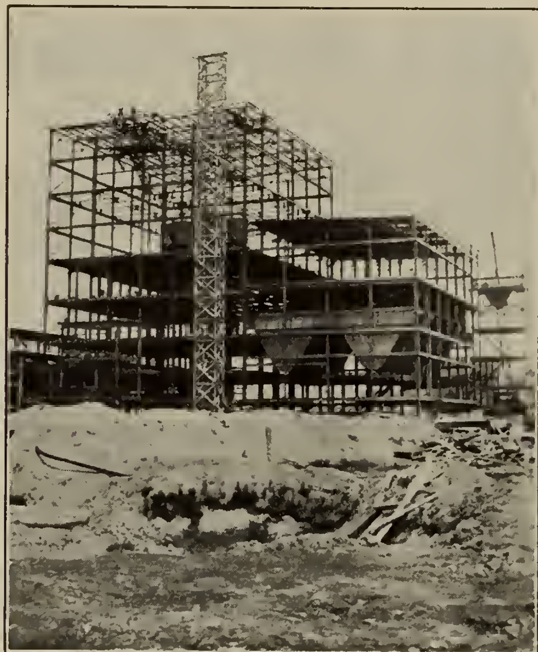

Figure No. 4.—Carbon Plant Buildings Under Construction.

space which will accommodate the operating staff and will contain a large laboratory for analysis of metal as well as the various materials entering into the manufacture of carbon electrodes and aluminum.

A hospital with modern equipment which will serve the plant employees and their families.

A group of service buildings consisting of a machine shop, a forge shop and a building for lining the furnaces which are used in the aluminum plant.

The present installation, so far as the aluminum plant is concerned, consists of four furnace rooms and a service building for handling and storing materials entering and leaving the furnace room. This building connects to one end of each furnace room. There is also a group of buildings located near the furnace rooms for unloading, storing and reloading ore to be transported to the furnace rooms. Each furnace room contains the electric furnaces in which aluminum is plated out from refined bauxite ore by an electrolytic process. The furnaces are connected in series to the main bus which runs through the centre of the building. Carbon electrodes are suspended in the furnaces, and these form the anode for the direct current which is used in this process. The cathode is formed by the carbon lining in the furnaces.

Refined bauxite, which is practically pure aluminum oxide having the appearance of a very fine white sand, is placed directly in the furnaces with a small amount of cryolite which acts as a solvent and electrolyte. When the current is applied the aluminum gradually plates out in the bottom of the furnaces, remaining in a molten state, the cryolite remaining at the top. Additional ore is applied at frequent intervals, the entire process being a continuous one. The furnaces are tapped through an orifice near the bottom, and the molten metal is allowed to flow out into a crucible. It is then transported by an electrically-operated overhead crane into one end of the building, poured into cast steel pig moulds and allowed to cool. A sample is taken from each pouring and analyzed in the laboratory. Each pig is then marked with a symbol which indicates the grade of purity of the metal. The metal is then ready for shipment, since no fabrication of any kind is done at Arvida.

The carbon plant, which consists of eight large buildings, is used for the manufacture of carbon electrodes. No doubt many will wonder why such a large installation is necessary in order to supply one accessory for four productive buildings. This is readily explained by the fact that it requires a very large number of electrodes to equip one furnace room, and the life of these is comparatively short.

The raw materials entering into the manufacture of carbons are petroleum coke and crude pitch. Petroleum coke is brought in during the shipping season, crushed and placed in storage in a large building having a floor area of about one and one-half acres. It is reclaimed from this building when needed by means of a drag line bucket, taken into another building and put through a calcining process in order to drive off the volatile gases. It is then carried by means of a belt conveyor into a grinding building and ground into dust. Crude pitch is likewise placed in a storage building, reclaimed as needed, and crushed and ground. The coke and pitch are then mixed in electrically-operated mixers. The mixture is next taken to large hydraulic presses and moulded into the shape of the electrodes under an intense pressure. The carbons are then placed in electric baking furnaces and thoroughly baked. After being baked they are taken into another building in order to make the

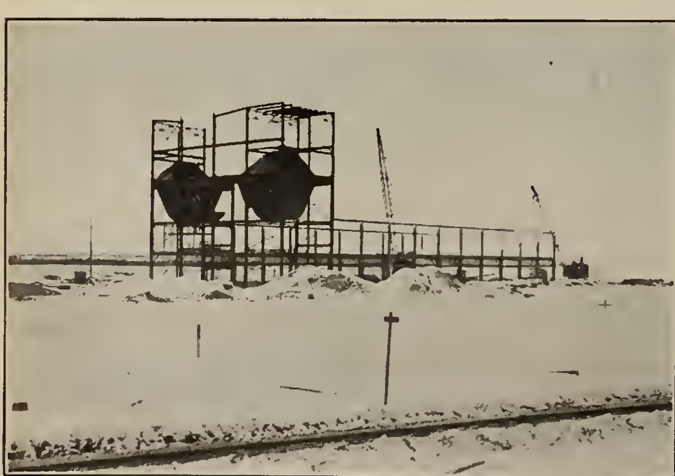

Figure No. 5.—Steel Framework for Pot Lining Building.

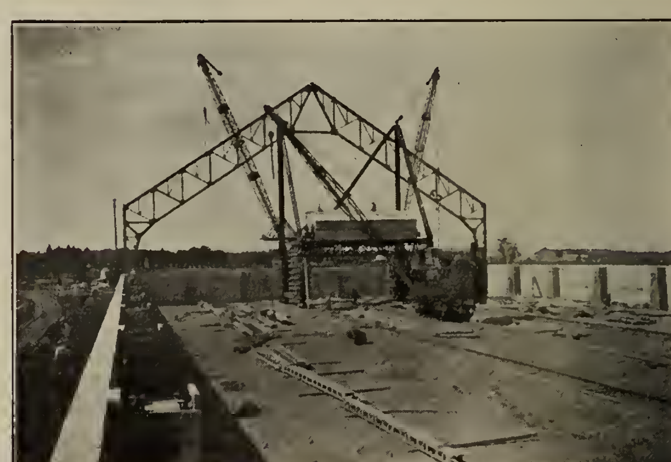

Figure No. 6.—Erection of Steelwork for Coke Storage Building.

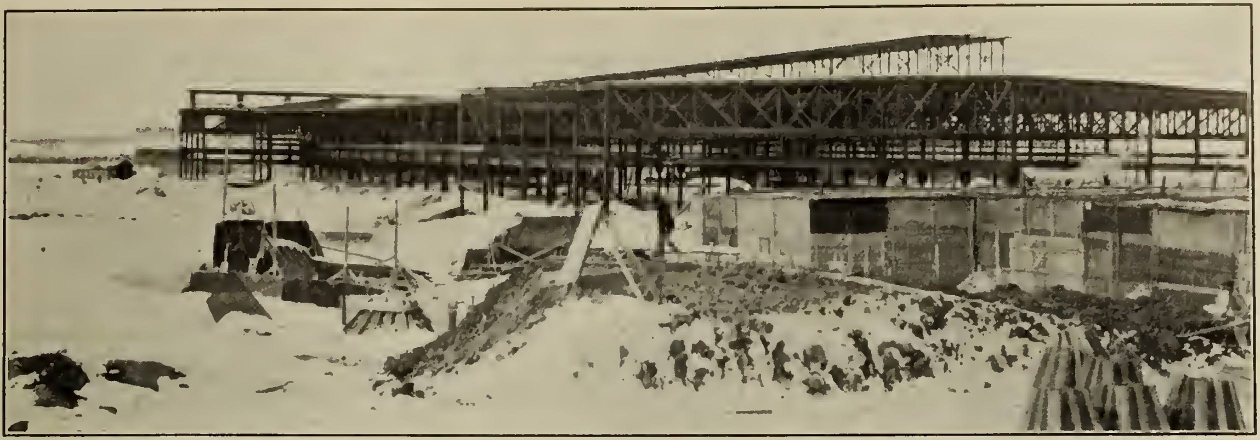

Figure No. 7.—Carbon Plant Buildings Under Construction.

electrical contact to them by means of which they are suspended over the furnaces. The electrodes are then transported into the furnace rooms and bolted on to the copper suspension rods.

Design of Plant Buildings

The general design of the plant buildings at Arvida does not differ materially from that which may be found at numerous other large manufacturing plants. All outside walls are placed on concrete foundations extending to a depth of six feet below the surface of the ground. The walls are of brick construction and framework of structural steel. The majority of the buildings contain electrically-operated travelling cranes varying in capacity from five to seventy-five tons. The carbon plant buildings contain numerous and varied types of conveyors, elevators, and other machinery for handling materials. Several of these buildings also contain large bunkers and tanks for the storage of materials, all of which are located in the upper part of the structure at a distance of from 60 to 75 feet above the ground. The steel framework for some of the buildings of this type is illustrated in figures Nos. 4 and 5. Special attention was given to the design of the framework for these buildings on account of the fact that the Saguenay district is known to be one in which frequent earth tremors occur. In the past few years a number of these disturbances have taken place. While they are not usually considered of sufficient magnitude to cause any serious damage to steel frame buildings, it will be noted from the illustrations that the principal mass in these buildings consists of the bunker. When filled with ground coke, pitch or other material the inertia of this mass is considerable. It was feared that any subterranean disturbance, transmitting its effect to the building through the column footings, would have a tendency to shear the columns at some point below the point of suspension of the bunker. Consequently, in addition to the wind bracing which is ordinarily placed in structures of this class, heavy diagonal bracing was placed wherever possible, without interfering with the operation of machinery within the building. Columns were also tied together at the base by placing steel reinforcing bars in the wall foundations, extending from one column foundation to the next.

A peculiar problem also arose in connection with the design of the building for the storage of petroleum coke. The steel framework for supporting the roof of this building consists essentially of fifteen three-hinged arch trusses, as illustrated in figure No. 6. These trusses have a span of 150 feet and are supported on reinforced concrete piers of cantilever construction, extending twelve feet above and seven feet below the ground surface. The horizontal thrust at the two lower extremities of these trusses is extremely high. This naturally produces both an overturning and a sliding effect on the concrete piers. The overturning effect was considered quite serious on account of the fact that any inequalities in the distribution of pressure across the pier foundation would cause unequal settlement and consequently a spreading of the lower extremities of the truss and a lowering of the ridge of the roof. The sliding effect was

Figure No. 8.—Construction of Rotary Station Under Winter Conditions.

equally as serious on account of the very low coefficient of friction between concrete and wet clay and also on account of the doubtful bearing capacity of the clay soil in a vertical plane, particularly after it has been disturbed from its natural state by excavation and backfilling. This problem was solved by tying together the opposite piers with heavy steel rods just below the floor surface and extending across the entire width of the building. These were then encased in concrete to prevent rusting.

The usual problems encountered in cold climates in connection with heaving on account of frost penetrating in the soil were given a careful study. In unheated buildings, all foundations for machinery and equipment were extended to a depth of five or six feet below floor level. The clay soil was also excavated for a depth of four feet below floor level and backfilled with sand up to the subgrade level for the floor.

Construction Operations

With the exception of cold weather operations, the principal problems in connection with the construction work were the proper scheduling of the work and selection of equipment. On account of the fact that concrete operations were quite scattered, this work was done with small mixers of one-half or one-quarter cubic yard capacity. In some cases a complete mixing plant was placed on an ordinary railway flat car and transported from place to place by means of a locomotive. The mixer and steam boiler were mounted on the car and housed with a wooden structure. This left sufficient space for a small quantity of cement, sand, crushed rock and coal for the boilers, and formed a complete portable unit for small concreting operations.

The various problems and hazards of winter construction are well known to the majority of Canadian engineers. However, the operations at Arvida are noteworthy on account of the fact that nearly every class of work was carried on during the winter months. Naturally, excavation presented the first problem, owing to a frost penetration of four or five feet. In some cases, where there was no danger of damage to nearby structures, the frozen crust of earth was broken with dynamite and shovelled out by hand. A wooden structure was then built of scrap lumber covering the site of the foundation. A structure of this type is shown at the lower right-hand corner of figure No. 7. This structure was heated with wood stoves or salamanders and both excavation and concrete work carried on inside, the men working under cover. In all cases, particular care was exercised not only to prevent freezing of the concrete before allowing a sufficient time for setting, but also to prevent freezing of the subsoil prior to the time of backfilling. The methods of covering the concrete work with tarpaulins and placing steam pipes under them, as well as double forming, with steam pipes inside, was tried. However, it was found that wherever there was any appreciable amount of work to be done, the method of housing the structure completely proved more economical on account of the greatly increased efficiency of labour, the men working in what practically amounted to a heated building. The fact that better results were secured is also unquestionable.

The use of calcium chloride as a preventative of freezing in concrete was also tried. This was placed in the mixer with the aggregates, in the proportion of about 6 pounds to a one-half cubic yard batch. It was found that at extremely low temperatures the other means of protection outlined above could not be dispensed with on account of its use, However, the use of calcium chloride unquestionably accelerates the setting of cement and reduces the length of time during which it is necessary to protect the concrete from frost action. In the opinion of the writer, it is not to be recommended for structures of reinforced concrete owing to the fact that its effect on reinforcing steel is at least questionable.

Work on the brick walls of the buildings at Arvida was started in November 1925, and was carried on continuously throughout the winter months with the exception of a few extremely cold days. During cold weather, both sand and water for the mortar were heated with steam and calcium chloride was added in the mortar mixer. Great care was taken to see that no frozen bricks were placed in the walls, but no attempt was made to protect the work from frost after the bricks were laid in place. A careful inspection was made during the following summer and no signs of buckling, deterioration of mortar, or other defects were observed. The fact that brickwork can be successfully carried on throughout the winter months at no great increase in cost was very clearly demonstrated. Also, the fact that the services of good bricklayers are much more readily obtained during the winter months, is an important item in favour of carrying on this work throughout the cold season.

Protection Against Seepage at Lake Kenogami

Preliminary Investigations, Features Governing Choice of Type of Dam, Construction Methods and Records of Results Attained

O. O. Lefebvre, M.E.I.C.
Chief Engineer, The Quebec Streams Commission, Montreal, Que.

Paper presented at the Annual General Professional Meeting of The Engineering Institute of Canada, at Quebec, Que., February 15th to 17th, 1927

Lake Kenogami is a body of water located south of the towns of Chicoutimi and Kenogami. It has a drainage area of 1,400 square miles and flows into the Saguenay by two outlets, namely, the Chicoutimi river flowing past the town of Chicoutimi, and the Au Sable river flowing past the towns of Jonquière and Kenogami. The elevation of the lake above the Saguenay river, which is a tidal stream, is slightly over 500 feet. This fall is concentrated in a distance of about seven miles on the Au Sable river and fifteen miles on the Chicoutimi outlet.

In order to assure the power owners on both outlets of a steady flow the water was impounded in lake Kenogami, the surface of which was raised from low water elevation 83 to elevation 115. This assures a capacity in the reservoir of thirteen and a half billions of cubic feet. With this reserve it is possible to regulate the flow out of the lake to 1,200 second-feet on the Chicoutimi river, and 600 second-feet on the Au Sable river. In addition to the two control dams in the two outlets, dykes were built at six other points in order to prevent the water from being diverted into the adjoining watershed.

When the survey of the lake was made to determine the maximum level to which it would be possible to store water, the governing factors were the area to be flooded and the number of dykes required across the gulleys, ravines, creeks, etc. It was found that level 115 was the maximum to which the water could be raised. Above that point the cost of the dykes became excessive.

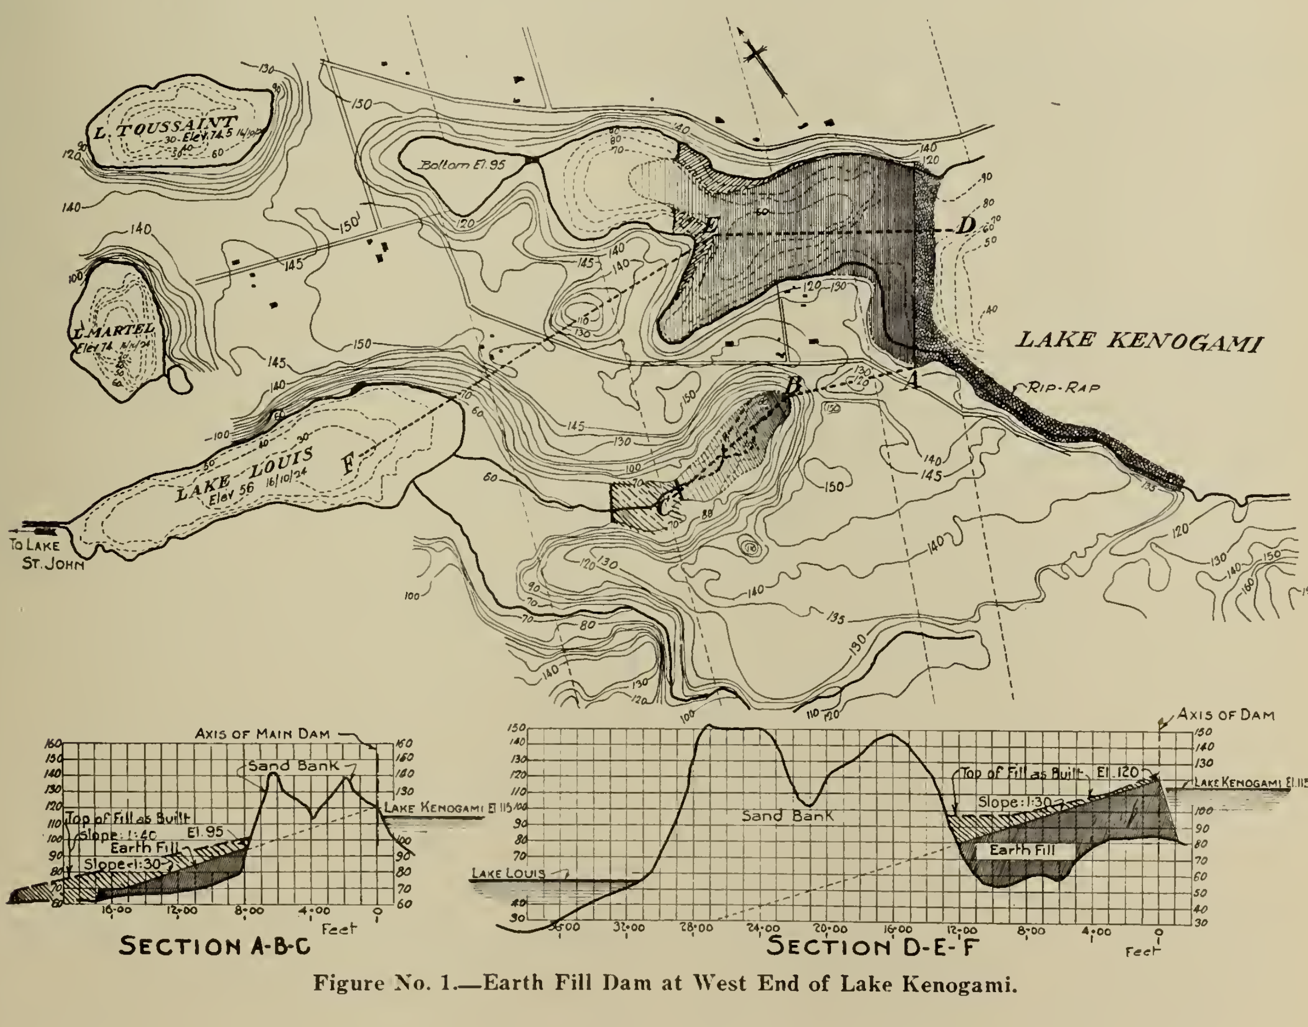

Figure No. 1.—Earth Fill Dam at West End of Lake Kenogami.

Lake Kenogami watershed is separated from the lake St. John watershed by a sandy bank having a minimum width of about 600 feet, and an elevation of 150 and more. An examination of this bank failed to alter the engineers' opinion that no additional work was required at that point. However, during the summer of 1924, the lake level was raised to elevation 102, and it was found that at that stage seepage was taking place through this bank to such an extent that it would be absolutely unsafe to raise the level of the lake an additional 13 feet without protecting the bank.

An examination of the nature of the ground by borings showed that sand was present as far down as elevation 38, or 64 feet below the level of the lake. The borings were not carried any deeper. No impervious bottom was available on the lake Kenogami side of the bank. On the lake St. John side of the bank, however, three-quarters of a mile from the lake, a clay foundation exists. Borings were carried in it to a depth of 90 feet and rock was not encountered. This clay formation stands at an elevation of about 100 on the plateau, and about 50 in the valley of the creek flowing into lake St. John. A dam at that point would have to be quite long, almost a mile, and about 80 feet high. The cost of such an earth bank would have been very high and the structure not without danger. This plan was soon abandoned and the problem was solved by enlarging the natural bank from both sides. On the lake Kenogami side a long and narrow bay was filled and on the lake St. John side a deep and narrow ravine was partly filled.

The principle governing this design is that the surface slope of the fill must cover the line of saturation at which the velocity of the water through the fill will be so small that no chance exists of any particle of material being carried away. The hydraulic gradient through the bank was determined by borings and was found to be in the ratio of 1 in 30.

It was then decided to arrange the fill so that its surface slope would be 1 in 30 or thereabout, and that the bank would have a width such that this slope of 1 in 30 would lead beyond the lowest points on the lake St. John side of the bank.

It was decided also that the surface of the fill should be at elevation five feet above the hydraulic gradient. This decision was made with the approval of S. H. Woodard, M.E.I.C., consulting engineer, who inspected the site in August, 1924. In order to determine what effect such a dyke would have, advantage was taken of a narrow gorge near the head of the bay in lake Kenogami, to construct at that point a sand bank so as to separate part of the bay from the lake. This sand bank was about 100 feet wide. Immediately after it was completed the part of the bay separated from the lake gradually drained off from level 102 down to ground level 95. This showed that the bank from this bay to the small lakes below was quite pervious and the sand fill proposed could hold the water at a certain head.

This seepage was observed in June, 1924. A careful survey of the bank and the lakes on the downstream side was made. The surface of these lakes stood then at elevation 74.5 for lake Toussaint, 74 for lake Martel and 56 for lake Louis. It appears that under natural conditions, lake Toussaint stood at elevation 70, lake Martel at elevation 73 and lake Louis at elevation 55. Complete records of the levels of these lakes have been kept since 1924.

The work of reinforcing the bank by an earth fill was carried out under contract. The material used was that available on the shores and on the top of the bank itself. Part of the fill was made by steam shovels and dump cars, and part of it was made by hydraulic sluicing. The hydraulic machinery was operated by electric power which was transmitted from the municipal plant of the town of Jonquière, a distance of twenty-one miles. A transmission line was built specially for that work, and the amount of power used was about 1,200 h.p.

The contract was awarded in September, 1924. The steam shovel work was commenced at the end of October, 1924, and continued day and night all through the winter. The hydraulic machinery was working for a few weeks in the fall of 1924, but had to be stopped during the winter. In April and May this sluicing process was used again with excellent results. As much as 350,000 cubic yards of material were sluiced in the month of April, 1925. The fill was completed early in May, 1925, and the lake Kenogami water was allowed to rise against it. The lake water reached its maximum height, elevation 114.9, on June 24th, and the fill did the work that was expected of it.

In order to ascertain under what conditions the water was acting in this fill, a series of pipes were left in the fill. Water rises in these pipes and its level may be measured very accurately. These elevations show that this sand bank gets partly saturated very slowly; the change in the water level being hardly noticeable from day to day. A comparison of observations separated by about a month, however, shows that the hydraulic gradient has risen during that time to quite a small degree, and that this movement of the water tending to adjust itself to a point where the resistance of the material in the fill prevents the water from any further movement, is very slow,—as shown by the following table:—

Water Level in the Earth Fill—Head of Lake Kenogami

(Station 25 being that next to the lake)

Date	Sta. 18	Sta. 19	Sta. 20	Sta. 21	Sta. 22	Sta. 23	Sta. 24	Lake Ken.
June 22..	...	...	103.40	105.60	107.10	108.90	111.00	114.83
July 22..	102.50	104.31	105.53	106.95	108.30	109.95	111.67	114.53
Aug. 21..	102.38	104.03	105.37	106.79	108.16	109.84	111.98	114.15

The aggregate amount of seepage which was measured in 1924 when lake Kenogami level was 102, was 23 cubic feet per second. Under these conditions, the level of lake Toussaint rose to elevation 77.2, that of lake Martel rose to 75 and lake Louis to elevation 56.

As a result of the construction of the small sand bank across the gorge, as mentioned before, the level of lake Toussaint decreased to elevation 74.5 on the 16th of October, 1924. In 1925, after the fill was completed and lake Kenogami had been raised to elevation 115, the level of lake Toussaint reached 74.8, that being 2.43 feet less than the level that lake had with water at elevation 102 in lake Kenogami prior to the completion of the fill.

Similar results were observed as to lake Martel. Lake Louis was lowered by about six inches and the total amount of seepage was reduced from 23 second-feet to about 13 second-feet.

Observations of water levels in the small lakes which are separated from lake Kenogami by a natural bank and the artificial bank added to it, show clearly that the movement of the water in this bank is exceedingly slow. For example, in 1926, lake Kenogami began to rise on the 1st of May when its level was 83, and on the 31st of May it stood at elevation 112.5, a rise of 29.5 feet. During the same period the level of the water in the bay separated

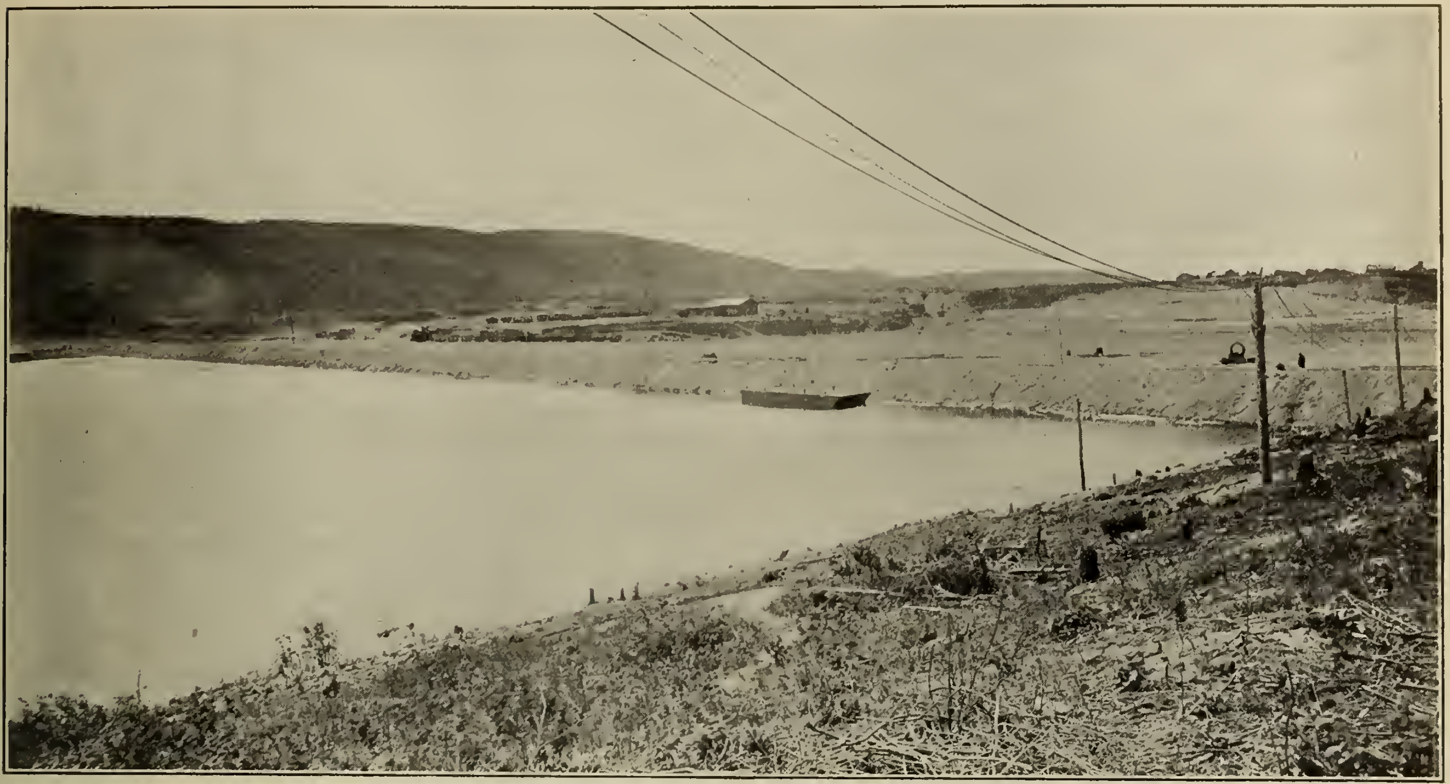

Figure No. 2.—General View of Dam From Lake Side.

from lake Kenogami by the earth fill practically did not change and remained at elevation 89. On the 1st of June it began to rise, and on June 20th, when lake Kenogami was practically full at 114.8, the level in this bay had risen 2½ feet. From June 20th to July 20th, though lake Kenogami level did not change, the level of the bay rose from 92½ to 96½, a rise along a straight line. The level in this bay reached its maximum on August 30th at 97.5, so that, while lake Kenogami was raised 29½ feet in the month, the level in the bay was not changed during that month. In the next month the level of the bay rose three feet and again in the next month practically another four feet. The rise in the lake was 32 feet and the rise in the bay was 8½ feet.

It will be interesting to note that very little settlement occurred in the material sluiced into place. A settlement varying from three or four feet to a few inches, according to the depth of the fill, took place in the material deposited from dump cars. About two million yards of material were put into this fill, and the average cost per yard was 42½ cents.

The original plans provided for a stone rip-rap three or four feet deep, covering the face of the fill on the lake Kenogami side, so as to protect the bank against erosion by wave action.

In the winter of 1925, while excavating, a gravel pit was found which contained a large proportion of boulders mixed with the sand. A survey of this pit showed suitable material for protection of the bank against erosion, and it was decided not to put in the stone rip-rap and substitute this very heavy gravel, which could be handled almost at the same price as earth. A depth of 25 feet of this material was dumped on the lake face of the bank and has proved to be quite effective as a protection.

Report of Council for the Year 1926

The improvement in industrial conditions occurring in Canada during the past year has not only resulted in an increased measure of general prosperity in the country, but has also been reflected in better conditions as regards the employment of engineers of practically all branches of the profession. It is encouraging to note the spectacular industrial developments which have taken place in the field of hydro-electric power engineering and in the pulp and paper industry; these have naturally influenced favourably other branches of construction work, and improvement has also been evident in the operating results of the railways and other transportation organizations.

No phenomenal developments have to be recorded this year as regards The Institute's affairs. The activities of our twenty-five branches have been well maintained, and these are The Institute's most effective means of influencing not only its own members but also the public. It is, therefore, satisfactory to record a year in which our branches, practically without exception, have carried out an enlarged programme, both as regards meetings for the interchange and discussion of professional data and information, and those other occasions, not so technical, which give opportunities for branch members to meet guests of other callings, or allied societies, and hear addresses on questions of more general interest.

Council desires particularly to express its appreciation of the unselfish work, (often done at considerable personal sacrifice), of the officers and secretaries of The Institute's branches, without which the successful operation of The Institute would be impossible and no progress could be made.

One of the most important and onerous duties of Council is in connection with the classification of applications for membership. The Institute, as the national engineering society of Canada, cannot guard too closely its well deserved reputation for careful scrutiny of applications for admission, and this has been the policy of the Council throughout the year.

It is regrettable that so far no practicable scheme has been found for enabling councillors residing at a distance from Headquarters to take an active part in the deliberations of Council. In the case of many decisions, councillors' opinions can be, and are, obtained by correspondence, but this is only a partial remedy, and it is felt that one or more meetings of Council should be held annually to which the travelling expenses of councillors from a distance would be defrayed by The Institute. Additional financial resources must, however, be provided if funds are to be available for this very desirable object of expenditure. This matter, in Council's opinion, might well be the subject of discussion at the Annual Meeting, together with other questions of Institute policy.

During the year, the Charter of the St. Maurice Valley Branch has been formally presented, and, after some unavoidable delay, the organization of this branch has been completed.

Attention is drawn to the meeting of delegates from the seven Provincial Associations of Professional Engineers held in Montreal in February last at the invitation of the Council of The Institute. The Institute is fortunate in having been the means of bringing together, for helpful mutual discussion, the representatives of these important bodies, and it is hoped that the movement thus inaugurated will result in other assemblies at which general and administrative problems of mutual interest to the associations will be further discussed and happily solved.

The part which the branches and members of The Institute were able to take in welcoming the important delegation of the International Electrotechnical Commission in April last has been a source of gratification to Council. The members of the party, all distinguished European and American electrical engineers, were cordially greeted and entertained at all points visited during their brief stay in Canada, and the Niagara Peninsula, Toronto, Ottawa and Montreal branches of The Institute took a very leading part in these activities.

During the year, Council has noted that the existing arrangements and regulations regarding the award of The Institute's prizes and medals could perhaps be modified with advantage. A special committee is now studying the matter, having regard to the fact that in certain cases prizes are offered by branches under conditions somewhat similar to those governing The Institute awards. The branches have been asked to express their views, and discussion and suggestions from members at the Annual Meeting would be welcome.

The list of members deceased during the year includes the names of an unusually large number of prominent engineers who had been active in Institute affairs, and whose loss is deeply regretted. Among these may be mentioned:—

Sir Alexander Bertram, Treasurer.
Thomas J. Brown.
James Ewing.
F. C. Gamble, Past-President.
L. A. Herdt.
Phelps Johnson, Past-President.
Martin Murphy, Past-President.

From the report of the Finance Committee, presented herewith, and from the statistics as regards membership, it will be noted that, while an unusually large number of names have been removed from the membership roll of The Institute during the year, there has been a substantial increase in the arrears of fees received; the action initiated by Council last year in dealing with arrears has resulted in some diminution in the nominal list of members of The Institute, but has placed the organization in a sounder financial condition than heretofore.

Meetings

Annual General and General Professional Meeting

The Fortieth Annual Meeting of The Institute convened at Headquarters on Tuesday, January the 26th, President Arthur Surveyer, M.E.I.C., in the Chair, and after the reading of minutes and the appointment of scrutineers and auditors, was adjourned to Toronto, where it reassembled on January the 27th, in the banquet hall of the King Edward Hotel.

The report of Council for the year 1925 was considered and adopted, together with the reports of the various committees and branches, considerable discussion taking place upon the proposed amendments to By-laws; this being followed by the valedictory address of the retiring president and the presentation to the officers of the Toronto Branch of the official Charter of the branch. The Charter was accepted and fittingly acknowledged by Professor T. R. Loudon, M.E.I.C.

The report of the scrutineers appointed to canvass the ballot for the election of officers was then submitted, after which the newly-elected President, Major George A. Walkem, M.E.I.C., took the Chair.

Four professional sessions were held, at which twelve papers were presented and discussed. Other functions in connection with the meeting included a luncheon on the first day, given by the Toronto Branch; a reception and smoker, and the annual dinner of The Institute, at which the leading speaker was Principal R. Bruce Taylor of Queen's University. The meeting concluded with a supper-dance on Friday, January the 29th. The total attendance at the meeting was five hundred and thirty-four, and the undoubted success of the whole gathering was in large measure due to the activity and excellent organization of the committee appointed by the Toronto Branch to take charge of the work.

Maritime Professional and General Meeting

A very satisfactory General Professional Meeting was held at Sydney, N.S., on August 17th and 18th under the auspices of the Cape Breton, Halifax, Moncton and St. John branches, this meeting being the sixth professional meeting held by The Institute in the Maritime Provinces.

Two technical sessions were held, the papers presented being "The Humber Developments of the Newfoundland Pulp and Paper Company," by H. C. Brown, A.M.E.I.C., and "The Characteristics and Utilization of Nova Scotia Coals," by W. S. Wilson, A.M.E.I.C., and M. W. Booth, M.E.I.C. Both papers were of an exhaustive character; they gave rise to active discussion, and it is to be noted that as a result of the discussion on the latter paper, a resolution was passed unanimously and forwarded to the Nova Scotia Government asking for the appointment of a board by the provincial government to carry on experimental investigations on Nova Scotia coals.

The social features of the meeting were equally successful, and included a luncheon, visits to the collieries, power stations and steel works, and a dinner and dance at the Lingan Country Club. On this occasion, The Institute was addressed by Mr. J. E. McLurg, vice-president, British Empire Steel Corporation, on "The Engineer in Industry"; the Hon. G. S. Harrington, minister of mines of the Nova Scotia Government, also spoke, announcing that measures had already been taken to give effect to the suggestions of the resolution above referred to.

The Cape Breton Branch was heartily congratulated by the visting members on the very effective arrangements made, and on the entire success of the meeting, both from a professional and social viewpoint.

Meeting at Estevan

Council has noted with appreciation the arrangements made by the Saskatchewan Branch for a joint meeting with the Southern Saskatchewan Section of the Canadian Institute of Mining and Metallurgy and the Saskatchewan Section of the American Institute of Electrical Engineers at Estevan, Sask., in July.

At this meeting, a number of papers of importance, including three upon the "Electrical Development of Southern Saskatchewan," "Rural Electrification in Western Canada" and "Mining in Northern Manitoba," were presented and discussed.

Accommodation was provided for visiting members on the civic camping ground, and, while weather conditions were not so favourable as might have been desired, the results of the meeting were both pleasant and satisfactory.

Joint meetings of this kind emphasize the cordial relations existing between The Institute and other technical bodies.

Branch Meetings

The activities of the various branches have been well maintained during the year, particulars being included in the accompanying reports.

Roll of the Institute

During the year nineteen twenty-six, two hundred and twelve persons have been elected to various grades of The Institute. These are classified as follows:—twenty-four Members, fifty-one Associate Members, twenty-six Juniors, ninety-nine Students and twelve Affiliates. The elections during the year 1925 totalled two hundred and twenty-nine.

Transfers from one grade to another were as follows:—Associate Member to Member, thirty-three; Junior to Associate Member, twenty-five; Student to Associate Member, thirty-two; Student to Junior, sixty-six; Junior to Affiliate, one; a total of one hundred and fifty-seven, as compared with one hundred and thirty-five in 1925.

A summary of these elections is given below. The names of those elected or transferred are published each month in the Journal, immediately following the election, and are added to the membership roll as acceptances are received.

Removals from the Roll

There have been removed from the membership roll during the year nineteen twenty-six, by resignation and for non-payment of fees, fifty-eight members; two hundred and eighty-four Associate Members; fifty-four Juniors; two hunhundred and sixteen Students; and four Affiliates, a total of six hundred and sixteen. Of this number, more than five hundred removals from the list were on account of non-payment of arrears of fees. The action in this matter, undertaken by direction of Council, has reduced the arrears of fees outstanding in our books from about $20,000 at the end of 1925 to approximately $8,000 at the end of 1926, this amount including the fees of all members in arrears for 1926 or more. Twenty-five reinstatements were effected and twelve Life Memberships were granted during 1926.

Deceased Members

During the year 1926 the deaths of thirty-eight of The Institute's members have been reported:—

Members

Adams, Walter C.
Barlow, John Rigney
Barnett, John Davis, LL.D.
Bertram, Major-Gen. Sir Alexander, K.B.
Brooks, Noel E.
Brower, John L.
Brown, Thomas J.
Burwell, Herbert M.
Ewing, James
Forrest, Benjamin J.
Gamble, F. C.
Hazlewood, Richard A.
Herdt, Louis A., D.Sc.
Hobson, Robert
Johnson, Phelps
Lefebvre, Henri Paul
Maxwell, David F.
McGown, James
Murphy, Martin, D.Sc.
O'Dwyer, J. Seabury
Parsons, W. R. W.
Pickard, Kenneth S.
Pilsworth, W. R.
Ramsey, Col. Colin W. P., C.M.G.
Redmond, Augustine V.
Rinfret, R.
Roy, Georges
Saunders, Col. B. Johnston
Shewen, Edward T. P.

Associate Members

Ainslie, Chas. M.
Bowes, LeRoy T.
Livingstone, Gilbert T.
Loudon, Andrew C.
Marchand, Art. J. H.
McLerie, Allan Gordon

Students

Bastedo, T. F.
Guscott, A. G.

Total Membership

The membership of The Institute at present totals four thousand seven hundred and thirty-eight, while there are eighty-four applications which have been favourably received, the addition of the names of these applicants to the roll being delayed pending the receipt of their formal acceptance of election. The corresponding numbers for 1925 were 5,119 and 82.

The corporate members now total 3,453, as compared with 3,651 on December 31, 1925.

	Dec. 31, 1926	Dec. 31, 1925

Legislation and By-laws Committee

The President and Council,—

The amendments to the By-laws approved by letter ballot in May last were made effective in due course, and have, so far, been found to work satisfactorily.

Questions have been raised, however, regarding certain points not dealt with last year, and have been referred by Council to the committee for consideration and report.

The first of these deals with the provisions in Section 13 of the By-laws regarding a vacancy in the office of president; after consideration, and in order to clear up any apparent ambiguity, it is recommended that in Section 13, paragraph 3, lines 2 and 3, the words: "priority of election to the office of Vice-President," be changed to read, "priority of election as a Vice-President." If changed in this manner, the wording will be similar to that now used in paragraph 4 of the same section regarding a vacancy in the office of vice-president.

Your committee is unable to recommend the insertion of any phrase dealing with the question of the eligibility of a president for re-election, for there has never been any section in the By-laws which would prevent the election of a member as president, or to any other office, for more than one term.

With reference to Section 38, several changes in which became effective during the year, experience has shown that with our present office arrangements it is very difficult, if not practically impossible, to give effect to the existing provision by which no member who is in arrears shall receive the publications of The Institute, as this would involve the maintenance and continued accuracy of two separate mailing lists, one for members in good standing, who would receive all publications, and one for members in arrears, who would receive notifications, etc., but not the publications of The Institute.

In connection with Section 38, the last line of paragraph 1, your committee therefore recommends the deletion of the words, "nor shall he receive the publications of The Institute," and the substitution therefor of the following:—"Council may take action in the case of a member who is in arrears by (*a*) directing that he shall not receive the publications of The Institute, and/or (*b*) removing his name from the register of members."

It is felt that this change, if approved, will give a much more workable arrangement.

The above proposals for amendment have already been submitted to the membership for consideration, and, in accordance with the By-laws, will be open to discussion at the annual meeting.

Your committee has given further consideration during the year to the question of harmonizing branch by-laws, but is not yet prepared with a final report on this matter, in view of the circumstances that branch by-laws cannot be made absolutely uniform, that freedom for the branches is desirable, and that branch by-laws must not conflict with any provisions of the By-laws of The Institute.

Respectfully submitted,

Geo. R. MacLeod, M.E.I.C., *Chairman.*

Nominating Committee—1927

The following nominations to the Nominating Committee for the year 1927 have been made by the various branches, have been noted by Council, and are herewith presented to be announced at the Annual Meeting in accordance with the By-laws.

Halifax Branch	C. H. Wright, M.E.I.C.
Cape Breton Branch	R. R. Moffatt, A.M.E.I.C.
St. John Branch	Alex. Gray, M.E.I.C.
Moncton Branch	G. C. Torrens, A.M.E.I.C.
Saguenay Branch	J. E. A. McConville, A.M.E.I.C.
Quebec Branch	A. Lariviere, A.M.E.I.C.
St. Maurice Valley Branch	A. A. Wickenden, A.M.E.I.C.
Montreal Branch	G. P. Cole, M.E.I.C.
Ottawa Branch	K. M. Cameron, M.E.I.C.
Peterborough Branch	A. L. Killaly, A.M.E.I.C.
Kingston Branch	L. T. Rutledge, M.E.I.C.
Toronto Branch	R. B. Young, M.E.I.C.
Hamilton Branch	H. A. Lumsden, M.E.I.C.
London Branch	F. C. Ball, A.M.E.I.C.
Niagara Peninsula Branch	C. G. Moon, A.M.E.I.C.
Border Cities Branch	M. E. Brian, A.M.E.I.C.
Sault Ste. Marie Branch	J. W. LeB. Ross, M.E.I.C.
Lakehead Branch	F. C. Graham, A.M.E.I.C.
Winnipeg Branch	J. N. Finlayson, M.E.I.C.
Saskatchewan Branch	W. H. Greene, M.E.I.C.
Lethbridge Branch	G. S. Brown, A.M.E.I.C.
Edmonton Branch	A. W. Haddow, A.M.E.I.C.
Calgary Branch	G. P. F. Boese, A.M.E.I.C.
Vancouver Branch	A. K. Robertson, M.E.I.C.
Victoria Branch	R. F. Davy, A.M.E.I.C.

Finance Committee

The President and Council,—

From the attached financial statement, it will be seen that The Institute's expenditure for the year ending December 31st, 1926, has been kept within the budgeted amount, and that instead of the small deficit anticipated in the budget there is actually a book surplus.

Your committee would point out, however, that this apparent surplus of revenue over expenditure does not represent a real reserve of any kind. It is due to two causes:—

First—The special measures taken by Council to recover the arrears of fees have yielded $6,989.73, as compared with the $4,500 anticipated in the budget. This will not recur in future years.

Second—No reduction has been made this year on the Mortgage Account.

The economy in expenditure which has necessarily been observed during the past year is therefore amply justified.

The financial report for last year showed that such economy is needed to keep the expenditure within the revenue, and your committee would again point out that the revenue and expenditure of The Institute are only made to balance by sacrificing services and activities which The Institute should and could give to its members if funds were available.

Respectfully submitted,

J. H. Hunter, M.E.I.C., *Chairman.*

STATEMENT OF ASSETS AND LIABILITIES AS AT DECEMBER 31st, 1926

Balance in bank	2,110.58	
		$4,090.37

Papers Committee

The President and Council,—

The Papers Committee, according to the By-laws, consists of a chairman and, as far as possible, a representative from each branch. It has been customary in recent years to name the branch secretaries, ex-officio, members of this committee. This is not an entirely satisfactory arrangement for two reasons; one being that the committee is so unwieldy that it is impossible to get representative action, and, second, that the branch secretary is frequently not the branch officer who is best acquainted with the local papers situation; in fact, it is found that many branch secretaries do not act as members of this committee, but refer correspondence to some other official.

An innovation was made this year by appointing an eastern and a western vice-chairman of the committee. W. J. Johnston, A.M.E.I.C., of St. John, acted for the Maritimes, while E. A. Wheatley, A.M.E.I.C., of Vancouver, represented the western branches. It has not been possible to prepare this report as a result of collaboration between the members of the committee, but simply of the chairman and vice-chairman.

The principal work performed by the committee in the past year has been the aiding of branches in obtaining speakers from outside their own immediate territory, and while it is not possible to give a list of concrete cases where this has been done, owing to the difficulty of segregating cases where the committee has only been of secondary use, nevertheless the work of the committee has borne fruit to the satisfaction of many branches. It is our recommendation that the work of the committee be continued along these lines.

We also respectfully suggest that Council give consideration to the desirability of either changing the By-law appointing the committee, so as to provide that the committee consists of about three or four members widely separated, or, if this is not found desirable, to have each branch appoint its special representative.

Mr. Johnston's view differs slightly from this. He is of opinion that a representative from each branch should be on the Papers Committee, its numbers therefore remaining as at present, thus ensuring that all meritorious papers originating in the different branches will be forwarded to Headquarters; in addition, since twenty-five members scattered across Canada cannot easily act together for effective work, there should be a working sub-committee of from three to five members chosen from the committee.

We also recommend that a definite appropriation be made by Council and placed at the disposal of the committee in order that some fund may be available from which may be paid the travelling expenses, in whole or in part, of a speaker who may be willing to devote his time to the presentation of a paper at a number of branches. We presume it is not necessary to dwell upon the difficulty smaller and outlying branches have in getting sufficient speakers. In many cases it is only possible to maintain interest in the branch if some outside speakers are obtained, and it is only by so doing that members of such branches can be expected to sustain their interest in The Institute.

The chairman of your committee has also collaborated from time to time with the general secretary and with the chairman of the Quebec branch with reference to papers for the annual meeting at Quebec.

Respectfully submitted,

J. L. Busfield, M.E.I.C., *Chairman.*

Publication Committee

The President and Council,—

The Publication Committee was not completely formed until after notification on May 25th, 1926, that Council had reached the decision to resume the publication of Transactions. Your committee had a number of meetings during the summer and fall months, and carefully studied all the papers which had been presented to The Institute or its branches during the years 1923, 1924 and 1925. After due consideration, the following twelve papers were approved for publication. In some cases, advice from members outside the committee was obtained as to the merit of papers.

Title	Author
The Cost of Hydro-Electric Power. Discussion	C. V. Christie, M.E.I.C.
An Economic Examination of the Hudson Bay Project	W. Nelson Smith, M.E.I.C.
The Hudson Bay Railway	J. L. Busfield, M.E.I.C.
Inductive Co-ordination as a Practical Problem	J. L. Clarke, A.M.E.I.C.
Steel Rails	C. B. Bronson.
Consideration of Rainfall and Run-off in Connection with Sewar Design in the Montreal District	J. G. Caron, A.M.E.I.C.
British Columbia Dams	E. Davis, M.E.I.C., and E. G. Marriott, A.M.E.I.C.
Cost of Electric Power	P. T. Davies, M.E.I.C.
The Municipal Underground Conduit System of Montreal	G. E. Templeman, A.M.E.I.C.
Hydraulic Regulating Gates	F. Newell, M.E.I.C.
The New Esquimalt Drydock	J. P. Forde, M.E.I.C.
Report on the Strength of Steel I-Beams Haunched with Concrete	Peter Gillespie, M.E.I.C., H. M. MacKay, M.E.I.C., and C. Leluau, M.E.I.C.

In view of the necessity of producing legible drawings of uniform standard, the committee requested authority to spend up to $1,000 for the preparation of suitable drawings. Upon the granting by Council of the necessary appropriation, the work was carried out under the supervision of the committee at a cost of about one-half the aforesaid amount.

Apart from the selections of papers for the Transactions, there has been no work before the committee.

Respectfully submitted,

J. L. Busfield, M.E.I.C., *Chairman.*

Library and House Committee

The President and Council,—

Substantial progress has been made during the past year in cataloguing and indexing the library, the present condition being as follows:—

Technical Books and Pamphlets:—The work of cataloguing, marking and shelving these is now almost up to date.

U. S. Government Material:—This has been catalogued and much of it has been marked and shelved.

British Patent Specifications:—These have been sorted and listed.

Canadian and U. S. Patent Specifications:—These have not yet been listed nor catalogued.

Transactions and Other Society Publications:—These have been shelved, but not yet catalogued.

Periodicals:—Our collection of technical periodicals is quite a representative and valuable one, and these are shelved and available for consultation, but are not yet catalogued.

New Books:—With the limited resources available, it is not possible to obtain for our library a very large or representative collection of new books.

Reference Work

During the year the reference and information service has been largely taken advantage of by members; information having been sent by mail as to source of information desired and, in many cases, photostat and other copies having been obtained for enquirers. The number of enquiries dealt with during 1926 was 185.

The important thing for a library such as that of the Engineering Institute of Canada is, however, to possess easily accessible information as to the books available on any particular subject, and, if not in our own library, where they can be found. We are, therefore, now adding cards to our catalogue that list new books which are not in our library, but are of importance in connection with our information service. These entries are on coloured cards, distinguishing them from the cards representing books in our possession. This list will be of considerable bibliographical aid.

The committee feels that, as far as financial resources permit, every effort should be made to render the library resources and information service more readily available for the membership at large. For this purpose, efforts are being made to make members familiar with the conditions under which they can obtain books on loan, and information and data on various topics.

The work in connection with the library has been greatly facilitated by the new steel shelving installed during the year, which has afforded much needed space for shelving books, transactions, etc., for which there previously was no room.

The expenditure on the library during the year amounted to $1,928.45, of which $684.95 represents expenditure on periodicals, binding and new books and the balance the cost of cataloguing work.

The thanks of The Institute are due to a number of individuals and organizations for the presentation of books and reports. These have been listed each month in The Engineering Journal on pages 174, 261, 312, 246, 421, 446, 478, 525.

The following is the list of books added to the library during the year:—

Economics of Highway Engineering, by H. T. Tudsbery.
Galvanizing, by Heinz Bablik.
Workshop Operations and Layouts for Economic Engineering Production, by Philip Gates.
Metal-Plate Work, by C. T. Millis.
Presented by E. & F. N. Spon & Company, London.
Metallurgy and its Influence on Modern Progress, by R. A. Hadfield.
Stainless Iron and Steel, by J. H. G. Monypenny.
Coal & Ash Handling Plant, by J. D. Troup.
Presented by Chapman & Hall.
Storage Batteries Simplified, by V. W. Page.
Standard Electrical Dictionary, by T. O'Conor Sloane.
Presented by Norman W. Henley Publishing Company.
A Century of Progress—History of Delaware and Hudson Company, 1823-1923.
Presented by L. F. Loree, President of the Delaware and Hudson Company.
Canadian Trade Index, 1926.
Presented by the Canadian Manufacturers' Association.
Concrete—Plain and Reinforced, vol. 1. By Taylor, Thompson and Smulski.
An Elementary Treatise on Statically Indeterminate Stresses, by J. I. Parcel and G. A. Maney.
Elements of Heat Power Engineering, part 1. By W. N. Barnard, F. O. Ellenwood, and G. F. Hirshfield.
Presented by John Wiley & Sons, Inc.
Superpower, its Genesis and Future, by W. S. Murray.
Bacteriology, by Stanley Thomas.
Fuels and Their Combustion, by R. T. Haslam and R. P. Russell.
Corrosion—Causes and Prevention, by F. N. Speller, M.E.I.C.
Concrete Designer's Manuel, by G. A. Hool and C. S. Whitney.
Presented by McGraw-Hill Book Company, Inc.
Draft and Capacity of Chimneys, by J. G. Mingle.
Elementary Steam Engineering, by E. V. Lallier.
Presented by D. Van Nostrand Company.
Depreciation in Public Utilities, by Delos F. Wilcox.
Presented by the National Municipal League.
Les Moteurs à Explosion, by E. Marcotte.
Les Moteurs à Combustion, by E. Marcotte.
La Transformation de l'énergie électrique—I, Transformateurs, by René Cartonet and Pierre Dumartin.
Presented by Librairie Armand Colin, Paris.
Combustibles Inférieurs et de Remplacement, by P. Appell
Presented by Gauthier-Villars, Paris.
The Ethics of Business, by E. Heermance.
Presented by Harper & Bros.
Materials and their Application to Engineering Design, by Professor E. A. Allcut, M.E.I.C., and E. Miller.
Engineering Inspection, by Professor E. A. Allcut, M.E.I.C., and C. J. King.
Presented by Professor E. A. Allcut, M.E.I.C.
Mathematical and Physical Papers, 1903-13, by B. O. Pierce.
Presented by the Harvard University Press.
Transmission Line Theory and Some Related Topics, by W. S. Franklin and F. E. Terman.
Presented by Franklin & Charles.
Thirteenth Edition New Volumes Encyclopedia Britannica.
Purchased from the Encyclopedia Britannica, Inc.
Northcliffe Collection.
Presented by Archives of Canada.
British Standard Glossary of Terms used in Electrical Engineering.
Presented by the British Engineering Standards Association.
Gazetteer of Canada, 1926.
Purchased from the Canadian Gazetteer Publishing Company, Toronto.

As regards the Headquarters building, the expenditure on repairs and maintenance during the year amounted to $468.21, including repairs to the outside steps in the front and sundry repairs to furniture.

Respectfully submitted,

O. O. Lefebvre, M.E.I.C., *Chairman.*

Board of Examiners and Education

The President and Council,—

The principal task of the Board during the year was a thorough revision of the syllabus for examinations. Upon the recommendation of the Board, amendments to Sections 8, 9 and 10 of the By-laws were drafted and submitted to the membership of The Institute providing that examinations under Schedule *A* shall be passed by candidates for admission as Student members who do not present satisfactory evidence as to their educational qualifications; and that, similarly, examinations under Schedule *B* shall be passed by candidates for the grade of Junior whose qualifications are not otherwise established. These amendments were adopted, and the syllabus was re-arranged accordingly.

Schedules *A* and *B* were revised to meet present-day conditions more satisfactorily, and Schedule *C* was completely revised and extended so as to provide, as far as practicable, for candidates in such branches as chemical and metallurgical engineering and electrical communications. Further, sub-division of Schedule *C* was also made in recognition of the growing diversity and tendency towards specialization in engineering practice.

The revised syllabus, together with typical examination papers, was prepared for publication, a step which, it is hoped, will prove helpful to candidates for examination.

Respectfully submitted,

H. M. MacKay, M.E.I.C., *Chairman.*

Gzowski Medal Committee

The President and Council,—

The undersigned, your committee appointed to canvass papers presented to The Institute during the season of 1925-1926, with a view to recommending the award of the Gzowski Medal to the most meritorious, respectfully reports as follows:—

Your committee has carefully canvassed the papers referred to, with the result that it recommends that the Gzowski Medal for this year be awarded to—

Lesslie Rielle Thomson, M.E.I.C., for his paper "The Fuel Problem in Canada," presented at the annual general meeting of The Institute in Toronto, January 29th, 1926, and published in The Engineering Journal for February 1926, pages 64-72.

Mr. Thomson's paper deals with a subject vital to Canada and its people. The committee believes that he has faced the facts without prejudice, and that the conclusions he has drawn from them are sound.

Respectfully submitted,

R. DeL. French, M.E.I.C., *Chairman.*
Frederick B. Brown, M.E.I.C.
H. V. Haight, M.E.I.C.
A. W. Campbell, M.E.I.C.
Peter Gillespie, M.E.I.C.

Leonard Medal Committee

The President and Council,—

After a study of the papers eligible for this prize, your committee has come to the conclusion that there is no paper of sufficient merit to be awarded the prize amongst those published between June 1925 and May 1926.

The chief reason for arriving at this decision is that none of the papers considered appear to contain original ideas, the best of them being only excellent compilations.

Respectfully submitted,

J. Colin Kemp, A.M.E.I.C., *Chairman.*

Plummer Medal Committee

The President and Council,—

The committee recommends that the Plummer Medal be awarded to Dean C. J. Mackenzie, M.E.I.C., and Professor T. Thorvaldson for their paper on "Differentiation of the Action of Acids, Alkali Waters and Frost on Normal Portland Cement Concrete," published in the Journal of The Institute, February 1926, page 79.

The committee again recommends that, if the consent of the donor can be obtained, the Plummer Medal shall be awarded in future for papers that have been presented either to The Engineering Institute of Canada or to The Canadian Institute of Mining and Metallurgy, as in the case of the Leonard Medal.

Respectfully submitted,

Alfred Stansfield, M.E.I.C., *Chairman.*

Students' Prize Committee

The President and Council,—

I have pleasure in recommending on behalf of this committee the following awards of the Students' Prizes of The Institute for 1925-26:—

For Chemical Engineering—W. T. D. Ross, S.E.I.C.,—"Salt Mining in Nova Scotia—A New Industry."

For Mechanical Engineering—R. G. Beck, S.E.I.C.,—"How the Fabrication of the Miehle Printing Press is Controlled."

For Electrical Engineering—B. C. Hicks, S.E.I.C.,—"The Ground Selector."

For Civil Engineering—H. A. Gauvin, S.E.I.C.,—"Scientific Principles Applied to Dwelling House Construction."

Essays submitted have been read by all members of the committee. Lack of time unfortunately prevents the committee from submitting a formal report signed by all its members, as it has already done with respect to the Gzowski Medal. The recommendations made above, however, conform to those made by individual members of the committee, in letters addressed to its chairman.

Respectfully submitted,

R. DeL. French, M.E.I.C., *Chairman.*

Committee on Engineering Education

The President and Council,—

This committee, consisting of T. H. Hogg, M.E.I.C., H. J. Lamb, M.E.I.C., J. D. Craig, M.E.I.C., C. C. Kirby, M.E.I.C., S. G. Porter, M.E.I.C., and the writer as chairman, was reappointed in February 1926, and the writer immediately communicated with the various members of the committee, with the Society for the Promotion of Engineering Education, with several of the universities and with certain individuals in connection with the work. The problem confronting the committee is a very large one, requiring a great deal of careful study which we find very difficult to arrange. There is so much work being done on this subject that it would seem unwise for your committee to attempt to make an independent study of the whole question, and it is our conclusion that better results would probably be obtained by offering our co-operation to the Society for the Promotion of Engineering Education for help in solving any problem upon which they might ask our assistance, particularly with regard to Canadian conditions.

Sets of progress reports were obtained from the Society for the Promotion of Engineering Education and distributed to the members of your committee for study, and they were also referred to the Journal of Engineering Education and other similar publications. Reports of committees have been received from McGill University, Queen's University, Leland Stanford University, from the Association of Professional Engineers of British Columbia and others, and a collection has been commenced of articles, documents and bibliography of the subject. The committee has had considerable correspondence amongst its members, but it has not yet been possible to formulate any definite recommendations or conclusions.

Some of the questions which seem to the committee to be of importance are as follows:—

(1) What is the present consensus of opinion as to the relation of the universities to the engineering profession?

(2) Are the universities attempting to do work which should be done by trade and technical schools?

(3) Is there a definite demand or field for apprenticeship courses for the engineering profession, either to supplement or take the place of a university training?

(4) Are the universities preparing men on the average to take subordinate industrial positions or are they attempting to train thinkers and leaders?

(5) Should engineering education be a training for the profession of engineering in a general

sense on broad fundamental lines, or should the attempt be made for more highly specialized training for specific and narrower fields of work?

(6) Should engineering education be considered as a course of culture, as a foundation for a future career in any walk of life, possibly taking the place of an arts course to some extent?

(7) Are the present standards of admission to the engineering courses too low and is the ordinary course of four years too short?

(8) Does the apparently large percentage of students failing to graduate, or being unsuccessful in engineering after graduation, indicate a deficiency in the methods or personnel of the teaching organization, or does the fault lie with the student in choosing the wrong career at an immature age with insufficient knowledge and preliminary preparation?

(9) What would be the effect of training a much smaller number of students annually with higher entrance requirements and possibly longer courses in much smaller classes?

(10) Should the teachers in high schools and preparatory schools make more direct efforts to find out the personal characteristics and qualifications of pupils and attempt to guide them as to their future life work, giving special preparation to those who seem to be fitted for university training in any one of the professional walks of life?

The above are some of the questions in one form or another which have been brought to the attention of members of your committee, and serve to indicate the magnitude of the task if we attempt to solve the various problems, especially as many of these questions and others are being considered by the Society for the Promotion of Engineering Education and by the various universities.

We, therefore, recommend that The Institute write to the Society for the Promotion of Engineering Education offering to co-operate actively with it in the field of engineering education, and saying that it will continue to appoint a committee which will hold itself in readiness to consider any points brought to its attention, particularly with regard to Canada, but not undertaking a complete or independent study of the whole matter.

Respectfully submitted,

Frederick B. Brown, M.E.I.C., *Chairman.*

Committee on International Co-operation

The President and Council,—

The outstanding feature of International Co-operation for the year 1926 was the work connected with the short visit to Niagara Falls, Toronto, Ottawa and Montreal, at the end of April and beginning of May, of 125 ladies and gentlemen, most of them from Europe, who had come to this continent to attend the Plenary Meeting of the International Electrotechnical Commission in New York from April 12th to 22nd.

The New York meeting was arranged for primarily by the members of the American Institute of Electrical Engineers, who have been actively connected with the International Electrotechnical Commission since its inception at the Louisiana Purchase Exposition, (the "World's Fair"), at St. Louis in 1904. American committees were formed embracing in their personnel representatives from not only all branches of engineering but from all branches of human activities in which engineering, particularly electrical engineering, plays a prominent part.

The "Americans" invited the Canadian National Committee of the International Electrotechnical Commission to share the honours and to act as joint hosts in welcoming the visitors to the American continent. The Canadian Committee tentatively accepted the proposal and sought the assistance of their engineering confreres, as well as all others in the "electrical business,"—light, power, communication and manufacturing,—in the district which was to be visited. The immediate response and the whole-hearted co-operation of the officers of the E.I.C. at Headquarters and of the officials and members of the branches in the Niagara district, at Hamilton, Toronto, Ottawa and Montreal made it unnecessary even to call a meeting of our International Co-operation Committee. The generous contributions of the power and communication companies and the manufacturers eliminated what otherwise might have become a financial burden on local committees; and through the kindness of Sir Henry Thornton, president and chairman of the Canadian National Railways, and his prompt appreciation of the advertising value to Canada of such a visit, the visitors' special train, supplied with the compliments of the American Committee, was gratuitously hauled from Windsor through Ontario and Quebec to the eastern international boundary,—on its way to Boston from Montreal.

Material assistance also came from members of the Ottawa Rotary Club, who, together with our Ottawa branch members, supplied the automobiles which took the visitors to the hydro-electric developments of the Gatineau Power Company. Mr. Guido Semenza, the International President of the I.E.C., is a member of the Rotary Club of Milan, Italy, and on that account the Ottawa Rotarians were glad to do honour to him and his party.

The manner in which all members of the Engineering Institute of Canada,—without regard to their specialties in chemical, mechanical, mining or any other "civil" pursuits,—took part in the work of entertaining the visitors provided a great object lesson which once again shows the wisdom of having in a country like Canada an Engineering Institute which embraces every branch of the profession.

Respectfully submitted,

John Murphy, M.E.I.C., *Chairman.*

Canadian National Committee of the International Electrotechnical Commission

The President and Council,—

The committee have had a very busy year in connection with the New York Conference last April, the first meeting of the I.E.C. to be held on this side of the Atlantic. The proceedings of that meeting and the ensuing Canadian tour of the visiting European delegates have already been reported.

The committee is now busily preparing for next year's conference, to be held in Italy during September, for which the Canadian National Committee, at the resquest of the Central Office, has nominated R. L. Hearn, M.E.I.C., to prepare the Paper on "The Necessity for an International Rating of Hydraulic Prime Movers for Electric Power Generation."

Work is also actively proceeding on the preparation of an International Technical Vocabulary, and considerable progress has to be reported in the matter of specifications for hydraulic and steam prime movers for electrical generators.

The work of the committee is increasing so rapidly that the regular quarterly meetings are insufficient to cope with it. During the year W. P. Dobson, M.E.I.C., joined the committee as representative of the Hydro-Electric Power Commission of Ontario, and at the request of the committee the Canadian Westinghouse Company have nominated Mr. C. A. Price as their representative on the committee.

At their October meeting at Ottawa the committee elected as officers for 1927, Mr. J. Kynoch as president, J. Murphy, M.E.I.C., as vice-president, and re-elected H. A. Dupré, M.E.I.C., as secretary-treasurer.

The personnel of the committee is now as follows:—

Howard T. Barnes, M.E.I.C.	O. Higman, M.E.I.C.
J. B. Challies, M.E.I.C.	A. Frigon, A.M.E.I.C.
W. P. Dobson, M.E.I.C.	G. Gordon Gale, M.E.I.C.
H. A. Dupré, M.E.I.C.	J. Kynoch.
R. J. Durley, M.E.I.C.	A. B. Lambe, A.M.E.I.C.
John Murphy, M.E.I.C.	A. Larivière, A.M.E.I.C.

L. W. Gill, M.E.I.C.

Respectfully submitted,

Howard T. Barnes, M.E.I.C., *Chairman.*

Code of Ethics Committee

The President and Council,—

The Committee on Code of Ethics begs to report that, having considered the matter, it does not wish to recommend any change at the present time.

Respectfully submitted,

Frederick B. Brown, M.E.I.C.
F. P. Shearwood, M.E.I.C.

Honour Roll and War Trophies Committee

The President and Council,—

It is gratifying to report that during the year 1926 the amount necessary for the completion of the work has been collected, and the sum of $4,090.37, (in Canadian Bank of Commerce $2,110.58, in Bonds $1,979.79), now stands to the credit of the committee.

Progress has been made in the important work of checking the nominal lists for the Memorial and the Record in bronze, members having been notified twice in the Journal, (September and October issues), and a circular regarding the matter having also been mailed to all members. Replies to these communications are still coming in. The corrected lists have still to be forwarded to National Defence Headquarters, Ottawa, for final confirmation.

Respectfully submitted,

Charles J. Armstrong, M.E.I.C., *Chairman.*

Report of the E.I.C. Members of the Main Committee of the Canadian Engineering Standards Association

The President and Council,—

The Institute nominees on the Main Committee of the C.E.S.A. are now as follows:—

F. B. Brown, M.E.I.C.,	(retires March 1927).
Prof. C. M. McKergow, M.E.I.C.,	(" " 1928).
Dean C. J. Mackenzie, M.E.I.C.,	(" " 1929).

Professor McKergow was nominated by the Council of the E.I.C. to succeed the late Sir Alexander Bertram, M.E.I.C.

The total number of working committees and panels now stands at 67 and the membership of the Association at 463.

During part of 1925, and up to April 1926, Professor W. F. McKnight, A.M.E.I.C., of the Nova Scotia Technical College, Halifax, was acting secretary, and on April 19th, B. Stuart McKenzie, M.E.I.C., was appointed secretary.

The Association is at present operating as the Associate Committee on Engineering Standards of the National Research Council, by whom it has been granted funds for operating expenses. The granting of these funds is contingent on the securing of financial support from various industries.

The year has been devoted to promoting interest in the Association's work, and in reviving the work of committees. Special work has also been done with regard to publicity and arrangements have been made for issuing a Year Book which will be used in an organized campaign for financial support.

Publications Issued in 1926

A19—1926. Standard Classification of Items of Highway Expenditure. This covers the classification of highway accounts in some detail, with the object of securing uniform practice throughout Canada.

A complete list of the publications issued by the Association to date is as follows:—

C.E.S.A. Publications

A1—1922 Standard Specification for Steel Railway Bridges.
A1a—1922 Material Specifications, Steel Railway Bridges (reprint).
C2—1920 Standard Requirements for Distribution Type Transformers.
C3—1924 Standard Specification for Galvanized Telegraph and Telephone Wire.
B4—1921 Standard Specification for Wire Rope for Mining, Dredging and Steam Shovel Purposes.
A5—1922 Standard Specification for Portland Cement.
A6—1922 Standard Specification for Steel Highway Bridges.
D7—1922 Standard Specification for Flexible Steel Wire Rope and Flexible Strand for Aircraft Purposes.
G8—1923 Standard General Specification for Commercial Bar Steels.
A9—1923 Standard Specifications for Reinforcing Materials for Concrete.
C10—1923 Standard Specification for Tungsten Incandescent Lamps.
D11—1924 Interim Report on the Manufacture, Testing and Use of Gasoline.
B12—1924 Standard General Specification for Galvanized Steel Wire Strand.
E13—1924 Standard Specification for Railway Wire-fencing and Gates.
C14—1924 Standard Specification for Reinforced Concrete Poles.
C15—1924 Standard Specification for Eastern Cedar Poles.
A16—1924 Standard Specification for Steel Structures for Buildings.
C17—1925 Standard Requirements for A.C. Watthour Meters.
B18—1925 Standard Specification for Stove Bolts.
A19—1926 Standard Classification of Items of Highway Expenditure.

Work in Progress

Civil Engineering and Construction

Moveable Bridges. Final revised draft is now receiving comments from the joint Bridge Committees.

Concrete and Reinforced Concrete. The majority of the reports from panels have been received from chairmen, and a definite report is promised early next year.

Reinforcing Materials for Concrete. The approval of the revised list of bars has been received and the list will be printed as an appendix to existing specification No. A9—1923.

Road Materials and Construction. Final drafts have been prepared covering block pavements, broken stone roads and sand clay roads. A final draft specification for asphalt pavement has now been criticized by the panel and one for concrete roads is out for comment by members of that panel. Nothing further has been done in regard to earth roads or foundation and sub-grade preparation. A specification for gravel roads is in the hands of the chairman of the panel. Specifications for road structures and for definitions of road and highway terms are now being re-drafted for submission to the respective panels.

Steel Highway and Steel Railway Bridges. A meeting of the joint committees was held in Montreal on September 22nd, and revisions were considered to the existing specifications. Revisions covering silicon steel, increased unit stresses in highway bridges, and bridge paint were considered, and some of these have been tabulated and submitted to the committees for comment. Specification for silicon steel will be added, and allowable unit stress in highway bridges has been increased from 16,000 to 18,000 pounds.

Steel Structures for Buildings. The question of raising allowable unit stresses is becoming more active, and this will be considered at an early meeting of the committee.

MECHANICAL ENGINEERING

Machine Screws. The committee held a meeting in Toronto on September 8th last, and appointed a panel to prepare data sheets showing suggested range of sizes, threads and tolerances. This panel will report shortly, and it is hoped to eliminate a great many types of machine screws and be able to supply the demand from a simplified list.

Sheet Metal Gauges. A committee has been formed and held a meeting in Toronto on September 8th. A panel was appointed to prepare recommendations, and this panel met in Toronto on December 10th, at which meeting a resolution was presented covering the adoption of a Canadian standard gauge. This resolution will be circulated among the members of the committee for final approval.

Cast Iron Pipe. A preliminary draft was prepared by the chairman and the secretary, and a revised draft has been submitted to the members of the committee for comments, which are now being received.

Corrugated Iron Pipe. At the suggestion of the chief engineer of the Nova Scotia Highway Board, arrangements have been made with the various provinces to collect reports as to the behaviour of corrugated iron pipe in service. As a result of these reports, it may be possible to prepare some sort of specification.

ELECTRICAL ENGINEERING

Western Cedar Poles. The final draft specification is being held until a report from a committee of the American Engineering Standards Committee is available.

Rating and Testing of Electrical Machinery. A report has been received from Panel *A* covering the rating and testing of large power rotating machinery. Panel *B*, covering rotating machinery under ordinary conditions, is active and a report is promised shortly. Panel *C* on transformers has discussed the question and a report is now being prepared.

Canadian Electrical Code. The first draft of Rules and Regulations was considered at a meeting of the committee in Ottawa on May 10th and 11th last, and considerable revision was made. Panels on grounding and radio, and a reference panel, were appointed and reports from these are expected before the end of the year. The committee has been greatly handicapped by the death of Mr. A. A. Dion, the efficient chairman of the committee.

Transformers. Meetings of the committee have been held in Montreal on September 24th and in Toronto on December 8th. Revisions to Specification C2—1920, for distribution type transformers, have been approved, and a report on the rating and testing of transformers is in preparation. The preparation of a specification for power transformers will be considered at the proposed meeting in Ottawa in January next.

Colour Code for Control Cable. A suggestion was received for the consideration of a colour code for control cable, and a committee has been formed to consider this question, also general specifications for control cable. The committee held its first meeting in Toronto on December 7th, at which a draft specification was approved and this will now be circulated among the members of the committee for comment.

AUTOMOTIVE WORK

Traffic Signals for Highways. A final draft specification was sent out to the committee for comment, and a meeting was held on December 17th at which the revised draft was approved. This will now be sent to the Sectional Committee and Main Committee for final approval.

FERROUS METALS

Heavy Steel Castings. Suggestions for a specification made by the chairman of the committee were considered at a meeting in Montreal on August 6th, at which meeting a panel was appointed to prepare a draft specification. This panel had a meeting in Montreal on November 22nd, and the proposed specification is well under way. It is proposed to include smaller castings, so that specification will be as general as possible.

Sampling for Check Analysis. A committee has been organized, and suggestions for scope of the specification are being received from members of the committee.

Forging Quality of Bar and Billet Steel. A committee has been organized, and is now considering the A.S.T.M. specification as a preliminary.

CO-OPERATION

Co-operation with other standardizing bodies has been continued, and representatives on various committees of the American Engineering Standards Committee are still acting, a representative for the Committee of Manhole Frames and Covers being appointed during the year.

There has been the usual exchange of information and specifications with other national standardizing bodies, and the Association has co-operated particularly with the British Engineering Standards Association in commenting on tentative specifications which have been issued.

Respectfully submitted,

C. J. MACKENZIE, M.E.I.C.

Committee on the Deterioration of Concrete in Alkali Soils

The President and Council,—

Your committee begs to report that during the past year work has progressed well on the Chemical Research. One paper, entitled "Action of Sodium and Magnesium Sulphates on Portland Cement," by G. R. Shelton, has been published in the Journal of Industrial and Engineering Chemistry *18*, 854, 1926. Two other papers have been prepared and are now ready for publication, as follows: (1) "The Expansion of Portland Cement Mortar Bars During Disintegration in Sulphate Solutions," by T. Thorvaldson, R. K. Larmour and V. A. Vigfusson, and (2) "The Action of Sulphate Solutions on High Alumina Cements," by T. Thorvaldson and D. Wolochow.

Further papers on other phases of the subject are in course of publication, and it is expected that they will be published during the coming year.

Plans were made to hold a detailed inspection of the field blocks this fall and to issue a report on the results of five years of exposure, but the unusually rainy weather experienced in the west made an inspection at that time impossible, but we hope to make such an inspection and report some time during the coming summer or fall.

Financial

The following summary of expenditures and receipts as to December 1st, 1926, is submitted. A detailed statement of expenditures from December 1st, 1925, to December 1st, 1926, is being sent to the financial supporters of the research.

Total Expenditures to December 1st, 1926

General:		
Committee meetings, travelling expenses	$1,836.56	
Miscellaneous telegrams, office expenses	353.85	
		$2,190.41
Physical Tests:		
Travelling allowances and expenses	$1,123.66	
Material, labour and equipment	1,745.67	
Freight and cartage	353.09	
		$3,222.42
Chemical Research:		
Travelling expenses	$ 340.81	
Salaries	32,659.85	
Materials	6,926.59	
		$39,927.25
		$45,340.08

Expenditures During Year December 1st, 1925-December 1st, 1926

Physical Tests:		
Labour at Winnipeg Test Pits		$ 17.09
Chemical Research:		
Salaries to laboratory assistants	$3,692.11	
Materials	1,469.59	
		$5,161.70
		$5,178.79

Total Receipts to December 1st, 1926

	1921	1922	1923	1924	1925	1926	Total
Research Council	$5,000	$5,000	$5,000	....	....	$5,000	$20,000,00
Can. Cement Co.	3,000	3,000	3,000	....	$2,997	....	11,997.00
Saskatchewan	3,000	3,000	3,000	....	....	....	9,000.00
Alberta	1,000	1,000	....	....	....	....	2,000.00
C. P. R.	1,000	1,000	1,000	....	....	....	3,000.00
City of Winnipeg	200	200	300	....	....	....	700.00
Interest on bank account			139.41	422.14	190.65	193.71	945.91

Total receipts	$47,642.91
Expenditures	45,340.08
Balance in bank December 1st, 1926	$2,302.83

From the above statement, it will be seen that we have received during the past year another $5,000 from the Research Council, (this money was received in December 1925), and that our expenses during the same period have been largely in connection with salaries to laboratory assistants.

Respectfully submitted,

C. J. Mackenzie, M.E.I.C., *Chairman.*

Committee on Young Graduates

During 1925 the Council appointed a Committee on Young Graduates, consisting of R. A. Ross, M.E.I.C., H. G. Acres, M.E.I.C., G. R. Marston, A.M.E.I.C., R. E. Smyth, Jr.E.I.C., C. E. MacDonald and H. E. T. Haultain, M.E.I.C. The chairman of this committee, Professor Haultain, has submitted to Council a fairly lengthy confidential report in which he points out that very little is being done by any organization in Canada for young technical graduates. He urges that the Engineering Institute of Canada throughout its branches should stir up this matter for discussion. He points out that the technically trained man is needed in all branches of commercial activity, but that employers as a rule are not "sold" on the product of the universities. After pointing out that the young engineering graduate is the nation's finest partially processed product, he asks: "Is it not a great national need that employers be properly 'sold' on this product?"

Branch Reports

Border Cities Branch

The President and Council,—

The Executive Committee of this branch begs to submit the following annual report for the year ending December 31st, 1926.

During the year some very interesting addresses were given. These, however, failed to bring the members' attendance to such numbers as might be expected, the number varying from 13 to 60, with an average attendance to date of 31, or a total of 217 for the year. There are but 77 resident members living on this side of the river, so that this attendance is, after all, not so bad. Thirty-four members live in Detroit and 19 are non-resident. The total now on our roster is 130.

Meetings

The Executive met regularly throughout the year for the consideration of matters before it, and the following general meetings of the branch were held:

Jan. 15.—Address by Mr. S. F. J. Fryer, past president of the Ontario Architects' Association. Present, 14 members and 12 guests.

Feb. 12.—J. Clarke Keith, A.M.E.I.C., chief engineer of the Essex Border Utilities Commission, spoke on, "**The Border Cities Water Supply.**" Present, 27 members and 1 guest.

Mar. 12.—Mr. A. McLay, of the Detroit Edison Company, spoke on "**Mechanical Refrigeration.**" Present, 26 members and 4 guests.

Apr. 27.—On this evening the Border Cities Branch members were the guests of Detroit Section of the American Society of Mechanical Engineers at the Detroit Engineering Society's headquarters in Detroit. Mr. William J. Kelley, consulting engineer for the National Electric Light Association and American member of the Saint Lawrence Deep Waterways Association, spoke on "**Lake Regulation and the Development of the Saint Lawrence River.**" There were present 25 members of the Border Cities Branch.

May 27.—The Honourable Charles McCrae, minister of mines for the province of Ontario, spoke on "**Mining Development in Northern Ontario.**" Present, 22 members and 13 guests.

Oct. 8.—M. E. Brian, A.M.E.I.C., city engineer of Windsor, spoke on "**The Functioning of the City Board of Public Works.**" Present, 13 members.

Nov. 12.—Mr. R. D. Malm, of the Lincoln Electric Company of Cleveland, Ohio, spoke on "**Structural Steel Welding.**" Present, 21 members at dinner, and a number arrived later. In addition about 39 non-members, who were interested in the subject, came in to hear the address.

Dec. 10.—No speaker on this evening; the time being devoted to the election of officers for the ensuing year.

The Papers and Entertainment Committee, and W. B. Pennock, Jr.E.I.C., and E. G. Ryley, A.M.E.I.C., merit the thanks of the branch for their efforts during the year. They work under difficulties here, owing to the small number of speakers available and the reluctance of the branch members to prepare and present papers.

On February 20th the branch was honoured by having Major George A. Walkem, M.E.I.C., president of The Institute, as its guest at an impromptu luncheon in the Prince Edward hotel. Major Walkem urged upon those present the necessity of the branch interesting itself in public affairs and urged a connection with the Chamber of Commerce. Following this suggestion, the Chamber of Commerce has appointed an Engineering Committee with A. J. M. Bowman, A.M.E.I.C., as chairman.

Two important matters have been referred to this committee for consideration and report, viz.: the removal of railroad tracks and yards from the river front with location of a union station, and consideration of traffic problems within the Border Cities. The committee is now giving consideration to these problems.

Financial Statement

Receipts

Balance in bank, January 1, 1926	$ 63.97	
Interest	.25	
Headquarters rebates	209.14	
Meals at meetings	171.25	
	———	$444.61

Expenditures

Meals at meetings	$218.50	
Printing notices	31.71	
Entertainment	58.03	
Camera	2.50	
Cash in bank	133.87	
	———	$444.61

Respectfully submitted,

A. J. M. Bowman, A.M.E.I.C., *Chairman.*
Will H. Baltzell, M.E.I.C., *Secretary-Treasurer.*

Calgary Branch

The President and Council,—

On behalf of the Executive Committee we beg to submit the following report on the activities of the Calgary Branch for the year ending December 31st, 1926:—

The slate of officers elected on March 15th, 1925, held office until March 13th, 1926. The following is a list of the officers elected on March 13th, 1926, for the branch year 1926-1927:—

Chairman	J. H. Ross, A.M.E.I.C.
Vice-Chairman	F. K. Beach, A.M.E.I.C.
Secretary-Treasurer	H. R. Carscallen, A.M.E.I.C.
Committee	G. P. F. Boese, A.M.E.I.C., past sec.-treas.
	A. L. Ford, M.E.I.C., past chairman
	J. Haddin, M.E.I.C.
	R. Mackay, A.M.E.I.C.
	W. St. J. Miller, A.M.E.I.C.
Ex-officio	A. S. Dawson, M.E.I.C.
	R. S. Trowsdale, A.M.E.I.C.
Auditors	O. H. Hoover, A.M.E.I.C.
	D. T. Townsend, A.M.E.I.C.
Branch News Editor	W. St. J. Miller, A.M.E.I.C.

Membership

The membership of the branch is as follows:—

	Resident	Non-Resident	Total as at Dec. 31, '26	Total at end of previous year
Members	20	5	25	25
Associate Members	45	21	66	74
Juniors	4	2	6	3
Students	2	1	3	4
Affiliates	..	..	..	1
Branch Affiliates	16	..	16	15
	87	29	116	122

Membership has fallen off slightly, due entirely to removal of members from the branch district.

Meetings

Ten executive meetings were held during the year in taking care of the business of the branch.

General meetings, dinners, luncheons, and special affairs were as follows:—

Jan. 7.—Annual dinner with entertainment provided by the Strathmore members, headed by G. H. Patrick, A.M.E.I.C.

Jan. 25.—"**Military Light Railway,**" by Major F. K. Beach, A.M.E.I.C., Dominion Water Power and Reclamation Service.

Feb. 18.—"**Underground Mapping of Oil, Gas, and Water Horizons Encountered in Drilling Explorations—Principally in Connection with Turner Valley Oil Field Development,**" by S. J. Davies, A.M.E.I.C., then petroleum engineer, Department of the Interior, now in consulting practice, Calgary). This was made an open meeting owing to the subject being of very great general interest, and resulted in the largest attendance (about 250) of any meeting in the history of the branch.

Mar. 1.—Luncheon in honour of the new president, Major Geo. A. Walkem, M.E.I.C. Address by Major Walkem.

Mar. 2.—"**Beet Sugar Manufacture,**" by C. R. Wing, superintendent of the Canadian Sugar Refineries, Raymond, Alberta. This lecture was followed by a short talk on "**Growing Beets Under Irrigation,**" by W. H. Snelson, irrigataion specialist, Dominion Water Power and Reclamation Service.

Mar. 13.—Annual meeting.

June 19.—Inspection of the plant of the Alberta Wood Preserving Company, Calgary.
June 24.—Dinner in honour of R. J. Durley, M.E.I.C., general secretary. Address by Mr. Durley.
July 24.—Automobile trip to Turney Valley oil field, including inspection of Royalite Oil Company gas scrubbing plant under personal direction of the superintendent, S. G. Coultis, M.E.I.C.
Nov. 1.—"**Some Problems of Water Power Development and Operation,**" by F. J. Robertson, A.M.E.I.C., general superintendent of the Calgary Power Company.
Nov. 15.—"**The Gas Scrubbing Plant in Turner Valley,**" by S. G. Coultis, M.E.I.C., superintendent of this plant of the Royalite Oil Company.
Dec. 6.—"Ladies' Night." Mr. James W. Davidson gave an illustrated lecture on "**The Head Hunters of Formosa.**" Supper was served after the lecture.

The average attendance at the above meetings was fifty-seven.

Cape Breton Branch

The President and Council,—

The Executive Committee of the Cape Breton Branch submits the following report of the branch activities for the year 1926:—

OFFICERS

The annual meeting was held last year at a dinner in the Oddfellows' Hall, Sydney, on December 9th. The following officers were elected:—

Chairman ....W. C. Risley, M.E.I.C.
Committeemen ....J. J. McDougall, M.E.I.C.
J. R. Morrison, A.M.E.I.C.

Those remaining on the executive from the year before were:—

S. C. Mifflen, A.M.E.I.C.
W. E. Clarke, M.E.I.C.
W. S. Wilson, A.M.E.I.C.

At the first meeting of the new executive, held on January 4th, W. S. Wilson, A.M.E.I.C., was appointed vice-chairman.

MEMBERSHIP

The number of resident branch members last year was thirty-four; it is now thirty-six, including one Affiliate and three Branch Affiliates.

MEETINGS

In February permission was granted by Council to hold a Maritime Professional Meeting in Cape Breton. This meeting was held on August 17th, 18th and 19th, and was very successful. About fifty out-of-town guests attended. Two technical papers were presented at this meeting: "**The Characteristics and Utilization of Nova Scotia Coals,**" by W. S. Wilson, A.M.E.I.C., and M. W. Booth, M.E.I.C., and "**The Humber Development of the Newfoundland Power and Paper Company,**" by H. C. Brown, A.M.E.I.C.

In addition to the above the following meetings were held during the year:—

Dec. 9.—Annual meeting, at which H. J. Kelly, general manager of steel plants, British Empire Steel Corporation, was the speaker.
Feb. 9.—"**Bills of Exchange,**" by His Honour, Judge Walter Crowe.
Apr. 13.—"**A Visit to the Coal Mines of Great Britain,**" by A. L. Hay, M.E.I.C., assistant mining engineer, Dominion Coal Company, Limited.
Sept. 2-7.—Visit to the Humber Valley, Newfoundland.
Nov. 18.—"**The Rouyn Gold District,**" by H. V. Haight, M.E.I.C., chief engineer, Canadian Ingersoll Rand, Limited, Sherbrooke.
Nov. 23.—"**Mechanical Aids at the Coal Face, Part I,**" by A. F. Cagney, director of Peacock Bros., Montreal.

Edmonton Branch

The President and Council,—

We beg to submit below the annual report of the Edmonton Branch for the year 1926.

Lectures have been given or papers read at the general meetings as follows:—

Jan. 20.—Mr. W. Dixon Craig spoke on the subject of "The Law and the Engineer."
Feb. 23.—Mr. J. Bathe Weig gave an address on the subject of "Straw Paper Making."

MEMBERSHIP

The branch membership in comparison with the same date in 1925 is as follows:—

	1925 Branch Resident	1925 Branch Non-Res.	1926 Branch Resident	1926 Branch Non-Res.
Members	15	2	16	2
Associate Members	46	8	30	5
Juniors	5	1	2	2
Students	10	0	2	1
Affiliates	2	0	2	0
Total	78	11	52	10

The branch regrets the loss through death of Lieut.-Col. Bryce Johnston Saunders, M.E.I.C., who was a distinguished member and one of Edmonton's best known and popular citizens.

During August a party composed of members of the American Society of Civil Engineers visited Edmonton and were entertained by branch members.

R. J. Durley's visit to Edmonton was very much appreciated by the branch.

Halifax Branch

The President and Council,—

During the year 1926 the Halifax Branch held eight meetings, most of which have taken the form of supper-meetings.

The branch was fortunate in obtaining speakers who presented very attractive subjects which, in one way or another, were of interest to almost every member. The attendance was very good and it was particularly gratifying because, on account of the prevailing industrial conditions, many members were out of town.

It was decided that the vice-chairman each year would automatically become chairman of the Papers Committee, and that the member elected in December would arrange for a programme of papers to cover the following fall and winter seasons. This means that the incoming executive takes office in the middle of a prearranged programme and so there is no confusion. The new vice-chairmen then has all the winter and summer in which to arrange the programme for the next season. This scheme has proved to be very satisfactory, and we have been able to publish our programme in advance.

Many members were fortunately able to attend the Maritime Professional Meeting in Sydney, which was of a very high order.

The general secretary, R. J. Durley, M.E.I.C., paid a visit to the branch in September, and a special luncheon was held at the Waegwoltic Club in his honour.

Three prizes were offered this year for a competition for engineering students at the Nova Scotia Technical College or affiliated universities for a paper describing some engineering work with which they had been connected during the previous summer.

A feature of the annual meeting and banquet was an address on "Industrial Relations," by Prof. A. Stanley Walker of King's University, which gave the members a new and broader outlook of the present labour unions. Valuable prizes were offered for "stunts" by the members, which certainly livened the meeting and provided some novel entertainment.

Taken generally, 1926 has been a very successful year.

MEETINGS

The meetings during the year were as follows:—

Jan. 28.—Regular monthly meeting in the Green Lantern, W. A. Winfield, M.E.I.C., chairman. H. F. Pickings, A.M.E.I.C., and C. St.J. Wilson gave an illustrated description of **"The Power and Pulp Developments Centred at Corner Brook, Newfoundland."**

Feb. 17.—Regular monthly meeting in the Green Lantern. To accommodate the larger attendance supper was served in the large banquet hall. H. W. L. Doane, M.E.I.C., chairman. F. A. Gaylord, manager, A. P. W. Pulp and Paper Company, Limited, gave the illustrated lecture on **"The Manufacture of Pulp and Paper,"** with particular reference to the mills at Sheet Harbour, N.S., and the fire protection of the company's timber areas. Present 53.

Mar. 3.—Regular monthly meeting in the Green Lantern. H. W. L. Doane, M.E.I.C., chairman. At the request of the chairman, J. W. MacDonald, Jr.E.I.C., of the engineering staff of the Imperial Oil Company, gave an account of the investigation into the bursting of the steel tank used for the storage of water at Imperoyal. H. S. Van Scoyoc, M.E.I.C., consulting engineer, Canada Cement Company, spoke on **"The Construction of the Toronto-Hamilton Highway,"** and on **"The Manufacture of Cement."** Each subject was illustrated by motion pictures. Present 24.

Apr. 1.—Regular monthly meeting held in the Green Lantern. H. W. L. Doane, M.E.I.C., chairman. Branch decided to offer prizes for a student essay competition. T. J. Locke, district engineer, Department of Public Works, read a paper on **"The Harbours of Nova Scotia and What They Mean to Us."** Present 29.

Sept. 15.—Special luncheon-meeting held at the Waegwoltic Club in honour of the visiting general secretary, R. J. Durley, M.E.I.C. H. W. L. Doane, M.E.I.C., chairman. Present 21.

Oct. 5.—Regular monthly meeting held in the Green Lantern. H. W. L. Doane, M.E.I.C., chairman. F. R. Faulkner, M.E.I.C., C. H. Wright, M.E.I.C., and W. F. McKnight, A.M.E.I.C., were appointed the 1927 Nominating Committee. A. G. Dalzell, M.E.I.C., consulting engineer, of Montreal, spoke on **"The Engineer and the Immigration Policy."** Present 22.

Nov. 11.—Regular monthly meeting held in the Green Lantern. H. W. L. Doane, M.E.I.C., chairman. J. H. Winfield, M.E.I.C., managing director, Maritime Telephone and Telegraph Company, gave an address on **"Executive Training for Engineers."** Present 27.

Dec. 16.—Annual meeting and dinner in the St. Julien room of the Halifax hotel. Chairman, H. W. L. Doane, M.E.I.C. The speaker of the evening was Prof. A. Stanley Walker, who addressed the members on **"Industrial Relations."** The presentation of prizes in Students' Essay Competition and the election of officers for 1927 took place at this meeting. Present 78.

Hamilton Branch

The President and Council,—

The Executive Meeting of the Hamilton Branch submits the following report for the year 1926.

The branch year dates from June 1st, so that there are two executive committees during 1926 as follows:

	January to May	June to December
Chairman	C. J. Nicholson, A.M.E.I.C.	L. W. Gill, M.E.I.C.
Vice-Chair.	F. P. Adams, A.M.E.I.C.	W. L. McFaul, M.E.I.C.
Sec.-Treas.	H. B. Stuart, A.M.E.I.C.	W. F. McLaren, M.E.I.C.
Com'te.	W. L. McFaul, M.E.I.C., (1 yr.)	H. A. Lumsden, M.E.I.C., (1 yr.)
	L. W. Gill, M.E.I.C., (1 yr.)	G. R. Marston, A.M.E.I.C., 1 yr.)
	H. A. Lumsden, M.E.I.C., (2 yrs.)	F. P. Adams, A.M.E.I.C., (2 yrs.)
	G. R. Marston, A.M.E.I.C.,	A. H. Munson, A.M.E.I.C., (2 yrs.)
Br. News Editor (2 yrs.)		J. R. Dunbar, Jr.E.I.C.
Ex-officio	W. F. McLaren, M.E.I.C.	W. F. McLaren, M.E.I.C.
Emeriti	J. J. MacKay, M.E.I.C.	C. J. Nicholson, A.M.E.I.C.
		H. B. Stuart, A.M.E.I.C.

MEETINGS

The following meetings were held:

Feb. 19.—Visit of President George A. Walkem, M.E.I.C. Address on Institute affairs and general discussion.

Apr. 23.—**"A High Power Laboratory,"** by W. R. Woodward, of Pittsburgh. This was a joint meeting with the Toronto section A.I.E.E. held in the Westinghouse auditorium. After the meeting refreshments were served by the Canadian Westinghouse Co. Attendance, 200.

Oct. 20.—Addresses by J. J. MacKay, M.E.I.C., on **"The Work of the Hamilton Harbour Commission,"** and W. L. McFaul, M.E.I.C., on **"The Hamilton Water Works."** The appointment of the new executive committee was ratified at this meeting. Attendance, 24.

Nov. 25.—"**The Geology of the Hamilton District,**" by Prof. A. P. Coleman, M.A., Ph.D., F.R.S., of the University of Toronto. Attendance, 180.

Dec. 14.—"**The Manufacture of Carbon Products,**" by J. C. Webster, National Carbon Co., Toronto, with moving pictures illustrating the various operations at the main plant at Cleveland. Refreshments were served. Attendance, 40.

Kingston Branch

The President and Council,—

On behalf of the Executive Committee of the Kingston Branch, we beg to submit the following report on the activities of our branch from January 1st, 1926, to December 31st, 1926.

Due to the fact that the science staff and students at Queen's University compose a large part of the membership of the branch, it is found feasible to hold meetings only during the first and last three or four months in the year. No meetings are attempted in the summer and autumn. Usually the records of the branch show some ten or twelve papers as having been delivered in the course of the year, but during 1926 the number was reduced to four. Troublesome conflicts accounted for a lesser number than usual in the spring, and the Queen's Endowment campaign, which took intensive form in Kingston during November and December, precluded the possibility of any fall meetings until late in December. The attendance noted was, however, considerably greater than that of other years, averaging almost twice that of 1925.

Meetings

The four meetings held were as follows:—

Jan. 21.—"**Mining Operations in Northwestern Quebec,**" and "**The Objects and Aims of the Professional Engineers' Association of Ontario,**" by Prof. S. N. Graham, of Queen's University.

Feb. 8.—"**The Diversion of Water at Chicago and its Effect on the Levels of the Lower Lakes and Rivers,**" by Mr. Francis King, K.C., of Kingston.

Mar. 17.—"**The Chicago Drainage Canal,**" by J. L. Busfield, M.E.I.C.

Dec. 10.—Annual business meeting and address on "**The Mercury Mines of Spain,**" by Dr. E. L. Bruce, of Queen's University.

Membership and Officers

The approximate membership of the branch is as follows:—

Honorary Members	1
Members	12
Associate Members	17
Junior Members	3
Student Members	8
Affiliate	1
Total	42

Executive Committee

The executive officers holding office during the parts of the two years covered by this report are as follows:—

1925-1926		1926-1927
R. J. McClelland, A.M.E.I.C.	Chairman	Prof. L. T. Rutledge, M.E.I.C.
Prof. L. T. Rutledge, M.E.I.C.	Vice-Chair	Prof. D. S. Ellis, A.M.E.I.C.
G. J. Smith, A.M.E.I.C.	Sec.-Treas.	G. J. Smith, A.M.E.I.C.
Prof. D. S. Ellis, A.M.E.I.C.	Executive	J. M. Campbell, M.E.I.C.
Prof. D. M. Jemmett, A.M.E.I.C.		Dr. L. F. Goodwin, M.E.I.C.
J. M. Campbell, M.E.I.C.		Prof. A. Jackson, A.M.E.I.C.

Financial Statement

The following is the financial statement for the year 1926:—

Receipts

Jan. 1	Balance brought forward	$ 81.57	
June 15	Rebates on fees	66.30	
June 15	Branch news	7.23	
June 31	Bank interest	.94	
Oct. 20	Rebates on fees	22.50	
Dec. 15	Rebates on fees	5.10	
Dec. 31	Accounts receivable	3.90	
			$187.54

Disbursements

Jan. 7	Bank exchange	$ .15

Dec. 31	Accounts payable	0.00	
Dec. 31	Balance carried forward	101.79	
			$187.54

Respectfully submitted,

L. T. Rutledge, M.E.I.C., *Chairman.*
Gordon J. Smith, A.M.E.I.C., *Secretary-Treasurer.*

Lakehead Branch

The President and Council,—

On behalf of the Executive Committee we beg to submit the following annual report of the Lakehead Branch:

Membership

On January 1st, 1926, there were 40 corporate members and 18 non-corporate members, and on December 31st, 1926, there were 36 corporate members and 8 non-corporate members, showing a loss during the year of 4 corporate and 10 non-corporate members. This loss is due to change of residence in most cases, the balance being struck off the roll for non-payment of dues.

Meetings

Meetings of the Lakehead Branch were held as follows:—

Apr. 28.—A dinner was held at the Shuniah Club, Port Arthur, at which J. Antonisen, M.E.I.C., gave a most interesting address on "**The Art of Living.**"

July 13.—A dinner was held at the Prince Arthur hotel, Port Arthur, in honour of the general secretary, R. J. Durley, M.E.I.C., who was paying his annual visit to the branch. Mr. Durley gave a most interesting address on Institute affairs, and on conditions as seen by him on his trip through the west. We also had an address from Mr. Francis Kiefer, of Port Arthur, on "**Forestry.**" Besides Mr. Durley, our guests at the dinner were Hon. Dr. Forbes-Godfrey, Dr. Bell of Toronto, Hon. F. H. Keefer, Col. Milton Francis, Mayor of Port Arthur, Dr. Laurie, and Messrs. Wynne-Roberts and Falkner, of the Toronto Branch.

Oct. 20.—A dinner was tendered Major Geo. A. Walkem, M.E.I.C., president of the Institute, at the Shuniah Club. Major Walkem addressed the members on Institute matters, and on his visit to the annual meeting of the American Society of Civil Engineers at Philadelphia; the power and pulp plants on the Saguenay; the plant of the Aluminum Company of Canada at Arvida. The president's visit, like that of the general secretary's, is always looked forward to by the Lakehead members. Major Walkem, during his stay with us, very kindly addressed the pupils of the collegiates in both cities on engineering and engineering courses.

The result of the ballot for officers of the branch for the year was announced at the dinner, resulting as follows:—

Chairman ....C. B. Symes, A.M.E.I.C.
Vice-Chairman ....D. G. Calvert, A.M.E.I.C.
Secretary-Treasurer ....Geo. P. Brophy, A.M.E.I.C.
Executive Committee......D. C. Chisholm, M.E.I.C.
J. C. Meader, A.M.E.I.C.
W. H. Souba, M.E.I.C.
M. W. Turner, A.M.E.I.C.

Owing to Mr. Turner's transfer to Winnipeg, G. R. Duncan, A.M.E.I.C., who was next on the list, was elected to take Mr. Turner's place.

At an Executive meeting the following branch committees were appointed:—

Nominating Committee—H. G. O'Leary, A.M.E.I.C., R. B. Chandler, M.E.I.C.

By-laws Committee—D. G. Calvert, A.M.E.I.C., J. C. Meader, A.M.E.I.C.

Membership Committee—G. R. Duncan, A.M.E.I.C., (Chairman), H. M. Lewis, A.M.E.I.C., D. C. Chisholm, M.E.I.C.

Programme Committee, Fort William—H. G. O'Leary, A.M.E.I.C., (Vice-Chairman), R. J. Askin, A.M.E.I.C., W. J. Hoover, Port Arthur, R. B. Chandler, M.E.I.C., (Vice-Chairman), W. T. Moodie, M.E.I.C., F. C. Graham, A.M.E.I.C.

The following members were nominated to represent the Lakehead Branch on the Council of the Institute:—

M. W. Jennings, A.M.E.I.C., J. Antonisen, M.E.I.C.

Lethbridge Branch

The President and Council,—

On behalf of the Executive Committee of the Lethbridge Branch we beg to submit the following report for the year ending December 31st, 1926:—

The officers elected March 7th, 1925, held office until the end of the branch year, March 6th, 1926. On this date the following officers were elected for the ensuing branch year:—

Chairman ....J. T. Watson, A.M.E.I.C.
Vice-Chairman ....G. N. Houston, M.E.I.C.
Secretary-Treasurer ....N. H. Bradley, A.M.E.I.C.
Committee ....J. B. deHart, M.E.I.C.
Chas. Raley, A.M.E.I.C.
A. Thomson, A.M.E.I.C.

MEETINGS

The Executive held five meetings during the year, and in addition there were nine regular, two special, and one joint meetings held.

The special meetings were the occasion of the visit of R. J. Durley, M.E.I.C., general secretary, on July 7th, and the visit of The Institute's president, Major Geo. A. Walkem, M.E.I.C. On December 18th a joint meeting with the Professional Engineers of Alberta was addressed by the Association president, B. L. Thorne, M.E.I.C.

Jan. 9.—"**Technical Education in the Province of Alberta,**" by A. G. Carpenter, director of technical education for Alberta.

Jan. 23.—"**Gothic Architecture,**" by H. M. Whiddington, Lethbridge.

Feb. 6.—"**The Art of Communication,**" by A. M. Mitchell, auditor, Alberta Government Telephones.

Feb. 20.—"**The Research Council of Alberta,**" by Edgar Stansfield, M.E.I.C., research engineer, Edmonton.

Mar. 6.—Branch annual meeting.

July 7.—"**Institute Affairs.**" Special meeting addressed by R. J. Durley, M.E.I.C., general secretary of The Institute.

Sept. 25.—"**Vancouver Harbour Developments,**" by Major Geo. A. Walkem, M.E.I.C., president of The Institute.

Oct. 23.—"**Brick and Clay Products,**" by E. H. Sellhorn, manager, Redcliff Brick and Coal Company, Medicine Hat.

Nov. 6.—"**The Modern Steam Turbine,**" by J. T. Watson, A.M.E.I.C., Lethbridge power plant superintendent.
Nov. 20.—"**Hydro Power,**" by A. B. Sanborn, manager, East Kootenay Power Company, Fernie, B.C.
Dec. 4.—"**Geological Problems of the Spray Lake Water Power Project,**" by Dr. John A. Allan, professor of geology, Alberta University, Edmonton.
Dec. 18.—Joint meeting with Professional Engineers of Alberta, addressed by B. L. Thorne, M.E.I.C., on "**The Sullivan Mine and Trail Smelter.**"

Respectfully submitted,

J. T. Watson, A.M.E.I.C., *Chairman.*
N. H. Bradley, A.M.E.I.C., *Secretary-Treasurer.*

London Branch

The President and Council,—

On behalf of the executive committee of the London Branch we beg to submit the following report for the year ending December 31st, 1926:

During the year six executive meetings and six regular meetings were held.

The annual dinner meeting on January 20th was addressed by Prof. Kingston of the University of Western Ontario, his subject being "**Wonders of the Skies.**" The address was illustrated with lantern slides. Vocal music by two soloists was much appreciated during the evening.

On February 18th the branch was honoured with the presence of President Geo. A. Walkem, M.E.I.C., who spoke on some interesting phases of engineering in British Columbia.

A dinner meeting was held on April 22nd to which the members of the branch were pleased to welcome General Secretary R. J. Durley, M.E.I.C., who gave an instructive outline of administration at headquarters. Mr. W. E. Piper of the Dorr Company of New York spoke on "**The Paracycle Pump and Compressor.**"

On May 15th a meeting was held at Woodstock, preceded by a trip of inspection which included the plant of the Independent Concrete Pipe Company, the Woodstock activated sludge sewage disposal plant, the waterworks pumping plant and the springs which are the source of the city water supply. The speaker of the evening was Wm. Storrie, M.E.I.C., and his subject, "**Engineering and Public Health.**"

On October 2nd the branch held its second motor trip to the Niagara Peninsula. Members of the Welland Ship Canal staff acted as guides over the entire length of the new canal, and Major A. W. L. Butler, A.M.E.I.C., a member of the staff, gave a very interesting illustrated address on the canal, at the evening meeting. The water filtration plant of St. Catharines, was also visited.

The last regular meeting of the year was held at the London Technical High School on December 17th. Principal H. B. Beal addressed the meeting on "**Vocational Education for Industrial Purposes.**" The address was followed by an inspection of the school.

Membership

The membership of the London Branch is as follows:—

	1925	1926
Members	13	12
Associate Members	32	30
Juniors	5	6
Students	35	10
Total	85	58

The decrease in membership is due to the removal by headquarters of the names of a number of Student members.

Financial Statement

Receipts

Balance in bank Jan. 1, 1926	$ 91.99	
Donations	8.00	
Rebates from headquarters (dues and branch news)	131.73	
		$231.72
Rebates due from headquarters	.60	
		$232.32

Expenditures

Notices, postage	$ 9.49	
Cigars for dinners	6.25	
Telegrams and long distance calls	.64	
Dinner, April 22nd	13.00	
Entertaining dinner guests	4.00	
Janitor services	5.00	
Flowers	12.00	
Discount on cheque	.15	
Balance in bank, Dec. 31st, 1926	181.19	
		$231.72
Rebates due from headquarters	.60	
		$232.32

We have examined the above statement prepared by the secretary-treasurer and find the same to be a correct and true account of the financial standing of the London Branch.

Respectfully submitted,

W. M. Veitch, A.M.E.I.C., } *Auditors.*
R. W. Garrett, A.M.E.I.C., }

Respectfully submitted,

W. P. Near, M.E.I.C., *Chairman.*
Frank C. Ball, A.M.E.I.C., *Secretary-Treasurer.*

Moncton Branch

The President and Council,—

On behalf of the Executive Committee, we beg to submit the seventh annual report of Moncton Branch.

The Executive Committee held six meetings during the year. There were nine meetings of the branch held, four of which were supper-meetings and two were open to the public. One meeting was held at Sackville for the benefit of the engineering students of Mount Allison University. A special meeting was held during the summer, at which we had the pleasure of having with us the general secretary, R. J. Durley, M.E.I.C., who gave a very interesting address on Institute affairs.

Membership

The membership at present is as follows:—

	Resident	Non-Resident
Members	7	2
Associate Members	24	7
Juniors	5	2
Students	6	1
Affiliates	1	..
Total	43	12

During the year the branch suffered the loss of two of its most prominent members in the death of J. S. O'Dwyer, M.E.I.C., right-of-way engineer, Canadian National Railways, Moncton, and K. S. Pickard, M.E.I.C., manager of the Sackville Light and Power Company, Sackville, N.B.

Executive Committee

The annual meeting of the branch was held on June 6th and the following officers were elected for 1926-27:—

Chairman	A. S. Gunn, A.M.E.I.C.
Vice-Chairman	G. C. Torrens, A.M.E.I.C.
Secretary-Treasurer	V. C. Blackett, A.M.E.I.C.
Executive Committee	Prof. F. L. West, A.M.E.I.C.
	James Pullar, A.M.E.I.C.
	G. E. Smith, A.M.E.I.C.

The members of the Executive Committee for 1926-27, in addition to the above, are as follows:—

A. F. Stewart, M.E.I.C.
J. D. McBeath, M.E.I.C.
J. R. Freeman, A.M.E.I.C.
F. O. Condon, M.E.I.C. (ex-officio)
C. S. G. Rogers, A.M.E.I.C. "
M. J. Murphy, A.M.E.I.C. "

Financial Statement

The financial statement for the year ending December 31st, 1926, is as follows:—

Revenue

Balance in bank, January 1st, 1926	$103.31	
Cash on hand, " " "	2.16	
Rebates on dues and branch news	122.33	
Tickets sold for supper-meetings	91.00	
Bank interest	2.28	
Refund from Halifax Branch on our contribution towards Maritime Professional Meeting	12.50	
Miscellaneous	.30	
Rebates due from headquarters	5.40	
		$339.28

Expenditures

Expenses of meetings	$134.96	
Postage	4.30	
Printing	38.63	
Telegrams and telephones	4.43	
Contribution towards Maritime Professional Meeting	15.00	
Miscellaneous	69.85	
Balance in bank	59.38	
Cash on hand	7.33	
Rebates due from headquarters	5.40	
		$339.28

Respectfully submitted,

V. C. Blackett, A.M.E.I.C., *Secretary-Treasurer.*
A. S. Gunn, A.M.E.I.C., *Chairman.*

Montreal Branch

The President and Council,—

On behalf of the Executive Committee we beg to make the following report covering the activities of the Montreal Branch for the year 1926.

The Executive Committee

The personnel of the Executive Committee during the past year is given in the following table:—

Name	*Office, etc.*
C. J. Desbaillets, M.E.I.C.	Chairman, 1926.
C. V. Christie, M.E.I.C.	Vice-Chairman, 1926.
A. Duperron, A.M.E.I.C.	Elected, 1926-1927.
A. R. Ketterson, M.E.I.C.	Elected, 1926-1927.
J. A. McCrory, M.E.I.C.	Elected, 1926-1927.
P. L. Pratley, M.E.I.C.	Elected, 1925-1926.
Jas. Robertson, A.M.E.I.C.	Elected, 1925-1926.
F. C. Laberge, M.E.I.C.	Elected, 1925-1926.
J. L. Busfield, M.E.I.C.	*Ex-officio*, Past Chairman & Councillor.
C. K. McLeod, A.M.E.I.C.	Secretary-Treasurer, 1926.
Arthur Surveyer, M.E.I.C.	*Ex-officio*, Past President, E.I.C.
J. M. R. Fairbairn, M.E.I.C.	*Ex-officio*, Past President, E.I.C.
R. A. Ross, M.E.I.C.	*Ex-officio*, Past President, E.I.C.
K. B. Thornton, M.E.I.C.	*Ex-officio*, Vice-President, E.I.C.
F. P. Shearwood, M.E.I.C.	*Ex-officio*.
O. O. Lefebvre, M.E.I.C.	*Ex-officio*, Councillor, E.I.C.
G. R. MacLeod, M.E.I.C.	*Ex-officio*, Councillor, E.I.C.
J. H. Hunter, M.E.I.C.	*Ex-officio*, Councillor, E.I.C.
J. T. Farmer, M.E.I.C.	*Ex-officio*, Councillor, E.I.C.
C. M. McKergow, M.E.I.C.	*Ex-officio*, Councillor, E.I.C.

There were nine meetings of the Executive Committee during the past year, all of which were well attended. In addition to the annual meeting, held December 16th, there were also three special general meetings of the branch during the year.

Papers and Meetings Committee

The branch by-laws provide that this committee consist of a chairman and vice-chairman, and also of the chairman and vice-chairman of the various sections of the branch, who were appointed as follows:—

Chairman	R. E. MacAfee, A.M.E.I.C.
Vice-Chairman	A. Duperron, A.M.E.I.C.
Ex-officio	C. K. McLeod, A.M.E.I.C.

Civil Section	A. Plamondon, A.M.E.I.C.	Chairman
	J. S. Hall, A.M.E.I.C.	Vice-Chairman
Electrical Section	G. A. Wallace, A.M.E.I.C.	Chairman
	L. A. Kenyon, A.M.E.I.C.	Vice-Chairman
Mechanical Section	J. A. McCammon, A.M.E.I.C.	Chairman
	F. S. B. Heward, A.M.E.I.C.	Vice-Chairman
Municipal Section	J. G. Caron, A.M.E.I.C.	Chairman
	J. F. Brett, A.M.E.I.C.	Vice-Chairman
Railway Section	D. Hillman, M.E.I.C.	Chairman
	J. A. Ellis, A.M.E.I.C.	Vice-Chairman
Student Section	L. A. Duchastel, S.E.I.C.	Chairman
	H. L. Johnston, Jr.E.I.C.	Vice-Chairman

This committee held five meetings during the year, at which the average attendance was nine. We feel that the programme of twenty-eight meetings arranged by this committee and the many outstanding speakers obtained, is sufficient proof of the work which they have done.

Reception Committee

A Reception Committee, under the chairmanship of H. G. Thompson, Jr.E.I.C., together with S. A. Neilson, A.M.E.I.C., E. T. Harbert, S.E.I.C., H. M. Morris, S.E.I.C., H. S. Petford, A.M.E.I.C., E. Roy, A.M.E.I.C., was appointed.

This committee has been on hand at every meeting of the branch and has kept the various records of attendance, which are reported further on in this report.

Publicity Committee

At the commencement of the year S. A. Neilson, A.M.E.I.C., and E. Prevost, Jr.E.I.C., constituted the Publicity Committee and did very valuable work. However, during the early part of the session Mr. Prevost resigned, as he was leaving town on business, and later in the year Mr. Neilson had to abandon his duties due to pressure of business in other directions. H. W. B. Swabey, M.E.I.C., was appointed to replace Mr. Neilson and E. Norman, Jr.E.I.C., to replace Mr. Prevost. The activities of this committee resulted in very satisfactory attention on the part of both the English and French newspapers. Their activities were also responsible for revenue obtained for Branch News to the amount of $66.34.

Special Committees

From time to time special committees have been appointed for carrying out of particular duties, amongst those might be mentioned the visit to Isle Maligne and the International Electrotechnical Commission. The latter item being reported more fully later on.

Nominating Committee

Following out the requirements of the By-laws, a Nominating Committee for the purpose of making nominations for the 1926 Executive Committee were appointed. Two members, namely, C. J. Desbaillets, M.E.I.C., and C. K. McLeod, A.M.E.I.C., were appointed at a regular meeting of the Executive Committee on October 25th, and H. W. B. Swabey, M.E.I.C., J. G. Caron, A.M.E.I.C., and W. C. Adams, M.E.I.C., were elected at a special meeting of the branch on October 28th.

Weekly Meetings

The meetings for the first half of the year were arranged by the Papers and Meetings Committee under the chairmanship of J. L. Busfield, M.E.I.C., and the meetings of the latter half, i.e., since October, have been arranged by the committee under the chairmanship of the R. E. MacAfee, A.M.E.I.C.

A complete list of meetings as held through the year is given in the following table, together with the total attendance:

Meetings—1926

Jan. 7.—"**Features of Design and Construction of Isle Maligne Station,**" by W. S. Lee, M.E.I.C. Attendance 237.

Jan. 14.—"**Effect of Personnel on Industry,**" by R. A. C. Henry, M.E.I.C. Attendance 73.

Jan. 21.—"**Pulp and Paper,**" by H. S. Taylor, M.E.I.C. Attendance 130.

Jan. 28.—"**Protective Features of Emergency Equipment of the "Montreal Aqueduct,**" by C. J. Desbaillets, M.E.I.C. Attendance 64.

Feb. 4.—"**Electrolysis,**" by P. LeBel, S.E.I.C. Attendance 120.

Feb. 11.—"**Pulverized Coal,**" by H. G. Barnhurst. Attendance 100.

Feb. 18.—"**Improvements in the General Plan of the City of Montreal,**" by Geo. R. MacLeod, M.E.I.C. Attendance 97.

Feb. 25.—"**The Development of the Outside Plant of the Bell Telephone Company,**" by W. H. Winter. Attendance 51.

Mar. 4.—"**Chicago Drainage Canal,**" by J. L. Busfield, M.E.I.C. Attendance 138.

Mar. 11.—"**Vancouver Narrows Bridge,**" by E. H. James, M.E.I.C. Attendance 70.

Mar. 18.—"**History of Locomotion, its Development and Future Possibilities,**" by W. E. Newman. Attendance 85.

Mar. 25.—"**The South Shore Bridge,**" by P. L. Pratley, M.E.I.C. Attendance 166.

Apr. 1.—"**Modern Problems of Synchronous Converters,**" by E. B. Shand. Attendance 50.

Apr. 8.—"**Cost System for a Large Engineering Establishment,**" by J. S. Houston. Attendance 61.

Apr. 15.—"**Some Features of Hemmings Falls Power Development,**" by J. S. H. Wurtele, M.E.I.C. Attendance 97.

Apr. 22.—"**History of Science,**" by Dr. L. E. Pariseau. Attendance 150.

Apr. 29.—"**Belgian State Railway,**" by Dr. F. Van Bruysel. Attendance 42.

Oct. 7.—"**Building the Town of Arvida,**" by H. R. Wake, A.M.E.I.C. Attendance 130.

Oct. 14.—"**Engineering Features in Breaking the Allegheny Ice Gorge,**" by Dr. H. T. Barnes, M.E.I.C. Attendance 156.

Oct. 21.—"**Manufacture of Carbide,**" by R. A. Witherspoon. Attendance 77.

Oct. 28.—"**Bearing Metal Bronzes,**" by H. J. Roast and F. Newell, M.E.I.C. Attendance 83.

Nov. 4.—"**The American Railway Engineering Association and Its Work,**" by J. E. Armstrong, M.E.I.C. Attendance 69.

Nov. 11.—"**Manufacture of Paper, with Special Reference to the Kraft Process,**" by J. B. Phillips. Attendance 103.

Nov. 18.—"**Use of Duralumin in the Manufacture by the Canadian Government of an all Metal Artificial Limb, with Some Detailed Information as to the Properties of Duralumin,**" by N. F. Parkinson, A.M.E.I.C. Attendance 57.

Nov. 25.—"**Hydro-Electric Development of Bryson,**" by H. E. Pawson, M.E.I.C. Attendance 103.

Dec. 2.—"**Railway Supplies,**" by L. C. Thompson. Attendance 58.
Dec. 9.—"**Building Foundations in Relation to Street Levels,**" by G. R. MacLeod, M.E.I.C. Attendance 80.
Dec. 16.—Annual meeting of Montreal Branch. Attendance 46.

Summer Excursion

Over the weekend of June 25th to 27th, some fifty-eight members and friends of the Montreal Branch visited the large industrial developments in the lake St. John district at the head of the Saguenay river. A full report of this trip is given in the August issue of the Journal.

Visit of the International Electrotechnical Commission

The Montreal Branch had the fortune this year in being privileged to entertain the delegates of the International Electrotechnical Commission on the evening of Saturday, May 1st, and during Sunday, May 2nd.

Arriving by special train at the Bonaventure station, the delegates were met by Vice-President K. B. Thornton, M.E.I.C., and conveyed by motor bus to the Windsor hotel, where rooms had been placed at the disposal of the delegates.

On Saturday evening the Commission was entertained at an informal dinner-dance in the Windsor. On Sunday morning a trip by motor bus through the city and environs was made, winding up at the Ritz-Carlton hotel, where a luncheon was given. At the luncheon Vice-President Thornton was the chairman, the address of welcome being given by Dr. Arthur Surveyer, M.E.I.C., past president of the Institute.

The delegates of this commission numbered some hundred and twenty and represented twenty-two different nationalities. Their appreciation of the entertainment may be summed up by the few words said by Signora Semenza, wife of the president, who remarked, "Since we left the European continent this is the first time we feel at home."

A special committee was formed to organize the entertainment for the International Electrotechnical Commission and was composed of K. B. Thornton, M.E.I.C., Chairman, Dr. H. T. Barnes, M.E.I.C., Frederick B. Brown, M.E.I.C., J. L. Busfield, M.E.I.C., J. B. Challies, M.E.I.C., C. V. Christie, M.E.I.C., C. J. Desbaillets, M.E.I.C., Fraser S. Keith, M.E.I.C., C. K. McLeod, A.M.E.I.C., and R. J. Durley, M.E.I.C.

The Montreal Branch was greatly assisted in its duties by the kind co-operation of the following: Bell Telephone Co. of Canada, Canadian National Railways, Montreal Light, Heat and Power Co., Montreal Tramways Company, Northern Electric Company, Shawinigan Water and Power Co., Southern Canada Power Company.

Annual and Professional Meeting

The Annual Meeting being held in Toronto on January 27th, 28th and 29th, the Executive Committee of the Montreal Branch decided to send J. L. Busfield, M.E.I.C., and C. K. McLeod, A.M.E.I.C., to Toronto to look after the interest of the branch.

Entertainment of Visitors

On the occasion of outstanding speakers visiting Montreal for the express purpose of addressing the branch, it has been the policy of the executive to entertain them at a small dinner prior to the meeting. Amongst others was W. S. Lee, M.E.I.C., of South Carolina, who addressed the branch on January 7th.

Another prominent visitor to Montreal was Sir Sefton Brancker, director of civil aviation of Great Britain. On March 19th the resident members of council and executive of the Montreal Branch entertained him at an informal luncheon at the University Club. Following the luncheon, Sir Sefton told those present of the progress that is being made in Britain in the field of civil aviation. He complimented Canada on the aerial survey work that was being done here, saying, in this particular line Canada leads the world.

Presentation of Branch Charter

Presentation to the Montreal Branch of its Charter from the parent organization was made on February 4th by Major Geo. A. Walkem, M.L.A., M.E.I.C., of Vancouver, and the president-elect of the Engineering Institute of Canada. The chairman of the branch accepted the Charter on behalf of its fellow members. Before proceeding to the formal presentation, Major Walkem delivered a short address directed particularly to the students present, upon the lives and contributions of the great men of science.

Membership

The membership of the Montreal Branch shows a slight falling off during the past year. This is no doubt due to pressure having been brought to bear on certain members who were in arrears, and we feel that the results will probably be of benefit to the branch in the long run. The analysis of the branch membership for the years 1925 and 1926 is as follows:

Statement of Membership, 1925-1926

		Dec. 31st, 1925	Dec. 31st, 1926	Increase or Decrease
Honorary Members	Resident	1	1	No change
Members	Resident	212	217	inc. 5
	Non-Resident	15	8	dec. 7
Associate Members	Resident	406	399	dec. 7
	Non-Resident	48	24	dec. 24
Juniors	Resident	65	76	inc. 11
	Non-Resident	12	8	dec. 4
Students	Resident	280	249	dec. 31
	Non-Resident	35	7	dec. 28
Affiliates	Institute	11	14	inc. 3
	Branch	20	19	dec. 1
Total		1,105	1,023	

During the past year we have with regret had to announce the loss sustained by the branch in the death of a number of its prominent members. These include:

Adams, Walter C.	Herdt, Dr. Louis A.
Barlow, John Rigney	Johnson, Phelps, LL.D.
Bertram, Maj.-Gen. Sir Alexander	Lefebvre, Henri Paul
	Loudon, Andrew C.
Ewing, James	Marchand, Art. J.
Forrest, Benj. J.	Ramsey, Col. C. W. P., C.M.G.

In the case of Major-Gen. Sir Alexander Bertram, Dr. Louis A. Herdt and Phelps Johnson, LL.D., the branch passed resolutions of regret which were forwarded to the families of the deceased.

Niagara Peninsula Branch

The President and Council,—

On behalf of the Executive Committee we beg to submit the annual report of the Niagara Peninsula Branch.

The activities of the branch were confined to one business meeting, six general meetings, four trips, and the annual dance. In addition the members of the branch were the guests of the American Waterworks Association, Canadian section, at their convention in St. Catharines in March.

The dinner-meetings were fairly well attended, when the size of the branch territory is considered, but a large proportion of the attendance is made up of non-members. The subjects were interesting and well handled by the different speakers. The average attendance was forty-seven.

The business meeting discussed the annual dance, proposed amendments to the by-laws, and branch affairs generally. The annual dance was, as usual, a social success and a financial burden. Although all trips were marred by bad weather, they were fairly well attended. The list of functions was as follows, all of which were reported at length in the Journal.

MEETINGS

Jan. 20.—Business meeting at St. Catharines. Attendance 17.
Feb. 3.—Trip over Queenston power plant, and meeting at Niagara Falls. "**Personal Experiences in Egypt,**" by D. A. Andrus, M.E.I.C. Attendance 80.
Mar. 3, 4 and 5.—Annual meeting of American Waterworks Association, Canadian section, at St. Catharines.
Apr. 7.—Annual dance.
Apr. 21.—Meeting at St. Catharines. "**The Chicago Water Diversion,**" by J. L. Busfield, M.E.I.C. Attendance 40.
May 12.—Meeting at Niagara Falls. "**Reminiscences of Many Lands,**" by Dr. J. McIntosh Bell. Attendance 59.
Sept. 25.—Meeting at Welland. Inspection of new waterworks. "**Diesel Engines,**" by Prof. E. A. Alcutt, M.E.I.C. Attendance 20.
Oct. 2, 3.—Visit of London Branch. Trip over Welland Ship Canal.
Oct. 20.—Meeting at St. Catharines. "**Hydro-Electric Development in Peru,**" by J. C. Street, M.E.I.C. Attendance 28.
Dec. 4.—Trip over International Peace Bridge, Fort Erie, and meeting at Niagara Falls. "**The International Peace Bridge,**" by Edward P. Lupfer, chief engineer. Attendance 54.

MEMBERSHIP

The membership of the branch shows a slight loss during the year.

Ottawa Branch

The President and Council,—

On behalf of the Managing Committee of the Ottawa Branch, we beg to submit the following report for the calendar year 1926:—

Looking back over the activities of the branch during the past year, it is a pleasure to note the many varied interests that have been opened up or touched upon, and to bear witness to the hearty co-operation evidenced by the officers and members throughout the year.

Early in the year we were favoured by a visit from our president, and some of the points brought out in his very interesting after-luncheon talk have borne fruit. He stressed, among other things, the necessity of the engineer taking a greater interest in community affairs if he is to properly fill his special sphere of activity in the world and the necessity of showing this interest, not by sitting back as the engineer seems inclined to do, but by seeing to it that our representatives, whoever they may be, shall endeavour to so conduct themselves that the engineering body shall come to be recognized as a substantial organization, composed of intelligent, if somewhat diffident, citizens who, in spite of appearances, are willing to do their share in municipal and public affairs. A small beginning to this end was made by the inclusion of one of our members on the Ottawa Centenary Committee last summer, and recently it has been agreed that the chairman of the branch shall be a member of the local Board of Trade. It is hoped that this is but a beginning of a really active interest on the part of the branch and its members in public affairs generally.

During the year the managing committee held eleven meetings. In addition, the branch held eight evening meetings and ten luncheons. The usual joint smoker with the Professional Institute of the Civil Service of Canada was a feature of the year's activities. The branch was able also to co-operate actively and gratifyingly with the Rotary Club in connection with the visit to Ottawa in May last of the delegates to the International Electro-technical Commission. The trip to the construction works at Chelsea, where the Fraser-Brace Engineering Company acted as hosts for the International Paper Company, was most enjoyable. Another outstanding feature was the opportunity afforded the members of having as their guest at luncheon Mr. Frederick Palmer, president of the British Institution of Civil Engineers, to whom a hearty greeting was extended.

The annual ball lived up to the reputation made by its predecessors, and continues to be one of the best means of publicity of The Institute locally, as well as one of the city's most enjoyable social functions.

The managing committee regrets the loss of one of its valuable members, S. J. Fisher, M.E.I.C., who resigned in September on account of his removal from the city. His resignation was received with great regret.

The balance sheet shows that we had a successful year financially, and that our assets have been increased by approximately $100, so that we now have a working capital of $1,704.46.

Owing to deaths, transfers, removal of names from the lists, etc., our membership shows a decrease of 57. In this connection it is with deep regret that we report the loss through death of four members, namely, Dr. Martin Murphy, F. A. Wise, Colonel Georges Roy and A. A. Dion; two associate members, LeRoy T. Bowes and E. C. Hutchinson, and one Branch Affiliate, Thomas Shanks.

PROCEEDINGS AND PUBLICITY

During the year ten luncheons and eight evening meetings were held, and two visits were made to Chelsea and Farmer's Rapids as guests of the Fraser, Brace Engineering Company. The meetings were as follows:—

Jan. 14.—"**The Role of the Engineer in the Organization of Defence,**" by Major-General J. H. MacBrien, C.B., C.M.G., D.S.O.; luncheon meeting at Chateau Laurier.
Jan. 14.—Annual meeting, Daffodil tea rooms.
Jan. 19.—Annual ball at the Chateau Laurier.
Feb. 5.—"**Engineering in British Columbia,**" by Major Geo. A. Walkem, M.E.I.C., president of The Engineering Institute of Canada; luncheon meeting at the Chateau Laurier.
Feb. 11.—"**Some Great Men of Science and Their Books,**" by Dr. Leo E. Pariseau, Hotel Dieu, Montreal; evening meeting at the Victoria Memorial Museum.
Mar. 2.—"**The Canadian Arctic Expedition of 1925,**" by George P. Mackenzie, officer in charge of the expedition, Ottawa; evening meeting at the Victoria Memorial Museum.
Mar. 19.—"**International Co-operation in Geodetic Survey Work,**" by Major C. V. Hodgson, assistant chief, Division of Geodesy, U. S. Coast and Geodetic Survey, Washington; luncheon meeting at the Chateau Laurier.
Mar. 25.—Joint smoker with the Professional Institute of the Civil Service of Canada at the Chaudiere Golf Club.
Apr. 8.—"**Irrigation,**" by Grote Stirling, M.P.; luncheon meeting at the Chateau Laurier.
Apr. 15.—"**Electrons and the Vacuum Tube as Used in Radio Reception.**" The annual popular lecture by Major W. Arthur Steel, M.C., A.M.E.I.C.; evening meeting at the Victoria Memorial Museum.
Apr. 29.—"**Power Development at Chelsea,**" by A. H. White, M.E.I.C., chief engineer, International Paper Company, New York; luncheon meeting at the Chateau Laurier.
May 1.—Visit to Chelsea with the delegates of the International Electrotechnical Commission. Luncheon served at Chelsea through the courtesy of the Canadian International Paper Company and the Fraser-Brace Engineering Company.

May 7.—"**The Chicago Drainage Canal,**" by J. L. Busfield, M.E.I.C., Montreal; evening meeting in the Palm Room, Chateau Laurier.

Oct. 16.—Luncheon and trip to Chelsea and Farmer's Rapids. "**The Plant Under Construction,**" by A. H. White, M.E.I.C., chief engineer, International Paper Company, New York. Luncheon served through the courtesy of the Fraser, Brace Engineering Company at the Chelsea plant.

Oct. 28.—"**Duralumin,**" by N. F. Parkinson, A.M.E.I.C., deputy minister, Department of Soldiers' Civil Re-establishment; luncheon meeting at the Chateau Laurier.

Nov. 18.—"**Patents,**" by Alex. E. MacRae, A.M.E.I.C.; luncheon meeting at the Chateau Laurier.

Dec. 3.—"**The Treatment of Fuels,**" by Dr. C. H. Lander, director of the British Fuel Research Bureau; luncheon meeting at the Chateau Laurier.

Dec. 9.—"**Use of Thermit in Ice Control Work,**" by Dr. Howard T. Barnes, M.E.I.C., professor of physics at McGill University; evening meeting in the Palm Room, Chateau Laurier.

Dec. 16.—"**Canadian Coal for Canadian Consumers,**" by E. J. Garland, M.P.; luncheon meeting at the Chateau Laurier.

Dec. 29.—Address by Frederick Palmer, president of the Institution of Civil Engineers, Great Britain; luncheon meeting at the Chateau Laurier.

The attendance at the luncheon meetings averaged about 100, the largest attendance being at the complimentary luncheon to Mr. Frederick Palmer, when 177 were present. The attendance at the evening lectures averaged 200, the largest attendance being at Mr. MacKenzie's lecture, when 400 were present.

Membership

Owing to deaths, transfers, etc., during the year, there was a decrease in the total membership of the branch from 472 to 417, and in the corporate membership from 357 to 325.

The following table shows in detail the comparative figures of the branch membership for the years 1924, 1925 and 1926:—

	1924	1925	1926
Honorary Members	1	1	0
Members	112	113	112
Associate Members	232	244	213
Juniors	35	35	26
Students	31	34	22
Affiliates of Institute	6	8	7
Branch Affiliates	35	37	37
Totals	452	471	417

Rooms and Library

The branch library is still situated on the third floor of the Stephen building, where it is open for consultation by members under the same conditions that have prevailed.

Accessions to the library during the year consisted chiefly of government reports, the proceedings of the Institution of Civil Engineers, presented by F. H. Peters, M.E.I.C., and the proceedings of the Institution of Civil Engineers, provided by the librarian.

Advertising in the Journal

Commissions for advertising secured in the Journal during 1926 amounted to $26.15, which is equivalent to the rebates received from thirteen Associate Members.

Finances

The financial position of the branch continues to be very satisfactory, as may be seen from the attached statements of assets and liabilities, and of receipts and expenditures. Although these statements show that the bank balance is approximately $100.00 less than last year, the assets have increased by approximately the same amount.

The branch closed the year with a balance of $452.90 in the bank, $9.36 cash on hand, and $1,000 in Victory Bonds, a total balance of $1,462.26. In addition to this balance the branch has assets of $41.20 in rebates due from headquarters, and $201.00 in furniture, equipment, etc., making a total balance of $1,704.46. The financial standing of the branch from 1910 to the present state is shown on the accompanying chart.

The income for the last two years was: for 1925, $712.59, and for 1926, $1,043.81; the expenditure for 1925, $833.66, and for 1926, $1,186.41. The annual income of the branch from Victory Bonds is $52.50.

Officers for 1927

The annual meeting of the branch will be held in Ottawa on the 13th January, when the officers and members of the managing committee will be elected for the year 1927.

Peterborough Branch

The President and Council,—

The Executive of the Peterborough Branch begs to present to you the annual report on the activities of the branch as follows:—

Meetings

The annual general meeting was held on Thursday, May 13th, 1926, and was arranged as a general business meeting to be followed by a social evening.

The election of officers resulted as follows:—

Past-Chairman	A. L. Killaly, A.M.E.I.C.
Chairman	B. L. Barns, A.M.E.I.C.
Treasurer	A. B. Gates, A.M.E.I.C.
Secretary	W. E. Ross, A.M.E.I.C.
Executive	A. E. Caddy, M.E.I.C.
	R. C. Flitton, A.M.E.I.C.
	W. M. Cruthers, A.M.E.I.C.
	J. A. G. Goulet, M.E.I.C.
	P. Manning, A.M.E.I.C.

Fifteen regular meetings were held during the year, the papers were of high standard throughout and the attendance was, in general, satisfactory.

The papers presented were as follows:—

Jan. 14.—"**Trees,**" by H. J. Moore, lecturer in horticulture, Department of Agriculture, Ontario Provincial Government.

Feb. 4.—"**Power Factor Correction,**" by B. L. Barns, A.M.E.I.C., engineer, Canadian General Electric Company, Peterborough, Ontario.

Feb. 11.—"**Aviation and Modern Engineering Practice,**" by Wing-Commander E. W. Stedman, O.B.E., M.E.I.C.

Feb. 25.—"**Story of a Lump of Coal,**" by Geo. W. Allen, secretary-treasurer, Canadian Gas Association.

Mar. 11.—"**Manufacturing of Portland Cement,**" by H. S. Van Scoyoc, M.E.I.C., manager of Publicity, Canada Cement Company.

Mar. 25.—"**Installation and Operation of the North West Territories Radio Systems,**" by Major W. A. Steel, A.M.E.I.C., Department of National Defence, Ottawa.

Apr. 8.—"**The Chicago Drainage Canal,**" by J. L. Busfield, M.E.I.C., of Beaubien, Busfield and Company, Montreal.

Apr. 22.—"**Montreal-South Shore Bridge,**" by P. L. Pratley ,M.E.I.C., Monsarrat and Pratley, Montreal.

May 13.—Annual meeting.

Sept. 22.—Visit to Peterborough Sewage Disposal Plant.

Oct. 14.—"**Work of the Canadian Air Force,**" by Flt.-Lieut. T. A. Lawrence.

Oct. 16.—Dinner to Major Geo. A. Walkem, M.E.I.C.

Nov. 11.—"**Life of Sir William Van Horne,**" by Mr. W. Flavelle Lindsay.

Nov. 23.—Annual banquet.

Dec. 9.—"**Fundamentals of Correct Illumination for Factories and Office,**" by H. D. Burnett, manager, Lighting Service Department, Canadian General Electric Company.

In addition to the meetings listed above, the branch had an outing on May 29th, when about eighty members and friends journeyed by automobile to Young's Point, where the new lock, then under construction, was examined, after which the party proceeded to South Beach for supper, baseball, etc.

The average attendance at the meetings throughout the year has been forty.

MEMBERSHIP

The membership of the branch now stands as follows:—

Quebec Branch

The President and Council,—

The Executive Committee of the Quebec Branch begs to present the following annual report on the work of the branch during the year 1926:—

MEMBERSHIP

	Resident	Non-Resident	Total
Members	18	1	19
Associate Members	57	11	68
Juniors	9	3	12
Students	11	1	12
Affiliates	1	..	1
Total membership			112

ANNUAL MEETING

The annual meeting of the Quebec Branch was held on May 25th, 1926, under the chairmanship of A. B. Normandin, A.M.E.I.C. The following officers were elected for the year 1926-1927:—

Honorary Chairman (for life)	A. R. Decary, M.E.I.C.
Chairman	A. B. Normandin, A.M.E.I.C.
Vice-Chairman	S. L. deCarteret, M.E.I.C.
Secretary-Treasurer	Louis Beaudry, A.M.E.I.C.
Executive Committee	T. E. Rousseau, M.E.I.C.
	Hector Cimon, A.M.E.I.C.
	L. C. Dupuis, A.M.E.I.C.
	Alex. Larivière, A.M.E.I.C.
Ex-officio	W. G. Mitchell, M.E.I.C.

MEETINGS

The Executive of the Quebec Branch has held meetings regularly during the year 1926.

The monthly luncheons and evening meetings of the branch were held regularly at the Chateau Frontenac and at the City Hall from January to June.

The Quebec Branch had the pleasure during the year of having a visit from Major Geo. A. Walkem, M.E.I.C., president of The Institute.

It has been our pleasure to have frequent opportunities of welcoming outside members of our Institute and also prominent men in public life at our different luncheons and evening meetings. All meetings were attended by practically the entire membership of the branch, and very good publicity of the activities of the branch was given through the press.

All questions submitted by the Council of The Institute have been studied, discussed and transacted.

Our branch has followed with interest the Institute deliberations and has devoted its full energy to all matters aiming to the protection and promotion of the interest of The Institute and its members.

Our special committee has followed closely, studied seriously and made as complete report as possible on all applications for membership which have been referred to this branch and the necessary recommendations have been made to the Council and The Institute.

MEETINGS

The following addresses were made at our different luncheons and evening meetings:—

"**Power Development in the Province of Quebec,**" by Fraser S. Keith, M.E.I.C., manager, Department of Development, Shawinigan Water and Power Company.

"**The Engineer and the Commission of Public Services,**" by F. Chas. Laberge, M.E.I.C., member of the Commission of Public Services.

"**The Telephone,**" by G. M. Hudson, A.M.E.I.C., division plant engineer, Bell Telephone Company of Canada, Limited.

"**Transportation,**" by R. A. C. Henry, M.E.I.C., director, Bureau of Economics, Canadian National Railways.

"**Water Diversion from the Great Lakes by the Chicago Drainage Canal,**" by de Gaspé Beaubien, M.E.I.C., consulting engineer, Montreal.

"**The Quebec Harbour,**" by Brig.-Gen. T. L. Tremblay, C.M.G., D.S.O., A.M.E.I.C., chief engineer, Quebec Harbour Commission.

Au Président et au Conseil,—

Le conseil de la section de Québec a l'honneur de vous soumettre son rapport annuel pour l'année 1926 comme suit:—

Rôle des Membres

	Résidents	Non résidents	Total
Membres	18	1	19
Membres associés	57	11	68
Membres juniors	9	3	12
Membres étudiants	11	1	12
Membres affiliés	1	..	1
Total des membres			112

Assemblée Annuelle

L'assemblée annuelle de la section de Québec a été tenue le 25 mai 1926, sous la présidence de A. B. Normandin, A.M.E.I.C. Les officiers dont les noms suivent ont été élus pour l'année 1926-1927:—

Président Honoraire à vie	A. R. Décary, M.E.I.C.
Président	A. B. Normandin, A.M.E.I.C.
Vice-Président	S. L. deCarteret, A.M.E.I.C.
Secrétaire-Trésorier	Louis Beaudry, A.M.E.I.C.
Conseillers	T. E. Rousseau, M.E.I.C.
	Hector Cimon, A.M.E.I.C.
	L. C. Dupuis, A.M.E.I.C.
	Alex. Larivière, A.M.E.I.C.
Ex-officio	W. G. Mitchell, M.E.I.C.

Assemblées

Le conseil de la section de Québec a tenu ses assemblées régulièrement durant l'année 1926.

Les désjeuners et assemblées du soir de chaque mois ont été tenues régulièrement au Château Frontenac et à l'Hôtel de Ville de Québec, à partir du mois de janvier jusq'au mois de juin.

La section de Québec a eu le plaisir, durant l'année, d'avoir la visite du Major Geo. A. Walkem, M.E.I.C., président de l'Institut.

A nos différents déjeuners et assemblées du soir, nous avons eu fréquemment l'occasion de compter parmi nous des membres de l'Institute étrangers à notre section, ainsi que des personnages de marque dans la vie publique. Toutes nos assemblées ont réuni la presque totalité des membres de notre branche, et la presse a toujours eu l'amabilité de donner de très bons comptes-rendus de nos travaux.

Toutes les questions soumises par le Conseil Général à la section de Québec ont été étudiées, discutées et transigées.

Notre section a suivi avec intérêt, les travaux de l'Institut et a prêté son plein concours à toutes les questions ayant pour but de protéger et de promouvoir les intérêts de l'Institut et de ses membres.

Notre comité spécial s'est occupé de surveiller, de faire une étude sérieuse et de faire un rapport aussi complet que possible sur toutes les demandes d'admission qui ont été référée à notre section, et les recommendations nécessaires ont été faites au Conseil Général de l'Institut qui a bien voulu en tenir compte.

Causeries

Les causeries suivantes ont été faites à nos différentes assemblées du soir et des déjeuners:—

"**Le développement des pouvoirs hydrauliques dans la province de Québec,**" par Fraser S. Keith, M.E.I.C., de la Shawinigan Water and Power Company.

"**L'ingénieur et la Commission des Services Publics,**" par F. Chas. Laberge, M.E.I.C., membre de la Commission des Services Publics.

"**Le téléphone,**" par G. M. Hudson, A.M.E.I.C., de la Bell Téléphone Companie de Canada.

"**Le transport,**" par R. A. C. Henry, M.E.I.C., directeur du bureau des économies de la Canadian National Railway.

"**Le détournement des eaux des grands lacs par le canal de Chicago,**" par deGaspé Beaubien, M.E.I.C., ingénieur conseil de Montréal.

"**Le port de Québec,**" par le brigadier-général T. L. Tremblay, C.M.G., D.S.O., A.M.E.I.C., ingénieur en chef de la Commission du Havre de Québec.

Saint John Branch

The President and Council,—

Herewith is submitted the ninth annual report of the Saint John Branch for the year ending December 31st, 1926.

Meetings

The executive met seven times during the year. The branch held ten meetings. One of these was a joint luncheon, under the auspices of the branch, with the Women's and Men's Canadian Clubs of Saint John. The branch held a joint dinner with the Association of Professional Engineers of the Province of New Brunswick at the time of the annual meeting of the Association. The annual meeting of the branch was held following a dinner. For the first time since its formation the branch held a summer picnic, which will be repeated. The members were present with the Men's Canadian Club at a luncheon meeting held by the Women's Canadian Club.

Members of the branch have shown an interest in, and have derived benefit from the general work of the Institute. A visit during the year from R. J. Durley, M.E.I.C., general secretary of the Institute, was appreciated; such visits from Institute officers are recognized as a splendid means of keeping the branch members in touch with Institute headquarters. Three members of the branch attended the annual meeting in Toronto during January and seven members visited Sydney for the Maritime Professional meeting in August.

The branch held a diversified programme of meetings during the year. Good interest in the meetings has been shown by members, and also by the general public, who are made welcome. Ladies are usually present at branch meetings and find the addresses of interest.

The branch has had good support from its various committees. The press of Saint John has generously published accounts of the various activities of the branch.

The branch has co-operated with other branches in the Maritime Provinces in having an interchange of speakers. Addresses have also been given before the branch by speakers from outside the Maritime Provinces. It is submitted that an interchange of speakers and papers between branches be encouraged as widely as possible.

Meetings—1926

Jan. 5.—Joint meeting of Saint John Branch and Men's and Women's Canadian Clubs. "**Canadian Arctic Expedition, 1925,**" by George P. MacKenzie.

Jan. 21.—"**Radio Direction Finding,**" by Lt.-Commander C. P. Edwards, O.B.E., A.M.E.I.C. Joint dinner with Association of Professional Engineers of New Brunswick.

Feb. 20.—"**The Interconnection of High and Low Pressure Turbines,**" by J. D. Garey, A.M.E.I.C.

Mar. 5.—"**The Manufacture of Cement,**" by H. S. Van Scoyoc, M.E.I.C.

Mar. 22.—"**What's the Matter With Europe?**" by D. Thomas Curtin. Joint meeting, Women's Canadian Club, Men's Canadian Club, and Saint John Branch, (under auspices of Women's Canadian Club).

Apr. 21.—"**Photography in Science, Industry and Medicine,**" by Prof. E. L. Harvey, M.A.

May 5.—Annual meeting.

Aug. 12.—Picnic at Belyea's Point. "**Institute Affairs,**" by R. J. Durley, M.E.I.C.

Oct. 27.—"**Coal and Other Fuels Derived from It,**" by K. L. Dawson, A.M.E.I.C.
Nov. 18.—"**The Architectural Design of Buildings,**" by W. W. Alward, A.R.I.B.A.
Dec. 9.—"**Industrial Lighting,**" by S. C. Webb, A.M.E.I.C.

MEMBERSHIP

The branch territory comprises the nine western counties of New Brunswick. The membership on December 31, 1926, is as follows:—

Grade	Branch Residents	Branch Non-residents	Total
Members	13	10	23
Associate Members	27	12	39
Juniors	5	3	8
Students	3	2	5
Affiliates	2	..	2
Branch Affiliates	2	..	2
Total	52	27	79

Total at end of 1925, 90; total at end of 1926, 79; net loss, 11.

FINANCIAL STATEMENT

Receipts

Saguenay Branch

The President and Council,—

On behalf of the Executive Committee we beg to submit the annual report of the Saguenay Branch for the year 1926.

The Saguenay Branch has had the pleasure of entertaining the president and the immediate past-president of The Institute during the past year. Early in the year Dr. Arthur Surveyer, M.E.I.C., and in October last, Major Geo. A. Walkem, M.E.I.C., were in the lake St. John district. Dr. Surveyer's trip was of a personal character, but Major Walkem was on an official tour. Although no regular meeting was held, an opportunity was afforded a number of prominent members to meet him informally at Chicoutimi, Arvida, Kenogami, Isle Maligne and Riverbend, in connection with which a motor outing had been organized.

R. J. Durley, M.E.I.C., general secretary of The Institute, accompanied Major Walkem. This is Mr. Durley's first visit to our branch, and it is hoped that he will again visit us with our next president, or more often if possible.

During the summer months an excursion of the Montreal Branch visited our territory. N. E. D. Sheppard, A.M.E.I.C., assistant secretary, and Fraser S. Keith, M.E.I.C., former general secretary, were among those who were welcomed by us on that occasion.

OFFICERS

The election of officers resulted as follows:—

Chairman .... Edouard Lavoie, M.E.I.C.
Vice-Chairman .... C. E. Legris, A.M.E.I.C.
Secretary-Treasurer ...... Burroughs Pelletier, A.M.E.I.C.
Executive .... J. L. Delisle, A.M.E.I.C., (1 year)
H. G. Cochrane, A.M.E.I.C. (2 years)
C. C. Lindsay, A.M.E.I.C. (2 ")
C. N. Shanly, M.E.I.C. (ex-officio)

MEMBERSHIP

The membership of the branch is as follows:—

Members	3
Associate Members	26
Juniors	9
Students	21
Total	59

Although the membership shows an increase, we have to record with regret the departure of several of our most esteemed members from Kenogami to Quebec.

FINANCIAL STATEMENT

(As at January 1st, 1927)

Receipts

Balance on hand from last report	$ 57.34	
Rebates from headquarters	103.35	
		$160.69

Disbursements

Expenses re annual elections	$ 16.34	
Postage, stationery, telegrams, exchange	4.21	
Expenses re Montreal Branch visit	66.32	
Balance on hand	73.82	
		$160.69

Respectfully submitted,

EDOUARD LAVOIE, M.E.I.C., *Chairman.*
BURROUGHS PELLETIER, A.M.E.I.C., *Secretary-Treasurer.*

Saskatchewan Branch

The President and Council,—

On behalf of the Executive Committee we beg to submit the following report concerning the activities of the Saskatchewan Branch for the calendar year 1926.

EXECUTIVE COMMITTEE

The present executive was elected on March 11th at the branch annual meeting, and with those continuing in office is as follows:—

Chairman .... W. H. Greene, M.E.I.C., Moose Jaw.
Vice-Chairman .... M. B. Weekes, M.E.I.C., Regina.
Secretary-Treasurer .... R. W. E. Loucks, A.M.E.I.C., Regina.
Executive ... (2 years) .. J. W. D. Farrell, A.M.E.I.C., Regina.
A. M. Macgillivray, A.M.E.I.C., Saskatoon.
P. C. Perry, A.M.E.I.C., Regina.
(1 year) .. J. M. Campbell, A.M.E.I.C., Moose Jaw.
R. H. Murray, A.M.E.I.C., Regina
D. A. R. McCannel, A.M.E.I.C., Regina.
R. N. Blackburn, M.E.I.C., Regina. (Past Chairman).
H. R. Mackenzie, A.M.E.I.C., Regina. (Councillor).

COMMITTEES

Chairmen of the standing committees are:—

Papers and Library .... D. A. R. McCannel, A.M.E.I.C.
Legislation .... R. N. Blackburn, M.E.I.C.
Nominating .... L. A. Thornton, M.E.I.C.
Attendance .... D. W. Houston, A.M.E.I.C.
T. McGuinness, A.M.E.I.C.
Publicity .... J. W. D. Farrell, A.M.E.I.C.
Meetings .... R. W. Allen, A.M.E.I.C.

The Saskatchewan Branch representative on the Nominating Committee of the Institute is R. N. Blackburn, M.E.I.C.

MEMBERSHIP

The membership of the branch has continued with the usual fluctuations due to transfers, etc.

The present membership of the branch is:—

	Branch Residents	Branch Non-residents	Total
Members	6	11	17
Associate Members	39	32	71
Juniors	3	3	6
Students	1	4	5
Affiliates	1	1	2
Branch Affiliates	5	0	5
Total	55	51	106

MEETINGS

The executive held seven meetings for the transaction of branch affairs. There were six regular meetings of the branch and one special summer meeting. The summer meeting was held in camp in River Park, at Estevan, Sask., on July 8th, 9th and 10th, and was attended by our general secretary, R. J. Durley, M.E.I.C., and by other notable guests. It was a joint meeting in conjunction with the Saskatchewan section of the American Institute of Electrical Engineers and the Southern Saskatchewan section of the Canadian Institute of Mining and Metallurgy.

Special matters referred to the executive by the general secretary, pertaining to Students' prizes, recruiting of new members, co-operation with Boards of Trade, etc., were considered and suitable action taken thereon.

The regular meetings have been well attended and considerable interest and enthusiasm shown by the officers and members. They were, in each case, preceded by a dinner. These meetings have been scheduled to fit in with the meetings of the Saskatchewan section of the A.I.E.E. and the branch has endeavoured to co-operate in every way with this sister organization.

PROGRAMME

The programme for the year was as follows:—

Jan. 20.—"Transportation Night." **"The Miracle of Transportation,"** by F. T. Lewis, division engineer, C.P.R.; **"The Street Railway Today and Tomorrow,"** by D. W. Houston, A.M.E.I.C.; **"Railway History in Canada,"** by P. C. Perry, A.M.E.I.C.

Feb. 18.—"Highways and Drainage Night" **"Progress in Construction of Provincial Highways,"** by H. R. Mackenzie, A.M.E.I.C.; **"Bridges and Bridge Sites,"** by D. C. M. Davies, A.M.E.I.C.; **"Drainage Development in Saskatchewan,"** by M. B. Weekes, M.E.I.C.

Mar. 11.—Ninth annual meeting. Reports of committees, election of officers, address by retiring chairman, R. N. Blackburn, M.E.I.C., banquet, toast list and other entertainment.

Oct. 20.—Meeting in Moose Jaw. **"Present Sewer and Water Conditions in Saskatchewan,"** by R. H. Murray, A.M.E.I.C.; **"Growth of Industrial Power in Saskatchewan,"** by J. D. Peters, A.M.E.I.C.; Presentation of Badges to Past Chairmen, J. R. C. Macredie, M.E.I.C., and G. D. Mackie, M.E.I.C.

Nov. 19.—**"Recent Advances in the Engineering Side of Building Construction,"** by J. H. Puntin, A.M.E.I.C.; **"Mineral Deposits of Southern Saskatchewan, their Location, Uses and the Possibilities for Development,"** by W. H. Hastings, B.SC., engineer with the Bureau of Labour and Industries, province of Saskatchewan; **"Outdoor Signs,"** by Stewart Young, A.M.E.I.C.

Dec. 10.—"Round the World Night." Addresses on the outstanding engineering achievements of ten countries as follows:— **"Africa,"** by J. C. Meade, A.M.E.I.C.; **"China,"** by J. G. Schaeffer, S.E.I.C.; **"France,"** by Capt. G. R. Chetwynd, A.M.E.I.C.; **"Germany,"** by P. R. Genders, A.M.E.I.C.; **"India,"** by D. D. Low, Jr.E.I.C.; **"Italy,"** by G. G. Fitzgerald, A.M.E.I.C.; **"Japan,"** by J. B. Parker, A.M.E.I.C.; **"Norway and Sweden,"** by Edwin Markham, A.M.E.I.C.; **"Russia,"** by W. T. E. Smith, BRANCH AFFILIATE; **"South America,"** by T. McGuinness, A.M.E.I.C.

July 8, 9 and 10.—Summer meeting at Estevan, Sask. **"Electrical Development of Southern Saskatchewan,"** by S. R. Parker, A.M.E.I.C.; **"Industrial Development of Southern Saskatchewan,"** by W. H. Greene, M.E.I.C.; **"Notes on Mining Claims and Mineral Prospects in the Mineral Belt North of The Pas, Manitoba,"** by W. T. Thompson, M.E.I.C.; **"The Preservative Treatment of Wood,"** by R. D. Prettie, of the Alberta Wood Preserving Co., Calgary, Alta.; **"Rural Electrification,"** by C. A. Clendening, A.M.E.I.C., Manitoba power commissioner.

SCHOLARSHIP

The annual scholarship of $50.00 offered by the branch to the most deserving student in the graduating class in engineering of the University of Saskatchewan, was awarded to Mr. G. N. Munro.

W. HARVEY GREENE, M.E.I.C., *Chairman.*

Sault Ste. Marie Branch

The President and Council,—

The attendance at the meetings for the year averaged twenty-seven, and all the meetings except one were preceded by a dinner at the Y.W.C.A. rooms, Queen street east. The attendance showed a marked improvement over 1925, and averaged fifty per cent of our resident members.

It is unfortunate that our district covers such an extended area, as our branch district members find it impossible to be at the meetings.

All the members greatly appreciated the efforts put forward by the Papers and Publicity Committee and the Entertainment Committee in providing most interesting papers. The only inspection trip was one through the Provincial Government hangar. About forty of our members took advantage of this privilege.

The entertaining of Major Geo. A. Walkem, M.E.I.C., president of The Institute, on February 22nd, and of R. J. Durley, M.E.I.C., general secretary of The Institute, on July 15th, were two very interesting events this year.

The regular meeetings were held on the last Friday of each month, except the special meetings held in February, March, June and July, and the papers given and the inspection trips made were as follows:—

Jan. 29.—**"Canadian Engineering and Architectural Problems,"** by Mr. James Govan, R.A.I.C., consulting architect of Toronto.

Feb. 22.—A special meeting was held to welcome Major Geo. A. Walkem, M.E.I.C., president of The Institute.

Mar. 5.—**"The Manufacture of Artificial Silk,"** by Mr. A. D. Hone, principal of the Technical school.

Mar. 26.—**"Wind Measurements,"** by Carl Stenbol, M.E.I.C., of the Algoma Steel Corporation.

Apr. 30.—Inspection trip through the Provincial Government hangar under the guidance of Major Thompson and Major Clayton.

June 1.—**"Mining Conditions as Found in South Africa,"** by T. F. Sutherland, chief inspector of mines for the Province of Ontario, assisted by G. C. Bateman, secretary of the Ontario Mining Association.

June 25.—**"Methods Employed at the Fish Hatchery,"** by Mr. C. Hartman, superintendent of the Provincial Government hatchery in the Sault.

July 15.—A special luncheon and meeting was held to welcome R. J. Durley, M.E.I.C., general secretary of The Institute.

Sept. 24.—The first regular meeting after the holiday. As no paper was available a general discussion was carried on.

Oct. 29.—**"The Chicago Drainage Canal,"** by R. S. McCormick, M.E.I.C., general manager and chief engineer of the Algoma Central and Hudson Bay Railway of the Sault.

Nov. 25.—**"The Manufacture and Composition of Alloy Steel,"** by Mr. H. B. Greenstead, engineer of tests for the Algoma Steel Corporation.

Dec. 17.—Annual meeting; reports of all committees; election of officers for 1927; address by retiring chairman C. H. Speer, M.E.I.C., also inspection trip through the plant of the Sault Daily Star under the guidance of Mr. J. W. Curran.

PRESENT MEMBERSHIP

	Branch Residents	Branch Non-residents	Total
Members	11	12	23

Juniors	9	5	14
Students	3	13	16
Affiliates	1	..	1
Branch Affiliates	17	..	17
Total	52	65	117

This is a decrease of four members as shown by the 1925 report. Conditions are about the same industrially throughout this district as last year. There are three or four applications for admission and transfer pending.

We would like to express our appreciation to Mr. Durley and his staff at headquarters for the assistance rendered in keeping track of the district members and in helping keep our membership list corrected to date.

Toronto Branch

The President and Council,—

The Executive Committee of the Toronto Branch respectfully submits the following report for the calendar year 1926:—

During this period the present Executive was elected in March at the branch annual meeting.

Executive Committee

January to March, 1926		March to December, 1926
T. R. Loudon, A.M.E.I.C.	Chair.	J. G. R. Wainwright, A.M.E.I.C.
J. G. R. Wainwright, A.M.E.I.C.	Vice-C.	R. B. Young, M.E.I.C.
C. B. Ferris, A.M.E.I.C.	Sec.-Trea.	J. W. Falkner, A.M.E.I.C.
R. W. Angus, M.E.I.C.	Exec'tive	A. E. K. Bunnell, M.E.I.C.
E. T. J. Brandon, A.M.E.I.C.		H. W. Tate, A.M.E.I.C.
R. B. Young, M.E.I.C.		L.W.Wynne-Roberts, A.M.E.I.C.
J. A. Knight, A.M.E.I.C.		A. T. C. McMaster, M.E.I.C.
A. C. Oxley, A.M.E.I.C.		I. H. Nevitt, M.E.I.C.
L.W.Wynne-Roberts, A.M.E.I.C.		J. A. Knight, A.M.E.I.C.
H. K. Wicksteed, M.E.I.C.	*Ex-officio*	T. R. Loudon, M.E.I.C.
G. T. Clark, A.M.E.I.C.		E. G. Hewson, M.E.I.C.
E. G. Hewson, M.E.I.C.		J. M. Oxley, M.E.I.C.
J. M. Oxley, M.E.I.C.		H. K. Wicksteed, M.E.I.C.
J. H. Curzon, A.M.E.I.C.		C. B. Ferris, A.M.E.I.C.

Standing Committees

The standing committees with the chairmen of each are:—

Programme	J. G. R. Wainwright, A.M.E.I.C.
	H. W. Tate, A.M.E.I.C.
Finance	R. B. Young, M.E.I.C.
Publicity—March to October	S. G. Talman, A.M.E.I.C.
October to date	James Hyslop, M.E.I.C.
Library	A. T. C. McMaster, M.E.I.C.
Attendance	L. W. Wynne-Roberts, A.M.E.I.C.
Student Relations	W. B. Dunbar, A.M.E.I.C.
Membership	E. T. J. Brandon, A.M.E.I.C.

The Toronto Branch representative on the Nominating Committee of The Institute is R. B. Young, M.E.I.C., who was elected by the Executive for this office during 1927.

Annual and Professional Meeting of the Institute, 1926

The Annual General and General Professional Meeting of The Institute was held in Toronto on January 27th, 28th and 29th, 1926. The Annual Meeting Committee consisted of the Executive Committee of the Toronto Branch together with the following members, under the chairmanship of Professor C. R. Young, M.E.I.C.:—

Chairman	C. R. Young, M.E.I.C.
Vice-Chairman and Papers	W. P. Dobson, M.E.I.C.
Secretary	L. W. Wynne-Roberts, A.M.E.I.C.
Finance	W. E. Douglas, A.M.E.I.C.
Dinner	Col. H. J. Lamb, M.E.I.C.
Entertainment	B. N. Simpson
Service	H. W. Tate, A.M.E.I.C.
Accommodation	J. B. Carswell, A.M.E.I.C.
Publicity	C. A. Meadows, A.M.E.I.C.
Reception	R. O. Wynne-Roberts, M.E.I.C.
Convener of Ladies' Committee	Mrs. C. H. Mitchell

Meetings

The branch Executive held thirteen meetings for the transaction of branch affairs. There were thirteen branch general meetings. Of these, three were luncheon-meetings, which were held down town at 12.30 noon on the first Thursday of the month, from time to time, and were well attended.

The January, February and March luncheon-meetings were addressed respectively by R. A. C. Henry, M.E.I.C., of the Canadian National Railway; George Hogarth, M.E.I.C., deputy minister of Public Works, and Geo. H. Ross, finance commissioner of Toronto.

For the branch general meetings it has been the desire and endeavour of the branch executive to have papers of as great an educational value as possible, one of the aims being to give the men entering the profession some information as to what phases of engineering are represented in our large organizations. The average attendance has been about seventy, the attendance on March 18th, when J. L. Busfield, M.E.I.C., addressed the branch on the "Chicago Drainage Canal," being approximately two hundred. It was decided by the branch Executive in October, after careful consideration, that for the coming season two regular evening meetings should be held each month, with additional luncheon meetings when speakers were available.

The branch was greatly pleased to welcome R. J. Durley, M.E.I.C., general secretary of The Institute, on his annual visit to the branch at the executive and regular meetings on November 25th, and thoroughly appreciated his visit.

The programme for the year has been the following:—

Jan. 7.—Luncheon-meeting. "**The Motor Vehicle vs. Other Forms of Transportation,**" by R. A. C. Henry, M.E.I.C.

Jan. 21.—"**The Work of the Ontario Experimental Station in Promoting the Art of Sewage Disposal,**" by F. A. Dallyn, M.E.I.C., and A. V. DeLaporte, M.E.I.C.

Jan. 27, 28 and 29.—Annual General and General Professional Meeting of the Engineering Institute, King Edward Hotel, Toronto.

Feb. 4.—Luncheon meeting to George Hogarth, M.E.I.C., deputy minister of Public Works, Ontario.

Feb. 11.—"**Engineering Specifications,**" by S. E. Craig.

Feb. 18.—"**The Economic and Engineering Situation in Canada,**" by Brig.-General C. H. Mitchell, C.B., C.M.G., D.S.O., M.E.I.C.

Feb. 25.—"**The Conservation of Rainfall in Southern India,**" by G. W. Winckler, M.E.I.C.

Mar. 4.—Luncheon-meeting. "**Civic Finance,**" by Geo. H. Ross, finance commissioner, city of Toronto.

Mar. 18.—"**The Chicago Drainage Canal,**" by J. L. Busfield, M.E.I.C.

Mar. 25.—Branch annual meeting and elections.

Oct. 28.—"**The Functioning of the Way Department of the Toronto Transportation Commission,**" by H. W. Tate, A.M.E.I.C.

Nov. 11.—"**Power Distribution Problems of the Toronto Transportation Commission,**" by J. F. Neild, M.A.I.E.E.

Nov. 25.—"**The Construction and Maintenance of Equipment on a Modern Electric Railway System,**" by W. R. McRae, M.A.I.E.E.

Dec. 16.—"**The Story of Compressed Air,**" by G. R. Southee.

Membership

The membership of the branch has continued with the usual fluctuations due to transfers, etc.

The total at December 31st, 1926, was:—

	Branch Residents	Branch Non-Residents	Total
Members	133	4	137
Associate Members	237	16	253
Juniors	46	1	47
Students	74	6	80
Affiliates	4	..	4
Branch Affiliates	2	..	2
Total	496	27	523

Financial Statement—For the Calendar Year 1926

Revenue

Balance as at Jan. 1st, 1926	$ 331.44	
Rebates and branch news	785.85	
Annual Meeting Committee surplus	615.86	
Branch Affiliates	40.00	
Refund from Engineers' Club	21.80

J. W. Falkner, a.m.e.i.c., *Secretary-Treasurer.*

Vancouver Branch

The President and Council,—

We have the honour to report on the affairs of the Vancouver Branch, for the year 1926, as follows:—

General

The policy of previous years of co-operating with the Association of Professional Engineers of British Columbia, and the Vancouver section of the American Institute of Electrical Engineers, and other Societies, has been continued through the year. The scope of the papers given before the branch has been broadened, with resulting increase of interest. It has been noted that it will take some years before the full effect of this broadening of the scope of the papers is fully appreciated.

The following meetings have been held by the branch during the year:—

Mar. 2.—In conjunction with the Vancouver section of the American Institute of Electrical Engineers, a moving picture film on:—"**From Mine to Consumer.**"

Mar. 13.—A special dinner of welcome was given to Major Geo. A Walkem, m.l.a., m.e.i.c., on account of his election to the presidency of The Institute.

Apr. 22.—"**Cloud Phenomena and the Upper Atmosphere,**" by Mr. E. Sherman.

May 26.—"**The Relation of the Profession to the University.**" Dean R. W. Brock, m.e.i.c., of the University of British Columbia.

June 3.—A record attendance of the branch and members of the Association of Professional Engineers, who visited Alouette lake as guests of the B. C. Electric Railway Company.

June 8.—"**The Generation of Steam at Critical Temperatures and at 3,200 Pounds Per Square Inch,**" by Dr. Mark Benson.

June 29.—A general meeting to meet R. J. Durley, m.e.i.c., the general secretary of The Institute.

Aug. 28.—A special trip to the B. C. pier of the Canadian Pacific Railway Company was held in conjunction with the other societies of the city, and a party of engineers from Bellingham, Wash., was entertained.

Sept. 11.—In co-operation with the Vancouver section of the American Institute of Electrical Engineers, a record all-day trip was made of inspection to the Britannia mine.

Oct. 6.—"**The Education of the Engineer,**" by Professor W. E. Duckering. This was the first of a series of addresses on the subject.

Oct. 13.—"**Changing Aspects of Mining,**" by Professor J. M. Turnbull.

Oct. 20.—Mr. Frank Sawford, together with J. Muirhead, m.e.i.c., discussed with the members "**The Professional Engineer Movement.**"

Oct. 29.—"**Seismic Disturbances and Their Effect on Buildings,**" by Mr. F. Napier Denison, superintendent of the Dominion Meteorological Service, British Columbia Division.

Nov. 3.—"**The Influence of the Medical Profession on the Education of a Medical Student,**" by Dr. H. W. Hill.

Nov. 10.—"**The Geology of Britannia Mines,**" by Dr. S. J. Schofield.

Nov. 24.—"**The Reproducing of Engineering Drawings,**" by H. B. Muckleston, m.e.i.c.

Dec. 8.—"**The Principles of Education and Their Bearing on Vocational Selection.**" By Dr. G. M. Weir.

A further eighteen meetings have been arranged for the remainder of the winter session.

Executive Committee Meetings

The Executive Committee held nine meetings during 1926, and dealt with a number of very important and interesting problems of great moment to the profession. Chief of these was an effort to create closer co-operation between engineers of the public services and the various associations administering engineering acts throughout the Dominion. This was undertaken at the request of the Council of the Association of Professional Engineers.

Membership

Grade	Dec. 13th, 1926	Dec. 17th, 1925	Dec. 18th, 1924
Branch Residents:—			
Members	56	60	61
Associate Members	73	90	87
Juniors	9	7	6
Students	28	42	40
Affiliates	0	0	0
	166	199	194
Branch Non-Residents:—

Associate Members	51	59	55
Juniors	8	12	10
Students	7	9	9
Affiliates	0	1	1
	81	101	94

Branch Elections

In connection with the election of branch officers, sixty-six ballots out of a total of one hundred and fifty-seven were returned.

Library

Library space has been increased at the University Club, and all that is necessary at the moment is the appointment of a librarian and assistants to arrange the library properly.

Students' Prize

The Walter Moberly Memorial Prize

The second award of this prize was made to Mr. F. G. A. Tarr, of the 1926 Class of the University of British Columbia, for an essay on "The Stave Falls, B.C., Hydro-Electric Development."

Financial Statement

December 18th, 1925, to December 15th, 1926

Receipts

Cash on hand		$ 60.60	
Rebates on fees, Aug., 1925-Aug., 1926		444.62	
Branch news		18.42	
Library:			
Loan from headquarters	$300.00		
Sale of bookcases	67.50		
Contributions from sister societies using library	100.00		
		$467.50	
Rent of library from sister societies		$ 50.00	
			$1,041.14

Disbursements

Library:			
Capital expenditures:—			
Moving library and storage	$ 42.00		
	17.50		
Bookcases	140.00		
	170.10		
Labels for shelves	1.97		
Binding books	66.02		
	———	$437.59	
Library:			
Operating expenses:—			
Rent	$100.00		
Subscription "Canadian Engineer"	3.15		
	———	$103.15	
Rent of offices, Birks' Building		$ 75.00	
" Auditorium, Board of Trade, for meetings	$ 35.00		
" University Club for meetings...	16.00		
	———	$ 51.00	
Printing and stationery		$ 92.40	
Postage		47.03	
Exchange on cheques		1.20	
Expenses joint meeting, March 2nd		5.00	
Expenses dinner, March 5th		15.80	
Address plates for addressograph		2.55	
Filing drawer and card index		9.90	
Honorarium secretary		50.00	
Balance on hand, December 15th, 1926		150.52	
		———	$1,041.14

The balance of cash on hand, $150.52, shows an improvement over the previous years. This is due to the saving effected by moving the library.

One cheque was drawn on the Walter Moberly Memorial Fund for $25.00 to cover the prize awarded to Mr. F. G. A. Tarr. The balance in this account is $45.38.

The loan of $300.00 from headquarters for the development of the library has been expended on bookshelves and binding. There remains of this capital sum a balance of $29.99 unexpended.

Respectfully submitted,

F. W. Alexander, m.e.i.c., *Chairman.*
E. A. Wheatley, a.m.e.i.c., *Secretary-Treasurer.*

Victoria Branch

The President and Council,—

A good many changes have occurred in the membership of the branch during the year. Two new names, those of R. W. Hibberson, a.m.e.i.c., and Major J. C. MacDonald, m.e.i.c., have been added to the roll, but a number of members have left the city or severed their connection with the branch, the Executive particularly regretting the loss of several members by the removal of their names from The Institute roll for non-payment of dues.

The Executive is sorry to report that two members, J. MacGowan, and F. C. Gamble, past president of The Institute, died during the year.

Membership

The branch membership is as follows:—

	Resident	Non-Resident
Members	25	4
Associate Members	30	5
Juniors	1	..
Students	2	..
Branch Affiliates	1	..
	—	—
	59	9

The total branch membership is 68, compared with a reported total of 89 last year.

Management

The branch executive for the year has been:—

Chairman	J. N. Anderson, a.m.e.i.c.
Vice-Chairman	M. P. Blair, m.e.i.c.
Secretary-Treasurer	E. G. Marriott, a.m.e.i.c.
Executive	E. E. Brydone-Jack, m.e.i.c.
	R. F. Davy, a.m.e.i.c.
	E. P. Girdwood, m.e.i.c.
	P. Philip, m.e.i.c.
Ex-officio	F. C. Green, m.e.i.c., councillor
	G. B. Mitchell, m.e.i.c., past chairman

The Executive held seven meetings during the year, at which branch business was attended to.

The convenors of committees for the year were as follows:—

Papers	F. L. Macpherson, m.e.i.c.
Social	W. M. Everall, a.m.e.i.c.
Library	F. W. Knewstubb, a.m.e.i.c.
Town Planning	M. P. Blair, m.e.i.c.
Publicity	G. B. Mitchell, m.e.i.c.

The whole Executive acted as Attendance, Legislation, and Credentials committees.

F. W. Knewstubb, convenor of the Library Committee, reports the discontinuance of the subscription to the Contract Record, in lieu of which the proceedings of the American Society of Civil Engineers are being obtained; it is also noted that the Engineering News-Record, Scientific American, and The Institute Journal have been arranged in half-yearly volumes.

Meetings

The branch has been fortunate this last year in having an excellent series of addresses, lunches and outings, beginning on December 9th with a description of **"Engineering Life in Nicaragua, Peru and Chile,"** by G. B. Mitchell, m.e.i.c., who gave an account of his experiences in these countries, with many interesting references to the customs, climate and natural history that came under his observation.

In January, J. P. Forde, m.e.i.c., district engineer for the Dominion Public Works, took us by word and picture to the land of glacier and mountain, where nature is slowly presenting a new Pacific port to Canada at Tarr Inlet, Glacier bay, Alaska.

There were attendances of over forty at each of the February meetings, when addresses were given as follows: **"Earthquakes,"** by F. Napier Denison of the Gonzales Hill Meteorological Observatory, and **"The Mining Industry in British Columbia,"** by J. P. Galloway, provincial mineralogist.

At a lunch on February 22nd some thirty engineers gathered to offer congratulations to E. A. Cleveland, m.e.i.c., on his appointment as commissioner of the Greater Vancouver Water Board, and chairman of the Vancouver and District Joint Sewerage and Drainage Board.

At an evening meeting in March, J. H. McIntosh, s.e.i.c., explained the details of **"The Manufacture of Portland Cement as Practised at Bamberton"**; the display of a good range of samples of materials used, and of the product at different stages in the process of manufacture added to the interest of his paper.

A visit to the central Victoria fire hall the same month, at the invitation of Fire Chief Stewart, gave the members an opportunity to learn something of this part of the city service.

The **"Pacific Great Eastern Railway"** was the subject of an address by T. Kilpatrick, general manager of the line, at a meeting on March 31st.

In April members of the branch witnessed the launching of the second caisson for the Songhees graving dock, upon the invitation of N. A. Yarrow, a.m.e.i.c., and four days later a large party motored to Tod Inlet, where the ladies of the party enjoyed the renowned gardens of Mr. and Mrs. R. P. Butchart, while the men crossed over to Bamberton and made a thorough inspection of the cement works.

Between these two outings, P. Philip, m.e.i.c., deputy minister of public works, presented a paper on **"The New Fraser Canyon Section of the Cariboo Road."**

On June 30th the members of the branch entertained General Secretary R. J. Durley, m.e.i.c., to lunch, and took the opportunity of obtaining first-hand information regarding Institute affairs.

A series of moving pictures illustrating the construction and development of roads in the province, and the various industries that make use of them, was appreciated by many members on August 13th. The picture was exhibited through the courtesy of P. Philip, m.e.i.c.

In September a visit of unusual interest that attracted some fifty members and their friends was paid to the cable ship "Restorer," when Captain Livingstone and his officers explained the details of cable laying and repairing and the particular design of ship required for this work. Tea was served on board to the visitors.

The first October meeting was addressed by Mr. Doyle, works superintendent of the British America Paint Company, who gave those present a lot of very useful information on the materials used in the manufacture of paints and varnishes, with expert hints as to their advantages and disadvantages.

October 19th witnessed one of the outstanding events of the branch activities when His Honour R. R. Bruce, Lieutenant-Governor of the province, who is an engineer, was entertained at a luncheon of members of The Institute, and of the British Columbia Association of Professional Engineers. His Honour's reminiscences, review of engineering progress in Canada and the province, and suggestions for the future were much appreciated.

Nominations for the Executive for the present year took place on November 3rd, and after business was disposed of Major J. C. MacDonald, comptroller of water rights, drew upon his seven years' experience in the Okanagan, to give a survey of the irrigation, production and marketing problems that faced the growers of the Okanagan valley and adjoining districts, and outlined the various methods that had been adopted to meet succeeding difficulties as they occurred.

It was suitable that the last meeting should be an engineering luncheon on November 16th, at which the guest was Major Geo. A. Walkem, M.E.I.C., president of The Institute, and president of the British Columbia Association of Professional Engineers. Major Walkem spoke of the environment and progress of several branches of The Institute, incidentally giving interesting glimpses of industrial expansion at many points in the Dominion.

FINANCES

The branch's financial statement shows an increase in the balance on hand, which is largely owing to the payment of back dues to The Institute, the branch receiving a larger sum in rebates than usual.

FINANCIAL STATEMENT

For year ending November 3rd, 1926

Receipts

Balance on hand, Dec. 1st, 1925	$ 63.25	
Branch dues, 1925	3.00	
Branch dues, 1926	124.50

E. DAVIS, M.E.I.C., *Chairman.*
KENNETH M. CHADWICK, M.E.I.C., *Secretary-Treasurer.*

Winnipeg Branch

The President and Council,—

The following report of the Winnipeg Branch is respectfully submitted:—

MEMBERSHIP

	Resident	Non-Resident	Total
Members	41	2	43
Associate Members	116	19	135
Juniors	14	4	18
Students	37	3	40
Affiliates	3	..	3
Branch Affiliates	10	..	10
Total	221	28	249

MEETINGS

Thirteen regular meetings were held according to the following list:—

Jan. 7.—"**Wood Destroying Fungi,**" by R. D. Prittie. Attendance 56.
Feb. 4.—"**Winter Operation of Motor Vehicles,**" by J. W. Dorsey. Attendance 64.
Feb. 18.—"**Story of Diphtheria,**" by Dr. J. A. Douglas. Attendance 27.
Mar. 4.—"**Advances in Artificial Illumination,**" by S. S. Vineberg, JR.E.I.C. Attendance 29.
Apr. 1.—"**Concrete Control,**" by L. J. Street, AFFILIATE E.I.C. Attendance 50.
Apr. 15.—"**Electrolytic Methods in Industry,**" by J. W. Sanger, A.M.E.I.C., and A. J. McDougall. Attendance 40.
May 6.— Annual meeting and election of officers. Attendance 40.
Oct. 7.—"**Foundations and Foundation Problems,**" by A. W. Fosness, A.M.E.I.C. Attendance 39.
Oct. 21.—Visit to plant of Canada Malting Company, Limited. Attendance 29.
Nov. 4.—"**Explosive Gases in Electric Boilers,**" by Dr. J. W. Shipley and C. F. Goodeve. Attendance 78.
Nov. 18.—"**Prospects for Mining in Manitoba,**" by Dr. J. S. Delury. Attendance 37.
Dec. 2.—"**Strength of Ice in Shear and Compression,**" by J. N. Finlayson, M.E.I.C., and H. E. Treble, S.E.I.C. Attendance 36.
Dec. 16.—"**The Automatic Telephone in Winnipeg,**" by E. H. Williams, and visit to the Sherbrooke street Exchange. Attendance 39.

In February the branch, jointly with the Association of Professional Engineers, entertained Major Geo. A. Walkem, M.E.I.C., president of The Institute, at a social evening in the Marlborough hotel.

In June the branch welcomed R. J. Durley, M.E.I.C., the general secretary, on his official visit.

In July the branch was represented at a joint meeting of the Saskatchewan branches of the E.I.C., A.I.E.E., and C.I.M. & M., at Estevan, where a very instructive and enjoyable convention took place.

In August over forty, including families, accepted the kind invitation of the Federation of Engineers and Architects of the adjoining States to meet with them at Duluth, where a most interesting and pleasant time was spent. In 1925 the convention was held in Winnipeg, and in 1927 a large number plan to accept the invitation to meet in St. Paul. On each occasion the branch was joined by members of the other engineering and mining bodies and the local architects, and it is earnestly hoped that the event will develop into an annual one, meeting from time to time in Winnipeg. The benefits arising from such meetings between engineers, whose problems are so similar, are many and far-reaching.

The branch has accepted the kind invitation of the local branch of the Canadian Institute of Mining and Metallurgy to join them in entertaining the members of the British Empire Mining Congress and British Iron and Steel Institute on their trans-Canadian tour, when they stop off in Manitoba next summer.

This has been the transition year when the official year of the branch, formerly closing in May, has been made to conform with that of headquarters. Hitherto considerable confusion has occurred due to them overlapping.

During the year the branch completed the revised by-laws, which have not as yet been formally approved by headquarters.

The following is a brief financial statement and is in detail only from May 6th, the close of the branch year 1925-26:—

FINANCIAL STATEMENT

Receipts

Bank balance, May 6th	$ 772.35	
Cash on hand	10.72	
Local dues received	361.50	
Rebates from headquarters	404.44

Bond interest	27.50	
Miscellaneous adjustments	23.37	
		$1,623.27

Expenditures

Total expenditures	$ 490.15	
Balance on hand	1,133.12	
		$1,623.27

Respectfully submitted,

N. M. HALL, M.E.I.C., *Chairman.*
JAMES QUAIL, A.M.E.I.C., *Secretary-Treasurer.*

THE
ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME X MARCH 1927 No. 3

The Report of the Joint Board of Engineers on the St. Lawrence Waterway Project

The text of this Report, (apart from the appendices), dated November 16th, 1926, is now available to the public, and, as might be expected in the case of any communication from such a distinguished body of engineers, merits the most careful study.

The personnel of the Joint Board consisted of an American and a Canadian section, the former composed of three officers of the United States Corps of Engineers, (Major-General Jadwin, Colonel Kelly and Lieut.-Colonel Pillsbury), the latter having as its members Messrs. D. W. McLachlan, O. O. Lefebvre, and Brigadier-General C. H. Mitchell, all Members of The Institute.

The Board's instructions touched on practically all the pressing engineering questions connected with the St. Lawrence river and the Great Lakes which have concerned the public of Canada and the United States so greatly during the past few years. It is important to note that while these instructions directed the Board to outline the works best adapted to give certain results, the Board was not asked for, and does not express, any opinion regarding the advisability of undertaking such works.

Questions relating to the improvement of the St. Lawrence between lake Ontario and Montreal for navigation and power purposes were referred to the International Joint Commission in 1920, and in 1921 a technical report by Colonel W. P. Wooten, United States Corps of Engineers, and the late Mr. W. A. Bowden, chief engineer of the Department of Railways and Canals, Ottawa, was submitted to the International Joint Commission. This Report of 1921, of course, formed part of the data available for the Joint Board's consideration. It estimated the cost of a 25-foot navigation channel between lake Ontario and Montreal at some two hundred and fifty million dollars, this figure including a power development of nearly two million horse power (installed capacity). As a matter of fact, the Joint Board of Engineers broadly endorses the Report of 1921, but recommends a number of important additions and modifications, which, while increasing the estimated cost, would, in the Board's opinion, provide to the best advantage for the development of the full capacity and possibilities of the waterway. The plans now suggested by the Board, would provide all the facilities contemplated in the Report of 1921, and would also render possible, first, the development of the entire power possibilities of the International Rapids Section of the river, (48 miles of rapids terminating at the head of lake St. Francis); secondly, the progressive development of power in addition to navigation facilities in the Soulanges section, (that between lake St. Francis and lake St. Louis); and, thirdly, important improvements in the navigation canal and in the control works at lake St. Louis affecting the section just below Montreal Harbour.

The total estimated cost of the works now outlined, (exclusive of interest during construction), is in the neighbourhood of four hundred million dollars. This amount would provide for a 25-foot navigation channel and the immediate development of more than two and a half million installed horse power. Subsequent complete development of the power resources of the river, with an additional installed capacity of another two and a half million horse power, would involve a further expenditure of about two hundred and twenty-five million dollars.

In treating of the vexed question of change of water levels in the river and on the Great Lakes, the Board is of the opinion that if the improvements they describe were constructed and operated under adequate government supervision they could be so controlled as neither to lower the summer levels in the lower river nor raise the winter and spring levels. The Board points out that the levels of the Great Lakes above lake Ontario cannot be affected by any works in the St. Lawrence proper.

The Board's study of the effect of the various diversions of water from the Great Lakes has led to the interesting conclusion that the diversion by the Chicago Sanitary District of 8,500 cu. ft. per second through the Chicago Drainage Canal, as licensed by the United States government, has lowered the water levels of the Great Lakes by from four- to five-tenths of a foot, and has had a lesser but very definite effect on points lower down, lowering the water level in Montreal Harbour by 0.37 ft. The effect of other diversions, including those for navigation and other purposes, is also dealt with in detail.

The Board finds further that the effect of the authorized diversions on the St. Lawrence water level at and below Montreal could be restored by dredging and accessory works at an estimated cost of between four and five million dollars, and points out that after the river has been fully developed for power production, no works could be constructed which would recover on the St. Lawrence the power lost by the diversion of water from the watershed.

It is considered that compensating works would be preferable to regulating works for the purpose of restoring the water levels of lakes Michigan, Huron and Erie, while the effect of the diversions on the levels of the lakes and the St. Lawrence above Montreal could be removed by the works provided for the improvement of this part of the St. Lawrence.

The Report regards it as essential that not only should the works within the international sections be designed and constructed under the technical supervision of an international authority, but that an international control board should be created, having full power to regulate the use of water by the power plants in the international sections, in order that such use may be prevented from creating conditions harmful to navigation, and so that the requirements of all the power plants on the river may be fully met at all times.

It is estimated that the new waterway could be opened to navigation in from seven to eight years from the time that active work is begun.

The Joint Board received its instructions from the United States and Canadian governments almost two years ago, and while a large volume of data collected for the Report of 1921 and for other purposes was available, it was found necessary to conduct a comprehensive programme of investigation, including borings, surveys and discharge meterings, which was completed in the summer of 1926. The Canadian section of the Board carried on in the winter an extensive set of temperature measurements to determine the rate of loss of heat in the river, and made a series of experiments to ascertain the resistance of ice as bearing on the design of dams. The Appendices to the Report, which will shortly be available, describe the Board's investigations more fully.

The result of the Board's labours is a lucid, authoritative document, bearing evidence of thorough study and expressing the verdict of a sound and mature judgment. The Report gives us a series of definite statements which should do much to remove the possibility of misunderstanding and afford a firm basis for international negotiations.

Award of Gzowski Medal

LESSLIE R. THOMSON, M.E.I.C.

The award of the Gzowski Medal, for the season 1925-1926, which was announced in the report of the Gzowski Medal Committee at the Annual Meeting of The Institute in Quebec on February 15th, was made to Lesslie R. Thomson, M.E.I.C., consulting engineer, Montreal, for his paper, "The Fuel Problem in Canada," presented at the Annual General Meeting of The Institute in Toronto on January 29th, 1926, and published in the Engineering Journal in February 1926.

Mr. Thomson's early education was received at Upper Canada College, Toronto, following which he attended the University of Toronto, graduating in mechanical engineering in 1905 and civil engineering in 1907. He later received his degree of B.A.Sc. after the completion of a course of study specializing in hydraulics and strength of materials.

During the summers of his university course he was assistant engineer with the late Jos. Rielle, of Montreal, and, following graduation, he was appointed, in 1910, lecturer in civil engineering of the University of Manitoba. Two years later he joined the Dominion Bridge Company, Montreal, as assistant engineer, remaining with this company for six years.

In 1918 Mr. Thomson was secretary to the Advisory Research Council at Ottawa, and was for six years secretary of the Lignite Utilization Board. In 1921 he was appointed special lecturer in structural engineering in the department of architecture at McGill University, which position he still holds. About two years ago he entered private practice in Montreal.

Mr. Thomson joined The Institute as an Associate Member on April 8th, 1911, and was transferred to the grade of Member on January 24th, 1919. He is also a member of the American Society of Civil Engineers, the Corporation of Professional Engineers of Quebec and a charter member of the Association of Consulting Engineers of Canada.

Mr. Thomson has made many contributions to technical literature, among which are:—"The Rolling and Floating Caissons of the Levis Dry Dock," presented to the Engineering Institute of Canada in 1915; "Transmission Lines, Poles and Towers," presented to the Engineering Institute of Canada in 1916; "The Briquetting of Lignites," presented to the Society of Chemical Industry in 1921; "Fuel Problem of Canada," presented to the Engineering Institute of Canada in January 1926, and "Low Temperature Semi-Coke in Briquetted Form as a Domestic Fuel," prepared in conjunction with Mr. C. V. McIntire, New York, and presented to the American Chemical Society in September 1926. He was also responsible for the first general report of the Lignite Utilization Board of Canada, published in March 1924.

A Disclaimer

With reference to the paper by Mr. Theo. C. Denis on the Mineral Deposits of the Rouyn-Harricana Region, presented at the recent Quebec Meeting and published in the Engineering Journal for February, we are informed that a firm of financial agents has addressed a letter-circular to all members of The Institute, in which allusion is made to Mr. Denis' paper; the circular suggests that members of The Institute should at once invest in a certain mining property in the district in question.

It is hardly necessary to point out that use of the article in the Journal in this manner has not been authorized, nor does it meet with the approval of either The Institute or the author of the paper. In this connection, it is thought desirable to call attention to the warning contained in the fourth paragraph from the end of Mr. Denis' paper.

The Forty-first Annual General and General Professional Meeting

Convened at Headquarters, Montreal, January 27th, and Adjourned to Quebec, February 15th, 16th and 17th, 1927

Annual General Meeting—Montreal Session

The Forty-first Annual General Meeting of The Institute was held at Headquarters on Thursday evening, January twenty-seventh, nineteen hundred and twenty-seven. Vice-President K. B. Thornton, M.E.I.C., took the chair at eighty-thirty p.m.

Reading of Minutes

The minutes of the fortieth annual general meeting were submitted, and on motion of Geo. R. MacLeod, M.E.I.C., seconded by J. L. Busfield, M.E.I.C., were taken as read, and confirmed.

Appointment of Scrutineers

On motion of J. T. Farmer, M.E.I.C., seconded by J. G. Caron, A.M.E.I.C., Messrs. L. T. G. Boisseau, A.M.E.I.C., and H. G. Thompson, Jr.E.I.C., were appointed scrutineers to report the result of the Officers' ballot.

Forty-First Annual General and General Professional Meeting of The Engineering Institute of Canada, Held at Quebec on the 15th, 16th and 17th February, 1927.

Appointment of Auditors

On motion of C. K. McLeod, A.M.E.I.C., seconded by J. A. Burnett, M.E.I.C., Messrs. Riddell, Stead, Graham and Hutchison were appointed auditors for the ensuing year.

There being no other formal business, it was resolved, on motion of J. L. Busfield, M.E.I.C., seconded by H. Massue, A.M.E.I.C., that the meeting should adjourn, to reconvene on Tuesday, February fifteenth, nineteen twenty-seven, at ten a.m., at the Chateau Frontenac, Quebec, Que.

The meeting adjourned at eight forty-five p.m.

Quebec Sessions

The meeting was called to order by Vice-President K. B. Thornton, M.E.I.C., at ten o'clock on February 15th, 1927, in the Jacques Cartier Room of the Chateau Frontenac, Quebec City. The Secretary read a telegram from President Geo. A. Walkem, M.L.A., M.E.I.C., expressing his regrets at being unable to be present, owing to the legislature of British Columbia being in session, and extending his good wishes.

Reading of Minutes

The secretary read the minutes of the formal business meeting held in Montreal on January 27th, 1927, which were adopted.

Reports of Council and Committees

In presenting the Report of Council for 1926, as published on page 138 of the March issue of the Journal, the chairman drew attention to Council's recommendation regarding the provision of facilities for councillors residing at a distance from Headquarters to attend a meeting of Council at least once a year, and also remarked on the sound financial condition disclosed by the Finance Committee's report, this being due to the action of Council in removing from the membership roll members seriously in arrears. On the motion of Brig.-Gen. C. H. Mitchell, M.E.I.C., seconded by E. A. Forward, M.E.I.C., the report of Council was adopted.

The report of the Legislation and By-laws Committee was presented by Geo. R. MacLeod, M.E.I.C., who outlined the reasons for recommending the amendments to the By-laws contained in the report, these amendments having been printed in the Journal on page 140 of the March issue. On motion by Geo. R. MacLeod, M.E.I.C., seconded by J. L. Busfield, M.E.I.C., the report was adopted, the secretary being instructed to send out the amendments for vote by the membership in accordance with section 76 of the By-laws.

The chairman stated that Council had appointed J. A. Burnett, M.E.I.C., as chairman of the Nominating Committee for 1927, and announced the membership of the committee as printed on page 140 of the March issue of the Journal.

After a brief discussion the report of the Finance Committee, as published on page 141 of the March issue of the Journal, was approved on the motion of F. P. Shearwood, M.E.I.C., seconded by J. A. McCrory, M.E.I.C.

The report of the Papers Committee, as published on page 143 of the March issue of the Journal, was presented by J. L. Busfield, M.E.I.C., who pointed out that the committee had in several cases been able to arrange for speakers to make tours, during which they addressed meetings at several branches. W. J. Johnston, A.M.E.I.C., considered that the Papers Committee should include a representative from each branch, but expressed his willingness to withdraw the paragraph in the report as printed emphasizing his views on this point. Mr. Johnston also pointed out that it was the duty of the branch secretary or the branch representative on the Papers Committee to see that copies of important papers presented at branches are forwarded to Headquarters for possible publication, or reference, or so as to be available for use for other branches. Brig.-Gen. Mitchell suggested that the report, if adopted, should carry the recommendation that expenses incurred by writers of papers, if presented at distant branches, should be covered to a certain extent by an appropriation by Council. On the motion of J. L. Busfield, M.E.I.C., seconded by C. H. Wright, M.E.I.C., the report was adopted, with a special recommendation to the incoming Council to give the above suggestions careful consideration.

The report of the Publications Committee, as published on page 143 of the March issue of the Journal, was adopted on the motion of J. L. Busfield, M.E.I.C., seconded by Geo. R. MacLeod, M.E.I.C.

The report of the Library and House Committee, as published on page 143 of the March issue of the Journal, was adopted on the motion of Geo. R. MacLeod, M.E.I.C., seconded by Major Stuart Howard, M.E.I.C.

On the motion of Geo. R. MacLeod, M.E.I.C., seconded by J. W. Seens, A.M.E.I.C., the report of the Board of Examiners and Education, as published on page 144 of the March issue of the Journal, was adopted.

The secretary read the report of the Gzowski Medal Committee, and on the motion of C. K. MacLeod, A.M.E.I.C., seconded by J. W. Seens, A.M.E.I.C., this report, together with those of the Leonard Medal, Plummer Medal and Students' Prizes Committees, as published on page 145 of the March issue of the Journal, were adopted.

In moving the adoption of the report of the Committee on International Co-operation, as published on page 146 of the March issue of the Journal, J. B. Challies, M.E.I.C., referred to the excellent work of this committee in connection with the visit of the International Electrotechnical Commission. On his motion, seconded by L. C. Dupuis, A.M.E.I.C., the report was adopted.

The report of the Canadian National Committee of the International Electrotechnical Commission, as published on page 146 of the March issue of the Journal, was adopted on the motion of J. B. Challies, M.E.I.C., seconded by Geo. R. MacLeod, M.E.I.C.

On the motion of F. P. Shearwood, M.E.I.C., seconded by J. W. Seens, A.M.E.I.C., the report of the Code of Ethics Committee, as published on page 147 of the March issue of the Journal, was adopted.

The report of the Honour Roll and War Trophies Committee, as published on page 147 of the March issue of the Journal, was adopted on the motion of Brig.-Gen. C. H. Mitchell, M.E.I.C., seconded by P. L. Pratley, M.E.I.C.

On motion of P. L. Pratley, M.E.I.C., seconded by L. C. Dupuis, A.M.E.I.C., the report of The Institute's Members of the Main Committee of the Canadian Engineering Standards Association, as published on page 147 of the March issue of the Journal, was adopted.

The report of the Committee on Deterioration of Con-

Quarante-et-Uniéme Assemblée Générale Annuelle et Général Professionel de L'Institut des Ingénieurs du Canada, Tenus à Québec, les 15, 16 et 17 Février, 1927.

crete in Alkali Soils, as published on page 148 of the March issue of the Journal, was adopted on the motion of Geo. R. MacLeod, M.E.I.C., seconded by J. W. Seens, A.M.E.I.C.

On the motion of K. M. Cameron, M.E.I.C., seconded by L. C. Dupuis, A.M.E.I.C., the report on the work of the Committee on Young Graduates, as published on page 149 of the March issue of the Journal, was adopted.

Branch Reports

The reports of the various branches, as published on pages 150 to 167 inclusive of the March issue of the Journal, were presented and briefly commented upon by branch representatives present, as follows:—Halifax Branch, C. H. Wright, M.E.I.C.; Toronto Branch, J. W. Falkner, A.M.E.I.C.; Border Cities Branch, C. M. Goodrich, M.E.I.C.; Quebec Branch, W. G. Mitchell, M.E.I.C.; Ottawa Branch, K. M. Cameron, M.E.I.C.

Mr. Busfield drew attention to the inconvenience arising from the facts that the various branch executive committees take office at different times of the year, and that branch fiscal years do not commence at the same time; he hoped that the Legislation and By-laws Committee would be asked to give consideration to this matter, and that the branches would be communicated with, to see if some uniform arrangement could not be made. C. K. MacLeod, A.M.E.I.C., did not think that a branch fiscal year need necessarily end on the same date as that of The Institute as a whole, but he thought that they should all end on the same date. After a brief discussion, and with the inclusion of this recommendation, the branch reports were adopted, on motion by J. W. Seens, A.M.E.I.C., seconded by C. K. MacLeod, A.M.E.I.C.

Retiring President's Address

The secretary read the retiring president's address, and on the motion of J. L. Busfield, M.E.I.C., seconded by Geo. R. MacLeod, M.E.I.C., a telegram was sent to Major Geo. A. Walkem, M.L.A., M.E.I.C., thanking him for his address and his work during the year, and regretting that he was unable to be present.

The meeting adjourned at 12:10 noon.

On re-assembling at 2:00 p.m., the report of the Committee on Engineering Education, as published on page 145 of the March issue of the Journal, was presented by its chairman, Frederick B. Brown, M.E.I.C., who drew attention to the magnitude of the problems before the committee, and their importance, not only to The Institute, but to the various Associations of Professional Engineers and to the universities. He expressed the hope that these bodies, as well as The Institute, would offer every possible assistance to the Society for the Promotion of Engineering Education. Active discussion took place upon the various problems and questions outlined in the report, important contributions being made by Brig.-Gen. C. H. Mitchell, M.E.I.C., Calvin W. Rice, secretary of A.S.M.E., L. W. Gill, M.E.I.C., Dr. A. Frigon, A.M.E.I.C., Geo. T. Seabury, secretary of A.S.C.E., A. A. Bowman, M.E.I.C., C. H. Wright, M.E.I.C., W. G. Chace, M.E.I.C., D. C. Tennant, M.E.I.C., and Prof. A. F. Baird, A.M.E.I.C. On the motion of Frederick B. Brown, M.E.I.C., seconded by J. C. Craig, M.E.I.C., the report on Engineering Education was adopted.

Election of Officers

The secretary read the report of the scrutineers, announcing the election of officers as follows:—

President	A. R. Decary, M.E.I.C.
Vice-Presidents:	
Zone A	S. G. Porter, M.E.I.C.
Zone C	J. H. Hunter, M.E.I.C.
Councillors:	
Victoria Branch District	J. N. Anderson, A.M.E.I.C.
Vancouver Branch District	E. A. Cleveland, M.E.I.C.
Calgary Branch District	A. L. Ford, M.E.I.C.
Edmonton Branch District	R. W. Boyle, M.E.I.C.
Lethbridge Branch District	P. M. Sauder, M.E.I.C.
Saskatchewan Branch District	H. R. MacKenzie, A.M.E.I.C.
Winnipeg Branch District	A. McGillivray, A.M.E.I.C.
Lakehead Branch District	J. Antonisen, M.E.I.C.
Sault Ste. Marie Branch District	C. H. E. Rounthwaite, A.M.E.I.C.
Border Cities Branch District	J. Clark Keith, A.M.E.I.C.
Niagara Peninsula Branch District	E. P. Johnson, A.M.E.I.C.
London Branch District	W. C. Miller, A.M.E.I.C.
Hamilton Branch District	W. F. McLaren, M.E.I.C.
Toronto Branch District	T. R. Loudon, M.E.I.C.
Kingston Branch District	L. F. Grant, A.M.E.I.C.
Peterborough Branch District	R. L. Dobbin, M.E.I.C.
Ottawa Branch District	A. F. Macallum, M.E.I.C.
Montreal Branch District	W. C. Adams, M.E.I.C.
	P. L. Pratley, M.E.I.C.
Quebec Branch District	A. B. Normandin, A.M.E.I.C.
Saguenay Branch District	G. F. Layne, A.M.E.I.C.
Moncton Branch District	H. W. McKiel, M.E.I.C.
Saint John Branch District	Geoffrey Stead, M.E.I.C.
Cape Breton Branch District	W. C. Risley, M.E.I.C.
Halifax Branch District	K. L. Dawson, A.M.E.I.C.

Inauguration of Newly-Elected President

The chairman requested C. H. Wright, M.E.I.C., and W. G. Chace, M.E.I.C., to conduct the incoming president to the chair. The newly-elected president, A. R. Decary, M.E.I.C., of Quebec City, accordingly took the chair, and in a few words expressed his appreciation of the honour done him, and his pleasure at the hearty welcome accorded to him.

Votes of Thanks

On the motion of A. A. Bowman, M.E.I.C., seconded by C. K. MacLeod, A.M.E.I.C., it was resolved to extend to the scrutineers a vote of thanks for their efficient work in connection with their duties.

On the motion of Brig.-Gen. C. H. Mitchell, M.E.I.C., seconded by W. G. Chace, M.E.I.C., it was unanimously resolved that the secretary convey to the officers and members of the Quebec Branch the thanks and appreciation of The Institute on the occasion of the Forty-First Annual General Meeting, expressing appreciation of the efficient manner in which the arrangements for the annual meeting had been made, and gratitude for their generous hospitality.

There being no further business, the meeting adjourned at 5:15 p.m.

Annual General Professional Meeting

The first session of the General Professional Meeting was held at 10 a.m. on Wednesday, February 16th, 1927, when the Hon. H. Mercier, Minister of Lands and Forests, province of Quebec, delivered a brief introductory address. Following Mr. Mercier's address technical sessions were held in the Jacques Cartier Room under the chairmanship of Major J. A. Duchastel, M.E.I.C., and in the Committee Room under the chairmanship of W. G. Mitchell, M.E.I.C., when the following papers were respectively presented:—

"Notes on the Forests of Quebec," by G. C. Piché, A.M.E.I.C.

"The Wood Consuming Industries of Canada," by John Stadler, M.E.I.C.

"Woodlands Management and Operation," by S. L. deCarteret, M.E.I.C.

"Transportation in Pulpwood Operations," by G. E. LaMothe, A.M.E.I.C.

"Electrical Characteristics of Quebec-Isle Maligne Transmission Line," by Prof. C. V. Christie, M.E.I.C.

"Alternating Current Electrolysis," by Prof. J. W. Shipley and Chas. F. Goodeve.

"Building an Industrial Plant in the Saguenay District," by John L. Guest, A.M.E.I.C.

"Protection Against Seepage at Lake Kenogami," by O. O. Lefebvre, M.E.I.C.

Active discussion took place, particularly on the papers dealing with forestry problems, and it was therefore necessary to defer the consideration of the papers by Messrs. deCarteret and LaMothe to the afternoon of Thursday.

The Meeting was resumed on Thursday morning when the following papers were presented and discussed under the chairmanship of J. B. Challies, M.E.I.C.:—

"Rack Structure and Penstock Intake of the Isle Maligne Hydro-Electric Power Station," by W. S. Lee, M.E.I.C.

"The Water Power Developments of the Alouette-Stave-Ruskin Group," by E. E. Carpenter, M.E.I.C.

"Hydro-Electric Developments on the Gatineau River," by J. A. McCrory, M.E.I.C.

In the afternoon, previous to the consideration of two mining papers by Theo. C. Denis on "Notes on the Ore Deposits of Western Quebec," and W. R. Rogers, A.M.E.I.C., on "The Metal Mining Industry of Northern Ontario," the Hon. J. E. Perrault, Minister of Mines, Province of Quebec, gave a brief introductory address.

Luncheons

At noon on Tuesday, February 15th, a complimentary luncheon to the visiting members was given by the members of the Quebec Branch, in the Riverview Dining Room of the Chateau Frontenac, when some two hundred were present. At this luncheon the members were welcomed by the chairman of the Quebec Branch, A. B. Normandin, A.M.E.I.C., and His Worship Mayor Martin, of Quebec, in speeches in both French and English. The Hon. W. Gerard Power, chairman of the Quebec Harbour Commissioners, gave a short address outlining the development of the Port of Quebec during the last two years, referring to the important part played by the engineers in this work.

At the same time the visiting ladies were the guests of the Quebec Branch at a luncheon held in the Private Dining Room, at which Mrs. S. L. deCarteret, chairman of the Ladies' Committee, presided, and in a very pleasing address welcomed the visiting ladies.

Smoker

Commencing at 8:30 p.m. on Tuesday, February 15th, a complimentary smoker for the visting members was held, and proved a most enjoyable function. It was originally intended to hold this event in the Riverview Dining Room, but on account of the large attendance the Ball Room had to be used. During the course of a continuous cabaret entertainment light refreshments were served.

Theatre Party for Ladies

On the same evening while the smoker was in progress the visiting ladies were entertained at a theatre party at the Auditorium.

Visit to the Quebec Bridge

On Wednesday, February 16th, at 2:00 p.m., the members gathered on the Dufferin Terrace, where the convention photograph was taken; embarking immediately afterwards on special cars provided by the Quebec Power Company for conveyance to the wharf where the Government Icebreaker "Mikula" was lying with steam up, ready to demonstrate its power in forcing a passage through the solid ice at the mouth of the St. Charles river and through the large ice floes in the tideway of the St. Lawrence. The "Mikula" left at 2:45 p.m. and steamed without any difficulty up the river as far as the Quebec bridge, returning to the dock shortly after 5 p.m. This instructive and interesting excursion was made possible through the courtesy of the officers of the Department of Marine and Fisheries, and afforded a most convincing illustration of the capabilities of the modern ice-breaking steamer.

During Wednesday afternoon the visiting ladies were the guests of the Quebec Ladies' Musical Club, where a most enjoyable programme was given.

Annual Dinner

The outstanding function of the meeting was the Annual Dinner, which was held in the Ball Room on Wednesday evening, February 16th, at which the newly-elected president, A. R. Decary, M.E.I.C., took the chair. The principal speaker of the evening was Sir Henry Worth Thornton, M.E.I.C., President, Canadian National Railways, whose address, while vibrant with humour, carried the message of the importance of a knowledge of the classics and general cultural subjects as an essential to the progress and advancement of the successful engineer. Previous to Sir Henry Thornton's speech, Sir François Lemieux, Administrator of the province of Quebec, delivered a felicitous address in both French and English. Other speakers of the evening were:—Mgr. Camille Roy, Rector of Laval University, Quebec; the Hon. Lucien Cannon, Solicitor-General, Ottawa; the Hon. J. L. Perron, Minister of Roads, province of Quebec; Mr. Calvin W. Rice, Secretary, American Society of Mechanical Engineers; and Mr. Geo. T. Seabury, Secretary, American Society of Civil Engineers.

On the same evening, Mrs. S. L. deCarteret presided at a dinner given to the ladies, which was largely attended and very much enjoyed. At its close, Mrs. A. F. Byers of Montreal, on behalf of the visiting ladies, thanked the ladies of Quebec in a happy speech for their most generous hospitality, after which the company adjourned to the gallery of the Ball Room, and heard the speeches at the Annual Dinner of The Institute.

Visit to Anglo-Canadian Pulp and Paper Mills

At noon on Thursday, February 17th, through the courtesy of W. I. Bishop, M.E.I.C., the members were given an opportunity to visit the Anglo-Canadian Pulp and Paper Mills under construction at Limoilou, Que., where they were entertained at luncheon at the company's canteen on the mill site, and were able to inspect the construction work of the new mills.

Afternoon Tea for Ladies

On the afternoon of Thursday, February 17th, the visiting ladies were entertained at tea.

Supper-Dance and Bridge

The closing function of the meeting was the Supper-Dance and Bridge, which was held in the Ball Room on the evening of Thursday, February 17th. Dancing commenced at 8:30 p.m. and supper was served at midnight. This proved one of the most enjoyable functions, and was a fitting climax to the other delightful social events of the meeting.

Albert R. Decary, M.E.I.C.

President, The Engineering Institute of Canada

A keen devotion to high standards coupled with the utmost energy and persistence towards reaching a goal are characteristic of both the engineering works and professional activities of Albert R. Decary, M.E.I.C., President of the Engineering Institute of Canada for the year nineteen hundred and twenty-seven, and are reflected in the services he faithfully rendered during twenty-seven years to one of the largest engineering organizations in the Dominion of Canada as well as to The Institute and the profession.

Mr. Decary was born in Montreal, Que., on the twenty-first day of October, eighteen hundred and seventy-five. He received his education at the St. Mary's College, (Jesuits), in Montreal, and at the Ecole Polytecnique de Montréal. After a few years of private practice in that city, he became associated with the Department of Public Works of Canada, for which he was engaged in hydrographic work on the St. Lawrence river, between Kingston and Quebec, from 1900 to 1905. At that date, he was appointed district engineer at Quebec, which office he held until 1913, when he became superintending engineer, having jurisdiction over the province of Quebec for the Department of Public Works of Canada.

He was intimately connected with all the important river and harbour works made by the Dominion Government since 1900, including the Champlain dry dock, at Quebec, and the New Esquimalt dry dock, in British Columbia; in connection with this latter big undertaking, he was chairman of the Board of Engineers specially entrusted with the designing and preparation of all plans.

ALBERT R. DECARY, M.E.I.C.

It was in 1900 that Mr. Decary joined the Engineering Institute of Canada, having been elected an Associate Member, and in 1907 that he was transferred to the grade of Member. From the beginning, he took a most active interest in the affairs of the organization and played a prominent part in all matters pertaining to the administration, the welfare and the advancement of The Institute. He was made a councillor in 1914 and sat on the Council of The Institute in that capacity until 1924, when he became vice-president. A number of important special committees of The Institute, such as the Committee on Memberships, the Committee on Society Affairs, the Committee on Classification and Remuneration, the Special Committee on Legislation, the Committee on Policy, the Committee on Professional Relationship, etc., have also taken much of his time and have largely benefited by his wide experience of men and things.

When the Quebec Branch of The Institute was formed, in January 1907, Mr. Decary was found among its principal promoters; he was one of the charter members of this branch and a member of the first Executive Committee, an officer of which he has remained ever since. No one has ever been so closely connected with the history of any branch of The Institute, or has performed a greater amount of useful work towards promoting the interests of The Institute and the profession in any locality. He was chairman of the Quebec Branch for eight years; in 1913 and from 1919 to 1925. Upon retiring from the active chairmanship of this branch, the Quebec members made him their Honorary Chairman for Life, by resolution of their annual meeting in 1925 and in recognition of his exceptionally capable management of the branch affairs and untiring activities which had practically identified him with the existence of the branch itself.

A biographical sketch of the new President of The Engineering Institute of Canada would be far from complete were it not mentioned that he was mainly responsible for the establishing of the Corporation of Professional Engineers of Quebec, a body which was granted the same privileges and legal powers long enjoyed by the other professions of that province. He was elected the first president of the Corporation in 1920, which highly responsible office has been committed to him from year to year since that date.

Mr. Decary is also a member of the Province of Quebec Association of Architects, a Fellow of the Royal Architectural Institute of Canada and holds membership in the Quebec Board of Trade, the Permanent International Association of Navigation Congresses, the Canadian Institute, the Quebec Geographic Society, the Canadian Forestry Association, the Canadian Club, the Quebec Garrison Club, the Engineers' Club of Montreal, the Quebec Golf Club, the Royal St. Lawrence Yacht Club of Montreal, the Quebec Yacht Club, (Honorary Member), and other organizations.

The loyalty and rare executive ability which Mr. Decary always displayed, although in a quiet but energetic manner, in the service of The Institute and the profession will not fail to be truly appreciated by all in the performance of the duties of the high office with which he has just been invested.

Address of the Retiring President,

Major Geo. A. Walkem, M.E.I.C.

Read before the Forty-first Annual General Meeting of The Engineering Institute of Canada, Quebec, Que., February 15th, 1927

Members of the Engineering Institute of Canada,

Gentlemen:—

It is with regret that I realize while writing this address that it will be impossible for me to be present in person at the Annual Meeting and deliver it. The Legislature of the Province of British Columbia, of which I am a Member, will be still in session when the Annual Meeting is held, and my legislative duties will therefore prevent me visiting the East at that time.

During my term as your President,—the President of the oldest and largest technical society in Canada,—I have felt a deep sense of responsibility. I realized that a President living three thousand miles from Headquarters cannot be very useful as an actual Presiding Officer, and decided, therefore, that I could best serve The Institute by acting as a kind of visiting director. Following out this idea, I visited the following branches during two trips, one in January 1926 and one last October:—Montreal, Quebec, Saguenay, Ottawa, Kingston, Peterborough, Toronto, Hamilton, London, Border Cities, Sault Ste. Marie, Port Arthur, Winnipeg, Regina, Saskatoon, Calgary, Lethbridge, Vancouver and Victoria, and it is my intention to visit Edmonton, (where, as Vice-President, I presented the charter), during the month of March. Everywhere, as your President, I had a warm welcome, and was afforded an opportunity of seeing something of the handicaps under which some of these branches operate, and their loyalty to The Institute. In the cities, of course, where the membership is large, the branches function well; in the smaller places, however, where the branch draws its membership from a large territory, the geographical difficulties of holding meetings and getting together make themselves felt. The problem of what Headquarters can do for such branches, to assist and interest, is one to which I have given a great deal of thought. It is further complicated by the formation of the various Associations of Professional Engineers in the different provinces. My conclusions are those that have already been suggested and discussed by Council, viz.:—

(1) Obtain papers on technical subjects by eminent engineers, with the necessary lantern slides, which papers and slides can be used by the different branches.

(2) Have, if possible, a three-day meeting at Headquarters in June, to which a councillor from each zone could come.

(3) Arrange for visits by your President and Secretary as often as possible.

(4) Continue publication of the Transactions.

I think by these means Headquarters will be able to keep in closer touch with the various branches, and, what is even of greater importance, bring the branches in closer touch with each other.

As mentioned in the Report of Council, a meeting of the representatives of the Associations of Professional Engineers was held at Headquarters in February last. They met at the suggestion and on the invitation of The Institute, but The Institute as an institute took no part in the deliberations. A three-day meeting was held, and I am sure that the result of these debates will eventually be of immense benefit to The Institute; in fact, it is my hope that after a period of some years all the Professional Engineers' Associations throughout Canada will be one body, with, perhaps, The Institute as a parent. I think I am right in saying that the discussion throughout showed that this must eventually be the case.

During the year Council has received communications from several members who were of opinion that Council should more frequently discuss questions of public importance that were at the time agitating the public mind, and that concerned engineers and engineering; and, being largely interested in public affairs, I personally have a great deal of sympathy with their views. I realize, however, that up to the present time The Institute has been careful to take no action which would leave it open to criticism, and I have no complaint to make of this policy, but I do suggest that in matters of public interest and importance an unbiased expression coming from The Institute might carry a great deal of weight and might be of benefit to The Institute at large. In every branch visited, I have stressed the importance of the engineer taking his place in public life and bringing himself before the public, and I should hardly be consistent if I did not urge The Institute to do the same.

The year 1926 has, in a way, been a disappointment in the West. Heralded as a year in which industry was to make great strides and prosper, it has come below our expectations. The province of Quebec is developing very rapidly, hydro plants being developed and pulp plants built, but this prosperity has not yet extended to all of Canada. This state of things is largely accounted for by the disturbed state of the country politically. Now that we have a government that is stable and can carry on for its full term, I believe conditions will change. The general opinion throughout the country is that prosperity is at hand and we are due for a period of what is commonly called "good times," which will afford employment for our members and will tend to the prosperity of The Institute.

As Council's Report points out, our membership has not increased during 1926; rather, it has fallen slightly. The reasons for this are two-fold: firstly, that in times like these the engineer finds it hard to pay two sets of fees, one to The Institute and the other to the Association of Professional Engineers to which he belongs; and, secondly, to the fact that this year Council has adopted a vigorous policy of "weeding out" those members who were in arrears. The net result of this has been that, while the membership is numerically less, it is actually stronger. A determined canvass should be made in all our branches for members among those engineers who, while living and practising in Canada, have never joined The Institute.

During the last year I have been amazed to learn to what extent engineers are taking part in commercial life. The tendency in large corporations in the United States and in some large railroad organizations has been to choose as executive officers men who have been trained as engineers. I prophesy that more and more will this be the case.

I would suggest to the membership at large that, instead of thinking only of things as engineers have in the past been in the habit of thinking of them, they view them from a wider standpoint; that they see the engineer not ultimately as a man who rises to the top of his profession only on the technical side, but as one who is capable of rising to any position in the commercial field. I take it as a great tribute to me and an acknowledgment of the point of view that I am setting forth, that The Institute should honour me by making me its President, because, for the last twenty-five years I have myself been in commercial life. It is true that my commercial life has been closely associated with engineering, but I have been acting more in an executive capacity than as an engineer. Personally, I think the rewards and emoluments of executive work are greater, and if the engineer can get this outlook and keep his eye fixed on the higher positions, it will mean that not only will his chances of reaching such a position be increased, but he will at once augment the influence of the profession of which he is a member.

The Report of Council calls attention to the losses we have suffered this year by death. I might especially mention—Past-Presidents Gamble, Murphy and Anderson, also Sir Alexander Bertram, Treasurer of The Institute for years, and a staunch and loyal friend not only to The Institute but to all engineers.

I should not like to leave office without expressing my appreciation of the work which Council has accomplished during the past year. I am not sure that the membership at large realize the amount of work that is required of Councillors in the conduct of Institute affairs. The Secretary, also, has been indefatigable in his work and zealous for the welfare of The Institute.

In conclusion, may I again express my appreciation of the great honour that you have done me in electing me to a position, the highest in the gift of The Institute. My only regret has been that geographical conditions have prevented me from taking a more active part personally in the deliberations of Council, but I can assure you that my interest in the affairs of The Institute will not wane, and I hope to be as active, and of far more use to The Institute, in the future than I have been in the past.

PERSONALS

J. Owen O'Sullivan, A.M.E.I.C., is assistant engineer with the Harbour Commissioners of Quebec.

A. J. M. Bowman, A.M.E.I.C., has recently been elected president of the Cadwell Sand and Gravel Company, of Windsor, Ont.

A. D. Campbell, M.E.I.C., formerly assistant manager, O'Brine Mine, Cobalt, has moved to Bestel, Ont., where he is manager of the Castle-Trethewey Mines, Limited, of Gowganda.

G. W. Coward, A.M.E.I.C., who was formerly assistant to the chief engineer of the Entre Rios Railways Company and the Argentine North Eastern Railway Company at Concordia, has been appointed divisional engineer for the Entre Rios Railways with headquarters at Basavilbaso.

A. Donaldson, J.E.I.C., who was with Burns McDonell Engineering Company, Los Angeles, California, has moved to Idaho Falls, Idaho, where he is engaged as engineer with H. L. Stevens and Company on the construction of a large hotel.

A. C. Penman, A.M.E.I.C., who until recently was Montreal manager for W. S. Lee, M.E.I.C., vice-president and chief engineer of the Quebec Development Company, Limited, is now associated with Henry L. Doherty and Company, 60 Wall Street, New York City, in an engineering capacity.

R. N. Geary, S.E.I.C., who for some years has been on the engineering staff of the Hydro-Electric Power Commission of Ontario at Niagara Falls, Ont., has joined the General Motors Corporation, Oshawa, in the office of plant records and appraisal department.

J. B. Pringle, S.E.I.C., assistant cable engineer of the Northern Electric Company, Limited, at Montreal, has joined the staff of the United Electric Light and Power Company, and is at present engaged on the new 132-kv. Pirilli cable installation between Hell Gate and Dunwoodie.

C. A. Mullen, M.E.I.C., director of paving department and chief consulting engineer of the Milton Hersey Company, Limited, was re-elected secretary-treasurer of the Association of Asphalt Paving Technologists at the society's recent annual meeting at the LaSalle Hotel, Chicago, on January 13th, 1927.

Allan T. Bone, A.M.E.I.C., who was formerly assistant superintendent and later superintendent for the Geo. A. Fuller Company, Limited, on the construction of the Metropolitan Life Insurance Building, Ottawa, has been transferred to Montreal, where he is acting as assistant superintendent on the construction of the new Royal Bank Building.

F. H. Cothran, M.E.I.C., formerly vice-president of the Quebec Development Company and in charge of construction on the Saguenay river projects, has been appointed chief engineer of the Piedmont and Northern Lines with office on the fifteenth floor of the Johnston Building, Charlotte, N.C.

Perry A. Borden, A.M.E.I.C., has been appointed research and development engineer with The Bristol Company, Waterbury, Conn. Mr. Borden graduated with honours in electrical engineering from Queen's University in 1911, and was for a number of years in charge of electrical meters and standards with the Hydro-Electric Power Commission of Ontario.

Alex. Ritchie, A.M.E.I.C., secretary-treasurer of the Edmonton Branch of The Institute and technical engineer of the power plant department of the city of Edmonton, has resigned to accept the position of service and research engineer with the Riley Engineering and Supply Company of Toronto. Mr. Ritchie is a native of Scotland and came to Canada in 1913, when he first entered the employ of the city of Edmonton as draughtsman. The following year he was placed in charge of the city of Edmonton's filtration plant, continuing in this position until 1919, when he was appointed to the position from which he has just resigned.

D. E. McPherson, A.M.E.I.C., who has been field engineer with H. H. Carrothers, Inc., engineers and constructors, Kansas City, Mo., during the construction of the memorial stadium for the University of Missouri at Columbia, Mo., has been transferred to the company's head office, where he will be engaged as engineer and estimator. Mr. McPherson is a graduate of the University of Manitoba of the year 1916, and following graduation he was for two years assistant engineer with the Winnipeg Aqueduct Construction Company and for a number of years he was on the engineering staff of the Canadian National Railways, both at Winnipeg and Eston, Sask.

J. R. Ross, Jr.E.I.C., who has been with the Provincial Forestry Air Service with headquarters at Sault Ste. Marie, Ont., for the past few years, has resigned from that service and leaves to join H. A. Oakes, Jr.E.I.C., at Hudson, Ont. They are going to operate the Western Canada Airways Service, with headquarters at Hudson, on the Canadian National Railways, about twelve miles west of Sioux Lookout. They will use two planes with a capacity of five passengers each or freight equivalent, these planes to operate between Hudson and Red Lake. Mr. Oakes was formerly with the Provincial Forestry Air Service, but resigned last year to organize the company with which he is now connected.

R. F. Howard, M.E.I.C., Joins Gatineau Power Company

R. F. Howard, M.E.I.C., has been appointed manager of power sales with the Gatineau Power Company with headquarters at Ottawa.

Mr. Howard, who is a graduate of McGill University of the year 1901, after completing the student course at the Westinghouse Electric and Manufacturing Company, Pittsburgh, Pa., spent four years in the construction department of the same company. In 1901 he was transferred to the Canadian Westinghouse Company at Montreal as district engineer, having charge of all engineering work for the company from Ottawa to the Maritime provinces.

Subsequently, he was in charge of the company's work at the city of Winnipeg hydro-electric plant and in 1917 was attached to the company's Winnipeg office as commercial engineer, but later resigned to accept the position of chief engineer of the British American Nickel Corporation at Ottawa, where he remained until 1921, when he became connected with Messrs. Kerry and Chace Limited, consulting engineers, Toronto, as assistant in connection with investigating and reporting on the proposed electrification of the Temiskaming and Northern Ontario Railway. In 1922 he entered private practice.

City Engineer of Sault Ste. Marie

A. H. Russell, A.M.E.I.C., secretary-treasurer of the Sault Ste. Marie Branch of The Institute, has been appointed city engineer of Sault Ste. Marie.

Mr. Russell was assistant city engineer from 1921 until July 1926, when he was appointed acting city engineer. He is a native of Renfrew and attended McGill University. In

A. H. RUSSELL, A.M.E.I.C.

E. R. SHIRLEY, M.E.I.C.

1909 he went to Sault Ste. Marie and joined the staff of the Lake Superior Power Company in the meter and operating department. In 1913 he became assistant to the field engineer of the water power department of the Algoma Steel Corporation, Limited, and two years later was appointed senior operator of the hydro-electric plant for this company. In 1916 he became connected with the Spanish River Pulp and Paper Company, engaged principally in field work, and two years later was promoted to assistant to the resident engineer of the same company.

E. R. Shirley, M.E.I.C., Elected to Peterborough Utilities Comission

Much has been said and written with a view to encouraging members of The Institute to take a greater interest in civic affairs in their respective localities, and the members will be interested in the announcement that at the municipal elections in Peterborough, Ont., held January 1st, 1927, E. R. Shirley, M.E.I.C., was elected to a seat on the Peterborough Utilities Commission. This is all the more gratifying in view of the fact that there were five candidates for one vacancy, including one ex-mayor and one ex-alderman, and that Mr. Shirley obtained a substantial majority.

Mr. Shirley holds the degree of B.A. with honours from the University of New Brunswick, received in 1903, and B.Sc. with honours from Queen's University, 1912. In the interval between his university courses he spent the years 1903-1909 and the summers of 1910 and 1911 with the Canadian General Electric Company, Peterborough.

From 1912 to 1913, Mr. Shirley was assistant superintendent of the British Canadian Power Company and Northern Ontario Light and Power Company, of Cobalt, Ont., and from 1913 to 1915 was electrical superintendent of the Canadian Exploration Company. He was then appointed superintendent of the Laurentian Power Company at Beaupré, Que., with which he served from 1915 to 1917. Since the latter date, Mr. Shirley has been in the switchboard engineering department of the Canadian General Electric Company, Peterborough.

It might be mentioned that this is the first occasion on which an engineer has stood for a position on the local

Utilities Commission since C. E. Sisson, M.E.I.C., moved to Toronto some years ago, but with the realization of the advantages of having a technically trained man as representative on the Utilities Commission, there is little doubt of the future election of any engineering candidate who may be proposed.

A. B. NORMANDIN, A.M.E.I.C.

A. B. Normandin, A.M.E.I.C., chairman of the Quebec Branch since 1925, and recently elected member of Council representing the Quebec Branch, was chairman of the Executive Committee in charge of arrangements for the Annual General Professional Meeting recently held in Quebec.

Mr. Normandin is assistant chief engineer of Hydraulic Service for the province of Quebec. He was born at St. Constant, county of Laprairie, Que., in 1883 and received his primary education at the Elementary School and Ecole Normale Jacques-Cartier, entering Laval University, Polytechnique School, in 1903, and graduating with the degree of B.Sc. in civil engineering in 1907. Following graduation he was engaged on municipal work and land survey until 1909, when he became city engineer of Three Rivers. In 1911 he became engaged with a firm of consulting engineers for La Compagnie de Pulpe de Chicoutimi, Le Chemin de Fer de la Baie des Ha! Ha!, La Compagnie du Havre de Chicoutimi and the town of Chicoutimi, following which he was appointed to his present position.

He is a member of the Corporation of the Quebec Land Surveyors, and was elected an Associate Member of The Institute in 1912.

A. B. NORMANDIN, A.M.E.I.C.

W. G. MITCHELL, M.E.I.C.

S. L. deCARTERET, M.E.I.C.

W. G. MITCHELL, M.E.I.C.

W. G. Mitchell, M.E.I.C., was chairman of the Finance Committee and Technical Papers Committee in connection with the Annual General Professional Meeting at Quebec. Mr. Mitchell is a vice-president of The Institute and was the first chairman of the Saguenay Branch. He is a native of Port Hope, Ont., where he was born on July 25th, 1888. He received his degree of B.Sc. in 1913 and that of M.Sc. in 1914 from McGill University.

From 1914-1916 he was in charge of the division of wood preservation for the Forest Products Laboratories, Montreal, and for the next three years he was with R. Martens and Company, Limited, of London, England, as mining engineer on the investigation of timber and mining industries in Scandinavia, Finland, European Russia, Serbia and Manchuria. During the latter part of 1919 he was engaged in private practice in Canada and the United States, following which he was appointed special technical representative of the Canadian Export Paper Company, Limited, Montreal. In March 1921 he became associated with Price Brothers and Company, Limited, and early in 1922 took charge of the operation of the company's pulp and paper mills as assistant to the president.

S. L. DECARTERET, M.E.I.C.

S. L. deCarteret, M.E.I.C., of the Hammermill Paper Company, Quebec, was chairman of the Reception and Entertainment Committee of the Annual General Professional Meeting at Quebec. Mr. deCarteret is a native of Auckland, New Zealand, where he was born on November 24th, 1885, and is a graduate of Yale University, from which he received the degree of Ph.B. in civil engineering in 1908.

His early engineering work, following his graduation from Yale, was with the Riordon Paper Company, with which company he was engaged on topographic and forest surveys and in charge of office work in connection with same. In 1910 he joined the Brown Corporation, being in charge of the department in connection with topographic and forest surveys and in charge of office work in connection with same. In 1910 he joined the Brown Corporation, being in charge of the department in connection with topographic and forest surveys and investigations of water supply and water storage for power purposes. Two years later, with the same company, he was engaged on the design and construction of dams, piers, etc., on the Ste. Anne river, Portneuf county, and subsequently on the construction and operation of the loading plant and private sidings at St. Casimir; the operation of the company's private railway and electric plant, Upper St. Maurice river, and the design and construction of various works at Bersimis, Saguenay county. In 1923 he joined the Hammermill Paper Company, and has been in charge of the company's properties and operations in the province of Quebec since that date.

L. C. Dupuis, A.M.E.I.C.

L. C. Dupuis, A.M.E.I.C., who was chairman of the Excursion Committee of the Annual General Professional Meeting in Quebec, is division engineer, maintenance-of-way and betterments, Levis Division, Canadian National Railways, Levis, Que. He was born in St. Roch des Aulnaies, County of L'Islet, Que., on November 8th, 1886. His education was received at Laval Normal School and Laval University Survey School and by private tuition.

His early work was in connection with land and timber surveys, and in 1911 he became assistant engineer with the Intercolonial Railway at Moncton, N.B., continuing the following year in the same position at Levis, Que. He has remained at Levis practically ever since occupying successively the positions of resident engineer with the Intercolonial Railway, engineer on double tracking, assistant engineer with the Canadian Government Railways and division engineer of the Saguenay Division, Canadian National Railways, and later in 1924 division engineer of the Levis Division of the Canadian National Railways.

L. C. DUPUIS, A.M.E.I.C.

HECTOR CIMON, A.M.E.I.C.

LOUIS BEAUDRY, A.M.E.I.C.

Hector Cimon, A.M.E.I.C.

Hector Cimon, A.M.E.I.C., formerly secretary-treasurer of the Quebec Branch, was chairman of the Registration, Publicity and Printing Committee at the Annual General Professional Meeting at Quebec, and is engineer of the Lands Department of the South Shore Logging Division with Price Brothers and Company, Limited, at Quebec. He was born at Rivière du Loup, county of Témiscouata, Que., on April 28th, 1893. His early education was received at the Quebec Seminary and Laval University at Quebec, from which he received the degree of B.A., completing his studies at Ecole Polytechnique, Montreal, with the degree of B.A.Sc. in civil engineering. In 1916 he joined the company with which he has remained ever since and was placed in charge of special surveys for the company.

He joined The Institute in 1912 at Student and was transferred to Associate Member in 1919. From 1921 to 1924 he was secretary-treasurer of the Quebec Branch.

Louis Beaudry, A.M.E.I.C.

Louis Beaudry, A.M.E.I.C., is secretary-treasurer of the Quebec Branch of The Institute, under whose auspices the recent Annual General Professional Meeting was held at Quebec.

Mr. Beaudry was born at Three Rivers, Que., on June 19th, 1897, and graduated from Ecole Polytechnique with the degree of B.A.Sc. in civil engineering in 1921. His work prior to graduation was with the Roads Department, province of Quebec, and with the city of Outremont.

For two years following graduation Mr. Beaudry was engaged on construction work under the firm name of Trepanier and Beaudry at Three Rivers. In February 1923 he joined the engineering staff of the Department of Public Works of the province of Quebec, with which he was engaged on the location, design and inspection of bridges, until accepting his present position with Messrs. Wm. I. Bishop Company, Limited, on the construction of the Anglo-Canadian Pulp Company's mill at Limoilou, Que., the latter part of 1926.

Committees in Charge of Arrangements

The committees of the Quebec Branch in charge of the arrangements were:—

Executive Committee

A. B. Normandin, A.M.E.I.C., *Chairman*	L. C. Dupuis, A.M.E.I.C.
Louis Beaudry, A.M.E.I.C., *Secretary*	T. J. F. King, A.M.E.I.C.
A. R. Decary, M.E.I.C.	A. Lariviere, A.M.E.I.C.
H. Cimon, A.M.E.I.C.	T. E. Rousseau, M.E.I.C.
S. L. deCarteret, M.E.I.C.	W. G. Mitchell, M.E.I.C.

Finance Committee

W. G. Mitchell, M.E.I.C., *Chairman*	S. L. deCarteret, M.E.I.C.
A. B. Normandin, A.M.E.I.C.	

Reception and Entertainment Committee

S. L. deCarteret, M.E.I.C., *Chairman*	J. A. Duchastel, M.E.I.C.
A. Amos, A.M.E.I.C.	R. L. Seaborne, A.M.E.I.C.

Registration, Publicity and Printing Committee

H. Cimon, A.M.E.I.C., *Chairman*	A. Lariviere, A.M.E.I.C.
H. Gauthier, A.M.E.I.C.	J. G. O'Donnell, A.M.E.I.C.

Excursion Committee

A. Dick, A.M.E.I.C.	T. E. Rousseau, M.E.I.C.
A. Lafleche, A.M.E.I.C.	

Ladies' Committee

Madame S. L. deCarteret, *Chairman*	Madame A. B. Normandin
" A. Amos	" H. Cimon
" J. A. Duchastel	" E. W. Gauvreau
" W. G. Mitchell	" R. L. Seaborne

Technical Papers Committee

W. G. Mitchell, M.E.I.C., *Chairman*	H. Cimon, A.M.E.I.C.
F. X. Ahern, A.M.E.I.C.	

Newly-Elected Vice-Presidents of the Institute

J. H. Hunter, M.E.I.C., whose election as vice-president of The Institute was announced at the Annual Meeting in Quebec on February 15th, is general superintendent of the Canada Starch Company.

Mr. Hunter has been a member of the Council of The Institute for the past two years, and during 1926 he was chairman of the Finance Committee. He is a native of Sorel, Que., where he was born on April 29th, 1865. He commenced his engineering work in 1881 with the Canadian Pacific Railway Company, and in the following year was on the engineering staff of the Montreal Harbour Commissioners. From 1885-87 he was with Wood Saxon and Company, hydraulic and electrical engineers, in New York, following which he was engaged on railway construction with the Baltimore and Ohio and Staten Island Rapid Transit Railway in connection with electric block signal installation. In 1893 he was with the Danbury Electric Light and Power Company and in the following year entered private practice.

J. H. HUNTER, M.E.I.C.

During his period of private practice as consulting engineer, he was responsible for the design and construction of a great many works, principally in the province of Quebec, among which are: Boston Rubber Company, St. Jerome; St. Jerome Electric Light Company; North River Power Company; Wiarton Binder Twine Company; Waterville Electric and Power Company; plans for Sault St. Louis Light and Power Company; unloading plant and coal pockets for Dominion Coal Company; Cardinal Electric Light and Power Company; Fort William Starch plant; concrete dock and grain elevator at Fort William; rebuilding of Canada Starch Company plant, Cardinal; and a number of reinforced concrete industrial buildings and other concrete structures. He was also engineer to the Canada Starch Company, St. Paul Land and Hydraulic Company and concreting engineer to Corn Products and Refining Company.

Sam G. Porter, M.E.I.C., assistant manager, Department of Natural Resources, Canadian Pacific Railway, at Calgary, Alta., has been elected vice-president of The Institute, representing Zone A.

Mr. Porter was born at Kyle, Texas, U.S.A., on September 1st, 1875, and received his early education at a private school in his home county, later entering Baylor University at Waco, Texas, from which he received the degrees of B.A. and M.A. Following graduation from Baylor University, he taught school in Texas for several years, subsequently entering the Massachusetts Institute of Technology, from which he graduated in civil engineering. He then entered United States Reclamation Service and was engaged on the preliminary and location surveys in the states of New Mexico, Colorado, Nebraska and Wyoming, during which time he was in charge of part of the construction programme of the inter-state canal between Wyoming and Nebraska. He later became chief engineer of the Arkansas Valley Sugar and Irrigated Land Company at Holly, Colo.

SAM G. PORTER, M.E.I.C.

In 1913 he was appointed inspection engineer for the Dominion government in Alberta in connection with the irrigation office of the Department of the Interior. He was later promoted to the position of assistant chief engineer and acting irrigation commissioner. Mr. Porter's next change was from the government service to the employ of the Canadian Pacific Railway, becoming superintendent of operation and maintenance of the southern section of the Canadian Pacific Railway system in 1918 with headquarters at Lethbridge, and, under his administration, many new works have been carried out.

Mr. Porter has taken a very active interest in the affairs of the Lethbridge Branch, and was for three years, 1921-1923, on the Council of The Institute. He has also been a member of Council and vice-president of the Association of Professional Engineers of Alberta.

OBITUARIES

Col. W. P. Anderson, C.M.G., M.E.I.C.

The engineering profession in Canada lost one of its outstanding members and The Institute one of its original members when death claimed Colonel William Patrick Anderson, C.M.G., V.D., F.R.G.S., M.INST.C.E., M.E.I.C., chief engineer and superintendent of lighthouses in the Department of Marine and Fisheries up to seven years ago. Colonel Anderson's death occurred at his home, 64 Cooper street, Ottawa, on February 1st, 1927, following an illness of about six weeks' duration. He was seized with an attack of angina pectoris on December 15th last, from which he failed to rally.

Few men can boast the wide and varied connections and interest which Colonel Anderson had cultivated during his lifetime. Not only in military circles of the city was he a prominent figure, but in engineering, geographical survey work and marksmanship he was one of the leaders of the Dominion. He was also well-known locally as a golfer, curler, naturalist and as a stamp collector.

But his greatest reputation is that of an engineer, and throughout the Dominion 500 lighthouses and 50 fog alarm stations stand as evidence of the efficient effort which he placed in his work in the Civil Service, controlling as he did all construction work in connection with aids to navigation and most of the technical work of the Department of Marine and Fisheries.

Colonel Anderson was born in Levis, Que., on September 4th, 1851, the eldest son of Thomas Anderson, late Crown lands and timber agent at Edmonton, Alberta, and Adelaide A. Smyth. He was educated at Bishop's College, Lennoxville, and Manitoba College, Winnipeg. In 1872 he went to the north country as an apprentice to a land surveyor, and there was introduced into practical survey work.

In 1874 he came to Ottawa, and entered the Civil Service as a draughtsman in the Department of Marine and Fisheries. He rose quickly, soon became assistant engineer, and in 1880 became chief engineer and superintendent of lighthouses, which post he held until 1919, when he was superannuated.

Colonel Anderson always took an active interest in military matters, and was at one time commanding officer of the 43rd Regiment. His military career began while he was attending college. When only thirteen years of age he entered the militia, in 1864, and interrupted his college education to serve in the ranks during the Fenian Raid of 1886. He served in the second raid, a few years later, also.

When he came to Ottawa in 1874, he joined the Governor-General's Foot Guards, and remained with that unit until 1881, when, upon the organization of the 43rd Ottawa and Carleton Rifles, he was transferred as an adjutant. He commanded the regiment with the rank of a lieutenant-colonel from 1882 to 1892. He retired from the command of the 43rd Regiment, but remained on the active militia list until about two years ago. In 1885 he established the Canadian Military Gazette, and edited it for two years.

He was an excellent rifle shot, and always took a great interest in shooting. At one time he was chairman of the Small Arms Committee of Canada, and was on the council of the Dominion of Canada Rifle Association and a life governor. In 1900 he won the Governor-General's prize at the D.C.R.A. meet at Rockliffe Park Rifle Ranges, and was on one occasion a member of the Canadian Bisley Team, and in 1904 was commandant of the team, during which

COL. W. P. ANDERSON, C.M.G., M.E.I.C.

year Perry, of the Canadian team, captured the King's Prize, the highest individual shooting award in the British Empire. From 1919 until last year he was treasurer of the D.C.R.A.

Colonel Anderson was one of the first members of The Canadian Society of Civil Engineers and assisted in its organization, his membership dating from January 20th, 1887, prior to the incorporation of the Society. He was councillor during the years 1890, 1891 and 1901, and vice-president in 1902. In 1904 he was president of the Society, and was always one of the most prominent and enthusiastic members of the Society, as well as of The Engineering Institute of Canada which succeeded it. In 1906 he was elected a fellow of the Royal Geographical Society, and also was a member of the Institute of Civil Engineers of Great Britain. Until recently he was chairman of the Geographical Board of Canada. On January 1st, 1913, in the King's New Year's honour list, he was created a C.M.G.

Colonel Anderson was one of the founders of the Ottawa Field Naturalists' Club. In 1885 he was president of the Ottawa Literary and Scientific Society. In 1898 he became public school trustee for Central ward, and continued on the board for many years, occupying the position of chairman in 1906. He later was a member of the Collegiate Institute Board for many years. An enthusiastic curler, he was one of the originators of the Rideau Curling Club. He also was a member of the Rideau Club for many years, and of the Royal Ottawa Golf Club. He was one of the best known stamp-collectors in Canada, specializing in British North America stamps.

On October 18, 1876, he married Dorothea S. Small, daughter of the late H. B. Small, secretary of the Department of Agriculture. Last year they celebrated their golden wedding anniversary, five children and ten grandchildren, the entire family, being present.

The funeral of the late Colonel Anderson was held at St. George's Church, Ottawa, interment taking place in the family plot at Beechwood Cemetery. The large congregation, numbering in the neighbourhood of 1,000 persons, and including many men prominent in the affairs of the Capital, bore evidence of the high esteem in which the deceased was held.

Representatives of many organizations, some outside of Ottawa, were on hand to pay their last tribute to an esteemed fellow-member. These included many professional and military societies in the affairs of which Colonel Anderson had taken a leading part. The cortege included many members of the Engineering Institute of Canada, Headquarters being represented as well as the Ottawa Branch.

Robert Clarence Forbes, S.E.I.C.

Deep regret is expressed at the news of the death of Robert Clarence Forbes, S.E.I.C., which occurred at the Montreal General Hospital on February 13th, 1927.

The late Mr. Forbes was born at Westmount, Que., on January 15th, 1902, and received his early education at the public and high schools of Westmount and his degree of B.Sc. from McGill University in 1924.

During the summer months of his university course, he was employed for three months in 1922 with the Hollinger Consolidated Gold Mines Limited as mechanical draughtsman and for two months in 1923 with the E. G. M. Cape and Company as assistant engineer on water works contract, Verdun, and was still engaged with this company at the time of his death.

Mr. Forbes joined The Institute as Student on October 29th, 1923.

Edgar Augustus James, M.E.I.C.

It is with regret that we record the death of Edgar Augustus James, M.E.I.C., which occurred at Toronto on February 12th, 1927.

The late Mr. James was born at Thornhill, Ont., on August 25th, 1875, and graduated from the University of Toronto with the degree of B.A.Sc. in 1905. During the summer vacations of his university course he was engaged as follows:—resident engineer, Drainage District No. 6, Manitoba, in 1902; and assistant district engineer, McLeod District, North West Territories, on irrigation, bridges, etc., in 1903.

The first three years after graduation were spent with the Canadian Pacific Railway Company as resident engineer on construction on the Sudbury branch, and for the next year he was editor of the "Canadian Engineer." From 1910-11 he was town engineer of North Toronto in charge of pavements, electric light construction, sewers and sewerage disposal works, water works, etc., and the following year was chief engineer of the York Highway Board and also consulting engineer for New Toronto, Leaside, Grand Valley Railway. In 1914 he entered private practice in Toronto as senior partner in the firm of James, Proctor and Redfern, and has since been identified with many municipal works throughout the province.

Mr. James joined The Institute as Student on April 23rd, 1903, transferred to Associate Member on May 2nd, 1907, and to Member on May 16th, 1914.

Meeting of Council

Meeting of February 8th, 1927

A meeting of Council was held at eight p.m. on Tuesday, February 8th, 1927, Vice-President K. B. Thornton, M.E.I.C., in the chair, and eight members of Council being present.

The following appointments were made:—Mr. J. A. Burnett, M.E.I.C., was unanimously appointed chairman of the Nominating Committee, and Professor R. deL. French, M.E.I.C., was unanimously appointed chairman of the Board of Examiners and Education.

A unanimous vote having been received from the Councillors, the Secretary was directed to request the new Governor-General, Lord Willingdon, to honour The Institute by becoming an Honorary Member.

With reference to the proposal to initiate discussion as to the best method to bring about substantial uniformity in the requirements of admission by examination to the seven provincial associations and to The Institute, the Secretary reported receipt of a reply from Mr. F. B. Brown to the letter which by direction of Council at the January meeting had been addressed to him, stating that this communication had been brought to the attention of the various governing bodies of the provincial associations. It was decided to refer the matter to the incoming Council for special consideration.

A communication was read from the St. John Branch of The Institute, stating that that branch had passed a resolution offering the co-operation of a committee to work with the St. John Board of Trade on any engineering problem of local or civic interest, which offer had been gratefully accepted. This was noted with approval by Council.

The Secretary reported the death of Colonel W. P. Anderson, which was noted with deep regret by the Council, and the following resolution was unanimously passed, the Secretary being directed to communicate it to the family of the late Colonel Anderson:—

> The Council of the Engineering Institute of Canada has learned with deep regret of the death of Colonel W. P. Anderson, C.M.G., and desires to convey to his family its sincere condolence on their bereavement.
>
> An active member of the small group of engineers who were originally concerned in the formation of the Canadian Society of Civil Engineers, he rendered invaluable service to the profession in building up that organization, in which he served successively as Councillor, Vice-President and President, always maintaining his interest in professional affairs, and aiding The Institute with his wise judgment and advice.
>
> The Council of The Institute places on record its appreciation of this service and The Institute's indebtedness to the eminent engineer who has passed away.

The report of the Committee on Biographies was submitted and approved.

Five requests for reinstatement were considered and approved, and ten resignations were accepted.

Ten applications for admission and transfer were scrutinized and classified for the ballot returnable March 22nd, 1927.

Three special cases were considered in connection with applications for admission.

The Council rose at ten-twenty o'clock p.m.

Engineers in Insurance Work

In connection with the statement, which is frequently made, that an engineering training fits a man for other spheres of work than that usually considered as engineering, attention may be drawn to the announcement appearing under the employment bureau column in this issue of the Journal, referring to the employment of engineers on special work in connection with one of our large life insurance companies. It is interesting to note that, in this apparently unrelated sphere, an engineer's special qualifications which, through his training, are reflected in his character and outlook, are being recognized in this manner.

It has recently been learned that in this particular line of work several graduates in engineering have received rapid promotion and that the policy inaugurated has yielded satisfactory results in practice.

There are, undoubtedly, a number of members of The Institute holding positions which offer small prospects of promotion who would be interested in such a proposition, and for this reason attention is directed to the notice referred to above.

ABSTRACT OF PAPER

The Hemmings Falls Power Development

S. H. Wurtele, M.E.I.C., Vice-President and Plant Manager, The Southern Canada Power Company, Limited

Peterborough Branch, January 27th, 1927

The Hemmings Falls power site, two and one-half miles above Drummondville, is at a point where a fifteen-foot fall terminated a series of rapids in which there was a total drop of fifty feet in a five-mile stretch of the river. There were favourable conditions in banks and riverbed at this point, and a practical scheme of development was evolved consisting essentially of a north wing wall, power house section, sluiceway section, spillway and south wing wall, together with an isolated earthfill dam.

In this scheme two of the principal considerations which determined the exact location of the power house were, that a natural declivity could be enlarged to afford a well protected tailrace without excessive excavation, and advantage could be taken of an opportunity to so place the gatehouse that it would be exposed to the morning sun in winter time.

CONSTRUCTION

A contract for the construction of the complete development was awarded to the Foundation Company of Canada, Limited, on September 1st, 1923. Two weeks later work was under way on a three-mile siding from the main line of the Canadian National Railway. This siding was ready for operation November 15th, by which time a temporary coffer dam had been built and the power house site and tailrace were well under way by December 18th, at which time a more or less expected ice barrage formed in the river below the tailrace, gradually drowned out the work, and necessitated abandoning this part of the excavation until April 15th, 1924. The river, loaded with frazil ice, rose to over fifteen feet above normal level. It is interesting to note that since the construction of the dam there has not been any trouble from frazil ice at the Drummondville power house, and that during the past winter there has not been any ice barrage or winter rise of tailrace water level at Hemmings Falls.

Excavation work was carried on throughout the winter at the site of the north wing walls, and some 3,000 cubic yards of concrete were poured at this point as a try-out for the concreting plant and other items of equipment. Other than this no actual work could be done before the middle of April, 1924, when the temporary cofferdam was again unwatered and rock excavation resumed. By May 20th actual concreting operation started and thereafter work was carried to completion with only one short delay.

The major items in the work were as follows: 62,000 cubic yards rock excavation, 108,000 cubic yards of earth excavation and embankment, 80,000 cubic yards of concrete, 530 tons of reinforcing steel, 530 tons of structural steel for buildings, 1,175,000 bricks.

All concrete from the mixers was handled by means of trains, hauled by gasoline locomotives, operating on a trestle with track elevation eighteen inches above the crest of the bulkhead sections of the dam. Each concrete train consisted of two cars and carried four cubic yards of mixed material. The trestle was about 2,000 feet in length, with a maximum height of 60 feet, and was located on the upstream face of the dam. Concrete was deposited into all parts of the work direct from this trestle, using short lengths of chutes and hoppers fixed to the trestle stringers. With these facilities, concrete could be placed at any number of different places during a single day's run without the usual delays incident to changing hoppers and chutes. It was also possible to carry on form work at a number of places simultaneously.

All reinforcing steel was bent on the job. Rail carbon steel was used for straight rods and medium steel for bent rods. The number of different sizes was kept to a minimum, and to avoid mixing the two grades in the field, the hard steel was carried in rounds and the medium steel in squares.

All construction plant was motor driven with the exception of steam shovels, locomotive crane and gasoline locomotives. Power was delivered to the site at 2,300 volts and stepped down to 550 volts for distribution to individual motors. The connected motor load was 800 horse power.

Fifteen hundred cubic feet per minute of air was provided for rock drills and other pneumatic equipment. The maximum force employed was 750 men.

A noteworthy feature of the construction work was the short time taken to pour the river bed section, some 950 feet long. Concreting of this portion started May 20th. By July 10th the upstream coffer dam in the deep water channel had been completed and the river diverted through temporary sluices left in the spillway section adjacent to the power house. A downstream coffer dam was built in the deep water channel. By August 1st excavation for the base of the dam at this point had been completed and concrete had been placed. In ten weeks the river had been completely coffer dammed, the flow diverted, the bed rock and cut-off trenches prepared, and concrete had been placed across 950 feet of river bed.

Saskatchewan Power Enquiry Commission

Recognizing the need for a fresh survey of the power situation in the province, the Saskatchewan government has by Order-in-Council appointed a Power Enquiry Commission. The personnel of the commission is: L. A. Thornton, M.E.I.C., city commissioner, Regina, chairman; Arthur Hitchcock, Moose Jaw; Prof. A. R. Greig, M.E.I.C., Saskatoon; with R. N. Blackburn, M.E.I.C., secretary to the commission.

The commission has been created on the advice of the minister in charge of the Bureau of Labour and Industries and has the power to summon witnesses and compel their attendance and the giving of evidence.

The commission is charged with inquiring into and reporting on the economic practicability of generating power at central power plants and water power sites in the province and the distribution of power throughout the province.

Particular mention is made of the following points of inquiry:—

Central power plants on the lignite fields of southern Saskatchewan.

Central power plants at other suitable points with a view to their ultimate interconnection.

Production of char, briquettes and other by-products at central plants.

Cost of power at central plants, economic limits of transmission and probable selling price of power at different points.

Existing power plants and their output, cost of production and selling price of current.

The tendency toward the use of electricity on farms already adjacent to power lines and the likelihood of creating a demand for power in farming communities.

Advisability of using existing pole lines for transmission in rural localities.

Advisability of municipalities selling power outside their corporate limits.

Hydro-electric possibilities.

Suitable type of transmission and distribution lines.

Present and possible future market for power.

The commission will very shortly hold an organization meeting for the purpose of planning the future steps of the enquiry.

Saskatchewan already produces large quantities of all agricultural products and is also rich in clay products in the south and minerals in the north. Any step towards increased manufacturing in the province would have a very beneficial effect on the industrial life of the whole province, particularly with regard to giving employment throughout the year.

Horn Shaped Shifting Sand Dunes.

C. B. R. Macdonald, A.M.E.I.C., who has been engaged on railway construction in the northern part of Peru, in a message extending New Year's greetings to all members of The Institute, submits the above interesting photograph showing the famous horn shaped shifting sand dunes along the road of the Southern Railway of Peru.

BOOK REVIEWS

Interpolation

By J. F. Steffensen, Ph.D., The Williams and Wilkins Company, Baltimore, Md., 1927. Cloth, 6¼ x 9½ in., 248 pp., tables, $8.00.

It is a pleasure to welcome this translation of Dr. Steffensen's important work on the theory of Interpolation, written with all the distinguished author's customary clarity and conciseness. The treatment is really elementary and requires merely a knowledge of the elements of the Differential and Integral Calculus. The first hundred pages cover Displacement-Symbols and Differences, Interpolation Formulae, Numerical Differentiation, Construction of Tables, Inverse Interpolation and Summation; they are easily within the grasp of the ordinary engineering undergraduate. The latter half of the book is of greater difficulty. It includes Bernouilli's Polynomials, Mechanical Quadrature and Cubature, Numerical Integration of Differential Equations, Interpolation with several Variables and the Calculus of Symbols.

The author derives the usual interpolation formulae from the "divided difference" formulae, and later on by the same method shows how to extend Stirling's and Bessel's formulae to functions of two variables. The outstanding feature of the book is the expression of the remainder term as some one of the derivatives of f (x) (where x lies within the range of interpolation) multiplied by a factor. This fixes a higher limit to the error than by merely giving the first neglected difference. But in practice this is not so useful as it appears, for the fluctuation of the derivative may be so great that the maximum error gives no indication of the actual error—and, of course, the method will not apply to a series of numbers whose mathematical formula is unknown. The author himself says "the result of such an interpolation must, under the circumstances, be considered as an hypothesis and not as a mathematically proven fact."

Everybody who is interested in the practical application of mathematics should certainly read this book. Unfortunately, the high price is likely to militate against its adoption as a text-book, and also, from the point of view of the methods of teaching in English-speaking countries, the absence of examples to be solved is undoubtedly a disadvantage. Perhaps we may add that the book is a text, and not a work of reference.

H. Tate.

Practical Structural Design in Timber, Steel and Concrete

By Ernest McCullough Scientific Book Corporation, New York, 1926. Cloth, 6 x 9 in., 416 pages, 224 illustrations, $4.00.

The object of the author. as set forth in his preface, was to present the subject of structural design in a way that can be understood "by men whose knowledge of mathematics does not extend beyond that taught in High School." No attempt has been made to prove the formulæ used in the solutions. The author states in a simple manner the method of procedure in design, illustrating his discussion with suitable diagrams.

The book has evidently been well received, for it is now in the third edition, the first edition having been placed before the public in 1917. Known errors of the previous edition have been corrected and new material added, notably a treatment of reinforced concrete. The subject matter is set forth in easily read type and the diagrams are clearly drawn.

The book treats almost entirely of the problems that arise in building design. After discussing the action of forces in a general way, the design of beams, girders and trusses, joints and connections are taken up. Chapter 6, on graphic statics, is followed by chapters on columns and structures, semi-rigid frames, miscellaneous data and reinforced concrete. Typical examples of timber, steel, and reinforced concrete members are used to illustrate the principles set out in the text.

There is included much practical information, short cuts and hints on procedure, gleaned from the author's forty years' experience, which are not ordinarily found in more technical books on structural design.

For the structural draughtsman desirous of learning something of design, and for the engineer who has not specialized in structural design but who may be called upon occasionally to design structural members, this book, in the opinion of the reviewer, should be very helpful.

W. P. Copp, M.E.I.C.

Machine Design Problems

By S. J. Berard and E. O. Waters, D. Van Nostrand Company, New York, 1927. Cloth, 6 x 9 in., 118 pp., illus., $1.50 net.

This book of problems is intended as a supplement to the text "The Elements of Machine Design," by the same authors.

The general arrangement of the book is very convenient. The problems are arranged in chapters corresponding to the chapters in the textbook. Each chapter contains problems of three kinds, grouped separately, the first group comprising problems to be solved by calculation; the second, free hand sketching exercises; and the third, complete working drawings; the latter two based on dimensions to be calculated.

The problems are of such a type, and so arranged, as to develop the intelligence and reasoning ability of the student, while at the same time illustrating sound engineering practice and practical methods of computation and design. The examples cover all of the more common machine elements, fastenings, shafts, bearings, belts and gearing of various kinds, as well as cams, linkages, pistons and piping.

The use of the book of problems, in conjunction with the text, in teaching, will facilitate the assignment of suitable exercises to illustrate the principles developed during lectures or class instruction and familiarize the student with units and proportions. For the engineer who desires to brush up his machine design, or the student or mechanic seeking to improve his knowledge of the subject in home study, the selection and arrangement of the problems should prove a great aid.

"The Elements of Machine Design" is a very clear, concise, and well-illustrated textbook, and "Machine Design Problems" is a worthy companion volume, the two constituting a handy and useful combination for either student or engineer.

J. H. Parkin.

ANNOUNCEMENT OF MEETINGS

CALGARY BRANCH

Secretary-Treasurer, H. R. Carscallen, A.M.E.I.C.

Mar. 4th: Address on "The Development of the Art of Communication," by A. M. Mitchell.
Mar. 12th: Annual Meeting.

LETHBRIDGE BRANCH

Secretary-Treasurer, N. H. Bradley, A.M.E.I.C.

Mar. 5th: Address by Prof. R. S. L. Wilson, M.E.I.C. (Subject not yet available.)
Mar. 19th: Annual Meeting.

MONCTON BRANCH

Secretary-Treasurer, V. C. Blackett, A.M.E.I.C.

Mar. 29th: Address on "Gunnery," by John Stephens, M.E.I.C.

VANCOUVER BRANCH

Secretary-Treasurer, F. P. V. Cowley, A.M.E.I.C.

Mar. 2nd: Address on "Education and the Legal Profession." (Speaker not yet definitely arranged.)
Mar. 9th: Address on "Recent Advances in Metallurgy," by Prof. H. N. Thomas, B.Sc.
Mar. 16th: Open date.
Mar. 23rd: Address on "The Work of the Vancouver and District Joint Sewerage and Drainage Board, by J. M. Begg, A.M.E.I.C.
Mar. 30th: Open date.

SAULT STE. MARIE BRANCH

Secretary-Treasurer, A. H. Russell, A.M.E.I.C.

March: Address on "Engineer and Industry," by Col. C. H. L. Jones, of the Spanish River Pulp & Paper Mills, Ltd.

MONTREAL BRANCH

Secretary-Treasurer, C. K. McLeod, A.M.E.I.C.

Mar. 3rd: Address on "The Scientific Method in Industry," by G. P. Cole, M.E.I.C.
Mar. 10th: Address on "Development in Steam Boiler Design," by F. A. Combe, M.E.I.C.
Mar. 17th: Address on "Locomotive Feed Water Heating," by W. C. Hamm, Esq.
Mar. 24th: Address on "Geology of Island of Montreal," by A. Mailhot, Esq.
Mar. 31st: Address on "Tele Vision," by Dr. L. E. Pariseau.

HAMILTON BRANCH

Secretary-Treasurer, W. F. McLaren, M.E.I.C.

March: Address on "Concrete Roads," by A. M. Jackson, A.M.E.I.C., and address on "Sewage Disposal Plant in Kitchener," by Stanley Shupe, M.E.I.C.

EMPLOYMENT BUREAU

Situations Wanted

Civil Engineer

Available at thirty days' notice after April first. Member of Association of Professional Engineers of Nova Scotia, and licensed Nova Scotia Land Surveyor. Twenty years' experience in eastern, central and western Canada and the United States, including railway location and construction, water power development surveys, construction of dams, factory and office buildings, general steel plant construction, coal mine development, including construction of bankheads, yard tracks, underground surveys, and mechanical installations. Apply box No. 219-W, Engineering Journal.

Pulp and Paper Mill Engineer

A.M.E.I.C., educated London University, age 32, speaking both languages, with eight years' experience on design and construction pulp and paper mills, industrial plants, desires connection with pulp and paper company on maintenance, or with engineering and contracting firm. At present employed but available on few weeks' notice. Apply box No. 220-W, Engineering Journal.

Civil Engineer

Graduate B.Sc., Associate Member of the Institution of Civil Engineers, 34 years of age, desires to make new connection early in April. Eleven years' experience on a variety of civil engineering work, including municipal utilities, highways, canals, reservoir dams, hydraulic surveys, estimating, design and construction. Four years' war record, engineer officer in France. Apply box No. 221-W, Engineering Journal.

Sales Engineer

Mechanical engineer, A.M.E.I.C., desires to hear from manufacturers requiring a representative in Western Canada. Specialist in power plant equipment of all kinds; well acquainted with territory. At present engaged; available at thirty days' notice. Apply box No. 222-W, Engineering Journal.

Situations Vacant

Town Manager

Manager for pulp and paper mill town now in progress of construction. Must have engineering experience and be able to speak French and English fluently. Apply with full particulars to box No. 164-V, Engineering Journal.

Electrical Draughtsman

A firm of consulting engineers in Toronto, Ont., require the services of an electrical draughtsman experienced in hydro-electric power station design. In applying give full particulars and experience and state salary expected and when available. Apply box No. 165-V, Engineering Journal.

Engineers for Life Insurance Work

A life insurance company of the highest standing has vacancies for specialized work for which trained engineers have proved to have more than ordinary aptitude. The duties of the positions, which offer very good opportunities for advancement, demand men between the ages of 30 and 40, of good address, and possessing the ability to meet business executives. Apply box No. 166-V, Engineering Journal.

Seventy Years to Map Canada

"At the present rate of progress it will take seventy years to explore Canada's rich northland to the extent of showing its principal features on our maps," President Frank D. Henderson, D.L.S., told the annual convention of Dominion Land Surveyors at Ottawa recently, in an address in which he urged Dominion land surveyors, "who had made possible the orderly settlement of the fertile wheat lands of Western Canada, to use their utmost efforts to speed up the colonization of the almost totally unexplored and unexploited hinterland of Canada."

The American Cable Company, Inc., have issued a booklet entitled "Mining Section of the Wire Rope Users' Handbook," which contains a great deal of very useful information for users of wire rope. This information includes the selection, use and care of wire rope for mining services. The booklet has 103 pages and is well illustrated. Copies may be secured through the Canadian representatives, The Dominion Wire Rope Company, Limited, Montreal, Toronto or Winnipeg.

BRANCH NEWS

Halifax Branch

K. L. Dawson, A.M.E.I.C., Secretary-Treasurer.

A meeting of the Halifax Branch was held on the evening of Thursday, January 27th. According to the well established custom of the branch, this was a supper-meeting and was largely attended, a pleasing feature being the presence of several of the out-of-town members, who were cordially welcomed. After the supper a short business meeting was held and then the chairman, C. A. D. Fowler, M.E.I.C., introduced the speaker of the evening, A. J. Grant, M.E.I.C., chief engineer of the Welland ship canal.

Mr. Grant prefaced his address by expressing his pleasure in being in Halifax for the first time in over twenty years and noted some of the improvements that had been made during that time. In opening his address, which was profusely illustrated by lantern slides, Mr. Grant spoke of the first historic Welland canal, which was built by a private company and opened for traffic in 1829. It had 40 wooden locks, each 110 feet long, 22 feet wide, with 8 feet of water on the sills. In 1841 the canal was purchased by the Legislature of Upper Canada and since then has been under the jurisdiction of the Provincial or Dominion governments. From time to time the canal was deepened and widened, the locks increased in length and decreased in number. It became evident, however, that the traffic offering was far in excess of the capacity of the canal and during the past quarter of a century exhaustive surveys were made to determine the feasibility and cost of a waterway that would accommodate ships of at least 25-foot draft. As the result of these surveys the "Ten-Mile Creek" location was decided upon and work started in 1913. Owing to the European war, work on the canal practically ceased in 1916, and in 1918 the contracts let in 1913 were cancelled and the work entirely closed down. After the Armistice, work was resumed in a more or less intermittent manner on the cost plus percentage basis until in 1921 and 1922 these contracts were cancelled and the work relet under unit prices. The development has progressed steadily since that time, and it is expected that it will be completed in 1930.

The speaker explained some of the problems necessitated by the fact that the new canal crosses the present one in places and at times has the same location, it being necessary to maintain the existing canal so that traffic can be handled while proceeding with construction. He mentioned the construction railway, a double track line along the site of the canal on which there was enough traffic to require a twenty-four hour operating service and train movements enough to be the envy of many double track commercial roads. He made some comparisons with the Panama canal, showing in what respects the Welland canal was the greater of the two, and, in answer to questions, stated that ships would operate in and out of the locks under their own power, whereas in the Panama canal they were locked in and out by electric mules operated by the canal forces.

In concluding his speech, Mr. Grant ventured to prophesy that, on the completion of the Welland ship canal and the St. Lawrence canals, it would not only be possible but highly probable that the wheat laden boats from the Great Lakes would carry their cargoes to some maritime port, such as Sydney, there to tranship the cargo to ocean-going ships and then return carrying Nova Scotia coal.

A general discussion followed the address, Mr. Grant answering many questions put to him and at times elaborating on points already mentioned in his address. At the conclusion of the meeting a vote of thanks was moved and tendered by the chairman.

Hamilton Branch

W. F. McLaren, M.E.I.C., Secretary-Treasurer.
J. R. Dunbar, Jr.E.I.C., Branch News Editor.

Regular Meeting, January 26th, 1927

A meeting of the Hamilton Branch of the Engineering Institute of Canada was held in the cafeteria of the Hamilton Technical Institute on Wednesday, January 26th, 1927, L. W. Gill, M.E.I.C., in the chair. There were fifty members and guests present. On the motion of C. J. Nicholson, A.M.E.I.C., seconded by J. J. MacKay, M.E.I.C., the following Nominating Committee was appointed:—

A. H. Munson, A.M.E.I.C.	A. R. Hannaford, A.M.E.I.C.
E. H. Darling, M.E.I.C.	Alex. Love, A.M.E.I.C.
W. B. Ford, A.M.E.I.C.	A. M. Jackson, A.M.E.I.C.

Mr. Gill introduced the guest of the evening, Lieut.-Col. H. J. Lamb, D.S.O., M.E.I.C., immediate past president of the Association of Professional Engineers of Ontario and supervising engineer of the Department of Public Works of the Dominion Government for Ontario. Col. Lamb has been actively engaged in the past twenty years on harbour and river works on the Great Lakes system of waterways and has had an opportunity of following the great development which has taken place during that period and has gained a thorough appreciation of the enormous asset that this waterway is to us, not only from a commercial point of view but also as a health and happiness factor in the welfare of so many communities situated along its shores and within easy reach of them. Col. Lamb's subject was "Engineering Problems and Traffic on the Great Lakes."

Engineering Problems and Traffic on the Great Lakes

The speaker pointed out that the Great Lakes waterway covered 95,160 square miles, a distance from Kingston at one end to Duluth at the other of 1,160 miles and 142 miles in the three connecting rivers. The drainage area of this is such that the supply practically balances the discharge through the St. Lawrence river, resulting in an unusual steady flow averaging 220,000 cubic feet per second. No other river of its size can compare with it in steadiness of flow.

The various engineering problems which were encountered in providing through navigation from one end of the lakes to the other were described in a very clear and interesting manner. The work involved has briefly been as follows:—

(1) Establishment of international boundary line.
(2) Charting the system and establishing aids to navigation.
(3) Construction of harbours.
(4) Construction of canals and locks.
(5) Improvement of the river channels.

Slides were shown illustrating the Great Lakes' system, the present international boundary, the types of breakwater and harbour construction used in the Great Lakes, the various canals, and types of steamers in use for Great Lakes traffic.

The Welland Ship Canal is the second largest work of its kind in the world and is estimated to cost about $115,000,000.

The first canal between lake Ontario and lake Erie was built by a private company in 1829 and has been followed by other canals, each being an improvement on the preceding one. The contrast between the original privately owned canal with forty locks and the new Welland ship canal with only seven locks is an outstanding example of engineering achievement.

The system of canals at Sault Ste. Marie is another outstanding feature. In 1923 the tonnage through the various canals on both sides of the river exceeded the combined tonnage through the Suez, Panama and the Manchester ship canals. The first canal was built by the North-West Fur Company in 1797-98 and was partly destroyed by United States troops in 1814.

The twin ports of Port Arthur and Fort William are equipped with twenty-five grain elevators, having a storage capacity of sixty-five million bushels. Ships can be loaded at the rate of eight million bushels per day. The largest boat in the Great Lakes service is the Canada Steamship Company's "Le Moigne," which has a capacity of 520,000 bushels and is 633 feet long.

After considerable discussion and questions from members, a hearty vote of thanks was tendered the speaker on the motion of W. L. McFaul, M.E.I.C., seconded by H. A. Lumsden, M.E.I.C.

After light refreshments and song singing there was some discussion regarding the Association of Professional Engineers. A strong appeal for support of the Professional Association was made by Col. Lamb, Mr. McFaul and Mr. Jackson. Col. Lamb spoke particularly of the close co-operation between The Engineering Institute of Canada and the various professional organizations, pointing out that there is no conflict between them since the function of The Engineering Institute of Canada is educative, whereas the Professional Associations are legislative.

Executive Meeting

A meeting of the Executive Committee of the Hamilton Branch was held in the office of W. L. McFaul, M.E.I.C., on February 7th, with six members of the Executive present.

A letter from the secretary of the Hamilton Chamber of Commerce announcing the approval by their board of directors of a permanent standing committee to which engineering and public utility questions could be referred and enclosing a list of Institute members in the Chamber of Commerce as a suggested nucleus for the committee was read. On the motion of H. A. Lumsden, M.E.I.C., seconded by H. B. Stuart, A.M.E.I.C., this committee was endorsed with the addition of the secretary and the chairman of the Hamilton Branch.

The personnel of this committee for the present year is as follows:—

W. D. Black, A.M.E.I.C.	H. A. Lumsden, M.E.I.C.
E. H. Darling, M.E.I.C.	W. G. Milne, A.M.E.I.C.
L. W. Gill, M.E.I.C.	J. J. MacKay, M.E.I.C.
H. U. Hart, M.E.I.C.	R. K. Palmer, M.E.I.C.
F. I. Ker, A.M.E.I.C.	F. W. Paulin, M.E.I.C.
R. L. Latham, M.E.I.C.	W. F. McLaren, M.E.I.C.

This year the branch chairman is also a member of the Chamber of Commerce.

Some discussion ensued regarding the annual general meeting in Quebec, and it was decided to pay a portion of the branch chairman's expenses as an official representative of the branch at the meeting.

Certain applications for admission or transfer were considered and referred to the Membership Committee. Details regarding the branch meeting on February 16th were discussed.

Regular Meeting

A very interesting meeting of the Hamilton Branch was held on Wednesday evening, February 16th, in the cafeteria of the Hamilton Technical Institute. Since the branch chairman, L. W. Gill, M.E.I.C., was in Quebec attending the Annual General Meeting of The Institute, W. L. McFaul, M.E.I.C., the vice-chairman of the branch, occupied the chair. After the minutes of the previous meeting had been read, Mr. McFaul announced that A. R. Decarey, M.E.I.C., had been elected president of The Institute and W. F. McLaren, M.E.I.C., had been elected councillor for the Hamilton Branch for the third time.

It was announced that a joint committee had been appointed consisting of members of the Chamber of Commerce who are also members of the Engineering Institute of Canada, together with the branch secretary and branch chairman.

On behalf of H. A. Lumsden, M.E.I.C., chairman of the Papers Committee, who was attending the Highway Engineers' convention in Atlantic City, it was announced that the next meeting of the branch would be held about March 16th. The speakers will be A. M. Jackson, A.M.E.I.C., of Brantford, who will speak on "Concrete Roads," and Stanley Shupe, M.E.I.C., of Kitchener, who will speak on the "Sewage Disposal Plant in Kitchener."

A little discussion followed regarding the prizes which the Executive Committee offered to members and students of the branch, and students of the Hamilton Technical Institute, and the action of the Executive Committee was confirmed. A motion was passed authorizing the branch Nominating Committee to nominate the Prize Committee, to be elected at the annual branch elections and to be representative of all branches of engineering so far as possible.

Electric Control of Movable Bridges

The programme for the evening consisted of short talks by various local engineers. Mr. J. P. Fraser, of the Canadian Westinghouse Company, gave an interesting talk on the electric control of movable bridges. He showed several slides illustrating different types of movable bridges and the complicated control apparatus. The types of bridges are: the swing bridge, the bascule bridge, of which the highway bridge across the canal is an excellent example, and the lift bridge, in which the movable portion is lifted straight up, remaining horizontal.

Mr. Fraser described the various interlocks and the safety devices which result in the operator merely having four simple operations to perform, namely, setting the traffic signals, closing the traffic gates, releasing the locks and opening the span.

In the discussion that ensued, E. H. Darling, M.E.I.C., remarked that a short time ago the control was very simple, consisting merely of one double throw switch which was thrown in one direction to open the bridge and in the other direction to close the bridge. He mentioned the contrast between the old simple control, which required a lot of skill on the part of the operator, and the present day complicated control, which makes the operator's job the sort of position Mr. Darling would like when it comes time for him to be superannuated.

Street Illumination

Mr. G. F. Mudgett, also of the Canadian Westinghouse Company, spoke on "Street Illumination." He pointed out that adequate illumination prevents crime and enhances property values, as well as beautifying the city and reducing the number of traffic accidents.

He traced the development of street illumination from the tall towers of twenty years ago that illuminated the roofs of houses beautifully but left the streets somewhat dim, through the intermediate stages, to the present day highly specialized units that distribute the light wherever it is desired. By the proper design of the light controlling device and the enclosing globes it is possible to distribute the light so that practically all of it is thrown on to the roadway.

Considerable discussion ensued, particularly regarding the street lighting problem in Hamilton. Mr. Andrew Bratt, of the Hamilton Hydro-Electric System, mentioned the layout of street lighting in Hamilton; single 750-watt lamps are in use in the central business district with 500-watt lamps in the secondary business area. In the residential district 100-watt lamps, spaced 100 feet apart, are used, with 200-watt lamps on the corners, and on street car streets lamps are placed on both sides. Since the largest unit in use for street lighting service is two 750-watt lamps on one standard, Hamilton has not yet reached the last word in street lighting. In fact, street lighting in Hamilton is far from good.

In the discussion it was pointed out that it was possible to improve the intensity of the light on the street surface by the use of new glass which would give a better distribution of light. This would be at the same annual cost of lighting, but there would, of course, be the installation charges. It was also recommended that glass canopies be used to replace the present metal reflectors.

Manufacture of Pig Iron

Mr. H. G. Girvin, of the Steel Company of Canada, spoke briefly on the "Manufacture of Pig Iron." He discussed the blast furnaces, including the hearth, tuyers, bosh, and the brick work, and he mentioned the precautions that had to be taken to eliminate or control the metalloids on account of the variation in properties of the finished material.

Traffic Signals

A. R. Hannaford, A.M.E.I.C., spoke on traffic signals as distinguished from mere signs indicating traffic direction. The first traffic signal was the "Indian Smoke Signal," which came to the attention of Europeans around 1517. He rapidly sketched the development of traffic signals and described the types of flashing signals in use in other cities, including the central suspended type, which is used in Hamilton, the central standard type, and the side bracket type. He pointed out that no one type of signal can be used entirely by any city, as different conditions demand different types. At Cannon street and Sherman avenue, in Hamilton, it was found necessary to use a bracket signal as well as a central suspended signal.

Mr. Hannaford described the timing devices for the signals used in Hamilton, which consist of a clock work machine operated by a 1/20-h. p. electric motor for the signals at James and Cannon streets and at the Delta, and of a magnetic control arrangement for the signals at Main and James, at Main and John and at King and Sherman. Each intersection in Hamilton is regulated by a separate control box, which was the most economical method to adopt, since the underground cable connecting two signals would have had a considerably higher cost. When the number of lights is increased these control boxes may be used to handle four to six intersections, according to conditions.

In Hamilton the timing is so arranged that there are thirty-five seconds of traffic on the main street, with twenty-five seconds on the cross streets. There is a five-second period during which the yellow light shows in a three-colour signal or the signal shows red in all directions in the two-colour signal. In the case of the Main and James and the Main and John signals, the timing is so arranged that an automobile going west on Main street at twenty miles per hour will find that the James street signal turns to green just as he reaches it, if he was held up at Main and John.

A lot of discussion ensued regarding the relative merits of the two-colour signals and the three-colour signals, also regarding the stop-street by-law which is in force in Hamilton and requires vehicles approaching certain through streets to come to a full stop before entering on the street, and the lighting of the signs marking the stop streets. It was pointed out that several of these signs are so much in the shadow that it is impossible to see them at night.

On the motion of J. J. MacKay, M.E.I.C., a hearty vote of thanks was tendered to the speakers. At the conclusion of the meeting sandwiches and coffee were served. The Mouthorgan orchestra of the Technical School rendered several selections during the serving of the refreshments. This was a very pleasant innovation. Considering everything, the fifty members present felt that this was one of the most successful meetings of the branch.

Lethbridge Branch

N. H. Bradley, A.M.E.I.C., Secretary-Treasurer.
C. J. Broderick, Branch Affiliate, Branch News Editor.

Concrete

Concrete is not a subject conducive to the usual small talk of the average dinner or social gathering, but on Saturday night, January 8th, 1927, when K. MacKenzie, Jr.E.I.C., service engineer of the Canada Cement Company, chose it as the subject of his address to the Lethbridge Branch at the regular bi-monthly dinner of the engineers, a discussion was started that lasted until eleven o'clock.

Master of his subject in all its varied details, Mr. Mackenzie stood for an hour, after completing his prepared paper, a target for questions fired at him from all quarters of the hall. As one of the engineers put it, "If Mr. Mackenzie had been talking politics in the same vein, he would have been branded a red revolutionist." Radical though his theories were, he carried conviction. Perhaps it is not quite fair to claim his arguments theoretical, for they have all been put to the test and proved sound, notably so in the construction of the mammoth new Hudson's Bay building at Winnipeg and in the Cement Company's own building at Montreal.

Briefly stated, his principle was that four gallons of water to one sack of cement would give the same strength of concrete regardless of what quantities of other materials are used, so long as the mixture is plastic and workable.

Questioned just before his address, he stated that while the year 1926 showed a cement consumption in western Canada of only 15 per cent increase over 1925, the coming year promises better than any year since before the war. "You will see a wonderful increase in municipal work this year," he said, "paving programmes are well advanced in the towns and cities of the west, and structural work will be heavy." All in all, he was very optimistic that the west has struck its stride and prosperous conditions were in sight. "I don't want to appear over optimistic," he declared, "we don't want any more booms through over-confidence."

The average man on the street listening to a discussion such as that on Saturday night would leave with a new respect for such prosaic things as a concrete sidewalk, or the pavement over which he drives his car. All over the continent men are studying this question of concrete. Every university has research engineers testing and experimenting. All to the end that the public may be safeguarded against faulty materials entering into their bridges, their buildings or their roads.

How important this research is may be understood from such statements as this of Mr. Mackenzie's: "Less than two and one-half gallons of water," he said, "are sufficient to hydrate one sack of cement, and while it is necessary to use more than this amount of water to produce a workable mix of concrete, any water in excess of that required to hydrate the cement reduces the strength and makes a more porous concrete. Excess water also tends to cause shrinkage cracks which may later develop and cause the concrete to fail."

This principle is evident when cement is likened to glue. The more a glue is diluted with water, the less is the strength obtained. It follows then that a concrete required to meet a certain definite strength must take into account the volume of water to be used per sack of cement. The other elements entering into concrete, the stone and the sand, only affect the strength as they affect the quantity of water required to produce a workable mixture. In this respect the volume of water used is affected also by the moisture in the sand. A cubic foot of sand ordinarily holds from a quarter to three-quarters of a gallon of moisture.

All this, of course, is directly of interest to the engineer and the contractor. The public sees merely the completed structure. It is only when a structure fails that the public realizes the importance of such principles, and gets some faint idea of what is going on behind the scenes among our scientists and engineers.

Mr. Mackenzie gave a graphic account of the cementing of an oil well. There is always a small opening between the casing and the drill hole and unless this opening is filled with a gas-tight material trouble occurs from water flowing into the well or gas escaping. Pure cement is used. The casing is raised a few feet and a high pressure pump forces water down. This water then rises between the casing and the drill hole to the surface forcing mud, oil, etc., ahead of it until the water that rises comes clear. A cement mixture is prepared containing calcium chloride. A wooden plug is inserted in the casing. The cement mixture is pumped in on top of the plug. Then a second plug is put in and water is pumped in, forcing the two plugs with the cement mixture between them down the well until the lower plug drops out, allowing the cement to be forced around the end of the casing and up between the casing and the drill hole. This pumping continues until the top plug rests on the lower plug and the casing itself is full of water, which produces sufficient pressure to keep everything in position until the cement hardens. Then the wooden plugs are drilled out and boring goes on as usual.

Technical though this lecture of Mr. Mackenzie's was, the thought predominated throughout that were it not for the hundreds of silent thinkers in our universities and laboratories of industrial concerns, this world would be a queer place.

The dinner was enlivened by the Rainbow Orchestra, community singing and songs by Mr. Smith. G. N. Houston, M.E.I.C., presided in the absence of the chairman, J. T. Watson, A.M.E.I.C., whose duties at the power house kept him away.

Water Powers of Canada

Doubters, if there be any, of Canada's position in world affairs must have had their fears dispelled after listening to an address such as that presented before the Lethbridge Branch on Saturday night, January 22, 1927, by A. L. Ford, M.E.I.C., engineer of the Dominion Water Powers Branch, who discussed in detail the water powers of Canada. It was the type of speech that must thrill Canadians with the immensity of our power resources—the greatest single agency behind modern industrial progress.

Available records show that Canada's power resources permit of a turbine installation of almost forty-two million horse power. But what is perhaps the most surprising statement is that in developed horse power Canada stands second only to the United States, having developed 4,290,000, and further, that Canada is second for developed horse power per unit of population, Norway coming first and the United States fifth. Among the provinces, Quebec comes first with 11,640,000 horse power and an installation of 1,915,000 horse power; Ontario is second and Manitoba third, British Columbia fourth and Alberta fifth with 1,137,000 horse power and an installation of 34,000 horse power. These figures do not consider storage possibilities.

Of the water powers in the Lethbridge and Crow's Nest area, Mr. Ford stated they were very limited and depended largely on the question of storage, and to a large extent the entire power problem of Alberta is one of storage.

"In Alberta," said Mr. Ford, "our streams are subject to seasonal fluctuation, high in summer and low in winter. The consumer demand is exactly the opposite, being low in summer and high in winter, due to the lack of steady loads such as for pulp and paper industry and manufacturers. If Alberta is to make the best use of its power streams, we must contemplate either storage reservoirs or steam stand-by plants."

Up to this point Mr. Ford had been discussing his subject with charts and graphs. Statistics are difficult to follow when presented in cold figures, but as the pointer followed these charts with their peaks and valleys, his figures were made to tell a wonderful story of progress and opportunity for Canada. This Dominion has come along in giant strides industrially since the beginning of the present century when the water power developed was a mere 150,000 horse power. By 1910 it was 965,000 horse power. Then witnessed a leap forward—in 1920 it was 2,500,000 horse power, while today there is a development amounting to 4,556,000 horse power. Only 11 per cent of the available resources have yet been touched. Looked at from statistics alone, it would appear that Canada's water power is unevenly distributed through the provinces, but industrially this is not so, for what power is available has been by a kind nature placed strategically to serve centres of industry.

By means of a most comprehensive series of aerial photographs thrown on the screen, it was easy to follow the growth of power plants across the Dominion, but it was when the speaker got down into Ontario and Quebec that the immensity of power development was apparent. In these two provinces, where pulp and paper mills are springing up like mushrooms, where provincial governments are working out gigantic schemes of electrical development, every possible source of supply is being canvassed. To those who would say that Canada is not advancing industrially, that we are falling back before the factories of our neighbour to the south, it is only necessary to produce the facts and figures so graphically presented by Mr. Ford. If the slides alone could be thrown on the screen of the movie houses across the Dominion, the people of Canada would realize something of the potential greatness of their country.

Canadians have come to believe that theirs is pre-eminently an agricultural country. In this respect it was surprising to hear from Mr. Ford that the value of manufactured products in Canada now exceeds the value of agriculture. Attracted by our resource of power foreign capital is coming into the country rapidly, making for an ever increasing export trade of manufactured goods. Low grade ores are found to be practical where once they were scorned. With inexpensive power there need be little fear for Canada's prosperity.

An important feature of this hydro-electric development applied to the marketing of coal. The big consumption of coal has in the past been in Ontario and Quebec. In proportion as these two provinces advance in their water powers, the importation of coal will decline and what is now proving to be something of a national problem may solve itself.

Mr. Ford touched upon the stability of invested capital in water power projects. He said that the amount of money now invested in this resource far exceeds that in any other industry, and investigation has shown that only one company involved during the last twelve years has failed.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

A combined meeting of the Moncton Branch and the Engineering Society of Mount Allison University was held at Sackville on January 13th. A. S. Gunn, A.M.E.I.C., occupied the chair. A very interesting paper was read by A. F. Dyer, M.E.I.C., chief engineer of the Nova Scotia Construction Company, Halifax, N.S., on the subject of the "Lake Kenogami Storage Dams." The address was illustrated by lantern slides.

Lake Kenogami Storage Dams

Lake Kenogami lies to the south of lake St. John and discharges into the Saguenay river by means of two outlets, the Chicoutimi and Ausable rivers. Increased demands for power led to the building of dams across the rivers with a consequent rise of twenty-three feet in the water level of the lake. The largest of these structures is the dam across the Chicoutimi river. It is 1,500 feet long, has a maximum height of 80 feet and is built entirely of concrete. A roadway 17 feet 6 inches wide extends along the top. A large part of the work was done during the winter months with temperatures ranging almost continuously from 10 to 20 degrees below zero. Notwithstanding the severe weather conditions, no damage whatever was experienced from frost. The concrete ingredients were heated with steam jets previous to mixing. The surface on to which the concrete was to be poured was warmed for at least twelve hours before the placing of concrete. This was done by covering over with tarpaulins, under which stoves were placed. Hot water was found far more efficient than steam for cleaning off snow and ice. In answer to a question, Mr. Dyer declared that he did not consider harmful the freezing of the top layer of concrete in a partly completed structure. When pouring was resumed the heat generated by the chemical action of the new concrete would quickly thaw out the frozen layer and cause it to again take on the properties it had when freshly mixed, resulting in a perfect bond between the new and old.

At the conclusion of the address a vote of thanks was tendered Mr. Dyer, moved by Prof. F. L. West, A.M.E.I.C., and seconded by E. Bannerman.

The Welland Ship Canal

Tracing the history of the Welland Ship canal from its beginning until the present time, Alexander J. Grant, M.E.I.C., engineer-in-charge of the project, gave an exhaustive résumé of the gigantic work before the members of the branch at a supper-meeting held in the Y.M.C.A. on January 26th. The address was profusely illustrated with lantern slides. A. S. Gunn, A.M.E.I.C., chairman of the branch, presided.

The canal under construction will be the fourth built across the Welland peninsula. The estimated cost is $115,000,000 and it is expected the work will be completed about 1930. The canal is 25 miles long and about 300 feet wide. The 325-foot difference in elevation between lakes Ontario and Erie is taken care of by seven locks, each having a lift of 46 feet 6 inches. It is interesting to make comparisons with the Panama canal, which has a total lift of 86 feet, the maximum single lift being 30 feet 4 inches.

The canal begins at port Weller on the lake Ontario side and goes through to port Colborne on the lake Erie side. It will allow vessels of 25-foot draught to pass through. At port Weller a harbour has been built which consists of two breakwaters extending into the lake a distance of one and a half miles, each being 800 feet wide at the shore end and tapering to 400 feet at the outer end. At port Colborne two converging breakwaters are also built, one mile from shore, protecting two piers placed inside, near which a 1,000,000-bushel elevator is erected.

No tolls are charged, the canal being free to both Canadian and American shipping. In this connection it is worthy of note that no attempt has ever been made to connect the two lakes by a canal built on American territory.

A hearty vote of thanks, moved by F. B. Fripp, A.M.E.I.C., and seconded by C. S. G. Rogers, A.M.E.I.C., was tendered the speaker by the chairman.

Previous to the address the members were entertained by enjoyable soprano solos by Mrs. R. L. Steeves and bassoon selections by Mr. Percy Belyea.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
H. W. B. Swabey, M.E.I.C., Branch News Editor.

Power Films, Shawinigan Water & Power Company

It would seem from the number of members present on Thursday evening, January 20th, that "movies" were much appreciated as a welcome change to the usual weekly papers. Through the courtesy of the Shawinigan Water and Power Company, a four-reel film was exhibited, showing the development of electrical power from the early stages to the present time.

An introductory description of the pictures was given by C. K. McLeod, A.M.E.I.C., after explaining the unavoidable absence of an officer of the Shawinigan Water and Power Company, who was to have given this description.

A comparison was made between the building of the Egyptian pyramids, as an early example of large construction work, with the difficulties of transportation and handling of material in those days, and the present day methods, with the use of electric power; the difference in speed and cost of transportation by old and new methods being illustrated. Included in the pictures were illustrations of the use of man's power, ox power, horse power, wind power, steam power and finally electric power.

Interesting views were shown of the Shawinigan Water and Power Company's dams and power plants at St. Maurice, Grand'-Mere and LaGabelle, as well as Montmorency falls, Chaudiere and others, and of industries which have arisen in areas well supplied by electrical power. Views of the largest transmission crossing in the world, over the St. Lawrence river at Three Rivers, Que., were shown, and also of streets in Montreal and Quebec lighted by electric power.

The Montreal Branch is much indebted to the company for the use of these films, which were much appreciated.

Railway Lands—Titles, Surveys, Leases and Taxes

On January 27th a paper was read on this subject by Frank Taylor, M.E.I.C., who is in charge of the department of the Canadian Pacific Railway which handles this work.

In view of the fact that the organization and functions of the land department are not quite similar on any two railways, the author dealt with this work as it is conducted by the right-of-way and tax agent of the Canadian Pacific Railway, whose functions include all matters in connection with the right-of-way, titles, surveys, leases and taxes of railway lands, other than agricultural lands in the western provinces, which are dealt with by the department of colonization and development.

The laws in the different provinces governing squatters' rights were cited and it was shown that without accurate records of property owned by the railway, how easy land may be lost by the exercise of these rights.

A description of the title record plans as used on the Canadian Pacific Railway was given. For ordinary right-of-way, these plans are made up, each covering ten miles of railway, and are plotted from the description contained in the title deed of each individual lot and each lot outlined in a different colour; changes are made on these title record plans as may be necessary from time to time when any of the land is sold or any adjacent land purchased. The preparation of these graphic records is much complicated in the case of large cities, and also in the case of small railways acquired at various times, and where title deeds may be missing for certain portions of the right-of-way. The author mentioned that during the past twenty years re-surveys and plans had been made of some 4,000 miles of railway on certain lines of the Canadian Pacific Railway. As these lines are mostly composed of many small railways constructed years ago, it was rarely the case that "as constructed" plans were available.

The various forms of occupancy of railway lands covered by lease were cited by the writer and the basis for assessing rentals on such property. He also dealt fully with the question of taxes, which is a large item of expense to a railway company, as not only are taxes paid to municipalities but to the provincial and federal governments.

Reference was made to land which was exempt or partially exempt from taxation, the forms applying mostly to the main line through Saskatchewan and Alberta, which was given perpetual exemption under the original charter.

A considerable amount of discussion followed the reading of the paper. The chairman of the evening was D. Hillman, M.E.I.C.

Traffic Regulations by Automatic Signals

On February 3rd Mr. K. W. Mackall, of the signal engineering department of the Crouse-Hinds Company, Syracuse, N.Y., gave a lecture on the use of automatic signals for the "Regulation of Street Traffic," which was illustrated by lantern slides. The speaker described the various types of traffic control signals that have been tried or installed in different cities, commencing with the traffic tower on Fifth avenue, New York, which was equipped with powerful search lights, down to the most modern electrically controlled systems. Diagrammatic pictures of street intersections were shown, illustrating the various positions in which controlled signal lights can be placed, and the advantages or disadvantages of each position were explained.

The lecturer stated that the first modern interlocking signal system was installed at Hewston, U.S.A., about five years ago. Various systems of coloured lights are in use, but the most common are "green" for "go," and "red" for "stop," and "amber" to clear traffic in one direction before traffic can start in the other, or for "caution." The three systems of control in use are known as the "synchronous control," the "progressive system of control," and the "co-ordinated system." Ninety per cent of the installations at present in use are of the synchronous control type.

The speaker referred to the haphazard way in which many cities are installing traffic control, and stated that it was very necessary that the matter should be given careful study, as a system which suited one city might not be at all suitable for another. He recommended that the traffic problems should be placed in the hands of a competent engineer, who should have the co-operation of all departments in any way associated with traffic matters.

In regard to street car traffic, Mr. Mackall stated that reports varied considerably as to the retarding or increasing the rate of this traffic.

C. J. Desbaillets, M.E.I.C., proposed a vote of thanks to the speaker. The chairman was J. F. Brett, A.M.E.I.C.

Radium

A most interesting lecture on the subject of "Radium" was delivered by Dr. J. E. Gendreau to the members of the Montreal Branch on the evening of February 10th in the Convocation Hall of the University of Montreal. Dr. Gendreau is the director of the Radium Institute, Montreal, and is well known as one of the outstanding authorities in Canada on the study and use of radium. The speaker dealt with the physical, chemical and biological properties of radium, giving a history of its accidental discovery and an outline of the work done by Monsieur and Madame Curie in a small laboratory in Paris in the development of this discovery. He explained and demonstrated the radio-activity of uranium, by which radium was first discovered, and also found to be in combination with pitch-blende, a dark pitch-like mineral from which uranium is extracted.

Dr. Gendreau gave a demonstration of fluorescence, the property of certain bodies, such as fluorspar, of producing or emitting light other than reflected or transmitted light. He also explained that the rays from radium, known as Bicquorel rays, named after Dr. Bicquerel, the discoverer of radio-activity, are not the same as Rontgen rays or X-rays.

A considerable amount of apparatus was used in interesting experiments to practically demonstrate the various points in the lecture and a half gramme of radium was exhibited, valued at $40,000.

Reference was made to the great work at present being carried on in connection with radium research by Dr. Rutherford, formerly of McGill, and pictures of the various persons mentioned were shown on the screen.

A vote of thanks to the lecturer was proposed by F. B. Brown, M.E.I.C., who spoke very highly of the work and accomplishments of Dr. Gendreau. The chairman of the evening was Mr. O. O. Lefebvre.

Niagara Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

At Welland on January 25th the branch held a very well attended dinner meeting.

Dredges and Dredging

W. E. Bonn, A.M.E.I.C., engineer-in-charge of dredging, Toronto Harbour Commission, was the speaker. His subject was, naturally, "Dredges and Dredging," and proved quite timely in view of the enormous quantities of material that are being handled on the canal work in the district.

E. G. Cameron, A.M.E.I.C., introduced the speaker as an old friend and co-worker of his in St. John, N.B., and intimated that dredging engineers have a technical vocabulary all their own and that even in the worst coast fogs he could tell when Mr. Bonn was in the vicinity by the strange sounding words and resonant tones that were used. Years of practice, endeavouring to drown out the din made by the average ladder dredge, was necessary to achieve such results.

Mr. Bonn then showed some excellent aerial views of the Toronto harbour development, where hydraulic or suction dredges are used almost exclusively, and explained the methods of conveying the material and dykeing for reclaiming land areas.

In order that navigation should not be interfered with a plan was developed whereby the pontoon or trestle carriers were partly eliminated and the conveyor pipe from the dredge to the shore line was sunk and laid along the harbour bottom. This proved to be less expensive than trestle work even in the first instance, six hundred feet a day being put into place as compared with about two hundred feet possible with trestles.

After this review of the Toronto work, Mr. Bonn went on to show other slides of various types of dredges and discuss their merits. The hydraulic dredge was conceded to be the most economical type for the finer classes of material from mud and silt to coarse sand. When gravel in any quantity was encountered, however, the dipper and ladder dredges came into their own, and for boulders the ladder dredge took the lead in efficiency.

The latest word in hydraulic dredges was the "Clakamas" at Portland, Oregon, with 3,400 horse power Diesel engines and motor-driven pumps. Her record was 754,000 transport units and 955 cubic yards per pumping hour as compared with the "Tualatin's" 450,000 transport units and 571 cubic yards. A "transport unit" being equal to 1,000 cubic yards pumped through 100 feet of line pipe with a lift of one foot.

J. R. Bond, A.M.E.I.C., moved a vote of thanks and referred in a humorous way to some of his experiences while Mr. Bonn was supervising the dredging near Chippawa. Owing to the similarity in their names, Mr. Bonn got all the credit, while if anything went wrong or if the dredge broke a gas main, Mr. Bond received all the blame from the local residents.

E. P. Johnson, M.E.I.C., seconded this vote of thanks and Chairman Alex. Milne, A.M.E.I.C., took occasion to say that the true spirit of thrift is economical progression, and that was dependent upon the dissemination of just such information about efficient machinery and methods as the speaker had conveyed to the meeting.

New Members of the Branch

Messrs. A. T. C. McMaster, M.E.I.C., and A. L. Mudge, M.E.I.C., have lately joined the staff of the Welland Ship canal as hydraulic engineer and electrical engineer respectively.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

The Annual Ball

Under the distinguished patronage of their Excellencies the Governor-General and the Viscountess Willingdon the Ottawa Branch of the Engineering Institute entertained at their annual ball in the Chateau Laurier on January 27th. No event of the season is more eagerly anticipated in Ottawa than this yearly dance, and it proved quite as delightful and successful as on former occasions.

Palms adorned the foyer of the Chateau, where the hostesses of the evening received their guests, just at the entrance. Mrs. Noulan Cauchon, wife of the chairman of the Ottawa Branch; Mrs. F. H. Peters and Mrs. Gordon Gale graciously welcomed everyone.

The ballroom was thronged with gay dancers. Here the emblem of The Institute, a large shield depicting the Canadian beaver, was placed between the two main windows. An excellent orchestra provided a lilting programme of dance numbers. The Tudor room was used for sitting out and for the serving of fruit punch.

Supper was served in the main dining room at 11.30 o'clock, the long buffet tables, which were placed at the sides of the room, being adorned with tall vases of cut spring blooms.

The committee in charge of the arrangements, which were most capably carried out, was composed of Mr. Russell K. Odell, convener, H. M. Barton, A.M.E.I.C., and J. D. Craig, M.E.I.C. Others who assisted the committee in looking after the guests were N. Cauchon, A.M.E.I.C., J. L. Rannie, M.E.I.C., Commander C. P. Edwards, A.M.E.I.C., K. N. Cameron, M.E.I.C., and J. B. McRae, M.E.I.C.

Noulan Cauchon, A.M.E.I.C., newly elected chairman of the Ottawa Branch, presided at a luncheon at the Chateau Laurier on February 10th, at which Engineer Commander T. C. Phillips, R.C.N., M.E.I.C., spoke on the subject of "Engineering Development in Fighting Ships."

In introducing the speaker, Mr. Cauchon extended a hearty welcome to Grote Stirling, M.P., whom he characterized as the only engineer in the House of Commons, and provoked considerable laughter in his remarks concerning some early engineers. He alluded to two early ornaments of the profession, Yu, Chinese emperor of ancient times, who owed his exalted post to his proficiency as an engineer, and to Julius Caesar.

Engineering Development in Fighting Ships

Commander Phillips traced the evolution of fighting ships, commencing with the galleon which held sway for 3,000 years and had some advantages over its successor, the sailing ship, in that it had a definite speed and could be manoeuvred for fighting. It was manned by hundreds of slaves—an unfailing motive power—in contrast to the sailing ship which was often becalmed within sight of the enemy. Then steam propulsion came and the earliest fighting ship of the Royal Navy, the "monkey," in 1821 was looked at askance, and little wonder, with its square boilers and 4 to 8 pounds pressure, and its paddle wheels which could be easily put out of commission with a well-directed shot. The screw propeller helped to break down the objections of the naval men. The replacement of wooden hulls with steel and development of the special ductile steel required for armour plate completed the transformation and we had the modern battle ship.

But was that all? said Commander Phillips, and he proceeded to speak of the great service which engineers had performed in providing a ship which could stand punishment as well as give it. A warship, like a pugilist, had to be able to give and take. The merchantship was entirely different from the warship in that it could not take punishment. The hull of the merchantman contained few watertight compartments and the puncturing of one or two rendered the ship unseaworthy. The battleship, with its many bulkheads, could have compartment after compartment pierced and not only remained seaworthy but could keep on fighting.

The internal arrangements of the fighting ship were most complex and a wonderful tribute to engineering efficiency in providing for disaster. Four separate sets of engines with separate propellers were provided to drive a battle cruiser of 45,000 tons. The "Hood," one of the most powerful, had engines of 150,000 horse power, which were capable of driving the ship at 38 miles per hour, or as fast as one of the express trains between Ottawa and Montreal.

Commander Phillips graphically described the mechanism of the up-to-date warship and its quadruple mechanisms to provide for every contingency. Light must be guaranteed for the bowels of the ship, and four lighting sets were installed; when one went out of action another was instantly started. Other duplication included four steering sets, four hydraulic sets and twelve refrigerating sets. Summing up, the speaker contrasted the "Hood" with the "Victory," Nelson's flagship. The range of the 18 hand-operated guns of the "Victory," to which 32-pound balls were fed by "powder monkeys," was 1,200 yards. The "Hood" has eight 15-inch guns firing a projectile weighing a ton and with a range of 30,000 yards. The whole main battery could fire fifty tons of projectiles in one minute. To keep this wonderful mechanism in operation required a crew of 1,500 officers and men. A comparison was also made between the old Mediterranean fleet and the present day fighting ships stationed there. These have, he said, a combined power capacity of two million horse power.

Surveying in the Mountains

On February 17th, at the Chateau Laurier, under the auspices of the Ottawa Branch, M. P. Bridgland gave an address on "Surveying in the Mountains." Mr. Bridgland, who has been mapping in the Canadian Rockies and Selkirks continuously for twenty-five years, is a recognized authority on photo-topographic methods of survey and his address, beautifully illustrated with Canadian mountain views, was listened to by a large and attentive audience.

Introduced by Chairman Noulan Cauchon, A.M.E.I.C., Mr. Bridgland outlined the methods of surveying and mapping the extremely rough country pertaining in a vast area of Alberta and British Columbia, where mountain peaks range from 8,000 to 11,000 feet above sea level, and where snow fields and glaciers of large size are very numerous. The difficulties of producing maps of this area, showing accurately the topographical features of the ground, were overcome by photographic methods of survey, introduced into Canada by the late Dr. Deville, surveyor general.

The principle upon which the photographic method depends is that if two views of the same terrain are taken from different camera stations, points common to both photographs can be plotted and their elevations determined. Views covering the entire country to be mapped are therefore taken from various mountain peaks in such a way that each part of the ground appears in at least two photographs from different viewpoints. The photographs are taken horizontally, the plate being held truly vertical in the specially constructed survey camera. These views are perspectives and the problem of plotting and subsequent contouring of the map is that of inverse perspective or reconstruction in plan.

Mr. Bridgland explained the system of control by which the positions of the camera stations are determined. This is a matter of triangulation and the climbing party carries both transit and surveying camera. Both these instruments are interchangeable on the same tripod and the camera is levelled up carefully the same as a transit. In concluding his address Mr. Bridgland explained the use of the various instruments.

Peterborough Branch

W. E. Ross, A.M.E.I.C., Secretary.
B. Ottewell, A.M.E.I.C., Branch News Editor.

The Manufacture of Carbon Products

At a regular meeting of the branch on Thursday, January 13th, 1927, a paper with the above title was presented by the late Mr. J. C. Webster, engineer with the Canadian National Carbon Company, Ltd.

This interesting address was illustrated by a fine three-reel moving picture depicting the processes described by the speaker. Complete details of the paper are not given here, as it had previously been delivered before the Hamilton Branch and reported in the January, 1927, issue of The Journal.

The branch has since been advised of Mr. Webster's death from pneumonia on February 4th, after only a few days' illness. As he was a valued friend of several members of the branch and had so recently visited us, a resolution of regret at this untimely event and of sympathy for Mrs. Webster was passed at the meeting of February 10th, 1927.

The Hemmings Falls Development

At a meeting of the branch held in the Chamber of Commerce council chambers, January 27th, 1927, J. S. H. Wurtele, M.E.I.C., vice-president and plant manager of the Southern Canada Power Company, Limited, delivered a most comprehensive and educational address on the Hemmings Falls development on the St. Francis river in Quebec.

His address was of peculiar interest to those present, as most of the equipment and machinery used in the development was supplied by the local factory of the Canadian General Electric Company.

The speaker of the evening was introduced by Max Sauer, M.E.I.C., who officiated as chairman for the occasion.

Illustrating his address with a variety of interesting views and diagrams showing the arrangement of the machinery, Mr. Wurtele entered into considerable detail regarding the activities of his company in that section of Quebec.

Mr. Wurtele was assisted at the lantern by H. S. Grove, A.M.E.I.C.

The thanks of the members was ably expressed to the speaker by A. L. Killaly, M.E.I.C. An abstract of this paper appears on another page of this Journal.

Students' Night

The meeting of February 10th, 1927, was devoted to a special "Students' Night," at which, under the able chairmanship of G. H. Burchell, S.E.I.C., the following three Students gave interesting papers:—

S. O. Shields. "Full Voltage Starting of Induction Motors."

W. T. Fanjoy. "Control of A. C. Motors."

F. J. Stewart, "Some Interesting Facts About Northern Alberta."

Mr. Shields introduced the subject of "Full Voltage Starting of Induction Motors" by drawing attention to the increasing demand for simplicity of control and operation of machines leading to a tendency to omit accessories such as starting compensators. He then pointed out that although the use of a starting compensator was intended to reduce the starting current and stresses on the windings of the motor, under certain circumstances, incorrect manipulation of the compensator could impose transients causing greatly increased stresses. A consideration also in some cases is the saving in space by the omission of a starting compensator.

Using the nomenclature adopted by the Canadian General Electric Company for their motors, Mr. Shields then described the general features of the following four classes of motors.

(1) Type KTE, with a high resistance, brass winding on the rotor, suitable for intermittent duty requiring high starting torque, such as elevator service.

(2) Type KTR, similar to the type KTE but with a lower resistance rotor winding, suitable for continuous running in service having a lower starting torque requirement.

(3) Type FTR, with composite rotor winding, consisting of copper bars at the bottom and brass bars at the top of the slots, separated by steel and copper bars. These are not general purpose motors, but are intended for applications requiring a high starting torque with moderate starting current when the motor is thrown directly on the line voltage.

(4) Type FT differs from the type FTR in having shallower slots with only a copper winding at the bottom of the slots and the top filled by steel bars. These motors are suitable for full voltage starting, but have a much lower starting torque than the type FTR. Suitable applications for this type are centrifugal pumps, fans, etc.

Control of A. C. Motors

In describing the various types of control for A. C. motors, W. T. Fanjoy, S.E.I.C., referred to control for squirrel cage and wound rotor induction motors suitable for starting, reversing and speed regulating, and for either hand, semi-automatic, or full automatic operation.

Reduced voltage starting is usually accomplished by means of a compensator or tapped auto transformer, having two or more reduced voltage taps and rated one minute in every four minutes for one hour. Compensators may be controlled either manually or by the use of contactors.

Other methods of reduced voltage starting are the resistor method, suitable for light duty, and inferior to the compensator method in that a higher current is drawn for the same torque; the reactance method, similar to the resistor method but more expensive; and the Y-delta method, which is equivalent to using 58 per cent starting tap, but has the same torque limitations as the resistance method. This latter method is not common owing to the fact that many motors have Y-connected windings and are, therefore, not suitable.

Mr. Fanjoy then referred to the full voltage starting of induction and synchronous motors, either by hand switch, magnetic switches, or breakers. He also referred to the starting and control of wound rotor induction motors and the various devices included in the control for protection against overload, undervoltage and phase failure, or reversal.

Some Interesting Facts About Northern Alberta

The third paper of the evening was given by F. J. Stewart, S.E.I.C., his subject being "Some Interesting Facts about Northern Alberta." Mr. Stewart described a trip made into this territory in 1922 which proved to be most instructive. During the course of the paper a large number of coloured slides were shown. The buffalo ranges, north of the Peace river and west of the Slave river, were described and several good photographs of these animals were shown. The speaker also covered the extensive mineral resources, such as galena, gypsum, salt and bitumen, of which there are many evidences, as well as the timber resources.

Development of these resources will only come with a solution of the power and fuel problems. Power sites were illustrated on the Slave river between Fitzgerald and Fort Smith, but it was pointed out that the nearest available coal supply was at Edmonton.

At the conclusion of each paper the speaker answered a number of questions. G. Coutts, A.M.E.I.C., proposed a vote of thanks to the three speakers, which was heartily approved by those present. In the absence of B. L. Barns, A.M.E.I.C., W. M. Cruthers, A.M.E.I.C., presented to G. H. Burchell, S.E.I.C., and each of the three speakers of the evening an Institute pin, donated by Mr. Barns for the first Students' papers to be given before this branch. This concluded a most interesting and entertaining evening.

Saskatchewan Branch

R. W. E. Loucks, A.M.E.I.C., Secretary-Treasurer.

Ladies' Night

The members of the branch, accompanied by their wives, spent a very enjoyable evening at the home of Mr. and Mrs. H. N. Macpherson, Regina, on Friday, January 7th, 1927. The early part of the evening was devoted to cards, followed later by refreshments and dancing. About sixty guests were present and all voted the function a huge success. Before leaving for home a vote of thanks was tendered Mr. and Mrs. Macpherson for their hospitality, after which the guests joined hands and sang "Auld Lang Syne."

Meeting of January 27th, 1927

A regular meeting was held in the Kitchener hotel on January 27th, preceded by a banquet. Chairman W. H. Greene, M.E.I.C., of Moose Jaw, presided. Following the banquet a unique form of spelling contest was staged by H. N. Macpherson, A.M.E.I.C., of the Entertainment Committee.

The Engineer and the Immigration Problem

A. G. Dalzell, M.E.I.C., consulting engineer of Toronto, Ont., gave a very instructive and interesting address on "The Engineer and the Immigration Problem." Mr. Dalzell declared that the engineer is responsible for the "Immigration Problem," as he had provided the modern means of overland and overseas transportation and facilitated electrical communication by telegraph, telephone and radio. The engineer should therefore rightly consider the problem and assist in its solution. Mr. Dalzell is of the opinion that we have in the past taken into western Canada immigrants more rapidly than they can be properly assimilated and they have been settled on the land without proper selection and supervision. The result is that a large number of farms are abandoned every year, and so long as this situation exists agriculturalists from northern Europe will not come to Canada. What is required is a proper survey and classification of our lands and soils and a correct invoice of our natural resources so that when settlers come to our shores they can be properly directed and advised in their settlement. Despite the fact that Canada is an agricultural country our urban population has increased in the past much more rapidly than our rural population, and this in spite of large numbers of immigrants arriving each year. There is a need to encourage and stimulate the populating of rural areas by assisting and directing the establishment of rural settlers. Past methods will not suffice. The cities of western Canada have been greatly over-subdivided without provision for settlement. Many of the errors of the past can be traced to speculators and the lack of proper control over subdivisions. These lands, whether urban or rural, must now be put to their proper use and in this the engineer can assist. He must carry on propaganda in public and take his rightful place in public life. The public do not appreciate the value of the engineer in directing the development of our cities, towns and rural areas. We should pay more attention to the human side of our development rather than the industrial and commercial, to strive to not only improve the tool, but improve the man who uses the tool.

At the conclusion of the address a hearty vote of thanks was tendered the speaker on motion of R. N. Blackburn, M.E.I.C., and H. S. Carpenter, M.E.I.C.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer.

A regular meeting was held on January 28th in the Y.W.C.A. rooms, following a dinner at which Mr. K. Gordon and Mr. R. Gascoigne of the Spanish River Pulp and Paper Company, and Mr. W. A. Burrows of the Turbine Equipment Company of Toronto, were the guests.

Owing to the absence of G. H. Kohl, A.M.E.I.C., chairman, and R. S. McCormick, M.E.I.C., vice-chairman, C. H. Speer, M.E.I.C., acted as chairman and called the meeting to order and expressed the feelings of all the members in extending to the visitors a hearty welcome.

At 8.15 p.m., after the completion of the regular business, the members, numbering thirty, under the guidance of Messrs. Dennison, Gordon and Gascoigne, made an inspection trip through the plant of the Lake Superior Paper Company. As the time was limited we started at the ground wood room inspecting the drum barkers and chippers, and then passed through the beater room on our way to the hydraulic and electrical grinder room. Great interest was shown here by the members. The next department visited was the paper machine room and the operation of the paper machines is still a conundrum to most of the members. From there we went through the sulphite mill and, to judge by the sneezing and coughing, the members thoroughly enjoyed this department. The board mill came next and we saw heavy wrapping paper being manufactured, and the smooth running steam plant of this part of the mill was well worth seeing. In the boiler house we had a chance to see the new pulverizing installation being installed and in the new power house the new turbo-generators and equipment were closely inspected by all. Last but not least came the corliss engines which supply power to the paper machines. The manner in which these engines are kept and operated shows that they are run by men who have a feeling for the machine they operate.

At 11 p.m., with a feeling that we would like to have had much longer to view the mysteries of paper making, the party broke up.

The executive wish to express their appreciation and thanks to the officials of the Spanish River Pulp and Paper Company for their courtesy in allowing the members of The Institute to go through the Sault plant and to thank those officials who so ably guided us through the mill.

Toronto Branch

J. W. Falkner, A.M.E.I.C., Secretary-Treasurer.
J. Hyslop, M.E.I.C., Branch News Editor.

At the regular meeting of the Toronto Branch on January 27th, 1927, a very interesting paper was presented by W. E. Bonn, A.M.E.I.C., on the subject of "Dredging."

Dredging

Mr. Bonn illustrated the various types of dredges in use, such as dipper, ladder and hydraulic types, describing the various classes of work for which each type was specially adapted. He dwelt at some length on the hydraulic dredge as used by the Toronto Harbour Commission, showing this machine filling in large industrial areas; he also described a new type of flexible joint for the discharge pipe line, this joint making it possible to lay a submerged pipe line so as not to interfere with navigation.

The paper was illustrated by many instructive lantern slides. At the end of the paper a discussion ensued, after which a hearty vote of thanks was extended to Mr. Bonn.

Inspection of New Testing Machine

At the conclusion of the above paper the meeting adjourned to the electrical building of the University of Toronto to witness tests on the new 400,000 pounds testing machine recently installed by the university. This machine is capable of testing beams 16 feet long and columns 10 feet long and is the largest of its type in Canada.

Speeches were delivered by Professor Peter Gillespie, M.E.I.C., who has had charge of the installation and arrangements; Sir Robert Falconer, president of the University of Toronto; T. A. Russell, a member of the Board of Governors, and Brig.-Gen. C. H. Mitchell, M.E.I.C., dean of the Faculty of Applied Science and Engineering, and A. T. Laing, associate professor of highway engineering. A number of slides illustrating the evolution of the testing machine were shown.

There were also present at this test Colonel Schwindin from Royal Military College, Kingston, and Professor Circe, from University of Montreal.

Concrete

At the regular meeting of the Toronto Branch on February 10th, 1927, a very instructive paper was presented by R. B. Young, M.E.I.C., on "Concrete."

Mr. Young touched in turn on the selection of raw materials, design of concrete mixtures, handling and measurement of materials and the manufacture of concrete. The selection of materials, he pointed out, was entirely an economic problem, uniformity of materials governing the quality of concrete. In designing the mix, different conditions of service require a different mix; two fundamental conditions must be met; first, requirement of the structure; second, the methods of manufacture.

Mr. Young then showed that the compressive strength of the concrete is related to the ratio of water to cement, the basic problem being to obtain the proper water cement ration and work ability simultaneously and continuously. A uniform mix is obtained only by absolute volume of cement aggregate and water, and if not abused will be uniform as to strength and other properties.

In measuring quantities the usual method is by volume, but this is liable to errors. An improved method on this is the use of some form of batcher. The inundation method provided a method of filling and eliminating the variations due to moisture, but not those due to grading. The weight method is a direct measure of its absolute volume so long as the specific gravity does not change.

In mixing, the standard recognized time is one minute after being placed in the drum. Good workmanship requires careful placing and that it be consolidated by paddling and pockets of coarse aggregate be prevented. Concrete must be properly cured to secure full advantage of its inherent possibilities.

The paper was well illustrated by slides, and at the end of Mr. Young's paper a vote of thanks was extended to him.

Saint John Branch

W. J. Johnston, A.M.E.I.C., Secretary-Treasurer.

Tuesday, January 25th, was a busy day for the members of the Saint John Branch of The Engineering Institute of Canada. The several events were held in the Admiral Beatty Hotel, as follows:—

3 p.m.—Annual meeting of Association of Professional Engineers of the Province of New Brunswick.

6 p.m.—Joint dinner, Association of Professional Engineers of the Province of New Brunswick and Saint John Branch of The Institute.

8 p.m.—Public meeting, Saint John Branch of The Institute.

Annual Meeting Association of Professional Engineers of New Brunswick

At the annual meeting the usual hearing and passing of reports and other incidental business was disposed of. Alex. Gray, M.E.I.C., presided over the meeting until the new officers were announced, when Geoffrey Stead, M.E.I.C., newly elected vice-president, took the chair in the absence of J. D. McBeath, M.E.I.C., newly elected president. The officers of the Association for 1927 are as follows:—

Past President	Alex. Gray, M.E.I.C., Saint John
President	*J. D. McBeath, M.E.I.C., Moncton
Vice-President	*Geoffrey Stead, M.E.I.C., Saint John
Councillors, Saint John District	S. R. Weston, M.E.I.C., Saint John
	*J. P. Mooney, A.M.E.I.C., Saint John
Councillors, Moncton District	G. C. Torrens, A.M.E.I.C., Moncton
	*F. Williams, A.M.E.I.C., Moncton
Councillor, Chatham District	W. R. Campbell, Campbellton.
Councillor, Fredericton District	Prof. J. Stephens, M.E.I.C., Fredericton
Auditors	*J. R. Freeman, M.E.I.C., Saint John
	*J. N. Flood, A.M.E.I.C., Saint John
Secretary-Treasurer	J. A. W. Waring, A.M.E.I.C., Saint John

* Elected at Annual Meeting, January 25, 1927.

Joint Dinner

The joint dinner of the Association of Professional Engineers of the Province of New Brunswick and the Saint John Branch of The Institute was a very enjoyable affair. A. R. Crookshank, M.E.I.C., chairman of the Saint John Branch of The Institute, presided, and on his right had as guest of honour, Alex. J. Grant, M.E.I.C., of St. Catharines, Ont.

Branch Meeting

The large attendance at the branch meeting was indicative of the interest in the subject,—the Welland Ship Canal,—as described by Alex. J. Grant, M.E.I.C., engineer-in-charge. The historical facts, dimensions and depths of three earlier canals across the Niagara peninsula, and the dimensions of the present canal now under construction, were thoroughly described. By a large number of lantern slides, the speaker showed various stages of construction in different sections of the new canal.

A vote of thanks was extended to Mr. Grant by A. R. Crookshank, M.E.I.C., on motion of Geoffrey Stead, M.E.I.C., and H. F. Morrisey, A.M.E.I.C.

Victoria Branch

K. M. Chadwick, M.E.I.C., Secretary-Treasurer.

Town Planning

Through the kind invitation of the British Columbia Land Surveyors' Association, members of the Victoria Branch were invited on January 11th, 1927, to hear a lecture by Horace L. Seymour, M.E.I.C., president of the Town Planning Institute of Canada, on "Town Planning." The lecturer said that town planning provides a centralized municipal control over development that is lacking in most municipalities. The Town Planning Act made it possible for the solution of problems of an intricate nature.

Town planning he regarded not only as effecting a system of arterial highways, matters of transit, transportation and provision for parks, but as a means of rationally controlling the whole development of a city so that "work" and "home" might be happily related.

There must be public support in order to have an effective system of town planning. Legislation is pending in British Columbia, according to the speaker, which would be most advantageous to the advocates of town planning. In conclusion, he said that Victoria should be careful to give consideration to every element of the town planning system, without which no zoning methods would be really successful.

J. A. Walker, A.M.E.I.C., secretary of the Vancouver City Town Planning Commission, gave a brief history of the development of town planning in that city.

Meeting of January 13th

On January 13th the Victoria Branch entertained Mayor Carl C. Pendray of Victoria at luncheon at Spencer's dining rooms.

After the luncheon E. Davis, M.E.I.C., chairman of the branch, in rising to introduce Mayor Pendray, spoke of his excellent service for two years, and drew attention to the fact that he was now entering on his third year of service to the city. He dealt with the growing industrial developments of the west coast of the island, pointing out that 141,000 cases of salmon, 1,900,000 gallons of fish oil, and 43,000 cases of salt fish had been shipped from the west coast last year, in addition to the shipments of the vast lumber industry.

Mayor Pendray spoke of the industrial possibilities of Victoria, pointing out that much of the shipping that was at present passing by Victoria from the west coast of the island and other points could be economically handled from here.

His Worship dealt with the cost of moving grain, etc., by rail and water, and quoted figures to show that an actual saving could be made by the use of Victoria for exporting certain articles.

A hearty vote of thanks was extended to the mayor on the motion of P. Philip, M.E.I.C., Deputy Minister of Public Works.

The members also welcomed to the gathering Major George A. Walkem, M.E.I.C., president of The Engineering Institute and representative in the provincial legislature for the constituency of Point Grey. Major Walkem addressed the meeting briefly, stating he had always taken an interest in Victoria and was glad to hear of its improved financial condition and good prospects as a port.

Calgary Branch

H. R. Carscallen, A.M.E.I.C., Secretary-Treasurer.
W. St. J. Miller, A.M.E.I.C., Branch News Editor

An interesting address was delivered by B. L. Thorne, M.E.I.C., to the branch on January 20th on the subject of "Mining at Kimberly and Smelting Operations at Trail, B.C."

Mining at Kimberly and Smelting Operations at Trail, B.C.

In his initial remarks Mr. Thorne outlined quite comprehensively the history of the mining industry in this area, which virtually started in 1892 on Mark creek, twenty miles north of Cranbrook, now known as the famous Sullivan mine. A branch railway was built in 1899, and in 1903 a smelter was erected at Marysville for the treatment of lead ore. The ores in this locality are of a very complex variety and consequently the best methods of concentrating and smelting formed a difficult problem. Between 1910 and 1915 some 188,000 tons of picked ore were shipped and smelted in the plant of the Consolidated Mining and Smelting Company, which was first incorporated in 1906. Development was carried on by the company on a highly systematic basis in a thoroughly proven ore body of high grade quality. In 1925 the tonnage treated at Trail amounted to 340,710 tons from company's mines and 39,570 tons from custom shippers, or a total of 380,280 tons. The total tonnage in 1926 is given as approximately 560,000 tons. The production for 1925 was approximately as follows: gold, 21,352 oz.; silver, 4,397,455 oz.; copper, 950 tons; lead, 117,504 tons; zinc, 48,611 tons; the value of these products being close to thirty million dollars as compared with seventeen million dollars in 1924.

Mr. Thorne explained that the process has been much improved since 1920, when the differential flotation method of extraction was first adopted. He mentioned that the plant covers an area of 250 acres and includes plants for lead-smelting, copper-smelting, zinc treatment with electrolyte, electrolytic lead, copper, and gold refineries, plants for hydrofluoric acid, bluestone, and sulphuric acid recovery, modern machine shops and foundries in which all mechanical appliances used in the concentrator and reduction plants are manufactured.

Some 52,000 horse power of electrical energy are taken from the West Kootenay Power Company, at Bonnington Falls, a subsidiary company of the Consolidated Mining and Smelting Company.

The Sullivan ore body is peculiar in that it is divided into two distinct sections with a large body of iron ore in between. This latter is all important in the blast furnace operations for zinc, as with the proper proportions of iron those ores containing a high percentage of zinc can be readily oxidized with the elimination of sulphur, which minimizes furnace troubles. This mine, the speaker went on to say, has produced five million tons of ore to date. He also stated that the Trail smelter treats the most diversified ores on this continent, also that the rated capacity of the zinc plant alone is 275 tons a day, and the total ore treated amounts to 3,000 tons a day and the plant is being enlarged to handle 4,000 tons.

With the aid of two reels of moving pictures kindly loaned by the Canadian Pacific Railway, the audience were taken through the many sections of the plant and the mines, and were able to follow the different phases of the work and the processes of treatment of the ores from the reception from the mine down to the actual handling of the gold and silver bricks and the many other metallic products such as lead pipe and copper rods. There were shown tank rooms for recovery of lead by electrolytic process on the cathode sheets, and of gold and silver on the anode plates.

The above are a few of the outstanding features explained by Mr. Thorne. There were many other points dwelt upon, largely statistical, which, with the pictures shown, resulted in a most interesting address.

C. C. Richards, M.E.I.C., moved a vote of thanks to the speaker, which was very heartily endorsed by all present. Chairman J. H. Ross, A.M.E.I.C., took the opportunity of emphasizing the thanks of the branch to Mr. Thorne for his instructive and interesting address.

The Coming Biological Age

"The Coming Biological Age" was the subject of a lecture delivered by Dr. R. W. Boyle, M.E.I.C., before the branch on February 4th. In presenting his subject the speaker warned his hearers that indulging in prophecy was of a somewhat gloomy and speculative strain. His declaration that our present mechanical civilization will decline and will be superseded by an age when the major concern of the human family will be biological, was startling to say the least. His principal contention was that the great effort would be to support vast populations on a too limited soil. On commenting on the present age, which is conceded to be the mechanical age, he stated that it had produced a reign of freedom more pronounced than any previous age. Machines have multiplied and not decreased labour, as many had imagined. It took probably some 400 years to build up this mechanical age. The question was, will it last? It was the speaker's endeavour to prove that the answer was in the negative. Dr. Boyle outlined his arguments in very clever sequence, and with a conviction that such changes would eventually come about, but in the nature of things these changes would undoubtedly be extremely gradual. He pointed out that there was not much difference between socialism and capitalism, and that here in Alberta the farmer was the most conservative and the least radical man. The individual, he was sure, played a smaller part today in the world than ever before, due to the prevalence of committees, associations, conventions, organizations, etc. He emphasized that while mechanics evolved rapidly, man's brain moved comparatively slowly, and that a change must take place in the not too far distant future when trade and tariff wars must occur, food prices rise and agriculture find its own and predominate, and mechanical industrialization will of necessity outrun itself. Today, he said, mechanical civilization depends on the metals, and an exhaustion of these must some day come about, and when metals fail industrialization fails.

Referring to oil, Dr. Boyle pointed out that this commodity holds a most conspicuous position amongst minerals, at the same time declaring that oil would most likely peter out before coal, and also that in his opinion water power will never be a source of lasting power.

He ventured to offer a solution of the problem of exhausted metal supplies by a scientific discovery of a method to separate electrons from matter and reconstitute or reconstruct them to form or recreate metals, but this would no doubt be at prohibitive cost.

It was interesting, he stated, to note that in the early period of Grecian history a well-to-do Greek would probably possess about forty slaves, whereas today in the United States, where some 500,000,000 horse power is in use, each individual has, roughly speaking, the equivalent man-power of about fifty slaves working for him—indeed, an age of mechanical luxury. He referred to the fact that, in the United States in particular, machines are today turning out more goods and commodities than the people can normally use, and consequently manufacturers are forced to create a larger demand. To do this they have had to resort to advertising on enormous scales, and also it has become necessary to invade foreign markets, which has created amongst the less conspicuously commercial nations a keener competition.

Dr. Boyle's argument was primarily that metals, and consequently machines, will cease to be, and man will therefore be forced to retire to a simpler life, eventually returning to the soil. It is in this way that the soil will gradually limit the earth's population. There will, however, be a period before the disappearance of machines when people will flock from the country to the cities to an increasing extent, until such times as the demand for agricultural products will increase enormously and prices rise. It is at this period that the mechanical age will decline and when cheaper food will be demanded. Activities in mining operations will increase on a highly intensive scale, ores previously discarded as worthless being treated again under advanced scientific methods. Coal reserves will become exhausted and the decline of mechanical industrialism will drive the population back to the primitive life,—certainly a somewhat gloomy vision to consider.

P. J. Jennings, M.E.I.C., moved a very warm vote of thanks to Dr. Boyle for his exceedingly interesting address and expressed a hope that the art of soap-making would not be lost during our lifetime at least, which might be assumed as a possibility according to some remarks of the speaker.

In the absence of the chairman, J. H. Ross, A.M.E.I.C., the vice-chairman, F. K. Beach, A.M.E.I.C., took the chair, and expressed the thanks of all present and of the branch in general, for the very able and cleverly thought-out address.

Preliminary Notice

of Applications for Admission and for Transfer

February 16th, 1927.

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in March 1927.

R. J. Durley, Secretary.

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council shall be required to pass an examination before a board of examiners appointed by the council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

CALLANDER—DELMER WALLACE, of Hamilton, Ont., Born at North Gower, Ont., Jan. 4th, 1887; Educ., B.Sc., McGill Univ., 1911; 1909-12, engrg. apptceship course, Can. Westinghouse Co.; 1912-21, engrg. dept., electrical design of a.c. and d.c. motors and generators; 1921 to date, Can. Westinghouse Co., transformer design.

The Expansion of Portland Cement Mortar Bars During Disintegration in Sulphate Solutions*

A Report of Special Research Undertaken by the Institute's Committee on the Deterioration of Concrete in Alkali Soils

T. Thorvaldson, R. K. Lamour and V. A. Vigfusson, University of Saskatchewan, Saskatoon, Sask.

It is well known that cement mortar and concrete possess the property of expanding on immersion in water and contracting on drying, and that this property is not lost even after the material has attained great age. Measurements of the absorption of water and the extent of the expansion or contraction of mortar and concrete specimens, when exposed for long intervals to water or dry air, have been made by several experimenters.† It has been found that the expansion on wetting takes place more rapidly than the contraction on drying, and that with increasing age of the test specimens both processes take place more slowly. On continued exposure to water or dry air the expansion or contraction is greatest at first and falls off rapidly to a small value, the volume, in case of all except the richer mixes, becoming soon practically constant. In the case of specimens made of neat cement the change in volume, especially on drying, continues for a score of years. The study of these volume changes has led White to the conclusion that, "alternate expansion and contraction due to changes in moisture is the greatest underlying cause of the destruction of concrete structures."

It seems reasonably certain that we are dealing here with the balance between the expansive forces, in water, of the gelatinous hydration products present in set cement, comparable to the imbibition pressure of a colloid gel, and the cohesive forces of the material. It may, however, be mentioned that H. Nitzche ‡, finding that sandstone also shows swelling and contraction when wetted and dried, the volume changes being greater the denser the sandstone, emphasizes the role that the aggregate plays in the volume changes of concrete. The part that the aggregate plays seems, however, to be a minor one, as rich mortars possess this property in a greater degree than lean mortars while neat cement possesses it in a still higher degree. Further, sandstone is composed of grains of sand cemented together by a foreign material and is thus analogous to a sand mortar, the denser sandstones being comparable to the richer mortars. Matsumoto also found that although dry limestone absorbed water to a greater extent than a 1 to 2 to 4 concrete, it showed practically no expansion and did not contract to a measurable extent on drying.

It is well known that mortar and concrete specimens made from Portland cement expand during disintegration by sulphate waters. This has generally been attributed to expansive forces due to crystallization of gypsum and hydrated calcium sulphoaluminate in the specimen and has been considered by many the real cause of failure of concrete in such waters. Without attempting to determine the cause, this paper gives some of the results of a study of this expansion with a view to using it as a measure, on the one hand, of the disintegrating action of sulphate solutions and, on the other hand, of the resistance of various samples of cement to sulphate action.

Physical Tests on Cements Used **

Laboratory No.	555	8425
Passing No. 200 mesh sieve	84.4%	87.2%
Normal consistency	22.5%	22.5%
Soundness in steam	O.K.	O.K.
Time of Setting (Gillmore)		
Initial	2 hrs. 45 min.	3 hrs. 45 min.
Final	6 " 30 "	6 " 10 "
Tensile strength 1 to 3 briquets standard sand mortar, pounds per square inch.		
7 day	230	219
28 day	335	347

Chemical Analysis of Cements Used

No.	555	8425
Loss on ignition	2.10	1.32
Silica (SiO_2)	20.55	23.10
Alumina (Al_2O_3)	6.85	6.34
Ferric oxide (Fe_2O_3)	2.65	2.10
Lime (CaO)	61.95	63.33
Magnesia (MgO)	3.52	2.39
Sulphuric anhydride (SO_3)	1.74	1.55

Experimental Procedure

The specimens used in the expansion experiments were mortar bars made of Portland cement and standard Ottawa sand, (20-30 mesh). Distilled water was used for the gauging. The proportion of the mixing water was at first fixed so as to give a flowability of the mix as nearly as possible the same as that used in the preparation of standard sand briquets. This introduced difficulties when dealing with very lean mixes of mortar so that later the standard quantity of water used for a 1 to 3 mix was also used for all leaner mixes. The proportions of cement to sand were determined by weight and the water by volume at 21°C. After mixing the cement and sand thoroughly the water was added and the whole mass well worked to ensure uniformity. The specimens were then moulded in collapsible steel frames so as to give bars measuring ⅝ by ⅝ by 7½ inches. When the moulds were being filled the tamping and trowelling were done as uniformly as possible so as to obtain uniform specimens. The charged frames were stored in a damp closet until the bars were strong enough to be removed, the time required varying with the richness of mortar. The bars were then cured in a damp closet, at least to the end of the twenty-eight-day period, unless otherwise stated.

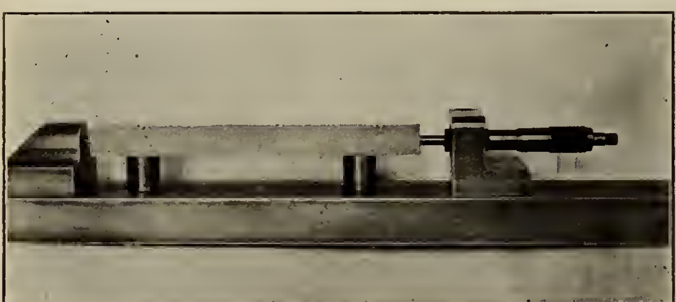

Figure No. 1.

The mortar briquets used for the corresponding tensile strength determinations were made up according to the standard specifications for Portland cement, the mix and the storage treatment being the same as that for the corresponding mortar bars. The determinations of tensile strength were made on a Riehlé machine adjusted to require one-half minute for developing a tension of 300 pounds per square inch.

Considerable difficulty was experienced in obtaining bars with ends suitable for accurate measurement of length. The ends must be smooth, free from easily detachable material and more resistant to the action of sulphates than the bar itself. After considerable experimentation the method finally adopted was to make the bars with a thin layer of neat cement on each end. This gave a suitable surface and reproducible measurements of length could be made.

The mortar bars were found to be well suited for the study of the action of sulphate solutions. They have sufficient strength for handling provided the mortar is not too lean. They allow very rapid penetration of solutions throughout the whole mass and their length is sufficient for the measurement of slight expansion.

Measurements of the length of the bars were made by means of a micrometer head, graduated to read to one-ten-thousandth of an inch, set in a frame made of tool steel (see figure No. 1). A series of measurements on a well made bar was found to fall usually within extremes of 0.0005 inch while the mean of several readings under similar conditions is reproducible at least to within 0.0002 inch.

The thermal expansion of the measuring device was determined between 20°C. and 35°C. and found to be 0.00009 inch per degree. The thermal expansion of wet mortar bars 7½ inches long, for the same temperature range, was found to be as follows:—

Mixture of Mortar	Expansion per °C. for bars 7½ inches long	Coefficient of expansion
1 cement to 2½ sand	55×10^{-6} inches	74×10^{-7} inches
1 " " 5 "	57×10^{-6} "	76×10^{-7} "
1 " " 7½ "	62×10^{-6} "	82×10^{-7} "

It will be seen that provided the bar and the micrometer are at the same temperature small changes in room temperature introduce no appreciable error. A change of 6°C. from the mean temperature of the room would produce a variation of 0.0002 inch in the apparent length of a 7½-inch, 1 to 5 mortar bar. The lag in expansion and contraction during rapid changes of temperature was found to introduce a much greater error. As is to be expected the lag is much more marked for the bars than for the metallic measuring device, and in the case of the bars especially, the lag is much greater during contraction than during expansion.

Exposure of the Bars to the Solutions

After the initial measurement at the end of the curing period the bars were placed in wide-mouthed stoppered glass jars containing the salt solution and measured at frequent intervals until disintegration made further measurements impossible. Three or four bars were generally used in each experiment and the average increase in length taken. In some experiments the bars were first measured damp at the end of the curing period and then dried in a current of carbon dioxide free air at 35°C. before they were immersed in the salt solutions. At first the sealed jars containing the bars and the salt solutions, were immersed in a water thermostat at 25°C. This method entailed so much labour when a large number of bars were being measured that it was abandoned and the bottles were left standing in the laboratory. This does not introduce errors into comparisons within series of experiments started at the same time, but, as the laboratory room varied a good deal in temperature, especially at different seasons of the year, it made difficult the comparison of the results of series carried out at different times. Later a thermostated room was used with a temperature variation of less than 1°C. from a mean value, and finally a room which varied only by about 0.2°C. from the mean.

In plotting the curves for the expansion or contraction of bars the initial measurement of the moist bars after the curing period is taken as the initial or zero point, contractions being expressed as negative and expansions as positive quantities. The expansion, (or contraction), is always expressed in 10^{-4} inches and is always given as the total expansion for a 7½-inch bar. The expansion per inch can therefore always be obtained from the curves by dividing the value for the y-axis at any point on the curve by 7.5, and the percentage expansion, by dividing the value so obtained by 100.

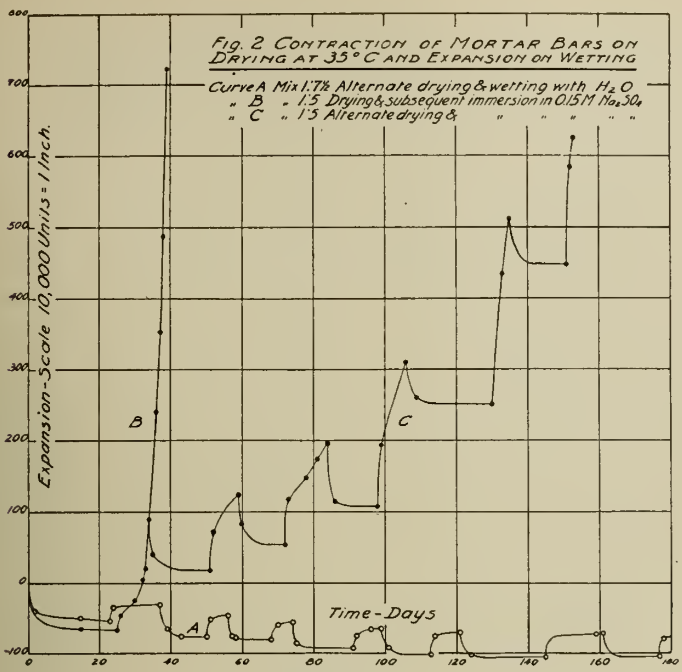

Figure No. 2.

pansion of the bars. Experiments showed that while bars of mixes approaching neat cement require a very long time to attain constant length, a few days' immersion is sufficient to attain very nearly constant length in the case of 1 to 7½ and 1 to 5 mortar bars. Thus the expansion of 1 to 5 mortar bars in five days and in two hundred and fifty days agreed within two ten-thousandths of an inch.

But while exposure of the dried, lean mortar bars to water for long periods produces very little change in length after the first few days, there is evidence of other changes taking place in the bar during the long period of wetting. This was shown by a group of bars which after having been repeatedly dried and wetted were left in water for two hundred and fifty days. After this long period of wetting their behaviour on drying and wetting was similar to that of freshly prepared bars. The curve for alternate drying and wetting was approximately a duplicate of the curve obtained during the initial period of treatment with the difference that the actual length of the bars was somewhat shorter.

These experiments, while of a preliminary nature, suggest that at least one of the colloid components of hydrated cement is rendered irreversible by drying at 35°C. while other colloid components dehydrate but remain reversible when dried at that temperature. The reappearance of the first mentioned type of colloid on long exposure to water may be due to further hydration of the unhydrated kernels of cement in the mortar.

When the wetting liquid contains sulphates the bars behave approximately the same way as in pure water for the first day or two. Then the rate of expansion gradually increases again until finally the bar loses its strength and falls to pieces. Curve B (figure No. 2) gives the expansion during the first fourteen days of immersion for 1 to 5 mortar bars in 0.15 molar solution sodium sulphate. The initial length of the damp bars after one month's curing in the damp closet is taken as the zero point. The bars were dried in a current of carbon dioxide free air at 35°C. for 25 days before being immersed in the sulphate solution.

The expansion of the bars may be stopped anywhere short of complete disintegration by drying them when a slight contraction, comparable to that of bars wetted in distilled water, takes place. Curve C (figure No. 2) gives the result when 1 to 5 mortar bars are alternately immersed in a 0.15 molar solution of sodium sulphate and dried at 35°C. in a current of carbon dioxide free air. The expansions and contractions are not equivalent, the bars increasing permanently in length at each immersion in the sulphate solution until they finally fall to pieces. Almost an identical curve was obtained for bars similarly treated in a 0.14 molar solution of magnesium sulphate.

Comparison of the Expansion of Mortar Bars in Water and in Sulphate Solutions

When Portland cement mortar bars, after curing for some time in the damp closet, are alternately dried in air free from carbon dioxide and wetted in distilled water the changes which take place appear approximately reversible, the contractions and expansions apparently nearly balancing one another except for a rather striking decrease in length on the initial drying which is only partly regained on wetting the bars. Curve A, (figure No. 2), gives the results of such an experiment carried on for a considerable length of time with 1 to 7½ Portland cement standard sand mortar bars which had been cured for thirty-five days in the damp closet before the initial drying. The drying was effected at 35°C. in a current of carbon dioxide free air and measurements were made at intervals until a constant length was attained. The bars were then placed in distilled water at room temperature and the measurements repeated until the length was constant. The portions of the curve with increasing values for the ordinates represent periods of wetting while the portions with decreasing ordinates represent periods of drying.

It will be seen from the curve that the original wet length of the bars is never attained by later immersions in water and that each successive drying and wetting of the bars produces a decrease in length, while the wet length approaches a constant value. Similarly the dry length of the bars decreases at each treatment and finally approaches a constant value. The changes are therefore not wholly reversible. Or one might state the result in a different way. The loss in length of the bars on drying is at first markedly greater than the gain in length on wetting, but on continued treatment the two quantities approach the same value.

A similar curve was obtained for 1 to 5 mortar bars, the numerical value of the contractions and expansions being larger than for 1 to 7½ mix. Richer mixes require very long periods of wetting and drying to attain constancy. Experiments with these were therefore not carried very far but several treatments of 1 to 2 mortar bars gave a similar curve.

The question might arise whether the time of immersion in water was long enough to give the maximum ex-

Expansion of Mortar Bars and Decrease in the Tensile Strenth of Mortar Briquets during Sulphate Action

The only quantitative method available for studying the action of sulphates on mortars is to determine the loss in strength of test pieces at various times during a period of exposure. The usual procedure is to immerse standard briquets or other test pieces in the salt solutions and to determine the tensile or compressive strength at intervals.

A very careful comparison was made of the expansion of mortar bars such as described above and the change in tensile strength of briquets in a 0.15 molar solution of sodium sulphate. A large number of briquets and a few bars were prepared using one part of cement No. 8425, five parts of standard sand and 10.25 per cent of water. After curing in the damp closet for seven days they were immersed in the sulphate solution contained in air-tight glass jars. The ratio of weight of mortar specimens to volume of the solution was about 300 grams to 1700 cubic centimetres of solution. The mean expansion of the bars was determined from time to time as well as the average tensile strength of the four briquets. The values for the tensile strength of the individual briquets were found to be somewhat erratic, especially during the latter part of the exposure to the sulphate solution, an occasional briquet losing strength much more quickly or slowly than the average. The tensile strength of some of the briquets immersed in distilled water was also determined from time to time.

In an attempt to make all the determinations of tensile strengths of the briquets comparable, the first break was made after the briquets had been kept in water for one day. When 1 to 5 standard sand briquets after curing in the damp closet for one week are placed in water they decrease in tensile strength by about 40 pounds per square inch during the first day as compared with a break made with the damp briquets. In a few days the briquets exposed to water regain this strength and soon exceed the original value.

Similar comparisons, using fewer briquets, were made with a 0.5 molar solution of sodium sulphate and 0.15 molar and 0.5 molar solutions of magnesium sulphate.

It is, of course, not fair to make a strict comparison between the two kinds of test pieces as the bars have only a cross-section of 5/8 by 5/8 inch, while the briquets have a cross-section of 1 x 1 inch at the narrowest part. But as 1 to 5 standard sand mortar is very permeable to water there is only very slight difference between the rates of disintegration of the two kinds of test pieces, some of the bars being too weak to handle by the twenty-ninth day, while after the thirty-seventh day most of the briquets became too weak to obtain tensile strengths.

A comparison of the curves, (figure No. 3), indicates several interesting facts. The briquets immersed in the sulphate solution increase at first in strength and this increase is more rapid than in the case of briquets stored in distilled water. After the sixth day there is a sudden rapid decrease in strength, the decrease in one day bringing the strength below that of the water stored briquets and this decrease in strength continues at a gradually decreasing rate until the curve becomes fairly flat as it approaches

Figure No. 3.

very low strengths, while the briquets stored in water continue to increase in strength. The experiments with briquets in 0.5 molar solution of sodium sulphate, also in 0.15 and 0.5 molar solutions of magnesium sulphate, gave similar curves, the increase in strength of the briquets over those stored in distilled water being marked in each case during the first few days. One of us* has already pointed out that presence of sodium sulphate in water with which powdered Portland cement is shaken speeds up the liberation of lime, which normally takes place on hydration of the cement. Also, that the presence of sulphates shifts the equilibrium attained on hydration of cement so that more lime is liberated. The explanation of the abnormal increase in strength of briquets immersed in sulphate solutions may be that this increase in the rate of liberation of lime represents an actual speeding up of normal hydration. It is, however, evident from the curve that further changes which cause rapid decrease in strength soon take place. It is possible that the shifting in the hydration equilibrium causes decomposition of the strength-conferring products of hydration with the formation of substances devoid of cementing properties.

Microscopic examination of the briquets exposed to the sulphate solutions did not indicate any change in the crystalline matter which would satisfactorily explain the shape of the curve. Crystals of sulphoaluminate were found in the briquets immersed in 0.15 and 0.50 molar sodium sulphate after the first day's exposure. These persisted and gradually increased in size. Gypsum crystals soon appeared in the briquets immersed in the more concentrated solution and a little later in those in the dilute solution but were never very numerous in the latter. Gypsum appeared almost immediately in the briquets exposed to the two solutions of magnesium sulphate and the crystals continued to grow in size as the action progressed. These observations are in general agreement with the results of shaking powdered cement with the corresponding sulphate solutions.† Apparently the microscopic data gives no clue as to the cause of the sudden change in the tensile strength of the briquets about the seventh day (in the 0.15 molar sodium sulphate) and one is therefore led to believe that the reason is to be sought in chemical changes taking place in the amorphous or colloid mass.

The curve for the expansion of the bars does not give any indication of the initial increase in strength. From a large number of experiments there is, during this period, some indication of contraction of the mortar specimens, this effect being masked by the expansion due to wetting and appearing in general only on the second or third day. Except for this, there is a gradual very slight expansion until the sixth or seventh day when the curve is definitely inflected upwards and finally the rate of expansion becomes almost constant until the bars become too weak to handle. The point of inflection occurs at the same time as the sharp turn downwards of the tensile strength curve for the briquets and the two seem therefore to be due to a common cause. Bars immersed in distilled water show a very similar expansion as those in sulphate solution during the first day, then expand very slowly until practically constant in length. This requires usually about one week for lean mixes, (1 to 7½ and 1 to 5). Thus while there is no evident relation between the curves for the expansion of bars and the increase in strength of briquets exposed to distilled water, there is a very marked relation (after the initial period of increase in strength) between the tensile strength curve for mortar briquets and the expansion curve

Figure No. 4.

of mortar bars of the same mix exposed to sulphate solutions.

While it would be possible to predict the value for the tensile strength of a mortar specimen from its expansion it is evident that the two curves have marked differences apart from the early increase in strength. The expansion is very gradual during the early stages and later the rate increases to an almost constant maximum value, while the loss in strength, after the sixth day, is at first very rapid and later slows down materially. The expansion curve is what one would expect from consideration of the tensile strength curve, if one assumes that the expansive force is constant, or nearly so, while the cohesive force, of which tensile strength is a measure, decreases rapidly at first and then more and more slowly.

A similar comparison of the expansion of mortar bars and the loss in tensile strength of mortar briquets in 0.16 molar solution of sodium sulphate was made, using cement No. 555, mix 1 to 5. The test pieces were cured in the damp closet for three months before being immersed in the sulphate solution. The tensile strength of these briquets, (average of 8 briquets), at the time of exposure to the sulphate solution was found to be 201 pounds per square inch, and this increased, on two days' immersion, to 218 pounds, while on the third day and thereafter there were losses in tensile strength. The tensile strength curve obtained was similar to that obtained from the corresponding mix of cement No. 8425, cured seven days, (figure No. 3), except that the period of increase in strength was shorter, (two days against six days), the increase in strength more rapid but not so great, (17 pounds per square inch in two days against 26 pounds in six days), and the loss in strength not so rapid during the first few days after the deflection of the curve downward. The total time of disintegration of the test pieces was not lengthened. The effect of storage on the expansion of bars is to produce corresponding changes, (i.e., slower rate of expansion during the early stages, without changing markedly the total expansion at time of disintegration) as may be seen by examining the curves of figure No. 4.

In considering the admissibility of the expansion method as an independent method for determining sulphate action, it should be remembered that failures of concrete structures exposed to "alkali" occur usually through buckling caused by expansion, long before the strength of the material is reduced to the point where there would be any danger to the structure were the expansion due to the action of sulphates absent. The expansion is thus one of the principal factors causing the failure. Although it appears that there is a definite relation between the curves for loss in tensile strength and expansion, it is possible that a thorough testing of the sulphate resistance of a cement should include a determination of both of these curves, or still better, the determination of the expansion curve and the curve for compressive strengths. The expansion method has been used in this laboratory mainly for experiments with cement mortars, but should be applicable to concrete, especially the leaner mixes.

The authors have used this method of measuring the expansion of mortar bars for following the effect of sulphate solutions on cement mortars since the summer of 1922 with a great deal of saving of time, energy and material, as compared with using briquets and determining loss in tensile strength. An expansion curve, such as the one given in figure No. 3, may be obtained by measuring about a dozen times three or four test pieces immersed in one and a half liters of solution. The tensile strength curve corresponding to it was obtained by the use of more than six dozen briquets and more than fifty liters of solution. It is also the experience of the authors that much more concordant and reproducible results can be obtained by the use of the expansion method. The values obtained for the tensile strength of a mortar using the so-called "standard" briquets carefully prepared and stored in water vary at times considerably, while these variations seem to be magnified when the briquets are exposed to disintegrating solutions. Thus the breaking strength of two briquets prepared and treated in the same way often varies by several hundred per cent during the later stages of sulphate action. Large differences in the rate of expansion of well made bars of the same batch are rare, and if a bar is exceptional the whole curve for its expansion is available instead of a single tensile strength of the briquet at one point on the curve.

It is evident that the expansion method for studying sulphate action has very marked advantages when the

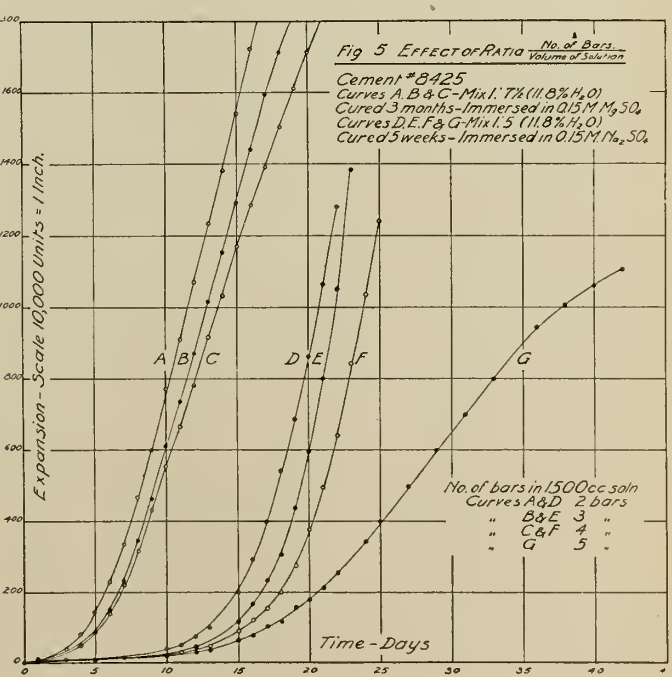

Figure No. 5.

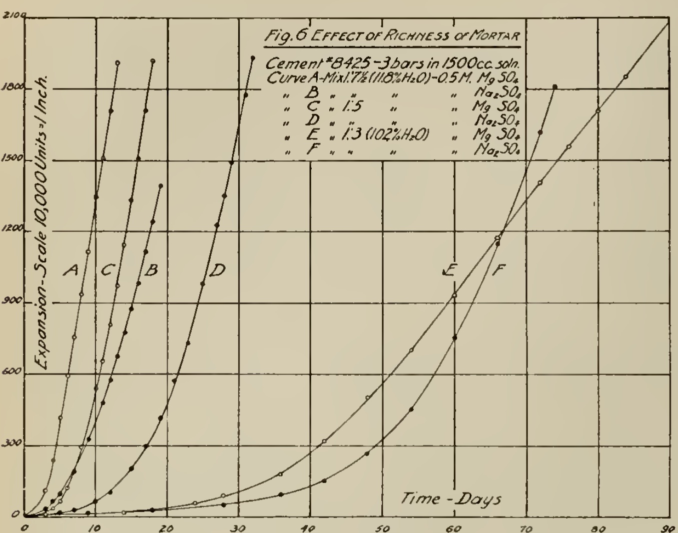

Figure No. 6.

action progresses very slowly and the series of experiments last for months or years. Only a few test pieces are necessary and these last throughout the experiment, while it is difficult to predict at the beginning of an experiment how many briquets are necessary as many are apt to be wasted on making unnecessary breaks. By measuring a few bars occasionally one can follow the progress of the action and make quantitative comparisons long before there is any visible effect of the action on any of the test pieces.

Effect of Time of Curing on Expansion in Solutions of Sodium and Magnesium Sulphate

This was determined for 1 to 5 mortar bars in a 0.15 molar solution of sodium sulphate and a 0.15 molar solution of magnesium sulphate. The bars were placed in a sealed damp desiccator as soon as they were removed from the steel frames so as to prevent absorption of carbon dioxide during the long period of curing. At the end of one week, five weeks and twenty-six weeks respectively, three bars were distintegrated in 1,500 cubic centimetres of each of the solutions. The curves (figure No. 4) show that there is a marked difference between the expansion curves for the week old and the five weeks old bars, the expansion of the latter being much slower during the early stages but later increasing more rapidly and in three weeks nearly equalling, in the case of sodium sulphate and surpassing, in the case of magnesium sulphate, the expansion of the one week old bars. There is very little change in the curves for further twenty weeks' curing except that the latter portion of the curve for the expansion in magnesium sulphate is slightly steeper.

These and other experiments indicate that although the time of curing is an important factor affecting expansion of mortar bars in sulphate solutions, comparisons of bars cured the same length of time, whether for one week or more, give similar results, and that after one month the effect of time of curing is very slight.

Effect of Variation in the Number of Bars Immersed in a Fixed Volume of Sulphate Solution on the Expansion of Mortar Bars

Figure No. 5 gives the results of experiments on the effect of variation in this ratio on the expansion of 1 to 5 mortar bars in a 0.15 molar solution of sodium sulphate and of 1 to 7½ mortar bars, in a 0.15 molar solution of magnesium sulphate. The curves were all obtained from experiments carried on concurrently and are therefore comparable although the room temperature varied somewhat.

Curves D, E, F, and G show that the expansion of 1 to 5 mortar bars in 0.15 molar sodium sulphate is retarded as the number of bars, immersed in a fixed volume of solution, increases. This retardation in the expansion from D, where two bars are immersed in 1,500 cubic centimetres of solution, to F, where four bars are used for the same volume of solution, is fairly uniform and amounts practically to a shifting of the curves from left to right. When five bars are immersed in the same volume, (curve G), there is a marked flattening of the curve and in addition a falling off in the rate of expansion after this has reached about 0.08 inch for the 7½-inch bars (a little over one per cent expansion). This is no doubt at least partly due to the decrease in the concentration of the sulphate in the solution due to formation of calcium sulphate as the action proceeds. In corresponding experiments with a 0.50 molar solution of sodium sulphate the four curves are all similar, the gradual shifting to the right with increase in the number of bars in 1,500 cubic centimetres of the solution, appearing as above while the curve for five bars in 1,500 cubic centimetres of solution does not differ in any other respect.

Curves A, B and C indicate the effect of variation of the same ratio on the expansion of 1 to 7½ mortar bars immersed in a 0.15 molar solution of magnesium sulphate. These curves show retardation to a somewhat smaller degree. The curves obtained from experiments with 1 to 5 mortar bars in 0.15 and 0.50 molar solutions of magnesium sulphate were similar to the curves obtained with the corresponding solutions of sodium sulphate except that the one for five bars in 1,500 cubic centimetres of the 0.15 molar solution showed no variation similar to that of curve G.

The weight of the 1 to 5 mortar bars used in the above experiments averaged about 100 grams each, while the 1 to 7½ bars averaged about 95 grams each.

It is evident from these experiments that comparisons of the expansion of mortar bars in sulphate solutions are not permissible when the ratio of amount of mortar to volume of solution varies.

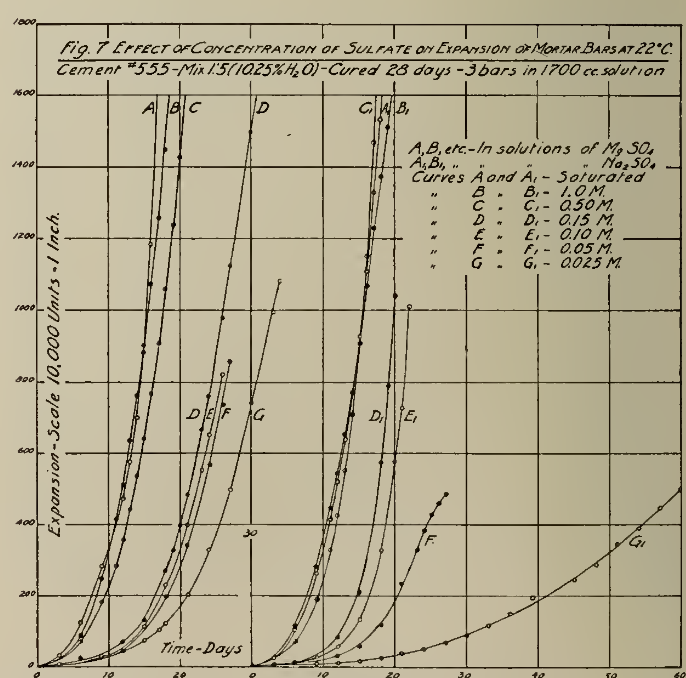

Figure No. 7.

Effect of Richness of Mortar on Expansion of Mortar Bars in Solutions of Sodium and Magnesium Sulphates

Expansion curves were determined for three different mixes of cement No. 8425, namely 1 to 7½, 1 to 5 and 1 to 3 standard sand mortar bars, in 0.15 and 0.50 molar solutions of both sodium sulphate and magnesium sulphate. The curves obtained with the 0.50 molar solutions are given in figure No. 6.

Curves A, C and E give the expansion for 1 to 7½, 1 to 5 and 1 to 3 mortar respectively, in a 0.50 molar solution of magnesium sulphate, while curves B, D and F represent the corresponding ones for a 0.50 molar solution of sodium sulphate. It is seen that the effect of richness of mix is somewhat greater in the case of solutions of magnesium sulphate, the difference between the number of days required for equivalent expansion of the 1 to 5 and 1 to 3 bars, being greater than in the case of sodium sulphate. The curves for the 1 to 3 mortar are not as steep as those for the leaner mixes and this effect is more marked in the magnesium sulphate solution. This may be due to decrease in permeability of the bars by the precipitation of magnesium hydroxide in the pores of the mortar.

It should be mentioned that the lower amount of mixing water used for the 1 to 3 bars prevents a strict comparison with the 1 to 5 and 1 to 7½ bars. If the two leaner mixes had been made with 10.25 per cent of water the result would have been a shifting of the curves to the right and therefore a decrease in the difference between the rate of expansion of these and the 1 to 3 bars.

The curves for the three mixes in 0.15 molar solutions of the two salts present a very similar picture. The rate of expansion of the two leaner mixes in the more dilute solution does not differ very much while the rate for the 1 to 3 mortar bars is markedly slower. As with the higher concentration the expansion of the 1 to 3 bars is at first more rapid in the magnesium sulphate solution, while later the relative rates are reversed, the two curves intersecting at an expansion of about 1,200 units (0.12 inch for a 7½-inch bar or 1.6 per cent expansion). The time required for this expansion in the 0.15 molar solution is ninety-seven days against sixty-seven days for the 0.5 molar solution.

Effect of Concentration of Sulphate Solutions on the Expansion of Mortar Bars

The curves of figure No. 7 indicate the effect of the concentration of solutions of sodium and magnesium sulphate on the expansion of 1 to 5 Portland cement mortar bars. The bars were made from cement No. 555 using 10.25 per cent of water and were cured for twenty-eight days in the damp closet. The temperature at which the comparison was made was 22°C. and the concentrations of the solutions were in each case saturated, 1.0, 0.5, 0.15, 0.1, 0.05, and 0.025 molar. Three bars were disintegrated in 1,700 cubic centimetres of the solutions.

The curves make possible not only a comparison of the expansion of bars in the various concentrations of each salt but also between corresponding concentrations of the two salts. For solutions of both salts the effect of concentration above molar is almost negligible and between molar and 0.5 molar very slight. For solutions of lower concentration the effect is more marked, and below 0.05 molar, the slowing down of the rate of expansion is especially marked in solutions of sodium sulphate.

The expansion in saturated solutions of the two salts is nearly identical. The same applies to 1.0 molar solutions, the bars in sodium sulphate expanding at first a little more rapidly and later a little more slowly than those in magnesium sulphate. Below this concentration there is a marked difference in the character of the curves for solutions of the two salts. The curves for magnesium sulphate have all approximately the same inclination, the curves becoming slightly less steep as the concentration decreases, while the curves for 0.5, 0.15 and 0.1 molar solutions of sodium sulphate become, after expansions to above 200 units, progressively steeper. On the other hand the curves for 0.05 and 0.025 molar sodium sulphate do not show this speeding up, the rate of expansion falls off and the bars fall to pieces before they have expanded 0.7 per cent of their length. A series using 1 to 7½ mortar bars of the same cement in solutions of sodium sulphate showed the same effects to a marked degree.

For solutions of magnesium sulphate the time required for a given expansion in the most dilute solution (0.025 molar or about 3,000 parts per million) is a little over twice that required to produce the same expansion in a saturated solution (about 26 per cent at 22°C.). This is a small effect for an almost ninety-fold increase in the concentration. In the case of the corresponding solutions of sodium sulphate (0.025 molar or about 3,500 parts per million or 0.35 per cent and saturated at 22°C. or about 18 per cent) the dilute solution requires about five times as much time as the concentrated one for equal expansion. The lower limit of concentration, one which causes 1 to 5 mortar to disintegrate fairly rapidly, is commonly found in the seep-

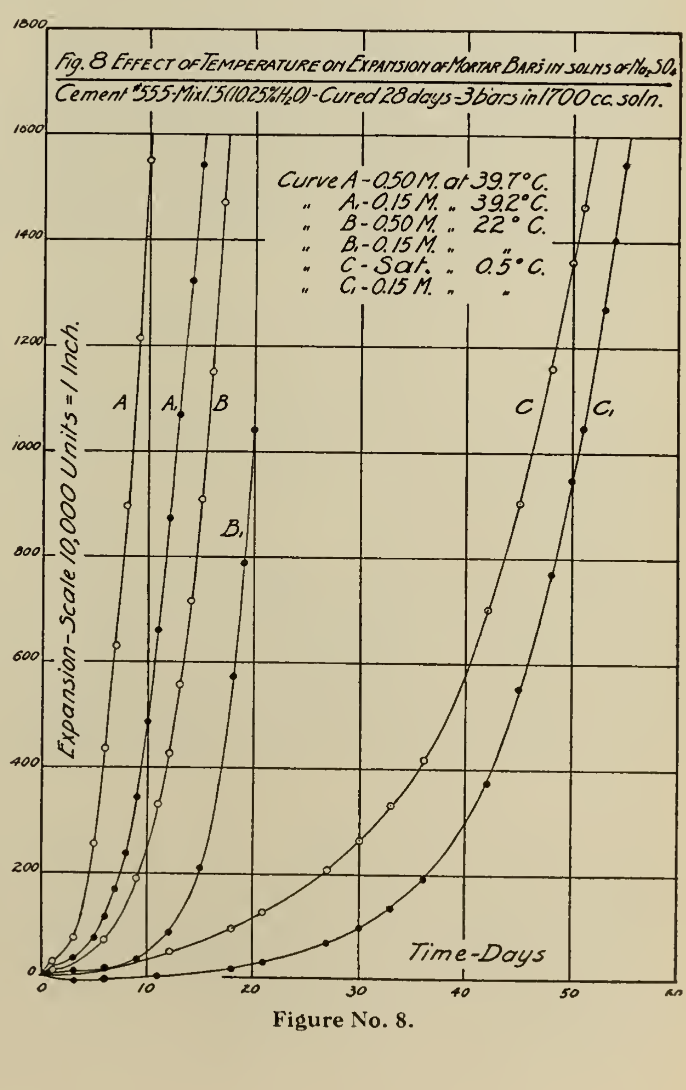

Figure No. 8.

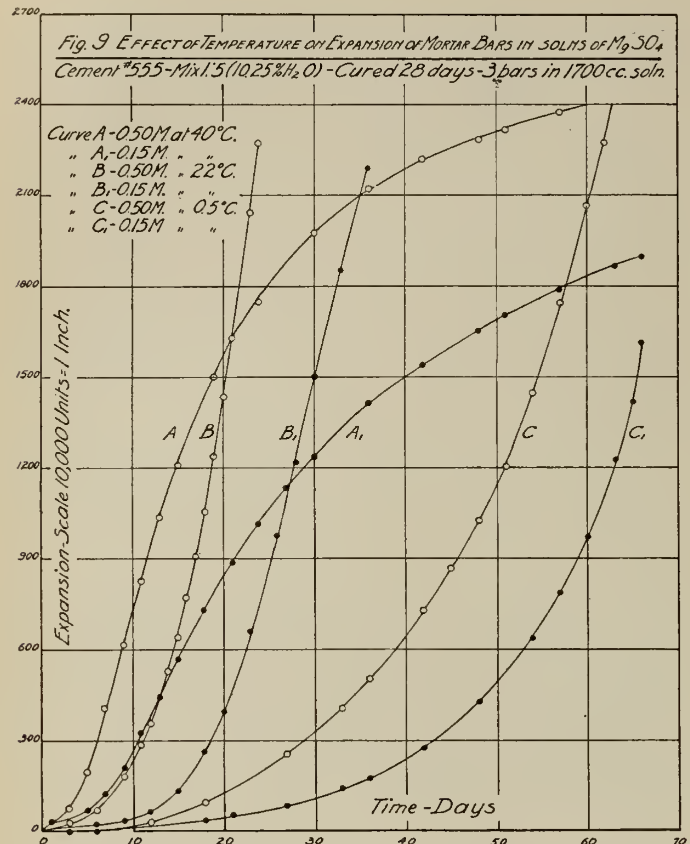

Figure No. 9.

age water in shallow wells on the central prairie even where the soil is not considered to be charged with alkali. It has been shown* that well made concrete may disintegrate when partly immersed in water containing less than 1,000 parts of sulphate per million, a concentration comparable to that of wells from which some cities on the central prairies draw their water supply.

Effect of Temperature on the Expansion of Mortar Bars

Figure No. 8 gives expansion curves for 1 to 5 mortar bars in 0.5 and 0.15 molar solutions of sodium sulphate for temperatures of 0.5°C., 22°C. and approximately 40°C. and figure No. 9 gives the corresponding curves for solutions of magnesium sulphate.

Plotting, from figure No. 8, temperature against time for expansions of 200, 600 and 1,000 units one finds that each increase of 10°C. in the temperature reduces the time necessary for equivalent expansion by about one-third with a slight tendency to a decrease in the reduction as the temperature rises. The speeding up of the action with rise in temperature may be due mainly to the increase in the rate of diffusion within the bars. Experiments with 1 to 7½ mortar bars give a somewhat larger effect for temperature.

The effect of temperature for solutions of magnesium sulphate between 0°C. and 22°C. is somewhat greater. The results with this salt at 40°C. indicate that there is a marked change in the action of the salt on the mortar, the bars expanding rapidly at first and then more slowly without falling to pieces until finally the bars kept at 0.5°C. show a greater expansion than those at 40°C. This effect of solutions of magnesium sulphate, above ordinary room temperature, is being studied further.

* Mackenzie and Thorvaldson: Engineering Journal, Feb. 1926.

The Effect of the Amount of Mixing Water

The percentage of mixing water has a very marked effect on the expansion of mortars in sulphate solutions. Experiments for the purpose of determining this effect accurately must be rigidly controlled since factors such as the degree of humidity of the room in which the specimens are prepared, slight changes in the saturation of the air in the damp closet, (such as may be brought about by slight fluctuations in temperature), the time of curing and other minor factors have a very marked effect on the results. As the matter is rather complicated, the experiments dealing with it will be discussed in a later paper.

Comparison of Cements Numbers 8425 and 555

Minute comparisons between the curves of the various figures given above can be made only with a good deal of caution since factors such as percentage of mixing water and time of curing often vary. Even when these are the same there may be differences due to variation in humidity conditions at time of preparing the specimens or in the temperature of the damp closet during storage. There is, however, a marked difference in the behaviour of the two cements, which may be seen from comparison of the curves.

From figure No. 7 we see that the expansion of 1 to 5 mortar bars of cement No. 555 is somewhat more rapid in solutions of sodium sulphate of medium concentration (0.5, 0.15 and 0.1 molar) than in solutions of magnesium sulphate of the corresponding concentrations. The curves of figure Nos. 8 and 9 indicate that the same holds for the solutions at other temperatures. On the other hand, from figure No. 4 it is evident that 1 to 5 bars made from cement No. 8425 expand more rapidly in a solution of 0.15 molar magnesium sulphate than in a sodium sulphate solution of the corresponding concentration. This is most marked in the bars cured for more than one week and for expansions below 1,000 units (0.1 inch for a 7½-inch bar or 1.3 per cent). The curves of figure No. 6 indicate that the same relation holds even more markedly in 0.5 molar solutions of the two salts. Thus cement No. 555 appears more resistant to the action of magnesium sulphate than to that of sodium sulphate while for cement No. 8425 the reverse is the case. A comparison made under the same conditions confirmed this conclusion.

Summary

(1) A comparison is made between the contraction and expansion of Portland cement mortar bars when alternately dried and wetted (*a*) in water and (*b*) in sulphate solutions.

(2) A method of measuring the progress of the action of sulphate solutions on cement mortars by determining the expansion of test pieces is described.

(3) This method is compared with the one of following sulphate action by determining at intervals the loss in tensile strength of mortar briquets.

(4) Curves are given which show the effect of various factors such as the time of curing, volume of disintegrating solution, richness of mortar, concentration of the solution and temperature on the expansion of Portland cement mortar bars in solutions of sodium and magnesium sulphate.

(5) Test pieces made from two normal Portland cements are compared as to their relative expansion in solutions of sodium and magnesium sulphate.

Valuation Work from the Engineer's Standpoint

A Brief Outline of General Valuation Work, Emphasizing the Valuation of Buildings, and Dealing with Depreciation

John Hole, A.M.E.I.C.
Construction Engineer, Toronto, Ont.

Paper read before the Toronto Branch of The Engineering Institute of Canada, March 10th, 1927

Most engineers, at one time or another, have had occasion to make valuations, either small or large, of some description of property, buildings, utilities, machinery or equipment, and it is with the intention of calling attention to this somewhat neglected branch of the profession and laying down a few broad general principles in connection with the work that has led to this statement of personal opinions formed in connection with this work over an extended period.

All the published works that the author has read on the subject approach the matter in a very general way, and give very minute instructions and excellent advice as to the methods of preparing and tabulating the items, the importance of photographs, the cost by years over a period, of several given general types of buildings, the findings of judicial bodies in special cases, tables of estimated life of different types of buildings, definitions of depreciation, etc., but all practically agree that the result depends upon the way the expert evidence is presented. It devolves upon the engineer in his evidence to convince a judge, (or arbitrator), that his point of view is reasonable.

Our profession comprises such a wide field that there is no part of any kind of business or plant, the knowledge of which is not covered by courses, either ordinary or special, of the engineer's curriculum, or by practical observation during a varied career.

The case of valuation of stocks of a special kind of merchandise solely involves reference to invoices and common sense as regards depreciation, obsolescence and market facilities.

Valuation of land demands a knowledge of surrounding values, recent sales prices and any special recommendations of location or formation for any special purpose.

In cases of some large structures it is often advisable to get opinions of several engineers, each having expert knowledge of a separate part of the valuation to be made and incorporate them for the complete valuation, but in many cases one man with varied experience can intelligently handle the whole.

The reason for a valuation is generally one of the following seven:—

(1) To check up book values under changing conditions.

(2) For insurance purposes, as basis of claim settlement after visible evidence is destroyed.

(3) For fixing or adjusting rentals.

(4) For assessment purposes or tax adjustment.

(5) When sale of business is intended.

(6) The purposes of company flotation.

(7) In case of expropriation by a governing body.

The Engineer's Attitude

It has been stated by some authority that the amount of a valuation is governed by the purpose for which it is being prepared. This may be the case in the final presentation, after it has left the engineer's hands, but the attitude of the engineer should not be biased by any of the foregoing reasons; he should not be tempted to inflate or deflate his estimates of value to accommodate the purpose for which the valuation is made. His report should impartially describe the defects as well as the advantages of the subject, so that when he submits his finished report the result is a fair, honest and comprehensive representation of the facts as he sees them, without prejudice as to which interest is going to use them. He must be prepared to be interrogated in a court of law on any point or points embodied in the report in the interests of the party for whom he prepared the report and know that his statements would be the same as if he had been engaged and paid by the opposing interest.

It sometimes happens that an expert prepares a report and makes statements of values before a judge for one interest, and within a short time has to do similar work and testify before the same judge for the opposing interests, who are this time in litigation with the group for whom he prepared the last report. It can be easily imagined that any discrepancy in his statements will be seized upon and turned to his discredit, unless there are circumstances that warrant these discrepancies. Of course, we all live and learn, (that is one of our excuses for living, to learn to be of value to the community), and a fixed conviction or pet theory of to-day may be greatly modified or entirely altered to-morrow by some convincing and unanswerable demonstration to the contrary, and we, of necessity and with good grace, are compelled to endorse the changed view and admit our error.

The cases are presented and findings given by members of the legal profession, yet the statistics and data are gathered and estimated by engineers, whose reports form the armament and ammunition for the lawyers, and it is most important to present the facts fully, showing both the good and the bad, so that the legal man can present or reject any features at his discretion, and, in any event, he will have been instructed as to the weak points of his case.

General Valuation Work

Valuation work to the engineer covers a vast field, from a building in a crowded metropolis to a power plant in the heart of a wild country, a mining property as a going concern or a railroad and its vast ramifications.

Of course, these widely varied subjects need the expert services of the electrical, hydraulic, mechanical and mining engineers, with their specialized knowledge of installation, equipment and operation of the different types of industries. The land values, irrespective of the riparian rights for the power plant or the mineral rights of a mining property, are fairly easy to arrive at, being governed by recent sales of similar land and other factors mentioned hereafter, and land is one item that enters into nearly every valuation; but on every developed property there will be buildings of some kind, of diversified type and construction, and although in some cases the value of the buildings upon a property will be but a small percentage of the whole, yet buildings occur in nearly every important valuation, and for this reason most of the space in this paper is being devoted to their consideration.

The following statement, from a work by William Arthur, published in New York, is submitted in its entirety as illustrating one man's views of the varying opinions of different authorities on the same subject in the United States:—

"After the physical valuation of a railroad is made, the work is only well started. A celebrated Frenchman once gave the right rule for doing anything. It ran, ' First of all, define your terms. The cost of a railroad is not its value; reproduction value is an indefinite term; there is or there is not such a thing as depreciation,' and so on, words without end.

" Some believe in public ownership of railroads and other utilities and others do not. Regardless of which is right, it may be safely concluded that few men are doing more for the success of the public ownership theory than the lawyers, who take hold of a physical valuation and make a rubber band of it, stretched long or short to suit the side that hired them. Regulation has failed in some countries and government ownership has come. Those who do not like that should do their best to get everything connected with their particular semi-public utility regulated on a fair basis.

" The Supreme Court of Minnesota considered that the cost of reproduction is practically the only element necessary to be considered by the state in fixing rates; the Supreme Court of the United States declared this to be only one element of several; the Washington State Commission, before determining the market value, ascertained:—

(1) The original cost of construction.
(2) Cost of reproduction new.
(3) The depreciated value.
(4) The amount and market value of outstanding stocks and bonds.
(5) The density of population and traffic.
(6) The nature and permanency of population and traffic.
(7) Facilities for doing business.
(8) The physical conditions under which the road is operated.

This concludes the quotation, and goes to show how widely different are the opinions of three governing judicial bodies on the same subject, and this divergence of opinion occurs in a greater or lesser degree in almost every branch of valuation.

Valuation of Land

In a busy city, this part of a valuation can best be looked after by a local real estate man, and unless the engineer has good local experience in this matter he had better transfer this responsibility to a reputable real estate man, as he has his finger on the pulse of the market, has knowledge of recent and remote sales, is aware of the present demand and maximum values.

In some cities it is the practice for those interested to divide the city into zones of varying radii from some focal point or heart of business section, and to roughly valuate the land within each limit at a fixed price per acre, varying with the distance from this point and whether of industrial or residential character. In some other cities the zones are laid out with reference to railroads, bridges across rivers, etc., and have little reference to any focal point. The results are the same; it is the demand that creates the values, and each successive sale acts as a guide or reference for future sales.

Some cities use the superficial foot as the unit for price comparison, while in other cities the frontage foot is the unit for small lots, but this is misleading unless the depth of lot is mentioned as well, and the price per acre becomes the ultimate comparative unit of cost.

The valuation of land, other than city properties or township lots, can be handled by the engineer in connection with any business project which he is formulating, for undeveloped land may be classified as being in one division of the following general category:—

(1) Farm lands,
(2) Forest lands,
(3) Barren lands,
(4) Marsh lands.

As such, it has a certain recognized value per acre as the minimum price, which by competition can be raised almost indefinitely by reason of any special speculative or proved advantages it may possess, such as mineral, adjacent water power, oil, agricultural, industrial, residential or as right-of-way for railroads, etc., and the estimating of values of such advantages is part of the business of an engineer.

In townsite properties, especially in the planning of such, there is great need for level-headed, far-seeing members of the engineering profession who will function outside th vortex of hectic optimism and almost criminal rapacity of subdivision cranks.

Valuation of Buildings

Before the World War, the practice of valuating a building by multiplying the cubic contents in feet by a unit cost was generally resorted to, and tabulated lists of different types of buildings and their approximate cost per cubic foot were used by some valuators, the lists being adjusted every year to suit market prices of labour and material. But the rise in prices was so rapid and so varied, with the many different materials used, until 1920, (when the peak cost was reached and a slight fall followed in 1921), that the units per cubic foot of cost, which had been adjusted to the varying prices, were found to be most unreliable and it became compulsory to carefully take off the quantities of labour and material of each trade's work of typical buildings and price them at current rates for new records.

This method of pricing the cubical contents is not reliable in any way, unless it is established where the vertical dimensions shall be calculated from. Some authorities use the top of basement floors as their starting point and others the bottoms of the footings of a building, and in the case of expensive foundations such as piling or caissons to rock, the foundations had better be separately calculated in any case, as it is very seldom that we get two buildings that are identical in every respect for our comparison of costs. The method of using a unit cost per square foot of floor of typical buildings gives perhaps a little more accurate results, but both methods are at best very rough and approximate means of arriving at a quick result.

Regarding the above mentioned rapid and uneven rises in prices of materials and labour, in the light of these changes, the best physical valuation that could be made was only good for the month during which it was made, and twelve months afterwards it was obsolete.

Another good reason for taking off quantities of the different trades' work combined in any structure and estimating replacement cost of each separately is the greater accuracy with which the depreciation of the whole can be estimated, as each trade represents a certain value upon which varying mortalities can be placed, and from these the mortality and depreciation of the building as a whole can be determined upon.

Present Value

The more you delve into any published statistics and the more you study the argued cases and findings of different arbitration proceedings in connection with this subject, the more you become convinced that the term " present value," used in connection with buildings or properties, is one of the most elastic in our language, depending upon the clever and intelligent presentation of the case by the experts for and against. In short, it is only a point of view taken by the judge or judges.

In the United States, it seems to be the opinion of the Interstate Commerce Commission, and apparently also of the Supreme Court, that the present value of a building, or even of an entire business, is the replacement cost less depreciation plus a " going concern " value.

This is without doubt correct as regards an entire business, but in any case it is best to keep the " going concern " portion of indemnity apart from the building proper and include it in the goodwill or business value. The author's views of this will be explained at greater length in dealing with depreciation.

After all, the " present value " is the goal at which we are aiming in a valuation, and in the case of a building is it not better to segregate from the structure and value separately all auxiliary matters which contribute to the value of the business as a whole, and thus minimize the chances of disagreement and error by tracking each item to its lair, as it were, and despatching it with a certain agreed value rather than by dealing in generalities and incorporating the structure with the volume of business?

Replacement Value

The practice of asking one or more contractors to make estimates from plans or actual buildings for the purpose of arriving at a fair replacement value is not any better, to my mind, than entrusting a qualified engineer, skilled in this work, to prepare an estimate. In works that have been actually carried out, when the engineer in charge has had reasonable time to prepare a carefully detailed estimate beforehand, we will generally find a very small percentage of difference between his estimate and the accepted tender which has passed through the fire of competition. It is not unusual to find a difference of 30 per cent between the lowest and highest tenders of reputable firms on important construction work, and it is not always easy to discover the cause for this difference. On the other hand, when contractors prepare the estimates for replacement value they know they will not be called upon to carry out the work if their tender is low and they will not lose a valuable contract if their estimate is high, so there is not the inducement to apply the same principles and energy to this kind of estimate as there is in a live issue concerning the erection of a proposed new structure.

Therefore, an engineer with special training and practice in this work is well equipped to give good results.

As the years pass, a structure in itself does not become more valuable, but deteriorates from the day it was built. If we make the statement that a building that cost $50,000 when it was built five years ago is worth $55,000 to-day, we mean that labour and material costs have risen in price and we are regarding the dollar value only.

A false valuation may be the outcome of mistaken ideas, careless valuation or trial figures set down as a basis for bargaining and inflated for that purpose. This is to be deplored and reflects discredit upon the appraiser, especially in the last mentioned case. Some people have the idea that it is quite allowable to inflate or deflate values according to the position of their principals, as vendors or purchasers, expecting that the opposing side will do the same and some happy medium will be struck as the result of tedious bargaining. The person who lends himself to this practice will have to continually change faces, according to the side of the bargain on which he finds himself retained.

In short, replacement value of a building should mean the present-day cost to erect a building of similar or equally good materials in like quantity and similar positions as those in the building under consideration, without reference to change in practice, obsolescence of building or any change in building by-laws which might make it imperative to erect a more expensive structure of different materials. The latter phase is being dealt with separately in another part of the valuation, under the heading of compulsory increased cost of business operation.

Depreciation

In the matter of valuating buildings, we have under the heading of depreciation one of the most debatable and potent factors of the whole valuation, for when the replacement valuation is agreed upon then comes the deduction for depreciation, which, judging by some interpretations, is an El Dorado for legal endeavour.

What is depreciation, as applied to buildings? It is the decrease in value to an owner or owners by reason of:—

(1) Natural decay of its component parts,
(2) Wear and tear,
(3) Obsolescence,
(4) Inadequacy.

Efficiency and depreciation are not synonymous. A plant or structure may be 100 per cent efficient for its present purpose, but the deterioration of its parts may be considerable, and the length of future useful life is the point to be determined, which can best be estimated by the number of years it has already been in service and the estimated life span agreed upon for similar plants or structures.

" Tiffany's Estimate of Depreciation of Buildings," as used by the United States government, is:—

Brick, occupied by owner	—1	to 1¼	per cent of investment per year
" " " tenant	—1¼	" 1½	" " " " " "
Frame, " " owner	—2	" 2½	" " " " " "
" " " tenant	—2½	" 3	" " " " " "

These figures for depreciation include buildings where ordinary maintenance expenses have been expended. If extraordinary repairs or replacements have been made, the discount should not be so heavy.

The practice of quoting abnormal cases of duration of different types of buildings is not sound, since it is the exception that proves the rule, and if a life of eighty years was agreed upon as a fair average life of a particular type of building, the quoting of some extreme case of two hundred years should not affect the average. Canada is a young country and one of increasing land and property values, and it is not the practice to build for more than one hundred years in any case, and in many cases for a lesser period, unless the buildings are of a memorial or public type, which are in a class by themselves and require individual consideration when valuation is necessary.

It is possible by expensive maintenance, repairs and renewals to prolong the life of some types of buildings almost indefinitely, but if we study this statement we will see that this amounts to practically rebuilding the whole several times, for to replace the building piecemeal is more costly than to rebuild the whole at one time, and if the percentage of generally accepted depreciation on a building of a certain type has been decreased owing to its prolongation of life by these means, the cost of maintenance, renewals and repairs has increased in proportion, so that we may leave this condition out of consideration.

The sales value of many articles and equipment drops considerably as soon as they are put into use, and after that the decrease in value proceeds very slowly, comparatively, while, on the other hand, from a maintenance standpoint the reverse would be true.

Automobile depreciation has been intelligently grappled with and the tabulated results are well understood and generally accepted.

A mortality basis similar to that used in connection with automobiles or plant units is the most satisfactory basis for computing depreciation, and some recognized scale of life values should be used and adapted to the classes of buildings under consideration. When this is generally adopted, the task of computing the depreciation is simplified, and of the many methods in vogue, that known as the *straight line formula* is the most simple and accurate, which is:—

> Annual depreciation in buildings shall be calculated by dividing the sum of the total investment, minus the probable final salvage value, by the given number of years of estimated life of building at the time of its erection.

There have been cases in Canada where the estimated depreciation has not been taken wholly on depreciation of the building itself, but has been adjusted to include some portion of value as a " going concern " because the building " fulfils its efficiency " for the purpose for which it is being used. The addition of this foreign matter into the subject is very confusing and involves a mixing of the tangible with the intangible, inasmuch as the replacement value of the building at current cost can be accurately established and the depreciation on the building can be demonstrated, (subject to date of erection, structural defects, necessity for repairs and obsolescence), and the estimated present value will be the difference between the replacement value and depreciation. Therefore, it is better to deal with the building separately and leave the question of goodwill or business value to be calculated in another portion of the schedule. Thus, for assessment or taxation purposes the present value of building will be what it is intended to be, without any business entanglements, and the business will be taxed separately.

For the placing of fire insurance, the present value of building will be taken, plus a sum to cover business disturbances during period of rebuilding should the building be a total loss through fire.

In the event of selling the business or for company flotation, the present value of building or buildings will be taken as a separate item and kept distinct from goodwill and other assets in the schedule.

If the land is legally expropriated and a concern is forced to relocate or go out of business, the present value of buildings should be taken separately, and any compensation for buildings as a " going concern " should be considered separately with the adjustments for loss of business.

As an instance where a mortality basis was evidently not used, the following case is mentioned:—

A list of tables prepared and used by the Interstate Commerce Commission of the United States gives a Corliss engine a life of from 25 to 35 years, or an average of 30 years; yet there was a recent case of a Corliss engine which was second-hand when installed 35 years ago and has been constantly working since that time which was valued by the appraiser at present-day price for a new engine less 20 per cent for depreciation.

Another instance noticed recently is that of a frame office building, built in the jig-saw period forty years ago, with much turned and fretted machine-made ornament to the exterior, flimsy studded walls and the clap boards held in position by liberal coats of paint; this building, which, according to the above mentioned tables, should have an average life of 33½ years, was given a depreciation on the present-day replacement cost of 30 per cent, which assumes the estimated life of this building to be 133 years.

Frank E. Barnes, supervising building valuations for the New York Central Railroad, says of depreciation:— " The intelligent use of any rule for depreciation presupposes a careful field inspection and the full knowledge of the conditions surrounding the building, machinery, etc., on which the depreciation is to be figured. It is also assumed that the rules will be applied by one familiar with the subject of depreciation, and who will use reasonable judgment."

An Applied Example

As mentioned above, the intensity of the demand for a building or property is a governing factor in setting the sale price, but it is not the structure itself that has increased in value; this depreciates year by year. The inflated or increased price is a premium or bonus for some advantage of location, thus capitalizing the scarcity of that type of structure or property.

As an example, let us quote the case of an old wooden frame stable existing in a district in which the municipality have decided to eliminate this type of building and have prohibited the erection of any further stables in the neighbourhood and have passed building by-laws since the stable was built which are much more strict, inasmuch as any future buildings to be erected must be of brick, stone, concrete or tile. Now, as long as the owners of the existing building keep it in repair, conduct it in such a manner that no nuisance exists and provide adequate fire protection as called for by the Fire Underwriters' Association, the building may function at an inflated rental value, (because of its unique position and circumstances of the case), so long as it will stand. In the event of a sale, these circumstances would form a potent factor in determining the sale price, depending on how badly the purchaser desired that particular location.

Now, let us view this particular case in the event of the property being legally expropriated by a governing body. The owners are obliged to go outside of this neighbourhood to another where the erection of a stable will be allowed, and they will be compelled to erect a brick or concrete structure to comply with the by-laws.

It is submitted that any compensation to cover extra cost of the compulsory better type of building and the location in a position which may not be nearly so good as the original position for distributing purposes, should be segregated from the compensation for the existing building proper, and should be considered part of the business disturbance and re-establishment.

Let us go a little further with this particular case and suggest a course that may commend itself to an arbitrator or judge, if properly presented. Dealing with the building alone, we find that it was built in 1887, (forty years ago). To build a similar building, of similar materials and in like form, would cost to-day about $7,000. Considering climatic conditions, nature of soil and trade or business carried on, we will assume that this type of structure would, with small annual repairs and preservative measures, last for fifty years. Then the depreciation would be 40/50 or 80 per cent and present value would be the replacement value, $7,000, less 80 per cent depreciation, leaving $1,400 as the present value of building.

The building in 1887, when erected, probably cost $3,000, and if the business had been conducted in a proper manner, a sum for annual depreciation should have been written off as such, apart from items such as interest on capital, repairs and renewals, insurance, taxes, etc.; this sum for depreciation being $60 per year, which would in fifty years amount to $3,000, the sum invested. As forty years have elapsed, the sum of $2,400 would have been written off to the credit of the building, which, added to the above estimated present value of $1,400, would give the owner $3,800 towards the cost of the new building.

Following this case further into the field of business disturbances and loss of trade, we find that the firm whose land and building have been expropriated is compelled to erect a building of similar capacity of brick or stone, and that it will cost them $11,000. Then the difference in rental values of the old building and new for a period of ten years, (which represents the remainder of estimated life of the old building), would be a fair compensation for this item, irrespective of other business losses. This rent would be as $700 is to $1,100, a difference of $400 per year for ten years, which gives $4,000 as the extra cost of operation due to the more expensive building. This item of $4,000, together with the sum allowed for present value of building, $1,400, and the sum already written off in the books of the firm, $2,400, would amount to $7,800, leaving the owners to supply $3,200 with which to build an up-to-date, efficient building costing $11,000, with a life of at least eighty years, which would have a book value at the end of ten years, (the estimated length of life remaining to old building), of $9,625.

If the building had only been built twenty-five years, the amount written off as depreciation in the books of the firm would be $1,500 and the present value would be the replacement value of $7,000 less 50 per cent depreciation, which amounts to $3,500, and the extra cost of operation due to building the $11,000 structure would be $400 per year for twenty-five years, which is $10,000. So the owners would receive $13,500 cash with which to build the $11,000 building and cover extra taxes, and at the end of twenty-five years, (the estimated remaining length of life of the old buildings), would have a book value of $7,562 upon the new building.

Salvage

In estimating the probable salvage value of a building for any specific purpose, the engineer will do well to remember that buildings of brick, cut stone, hollow tile, structural steel or heavy lumber would yield second-hand materials for which there may be a good market, yet mass concrete and reinforced concrete structures give no saleable old materials, except for fixtures, trim and equipment.

The best method to get results is to organize a gang on paper, with necessary plant, and estimate it as a job of work, taking off rough quantities for different materials and allowing for a percentage of these materials which will be recovered, cleaned and prepared for sale. Guard fences and shoring must be considered for the protection of life and adjoining property, and provision must be made against dust. Insurance must be provided, all débris and rubbish must be disposed of and allowance made for teaming and trucking of odd materials. The approximate second-hand market price of the recoverable units may be ascertained, but from 50 to 60 per cent must be deducted from these selling prices for transportation, storage and profit. The difference between these estimated recoverable prices and cost of wrecking will be the salvage value.

Machinery and Fixed Equipment

It is not intended in this paper to more than touch upon this subject, as the types are so varied and the conclusions so debatable, but it is safe to say that the second-hand selling price is governed by the demand, and this demand is well-known and catered to by firms who make a specialty of second-hand machinery and equipment and will quote a price for or give opinion on any collection of machinery of which the engineer may make a list. This inventory should contain makers' names, trade marks and serial numbers, as well as notes on condition and efficiency and how long they have been installed and whether they have been used constantly during that time, and also whether they have been used constantly for days of twenty-four hours each, as is the custom of some industries. From this data, and from his own observance of wear and tear, efficiency and obsolescence, a good engineer can arrive at present values.

Valuators of machinery are very prone to, in a manner of speaking, put everything on the bargain counter and price the machinery accordingly, but if the business has been operated with any degree of efficiency this machinery, although well used, has a present value much more than the salvage or bargain value, and it is here that the standard compiled lists of the average useful life of all types of machinery may be used.

Business Disturbance

In cases of forced re-location by reason of expropriation, claims for business losses or business disturbance and increased cost of production are many and varied, and only a few of the more common questions that arise will be mentioned here:—

(1) Moving machinery, equipment, stock and fixtures.

(2) Renting temporary premises until new premises are ready.

(3) Increased cost of deliveries from new location.

(4) Loss of business directly traceable to the change.

(5) Increased cost of carrying on business, by reason of an expropriation forcing a business concern to spend money on new buildings that they would not otherwise be called upon to do during the operation of the existing lease or a certain period of years.

The first three of these items are easily calculated, but the fourth is one that only time and the books of the business can show, and if claimed, and a direct settlement is desired, should be made the subject of discussion with full access to the books of the business for corroborative evidence.

Providing no argument can be successfully maintained that would prove increased efficiency, cheaper and better production costs or other important advantages to partly or wholly offset this increased cost, it would appear to be the fairest way to calculate this increased cost referred to in the fifth item by multiplying the difference between the estimated rental value of the old building and the estimated rental value of the new building by the number of years already agreed upon as the remaining useful life of the existing building, this sum representing the increased cost to be taken care of in business disturbance.

One might naturally ask, why rental values? By rental values is meant fair rental values on both buildings, calculated by including the same minimum percentage of profit on the invested capital for both and estimating separately a sufficient annual depreciation; also an annual sum for decorations and superficial repairs; annual sums to replace any parts of the equipment or building that might need renewing before the life of the more permanent parts of the building has ended; also, an annual sum for fire insurance, taxes on land and building; a percentage for rental lost by the building being vacant for a period during its life; in short, everything that a fair rental value should mean, viz., a sufficient annual sum to make the building self-supporting for the duration of its estimated life and return a fair interest on the invested capital, irrespective of the problematical rise and fall of land or building values.

Perhaps in the foregoing there has not been much established as to hard and fast rules to be observed. It has rather been a citation of cases, of snags that are likely to occur and of debatable points which the valuator may expect to have to do battle with, but it is hoped that it has made clear the fact that the necessity for more detailed valuations at frequent intervals is becoming greater every year, and it behoves the engineer who intends to specialize on this work, or who may wish to be able to do this work on occasions, to familiarize himself with the taking off of quantities of every trade in building construction, from plans or the actual work, together with the recognized trade allowances for difficult work, deductions for openings, etc., to understand the qualities of building materials, and to keep in touch with market prices of materials, local conditions and rates of pay for labour. He should also set up his own method of short cuts for preparing preliminary quick estimates or for proving or checking detailed estimates; and who is better equipped to study and specialize on this work than the professional engineer?

Bearing Metal Bronzes*

The Essential Constants of Bronzes in Every Day Use as Determined by a Series of Tests with Metals Carried Out Under Practical Working Conditions

Harold J. Roast, F.C.S., President and General Manager, National Bronze Company, Montreal, Que.

and

Fred Newell, M.E.I.C., Mechanical Engineer, Dominion Bridge Company, Limited, Montreal, Que.

Paper read before the Montreal Branch of The Engineering Institute of Canada, October 28th, 1926

The engineer frequently has occasion to look up data relative to bronzes, and often finds that he cannot get such data all on the same metal under the same conditions, and, further, that where details of the conditions prevailing are not clearly stated it is difficult to be certain that the various data secured from different sources are strictly comparable. While it is not claimed that the present investigation is complete, an attempt has been made to contribute something that it is hoped may be of use to Canadian engineers because it deals with Canadian conditions.

The question may arise, can a cheaper alloy be used for some given set of conditions that will be equally as satisfactory as a more expensive product? This in turn brings up the matter of specifications and the question as to whether all virgin metals must be specified, or whether good used metal is permissible, it being obvious that insofar as cost is concerned the use of good used metal is much more economical, not only as to price paid, but also as to the utilization of material.

All too rarely does one meet with a metal specification drawn up in such a manner as to give the purchaser the article best suited to his purpose for the fairest and most reasonable price. Such a specification must demand only an article that can be manufactured under ordinary conditions, for a price that shall be fair alike to both buyer and seller. To ask for a bronze, for instance, to be made out of unnecessarily high grade metal, expecting, at the same time, to purchase it at an extremely low price is unreasonable. It would be far better to require a product to pass certain rigid minimum tests irrespective of the origin of its component parts, provided that such tests are known to adequately ensure the product being thoroughly sound.

Although the alloys were all made especially for the experiments referred to in this paper, they have nevertheless been fabricated under strictly commercial conditions. Melts of the ordinary amount and metals, either virgin or used metals, as ordinarily obtainable on the open market were employed. In some cases the bronzes were made entirely from used metal with results equal to virgin metal, as shown by the constants obtained.

Altogether some three hundred tests were made, involving between eight and nine hundred measurements, and the figures given are based on the averages, the maximum and minimum of which differed but slightly.

The following alloys formed the basis of this investigation:—

No.	Tin %	Lead %	Zinc %	Copper %	Phosphorus %
1.	..	..	40	60	....
2.	..	..	30	70	....
3.	4	4	4	88	....
4.	8	15	1.5	75.25	....
5.	8	15	..	77	....
6.	10	10	..	80	....
7.	10	..	2	88	....
8.	10	..	..	90	0.25
9.	17	..	..	83	....
10.	Manganese bronze (copper-zinc alloy)				
11.	Lumen bronze (zinc-copper-aluminium alloy).				

AUTHORS' NOTE.—* In presenting this paper the authors desire to state that it is intended to present the most essential constants of the bronzes in everyday use, all of which have been determined on the same lots of metal under strictly commercial conditions, conditions which you may reasonably expect to have fulfilled in any bronze foundry operated under modern scientific control.

In discussing the question of the forms of crystals and the phases of various alloys, the terms "eutectic" and "solid solution" are used. Perhaps one may be pardoned for making an explanation in regard to these words. This can perhaps best be accomplished by taking a concrete example.

The metals lead and tin if melted down together, cast, and allowed to cool, form an alloy which differs in its structure according to the ratio of these two metals present.

If 63 per cent of tin and 37 per cent of lead be melted up together and the source of heat shut off, a thermometer being inserted in the molten metal, it will be found that the temperature recorded on the thermometer will steadily fall until a temperature of 358° F. is reached, at which point there will be a period during which no further drop in temperature occurs. When the thermometer records a decrease in temperature again it will be found that the whole of the metal has become solid. The melting point of this alloy is, therefore, 358° F. The melting point of lead is 621° F., and that of tin 450° F.

If the alloy just referred to is melted again and some tin or some lead added to it, the point at which the alloy becomes solid will be found to be higher than was the case in the first alloy. This, notwithstanding the difference in temperature of the melting point of the two metals, whether tin or lead are added, the temperature of the solidification point is raised. It follows, therefore, that the alloy mentioned, containing 63 per cent tin, is the lowest melting point alloy of the series lead and tin. Such an alloy is called an eutectic, from the Greek word meaning well melting.

Putting it in the form of a definition, an eutectic is the lowest melting point alloy for any given series of metals.

The term solid solution may at first seem paradoxical, but this is merely because we are apt to consider solution as taking place only in the liquid phase, whereas it can equally well take place in the solid phase.

When copper sulphate goes into solution in water the resultant liquid shows no sign of the crystals of copper sulphate, nor of the characteristic appearance of water; in other words, their identity is merged the one into the other, and they cannot be recognized by ordinary physical means.

A piece of cast steel, upon examination under the microscope, will be found to consist of a network of large white crystals on a dark background. If such a piece of steel be heated to a temperature above 1,652° F. the steel will still be solid and at a red heat, but at this temperature all the crystals will have disappeared. They will have gone into solution, or the crystals and the dark background will have dissolved, the one into the other. Inasmuch as the steel has been solid throughout the operation, one could say that the crystals have gone into solid solution. It follows that an alloy that is made up of solid solutions has a uniform appearance under the microscope, because the various constituents are merged into each other, with complete loss of identity.

Another example is that of ordinary brass containing 70 per cent copper, 30 per cent zinc. The alloy is a solid solution alloy, the copper and zinc being soluble in each other, and therefore there is only one phase.

If, on the other hand, we take a brass containing 60 per cent copper and 40 per cent zinc, the alloy is not a solid solution, but crystals of one kind of brass are to be seen in a matrix of another form of brass. It is, therefore, impossible to identify the constituents of an alloy which are in a state of solid solution.

On these alloys the following constants were determined:

(a) Composition
(b) Metal cost
(c) Yield point

Where pertinent the above tests were made on:—

(1) Original melt
(2) Remelt
(3) Annealed metal.

It was thought that the best thing would be to present all these tests together and then discuss the various points that suggest themselves. The following details indicate the manner in which the various bronzes were fabricated, and also the metal used and final product:—

Metals Used

Copper—Copper trolley wire.
Tin—William and Harvey pig tin.
Lead—Kingdon lead.
Zinc—Tadanac slab zinc.
Aluminium—99% or over, virgin ingot.
Phosphorus—As phosphor copper 15% phosphorus.
Manganese—As manganese copper 30% managanese.

Melting Unit Employed—City gas gas-fired crucible furnaces, using a 35-pound crucible.

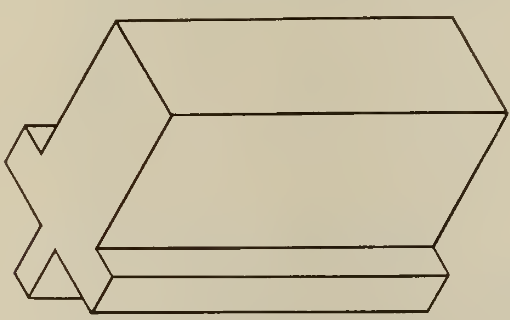

Figure No. 1.—Keel Block Test Bar.

The various alloys were founded in accordance with standard metallurgical practice, at least two hundred pounds of each being used, and poured at the temperatures indicated into green sand "keel block" test bar moulds and left undisturbed until cold. The excess metal, over and above that required for test bars, was cast into ingots. These ingots and the test bar blocks, minus the test bars, were then remelted and cast as "remelt" exactly as before. Some of the test bars of each melt were placed in a "Hump" electric furnace and slowly heated during two hours, to 1500°F., and maintained at that temperature for one hour and then allowed to slowly and regularly cool to room temperature, taking eighteen hours to do so. These bars were marked *"A"* following their ordinary numbers.

Attention is drawn to the form of the test bar, shown in the accompanying figure No. 1, (which is not original), as being one which gives no undue chilling effect but rather conditions that are frequently duplicated in heavy cross-sections of fairly large castings, so that it is reasonable to assume that castings of smaller cross-section will be stronger and not weaker than the tests, although probably, in some cases, having less ductility. The amount of metal required for such a test bar block is from 40 to 50 pounds, the rate of cooling is slow and the resultant grain size "average." The same form of test bar was used for all tests.

In the case of forged manganese bronze, one of the lower bars was heated in a blacksmith's forge until a bright red heat had been reached, soaked at this temperature, and then placed under a steam hammer and forged down from 1⅝ to 1 inch square, the bar still being red hot when finished.

Preparation of Test Specimens

The bars for tensile strength were turned according to American Society for Testing Materials specifications; finished 0.505-inch diameter, distance between punch marks 2 inches, ends left rough and held in slotted steel grips. The bars were then smoked and the yield point taken at that point at which a double line appeared when scribed from a fixed point on the bar. No attempt was made to notice the first 1/1000th of an inch elongation, the whole of these tests being conducted on essentially practical lines calling for as little super-refinement as possible. The machine used for the tensile and crushing tests was an Olsen 100,000-pound capacity, multiple lever type, and in the case of yield point and tensile tests was run at its slowest speed. This gave an average rate of loading of 2,000 pounds per minute. In the case of the compression tests the average rate of loading was 20,000 pounds per minute, and the load was reapplied when necessary until the beam remained stationary for ten seconds. This means that the specimens really supported the loads indicated. The test pieces for compression tests, unless otherwise indicated, were cylinders of one square inch area, one inch high. All measurements of height were made with a micrometer sensitive to 1/10,000 of an inch. In a few cases cubes were used instead of cylinders. The devices used for tensile and compression tests are shown in figures Nos. 2 and 3.

Brinell Tests

These were made on pieces cut from the ends of the tensile test bars. The inside tests were made on the cross-section and the outside tests on the face of the rectangular ends after machining and grinding off about 1/16 of an inch. A load of 500 kilogrammes was maintained for thirty seconds. In some cases the load was applied for ten seconds, fifteen seconds and forty-five seconds with no change in the figures. Again, in the case of the hard alloy No. 9 the Brinell figure of 150 was obtained with 500 kilogrammes for thirty seconds, and a check using 3,000 kilogrammes for thirty seconds gave a figure of 149. Manganese bronze gave similar results. Brinell formula hardness number equals $\frac{L}{A}\,{}^{5}\sqrt{p}$ where L is load in kilos, A is superficial area of concave surface of indentation and p the radius of the ball, in this case 10 mm.

Microscopic Investigation*

Pieces were taken from test bars and prepared in the usual manner and represented original melt, remelt and annealed specimens. Each of these were photographed, unless otherwise stated, at 100 diameters, both *plain polished* and *etched*. The photomicrographs represent the average condition of the metal, unless otherwise designated. Some seventy photomicrographs were taken in all and thirty representative illustrations have been prepared for this paper.

* For the purposes of publication these photo-micrographs have been reduced to 75 diameters, and due allowance must be made when comparing the measurements given in the text with measurements made on the accompanying illustrations.

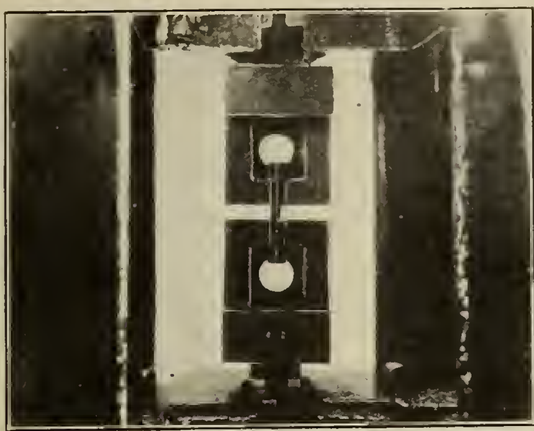

Figure No. 2.—Tensile Test Apparatus.

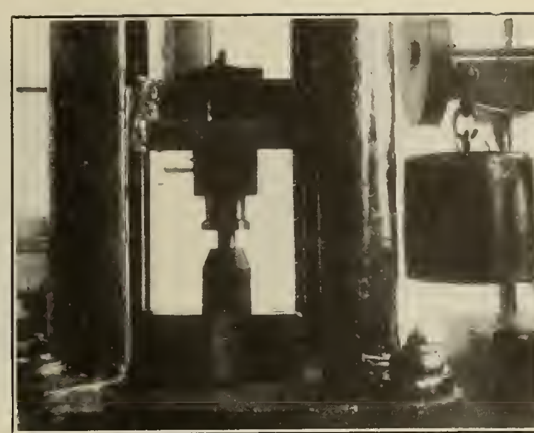

Figure No. 3.—Compression Test Apparatus.

Metal Cost

The bronzes have been arranged in order of the cost of their component metals, including the addition of 5 per cent to cover foundry loss. The base prices used were as follows:—

Tin	70 cents per pound
Lead	10 " " "
Zinc	9 " " "
Copper	16 " " "

These are metal prices only and do not represent in any way the foundry cost.

Apart from the usual data submitted, the writers feel that the following items of interest are worth discussion:—

(1) That the casting of an alloy into ingots and subsequently remelting these for the actual casting is not a necessity and it does not necessarily make for a metal having superior constants, provided that the original melting and alloying were properly carried out.

(2) That the increasing of lead and the decreasing of tin in a bronze does not necessarily soften it, and that therefore lead can be used with greater freedom than some have thought, provided that it is properly alloyed.

(3) That a bronze made from a good used metal will make just as satisfactory castings as when virgin metal is employed, with a natural saving in cost. It is better to pay an increase in price for superior metallurgical practice resulting in good castings from used metal rather than for the use of virgin metal with inferior metallurgical practice resulting in poor and defective castings. This is contrary to the fairly widespread idea that one should be ashamed to admit the use of used metal, but always state that virgin metal is exclusively used.

(4) That a white metal alloy composed of zinc, copper and aluminium can be satisfactorily used in place of the more costly high tin bronze for heavy pressure duty such as bridge turntables, etc.

(5) That in requiring the Brinell hardness figure as part of a specification for a bronze a clear statement should be made as to where and how such a test is to be applied.

Taking up the first point raised, referring to the data chart, table No. 1, you will notice that comparing the yield point and tensile strength figures for the original melt and the remelt for alloys 1, 3, 5, 6, 7, 8 and 9, that the original melt is either equal to or better than the remelt in each of the cases cited. The fact that the difference is very little would indicate that the remelting properly conducted is not injurious, and on the other hand that the original alloying had been such as to produce a satisfactory metal. It is probable that the idea of calling for a remelting of bronzes was to ensure double mixing of the constituents. Insofar as mechanical stirring of the molten metal is concerned, the remelting has this advantage in that the stirring is conducted twice over, as well as the fact that an unhomogeneous ingot may to some extent stabilize itself on remelting and give a more uniform alloy. It is the authors' contention that if the right care is taken in the first place in alloying, including the mechanical mixing where necessary, there is no need for further melting of the metal. On the other hand, it should be quite possible to melt metal several times under the right conditions without loss of mechanical properties. An extreme case of this came to the writers' attention, namely, the remelting of manganese bronze twenty-three times with almost negligible reduction in the physical constants. The saving of an extra melting, other things being equal, should make for economy on the part of the purchaser.

Passing to the second item, dealing with the addition of lead, it will be seen by referring to alloys 6, 5 and 4, under the heading of Brinell tests on the inside of the bars, that alloy 6 has 10 per cent of tin and 10 per cent of lead. In the case of 5 the tin, which is commonly looked upon as the hardening constituent, has been reduced 2 per cent and the lead, which might be considered the softening consti-

Figure No. 4.

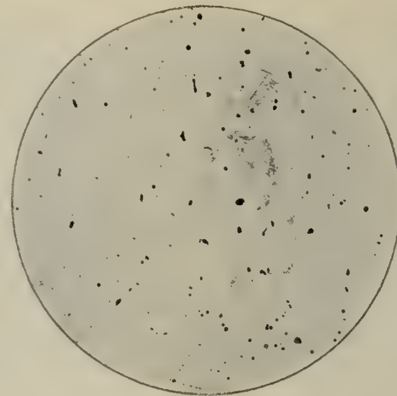

Figure No. 5.

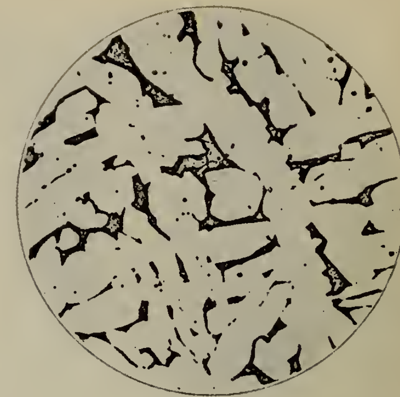

Figure No. 6.

tuent, has been raised 5 per cent. A similar reduction of tin and increase in lead has been made in the case of alloy 4, with the further addition of what is commonly looked upon as a softening agent, namely, 1.5 per cent of zinc. All these changes producing alloys having the same Brinell hardness, namely, 55. If it be a fact that the addition of lead does not produce a softer metal, at least within the limits referred to, then one of the serious objections raised to leaded bronzes for acid resisting purposes in pulp and paper mill work has been removed. Several tests made in recent years have all tended to show that practice bears out the theory just stated. Again, it is commonly stated that lead would be the ideal bearing metal were it only possible to retain it in position under the conditions of hammering and pressure to which bearings are subjected. It is not unreasonable to argue from this that the more lead one can get into a bearing the better, other things being equal.

Turning to the third item, dealing with the relative merits of used and virgin metal, alloy 5 was made from virgin metal and alloy 4 from metal that had been used many times, both being of essentially the same composition. The alloy made of used metal has practically the same tensile strength as the new metal, and has practically the same elongation, in fact, in this particular instance, a trifle better elongation. Elongation is the figure most affected by remelting. The deformation limit is common to both, as also is the Brinell test on the inside of the bars. The microscopic investigation discloses no appreciable areas of oxide, which is a common impurity of poorly melted metal. Although this is the only case illustrated in the present paper, it is only one of many which have come under the writers' attention over a period of many years.

In connection with the fourth item, comparing a zinc alloy with a high tin bronze for heavy pressure duty, very little discussion is required so far as the present figures are concerned. The tests required for alloys subjected to heavy pressure and slow movement are the deformation limit and the Brinell hardness. The deformation limit of the high tin alloy 9 is 25,000 pounds, that of alloy 11, a white metal bronze, is the same. The Brinell hardness of the inside of the bars is 96 for alloy 9 and 124 for alloy 11, the outside of the bars gave for alloy 9, 150, and for alloy 11, 124. At the same time the annealed sample of alloy 9 gave 124 Brinell hardness, or the same as alloy 11. Comparing the compression at 50,000 pounds, alloy 9 had 0.024 inch compression and alloy 11 only 0.015 inch. At 100,000 pounds, alloy 9 gave 0.144 inch for the virgin metal and 0.193 inch for the anneal, as against 0.189 inch for the white metal bronze. Neither bronze has any elongation, so that there is practically nothing to choose between them as far as these tests go, and there is a distinct saving to be made by the use of the white metal bronze. The use of such a white metal bronze in large bridge work has been frequently demonstrated. A warning should be given here to the effect that such a white metal bronze requires extreme purity of its constituents and extreme care in handling, as for that matter does any high grade bronze.

The fifth point, namely, the need for stating clearly under what conditions Brinell tests are to be made, brings to notice the fact that in nearly every case the cross-section of a test bar gives a lower Brinell number for hardness than the outside portion of the bar. The fabrication of a piece of bronze generally requires that it be machined and, unless the metal removed be heavier than usual, the hardness that the tool encounters is that corresponding to the figures given as outside Brinell figures. This may be the figure the engineer desires to control in order to assure as low a machining cost as is consistent with the alloy in question. If, on the other hand, the engineer desires to use the Brinell figure as a measure of the strength of the material, and a very distinct relationship is shown between the Brinell figure and the tensile strength, he would require that the inside or

Figure No. 7.

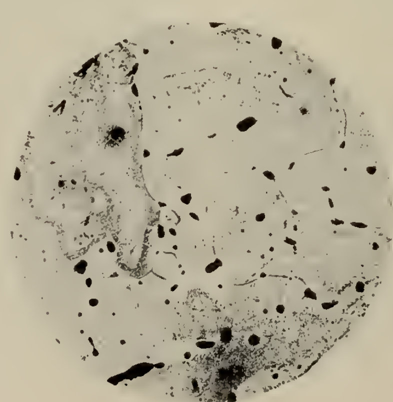

Figure No. 8.

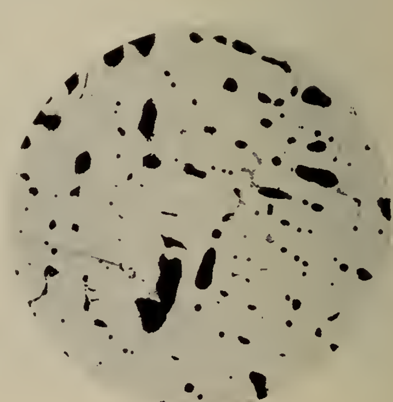

Figure No. 9.

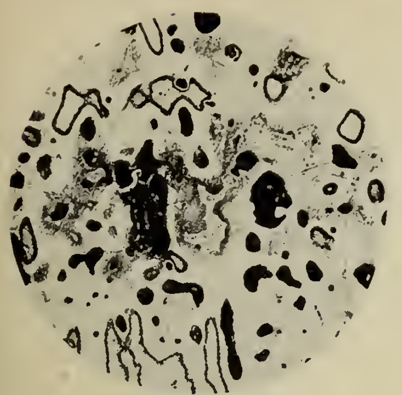

Figure No. 10.

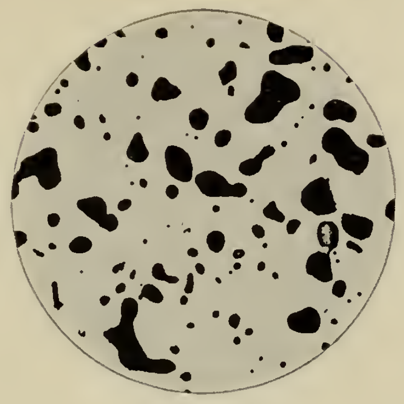

Figure No. 11.

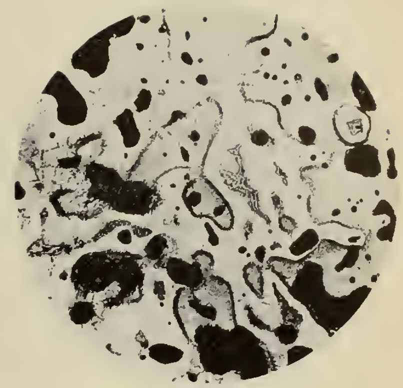

Figure No. 12.

cross-section of the test bar be used for the Brinell figure, which lower figure more truly represents the average of the cross-section of any reasonably heavy casting. The reason for the difference between inside and outside is, of course, obvious, namely, the chill effect and consequent reduction of the grain size.

There are several points of interest that might be discussed, such as the size of the lead particles as affecting the physical constants and some particular discussion in regard to the alloy manganese bronze, an example of which is given as alloy 10 of this series. It will, however, probably be better to discuss each of the photomicrographs in turn.

Yellow Brass

Figure No. 4 shows the characteristic structure of alloy 2, the yellow brass carrying 0.35 per cent of lead. On the upper right-hand corner will be noted the crystal boundary, which in itself indicates that the sample has been etched. The whole metal is formed of a solid solution. The black areas are the lead areas, the largest of which, at seven o'clock, has an actual measurement of 1/600 of an inch. When such an alloy is annealed, the only change one expects is an increase in grain size, which has a marked effect on the elongation. The coarser the crystals the less the elongation, which, in this case, fell from 41 to 28 per cent. There is not much effect on the hardness of this class of alloy, insofar as unworked metal is concerned.

Muntz Metal

The plain polished metal of alloy 1 is illustrated in figure No. 5, and shows the presence of lead particles, representing the 0.35 per cent present, the largest of which is 0.0006 inch in diameter and the smallest visible particle on the photograph approximately one-tenth this size. If there were any oxide areas in this metal they would show up in a manner similar to lead. Upon etching this sample we obtain the result as shown in figure No. 6. Here we see that two constituents are present, the light ground mass being alpha brass and the dark being beta brass. It is the presence of this beta constituent that makes this alloy forgeable at a red heat, whereas the yellow brass is not etched so as not to show the alpha crystals, therefore throwing the beta in relief.

Alloy 3, plain polished, containing 4 per cent of tin, lead and zinc respectively with 88 per cent of copper is shown in figure No. 7. The 4 per cent of lead is more or less uniformly distributed, the largest particle measuring about 0.0004 inch. A freak chain of lead particles will be noticed running across the centre of the photograph.

The same alloy, etched, is shown in figure No. 8, as evidenced by the crystal boundaries. This is evidently not an annealed sample, as the shaded portions show unhomogeneous solid solution. The lead areas are more or less spherical in nature, and as such do not exert a harmful influence such as would be the case if the lead areas were attenuated and lying between the grain boundaries.

Figure No. 9 shows alloy 6, plain polished. The plain polished photograph shows the lead particles, as usual, but in addition the presence of tin-copper compound containing possibly a little copper-phosphorus compound in the form of a triple cutectic. This substance is very hard, as is shown by its standing out in relief in the course of polishing. These areas are visible in the centre of the field.

In figure No. 10 is shown the same alloy, etched. The etching brings out the tin-copper compound, and this particular area was chosen as showing the maximum size of lead particles as found in this alloy. One of the largest measured 1/200 of an inch in diameter. The average physical characteristics of this alloy are quite satisfactory, notwithstanding the presence of the apparently large particles of lead.

Figure No. 11 represents the alloy 5, containing 8 per

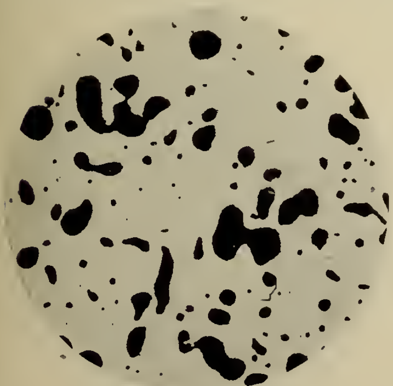

Figure No. 13.

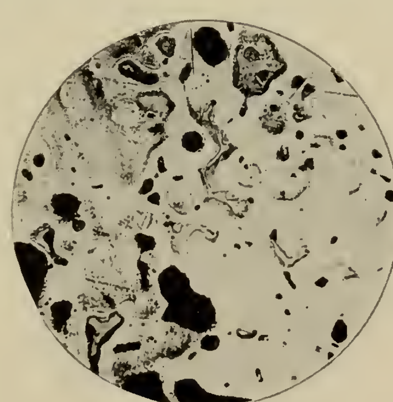

Figure No. 14.

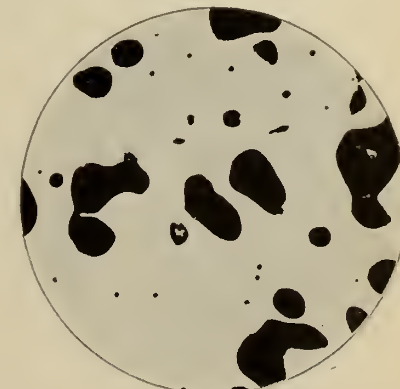

Figure No. 15.

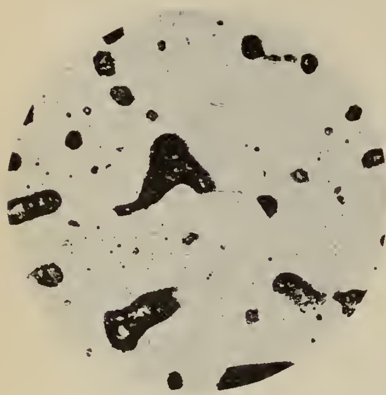

Figure No. 16.

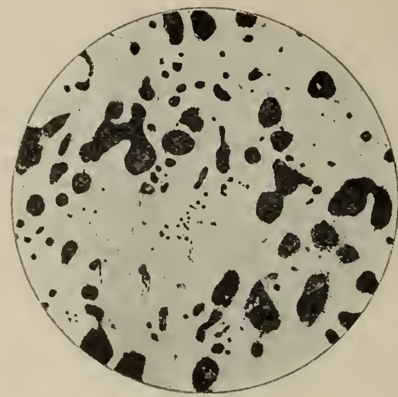

Figure No. 17.

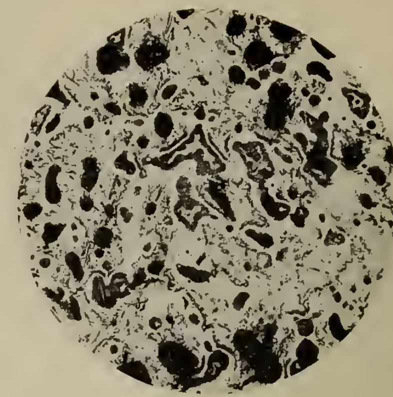

Figure No. 18.

cent of tin, 15 per cent of lead and the balance copper. There is comparatively uniform distribution of lead, the maximum particle of which measures about 1/200 of an inch in diameter.

The same alloy, etched, is shown in figure No. 12. The grain boundary, the unhomogeneous solid solution and the presence of the tin-copper compound, as before described, will be noticed.

Figures Nos. 13 and 14 show the remelt, plain polished and the etched specimen, respectively, the structure being similar to the original melt.

In figure No. 15 is shown the annealed sample, plain polished. This shows the increase in size of the lead particles, from an average of 1/400 of an inch to an average of 1/200 of an inch. This increase in size of the lead particle in the annealed specimens over and above the unannealed, which has occurred in several of the alloys under discussion, indicates the possibility either of the lead, which is molten at the temperature of anneal, coalescing through minute fissures existing in the metal at that temperature or of the lead dissolving some of the alloy in itself and thus increasing in size, or both. It will be noted that the deformation limit of this sample is higher than for the unannealed, which indicates that the increase in size of the lead particles does not adversely affect its resistance to crushing strain. It will also be noticed that the Brinell number is higher.

Figure No. 16 shows the annealed area etched. In comparing this with the previous etched sample, it will be observed that the tin-copper compound has all gone into solution, leaving the alloy in the solid solution form, showing only the lead particles and grain boundaries. It is probable that it is this absorption of the hard tin-copper compound that is the reason for the increase in hardness of the annealed specimen. The average size of lead in the annealed specimen is 1/200 of an inch, and you will note that this gives satisfactory physical properties.

Figure No. 17 shows alloy 4, plain polished, which was made entirely from metal that had been used many times. It contains 8 per cent of tin and 15 per cent of lead, as did the metal shown in figure No. 13. The reasonably uniform distribution of lead particles, the average size of which is about 1/400 of an inch in diameter, is clearly indicated. Notwithstanding the numerous remeltings of this alloy, no appreciable areas of oxide were found therein. These, if present, would appear as irregular formations of a similar appearance to lead. The lead particles have been tested by scratching them with a needle under the microscope and turning up the fresh blue surface of lead. When the suspected lead area is large enough, that is to say, not less than 1/1000 of an inch in diameter, this is the most satisfactory test to apply, although some patience is required.

The next illustration, figure No. 18, is the same area etched, showing the lead areas and the unhomogeneous solid solution and, particularly in the centre, some tin-copper compound.

One of these areas of tin-copper compound, magnified at four hundred diameters, is shown in figure No. 19; the large " shell hole " representing one of the lead particles at this higher magnification. It will be noticed that with the lead areas of the size mentioned the physical characteristics are satisfactory.

Figure No. 20 shows the annealed alloy 8, plain polished, containing 10 per cent tin and 87 per cent copper, and indicates the largest individual lead areas present in an alloy supposed not to contain lead; these areas measuring approximately 1/500 of an inch. The finding of such leaded areas caused us to make an analysis of the alloy for lead, 0.05 per cent of which was found to be present. This emphasizes, therefore, the fact that the occasional presence of lead particles in an alloy, although apparently considerable in some microscopic field, may represent only a trace of lead present in the melt. The alloy gives a particularly high

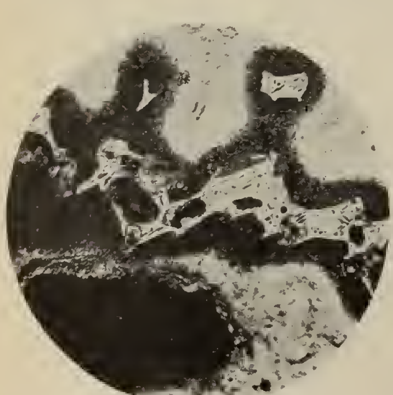

Figure No. 19.

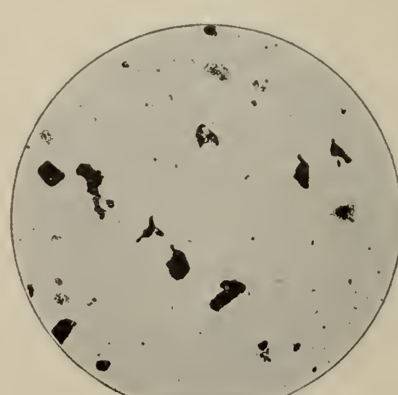

Figure No. 20.

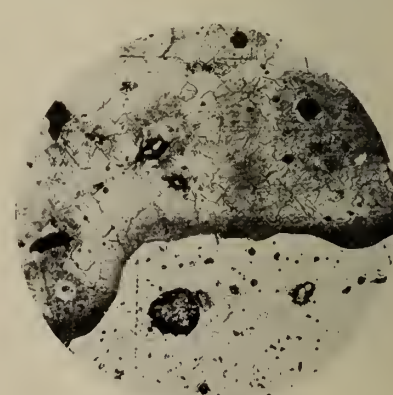

Figure No. 21.

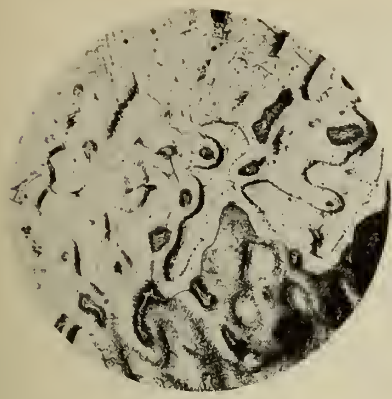

Figure No. 22.

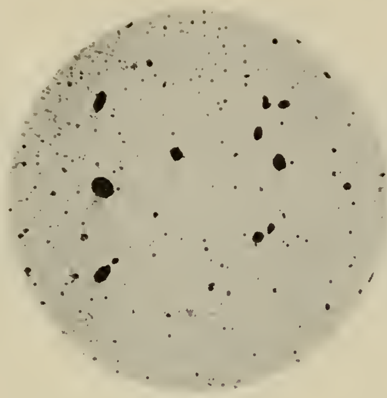

Figure No. 23.

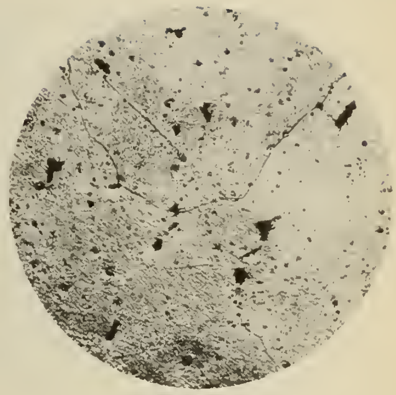

Figure No. 24.

tensile strength and good elongation and the deformation limit is high.

The same area etched is shown in figure No. 21, and gives a particularly good example of the crystal boundaries and serves to illustrate the fact that these differences in colour of the crystals are due to the orientation of light, the proof of which is that, if you change the angle of light upon the specimen, the dark crystal will become light and the light crystal dark, which obviously cannot be due to an inherent physical property of the crystal, save its power of light reflection. This is one of the proofs of the crystalline structure of metal.

Figure No. 22, etched, shows the typical structure of alloy 7, a sand cast Admiralty bronze, 88, 10 and 2 per cent.

In figure No. 23 is shown the plain polished sample of the annealed specimen, the average lead particles of which were a little larger than the unannealed sample, and, notwithstanding the apparently large amount of lead present, careful analysis showed only 0.05 per cent in the average of the metal.

The same sample etched is shown in figure No. 24, and, upon comparing it with figure No. 22, it will be noted that the unhomogeneous solid solution has been wiped out and that the small amounts of tin-copper compound have been absorbed. Attention is directed also to the grain boundaries and the typical solid solution structure. In this instance, however, not sufficient tin-copper compound was present to go into solution to harden the alloy. On the other hand, the deformation limit was not changed by the anneal.

Alloy 9, etched, the American Society for Testing Materials B-22-21, B alloy, is shown in figure No. 25, containing 17 per cent of tin and the balance copper. The continuous network of the tin-copper compound, which, as before stated, is extremely hard, and is supported by a comparatively soft matrix beneath.

Figure No. 26 is shown because it gives a good example of an unsatisfactory anatomical structure for this or any other alloy, namely, that the hard crystals have aligned themselves along the grain boundary. From the physical results obtained, it would seem that this condition is not the average condition of the alloy, and, in fact, this was supported by further microscopic investigation. Had this condition prevailed, the tensile strength of the metal would have been lower than it was, inasmuch as the amorphous cement present at the grain boundary, and which is the strongest portion of an alloy, would have been replaced by a weaker constituent. It is the tendency of this alloy to have these crystals along its grain boundary that accounts to some extent for the fact that the elongation of this series is negligible.

Figure No. 27 is one of the same alloy, showing the maximum particles found, the size of which is over 1/100 of an inch in diameter. This time the areas represent shrinkage cavities, some of which are partly filled with oxide of tin and copper, the natural result of gas cavities where oxidizing influences can come into play. The lead content of this alloy is under 0.05 per cent as taken in the average, and the physical properties were well within the specification called for by the American Society for Testing Materials, notwithstanding the presence of some voids and oxide, as well as a trace of lead.

Turning now to alloy 10, which represents the manganese bronze, figure No. 28 shows the plain polished sample which you will notice contains three constituents, one a background which is the beta bronze, on which stand out more or less in relief the alpha bronze crystals. Standing out in still greater relief because of their superior hardness are the small white crystals, which under direct microscopic examination are of a characteristic blue colour. These crystals have been the subject of considerable research, particularly in a paper entitled "Occurrence of Blue Constituent in High-Strength Manganese Bronze,"* by E. H. Dix, Jr.,

* Trans. A.I.M.M.E., vol. 68, 1923, pp. 642.

Figure No. 30.

and are considered as being composed of iron and copper, which compound, although soluble in manganese bronze alloy until the zinc is added, is by the zinc thrown out of solution. These crystals are very persistent. They occur in the sand cast alloy and persist after forging and after prolonged annealing.

Figure No. 29 shows another aspect of this condition, while figure No. 30, at four hundred diameters, shows more clearly the fact that these crystals are solid solutions.

The etched specimen of alloy 10 is shown in figure No. 31, from which will be noted the large crystals of alpha brass on a background of beta brass. The small black particles are due to the 0.30 per cent of lead that was present in this particular sample.

Figure No. 32 shows the annealed bar, which has been very little changed insofar as the size of the alpha particles are concerned. Microscopic examination of the annealed specimen, however, shows an enormous increase in growth in the real grain size of the metal, the crystals measuring something like one-half inch in diameter, as opposed to something less than 2/100 of an inch. Notwithstanding this enormous increase in grain growth, very little reduction in yield point or tensile strength is produced. It is an outstanding feature of manganese bronze that annealing, forging, or casting in chill makes but little difference in the strength, as compared with the original sand cast metal.

The original bar, after having been heated in a blacksmith's forge to a bright red heat and soaked at this temperature and forged under the steam hammer, is illustrated in figure No. 33. The data sheet shows the increase in tensile strength and yield point with no sacrifice in elongation.

Another bar, which is not shown here, was cold worked under the steam hammer, giving about the same tensile strength, but only 6 per cent elongation.

A test which may be of interest was carried out with a piece of manganese bronze sand cast, the tensile strength of which was 64,400 pounds, elongation 32 per cent at the usual temperature, namely, 72°F. The specimen referred to is the same metal, the tensile strength and elongation of which were taken when the metal was at a temperature of 332°F. below freezing, or minus 300°F. The figures obtained were, tensile strength 73,200 pounds, elongation 26 per cent. This is interesting as showing that this kind of manganese bronze may be safely used at extremely low temperatures, whereas some other alloys are extremely brittle under the same conditions. Another test bar of the same lot of metal was put under tension in the testing machine at 50,000 pounds per square inch and while under this strain was struck repeatedly with a heavy hammer so that the bar was bent, the whole of this operation being conducted at the liquid air temperature. No fracture occurred and the bar was quite sound when removed.

Another bar of the same pot of metal was secured in a vise and reduced to the liquid air temperature, and while at this temperature was bent to an angle of about 120°. The bar showed no sign of fracture or cracking, although the tin container holding the liquid air surrounding the test bar was as brittle as glass and broke as soon as the bending test was applied.

The foregoing tests show that *manganese bronze rightly made combines in itself greater strength, greater ductility and greater hardness than any other one of the ordinary bronzes*, and as such should commend itself to the engineer where such a combination of properties is desired.

Figure No. 34 shows alloy 11, which is the white metal bronze referred to as being suitable for heavy pressures where very little motion occurs, (this alloy is also successfully used for high-speed and low pressures, such as bearings, etc.).

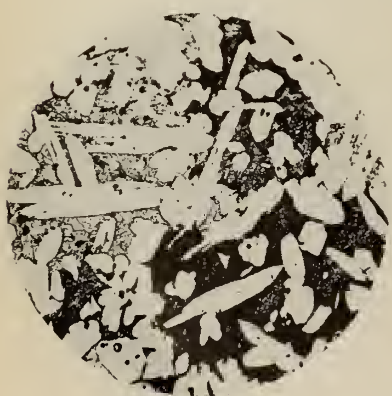

Figure No. 31.

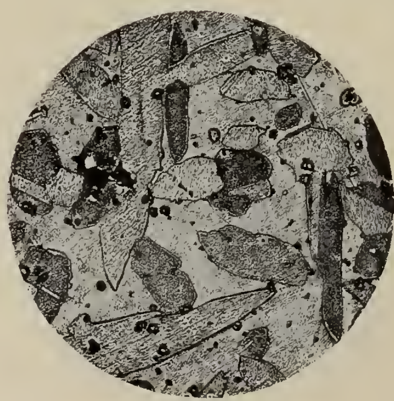

Figure No. 32.

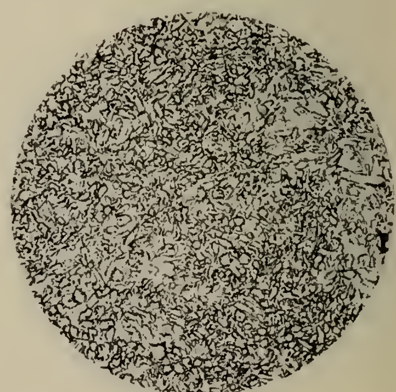

Figure No. 33.

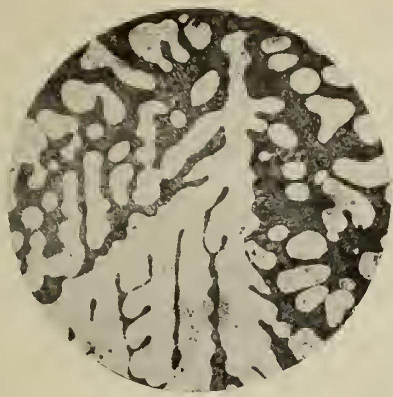

Figure No. 34.

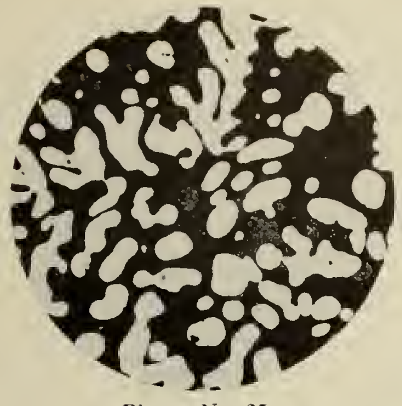

Figure No. 35.

This slide shows the unetched sample, the structure standing out in relief being zinc-aluminium-copper compound, which is much harder than the matrix and so becomes evident under the conditions of plain polishing. The matrix shows a tendency to eutectic structure.

The same area, etched to show maximum contrast, is shown in figure No. 35. This shows that this alloy has the essential characteristics of the bearing metal, namely, hard crystals to carry the load and buried in a softer matrix to permit of self-adjustment of the whole system as may be required by the irregularities of the journal.

In connection with the temperatures used for annealing the specimens, an arbitrary temperature of 1500°F. was taken intentionally, the object of the anneal being not so much to represent the correct heat treatment for each alloy in regard to the dissolving or otherwise of its constituents, but rather to obtain information as to the internal condition of a heavy cross-section of a large casting made from any of these alloys. It is reasonable to assume that the strength, structure and elongation will lie somewhere between the sand cast constants and those for the annealed metal.

In conclusion, the writers would take this opportunity of saying that the work done in connection with this paper has proved very interesting to them, and many other lines of investigation have suggested themselves as the work proceeded. The limitations of time and space have prevented the making of this paper as complete as we should have wished, but if it has provided a nucleus around which further experimental work and discussion may centre, its production will have been justified.

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME X APRIL 1927 No. 4

Lord Willingdon Accepts Honorary Membership

The Institute has been honoured by His Excellency the Governor-General Lord Willingdon, G.C.S.I., G.C.M.G., G.C.I.E., G.B.E., who has graciously consented to accept Honorary Membership in The Institute. Council has accordingly added his Excellency's name to the list of Honorary Members.

Meetings and Discussions

A characteristic feature of social life on the North American continent is the multiplicity of meetings and conventions of social, fraternal, professional and other organizations. Some of these take place almost on the scale of a medieval pilgrimage and involve months of preparatory work, the expenditure of vast sums of money, the wearing of gorgeous uniforms, much golf playing and travel across the continent in expensive special trains. Others, not less entertaining in their methods, and certainly exhibiting equal individual enthusiasm, draw their members from smaller areas, or are held by local bodies, but attach just as much importance to the benefit and recreation to be derived from the "convention habit."

The meetings of scientific and technical bodies are usually not carried out on such an imposing scale, are more serious in their aims and have an important influence on professional life. In the case of The Institute, it is not too much to say that our general and branch meetings are one of the principal means of carrying out the purpose set forth each month on the cover of the Journal "to facilitate the acquirement and interchange of professional knowledge among our members."

The Institute is to be congratulated on the success which has attended our meetings during the past year, not only as regards the social activities organized by the branches concerned, but also in connection with the technical sessions, the papers presented and the discussions arising from them.

Institute meetings are of two kinds, each with its own function and purpose as regards the promotion of professional intercourse.

At our branch centres, it is not reasonable to expect that the papers or addresses given every week, or every fortnight, shall invariably deal authoritatively with engineering topics of Dominion-wide interest and importance. The principal function of branch meetings, and it is a very valuable one, is rather to afford opportunities for the exchange of information and experience in regard to engineering work carried on by members of the branch or in connection with technical developments in the branch district. Less formal in their programme than the general professional meetings, they afford excellent opportunities for the younger members of the profession to take part in verbal discussion, a privilege which at the present time is not taken advantage of as it should be. Among suggestions for extending the usefulness of the branch meetings, none is more important than the organization and encouragement of discussion of the papers read. To discuss an engineering paper, a speaker must obviously have some familiarity, not only with the subject dealt with, but also with the way in which the author is treating it, and we should have a greater number of adequately prepared discussions at branch meetings, if it were the custom to furnish with the notice announcing the meeting a synopsis of the paper to be presented. It is somewhat difficult to do this, as in many cases papers are not in the branch secretaries' hands until just before the date set for the meeting, but the result would well repay the additional work. Attention to this point, and a little preparatory work by the branch committee on papers will lead to a considerable improvement in our branch meetings and in the discussions of the papers presented. Much can be done in this respect also by the authors of the papers, who are too often content with merely reading their manuscript, without giving to their presentation of the subject that personal and interesting touch which cannot be attained in reading from a typewritten copy.

As regards the general professional meetings of The Institute, it cannot be too strongly impressed upon members that if the topics dealt with are to be worthy of The Institute, and are to give, as they should, adequate recognition to the important work of Canadian engineers, it is each member's duty to see that an account of any work of this character with which he is concerned is presented first to his own national engineering society. Such papers should be more than mere general descriptions of the work accomplished, with a few statistics and particulars as to leading dimensions; they should contain a real technical message and deal with specific problems met with in design and construction, recording for the benefit of fellow-members of the profession the way in which such difficulties have been met or such problems have been solved. The majority of the papers presented at our professional meetings are of this kind, but there is room for more.

Engineers are too apt to think that because they are themselves familiar with the difficulties and every-day problems encountered in carrying out their daily duty, information on such humdrum activities will be of little or no interest to their professional brethren. This is a common error; some of the most valuable and helpful communications and discussions in The Institute's publications deal with just such topics.

Discussion is, after all, the most essential feature of a technical meeting, whether general or local, and participation in technical discussions is one of the most valuable privileges which The Institute offers to its members.

The Institute Receives Invitation to University of Toronto Centenary Celebration

There is reproduced below the invitation extended to The Engineering Institute of Canada to participate in the Centenary Celebration of the University of Toronto, which will take place in Toronto on October 6th, 1927, and the two following days.

1827 VELUT ARBOR AEVO 1927

The

UNIVERSITY OF TORONTO

to

The Engineering Institute of Canada

Greeting

ON March 15th, 1927, one hundred years have elapsed since His Majesty, King George IV, granted a Charter for the founding of a University for the Province of Upper Canada to be known as King's College at Toronto. In 1850 the name was changed to the University of Toronto, in 1853 University College was created, and under the Act of 1887 a federal system inclusive of other universities and colleges of the province was called into being. The legislation of 1906 inaugurated a period of great expansion in which the University, keeping pace with the spirit of modern learning and science, has developed its faculties and departments and is endeavouring to fulfil its function through the diffusion of knowledge and the promotion of research.

The University has decided to commemorate the centenary of the granting of the Charter of King's College, Toronto, on Thursday, October 6th, 1927 and the two following days, and is inviting the Universities and the Learned and Scientific Societies of the world to join with it in celebrating that event.

The University therefore has much pleasure in extending to you an invitation to participate in the celebration by sending a delegate on your behalf, and it will assist us in the conduct of our arrangements if the name of your representative be communicated to the Secretary of the Centenary Committee, University of Toronto, Toronto 5, Canada, not later than June 15th, 1927.

Chairman of the Governors *Chancellor.*

President.

Dated at Toronto,
March 15th, 1927

Meetings of Council

Meeting of March 15th, 1927.

A meeting of Council was held at eight p.m. on Tuesday, March 15th, 1927, President A. R. Decary, M.E.I.C., in the chair, and Vice-President J. H. Hunter, M.E.I.C., and twelve other members of Council being present.

The recommendations of the Annual Meeting were considered to the effect that the expenses incurred by authors of papers presented at branches distant from their own should be covered to a certain extent by an appropriation of Council. After discussion this matter was referred to the Finance Committee for consideration and report.

The secretary reported that he had been present at the funeral of Mr. George A. Mountain, and had arranged for flowers to be sent on behalf of The Institute. The following resolution of condolence was unanimously passed, the secretary being directed to communicate it to the family of the late Mr. Mountain:—

> Through the death of George A. Mountain, The Engineering Institute of Canada has suffered the loss of one of its oldest members.
>
> Connected with The Institute since its original inception in 1887 as the Canadian Society of Civil Engineers, Mr. Mountain, after holding office as Councillor and Vice-President, occupied the Presidential Chair in 1909, and throughout his professional career took a leading part in the activities of The Institute, and in all movements for the advancement of the interests of the profession.
>
> With great regret, the Council of The Institute records his death and extends to his family its sincere condolence in their bereavement.

Council noted with much gratification that His Excellency the Governor-General has honoured The Institute by accepting election as an Honorary Member.

In accordance with Section 13 of the By-laws, Bruno Grand Mont, A.M.E.I.C., was appointed by Council as Councillor for the St. Maurice Valley Branch for the year 1927.

Lengthy discussion took place with regard to representations submitted by the Toronto Councillors, and as a result it was decided that a plenary meeting of Council should be held in June of this year, either in Montreal, Ottawa or Toronto, to which transportation expenses of Councillors would be paid by The Institute. It was felt that the holding of such a meeting would not only fulfil the wishes expressed by members at the Annual Meeting, but would also have a very happy effect in bringing members of Council together.

A number of suggestions as to amendments in the By-laws were received and referred to the Legislation and By-laws Committee for consideration and report.

On the representation of one of the Toronto Councillors, discussion took place as to the desirability of instituting a general policy with reference to the promotion of increased interest in The Institute activities on the part of members. A small committee under the chairmanship of Professor T. R. Loudon, M.E.I.C., was appointed to investigate this matter and report at an early meeting of Council.

Life membership was granted to Mr. A. B. Ross, of Toronto, Corporate Member since 1889.

The following were unanimously appointed chairmen of the several committees on Medals and Prizes:—

Gzowski Medal and Students' Prizes Committee—
PROFESSOR C. V. CHRISTIE, M.E.I.C.

Leonard Medal Committee—
Professor H. E. T. Haultain, m.e.i.c.
Plummer Medal Committee—
J. R. Donald, a.m.e.i.c.

It was unanimously resolved that the following committees of The Institute be reappointed with the same personnel as last year:—

- Board of Examiners and Education.
- Canadian National Committee of the International Electrotechnical Commission.
- International Co-operation.
- Concrete Deterioration in Alkali Soils.
- Honour Roll and War Trophies Committee.
- Committee on Biographies.
- Engineering Education.

It was unanimously resolved that J. M. Oxley, m.e.i.c., be appointed to succeed F. B. Brown, m.e.i.c., as a nominee of The Institute on the Main Committee of the Canadian Engineering Standards Association.

Past Presidents J. G. Sullivan, m.e.i.c., Arthur Surveyer, m.e.i.c., and George A. Walkem, m.l.a., m.e.i.c., were unanimously appointed a committee to administer the Past Presidents' Fund.

The small committee which is at present studying the question of students' and other prizes under the chairmanship of J. L. Busfield, m.e.i.c., was unanimously reappointed.

The personnel of the Publication Committee, Library and House Committee and Legislation and By-laws Committee were noted and approved.

Discussion took place on the request from the Association of Canadian Building and Construction Industries for the co-operation of The Institute in the adoption of a standard form of contract for construction work. The secretary was directed to send copies of the Association's present form, together with other information to all members of Council for their consideration, the matter to be brought up again at a later date.

A letter was submitted from the secretary of the Canadian Engineering Standards Association requesting that a representative of The Institute be appointed to act on the committee which is being formed to consider the standardization of sizes of building brick. The secretary was directed to request J. E. Noulan Cauchon, a.m.e.i.c., to represent The Institute at the meeting of the committee in question held on March 18th, in Ottawa.

The attention of Council was drawn to a circular letter sent out by a Corporate Member of The Institute in which The Institute's name and list of members are made use of for business purposes. The secretary was directed to write to the member in question informing him that reference of this kind to The Institute and Institute membership does not meet with the approval of Council.

Three reinstatements were effected and eight resignations accepted.

The meeting adjourned at 1:35 a.m. until Tuesday, the 22nd of March, at eight o'clock p.m.

Adjourned Meeting March 22nd, 1927.

The adjourned meeting of Council was held at eight p.m. on Tuesday, March 22nd, 1927, President A. R. Decary, m.e.i.c., in the chair, and Vice-President J. H. Hunter, m.e.i.c., and five members of Council being present.

The budget of The Institute for the current year was presented by the chairman of the Finance Committee, and unanimously approved and adopted.

A request was submitted from the Vancouver Branch for permission to inaugurate a "university chapter" or students' branch of The Engineering Institute at the University of British Columbia. Considerable discussion followed, during which reference was made to the report of the Students' Activities Committee presented at the Annual Meeting 1924, and printed in the Journal for February 1924, page 63. The secretary was directed to express Council's gratification at the steps taken to establish a connection with the engineering students at the University of British Columbia, calling attention to the report of the above mentioned committee in 1924, and explaining the procedure to be followed in forming Students' Sections.

The following elections and transfers were effected:—

Elections	
Members	2
Associate Members	10
Affiliate	1
Transfers	
Associate Member to Member	4
Junior to Associate Member	2
Student to Associate Member	3
Student to Junior	4

Twenty-four applications for admission and transfer were scrutinized and classified for the ballot returnable April 22nd, 1927.

Two special cases were considered in connection with applications for admission.

The Council rose at 11:20 p.m.

Engineering Act—British Columbia

An important change in the Engineering Act has recently passed the British Columbia Legislature, and has removed a very real obstacle to the development of the work of the Association of Professional Engineers of British Columbia.

The far-reaching effect of the amendment may be judged by comparing the old and new versions of subsection 4 of section 7 of the Act, which read as follows:—

Old wording:—"Notwithstanding anything to the contrary in this Act, any person may practice without being licensed in the Province for the sole purpose of examining, consulting on, advising on, or reporting on, properties and works in the Province; and such person may, without being licensed, superintend operations directly connected therewith; but such privilege of superintendence shall not be construed as entitling such person to hold himself out as or to generally engage in the practice of professional engineering."

As amended:—"Non-resident consulting engineers may practice in this Province temporarily, provided written notification has been given to the Council of the Association, and provided evidence of satisfactory qualifications shall be submitted if requested by the Council."

In a memorandum regarding this matter, the secretary of the Association points out that it would have been impossible to have obtained this really important amendment at this time unless the members of The Engineering Institute of Canada throughout the province had given it their active support. Moreover, the favourable consideration which has now been granted to the representations of the engineers of British Columbia, after some six years of patience on their part, is in no small measure due to the aid and sympathetic attitude of The Institute's Past President, Major Geo. A. Walkem, m.l.a., m.e.i.c.

The engineers of the province are to be congratulated on the additional measure of recognition which the profession has now received from the Legislature of British Columbia.

Addresses Delivered at the Annual Dinner of the Engineering Institute of Canada, Chateau Frontenac, Quebec, February 16th, 1927

Address of Sir Henry W. Thornton, M.E.I.C., Chairman and President, Canadian National Railways

Mr. President, Your Excellency, Monseigneur, and Gentlemen:—

If I were ever repaid for the laborious hours I spent in the study of calculus and mechanics of materials and various other dry and musty subjects which have enabled me to humbly claim a title as an engineer, I am repaid this evening, and I am happy and proud to find myself this evening amongst brother engineers.

One is always handicapped in speaking after a dinner in the good, hospitable city of Quebec, especially if you have been since two-thirty in the afternoon in this beautiful city. The mind is undoubtedly crowded with thoughts and ideas, but the tongue, for some mysterious reason, seems to be inarticulate and to find difficulty with the sibilant syllables. A journey of a thousand miles for an evening in Quebec is time well spent; there is something about the atmosphere of this delightful city, something about its welcoming arms that brings a glow of happiness and a feeling of contentment.

The profession which all of us are proud to own is an ancient and a respected one. Much has been written and said about it; so much, that I fear it passes my powers of imagination to add anything useful. The engineer has produced all forms of construction from ancient days to modern times; engineers planned all great works of antiquity; theirs are the responsibilities for all of the mighty achievements of men which we find to-day, and they are also responsible for all of those constructive works which are essential for the development of civilization. So that, after all, we may claim as engineers to have accomplished all of those monuments which date from the days of the Pharaohs to modern times. The ancient engineer evolved those fundamental principles of engineering, the inclined plane, the wedge, the lever and all those simple things which, coupled with the inexhaustible supply of labour at substantially no other cost than the expense of conquest, made possible the great engineering works of antiquity. The difference between the ancient and the modern engineer is that the constructionists of the days of Egypt and Babylon had at their disposal unlimited human labour. As time wore on and slavery disappeared and the masses were released from thraldom, the activities and ingenuity of the engineer were bent upon supplanting unlimited labour with mechanical devices, and that marks the distinction between the engineer of olden times and the engineer of modern times.

Our profession is divided, perhaps, into two classes, those who teach and those practice. Every one of us can recall with affectionate memory the days of our colleges and our universities and the tender and esteemed instruction which we had from our engineering masters, and I desire this evening to pay a tribute, in which all of you will join, to those fine instructors, those professors of our profession, who taught us in our earlier days, perhaps reluctantly on our part, who guided our steps and who to-day constitute the genesis of our profession,—our great engineering professors.

Financially, their reward has been poor, but, however that may be, they can think with contentment and with pride upon the devoted services which they have given to the profession of engineering, and I say, Mr. President and Gentlemen, all honour to those fine instructors to whom each and every one of us owe what knowledge we may have of engineering.

Engineering education must necessarily and fundamentally be scientific in most of its aspects, but if I were to make any suggestions or be so bold as to offer any criticism, I should say that a knowledge of the classics and general culture subjects is just as essential to the progress and advancement of the successful engineer as a knowledge of mathematics and stresses in materials or any of those subjects which are ordinarily found in the curriculum of any engineering school. You may say that Latin and Greek may have but little bearing and small utility in the golf-bags of engineering equipment, but I do assure you from practical experience, and from my own knowledge, that an acquaintanceship with general culture subjects eventually becomes of almost major importance to the engineer after he reaches a certain position of prominence in his profession.

I am reminded of this incident: a very famous and well-known bridge engineer once wrote a book on engineering, which he entitled "De Pontibus," which, being done into English, means "Concerning Bridges," as all of you classical scholars will know. This book was distinguished for its excellence and lucidity of expression. A brother engineer once wrote to him and congratulated him upon the title he had selected for his book, whereupon the author in reply said that he had studied Latin for many years and that was the only use he could think of to which he could put it. His friend, thereupon, wrote back and said to him, "All of the fine English which is found in your book is due to your knowledge of Latin," and he was not very far wrong. So that, let our engineering schools and universities by no means overlook the necessity of not only turning out finished engineers from the scientific point of view, but also cultured gentlemen, who understand and appreciate good English.

I remember well the parting words of advice which were given to me by my dear old professor of civil engineering at my university, now dead, but whose memory I shall always revere, who said to me, "I have but one word of advice to give you; if ever, by any chance, you should prove to be a good draughtsman"—and there was small prospect of it,—"never let anyone find it out." There was much wisdom and sagacity in that thought, because just as many brilliant careers have been wrecked on the draughting table as have been wrecked by a permanent wave.

Mr. President and Gentlemen, in the larger sense we are the engineers of a nation; we are building to-day in Canada a nation. I have always maintained that in the construction of any great enterprise, be it a railway or a great industrial establishment, in its initial stages, what is needed are the best brains that money can buy. How many of us have seen in railway construction an example of mistaken location, which lives forever after as an expense and plague to the operating officers? When a railway is being projected is the time to employ the best brains and to pay the highest price to obtain those brains. It is a comparatively simple matter to maintain and operate a railway after it is built, but it is quite a different thing to plunge into a wilderness and to cross mountain chains to locate a railway which will best serve the needs of following generations, and that is the time when the engineer is most needed, so that what we are doing to-day, whether it be in railway construction or in the building up of our nation, are the things which will help or hinder succeeding generations.

In this Dominion of ours,—indeed, one may accurately describe it as a continent, stretching, as it does, from the Atlantic to the Pacific, and from the international boundary to the North Pole,—in all of this great expanse of territory, peopled by individuals of different conceptions of life, with different occupations, there are constantly arising difficult problems which, however sectional they may be in character, have a deep and profound bearing on the future of our Dominion. Upon our manner of dealing with those problems to-day will largely depend the future of our nation, and I take it as a happy thing that there are in the Dominion of Canada so many of those who call themselves engineers, who bring to bear on their engineering problems trained minds, and, in a larger sense, can bring to bear on our national problems minds which have passed through the trial and experience of a college or university education.

The one thing which knowledge teaches more than any other single thing is tolerance, the ability to approach problems from an unprejudiced standpoint, a refusal to become excited over fluttering papers which the wind may blow and a refusal to be distracted from the rational conceptions of things by the rantings of the intolerant critic and by the prejudiced soap-box orator. Those are the things which education brings to us in the building of this nation and in the building of that edifice which we are engaged upon to-day; in that work, let us bring to bear those fine things called poise and tolerance, which builds surely, which builds with accuracy and which lays a foundation upon which our children and our children's children may continue to work that which we have been instrumental in starting.

No country of the world has finer traditions than the Dominion of Canada; the history of no country affords so many examples of fine self-sacrifices, from the early priests of the Church, who came to this country shortly after the discovery of North America by Columbus, who penetrated the wilderness and in spite of tortures by beasts and savages carried the word of God from the Atlantic to the Pacific, down to the day in which our own modern engineers penetrated the Rocky mountains and were responsible for the construction of the two great transportation systems which serve Canada,—all of the engineering achievements constitute fine traditions and fine examples.

We have within the borders of this great country two races. Let us be thankful that we have them, because each one is the complement of the other; each can teach much to the other. Let me compliment, if I may be so bold, the Administrator of this province upon his fine address which was delivered in both French and English; so, I say, that with these splendid traditions, with these fine courageous peoples which inhabit Canada to-day, with all of Canada's natural resources, there is no country which can face with greater confidence, with a brighter outlook for the future, the coming years of this great Dominion.

Mr. President and Gentlemen, I thank you for the privilege of addressing you; I am proud to attend a gathering of brother engineers. We are proud of our profession; we are proud of its achievements; it is for us to see that the traditions of our profession, its ethics and its fine principles are maintained, and I know that all of these things may be safely left in the hands of this Institute of Canadian engineers. I thank you.

Address of Mgr. Camille Roy, M.A., Ph.D., F.R.S.C., Chevalier de la Légion d'Honneur, Rector of Laval University, Quebec

Mr. President and Gentlemen:—

Laval University did not desire to remain indifferent to the very useful work of your convention. The university has lent her assistance to your technical sessions by some of her professors, and this evening, by her Rector, she wishes to congratulate you on those annual meetings at which you exchange your views and your experiences, in order to better contribute to the economical development of our country.

You have chosen Quebec as a suitable place for your congress. Quebec is an ancient and quiet city. She gives to mental labours the assurance of all the necessary tranquillity, and by this tranquillity she favours in a special manner the meditations necessary for the abstract designs of the engineer. Therefore, the engineers are really right at home here in Quebec. I have no doubt that your meeting, held in this atmosphere of peace and light, will be most fruitful.

The science of the engineer is more than ever useful in the development of our national resources, and we admire your zeal in developing them and thus increasing our public wealth.

The universities are the principal seats of the study and progress of science, and our university, with her schools of chemistry, surveying and forest engineering, and with her affiliated school of agriculture, endeavours to serve the best economic interests of this country and to create more and more improved centres of scientific study.

She is thus happy to second your efforts by training in her schools able workers for the advancement of the engineering profession.

It is this desire of co-operation which leads her to wish you, this evening, for your congress in Quebec, the most brilliant success.

Discours prononcé par Monseigneur Camille Roy, M.A., Ph.D., F.R.S.C. Chevalier de la Légion d'Honneur, Recteur de l'Université Laval, Québec

Je vous remercie d'abord d'avoir convié l'Université Laval à votre banquet. Vous lui avez donné, par cette invitation, un témoignage d'estime qu'elle apprécie.

Vous êtes réunis à Québec pour étudier ensemble les ressources naturelles de la province; vous vous appliquez à les bien connaître, afin de mieux faire servir votre science à l'exploitation et à l'utilisation de ces richesses. Notre province ne peut que bénéficier de cette mise en commun de vos études, de votre savoir, de votre expérience.

Et l'Université Laval qui veut contribuer au développement économique de la province, qui a pour mission de former des hommes de science dans tous les domaines de l'activité nationale, ne peut que se réjouir de vos travaux consciencieux, de votre zèle mis au service de nos grands intérêts publics.

Notre pays n'est pas neuf, mais il est réellement jeune. Depuis longtemps déjà nos hommes publics s'efforcent de le mettre en valeur; mais il est incontestable qu'il enferme encore des ressources insoupçonnées, non seulement pour l'agriculture, mais aussi pour le commerce et l'industrie. A mesure que notre activité élargit ses frontières dans notre province, on constate de mieux en mieux qu'elle est appelée à jouer un rôle considérable dans tous les domaines de l'économie.

Dans l'exploitation et l'utilisation des ressources naturelles d'un pays, la science est un facteur de plus en plus efficace. Elle a des moyens d'action, aujourd'hui, qui, sous la main de l'ingénieur, captent les forces de la nature, abolissent les obstacles, concentrent les énergies, et créent de la richesse publique.

L'ingénieur est en train d'écrire l'une des pages les plus importantes de l'histoire économique de notre province, et du Canada. Terres et forêts, mines et pêcheries, colonisation et agriculture, travaux publics de toutes sortes bénéficient de toutes les applications que vous faites de votre science: et voilà que sur toutes les aridités techniques de cette science, vous faites croître et fleurir la prospérité.

Messieurs, les universités qui contribuent à faire la science, à former les savants et en particulier ces grands artisans du progrès que sont les ingénieurs, ne peuvent que se féliciter de contribuer pour leur part à tous les progrès. L'Université Laval ne désire rien tant que d'agrandir en ces domaines économiques sa part d'activité. Ce soir, elle s'empresse surtout de rendre hommage à votre zèle pour perfectionner votre art; elle souhaite vous voir multiplier vos congrès pour multiplier vos bienfaits.

Address of The Hon. Lucien Cannon, Solicitor General of Canada

Mr. President, My Lord Chief Justice, and Members of The Engineering Institute of Canada:—

The Toastmaster, in introducing me, was kind enough to call upon your indulgence by mentioning that I was somewhat a creditor, and that you were indebted to the Government of which I am a member, for having, to some extent, broken the ice during your stay here.

Gentlemen, you have heard Sir Henry Thornton speak, and you will realize how difficult it is to follow a speaker of Sir Henry's experience and eloquence. To add to the difficulties of my task, I have to follow also this evening no less a personage than the Chief Justice of the province of Quebec, before whom in the early days of my active practice at the Bar, I always spoke with a great reluctance, not to say with trepidation.

Sir Henry Thornton, this evening, gave the secret of his successful management of our Canadian National Railways system, when he informed us that he was an engineer. Evidently he has mastered the feat well known to all engineers of having a structural section stand by its own dead weight.

When Mr. Decary was kind enough to tender to me an invitation to attend your banquet this evening, I accepted with pleasure on behalf of the government of Canada and also on behalf of those citizens of Quebec whom you honour by having chosen our city as the locale of your meeting this year. I have no intention of keeping you for any length of time, but may I call attention to the extraordinary features of our old Citadel City, as far as engineering is concerned and insofar as it enables any layman to understand the history of your order and the achievements of your profession?

Within the walls of Quebec we have tokens of the engineering attainments of many generations. If you look at the houses of our city in the older section you will see the workmanship of the French engineers who came here with the first governors, under the guidance of Frontenac and others and with the help of the kings of France. You will see, also, the workmanship of the English engineers who, after the Conquest, came into our country to establish the rules of the British Crown, under which we now enjoy so much freedom and so much liberty. The military walls of Quebec show what the genius of these British engineers could accomplish; and may I broaden this idea to some extent by calling your attention to the very gigantic masterpiece of Canadian engineers by mentioning the great bridge which connects the two shores of the river St. Lawrence? This bridge is a living example of our Canadian initiative and confident boldness; it is also an inducement to every young man who lives within the boundaries of Canada to exert the utmost of his energy to contribute his share in the building up of our country.

To be a real nation, our country must be a self-contained one. Up to very recent years we used to borrow from the neighbouring republic to the south most of the engineers who carried on the great undertakings,—industrial and others,—within the shores of Canada. In 1910, for the first time, the Premier of Canada called upon Canadian engineers to build this great bridge, the greatest of its kind in the world, and Canadian engineers succeeded in doing so.

The Chief Justice and Sir Henry have mentioned the ideals and the objects of the engineering profession. May I ask you to direct your attention for a moment to another angle of your great national usefulness, and that is, in building up our country?

If Confederation to-day is an accomplished fact, if we have throughout our Dominion nine prosperous provinces, competing in sisterly spirit toward the prosperity of Canada as a whole, we owe it to the engineers who have linked these provinces together. The Maritime Provinces never would have joined in Confederation if the Intercolonial Railway had not been built, and the Intercolonial would never have become a railway if we had not had engineers to build it. In the extreme west, in British Columbia, we find the same situation; British Columbia never would have become part of our Confederation if the engineers had not linked British Columbia with central and eastern Canada by the construction of the Canadian Pacific Railway. We owe Confederation to the engineers, and if the pioneers in your profession have achieved these wonderful things in the past, those who listen to me here to-night are also called upon to continue this great work.

The province of Quebec realizes how great may be the industrial expansion of the province if her natural resources are properly developed. We have, at our very gates, the spectacle of the building up of one of the largest industrial plants, in the lake St. John district, which the world has ever known; we have within the gates of our own city immense mills which are being built. Quebec is doing her share; the rest of Canada is also doing its share, and may I say, in conclusion, Gentlemen, that you, who represent every province of this great Dominion, who have come here to confer with other members of your Institute belonging to other provinces, in order to devise the best means and the best methods of promoting the welfare of Canada, will do your share; and your deliberations here this week will, I am sure, bear a fruit that every citizen of Canada will taste with pleasure if you go back to the very ends of our country, to the localities to which you belong, and continue the great work and maintain the great traditions of the organization of which you are members. I thank you.

OBITUARIES

George Alphonso Mountain, M.E.I.C.

One of the most popular, most widely known and highly respected members of the engineering profession in Canada passed away at Ottawa on February 26th in the person of George Alphonso Mountain, M.E.I.C., late chief engineer of the Board of Railway Commissioners. In his passing, Canada loses a man who for many years held one of the most important positions of national responsibility in the Dominion.

The late Mr. Mountain took a leading part in the affairs of The Canadian Society of Civil Engineers, later The Engineering Institute of Canada. One of the first members of the former society, when it came into existence in 1887, he served on its Council in 1893, 1899, 1900 and 1901. He was vice-president in 1903 and 1905, and in 1909 was elected president, a position he filled with great distinction. He was always keenly interested in promoting the welfare of the engineering profession, and his opinions were held in high esteem. The Ottawa Branch honoured him with the chairmanship of the branch in 1913-14, and until his recent illness he was rarely absent from any of the activities of that organization.

Mr. Mountain was born in Quebec City in September 1860. He studied for his profession with the city engineer at Quebec, and in his early engineering work was with survey parties of the Quebec and Lake St. John Railway on engineering work at the Quebec graving docks and on the Newfoundland Railway. In 1881 he joined the staff of the Canada Atlantic Railway. Previous to 1887 he held the position of assistant engineer, in that year being appointed chief engineer, which office he held until in 1904 he accepted the position of chief engineer with the Board of Railway Commissioners. For twenty years he held the latter important post, resigning in November 1924 because of ill health. While he was with the Canada Atlantic Railway, the Ottawa, Arnprior and Parry Sound section of the line was built, and he was also engineer of the Coteau bridge across the St. Lawrence river. For the last two years of his association with the Canada Atlantic Railway, Mr. Mountain was also consulting engineer for the Temiskaming Railway Commission. In 1882 he was commissioned as a Dominion Land Surveyor. In addition to his association with the Engineering Institute, the late Mr. Mountain was connected with various other technical organizations and societies. He was a member of the American Railway Engineers and Maintenance-of-Way associations, and a member of the Royal Astronomical Society of Canada.

In social and sports clubs he was very popular and was a member of the Rideau Club, the Ottawa Hunt and Golf Club and the National Club, Toronto. He took great enjoyment in outdoor sports, particularly in shooting, fishing and golf.

The funeral was held on Tuesday, March 1st, and the long cortege included many citizens prominent in railway circles and the public life of Canada, as well as numerous members of the professional associations in which Mr. Mountain took such a leading part. The Institue was represented by R. J. Durley, M.E.I.C., general secretary, and Noulan Cauchon, A.M.E.I.C., chairman of the Ottawa Branch, as well as by many other members.

Andrew Rainsford Wetmore, M.E.I.C.

In the death of Andrew Rainsford Wetmore, M.E.I.C., who for the past thirty-four years has been provincial bridge engineer for the Department of Public Works of the Province of New Brunswick, the engineering profession has lost one of its prominent members.

Mr. Wetmore had been in ill health for some months, but it was believed that he was rapidly recovering, and his death, following a relapse, came as a great shock to his many friends both within the profession and private life.

The late Mr. Wetmore was born at St. John, N.B., on October 14th, 1862, and received his early education at the high school at Fredericton, finally graduating from the Royal Military College, Kingston, with honours in civil engineering in July 1882.

Following graduation, his first work was in connection with the survey of the Chignecto Marine Railway, on which he was employed in a junior capacity. In January 1883 he became assistant engineer of bridges and buildings for the Montreal and European Short Line Railway along the north shore of Nova Scotia from Pugwash to Pictou. In July of the same year he was appointed junior assistant engineer on bridge construction and railway extension at St. John, N.B.

During the summer of 1884 and until the fall of 1885, Mr. Wetmore was engaged in the relocation and was engineer-in-charge of construction of the Elgin Petitcodiac and Havelock Railway, and in the following year was on preliminary survey of the Short Line Railway from Salisbury to Fredericton, N.B. During the next three years he was with the Canadian Pacific Railway on preliminary and final location surveys between Montreal and Sherbrooke, and was sectional engineer under the chief engineer on the construction of a portion of this line. Subsequently, in 1890, he was engaged in the location of the Quebec Central Railway and in the spring of the following year he was appointed assistant engineer on the double tracking of the Grand Trunk Railway between Port Hope and Toronto. In the fall of the same year he returned to the Quebec Central Railway and was engineer in charge of preliminary and final location survey on the extension from Tring station to Megantic in Quebec. During the winter of 1892-93 he was engineer in charge of surveys of St. John Valley and River du Loup Railway, after which he went to Boston, Mass., where he received private instruction at the Institute of Technology and in the office of a consulting bridge engineer. In the fall of 1893 he was appointed provincial bridge engineer with the Department of Public Works of the province of New Brunswick, which position he held until the time of his death.

The late Mr. Wetmore joined The Institute in 1920, being elected Member on March 23rd of that year.

In the editorial columns of the Telegraph-Journal, St. John, N.B., there appears the following tribute to the late Mr. Wetmore:—

> In the passing of Mr. A. Rainsford Wetmore, chief engineer of the bridge department in the Public Works Department, the province loses a faithful servant whose long service was marked by an unfailing devotion to official duty. For thirty-four years he has

occupied the position of chief engineer, and in that period a complete revolution has taken place in methods of road and bridge building. Mr. Wetmore had valuable experience in his earlier life as a railway engineer, and came to his official duties well equipped. Necessarily, during his long period of service he visited all parts of the province, and made friends among all classes of people who will pay kindly tribute to his memory. There have been many changes of government in New Brunswick since the early 'nineties of the last century, but each succeeding cabinet found Mr. Wetmore competent and entirely trustworthy and retained him in office. He has suffered from ill health for a considerable period, but hope had been entertained that rest and change would restore his vigour. He was a worthy representative of a family distinguished in the public service of New Brunswick, and widespread sympathy goes out to the bereaved family.

Guy Carleton Read, A.M.E.I.C.

It is with regret that we record the death of Guy Carleton Read, A.M.E.I.C., which occurred at his home in Lachine, Que., on February 25th, 1927.

The late Mr. Read was electrical engineer with Messrs. Fred. Thomson Company, Limited, and had been with that firm since 1921. He was born at Kenora, Ont., on July 10th, 1883, and received his early education at the Lindsay Collegiate.

In 1901 he entered the shops of the Canadian General Electric Company, remaining on that work until 1905, when he was appointed assistant engineer for the same company in charge of installation and operation of rotary converters for the Toronto Street Railway Company. From 1907-09 he was assistant to the engineer in charge of installation and operation of substations with the Toronto Electric Light Company. Later he was appointed electrical engineer and superintendent with the Cobalt Light, Power and Water Company, remaining with that company until 1910, when he joined the staff of the Canadian Westinghouse Company as electrical engineer, and during the next six years was in charge of various installations for that company. In 1916 he was with the Shawinigan Water and Power Company in charge of certain electrical installations and in the following year joined the staff of Messrs. J. M. Robertson Limited as assistant engineer until accepting the position which he occupied at the time of his death.

The late Mr. Read joined The Institute in 1925, having been elected an Associate Member on September 15th of that year.

Col. Charles O'Connor Coslette Donnelly, M.E.I.C.

Sincere regret is expressed in recording the death of Col. Charles O'Connor Coslette Donnelly, M.E.I.C., assistant district engineer of the Public Works Department of the province of British Columbia, which occurred at Northfield, Vancouver Island, on December 20th, 1926.

The late Col. Donnelly was born at London, England, on January 1st, 1861, and received his early education in Dublin and London.

In 1886 he was engaged with Edward Jones, consulting engineer, on general engineering works and for the following two years was first assistant to John Maitland Grant, district engineer, Cape Government Railway, and later consulting engineer. From 1888 to 1891 he was engaged in private practice, following which he joined G. H. Poole and Company, Elsburgh Netherlands Government Railway. He was also with a firm of contractors engaged in railway work. For one year he was engineer with H. Douglass and Dupreez on the Klip river section of the Cape Railway, Natal Government Service.

From 1894 to 1901 he was senior district engineer for the Public Works Department, Imperial Government Service. The following three years were spent as senior district engineer for southern districts. On July 1st, 1904, he was appointed government surveyor of works for the Colony, and from then until 1905 he was surveyor of maintenance in addition to the foregoing position. From that date until 1907 he was chief engineer of construction.

In 1910, Col. Donnelly was located at Winnipeg in the government service and subsequently moved to Ottawa, where he was connected with the federal Department of Public Works, remaining there until about two years ago, when he moved to British Columbia.

The late Col. Donnelly served with the British Forces throughout the Boer War and was Colonel with the Canadian Engineers in the Great War, where he gained distinction and was mentioned in despatches.

Col. Donnelly joined The Institute as Member on October 8th, 1910.

St. George James Boswell, M.E.I.C.

The death of St. George James Boswell, M.E.I.C., at his home in Quebec on March 3rd, 1927, marks the passing of one of The Institute's earliest members, and one of the most highly respected citizens of the ancient capital, and the announcement of his death has come as a shock to his many friends.

The late Mr. Boswell was in his seventy-third year at the time of his death, and was consulting engineer of the Quebec Harbour Commission. He was a graduate of McGill University, from which he received the degree of Bachelor of Applied Science in 1874.

He joined the Royal Canadian Engineers regiment in Montreal immediately following graduation, and within a year rose to lieutenant in that unit. From 1875 to 1877 he was connected with the work of building Mount Royal Park, in Montreal, and was subsequently assistant engineer on sewerage and other works in Montreal. In April 1887 he joined the staff of the Quebec Harbour Commission as assistant engineer, being appointed general assistant engineer in 1881 and resident engineer in January 1887. Ten years later he was promoted to chief engineer of the commission.

While still a young man, the late Mr. Boswell's ability as a civil engineer was recognized and he was entrusted with important missions by various governments and private corporations. He was requested by the chief engineer of the federal Department of Public Works to supervise certain work in connection with the port of Halifax, and subsequently he was retained as consulting engineer to the city of St. John, N.B.

His membership in The Institute dates back to the formation of the Canadian Society of Civil Engineers, his election as Member having taken place on January 20th, 1887.

PERSONALS

H. P. Fuller, A.M.E.I.C., assistant engineer, Canadian National Railways, Kamsack, Sask., has moved to The Pas, Man., where he is engaged on the work in connection with the Hudson Bay Railway.

D. W. Hodsdon, A.M.E.I.C., has resigned from his position as engineer, Department of Lands, Water Rights Branch, Victoria, B.C., and has accepted a position with the Canadian Crown Willamette, Limited, Campbell River, B.C.

R. L. Dobbin, M.E.I.C., who has been acting manager of the Peterborough Utilities since the resignation of H. O. Fisk, M.E.I.C., has now been appointed manager. Mr. Dobbin has also been honoured by election as an engineering representative on the senate of Toronto University.

Major G. R. Turner, R.C.E., A.M.E.I.C., has returned from the Staff College at Quetta, India, as he has been appointed district engineer-officer of Military District No. 10, Winnipeg, Man. Major Turner has been in India for the past two years.

J. C. K. Stuart, A.M.E.I.C., of the firm of Stuart and Sinclair, Limited, Hamilton, Ont., was elected president of the Hamilton branch of the Association of Canadian Building and Construction Industries at the annual meeting which was held in the Royal Connaught Hotel on March 3rd, 1927.

Harold M. Thompson, A.M.E.I.C., who, prior to sailing to England last fall, was chief mechanical engineer for Sawyer-Massey Company, Limited, Hamilton, Ont., has joined the engineering staff of John Fowler (Leeds) Company, as designing draughtsman.

H. W. Buzzell, S.E.I.C., who for some time past has been located in Kansas City, Mo., has recently been transferred to Cape Girardean, Mo., where he is engaged as assistant resident engineer on the construction of a highway bridge over the Mississippi river. Mr. Buzzell graduated with the degree of B.Sc. from McGill University in 1924.

H. Davison Hyman, Jr.E.I.C., formerly draughtsman with the Riordon Pulp Corporation, Limited, Temiskaming, Que., has accepted a position with the Spruce Falls Power and Paper Company, at Kapuskasing, Ont. Mr. Hyman graduated with the degree of B.Sc. in civil engineering from McGill University in 1925.

Narcisse J. A. Vermette, A.M.E.I.C., who was previously connected with the Technical Service, city of Montreal, has been appointed city manager for Shawinigan Falls, Que. Mr. Vermette graduated in civil and electrical engineering from Laval University in 1915, and following graduation was employed as chief engineer by the firm of Ouimet and LeSage.

Professor Duff A. Abrams, M.E.I.C., director of the research laboratory of the Portland Cement Association, has resigned, according to an announcement issued by the Association. The work that Professor Abrams has carried out in the field of research in connection with concrete and the bulletins and scientific papers prepared by him are well-known throughout this country. He is a graduate of the University of Illinois, and was for a time a member of the faculty staff of that university.

Edward Hughes, A.M.E.I.C., has been appointed to the engineering staff of the Granby Consolidated Mining, Smelting and Power Company, Limited, and is located at Copper Mountain, B.C. Mr. Hughes was for a time engineer with the Crow's Nest Pass Coal Company, Limited, at Fernie, B.C., as mine surveyor, and later with the Calumet and Hecla Consolidated Copper Company. Subsequently, he was engaged with the Western Chemical Company at Camp Verde, Arizona, and during the latter part of 1926 he was engaged on Canadian Geological survey work in northern British Columbia.

President Decary Receives Honorary Degree

A. R. Decary, M.E.I.C., president of The Institute and superintending engineer of the federal Department of Public Works for the province of Quebec, was the recipient of the Honorary Degree of Doctor of Applied Science, (Docteur ès Sciences Appliquées), which was conferred upon him by the University of Montreal.

Mr. Decary is a distinguished alumnus of the Ecole Polytechnique, Montreal.

D. A. Evans, M.E.I.C., Joins Lake St. John Power and Paper Company

D. A. Evans, M.E.I.C., formerly with the Newfoundland Power and Paper Utilities Corporation, Limited, Corner Brook, Nfld., has joined the staff of the Lake St. John Power and Paper Company, Limited, and is located at Mistassini, Que.

Mr. Evans is a native of Wales, and received his diploma in mechanical engineering from the University of Wales in 1908. His first engineering work in Canada was in the shops of the Grand Trunk Railway at Montreal in 1908. He later became connected with National Transcontinental Railway in the designing department and continued with this organization for a number of years, occupying various positions. He was later with the Canadian Pacific Railway, and subsequently with the Canadian Explosives Limited. In 1915 he was with the Canada Carbide Company, and in February 1917 was appointed manager of the St. Maurice River Boom and Driving Company, which position he held for six years until 1924, when he became associated with the Newfoundland Power and Paper Utilities Corporation.

ANNOUNCEMENT OF MEETINGS

MONTREAL BRANCH

Secretary-Treasurer, C. K. McLeod, A.M.E.I.C.

Apr. 7th: Address on "Recent Development in Aviation," by Mr. Reid.
Apr. 14th: Address on "Manufacture and Uses of Carbon Dioxide," by J. R. Donald, A.M.E.I.C.
Apr. 21st: Address on "Vallee Street Substation," by H. Milliken, A.M.E.I.C.
Apr. 28th: Address on "Gatineau Development," by A. H. White, M.E.I.C.

HAMILTON BRANCH

Secretary-Treasurer, W. F. McLaren, M.E.I.C.

Apr. 22nd: Address on "A Mechanical Transmission Model," by R. C. Bergvall.

VANCOUVER BRANCH

Secretary-Treasurer, F. P. V. Cowley, A.M.E.I.C.

Apr. 6th: Address on "The Engineering Profession and Its Relation to Engineering Education," by E. A. Wheatley, A.M.E.I.C.
Apr. 13th: Address on "Britannia Mines," by C. P. Browning, A.B.
Apr. 20th: Address on "Modern Telephone Practice." Speaker not yet definitely arranged.
Apr. 27th: Open date.

SAULT STE. MARIE BRANCH

Secretary-Treasurer, A. H. Russell, A.M.E.I.C.

April : Address on "Radio," by Mr. B. M. Owen.

ELECTIONS AND TRANSFERS

At the adjourned meeting of Council held on March 22nd, 1927, the following elections and transfers were effected:—

Members

CROPPER, William Charles McDonald, B.Sc., (McGill Univ.), apparatus engr., Northern Electric Co., Montreal, Que.

STIRLING, Grote, private practice in B.C., M.P. for Yale, B.C., Kelowna, B.C.

Associate Members

BUSS, Paul E., plant engr., Provincial Paper Mills, Ltd., Thorold, Ont.

FREELAND, John James, B.Sc., (McGill Univ.), dftsman on paper mill work, Mistassini Power & Paper Co. Ltd., Montreal, Que.

GRAY, Bjarne, M.E., (Kristiania Tekniske Skole), res. engr. i/c mill mtce. and constrn., Kipawa mill, Temiskaming, Que.

HASTINGS, Walter Hindson, B.Sc., (McGill Univ.), engr. to Bureau of Labour and Industries, Sask. Gov't., Regina, Sask.

LOMER, Gerald B., B.Sc., (McGill Univ.), steam engr. with Power Corp. of Canada, Montreal, Que.

PARKS, Ralph E., B.S., (Purdue Univ.), Aluminum Co. of America, design work connected with Arvida Plant, Arvida, Que.

SILCOX, Clifford Henry, asst. engr. survey, Gold Coast Rly.

STEVENS, Robert Herbert, asst. in waterworks office, City of Edmonton, Alta.

VINCENT, Roch Arthur, B.A.Sc., (Laval Univ.), general engrg., architecture, surveying, etc., with Mr. Arthur Vincent, Montreal, Que.

WATSON, Hugh Monroe, Jr., B.Sc., (McGill Univ.), ch. asst. to contracting engr. of Dom. Bridge Co., Montreal, Que.

Affiliate

ANNETT, Fred. A., "Power" editorial staff, New York, N.Y.

Transferred from class of Associate Member to that of Member

BAIRD, Albert Foster, B.Sc., (Univ. of N.B.), prof. of physics and elect'l engrg., Univ. of N.B., Fredericton, N.B.

KOHL, George Hutton, B.Sc., (McGill Univ.), hydraulic engr., Spanish River Pulp & Paper Mills, Ltd., Sault Ste. Marie, Ont.

PRATT, Forest Millen, B.A.Sc., (Univ. of Toronto), ch. engr. i/c plant improvements and mtce., E. B. Eddy Co., Ottawa, Ont.

WEST, Frank Leslie, B.Sc., (McGill Univ.), professor of engrg., Mt. Allison Univ., Sackville, N.B.

Transferred from class of Junior to that of Associate Member

GIFFORD, Francis Darrell, i/c field work on Crow river storage project under Jas. Mackintosh, Midland, Ont.

PERRY, Lewis Alan, asst. engr., Long-Bell Lumber Co., Longview, Wash.

Transferred from class of Student to that of Associate Member

CALDWELL, Charles Edward, B.Sc., (McGill Univ.), time study engr. installing Bedaux System in machine shop, Taylor Instrument Cos., Rochester, N.Y.

GRENZEBACH, Sylvester Leslie, B.A.Sc., (Univ. of Toronto), with Toronto Hydro-Electric System, Toronto, Ont.

HULBURD, William Chauncey, B.Sc. (McGill Univ.), mech. engr. and ch. dftsman, Harland Engrg. Co., Montreal,, Que.

Transferred from class of Student to that of Junior

BLUE, Albert Crawford, B.A.Sc., (Univ. of Toronto), asst. ch. engr., Riley Engrg. & Supply Co. Ltd., Toronto, Ont.

INGS, Jasper H., B.A.Sc., (Univ. of Toronto), res. engr. on Sect. 7 of Kapuskasing-Smokey Falls Ry., Smokey Falls, Ont.

MILLS, Charles Perkins, B.Sc., (McGill Univ.), sales mgr., S. Georgia Power Co., Albany, Ga.

MOULTON, Reginald Heath, B.Sc., (Queen's Univ.), special studies on traffic and cost results, Bell Tel. Co., Montreal, Que.

EMPLOYMENT BUREAU

Situations Wanted

Civil Engineer

Available at thirty days' notice after April 1st. Member of Association of Professional Engineers of Nova Scotia, and licensed Nova Scotia Land Surveyor. Twenty years' experience in eastern, central and western Canada and the United States, including railway location and construction, water power development surveys, construction of dams, factory and office buildings, general steel plant construction, coal mine development, including construction of bankheads, yard tracks, underground systems and mechanical installations. Apply Box 219-W, Engineering Journal.

Mechanical and Construction Engineer

A.M.E.I.C., graduate in mechanical engineering, McGill University '07, with extensive experience in steel and concrete, foundation work, and installation and operation of steam power plant equipment, desires position with consulting engineer or general contractor. Experience also includes the handling of skilled and unskilled labour. Available at once. Apply Box No. 223-W, Engineering Journal.

Civil Engineer

Engineer with a number of years' experience in connection with industrial plants, and particularly in design and construction of pulp and paper mills, wishes to become associated with an engineering or contracting firm or with a pulp company. Speaks both French and English. At present employed. Apply Box No. 224-W, Engineering Journal.

Civil Engineer

Open for an engagement about May 20th, M.E.I.C., returned soldier, twenty-five years' experience in all parts of Canada and United States; railway location and construction, canals, concrete structures, sewers, water systems, buildings, highway location and construction, all classes of pavements; experience as engineer-in-charge and superintendent for contractor. Apply box No. 225-W, Engineering Journal.

Situation Vacant

Structural Designer

Prefer young man, university graduate, with at least two years' experience in structural detailing as well as designing experience with structural steel contractors. State fully, education and experience and when available. Address replies to Dominion Bridge Company, Limited, Winnipeg, Man.

Members' Exchange

For Sale

One Troughton and Simms transit theodolite, on three levelling screws, 6½ inches horizontal circle, 5-inch vertical circle, both graduated to twenty minutes, reading to twenty seconds. Three-inch circular needle, English form tripod; good condition. Also one surveyors' compass, 4-inch needle, 5½-inch sights, 12½ inches apart; all in box, fitted for jacob staff. Can be used on tripod; good condition. Apply to E. T. Wilkie, M.E.I.C., 56 Marmaduke street, Toronto, 3, Ont.

Map of District Northeast of Winnipeg

In the past few years interest has been turned to the region in western Ontario lying north of our transcontinental railway lines, due to mineral activities in such localities as Red lake and the surrounding territory.

Aerial flying in this general region has assumed such importance that it has been considered advisable to issue an "aeronautical map" for the special use of air pilots. This map, known as the Winnipeg district aeronautical map, is printed in colours on the scale of eight miles to an inch and covers an area from Winnipeg to a point about fifty miles east of Kenora, and from the latter place to the point where the Ontario-Manitoba boundary line turns in its course from due north to northeasterly.

The map, although designed particularly for use of aviators, should prove equally serviceable to the general public. It may be obtained from the Topographical Survey, Department of the Interior, Ottawa.

ABSTRACTS OF PAPERS READ BEFORE BRANCHES

The Influence of the Medical Profession on the Education of a Medical Student

W. H. Hill, M.D., D.P.H.

Vancouver Branch, November 3rd, 1926.

In dealing with medical education as a type of successful professional education which might appear to serve as a guide to other professions, particularly to engineering, it will be necessary to speak from the medical standpoint, and to describe the relations which it seems to bear to the engineering standpoint.

Education is that process which elicits those potentialities with which each of us is born, to the number and extent required to make us thoroughly at home in that part of the universe in which we individually may find ourselves.

Now, the very art and science of all living consists in making constantly, daily, hourly, minute by minute, second by second, successful adjustments between ourselves and our surroundings. Our surroundings may be defined broadly as all the things in the universe that affect us in any way. Our surroundings are continuously making demands upon us which we must as continuously meet,—physical, mechanical, chemical, biological, psychological demands; any failure to meet any one of these demands adequately means disaster, disease, even death.

The possession of potentialities for such adjustments constitutes the difference between the living thing and the dead thing. But these *potentialities* must be developed from mere potentialities to actual *abilities* to meet the demands of the surroundings, or the living thing will soon become a dead thing. It is this development of the potentialities which constitutes education.

The demands of everyday life,—physical, mechanical, chemical, biological, psychological,—constitute the most important essential and, in fact, quantitatively, the vast bulk of all education; schools and universities exist merely as development-specialists in small, particular fields, largely psychological.

A university education is a system by which certain demands are collected and marshalled upon us; either those demands for which we ourselves decide to develop potentialities, or, especially in a professional education, those demands which are selected by the wisdom of our predecessors as those which it will be our special province to meet in later life. In the university these demands are made upon us, not haphazardly, irregularly and at great intervals, as in real life, but systematically, progressively, without break in sequence, so that a university education of four years means a training in the meeting of demands, of which in real life no one man would be likely to meet all in forty years; and which he would never have presented to him in systematic, progressive, consecutive order in four hundred years.

The whole art and science of the developing of potentialities lies in so adjusting the demands that each may be met, at first, a little at a time; later with a gradual increase in the degree of the demand; but always with intervals of rest between doses. This graduated dosage is provided in all properly constructed educational courses; and intervals of rest are provided as an essential part of the whole scheme.

It is because the university courses are so laid out as to follow these fundamental rules, biological and psychological, for the development of potentialities, that there can be successfully crowded into them a content of far more than an ordinary life-time will furnish.

This marshalling of demands is the first factor of a university training. Two others are perhaps even more important, and both are inherent in it; the second, included in the first, is that in undergoing intensive development of potentialities, the methods for developing those potentialities are themselves so learned as to be later applied easily, almost automatically, to other potentialities which the university course leaves untouched; and the third, included in the other two, is that the student learns of, not only those demands selected to be made upon him during his course, but of thousands of others also, to deal with neither time nor opportunity exist then, and for which he must later develop his potentialities himself.

To epitomize,—he learns some things; he learns of the existence of many other things; but above all, he learns how to learn. That is to say, this is true of the real student, he who goes to school to learn, not to be taught. One teaches a dog or a horse or a seal; but the real student is not taught,—he learns. The difference is that between a scow and a tug,—between being towed and going under one's own steam.

Cultural education as contrasted with professional education is a preparation to meet a different set of demands, those made artificially, i.e., by man himself, rather than by nature apart from man. Cultural education therefore leads rather to a meeting of the demands of the social organism than to a meeting of the demands of the natural universe, from which the social organism springs. A cultural education, therefore, is of primary value to the individual cultivated, permitting him to fit comfortably into the present social system. A professional education is primarily of value to the race, since it equips the individual thus trained not only to fit into, but to deal with, serve or even modify the underlying foundations of every social system.

But there exists also another important distinction between the cultural and the professional school as we see it in medicine. The distinction arises thus: as already said, the aim of the cultural education in public school, high school and university is, or ought to be, the development of the potentialities of the individual for his own good primarily; to provide him with such a development of his potentialities that he may successfully meet the demands of his human surroundings in after life, that he may be " at home " amongst his fellows in this world. Therefore cultural education is, or ought to be, designed to help, aid and individually encourage and cultivate the individual, to advise and direct him, and so make the most of such capacities as he may have, and especially " to help the lame dog over the stile."

But the professional school in medicine exists primarily to prepare the individual not for his own good, but for the good of the race. Therefore its procedure is not to help the lame dog over the stile, but to erect stiles such that no lame dog can possibly climb them. One object, therefore, of the professional school in medicine is to eliminate, not to patch up or help. For those thus eliminated medicine has no use. Hence it is that the medical professional school of to-day has no cultural aims in the ordinary sense. We realize, of course, that the medical man is an individual with his own life to live; that he needs the cultural features of education for his own benefit, " to make it easy for him to live with himself," as well as the professional features for the benefit of others; and we cannot, if we would, prevent the professional medical training from having incidentally an immense cultural effect. But cultural training *per se* we cannot give; there is no time or energy left for it in the modern medical curriculum, which is quite the most strenuous curriculum on any university campus to-day.

This situation is met by the provision of a required pre-medical course in cultural subjects, and so successfully that the only marked criticism that the author has heard frequently repeated is the lack of training in English composition and in public speaking, particularly the latter. These two things our profession so lacks that the term the " Inarticulate Profession " has been coined for medicine and really quite well fits it. It is interesting to learn that these two lacks are felt in engineering circles also.

Granted all this, then the university education for a profession means no more than an intensification and concentration of cultural education along lines in which it is desirable that the student's potentialities shall be very highly developed, and this for the benefit of the race primarily, and of the individual only secondarily.

Indeed, university education properly considered is far less a matter of preparing a student to meet definitely specified demands than it is a training of the student in how to prepare himself to meet demands not yet definitely specified. In brief, the difference between the man trained only by practice and the university man is, or ought to be, that while the former may be more perfect in meeting the demands of those surroundings that he already knows, the university man is capable of meeting the as yet unknown. The man solely of practice meets the routine well, but is lost completely in the emergency; the university trained man can with practice become just as perfect in routine, but also he can meet and triumph over the emergency as well.

How apply all this to medical and to engineering education? That the applications in actuality shall fall far short of the ideals laid down goes without saying, but how apply them even approximately?

In medicine the demands of humanity have forced the selection of the content of medical education, as indeed is quite right and proper, and as indeed they must. The medical man exists for the patient, not the patient for the medical man. Simple and obvious as this is, it is not always kept steadily in view by every member of the medical profession, but it is certainly the viewpoint of every member of the profession worthy of the name.

Since any patient applying to a physician at any hour of the day or night may present any problem in medicine that has ever been presented, or a problem that has never yet been presented to any physician anywhere, may present that problem in any stage, under any disguise and in any combination with other medical problems, and under any modification of circumstance, such as age, sex, nationality, personal history, etc., every physician, ideally, must be ready at any moment to deal with any application of medicine ever known or to invent new applications, and all as an emergency. Hence, ideally, the graduate in medicine should have all the knowledge of medicine, surgery, nursing, anatomy, physiology, biology, biochemistry, diagnosis, prognosis, therapeutics, etc., at his finger ends, so organized and in such smooth working order that he automatically selects and uses, promptly and well, exactly what is needed to discover what is the matter with his patient and how best to correct it, and all in the shortest possible time. Now, it is absolutely impossible that, in four or even seven years, the university student of medicine should have seen, known at first hand, and become familiar with one-tenth of any one subdivision of his work, even of the main fundamentals of anatomy, physiology, biochemistry, diagnosis and treatment. All that can be hoped is that he will have such a familiarity with the general facts, and more particularly with the general principles, that he will recognize the guiding features of a case presented to him and skilfully and intelligently work out the heretofore to him unfamiliar combinations.

Because then the demands of his patient compel the physician to work out each case in detail, rapidly and usually by himself, at the best with help from consultants, who must themselves see the patient and make their own examinations, the problems of the physician are intensely individualistic and dependent upon his own individual powers.

Others cannot do his work for him; he must know for himself that which he discovers himself with his own eyes, ears and hands. True, his knowledge is pieced out by the extensions of his eyes, (the microscope), of his ears, (the stethoscope), of his hands, (the various registering devices for heart beat, blood pressure, respiration, heat determinations; the thermometer, etc.), and so on, but after all he must know in general what all this evidence put together means, and decide what it means to the particular patient.

Hence exists the sharp-cut outline of medical education. It is inconceivable that a man intending to practice medicine could go part way with his course or even take all of a given portion only. He must graduate in full with a complete training or never join the ranks of the profession at all. In this exists one very definite distinction from engineering to-day. The medical profession necessarily consists of an aggregation of individual champions, while engineering consists rather of an army of all grades, from private to general. Again, valuable as the earlier years of medicine might be culturally to any citizen, the pace is too hard, the requirements too high, and the cultural returns too small, (in the estimation of the average student), for the game to be worth the candle, culturally; and there is no profession, no work other than medicine, for which the earlier years of the medical course fit a man. Once entered upon medicine he must finish or take up something else. It appears that this is not equally true of the engineering course, so that a man having had one year in engineering is equipped for certain industrial demands; after two years he has a wider field open to him; after three years he is still more useful, and so on. Even after he graduates in engineering he may never practice engineering, yet find his course invaluable to him in other lines.

To provide a body of men in engineering that shall approximate to the body of men who constitute the profession of medicine, it will be necessary, as a minimum, to differentiate, as in medicine, between those trained to meet emergencies in every field of the profession and those whose training is such that they are merely auxiliaries in special fields. You must differentiate between your physicians and surgeons on the one hand, and your nurses, laboratory technicians and orderlies on the other; you must distinguish between your university man of training in all branches of engineering and your technician who is expert only in one part of one branch.

It must be said that the development of medicine as a profession, for reasons quite obviously involved in the demands of the human race already outlined, is of very ancient date. *Esprit de corps*, dependent on the need for protection in dangerous, difficult, responsible decisions, that must usually be made quickly, individually, and which often involve life and death, set apart the physician, very early in history, as a distinct entity. He was in early days almost the only man of his community supposed to be learned in the sciences generally, and quite the only man who was supposed to know anything at all at first hand of human anatomy or physiology. Much of these subjects he learned by the study of human bodies stolen from the cemetery or of animals experimented on in remote or concealed places, often at the risk of his own life from ignorant, superstitious neighbours, who expected him to know all these things perfectly, but strenuously objected to the only method by which he could possibly learn them.

This situation also lent itself to driving the members of the profession into a single, almost fraternal, union. True, these early days have passed, but the traditions remain, and there is to-day no "Freemasonry" in any craft more close than that of medicine. In this respect engineering is much more like the army than like medicine; and, if I mistake not, the engineer of early days rose into prominence without persecution and on account of important public military demands, rather than on account of individual private civil demands.

On the other hand, while medical opinion and medical ethics have greatly controlled the admission of men to the profession and the standards that each member must reach practically and ethically, the medical profession as such has had a very small part in the direct development of the medical curriculum. Rather has the university education made the profession what it is today than the converse.

True, individual great medical leaders and medical teachers have arisen who have carried out research and have taught students new things or in new and striking ways. The earlier schools of medicine each centred on some such one great man as a rule. But it is the universities who gave these men their opportunities and who have adopted and developed the content and methods of such teachings—not the medical profession which has formally demanded these developments of the universities.

Of course, the great leaders, and especially the great teachers in medicine, have generally been in very close touch with the rest of the profession, which latter therefore has had the opportunity to exercise what Dr. J. M. Pearson calls a "silent pressure" on medical education,—a pressure applied indirectly and individually rather than directly and as a body. One thing which gives to the leaders of the profession these very opportunities in leadership to-day is the practice of securing outstanding practising physicians and surgeons as lecturers and clinical (hospital) teachers. The pure sciences can nowadays only be taught by the specialists, who alone are able to devote their whole time each to his own line; anatomy, physiology, bacteriology, physics, biology, chemistry, could not now be taught as they once were, not so long ago, by practising physicians. Equally impossible would it be for such specialists to teach the practical bedside handling of the actual patient.

The university, in co-operation with and guided by outstanding members of the medical profession, is the real power behind the medical curriculum, especially the scientific side. The practical branches are almost wholly conducted under university control by practising physicians. (Even here whole time university professors not in practice have been recently experimented with at a number of universities, although the results are still in doubt.)

The medical profession as such has had little effect on the medical curriculum to-day, but much upon the selection and general development of the student, particularly upon the elimination of the unfit.

Practice is merely the carrying out in daily life of principles established by long, patient research. If the principles of engineering education can be established broadly and firmly, the adjustment of the practice of engineering education to them should not be difficult. Agreement as to these principles is obviously an essential preliminary to the formulation of any concrete plan.

Petroleum

Dr. Bruce Rose, Geology Department, Queen's University.
Kingston Branch, February 1st, 1927.

In his opening remarks Dr. Rose said that the world production of petroleum in 1857 was 2,000 barrels, all of which came from Russia. Today world production is over 1,000,000,000 barrels per year, and approximately two-thirds of this comes from the United States.

Industrial development has kept pace with increasing oil production, and is indeed so largely dependent on it in its three chief uses,—for internal combustion engines, for fuel, and for lubricants,—that it behooves us to enquire if there be a danger of a failure of supply. Up to date the finding of oil has kept pace with the demand, but eventually, as the known fields become exhausted, there will be a falling-off in the supply of liquid petroleum, (that which we ordinarily think of as coming from flowing or pump wells). A few years ago it was estimated that the supply would last less than twenty years, but new fields are being found from time to time, and the estimate of future supply is correspondingly increased.

United States, the most thoroughly prospected country, has been brought to the point of producing two-thirds of the present world supply. Within the last year Columbia has become a big producer. No doubt, as other parts of the world are more thoroughly prospected, new fields will be found, and the time for world exhaustion will be postponed.

Those most competent to judge the situation say that the supply will last for at least fifty years, and probably much longer, for the potential reserve is being constantly increased by the bringing into production of new fields, by better recovery methods, by deeper drilling with the consequent tapping of hitherto unavailable reservoirs, and by better methods of distillation giving higher recovery of the light oils from the crudes. However, the liquid supply is limited; and, although there is no danger of failure of supply in the near future, the hope is that, by the time it begins to fail, new and commercial methods for extracting oils from shales, from bituminous sands, and from coals, will be perfected. The opinion seems to be that science and invention will thus take care of the future.

In Canada upwards of 20,000,000 barrels per year are consumed, and less than 500,000 barrels produced. The official figures for 1925 are 318,253 barrels. However, the production is increasing rapidly with the development of new wells in the Turner valley field in Alberta within the last two years, and particularly within the last few weeks, and may pass the half million mark this year.

The chances of finding new fields in Canada are confined largely to the flat-lying, or gently folded rocks of Ontario and the great plains, particularly of Alberta. Ontario production reached its peak at the beginning of the present century, and is likely to decrease gradually, although with new and better recovery methods Ontario will continue to produce for a long while.

The best possibilities for finding oil in Alberta are in the most easterly pronounced folds of the foothills region, east of the faulted area, and west of the more flat-lying rocks of the great plains. It is from one of the structures that the Turner valley production comes. There are many similar structures along the foothills from Montana to the Yukon. Many of these are not prospected. The success of Turner valley leads to the hope that other fields will be equally productive.

The finding of small amounts of oil farther east in Alberta, in the more flat-lying rocks at a number of points, holds forth the hope that, with more extensive study of the structures, and with the later improved methods of oil finding, many pools may be found, not only in eastern Alberta but also in Saskatchewan and Manitoba, where similar geological conditions occur.

The most significant thing with regard to oil possibilities in Alberta is that the new fields are in Paleozoic rocks Until two years ago the production was all from lower Cretaceous horizons. Then, with the deeper drilling of Royalite No. 4 well into the underlying Paleozoic rocks, a flow of over 500 barrels was obtained. This well continues to produce at this rate, and the development of the last few weeks records a number of wells coming in from this new horizon. It is consequently very likely that many more wells will be drilled to this horizon, not only in Turner valley but in other similar structures, with the hope of like success.

The find at Fort Norman, within the Arctic circle, has proved to be not nearly so important as at first thought, but is significant in that similar occurrences may be found in many places in the vast north. It indicates that there may be worthwhile areas which will be utilized in the future if failure in more available regions makes it economically advisable to exploit them.

There is an increasing supply of oil coming from Alberta and, although it is not safe to make any predictions as to what this may eventually reach, it is to be hoped that the success in Turner valley may be duplicated at other points.

The recovery of oil from shales, bituminous sands, and coal may present the hope of the future. Here Canada has tremendous possibilities. There are shales in unlimited amounts in all the provinces of the Dominion. Little is known of their potentialities as oil producers, except at a few points where they have been tested. The best known areas are in New Brunswick near Moncton, where recoveries of from twenty to thirty and more gallons per ton have been made. The fact that these are being actively prospected and tested in commercial plants is the best evidence of their practical and commercial possibilities.

As regards bituminous sands, there are in Alberta, in the vicinity of McMurray, outcrops of the so-called "tar sands." Here, along the Athabasca and Clearwater rivers for a number of miles, a thickness of approximately 75 feet of bed-rock consists of a sandstone, the cementing material of which is largely a thick bitumen. A cubic yard of this rock yields, on distillation, about thirty gallons of oil. Conservative estimates of the extent of these sands available place the area at twenty thousand square miles. A slight calculation will show that there is here tremendous potential oil supply. Up to date the mechanical and physical difficulties of extracting this oil from the sands on a commercial basis have not been overcome, but doubtless an economical and practical method for the recovery of the oil will eventually be found.

As regards coal as a source of oil, it is well known that the high volatile coals will yield on distillation a considerable percentage of oil. In Canada there is bituminous and lignite coal equal to more than one-eighth of the world's supply. There is, therefore, no lack of coal if the time should come when the oil supply must depend on such a source.

Canada imports most of her liquid petroleum and will continue to do so unless the fondest hopes are realized and large oil reservoirs are discovered in the great plains area. As long as oil from wells is available at anything like the present prices, Canada is likely to depend largely on such a source; but it is comforting to know that when it begins to fail, as it will in the not distant future, Canada still has vast potential reserves in her shales, coals and bituminous sands.

BOOK REVIEWS

Solving Sewage Problems

By George W. Fuller, M.E.I.C., and James R. McClintock. McGraw-Hill Book Company, New York, 1926. Cloth, 6 x 9 in., 548 pp., illus., tables, $6.00 net.

"Solving Sewage Problems" seems to fill a hitherto vacant gap in the literature of sewage disposal. Written in a style sufficiently simple to be easily understood by the non-technical reader, it is thorough in its treatment of the matters it discusses. Few engineering readers, though experienced in sewage disposal, will lay this book down without feeling that something has been added to their knowledge, particularly on the more recent processes.

Fourteen chapters, comprising 180 pages, are devoted to fundamental considerations,—an outline of the problems, legal, legislative and administrative, oxygen and biological balances, etc. The remaining 350 pages are given over to a discussion of the basic factors governing the choice of disposal methods, the design of the necessary works and operating data.

Especially to be noted is the emphasis placed on the newer sewage disposal methods and apparatus. Among these may be mentioned the use of skimming tanks, separate sludge digestion, gas collectors and utilization, electrolytic processes, fish pond treatment and the activated sludge process. This last, as befits its importance, is discussed from the standpoints of theory, design of plant, disposal of sludge and its fertilizing value.

The book closes with a non-technical summary, one of its most valuable features, and two appendices, one on waste control procedure and the other on the treatment of phenol wastes.

If city officials could be induced to read "Solving Sewage Problems," they might perhaps gain some understanding of the numerous and complicated problems their engineers must face,—and solve. Engineers will find in it numerous data not elsewhere available in English.

R. deL. French, M.E.I.C.

Waterworks Handbook

By Alfred D. Flinn, Robert Spurr Weston, M.E.I.C., and Clinton L. Bogert. Third Edition. McGraw-Hill Book Company, New York, 1927. Cloth, 6 x 9 in., 871 pp., diagrams, tables, $7.00 net.

The third edition of the "Waterworks Handbook" is as detailed as "Solving Sewage Problems" is general. In the ten years which have elapsed since the appearance of the original edition, waterworks practice has progressed and new data have become available, both of which facts are duly recognized by this new edition.

In 850 pages, divided into six parts and 38 chapters, the authors have contrived to compress information which must have occupied many times that space in its original form, and to do this without impairing its value. The art of skilful digestion has been brought to a high pitch of perfection in this handbook.

Whenever practicable, tabular and graphical presentation of data makes reference quick and easy. A humorous touch here and there,—for example, in figure 250,—serves to emphasize points and to relieve the monotony, thereby making effective cautions which have been preached to waterworks men for so many years that they have long lost most of their original effectiveness, though perhaps they are even now more necessary than formerly. A very complete bibliography follows each chapter, and a complete system of indexing textual references adds greatly to the book's value.

It is useless to itemize the contents in this short review,—something regarding practically everything of which the waterworks engineer may be in search may be found, the gist of it extracted and served with useful comment, and the source referred to. This is the function of any "handbook," and this one fulfils its function excellently well.

Let us hope that in another decade we may have another edition, revised and brought up to date, and that the "Waterworks Handbook" may attain service as perennial as Kent, Trautwine or our other engineering standbys.

R. deL. French, M.E.I.C.

Diesel Engines

By Arthur H. Goldingham. Third Edition. E. and F. N. Spon, Limited, London, 1927. Cloth, 6 x 9 in., 249 pp., 197 illus., 21/- net.

The new edition of this well-known book has been largely rewritten and will be found of value to any engineer engaged on the purchase, design or operation of Diésel engines. Its utility to the student of the subject is increased by the excellent sectional and photographic illustrations of the latest types of two- and four-cycle, single- and double-acting Diesel engines, showing not only general arrangements but also many important details of design. The advantages and disadvantages of various types are classified and compared, and this will aid the engineer or owner in forming an opinion as to the particular type best fitted for his special needs. Testing and operation are dealt with in some detail, and, as an introductory chapter, a brief résumé of the first principles and theory of internal combustion engines is given.

The author correctly points out that the present reliable and economical Diesel engine has been developed by investigation and close co-operation between the metallurgist and the mechanical engineer. The many practical problems in connection with fuel injection, ignition, starting, cylinder and piston cooling and lubrication in Diesel engines have all required prolonged experiment for their solution, and the results are well set forth.

The book can be recommended as a clear and comprehensive work on an important subject.

Aerial Cableways

By G. Ceretti, translated by Wm. J. Walker. E. and F. N. Spon, Limited, London, 1927. Cloth, 4 x 6½ in., 110 pp., diagrams, tables, 5/ net.

The work of an Italian engineer with long experience in the construction of aerial cableways, this book is based on his notes, and deals briefly with the design calculations for the various component parts of such installations. The utility of the book for the engineer interested in the general design and layout of cableways would have been increased by including a chapter treating of supporting towers, as comparatively little reference is made to these structures. It will, however, prove of substantial use to constructors of aerial cableways and those who are already familiar with the arrangement of wire rope transporters and desire to decide the outline of a proposed installation or verify the calculations for its design.

Concrete Designers' Manual

By George A. Hool and Charles S. Whitney. New Second Edition. McGraw-Hill Book Co., Inc., New York, 1926. Cloth, 6 x 9 in., 328 pp., diagrams, tables; $4.00.

The second edition of this manual has been revised and new sections have been added so as to include material useful to the engineer engaged largely in the design of reinforced concrete structures. The book is in no sense a treatise on the principles of design, but is a collection of tables and diagrams for the rapid design of reinforced structures by those familiar with the use of such diagrams. The formulae which the diagrams and tables represent are quoted, and examples of the uses of the diagrams are given where necessary. A large field of practice is covered in this way, including ordinary beams and slabs, T-beams, flat slabs, shear reinforcement, columns, bending and direct stress, footings and symmetrical arches. At the end of the book there is a collection of miscellaneous information, such as approximate quantities for rough estimating purposes; weights of building materials and contents of warehouses; tables showing the dimensions and reinforcement required for retaining walls under various loading conditions; shear and moment coefficients and influence lines for continuous beams. The specification of the Joint Committee for Concrete and Reinforced Concrete, (1924), and the Building Codes of New York and Chicago are also included.

The authors are careful, and rightly so, to state that final designs for structures, such as flat slabs and arches, should be worked out in every case by an experienced engineer. Thus in Section 10, dealing with symmetrical arches, and containing the data published by one of the authors, Mr. Whitney, in the Transactions of the American Society of Civil Engineers, Vol. LXXXVIII, the following sentence occurs:—"It is not the intention of the authors to present these data for use by designers not familiar with the general theory of elasticity and its limitations as applied to concrete arches, but, in the hands of an experienced designer, the method given in this section should effect economy in both design and construction of arches." This is a proper attitude, and the remarks are obviously applicable in some measure to all sections of such a book.

In many cases diagrams and tables have been added or revised to include the requirements of the 1924 Report of the Joint Committee, but in the case of flat slabs tables are given covering the recommendations of the American Concrete Institute, and of the Building Codes of New York and Chicago. The authors refer to these as being sufficiently like the requirements of the 1924 Joint Committee Report to enable preliminary designs to be made under the latter code. This is probably quite true, and is in harmony with the recommendation referred to above, that the tables be used for preliminary designs leading to the preparation of final designs by an experienced engineer.

Formulae for reinforced concrete columns threaten to become as numerous as formulae for steel columns, but the authors are not responsible for this, and tables covering many different specifications are provided.

Naturally, the reviewer has not *read* this book, but in glancing over the notation and formulae given at the beginning of the book, he noted that the formula for inclined web reinforcement is wrongly quoted in two places on page 4. The correct formula is given in section 127 of the 1924 Joint Committee Report at the end of the book. The error is of little consequence, as this is not a book of formulae to be worked out, but rather a book of tables and diagrams to enable people to avoid arithmetical work.

The tables and diagrams are on the whole well arranged, and those whose duty it is to work largely in one field of engineering design will find them useful.

E. Brown, M.E.I.C.

Standardization of Brick Sizes

Under the auspices of the Canadian Engineering Standards Association a conference on standardization of brick sizes was held in the board room of the National Research Council in Ottawa on March 18th, 1927.

The different interests were represented as follows:—J. E. Noulan Cauchon, A.M.E.I.C., Engineering Institute of Canada; E. L. Horwood, Ontario Association of Architects; B. Stuart McKenzie, M.E.I.C., secretary, Canadian Engineering Standards Association; Howells Frechette, Ceramics Division, Department of Mines; J. F. Meagher and J. Clark Reilly, Association of Canadian Building and Construction Industries; J. F. B. McFarren, D. C. Markley and G. C. Keith, Canadian National Clay Products Association; F. W. Jackson, Bricklayers, Masons and Plasterers International Union; A. U. Cote, Tile Manufacturers Association.

The question of standardizing on brick sizes is one that has been occupying the attention of Canadian manufacturing and construction interests for some years, and various attempts have been made to come to an understanding. The most active organization has been the Canadian National Clay Products Association, and at their convention, held in Toronto in February this year, a formal resolution was passed standardizing on the following sizes:—

Common brick, 8 x 2¼ x 3¾
Rough face brick, 8 x 2¼ x 3¾
Smooth face brick, 8 x 2¼ x 3⅞

These sizes have already been recommended by the Division of Simplified Practice in the United States, and generally accepted by construction interests.

Following the resolution above mentioned, the Canadian Engineering Standards Association was requested by the Clay Products Association to take action in the matter.

After a thorough discussion of the situation, in which all present took part, it was resolved that the sizes of brick specified above be adopted, and that manufacturers take immediate steps to manufacture on this basis. The resolution was unanimously carried, and nominations, subject to the approval of the interests represented, for a committee of the Canadian Engineering Standards Association were received. When this committee has been regularly constituted it will arrange for the preparation of a specification.

New Map of Northwestern Canada

In a new map just issued by the Topographical Survey, Department of the Interior, the great district comprising northern portions of Alberta and British Columbia, Yukon Territory and Mackenzie district, are shown with the most complete information available. The topography is corrected to the latest surveys and all data relating to settlements, trading posts, missions, and other activities are included.

The map is on a scale of fifty miles to the inch and is twenty-four inches by thirty-four inches in size.

Technical Books

Presented by Gauthier-Villars et cie:
Art de l'ingenieur et metallurgie, by L. Descroix, (Annual Tables of Constants and Numerical Data, Chemical, Physical and Technical).

Presented by E. & F. N. Spon:
An Introduction to Metal Work, by T. R. Parsons.

Presented by the Canadian Manufacturers' Association:
Canadian Trade Index, 1927.

Presented by Williams and Wilkins, Baltimore:
Interpolation, by J. F. Steffensen.

Trade Publications

The Canadian Ingersoll-Rand Company, Limited, have for distribution to those interested two handbooks entitled "Modern Central Stations." These handbooks consist of a collection of reprints of articles describing central stations, which articles have appeared from time to time in leading technical journals. The booklets are bound in loose-leaf form, convenient for fyling, and provide an excellent ready reference of published data on modern fuel power stations. To date, the company has issued the first and second sections of this compilation, and it is their intention to reprint and make available for distribution future articles of the same nature. Copies may be secured from The Canadian Ingersoll-Rand Company, Limited, 260 St. James Street, Montreal, Que.

The Dominion Oxygen Company, Limited, have issued a comprehensive text-book on welding and cutting by the oxy-acetylene process, entitled "Oxwelder's Manual."

The book comprises 216 pages, profusely illustrated. It includes tables of data on welding and cutting and a complete index. The thorough and practical manner in which the subject is treated is indicated by a survey of the contents:—

Historical Development of Oxy-Acetylene Welding; Oxygen and Acetylene; The Process of Oxy-Acetylene Welding and Cutting; Equipment for Welding and Cutting, Blowpipes—Construction and Operation; Regulators—Construction and Operation; Welding and Cutting Accessories; Cutting; Welding Cast Steel; Welding Practices for Cast Iron; Welding Large Gray Iron Castings; Bronze-Welding of Cast Iron and Malleable Iron; Welding Brass and Bronze; Welding Monel Sheet and Castings; Welding Sheet Aluminum; Welding Cast Aluminum, High Carbon Steel and Alloy Steels; Welding Copper; Stelliting; Cutting Heavy Steel Sections and Heavy Cast Iron Sections; Precautions and Safe Practices; Shop Layout and Organization.

This new book is taking the place of the former publication "Oxwelding and Cutting," which ran through eight editions, and although this is marked the ninth edition it is apparent that the publishers have started from the ground and built up an entirely new manual.

Copies of the manual can be secured by addressing the Dominion Oxygen Company, Limited, 92 Adelaide Street West, Toronto, Ont.

Canadian Government Ice Breaker "Mikula" Leaving the Wharf at Quebec for Trip to the Quebec Bridge on Occasion of the Annual General Meeting of The Institute, February 16th, 1927.

BRANCH NEWS

Calgary Branch

H. R. Carscallen, A.M.E.I.C., Secretary-Treasurer.
W. St. J. Miller, A.M.E.I.C., Branch News Editor.

Forest Conservation and Timber Preservation

On February 17th, A. S. Dawson, M.E.I.C., gave an address on "Forest Conservation and Timber Preservation," which was listened to with great interest by a large number of members and friends. Mr. Dawson's paper was of a most exhaustive and comprehensive nature, containing a fund of useful knowledge and statistics that, when published, will form a valuable asset to anyone's library. The information gathered and compiled from so many sources and put into such shape must prove of considerable use to all interested. Many excellent slides were shown in connection with the treatment of timber and the condition of timber in use. J. H. Ross, A.M.E.I.C., was chairman, and J. S. Tempest, M.E.I.C., moved a cordial vote of thanks to Mr. Dawson.

Development of the Art of Communication

On March 3rd, Mr. A. M. Mitchell, auditor of the Alberta Government Telephones at Edmonton, gave an address before the branch on the "Development of the Art of Communication." Commencing with a description of the earliest forms of communication, Mr. Mitchell outlined these in chronological sequence in a decidedly interesting manner. He related how communication between man and man had existed in some shape or form throughout the centuries, the earliest of which was probably by burning beacons. Then he recounted how coloured sails were used by the Greeks in marine signalling and how Marathon ran 140 miles in two days to carry the news of victory; also how the early Gauls employed sentinels to shout the message one to another. It was interesting to learn that the forerunner of our modern heliograph was the sunlight flashed from a polished Roman shield, these same people using flags and various forms of light flashes to signify letters of the alphabet. Then we come to the Indian smoke signals controlled by blankets over a smoke fire, and the shooting into the air of flaming arrows. In Africa the drum was used as a means of transmitting messages by sound. A peculiar method related by the speaker as a news medium was the method adopted by the southern darky slaves in the civil war in the United States, who cleverly wove important news of battles from the northern armies into their folk-songs. Then followed the more advanced flag signalling at sea and the semaphore originally used by Napoleon in Europe.

Mr. Mitchell spoke of the first germ of the telegraph being sown in a Scottish magazine in 1855 by an unknown writer whose initials were "C. M.", probably Charles Morrison. This inventor adopted, in theory at least, the principles of the magnetic or static influence of glass friction rods on small bits of paper. Then followed the battery which somewhat revolutionized matters. Then Ampere discovered the magnetic deflecting influence of a coil of wire on the needle, and in 1837 Charles Wheatstone invented the first practical telegraph adapting the combination of a needle and a loop of wire. In 1841 the telegraph instrument was first on public exhibition and about this time the Great Western Railway installed thirteen miles of telegraph line.

In 1868 Wheatstone was knighted for his invention. Then followed Samuel Morse, from whom, in conjunction with one named Watson, we obtained the Morse code used today. Much success was attained in the United States in 1845 in connection with improvements in telegraph transmission. In 1850 the English channel cable was successfully laid and installed for communication. Then followed four unsuccessful attempts to cross the Atlantic ocean, which was finally achieved on the voyage of the steamship Great Eastern.

The speaker then told of the wonders of the telephone. How in 1876 Alexander Graham Bell invented the first successful telephone, and how during the next twenty-five years feverish experimentation took place, and also that, from 1900 to 1925, development of extraordinary rapidity was evident. In 1888 as many as one hundred wires were enclosed in one cable, but today we find that one cable can accommodate as many as 2,440 wires. In 1915, one of the greatest achievements took place when Bell sat in New York and telephoned to San Francisco, a distance of 3,400 miles.

Many excellent slides were shown on the screen, kindly manipulated by Mr. J. D. Baker, plant superintendent at Edmonton. These showed many phases of telephonic and telegraphic communication, and also in chematic form the principle of picture transmission by wireless. This latter was clearly outlined by the speaker in a purposely non-technical way and, being the very latest thing in wireless science, was of particular interest to the audience. Pictures of many ancient and modern telephone exchanges and instruments were shown, also one of the "weavers of speed," as he happily termed the modern girl operator seated at the switchboard amidst many wires.

Referring further to the telephone, he named the three types in use, namely: the magneto type, the common battery type, and the automatic type used in Calgary. He extended a pressing invitation to all to visit the automatic exchanges in Calgary, and especially to see the new "repeater" which has made it possible for Albertans to talk to practically all points on this continent. These repeaters are necessary at intervals along the lines to amplify the voice sounds, and are similar in form to the tubes used in radio engineering. Mr. Mitchell was quite optimistic over the possibility of being able to talk to England from Alberta in the not very distant future.

He mentioned the wireless inventions of Marconi in 1897, when experiments were successfully carried out across the English channel, and also what radio enthusiasts owe to De Forrest for his experiments in 1905.

At the conclusion of the address, T. Schulte, A.M.E.I.C., moved a very hearty vote of thanks to the speaker and, on behalf of the branch and Chairman J. H. Ross, A.M.E.I.C., extended many thanks for one of the most pleasant and instructive evenings the branch has spent this season.

Record Oil Production

The Royalite No. 4 well, situated in the centre of Turner valley, about forty miles south of Calgary, produced approximately 18,700 barrels of 72 gravity natural gasoline during January, which is a new monthly record. Instead of a decreased flow, as might be expected, this well has shown a steady increase as demonstrated by the following figures:—

November, 1926—15,563 barrels
December, 1926—18,447 "
January, 1927—18,703 "

This well has been flowing steadily since October, 1924, and in 1926 production exceeded that of 1925 by 30,000 barrels. The total for 1925 was 167,722 barrels and for 1926 approximately 200,000 barrels of naphtha.

Halifax Branch

K. L. Dawson, A.M.E.I.C., Secretary-Treasurer.

At a meeting of the Halifax Branch, held at the Green Lantern on March 4th, the following papers were read by members of the staff of the Nova Scotia Highways Board:—

"Highway Bridges," by J. E. Belliveau, A.M.E.I.C.
"Construction of Gravel and Crushed Stone Roads," by A. B. Blanchard, M.E.I.C.
"Dust Palliatives for Roads Surfaced with Gravel or Crushed Rock," by H. F. Laurence, M.E.I.C.
"Maintenance of Gravel Roads," by Lt.-Col. J. MacMillar.

Highway Bridges—Nova Scotia

In introducing this subject Mr. Belliveau stated that the type of structure to be chosen to fulfil the conditions required for any particular situation must necessarily be governed by the class of traffic to be served and, especially in the expenditure of public monies, the authorization available for the project. In general, a permanent bridge means high original cost and low maintenance, and a wooden bridge low original cost and high maintenance, and it is the duty of the engineer to erect a bridge suited to present and anticipated future requirements which, over a period of years will, including original cost, replacements and maintenance, require a minimum annual expenditure. In the province of Nova Scotia, with two thousand large bridges and some twenty-five thousand of smaller type, the engineer must decide whether it is more economical to erect a wooden bridge with a consequent rapid deterioration and comparatively early replacement, or to design a permanent steel structure with permanent foundations and consequent long life and low maintenance cost.

Owing to rapidly increasing traffic on our highways, the cost of replacing a bridge is generally many times its original cost, and the problem of providing adequate accommodation for future requirements must be fully considered by the designing engineer. In general there are four requirements which constantly increase with growing traffic, namely, firmer foundations, longer spans, wider roadway, and greater strength to take care of greater loading.

Formerly the foundations were, like the superstructure, constructed of non-permanent materials and without deep excavation. Now the foundations are built of permanent materials bedded on ledge or on bottoms prepared by deep excavation.

Freshets have greater effect today than in the past owing to the depletion of forest growth, which allows a more rapid discharge of the rainfall into the streams, necessitating a greater opening between bridge abutments with consequent longer bridge spans.

The rapidly growing automobile traffic is mainly responsible for the demand for increased width of roadway, and other conditions which were suitable for horse traffic are entirely inadequate for motor vehicles.

Increasing traffic and modern motor vehicles are, through greater loading, demanding stronger bridge construction. Almost all steel bridges of this province are equipped with wooden stringers and planking capable of carrying a live load of eighty pounds per square foot of floor area, and all steel bridges on important highways are built strong enough to carry a concrete floor, whether the concrete floor is put down at the time of construction or later.

In discussing the maintenance of steel spans, Mr. Belliveau stressed the importance of keeping the steel well protected with paint of approved quality. The experience of the Highways Department of Nova Scotia has been that the best results are attained by the application of a first coat of red lead and a second coat of graphite, of the following analyses:—

First coat—	Red lead,	56 per cent.
	Asbestine,	18 " "
	Boiled linseed oil,	13 " "
	Raw linseed oil,	13 " "
Second coat—	Graphite,	44 per cent.
	Raw linseed oil,	25 " "
	Boiled linseed oil,	25 " "
	Drier,	6 " "

The speaker gave an interesting historical sketch of the bridge development of the highway system of the province, giving detailed accounts of the remarkable life and service of some of the older bridges, tracing the steps in foundation development and describing the various types of trusses in general use.

Construction of Gravel and Crushed Stone Roads

The transition which has taken place since the beginning of the present century, from horse-drawn vehicles to automobiles and auto trucks, has brought with it a corresponding change in highway requirements. The roads, which were suitable for comparatively slow-moving vehicles, are entirely inadequate to stand up under the present-day motor traffic with pneumatic tires and greater speed. It therefore becomes important that the highways engineers of Nova Scotia should not allow themselves to be outdistanced in this race for development. With a total of 15,000 miles of public highways, or about one mile to every thirty-six of our population, the programme must be confined to that class of road which will give reasonably good results for a minimum expenditure of public funds. That class of road is the gravel road, and the most important problem of transportation in this province for many years to come will be the construction and maintenance of gravel roads. Gravel roads are more economical than paved surfaces, when the volume of motor traffic does not exceed 500 to 800 cars per day,—the number depending on local costs and the distribution and wearing qualities of the gravel obtainable.

Mr. Blanchard prefaced his remarks on gravel surfacing with a brief discussion of the preparation of the subgrade. He stated that it has been his experience that, with a 10-ton tractor and suitable grader, a road can be grubbed and graded for about 25 per cent of the cost required to do the same work with the largest horse grader, with the additional advantage of obtaining a more uniform subgrade. It has become the practice in Nova Scotia to build the subgrade flat, or almost flat, between the shoulders of the road, allowing the gravel alone to make the crown of about one-half inch to the foot, rather than, as was formerly the custom, to crown the subgrade to conform to the crown of the finished road. A road with a high peaked crown confines the traffic to two wheel tracks, whereas a flat road invites traffic over all of the gravelled surface.

Referring to gravel surfaces, the speaker said that the erroneous belief prevails among a large percentage of the travelling public that gravel to be suitable for road surfacing must contain sufficient binder to form a smooth, solid cemented mass. Such a surface will very shortly begin to ravel and become full of little pot holes and ripples.

It was formerly the practice in Nova Scotia to put the gravel on in two courses, spread by hand and rolled with a heavy roller. The first course consisted of gravel with a maximum size of four inches and the top course had a maximum size of two inches. The system now in use is to place the gravel in one course of a uniform aggregate with a maximum size of stone of 1½-inch in diameter. The full amount of gravel is all placed in one windrow down the centre of the road, and this gravel is spread with a grader until only about two or three inches is left on the centre of the travelled way, with a windrow on each shoulder of the road. As the centre becomes consolidated with traffic the gravel from the sides is gradually graded into it. The only sort of gravel surface which can be maintained is one where there is enough loose gravel on top to protect the consolidated road underneath with a floating gravel cover of about one inch in depth.

Speaking of the superior surface obtained by spreading gravel with the grader rather than by hand, Mr. Blanchard said: "It is a fact patent to all, that articles manufactured by machinery must of necessity have that mechanical uniformity in their product which the hand-made piece does not display, and here is the special attractiveness of a gravelled road. The great bulk of the work can be machined, and while other surfaces may be more durable, none can compete with its smooth uniformity when properly constructed."

Referring to the deposits of gravel in Nova Scotia available for highway use, the speaker stated that owing to the growing traffic and increased mileage more and more attention will have to be given to the matter of rock crushing as the supply of suitable gravel becomes depleted.

Dust Palliatives

The dust nuisance to the road users, the adjacent residents and to the road builder, has been especially dealt with by the highway engineer in an effort to save his protecting road cushion, his cement and the very road itself, which is literally floating away in clouds of dust. The old time method of water sprinkling is impracticable for country roads, and it has been necessary to apply other means of combating this nuisance.

Heavy oil, light oil, calcium chloride and common salt have been applied with varying results. The Nova Scotia Highways Board has found the use of dust palliatives, such as light oil, or calcium chloride, to be an economical success in the saving of road surfacing. Mr. Laurence explained the system in vogue as follows:—

For trunk roads of twenty to twenty-two feet width between shoulders, the calcium chloride should be spread to a width of about ten feet, which means that when using the motor truck only, a return trip would have to be made to get the desired width. If the supply is kept conveniently at hand, this outfit of motor truck and two men, making the return trip, should be able to cover ten miles of road in a day. The cost per mile of distribution by this method should not exceed $2.50 per mile.

In Nova Scotia two applications will generally be found sufficient for the whole season. The first application should be made in the spring after the road has dried out, and the second application probably about the latter part of August, depending largely upon the amount of rainfall during the summer months.

For the first application, about two pounds per square yard should be applied, and for the second one pound. In other words, the first application requires approximately six tons per mile, and the second application would be three tons per mile. These quantities will, of course, need to be varied to suit the quality of the surfacing material. If there is a percentage of clay present, care must be taken not to give too heavy a coating of the calcium chloride, otherwise the surface may become too wet. These quantities are given for a roadway which has not been treated the previous year. For second year treatment, no doubt one-half of this quantity would be sufficient. Calcium chloride costs approximately $40.00 per ton delivered at any Canadian Government railway station in Nova Scotia, so that the cost of the first application, spread on a newly treated road, would be approximately $242.50 per mile, and for the second application would be $122.50. This makes the total cost for the season $365.00 per mile. For second and subsequent seasons the cost would be about one-half of this.

To maintain a floating surface of about one inch in thickness on a hard gravel or macadam road, under a traffic of from four hundred to five hundred cars per twenty-four hours, approximately two hundred and fifty yards of gravel or crushed rock per mile are required each season. This amount would cost on an average about $750.00. With the use of a light oil or calcium chloride, this amount could be reduced from 25 to 50 per cent, so that where the cost of the gravel or crushed stone is as stated the cost of the treated road would be approximately the same as the untreated. If, therefore, the statements and conclusions given above are to be relied upon at all, it is evident that the Highway Department will be justified in making a far more extensive use of these palliatives than it has done in the past.

Gravel Road Maintenance

Lt.-Col. Miller in discussing the maintenance of Nova Scotia roads stated that, in a maritime district, and one very much cut up with water courses such as Nova Scotia, it is possible to obtain gravel of one sort or another over a very considerable area, and this material, owing to its ease of working and the cheapness of supply, lends itself admirably to road surfacing.

The time has not yet arrived in Nova Scotia for an intensive patrol system on all highways, but experience on main trunk avenues of travel during the past five years has proved that no system can give better results. The patrolman is able to give timely repairs when a small outlay will prevent further ravelling of the surface.

In Nova Scotia frost penetrates to a considerable depth, and when it comes out it leaves a spongy and soft surface which must be worked and consolidated before the traffic cuts it up. Ditches and waterways must be cleared to allow the free flow of moisture from the roadbed and the shedding of rain during the season.

Sufficient gravel in stock piles should be available for the repair of damage and to provide a floating road surface. In gravel it has been found necessary to drag the road surface once for every 600 to 700 cars that pass. It should always be dragged as soon after a rain as possible.

No matter, however, what rules and regulations may be laid down for the maintenance of gravelled roads, the personal factor of the patrolman or the gang foreman must be taken into account. These are the men who do the work ultimately, and the results depend on their judgment. A permanent man must be selected and employed, one of reasonable intelligence, an honest worker, who is not afraid of weather conditions or the ten-hour day. By careful instructions this man's work will soon become a routine, and the maintenance of the roads will be carried on in a creditable manner.

At the conclusion of the papers considerable discussion took place, following which three reels of pictures showing the making of bituminous roads were shown under the direction of H. W. L. Doane, M.E.I.C.

A vote of thanks was moved by A. F. Dyer, A.M.E.I.C., and Mr. F. Thompson for the splendid presentation of the highway problem by the several speakers.

Hamilton Branch

W. F. McLaren, M.E.I.C., Secretary-Treasurer.
J. R. Dunbar, Jr.E.I.C., Branch News Editor.

A meeting of the Executive Committee of the Hamilton Branch was held on March 16th, 1927, eight members of the executive being present. Several routine matters were discussed, including applications for membership and the report of the nominating committee, which had held a meeting on March 8th. There was a slight amount of discussion regarding the joint meeting with the Toronto section of the A.I.E.E., which is to be held in the Westinghouse Auditorium on April 22nd. Mr. R. C. Bergvall, of the Westinghouse Electric and Manufacturing Company, will deliver an address on "A Mechanical Transmission Model."

A letter from General Secretary R. J. Durley, M.E.I.C., regarding the Papers Committee was read and H. A. Lumsden, M.E.I.C., was nominated as representative of the Hamilton Branch on this committee for the year 1927.

Kingston Branch

G. J. Smith, A.M.E.I.C., Secretary-Treasurer.

The Lighthouse Service of Canada

On the evening of Friday, March 11th, a very successful meeting of the Kingston Branch was held in Ontario hall, Queen's University, to hear an address by J. G. Macphail, M.E.I.C., commissioner of lights in the Department of Marine and Fisheries, Ottawa.

Mr. Macphail took for his subject "The Lighthouse Service of Canada," and dealt with it from both technical and popular viewpoints. A number of very excellent slides and two rolls of motion pictures were shown, Mr. Macphail explaining these as they appeared.

The speaker dwelt on the extent of the lighthouse service, and gave some figures showing that the service is distributed over a coastline of 52,800 miles, which includes both the Atlantic and Pacific coasts, the Great Lakes, and inland lakes and rivers. It is maintained as far north as the Great Slave lake and the Mackenzie river. In addition to the establishments in Canada itself, a number of costly stations are maintained in Newfoundland and Labrador, to serve transatlantic ships destined for the maritime provinces and the St. Lawrence.

Mr. Macphail stated that there are 1,675 lighthouses, 362 fog signals, 556 gas, whistling, and bell buoys, 6 submarine bells, 11 light ships, 8,311 unlighted aids to navigation,—a total of 10,911. The expense of this service is wholly defrayed by the Canadian government. In every other maritime country in the world, except the United States, the whole cost of maintenance of navigation aids is borne by shipping, the cost being collected in the form of "light dues," which are collected before a vessel receives a clearance from customs. A vessel of 10,000 tons, trading between Montreal or Halifax and Liverpool, pays nearly $4,000 a year for light dues in England. She pays nothing in Canada. Consequently, one of the difficulties, the speaker remarked, is that of keeping expenses within bounds. Shipowners in Canada are prone to be extravagant in their demands, but the lighthouse service, while investigating all cases, adopts the attitude of meeting the most vital requirements only; supplying the aids where safety demands them, rather than for spectacular display.

The series of slides and motion pictures illustrated the various types and kinds of lighthouse apparatus, and the methods of operation. Duplicate machines are installed in every case where machinery is necessary, and are used turn and turn about, so that each machine lasts considerably more than twice as long, due to its receiving better attention and care than it would if it were in continuous service. The reels showing the laying and taking up of the buoys between Montreal and Quebec were particularly interesting. The opening and closing of navigation constitutes the most difficult season for the lighthouse service, involving as it does the placing in position of light ships, gas and signal buoys, and a total of 2,818 floating aids to navigation, which must be placed immediately ice conditions will permit in the spring. This work extends from Gaspe to Fort William, and is usually completed within a week. At the close of navigation in the fall, all floating aids to navigation must be removed, but they must be kept in position to the very latest date possible. Long after commercial shipping is safe in winter quarters, the men and steamers of the lighthouse service are still battling with winter conditions in the work of recovering expensive buoys.

In conclusion Mr. Macphail mentioned something of the human side of the service. The men and women of the stations must be within reach of their posts twenty-four hours a day and three hundred and sixty-five days in the year. They cannot fail. Other activities may stop and go. The lighthouse service must be maintained, and in it failure cannot be tolerated. The lights must be kept working, and the other signals constantly efficient. There has never been a failure at any of the principal stations due to inattention to duty. The close contact with nature at the isolated posts develops men and women of a serious, purposeful character, and not a day passes that the marvellous faithfulness of the staff of the lighthouse service is not well shown.

At the close of the address a vote of thanks was moved by Major L. F. Grant, A.M.E.I.C., and received the hearty endorsement of the very large audience present.

Petroleum

A regular meeting of the Kingston Branch was held in Carruthers hall, Queen's University, on Tuesday evening, February 1st. Dr. Bruce Rose, of the Geology Department at Queen's, gave an address on "Petroleum, with Particular Reference to Western Canada."

Dr. Rose has done considerable scientific work in various oil fields, and has spent several seasons investigating the petroleum possibilities of Alberta. His lecture showed a splendid grasp of this very important subject, and proved most interesting to the members present. The lecture was illustrated with a number of maps and geological sketches, showing the nature of the occurrences in Canada and other countries, and numerous statistics were given as to world and different country production.

At the close of the address a hearty vote of thanks was tendered the speaker. An abstract of this paper appears on another page of this Journal.

London Branch

F. C. Ball, A.M.E.I.C., Secretary-Treasurer.

A regular meeting of the London Branch was held in the London Technical and Commercial High School on December 17th, 1926. After a short business session the speaker of the evening, Principal H. B. Beal, was introduced by Chairman W. P. Near, M.E.I.C. Mr. Beal is one of the pioneers of the technical education movement in London and has made an extensive study of the subject which he chose for his address, "Vocational Education for Industrial Purposes."

Vocational Education for Industrial Purposes

It was pointed out that former educational systems led only to the learned professions. In preparing a youth for one of the trades the apprentice system was wasteful of time, about seven years being the usual length of apprenticeship. At the present time the collegiate institutes prepare pupils only for the universities, whereas statistics show that less than five per cent of collegiate students enter a university.

The technical school provides a thorough academic training plus a specialized course. It also helps to meet a great demand for adult education, a demand that is shown by the Carnegie Institute report on correspondence schools.

In regard to the local situation, forty-five per cent of the pupils who go higher than public school choose the technical school. In the first year they spend half their time on general subjects and the other half on more specialized subjects. In the second year, after the pupils have had an opportunity to judge as to the course they wish to follow they are given a specialized course.

The technical school also has a large commercial department, this work having been eliminated from the collegiate institute course. There is a separate secretarial course for those who have had a previous commercial training.

Mr. Beal pointed out that a student may get his matriculation through a technical school without Latin. Boys who contemplate going into engineering would do better to get their matriculation along with drafting, applied science and mathematics in the atmosphere of a technical school.

Mr. Beal mentioned the vocational guidance furnished by the staff and also described the placement department. This department does all in its power to place students, after graduation, in positions in the industrial and commercial world, so that both employer and employee will be satisfied. The products of the school are students. The staff does not claim to turn out skilled mechanics.

Mr. Beal's address was followed by a tour of inspection through the school. Members of the staff very kindly described the work in the departments that were most interesting to engineers.

Annual Dinner Meeting

The annual dinner meeting and election of officers of the London Branch was held in the Blue Dragon tea room on Tuesday evening, January 18th, the speaker of the evening being Brig.-General C. J. Armstrong C.B., C.M.A., M.E.I.C., G.O.C. Military District No. 1.

W. P. Near, M.E.I.C., the retiring chairman, presided until the business of the meeting was concluded. The officers elected for the ensuing year are as follows:—

Chairman	J. R. Rostron, A.M.E.I.C.
Vice-Chairman	J. A. Vance, A.M.E.I.C.
Secretary-Treasurer	Frank C. Ball, A.M.E.I.C.
Executive Committee	H. A. Brazier, M.E.I.C.
	E. V. Buchanan, M.E.I.C.
	Col. I. Leonard, M.E.I.C.
	G. E. Martin, A.M.E.I.C.
	W. M. Veitch, A.M.E.I.C.
Ex-Officio	W. C. Miller, M.E.I.C.
	W. P. Near, M.E.I.C.

Mr. Near in resigning the chair thanked the members for their co-operation during the past year and introduced the chairman-elect and called upon him to address the meeting. Mr. Rostron, after expressing his thanks for the honour accorded him, referred to the very much punctuated attendance at the monthly meetings of some of the members, and pointed out that if any of them stayed away because they considered that the subject listed for discussion was not in their line, they made a great mistake, for, in the first place, a professional engineer was supposed to be fairly well-informed on most subjects, and in the second place, an engineer never knows when he might require knowledge of other branches of work than the one on which he, at the moment, might be engaged. The information thus gained at a meeting, however little, might be of great help to him in the future.

In outlining his programme for the coming year, Mr. Rostron said he hoped to be able to have further visits to engineering works of interest, and speakers on up-to-date engineering subjects, such as arc welding and the use and effects of calcium chloride in concrete, etc. Also the holding of social gatherings now and then to promote comradeship and good feeling amongst the members.

The chairman also stated that he would do his best to uphold the code of ethics of The Institute and also to improve the status of the branch, as he considered that the opinions of a body of professional men such as constitutes the membership of this organization should be given due regard in public matters, particularly those of local import.

Introducing the speaker of the evening, Mr. Rostron called the attention of the members to the fact that the speaker, by reason of his recent location, was now a member of the London Branch, and although this was his first appearance at a meeting, we hoped to see him often in the future at our monthly gatherings.

Work of Canadian Engineers During the Great War

Brig.-General Armstrong, after being acclaimed with musical honours, rose to address the meeting. Reviewing the activities of the Canadian engineers during the war, he outlined the remarkable achievements under the greatest difficulties, and in many cases gunfire, which gave this corps wide reputation. To the Royal Engineers Brig.-Gen. Armstrong paid high tribute, declaring that it was due to their aid and advice that made the work of the corps successful and brilliant. Exigencies of war brought a large number of new branches of engineering service, such as sound-ranging companies which located the exact position of enemy artillery, inland water companies, mechanical companies, forestry corps, mining engineers and railway companies.

Telling of the capture of the Messine Ridge that took place in May of 1917, Gen. Armstrong graphically described the tribulations gone through by the engineers before they were finally able to tunnel under the German lines to a depth of 80 feet and store over a million pounds of high explosives that blew the ridge and its defenders to atoms. The work was accomplished after months of effort, but the million pounds of explosive was not discharged for a year after it was deposited under the Boche entrenchments.

He also described how the engineers cleared the canals along the Scheldt river that had been dammed by the Germans in an endeavour to inundate the countryside that was held by the Allied forces.

Transport of troops, heavy guns and caterpillars across rivers was accomplished by means of pontoons and timber and steel bridges. Many of the bridges were of three spans, necessitating the driving of piles in the river beds with no better equipment than hand pile drivers. The work was often under the enemy's fire, and for that reason it was necessary to construct the bridges in duplicate so that if one was destroyed at a critical moment the other was available. A remarkable feat was the erection of twenty-six bridges, many of them of two- or three-span, in thirteen days. One feature of engineering work in which the Canadians excelled was the making of plank roads over marshy ground.

The chairman in proposing a vote of thanks to the speaker said that he thought "military" engineering might also be called "emergency" engineering, and in that case any engineer in times of peace was liable to be faced with some of the problems of the military engineer, so that any engineer who considered that tonight's subject was not in his line might take note. The vote of thanks was heartily and unanimously accorded.

Mr. Near, city engineer of London, sympathized with the General in the dangerous nature of the military engineer's work under the enemy's fire, but assured him that was nothing to the fire from the public to which a municipal engineer was subjected, for he got it from each side, in front and in the back.

The musical part of the programme was efficiently attended to by Mr. E. G. Wood, who contributed several vocal solos and led the community singing, and by Mr. E. O'Dell, who officiated at the piano, and a hearty vote of thanks was tendered to them.

About twenty-five members and guests were present.

Smoker and Meeting

Looking more to the social side of the branch activities, the London Branch replaced its regular February meeting by a "Smoker and Social," held on February 23rd, 1927. It was thought desirable to foster a spirit of comradeship among the branch members and also to stimulate outside interest in the local activities of The Institute. The branch was pleased to have as its guests a number of men who were interested in construction work and some members from other branches of The Institute. The entertainment was provided by four soloists, who provided a variety of numbers during the evening. Toasts were proposed and responded to at intervals and a spirit of goodwill prevailed throughout.

The attendance at the "Smoker" and at a subsequent regular meeting has demonstrated that the departure from the usual type of meeting was entirely justified.

Recent Progress in Electric Welding

The chairman opened the meeting of March 16th by a short address in which he voiced the importance of the recent advances made in the application of the process of electric welding to structural work, and explained that it was the endeavour of the London Branch to keep its members well informed on up-to-date methods.

He then introduced the speaker of the evening, R. E. Smythies, M.E.I.C., vice-president, Lincoln Electric Company, Toronto, his subject being "Recent Progress in Electric Welding."

Mr. Smythies first described the process and the machinery used, by which it was possible to accomplish two hundred and fifty feet of welding per hour as against a maximum of fifty feet by the acetylene method. He explained that where welding had been employed mostly in the past for mending or patching broken parts it was now, in addition to this, used for structural purposes. Where it was customary to use cast iron for bases and frames of heavy machinery it was now possible to use welded steel frames at a great saving of weight and cost of patterns. He illustrated its application to structural steel work, showing that where tests to destruction had been made the failure occurred in the steel itself, while the welded joints remained intact. The consequent saving in the weight of steel required for construction was obvious, as no allowance had to be made for the loss of metal in the rivet holes. He instanced the saving of cost on the Governor's bridge at Toronto, in which round bars electrically welded were used.

He gave a number of other uses to which the process can be applied with a like advantage, including railway fish plates, concrete reinforcing, boilers and tanks, ships and launches, large pipes, etc. He instanced the construction of a pipe line some three or four feet in diameter and ninety miles long, in California, where all joints are electrically welded. In this work each length of pipe was tested by the application of 250 pounds to the square inch of hydrostatic pressure internally and the seams subjected to a series of blows from nineteen-pound trip hammers applied externally. Another illustration given by the speaker was that of a large gasometer, together with all the steel framing, at Melbourne, Australia, which was erected by the electric welding process without the use of a rivet. The address was well illustrated with lantern slides.

About thirty-four members and others were at the meeting and a thoroughly technical discussion followed, there being representatives present from manufacturing, construction and transportation companies.

The chairman, in calling for a hearty vote of thanks to the speaker, spoke of the value of the process to all structural engineers and predicted increased use for it in the future. The vote was seconded by A. H. Morgan, M.E.I.C., chief engineer of E. Leonard and Sons, and unanimously carried.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

"New Brunswick Night" was celebrated at the regular monthly supper-meeting of the branch, held in the Y.M.C.A. on March 2nd. A. S. Gunn, A.M.E.I.C., chairman of the branch, presided. Excellent vocal and trombone selections were rendered by Mr. Alonzo Johnson. These were greatly enjoyed and heartily encored.

Forest and Ornamental Trees of New Brunswick

Following the supper a paper was read by Prof. H. W. McKiel, M.E.I.C., on the "Forest and Ornamental Trees of New Brunswick." This paper, written by D. R. Munro in 1862, and never published, was obtained through the courtesy of A. G. Tapley, A.M.E.I.C., of Saint John. It depicts in great detail the trees of the province as they existed at that time.

Probably few people are aware that trees once grew in New Brunswick to a height of 150 feet, with a 5-foot diameter base, and yet, sixty-five years ago these giants of the forest were by no means uncommon. Furthermore, species now practically extinct flourished in great abundance. Among the more important commercial woods were tamarack, birch, spruce, fir, maple, oak, pine, elm, walnut, beech, white cedar, ash and hemlock.

During the reading of the paper, illuminated transparencies of the grain and cross-section of the different woods were shown, the slides being kindly loaned by A. C. Selig, M.E.I.C.

Captain J. E. Masters, who was present, spoke briefly, deploring the depletion of our forests. He recalled his first voyage out of Saint John, when the ship on which he sailed carried timber two feet square. Now, he was almost tempted to say, there was not a stick of standing timber suitable for the making of an axe handle.

Mr. Paul Lea, formerly prominent in the lumbering interests in Moncton, said he knew of the forest depletion that was taking place all over the Dominion, and he cited the province of British Columbia, where the ruthless cutting of timber would see that province divested of its timber inside of twenty-five years. Not only were the large timbers falling a prey to the axe of the lumberman, but the fact that in taking out the timber many young trees were destroyed as the larger timbers were dragged over them.

C. S. G. Rogers, A.M.E.I.C., referred to the tragic note sounded in Mr. Munro's paper. Practically every description had ended with the words, "the supply is unlimited." Now, there seems to be nothing worth while so far as large timber is concerned.

Following the discussion on forest preservation, seventy lantern slides showing the resources and tourist attractions of the province of New Brunswick were thrown on the screen. These were obtained from the Natural Resources Intelligence Branch of the Federal Government. The lecture which accompanied the slides was read by Mr. Rogers.

Election of Officers

Immediately following the showing of the slides the meeting was called upon to nominate officers for the season 1927-28. The following officers were elected by acclamation:—

Chairman, G. C. Torrens, A.M.E.I.C.
Vice-Chairman, H. J. Crudge, A.M.E.I.C.
Secretary-Treasurer, V. C. Blackett, A.M.E.I.C.

Professor H. W. McKiel, M.E.I.C., will be an ex-officio member of the executive for the coming year.

More than the required number of candidates were nominated for the offices of committeemen, making an election necessary. This will be held during the coming month and the result announced at the annual meeting of the branch.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
H. W. B. Swabey, M.E.I.C., Branch News Editor.

Aerial Surveying

Thursday evening, February 24th, was reserved for the presentation of a paper by a student. The chairman of the evening, H. L. Johnston, S.E.I.C., in opening the meeting remarked that it was the custom to have a paper by a McGill student during the fall session and one by a student from the University of Montreal during the spring session. As no student from the latter university had a paper prepared, Flight Lieutenant Wait, of the Royal Canadian Air Force, a graduate of the Royal Military College, Kingston, and now in the fourth year, civil engineering, at McGill, had kindly consented to read a paper on "Aerial Surveying."

The author mentioned that the making of maps from aerial photographs was first used to any extent on the western front during the Great War, and referred briefly to the subsequent development in aerial surveying.

Mr. Wait described successively the vertical and oblique methods of aerial photographic surveying, by either of which methods the mapping of large tracts of unsurveyed areas is being rapidly and economically carried out by the Topographic Surveys Branch of the federal government in conjunction with the Royal Canadian Air Force, who have done a great deal of pioneer work, particularly in the development of the oblique method of aerial photography. About fifteen photographic crews were employed during last season on this work in different parts of Canada.

In determining the type of survey to be carried out over any particular piece of country the author referred to three points which have to be considered:—(1) geometric accuracy required; (2) economy of time and material; (3) detail.

The first consideration mentioned may react against aerial methods, although the error incurred is comparatively small. The other two considerations will generally be in favour of aerial methods.

The author then described both the vertical and oblique methods of aerial surveying, and the general preparation for the carrying out of the work. The author then gave a brief description of the ground control, by the use of which any error in mapping by oblique photography can be reduced to a minimum.

The paper was illustrated by lantern slides, showing various features in connection with the aerial survey work. Following the paper there was a brief discussion.

The Scientific Method in Industry

That modern industry affords a splendid field for the scientific mind of the engineer was illustrated in the paper presented to the branch on March 3rd by G. Percy Cole, M.E.I.C., technical engineer, Dominion Glass Company.

Already the pulp, paper and varnish industries were entirely under technical control, no major decisions being acted upon without obtaining technical advice.

That any industry might take advantage of scientific methods it was necessary only that someone in the organization possess a scientific attitude of mind with a mania for investigation. To-day countless aids in the way of hand books and scientific instruments of measurement rendered science readily available to even the smallest manufacturer.

However, there existed a more specific and exact application of scientific methods which consisted in, first, reducing the problem to its independent variables, and then ascertaining the laws that influenced each of those variables in turn. Such an application had been demonstrated in the formulation of a law on the cutting of metals, by Frederick W. Taylor.

So, in accordance with these two main principles, the fundamental steps in the investigation of any problem become belief in the necessity for natural law, or the doctrine of "determinism," analysis of the problem with a view to determining the goal, study of the means to be employed toward its attainment, assemblage of the facts bearing on the problem, execution of the projected studies and experiments, and finally, discussion of the results, with utilization of the facts obtained controlled as to accuracy.

"Determinism" is belief in the natural law of cause and effect; it implies disbelief in chance. The active belief in determinism urges us to look for the cause of all anomalies and nearly always enables us to discover the unknown variable. Before a problem may be studied it must be defined, its objective determined and a working hypothesis devised. When once the programme of study has been arranged and the facts assembled, it will then be necessary for the investigator to carry out the experiments with the greatest care, noting all the conditions and confining himself closely to the programme laid down in the beginning. As the purpose of the study has been to discover, a conclusion must be drawn and interpreted, after which recommendations may be offered to correct the conditions for reason of which the investigation was made. Every resource of industrial experience must be brought into play to devise new and improved processes and methods which are at the same time practical; to accomplish this, the investigator must cultivate always a constructive imagination.

In the field of human endeavour, there is no more interesting work than to follow through to a logical conclusion any problem concerning which little is known and where the solution is not evident until all the facts have been determined.

Aside from technical literature there are aids within the reach of every manufacturer which will enable him to scientifically control his product. Foremost among these is the chemical or physical laboratory, where the purity or suitability of any material may be determined. Should it not be economical or advisable to maintain a laboratory of his own, the manufacturer may engage a firm of consultants. This course has the merit of associating with his organization a firm which is in touch with various industries and may thus summon to his aid a wealth of experience which his own organization could hardly be expected to possess, and also of keeping himself in touch with the very latest developments.

One of the greatest aids that is increasing in use implies money invested in indicating and recording instruments. In any event it is well spent, but in relation to the combustion of fuel it is essential.

Another source of help may be had from the standard specification, and such specialized information as is published in the bulletins of the federal and provincial governments and various other organizations.

The scientific method is applicable to the simplification of products, standardization of parts, elimination of waste, determination of costs, distribution and sale of output, survey of markets, location of new industries and to the analysis and investigation of all business and financial ventures.

The author closed his address with the words of Napoleon: "For everything you must have a plan. Whatever is not profoundly considered in its detail produces no good results. Trust nothing to chance."

The meeting was presided over by A. C. Tagge, M.E.I.C., and a vote of thanks to the speaker was moved by F. P. Shearwood, M.E.I.C.

The Purification of Water for Boiler Feed Purposes

A paper on this subject, so vitally important to many enquirers, was delivered on the evening of March 10th by T. R. Duggan, Ph.D., and technical manager of the Permutit Company of Canada Limited.

Dr. Duggan commenced by giving particulars of the impurities in water and how they are absorbed into the water, first in its form as vapour, rain or snow, and later as it flows along in rivers or subterranean streams. In many industrial processes, impurities present in water cause serious damage and loss. In boilers, the impurities in the feed water precipitate as mud, sludge or scale, varying in thickness and hardness. These deposits not only act as insulations, causing loss of boiler efficiency and waste of fuel, but frequently cause local overheating of the tubes, etc., resulting in bulging, tube blowouts, blisters, etc., and the ultimate shutting down of the boilers for cleaning and possible repairs.

These troubles and the expense caused by them resulted in various methods of water purification being devised; those in use at the present day being classified by the author as follows:—removal of suspended matter; settling, coagulation and settling, filtration; removal of dissolved matter. A comprehensive description of the various ways of carrying out these methods of purification was then given.

Dr. Duggan discounted the claims made for the many "compounds" sold for treating boiler feed water and gave his reasons for stating that in most cases they were ineffective in producing the required results.

He referred to the use of precipitation water softeners, the operation of plants for their use and their limitations.

A full description was given of zeolite water softeners and their action in removing impurities. Zeolite plants accomplish the removal of the hardness by percolation of the water through a bed of zeolite material suitably supported and distributed in a container with piping and valves attached to properly distribute and control the flow of water. The hardness is removed by the base exchange principle, the zeolite exchanging its sodium base for the calcium and magnesium bases in the water. A meter is provided to indicate when the softener has passed the quantity of water it was designed to soften. The zeolite bed is then automatically regenerated by passing a solution of salt through the softener. The brine, by a reverse exchange reaction, gives its sodium base to the zeolite, and as it leaves the softener it carries with it in a clear solution the calcium and magnesium extracted from the zeolite. The zeolite is then rinsed free of brine and the softener is again thrown into service by opening the necessary valves.

"Zeolite" was given as originally a mineralogical term derived from two Greek words, meaning "to boil" and "stone," and applied only to a family of well defined hydrous silicates, but now is applied to all base exchange silicates which are used in water softening.

A brief summary was given by the author of the work of chemists on zeolites. Their physical structure is classified into two groups:—(a) porous zeolites, (b) practically non-porous or solid zeolites; a description of each group being given.

The water softening capacity of zeolite is directly proportionate to the active surface of the zeolite in contact with the water. It therefore follows that the porous zeolites have a greater water softening capacity than the solid zeolites.

Particulars were given of the softening capacity of zeolite, rate of softening and rate of regeneration as also of the salt requirements. A description of the operation of zeolite water softening plants followed, and a comparison of the results of zeolite and lime soda,—as also their comparative cost of operation.

The chairman of the meeting was R. E. MacAfee, M.E.I.C. A vote of thanks to Dr. Duggan for his paper was proposed by G. P. Cole, M.E.I.C.

Niagara Peninsula Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

Electric Arc Welding

R. E. Smythies, M.E.I.C., vice-president of the Lincoln Electric Company of Canada, gave an illustrated lecture on "Recent Progress in Electric Arc Welding" before the branch at St. Catharines on February 28th, 1927. This lecture was given before the Toronto Branch at an earlier date.

The meeting was very well attended, indicative of the interest with which engineers are getting this comparatively modern method of not only repair but construction.

Most of the harder metals used in structural work can be welded; Mr. Smythies particularly mentioned bronze, cast iron, (except the poorer grades), manganese, chromium and other steel alloys.

There are great possibilities in curtailing capital expenditures for plant if, and when, structural steel weldings replace cast iron or cast steel. Instead of the heavy outlay for a large area of land and foundry buildings, together with the necessary furnaces, moulds and patterns, there will be required a comparatively small storage shed containing a limited stock of structural steel shapes and plates. One company mentioned by Mr. Smythies reduced their inventory in this way from some $760,000 to $60,000.

Carl H. Scheman, M.E.I.C., asked the speaker for an opinion as to the relative merits of a.c. and d.c. arc welding. In reply, Mr. Smythies stated that both a.c. and d.c. welding machines were on the market and more or less competitive. His own experience led him to favour the d.c. machines, as, operated at 20 volts against the 100 to 125 volts of the a.c., they seemed to him less dangerous and more easily controlled. Patent rights, he understood, had recently been granted covering a.c. machines, while on the other hand it is unlikely that d.c. machines could be patented.

Mr. Beatie moved a cordial vote of thanks, seconded by S. R. Frost, A.M.E.I.C. Alex. Milne, A.M.E.I.C., was in the chair.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

The Bituminous Sands of Northern Alberta

At an evening meeting of the Ottawa Branch, held in the Chateau Laurier on February 25th, S. C. Ells, M.E.I.C., mineral technologist of the Department of Mines, delivered an address on "The Bituminous Sands of Northern Alberta." Mr. Ells has been engaged since 1913 in the investigation of these sands and believes that they constitute one of the most potentially valuable resources of Canada. The meeting was open to the public, and those who attended gained valuable first-hand information on the extent and value of these deposits, both from Mr. Ells' interesting address and from the slides which showed the deposits in Alberta, the experiments being conducted in Canada and the large commercial developments of similar deposits in the United States and other countries.

Noulan Cauchon, A.M.E.I.C., chairman of the Ottawa Branch, in introducing the speaker, said that he considered it most unfortunate that the deposits of which Mr. Ells would speak were called in Canada, tar or bituminous sands. If only we called them "rock asphalt," people would understand their nature and would realize that rock asphalt is found in many places in the United States and is being largely exploited. It is nothing new, he said, as everybody else is developing it.

Mr. Ells said that if he were an after-dinner speaker he would entitle his address "The Birth of a New Industry." It had been a pioneering job, and he referred to transportation problems and how remote the deposits and their development seemed when he first started to study them. Now, through the modern attainments of the chemical engineer and a study of the problems of transportation and marketing, development of these remarkable deposits seemed to be on the eve of solution.

The bituminous sands of northern Alberta, Mr. Ells told the audience, cover probably from 5,000 to 10,000 square miles. The country had been mapped over an area of 1,250 square miles and a considerable amount of boring had been done, so that now they were in a position to pick out the areas where the overburden was light and the deposits of such high quality as to offer attractive possibilities of development. These bituminous sands, he said, were the largest known deposits of solid hydro-carbons in the world. They would supply paving material for all the roads in Canada and the United States. Just now there appeared to be a market for 150,000 tons per annum and he hoped that shipments would reach to Winnipeg. The development of the deposits was in its entirety an economic proposition, and all that was needed was greater population and reasonable rates of transportation.

Mr. Ells took his audience on a tour to some of the great rock asphalt industries in other countries, illustrating with slides the magnitude of their developments. In Alabama, for instance, a contract had been signed for 1,000,000 tons of rock asphalt at $3.50 per ton. The cost of mining in Alberta would be only about 25 cents per ton as against $1.50 in Kentucky, and yet rock asphalt is being shipped 1,000 miles by rail in the United States. In Sicily a 6 per cent rock is being mined and is shipped to many countries, including India and Brazil. The northern Alberta deposits are very much richer, with a bitumen content of 14 to 18 per cent.

The best surfaces on roads in the United States are of rock asphalt, Mr. Ells said, and pointed out that paving with this material is not a theory but an accomplished fact. In Canada paving experiments dated back to 1915, when a surface was laid in Edmonton on Kinnaird street and it has stood up ever since without cost of maintenance. Mr. Ells strongly commended the work of the Dominion Parks Branch, Department of the Interior, for the work done in experimental paving in Jasper park and of the Mines Department for their enterprise in laying the Edmonton pavement. Next summer the demonstration work with Alberta's rock asphalt will go further, and it is planned to lay this material on clay roads without foundational work. The field of usefulness is constantly widening, the speaker said, and asphalt mastic is coming into use for floors in churches, stations and other buildings. It is very pretty, he said, and provides a good wearing surface. It is also used for lining swimming pools. There is no difficulty, he said, in getting proper paving material in the deposits of northern Alberta and, as for their handling, there is no more trick in laying bituminous pavement than in laying Portland cement.

A lively discussion followed Mr. Ells' address. Replying to a query as to the petroleum content of these deposits, the speaker said he had recently made a very rough calculation which gave the stupendous quantity of 350,000,000,000 barrels of crude petroleum. It constituted the largest potential supply of liquid hydro-carbons in the world. As for asphaltic materials, Mr. Ells said that the Trinidad lake deposit was relatively insignificant when compared with the McMurray, Alberta, deposits.

Operation and Construction of Water Tube Boilers

A highly instructive lecture on the "Operation and Construction of Water Tube Boilers" was delivered at the Victoria Memorial Museum on the evening of March 4th, by J. O. Twinberrow, A.M.E.I.C., under the auspices of the Ottawa Branch. Mr. Twinberrow's address was illustrated with four reels of motion pictures and was enjoyed by a large attendance, including many local boiler engineers and operators.

Introduced by Noulan Cauchon, A.M.E.I.C., chairman of the Ottawa Branch, Mr. Twinberrow, who is engineer-in-charge of boiler, furnace and stoker designs of Babcock-Wilcox and Goldie-McCullough, Limited, briefly reviewed the progress in power plant design, showing how from 1887 to 1925 the coal consumption per kilowatt hour had been reduced from twelve pounds of coal to one pound of coal, and how the boiler pressure had risen from 250 pounds in 1916 to 1,400 pounds in 1926.

These changes have altered completely the methods and ideas of boiler manufacture, Mr. Twinberrow said, and the moving pictures nicely illustrated not only the operation of the modern water tube boiler, but also all the details of its fabrication. The researches between the years 1916 and 1925 necessary to produce the modern high-pressure and high superheat boiler unit were described.

Dealing with some of the details which had to be solved, Mr. Twinberrow pointed out that boiler shells were now made up to five inches in thickness. The tremendous pressure made it necessary to give close attention to the matter of correct fitting of the plates covering the seams. The edges of the shell itself were required to meet within one-sixteenth of an inch. The seam was then covered with a plate machined to exactly fit, and even the rivetting had undergone a great change. The rivets were now machined and ground to give a perfect fit and were rivetted by a special pressure mechanism instead of by hammering.

Speaking of superheaters, Mr. Twinberrow said that because of the belief that previously available steels might lead to difficulty with high temperatures, a new heat resisting chrome-steel alloy had been developed, and with this alloy superheater units may be built capable of withstanding a heat of 900° Fahrenheit.

Many details had been worked out to increase the efficiency of boiler plants, and one which was of especial importance was the heating of the air for draft and combustion.

Joint Luncheon

At a largely attended luncheon in the Chateau Laurier on March 1st, arranged under the joint auspices of the Ottawa Branch of the Engineering Institute and the Ottawa Branch of the Canadian Institute of Mining and Metallurgy, Dr. D. A. Lyon, chief metallurgist of the United States Bureau of Mines, Washington, was the speaker. Noulan Cauchon, A.M.E.I.C., presided.

Dr. Lyon's Address

Dr. Lyon traced the history of the Bureau of Mines of the United States since its inception, stating that at present it consisted of three main branches, technological, economics, and health and safety. The function of the Bureau of Mines, he said, was to provide fundamental data for the information of state governments and mine owners. It could not be accused of acting in a consultative capacity or in any way displacing the consulting geologist or mining engineer, but it did carry on investigations and research which gave the consulting engineer fundamental facts to deal with. As regards the health and safety work, which is an important branch of the Department of Mines' activities, the bureau has not police power, and cannot make regulations, but only recommendations. He spoke of the good results which had come from the investigations of mine operating conditions. The work was largely educational, and to prove to some doubting Thomases the effect of dust explosion they had actually staged an explosion in a mine which the bureau maintained for investigational work.

Dr. Lyon spoke more particularly of his own division of the work, the technological branch. This, he said, is purely a field organization, gathering data to be used by the engineer in his work. One of their greatest problems was the utilization of low grade ores. Just how acute this problem is, Dr. Lyon said, is illustrated by the fact that the use of metals is doubling every ten years. As for the economic results of such investigational work, he said that one-third of the output of copper in the United States is now coming from low-grade porphyry ores which were not considered a feasible source of supply in 1904.

Referring to their co-operative work with the British Government, Dr. Lyon explained that they send one or two of their mining experts to England, and the British Government sends one or two to the United States, and that they exchange information on all subjects of mutual interest.

Peterborough Branch

W. E. Ross, A.M.E.I.C., Secretary.
B. Ottewell, A.M.E.I.C., Branch News Editor.

With Canadian Engineers in Palestine

At the regular meeting held on the evening of February 24th the members, together with a number of visitors, listened to a very interesting address by Prof. J. Roy Cockburn, M.E.I.C., now associate professor of descriptive geometry, University of Toronto. Prof.

Cockburn's lecture was entitled "With Canadian Engineers Under Allenby in Palestine," and was illustrated with a large number of coloured lantern slides. Some of these photographs had been taken by the official Turkish photographer, who remained behind in Jerusalem when the British arrived. Other photographs were taken by Mr. Cockburn with a pocket kodak. These pictures illustrated very well the varied nature of the country over which these operations were carried out.

Mr. Cockburn was in command of the Seventh Field Survey Company, Royal Engineers, and briefly described first, the military railway from Kantara across the desert to Gaza and Beer-Sheba, and also the water pipe line which ran parallel with the railway. He then passed on to a description of the manner in which the ancient water system of Jerusalem was modernized and put into operating condition by the Royal Engineers.

One interesting point mentioned was the use of wire netting in the making of roads over the desert. These "chicken wire roads" were excellent for infantry and motor traffic. The chief work upon which Major Cockburn was engaged, however, was survey work of various kinds, including location of enemy batteries, photography, map making, etc. The location of batteries was sometimes impossible by visual operation or aerial photography, and it then became necessary for the field survey engineers to use the sound ranging method. This was particularly the case in the Judean hills, where visual operation was practically impossible. The address and slides were very favourably received by those present and a number of questions were asked. A vote of thanks to Mr. Cockburn was proposed by H. O. Fisk, M.E.I.C., and was heartily approved.

Ancient Engineering

Mr. F. H. Dobbin, an old friend of the Peterborough Branch, gave an interesting paper of a rather unusual type at the meeting held on March 10th. His subject was "Ancient Engineering," which he dealt with in a most descriptive and instructive manner.

Pointing out that the science of engineering did not have its origin in any particular stage of history and that no one race or era can lay claim to its inception or birth, every civilization may be said to have contributed its share to the development of this science.

Bridge building may be said to have had its beginning when the first log was thrown across the brook or stream too deep to ford. Hydraulic engineering had its inception when the aboriginal deepened the bed of the rivulet with his naked hand or wooden paddle that he might increase the supply of water for his flocks and herds. The science of steam engineering probably began when Nero or Alexander amused his friends with his revolving steam toy, and electrical engineering when the Chinese coaster steered his junk by a sea shell filled with oil upon which floated a bit of reed with a magnetic needle pointing always to the Southern Cross.

The speaker then described some of the outstanding engineering achievements of ancient times and the manner in which it is believed they were constructed. The pools of Solomon supplying water to the city of Jerusalem consisted of three reservoirs, the smallest one being 400 or 500 feet in length, the waters discharging from one to another in terraced fashion and from the lowest into the city. The principle of aeration for purifying water was, therefore, appreciated even at that time.

The Hanging Gardens of Babylon contained the most interesting hydraulic work of ancient times, providing the means of raising water to the top of the walls, which were said to be 350 feet in height, by means of an endless chain of buckets.

The ability of the Romans to bore tunnels without the aid of explosives was remarkable, there being an instance near Naples, the grotto of Posilippo, length 2,316 feet, width 22 feet, average height 39 feet. There is no record of when or how this piece of tunnelling was done, but it is through carnelian rock, so hard that every inch had to be worked by the chisel.

The Egyptians excelled all other nations in the transportation of heavy masses of stone, and there are examples of columns 47 feet in height, containing 11,500 cubic feet and of about 1,000 tons weight, which were cut from the quarries, transported by land and water, and erected in place. For transportation on the Nile, flat bottomed boats were used, being brought to a basin on the side of the river, heavily ballasted with stone until sunk to the level of the banks, and the monolith of stone then rolled upon the boat and the ballast thrown out.

The architects and engineers of Asia Minor also deserve great credit for the invention of original methods of transportation, for example, the Temple of Diana at Ephesus, (600 B.C.), contained some 127 columns of marble 60 feet in height and about 7 feet in diameter. These were cut and transported from a quarry at a distance of some eight miles, and there still lies in this quarry a partly cut block roughly 70 feet long, 14 feet wide and 11 feet deep.

The use of the inclined plane or ramp was early recognized by the ancients and was undoubtedly used in the building of the Pyramids. Calculations and estimates show this inclined plane was over 3,000 feet in length by 62 or more feet in width and 164 feet above the level of the river Nile. The forging of metals was known without doubt in Egypt and some parts of Asia in the most distant times, a famous example being a forged iron pillar at Kallub, near Delhi, 16 inches in diameter and over 50 feet long.

That there were recognized professional engineers from the earliest times is evidenced from the fact that there existed in Egypt in 3700 B.C. a "superintendent of works" who had charge of the construction and repairs of public edifices and roads, which fact is proved by the discovery of a wooden statue at Sakarah, now in the Bulak museum.

At the conclusion of the paper Mr. Dobbin answered some questions and gave still further examples of primitive engineering work and was tendered a very hearty vote of thanks for his paper.

Quebec Branch

Louis Beaudry, A.M.E.I.C., Secretary-Treasurer.

The Montreal-South Shore Bridge

"The Montreal-South Shore Bridge" formed the subject of a very interesting lecture, illustrated by lantern slides, which was delivered by P. L. Pratley, M.E.I.C., of Monsarrat and Pratley, consulting engineer for the bridge, at an evening meeting held at the Chateau Frontenac on Monday, January 17th.

The speaker, who was introduced to the gathering by A. R. Decary, M.E.I.C., honorary president of the Quebec Branch, gave at first the historic facts concerning the construction of the various bridges between the island of Montreal and the south shore of the St. Lawrence river. He thus showed that the bridge now in course of construction was not a new project by any means, but that it dated back to 1876, when plans were made for the Royal Albert bridge, the purpose at that time being to relieve the railway traffic problem, which has always been a serious one to Montreal, due to its island position. At that early date it was foreseen that ten years later the existing Victoria bridge would be inadequate for the requirements of its owners, the Grand Trunk Railway.

The estimated cost had been five million dollars.

The Lachine bridge was then built by the Canadian Pacific Railway, and the railway traffic congestion was relieved for the time being. In 1897 it was again proposed to erect the Royal Albert bridge, and many engineers from Canada, United States and Europe took part in the competition.

Many of the plans submitted were illustrated with slides and were commented upon by the speaker. Among these plans were those of G. Shaw, which were declared by Mr. Pratley to be a masterpiece in bridge designing, while Henry Szlapka, who designed the plans for the Quebec bridge, was also a contestant. Shaw's plans were approved, but the scheme fell by the wayside through lack of financial backing from the government of that time. The Grand Trunk Railway then rebuilt the Victoria bridge, replacing the tubular structure by the existing bridge and installing double railway tracks. The situation was further relieved in 1909 when the Canadian Pacific Railway double-tracked the Lachine bridge.

From then on the railway traffic situation was improved, but with the advent of the automobile, Montreal's problem became a highway problem insofar as communication with the south shore was concerned. Changes were made on the Victoria bridge in order to improve conditions, but in 1920, following a fire near one end of the bridge, which resulted in the blocking of all traffic on the bridge for four days, a new structure was demanded by the general public.

With this in view the government was approached, but it declined to guarantee the interest on the capital necessary to finance the bridge. Finally, the chairman of the Montreal Harbour Commission persuaded the government to permit the commission to guarantee the cost of building the bridge.

After studying several sites for the approaches and other special features, it was finally decided that the old Delorimier street plan was the most practicable, and work on the structure was commenced.

Several projects presented to the commission in 1924 were shown on the screen. Mr. Pratley then outlined the design of the bridge now under construction, particularly the section over the north branch of the river, which is a cantilever structure with a central span 1,096 feet in length.

The clearance at the centre of the central span is 163 feet at high water, and the greatest height of the main piers, from rock foundation to their top, is 310 feet. The width of the bridge allotted to vehicular traffic is 37 feet, this space being flanked on both sides by street railway tracks enclosed by fences, while footwalks five feet wide will extend from end to end on both sides of the superstructure.

Explaining the scheme adopted for financing the project, the speaker said that the Montreal Harbour Commission was authorized by the federal government to issue bonds covering the cost of the construction, while the provincial and the municipal (Montreal) governments agreed to contribute the deficit on the total amount of the bond issue which is expected to be experienced for the first four or five years.

Mr. Pratley afterwards showed a large number of pictures, illustrating the various operations connected with the building of the bridge and the progress made in this connection. The open and pneumatic caissons were fully described and illustrated.

F. T. Cole, M.E.I.C., thanked the speaker on behalf of the gathering for his address, which proved very interesting.

Saint John Branch

W. J. Johnston, A.M.E.I.C., Secretary-Treasurer.

Provincial Power

On February 10th the members of the Saint John Branch were addressed by S. R. Weston, M.E.I.C., chief engineer of the New Brunswick Electric Power Commission, on the subject "Provincial Power." A. R. Crookshank, M.E.I.C., branch chairman, presided at the meeting.

In his address Mr. Weston outlined the potential and developed water powers of New Brunswick. The advantages of having all sources of power connected by one transmission system, thus stabilizing demand and load, and the further advantage of having all power markets within the province linked together in one system by transmission lines, was explained in detail. The subject was treated in a broad technical manner without any attempt of indicating policy or method of development. The subject is of general interest at the present time on account of the works under construction and contemplated for the near future.

A vote of thanks to the speaker was tendered by the chairman on motion of Geoffrey Stead, M.E.I.C., and J. N. Flood, A.M.E.I.C.

Joint Meeting at Fredericton

On Friday, March 4th, a party of fourteen members of the Saint John Branch left by an afternoon train for Fredericton for the purpose of holding a joint meeting with the Engineering Society of the University of New Brunswick. On arrival at Fredericton the members went directly to the university and were the guests of the students at supper, following which a tour was made of the college buildings.

The meeting was opened by C. M. Steeves, S.E.I.C., president of the Engineering Society, who welcomed the members of the Saint John Branch to the meeting and then called on A. R. Crookshank, M.E.I.C., to take charge. The programme had been prepared to embrace several phases of engineering, and the Papers Committee was fortunate in their choice of subjects and in their arrangement of a diversified programme.

Railway Location

The first paper was read by A. S. Gunn, A.M.E.I.C., of the Canadian National Railways, Moncton, on the subject of "Railway Location." This paper related the experiences anyone might expect to encounter who, as the speaker expressed it, "by ill-fortune or ill-advice found himself a member of a railway survey party." It related personal experiences and made the older men reminiscent of similar experiences in their own early survey days. The various features of reconnaisance, preliminary and location surveys were dealt with in turn. What otherwise would have been a dry subject was treated in a humorous manner and yet brought home necessary truths which every student and novice must observe on railway and general survey work.

Operation of Electric Systems

The second paper was delivered by G. A. Vandervort, A.M.E.I.C., of the New Brunswick Electric Power Commission, on "Operation of Electric Systems." The matter was treated as dealing with operating practice in general and was not a description of any particular system. It again related incidents as gained from personal experience and gave the students in particular a practical idea of what might be expected when employed in the electrical business. The speaker described the organization required and the methods used in the operation of a combined generating, transmitting and distributing system. A noteworthy feature of this address was the well-deserved tribute paid to the high type of men attracted to this branch of work and their devotion to duty in all kinds of weather and other inconveniences.

Features of Saint John River Power Company's Development at Grand Falls

The third address on the programme was given by A. C. D. Blanchard, M.E.I.C., speaking on "Some Features of the Saint John River Power Company's Development at Grand Falls, N.B." The speaker described the early history relative to the power at Grand falls on the Saint John river, and of the various groups to whom was intrusted its development during the past quarter century. Finally, Grand falls is now being developed by the Saint John River Power Company, a subsidiary of the International Paper Company. The various engineering investigations preliminary to construction were briefly traced by the speaker, who stressed the necessity for storage on this river with a discharge ranging from 1,000 to 130,000 cubic feet per second. The natural head at Grand falls is between 112 and 118 feet, depending on the stage of the river, and this is being increased by about 14 feet by a dam now being built. A feature of the development is the construction of a tunnel with 24½ feet finished diameter under the town of Grand falls. The development provides for three units of 20,000 h.p., with present construction to be completed by July, 1928.

A number of slides of Grand falls construction scenes were shown, and a discussion followed the reading of the papers.

A resolution of regret at the death of A. R. Wetmore, M.E.I.C., whose funeral was held at Fredericton that afternoon, was moved by Geoffrey Stead, M.E.I.C., and seconded by G. G. Murdoch, M.E.I.C. Mr. Wetmore, as provincial bridge engineer, was held in high esteem throughout the province.

A vote of thanks to the chancellor and faculty of the University of New Brunswick for the invitation to hold the meeting at the college buildings, and to the several speakers for preparing and delivering addresses was passed on motion of Alex. Gray, M.E.I.C., and E. A. Thomas, A.M.E.I.C.

At this stage of the meeting the branch chairman retired from the chair and the Engineering Society again took charge. Dr. C. C. Jones, chancellor of the university, thanked the members of the Saint John Branch for coming to Fredericton for the meeting and generously extended an invitation for similar meetings in the future.

A number of citizens of Fredericton, including some members of The Institute resident there, were present at the meeting.

The members of the Saint John party returned to Saint John by various trains the following day. All voted having had a most enjoyable trip, as all similar preceding trips have also been. The Saint John Branch attempts to hold one joint meeting in Fredericton each year as a means of showing its interest in the university within its branch territory. This is in line with the policy of The Institute of co-operating with all colleges giving courses in engineering.

St. Maurice Valley Branch

R. Morrissette, A.M.E.I.C., Secretary-Treasurer.

The monthly meeting of the St. Maurice Valley Branch of the Engineering Institute of Canada took place on Saturday, March 19th, at 4 o'clock p.m. in the rooms of the Chamber of Commerce, Three Rivers. There were present Ellwood Wilson, M.E.I.C., C. L. Arcand, A.M.E.I.C., J. A. Bernier, A.M.E.I.C., H. Dessaulles, A.M.E.I.C., B. Grand Mont, A.M.E.I.C., C. H. Jette, A.M.E.I.C., L. E. McCoy, A.M.E.I.C., R. Morrissette, A.M.E.I.C., H. J. Ward, A.M.E.I.C., A. A. Wickenden, A.M.E.I.C.

Bruno Grand Mont, A.M.E.I.C., was nominated as councillor of the St. Maurice Valley Branch, and S. W. Slater, A.M.E.I.C., was nominated as representative of the branch on the Papers Committee. A motion was passed congratulating President A. R. Decary, M.E.I.C., on the great honour accorded him by the University of Montreal in conferring on him the degree of D.A.Sc.

Aerial Surveying

Ellwood Wilson, M.E.I.C., chairman of the branch, delivered an address on aerial surveying, which was illustrated with slides. He pointed out that aerial surveying readily furnishes details which ordinary surveying methods have not been able to give, and these are obtained at a very moderate expense. A survey ordinarily costing from $700 to $800 per square mile can be made by aerial methods for from $40 to $100 per square mile.

Aerial methods have the further advantage that if an error or omission is made in the notes of an ordinary survey it is difficult, if not impossible, to correct it, whereas the photographic methods do not overlook anything.

A survey which would last for months if ordinary methods were used, can be made by aerial methods in a few days. In the case of the plan of a city, many details are shown which it is impossible to show on a map plotted from an ordinary survey. The principal aerial surveys made to date are those of the cities of Ottawa, Quebec and New York. In the case of a transmission line, it is possible to take a series of pictures from the air and use these in purchasing land for right-of-way. This has been done by the Hydro-Electric Power Commission of Ontario, the Shawinigan Water and Power Company and the Belgo-Canadian Company. Large purchases of timber limits have been made on the results of aerial surveys; for example, the limits of the Laurentide Company and those on the Gatineau, which have been bought by the Canadian International Paper Company.

Aerial surveys have also been found of great value in the preparation of plans for taxation in cities and rural districts, and also plans for insurance companies, giving all the details of the relations of a property with the neighbouring properties, thus assisting greatly in judging of the nature of the risk.

Mr. Wilson explained the opertation of the camera in the aeroplane, and stated that an apparatus is now available which takes nineteen square miles in one operation. He thought that in the district of Three Rivers a very suitable landing place can be found at Cap de la Madeleine, and expressed the hope that an aerial service between Montreal and Quebec will be operation this summer.

On motion of Mr. Dessaulles a cordial vote of thanks was passed to Mr. Wilson, which concluded a very successful meeting.

Saskatchewan Branch

R. W. E. Loucks, A.M.E.I.C., Secretary-Treasurer.

A regular meeting was held in the Kitchener hotel, Regina, on February 18th, preceded by a banquet. Vice-Chairman M. B. Weekes, M.E.I.C., presided at the meeting, which was attended by thirty members and guests.

At noon, prior to the meeting, some fifty members of the branch made an inspection tour of the C.P.R. hotel at Regina, now in course of construction. The details of construction were explained by H. S. Bare, A.M.E.I.C., resident engineer for the company. Mr. D. Smith, of Smith Bros. and Wilson, general contractors for the building, accompanied the party.

Construction of C.P.R. Hotel at Regina

At the evening meeting Mr. Bare gave an address on the construction of the hotel. Excavation was commenced in June, 1926, and it is expected that the building will be ready for occupancy by June first next. There has been no cessation of work on account of the winter season. The building is a steel-framed structure of modern type, having span-drill beams at every floor to carry exterior walls independent of the wall below. Concrete and brick work were carried on in November and December with temperatures ranging from zero to 20 degrees below. Gravel concrete was used throughout, having an aggregate of about 1-3-5 for walls and 1-2-4 for structural slabs. Steam coils were used to heat the gravel and the mixing water for concrete, and as an additional aid to rapid setting one hundred pounds of calcium chloride were added to each twenty-five gallons of mixing water. One-half gallon of the solution was used per sack of cement, less water being used in the mix due to the presence of the calcium chloride.

The foundation was excavated with a one-yard drag line gasoline operated shovel, and the banks of the excavation stood with a fairly steep slope without the use of sheet piling. As only the rear portion was carried down to the 24-foot level a heavy retaining wall had to be built the full length of the basement foundations. This wall had buttresses at about 10-foot centres and to prevent any settlement at their base ordinary wood piling was used.

After the excavation was complete four to six inches of concrete was poured over the whole area, and this slab was given three coats of pitch and three-ply felt protection against damp before the mat foundation proper was put in place. The latter is of the ordinary inverted reinforced T-beam construction, the inverted slabs being generally about 2 feet thick, and the webbs of the T-beam 34 inches deep, including slab thickness, by 36 inches wide, the span generally being about 12 feet 6 inches. Both the slab and the T-beam webbs are heavily reinforced to prevent settlement, and in some cases steel girders over 40 feet in length were imbedded in the webbs for this purpose.

The mat was carried out about nine feet in front of exterior walls to increase bearing area and as the sub-basement is below the level of the city sewers a sump and ejector pumps have been provided to take care of the lower drainage system.

The walls are all thirteen inches thick, while the partitions are mostly four inches thick and are built of either clay tile or gypsum blocks.

The floor slabs are mostly two inches thick. They are composed of gravel concrete and are supported by joists spaced at about two foot centres except under partitions, where they are doubled up. The joists are from eight to ten inches deep and generally have a span of about twelve feet six inches. They are supported directly on steel I-beams, to which they are wedged, and the concrete was poured directly on to a very light low rib mesh, the latter being carried by and wired to the joists. No wooden forms were used, and while there is a certain leakage of concrete through the mesh this was easily scraped up on the floor below and put back into place.

There are numerous kinds of floorings used in the public space, principally red quarry tile in the service portion and Terrazzo with brass strips in the principal rooms. The ball room floor will be of hard wood. The bedroom floors and corridors are all concrete; the former being ¾ of an inch thick and the latter 1½ inches. This finish consists of a mortar composed of three parts sand and two parts Portland cement. As a dust preventative the concrete finish will be treated with a solution of sodium silicate.

There are three 200 h.p. boilers of the water-tube type to take care of heating and power requirements. Exhaust steam is utilized for heating purposes. All returns are carried back to a feed water heater from which they are pumped into the boilers by feed pumps. Mechanical stokers are installed, also blower equipment for induced draft.

A complete water softening plant is provided, having a capacity of eighty-two hundred imperial gallons per hour and a total capacity of not less than thirty-two thousand gallons per regeneration. The plant is designed to treat Regina water to zero hardness, based on the water having not less than forty-four grains of hardness per imperial gallon, and all the water used in the building, including pump make up, is treated before it enters a suction tank in the sub-basement, from which it is pumped to storage tanks on the roof.

Mr. T. E. Chester, manager of the C.P.R. hotel, gave an address on the management of a modern hotel. He described the duties of his staff, which he is now selecting, which will number two hundred and thirty, about sixty of whom will be imported. The public spaces include a ball room, main dining room and grill room, with accommodation for four hundred and fifty, three hundred and twenty-five and one hundred and twenty-five guests respectively. Each of the two hundred and eighty bed rooms is supplied with a bath. A unique feature is being introduced in that all female help will live outside the hotel. A modern garage and filling station will be operated at the rear of the hotel for the benefit of the guests. The name of the hotel has not yet been announced by the company.

Annual Meeting

The tenth annual meeting of the branch was celebrated by a banquet at the Kitchener hotel, Regina, on the evening of March 8th, 1927. W. H. Greene, M.E.I.C., of Moose Jaw, presided over the gathering of forty-one members and guests. Following the dinner each member and guest was introduced by the party sitting on his left. The guests were then welcomed by the chairman.

The toast list was commenced by drinking to "The King." After the toast the minutes of last regular meeting were read and adopted. The business part of the programme consisted of reports of executive and standing committees.

Mr. W. G. Laird delighted the audience with a solo, after which the retiring chairman, W. H. Greene, M.E.I.C., thanked the officers and members of the branch for the support they had given him during his term as chairman.

Prof. A. R. Greig, M.E.I.C., of the University of Saskatchewan, extended greetings from the Saskatoon members. He stated that the staff and students of the university appreciate the scholarship which is given annually by the branch. He next described his recent extended tour of Europe, referring briefly to many of the outstanding engineering achievements in power production and research in England, France, Italy, Switzerland, etc.

Miss "Slippod," the crystal gazer, entertained the audience by some clever delineations of the past and the future of a number of the members present. The pronouncements caused some surprises and much amusement.

R. N. Blackburn, M.E.I.C., on behalf of the branch, presented Prof. Greig with an Institute badge in recognition of his services as past chairman of the branch. Prof. Greig joined The Institute in 1895 and has always been an active member.

Mr. E. T. Fitzsimmons, who was a guest at the meeting, told of his activities in gold mining at Cedar creek, in the Cariboo district of British Columbia. He sounded an optimistic note as to the mineral potentialities of northern Saskatchewan.

The toast to "The Province" was proposed by M. L. Moyer, BRANCH AFFILIATE, who prophesied great development in the near future in clays, coal, water powers, etc. He believed that within a few years many of our highways would be paved, and Regina and

Moose Jaw would be drawing their water supplies from the South Saskatchewan river. The response was made by D. A. McNiven, M.L.A., for Regina city. Mr. McNiven, in a rousing address, complimented the branch and engineers in general on their achievements. He referred to the boundless assets of the province in our coal and clay fields, sodium sulphate deposits, minerals, water powers, etc. He complimented the branch on the inclusion of three of its members on the Power Commission recently appointed by the provincial government. In Australia a similar power commission had been a success in aiding commercial development from the lignite coal fields. He referred to the Power Commission as the "White Hope of Saskatchewan." "The greatest asset of our province is our people," declared Mr. McNiven. "Composed of many races, our citizens were virile, energetic and leaders, as evidenced by the many world's championships won in grains, stock, etc."

The toast to "The Institute" was proposed by T. M. Molloy, BRANCH AFFILIATE, commissioner of the Bureau of Labour and Industries for the province. Mr. Molloy stated that all we require is people with vision and capital to put all our engineers and many more to work. The Institute means a great deal to the engineer; it is an incentive to study and maintains the ethics of the profession. The response was given by Lt.-Col. A. C. Garner, M.E.I.C., who briefly traced the history and traditions of The Institute from its beginning as the Canadian Society of Civil Engineers. The speaker congratulated Dean C. J. Mackenzie, M.E.I.C., of the University of Saskatchewan, a past chairman of the branch, on his winning the Plummer medal, awarded at the recent annual meeting of The Institute at Quebec. In Saskatchewan the opportunities in engineering have been limited, but with the appointment of a power commission the entry of our members into public life, he predicted great possibilities for the future. Col. Garner ended with the admonition, "who dreams shall live."

Election of Officers

The scrutineers presented their report as showing the election of officers to be as follows:—

Chairman, M. B. Weekes, M.E.I.C. .... Regina
Vice-Chairman, A. M. Macgillivray, A.M.E.I.C. .... Saskatoon
Secretary-Treasurer, R. W. E. Loucks, A.M.E.I.C. .... Regina
Executive Committee (elected for two years):
- D. A. R. McCannel, A.M.E.I.C. .... Regina
- W. R. Warren, A.M.E.I.C. .... Regina
- W. G. Worcester, M.E.I.C. .... Saskatoon

Nominating Committee:
- R. N. Blackburn, M.E.I.C. .... Regina
- H. S. Carpenter, M.E.I.C. .... Regina
- A. R. Greig, M.E.I.C. .... Saskatoon
- C. J. Mackenzie, M.E.I.C. .... Saskatoon
- J. R. C. Macredie, M.E.I.C. .... Moose Jaw, (convenor)

D. H. Lunan, BRANCH AFFILIATE, and G. G. Fitzgerald, A.M.E.I.C., were elected auditors by acclamation.

M. B. Weekes, M.E.I.C., the newly-elected chairman, took the chair and thanked the members for the honour they had conferred upon him.

A vote of thanks was tendered the retiring executive and committees, and to those who had taken part in the annual meeting.

Report of Executive Committee

Your Executive Committee respectfully submits the following report covering the conditions of the branch and its operation during the past year.

The membership is 107, as compared with 112 reported this time last year, and is made up as follows:—

Honorary Members	1
Members	16
Associate Members	70
Juniors	6
Students	6
Affiliates	2
Branch Affiliates	6
Total	107

The executive held seven meetings for the transaction of branch affairs. There were six regular meetings of the branch, one social evening and one special summer meeting. The summer meeting was held in camp in River Park at Estevan, Sask., on July 8th, 9th and 10th, and was attended by our general secretary, R. J. Durley, M.E.I.C., and by other notable guests. It was a joint meeting in conjunction with the Saskatchewan section of the American Institute of Electrical Engineers and the Southern Saskatchewan section of the Canadian Institute of Mining and Metallurgy.

Special matters referred to the executive by the general secretary pertaining to Students' prizes, recruiting of new members, cooperation with Boards of Trade, etc., were considered and suitable action taken thereon.

Attached hereto is the financial statement for the year, showing revenue and expenditure, also assets and liabilities. This statement has been examined by your auditors. Although no branch assessment has been levied since 1925, the assets show a surplus over liabilities of $418.79 as against a corresponding surplus last year of $317.61, or an increase of $101.18. Accounts payable this year are $48.75, as against $156.47 last year. Branch news produced a revenue of $34.64, and with the exception of the summer meeting at Estevan, towards which a special donation of $50.00 was received, the meetings have been practically self sustaining.

During the past year we have received rebates of 30 per cent from the dues paid to headquarters, owing to our corporate membership being less than one hundred.

On behalf of the Executive,

R. W. E. Loucks, A.M.E.I.C., *Secretary-Treasurer.*

Financial Statement—1926-27

Revenue		
On hand from 1926	$113.38	
Meetings	185.25	
Headquarters rebates	221.40	
Branch dues	55.00	
Donation towards Estevan meeting	50.00	
Branch News	34.64	
		$659.67
Expenditure		
Office expenses	$ 67.47	
Meeting expenses	250.16	
Honorariums	150.00	
Scholarship	50.00	
Sundries	26.50	
Bank balance	115.54	
		$659.67
Assets		
Bank balance	$115.54	
Estimated headquarters rebates, 1927	220.80	
" " arrears, 1924-25-26	92.70	
" branch dues, 1927	25.00	
" " assessments, arrears 1923 and '25.	36.50	
Furniture and library	50.00	
		$540.54
Liabilities		
Branch dues paid in advance	$ 23.00	
Scholarship for 1927	50.00	
Accounts payable	48.75	
Surplus	418.79	
		$540.54

This is to certify that we, your auditors, have examined the books and vouchers of the Saskatchewan Branch of the Engineering Institute of Canada and believe the above statement represents the correct financial position of the branch.

J. McD. Patton, A.M.E.I.C.,
Stewart Young, A.M.E.I.C.,
Auditors.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer.

The regular meeting was held in the Y.W.C.A. rooms on February 25th, 1927, with G. H. Kohl, A.M.E.I.C., chairman, presiding.

The guests at the dinner were Messrs. E. V. Ahara, A. H. Clarke and H. Schofield, of the Combustion Engineering Equipment of Montreal and Toronto, and also Mr. Charlton, of the Reynolds Company, of England.

Mr. Ahara gave a splendid paper on "Economy in Steam Generation," which was well explained by the use of a splendid series of slides prepared by the speaker.

Mr. Charlton gave a short talk on "The Comparison of Fuels Used in Great Britain and Canada."

Following Mr. Ahara's address, a lengthy discussion was carried on. The principals who took part were Messrs. R. Gascoigne, chief steam engineer of the Lake Superior Paper Company; John Shields, chief steam engineer of the Algoma Steel Corporation, and Carl Stenbol, M.E.I.C., mechanical superintendent of the Algoma Steel Corporation.

C. H. E. Rounthwaite, A.M.E.I.C., moved a hearty vote of thanks to the speakers and those taking part in the discussion. His expression of appreciation was seconded by all present.

Vancouver Branch

F. P. V. Cowley, A.M.E.I.C., Secretary-Treasurer.

Recent Developments in Oil Engines

At the regular meeting of the branch on February 16th, a paper was presented by Dr. H. F. C. Letson, M.C., Ph.D., on "Recent Developments in Oil Engines." There was a record attendance of members to hear this very interesting paper.

Recent Advances in Metallurgy

On March 9th Prof. H. N. Thomson delivered an address on "Recent Advances in Metallurgy."

Speaking at first in humorous vein on the subject of "lost arts," Prof. Thomson brought home to his hearers the fact that at least in the "art" of smelting most substantial advances had been made in modern times, and especially in very recent years, over any methods used or results obtained by the ancients.

He referred in the copper industry to flotation and differential flotation, showing how now from 76 to 95 per cent of the copper is saved by modern methods, and that whereas in 1884 the output per furnace per day was about twenty tons of copper, it is now six hundred.

In referring to the iron and steel industry, Prof. Thomson exemplified the advances made by showing that in India, by ancient methods four people in ten hours produce fifty pounds of iron. Using the same methods it would require 100,000 people to produce as much iron as one modern blast furnace. Tremendous advances had been made in furnace methods. Early furnaces had required five tons of charcoal to make one ton of iron, whereas now only one ton of coke was required to make one ton of iron.

The advances in the use of chromium steel were also briefly touched upon; and in the very instructive discussion following the paper reference was made to monel metal, stainless steel, corrosion of ships' hulls, and other subjects, illustrating the interest taken generally in metallurgy.

At the conclusion of the discussion a hearty vote of thanks was tendered the speaker on the motion of W. H. Powell, M.E.I.C.

Victoria Branch

K. M. Chadwick, M.E.I.C., Secretary-Treasurer.

At a well attended meeting of the branch on January 26th, F. G. Aldous, A.M.E.I.C., lieutenant of the Royal Engineers, gave an illustrated lecture on his "Experiences of an Exploratory Mapping Expedition in Syria."

Mr. Aldous described the work of a survey carried out between Damascus in the south and Aleppo in the north, which was undertaken at the instance of the War Office by the Seventh Field Survey Company, Royal Engineers, under the technical control of the Survey of Egypt. He explained that the survey of Egypt extended as far as the Suez canal, but that during the early part of the Great War the work was extended ten miles eastwards of the canal. In this work the usual plane table methods based on triangulation were used. The survey covered an area five to fifteen miles wide along the coast north of Sinai and in Palestine it covered the whole of the theatre of operations past Gaza, where the Turks were defeated, and through to Damascus. The instructions were to carry on this work through to Aleppo.

In the course of his address Mr. Aldous referred to a large map and explained how the deep gorge of the Abana river became narrow just north of Damascus, causing considerable difficulty in the triangulation work at this point.

Mr. Aldous described the various towns through which the survey passed and showed a number of interesting slides of local conditions. At the close of the address a hearty vote of thanks was tendered to Mr. Aldous.

Town Planning

On February 25th an interesting and instructive address was delivered before the branch on the subject of "Town Planning" by W. Brand Young, A.M.E.I.C., of Vancouver.

Mr. Young emphasized the importance of this work, which he defined as "laying out the skeleton of a city in order that its control and growth may follow along logical lines." He gave a detailed description of the garden city established at Letchworth, Herts, England, in 1903, the plans of which were inspired by Sir E. Howard's book, "Garden Cities of Tomorrow," published in London in 1898. He then described at some length the principles of the zoning system and concluded by emphasizing the importance of careful planning of the street system in connection with any proposed city planned.

Preliminary Notice

of Applications for Admission and for Transfer

March 16th, 1927.

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in April, 1927.

R. J. Durley, *Secretary.*

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council shall be required to pass an examination before a board of examiners appointed by the council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ALDEN—LANGFORD TAYLOR, of Vancouver, B.C., Born at Troy, N.Y., Jan. 7th, 1887; Educ., C.E., Rensselaer Poly. Institute, 1909; 1909, 6 mos. Nat. Bridge Works, N.Y.C., dftsman; 1910, 4 mos. N.Y., New Haven & Hartford Ry., mtce. of way; 1910-11, Mexico N.W. Ry., dftsman, designer and i/c erection of bridge abutments; 4 mos. Standard Oil Co. designer and 8 mos. as head dftsman; 1912-15, designer (3 mos.) and designing engr., Board of State Hbr. Comm'nrs of San Francisco; 1914-15, design of piers, apt. houses, theatre, bridges, in partnership with Alden & Pyle; 1916-19, in French Army, demob. as lieut.; 1919, report on economics and design of wireless towers with J. G. White Engrg. Corp., N.Y.C.; 1920-21, with Fowler, Boyd, Leighton & Dubois, Inc., as engr. for the Orient, headquarters in Kobe, Japan, on importation of engrg. material and machinery with preliminary estimates and layouts for industrial plants, last 8 mos. as mgr. for Japan; 1922, with Bureau of Highways of State of Idaho i/c design of 80 bridges; 1923-24, with J. G. White Engrg. Corp., N.Y.C., as asst. engr. i/c design 2 refineries and some power plants; 1924-26, with Sydney E. Junkins Co. Ltd. as asst. engr. on Pier B.C. at Vancouver; 1926, preparation of preliminary plans and approx. costs for new pier development in Vancouver Harbour; at present, in private practice as consulting engr. in Vancouver.

Modern Mercury-Arc Power Rectifiers

Their Uses and Application in Converting Alternating to Direct Current

Othmar K. Marti.
Resident Engineer, American Brown Boveri Electric Corporation, Camden, N.J.

Paper read before the Montreal Branch of The Engineering Institute of Canada, January 13th, 1927

Modern Mercury-Arc Power Rectifiers

Although alternating current has many great advantages, it is well known that there are numerous fields with great possibilities for the use of direct current, some of which are: trolley lines, subways, main line railroads, special drives and electrolysis. It is usually disadvantageous to produce the power required for these purposes by means of direct current generators, and, furthermore, it is often uneconomical to transmit direct current over a long distance. An efficient use of direct current is therefore possible only by distributing the power by means of high-voltage alternating current lines and converting it at or near the site of application into direct current. So far, this has been done for power purposes of the above-mentioned character by means of rotating converters of the following types:—

Motor-generator sets, which consist of two separate machines, namely, a motor driving a direct current generator. The performance characteristics of such a set depend on the characteristics of the individual machines which constitute it, and the efficiency is the product of the efficiencies of the two machines.

Synchronous converters, or rotary converters, which are a combination of a synchronous machine and a direct current machine having a common armature and field structure.

Cascade converters, or motor converters, which are combinations of an induction motor with a synchronous converter, the second circuit of the former feeding directly into the armature of the latter.

Glass-bulb rectifiers, as well as the electrolytic, thermionic, and mechanical or vibrating rectifiers, are not built for large power outputs.

The most recent device for converting alternating into direct current is an outgrowth of the glass-bulb rectifier commercialized twenty-five years ago, the principle of which is well known. The present-day development of the power rectifier, as it is usually called to distinguish it from the glass-bulb type, utilizes transformers with a larger number of phases and special connections, as well as metal tanks. The adoption of these made a number of things possible, such as efficient cooling of the tank by means of water and the use of a greater number of anodes and therefore a larger power output. However, it also introduced difficulties which at that time seemed unsurmountable.

The difficulties in the commercial development of the rectifier for large capacity outputs were due to conditions arising from the necessity of using containers suitable for capacities in excess of those possible with glass containers. Among these difficulties may be mentioned uncontrolled mercury-vapour arc phenomena, the obtaining and maintaining of an air-tight sealing of the anodes and the cathode in the container, as well as their insulation from it. In a glass-bulb rectifier the bulb itself is an insulating material, and sealing could easily be accomplished by fusing the wire into the bulb. Both of these difficulties have been overcome, which has made possible the growth of the metal-enclosed mercury-arc rectifier.

Installations on a commercial scale were begun in Europe in 1912, and then in capacities of less than 100 kw. output. One of the earliest installations is shown in figure No. 1, for an interurban trolley line. About 1915, such perfection of detail had been effected that a general application of rectifiers began and has continued at an increasing rate each year, except for a short period due to the effect of the war, as can be seen from figure No. 2. The lower curve in this figure gives the total capacity of the rectifiers

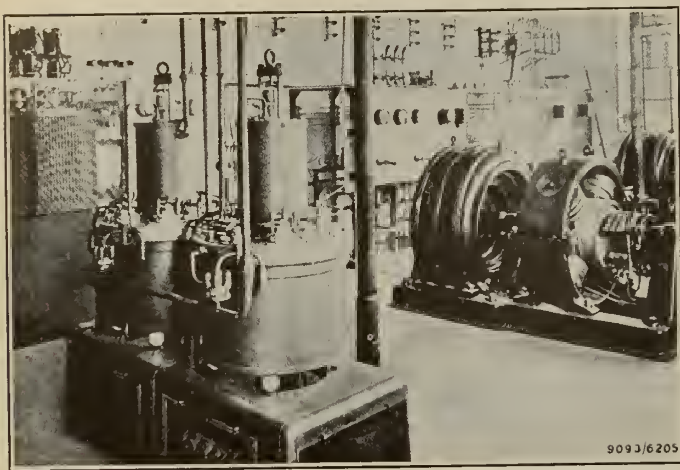

Figure No. 1.—First Large Installation of Power Rectifiers.

installed in each year for railway service, including tramway as well as main line railroad electrification, and it can be seen that in 1925, for instance, 80,000 kw. were sold for railway service. In figure No. 3 is illustrated the increase of capacities for which such metal-enclosed rectifiers were built, for 600 volts and for 1,500 volts. In figure No. 4 is shown the increase in the voltages on the direct current side, successfully used with rectifiers during the past fifteen years. All three of these graphs show that especially during the last five years, i.e., in the period from 1920 to 1925, an astonishing broadening of the field of application of such rectifiers has taken place. It can clearly be seen, from figures Nos. 3 and 4, that much can be expected in the future, not only in increases in the capacity but also in higher voltages, and that this device will keep pace with the general progress in these two respects.

Up to the present there have already been installed more than 460 rectifier plants with more than 950 rectifier tanks of one make alone, of a total capacity of over 460,000 kw. The total output of all rectifiers installed by European manufacturers to date is approximately 600,000 kw.

A standard type rectifier with vacuum pump is shown in figure No. 5. This unit has a rated capacity of 1,500 kw. at 1,500 volts. Its overload capacity is 2,250 kw. for fifteen minutes, 3,000 kw. for five minutes and 4,500 kw. for one minute.

Several large installations for rolling mills were recently completed in Europe; the largest of these, in Belgium, have a rating of 2,000 kw. and 2,400 kw., respectively. The Dutch State Railways have installed seven substations whose total capacity reaches the very considerable figure of 27,000 kw. at 1,500 volts. The substations' ratings are 3,000 kw. and 4,500 kw., respectively, and most of them are entirely automatic in their operation.

In addition to these high-capacity installations at comparatively low voltages, there might be mentioned several high-voltage installations which have been in successful operation for several years: a 2,300-volt, 1,000-kw. substation for the London, Midland and Scottish Railway; a 3,000-volt, 1,700-kw. installation for the Italian State Railways; and the rectifier with the highest direct current voltage in the world, that of 4,000 volts at 1,000 kw., which takes care of the entire twenty-five miles of the Torino-Lanzo-Ceres Railway in Italy. This last is illustrated in figure No. 6.

An installation which shows how easily rectifiers lend themselves to almost any location is a station of the Chemin de fer Metropolitain of Paris. The complete equipment is mounted on one of the platforms of a subway station, without any structural changes whatever having been made in the station. (See figure No. 7.)

Probably the two factors which appealed most to those responsible for the early acceptance of the rectifier were the high efficiency at all loads and the minimum of attendance required. Both of these factors are immediately reflected in the operating accounts, and in some instances in so pronounced a manner as to establish large credits towards amortization of the replacement investment where the rectifier was brought in to modernize a substation and supplant rotating machinery of early design. Especially is this so where machinery employed for conversion is operated under conditions which imposed a low annual load factor, as in the supply of direct current power to rolling mill drives, elevators, dredge drives, mine, street railway and heavy electric traction haulage, etc.

The confidence which is placed in this device in Europe is probably best illustrated by the fact that the Berlin Rapid Transit recently placed one order for ninety-five rectifiers of a total capacity of more than 114,000 kw. continuous load and 228,000 kw. overload for the entire electrification of a belt line interconnecting all the suburbs of the city.

Elementary Theory of Alternating Current Rectification

It has been known for more than forty years that if a source of alternating current is connected to two electrodes,

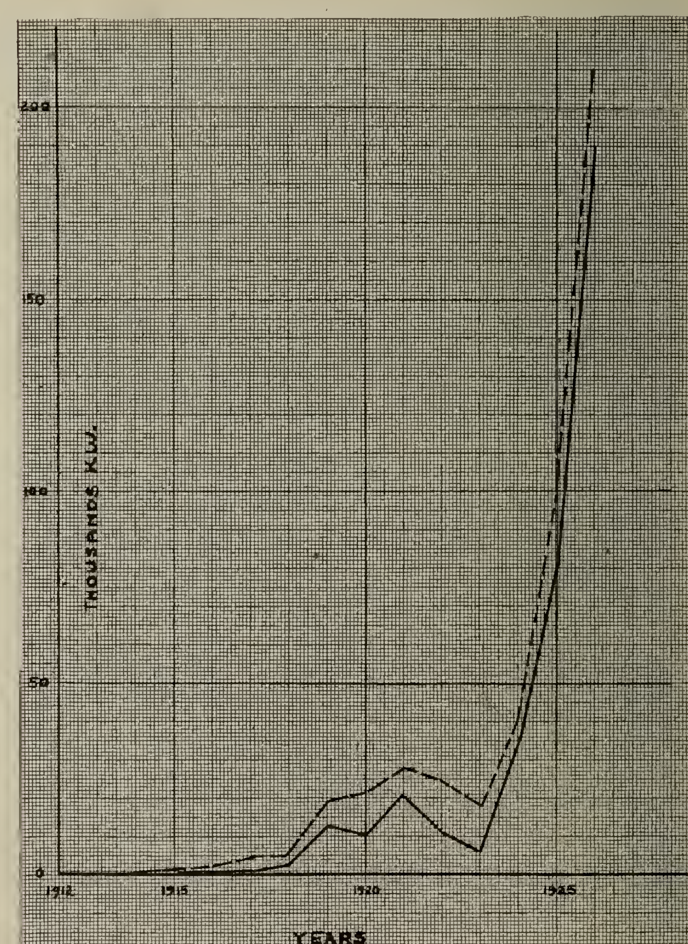

Figure No. 2.—Yearly Production of Brown-Boveri Type Rectifiers, Showing Total Capacity in Kilowatts.

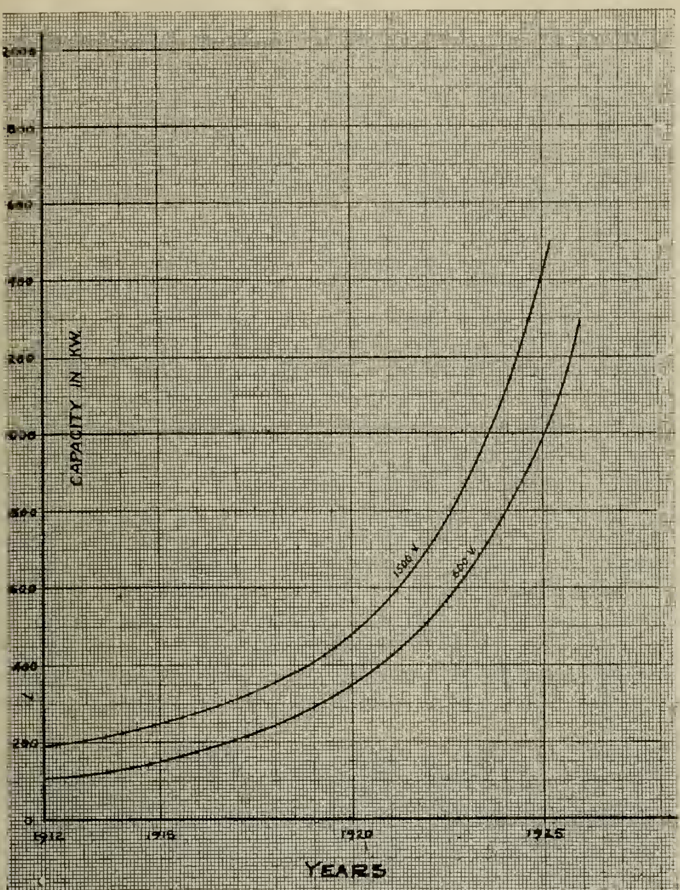

Figure No. 3.—Maximum Ratings of 600-Volt and 1,500-Volt Rectifiers in Various Years.

one of which is mercury, and the space between the electrodes is evacuated, a valve action is obtained, so that if a sufficiently high potential is impressed upon these electrodes a unidirectional flow of current results from anode to mercury cathode. A single-phase rectifier has several well-known disadvantages; first, only half of each cycle of alternating current voltage can be utilized; second, there is no provision for maintaining the arc during periods of reversed voltage; third, the resulting direct current is very uneven. The effect of using polyphase connections,—more than two anodes,—can be seen very clearly on the right-hand side of figure No. 8. In the case of a two-anode connection, as shown on the left-hand side of figure No. 8, it can be seen that for this arrangement both halves of the wave are utilized. This means that the current will flow in the same direction through the secondary circuit with reference to the load resistance.

Due to the inherent inertia of reactance, which is a characteristic of every electric circuit, both anodes are active for a short fraction of a cycle, and the arc is transferred from one anode to the other without interruption of current in the load circuit, because enough energy is provided to maintain a voltage according to the law of induction to carry the arc over the zero period of the voltage wave. In the case of a three-phase connection with three anodes, it may be assumed that at any instant only that anode is active whose potential with respect to the cathode is the highest, and much less pronounced undulations will be found in the direct current than with the two-anode connection. An arrangement with six, twelve or even twenty-four anodes will give an even better form of the direct current.

With small battery-charging rectifiers the arc is "struck" by tilting the container to establish a physical electrical connection between the cathode and an anode. Obviously, this could not be done with large power rectifiers because of size and weight. Other arrangements had therefore to be developed for this purpose. Figure No. 9 is a schematic diagram of connections, illustrating an arrangement for "striking" the arc and for maintaining it during periods of low current, which is connected to an auxiliary source of current supply and resembles the connections of a two-anode rectifier. The arc is "struck" as soon as the starting anode is withdrawn from the cathode, producing ionized mercury vapour in the container to establish an arc between the cathode and the maintaining anodes. This operation puts the plant into condition for immediately picking up the load.

The potential drop in the arc between the anodes and the cathode is about 20 volts. The losses due to starting and maintaining the auxiliary arc are negligible for tanks of larger capacity. A peculiarity of this arc is that the voltage drop remains practically constant for any current and any direct current voltage. This shows immediately the reason why such a type of rectifying device has a very high efficiency at higher voltages. Assuming a direct current potential of about 20 volts, the losses would be 50 per cent, or an efficiency of 50 per cent. For 200 volts, the efficiency would be 90 per cent; for 2,000 volts, 99 per cent. For higher voltages the efficiency becomes practically 100 per cent. These percentages apply to the rectifier alone.

In figure No. 10-A are shown the overall efficiencies, including the rectifier, transformer and auxiliary apparatus for various voltages. The overall efficiencies over the whole working range for rectifiers of 600, 1,500, 3,000 and 5,000 volts are shown in figure No. 10-B. It might be well to note here the fact that this efficiency drops very little at partial loads. Were it not for the increase of losses in transformers at overloads and at partial loads the overall efficiency of a rectifier would be practically constant at all load conditions.

Another outstanding advantage of the rectifier is the simple and quick process of starting, which is easily comprehensible by reference to the foregoing. In commercial practice the arc is "struck" and the rectifier brought to full capacity operation in a short space of time. It can readily

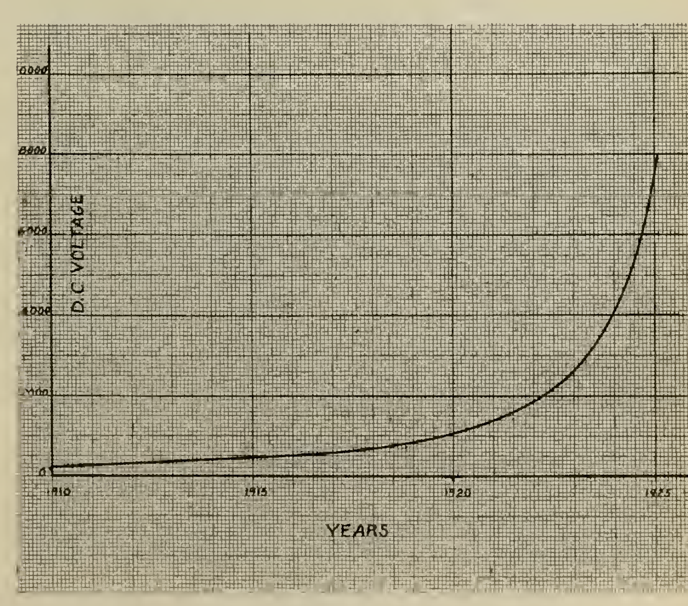

Figure No. 4.—Maximum Direct Current Voltages of Rectifiers in Various Years.

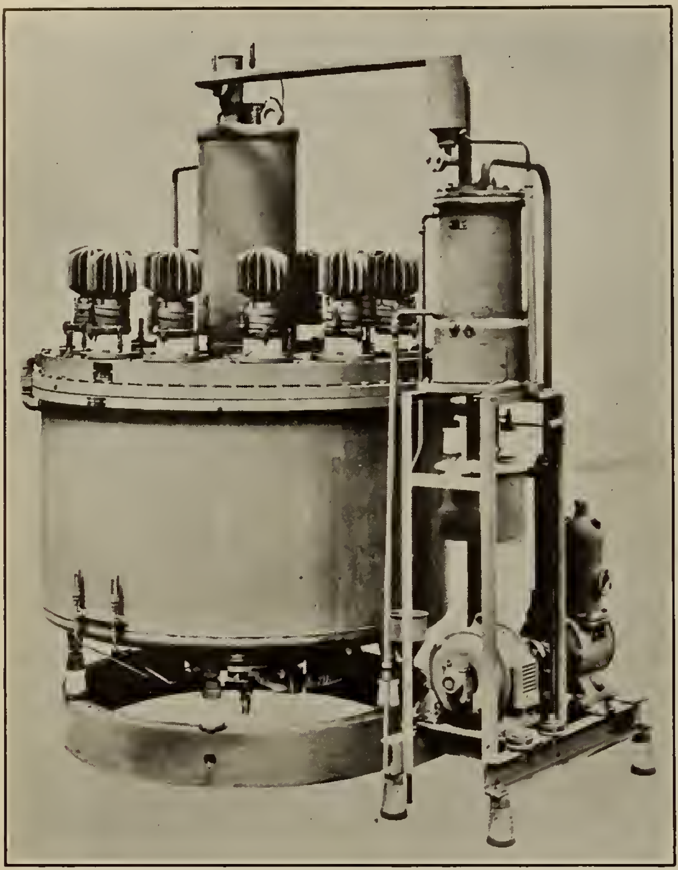

Figure No. 5.—One of the Larger Types of Modern Power Rectifiers.

be realized that from the time the operator closes the starting circuit,—whether by operating the main circuit breaker mechanically interlocked with the starting switch, or separately, or automatically,—until the rectifier can be connected to the line, only a second or two need elapse. Moreover, no mistake can be made by the operator because the actions are made to take place in the proper sequence.

There is one other thing which has to be considered in a modern rectifier, and that is the vacuum in the container. Thus far it has been noted only that the container has to be kept sealed. The reason for this is to maintain the degree of vacuum necessary for the proper functioning of the arc.

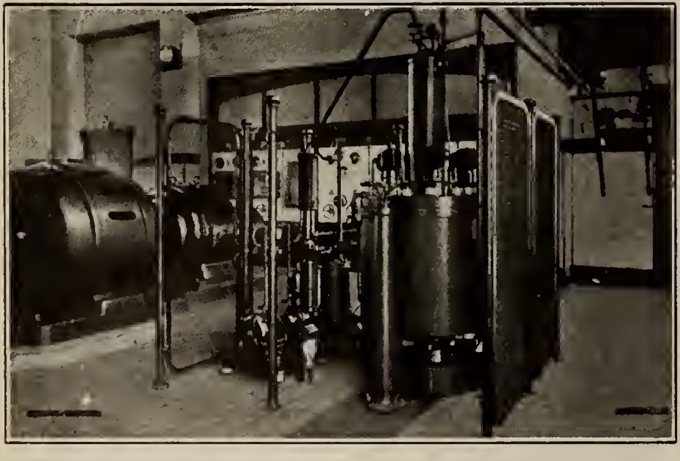

Figure No. 6.—Installation of Rectifier with the Highest Direct Current Voltage.

It was an easy matter to design a vacuum pump for this purpose, and no difficulty has ever been experienced with this part of the apparatus. The pump is permanently connected to the tank of the rectifier by means of an air-tight pipe, as shown in figure No. 9. However, the part which required a great deal of work and development before it reached its present state of perfection was the continuous-reading vacuum meter.

Figure No. 11 is a diagram of connections for a fully automatic vacuum maintaining equipment. The vacuum pump is driven by a small motor connected to an auxiliary circuit. Its controlling relays are connected to a contact voltmeter. The contact voltmeter is energized by means of two windings placed at right angles to each other and located at the bottom of the instrument. These two windings are connected to the hot-wire element, which in turn is connected to the pipe joining the vacuum pump and the rectifier container. The principle of this gauge is that the thermal conductivity of gases depends on the pressure of the gases. As soon as the pressure changes, the Wheatstone bridge consisting of the four wires, shown in figure No. 11, becomes unbalanced and therefore the contact voltmeter is affected. Should the vacuum drop to a low value, its moving part establishes a circuit through the left-hand contact and the closing coil of the circuit breaker controlling the vacuum pump motor is energized, thus putting the pump into opera-

Figure No. 7.—Rectifier Installation, Mounted on Platform of Subway Station.

tion. After the vacuum has been increased to a certain value, the Wheatstone bridge again affects the voltmeter so that the circuit is established through the other contact, on the right-hand side, thus stopping the vacuum pump.

This arrangement works entirely automatically and therefore the station attendant does not have to look after it, except for an occasional inspection. The only operation necessary to connect the rectifier with the line is to close the main circuit breaker.

In order to maintain vacuum in the cylinders several arrangements have been developed, the most successful of which is the employment of mercury. This arrangement has many advantages:—first, it seals perfectly; second, it can very easily be inspected should leakage develop; and, third, leakage, as soon as detected, can be eliminated by a mere tightening of screws. In all other arrangements so far developed, the main disadvantage has been the inability to maintain the joints tight for any reasonable time. Furthermore, in none of the other arrangements can leakage be

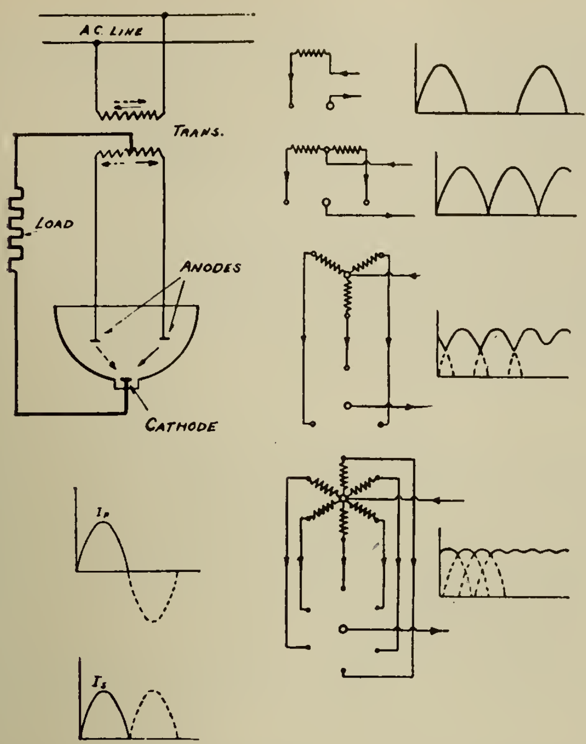

Figure No. 8.—Elementary Diagram of Rectification and Forms of Direct Current Obtained with Various Transformer Connections.

detected; the vacuum may drop, and the attendant may be unable to determine the cause, while with the mercury arrangement inspection will immediately show the location of the fault. Moreover, should mercury leak through into the interior of the container, no harm is done, as it will merely be added to the mercury in the cathode.

As pointed out, one of the factors which brought the rectifier to its present advanced state of perfection and which makes it competitive with rotary converters in size, voltage regulation and price, was the development of a polyphase transformer with special connections, permitting the desired performance characteristic as well as greatly increased capacity.

The rectifier transformer differs from the standard power transformer, not only in respect to connections, but also in the provision for certain electro-dynamic forces which made it necessary to provide different mechanical construction. In figure No. 12 is shown a standard rectifier transformer for 3/6 phases. The coils of these transformers are kept under a certain pressure by means of a specially designed support. It can be seen that the cast steel pressure rings at the top of the coils are pressed down by springs, thus forming a solid unit.

Comparison of Mercury-Arc Rectifiers and Rotary Converters

It is difficult to put both types of apparatus on a strictly comparative basis regarding load, space needed and price. Due to the fact that the rectifier has a very low thermal capacity, its overload capacity is relatively small for longer periods, while on the other side the overload capacity is higher for momentary and relatively short periods. This is principally due to the absence of current-collecting parts.

From the efficiency curves shown in figure No. 10, it is obvious that as soon as the potential rises above 600 volts there is a very great advantage in favour of the rectifier. Although the efficiency of a 600-volt rectifier set at full load is about the same as for a rotary converter set at full load, the difference in the efficiencies of these two types of equipment becomes very noticeable at partial loads, which can be seen from figure No. 13. The difference in the converting losses for these two types of equipment is represented by the shaded area at the bottom of the figure for a load distribution as given in the middle section.

The costs of operation and maintenance of a rectifier are somewhat less than for other types of conversion apparatus. Moreover, the scheme of control is very much simpler than with any of the well-known methods for starting converters. From the outline of the starting procedure of a rectifier and considering the above, it will be appreciated that the adaptability of the rectifier to automatic control is generally greater than that of the synchronous converter. Another advantage is the fact that practically no noise is produced, except the occasional cut-in of relays and breakers and of the pump, which is negligible, since there is very little rotating mass.

In congested districts, where it may be necessary to install a conversion unit in the basement of the building, satisfactory ventilation for converter installations is usually obtained only by resorting to elaborate and extensive alterations, involving air ducts, fans, filtering systems, etc.

As mentioned above, the rectifier losses are dissipated by water cooling, and therefore the removal of the heat outside the rectifier room is a relatively easy matter. The problem is about the same as with a water-cooled transformer. The simplest cooling scheme is to use tap water, or, if that is not available, or too expensive, a well or spring could be utilized. There are also closed-cooling methods, in which the water is cooled by a fan and recirculated.

In regard to floor space requirements, it might be said that a 600-volt rectifier installation requires about the same space as a comparable synchronous converter installation.

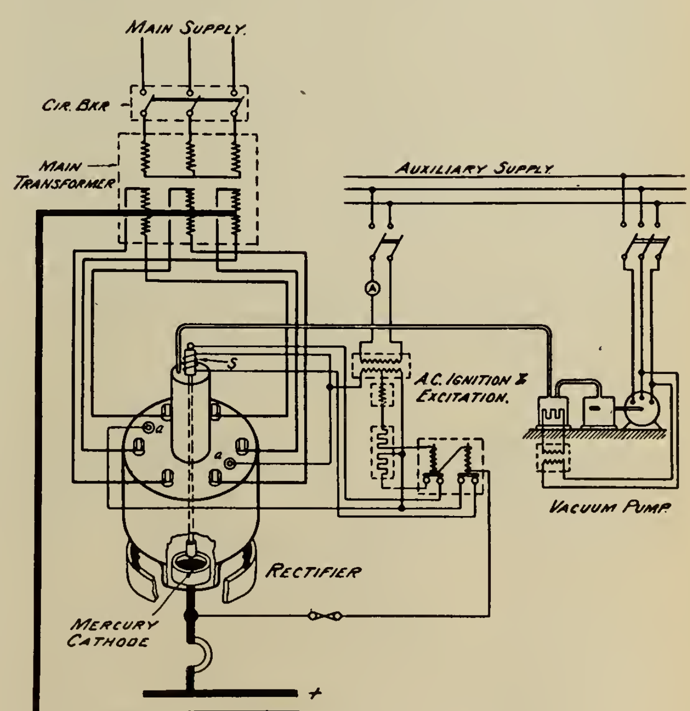

Figure No. 9.—Schematic Diagram of Connections, Showing Starting and Maintaining Equipment as well as the Vacuum Pump Arrangement.

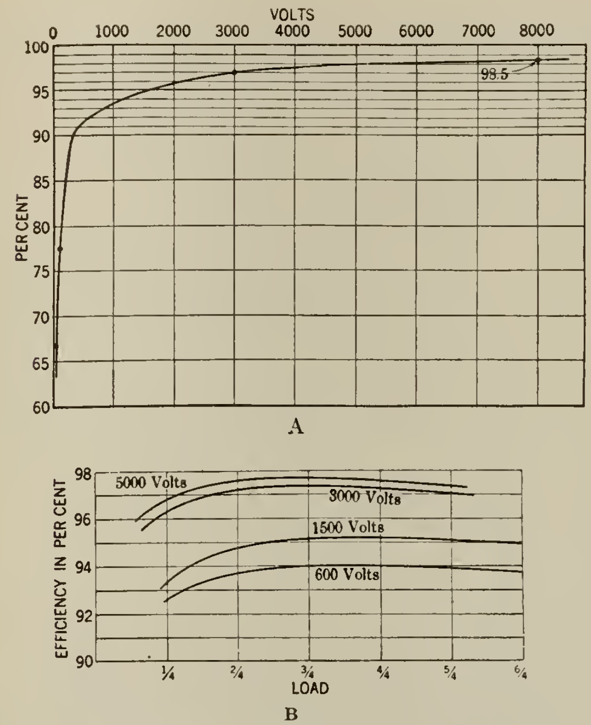

Figure No. 10.—Overall Efficiencies of Rectifier Plants of Various Voltages.

For high voltages the rectifier installation requires less space. However, it must be kept in mind that due to the light weight of the equipment, and due to the absence of rotating parts, practically no foundations or other special building construction is necessary. Furthermore, the various parts of the equipment belonging to a rectifier installation can be distributed and placed in more advantageous locations than with rotary converter installations, permitting a fuller utilization of the available space. This fact is very well illustrated by figure No. 7, showing the rectifier placed on the platform of a subway, and by figure No. 14, which shows the transformers located in the basement and the rectifiers on the floor above, with some of the auxiliary apparatus, as vacuum pump, etc., allowing a good utilization of the space by distributing the equipment on different floors of a building. In figure No. 14 it can be seen that for

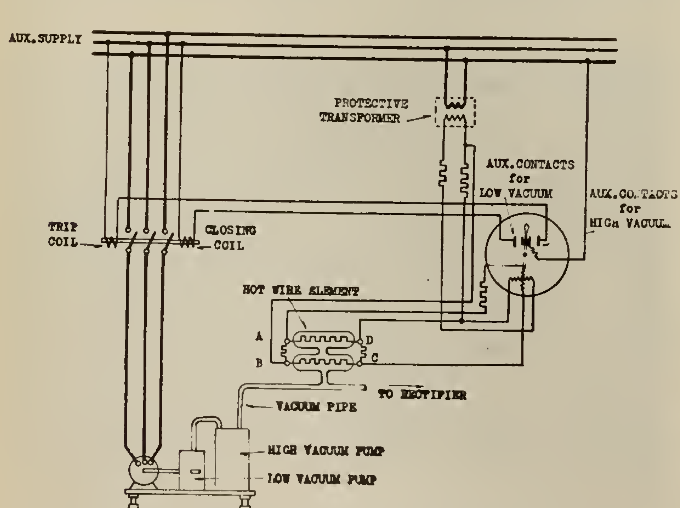

Figure No. 11.—Schematic Diagram for Automatic Control of Vacuum Pump with Novel Hot-Wire Vacuum Gauge.

a rectifier installation far less unoccupied space is necessary, particularly in the height of the room in which the rectifiers are housed. This might be a material advantage in congested districts where special attention would have to be given to the layout.

One example of the above mentioned fact is that of an elevated railroad passing through the heart of a large city, where it was necessary to place the converting units at the points of highest traffic peak loads in order to eliminate the feeder cables and secure the highest economy of operation. This was accomplished by placing the rectifiers in the arches of the elevated structure, a procedure which would have been impossible with any other type of converting unit.

Special Advantages of Rectifiers for Railway Service

In figure No. 13 is illustrated the saving obtained with mercury-arc rectifiers due to their high efficiency at partial loads. That the saving due to decreased conversion losses will be considerably more for higher voltages can readily be appreciated from this efficiency curve, where the saving is not only at partial loads, but at all load conditions, and to a very pronounced degree.

Due to the fact that the rectifier has an ampere rating rather than a watt rating, and since the losses in the arc are practically the same for any direct current voltage, this device lends itself admirably as a high-voltage converter. Not only does its efficiency increase with higher voltage, but also the capacity per container, and this without any alterations of importance, up to 5,000 volts direct current. The limited use of direct current for heavy traction work has been largely due to the fact that no efficient converting

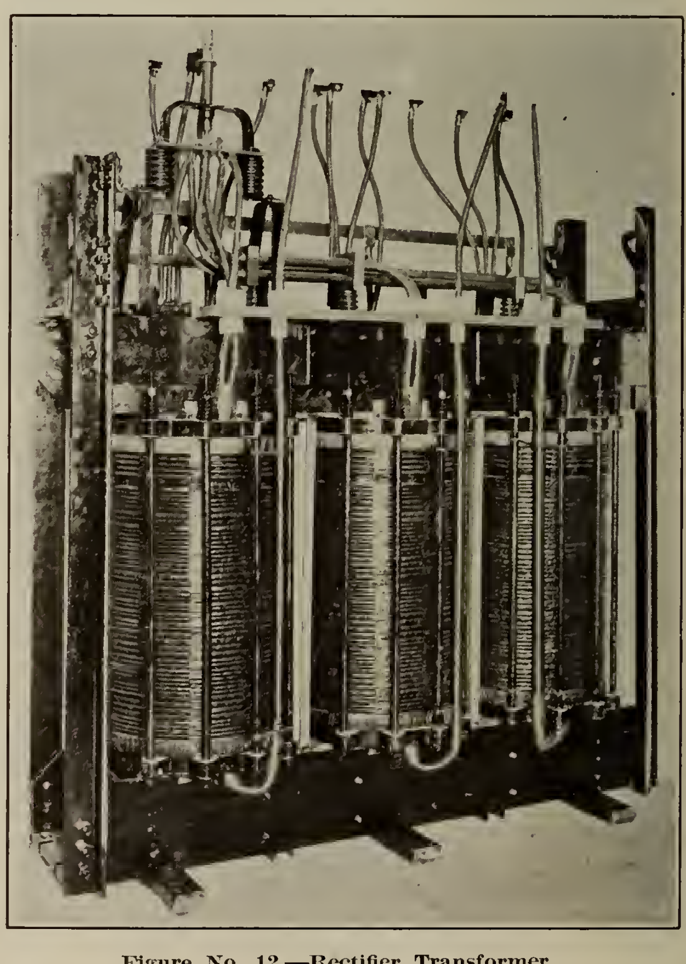

Figure No. 12.—Rectifier Transformer.

device for high voltages was available. Heretofore, 1,500-volt direct current conversion was likely to be considered critical from the point of view of the converting device, except in the case of motor-generator sets. Above that voltage, the use of a synchronous converter was out of question, and the problem could be solved only by the use of motor-generator sets, which involved a great sacrifice in efficiency and in cost.

In order to bring out the main advantages, an electrified line with a 3,000-volt direct current system will be considered. This voltage cannot any longer be considered high with reference either to rolling stock or catenary equipment, as is well demonstrated by railway electrifications for this

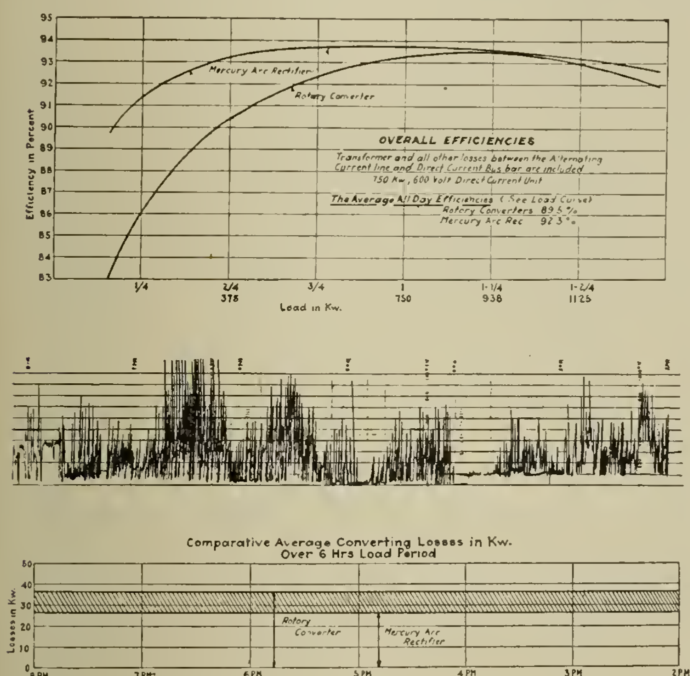

Figure No. 13.—Efficiency of a 600-Volt, 600-Kw., Rotary Converter and Mercury-Arc Rectifier; Load Chart; Performance Chart.

voltage both on this continent and abroad. The main advantages are:—

First, the converting equipment is about half the cost of a motor generating set,—which is the only other conversion device which can give such high direct current voltages,—and even less, as a saving will also be effected due to simpler substations and simpler control equipment.

Second, elimination of practically all feeder cables, because the rectifier can be located at points with the heaviest load peaks. Furthermore, centralization of the converting equipment is not necessary. The reason for this is largely due to the fact that the control equipment and the substations necessary to house a rectifier are less complicated and cheaper than for motor-generator sets.

Third, smaller losses in trolley lines, since a greater number of substations with closer spacing do not materially affect the cost of electrification. This is due to the same reason as mentioned above.

Fourth, doing away with special control devices, supervisory equipment, etc., since rectification at high efficiency is made possible at all loads, and therefore floating on the line of rectifiers does not impair the economic aspects of the rectifier installation. Control can be easily accomplished by a simple device, as, for instance, by a time-switch which would connect or dis-

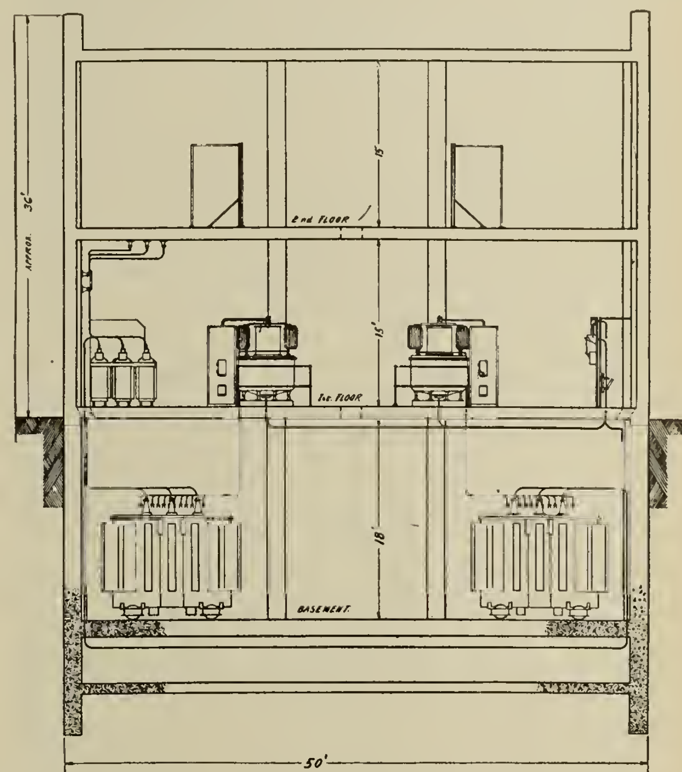

Figure No. 14.—Typical Rectifier Substation Layout.

connect, respectively, the rectifying sets from the trolley line at certain predetermined intervals.

Most of the above mentioned high-voltage direct current electrifications employing mercury-arc rectifiers as a conversion device were the result of studies taking into account the above considerations. Rolling stock for voltages of 3,000 and 4,000 volts has proven to give full satisfaction in practical installations, both on this continent and abroad.

The writer is fully convinced that in the not far distant future the rectifier, with its extreme adaptability to higher voltages, will revolutionize the electrification programmes as well as the system questions so long discussed in every country.

Discussion on Modern Mercury-Arc Power Rectifiers*

Mr. M. L. de Angelis.

Mr. de Angelis remarked that the mercury-arc power rectifier was now an industrial apparatus, with at least seven years of satisfactory operation behind it, and had shown itself just as reliable as rotary converters or motor-generator sets.

All engineers who had had experience with railway sub-station converting apparatus would agree on the fact that the simpler it is the better, and there could be no doubt that the mercury-arc rectifier fulfilled this requirement in a greater degree than any rotating and commutating machine. It should be noted, however, that the 60-cycle rotary converter had been greatly improved during the last decade, and, with the use of flash-barriers, high-reluctance commutating poles, and, above all, with the adoption of high-speed circuit-breakers, it was now possible to make several consecutive short-circuits on 600- and 750-volt machines without any flashing. He had made thirty consecutive short-circuits at intervals of one minute on a 750-volt converter for use on 1,500-volt sets and obtained remarkable results, but could not make the same statement for converters giving 1,500 volts directly on one machine.

Having had the opportunity of examining, while in operation, the two 540-kw., 600-volt rectifiers of the Metropolitan Railway of Paris, which had been running quite satisfactorily since early in 1923, he could say that they stood high overloads while feeding a section of the most important subway line of Paris, carrying a high peak load at rush hours. The headway between trains was 90 seconds and each train took 1,800 amperes at starting current. Several trains could start simultaneously in a section.

This installation was considered as a trial, and, obviously, the Metropolitan Railway Company did not want to go into the expense of a building to house the apparatus, so they decided to have it erected on a part of one of their passenger station platforms. This was done with satisfactory results, and proved how easily rectifiers could be accommodated, even in restricted quarters, and that they did not need special costly foundations.

In Europe, the general consensus of opinion was one of complete satisfaction with mercury-arc rectifiers; he did not see any particular reason why it should not also be so in Canada.

Their good efficiency at practically all loads, together with their simplicity in starting and running, made the rectifiers very well suited to automatic operation, and their use should be seriously considered when studying new railway substations for surface or underground lines.

It was interesting to compare the weights of a rotary converter and a mercury-arc rectifier installation. For example:—

Apparatus	Net weight
1,200-kw. rectifier set, consisting of two tanks, one vacuum pump and necessary vacuum piping	10,300 lbs.
Transformer without oil	14,500 "
Oil for transformer	6,700 "
Total	31,500 lbs.
or 26.25 lbs per kw.	
2,000-kw. rotary converter, complete	56,800 lbs.
Three transformers with oil	29,130 "
Total	85,930 lbs.
or 42.9 lbs. per kw.	

It could be seen from the figures giving the weight per kilowatt that rectifiers had the advantage over rotary converters from the point of view of weight. Since a rectifier was a stationary piece of equipment, a simple and cheap foundation was all that is necessary for mounting it.

The recent important decision arrived at after several years of careful study by the engineers of the Berlin Metropolitan Railways was very significant, and spoke well for the mercury-arc rectifier. He hoped that complete information on the theory and working of the mercury-arc power rectifier would soon be published in book form by those engineers who have been responsible for its development. Perhaps the author would find it possible to favour us with such a useful and much-needed book.

Mr. A. J. Westman.

Mr. Westman desired further information on the following points:—

1. The difficulties to be expected in the parallel operation of mercury-arc rectifiers and compound-wound direct current apparatus. Is the regulation of the mercury-arc rectifier altered to meet the characteristics of the direct current apparatus, or are the characteristics of the compound-wound direct current apparatus altered to suit the rectifier?
2. The suitability of the mercury-arc rectifier for high-voltage main line railroad electrification. Comparative efficiencies of rectifiers and motor generators.
3. Nominal rating of rectifiers as compared with rotary converters.

Mr. H. G. Owen.

Mr. Owen had noted that the author had made no reference to interference with communication circuits and,—due to the arc,—with radio. He asked whether some data on these matters could be given.

Mr. C. J. Desbaillets, m.e.i.c.

Mr. Desbaillets observed that the author had given us very valuable information on the operation of the rectifier itself. It could be seen that it was not possible to furnish any wattless current back to the net-work with a rectifier, and thus to correct the power factor. He would ask to what extent power-factor correction entered into the operation of converting devices, and whether the lack of such correction with rectifiers might not be an argument against the installation of rectifiers in certain instances.

Mr. F. T. Kaelin, m.e.i.c.

Mr. Kaelin thanked the author for his very complete paper, and thought that it would be interesting to have some comparative data as to the cost of rectifier and rotary converter installations.

Mr. K. B. Thornton, m.e.i.c.

Mr. Thornton remarked that in the very near future two new mercury-arc rectifier substations would be put into operation in this country; one of them by the Montreal Tramways Company, rated at 2,400 kw. full-automatic; and one at 600 kw., manually-operated set, at Three Rivers.

In the discussion, mention had been made of the efficiency of rectifiers as compared to rotary converter or motor-generator sets. In his opinion, the value of a rectifier could only be properly estimated if the saving in maintenance and attendance were also taken into account. The diagram of connections, figure No. 9, gave an idea of the simplicity of the auxiliary apparatus necessary to make a station full-automatic, since a rectifier need not be brought up to speed during starting, or need its polarity be checked.

* This discussion took place following the presentation of the paper by the author at the meeting of the Montreal Branch of The Institute held on January 13th, 1927.

Evidently, therefore, a large saving was realized in the automatic equipment, and, moreover, far better operation would be ensured, due to the simplified arrangements and the doing away with numerous relays and auxiliary devices.

Mr. O. K. Marti.

The author in reply, referring to Mr. Westman's questions, stated that it must be kept in mind that mercury-arc rectifier equipment would have a constant voltage characteristic were it not for the voltage drop in the transformer. The voltage regulation of a rectifier set could therefore be made to fall within certain limits by a proper design of the transformer. The normal voltage characteristic of a transformer is drooping, and if, therefore, parallel operation with a flat-compounded, or over-compounded, rotary converter set were desired, the only solution was to shunt the compound winding of the rotary converter; in other words, to make the voltage regulation of the converter somewhat drooping also. A standard design of rectifier transformer produced a direct current voltage regulation of 5 to 9 per cent, as desired. It was, however, possible, with a special arrangement, to make a rectifier installation flat-compounded, or over-compounded, just like a rotary converter set. Several such sets had been built more than twelve years ago, but were never put on a commercial basis, as the tendency in Europe was to do away with flat-compounding, or over-compounding, as was beginning to be the case here also.

Personally, he could not see any advantage in an over-compounded machine, but was convinced of the many advantages of a drooping characteristic. Such a characteristic guaranteed far more flexible operation and a much better distribution of the load between neighbouring substations, thus giving the same service with a lower station capacity, and resulting in a better load factor as well as smaller losses in the feeders. It also did away, even under the most extreme load conditions, with a load-limiting resistor.

Regarding the suitability of mercury-arc rectifiers for high-voltage main line railroad electrification, he believed that due to the fact that the rectifier lends itself very easily to a relatively high direct current voltage, up to several thousand volts, it would seem that high-voltage power rectifiers would to some extent settle the long discussed question of what system should be adopted for main-line railways. A rectifier gave the same safety of operation as a motor-generator set,—which was otherwise absolutely necessary for voltages of several thousands of volts,—with less than half the cost of such a set. In addition to this, the efficiency of such a converting device was extremely high as compared to that of a motor-generator set.

In regard to nominal rating, it must be kept in mind that the rectifier could not be brought to a strictly comparable basis with a synchronous converter, on account of the inherently different thermal characteristics of the two devices. The nominal rating, or two-hour rating, of the rectifier was for practical purposes a continuous rating, on account of the low thermal capacity, whereas the synchronous converter had a somewhat higher thermal capacity. However, a converter of modern design with forced ventilation had such a small thermal capacity that an appreciable temperature rise would take place even at a small overload extending over only a short time, and it was therefore necessary, in order to meet the overload of 50 per cent at present required by the Standards of the American Institute of Electrical Engineers, to underrate the machine for continuous load if the nominal rating were asked for,—a course which he considered very arbitrary.

With reference to the question of Mr. H. G. Owen on interference, he desired to call attention to figure No. 8 in the paper, from which it could be seen that the current and voltage waves could be flattened by using polyphase rectifiers. The question of interference was not only a matter of the amplitude of the ripples, but also a function of their frequency, in the same way as with rotary converters or other power-producing devices which give rise to higher harmonics. With regard to radio interference, it might be said that no such phenomena, due to the arc in the rectifier, could be observed. The rectifier arc was, as far as measurements showed, unable to emit radio waves like an arc in air. The phenomena involved in an arc in vacuo and in air were so different that this fact could easily be understood. Besides this, the arc was enclosed by a steel container which acted as a shield.

Replying to Mr. Desbaillets' question in regard to power-factor correction by means of a rectifier set, he admitted that in this respect a rectifier had some drawbacks. However, the correction possible by means of a synchronous converter was also very small, and it might therefore be said that compared to a motor-generator set both the mercury-arc rectifier and the synchronous converter must be considered to be practically of equal value for power-factor correction. The cases where power-factor correction is a main item in a converting station were very few, and were becoming more and more scarce as static condensers, or large synchronous condensers, were being used increasingly.

Mr. Kaelin's question relating to comparative prices of synchronous converters and mercury-arc rectifiers could probably best be answered by Mr. DeMulinen, to whom he therefore referred this enquiry.

Mr. E. DeMulinen.

Mr. DeMulinen drew attention to the author's statement that the rectifier functioned as a current valve independently of the voltage of the system, and stated that the insulation of the current-carrying parts of steel-enclosed mercury-arc rectifiers was practically the same from 200 to 5,000 volts, this being required to give the insulation the necessary mechanical strength. There was therefore practically no difference between a 250-volt and a 3,000-volt rectifier for a given current, except that the transformer had to be larger to take care of the increased output. The first cost per kilowatt of a rectifier, including all accessories, from the alternating current to the direct current side as compared to a rotary was higher at 250 volts direct current, about equal at 600 volts, and considerably lower at 1,500 volts. At 3,000 volts the price of a rectifier equipment was only about 40 per cent of the cost of a motor generator.

Comparative price data, however, would not be complete without a comparison of the erection, operating and maintenance costs. The author had calculated that the weight of a rectifier equipment was only about 60 per cent of the weight of a rotary equipment of the same capacity, including the necessary transformers. Furthermore, the rectifier did not need special foundations, since it had no rotating parts. The costs of building and erection were considerably less for a rectifier substation than for a rotary converter substation.

The over-all efficiency curve of a rectifier, being a practically flat curve from light loads to overloads, brought about a considerable saving in the power bill in all systems with fluctuating load. The over-all efficiency of a 3,000-volt rectifier at full load was 97 per cent, and at 25 per cent load 95 per cent. The corresponding figures for a motor generator were 90.5 and 80 per cent. The mean efficiency of the rectifier would be 96.3 per cent, or about 12 per cent higher than the motor generator, when considering a load factor of 50 per cent and load fluctuations of from 25 to 200 per cent. In other words, the rectifier would effect a saving of 150 kw. hrs. per hour, or 1,300,000 kw. hrs. per year.

Electric Arc Welding

Recent Progress in the Application of Electric Arc Welding

R. E. Smythies, M.E.I.C.
Vice-President, Lincoln Electric Company of Canada, Limited.

Paper read before the Toronto Branch of The Engineering Institute of Canada, January 13th, 1927

Arc welding is destined to play an important part in the metal-working industries. It is probably true, however, that the importance of the change which is coming is not yet appreciated except by men who are actively engaged in the development of the process. These men know that before long there will be basic changes in this great industry, resulting from the use of arc welding. As a result of these changes, the established methods and traditions of metal working will be cast aside and sweeping changes in designs and processes will take place in every plant in which iron and steel is used as raw material.

Few engineers have hitherto given much thought to the idea of substituting welded steel parts for iron castings, and yet it is probable that progress in this field will be relatively much more rapid than in others. The economic arguments in favour of this change are so powerful as to be compelling, and there are fewer serious obstacles to be overcome than there are, for instance, in the field of structural steel engineering.

The almost universal reaction to this idea, when first confronted by it, is the thought that steel is less rigid than cast iron and that this necessarily limits the application very materially. The greater rigidity of cast iron is a fallacy, probably arising out of the fact that steel will stretch without breaking whereas cast iron, practically speaking, will not.

The fact is that if a steel beam carrying a given load and bending or sagging a certain amount were replaced by a cast iron beam of the same dimensions, the sag of the cast iron beam would be just two and one-half times as great as that of the steel beam, provided it did not break because of its lesser strength. Therefore, if a cast iron member subject to bending be replaced by an equal section of steel, the sag or bending would be reduced 60 per cent and the cost from 50 to 70 per cent, owing to the lower cost per pound of steel.

Actually, however, the cost would be reduced much more than this because the designer would naturally take advantage of the superior strength and stiffness of steel to reduce the section and also by using a section of a size and shape calculated to resist the stresses to the greatest advantage. Any shape which can be readily cast in iron is frequently not of the best design to resist bending stresses. Taking full advantage of all the possibilities, a saving in cost of as much as 80 per cent would be effected. This may seem like the wild statement of a visionary, but it is a statement the truth of which may be proved easily by anyone sufficiently interested to take the trouble to investigate.

The saving to be effected by substituting steel for cast iron parts in compression is not quite as great, although still considerable. The ultimate strength of cast iron in compression is greater than steel, but cast iron requires a much higher factor of safety so that the permissible working stresses for the two metals are approximately the same. The saving to be effected, therefore, is the amount of the difference in the cost per pound.

The superior strength of steel in tension is too well known to permit of discussion, and it follows that the arguments in favour of the use of steel for parts subject to bending apply with even greater force, and that there would be more striking reductions in cost.

The perfection of the arc welding process has made it possible to take advantage of the superior qualities of steel. It is another fairly widespread fallacy that arc welding is an expensive process. It is, in fact, by far the most economical process in use to-day for joining two pieces of steel together. The use of the process along the lines described

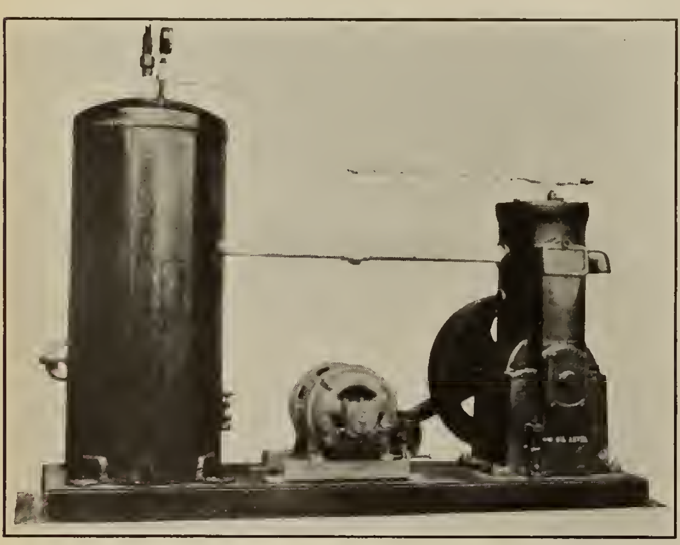

Figure No. 1—Motor with Welded Steel Frame Driving Compressor Mounted on Welded Steel Base, with Welded Steel Receiver; Illustrating Trend in Machine Design towards this type of Construction.

Figure No. 2—Method of Fastening Shelf Support for Brick Walls to Spandrel Beam.

Figure No. 3—Method of Welding Flanges and Window Supports to Floor Beam.

above has developed far enough to demonstrate that the actual cost of such welding, when efficiently done, should fall somewhere between one cent and half a cent per pound of the weight of material in the parts welded.

When considering the direct savings which can be made in production costs by this means, it should not be forgotten that in many cases the indirect savings are almost as striking. The work of designing and draughting is very much simplified and the cost of patterns is entirely eliminated. It is not necessary to carry large stocks of castings on hand over a period of time long enough to allow them to " season."

In one case, a machinery manufacturer's inventory was actually reduced from $750,000 to $60.000 by the substitution of welded steel for cast iron in his product.

The reduced cost of making changes in design and the elimination of stocks of obsolete parts are other obvious advantages. In many cases it is possible to cut down the amount of machine work necessary, and actual experience has shown that the amount of floor space required for a given output is also materially reduced.

Cast iron has been used so extensively because of the relative ease with which it may be cast into a predetermined shape. For this reason, engineers have overlooked its fundamental unsuitability for many of the purposes for which it is used.

Now that the arc welder has made it possible to economically fabricate standard steel shapes into any desired form, the last reason for the continued use of cast iron for many purposes has disappeared. This does not necessarily mean that many of the iron foundries will go out of business. There is no reason why the iron founder should not adopt the new process and turn it to the advantage of his customers and therefore benefit his own business. In fact, this would seem to be the logical thing to do. Industrial history proves that the greatest successes have been achieved by men who were quick to see new developments coming and had the vision to apply such developments to their own products.

There are also plenty of examples in history to prove that those who are most affected by great changes are usually the last to see them coming. The builders of wooden ships scoffed at the first iron vessel and the buggy-maker laughed at the first automobile, but neither the wooden shipyard nor the buggy factory ranks among the leading industries to-day.

Arc Welding vs. Riveting

It is safe to say that arc welding may be substituted for riveting in every case at an appreciable saving in cost. The new process has already made great strides in the manufacture of steel storage tanks and in other lines in which there are not any artificial obstacles in the form of official codes of rules and regulations governing methods of fabrication. Where such codes exist, as in connection with pressure vessels and steel buildings, for instance, progress is necessarily slower.

One does not need unusual vision, however, to foresee the gradual elimination of the rivet, from even the most jealously guarded fields, by means of the economic pressure exerted by the new process. The savings to be effected by the substitution of arc welding for riveting are many, and are both direct and indirect. Riveting is a complicated, costly and clumsy process. Every joint in a riveted structure must be carefully figured out in detail in the draughting room and every rivet hole carefully located in the shop and matched up with the holes in the various pieces which are to be joined together. Every member of the structure is

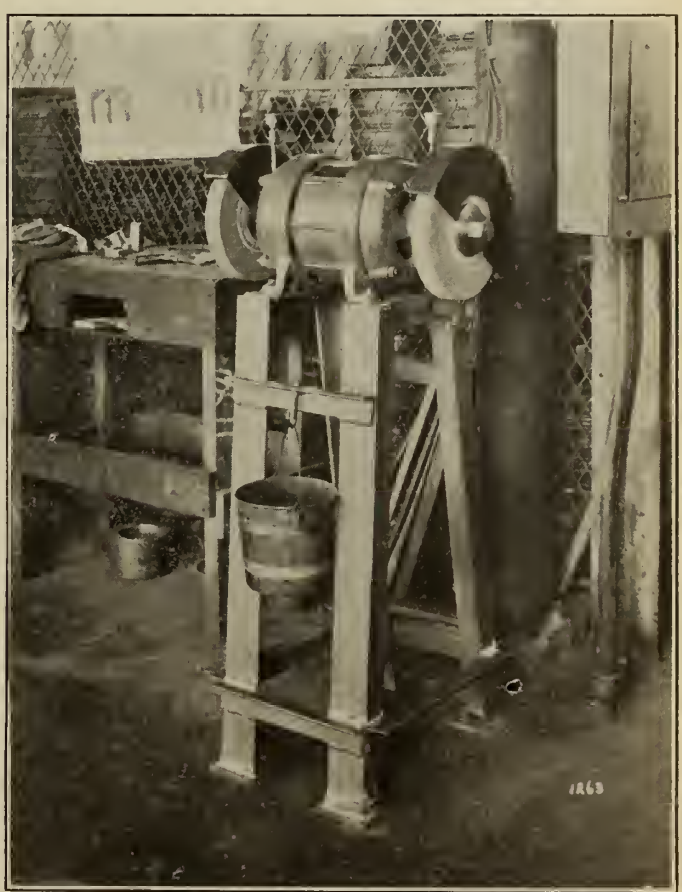

Figure No. 4—Steel Stand for Motor-Driven Grinder. Lighter, Stronger and Cheaper Than Cast Iron.

Figure No. 5—Special Automatic Spot-Welder; Frame Made of Welded Steel.

weakened by the amount of metal removed in making rivet holes.

Welding adds metal instead of removing it. Therefore, it is quite practicable to make a welded joint which is considerably stronger than the pieces joined, or, in other words, a joint having well over 100 per cent efficiency. A slight study of the theory of welded joint design makes this obvious, and it has been proved many times by practical tests.

Possibly the largest welding contract hitherto undertaken is the fabrication of the 90-mile steel pipe line for supplying water to the city of Oakland, California. This contract was let for arc welded pipe at a saving of some $3,000,000, or 40 per cent, as compared with riveted pipe. This saving may be considered as typical rather than exceptional and may be duplicated or even exceeded on most work involving the joining together of pieces of steel hitherto accomplished by the process of riveting.

Some progress has been made in the erection of structural steel buildings by arc welding and entirely without the use of rivets. One of the most striking examples was the erection of a large gas-holder with all the usual auxiliary steel work in Melbourne, Australia. The engineers responsible for this work investigated the matter of joint design very thoroughly and compiled a great amount of valuable data on the subject which is available to anyone interested. The Bureau of Standards at Washington has made some fairly extensive tests of welded structural steel members, and many of the universities have done likewise. It is no longer true, therefore, that there is no unbiased and authoritative information available as to welded joint design and the relative strength of welded and riveted joints.

One objection often raised to the use of welding is that it is impossible to determine the strength of a welded structure without destroying it. There is some truth in this, but surely it is also true of structures put together by any other process. The ultimate strength of any building is not really known until an earthquake or a hurricane of exceptional violence comes along and proves that they were not strong enough. It is certainly possible by the scientific use of arc welding to develop the full strength of the steel in any structure and so make the completed building considerably stronger than by any system of riveting that could be devised, at the same time effecting considerable savings in cost.

Many engineers seem to feel that the process of welding has a harmful effect on the physical structure of the steel. There is possibly some foundation for this belief. Here again it depends on whether the welding is done in a scientific way or by haphazard, rule-of-thumb methods. There is plenty of evidence to show that it is quite commercially practicable to make welded joints which, when tested to destruction, will not fail either in or anywhere near the weld.

In the case of the Governor's bridge in Toronto, the specifications called for joints to be made 25 per cent stronger than the steel bars which were joined. This was done without any great difficulty and, although the entire design of this structure hinged on the use of arc welded steel, the total cost of the welding was only about 1½ per cent of the value of the contract. The steel consisted of 2½-inch diameter round bars of special steel having an ultimate tensile strength of 92,000 pounds per square inch and the joints were certainly more difficult and costly to make than would be the case with standard structural steel members.

Arc Welding in the Tool Room

Of the many fields of usefulness open to the arc welder, there are few in which the striking economies to be achieved by the process can be more readily demonstrated than in the tool room. The tool room in the average modern manufacturing plant is generally accepted by the cost department, with more or less resignation, as being something of a paradox, and a paradox which it cannot control, much as it would like to do so.

The tool room produces the jigs, dies and fixtures of various kinds which enable the rest of the plant to function efficiently and cut manufacturing costs down to a small fraction of what they would otherwise be. The tool room itself, however, is the one place in which costs cannot be controlled. Here the most highly skilled mechanics have practically a free hand as to the methods which they use and the time taken to produce a given article. These mechanics are very often men who received their training in European countries, and are really something more than

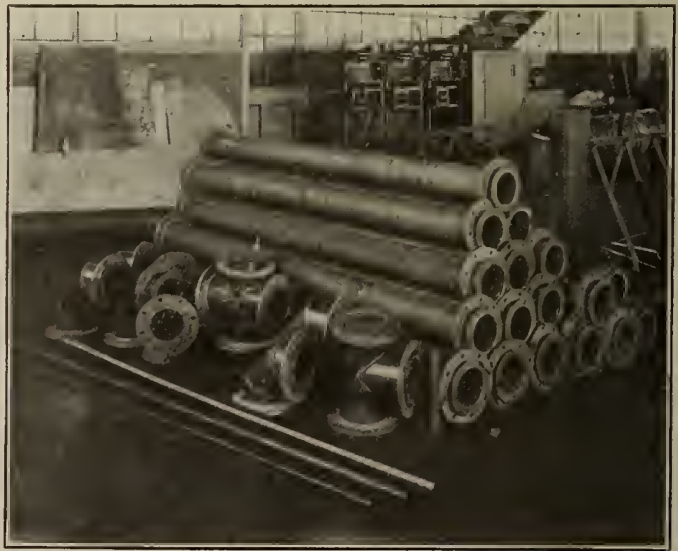

Figure No. 6—Arc Welded Pipe and Fittings Made of Stainless Steel. This is 6-inch Pipe with a Chromium Content of 28 Per Cent. This High Chromium Alloy Can Be Welded Very Successfully.

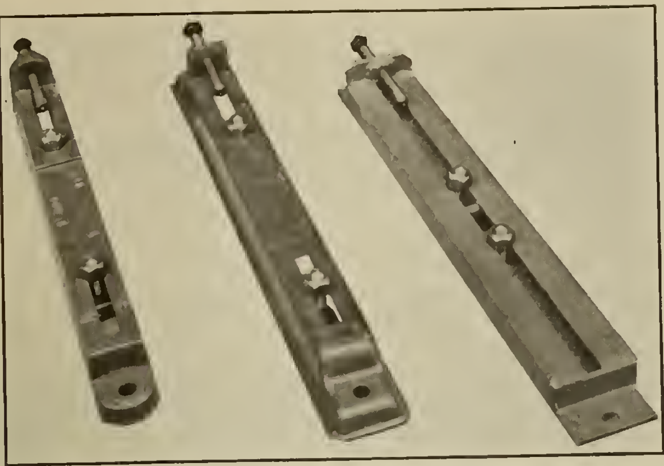

Figure No. 7—Motor Base Rails.

Cast Iron		Pressed Steel		Structural Steel	
Material...	$1.07	Material...	$ .66	Material...	$ .44
Labour....	.05	Labour....	.08	Labour....	.29
Total....	$1.12	Total....	$ .74	Total....	$ .73

mechanics. They are intelligent and highly skilled craftsmen who make fine tools because they like to make fine tools. Unfortunately, they often insist on making fine tools for operations which could be performed just as well with tools which could be made at one-tenth the cost.

In many plants the tool room cost is a very heavy item indeed. Any slight change made in one operation on the product may mean changing tools and fixtures all along the line. It may mean complete new fixtures for some preceding or subsequent operation. This causes delay in getting into production and entails large outlays of cash for skilled labour and supervision in making the changes. If production must be continued during the change, while the tool room is doing its job according to European standards of thirty years ago, the cost of the product usually mounts rapidly and may for a time exceed the selling price.

In a typical factory, it was calculated from carefully compiled data that the time required for making such changes in the product was cut by 90 per cent by the use of arc welding in the tool room. The conditions in this plant were easy as compared with a plant in which an entirely new product is to be turned out. Quite apart from the general saving of time in the producing departments of this plant, as distinct from the tool room, a careful comparison of a representative set of welded fixtures with a similar set made according to the old methods showed the cost of the former to be $175 as against $2,800 for the latter.

The fixtures used in the plant of a well-known manufacturer of washing machines for the purpose of holding the frames while spot-welding were made at a cost of $35 each as against an estimate of $625 each for making the same fixtures by the old methods.

Fixtures used in the manufacture of a welded steel joist were made at a cost of $130 each as against $1,250 each for similar fixtures previously made.

Instances of this kind could be quoted in great number, but perhaps the most striking is the case which occurred in the plant of a large and well-known factory producing telephone apparatus. Fixtures were to be made for use in the welding of machine switching frames. A complete set of fixtures was turned out by the foreman welder at a cost of $85. These were, however, regarded as temporary fixtures, and the tool design department and the tool room undertook to furnish permanent fixtures by the usual methods. These permanent fixtures when finished cost $15,000, but were never quite as satisfactory in operation as the welded fixtures which had cost only $85.

So far, however, it is only in a very few plants that electric welding has penetrated to the tool room. The highly skilled tool-maker still thinks in terms of riveting or bolting for joining two pieces of metal together, or, what is considerably worse, he thinks of cutting a tool or fixture out of a solid block of metal, whereas arc welding offers a cheap and ready means of putting various pieces of metal together to accomplish exactly the same result.

In many cases dies which have become worn in service may be saved from the scrap heap by having the worn surfaces built up by the arc welder. By judicious selection of a suitable welding rod it is possible to deposit metal of almost any desired degree of hardness, and a welded die may be subject to the usual heat treatment afterwards with good results.

There are, of course, limitations to the use of the process in this field. It is a fundamental characteristic of the metal deposited by the arc welder that it is a cast metal and does not have the property of ductility to the same degree as the forged material from which many die blocks are originally made.

It is now generally recognized by manufacturers that in an era of falling prices and shrinking dollar volume of sales an industrial enterprise, to survive, must reduce costs by the use of more efficient methods. The introduction of arc welding into the tool room offers the opportunity to very materially reduce expenses in an important department which is generally regarded as enjoying a special immunity in the matter of costs.

Incidentally, it has been found that it tends to eliminate a great deal of lost motion, friction and circumlocution between the various departments of a factory. The engineering department usually designs jigs, fixtures, dies and such special equipment as cannot be purchased in the open market. When the drawings are made the engineering department turns the job over to the tool room to make, and that is frequently the signal for the commencement of a three-cornered wrangle between these two departments and the production department which has to use the jigs when made. Much time is lost in this way, and if the jigs or fixtures do not work satisfactorily when made each department blames the other for the trouble.

Table No. 1—Shearing Values for Welds and Equivalent Size of Rivets.

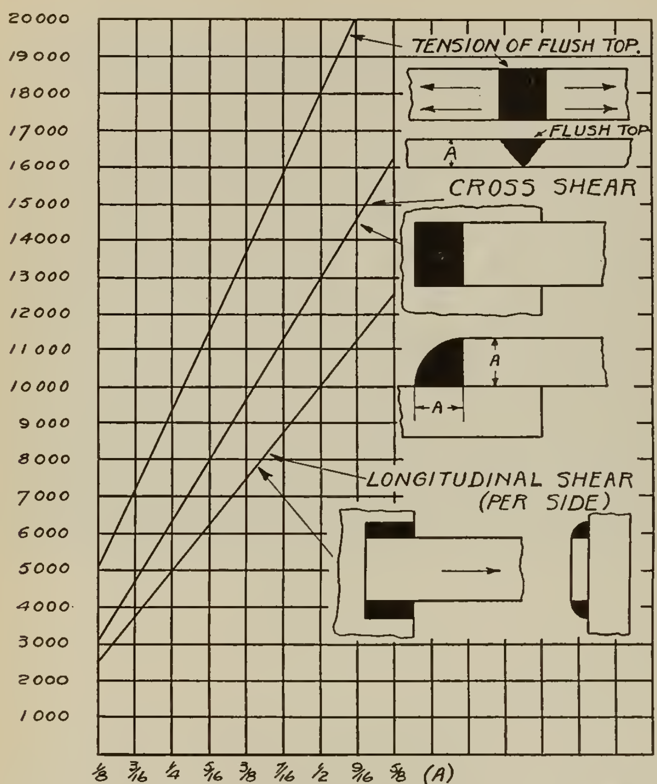

Figure No. 8—Rupturing Force Per Linear Inch of Weld.

In many cases a fixture could be made by welding, to a rough sketch at a trifling cost, and then, if necessary, an improved design worked out from the fixture in actual use.

Arc welder equipment costs little enough, as compared with its wonderful field of usefulness and with the cost of ordinary machine tools, such as lathes, drills, milling machines and planers which are usually purchased readily enough when the tool room requires them.

The arc welder is not a difficult tool to use. Any mechanic as intelligent and skilled as a tool-maker can learn how to operate it quite satisfactorily in a very short time. Some tool-makers are naturally conservative in their ideas and inclined to be prejudiced against innovations of this kind. Generally speaking, however, they will see that their prosperity is bound up with that of their employers and that in times such as the present keen competition makes it imperative to take advantage of such economies as the arc welder offers.

At the present time some well-known firms are using the arc welder extensively in their tool rooms, and the results they are getting would seem to make it certain that the practice will spread rapidly.

Arc Welding of Alloy Steels

Interesting developments are looked for in the near future in the direction of the more extended use of rust-resisting or " stainless " steels and other special alloys which are developed for particular purposes.

It has been demonstrated that the high chromium alloy which is now being turned out in large quantities by several mills can be welded by the electric arc process very successfully indeed. On account of the relatively high cost of this alloy, it is of the utmost importance that full advantage should be taken of the cheapest possible method of fabrication.

The welding of high, (14 per cent), manganese steel has also been carried out with entire success and great economies in connection with such applications as the building up of crusher jaws, switch points and cross-overs in railway tracks and other parts manufactured from this extremely hard and expensive metal.

There is ample evidence to prove that it is quite practicable to obtain a deposit or weld metal of almost any desired analysis and characteristics. At the same time, it is obvious that arc welding is in its infancy and that there is a vast and interesting field for research open to electrical and mechanical engineers, metallurgists and others.

Need for Official Recognition

There is undoubtedly a great need for official recognition and acceptance of the welding process by engineering societies and public authorities generally. There is need for a code of rules and regulations on welding similar to the codes which have long been in existence for riveting.

The economic reasons for the increased use of the arc welding process are so strong that progress is sure to be rapid, although it may be delayed by tardy official recognition of the process.

Oil Paints and Their Application

Some Practical Notes on Materials Used and Methods to be Adopted to Obtain the Best Results under Various Conditions

A. K. Light, B.Sc.
Chemist, Department of Public Works, Ottawa.

Paper read before the Ottawa Branch of The Engineering Institute of Canada, April 7th, 1927

In the following paper the writer has endeavoured to treat the subject from an entirely practical point of view, and has therefore omitted considerable technical discussion and given a brief explanation of the materials used for oil paints and the methods to be adopted to obtain the best results from the application of these paints under various conditions.

A good oil or varnish paint should have a high degree of opacity or hiding power, that is, it should not take more than three coats to obliterate the darkest background upon which it may be applied; its pigment should be ground to a very fine state, the more nearly colloidal the better, in order to obtain higher opacity, a smoother film, greater covering capacity, greater impermeability of the film to moisture, and longer life owing to greater protection of the oil film to decay from the effects of the weather or actinic rays. A good paint should not cake or settle to a hard mass in the container, which is another reason for greater fineness; it should brush and spread well, giving a smooth film free from brush marks, but should not be so thin that it will run or sag; it should dry in a reasonable time—oil paints should be dry to touch in from eight to ten hours at 70°F., varnish paints should be dry to touch in from four to six hours and hard dry in twenty-four hours at the same temperature; and it should form, on drying, a film that will resist as long as possible the conditions to which it is to be exposed. No paint, however well made or however high grade its constituents, will serve all purposes. A paint that will stand well under dry conditions would be useless under moisture, and a paint designed for interior purposes would fail utterly when applied on an exterior surface; a paint intended for mural decoration would not last any time if used on a floor. Thus, paints have to be designed and applied with a view to their ultimate purpose, and it is hoped that consideration of what follows may help to shed a little knowledge on this subject.

Pigments

Paint is a suspension of a pigment, or pigments, in a vehicle. The use of pigments is necessary to furnish colour and opacity for obscuring the background, to promote hardness, impermeability and weather-resistance in the film, and, by the formation of a two-phase solid-liquid system, to allow the application of thicker films than would be possible with an unpigmented vehicle.

Pigments may be divided into two classes, (1) basic or tinting pigments and (2) fillers and extenders. There is no hard and fast division between the basic and tinting pigments, as some may be used for both purposes. The important pigments used in paints are the following:—

White— White lead, zinc oxide, lithopone, antimony oxide and titanox.
Yellow—Chrome yellows and ochres.
Red— Red lead, iron oxides, (indian, venetian and turkey reds), and lakes.
Brown—Siennas, umbers and iron oxide.
Blue— Prussian, ultramarine and cobalt blues and lakes.
Green— Chrome greens and chromium oxide.
Black— Black oxide of iron, graphite and the various lamp, drop, ivory or bone and carbon blacks.

The fillers and extenders chiefly used in paint making are barytes (barium sulphate), asbestine, silica, china clay and whiting.

Of the white pigments, lithopone is the only one not used to any extent for exterior work. It may be used, however, providing it is ground with a strong vehicle, such as a good exterior or spar varnish, or else in combination with about 50 per cent zinc oxide. The same holds true, though perhaps to not such a great extent, in the case of antimony oxide and titanox. The white pigments most commonly used for outside work at the present time are white lead and zinc oxide, usually a mixture of the two in the proportions of about 70 per cent of the former to 30 per cent of the latter. Antimony oxide and titanox are newer pigments, but are being quite extensively used and are giving very good results. The so-called active pigments, white lead and zinc oxide, give tougher and longer-wearing films than the other white pigments due to their chemical reaction with the oil. As stated above, white lead and zinc oxide should be used in combination for all ordinary exterior purposes. In places, however, where the film is liable to come in contact with sulphur or sulphides, white lead should not be used owing to its tendency to turn black, (formation of lead sulphide). In such a case it would be better to use one of the newer pigments, antimony oxide or titanox, together with about 30 per cent zinc oxide. In damp places, or under water, the amount of zinc oxide with the white lead may be varied from 50 per cent upward, or zinc oxide alone may be used, depending on the conditions, as the hard film formed by this pigment resists the action of moisture well. It may be noted here that from the results of recent experiments it has been shown that zinc oxide is the most resistant of all white pigments to actinic or ultra-violet rays. These rays are one of the greatest causes of deterioration of paint films on exterior exposures, and therefore the inclusion of from 10 to 30 per cent of zinc oxide in all white or light coloured paints intended for exterior use is claimed to extend the life of a paint film to a large degree.

Most of the coloured pigments are used for tinting the white pigments to the different shades of greys, greens, buffs, creams, etc., which are used for body colours for exterior and interior painting. It is a well-established fact that tinted paints resist weathering and the actinic rays for a much longer time than white, and in this respect the darker colours or shades usually wear better than the lighter ones. However, the choice of colour is purely a case of individual taste, which as a general rule runs to the lighter shades, they being brighter and more cheerful.

Besides being used as tinters, many of the colours, such as the ochres, chrome greens, some of the iron oxides, and blacks, etc., are used alone as trim colours on the body colours mentioned above. Certain other colours, such as chrome yellows, red lakes, blues, etc., owing to their brightness, are used extensively for signals or signs, or special purposes for attracting attention.

Of the coloured pigments, red lead, iron oxide and graphite find extended use in the protection of metals, red lead being the best for this purpose, and the other two about equal. Present practice is to use 15 to 20 per cent of zinc oxide with iron oxide to give a harder and better wearing film. This is due to the active zinc oxide uniting with the oil and to its resistance to actinic rays, as already mentioned. Red lead is one of the active pigments, and the strength which it imparts to the paint film is due to its union with the oil. Red lead for paint purposes should contain at least 96 per cent Pb_3O_4, true red lead, the remainder being PbO, litharge, and should be ground extremely fine. The ordinary so-called painters' red lead contains about 15 to 20 per cent litharge and is fairly coarse. This litharge and the coarse particles are the cause of the serious objections made in the past to red lead paint. The litharge caused the paint to become viscid and ropy, and thus hard to apply, and if allowed to stand for any length of time made a hard, compact, heavy, cement-like solid in the bottom of the container. The coarse particles in it caused runs and uneven lumps and streaks, spoiling the appearance and wearing qualities. With the appearance of the present-day high grade red lead, which runs as high as 98 per cent true red lead, all the objections against red lead are done away with and first-class results are obtained.

Extenders and fillers have little or no colouring capacity, and for this reason find a useful place where consistency is desired without changing the colour. Of these materials, barytes, asbestine and china clay find their greatest use in reducing many of the coloured pigments which in themselves are too powerful to be used alone in paints. Whiting is mostly used in making putty and cold-water paints, but is not a good extender for oil paints owing to its poor wearing qualities. Silica, due to its hardness, is considered an ideal extender, but owing to the difficulty of grinding it to a sufficient fineness, and the heavy abrasive wear it causes in the paint mills, is not used as much as it might be. It finds its greatest use in wood fillers and in some classes of paint where "tooth" is required.

Vehicles

The vehicle is the most important part of a paint, and may be of three parts,—(1) the oil or varnish which binds the pigment particles together and the film to the surface upon which it is applied, (2) the volatile thinner which gives the paint the necessary working qualities, and (3) a liquid or japan drier which may be added to hasten the drying process, especially where an oil, such as raw linseed oil, containing no drier is used.

For all ordinary purposes, raw and boiled linseed oils and china wood oil are those chiefly used. In certain cases where the surface to be painted is to be subjected to considerable wear it is advisable to use good long-oil exterior, or spar varnish in the vehicle. The use of all these various oils and varnishes will be discussed under the section on "Paint Coatings." The use of other drying oils, such as perilla, fish or soya bean, should not be attempted by the painter unless he is an expert, as they require very careful manipulation. As a rule, they are only used by manufacturers of paint for special purposes.

The volatile portion of the vehicle may be pure gum turpentine, wood turpentine or one of the turpentine substitutes, such as mineral spirits or coal-tar naphtha. Present practice has shown that the substitutes produce just as good results as pure gum turpentine, and they are much cheaper. In the section on paint coatings, where volatile thinners are mentioned, any of the above may be used.

Liquid or japan driers should be used with great caution, as an otherwise good paint may be ruined by their improper use. They should not be used by anyone who does not thoroughly understand their action. Boiled linseed or china wood oils and the long-oil or spar varnishes all contain sufficient driers to cause them to dry within a reasonable time. If raw linseed oil is used only as indicated under "Paint Coatings," no drier need be added to it.

Preparation of Surfaces for Painting

Woodwork

All surfaces to which paint is to be applied must be thoroughly clean, dry and free from grease. Many woods, such as yellow pine, spruce and cypress, contain resins that tend to destroy any paint put upon them. Exposure of exterior woodwork to the weather for about six months prior to painting would bring these resins to the surface, where they would be either washed away or hardened, leaving the wood in a much better condition for painting. However, it is not always advisable to leave wood thus exposed for any length of time, as temperature changes, alternate rain and sunshine, etc., are liable to cause cracks or otherwise injure the wood.

As an alternative for this treatment, several other methods for both exterior and interior woodwork are resorted to by painters. The vehicle of the priming coat may be made up of equal parts linseed oil and turpentine, or benzol, (coal-tar naphtha), may replace 30 to 40 per cent of the turpentine. This vehicle is claimed to dissolve the surface layers of resin and allow the paint pigments to penetrate into the fibres of the wood and prevent the resins being forced to the surface. Knots and very sappy woods are often treated by the application of one or more coats of shellac varnish or with a brush coat of turpentine not more than one hour before the application of the priming coat.

Another good method, although entailing more work and expense, is to use a mixture of equal parts by weight of white lead in oil and pure dry red lead. The latter is mixed in a vehicle of two parts of raw linseed oil and one part of turpentine, the white lead is incorporated, and then the mixture thinned with more of the vehicle to a thin consistency and applied as a priming coat, which should be well brushed in. All these treatments are likely to fail, however, in the case of improperly seasoned wood, especially on a southern exposure. A method which has met with a great deal of success under all conditions is to coat all knots, or sappy, or resinous parts of the wood with one or more coats of aluminum bronze paint previous to the application of the priming coat.

In the case of woodwork which has previously been painted, the condition of the old paint must be taken into consideration. If it adheres firmly to the wood it may be regarded as a priming coat after first removing, by washing, brushing, scraping or sandpapering, all dust, soot or loose scales. For surfaces that require washing it is better not to use soap unless it is thoroughly rinsed off, as soap will leave a greasy film detrimental to the adhesion of the paint to the surface. Washing soda or tri-sodium phosphate are recommended instead of soap, and even with these several rinses are most advisable, including at least one wash with weak vinegar.

If the old paint is loose or badly checked or cracked, it is better to remove it. This may be done most efficiently by burning it off with a torch, which causes the paint film to soften so that it may be readily scraped off. Great care must be used to prevent excessive scorching of the wood, which is difficult to prevent on other than flat surfaces. Where the torch is not applicable, one of the following solutions may be applied hot with a fibre, (not bristle), brush, or swab, until the paint softens sufficiently to be removed with a scraper or wire brush:—

(*a*) One pound caustic soda to two gallons water
or (*b*) One pound tri-sodium phosphate to two gallons of water
or (*c*) Two pounds ordinary laundry soap, one quart ammonia and one pound saltpetre in two gallons water.

These solutions should be used with great care, as they are very injurious to the skin and clothing. If the alkalies are left in the wood they will damage the paint film when it is applied, and for this reason these treatments should be followed by a thorough washing with water, then one of strong vinegar and then two more of clean water. After the wood is thoroughly dry it must be well sandpapered, as these treatments raise the grain of the wood, thus making the surface rough.

A number of paint removers on the market consist of mixtures of benzol, acetone and methyl alcohol in which are often dissolved certain waxes to retard the evaporation of the solvents. Any waxy residue left from the use of these types of paint removers must be thoroughly cleaned off the work by washing with gasoline. These removers, while doing their work well, are costly, due to the high price of their ingredients and the large quantity required owing to rapid evaporation. Care should be taken in their use owing to the toxic effects of benzol and methyl alcohol.

Plaster, Cement and Brick

Old surfaces must be thoroughly washed with washing soda and water to which a little ammonia may be added in order to remove soot, grease and other dirt which collects on them. If the surfaces have been previously whitewashed or calcimined it is absolutely necessary to wash this all off before preparing the surface for painting.

All cracks should be wetted and filled with cement mortar or plaster of paris. Plaster of paris filling is liable to be more porous than the surrounding wall, and therefore should be given one or two preliminary applications of the same paint that is to be used on the whole surface. In the case of brick surfaces, all loose plaster and crumbling brick must be removed by thorough washing and scraping and any mould cleaned off with a solution of equal parts muriatic acid and water.

After the surface is thoroughly clean it must be neutralized by treating it with a solution of aluminum sulphate or zinc sulphate, which not only neutralizes any alkali but also helps to fill the pores with the products of the reaction that takes place. The sulphate solutions are made by dissolving two pounds of either of these commercial salts in one gallon of water. Glue size should never be used to fill the pores of the surfaces previous to painting, as is often done, as it has a tendency to take up moisture to the detriment of the paint film. To fill the pores in plaster or cement use ordinary paint, or the paint intended to finish the job, thinned with linseed oil to about half its original consistency. In the case of brick surfaces, it is customary to apply a preliminary treatment of boiled linseed oil thinned with turpentine. No paint of any kind should be applied to surfaces of this type until they are absolutely dry, as any moisture remaining in the wall or floor will eventually come out, causing the paint film to blister.

Metals

All metals, especially if the surface is smooth and polished, present difficulties in painting, as the film is liable to peel off, due to the lack of firm anchorage or to the presence of a very thin film of grease. The latter may be removed by thoroughly cleaning with benzol or gasoline. The best method for removing rust or dirt is by sand-blasting. Tests carried out in the United States have conclusively shown that paint applied to metal surfaces which had been cleaned in this manner adhered much more firmly to the metal and thus had longer life. However, it is not always possible to use the sand-blast, owing to the special equipment required; or economical from the standpoint of the size of the job. In such cases rust or dirt must be removed down to the base metal by means of scrapers, wire brushes or sand paper. Sandpapering any smooth metal surface increases the anchorage for the paint to a great extent, and should always be done. Of special interest here might be noted the invariable tendency of steel structures to rust at the rivets and edges of the members. In fact, the rusting in the former case often reaches such serious proportions that it develops sufficient expansive force to rupture the connecting rivets, which have to be renewed from time to time, especially in the case of bridges. The cause of this rusting is claimed to be due to shrinkage of the paint film with subsequent cracking at these points. As a means of perhaps preventing this tendency, to some extent at least, all rivets and angles should be given an extra coat of paint following the priming coat and previous to any other coats. Frequent inspection, and thorough cleaning and painting before such rust progresses to a marked degree, is recommended as a further preventive.

Galvanized iron and zinc are particularly difficult to paint on, but may be made to hold paint if first treated with a solution of four ounces of copper sulphate or eight ounces of ammonium chloride, (sal ammoniac), to a gallon of water. The copper sulphate solution should be made in a stoneware vessel, and should be applied in a thin coat to the metal surface and allowed to dry overnight. The ammonium chloride solution may be mixed in any type of container and after application should be washed off with clean water.

Paint Coatings

Priming Coats

The purpose of the priming coat is to fill the pores of the surface being painted, and to furnish a foundation on which the subsequent coats may be applied. For this reason it should be composed of good materials and applied with great care, being brushed in thoroughly so that it is evenly distributed with no tendency to run. Many paint failures may be traced directly to faulty priming, especially those where considerable peeling occurs. The composition of the priming coat, as a rule, should be the same as the succeeding coats, except that it contains considerably less pigment. It should be made thin, and the replacement of some of the oil by a volatile thinner makes a flat and harder surface.

The reason for using a thin paint of this type for priming becomes apparent when it is to be applied to a very absorbent surface like wood. Owing to the capillarity of the wood cells it is necessary to apply a coating which will penetrate the grain of the wood to form a "key" for the next coating, but which will not at the same time, when once dried, be so reduced in its oil medium or "binder" by that capillarity that it will powder off. This end is attained by pigmenting the paint more lightly in order to ensure more available medium, and at the same time reducing the viscosity and thereby increasing the penetrative power by diluting the oil medium with a volatile thinner.

A priming coat for woodwork may be made with twenty pounds of white lead oil-paste thinned with one gallon of equal parts boiled linseed oil and volatile thinner. A mixture of two parts white lead to one part red lead may be substituted for all white lead, and is used a great deal for exterior work.

For plaster walls the paint to be used for the finishing coat may be used as a primer after thinning to about half consistency with boiled linseed oil. The new flat wall paints may be used for priming as well as finishing, and when used for the former purpose should be thinned with about one quart boiled linseed oil to one gallon of the paint.

Concrete surfaces are best primed with a paint made in the proportions of ten pounds of white lead paste to one gallon of boiled linseed oil, unless previously treated with aluminum or zinc sulphates, when it would be permissible to prime with the finishing paint.

For brick, the priming may be done with boiled linseed oil, as mentioned before, and on this any desired paint may be used.

No better paint than high grade red lead is known for adhering to and protecting metal work. A priming coat for metal surfaces is made by mixing twenty-five to thirty pounds of pure, dry, high grade red lead in one gallon of boiled linseed oil and thinning with one-half pint of a volatile thinner.

All holes and cracks should be filled with putty after the priming coat is thoroughly dry and before any other coats are applied.

Intermediate Coats

All surfaces should have at least one intermediate coat between the priming and finishing coats, and, for best results, especially on new work, two or three are recommended. All intermediate coats should contain enough thinners to cause the paint to dry flat, in order to furnish a good foundation for the next coat. An intermediate coat may be of the same kind of paint as an oil finishing coat with part of the oil substituted with a volatile thinner. As the thinners have roughly twice the thinning power of oil, only half as much thinner should be added for the quantity of oil being replaced, otherwise a smaller amount of pigment per unit area of surface will result, thereby producing a weaker film. All coats should be well brushed and spread, and it must be borne in mind that a larger number of thin coats, well applied, will give far better results than a few thick coats slopped on in any fashion. Ample time should be allowed between coats for thorough drying, and paint should be applied under warm, dry conditions whenever possible. The colder and more moist the surroundings the longer the time required for drying. As an example, most paints are made to dry to touch in eight to ten hours at 70°F., but it has been proven that at 60°F. the same paint takes about twenty hours to dry, or double the time, or at a still lower temperature, especially if the humidity is high, the paint may take from two to three days or longer to dry.

Finishing Coats

The finishing coat is the one that has to stand wear and tear and weathering, as well as give a pleasing effect to the painted surface, and for this reason great care should be exercised in its choice and application.

In all cases, except perhaps for interior mural decorations, it should dry with a high gloss, as a high glossy surface is much more durable than one which has a dull finish. This may be accomplished by leaving out all, or nearly all, of the thinners, or by substituting a good long-oil exterior varnish for the thinners and about 10 per cent of the oil.

Ordinary finishing paints to be applied to exterior surfaces should contain little or no thinners, the vehicle consisting of equal parts raw and boiled linseed oil. For floors, both exterior and interior, a durable hard-drying varnish should replace the raw linseed oil. For finishing paints that will be immersed in water or subjected to excessive dampness the vehicle should consist of the best grade spar varnish only. For interior woodwork durability is perhaps not as essential as appearance, and paints may be chosen accordingly. For white or light tints to be used in interiors little or no linseed oil should be used, owing to its tendency to yellow; china wood oil may be substituted. A little china wood oil varnish may be added to interior paints to give a higher gloss. For high grade interior work, good quality enamels may be used in any desired tint.

Interior plastered walls may be finished either with the new flat, washable wall paints which are usually made with lithopone, china wood oil, a large percentage of petroleum spirit, and tinting colours, or they may be finished with the glossy paints mentioned for interior woodwork. Cement and brick walls may be finished in a similar manner to woodwork, having due regard for the exposure, etc.

For metal work, as already stated, no paint can be recommended more highly than red lead for all coats; the final coat being tinted brown, black or grey to suit the taste.

Mixing of Paints

Having briefly described the various important materials used in paints and the best ways of using them, it might be in order at this point to say a few words as to the methods of mixing these ingredients in order to produce paints.

In the first place, it is an utter impossibility to make thoroughly homogeneous mixtures of oil and dry pigment without the use of a special grinding mill such as used by paint manufacturers. For this reason this part of the operation should be left to them, and the desired combination of oil and pigments should either be purchased in the form of a mixed paint ready for application or the various pigments may be obtained in the form of pastes, which the purchaser may dilute and blend with oil and thinners to meet his needs as regard consistency, colour and use. This latter method is to be recommended, as by it a check may be made on the pigments, as well as the oil, varnish or thinners. Once a paint is mixed it is practically impossible for an analyst or anyone else to tell much regarding the vehicle portion, which is the really important part of the paint, but by buying the ingredients separately each one may be examined for quality.

Other advantages of buying paints in paste form show themselves in the economy of transportation, the possibility of storage without loss by evaporation, excessive formation of skins, or hard settling in the containers, and the fact that they may be thinned down to a working consistency with any medium to suit the conditions of application, and only sufficient need be mixed at any one time to meet immediate requirements. Except in the case of certain colours which are such complicated mixtures that they require special mixing, all the ordinary paints may be made by purchasing the necessary pigments in paste form, and, after breaking them up with oil, mixing them thoroughly to obtain the shade or colour required.

In mixing paints, all the paste ingredients should be broken up to a thick creamy consistency with oil, and then incorporated one at a time with the basic pigment by thorough stirring. When the paste colours are thoroughly blended, the necessary oils, varnish or thinners may be added in the order named, and in accordance with the requirements of the surface to which the paint is to be applied. A paint made up in this manner should be strained before use through muslin or a fine wire strainer, in order to remove any skins or lumps of paste that may not have been properly broken up and would have a tendency to cause streaks.

Different colours and shades may be produced by the blending of certain standard colours which may be readily purchased in paste form. The blending of these colours cannot be made by any hard and fast rule, as different samples of the same colour vary in strength and tone, so that the same quantity will not always produce the same results. However, the following illustrations are given as a rough guide to the shades usually met with:—

A white pigment and lampblack give a series of greys varying in depth of colour according to the proportions of black and white. If this grey is considered "cold," the addition of a little yellow ochre or sienna will make a much "warmer" shade. Burnt umber used in the place of the ochre or sienna will give a series of grey drabs.

A white pigment and yellow ochre give a series of buffs, and the addition of a touch of venetian red to a light buff gives cream. Ivory is best produced by the addition of a very little medium chrome yellow to white. Yellow drabs or drab stone colour may be produced with white, yellow ochre or chrome yellow, and burnt umber.

A series of browns may be produced by mixing, in varying proportions, indian or venetian red, lampblack and yellow ochre. Brown drabs will be obtained by the addition of white to the above.

Brick reds are produced with yellow ochre, venetian red and white, the colour depending on the proportions used.

Various blues are obtained by tinting white with either ultramarine or prussian blues.

Chrome greens are obtained in many shades, which may be further modified by the addition of white, black or some other colour. For instance, pea green is obtained by tinting white with medium chrome green, or apple green by adding a little chrome yellow to pea green. Lampblack and dark chrome green give bronze green, or a richer shade may be produced by adding ivory black and a little raw umber to medium chrome green.

Selection and Care of Brushes

A few words may not be out of place here with regard to the selection and care of brushes. Only the best brushes should be used in order to obtain the best results, and these brushes should be kept in good condition.

For large work, the so-called pound brush is recommended. This is a round brush, with bristles about six inches long when new. Owing to their length, such bristles would be too flexible and it is customary to "bridle" the brush by winding a strong cord for from 2 to 2½ inches on the base of the bristles. This may be removed as the bristles wear down. The object of the binding is to prevent the brush from being too soft and spreading like a mop, its purpose being to rub the paint into the surface and remove the air film and probably a thin film of moisture which adhere strongly to it, especially if it be metal. This is one reason why brushing is preferred to spraying. A new bristle terminates in a fork or feather, that is, it is split up a short distance, and it is this that holds the paint. A good brush should have such bristles of different lengths all through it, so that as it wears down it will still have this necessary quality.

Flat brushes up to 5 or 6 inches wide may also be used, especially for flat surfaces, though it is claimed that round brushes are more suitable for spreading the paint. Small oval brushes with a chisel-shaped end are most satisfactory for painting sashes and other small surfaces.

Brushes for oil paints should be well cleaned after use, though for overnight it is sufficient to wrap them in several thicknesses of newspaper or place them in a jar of water. To clean a brush, wash thoroughly in kerosene or gasoline, and, after shaking as dry as possible, wash with soap and water and finally with clean water. Shake out as much of the water as possible and hang the brush, with the bristles down, to dry. Brushes that have become hardened through not being cleaned after painting may sometimes be made fairly serviceable by immersing them in a mixture of benzol, wood alcohol and acetone, (proportions 5:4:1). After the bristles become loosened wash thoroughly with soap and water as before. If much painting is to be done, it is better to hang the brushes in a pail containing raw linseed oil. Do not allow the brushes to rest on their bristles on the bottom of the pail, but hang them from hooks attached to the side of the pail in such a manner that the bristles are just submerged. As much of the oil as possible should be removed from the brush before it is again used for painting.

The Economies of Painting

All the factors in connection with painting or repainting must be carefully followed, so that not only shall the surface to which the paint is applied be thoroughly protected against destructive agencies, but also that the paint film itself shall give the longest life possible under the conditions to which it is exposed. These factors have been pointed out, but before concluding certain salient features should be emphasized, especially as regards the economy of using high quality paint and good methods of application.

At first sight, the application of paint seems to be a costly matter, and for this reason it is often carried out as seldom as possible with cheap materials and in a slap-dash manner, in order to get it over with the least expenditure of time and money. However, a little thought will bring one to realize that with the present high cost of materials of construction and labour, any means that will help to preserve a structure, at a cost that is infinitesimal when compared with the value of that structure, is worthy of the fullest consideration.

The thorough cleansing and preparing of the surface to be painted is an absolute necessity, as, unless the foundation is good, it cannot be expected that the applied paint, however high grade it may be, will have a maximum life. Moisture, dirt or grease on the surface will prevent adhesion of the film, and thus blistering and scaling will result. Rust should be removed scrupulously, as, even though it may look dry, it holds moisture and carbonic acid, and these act on the metal, forming more rust which swells and cracks the paint film. Once cracked, the film allows oxygen and moisture to come in contact with the metal, and thus more rust is formed, and thus the corrosion goes on. No matter what type of paint coating is applied, rust will form progressively under the film if it once gets started and is allowed to remain.

Choose a paint which is designed for the conditions to which it will be subjected. Whether purchased ready mixed or in paste form, specify the type of pigments and vehicles suitable for the purpose. The pigment should be in a very fine state of division; as a rule, very little should be retained on a 325-mesh sieve, and both it and the vehicle should be high grade.

Do not use cheap paint, for it is more costly in the long run. An inferior paint spreads over less surface, because it is made of greater viscosity, since it is necessary to have a thicker film to get the required freedom from porosity and have fair quality. A free working paint of high durability can be readily brushed out, getting better results with greater covering capacity and much economy of time, which reduces the cost of the job by saving in both paint and labour. The actual cost of the paint is a small item when compared with the total cost of the job; in fact, it runs from about 10 per cent to 50 per cent of the total, depending on conditions, the remainder being the labour cost of preparation and application. Extra paintings are a squandering of money, not simply for the paint, but still more for the labour, which is costly, and it is poor economy to save a few dollars on a paint that will last, say, only one or two years, and have to repeat the high labour cost in that short period, when, by using a good paint, costing only a little more, repainting would not be necessary for three or four years or perhaps longer. As an example, suppose for a certain job 100 gallons of paint at $3.00 a gallon were used. By figuring the cost of the paint at an average of 30 per cent and the labour at 70 per cent of the total cost, we get:—

100 gallons paint @ $3.00	$ 300.00
Labour, 70% of the total	700.00
Total cost of the job	$1,000.00

This paint, judging from its cost per gallon, would probably give service for not more than two years, at which time repainting would be necessary. Now, if a more highly durable paint, costing about $4.50 or $5.00 per gallon, had been used it would have increased the cost of the job by only $150.00 to $200.00, the labour charge being about the same, and at the same time would have given protection for at least three or four years without repainting being necessary. Comparing these figures, we find that in the first case we have a cost of $1,000.00 spread over two years while in the second we have a cost of $1,150.00 or $1,200.00 spread over at least three or four years, which is a considerable saving. These figures are conservative, but they serve to illustrate the statement made above, that cheap paint is more costly in the long run.

In applying paints, take care to brush and spread them well. Brushing, when properly carried out, is far superior to spraying or dipping, though these methods are expedient for certain purposes. Good brushing rubs the paint into the pores of the surface to which it is being applied, thus ensuring a better bond and longer life, and at the same time it spreads the paint into a thin film which dries readily into a tough, durable coating. Thick films form a skin on the surface but remain soft underneath. The skin cannot harden, due to the soft paint under it, and the soft paint takes a very long time to dry, due to the skin over it, and in this way paint which is applied in a thick coating lacks durability and has a tendency to wrinkle and lose its smooth appearance. Thick coatings are thus wasteful, and therefore good brushing and spreading, while entailing a little more labour, is economical, not only by saving paint, but also by producing a durable, long-wearing film.

Finally, at the risk of tiresome repetition, the fact should again be emphasized that a little extra expenditure on the thorough preparation of the surface and the use of high quality paint, suitable to the existing conditions and well applied, will be more than compensated for by the durability and long life of the resulting paint film.

Discussion of Paper on Notes on the Forests of Quebec, by G. C. Piché, A.M.E.I.C.*

Mr. Ellwood Wilson, m.e.i.c.

Mr. Wilson drew attention to the fact that the province of Quebec has for a long time been working towards a definite programme which will put its forest industries on a permanent basis. The establishment of a school for training forestry engineers, mainly for government service, had been an excellent piece of work, and the results attained by the forest nursery at Berthierville and in the plantations at Oka were most noteworthy.

He considered that the problem of transportation was probably the most important one before the wood-using industries to-day, men of skill and technical training being certainly needed for this work. He believed that there was much avoidable waste in woods operations, and was of opinion that the work in the woods should receive the same attention and technical skill as is devoted to mill operations. The provincial government was to be congratulated on its policy of limiting the number of mills in the province in proportion to the capacity of the forests, and he hoped that, for the good of the country, this policy would be thoroughly carried out. He pointed out the great amount of damage that can be done by careless or ignorant operation when the forest is originally cut. Such operations should be carefully planned with reference to keeping the forest's productivity on a sound basis, and this work could only be carried out by men of forest experience. He deprecated the system, so common in the United States and Canada at the present time, of practising forestry in the office rather than in the woods. The author of the paper had accomplished admirable work, one of the most useful features of which had been the education, not only of the government, but also of the pulp and paper manufacturers, to the necessity for adequate fire protection and the benefits derived from proper cutting methods and plans for forest utilization.

With regard to fire protection, Mr. Wilson considered that the province of Quebec was on the whole well equipped for the detection of fires, the weak point, however, being the lack of means of getting men and other equipment rapidly to the fires.

He questioned whether the revenue coming in from forests should be turned over to the general funds of the province, pointing out that the trees which have taken years to grow are the stored-up capital of the country; the return obtained by using these should certainly not be treated as current income. He would like to see the whole of the provincial revenue from the forests put back into the forests, so that these great resources would be guaranteed to us for all future time.

Mr. John Stadler, m.e.i.c.

Mr. Stadler was unable to agree with Mr. Wilson in recommending the reinvestment in the forests of the whole of the revenue coming into the provincial treasury from the forests. He believed that a large percentage of the money derived from forest resources should go back for the improvement and maintenance of that valuable asset, but thought it was too much to ask that the whole amount of the revenue should be so used. He trusted, however, that in the future the government would devote a larger proportion of its forest revenue to the improvement and conservation of this great national resource.

The Hon. Mr. Mercier.

The Hon. Mr. Mercier pointed out that last year over $400,000 was spent in the province of Quebec for forest protection alone, and, taking into account the expenditure of $100,000 a year for reforestation, the cost of the nursery at Berthierville, that of the research bureau, and other similar items of expenditure, the province's annual expenditure on forest work reached a very substantial figure; in fact, for the past three years, the amount put at the disposal of his department for forest work had been from $900,000 to $1,100,000 per annum

While noting these facts, he might say that, in his opinion, this expenditure could be increased with advantage to the country, but it was necessary to bear in mind the many calls on the taxpayer and the legitimate demands of other departments.

Mr. Otto Schierbeck.

Mr. Schierbeck thought that Mr. Piché's paper would give the impression that the operating conditions of Canadian forests were in the hands of highly educated, technically trained men, and that these forests were on the highroad to be operated on the basis of a sustained yield. This, he felt, was too favourable a view, as the profession of forestry engineering was now passing through a stage of competition between the technically trained man and the so-called practical man. The papers presented all showed that many important problems awaited the forest engineer.

While pulp and paper mills were run with a high degree of efficiency, and many improvements were invented and installed every year, forest management, surveys and logging operations in the forests were still largely in the hands of non-technical men, the so-called practical woodsmen, and were carried on to a great extent by rule of thumb along the lines employed by the early settlers. There were some notable exceptions, and he wished to take the opportunity of complimenting Mr. LaMothe on his paper, which showed that in some instances new trails were being broken in introducing engineering skill in the handling of logging operations.

When the first settlers came to Canada, they found a virgin forest, in which when trees died of old age they were replaced by a younger generation. When the settlers began to clear the land and lumbermen started to cut the forests, this natural régime was disturbed, especially as cutting and clearing was nearly always followed by forest fires, so that since the advent of the white man Canadian forests had been reduced by 73 per cent. Of this, 13 per cent represented timber which had been cut and 60 per cent that which had been destroyed by fire. Notwithstanding this well-known fact, people still spoke of sustained yield and annual increment. In his opinion, the only way by which an annual increment could be obtained would be by reinvesting some of the capital which was being taken out of the forests every year.

As regards the work of the forestry engineer in Canada, very little experimental work was being carried on, and little had been done as regards working plans based on continuous yield. In Canadian forestry, practically nothing

* This paper was presented at the Annual General Professional Meeting of The Institute, Quebec, February 16th, 1927, and published in The Engineering Journal, February, 1927.

was known about regeneration, protection against damage from fire was inadequate, and great injury was being done to trees by insects. The study of this important subject was in the hands of a staff of entomologists, totally inadequate as regards number, four men having to cover the enormous area from Halifax to Vancouver.

He considered that the profession of the forest engineer in Canada was as yet in its infancy, his work being hampered by misunderstanding and fear of restriction from lumbermen and pulp mill operators, by the antagonism of the practical lumberman who saw his job disappearing, and by the ignorance of the man in the street, who allowed his natural inheritance to be despoiled at an alarming rate.

Mr. Schierbeck welcomed the series of papers presented at the Quebec meeting as being likely to render great service to the Dominion by helping the newest branch of the engineering profession on its way.

Mr. R. L. Seaborne, a.m.e.i.c.

Mr. Seaborne had read Mr. Piché's paper with great interest, and desired to congratulate him on having put so much emphasis on forest protection and forest management. Mr. Seaborne believed that it was the general feeling of foresters that the existing system of forest protection and management, while greatly improved as compared with the past, still left something to be desired.

He was unable to agree with Mr. Wilson that the immediate and most important requirement at present was forest protection only, the question of proper forest management being, in his opinion, even a more pressing one. No one could state at present with assurance what would be a proper scheme of forest management for the province, or for any particular section of it, knowledge as to this being greatly needed. Arrangements that had been successful in Norway, Sweden and Germany would not necessarily fill Canadian needs.

He had been pleased to hear from the Provincial Minister of Forests that a bureau of forest research to study questions of this kind was to be put into operation before long. Those responsible for woods operations would welcome definite facts and information to guide them, so that cutting might be done in such a way that regeneration might be assured without too great an increase in operating costs. He feared that the public was being led to suppose that a perfect forest protection system was now in operation, but did not believe that all of the undoubted success in fire protection during the last few years could be attributed to the system, as weather conditions during the past three years had been unusually favourable to fire protection. In his opinion, more time, money and thought should be spent in improving our fire protection systems than had been the case up to the present.

Mr. R. H. Nisbet.

Mr. Nisbet was of the opinion that the three fundamental requirements for successful forestry work were:—immunity from fire, knowledge of the standing stock, and the assurance that the land upon which the trees stand would remain in forest for a period of at least two rotations.

In regard to the first of these points, a system of fire detection, not entirely prevention, had been developed, and appeared to be sound, but, as pointed out by Mr. Seaborne, it remained yet to be tested, the test coming with the next year of extreme fire hazard; but what was being done to prevent fires? The immunity from forest fires in Sweden, referred to by the author of the paper, had been obtained through educating the people to prevent fires being set. In the province of Quebec, large sums of money were being spent on fire detection, but, in his opinion, sufficient attention was not being given to decreasing the fire hazard by educating the people regarding the evil results to themselves of forest fires. In other words, it would be better to apply to educational methods some of the money now spent in fire detection. He considered it difficult to educate the older generation, because for many years they had been taught that the forest was something that must be got rid of before land could be cultivated, and he believed it much less difficult to teach children through the schools. Such an educational campaign was of great importance, and should not be restricted to newspapers circulated in cities, as for the most part it is to-day.

The next essential was knowledge of standing stock, which could be easily obtained if a sufficient number of technically trained men with proper experience were employed on forest surveys, and if the necessary funds for such surveys were forthcoming.

The remaining essential he considered to be security of tenure for the organizations engaged in lumbering. Such security would necessitate the land now in forests being classified, so as to separate from the forest that portion of it which could profitably grow field crops. He did not agree with the author that inventories must precede classification. Inventories were expensive, and the forest owners could not be expected to spend money upon them unless assured that some advantage would accrue therefrom. He believed that the most progressive step in a provincial forest policy would be to adopt immediately a policy of wholesale land classification, and, based upon that classification, to devote to forest in perpetuity the areas found suitable for the purpose of growing trees. He believed that if this were done the government would find that inventories and forest management would readily follow.

Mr. H. K. Wicksteed, m.e.i.c.

Mr. Wicksteed believed that as regards forest conservation and operation we were living too much on our capital. He drew attention to the serious consequences following the deforestation of a country, particularly with regard to the effect on the drainage and run-off of the rivers and its influence on power developments.

The value of the forest was not only commercial, that of its industrial products, but was also due to its profound and beneficial influence on the life, climate, recreation and progress of the country.

Mr. Henri Kieffer.

Having recently been in touch with conditions in Sweden, to which the author of the paper had referred, Mr. Kieffer believed that the fire loss in that country was much less proportionately than in Canada. This was due to the facts that transportation was easier, there were more roads, very little underbrush, and, further, refuse and tops were collected and made into charcoal.

The public in Sweden was much more highly educated as regards forest protection than was the case in Canada. He did not believe, however, that in Canada we could go as far in educating the public as was done in Sweden. In that country regulations and laws relative to forest protection were more generally followed, and the forests were more closely under government control. For example, in the case of any land pronounced by a government officer as not fit for cultivation, a settler could not cut any timber without permission from the Crown. Forest organizations and local committees existed in practically all districts of Sweden.

He was glad to see that marked progress had been made in the education of young people in the province of Quebec as regards forest protection, and he would urge that particular attention should be paid to the instruction of people from the cities, tourists, and so on, who often travelled through the bush without taking the necessary precautions against fire.

Mr. W. G. Mitchell, M.E.I.C.

Mr. Mitchell congratulated the author on giving such an excellent outline of the work now being carried on in the province of Quebec under the policy initiated in 1922, aiming at the completion of an inventory of the forest resources of the province. Such an inventory should include a classification of the economic potentialities of the timber lands, having in view the setting apart for timber growing those areas economically suitable only for that purpose. With regard to the creation of forest reserves, Mr. Mitchell was of the opinion that bona fide industrial interests with large commitments depending on the forests for their operations would much prefer to bid on new leases on a basis of thoroughly made and comprehensive surveys than to gamble on the uncertainties incident to the fragmentary or incorrect information which to-day was too often the only data available in such cases.

Citing the case of modern pulp and paper mills requiring a capital outlay for physical plant of from $25,000 to $40,000 per ton of daily production capacity or a modern newsprint mill, involving the expenditure of from $35,000 to $60,000 per ton daily capacity, the higher figures including an allowance for the necessary power developments, he pointed out that such enterprises could not be soundly conceived economically on a life expectancy of ten, fifteen or twenty years, but must look forward for a longer period, and were therefore vitally interested in the security of tenure of the leasehold lands upon which their industries were dependent. In a number of cases, land had been withdrawn from timber leasehold and made available for colonization, and when settled and cleared of the timber by settlers had proved so barren that no farmer, however industrious and thrifty, could wring a livelihood from it. The existence of such conditions caused industrial corporations to hope that government policy in the future would take fully into account the lessons afforded by past experience.

Those responsible for the supply of large pulp and paper mills should think in terms of thirty, forty or even fifty years hence, and should plan a forestry and logging operation policy which would ensure an adequate supply of raw material during that time, so arranged that reasonable uniformity of costs could be maintained while providing for the expense of fire prevention and the construction and maintenance of modern transportation facilities.

He believed that if long vision were not being applied to this question in eastern Canada to-day to the extent that should be the case, it was because from the viewpoint of the leaseholder, who might be following a sound forestry policy, no benefit or return available in material form could be expected for a considerable period of years; under these circumstances, no industrial concern dependent upon extensive timber land leasehold could embark on such a policy without very definite assurance of security of tenure over a long period.

The author had referred more than once to Sweden as a country where wood-using industries had a large development, and, in his opinion, the history of Swedish forestry and Swedish wood-using industries afford more lessons of value and interest to eastern Canada at the present time than that of any other country in the world, not even excepting the United States. Sweden had developed a national forestry policy and standards of forestry practice, and these were employed, not only by the state, but also by the large wood-consuming, land-owning and land-leasing interests.

Much of the most important existing forestry legislation in Sweden dated from 1900 to 1905, when growing concern as to the future of the timber resources in the country had led to a revision of older laws and the enactment of many new regulations dealing with the whole question of forest conservation. Within the past twenty-five years a strong national sentiment had developed in Sweden, in support of a sound forestry policy, and one of the most valuable and constructive influences in the forestry situation there was the attitude of the majority of the larger industrial companies owning extensive timber lands.

The total area in Sweden classed as "productive forest land" amounted to approximately 86,500 square miles, of which approximately 65,800 square miles, or, say, 76 per cent of the total timber lands of the country, were owned by private, (individual or corporate), holders. In addition to the area referred to above as "productive forest land," there was a total of approximately 30,500 square miles of so-called "waste areas" of little or no present value as regards timber production, of which 22,400 square miles, (42 per cent), were owned by individuals or companies. The author had stated that the total area of timber lands in the province of Quebec might be taken as approximately 200,000 square miles, of which about 11,000 square miles, (5½ per cent), were referred to as "private forests" held in freehold by various interests, whether individual or corporate.

In Sweden it was the general rule, rather than the exception, for large wood-using industrial interests to regard their forest lands as their fundamental capital, and to recognize that the most efficient development and proper conservation of these was an issue of direct and vital concern to the industries which they support. This attitude on the part of large land-owning interests in Sweden had been one of the most direct and effective instruments in bringing about the conditions existing in that country to-day. He believed that there was real significance in the fact that some 75 per cent of the timber lands of Sweden were actually owned and controlled by private or corporate interests, who had a direct stake in the proper conservation of those resources. He did not suggest that freehold tenure of timber lands on a large scale was possible or even desirable in this country, for in the past history of Canada and the United States there had been many impressive examples of the dangers incident to the complete alienation of the public domain from State control.

He did suggest, however, that the maximum security of tenure of leased lands, compatible with the protection of the public interest, was necessary to secure from large industrial concerns their full effective co-operation in the development of a safe and logical forestry policy.

The development of policies on the part of our government authorities aiming at the creation and maintenance of large forest reserve areas, planned on broadly conceived lines and based in part upon the results of investigation of the natural suitability of land areas for timber growing or other economic use, would be one of the most convincing assurances that could be given to large corporate interests that the real significance of that phase of our forestry problem had been clearly appreciated. In eastern Canada, the problem of the conservation and utilization of our forest resources had in recent years become one of the most important questions directly affecting the economic welfare of the country. The creation of a well-informed and constructive public opinion on such a question would be a slow and difficult development.

This forestry problem had not affected the taxpayer's pocket as yet, and indeed, as the author had stated, a substantial revenue accrued to the provinces from this source; further, much general industrial and commercial prosperity could be directly attributed to the rapid development of wood-consuming industries in eastern Canada in recent years. These obvious and surface evidences were before the public to-day, but there was much graver and more important significance in this situation, as he had attempted to indicate.

Discussion of Paper on Woodlands Management and Operation, by S. L. de Carteret, M.E.I.C.*

Mr. J. V. Perrin.

In Mr. Perrin's opinion, the author had drawn attention to a very important point in mentioning those stands of timber which are mature, or even over-matured, and which are not gaining in value or even maintaining their present value, and in many cases are even deteriorating. Such areas should receive particular attention in classification.

Mr. R. H. Nisbet.

Mr. Nisbet remarked that he could not quite agree with the author's statement that working plans should be made for periods of five or ten years in advance. He believed that this would not be a working plan in the true sense of the term, as a working plan should deal with at least one, or, better, two, rotations of the crop, and should prescribe a method or methods designed to establish reproduction. In Quebec, for mixed spruce and balsam, one rotation would probably be from eighty to one hundred years. Detailed plans dealing with actual logging operations should be based upon the description of such a working plan, and might properly deal with periods of five, ten or twenty years. He felt sure that the author would agree with this statement of the case.

Mr. D. McLachlin, affiliate e.i.c.

Mr. McLachlin pointed out that in the case of white pine areas where crop rotation is at least one hundred and fifty years, it had not been found possible to adopt a working plan and reforestation had not been tried out, on account of the great length of the cycle.

Mr. S. L. deCarteret, a.m.e.i.c.

The author, in reply, pointed out that he had referred in the paper to the necessity of a proper sylvicultural system which would naturally follow, or be part of, the forest inventory, and would be the basis for the actual operating plan. He had treated this subject almost entirely from an operating point of view, assuming that a suitable sylvicultural system had been devised. He believed that every piece of timber land had to be studied by itself, and that no general rule would suit all sections of the country. Having taken a block of reasonable size and worked out the sylvicultural system for that block, the operating plan should be applied to it. He did not think it practical to make a working plan from the operating standpoint, and work it out in detail for more than five or ten years in advance. A complete working plan should show the improvements to be carried out each year, and these would have to be considered, with the varying rates of depreciation and the amount to be written off each year, before the estimated cost of the wood could be arrived at. He considered it very difficult to estimate with any reliability the cost of improvements to be built in the future, if a period longer than five or ten years were taken.

Discussion of Paper on Building an Industrial Plant in the Saguenay District, by John L. Guest, A.M.E.I.C.**

Mr. F. Newell, m.e.i.c.

Mr. Newell remarked that the paper had been of great interest to him, as he had been connected with the work at Arvida. Would the author explain the reasons for using indoor transformers? He believed that these must have been used, as the paper stated that pumps and water for circulating purposes were supplied. He would have thought that outside transformers might have been better for the conditions at Arvida.

Mr. J. L. Guest, a.m.e.i.c.

The author thought that Mr. Lee could probably answer the question, if he would do so.

Mr. W. S. Lee, m.e.i.c.

Mr. Lee pointed out that in a large transformer station quite a number of switching connections were necessary, and they, of course, required housing. It was also necessary to have a very large and adequate crane for assembling and repairs. There were six 25,000-kva. transformers on tracks by which they could be brought under the 100-ton crane and taken over the pit. Thus, it was not so much a question of housing in the transformers as housing in space

* This paper was presented at the Annual General Professional Meeting of The Institute, Quebec, February 17th, 1927, and published in The Engineering Journal, February, 1927.

** This paper was presented at the Annual General Professional Meeting of The Institute, Quebec, February 16th, 1927, and published in The Engineering Journal, March, 1927.

for repairs and accessory equipment, and the building for transformers was not as big as it might seem to be.

The work at Arvida had been constructed very rapidly. In September the oats had been taken off the fields, and the following July aluminum was being made.

Mr. W. G. Chace, m.e.i.c.

Mr. Chace observed that some of the foundation problems experienced in Manitoba had been fairly well described in the author's story about the foundation soil at Arvida. In the Winnipeg aqueduct they had encountered a soil which was practically impervious to the flow of water, having a high moisture content: 50 per cent being quite characteristic. In some areas it was of such a nature that if a ditch should be excavated to a depth of 12 or 14 feet, the weight of the soil along the wall would cause the bottom to rise. The soil was exceedingly plastic, without any grit whatever. Several difficulties of that sort occurred while building the aqueduct and several devices were used in an endeavour to overcome the trouble, such as widening the trench, throwing the earth farther away and distributing the excavated material in order to reduce the over-pressure on the banks of the excavation. Part of the aqueduct had actually been built on a stone raft on the pitchy clay, which was the means of consolidating the soil and carrying the aqueduct burden.

The particular difficulty in the city of Winnipeg was that a water-bearing stratum of sandy material had been found at a depth of from 8 to 12 feet, and throughout the city it was frequently necessary, in designing the foundations of apartment buildings, industrial plants, and so forth, to fix bearing loads not to exceed three thousand pounds per square foot, which was found to be about the maximum allowable, and, on account of the plastic condition of the soil, many of the foundations had to be on the stiffer upper soil and thus better distributed.

With regard to the question of setting of concrete foundations during cold weather, the common practice in Winnipeg was to use manure or straw or hay, or some material of that nature, to protect the exposed trench bottom while the foundations were setting.

Housing was also a common practice. In 1909 the city power plant had been built in that very way; an area of 120 by 200 feet was housed in with a structure 50 or 60 feet high, and with salamanders and boilers and other devices it was made quite practicable to get the very best of concrete work on the banks of the river, and assisted in keeping the construction materials in order.

He had been impressed with the novel method employed in tying together the foundations of the coke storage building in the clay soil. This appeared to be a very wise precaution.

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME X MAY 1927 No. 5

Circulars to Members

Referring to the disclaimer published in the March number of the Engineering Journal, page 169, the firm in question has addressed a second circular letter to the members of The Engineering Institute of Canada.

Council again desires it to be understood that such improper use of the membership list of The Institute by this firm, or others, is unauthorized.

Members are cautioned against permitting the membership list of The Institute to be used for the promotion of the commercial interests of non-members.

The Institute's Medals and Prizes

On several occasions during the past few years, the attention of Council has been drawn to the fact that the prizes and medals offered for competition by The Institute do not call forth such activity on the part of members as might be expected, and that, more particularly in connection with the Students' prizes, the number of papers submitted from centres other than Montreal and Toronto is very limited.

During the period referred to, the Past-Presidents' Fund has increased in value owing to the liberality of the various past-presidents and has now become available as an additional resource.

Accordingly, in 1926, Council appointed a small committee for the purpose of reviewing and studying the whole situation in The Institute and its branches and making recommendations as to the best method of expending the funds available for medals and prizes.

The preliminary report of this committee has now been presented to, and approved by, Council and is printed in full on page 284 of this issue of the Journal.

The committee has been continued, and has been requested to draw up for the approval of the membership of The Institute a revised set of rules and regulations for the award of The Institute's prizes and medals.

In the preparation of its report, the committee has consulted with all of the branches by correspondence, and has so made its proposals as to leave the branches the fullest liberty in the award of any local or branch prizes which they may see fit to offer in competition. The matter will come up for final discussion and decision at the Annual General Meeting of 1928.

The benefits accruing to The Institute from a well-arranged scheme for the award of distinctions such as prizes and medals are considerable. Such awards are primarily intended to encourage the preparation of original papers, both by senior and junior members, in this way bringing out meritorious communications which would otherwise not be available, and they also afford to the Council of The Institute a means of giving official recognition to members who have distinguished themselves and have rendered noteworthy service to The Institute.

A particularly interesting feature of the report lies in the suggestion that the five Students' prizes awarded by The Institute should be distinguished by being named after various prominent past-presidents of The Institute, thus commemorating these past-presidents' services and their connection with the several zones in which the various prizes are to be awarded.

It will be noted further that the committee recommends that a gold medal named after a prominent past-president should be at the disposal of Council for award on special occasions, when it is desirable to recognize outstanding merit in the profession or distinguished service in the interest of The Institute or of the profession. These conditions would give to the proposed medal a very special value, and would, no doubt, cause it to be a greatly coveted distinction.

It is hoped that The Institute's membership will aid Council in carefully considering the important question of Institute prizes and medals, by studying the committee's report and offering such suggestions or criticisms as will assist in perfecting the scheme.

Address Delivered at the Annual Dinner of The Engineering Institute of Canada, Chateau Frontenac, Quebec, February 16th, 1927

Address of His Excellency Sir François Lemieux, Chief Justice and Administrator, Province of Quebec

Mr. President, Monseigneur, Sir Henry and Gentlemen:—

I feel proud and honoured to attend this elegant and intellectual banquet, and, as Chief Justice and Governor pro tempore, I also wish you, not what is commonly called a cordial welcome, not a Quebec welcome, but something better and above that, I wish to all and every one of you a sincere French welcome.

You belong to a very useful and noble profession.

Engineering is, nowadays, a most interesting art or science. An engineer is a man who must have a full knowledge of and be well acquainted with the principles of mathematics, mechanics, hydraulics, and, indeed, with all the branches of natural philosophy.

Upon you devolves the scientific planning of the construction of public roads, bridges, railways, harbours, drainage works, mining enterprises, military constructions and every line of industrial domain.

Your profession has not only an industrial, but also a national character, because you are an essential element in the economic life of the world.

The future prosperity of nations and, particularly, of Canada and the United States, depends, in a large measure, on eminent engineers and on the hands and brains of the highest type of engineering skill.

Thus, you deserve the most sincere wishes of all for your personal happiness and success in life.

Discours prononcé par Son Excellence Sir François Lemieux, Juge en Chef et Administrateur de la Province de Québec

Ce n'est pas sans hésitation que, dans les occasions même quasi-officielles, je remplace Son Excellence, Monsieur le Gouverneur Pérodeau, qui, par sa bienveillance native et surtout par sa munificence princière, a rendu la tâche redoutable à ses successeurs.

Cependant, je me sens à l'aise et surtout honoré de prendre part à ces agapes intellectuelles et de rompre avec vous le pain bénit de la confraternité professionnelle.

En effet, messieurs les Ingénieurs, vous n'appartenez pas à un état manuel, vous ne faites pas partie d'un métier qui pourrait être honorable, mais vous êtes les membres d'une grande profession libérale.

Dans l'antiquité, les professions libérales étaient closes et fermées et n'étaient composées que des hommes libres et nobles, tandis que les professions industrielles étaient dévolues aux esclaves, aux affranchis et aux étrangers.

Les temps sont changés et vous, messieurs du génie, vous avez obtenu des titres de noblesse professionnelle par le développement intellectuel et par la maîtrise des ces nombreuses sciences utiles à la société et qui rendent à la civilisation des services si appréciables.

Ce n'est pas sans raison qu'aujourd'hui l'on assemble le prêtre, l'homme de loi, le médecin et l'homme de génie, car ces professions sont les grands leviers de la civilisation et représentent la société dans les quatre principaux termes d'existence: la conscience, le droit, la santé et la prospérité.

En effet, le prêtre a la mission sacrée de guérir et de panser les plaies de l'âme et de graver surtout dans la conscience de l'homme de bien l'espoir d'une éternité de bonheur.

L'homme de loi a l'apostolat presque sacré de démêler le juste de l'injuste, de défendre la liberté, la propriété, l'honneur du riche et du puissant, mais surtout du faible et du pauvre qui trouvent, dans le dévouement et la science de l'avocat, un rempart solide contre lesquels l'or et les influences viennent souvent s'effrondrer.

Le médecin, lui, est un des grands bienfaiteurs de l'humanité, car, souvent, il dépense sa vie, avec un sublime dévouement et désintéressement, au chevet des malades, des désespérés et des agonisants, pour soulanger des douleurs et des souffrances.

Le génie, lui, préside aux grandes entreprises nationales, s'associe au progrès de la civilisation qui assure le bien-être des peuples.

Soyez fiers, messieurs, d'appartenir à une confrérie qui, depuis au-delà d'un siècle, a pris une extension si considérable dans le mouvement industriel moderne, soit en matières de communications publiques, canaux, chemins de fer, ponts, digues, dans l'exploitation des mines, dans l'art géologique et aussi dans les constructions de guerre.

Vous appartenez, messieurs, à une profession qui a réalisé des oeuvres titanesques et souvent considérées comme chimériques et irréalisables. L'ingénieur a révolutionné, pour ainsi dire, la face du monde et les pays ne peuvent plus grandir et rester grands sans de grands ingénieurs.

L'art militaire—la dernière grande guerre l'a démontré—requiert le secours constant de l'ingénieur.

Le grand Napoléon ne disait-il pas, à Sainte-Hélène, que si Waterloo avait été perdue ce n'était pas parce que les Français avaient manqué de courage et d'intrépidité, mais parce que le corps des ingénieurs chargé de préparer, en partie, la défense et l'attaque, faisait partie de l'armée de Grouchy qui n'avait pas fait sa jonction avec la sienne.

Tous les grands conquérants, d'ailleurs, Alexandre, César, Godefroi-de-Bouillon, Condé, ont été soutenus dans leurs entreprises militaires et dans leur conquêtes, par des corps d'ingénieurs.

Si vous êtes des professionnels dans le véritable sens du mot, vous avez déjà dû réaliser qu'il vous incombe, tant au point de vue moral que national, de porter avec orgueil le titre de citoyen.

A Rome, le *civis romanus* était rangé parmi les nobles. A son passage l'esclave se rangeait, et il avait droit au salut de César.

On ne peut être citoyen, et c'est là un de ses véritables attributs, sans avoir la qualité dominante de la volonté de contribuer à la grandeur de la patrie.

On ne peut être vrai et loyal sujet de Sa Majesté sans vivre de foi et d'espérance, qui sont les plus robustes auxiliaires de la volonté de l'homme, sans vivre, dis-je, de foi et d'espérance en l'avenir de son pays.

Mais, ne vous contentez pas de vaines espérances, accomplissez celles qui sont raisonnables.

On ne peut être citoyen sans prendre une part virile à la chose publique, car, celui qui meurt sans avoir été citoyen, meurt—excusez-moi l'expression—en état de péché national, et celui-là n'a jamais l'absolution de ses compatriotes.

Le professionnel doit être un éducateur et jeter, par son exemple, et, à l'occasion, par des bonnes paroles, dans le coeur de l'homme du peuple, de l'ouvrier en blouse, des paroles d'espoir et d'encouragement.

Il incombe à l'homme de profession d'enseigner à ses compatriotes le respect des institutions nationales qui ont eu pour base le dévouement, le courage et la haute intelligence de leurs fondateurs.

Dites-leur de se méfier de ces doctrines perverses qui amoindrissent l'esprit public et qui détruisent l'idée vraie d'union et de coopération sur laquelle la Providence fait reposer la société civile.

Enseignez-leur de ne pas prêter l'oreille à ces bruits alarmants, et surtout à ces faiseurs de promesses impossibles à réaliser, et de se méfier de ceux qui amoindrissent et rapetissent notre cher pays, notre chère Province de Québec.

Un grand connaisseur du coeur humain, un homme qui a écrit et parlé toujours pour émouvoir, Lamartine, a dit:—" Il ne faut pas que le peuple souffrant méconnaisse les efforts faits pour produire des institutions secourables, des institutions de charité démocratique, que l'humanité et la religion ont inspiré aux classes intelligentes et dirigeantes." " Car l'oubli," a-t-il ajouté, " est le commencement de l'ingratitude."

Notre peuple est trop reconnaissant pour méconnaître les avantages des établissements d'education, d'asiles de bienfaisance et de santé et les institutions de toutes natures fondées par la charité, le coeur, la munificence publique et privée, et surtout par le patriotisme éclairé de chefs de la nation.

Deux mots de plus et j'ai fini.

Messieurs les Ingénieurs, comme citoyens et professionnels, dressez-vous hardiment devant vos compatriotes et surtout devant les étrangers et répétez la fière parole de Sir Wilfrid, qui est en train de se réaliser à la lettre:—" Que le vingtième siècle sera le siècle du Canada;" affirmez, sans crainte, que l'heure a sonné, que l'heure est arrivée où le Canada, qui est un des joyaux de l'Empire Britannique, a droit de se tenir fièrement à côté des nations et d'avoir une large place sous le soleil du Bon Dieu.

Meeting of Council

Meeting of April 22nd, 1927

A meeting of Council was held at eight p.m. on Friday, April 22nd, 1927, President A. R. Decary, M.E.I.C., in the chair, and nine other members of Council being present.

In connection with the proposed plenary meeting of Council the views of various councillors expressed in correspondence were presented, and after consideration of the replies it was decided that the meeting should be held in Montreal during the third week in October, to last three days; and a small committee was appointed to consider and draw up the agenda for this meeting, such agenda to be submitted to all members of Council before final adoption.

Professor T. R. Loudon, M.E.I.C., as chairman of the committee appointed to consider means by which interest in Institute affairs can best be stimulated among its members reported progress on behalf of his committee.

J. E. N. Cauchon, A.M.E.I.C., reported that, as requested, he had represented The Engineering Institute at the first meeting of the Canadian Engineering Standards Association Committee on Brick Sizes, and that there seemed good prospects of effective agreement being reached with the industry on the reduction of the number of sizes of common and face brick.

The financial statement to March 31st, 1927, was submitted and approved.

A report was submitted from the Board of Examiners in connection with an enquiry received from Council as to whether, in the Board's opinion, an applicant for admission to The Institute who holds the Dominion Land Surveyors' certificate, but who has not graduated from a school of engineering recognized by the Council, or passed the third year examinations in such a course, can properly be exempted from the examinations of Schedule B.

The Board reported that, after discussing the course of study necessary for the Dominion Land Surveyors' certificate, it was unanimously of the opinion that the Dominion Land Surveyors' certificate does not give the necessary assurance of the student's knowledge of elementary physics, mechanics and strength of materials, nor does it cover any requirements for chemistry, for which reasons it cannot be considered as entitling the holder to exemption from the examinations under Schedule B.

J. L. Busfield, M.E.I.C., presented the report of the committee appointed to review and study the question of The Institute's prizes and medals, and the report was approved, the committee being continued and requested to take in hand the preparation of the detailed rules necessary for carrying out its recommendations, these to be brought up at the next Annual Meeting for the approval of the membership. (The report appears on page 284 of the present issue of the Journal.)

A report was submitted from the Legislation and By-laws Committee, recommending the approval of the proposed revised by-laws of the Lethbridge Branch, and approval was accordingly given.

A letter was presented from Past-President Walkem, stating that in view of the number of other important meetings which are to be held in Vancouver this year, the executive committee of the Vancouver Branch considers that it would be well not to hold a Western Professional Meeting of The Institute there until 1928, and Council approved this conclusion.

A letter was presented from the Montreal Branch requesting permission to hold the Annual Professional Meeting for 1928 in Montreal. This suggestion was unanimously concurred in.

The revised design for the Royal Engineers' Memorial Tablet, to be placed on the Cariboo Road by The Engineering Institute of Canada and the Association of Professional Engineers of British Columbia, was submitted and unanimously approved.

A notice of the centennial celebrations to be held at the University of Toronto on October 6th, 7th and 8th, 1927, together with an invitation from the University to The Institute to be represented on that occasion, was presented and noted, and President Decary was requested to act as the representative of The Institute on that occasion.

The names of the officers of the Halifax, Cape Breton and Calgary Branches were submitted and their appointment approved.

The personnel of the Plummer Medal Committee for the current year was submitted and approved.

The recommendations of the Finance Committee in connection with seven special cases were approved.

Two reinstatements were effected.

Seven resignations were accepted.

The following elections and transfers were effected:—

Elections

Member	1
Associate Members	6
Juniors	4
Students	25

Transfers

Associate Member to Member	3
Junior to Associate Member	2
Student to Associate Member	2
Student to Junior	5
Affiliate to Associate Member	1

Twenty-one applications for admission and transfer were scrutinized and classified for the ballot returnable May 20th, 1927.

Six special cases were considered in connection with applications for admission.

The Council rose at twelve-twenty a.m.

OBITUARIES

Donald Cole, A.M.E.I.C.

Regret is expressed at the untimely death of Donald Cole, A.M.E.I.C., which occurred at Detroit, Mich., on December 16th, 1926, following an automobile accident.

The late Mr. Cole joined The Institute as an Associate Member on June 27th, 1922, and at the time of his death was consulting engineer with the Absopure Ice Company, Detroit, Mich. He was born at Baltimore, Maryland, on November 29th, 1885, and received his early education at the Baltimore City College.

Mr. Cole specialized in refrigeration, and was engaged on this work practically throughout his engineering career. His earliest employment was in 1903, when he was draughtsman with The Arctic Ice Machine Company, Canton, Ohio, two years later accepting a similar position with the Frick Company at Waynesboro, Pa. In 1906 he returned to The Arctic Ice Machine Company and for six years occupied various positions, including chief draughtsman, sales engineer and assistant chief engineer. In 1911 he joined the staff of The Timken Detroit Axle Company as assistant engineer, remaining with this company until 1914, when for three years he held the position of chief of plants for The General Ice Delivery Company.

From 1917 to 1920 he was with the United States Army, for the first two years as civilian refrigerating engineer and later as Captain, Q.M. Corps, construction division, in charge of all army cold storage and ice-making plants. In 1920 he entered consulting practice, specializing in refrigeration, and had an office at Windsor, Ont.

Alvah Seymour Going, M.E.I.C.

It is with regret that we record the death of Alvah Seymour Going, M.E.I.C., which occurred at his home in Montreal on March 21st, 1927.

The late Mr. Going was terminal engineer with the Bureau of Economics of the Canadian National Railways, to which position he was appointed on April 1st, 1923.

He was born at Portland, Oregon, on April 7th, 1860, and commenced his engineering work with the Seattle Lake Shore and Eastern Railway in 1886. Subsequently, he was employed by the Northern Pacific Railway and Great Northern Railway and as chief engineer of the Port Crescent Harbour Improvements. He was also at one time reconnaissance engineer with the Grand Trunk Railway and division engineer of the Minneapolis and St. Louis Railway. In 1907 he joined the Grand Trunk Railway staff at Montreal as locating engineer, continuing in that capacity until 1910 when he became engineer of construction, which position he occupied until his appointment as terminal engineer with the Canadian National Railways.

The late Mr. Going joined The Institute as an Associate Member on May 20th, 1892, and transferred to Member on May 14th, 1910.

PERSONALS

T. H. Hogg, M.E.I.C., chief hydraulic engineer of the Hydro-Electric Power Commission of Ontario, has been appointed member of the Lake of the Woods Control Board.

Major P. Earnshaw, D.S.O., M.C., A.M.E.I.C., who has been with the Department of National Defence at Camp Borden, Ont., is now attending the Royal Staff College, Camberley, England.

W. E. Hall, A.M.E.I.C., formerly on the engineering staff of the Anticosti Corporation, Three Rivers, has accepted a position as engineer and construction superintendent to build a railroad at Chevrie, N.S., to haul gypsum from the quarry to tide water.

Professor Duff A. Abrams, M.E.I.C., whose resignation from the directorship of the research laboratory of the Portland Cement Association was announced in last month's Journal, is now director of research of the International Cement Corporation, New York City.

T. R. Emerson, S.E.I.C., is located at Toronto with the Canadian National Railways on the terminal engineer's staff with H. L. Currie, A.M.E.I.C., on the construction of the new engine and car facilities. Mr. Emerson graduated from the University of Toronto in 1924.

F. H. Dentith, S.E.I.C., who graduated from McGill University in 1925, has joined the engineering staff of the Bell Telephone Company of Canada and is in the machine switching engineering equipment division. Following graduation, Mr. Dentith was junior chemist with the Brandram-Henderson, Limited, Montreal.

W. T. D. Ross, S.E.I.C., who graduated with the degree of B.Sc. from McGill University in 1926, has accepted a position as chemist with the Canadian Explosives, Limited, Nobel, Ont. Mr. Ross won a Students' prize in chemical engineering this year for his paper entitled "Salt Mining in Nova Scotia—A new Industry."

J. W. Lewis, Jr.E.I.C., has resigned from the staff of the Canadian Pacific Railway Company, New Brunswick division, to accept a position with the Portland Cement Association, Chicago, Ill. From 1914 to 1917 he was on the engineering staff of the Department of Public Works of Canada at St. John, N.B.

J. J. McNiven, A.M.E.I.C., has been appointed to the sales staff of the General Supply Company of Canada at Montreal. Mr. McNiven graduated from McGill University in 1912 and for some twelve years was with the British Columbia Electric Railway Company engaged in design, construction and operation in connection with the hydro-electric steam power plants of that company.

D. C. Macpherson, S.E.I.C., of the Dominion Bridge Company, Limited, has been transferred from East Templeton, Que., to Quebec City. Mr. Macpherson is a graduate of Queen's University of the year 1924. He has been with the Dominion Bridge Company, Limited, on the construction of the Gatineau mill of the Canadian International Paper Company, and is now on the construction of the Limoilou mill of the Anglo-Canadian Paper Mills, Limited, at Quebec.

A. D. Ross, A.M.E.I.C., assistant engineer of the Wayagamack Pulp and Paper Company, Limited, Three Rivers, Que., since 1925, has joined the staff of the Canadian Comstock Company, Limited, Montreal. Mr. Ross is a graduate of the Massachusetts Institute of Technology, from which he received the degree of M.Sc. in electrical engineering. Following graduation, he took the students' engineering course with the General Electric Company, later being appointed electrical engineer with this company, specializing in paper mill work.

F. D. Farnsworth, A.M.E.I.C., resident engineer with the State Highway Commission of Maine, has been appointed town manager of Fort Fairfield, Maine. From May 1913 until December 1914 he was assistant engineer to the late H. N. Ruttan, HON. M.E.I.C., Winnipeg, Man. For the next three years he was on the engineering staff of the Canadian Overseas Railway Construction Corps, following which he was connected with the Nova Scotia Provincial Highway Board. He was chief engineer of the firm, Reid, Farnsworth and Shafner, Limited, from 1920 until 1926, when he was appointed to the position from which he has just resigned.

A. L. Mudge, M.E.I.C., of Toronto, Ont., has been appointed senior electrical engineer for the Welland Ship Canal with headquarters at St. Catharines. For the past few years, Mr. Mudge was located in Ottawa as power plant engineer on the staff of the Canadian section of the Joint Board of Engineers for the St. Lawrence Deep Waterways Project, prior to which he was for many years actively engaged in private practice with the firm of Kerry and Chace, Limited, consulting engineers, Toronto, with which firm he devoted most of his time to water power development and industrial electrical engineering work.

R. S. Baker, A.M.E.I.C., who has recently been engaged on the installation of the Thorne continuous bleaching system for the Mattagami Pulp and Paper Company, now known as the Abitibi Fibre Company, is at present located at Temiskaming as research engineer with the Riordon Pulp Corporation, Limited. Mr. Baker previously occupied this position, together with that of assistant mill engineer, with the Riordon Corporation. Following his service overseas, Mr. Baker was appointed engineer with the Wayagamack Pulp and Paper Company at Three Rivers, at which time he was engaged on construction work in connection with the woods operation.

G. C. Read, A.M.E.I.C., has been located in England for the past twelve months, and is at present resident engineer for the city of Birmingham on the construction of the first super-power station in that city. Mr. Read was for a number of years in Halifax connected with the engineering staff of the Provincial Highways Board of Nova Scotia. He is a native of England, and received his education at London University, Kingston Technical College and Regent Street Polytechnic. On coming to Canada in 1911, his first work was with the Canadian Pacific Railway Company on maintenance, location and construction. Subsequently, he worked at various points in Canada in connection with railway work.

W. R. Warren, A.M.E.I.C., Deputy Minister of Telephones in Saskatchewan

W. R. Warren, A.M.E.I.C., until recently chief engineer of the department of telephones, Saskatchewan government, has been appointed deputy minister of telephones of Saskatchewan to succeed the late D. C. McNab.

Mr. Warren's connection with the provincial telephone system of Saskatchewan dates back to August 1908, when he was appointed engineer of the system. In 1912 he was promoted to chief engineer, and in this capacity has been in charge of the construction, maintenance and operation of the system ever since. Prior to coming to Saskatchewan he was local superintendent in charge of construction, maintenance and operation of telephone system in Winnipeg.

G. C. Perkins, A.M.E.I.C., Engaged on Work in India

G. C. Perkins, A.M.E.I.C., who has been in India for the past two years, is assistant bridge engineer with the North Western Railway and is located at Attock, Punjab, India, where he is engaged on the reconstruction of the Attock bridge.

Mr. Perkins was born in India and received his education in England. He spent a number of years in Canada, with the Railway Signal Company of Canada at Lachine, Que., in 1911-12, and for the next three years on railway surveys, first with the Canadian Pacific Railway and later with the Canadian Government Railways. During part of the war he was with the Imperial Ammunition Board as gauge inspector, later going overseas and serving in France. Upon his return to Canada, he was engaged in various construction works.

C. V. von Abo, Jr.E.I.C., Located in South Africa

C. V. von Abo, Jr.E.I.C., whose thesis on "The Present Status of Our Knowledge of Secondary Stresses in Bridges" earned for him the degree of Ph.D. from McGill University in 1922, has since that date been in South Africa, where from January 1923 to June 1925 he was connected with the staff of the Cape Technical College at Cape Town. Since that time he was attached to the department of the chief civil engineer of the South Africa Railways as research officer engaged on special investigations. At the present time he is temporarily connected with the bridge department of the South Africa Railways for a period of six months, after which he will return to his former position.

Mr. von Abo is a native of Orange Free State, South Africa, and received his degree of B.A. from the University of Cape of Good Hope in 1913 and the following degrees from the University of Cape Town:—B.Sc. in civil engineering in 1917; M.A. in pure mathematics in 1918 and M.A. in applied mathematics in 1919.

J. A. Beauchemin, A.M.E.I.C., Appointed Town Manager

J. A. Beauchemin, A.M.E.I.C., has been appointed town manager for the new town of Dolbeau in the county of Lake St. John, Que. The townsite of Dolbeau is being developed by the Lake St. John Power and Paper Company, Limited.

Mr. Beauchemin graduated from the University of Montreal in 1911 and was assistant engineer in the hydraulic division of the Department of Public Works, Ottawa, from 1911-18, when he joined the staff of the Riordon Pulp Corporation, Limited, at Temiskaming, Que., as assistant to the chief engineer in charge of hydro-electric power investigations. In 1920 he resigned from the Riordon Corporation and became associated with the Donnacona Paper Company, later becoming mill engineer for this company and remaining in that position until 1926. He was then appointed mill engineer on maintenance and construction with the Port Alfred Pulp and Paper Corporation, Port Alfred, Que., with which company he remained until his present appointment.

Dr. J. B. Porter, M.E.I.C., Retires

Dr. J. B. Porter, M.E.I.C., will retire from the chair of the mining engineering at McGill University at the close of the college session, according to a recent announcement.

Dr. Porter's connection with McGill covers a period of some thirty years, commencing with his appointment as

Macdonald professor of mining and metallurgy in 1896, when that department was inaugurated. In 1904 he became professor of mining and director of the department.

He is a graduate of Columbia University of the year 1882, from which he received the degree of E.M. During the following year he was engaged as instructor in mining at the University of Cincinnati, and in 1884, as the result of a study of the economic geology of the coals and iron ores of Tennessee and Alabama, he obtained the degree of Ph.D. from Columbia University. During the following twelve years he was engaged in provincial work, holding many positions of responsibility.

Dr. Porter was elected a Member of The Institute on December 3rd, 1896, and served on the Council during the years 1904 to 1906. He is a member of the council and chairman of the Canadian Advisory Committee of the Institution of Civil Engineers of Great Britain; corresponding member of the council of the Institute of Mining and Metallurgy of Great Britain; one of the founders and past-president of the Sigma Xi Society of McGill University; and one of the founders of the Canadian Engineering Standards Association, of which he is vice-chairman.

In 1905 he received the honorary degree of D.Sc. from the University of Cape of Good Hope on the occasion of the visit of the British Association for the Advancement of Science to South Africa. He has been a member of the Canadian Institute of Mining and Metallurgy since its incorporation and served on its council for many years and as vice-president in 1907-08.

Dr. Porter has written a number of books and papers dealing particularly with coal and was the senior author of "Investigation of the Coals of Canada," which was published in six volumes, about fifteen years ago, by the Mines Branch of the Department of Mines.

EMPLOYMENT BUREAU

Situations Wanted

CIVIL ENGINEER

Open for an engagement about May 20th, M.E.I.C., returned soldier, twenty-five years experience in all parts of Canada and United States; railway location and construction, canals, concrete structures, sewers, water systems, buildings, highway location and construction, all classes of pavements; experience as engineer-in-charge and superintendent for contractor. Apply box No. 225-W, Engineering Journal.

ELECTRICAL ENGINEER

B.A.Sc., University of Toronto. Two years testing with large electrical company. Three years in engineering department on design of railway control apparatus. Desires new connection with firm located in central Ontario. Employed, but available on few weeks notice. Apply box No. 226-W, Engineering Journal.

Situation Vacant

ELECTRICAL OR MECHANICAL ENGINEER

A large public service corporation requires the services of an electrical or mechanical engineer with several years experience. The work is of a technical nature and offers good possibilities for advancement. Apply box 167-V, Engineering Journal.

Members' Exchange

TRANSIT FOR SALE

One Troughton and Simms transit theodolite, on three levelling screws, 6½ inches horizontal circle, 5-inch vertical circle, both graduated to twenty minutes, reading to twenty seconds. Three-inch circular needle, English form tripod; good condition. Also one surveyors' compass, 4-inch needle, 5½-inch sights, 12½ inches apart; all in box, fitted for jacob staff. Can be used on tripod; good condition. Apply to E. T. Wilkie, M.E.I.C., 56 Marmaduke Street, Toronto, Ont.

ELECTIONS AND TRANSFERS

At the meeting of Council held on April 22nd, the following elections and transfers were effected:—

Member

NOYES, Donald Franklin, B.S., (Clarkson College of Tech.), supt. of constrn. for Quebec Devel. Co., Duke-Price Power Co. and Alma & Jonquiere Ry., Isle Maligne, Que.

Associate Members

BIRKETT, Leonard Harris, sales engr., Superheater Co., Ltd., Montreal, Que.

CALLANDER, Delmer Wallace, B.Sc., (McGill Univ.), transformer design, Can. Westinghouse Co., Hamilton, Ont.

CARNWATH, James, B.Sc., (McGill Univ.), manager, Independent Concrete Pipe Co., Ltd., Woodstock, Ont.

LOTIMER, James Stanley, supt. of elect'l mtce., Niagara District, Niagara Falls, Ont.

TREGARTHEN, Mark Elmer, B.E., (Sydney Univ.), with Comstock at Gatineau paper mill, Hull, Que.

WEBSTER, James Clarence, A.B., (Western Reserve Univ.), sales engr., Can. Nat. Carbon Co. and Prest-O-Lite Co. of Can., Ltd., Toronto, Ont.

Juniors

ASHBY, Reginald Beale, B.Sc., (McGill Univ.), engrg. staff, Foundation Co. of Can., Ltd., Montreal, Que.

GIBBON, Hubert Stuart Vroom, engr. with Quebec Devel. Co., Isle Maligne, Que.

PHILLIPS, John Bernard, 4th year applied science, McGill Univ., Montreal, Que.

WICKWIRE, James Leander, B.Sc., (McGill Univ.), grain elevator design work with C. D. Howe & Co., Port Arthur, Ont.

Transferred from class of Associate Member to that of Member

GRANT, LeRoy Fraser, B.Sc., (Queen's Univ.), associate prof. of engrg., R.M.C., Kingston, Ont.

ROBINSON, Leonard Hiram, C.E., (Univ. of Toronto), div. engr. mtce. of way, C.N.R., Campbellton, N.B.

WALL, Arthur Stanford, i/c plate and tank dept., Dom. Bridge Co., Ltd., Montreal, Que.

Transferred from class of Junior to that of Associate Member

DUNBAR, John Robert, B.Sc., (McGill Univ.), i/c a.c. generator and synchronous motor design, Can. Westinghouse Co., Hamilton, Ont.

HENRY, Thomas Haliburton, B.Sc., (McGill Univ.), supt., A. F. Byers & Co., Ltd., Montreal, Que.

Transferred from class of Student to that of Associate Member

MacISAAC, Vernon, W. B.Sc., (Queen's Univ.), ch. engr., Howard Smith Paper Mills, Cornwall, Ont.

McCULLOCH, Orval James, B.Sc., (McGill Univ.), asst. structural engr., Welland Ship Canal, St. Catharines, Ont.

Transferred from class of Student to that of Junior

DAVIES, Ewart John, B.Sc., (N.S. Tech. Coll.), with Babcock-Wilcox & Goldie-McCulloch, Ltd., Galt, Ont.

HARVIE, Allin C., B.Sc., (Queen's Univ.), inspector on constrn. work, instrumentman and dftsman, engrg. dept., Int. Nickel Co. of Can., Ltd., Port Colborne, Ont.

KINGSTON, Thomas Martyn Sibbald, B.A.Sc., (Univ. of Toronto), field engr., Fed. Portland Cement Co., Buffalo, N.Y.

RAPLEY, Blake P., B.Sc., (Queen's Univ.), dftsman, Imperial Oil Refineries, Ltd., Sarnia, Ont.

WEBB, Harry Randell, M.Sc., (Univ. of Alta.), lecturer in civil engrg., Univ. of Alta., Edmonton, Alta.

Transferred from class of Affiliate to that of Associate Member

EISENHAUER, Erle Eli, B.Sc., (Univ. of Sask.), irrig. specialist with Alta. government schools of agriculture, Claresholm, Alta.

BOOK REVIEWS

Movable Bridges

Vol. I, Superstructure, Vol. II, Machinery

By Otis Ellis Hovey, John Wiley & Sons, New York, 1926. Cloth, 6½ x 9½ in., 352, 344 pp., illus., figs., tables, $6.00 per vol.

The first impression produced on the reviewer by a careful reading of Hovey's Movable Bridges is one of completeness. It would seem that nothing remains to be said, and that notwithstanding the author's admitted limitation to United States practice and American Bridge Company design, the whole field is well and ably covered. The principles given, whether of analysis or of economy, are universal in their application, and it only remains for the responsible engineer using this text as a reference book, to appraise properly his own local and governing conditions, when considering the questions of type of bridge, type of power, and general details, structural or mechanical.

The critical and comparative surveys of the various species of movable bridges, their subdivisions and particular examples, are especially to be commended as being sound and fair beyond cavil. The long and intimate experience of the author endows these observations with a weight of authority not previously obtainable in published texts. It is gratifying to find such definite confirmation of personal conviction regarding the inherent superiority of swing-spans, where local circumstances do not rule them out. The unfortunate fact that swing spans alone involve no proprietary features has led many public authorities, and not a few engineers, to neglect them in favour of "modern" types generally advocated with all the advantages of "modern" salesmanship.

To Canadian engineers, the items of freight, duty, minimum of attention after erection in inaccessible districts, and the susceptibility to manufacture in the greater number of Canadian shops are other features which operate still further in favour of the lighter, simpler types with the minimum of complex machinery or machined parts.

The second impression is rather different in nature and arises from the too general use of the term "draw." Very few existing, and virtually no new, movable spans are "draw-spans," and the term ought to be discouraged in present day literature.

The historical review in volume I, although brief, is of considerable interest and evinces very wide and painstaking research on the part of the author.

Some very valuable tables and curves are given in the chapters on superstructure design, but the reader should use only with judgment those such as 3-V and 3W where the data are very sketchy in relation to the resulting graphs.

Chapter IX, on deflections, is a well arranged and concise presentation of general principles and comparative methods, and in table 9-H contains a most informing selection of figures regarding turntables. As is usually the case where analytical material is included in the text, some corrigenda have escaped the proofreader.

The treatment of end-lifting mechanisms and their duties in chapter X is clear and broad. The examples are well chosen and the criticism is again sound and fair. Perhaps the paragraph on page 273 dealing with swinging clearance could, with advantage, be revised to state more directly that the details at the end of the span and on the abutments should be so designed as to provide swinging clearance under all possible conditions of temperature and teetering about balance wheels when wedges are withdrawn, etc. The same chapter discusses centre bearings, discs, pinions, live-rings, and offers pertinent and valuable hints to the mechanical-design office. The author definitely prefers two discs to three and refers to the European practice in this regard, although it would appear from the illustrations that for larger spans in the United States, as here, three discs is the commoner arrangement. Incidentally, it is at least doubtful whether French engineers had arrived at "steel discs" in 1625, as the text suggests on page 13.

The appendices are interesting though not conclusive. That which treats of disc radii and disc pressures seems to the reviewer to be rather more fortunate in its results than rigid in its analysis. On page 337 when evaluating a mean E the use of "dia." for diameter, instead of "d" (in two fonts) would render the comprehensibility rather more facile. On page 338 the last equation but one needs restating to show that x = 11.145 inches.

The other appendix, dealing with line contact between segmental treads and track girders, is admittedly incomplete, although indicative of much serious thought along productive lines. It can hardly be interpreted as providing a full solution of those continually recurring problems as to where contact stops and how the pressure varies within the limits of contact. The author's discussion and the investigation to which he refers will nevertheless be very welcome steps toward a practical method of providing for the really serious loading conditions which occur on rolling-lift segment-to-track surfaces.

Volume II treats mainly of the design of operating machinery and is adequately illustrated by views of actual bridges. After an introduction where observations, based on wide experience, are given on the theoretical and practical problems involved, the author proceeds to a recital of the work to be performed by the power applied, and then to typical cases of swing, bascule, and lift-span installations. Some very interesting examples of long and useful service by swing-span machinery are instanced, drawing attention to the advantage of simple layout, careful workmanship and proper maintenance. The obvious misprint of a date under figure 3-0 will not confuse the thoughtful reader. A very comprehensive discussion on bearing metals occurs in chapter IV, reference being made to the various alloys and their properties, both as revealed by miscroscopic examination in the metallurgical laboratory and by actual service tests.

The resistances in the machinery itself are then taken up, followed by chapters on the individual parts, such as shafts, journals, gears, cranks, springs and sheaves. A most interesting analysis on wire ropes as used in vertical lift bridges is presented in chapter XII, with particular reference to the use of the elastic modulus of the built-up rope rather than that of the metal in the wires.

The next matter treated is the usually troublesome question of brakes, after which the author offers a few ideas on the details of hydraulic machinery parts. A separate chapter is devoted to unit stresses permissible on the various materials which enter into the mechanical construction, and in appendix A appears a complete set of specifications covering superstructure and machinery design for all types of moving spans. Arranged on the general lines of the A.R.E.A. specification, this set of rules and requirements furnishes a mine of information, sufficient with but few modifications for the guidance of, or even the adoption by, any engineer called upon to prepare plans or designs, where the specification is not already standardized.

Appendix C contains a multitude of tabulated data, some being of the usual handbook type but elaborated, others being of a more rarely compiled nature, for instance, the elastic properties of loaded cantilever columns, and the geometrical tables 6 to 11. They are all expressed clearly and the printing is generally equally satisfactory. In table 3, on page 308, a note should be added to indicate that the curve dealt with in the third figure is a parabola only.

Taken together, the two volumes comprise a masterly treatment of the subject, replete with information, yet not overloaded with unnecessary or elementary detail, and they will constitute a more than ordinarily useful addition to the working library of those engineers who are regularly engaged in, or occasionally consulted upon, the design of movable bridges.

P. L. Pratley, M.E.I.C.
Consulting Engineer, Montreal.

CORRESPONDENCE

Interim Report of the Committee on The Institute's Prizes and Medals

(Presented to the Council April 22nd, 1927)

To the President and Members of Council,
The Engineering Institute of Canada, Montreal.
Gentlemen:—

Your Committee on Prizes has made a careful study of the subject of awarding prizes by The Engineering Institute and its branches.

Briefly, the present situation is that The Institute awards:—

The Gzowski Medal for the best paper in any one year;

The Leonard Medal for the best paper on a mining subject.

(This is a joint medal with the Canadian Institute of Mining and Metallurgy.)

The Plummer Medal for the best paper on a metallurgical or chemical subject; further:

Five Student prizes, each twenty-five dollars cash, are awarded, one in each of the five sections, namely, general, mechanical, electrical, mining and chemical.

Branch prizes are or have been awarded by the Vancouver, Winnipeg and Hamilton Branches. The Saskatchewan Branch offers a scholarship to the most deserving member of the graduating class in engineering of the University of Saskatchewan. The practice of awarding prizes is not sufficiently general among the branches to have more than a passing bearing on the broad policy of The Institute.

Your committee has been in communication with every branch of The Institute, many of which have sent in recommendations which have been used as a basis for the recommendations which follow.

Recommendations.

No change can be made regarding the Gzowski, Leonard or Plummer medals.

Instead of the five Student prizes now awarded of twenty-five dollars each, your committee recommends that five prizes be awarded, distributed geographically by vice-presidential zones as follows: one for Zone A, the four western provinces; one for Zone B, the province of Ontario; two for Zone C, the province of Quebec; one for Zone D, the maritime provinces. Two prizes are recommended for Zone C, the province of Quebec, in view of the fact that 50 per cent of the student membership is in this province; further, in view of the fact that there are both English and French universities, it is recommended that one prize should be English and one French. Each prize should be in the form of books or instruments to be selected by the recipient to the value of twenty-five dollars. It is also recommended that each prize be named after a prominent past-president of The Institute from the territory in which the prize is to be awarded. For example, the Ontario prize might well be called the *John Galbraith Prize*. Names should only be allocated after very careful consideration, and after conferring with representatives of the zones. The present arrangement whereby Juniors are eligible for Student prizes should be continued.

Your committee recommends that a new prize in cash, of one hundred dollars, be awarded annually for the best contribution submitted by any member of The Institute on a subject selected by Council and announced at the commencement of each year. It is recommended that this prize be called *The Past-President's Prize*, in recognition of the fund established by past-presidents.

Your committee also recommends that a gold medal named after a prominent past-president, such as, for example, *The Sir John Kennedy Medal*, might be awarded, only when the occasion warrants, as a recognition of outstanding merit in the profession or of noteworthy contribution to the benefit of The Institute or of the profession. This prize should be looked upon as of such outstanding value that it would only be awarded occasionally and limited to corporate members. It is suggested that each branch should be asked for recommendations every year, but that Council should only make the award if it considers the occasion warranted.

The foregoing recommendations are submitted for your consideration as indicating the broad principles only. It is suggested that if these principles meet with the approval of Council a set of rules be very carefully prepared and in such rules there would be incorporated a very definite specification under which the prizes should be awarded.

Yours very truly,

COMMITTEE ON PRIZES.

Per J. L. BUSFIELD, M.E.I.C.,

Chairman.

Committee:—
J. L. BUSFIELD, M.E.I.C., Chairman.
GEO. R. MACLEOD, M.E.I.C.
A. FRIGON, A.M.E.I.C.

Lincoln Arc Welding Prizes

The American Society of Mechanical Engineers have just published a bulletin entitled "Conditions Governing the Award of Lincoln Arc Welding Prizes," containing details regarding the award of these prizes.

The Society has accepted the custody of $17,500 given by the Lincoln Electric Company of Cleveland, Ohio, as prize money in connection with this competition, a preliminary announcement of which appeared in the February issue of the Engineering Journal.

All enquiries for further information should be addressed to the secretary, Calvin W. Rice, The American Society of Mechanical Engineers, 29 West Thirty-ninth Street, New York, N.Y.

Trade Publications

The Canadian S.K.F. Company, Limited, have issued a conversion table chart giving the decimal equivalent parts of an inch in six figures. This chart is available in two sizes,—one 30" x 26" and the other 8" x 5",—and should prove useful to those whose work frequently requires the conversion of fractions of inches to decimals. Copies may be secured from the company's office at 1057 Bay Street, Toronto, 5, Ont.

Western Wheeled Scraper Company, Aurora, Ill., have issued an instructive and interesting souvenir booklet entitled "Fifty Years of Service," containing details and illustrations of the application of this company's equipment to various engineering construction works.

The Garlock Packing Company announce the removal of their general office from Hamilton, Ont., to New Birks Building, Montreal, and, while the company's general factory will be located in Hamilton, all business will be transacted through their office at Montreal.

BRANCH NEWS

Calgary Branch

H. R. Carscallen, A.M.E.I.C., Secretary-Treasurer.
W. St. J. Miller, A.M.E.I.C., Branch News Editor.

ANNUAL MEETING

On Saturday, March 12th, the annual meeting of the branch was held following a luncheon, when some thirty members were present.

Reports from the conveners of the various committees were read and duly adopted. It was shown that the attendance throughout the season had been quite satisfactory. The secretary-treasurer's report showed that the membership had dropped slightly but was keeping up to the average for the past few years. This is to be expected in a city such as Calgary, where, comparatively speaking, very little actual engineering work takes place. His financial report was clear and gratifying, especially as a fair balance was showing to our credit in the bank. It is felt that the secretary gets very little thanks in proportion to the amount of real hard work he does. The branch members, of course, show their appreciation, but would like also to express it through our columns in the Journal.

Following the work of the scrutineers who counted the ballots, Chairman J. H. Ross, A.M.E.I.C., announced the election of officers of the branch for the ensuing year as follows:—

Chairman	F. K. Beach, A.M.E.I.C.
Vice-Chairman	Thos. Lees, A.M.E.I.C.
Secretary-Treasurer	H. R. Carscallen, A.M.E.I.C.
Executive Committee	F. M. Steel, M.E.I.C.
	F. J. Robertson, A.M.E.I.C.
	J. J. Hanna, A.M.E.I.C.
Auditors	O. H. Hoover, A.M.E.I.C.
	J. C. Milligan, A.M.E.I.C.

As previously announced, the branch has been honoured again by the election of one of its members, in the name of S. G. Porter, M.E.I.C., to the office of western vice-president of The Institute. A. L. Ford, M.E.I.C., is the new representative of the branch on this year's Council. W. St. J. Miller, A.M.E.I.C., has been elected as a member of the Papers Committee at Headquarters.

Chairman Ross delivered a short and appropriate farewell speech before retiring, and handed the leadership of the branch over to the new chairman, F. K. Beach, A.M.E.I.C., who spoke briefly but to the point, and thanked the members for the honour they had bestowed on him by his election.

Halifax Branch

Harry F. Bennett, A.M.E.I.C., Acting Secretary.

Through the kindness of Dr. F. H. Sexton, of the Nova Scotia Technical College, the members of the branch were permitted to see several excellent motion pictures covering the subjects of oil, asbestos and water power, shown at the Technical College on April 1st.

These films were prepared by the United States Bureau of Mines, and were of an unusual educational value. The story of oil dealt fully with the subject, including the boring, its purification and the wide use of its products. The asbestos film depicted mining operations in Arizona and Quebec and its manufacture. A part of the film dealt with magnesia, with which asbestos is closely associated in the arts.

CARBONIFEROUS LIMESTONES AND COAL MEASURES IN NORTH WESTERN EUROPE

Canon Delepine, professor of geology at the University of Lille, France, visited Halifax on April 4th, and lectured at Dalhousie University on "Carboniferous Limestones and Coal Measures in North Western Europe." The members of the branch were invited and availed themselves of the opportunity of hearing Canon Delepine.

He dealt with the several geological periods when coal and limestone were formed, and by splendid illustrations showed the parts of Europe where these deposits are found. The origin of the coal measures and the relation of the North American coal fields with those of Europe were traced through the organisms found in the various deposits. The members of The Institute appreciated the privileges extended to them by the two local universities.

Hamilton Branch

W. F. McLaren, M.E.I.C., Secretary-Treasurer.
J. R. Dunbar, Jr.E.I.C., Branch News Editor.

Regular Meeting, March 16th

A meeting of the Hamilton Branch was held in the cafeteria of the Hamilton Technical Institute on Wednesday, March 16th, 1927, at 8.15 p.m., with L. W. Gill, M.E.I.C., presiding. Approximately thirty were present.

The report of the nominating committee was read and after amendment was adopted.

The present executive committee, composed as follows, is continuing in office for the next year:—

Chairman ....L. W. Gill, M.E.I.C.
Vice-Chairman ....W. L. McFaul, M.E.I.C.
Secretary-Treasurer ....W. F. McLaren, M.E.I.C.
Executive Committee .....H. A. Lumsden, M.E.I.C.
G. R. Marston, A.M.E.I.C.
F. P. Adams, A.M.E.I.C.
Arthur H. Munson, A.M.E.I.C.
Branch News Editor ....J. R. Dunbar, Jr.E.I.C.
Past Chairman ....C. J. Nicholson, A.M.E.I.C.
Past Secretary-Treasurer....H. B. Stuart, A.M.E.I.C.

The following Hamilton Branch Prize Committee were appointed:—

Chemical Section ....H. G. Girvin.
Civil Section ....E. H. Darling, M.E.I.C.
Mechanical Section ....W. G. Milne, A.M.E.I.C.
Engineering Education .... L. W. Gill, M.E.I.C.
Electrical Section ....D. W. Callander.

A. M. Jackson, A.M.E.I.C., then addressed the meeting on "The Use of the Local Material for Concrete Construction." He described the methods of inspection whereby it was possible to use local materials in the construction of concrete roads in Brant county, thereby effecting a considerable saving over the use of outside materials. He mentioned the procedure of predetermining the strength of the concrete.

Mr. Jackson's paper is the first paper which has been presented before the Hamilton Branch to be eligible for a Hamilton Branch prize, and it is hoped that several more papers will be entered in the competition during the coming year.

G. R. Marston, A.M.E.I.C., discussed the paper and suggested a comparison between the Hamilton-Toronto concrete highway and the asphaltum surface of Dundas street. F. P. Adams, A.M.E.I.C., when moving a vote of thanks, commended the work done by Mr. Jackson. The vote of thanks was seconded by H. A. Lumsden, M.E.I.C., and was carried.

Stanley Shupe, M.E.I.C., then gave an excellent address on the "Sewage Disposal Plant at Kitchener," which has special difficulties to contend with on account of the waste from the tanneries and abbatoirs. The first method used was the distribution method by spreading over ploughed land. They next went to sand filtration and finally the Imhoff tank was adopted.

Mr. Adams also contributed to the discussion on this paper. A vote of thanks was moved by Mr. Marston and seconded by W. L. McFaul, M.E.I.C.

Mr. W. H. Mackie, of the Ontario Tractor Company, Toronto, showed moving pictures of the caterpillar tractor clearing snow from the streets and levelling roads.

Refreshments were served at the conclusion of the meeting and music was furnished by the school jazz band.

Visit of the General Secretary

Seven members of the executive committee of the Hamilton Branch met at luncheon at the Wentworth Arms on April 14th, 1927, to meet R. J. Durley, M.E.I.C., general secretary of The Institute, who was visiting Hamilton. Several matters of interest to The Institute at large, and to the Hamilton Branch in particular, were discussed during luncheon.

During the day Mr. Durley visited a number of the manufacturing plants in the city, under the guidance of various members of the Hamilton Branch.

Lethbridge Branch

Wm. Meldrum, A.M.E.I.C., Secretary-Treasurer.

Mine Timber Tests

On Saturday, March 5th, Professor R. S. L. Wilson, A.M.E.I.C., addressed the Lethbridge Branch on "Mine Timber Tests."

Every once in a while, Albertans hear of an organization known as The Scientific and Industrial Research Council of Alberta. Now and then a glimmer of light is thrown on its work. Its personnel, made up of the faculty of the university, work along silently. A problem is offered for solution. Some one professor makes it his particular hobby, takes it home with him, sleeps with it, eats with it, uses it for relaxation from his routine of teaching, and finally becomes so intimately acquainted with that particular problem that he knows all its whims and secrets. It is something like breaking a broncho or training an ant. Years later, after most people have forgotten it, he brings the problem into your parlour, tamed and docile. It is a problem no longer. It has become an economic fact, and ready to serve Mr. Average Citizen in reducing his working costs or increasing his comfort.

Take the lodgepole pine, or jackpine, for instance. Professor R. S. L. Wilson, A.M.E.I.C., of Alberta University, on Saturday night, in an address before the Lethbridge Branch, dissolved this common tree and analyzed its moisture content, its seasoning period, the effect of peeling, how it stood up in mining practice and explained its bending and crushing loads. Ever since 1921 the Research Council has been collecting data on forest resources, and Professor Wilson's task has been with mining timbers, and the lodgepole in particular.

Timbers were placed in a working mine. Some of the test pieces were peeled, others had the bark on, others were fully seasoned. They were left for varying periods of time, and then removed for laboratory test. An ingenious machine was constructed at the university to subject the timbers to bending and crushing loads and to ascertain rate of deflection.

As an instance of how painstaking these investigations are, the method of ascertaining moisture content is an illustration: a one-inch disk is cut from the boom or prop and weighed. Then it is dried in an oven at 100 degrees centigrade and weighed each day until the two last weights show less than one per cent variation from each other. This is the dry weight. The difference between this and the original weight is expressed as a percentage of the dry weight and called the moisture content.

Then there is the question of fungus growth,—what particular germ is present when a timber rots? Here enters the botanist, who works much as a physician would work on tissue, and at this point the professor mentioned discovering a puzzling type of rot or disease that so far has baffled the botanist. Professor Wilson never lets his hobby get far from him, and for some months he had on his desk a piece of wood. One day a powdery dust appeared, and, when brushed off, reappeared day after day. The wood was slowly dissolving into dust. What caused it? What was the preventative? No one knows, but some day someone will find out. Of such intangible things does scientific research thrive on.

The professor's investigations are not complete. It may be two years yet before he may find what he requires. It may be that he will not find it in all its details. Results so far are encouraging. Mine timbers are costly in the aggregate. Anything that prolongs their life means money saved, may even mean greater security among those whose work takes them underground. Seven years is a long time to spend on one problem. To most people the subject would become monotonous, but to those who heard the professor Saturday night, there was no mistaking his enthusiasm. He will see it through, as others of this Research Council are seeing similar problems through.

Mining men were at the meeting, and the discussion which resulted showed how closely they had followed the address, which was illustrated with graphs and slides.

J. T. Watson, A.M.E.I.C., presided at the meeting, and there were about forty members and friends present. During the dinner that preceded the address, the Rainbow Orchestra supplied music and there were songs by Messrs. Meldrum and Fred. Rose. In fact, as is usual with these engineers' meetings, the musical entertainment was of a high order.

Annual Meeting

The annual meeting of the Lethbridge Branch was held on Saturday, March 19th, and the following were elected as members of the Executive Committee:—

G. S. Brown, A.M.E.I.C...............*Chairman.*
Nat. Marshall, M.E.I.C...............*Vice-Chairman.*
Wm. Meldrum, A.M.E.I.C.............*Secretary-Treasurer.*
N. H. Bradley, A.M.E.I.C.............*H.Q. Council.*
C. S. Clendening, A.M.E.I.C............
J. B. deHart, M.E.I.C.................
P. M. Sauder, M.E.I.C.................
J. T. Watson, A.M.E.I.C................*Ex-officio.*
Robt. Livingstone, M.E.I.C............
C. S. Clendening, A.M.E.I.C........... *Auditors.*
W. L. McKenzie, A.M.E.I.C............

The meeting opened with one of the regular luncheons, during which the Rainbow Orchestra performed. After luncheon, community singing and solos by R. S. Lawrence, A.M.E.I.C., and Wm. Meldrum, A.M.E.I.C., were much appreciated. The financial statement and report of the retiring executive were read by Secretary-Treasurer N. H.

Bradly, A.M.E.I.C., and adopted. Some good discussion on branch affairs was indulged in by many present. The meeting was well attended and received the announcement of the results of the election with hearty applause. The retiring chairman gave thanks where thanks was due, to the Entertainment Committee, Programme Committee and the Publicity Committee. His statements were heartily endorsed by the other members present. The new chairman, G. S. Brown, A.M.E.I.C., accepted his responsibilities in a nicely worded speech.

London Branch

F. C. Ball, A.M.E.I.C., Secretary-Treasurer.

Meeting of March 30th

A moving picture exhibition of the capabilities of caterpillar tractors for use in engineering works was given before the London Branch at the city engineer's office, Princess avenue school, on Wednesday evening, March 30th, 1927.

The lecture was given by Mr. Mackie, representing the firm of Best and Holt Caterpillar Tractor Company, at Toronto. The use of these machines for road grading, ditching and excavating large quantities of earth was clearly shown, together with the ease with which they are manipulated. A number of views of snow handling and general haulage of earth, stone, etc., up to twenty cubic yards at a time were shown, demonstrating the great saving of time and labour by the use of these tractors.

A general discussion followed on several practical phases of the use of these machines and on their life and cost. An interesting comparison was made between the cost of operating a tractor per day and the cost of a team and rig, which showed that while the cost of operating the tractor might be slightly higher the work would be done in a fraction of the time required by the team.

About thirty members and guests were present, amongst them being several local contractors. In conclusion, a vote of thanks to Mr. Mackie was proposed by the chairman, J. R. Rostron, A.M.E.I.C., and seconded by Charles Talbot, A.M.E.I.C., county engineer, and was unanimously carried.

Operation and Construction of B. & W. Type Water Tube Boilers

On Monday, April 11th, 1927, a lecture, illustrated by moving pictures, on the "Operation and Construction of B. & W. Type Water Tube Boilers," was given at the London Technical School. The speaker was J. O. Twinberrow, A.M.E.I.C., of Babcock-Wilcox and Goldie-McCulloch, Limited.

The lecture was specially interesting to those engaged in work of the nature and a number of members of the London Branch availed themselves of the opportunity to attend.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

Gunnery in the Great War

"Gunnery in the Great War" was the subject of an address given before the branch on March 29th by Professor John Stephens, M.E.I.C., of the University of New Brunswick. The meeting was held in the city hall and was open to the public, many members of military units being in attendance.

Professor Stephens, who was formerly an artillery instructor in England, opened his address with an historical outline of the development of artillery from the earliest times up to the present. The various problems entering into the theory of the science of gunnery were discussed, and the difficulties encountered in putting these theories into practice explained. In the opinion of the speaker, gun laying was now, as in olden times, to a great extent a matter of trial and error.

At the conclusion of the address one hundred slides, taken from photos of the official Canadian war records, were shown. Scenes taken on the various fronts, showing ammunition dumps, guns, towns in France and Belgium, were readily recognized by returned men present and brought back memories of the great war where many Moncton boys remain in foreign lands, having made the supreme sacrifice.

After the public meeting a short session of the branch was held, at which, on motion of A. F. Stewart, M.E.I.C., seconded by F. O. Condon, M.E.I.C., a resolution of sympathy was extended to the family of Mr. Hugh Jardine, a former member of the branch, whose death occurred recently.

Our Maritime Harbours

The regular monthly supper meeting was held in the Palm room of the Brunswick hotel on April 8th. G. C. Torrens, A.M.E.I.C., vice-chairman of the branch, presided, and during the supper hour referred to the time of meeting coming within a few hours of the tenth anniversary of the taking of Vimy ridge by the Canadians. The members were requested to rise and observe a one-minute silence in honour of those who had fought and would never return.

During the evening vocal solos were rendered by Mr. F. S. Wilkins, and trumpet selections by Mr. Fred. Cosman.

The vice-chairman then introduced the speaker of the evening, Mr. Thos. J. Locke, district engineer, Department of Public Works, Halifax, who delivered a very interesting address on "Our Maritime Harbours, Their Treatment and What They Mean to Us."

There is no other territory of similar size that possesses as extensive a coast line with as many bays, coves, harbours and shelters as the maritime provinces, with its 4.000 miles of coast line, upon whose inlets the Department of Public Works has placed nearly 1,000 coastal improvements. A harbour is a sheltered area which can be safely and surely navigated by shipping. Because a harbour is sheltered, however, does not relieve us from its improvement. A natural harbour is a haven of refuge for shipping, but shipping cannot ply the seven seas unless facilities for loading, discharging and repairing ships are provided.

Mr. Locke mentioned the various types of wharves, their construction and the different kinds of material used. Starting from the shore, they generally commence with a rock bank approach which is continued as far as the economical factor will permit. The character of the remainder of the wharf depends entirely on the nature of the bottom. If the material is penetrable a structure resting upon pile trestle bents is much to be preferred on account of low first cost and cost of repairs. The bracing of trestle work is somewhat changed. Instead of the old "V" or "X" bracing, which thirty years ago was universal, brace piles are used, and in all cases where heavy traffic does not exist no additional bracing has been found necessary. Where the bottom is not penetrable a cribwork form of construction is adopted. This is generally of the alternate block and span type.

In many of our coastal waters it is necessary to combat marine pests which attack the wooden members of the structures. Up to the present, the use of creosoted timber has been found to be the only real protection against these pests. Sixteen-pound treatment is specified with the additional proviso that the oil used in the treatment must contain not less than 40 per cent naphthalene. As an example of the necessity for a high percentage of naphthalene last fall a sample of creosoted log was obtained which had been submerged for twenty years. This sample was forwarded to the government analyst at Ottawa, who reported that practically all traces of creosote had, either through saturation or other causes, disappeared, except the naphthalene which had originally been present in the oil when the log was treated.

Breakwaters were mentioned by the speaker, who explained the different types required, according to location. Dredging was another matter touched upon and its importance stressed in making our harbours of more value.

At the conclusion of the address a hearty vote of thanks, moved by H. J. Crudge, A.M.E.I.C., and seconded by A. C. Selig, M.E.I.C., was tendered Mr. Locke for his address.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.
H. W. B. Swabey, M.E.I.C., Branch News Editor.

Locomotive Feed Water Heating

A comparatively recent and successful development in the locomotive field was reviewed by Mr. W. C. Hamm, mechanical engineer for the Central Vermont Railway, in a paper on "Locomotive Feed Water Heating," presented to the branch on March 17th, 1927.

"The application of feed water heaters to locomotives in the United States, commencing in 1916 has increased until at present there are approximately 4,100 in service on this continent and several thousand in Europe.

"This was due," said the author, "to the increasing cost of locomotive fuel, the need for a more efficient locomotive and the size of the locomotives themselves, which makes the savings obtained show up quite handsomely."

Of the two-fold benefit obtainable through the application of the feed water heaters to locomotives, the first and generally more important benefit accrues from fuel saving, and the second, though equally or more important on low gradient lines, is the possible increase in boiler capacity resulting in an increased gross ton hour figure.

As only about 7 per cent of the fuel value is realized at the drawbar, a notable economy will be effected by any device that is capable of utilizing any portion of the approximately 25 per cent lost with the hot gases or the 58 per cent escaping with the exhaust steam. It is in this latter division that we have available a source of power which, if reclaimed, will result in substantial savings.

More than sufficient heat is available in the steam exhausted to preheat the feed water to within an average of ten degrees of the temperature of the exhaust steam. This then is an appreciable and direct saving in the use of fuel.

Offsetting this saving is the live steam consumption of the feed water pump and on an old locomotive, a loss in initial superheat, but these are largely compensated for by the increased evaporating efficiency of the boiler obtained by the lower fuel rate required, which, in turn, renders possible a reduction in the cylinder back pressure.

Another feature of the feed water heater which is often important is the return of the distillate from the exhaust steam to the boiler. This distillate, approximating 10 per cent of the feed water requirements, is distilled water, thereby eliminating immediately a corresponding per cent of the impurities carried in to the boiler besides obviating, in many cases, a water stop with its attendant delays.

The speaker proceeded to give very interesting service data from some fifty feed water heaters of both the closed and open types, operated in freight and passenger locomotives. These were all fully illustrated. Following this, a set of excellent lantern slides described in detail the four principal types of heaters that are being developed on American railroads. In the closed type there were the Elesco and the Coffin, and in the open type the Worthington and the Debig.

A discussion, led by Mr. E. A. Averill of the Superheater Company, followed by Messrs. R. S. Griffiths, John Roberts, E. Sauny and J. D. Alder, M.E.I.C., brought out the fact that it was possible some 14 per cent of the feed water was reclaimable, as the distillate, up to 30 per cent of the heat from the exhaust steam recoverable, and the boiler efficiency possibly increased by some 4 per cent.

The fuel saved on a $2,500 installation amounted to $1,650 a year, or a 65 per cent net return.

C. K. McLeod, A.M.E.I.C., in fitting terms expressed the appreciation of the meeting, which was presided over by J. S. Hall, A.M.E.I.C.

Geological Features of the District of Montreal

On March 24th, 1927, A. Mailhot, B.Sc., professor of geology at Ecole Polytechnique, presented to the branch an historical and descriptive narrative depicting the formation of the island of Montreal from earliest times.

The district of Montreal, affirmed the speaker, had once been covered at a remote epoch by a sea which remained sufficiently long to permit the deposition of many hundred feet of sediments. These sediments in time had been consolidated to form what is now the rocky substratum of the island.

These rocks constitute bands very nearly parallel to the Laurentian border, somewhat after the manner of a deck of cards; the first card, some 400 to 1,000 feet thick, would represent the Potsdam sandstone; the next, 1,065 feet thick, the Beckmanstown sandstone; the third, 785 feet thick, the Chazy limestone; the fourth, 695 feet thick, the Trenton limestone, and the fifth, 210 feet thick, the Utica shales.

After these Paleozoic formations were laid down the plain of the St. Lawrence in the vicinity of Montreal became the scene of great volcanic activity. Intrusions first of esseite and then of nepheline-syenite opened a passage through the limestone to form the igneous mass of Mount Royal over a surface of one and one-half square miles.

Following this era of volcanic activity, a great glacier covered the North American continent during the Pleistocene period. On its retreat, moraines of boulder clay were left on the solid rock beneath it, which, with the exception of the hard outcrops of Mount Royal, cover almost the whole of the island.

When the glaciers retreated to the north, the Atlantic ocean again entered the relatively depressed lower St. Lawrence valley to deposit the leda or bluish gray clay and the saxicava sands which cover the boulder clay in large areas on the island.

Though the sand and gravel will generally provide dry cellars, this cannot be said of the boulder and leda clays, which absolutely require the installation of a good drainage system under the foundations.

The speaker concluded his address by delineating the districts in which the solid rock approached the surface, a desirable feature for the erection of large factories, office buildings and departmental stores requiring a firm and solid foundation.

J. L. Busfield, M.E.I.C., expressed the appreciation of the meeting, which was presided over by A. Plamondon, A.M.E.I.C.

The Theory of Telephony Made Visible

Six reels of films, as certainly displaying the evidences of genius as does the marvellous art of telephony which they illustrated, were exhibited to the branch on April 7th, 1927, through the courtesy of the Bell Telephone Company of Canada and Mr. L. St. J. Haskell, assistant to the vice-president.

The first reel, entitled "Over Half a Century of Telephone Progress," showed the telephone pixy springing from the mouthpiece of a telephone desk set to disclose the secret of a long distance connection between San Francisco and Havana. By the aid of novel and fascinating illustrations she proceeded to explain the principles of loading and filter coils, carrier currents, phantom circuits, telephone repeater tubes and to describe the gradual progression from old time to present day equipment.

The subsequent reel illustrating the "Electrical Transmission of Speech" showed an ingenious device by which a beam of light is reflected from a system of moving mirrors to depict the oscillation of a sound wave. Illustrations of simple and complex waves in this device, both with and without the use of a resonator, led to a detailed description of the present telephone transmitter and receiver.

"The Magic of Communication" described in the third and fourth reel, revealed in very clear and entertaining manner the operation of a vacuum tube when used as a telephone amplifying instrument. Filaments, grids and plates lost their power to puzzle in the light of this splendid film.

The final reels presented "A Circuit Study of a Telephone Call," in eight steps. The intricate connections ensuing from the instant the subscriber raised his receiver from its hook until the operator finally disconnected the lines on the conclusion of the call, were taken up in logical sequence.

The well attended meeting, presided over by C. M. McKergow, M.E.I.C., concluded with motions of appreciation and thanks to the Bell Telephone Company by Howard T. Barnes, D.Sc., M.E.I.C., and H. S. Van Scoyoc, M.E.I.C.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Northern Canada

An evening meeting of the Ottawa Branch, to which the public was invited, was held at the Chateau Laurier on March 24th for the purpose of hearing G. H. Blanchet, A.M.E.I.C., and Major L. T. Burwash, B.A.Sc., M.E., lecture on northern Canada. Both these gentlemen, who are fellows of the Royal Geographical Society, have travelled widely in the far north.

The addresses were profusely illustrated with many excellent lantern slides through the use of which the lecturers were able to convey to the audience some clear impressions of the character of the country, its people and resources, in the area from Lake Athabaska to the Arctic coast.

The chairman of the Ottawa Branch, Noulan Cauchon, A.M.E.I.C., presided, and first called on Mr. Blanchet, who spoke of his explorations of the past several years in the country surrounding Great Slave lake and extending to the sources of the Thelon and Coppermine rivers. He described the country in its relation to the base level of Great Slave lake and how it rises away from the lake to a great interior plateau which is the source of rivers draining to Hudson bay, Great Slave lake and the Arctic ocean. The first part of the journey in ascending from the Great Slave lake invariably led through hilly and rocky wooded country very similar to the Laurentians. Eventually one reached the great open spaces of the northern plains, and Mr. Blanchet described at some length the gradual thinning out of the woods, and the struggle for existence of the trees at the last line of the forest, where the trees which succeeded in growing in spite of the Arctic blasts, were very much dwarfed. He showed that the country beyond on the plateau was not barren, but grew considerable grass and moss, the food of the caribou and musk ox. His slides conveyed definite notions of the water powers, forest resources, game, fish, the Indian population, and methods of travelling and camping in the north.

Major Burwash followed Mr. Blanchet with a description of a trip he had made from the mouth of the Mackenzie river along the Arctic coast to Hudson bay. Mr. Burwash spoke particularly of the Eskimo settlements and trading posts along the way, and had numerous very fine slides of these people which were excellent character studies. He spoke of their primitive life in living off the game and fish of the country, and their trade in furs. Major Burwash travelled by steamer and schooner as far as Coronation gulf and afterwards continued his trip with sled and dog-team, eventually coming out at Hudson bay after traversing the greater part of the Arctic coast of Canada.

Commercial Aviation in Canada

Ellwood Wilson, M.E.I.C., president of the Fairchild Aerial Surveys Company of Canada, was the guest and speaker at a luncheon of the Ottawa Branch held on March 31st at the Chateau Laurier. He chose as his topic "Commercial Aviation in Canada." The speaker was introduced by Noulan Cauchon, A.M.E.I.C., chairman of the Ottawa Branch, who alluded to the presence of Albert R. Decary, D.A.Sc., M.E.I.C., President of The Engineering Institute of Canada, Hon. Chas. Stewart, Minister of the Interior, and G. J. Desbarats, M.E.I.C., Deputy Minister of National Defence. Mr. Cauchon eulogized the efforts of the last two named in connection with the development of aviation in Canada.

Mr. Wilson in introducing his subject drew a distinction between civil aviation and commercial aviation. The former, he said, was a government activity, distinct, to be sure, from military flying, but nevertheless paid for by the tax payers of Canada. Commercial aviation, on the other hand, was paid for by private enterprise and must earn a fair rate of interest. The Dominion Government, he said, had pioneered in aviation, and the costs of its experiments in the civil field should be made available for the study and benefit of commercial enterprise. He spoke of the work of the Government as really wonderful in blazing out the lines of effort and the maps of the Topographical Survey were models for everyone and would do a great deal to open up the country. This work of mapping, which had largely been confined to northern Ontario and certain sections of western Canada, should, he thought, be carried out in other sections of the Dominion.

Commercial aviation, Mr. Wilson said, is carried on in Canada by three companies in Quebec, two in Ontario and one in British Columbia. Canada and the United States, he said, were the only countries which have given no subsidies to aid commercial aviation, though they had given some encouragement in the way of contracts. He thought that the government's attitude towards commercial aviation should be clearly expressed within a reasonable time. Regarding air transportation, there were two courses open: either the government should definitely undertake it as a national enterprise like the Canadian National Railways, or it should definitely leave it to commercial companies. The government should say whether there is a field in Canada or not for commercial aviation.

So far in Canada, Mr. Wilson said, aerial activities have been directed towards the back country and have mostly consisted of aerial photography, fire patrol, transportation to equip survey parties and transportation to mining fields. His sphere had been mostly aerial photography, particularly as applied to forests. His original experiments in estimating timber from the air had been conducted in 1919, and now it was possible to make close estimates without going on the ground. The estimates of two ground parties on Anticosti island differed from the aerial estimates by not more than half a cord per acre. In Germany they were going so far as to give the size of trees from aerial photographs.

A great opportunity in the transport by air of mail and other matter is knocking at our doors, Mr. Wilson continued, and there is money and enterprise in Canada to start routes just as soon as traffic demands. He said that where there is a large volume of traffic warranting the use of large machines, air transportation can be performed at a rate to compare with the high class, extra-charge railroad trains. Flying is the perfect method of transportation, he said, and is the safest; the records show this fact, he maintained, and referred to the great and increasing number of automobile accidents. As for costs, he said that air mail contracts in the United States were placed at 0.22 cents per pound per mile, and that in England and other countries the cost was about the same. At present in Canada with small machines the cost could be estimated at $100 per hour, or one dollar per mile, but with an assured volume of traffic transportation could be made as reasonable as in other countries.

The use of airplanes, Mr. Wilson said, can play an increasing part in the development of the north in advance of the railroads. If aviation is not fostered the whole development will be delayed. He concluded his address with a plea for "airmindedness," and a realization of the advantages which are knocking at our doors.

At the conclusion of Mr. Wilson's address, which was enjoyed by a large attendance, Mr. Cauchon asked Mr. Decary to speak, and the President of The Institute expressed his pleasure at being present and hoped that the day would not be far distant when he could come to Ottawa for a luncheon and return to his office in time to carry out the afternoon's work.

Practical Notes on Oil Paints

An evening meeting of the Ottawa Branch was arranged for April 7th for the purpose of hearing a paper by A. K. Light, B.Sc. chemist of the Public Works Department, entitled "Some Practical Notes on Oil Paints and their Application." This paper is published on page 267 of this issue of the Journal.

Mr. Light has been connected with the testing laboratories of the Public Works for six years, during which time he has made a special study of paints for the purpose of determining the best types and methods of application to be used for various purposes. At this season of the year this subject is of special interest to all those who have to look after the preservation of structures, and there was a good attendance.

Mr. Light outlined the various qualities demanded of a good paint or varnish, the necessity for a high degree of opacity, great covering power, impermeability to moisture. No paint, however, will, he said, serve all purposes, and those which will serve well under dry conditions would be useless under moisture, or one intended for mural decoration would not last any time if used on a floor.

Mr. Light dealt with the various requirements of paints and their use, under the headings of pigments, vehicles, preparation of surfaces of wood, plaster, cement, brick and metals, the methods of applying the various coatings, the mixing of paints, the selection and care of brushes, and the economies of painting. He emphasized the folly of using cheap paint, and said that a little extra expenditure on the thorough preparation of the surface and for high quality paint carefully chosen for existing conditions, would be more than compensated for by the durability and long life of the resulting paint film.

Mr. Cauchon presided, and a feature of the evening was the presentation of a prize awarded by the Students' Prize Committee of The Institute to Henri A. Gauvin, S.E.I.C., of Ottawa, for a paper on "Scientific Principles and their Application to Dwelling House Construction."

Peterborough Branch

W. E. Ross, A.M.E.I.C., Secretary.
B. Ottewell, A.M.E.I.C., Branch News Editor.

Recent Progress in Electric Welding

At the regular meeting held on March 31st, 1927, R. E. Smythies, M.E.I.C., vice-president of the Lincoln Electric Company, Limited, Toronto, gave a paper on this subject, illustrated with a large number of lantern slides. This paper was previously presented before the Hamilton and Toronto branches, and is published on page 262 of this issue of the Journal.

The speaker mentioned that the art of electric welding began some forty years ago, but has only become a commercial proposition during the past eight years or so. A large number of typical examples of arc welding were shown on the screen and described by the speaker. In the case of steel tank and pipe work welding has almost entirely replaced riveting. An outstanding example is a water pipe for the city of Oakland, Cal., 5 feet 6 inches in diameter, 90 miles long, built up from 30-foot sections ⅝-inch thick. The longitudinal seams of these sections were welded in the shop on automatic seam welders and subjected to extremely rigid tests before acceptance. Other examples given were bronze turbine runners, manganese steel tramrails, fish plate joints, drilling jigs, etc.

Mr. Smythies stated that the actual cost of arc welding should be from one-half to one cent per pound of metal deposited. Amongst the advantages not usually mentioned in connection with arc welding is the saving in inventory and storage space required owing to the facility with which articles can be built up from standard material.

Mr. Smythies was an advocate of the heaviest welding current which the job will stand and stated that at present there is considerable variation between individual operators. He remarked that progress in the use of arc welding in structural steel work is relatively slow, apparently due to the difficulty of persuading structural engineers of the efficiency of arc welding.

The speaker was accorded a hearty vote of thanks for his interesting address.

Long Span Bridges

A meeting of the branch was held on April 14th, 1927, the speaker being Professor C. R. Young, M.E.I.C., professor of structural engineering, University of Toronto. His address on "Long Span Bridges" was given in characteristically lucid and attractive style and was illustrated with many fine lantern slides of bridges all over the world.

Professor Young dealt with his subject under the various classes of bridges.

Stone. Many of the earliest bridges were built of stone, and a classical example is the remains of a bridge in Italy built in 1371 with a span of 250 feet. The limit to the construction of stone bridges was reached in about 1905 with the building of a bridge in Saxony with a single span of 295 feet.

Cast Iron. The next material resorted to was cast iron, owing to the comparative ease of producing parts to any design. Robert Stephenson designed a 450-foot span in cast iron for the Britannia bridge (Menai Straits), but this was not used, the final bridge being of the tubular type.

Suspension Bridges. A noteworthy example of this type is the Menai Straits bridge, built by Robert Telford in 1825 with a centre span of 580 feet. The problem of stiffening the suspension type bridge and preventing waving of the floor under load was solved by Mr. John A. Roebling, and later bridges of this type are quite satisfactory.

The suspension bridge at Niagara Falls, built in 1855, safely carried railway traffic for forty-two years before being replaced by the present bridge. The Brooklyn bridge, 1,595-foot span, and the Manhattan bridge over the East river, New York, 1,470-foot span, are noteworthy examples of the type. Most suspension bridges utilize parallel wire steel cables, as this material has the highest strength, namely, over 200,000 pounds per square inch ultimate. Some suspension bridges, however, have been constructed with I-bar cables, an early example being the Elizabeth bridge at Buda Pesth, span 951 feet.

Mention was made of two types of towers, namely, the hinged or pin supported type and the flexible type, the speaker expressing a personal preference for the former. The present high water mark of suspension bridge construction was stated to have been reached in the Delaware river bridge, in which the principle of loaded back stays gives a pleasing appearance. This bridge carries six lanes of traffic and is carried by two steel cables thirty inches in diameter.

At this point the speaker took occasion to describe the method of using pneumatic caissons.

Arch Type. Examples of this type mentioned were the Hell Gate bridge at New York and the Sydney bridge, Australia, now building, for a span of 1,650 feet.

Brief mention of the truss type and continuous girder type was made before passing to the cantilever type.

Cantilever Type. The classical example of the cantilever is the Forth bridge, with two spans of 1,710 feet each, but the design, using tubular compression members, would not be considered economical at the present time. Professor Young next described the Quebec bridges, giving the reasons for the first and second failures and a description of the final bridge.

Concrete Bridges. In giving examples of this construction, the speaker expressed great admiration for the advanced work done by French engineers with this material. A good example on this continent is the 400-foot concrete span at Minneapolis.

Projected Bridges. The speaker mentioned two very long span bridges now projected, and which seem to have a fair possibility of being proceeded with, namely, Hudson river bridge, 3,500 feet, and the Golden Gate bridge, San Francisco, about 4,000 feet.

A vote of thanks to Professor Young was proposed by R. L. Dobbin, M.E.I.C., and heartily approved.

Saint John Branch

W. J. Johnston, A.M.E.I.C., Secretary-Treasurer.

Town Planning in Saint John

The Saint John Branch of The Engineering Institute of Canada assisted in a worthwhile community effort recently when one of its meetings was devoted to the discussion of the subject of local town planning. Curiously enough, Saint John was one of the first cities on the American continent to consider the subject of modern town planning as a means of directing in an orderly and comprehensive manner the future growth of the city. It had a town planning commission in active consultation over a period of several years, and had a town planning map prepared covering the city proper and suburbs, but with town planning proposed for the present not applying to the built-up sections of the city and outskirts. Here the matter has rested for some four years until the Saint John Branch revived the subject as one of engineering as well as of general interest

The subject introduced by a paper entitled "Town Planning in Saint John," was delivered by Mr. W. F. Burditt in the Board of Trade rooms before the branch on the evening of March 31st, 1927. Mr. Burditt was a member of the Town Planning Commission of Saint John and is well informed on all phases of town planning. A. R. Crookshank, M.E.I.C., acted as chairman of the meeting.

The first section of the address dealt in a general way with the subject of town planning; the need of traffic arteries, zoning regulations, set-back restrictions on streets ear-marked for later widening; provision for parks and recreation areas, etc. Lantern slides were shown of different features of town planning applied in a number of cities throughout the world.

Tracing the history of the town planning movement in this province, the speaker mentioned that the Town Planning Act was passed in New Brunswick in 1912. This was merely a permissive act by which any local authority or town planning commission might apply to the government to have some scheme passed on before its adoption. In Saint John a town planning scheme was prepared largely under the guidance of Mr. Thomas Adams and his assistants on the Commission of Conservation.

As applied to Saint John it is proposed, under the town planning scheme, to lay out a system of skeleton roads on the outskirts of Saint John so that any later subdivisions may conform with the general scheme. It provides that such necessities as water and sewerage systems be built and roads graded over a small area before building lots be sold, to prevent scattered building over a large area with resulting high taxes. Certain roads which must eventually carry more traffic it is proposed to widen, and any later building along such roads cannot be built to the present side lines. Provision is made for certain desirable areas to be maintained as in open spaces and parks. All restrictions are reasonable and have been successfully applied in other places. A large town planning map of Saint John and environs was used for demonstration purposes.

A number of interested citizens, not members of the branch, were in attendance at the meeting. Dr. W. W. White, mayor of Saint John, was present and in a speech expressed his sympathy with the town planning movement and the benefits Saint John and surrounding district would derive from it.

The branch members were pleased to welcome to the meeting R. A. Ross, D.SC., M.E.I.C., of Montreal, a past president of The Institute. Mr. Ross was called upon for a few remarks.

A vote of thanks to Mr. Burditt was moved by Alex. Gray, M.E.I.C., and Geoffrey Stead, M.E.I.C., and extended to the speaker on behalf of those present by the chairman of the meeting.

Maritime Harbours

At a branch meeting on April 7th, 1927, the members were addressed by Thomas J. Locke, district engineer of the Department of Public Works, Canada, Halifax, N.S., on the subject of "Maritime Harbours, How Treated and What They Mean to Us." A. R. Crookshank, M.E.I.C., presided as chairman of the meeting.

The speaker discussed the extensive coast line of the Maritime provinces and described the work done by the Dominion government in affording means for the protection and development of the fishery harbours and facilities for general shipping.

The development of harbours naturally included sites where there was natural protection as well as sites on barren, exposed coasts where all protection works had to be provided; the latter being usually handy to a good fishing ground. The works constructed on the exposed Sable island, lying in the Atlantic south of Nova Scotia, were mentioned as a good example.

Harbour protection works were vital to many isolated fishing communities. The speaker cited the case of works built in 1901 at a cost of $19,000, in a locality where, for want of previous protection, only seven fishing boats had remained in service and the catch did not exceed $500 per boat annually. By 1911, forty fishing boats were engaged with a yearly income of $900 each, while to-day sixty boats are in commission at this place and the yearly catch is $1,500 per boat. Without harbour protection works at this place the entire district would probably have been depopulated by this time.

The speaker mentioned various types of crib and pile wharves, and also the use of rock-fill construction at suitable localities. The damage to timber structures from teredo and limnoria was also described as being extensive within these waters.

A lively discussion was engaged in by many of those present, and many questions were answered by Mr. Locke, and it was evident once more that an intelligent discussion on a paper is a means of bringing out much valuable additional information.

A vote of thanks was extended to Mr. Locke on the motion of Geoffrey Stead, M.E.I.C., and Alex. Gray, M.E.I.C. W. C. Risley, M.E.I.C., councillor of the Sydney Branch, was welcomed to the meeting.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary.

Visit to Carbide Company's Plant

On Friday, April 1st, 1927, at 6.45 p.m., thirty-seven members met at the dock of the International Transit Company. Owing to the ferry being out of order, Mr. Pickering, the manager, had kindly arranged to have a launch there which took the members across the St. Mary's river to the Union Carbide Company's dock on the Michigan side. Awaiting on the dock to greet the party from Sault, Canada were Mr. Boult, works engineer, Mr. Baker, assistant superintendent, and Mr. Brown, all of the Union Carbide Company of Sault Ste. Marie, Michigan.

Mr. Boult took the party through the spacious and well-equipped offices, arriving at the draughting room, where the following members of the Carbide staff, Messrs. Griffin, Hansen, Comb, McGovern and Thomas, were waiting to add their welcome to the visitors from across the river. From the draughting room, Mr. Boult led the party upstairs to a large and fully-equipped dining room which is for the use of the employees of the company. There, as guests of the Carbide Company, the entire party of visitors and members of the staff thoroughly enjoyed themselves, judging by the numerous times that those serving were called upon to pass and refill the platters with well-cooked lake trout, vegetables, etc. Mr. Boult called it a luncheon, and everyone wondered what a dinner served there would be like.

Geo. Kohl, A.M.E.I.C., as chairman of the Sault Ste. Marie Branch, expressed his thanks and appreciation and also, on behalf of the members, he thanked Mr. Boult and fellow-employees of the Carbide Company for the royal manner in which they entertained the members. He outlined the growth of The Institute since it was organized in 1887, and extended an invitation to the Carbide Company employees and also to all engineers in the Michigan Sault to come over and attend the meetings which are held on the last Friday of each month.

J. Hayes Jenkinson, A.M.E.I.C., seconded Mr. Kohl's remarks, and expressed his appreciation of the company's hospitality.

Mr. Boult expressed his pleasure in having and in being able to entertain the Canadian engineers at this luncheon. He said that this visit had been talked about for some time, and at last realized, and the only thing that he was sorry about was that Mr. White, the superintendent of the company, was unable to be present, but that he had sent his regrets.

Mr. Baker also expressed his pleasure in having the members from Sault, Canada, visit the plant.

Mr. Boult called upon Mr. W. E. Comb, who read an article written by H. L. Moyes, chief engineer, Union Carbide Company, in the Engineering News Record of October 2nd, 1924. This article gave a complete and most comprehensive description of the lime-burning plant and its operation at the plant in Sault Ste. Marie, Mich.

Mr. Boult read another article from the Acetylene Journal, June 1926, on the "Construction of Kilns" as used in their lime-burning plant and also on the various tests that have been made in the kilns since having been put into operation. It gave a comparison of the riveted and welded kilns. These tests showed that the welded kiln could be put in at less cost and also that, after having been in use for some time, it remained the truest and in much better condition.

The visitors were divided into parties of four and five and, under the guidance of the members of the staff, an inspection was made of the calcining plant. The coal pulverizing plant was most interesting. The lime-burning kilns were visited, and the manufacture of lime from crushed limestone in the rotary kilns was a very interesting operation. The capacity of the plant is 300 tons of lime per day.

After leaving the lime-burning plant, the party visited the recreation building. This is a fine red brick building, well equipped, for the use of the employees of the company. The first floor has a splendid gymnasium, kitchen and reading room. The second has card rooms and a large lounge or sitting room. The basement is finished and has bowling alleys and pool tables in the main part, and under the front entrance is situated the wash and cloak rooms. As there was nearly an hour to wait for the launch, the members amused themselves in various ways, and the exhibition of bowling by some of the members was well worth watching.

The executive and members wish to express their appreciation to the management and to those of the staff of the Union Carbide Company for their hospitality.

Toronto Branch

W. B. Dunbar, A.M.E.I.C., Secretary-Treasurer.
J. Hyslop, M.E.I.C., Branch News Editor.

Annual Meeting

The annual meeting of the Toronto Branch was held on Thursday evening, March 24th, in room 22 of the Mining building, University of Toronto, about thirty members being present.

Owing to the illness of J. G. R. Wainwright, A.M.E.I.C., the chair was taken by R. B. Young, M.E.I.C., vice-chairman.

The secretary read the notice to members calling the annual meeting, following which the minutes of the annual meeting held on March 25th, 1926, were read and confirmed.

Owing to the absence of the chairman, there was no regular chairman's address, but the vice-chairman gave an informal talk referring to the executive's policy regarding meetings and finances during the past year.

The following acted as scrutineers in connection with the election of officers for the coming year:—

George McCarthy, M.E.I.C.
J. J. Traill, M.E.I.C.
A. V. DeLaporte, M.E.I.C.
F. B. Goedike, A.M.E.I.C.
E. C. Higgins, Jr.E.I.C.

The secretary-treasurer presented his report and financial statement, which was examined by the auditors, and, after some discussion, was adopted by the meeting.

Reports were presented by the chairmen of the following sub-committees, which, after discussion, were adopted by the meeting and any suggestions contained in the reports referred to the incoming executive:—

Programme Committee ....J. G. R. Wainwright, A.M.E.I.C.
Finance " ....R. B. Young, M.E.I.C.
Publicity " ....James Hyslop, M.E.I.C.
Attendance Committee ....L. W. Wynne-Roberts, A.M.E.I.C.
Library " ....A. T. C. McMaster, M.E.I.C.
Student Relations ....W. B. Dunbar, A.M.E.I.C.
Membership " ....E. T. J. Brandon, A.M.E.I.C.

Considerable interest was shown in these reports, as they indicated the excellent work done by the committees in promoting the interests of the branch.

The report of the Finance Committee showed that the expenditures had been within the revenue and that the branch had entered the new year without any outstanding debts. The committee recommended that the system of budgeting be adopted for the forthcoming year.

In discussing the report of the Student Relations Committee, a number of valuable suggestions were made by various speakers. There ensued a lengthy discussion on branch affairs, with particular reference to meetings, membership, methods of promoting discussion and the general objects of The Institute. It was decided that the branch should continue the policy of holding two regular meetings each month.

The report of the scrutineers was then presented showing the following officers elected for the year 1927-28:—

Chairman ....R. B. Young, M.E.I.C.
Vice-Chairman ....J. A. Knight, A.M.E.I.C.
Secretary-Treasurer ....W. B. Dunbar, A.M.E.I.C.
Committeemen (2 years) ...C. S. L. Hertzberg, M.E.I.C.
J. J. Traill, M.E.I.C.
Thomas Taylor, M.E.I.C.

The newly-elected officers were then installed, following which Mr. Young thanked the executive and members on behalf of the retiring chairman for their support during the past year and asked for continuance of this support during his term of office. The newly-elected officers then thanked the members for the honour conferred upon them, after which a hearty vote of thanks was moved to the retiring chairman, secretary and members of the executive.

Vancouver Branch

F. P. V. Cowley, A.M.E.I.C., Secretary-Treasurer.

The Reading and Writing of an Engineer

A regular meeting of the branch was held on March 16th when an instructive address on "The Reading and Writing of an Engineer," was delivered by J. Porter, Esq., B.E.

The speaker showed the futility of reading technical books only, advised engineers to allot but brief time to the reading of the daily press, and suggested a broad field of general reading. In writing, Mr. Porter stressed the dangers of ambiguity, self-advertising, and public controversy, and pleaded for more lucid reports for public bodies, and for those not technically highly educated. The speaker urged a more active interest in community affairs, especially on the part of younger engineers.

Meeting of March 23rd

J. M. Begg, A.M.E.I.C., the chief engineer of the Vancouver and Districts Joint Sewerage and Drainage Board spoke on the work of the Board, illustrating his remarks with a large wall map. Sketching briefly the work of the Board since its inception, he brought his hearers to a better realization of the difficulties which had been overcome. Mr. Begg outlined the situation as at present existing, and showed how a continuous growth of the whole community was being provided for. The area served by the board included the city of Vancouver, and the municipalities of Point Grey, South Vancouver and Burnaby. The paper was followed by a lively discussion, many members taking part, the attendance establishing a record for the month of March.

The Engineering Profession and Its Relation to Engineering Education

At the meeting of the branch, held on April 6th, the fifth paper of the series on engineering education entitled "The Engineering Profession and Its Relation to Engineering Education," was read by E. A. Wheatley, A.M.E.I.C. Mr. Wheatley told of the co-operation between the Association of Professional Engineers of British Columbia and the University of British Columbia, which he, as registrar, had been striving to advance for five years. Progress had been made, but much was yet to be accomplished, and he looked for the time when the engineering profession would be more adequately represented on the council of the university.

Canadian Ingersoll-Rand Company, Limited, have announced that they have moved their executive offices from 260 St. James Street, Montreal, to 10 Phillips Square, Montreal, Que.

Preliminary Notice

of Applications for Admission and for Transfer

April 16th, 1927.

The By-laws now provide that the Council of the Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and election of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in May 1927.

R. J. Durley, *Secretary.*

*The professional requirements are as follows:—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the council. The term of twelve years may, at the discretion of the council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science or engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the council shall be required to pass an examination before a board of examiners appointed by the council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year, at the discretion of the council, if the candidate for election has graduated from a school of engineering recognized by the council. He shall not remain in the class of Junior after he has attained the age of thirty-three years.

Every candidate who has not graduated from a school of engineering recognized by the council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience, qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BOSSU—FRANCOIS, of Montreal, Que., Born at Loos-en-Gohelle, France, Dec. 12th, 1898; Educ., C.E., Univ. of Montreal, 1924; 1920 (summer), mechanical drawing, Northern Electric Co.; 1921 (summer), Dept. of Rys. and Canals, asst. engr.; 1922-27, Quebec Streams Commission, asst. engr.; April 1926 to Jan. 1927, on constrn. of Int. Paper Co.'s Bitobee dam; 1927 to date, civil engineer with City of Montreal.

References: H. A. Terreault, G. R. MacLeod, O. O. Lefebvre, A. Duperron, H. Massue, L. A. Dubreuil.

BRODSKY—GREGORY, of London, Ont., Born at Kiev, Russia, Jan. 17th, 1882; Educ., equivalent to M.A., Kiev University, 1907; research student in physics, Cambridge, 1906-07; 1902-03, study in mech'l engrg. at Darmstadt, Germany; 1899-1902, practical work in beet sugar making, brewing and mechanical shops; engaged in independent scientific research and development of own inventions; advisor to Govt. depts. in England on optical signalling apparatus, studying agriculture and other sciences, until the war; 1915-16, deputy asst. inspector of aeroplanes; 1917-19, deputy asst. commission to Baltic States; in Canada since 1921; taught maths. and languages at Pictou Academy, 1923-24; physics at Univ. of Western Ont., 1924-25; for past year developed own inventions; was in the service from August 1914 to May 1920, demobilized as captain.

References: J. R. Rostron, W. P. Near, E. V. Buchanan, W. M. Veitch, F. C. Ball.

GORMAN—JOHN J., of Grand Falls, N.B., Born at St. John, N.B., Nov. 12th, 1896; Educ., B.Sc., Univ. of N.B., 1924; with N.B. E.P.C.—1922 (summer), rodman and instrumentman on transmission lines; 1922 (fall), 2 mos. i/c constrn. of storage dam at Seven Mile Lake; 1923 (summer), concrete inspector on Musquash reconstruction; May to Oct. 1924, i/c transit party on storage survey of St. Francis River; Oct. to Jan. 1925, in office of St. John working on storage plans; Jan. to March, i/c transit party on storage work at Temiscouata Lake; March to Sept., office work at Grand Falls; Oct. 1925 to July 1926, salesman for Miami Supply Co., Miami, Fla.; Aug. 1st, 1926, to date, field engr. i/c construction of main dam and tunnel intake for St. John River Power Co., Grand Falls, N.B.

References: A. C. D. Blanchard, G. H. Lowry, S. R. Weston, T. C. McCarthy, E. O. Turner, J. Stephens.

HERMANN—GEORGE ELLIOTT, of N. Vancouver, B.C., Born at Philadelphia, Penn., Oct. 31st, 1886; 3 yrs. practical course in structural steel fabrication with Am. Bridge Co. at Ambridge, Penn.; 4 yrs. until 1911 inspector for R. W. Hunt & Co. in Pittsburgh, on bridges, bldgs. and steel structures; 1911-16, mgr. of Pacific N.W. district, inc. B.C. and states of Washington and Oregon, for R. W. Hunt & Co.; 1916 to date, managing director, Vancouver Creosoting Co. Ltd.

References: W. G. Swan, G. F. Stirrett, H. Rindal, G. A. Walkem, T. A. McElhanney.

KINGSMILL—CHARLES GRANGE, of Ottawa, Ont., Born at Toronto, March 25th, 1903; Educ., B.A.Sc., Univ. of Toronto, 1924; 1918-21, Royal Naval Coll. of Canada; 1922 (summer), Manitoba Power Co., Great Falls, Man.; 1924-25, Quebec Development Co. at Isle Maligne, laying out and supervising constrn., including excavation, reinforced concrete and structural steel; 1925-26, with Aluminum Co. of Canada at Arvida, Que., on same work.

References: C. E. Legris, F. H. Cochran, R. W. Angus, H. R. Wake, P. Gillespie, W. S. Lee, C. P. Disney.

NICOLLS—JASPER HENRY HUME, of Ottawa, Ont., Born at Quebec, Que., Feb. 7th, 1886; Educ., B.Sc., McGill Univ., 1908; M.Sc., McGill Univ., 1912; 1908-09, asst. chemist, Govt. coal tests, McGill University; Oct. to Dec. 1909, asst. chemist, J. S. Donald & Co., Montreal; Jan. to July, 1910, asst. chemist, Northern Explosives Ltd., Rigaud; 1910-11, demonstrator in chemistry, McGill Univ.; Feb. to Mch. 1912, asst. chemist, coke ovens lab., Dominion Iron & Steel Co., Sidney; 1912-14, asst. chemist and chemist, Canada Cement Co. Ltd., at Montreal, Winnipeg, Exshaw and Calgary; Nov. 1914 to date, as asst. chemist and for last five years as research chemist and supervisor of routine laboratory, Fuel Testing Labs., Dept. of Mines, Ottawa.

References: C. Camsell, J. McLeish, B. F. Haanel, R. E. Gilmore, A. Ferguson, H. T. Barnes, E. Stansfield, C. K. McLeod.

FOR TRANSFER FROM ASSOCIATE MEMBER TO MEMBER

BLAIR—DAVID EDWARD, of Montreal, Que., Born at Montmagny, Que., July 25th, 1877; Educ., B.Sc., McGill Univ., 1897; 1897-03, electrical and mech'l engr. on constrn. and operation, Quebec Street Railway Co.; 1903-25, supt. of rolling stock, Montreal Tramways Co., i/c all elect'l and mechanical engineering work as well as full executive responsibility; Jan. 1925 to date, general supt., Montreal Tramways Company.

References: K. B. Thornton, G. R. McLeod, J. H. Hunter, R. M. Hannaford, P. S. Gregory.

MONKMAN—GEORGE HUMPHREY NELSON, of Bromhead, Sask., Born at Winnipeg, Oct. 22nd, 1888; Educ., collegiate and private tuition in maths. and mechanics; 1904-09, chainman, rodman, topographer and instrumentman on C.P.R. constrn. work; 1909-12, res. engr. i/c grading; 1912-14, res. engr. on bridge constrn.; 1915-18, overseas with C.E.F. as, surveying corporal for Can. Ry. Constrn. Corps, lieut. Corps of Royal Engr. and captain with same Corps; 1919-20, res. engr., C.P.R.; Nov. 1919-Mch. 1920, locating engr.; 1921-23, office engr., Dept. of Highways, Regina, Sask.; 1923-26, asst. engr. i/c constrn. Leader southeasterly branch and Pashley northeasterly branch for C.P.R., also i/c location of 120 miles railway in southern Sask.; Sept. 1926 to Mch. 1927, i/c constrn. of Bromhead westerly branch of C.P.R. and i/c railway location party in western Sask.; at present, asst. engr., C.P.R. engrg. dept., Winnipeg, Man.

References: W. A. James, C. Flint, V. Michie, J. R. C. Macredie, H. R. McKenzie, D. Hillman, C. L. Hervey, T. C. Macnabb.

FOR TRANSFER FROM STUDENT TO A HIGHER GRADE

KEITH—WILLIAM HARGREAVE, of Islington, Ont., Born at Newmarket, Ont., March 28th, 1900; Educ., B.A.Sc., Univ. of Toronto, 1924; 1916-17-19 (summers), chainman, rodman, concrete inspector, etc., James Proctor & Redfern, Toronto; 1918, R.A.F.; 1920 (summer), i/c waterworks constrn. for James Proctor & Redfern in Acton, Ont.; 1921, i/c pavement and bridge constrn. for Toronto & York Roads Commission; 1922 (summer), cost accountant, etc., Warren Bituminous Paving Co. of Ont. at Toronto; 1923 (summer), i/c waterworks constrn. for James Proctor & Redfern; 1924 to date, asst. engr. i/c waterworks and pavements, design and constrn. and chief dftsman, Twp. of Etobicoke, Islington, Ont.

References: P. Gillespie, T. R. Loudon, E. M. Proctor, W. B. Redfern, R. O. Wynne-Roberts, C. R. Young, R. M. Smith.

McCUAIG—DONALD ALEXANDER, of Toronto, Ont., Born at Minto, Man., April 7th, 1897; Educ., B.Sc., Univ. of Man., 1923; Aug. to Dec. 1916, drainage survey; Jan. to May 1917, survey, Greater Wpg. water district; 1917-19, lieut., R.F.C.; 1922-23, records engr., Fraser Brace Constrn. Co., Great Falls, Man.; May to July 1923, electrician, Man. Power Co., Great Falls; July to Sept. 1923, dftsman, Duquesne Light Co., Pittsburgh, Penn.; 1923-26, designer and checker, hydro-electric and steam power stations, Stone & Webster, Inc., Boston, Mass.; 1926-27, asst. electrical engr. to ch. electrical engr. on design of power station for Susquehanna Power Co., Stone & Webster, Inc.; at present, i/c western office, at Winnipeg, of Ferranti Electric Limited.

References: J. B. D'Aeth, E. P. Fetherstonhaugh, N. M. Hall, J. N. Finlayson, A. B. Cooper.

FOR TRANSFER FROM AFFILIATE TO A HIGHER GRADE

EVANS—HUBERT GEORGE, of St. John, N.B., Born at London, Ont., July 15th, 1886; Educ., 1903-10, apptce. erecting and operating steam and gasoline engines, boilers, pumps, etc., and studying dfting and mech'l engrg.; 1910-15, dist. mgr. for E. Leonard & Sons Ltd. of London at Wpg., specializing in power plant equipment, i/c installations such as generating unit, electric generating plant, etc.; 1912, secured first class engineer's license for Saskatchewan; 1915-17, supt., McAvity shell plant, St. John; 1917-19, night supt., McAvity shell plant, where, in addition to regular duties, had charge of laying out machine tools, power transmission and work routine for two additional shops; 1921 to present, dist. mgr. for Can. Ingersoll-Rand Co. for N.B., specializing in engrg. sales work on compression rock drilling, centrifugal pumps, steam pumps and power plant equipment.

Experimental Determination of Hydraulic Constants in a Large Aqueduct

A Series of Tests to Determine the Discharge of the Greater Winnipeg Water District Concrete Aqueduct by the Use of the Salt-Velocity Method

John N. Finlayson, M.E.I.C.
Professor of Civil Engineering, University of Manitoba.

Paper read before the Winnipeg Branch of The Engineering Institute of Canada, March 3rd, 1927

In the autumn of 1925, a series of tests was conducted for the purpose of determining the discharge of the concrete aqueduct of the Greater Winnipeg Water District, which had been in continuous service for six years. This aqueduct, which is nearly one hundred miles long, is of the open flow type except at river crossings. A typical cross-section of the aqueduct is shown in figure No. 2. It was designed for a maximum carrying capacity of 85,000,000 imperial gallons per day, a value of 0.013 being used for the coefficient of roughness in Kutter's formula. At the time of the opening of the aqueduct, measurements of discharge were made, using the colorimetric method. The results, shown in figure No. 3, indicated that the new aqueduct could discharge twenty million gallons in excess of its estimated capacity, the value of the coefficient of roughness being well below 0.012. The objects in making the tests herein described were to check these measurements by other methods and incidentally ascertain the effect on the concrete of six years of service.

It is recognized that the colorimetric method has certain defects and limitations; the error arising from the personal equation is probably the most noteworthy. Moreover, it is not adaptable for gauging flows in water for domestic use. It was decided to use the salt-velocity method in making this series of tests, a method used successfully in measuring the flow of water through penstocks of hydraulic power plants, but not generally applied in gauging that in long water-supply conduits.

The sites chosen for the experiments were those used by the previous observers, namely, between manholes at miles 96.7, 95.7 and 94.7, near the intake in that length of aqueduct designated " S " section, and those at miles 86.6, 85.6 and 84.9, in the length known as " B " section. The slopes of the inverts were determined precisely, on the completion of the aqueduct, before the water was admitted, and are noted in table No. 1. The inside dimensions of the finished sections were also measured carefully, those of section " S " being shown in figure No. 3. The height of section " B " is 7 feet 4⅝ inches and its maximum width 8 feet 9 inches. Bench marks are established beside each manhole.

As the sites chosen were unsheltered and far removed from power lines, it was impossible to apply any of the refined measuring devices employed in penstock gauging. It was found by trial that fifteen handfuls of coarse salt dissolved in three gallons of water would form a brine sufficiently strong to cause an increase in electrical conductivity in the water in the aqueduct capable of giving adequate deflections in the ammeter connected to electrodes which were placed in the water at the manhole one mile farther downstream than the point of injection. The current applied to the circuit was obtained from two six-volt storage batteries as used in automobiles. A milli-voltmeter was used as an ammeter. The electrodes were strips twelve inches long by four inches wide cut from sheet iron roofing placed one and one-half inches apart. It is suggested that smaller electrodes made of insulated plates placed about one-half

Figure No. 2.—Profile of Aqueduct with Cross-section of Openflow Arch Type Section.

inch apart might be used to advantage in making subsequent tests, these being more easily inserted, offering less resistance to the flow and giving more steady ammeter readings.

The elapsed times between the injection of the brine through the manhole and the indicated increases of the amperage as read in the ammeter were obtained from two pocket watches of good make, previously compared, which were sheltered in the hands of the observers during the periods of the tests. At first, stop watches were used which were found to give inaccurate results over long periods of time, the extent of the inaccuracy, as determined later, amounting to as much as 48 seconds in an interval of two hours, with indications pointing to varying rates of gain and loss.

The brine was lowered swiftly and carefully through the upstream manhole at prearranged times, and the times of its arrival at the electrodes one mile downstream with the corresponding amperages were noted carefully and listed by the recorders at that station. The amperages were afterwards plotted to time bases and the centres of area of these curves obtained. The time measured between a centre of area and the time of injection is the mean time, which, divided into the distance between manholes, gives the mean velocity of flow, which is used in the calculation of the discharge.

Some preliminary tests were made for the purpose of determining the effect of placing the pair of electrodes in different positions in the cross-section of the aqueduct. Points at one-third depth, near the centre line of the cross-section; at two-third depth near this same line; and near the sides at varying depths were selected, and readings were taken, recorded and plotted. Not one of the computed mean times showed a disagreement from the average mean time of more than 0.2 of one per cent. These results, shown in figure No. 5, indicate that, for these lengths of aqueduct between manholes, there is no necessity of placing the electrodes at any particular spot. Similar experiments showed that no greater accuracy was obtained by throwing in the brine in any particular area in the cross-section. The conclusion is that complete diffusion of the brine throughout the water is obtained at short distances from the point of injection and, although the passage of water in the central portion of the aqueduct is more rapid than near the sides and invert, the observed mean time is not affected by the position of the electrodes.

The measurements of discharges as determined by the salt-velocity method were checked by the Venturi meter placed in the section of the pressure pipe line at the Falcon river crossing, which was also used to determine when the

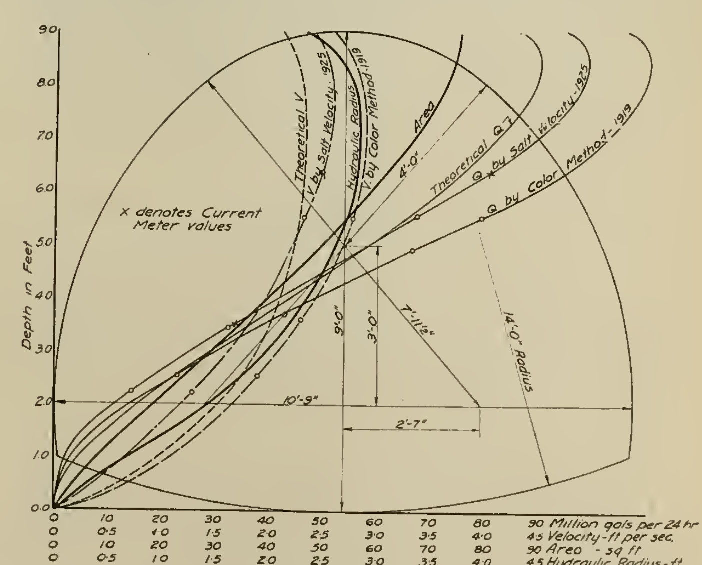

Figure No. 3.

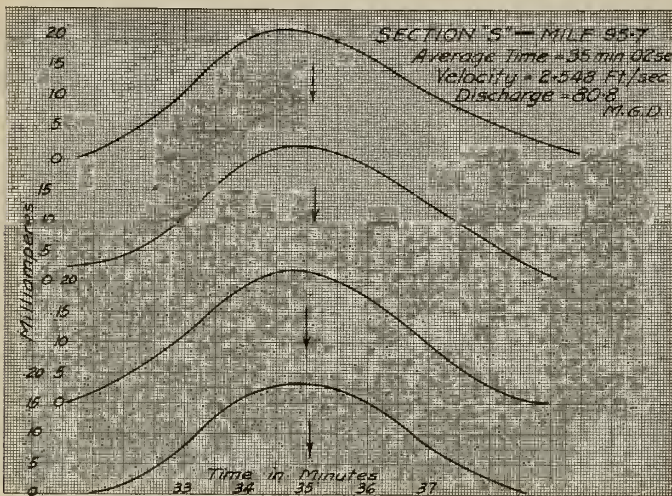

Figure No. 4.—Curves showing Electrical Conductivity.

flow was steady, and by metering the flow through a "boat house," an expansion of the aqueduct, with a Price current meter, a traverse of the boat house having been made. An attempt was made to use the current meter in the "S" section of the aqueduct, but the shape of the section precluded satisfactory measurements of flow. The current meter was fastened to a braced rod, as the weights commonly used were found to impede operation.

Three successive rates of flow were measured at all the manholes mentioned above, namely, 30 m.g.d., 67 m.g.d. and 80 m.g.d., as recorded by the Venturi meter, and each measurement was repeated on successive days. One series of measurements was made in the "S" section only of a flow of 14 m.g.d., but as the normal demand of the Greater Winnipeg Water District is nearly 30 m.g.d., and the reservoir capacity relatively small, only a limited time could be allowed for this reduced flow.

For all runs, the elevation of the mean water surface was obtained by carrying bench mark elevations down the manholes with steel tapes with sharp plumb bobs attached. Readings were taken by at least two men before and after each run, and if there was any difference noted mean values were used in the calculations for Q. Adequate precautions were taken to insure a steady flow during each run; whenever possible, the flow was regulated on the day prior to the measurement. In only one run was any trouble experienced from unsteady flow, when the average of several readings had to be used.

A comparison of results from the three methods of measuring discharges is seen in table No. 2.

Table No. 2.—Comparison of Results from Three Methods of Measuring Discharges.

Average Q (m.g.d.)			Per centage difference between "B" & "C"
By Venturi Meter A	By Current Meter B	By Salt-Velocity Method C	
30	33.45	32.5	3.
67	70.20	68.1	3.
80	80.98	81.4	0.5

As was to be expected, there is a closer agreement in the current meter results, and those obtainable by the salt-velocity method in the larger flows, when there is an increased ratio of fast water to sluggish flow. (The low velocities near the sides and bottom are inaccurately registered by the current meter.) For example, by increasing the flow from 67 m.g.d. to 80 m.g.d. the depth of water is increased 30 per cent, the velocity 40 per cent and the wetted perimeter very slightly. The comparison is seen more clearly in table No. 3.

Table No. 3.—Changes in Constants Resulting from Increase in Flow.

Flow increased (m.g.d.)	Increase in			
	Area sq. ft.	Depth ft.	Velocity ft. per second	Q sec.-ft.
From 30 to 67	21.7	2.17	0.48	35.5
From 67 to 80	5.3	0.60	0.21	13.4

The tests were made on lengths of aqueduct which were straight or nearly straight. Where curves existed, the location of the manholes precluded any attempt to measure the friction losses due to bends alone.

The times taken by the charged water to pass the electrodes and the distance between manholes are noted in table No. 4.

Table No. 4.—Time Taken by Charged Water to Pass Electrodes and to Traverse One Mile.

Flow	Station	Time taken to pass electrodes	Time taken to traverse one mile
14	Mile 95.7 to Mile 96.7	7 min.	68 min. 12 sec.
30	"	7 "	48 " 23 "
67	"	4 "	38 " 14 "
80	"	4 "	35 " 02 "

It will be observed that the length of water affected by the charge is over 500 feet at a point one mile below the point of injection. The degree of density, (as indicated by the increase in electrical conductivity), and also the close agreement in the position of the centres of area for consecutive tests of a constant flow are shown in figure No. 4. After the charged water had passed the electrodes, the needle of the ammeter remained steady. Thus, charges could be injected at regular intervals of, say, ten minutes and the needle would begin to deflect in exactly the same time interval as in the preceding test. It will be observed that

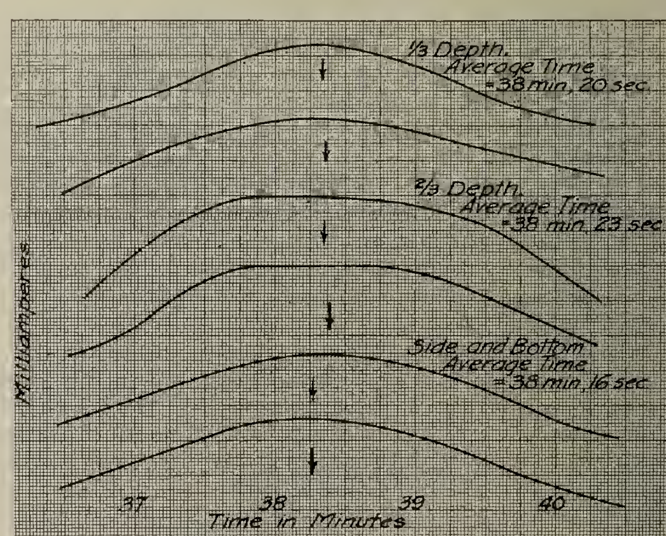

Figure No. 5.—Comparative Velocities over Section "S," Mile 95.7.

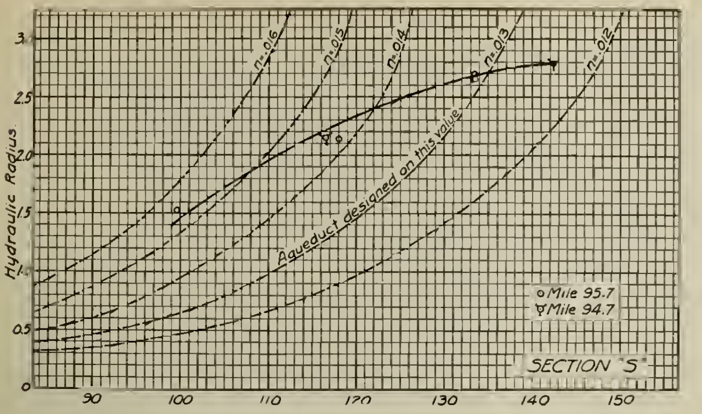

Figure No. 6.—Values of "C" in Chezy's Formulae.

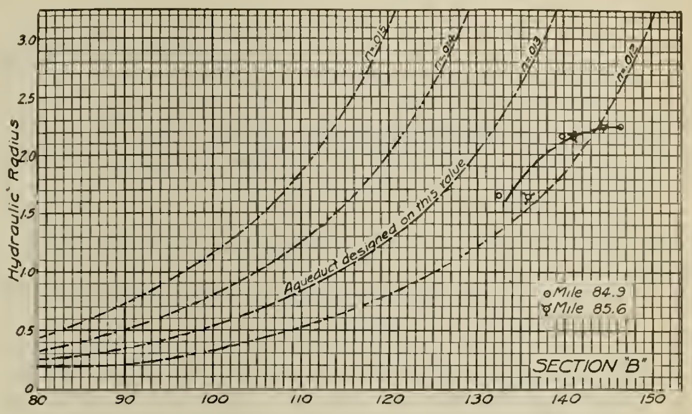

Figure No. 7.—Values of "C" in Chezy's Formulae.

although the peaks of the amperage-time curves occur at varying times in successive tests, there is a very close agreement in the centres of area. Thus, the claim that the centres of area give a true measure of the mean time of passage is substantiated by the results of the experiments.

It is believed by some engineers that the earlier deflections of the needle are caused by the passage of the fast moving water in the central portions of the stream, and the tailing of the curve by the slowly moving particles near the bottom and sides of the aqueduct; while the agreement of results, regardless of the position of the electrodes, would seem to indicate that the path of the current from one electrode to the other is through the entire cross-section of the stream, and not merely across the passage between the electrodes.

The deduced values of the coefficient of roughness and of other hydraulic constants are noted in the accompanying table and in figures Nos. 3, 6 and 7. For reasons stated above, tests of the 14 m.g.d. were made only on section "S," and the value of n for that flow is 0.0155. Values of 0.012 and 0.013 are obtained for the greater flows, which would appear to warrant the use of $n = 0.013$ in the design of the aqueduct. The corresponding value of Chezy's constant C is 140. The higher values of n in the 30 m.g.d. in the "S" sections may be explained by stating that these sections are situated about three miles from the intake and are subject to depositions of algae, notwithstanding the fact that these sections were cleaned thoroughly about a year prior to the date of making the tests.

In the "B" section, which is fourteen miles from the intake, the value of n was found to be fairly constant at 0.012, increasing slightly with decreasing flows. The corresponding value of C is about 140. The maximum discharge through the section is 96 m.g.d., 11 m.g.d. in excess of the designed value. The Q curve in the figure corresponding to figure No. 3 crosses the theoretical Q curve at a flow of 20 m.g.d., the mean velocity at that flow being about one foot per second.

The results show that the salt-velocity method is a simple, speedy, accurate and economical means of determining the condition of pipe lines. In the present case, four tests at each of the four stations were made in the time taken to traverse one section with the current meter. The degree of accuracy is noted in the figures. It would appear that the use of 0.013 as a value of n in the design of concrete structures may be considered good practice, also that concrete is a suitable material for the construction of aqueducts of this type, there being a very small loss in hydraulic efficiency during its six years of service.

The tests were carried out under the writer's direction by three graduate students in the Department of Civil Engineering, University of Manitoba, J. H. Grant, J. A. McFadden and F. T. Robertson, assisted by two senior undergraduate students, F. S. Adamson and J. M. Kennedy. C. W. Carry traced the curves and tables which appear in this paper. Thanks are due to W. M. Scott, chief commissioner of the Greater Winnipeg Water District, and his assistant engineers for assistance and advice, and to C. H. Attwood, district chief engineer of the Dominion Water Power Branch of the Department of the Interior, for the loan of equipment and for general direction of the current meter measurements.

Locomotive Feed Water Heating

Its Application and Advantages, Economies Effected under Operating Conditions and a Description of Various Types of Heaters in Use

W. C. Hamm, Esq.
Mechanical Engineer, Central Vermont Railway Company.

Paper read before the Montreal Branch of The Engineering Institute of Canada, March 17th, 1927

The subject of locomotive feed water heating is becoming increasingly important from the standpoint of transportation. This is due to the fact, that with the constantly mounting expense of operation, any device that can be applied to a locomotive to increase its efficiency as an operating unit and yet not introduce elements detrimental to its handling in service must receive serious consideration.

Whereas the preheating of the boiler feed water has long been standard practice in stationary and marine service, it is only in recent years that it has become sufficiently developed to be applied generally in the locomotive field.

There have been many papers written on this subject from a purely theoretical standpoint, but this paper is intended to present the subject in general, to emphasize the benefits which may be expected from the application of a feed water heater, and to present some actual results obtained in service.

Feed water heaters have received attention from the days of the earliest locomotives and experiments have been carried out with many different designs. However, in the last few years the need for a successful heater has been emphasized by the increasing cost of locomotive fuel.

As a result, a feed water heater was produced and applied to a large Pacific type locomotive in the United States in the year 1916 which has since developed into one of several very satisfactory designs. Although the further development was somewhat hindered by war conditions, yet at the present time approximately 4,100 are in service on locomotives on this continent.

Meanwhile, on European railroads this same development has been taking place only somewhat more rapidly on account of the higher proportionate cost of fuel and the need for a more rigid operating economy, and at present there are several thousand locomotives equipped with devices of this nature.

Advantages to be Derived

The savings and benefits to be derived by the application of feed water heaters to locomotives take several different forms, all of which should be taken into account. First is the important benefit accruing from fuel saving. A second equally important one is the possible increase in boiler capacity attained by its application whereby a heavier tonnage train can be handled over a division in the same or shorter time, resulting in an increased gross ton-miles per hour figure. Which of these two points should be stressed in any particular application depends upon the physical characteristics of the road and equipment.

The maximum horse power of a locomotive, which, of course, is the period of the greatest steam consumption, is not developed until a speed of around twenty-five to thirty miles per hour is attained, assuming that the locomotive is also being worked to the maximum. Therefore, if the territory in question is a low gradient line where, in order to obtain the best transportation results heavy trains are to be handled at speed, any increase in boiler capacity is a direct boon to operation and this point becomes the more important of the two. At the present time, one of the principal aims of locomotive design is to increase the capacity and efficiency of the boiler.

On the other hand, if the profile of the engine district has some heavy grades and the boilers are reasonably well designed, then, under ordinary working conditions, the theoretical maximum steam consumption will never be reached, for when the locomotive is working the hardest it will be at a relatively slow speed while on the remaining stretches the locomotive will be underloaded, due to the fact that the grades have set the tonnage rating. Under these conditions, which exist in many places, the feed water heater is not required as a boiler capacity increaser, but full advantage can be taken with it as a fuel saver. Other lines very often are choppy, that is, they have numerous sharp grades that cannot be taken at momentum and which limit the tonnage rating. In many such cases at the present time booster engines of the trailer and tender truck types are being used with the regular locomotives so as to assist at these hard points, resulting in a more economical tonnage loading over the engine district. As this becomes an added drain on the

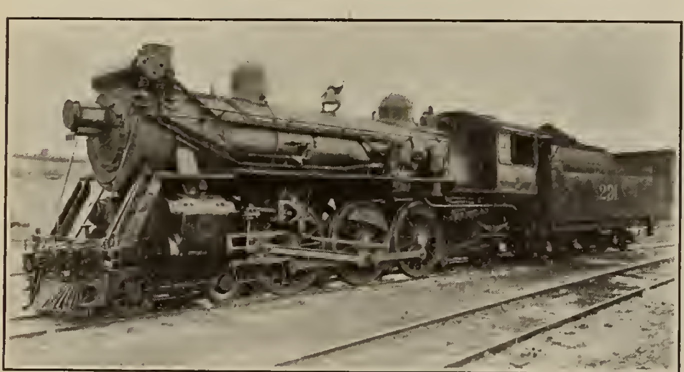

Figure No. 1.—Locomotive Equipped with Elesco Heater.

Figure No. 2.—Locomotive Equipped with Coffin Heater.

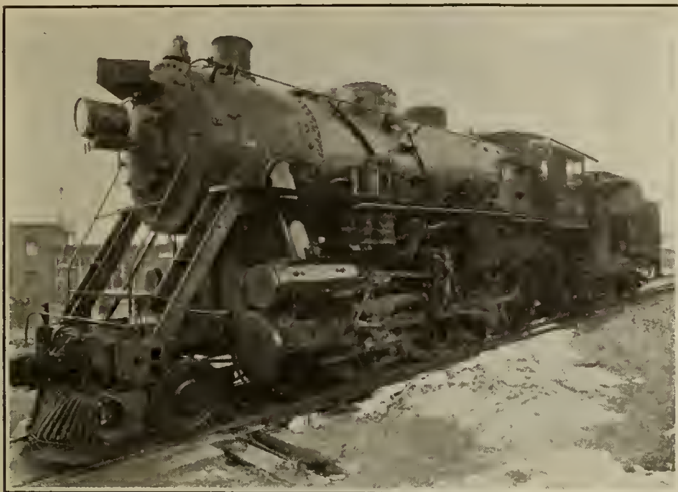

Figure No. 3.—Locomotive Equipped with Worthington Heater.

boiler, the application of feed water heaters will increase their capacity and so furnish sufficient steam at the critical points.

Saving in Fuel

Now, as to fuel saving, a few explanatory figures will be given as to how this can be arrived at theoretically and then later some figures obtained in actual service.

It has been found that out of every pound of coal fired into the firebox of a locomotive only about seven per cent is turned into useful work at the drawbar. The other ninety-three per cent is consumed partly in the operation of the various auxiliaries such as the air pump, stokers, power operated grate shakers, etc., while the greater part is lost through the exhaust steam from the cylinders, hot gases from the stack, pops and ashes.

The hot gases from the stack represent approximately twenty-five per cent of the total and the exhaust steam about fifty-eight per cent. Therefore, it can be seen that the greatest loss is in the exhaust steam and that this provides a source of power which, if reclaimed, will result in substantial savings.

In the many years of experimentation in the past, feed water heaters were designed to utilize the loss represented in the exhaust steam, while economizers were developed to reclaim that in the gases from the stack. This latter development has not become successful as yet for two reasons. First, the very hot exhaust gases, ranging from temperatures of 450° to 1,100° Fahrenheit, in striking the cold economizer tubes, cause a film of moisture to be precipitated on the outside surface of the tubes, and the soot which naturally collects forms a non-conductive medium, preventing the transfer of heat to the feed water. Secondly, a chemical action is set up in the feed water which causes the precipitation of part of the solids in this water, thus forming a scale on the water surface of the tubes. For these reasons and the fact that the lack of space in the locomotive front end does not allow the application of a two-stage economizer, the successful development of an apparatus of this type has been prevented, although at present, outside of European experiments, one company at least in America

Figure No. 5.—Curve showing Temperatures on Light and Heavy Grades.

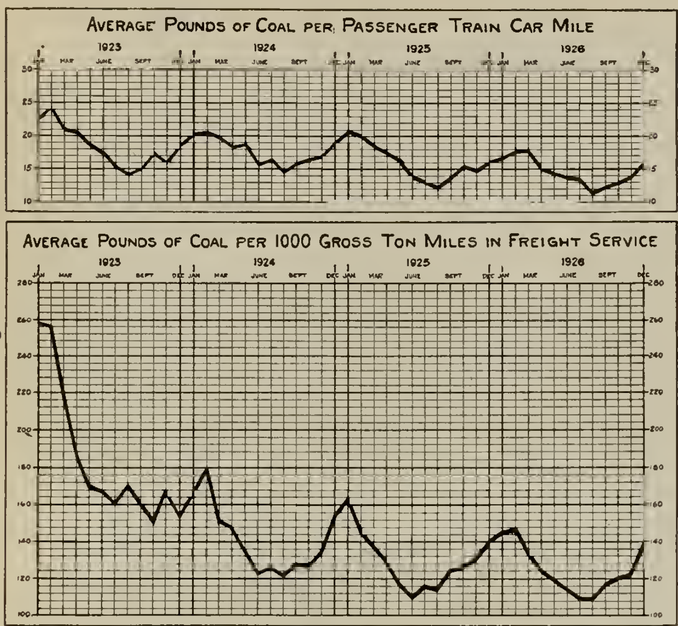

Figure No. 6.—Locomotive Fuel Consumption in Passenger and Freight Train Service.

is working on a combination feed water heater economizer system for locomotive use. There still remains, however, the possibility of saving a portion of the heat wasted in the exhaust steam by transferring it to the feed water before the latter goes to the boiler, and it is this phase of the problem that will now be considered.

The unit of heat measurement is, of course, the British thermal unit, (B.t.u.), which is the amount of heat required to raise the temperature of a pound of water one degree, from 62° to 63° F. If we assume that the average temperature of the water in the tender tank, summer and winter, will be 55°, it is found on consulting tables of the properties of steam that 1,311 B.t.u. must be supplied to each pound of water at 55° in order to convert it into steam at 200 pounds boiler pressure with 250° of initial superheat, the conditions which will be assumed as an example. Further, it will be assumed that, considering the service in which the locomotive is to be operated and the draught requirements, the average running back pressure will be 5 pounds, and steam tables show that the temperature of exhaust steam at this pressure will be 225° F.

A properly designed feed water heater with sufficient heating surface to give an adequate transfer of heat should be able to bring the temperature of the feed water up to within about 10° of the temperature of the exhaust steam, or, say, 215° for the engine in question. The temperature of each pound of feed water would therefore be increased from 55° to 215°, or through 160°, while a portion of the exhaust steam would be condensed at 225°.

It is now possible to estimate the saving from the operation of a feed water heater under these conditions, and it will be assumed that the locomotive requires 38,000 pounds of steam per hour to develop its maximum power in the cylinders and that five per cent of its boiler capacity is required to cover radiation losses, requirements for train heating, etc. A total boiler capacity of 40,000 pounds of steam per hour is therefore assumed, which also means that 40,000 pounds of feed water per hour will have to be heated through 160°. The heat required per hour to heat the feed water is therefore:—

$$40{,}000 \times 160 = 6{,}400{,}000 \text{ B.t.u.} \quad (1)$$

From the steam tables it is found that each pound of exhaust steam in being condensed from steam at 225° to water at the same temperature supplies 962 B.t.u. to the feed water; the amount of exhaust steam required to heat the feed water is therefore:—

$$\frac{6{,}400{,}000}{962} = 6{,}650 \text{ pounds per hour} \quad (2)$$

The total heat expended in producing 40,000 pounds of

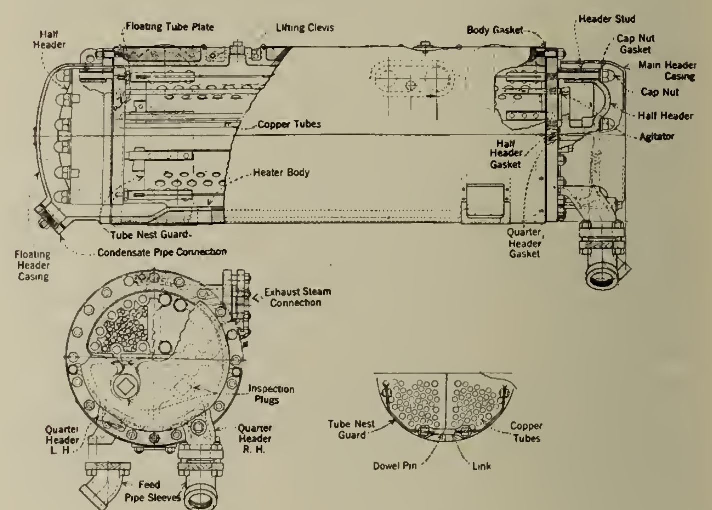

Figure No. 8.—Details of Elesco Heater.

superheated steam per hour from cold water at 55° is:—

$$1{,}311 \times 40{,}000 = 52{,}440{,}000 \text{ B.t.u. per hour} \quad (3)$$

In order to effect an economy of one per cent on this amount, it would have to be diminished by one one-hundredth or 524,400 B.t.u. per hour; but as appears from (1) the feed water heater actually saves 6,400,000 B.t.u. per hour, so that the saving on the total heat expended is:—

$$\frac{524{,}400}{6{,}400{,}000} = 12.2 \text{ per cent} \quad (4)$$

Further, this economy is effected by the use of a proportion of the total exhaust steam which will amount to, (after allowing for that volume of exhaust steam from the auxiliaries which may be utilized in the feed water heater), between fourteen and fifteen per cent of the total exhausted from the cylinders.

The foregoing shows that an appreciable and direct saving can be obtained from a feed water heater in regard to fuel economy. There are, however, other factors that work both with and against it. First, there is the added drain on the boiler due to the live steam consumption of the feed water pump. This will vary from one and-one-half to two and one-half per cent of the boiler capacity, depending on the type of pump used and its physical condition. As an

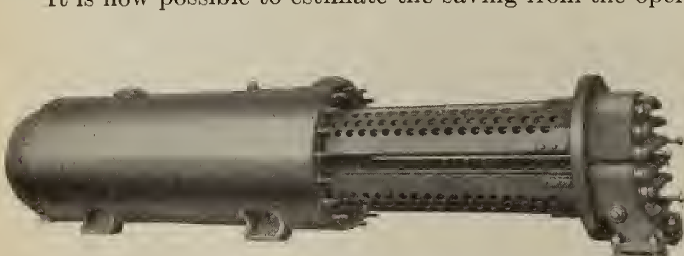

Figure No. 7.—Elesco Heater.

Figure No. 9.—Two-Cylinder Elesco Pump.

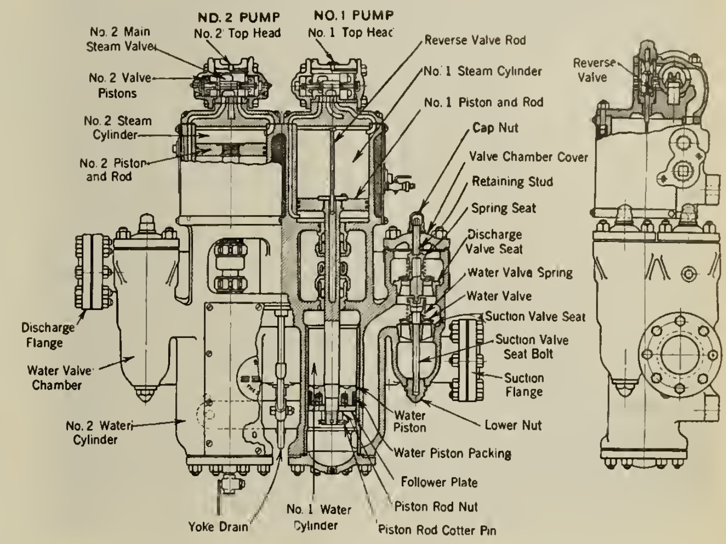

Figure No. 10.—Details of Two-Cylinder Elesco Pump.

offset to this apparent loss is the increased evaporating efficiency of the boiler obtained by the lower fuel rate required. As has already been seen, a large amount of heat has been reclaimed from the exhaust steam, which, of course, has resulted in an increased evaporation of pounds of water per pound of coal. Therefore, for the same boiler output, less fuel is required and the firing rate in pounds of coal per square foot of grate per hour is decreased. This will increase the boiler efficiency approximately four to five per cent, depending on the service in which the locomotive is used and the point of cut-off at which it is worked.

As less coal is burned, there is formed a smaller volume of gases that has to be exhausted through the stack. This in turn means that the exhaust blast can be softened and a reduced cylinder back pressure maintained. A reduction of two pounds in back pressure should readily be obtained which on a two hundred pound boiler pressure engine will be an increase in cylinder power of one per cent.

A detrimental factor which can generally be expected when a feed water heater is applied to an old locomotive is a loss in initial superheat. This has been found to average about twenty degrees on some locomotives tested. The loss is caused by the lower fuel consumption whereby the ratio of the exhaust gases to the steam consumption is lessened. In new locomotives this fact can be taken care of in the design and a larger proportionate superheating surface can be installed. However, this point is not particularly serious as the apparent loss is partially at least compensated for in the reduced cylinder back pressure.

Effect of Superheat in Exhaust Steam

This brings up a point which the writer believes is not thoroughly understood at present and which will have to be worked out in the matter of design and proportion, i.e., the effect of superheat in the exhaust steam. It has been found by experience that the transfer of heat to the feed water is quite seriously affected when the temperature of the exhaust steam entering the heater is above that of saturated steam of the same pressure, and that the greater this difference becomes the more marked becomes the effect. Therefore, if a locomotive is so designed and worked in service that the exhaust steam from the cylinders is in a superheated form, the effect, particularly in the closed type of feed water heater, is to reduce the delivery temperature of the feed water, for there is apparently but little heat absorption through the tubes in the area of this highly heated steam.

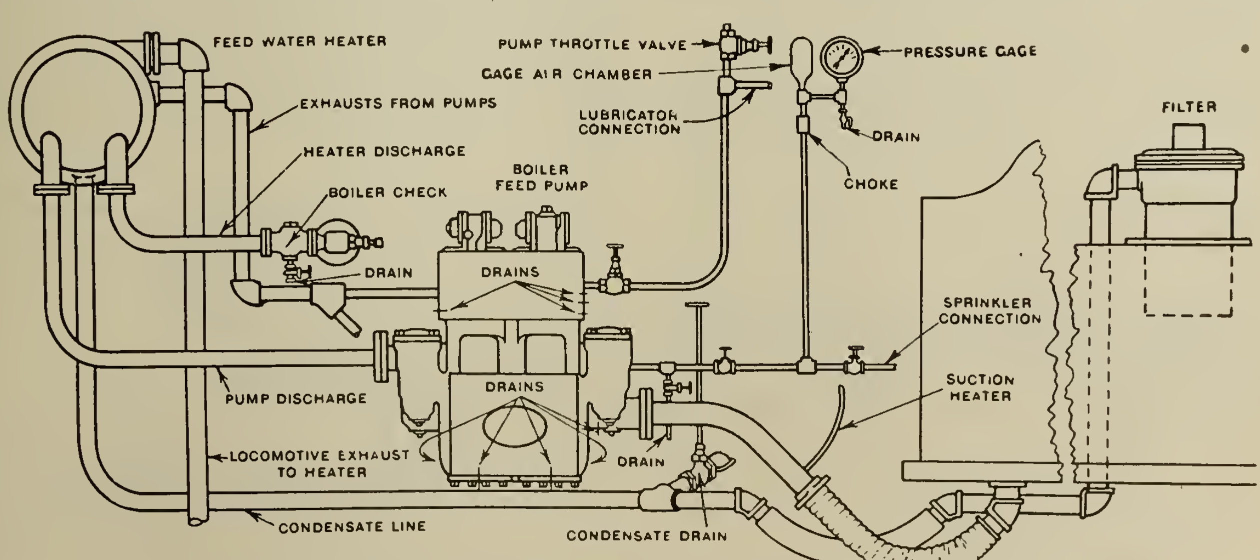

Figure No. 11.—Piping Diagram showing Layout and Application of Elesco Heater.

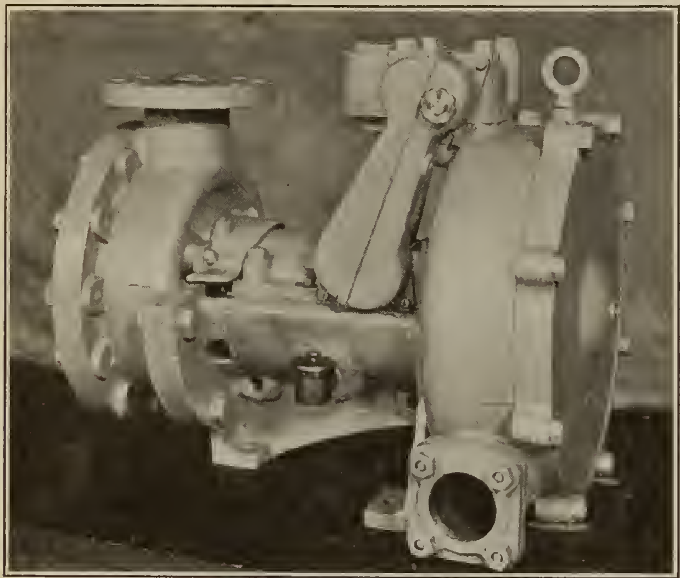

Figure No. 12.—Coffin Pump.

This has been found to exist as the result of many test readings and may be the result of several contributing causes. A typical curve illustrating this condition is shown in figure No. 4.

Saving of Water

Another feature of the feed water heater which is often important from the transportation viewpoint is the water saving. In all systems in use in America, the condensate from the exhaust steam utilized in the feed water heater is saved and returned to the boiler. This water, which varies in amount somewhat with the working of the locomotive, approximates 10 per cent of the whole as an average. This condensate is in effect distilled water and thereby eliminates immediately a corresponding per cent of the impurities carried in with the raw water, and will prevent to that extent the formation of scale and the accumulation of mud in the boiler. In bad water districts the good effect of this is very noticeable on not only the maintenance of the boiler but on the cost of the water, as a smaller amount of the treated water is required. In fact, one large western railroad system in the United States found that feed water heaters paid for themselves on the item of boiler maintenance alone. The return of the condensate to the tender virtually results in an equivalent larger tank and in many cases eliminates a water stop with its attendant delays.

The Injector

It may not be amiss to say a word here about the well-known injector. In itself it is a feed water heater, inasmuch as the live steam required by it to force the water into the boiler is condensed and mixed with the water, thereby heating it to a high temperature. This, however, does not result in other than an incidental saving, as the heat units used are a drain on perhaps an overloaded boiler and not a recovery of the heat units going to waste. An injector has the advantage of being a simple device, light in weight and easily maintained, although at its most efficient state it will deliver only about ten pounds of water to the boiler per pound of live steam, while the various feed water heater pumps will deliver anywhere from forty to sixty-six pounds.

The exhaust steam injector is also being developed into a satisfactory device, and it utilizes in its operation exhaust steam the proportion of which varies with the working of the locomotive. If standing or drifting, live steam has to be used entirely. The injector is light in weight compared with a feed water heater and much cheaper, but at present the control is rather complicated. About three hundred and fifty have been applied in America, although quite a number are in service in England.

Results

Some average results and figures obtained in actual service from some fifty feed water heaters of both the closed and open types, operated in freight and passenger service, are given in the following table and curves. The curves shown in figure No. 5, which are of a representative run, show the heat transfer obtained from the exhaust steam through the heater to the delivery water.

Table No. 1 gives the results of a number of typical runs. No doubt some may take exception to the high percentage of savings shown, since they are so much in excess of possible theoretical calculations. In all cases, however, the coal and water were carefully measured. Accurate records were kept, and they are borne out by check records that are constantly being made and by fuel consumption statistics. There are so many elements affecting and improving the operation of the locomotive when a feed water heater is applied that it is rather impossible to separate one from another in ordinary running and test service. Therefore, a complete explanation cannot be made of them, but these results can be taken as the average obtained in every-day service as shown in table No. 1.

Effect on Terminal and Shop Facilities

There is another phase of the subject that should be considered equally as well as the saving in fuel and the train operating benefits, and that is the effect on terminal and shop facilities due to the added maintenance expense. This not only directly affects the locomotive as an economical unit but might seriously increase shop forces. However, from records carefully compiled, in a certain instance, this

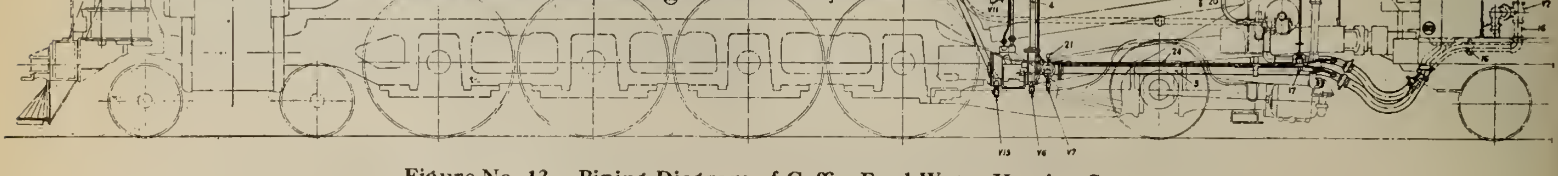

Figure No. 13.—Piping Diagram of Coffin Feed Water Heating System.

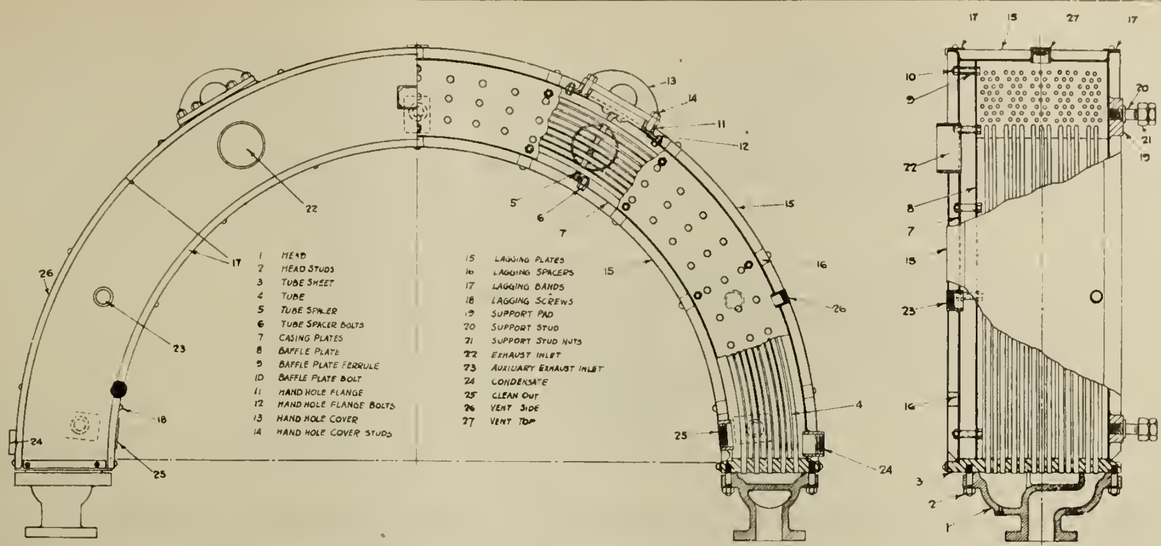

Figure No. 14.—Details of Construction of the Coffin Heater.

expense including everything in regard to maintenance, that is, labour, material for repairs, running expenses, general overhaulings, and monthly inspections, has been found to average 24.1 cents per 100 miles. This represents a test of a set of twenty-three heaters, including both closed and open types that were between three and four years old. For another set of twenty-four heaters under two years old this average cost is only 4.15 cents per 100 miles. These figures represent maintenance costs in a good water district and would naturally be increased under more adverse conditions.

Savings Effected

To show just what these savings will amount to as regards locomotive and fuel performance, the following figures are given:—

First cost of feed water heater applied..........	$2,500.00
Interest on investment and deferred maintenance at 12 per cent..............................	300.00
Maintenance for 40,000 miles at 24.1 cents per 100 miles	96.40
Total cost per year.....................	$ 396.40
Cost of 2,947 tons of coal (injector fed engine) at $5.35 per ton............................	$15,766.45
Average fuel saving in freight service of a feed water heater equipped locomotive over one injector fed (from table No. 1), 11.5 per cent.	338 tons
Saving in fuel, 338 tons coal at $5.35 per ton.....	$1,808.30
Net saving per year of feed water heater equipped locomotive	$1,411.90

As a concrete illustration, the Central Vermont Railway can be considered, on which at the present time forty-eight and one-half per cent of the locomotives are equipped with feed water heaters, while within the next few months this will be increased to sixty-six per cent. These feed water heater equipped locomotives handle approximately ninety-five per cent of the road freight tonnage and fifty per cent of the steam locomotive operated passenger traffic in car miles. A very appreciable saving in fuel has been obtained since the application of feed water heaters, and this is shown graphically by the curves in figure No. 6. It is not intended to convey the impression that all the improvement is due to this one source, as it is not. Part is attributable to the scrapping of obsolete power and its replacement by modern units and part to better operating conditions. This in turn cuts down train delays, but, nevertheless, since the application of feed water heaters was started the fuel consumption rate, as shown by these curves, has decreased with each new lot of heaters applied, and therefore bears out very clearly the fact of the economies to be obtained from this source.

Various Types of Heaters in Use

The several designs of heaters that are being developed on American railroads can be divided into two general types, the closed and the open. In the first the feed water

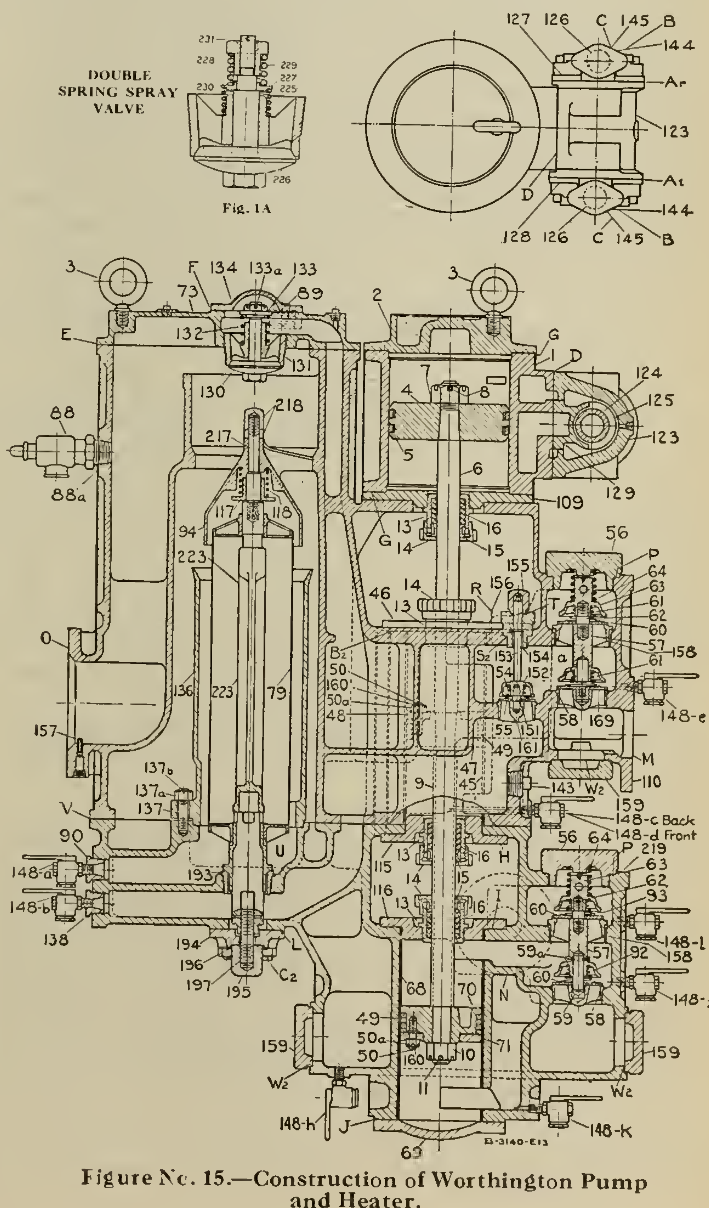

Figure No. 15.—Construction of Worthington Pump and Heater.

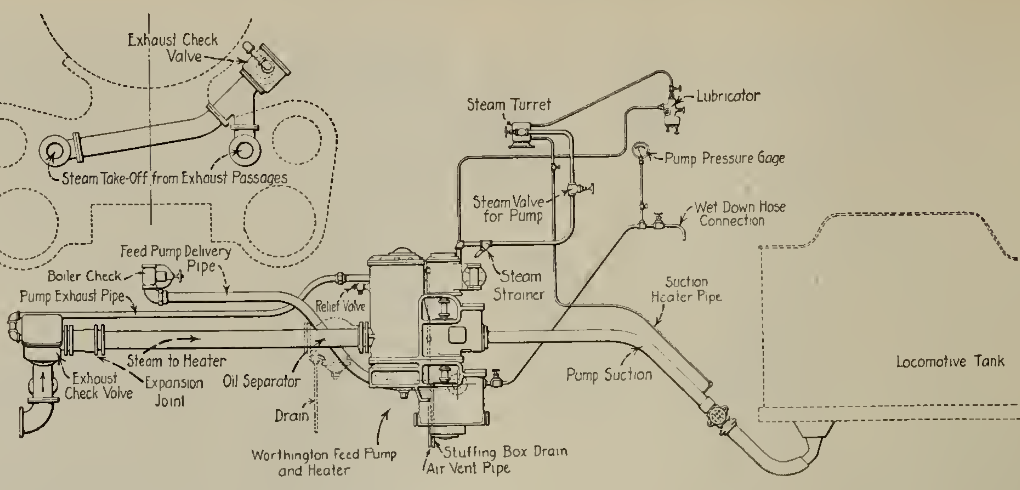

Figure No. 16.—Piping Diagram showing General Layout of a Typical Application of Worthington Heater.

does not come into direct contact with the exhaust steam, while in the latter type the exhaust steam is condensed by and is carried on into the boiler with the feed water.

In the closed type, the two heaters that are most extensively applied are the Elesco and the Coffin.

The Elesco consists of a cylindrical heater containing four nests or passes of small tubes located generally on top of the smoke box ahead of the stack which allows the condensate to drain back to the tender tank by gravity. This heater is shown in detail by figures Nos. 7 and 8. The exhaust steam is taken from the cylinders and surrounds the small tubes through which the feed water is forced to the boiler, while the condensate formed from the exhaust steam drains back to the tank and is then used over again. A two-cylinder pump, shown in figures Nos. 9 and 10, located on the side of the boiler and driven by live steam, sucks the feed water from the tank and forces it under pressure through the heater into the boiler. The piping diagram, figure No. 11, shows the general layout and application of the Elesco feed water heater.

The Coffin feed water heater is designed in a curved shape to conform to the contour of the locomotive smokebox. It is rectangular in cross-section and has five nests or passes of small tubes surrounded by the exhaust steam, through which the feed water is forced by the pump. This heater is vented to the air and the condensate from it is carried back to a small auxiliary heater in the tank, where it is thoroughly mixed with and preheats the tank water before going to the pump, thereby increasing the efficiency of the heater. The pump is the centrifugal type with two rows of buckets in the steam end and has an automatic governor which limits its speed. It is light in weight and can generally be located on a bracket attached to the engine frame under the cab. If desired, the exhaust from the pump can be run into the condensate line and returned to the auxiliary heater for preheating purposes. Figure No. 12 shows the Coffin pump, while figure No. 13 illustrates a typical application, and figure No. 14 details of the construction of the Coffin heater.

Of the open type heaters, the Worthington is the outstanding example, and practically all of this type applied so far are of this design, which consists of a combined pump and heater in one unit. Figure No. 15 shows the construction of the pump and heater, while figure No. 16 is a diagram giving the general layout of a typical application. This pump is steam-driven and consists of three cylinders arranged in tandem form with the three pistons on one common piston rod. The top cylinder is the steam unit, while the middle cylinder draws the cold water from the tank and delivers it to the exhaust steam chamber of the heater section in the form of a spray. This spray in condensing the exhaust steam absorbs the heat units and the mixture of the hot water and condensate is then forced into the boiler from the bottom or hot water cylinder. An oil separator is applied in the exhaust steam line when desired so as to prevent the carrying into the boiler by the feed water of the lubricating oil which may be in suspension in the exhaust steam.

The other closed type that is now attracting attention is the Dabeg, a successful Austrian design that has been applied on several American locomotives. In this, as in other open type heaters, the cold water is sprayed into the exhaust steam chamber, but instead of having a steam-driven pump it is actuated mechanically.

There are other instances of the application of special type and experimental heaters, but the foregoing covers the four principal ones now in service in Canada and the United States.

Table No. 1.—Results Obtained on a Number of Typical Runs.

Service	Type of Engine	Length of Run in Miles	Weight Train in Tons	Per Cent Increase in Evaporation Feed Water Heater over Injector	Per Cent Decrease in Fuel Consumption Feed water Heater over Injector	Pounds Coal per Square Foot Grate per Hour

The Use of Local Materials for Concrete Construction

Precautions Taken in Construction of Roads in Brant County, Including the Predetermination of the Strength of Concrete

Alan Mair Jackson, A.M.E.I.C.
County Engineer, Brant County, Brantford, Ont.

Paper read before the Hamilton Branch of The Engineering Institute of Canada, March 16th, 1927

It seems only a very few years ago that gravel for ordinary concrete structures was accepted or rejected by what might be called the palm-of-hand method. A small quantity of the finer gravel was rubbed between the palms of the two hands, and if it left a very dirty mark it was rejected or if it felt smooth and soft it might be rejected. The experiments carried out by the Lewis Institute under Professor Duff Abrams, M.E.I.C., have done more to disseminate an accurate knowledge of concrete ingredients than any other theory that has been advanced in modern times, and, to the writer's knowledge, there are not any simpler methods of testing concrete aggregates, and it is intended to demonstrate in this paper that results can be obtained from doubtful material by the use of these methods which should give the engineer absolute confidence in his choice of aggregates.

The fundamental theory put forward by the Lewis Institute is the water ratio theory which is that, " for given materials and conditions of manipulation, the strength of concrete is determined by the ratio of the volume of mixing water to the volume of cement so long as workable mixtures are obtained. In other words, if one cubic foot of water is used for each cubic foot of cement in a concrete mixture, the strength at a given age is fixed regardless of what quantities of other materials are used, so long as the mixture is plastic and workable and the aggregates are clean and made up of sound durable particles. The significance of this important conclusion is more readily appreciated when the cement is thought of as a glue binding the aggregates together. The adding of excess mixing water serves only to dilute the glue and reduce the strength. The quantity of cement, the plastic condition or workability of the concrete and the size of the aggregate affect the strength of concrete only insofar as they affect the quantity of water required in the mix. If the other conditions are maintained constant the strength of concrete is increased by:—

(1) Mixing the concrete drier.
(2) Increasing the cement contents.
(3) Using coarser aggregates.

" Each of these changes, or combination of changes in the mixture, reduces the water ratio and the strength of the concrete is increased as the water ratio is decreased. The limit to which these changes may be carried is determined by the plasticity of the concrete. The amount of mixing water used must be sufficient to produce a plastic mixture, and the aggregate must not be too coarse for the amount of cement used."

To make use, then, of local materials which without careful testing are of doubtful quality, the first points to be determined are whether they are clean and sound. The importance of using local materials is very readily understood when the high freight rate still existing for such low grade commodities as gravel, sand and crushed stone is considered.

In addition to the water ratio theory, there is what is known as the fineness modulus of the aggregate, which has been more definitely defined by the Lewis Institute as " assuming a given consistency which should always be as stiff as the nature of the work permits, and a given mix, (proportion of cement to volume of mixed aggregate), the strength of the resulting concrete depends on the size and grading of the aggregate." In general, the larger and coarser the aggregate, the stronger will be the concrete. Coarse sand will produce stronger concrete than fine sand, while stone or pebbles in which the larger size predominate will produce stronger concrete than smaller stone or pebbles.

To determine the fineness modulus of an aggregate, it is necessary to make a simple sieve analysis. A set of standard square mesh sieves is used, each sieve having a clear opening double the width of the next smaller size; these sizes are 100, 50, 30, 16, 8 and 4 meshes per linear inch and 3/8-inch, 3/4-inch and 1½-inch. The percentage of aggregate coarser than each sieve is weighed, the sum of these percentages divided by one hundred is called the " fineness modulus." This is the most convenient method and an extremely simple one for making a comparison between any aggregates or combination of aggregates.

In order to illustrate the principles outlined above the details of the tests conducted in connection with the laying of a rural pavement in Brant county will be described. The choice of three or four deposits of local material was settled during the previous winter by the result of colour and silt tests and sieve tests to determine the grading of pit run material. An abrasion test was obtained from an outside source which proved the aggregate to have a French coefficient entirely suitable for concrete pavement.

A field laboratory was established in the pit consisting of an ordinary caboose on wheels with a bench, a set of scales weighing decimally up to twenty-five pounds, a set of standard sieves from 1½-inch to 100 meshes, a heater for drying samples, some 3 per cent sodium hydroxide, twelve-ounce prescription bottles, a sampling sheet, trowel, etc.

During the use of this local material in the construction of the concrete pavement, daily colour and silt tests were taken. These well known tests need hardly be described. The colour proved satisfactory and the silt by decantation test ran from 0.08 to 2.5 per cent, with an average for the season of 2 per cent. Thus the situation at this point was that the material was found to be comparatively clean and sound.

The gravel pit which was used in preference to imported material was such that when opened on a long face there was a very considerable body of coarse sand at one end of the pit and a fairly well graded gravel at the other end. The equipment used was two waggon loaders of the ordinary type discharging into a batch hopper at sufficient elevation for the hopper to empty into compartments in trucks. On the top of the hopper a sloping grizzly was arranged with the bars set slightly fanwise. With the waggon loader discharging on these bars, stones were found to jam continually when the bars of the grizzly were set parallel and a slight fanning of the bars overcame the difficulty. The waggon loaders, instead of working into the face of the material, were stationary, working only into a pile of gravel which was supplied by teams and slip scrapers. It was thus readily possible to change the mixture of gravel in the pile in front of each waggon loader by increasing the number of scraperfuls of sand or of coarser material.

The sampling of the gravel was done as follows:—A one hundred pound bag was filled from the discharge of the batch hopper, this was spread on the canvas sheet, thoroughly mixed, spread flat in a circle and quartered and a sample of about twenty-five pounds was dried. When dry, twenty-five pounds of this material was accurately weighed.

The strength of concrete aimed at in the pavement was 3,000 pounds at twenty-eight days. Hand-finishing was adopted, and for this result a fineness modulus of 5.8 was sample was put through the sieves and its fineness modulus obtained and instructions immediately given to the teamsters as to how the proportions of fine and coarse in the piles in front of the loaders should be varied to obtain the correct fineness modulus. Three samples of aggregate grading obtained are given in table No. 1.

An inspection of these three gradings will show that (*A*) has too high a proportion of fine material as reflected in the low fineness modulus while (*C*) has too small a proportion of fine material as reflected by the high fineness modulus. Both are readily corrected by adjusting the amount of fine and coarse material fed to the loaders, and sample (*B*) shows the correct fineness modulus for the strength of concrete determined upon.

The quantity of water could not be mechanically governed within very fine limits. The mixer had an automatic measuring pump which, while comparatively accurate, was, of course, entirely in the control of the operator, who could throw his lever twice for the same batch as well as once. Very strict inspection and the integrity of the operator was all that could be relied on for control of the water, except the constant use of the slump test.

If the mixed concrete had to be helped down the spout at the discharge of the mixer the concrete was sure to give

Table No. 1.—Determination of Fineness Modulus of Three Samples of Aggregate Grading.

set and became the daily task of the tester and sampler in the pit.

From Professor Abrams' table, the strength of concrete to be obtained is decided from a combination of the three factors slump, (governing water ratio), volume of cement and fineness modulus. The average, for the materials used, gave a mixture of about one to four. Allowance was made each day for the increase in volume of the aggregate, due to moisture, so that an unduly rich mix would not be obtained.

Bulking of the material due to its moisture content was investigated by examining another twenty-five pounds of the same sample. The bulking of the aggregate ran from 8½ to 16½ per cent, the average being 11 per cent and allowance was made on the basis of dry aggregate in fixing the quantity of cement used. The dried twenty-five pound a satisfactory slump, and a man working near the discharge had a hoe with which he continually cleared the chute. Slump tests were taken as often as six times a day and the average result obtained was one inch. The slump test cone was filled always by the same man. The twelve inches of the cone were filled in three layers, rodding each layer thirty times with a pointed steel rod. Test cylinders were taken in an exactly similar manner, the material in all cases being shovelled off the road and put into the slump cone or test cylinder.

The test cylinders were rodded in the same manner as the slump cones, and were tooled off and set aside for twenty-four hours and then laid in the ditch beside the road and kept covered with damp sand until it was time to dispatch them to the laboratory for crushing. There was little loss of time in sending these cylinders to Toronto for

crushing, as they usually were forwarded by truck one day and were crushed the next. The cylinders were largely broken at seven days and what the writer believes to be a standard formula was used in obtaining from this result the twenty-eight-day strength, i.e., 28-day strength = 7-day strength + $\sqrt{7\text{-day strength}}$. Cylinders were occasionally broken at twenty-eight days as a check on this formula, and the results are given in table No. 2. Calcium chloride admixture of 1½ pound per bag of cement gave strengths of about 2,200 pounds in three days. As the pavement laid was a rural one and was laid nine feet in width on one side of the centre line of the road, calcium chloride admixture was used at farm entrances, thus enabling the farmer to drive over the green concrete with light loads after three days, obviating the expense of building light bridges.

While results may check fairly accurately down to the point where the cylinders were tested, there is no guarantee that the cylinders had not been cured better than the pavement. If this is the case, then the results obtained are not a guarantee that the pavement is of the strength shown by the cylinders, and there does not seem to be any method short of the use of a coring machine which would prove the strength of the concrete in the finished pavement. The strengths obtained from the test cylinders given above, while they are not as uniform as might be desired, show a fairly satisfactory minimum considering the quality of the materials and the saving effected by the elimination of freight charges and the use of local material.

Discussion of Paper on Protection Against Seepage at Lake Kenogami, by O. O. Lefebvre, M.E.I.C.*

Mr. O. O. Lefebvre, m.e.i.c.

The author, in presenting the paper, remarked that in deciding the economical height to which the water could be raised in lake Kenogami, the governing factor was the topography around the lake, and not the water supply, because, as built, the reservoir could only hold slightly less than half the available amount of water, and elevation 115 could not be exceeded, the low water of the lake being 83 feet. Beyond that, level 115, the cost of dyking across ravines and creeks would have been altogether beyond the benefits to be derived from the additional water to be stored.

It so happened that in locating this contour 115, it was found that numerous dykes had to be built, but at one particular point,—at the " head of the lake,"—no dykes or other work had been provided because it had been thought that none would be necessary. At this point the lake Kenogami watershed is separated from the lake St. John watershed by a bank of sand of a minimum width of about 600 feet and a maximum of about 1,300 to 1,400 feet. Lake St. John lies approximately twenty miles in a northly direction from this point and is practically 290 feet below lake Kenogami. This sand bank, which it was thought would be sufficient to hold water when raised to a higher elevation, proved otherwise, and in 1924, when the lake was raised 10 feet, it was found that seepage was taking place through the sand bank and that it would be far from safe when it would be called upon to hold back an additional 13 feet of water.

The work to be done to prevent the seepage constituted quite a problem. If an impervious bottom had been found, it would have been rather easy, because an earth dyke with a core wall would have sufficed, but a boring carried 64 feet below the level of lake Kenogami showed nothing but sand. The method finally adopted really amounted to widening the sand bank of lake Kenogami.

Figure No. 1 of the author's original paper showed a topographical plan of the western end of lake Kenogami, and indicated the bank separating lake Kenogami from the lake St. John watershed. From the head of the ravine, the water flowed into lake St. John. the head of the ravine being at about elevation 70, as compared with lake Kenogami, which, in 1924, was at elevation 102, having been raised ten feet over its previous high water level of 92. Seepage was then noticed all round the bank and water was flowing down to lake St. John. Seepage was also detected as far down as lake Toussaint, which was found to have risen a few feet, and the same for lake Martel, while lake Louis had risen about a foot. A scheme was adopted of separating the bay from lake Kenogami, and the ravine, at *B-C*, was also filled. The width of the bank thus formed was such that water going through would have its velocity reduced to such an extent that there would be no danger whatever of any material being carried away. Many borings through the bank showed the hydraulic gradient to be about one foot in thirty feet, and the additional fill was designed on that basis, the idea being that the hydraulic gradient would lie always within or underneath the surface of the fill. The estimated amount of material required was about one million cubic yards.

Immediately the sand bank was completed, the water in the bay, separated from lake Kenogami, drained off from elevation 102 to about 95. It ran practically dry, which showed that below it the material was exceedingly pervious; in fact, it was more pervious than the sand bank built from material on the shore, and, of course, this gave further confidence in the proposed scheme.

In following the progress of the penetration of the water through the bank it was found that at the end of May the level of the lake had risen considerably, while the level in the bay had not changed. But in the next two months a very gradual movement of the water took place through the bank while the level of the lake was practically constant. Water was actually seen seeping through the surface of the bank.

The hydraulic gradient in the bank was then about forty to one. The bank was begun at a slope of thirty to one, but, while the machinery was there, it was thought that additional yardage would be advisable and less expensive than if it had to be done later. The slope was therefore changed to forty to one, and the yardage was increased in the two fills by one million cubic yards, the total yardage being two million cubic yards. The work was done by two

* This paper was presented at the Annual General Professional Meeting of The Institute, Quebec, February 16th, 1927, and published in the Engineering Journal, March, 1927.

methods, steam shovelling and hydraulic sluicing. Work was started in the fall of 1924, and the steam shovels were ready to work in October, and worked steadily day and night until the fill was completed in the month of July 1925. The coal for the steam shovels had to be hauled a distance of eleven miles, although much of it was hauled from the Chicoutimi end of the lake, which is connected to rail. The electric power for the sluicing machinery was transmitted especially for that job from the town of Jonquiere, a distance of twenty-one miles. The transmission line cost in the neighbourhood of $30,000. It had a capacity of 1,200 h.p. and the voltage was 33,000.

Sluicing practically commenced in the spring, although it was actually started in the latter part of November, but it was not practicable to use that system in winter. The progress of the work was very rapid. For example, in the month of April the monitors sluiced about 350,000 cubic yards, and, in the month of May, nearly as much. They had two monitors, each connected to two pumps, each pump driven by one 200-h.p. motor. The water was taken from the lake and delivered to the monitors at eighty pounds pressure through 16-inch pipes, and was pumped quite a long distance. All the material sluiced was very fine sand, and it was found that this material would sluice properly in a slope of about two and one-half per cent. The monitors had five-inch nozzles.

The cost of this sluicing was very much lower than the cost of the steam shovel work, if taken from day to day, but, on the whole, the two systems competed with one another. Some material was encountered which could not be moved by sluicing, such as material that was heavy or sand in which there was a lot of stone or gravel.

Mr. T. H. Hogg, M.E.I.C.

Mr. Hogg enquired if it was the case that part of the work was handled by shovels, while the monitors were used for washing the material into place.

Mr. O. O. Lefebvre, M.E.I.C.

The author replied that the two systems were completely separated; in fact, the steam shovels worked from one side and the monitors worked from the other side of the bank. The monitors actually sluiced the material into the bank from the pit.

Mr. T. H. Hogg, M.E.I.C.

Mr. Hogg asked whether any of the fill from the shovels had been placed on trestles or were the fills built out with end dump-cars.

Mr. O. O. Lefebvre, M.E.I.C.

The author replied that end dump-cars had been used.

Brig.-Gen. C. H. Mitchell, M.E.I.C.

General Mitchell asked for information as to the changes in level of lakes Louis, Martel and Toussaint after the completion of the work.

Mr. O. O. Lefebvre, M.E.I.C.

The author replied that when lake Kenogami stood at an elevation of 102 in 1924 the seepage was measured in the creek at lake Louis, and the discharge of the lake was found to be 23 cubic feet per second, and it was estimated that practically 100 per cent of that was due to seepage. This was the case with the lake level at 102. After the fill was completed and the lake level was raised to 115, and maintained there for a month, the seepage was again measured, and it was reduced to seventeen cubic feet per second, which amount could not be stopped.

The level of lakes Toussaint and Martel dropped two and a half feet. These two lakes. peculiarly enough, had no visible outlet; apparently they discharged through the ground, and, with existing conditions, with lake Kenogami standing at 115, these lakes had a level about 2.4 feet lower than their level when lake Kenogami was 102, previous to the completion of this work.

It appeared that the whole bank, which was pervious, was quite saturated, and, as the level of lake Kenogami rose, the saturation increased. He believed that if the level stood at 115 for twelve months the saturation might be different, but fortunately that was not necessary.

Mr. E. A. Forward, M.E.I.C.

Mr. Forward enquired as to the loss of water storage caused by putting in the dam and cutting out the end of the lake.

Mr. O. O. Lefebvre, M.E.I.C.

The author replied that the loss of storage was negligible.

Discussion of Paper on Rack Structure and Penstock Intake of the Isle Maligne Hydro-Electric Power Station, by W. S. Lee, M.E.I.C.*

Mr. W. S. Lee, M.E.I.C.

The author, in presenting the paper, remarked that it gave a general outline of some of the novel features in connection with the intake structure at the Isle Maligne power station.

Engineers were not given to breaking away from precedent, but in view of the rigid conditions which confronted them in the province of Quebec special study had to be given. They had the low temperature problem to deal with and the effect of these low temperatures on large structures. Contraction and expansion, handling ice, etc., had been very carefully considered.

On referring to figure No. 1, which is a typical section through the Isle Maligne station, it would be noted that a moveable crane traversed the entire length of the bulkhead. At the end of the power house, where a railroad car could be put under it, this crane could pick up any size load up to 60 tons, hoist it about 80 feet and traverse the entire

* This paper was presented at the Annual General Professional Meeting of The Institute, Quebec, February 17th, 1927, and was published in the Engineering Journal, January, 1927.

length of the bulkhead. This design had worked well, and the cost of the crane had been saved in erection. All of the large gates had been erected from the top of the bulkhead with this gantry crane.

They had deviated somewhat from Canadian practice in not having any intake building or housing over the bulkhead. In analyzing possible ice troubles, they had reached the conclusion that there would not be any frazil ice at all, since the water was impounded from Isle Maligne up to lake St. John, a distance of seven miles, and the nearest river of any size was probably twenty-five miles from the intake. Slush ice which came down the river stopped in the lake, and did not get to the power house on account of the quiet water. As yet there had not been any ice trouble.

Again referring to figure No. 1, near the top of the bulkhead to the right, where the gate stems go up, a tunnel could be seen, marked "elevation 258.9." This tunnel, running the entire length of the bulkhead, was put in there as an air duct. By this means the bulkhead was warmed by air from the generator room, and a continuous current of warm air was led into every gate chamber in the whole bulkhead. In this way there was a column of air rising over the opening to the gate stems, and the gates were warmed so as to operate irrespective of outside temperature. The arrangement worked automatically, and a study of it could be recommended.

The gates could be operated from the switchboard in case of emergency, as there was an emergency switch on the benchboard in the power house, so that the pivoted gate could be closed under full head and full gate opening of the water wheels; the importance of keeping the gates clear of ice was therefore obvious.

While discussing temperature conditions, the author referred to the question of ventilating the generator room. On the downstream side, windows had been provided in the basement. The governors were located in the basement near the servo-motors; the operators for the wheels were down there, and there were quite large windows along the entire length. If it were necessary to open these windows in extremely cold weather, admitting too much cold air, a temperature might result which would freeze the oil or small working parts of the governor. It would be noticed that the railroad track ran on two concrete beams the entire length of the power house, and, along and between the railroad track, gratings had been provided to allow the air to recirculate. By controlling the windows and gratings, any temperature desired could be maintained in the generating room. He considered that in large structures such as the Isle Maligne station it was very desirable, on account of contraction and expansion, to subject them to as little temperature variation as possible during construction. This was especially true when after completion they had a temperature regulating effect due to heat generated in the power house.

The work of excavating foundations for the Isle Maligne station began in May, and the structure was completed by December. When the weather began to get cold in the late fall the draught tube entrances were boarded up and covered with tar paper; salamanders were placed in the draught tubes, and this kept the temperature fairly uniform until the excavation of the tailrace was completed and the water admitted. By this arrangement the temperature variation of the whole structure had only undergone comparatively slight changes.

Number six unit in the station was turned over under its own water nine months after the commencement of excavation for the foundation. The short time consumed in the construction of the Isle Maligne plant necessitated the job being very heavily rigged, and more work had been done on designing the construction equipment and layout than on the power plant.

In dealing with the various drains and expansion joint seepages going down through the section into the draught tubes, these had to be drained under water to keep them from piling up ice at their outlets.

The pivoted gates were operated with one stem each by a motor controlled from the switchboard. Each gate weighed 54 tons, was 16 by 22 feet and was assembled complete at the shops.

Mr. W. G. Chace, m.e.i.c.

Mr. Chace enquired as to the rack velocities.

Mr. W. S. Lee, m.e.i.c.

The author replied that the rack velocities on about 90 per cent load were from 2.4 to 3 feet per second, depending on the variation in head. The discharge velocity in the tailrace would be about 4 feet per second.

Mr. J. A. McCrory, m.e.i.c.

Mr. McCrory had observed that the Isle Maligne racks were fixed in place, which he believed was rather an unusual practice for a large plant in that region. In operating one of the Shawinigan Company's plants, not unfavourably situated as regards the formation of frazil in the winter before the ice sheet formed, they still did get frazil after a stretch of very severe weather, and it had been necessary at times to lift the racks to take care of this condition for the few days during which it lasted. He would ask whether there had been difficulty at Isle Maligne with the formation of frazil on the racks, and, if so, how it had been dealt with.

Mr. W. S. Lee, m.e.i.c.

The author stated regarding the fixed racks that at Isle Maligne the Shawinigan conditions did not exist; they had a reservoir of water extending miles back before reaching any turbulent or frazil-forming water. He was aware that on a sheet of water a certain amount of frazil would be formed with the water almost quiescent. It was the intention always to fill up lake St. John in the fall or the summer, when the racks would be submerged about 20 feet, and the area would be so great at the entrance to the penstock that there would be practically no velocity that could carry down any frazil that would form on top of the water. Such an arrangement would not be suitable for a partially open stream, but was adapted to existing conditions in the north channel of the river, which was 700 to 800 feet wide and 80 to 90 feet deep, so that the velocity was low. He would point out that all the frames of the racks and concrete structures were fixed; the rack bars themselves were not, but were in slots with a keeper on top.

Mr. W. G. Chace, m.e.i.c.

Mr. Chace remarked that water velocities were a great deal more important than was generally believed by theorists. In 1911, when the Winnipeg plant was built, it was expected that it would take many years to build up the load. They sold 20,000 h.p., which was the initial installation, in about two or three years; the present installed capacity was 95,000 h.p. and they had recently bought 30,000 h.p., which total load had been developed in municipal service since 1911 in a city of about 200,000 population. Their canal was originally designed for one-half to two-thirds capacity, expecting that, as the plant developed, a further capital expenditure would be made, but this has not yet been done, and, in consequence, in a canal 1,000 feet long, they had a loss under full load of one and one-half feet, and they had, therefore, a velocity in the canal which tended constantly to break up the sheet of ice which formed over the surface. This occurred especially with the " kick-off " of load, when the whole sheet would break up and come down to the power house; some of that ice a month later could still be seen inside the rack rooms.

The racks were under shelter, and in recent years the hot air from the generator room had been turned into the rack room by means of fans, which made it possible to work comfortably there. The rack velocities at the Winnipeg plant were much lower than Mr. Lee had chosen for his Isle Maligne plant; the average velocity being about one and one-half feet per second; and still the ice and floating timber was driven against the racks and required constant attention. The racks were built in removable sections. He believed that as yet there had been no occasion to remove any sections except for maintenance purposes. Their low velocities were obtained by using an inclined rack some 45 feet in length from top to bottom, and over the entire entrance, so that the water did not enter the bays until after it had passed the racks; in other words, it was passed from unit to unit behind the rack, which had been found to be a very desirable condition.

He desired to ask the author for further information regarding the seal used against the butterfly gate and shown in figure No. 5 as a spring bronze leaf. That leaf, he supposed, had but little flexibility in a longitudinal direction. He enquired whether that had been found a satisfactory type of seal. The problem of sealing the gates had occurred at the Winnipeg plant and had not been met successfully originally, and as yet there had not been devised a means of keeping the gates sealed satisfactorily at the edges.

Mr. W. S. Lee, M.E.I.C.

The author was inclined to think that Mr. Chace's difficulty in bringing the debris and ice was not rack velocity, but canal velocity, since there was a rack velocity of one and one-half feet per second, and a much higher one in the canal. No such trouble had occurred at Isle Maligne, where the power house was placed across one channel of the river and the approach velocities were very low.

The seal to which Mr. Chace referred was of bronze and was tightened by water pressure when the gate was raised. A heavy angle sticking out to protect it from any pieces of ice which might bend it should have been shown in the drawing. He had been in the Isle Maligne penstocks while the gates were under head, and did not believe that enough water was leaking through the gate to fill a two-inch pipe.

Mr. F. Newell, M.E.I.C.

Mr. Newell was somewhat diffident in contributing to the discussion, but felt that a short description of the manufacturing work on the butterfly type head gates might be of interest.

The necessity for first class workmanship and the best modern machine shop practice had been realized by all concerned at the outset, and every effort was made to produce a gate that would be thoroughly watertight with a minimum of fitting and adjusting in assembly at the site. The centre castings were first turned accurately to diameter on the trunnion and then planed exactly parallel and true with the finished trunnion. Care was also take to plane the cast iron leaves so that they were both parallel and square, particular accuracy being looked for in the faces mating with the centre casting and also the faces on which the head of the shrink links took their bearing, as it would be seen that the length of the shrink links depended upon the accuracy of six machined faces and their parallelism when assembled.

In the interest of economical production, it was necessary that the links be machined to an exact predetermined length, so that any link could be shrunk into any place on the valves without having to make each link for a special location. That this had been accomplished was evidenced by the fact that the wings and centre casting when bolted together did not vary more than a few thousandths of an inch from parallelism and the nominal drawing dimension. The links were all machined 3/32 of an inch shorter than this dimension, and then shrunk into place after the wings were assembled with the centre casting.

The links being 3 feet 9 inches between the heads, 1/1,000 of an inch shrinkage per inch of length would give a stress of 30,000 pounds per square inch, but the higher shrinkage allowed was intended to take care of the compression taking place on the four pairs of mating surfaces, the compression of the metal itself and the elongation of the link. The links were made of a low carbon steel having an ultimate strength of 50,000 to 60,000 pounds per square inch and an elongation of 20 per cent, with a reduction of area of 40 per cent.

The trunnions, as mentioned by the author, were bushed with phosphor bronze, and the bearings were also fitted with a cast iron liner, so as to permit of easy replacement in case of wear of either part. In order to provide a free-running bearing, a clearance of 1/16 inch had been allowed between the bushing and liner, but, as oil lubrication was provided for from the operating machinery floor and the whole of this clearance would come into the cap and allow the oil to flow freely out of the bearing without lubricating it, it was decided to line the cap with close-fitting babbit strips which could be brought down on the trunnion and would retain the oil for lubricating purposes in pockets formed between these strips.

The centre castings, gate wings, bearings and frames were all completely assembled in the shop; all joints were reamed for fitted bolts; the spring seals fitted in place; and all pieces match-marked and then taken apart for shipment, in order to facilitate accurate assembly in the field.

On account of the heavy weight of the assembled valve, it had been necessary to do the shop assembly at a convenient height, and over railway tracks, so that flat cars could be run under, and the piece taken away to be handled by a large capacity yard crane for shipment on specially constructed well cars; the pieces being placed so that the centre casting was vertical and in the middle of the car.

The spring seals which Mr. Chace had mentioned were of the type which had been used on a number of head gates, and if care were taken in the shop and in the field these seals could be made absolutely watertight. There were many instances in which they were practically watertight, the only leakage being in the corners, where leakage would occur in any seal.

The spring seals had been made of triple leaf spring bronze, and as it was considered that with the gate just cracked open these seals would have to withstand the full hydrostatic head and at the same time must be flexible enough to take up any deflection in the gate leaf, a good deal of care was taken with their design and construction. Before determining their size and proportions, particulars were obtained of the elastic limit, ultimate strength and Young's modulus of the material used. Also, the springs were formed in dies so as to maintain an exact uniformity of shape, and a great deal of care was exercised in the works to construct the dies so that the correct final form was obtained.

He mentioned this because it had been found that when the springs were first made up in dies they always sprung back a little out of shape, and it was therefore necessary to try various forms to find exactly what shape the dies should be in order to produce the shape of spring which was finally used on the job.

Two points in connection with the screw-stem hoists were worthy of mention, although they were questions of design rather than workmanship. These were the limit switches and push button contacts provided so that the gates could, if necessary, be operated from the power house floor, and also the spring buffer devices on the closing side, arranged so that the motor would be brought to rest without impact to the machinery should the limit switch for any reason fail to act. The machinery, of course, had been designed to withstand the full torque of the motor determined from the setting of the overload coil on the circuit breaker.

Mr. T. H. Hogg, m.e.i.c.

Mr. Hogg remarked that the rack structure at Isle Maligne was of special interest, and the advantage of shipping with the rack bars removed was important from the point of view of economy of fabrication. He noted, however, that the framework holding the rack bars was embedded in the concrete and the racks could not be removed without unwatering with the stop-logs. It was also apparently necessary to take out each bar separately. This type of fixed rack structure had to be designed to withstand full hydrostatic head with the penstock empty, and the openings through the racks clogged so as to guard against the possibility of failure of the racks, as such failure would require shutting down the unit to effect repairs.

It has been the practice of the Hydro-Electric Power Commission of Ontario to design racks in panels of convenient size for handling with a follower and to install them in checks similar to those provided for stop-logs or steel gate sections. This obviated the necessity of designing the racks for full hydrostatic pressure, thereby effecting a considerable saving in steel and guarding against shut-downs. Any damaged panels could be removed and replaced with spares without shutting down the unit. It also enabled the removal of the racks for the passage of slush or frazil ice in case they should become clogged and the flow through the bars restricted.

He noted further that by-passes had been provided for filling the penstock before opening the butterfly gates. These were installed possibly for the purpose of protecting the bronze spring leaf water seal on the gate frame and to prevent chattering in the gate. Such provision was seldom required where head gates of the Stoney roller type were used. The butterfly gate possessed the advantage of requiring a relatively light motor for its operation compared with that necessary for the Stoney type of gate, but the latter type had a distinct advantage in that it could be closed in case of emergency in a few seconds, the butterfly type referred to by the author apparently requiring about five minutes.

It would be of interest to know whether the air tunnel underneath the headworks deck, for providing air to the penstocks in case of a sudden closure of the gates and to allow the escape of air when filling the penstocks, was continuous throughout the length of the head works, whether it was confined to each individual unit or whether partial barriers were provided between units in order to prevent water surging up from one unit to another which might be unwatered and under repair or inspection. The author had stated that warm air was supplied to the air vent and to the space beneath the head works deck through the opening near the roof of the circuit-breaker and transformer room. This would necessitate the warm air passing down into the air tunnel and across through the opening to the space benear the roof of the circuit breaker and transformer room. to be rather difficult to induce, and it would be of interest to know if fans or other means of forcing the air into these passages had been provided or if variation in the load on the unit were relied on to cause the necessary movement.

THE ENGINEERING JOURNAL

THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

VOLUME X JUNE 1927 No. 6

Annual General and General Professional Meeting—1928

At the meeting of Council on April 22nd, a request was received from the Montreal Branch that the Annual General and General Professional Meeting of The Institute for the year 1928 be held in Montreal, which suggestion was approved by Council. Subsequently, the Montreal Branch appointed a special committee to take charge of arrangements in connection with the Annual Meeting. At the meeting of Council on May 20th, there was presented a report prepared by this committee suggesting that the Annual General Professional Meeting be held on February 14th, 15th and 16th, 1928, and, as this report was adopted, these dates are tentatively fixed for the meeting of next year.

It was further resolved at the last meeting of Council that the Annual General Meeting be convened on the evening of the third Thursday in January for the transaction of formal business, and that this meeting be adjourned to the date set for the holding of the Annual General Professional Meeting.

It may seem to many members an early date to be making arrangements for a meeting which is to be held in February of next year, but it has been found by experience that in order to procure papers of general interest and of a quality in keeping with such a meeting, and in order that these papers may be distributed in advance of the meeting so that a thorough discussion may be presented, it is by no means too early to attend to the preliminary details.

The success of the technical sessions at the last Annual Meeting was largely due to the excellent discussions of the various technical papers which were presented, and much favourable comment has been made regarding this feature of the programme.

It is the aim of the committee to make the 1928 meeting one to be long remembered, and to this end no effort will be spared in the preparation of the details of the programme in order that every member of The Institute may find much of interest at the meeting.

Amendments to By-laws

The result of the ballot for the amendments to the By-laws of The Institute was contained in a report of the scrutineers presented to Council at its meeting on May twentieth, nineteen hundred and twenty-seven, which showed that both changes were approved by a large majority of the members of The Institute whose ballots were cast, and accordingly these changes have now become effective. The amended sections of the By-laws are as follows:—

Section 13.—A vacancy in the office of president shall be filled by the senior vice-president. Seniority shall be determined by priority of election as a vice-president, and, failing that, by priority of admission to corporate membership.

Section 38.—The secretary shall notify any member whose fees become in arrears. No member shall be considered in arrears for any year until after the thirty-first day of March of that year. On the first day of January next following, six per cent per annum shall be added as interest on the subscriptions in arrears, and the same sum shall be added on the first day of January of each year until the said arrears are paid. No member who is in arrears after June thirtieth shall have the right to vote. Council may take action in the case of a member who is in arrears by:—

(*a*) Directing that he shall not receive the publications of The Institute and/or

(*b*) Removing his name from the register of members.

It will be recalled that these amendments were drawn up by the Committee on Legislation and By-laws, and subsequently approved by Council and presented for discussion at the Annual General Meeting on February fifteenth, nineteen hundred and twenty-seven, and then submitted by letter ballot to the corporate membership, the result of which is announced above.

Honorary Degree Conferred on President Decary

An impressive and interesting ceremony took place when the degree of Doctor of Applied Science, *honoris causa,* was conferred by the University of Montreal on the President of The Engineering Institute of Canada, Albert R.

Decary, M.E.I.C., on April 30th, 1927, at the Cercle Universitaire de Montreal.

There were present on this occasion Mgr. A. V. J. Piette, rector of the university; the Hon. Sir Lomer Gouin, president of the university; the Hon. L. J. Perron, one of the governors of the university, and a large gathering of graduates in engineering of the Ecole Polytechnique of Montreal, together with the students of the graduating class of the school, in whose honour a banquet was being given by the older graduates.

It will be recalled that the granting of this Honorary Degree to Mr. Decary was announced in the April 1927 issue of the Journal, shortly after the announcement of his election to the presidency of The Institute, and it will be most gratifying to members of The Institute to note that, in the extract of the minutes of a special meeting of the Corporation of the Ecole Polytechnique, held on February 21st, 1927, which was read by Dr. Augustin Frigon, A.M.E.I.C., director of Ecole Polytechnique at the commencement of the ceremony, the resolution granting the degree referred first to his recent election as president of The Institute and to the fact that he has been president of the Corporation of Professional Engineers of the Province of Quebec since its formation. It also referred to his being an old pupil of the Ecole Polytechnique, the importance of his position as superintending engineer for the province of Quebec of the Department of Public Works of Canada, and the great honour he has done to his Alma Mater and his profession.

In his address, Mgr. A. V. J. Piette, as rector of the University of Montreal, praised Mr. Decary for his successful achievements in his profession and referred at length to the high esteem with which he is held. He then asked the Honourable Sir Lomer Gouin, as president of the university, to present the degree to Mr. Decary. Sir Lomer spoke in high terms of Mr. Decary, and expressed his pleasure in being present to take part in the ceremony and especially in having the honour of presenting the degree to his friend, the new Doctor of Science. In a brief address, Dr. Decary, dressed with ermine toga, expressed his thanks to the university of Montreal and the Ecole Polytechnique for the honour bestowed upon him.

At the banquet following the ceremony, the president of the graduating class, Mr. S. Picard, presided, while among those at the head table were: Mgr. A. V. J. Piette, Sir Lomer Gouin, the Hon. Mr. L. J. Perron, Mr. C. J. Simard, assistant provincial secretary, Dr. A. R. Decary, M.E.I.C., Dr. J. Emile Vanier, A.M.E.I.C., to whom the degree of Doctor of Applied Science was also granted, Mr. U. P. Boucher, A.M.E.I.C., president of the Alumni Society of the Ecole Polytechnique, Dr. Arthur Surveyer, M.E.I.C., Dr. A. Frigon, A.M.E.I.C., Mr. Aurelien Boyer, A.M.E.I.C., principal of Ecole Polytechnique.

Empire Mining and Metallurgical Congress

The Second (Triennial) Empire Mining and Metallurgical Congress will be held in Canada from August 22nd to September 28th, 1927. During that time two simultaneous tours, in special trains, will be made of the Dominion of Canada. Tour "A" will visit the principal mining centres of Ontario, Quebec and western Canada. Tour "B" will travel through Ontario with Tour "A," and then examine the mining areas of Quebec, eastern Canada and Newfoundland. Meetings and technical sessions will be held in the following cities:—

Montreal, Que. ....August 22nd and 23rd.
Toronto, Ont. .....August 25th and 26th.
Winnipeg, Man. ...September 3rd and 4th.
Sydney, N.S. ......September 9th and 10th.
Vancouver, B.C. ...September 14th.
Edmonton, Alta. ...September 20th.

It has been decided to extend to fifteen members of The Engineering Institute of Canada the privilege of reserving space on these trans-Canada tours, and such reservations should be made as early as possible through the general secretary of the Congress, Geo. C. Mackenzie, M.E.I.C., 623 Drummond Building, Montreal, from whom further information can be obtained.

Meeting of Council

MEETING OF MAY 20TH, 1927.

A meeting of Council was held at eight o'clock p.m. on Friday, May 20th, 1927, President A. R. Decary, M.E.I.C., in the chair, and seven other members of Council being present.

The financial statement to April 30th was submitted and approved.

The recommendations of the Finance Committee in connection with eight special cases were considered and approved.

The report of the scrutineers on the letter ballot closing April 25th, 1927, for amendments to By-laws was submitted and accepted, and the amendments voted upon for Sections 13 and 38 were declared carried.

A letter from the Peterborough Branch was considered, drawing attention to certain points in connection with the organization of The Institute, and these were referred for consideration at the Plenary Meeting of Council to be held in October.

The offer of the Canadian Institute of Mining and Metallurgy to hold fifteen reservations for members of The Engineering Institute on the special Congress Tour train was noted with appreciation.

A letter was presented from a corporate member remarking on the difficulty experienced by him in securing reliable information as to relative building costs in Canada, and suggesting that The Institute might be willing to investigate the situation with a view of furnishing through the medium of The Engineering Journal a set of index numbers for the Dominion of Canada, and providing a monthly or quarterly service. After consideration, the Secretary was directed to advise the member in question that funds are lacking to do this effectively, and therefore that it is at present impossible to comply with his request.

The lists of officers of the St. John and Edmonton Branches for the year 1927-28 were submitted and approved.

The personnel of the Gzowski Medal and Students' Prizes Committee for the year 1927 was submitted and approved.

Decisions were given in the cases of two requests for reinstatement.

The following elections and transfers were effected:—

Elections	
Members	2
Associate Members	8
Affiliate	1
Students	7

Transfers	
Associate Member to Member	3
Junior to Associate Member	4
Student to Associate Member	2
Student to Junior	1

Thirteen applications for admission and transfer were scrutinized and classified for the ballot returnable June 21st, 1927.

Ten special cases were considered in connection with applications for admission.

The Council rose at ten-thirty p.m.

Recent Graduates in Engineering

Congratulations are in order to the following Students and Juniors of The Institute who have recently completed their courses at the various universities.

University of Manitoba

Special Prize

Rigby, Charles Arthur,—Joseph Doupe Gold Medal in Civil Engineering.

Degree of B.Sc.

Akins, Ernest Joseph William, B.Sc., (Ci.), Winnipeg, Man.
Benditt, Harry, B.Sc., (El.), Winnipeg, Man.
Evans, Frank Lloyd, B.Sc., (Ci.), Winnipeg, Man.
Genik, Alexander Charles, B.Sc., (El.), Winnipeg, Man.
Ingimundson, Ingimundur Carl, B.Sc., (El.), Winnipeg, Man.
Kennedy, Leslie John, B.Sc., (Ci.), Winnipeg, Man.
Mackay, Leslie, B.Sc., (Ci.), Winnipeg, Man.
McDermid, George, B.Sc., (El.), Winnipeg, Man.
Payne, Harold, B.Sc., (Ci.), Winnipeg, Man.
Reid, William Paul, B.Sc., (El.), Winnipeg, Man.
Rigby, Charles Arthur, B.Sc., (Ci.), Winnipeg, Man.
Rowan, John William, B.Sc., (Ci.), Winnipeg, Man.
Rowe, Gordon William, B.Sc., (Ci.), Winnipeg, Man.
Sinclair, Archie B., B.Sc., (El.), Winnipeg, Man.
Treble, Harold Edison, B.Sc., (El.), Winnipeg, Man.

Queen's University

Medal in Applied Science

Culver, Don Newton,—Governor-General's Silver Medal in Applied Science.

Degree of B.Sc. (with honours)

Culver, Don Newton, B.Sc., (El.), Kingston, Ont.
Houlden, James Walter, B.Sc., (Me.), Hamilton, Ont.
Jenkinson, Hugh Cameron, B.Sc., (Me.), Niagara Falls, Ont.

Degree of B.Sc.

Adams, George Ronald, B.Sc., (Ci.), Kingston, Ont.
Davis, George Roland, B.Sc., (El.), Smith Falls, Ont.
Gathercole, John William, B.Sc., (Me.), Hamilton, Ont.
Howard, James P., B.Sc., (Ci.), Kingston, Ont.
Knapp, Allen Clifton, B.Sc., (Me.), Sydenham, Ont.
Orange, Frank Angel, B.Sc., (Me.), Sudbury, Ont.
Robinson, Jack Spriggs, B.Sc., (Me.), Kingston, Ont.

University of Toronto

Degree of B.A.Sc. (with honours)

Grundy, Ernest, B.A.Sc., (Ci.), Toronto, Ont.
Jones, John Hugh Mowbray, B.A.Sc., (Me.), Toronto, Ont.

Degree of B.A.Sc.

Barr, Frederick Gordon Fordyce, B.A.Sc., (Me.), Toronto, Ont.
Fox, John Halloway, B.A.Sc., (Ci.), Toronto, Ont.
Thompson, William Lennox, B.A.Sc., (Me.), Toronto, Ont.

Ecole Polytechnique of Montreal

Prize in Architecture

Dechêne, Theo Miville,—The Ernest Cormier Prize.
Burdett, Georges Henry,—The Ernest Cormier Prize.

Prize in Industrial Chemistry

Perrault, Lucien,—The Louis Bourgoin Prize.

Diploma in Civil Engineering

Burdett, Georges Henry, (Ci.), Montreal, Que.

Diploma in Civil Engineering and Degree of B.A.Sc.

Archambault, Ubald, B.A.Sc., (Ci.), Outremont, Que.
Dechêne, Theo Miville, B.A.Sc., (Ci.), Westmount, Que.
Gravel, Louis Philippe, B.A.Sc., (Ci.), Beauport, Que.

Diploma in Chemical Engineering (with honours)

Perrault, Lucien, (Chem.), Outremont, Que.

McGill University

Honours in the Graduating Class, Medals and Prizes

Beck, Robert George, Winnipeg, Man.,—Crosby Steam Gauge & Valve Company's Prize for Summer Essay; Babcock & Wilcox Scholarship; Honours in Mechanical Engineering.
Coleman, Charles Lester, Providence, R.I.,—Undergraduates' Society's Second Prize for Summer Essay; also Departmental Prize for Summer Essay; Dr. James Douglas Research Fellowship in Mining Engineering.
Fraser, Willard Bruce, Stellarton, N.S.—British Association Medal (Electrical Engineering); Montreal Light, Heat and Power Cons. Prize; Honours in Electrical Engineering.
Johnston, Harry Lloyd, Victoria, B.C.,—Departmental Prize for Summer Essay.
Killam, Donald Alexander, Weymouth, N.S.,—British Association Medal (Civil Engineering); Honours in Civil Engineering.
Petzold, Henry Paul, Westmount, Que.,—Babcock & Wilcox Scholarship; Honours in Mechanical Engineering; British Association Medal (Mechanical Engineering).
Phillips, John Bernard, Montreal, Que.—British Association Medal (Chemical Engineering); Undergraduates' Society's Second Prize for Summer Essay; Honours in Chemical Engineering.
Silver, Ralph Charles, Danville, Que.,—British Association Medal (Electrical Engineering); Montreal Light, Heat and Power Cons. Prize; Jenkins Bros. Limited Scholarship; Honours in Electrical Engineering.

Degree of M.Sc.

Greenberg, Harry, B.Sc., M.Sc., (Chem.), Montreal, Que.
Katz, Morris, B.Sc., M.Sc., (Chem.), Montreal, Que.
McCurdy, Lyall Radcliffe, B.Sc., M.Sc., New Glasgow, N.S.
White, Thomas Nash, B.Sc., M.Sc., (Physics and Mathematics), Montreal, Que.

Degree of B.Sc.

Bauman, Bert Eric Frederick, B.Sc., (Ci.), Buckingham, Que.
Beck, Robert George, B.Sc., (Me.), Winnipeg, Man.
Bennett, Arthur Joseph, B.Sc., (El.), Maniwaki, Que.
Blackmore, Cyril Leslie, B.Sc., (El.), St. John's, Nfld.
Coleman, Charles Lester, B.Sc., (Mi.), Providence, R.I.
Darling, Thomas Creighton, B.Sc., (El.), Montreal, Que.
DesBrisay, Aretas William Young, B.Sc., (El.), Petit Rocher, N.B.
Dewar, Kenneth McIntyre, B.Sc., (Mi.), Dewar Lake, Sask.
Evans, Thomas Owen, B.Sc., (El.), Montreal, Que.
Fraser, Willard Bruce, B.Sc., (El.), Stellarton, N.S.
Gregory, Hurd Anthony Forbes, B.Sc., (El.), Fredericton, N.B.
Hamel, Joseph Albert, B.Sc., (Ci.), Three Rivers, Que.
Hicks, Ben Church, B.Sc., (El.), Bridgetown, N.S.
Johnson, Edward Lawrence, B.Sc., (El.), Welland, Ont.
Johnston, Harry Lloyd, B.Sc., (Ci.), Victoria, B.C.
Keene, Thomas Ross, B.Sc., (El.), Montreal, Que.
Killam, Donald Alexander, B.Sc., (Ci.), Weymouth, N.S.
Kingston, George Harold, B.Sc., (El.), Prescott, Ont.
McClure, Lindley Wilberforce, B.Sc., (El.), Verdun, Que.
Moffatt, Thomas Stuart, B.Sc., (El.), Victoria, B.C.
Moore, Lewis Nicholas, B.Sc., (El.), Ottawa, Ont.
Moore, William Herbert, B.Sc., (El.), Westmount, Que.
Mules, Nathan Ernest, B.Sc., (Chem.), Montreal, Que.
Petzold, Henry Paul, B.Sc., (Mech.), Westmount, Que.
Phillips, John Bernard, B.Sc., (Chem.), Montreal, Que.
Silver, Ralph Charles, B.Sc., (El.), Danville, Que.
Stewart, John Rufus, B.Sc., (Mech.), Beebe, Que.
Stewart, Leslie Baxter, B.Sc., (El.), Antigonish, N.S.
Villella, Frank R., B.Sc., (Ci.), Montreal, Que.
Wise, Alfred J., B.Sc., (El.), Rosemount, Que.
Yuile, William S., B.Sc., (Met.), Montreal, Que.

University of Alberta

Special Prize and Degree of B.Sc. (with honours)

Hunter, Harry Melville, B.Sc., (Mi.), Calgary, Alta.,—Prize of the Association of Professional Engineers of Alberta.

Dalhousie University

Diploma in Engineering

Armstrong, Owen Fred. Calder, Tupperville, N.S.

University of British Columbia

Special Prize

Millar, James Wallace,—The Convocation Prize (General Proficiency).

Degree of B.A.Sc.

Barnsley, Frank Richard, B.A.Sc., (El.), Vancouver, B.C.
Farrar, Ben Kerslake, B.A.Sc., (Met.), Vancouver, B.C.
Gale, Stanley Cuthbert, B.A.Sc., (El.), Vancouver, B.C.
Gordon, Arthur Illingworth Elmsly, B.A.Sc., (Ci.), Vancouver, B.C.
Millar, James Wallace, B.A.Sc., (Me.), Field, B.C.
North, John Terry, B.A.Sc., (El.), Vancouver, B.C.
Oliver, John Craig, B.A.Sc., (Ci.), Vancouver, B.C.
Todd, Robert Lawrie, B.A.Sc., (Ci.), Vancouver, B.C.
Wainman, Philip Richard, B.A.Sc., (El.), Vernon, B.C.

ELECTIONS AND TRANSFERS

At the meeting of Council held on May 20th, the following elections and transfers were effected:—

Members

O'HARA, George Dennis, B.Sc., (Princeton), consulting engineer, Vancouver, B.C.

SMITH, George Barnett, B.Sc., (McGill Univ.), i/c central Ont. system of H.E.P.C., Belleville, Ont.

Associate Members

CARRUTHERS, James Alexander, master mech. and ch. engr., C.P.R. mines, Lethbridge, Alta.

HANNAN, Ralph D., Ph.B. in C.E., (Yale), Dom. Bridge Co. Ltd., Montreal, Que.

MacKAY, James Arthur, B.Sc., (N. S. Tech. Coll.), asst. engr. with C.N.R., Bedford, N.S.

MANOCK, Wilbur R., B.S. in C.E., (Univ. of Ill.), mgr. of operations, Horton Steel Works, Bridgeburg, Ont.

McMURTRY, Lawrence Carleton, B.A.Sc., (Univ. of Toronto), supt. of erection Horton Steel Works, Bridgeburg, Ont.

PAINE, Nathan Deane, B.Sc., (New Hampshire Univ.), Price Brothers & Co. Ltd., Kenogami, Que.

PATERSON, E. L., B.A.Sc., (Univ. of Toronto), Imperial Oil Limited, Hamilton, Ont.

PORTUGAIS, Joseph Maurice, B.A.Sc., (Univ. of Montreal), tech. engr., Canada Cement Company, Montreal, Que.

Affiliate

ROSS, Robert Bruce, Ont. mgr. Milton Hersey Co. Ltd., London, Ont.

Transferred from class of Associate Member to that of Member

FINLAYSON, Ernest Herbert, B.Sc., (Univ. of Toronto), Director of Forestry, Forest Service, Ottawa, Ont.

RYAN, Edward A., B.Sc., (McGill Univ.), consulting engr., Montreal, Que.

SHARPE, D. Neville, C.E., (Univ. of Toronto), supt. of laying operations, Lock Joint Pipe Co., Washington, D.C.

Transferred from class of Junior to that of Associate Member

BAYNE, Blair Edmonston, with C.N.R., Moncton, N.B.

LAWSON, William John, B.Sc., (Univ. of N.B.), locating engr. Highway Constrn. Dept. of P. W., Fredericton, N.B.

McKILLOP, Vernon Archibald, B.A.Sc., (Univ. of Toronto), engr. Public Utilities Comm'n., London, Ont.

SIMPSON, Bruce Napier, B.A.Sc., (Univ. of Toronto), engrg. sec., hydraulic dept., H.E.P.C., Toronto, Ont.

Transferred from class of Student to that of Associate Member

BYRAM, Arthur Tennyson, B.A.Sc., (Univ. of Toronto), asst. engr. Dept. of Health, Toronto, Ont.

WIGGS, Gordon Lorne, B.Sc., (McGill Univ.), mgr. engrg. dept., Mechanics Supply Co. Ltd., Quebec, Que.

Transferred from class of Student to that of Junior

McLAREN, Leo G., B.A., (Laval Univ.), B.Sc., (McGill Univ.), Shawinigan Engrg. Co., Hebertville, Que.

OBITUARIES

Archibald William Campbell, M.E.I.C.

In the death of Archibald William Campbell, M.E.I.C., which occurred at his home in Ottawa on May 9th, 1927, Canada has lost one of its outstanding public men and one who has done a great deal for the advancement of the highway systems in Canada, and particularly in the province of Ontario. Through his long and enthusiastic service in the interests of highway development, the late Mr. Campbell was known throughout the country as "Good Roads" Campbell.

At the time of his death, Mr. Campbell was in his sixty-fourth year and was commissioner of highways for the federal government. He was born at Wardsville, Ont., on May 14th, 1863, and received his early education at the high school at St. Thomas, Ont. His first engineering experience was secured as a student in the office of James A. Bell, M.E.I.C., with whom he served for three years. Part of his earlier work was in connection with surveys on the Essex Centre and Welland Branch of the Canada Southern Railway.

In April 1885 he was commissioned an Ontario Land Surveyor, following which he engaged in private practice as civil engineer and provincial land surveyor. In 1888 he became associated with James A. Bell, M.E.I.C., under the firm name of Bell and Campbell, and was engaged in general engineering work, specializing in drainage systems, water works and bridges. On May 1st, 1891, he was appointed city engineer of St. Thomas, which position he held until 1896, when he was appointed good roads commissioner for the province of Ontario. Four years later he became deputy minister of public works with the federal government and in 1910 deputy minister of railways and canals in the federal government and later commissioner of highways for the Dominion government.

When, following the war, the Dominion government decided to appropriate $20,000,000 to subsidize the construction of a Dominion-wide system of main and market roads and interprovincial highways, Mr. Campbell was placed in executive control to administer the Canada Highways Act and supervise the carrying out of its provisions. In the organization of his work he was called upon to study the conditions in the different provinces of Canada and to devise a uniform classification of roads and to organize the necessary field and office staff. In connection with that work, he conferred with the various provincial highway departments as to the best methods of improving the roads of each province, and in due course prepared standard specifications for the several classes of highway contemplated by the federal act.

Mr. Campbell's technical training made his services of special value to the provincial highway departments in the consideration of the economic value of the road materials available in the various provinces, their transport and utilization. He was called upon to furnish, from time to time, technical advice based on the best engineering practice relating to road matters, and, in that connection, during his tenure of office, he prepared and issued, in addition to the annual reports of his branch, a number of circulars and bulletins containing a great deal of useful information on matters of road construction and motor transport.

The late Mr. Campbell joined The Institute as an Associate Member on March 22nd, 1888, and was transferred to Member on June 18th, 1896.

Joseph Lovitt Wilson, A.M.E.I.C.

News of the untimely death of Joseph Lovitt Wilson, A.M.E.I.C., has been received with profound regret by his many friends in the engineering profession as well as those in other walks of life.

The late Mr. Wilson was engaged on engineering work in Mexico, and, while in the field, without any thought of his own safety, he rescued one of his rodmen from drowning in one of the numerous deep water ditches. As a result of his experience, he contracted fever and was confined to the hospital in Mexico City for six months until the time of his death on March 16th, 1927.

Mr. Wilson was born at Bridgewater, N.S., on October 6th, 1880, and, after completing his primary education, he entered Dalhousie University at Halifax, N.S., from which he received the degree of B.Sc. in 1900. Immediately following graduation he joined the staff of the provincial engineer of Nova Scotia at Halifax, N.S., where he remained during the balance of that year, and in the following two years he was on railway work with the Nova Scotia Eastern Railway and Halifax and South Western Railway. In December 1902 he again joined the staff of the provincial engineer, where he remained until 1904, after which he returned to railway work and was engaged on surveys in the Maritime provinces and Ontario until 1913, when for a short period he was with the Cedar Rapids Manufacturing and Power Company on power line work in Quebec. During the following years he was first with the Montreal Tramways Company and later on maintenance work for the Canadian Northern Railway in New Brunswick. In May 1923 he was appointed resident engineer on the power development construction for the Puebla Tramways Light and Power Company, Orizaba, Mexico.

The late Mr. Wilson joined The Institute as Student on April 10th, 1902, and was transferred to Associate Member on October 9th, 1909.

Needham Everett Waddell

News of the death of Needham Everett Waddell, son of J. A. L. Waddell, M.E.I.C., of New York, which occurred on April 29th, 1927, has been received with deep regret.

The late Mr. Waddell was born at Tokyo, Japan, on June 21st, 1884. He came to America with his parents in 1886 and spent the early years of his life at Kansas City, Mo., attending several schools there. He was sent later to St. Paul's school at Concord, N.H., where he prepared for college. He elected to go to Rensselaer Polytechnic Institute, from which school he graduated with the class of 1908. For some years he worked in various capacities to obtain engineering experience. With McClintic-Marshall Company he helped build the Armour-Swift-Burlington bridge over the Missouri river at Kansas City. He served for a time with the Grand Trunk Railway Company of Canada, reporting concerning bridges on that company's lines located in the United States. For a while he worked in the employ of Waddell and Harrington on general bridge work, and later with his father. He was greatly interested in the construction of the highway bridge over the Missouri river at Lexington, Mo., designed by his father and erected by the state. He was the contractor's engineer on both superstructure and substructure. Later he entered the employ of the Foundation Company, with whom he remained until his death.

Mr. Waddell joined The Institute, in the days of The Canadian Society of Civil Engineers, as a Student on October 8th, 1908; transferred to Associate Member on October 14th, 1913, and to Member on April 23rd, 1918.

PERSONALS

C. M. Goodrich, M.E.I.C., has been appointed chief engineer of the Canadian Bridge Company, Limited. Mr. Goodrich was formerly designing engineer of the company. He entered the service of this company in the fall of 1901, where he has remained ever since.

W. D. MacKinnon, S.E.I.C., has been appointed to the engineering staff of the Donnacona Paper Company, Donnacona, Que. Mr. MacKinnon graduated from Queen's University in mechanical engineering in 1925, and was subsequently with the Bailey Meter Company, Limited, in Montreal.

A. L. Ford, M.E.I.C., district chief engineer with the Dominion Water Power and Reclamation Service, Calgary, Alta., has been appointed acting associate superintendent of Rocky Mountains Park at Banff, Alta. Mr. Ford is a graduate of the University of Toronto, from which he received the degree of B.A.Sc. in 1905.

S. E. McGorman, M.E.I.C., whose appointment as contracting engineer of the Canadian Bridge Company, Limited, has been announced, was formerly sales engineer with this company. He is a graduate of the School of Practical Science, University of Toronto, of the year 1905, and during the war he represented the Canadian Bridge Company in connection with its war work and its relation with the Imperial Munitions Board of the United States Ordnance Department.

Frank B. Thompson, S.E.I.C., who for the past four years has been on the staff of the Engineering Journal, first as assistant at Headquarters and later as Toronto representative of the Journal, has resigned to accept a position with B. L. Smith, of Toronto, publishers' representatives. Prior to joining The Institute, Mr. Thompson was in the draughting department of Messrs. Sproatt and Rolph, architects, Toronto, and at the same time was completing a course of studies in architecture and structural design.

FRANK B. THOMPSON, S.E.I.C.

P. T. Davies, M.E.I.C., commercial manager of the Southern Canada Power Company, Limited, was elected president of the Electrical Club of Montreal at their recent annual meeting. At this same meeting, Fraser S. Keith, M.E.I.C., was elected first vice-president and H. M. Lyster, A.M.E.I.C., was re-elected secretary-treasurer.

William E. Walsh, Jr.E.I.C., who up until April 1926 was designing engineer with the Preston Woodworking Machinery Company, Preston, Ont., and during the past year designing engineer with the Mechanical Manufacturing Company, Chicago, Ill., is now with the Illinois Tool Works, Chicago, Ill., in the capacity of research engineer.

H. C. Lott, A.M.E.I.C., who is located in London, England, has left on a three or four months trip to Kenya Colony in connection with hydro-electric developments there. Mr. Lott was born and educated in the Old Country, but was for a number of years engaged on engineering works in Canada. His present mailing address is 66 Queen Street, London, E.C. 4.

A. G. Moore, S.E.I.C., has joined the engineering staff of the Bell Telephone Company of Canada at Montreal and will be engaged on transmission work in the eastern division of the company. Mr. Moore graduated from the Nova Scotia Technical College in 1925, and since graduation has been located in Wilkinsburg, Pa., with the Canadian Westinghouse Company on their students' test course.

Charles A. Mullen, M.E.I.C., director of the paving department of the Milton Hersey Company, Limited, Montreal, has been appointed vice-president and managing director of the newly formed company known as Milton Hersey Ontario Limited. In addition to his new duties, Mr. Mullen will continue his former work and practice as an independent consulting paving engineer.

D. N. Culver, S.E.I.C., of Orillia, Ont., who graduated with honours from Queen's University this year, was the recipient of the Governor-General's Medal in Science, which is awarded to the science student with the highest standing in all subjects for the third and fourth years. Mr. Culver is at present with the Canadian General Electric Company and is located at Peterborough, Ont.

A. E. West, A.M.E.I.C., formerly manager of construction of the Canadian Bridge Company, Limited, has been appointed operating manager of the company. His connection with this company dates back to January 1911, and during this time he has occupied various positions, including squad foreman, chief draughtsman and manager of construction.

Geo. F. Porter, M.E.I.C., LL.D., formerly chief engineer of the Canadian Bridge Company, Limited, has been appointed consulting engineer of the company. Mr. Porter's first connection with this company dates from its organization in 1900. He was awarded the Gzowski Medal of The Institute in 1919 with G. H. Duggan, M.E.I.C., and the late Phelps Johnson, M.E.I.C., for a paper entitled "The Design, Manufacture and Erection of the Superstructure of the Quebec Bridge."

F. H. Kester, M.E.I.C., formerly contracting engineer of the Canadian Bridge Company, Limited, Walkerville, Ont., has been elected a director and vice-president of the company. Mr. Kester was born at Richland, Mich., in 1885. His early education was received at the high school at Richland and his engineering education at the University of Wisconsin. He joined the staff of the Canadian Bridge Company as draughtsman in 1907 and served in various engineering capacities until 1919, when he was appointed to the position from which he has now been promoted.

Harold S. Weldon, Jr.E.I.C., for the past two years District manager of the Montreal office of the Canadian Inspection and Testing Company, Limited, has been appointed assistant to the general mechanical superintendent of the Dominion Textile Company, Limited, Montreal. Mr. Weldon graduated from the University of Toronto in 1922 with the degree of B.A.Sc. He had commenced his university course prior to the outbreak of the war, but due to his service overseas he was unable to complete it until 1922. During the summer of 1921 he was with the Canadian Inspection and Testing Company at Toronto, and upon graduation he returned to that office as engineer in charge of electrical tests.

J. M. Portugais, A.M.E.I.C., has joined the staff of the Canada Cement Company, Limited, as technical engineer, his field of work comprising principally the province of Quebec, together with a portion of eastern Ontario and the Maritime provinces. He was born at Rimouski, Que., and after receiving his primary education at Rimouski College and Levis College he entered the University of Montreal, receiving his degree of B.A.Sc. in civil engineering in 1924. He later returned to the same university for post-graduate work in electricity, receiving the degree of E.E. His practical experience includes work with the Quebec Streams Commission; Department of Public Works, Quebec; Shawinigan Engineering Company; Southern Canada Power Company, and the water board of the city of Montreal.

E. Blake Allan, A.M.E.I.C., Appointed Town Manager

E. Blake Allan, A.M.E.I.C., formerly on the staff of the Department of Civil Engineering of the University of Toronto, has been appointed town manager of Woodstock, N.B., succeeding M. J. Rutledge, M.E.I.C., who recently resigned.

Mr. Allan is a native of Nova Scotia and is a graduate of the University of Toronto, from which he received the degree of B.A.Sc. in civil engineering in 1916. He is also a former student of Dalhousie University, where he spent two years in the engineering course. In consideration of a thesis on the construction of sheet asphalt pavement, the University of Toronto conferred upon him the professional degree of C.E.

Prior to entering the university, Mr. Allan had two years experience in railroad construction. The year 1913 was spent as assistant to the town engineer of Yorkton, Sask., while for six months during 1914 he was engaged on an extensive drainage scheme at Cobalt, Ont. Following his return from overseas, where he served as an officer in the Imperial Army from 1916 to 1919, he was engaged for thirteen months on general construction work with the Laurentide Company of Grand'Mere, Que., and from 1920 to 1926 he was engaged in municipal work under the city engineer of Hamilton, Ont.

J. Harold Wallis, A.M.E.I.C., Receives Appointment

J. Harold Wallis, A.M.E.I.C., has been appointed manager of purchasing for the Ste. Anne Paper Company, Limited, at Quebec city. Mr. Wallis, who is a native of California, has been engaged on engineering work in Canada since 1909, his early work being land surveys, railway surveys and construction. In August 1914 he enlisted for overseas service as a private with the British Expeditionary Force, and throughout the war served overseas with distinction. In July 1915 he received his commission as Lieutenant and in 1916 that of Captain and in the following year that of Major.

Following his return to civilian life in 1919, Mr. Wallis entered the service of the Canadian Pacific Railway Company on maintenance-of-way on the Bowmanville division. In June 1920 he was appointed assistant engineer with the Department of Railways in connection with the Grand Trunk arbitration, and later in that year joined the engineering staff of the Canada Creosoting Company in Toronto. Subsequently, he was appointed supply engineer with the Riordon Pulp Corporation, Limited, at Temiskaming, Que., and, following the acquisition of this company by the Canadian International Paper Company, he was transferred to the construction department in charge of the purchase of equipment and materials for the extension to the mill.

Recent Appointments by Montreal Harbour Commissioners

T. W. Harvie, M.E.I.C., general manager of the port of Montreal, has been appointed general manager and secretary of the port, the two positions having recently been merged. Mr. Harvie is a native of Scotland, and on coming to Canada was appointed resident engineer on the construction of various works in the port of Montreal. In 1913 he became assistant chief engineer of the Harbour Commissioners and in 1922 chief engineer, which position he held until his appointment as general manager.

T. W. HARVIE, M.E.I.C.

Alexander Ferguson, M.E.I.C., of the Department of Railways and Canals, Ottawa, has been appointed to the office of assistant general manager of the port of Montreal, which position was recently created by the Harbour Commissioners. Mr. Ferguson is a native of Scotland, and after serving his apprenticeship in Glasgow engaged in various engineering works. He came to Canada in 1905, joining the engineering staff of the National Transcontinental Railway, with which he remained in various capacities for a number of years, finally occupying the position of divisional engineer at Quebec. In 1914 he entered the federal service of the Department of Railways and Canals at Ottawa, and occupied the position of general assistant engineer at the time of his recent appointment.

J. W. Seens, A.M.E.I.C., Appointed President and General Manager of Canadian Bridge Company

J. W. Seens, A.M.E.I.C., has been appointed president and general manager of the Canadian Bridge Company, Limited, of Walkerville, Ont., succeeding L. A. Paddock, who has resigned.

Mr. Seens was formerly vice-president of the company. He was born at Cincinnati, Ohio, on November 8th, 1881, and received his early education at the high school at Grand Rapids, Mich., later entering the department of civil engineering of the University of Michigan, from which he graduated with the degree of B.S. in 1901.

Immediately following graduation, Mr. Seens joined the staff of the Canadian Bridge Company, Limited, as draughtsman, but in October 1905 returned to Grand Rapids, Mich., where he was engaged on engineering work with the city engineer. In February 1906 he returned to Canada, and once more entered the employ of the Canadian Bridge Company. In 1911 he was appointed manager of the Structural Steel Company, Limited, Montreal, and in 1918 he was appointed by the Canadian Bridge Company manager of sales with headquarters at Montreal. Since that date he has remained with this company, and in 1920 took out naturalization papers of Canadian citizenship. He was elected a director of the company in 1922 and vice-president in 1926. He is also a director and president of the Essex Terminal Railway.

J. W. SEENS, A.M.E.I.C.

New Maps Issued

The Topographical Survey of Canada, Department of the Interior, Ottawa, has recently issued a map known as the Sussex Sheet of the National Topographic Series, on the scale of one mile to the inch. This map, which includes an area of about four hundred square miles lying between latitudes 45°45′ and longitudes 66°0′, covers part of Kings, Queens and Saint John counties in the province of New Brunswick, although the major portion is comprised of the Kings county.

The Topographical Survey of Canada has also issued the Touchwood Sheet of the Sectional Map of Canada, which is on the scale of three miles to the inch. This sheet covers the area in townships 25 to 32, ranges 16 to 29 inclusive, west of the second meridian.

BOOK REVIEWS

Hydro-Electric Handbook

By William P. Creager and Joel D. Justin, John Wiley & Sons, Inc., New York. Leather, 6 x 9¼ in., 897 pp., illus., diagrams, $8.00.

In their preface the authors state that the book aims to present a compendium of all phases of modern hydro-electric practice; that it is designed to contain sufficient descriptive matter to make it valuable to the student, and that it includes the latest ideas in theory and practice, making it of considerable interest to practising engineers.

The task to which they set themselves is large, but they have succeeded admirably and have produced a book of great value to the engineering profession. The material is well selected and is well arranged, and the insertion of duplicates of important curve sheets is a valuable feature. The best authorities have been freely canvassed by the authors to supplement their own knowledge of the subjects treated and a carefully compiled bibliography rounds out the book.

The first chapter on rainfall or precipitation gives a very complete outline of the scientific methods of collecting and using rainfall data, particularly as applied to the United States. It is followed by studies of evaporation and run-off and the methods of estimating stream flow, floods and the effect of artificial storage.

The important question of the capacity of a proposed development is viewed from many angles and a clear explanation is given of the terms, primary power, secondary power, demand factor, diversity factor and plant factor.

A very interesting chapter reviews the principles of hydraulics and contains a large number of formulæ and other useful data.

The design of the hydraulic side of the development is treated in a series of eighteen chapters which go into great detail and the most up-to-date methods are discussed.

The chapters on electrical designs contain a wealth of material, and while some of the calculations are necessarily abridged they are always suggestive and references are given which enable the reader to gain further information without loss of time.

Both authors and publishers are to be congratulated on the production of an excellent book.

C. V. Christie, M.E.I.C.

Professor of Electrical Engineering, McGill University, and Consulting Engineer, Montreal.

Proceedings of International Conference on Bituminous Coal, November 15-18, 1926.

Published by Carnegie Institute of Technology, Pittsburgh, Pa. Cloth, 6 x 9 in., 830 pp., illus., diagrams, tables, $7.00.

Every one interested in the subject of bituminous coal, its treatment and utilization, must be indebted to the Carnegie Institute of Technology for planning the International Conference on Bituminous Coal held in Pittsburgh last November.

The proceedings of the meeting held include papers from leading authorities in England, Germany, France, Japan and the United States, covering every phase of the subject, and form a complete and comprehensive review of the work done up to the present time by different investigators and men connected with related industries.

The scientist, the chemist and the engineer are all closely associated in the field of coal treatment and the recovery of valuable derivatives. Coal can no longer be considered merely as a fuel to be burned in its raw state, and especially is this the case in England and European countries, where necessity compels a husbanding of natural resources and the provision of chemical substitutes for petroleum products to a greater extent than is at present felt in Canada or the United States.

Few people realize the amount of research work that has been done and is being done, and the successful commercial applications of the results obtained, and an assembly of papers of the highest order such as are included in this one volume of the proceedings of the conference is of very great value.

It is impossible to make any attempt to review in a short space a large number of papers of such wide scope and variety, but mention should be made of the very interesting and valuable paper by Dr. Bergius on the "Transformation of Coal into Oil by Means of Hydrogenation." The liquefaction of coal and the manufacture of a synthetic motor fuel are of first importance to every one, and Germany has contributed largely to the attainment of these results.

The production of a smokeless fuel from bituminous coal for domestic use, with the recovery of valuable by-products, is also very timely and is treated in detail in a number of the papers, including descriptions of several commercial systems.

The particular appeal of each paper depends of course upon the interest of the reader in the subject covered, and a résumé of the subjects dealt with in the various papers will no doubt be appreciated by members of The Institute as indicating the scope and importance of the book.

The details of the papers, in addition to which there are also printed the discussions, are as follows:—

Our Coal Supply: Its Quantity, Quality and Distribution; British Research on Fuel Utilization; the Practical Value of Fundamental Research on Coal; the Transformation of Coal Into Oil by Means of Hydrogenation; the Industrial Transformation of Bituminous Coal Into Organic Technical Products; Methyl Alcohol as a Motor Fuel; Coal and Its Mineral Matter; National Supplies of Power; What Bituminous Coal is Doing for Itself and for the Nation; the Coming of the New Coal Age; the Synthesis of Petroleum; English Development in Carbonization of Coal in Gas Works; Some New Uses for Pulverized Coal; Powdered Coal for Power Purposes; Mouth of Mine Power Stations; the Relation of Thermal Storage in Boiler and Furnace to Fuel Application; Bituminous Coal as a Source of Chemical Products; the Instantaneous Carbonization of Crushed Coal; Utilization of Coal Tar Products; Coal Tar Disposal; the Recovery of Phenols from Steel Plant Fuel Tars; the Formation of Naphthalene During High Temperature Carbonization; Utilization of Bituminous Coal in the Manufacture of Water Gas; a Revolutionary Improvement in Gas Production; Possibilities of Fuel Economy in the Iron and Steel Industry; Coal in Relation to the Production of Fixed Nitrogen; Coal as a Source for Fertilizer; Economic Aspects of the Fertilizer Industry; the Relation of Coal to Fertilizer; the Economic Aspect of the Conversion of Coal Into Smokeless Fuel; Smokeless Fuel; the Smoke Problem of Cities; Fundamental Studies on Coal to Carbonization Problems; Development in Low Temperature Distillation of Coal at Fairmont, West Virginia; Distillation of Coal; Internal Heating; the L. & N. Process; the McEwen-Runge Process for the Low Temperature Distillation of Coal; the Greene-Laucks Process; the Piron Coal Distillation Process; the Low Temperature Distillation of Coal in Rotary Retorts; Low Temperature Carbonization of Coal; the Bussey Process of Low Temperature Distillation; the Cracking of Low Temperature Tars by the Dubbs Process; the Missing Link in Low Temperature Carbonization.

F. A. Combe, M.E.I.C.,

Consulting Engineer, Montreal.

EMPLOYMENT BUREAU

Situations Wanted

Civil Engineer

Open for an engagement about May 20th, M.E.I.C., returned soldier, twenty-five years experience in all parts of Canada and United States; railway location and construction, canals, concrete structures, sewers, water systems, buildings, highway location and construction, all classes of pavements; experience as engineer-in-charge and superintendent for contractor. Apply box No. 225-W, Engineering Journal.

Electrical Engineer

B.A.Sc., University of Toronto. Two years testing with large electrical company. Three years in engineering department on design of railway control apparatus. Desires new connection with firm located in central Ontario. Employed, but available on few weeks notice. Apply box No. 226-W, Engineering Journal.

Back Numbers of Journal

Requests have been received for various back numbers of The Engineering Journal of which the supply at Headquarters has been exhausted. If any member has copies of the issues mentioned below, the Secretary would appreciate receiving them at Headquarters. The issues wanted are:—March 1919, July 1920, and January and April 1921.

ABSTRACT OF PAPER

Long Span Bridges

Professor C. R. Young, M.E.I.C., Department of Civil Engineering, University of Toronto.

Kingston Branch, March 23rd, 1927.

Little progress in the development of long span arches in stone masonry has come about in the last five or six centuries. As early as 1377 A.D., when the Trezzo arch over the river Adda in Italy was built, with a span of 251 feet in the clear, the approximate limits of stone arch construction were reached. The longest span ever attained in this material is in the arch at Plauen, Saxony, with a clear span of 295 feet.

Metallic bridges were constructed first of cast iron. While unsuccessful attempts were made as early as 1755, it was not until 1776, when the Coalbrookdale arch over the Severn river, England, was built, with its span of 100.5 feet, that cast iron really was placed on a practicable basis for bridge construction. In 1795 the Sunderland bridge over the river Wear was erected with a single cast iron arch of 236 feet in span. The record appears to have been attained in the 240-foot central span of the Southwark bridge over the Thames, London, one of the elder Rennie's most notable works. Spans of 450 feet were proposed by Robert Stephenson for the Menai straits crossing, and Telford and Douglas actually designed a 600-foot cast iron arch for a bridge to replace London bridge, but no actual construction appears to have surpassed that attained in the Sunderland and Southwark bridges.

Forced by the rejection of his cast iron design for the Menai straits crossing, Robert Stephenson developed the tubular type of bridge and built at first the 400-foot span at Conway in 1848, and in 1850 the celebrated Britannia bridge containing two spans of 460 feet. While the Victoria tubular bridge, completed in 1860, was much more extensive in total length than any other bridges of the type previously constructed, none of its spans equalled in length the Conway and Britannia spans above noted.

Very early employment of the suspension principles for bridges in primitive materials is on record, and it is said that spans upwards of 600 feet have been attained by the use of twisted vine cables in China, India, Thibet, and South America. A very extensive use of the suspension principle grew up about the beginning of the 19th century and there are still numbers of these early bridges in existence. One of the most notable of the earlier bridges is the highway bridge built by Telford over the Menai straits in 1825. This had a central span of 580 feet. While Robert Stephenson had abandoned the idea of a suspension bridge for railway traffic over the Menai straits, basing his decision upon previous disappointments with the type, John A. Roebling completed, in 1855, the 821-foot span that has given the name " Suspension Bridge " to the Canadian National crossing of the Niagara gorge. By careful attention to stiffening devices, Roebling was able to construct a bridge that carried railway traffic successfully for 43 years. Soon after, he completed the Ohio river bridge at Cincinnati with a span of 1,057 feet, the first bridge to exceed 1,000 feet in span. The great Brooklyn bridge, with its span of 1,595.5 feet was Roebling's crowning achievement, although, unfortunately, he lost his life through an accident at the bridge site when the work was still in the foundation stage. While the Williamsburg bridge, with a span of 1,600 feet, and the Manhattan bridge, of 1,470 feet, both across the East river at New York, greatly exceeded in capacity the Brooklyn bridge, it must be conceded that the latter was, in view of the early date of its construction and the boldness exhibited therein, perhaps the most notable suspension bridge achievement on record.

The record for span in the suspension type rests with the bridge over the Delaware river between Philadelphia and Camden, with its 1,750-foot central span, only 50 feet less than that of the Quebec bridge. A striking departure was made in this structure by employing only two cables, these being each 30 inches in diameter and containing each 18,666 wires of 0.195-inch diameter. The speaker described at length the method of cable spinning and construction employed upon this great bridge.

While, so far, no every extensive employment of the eye-bar cable type has been made, there nevertheless is reason to believe that it will be employed more extensively in the future. For a considerable number of years the record for span was held by the Elizabeth bridge over the Danube at Budapest with its span of 951 feet. The record is now held by the Florianopolis bridge, Brazil, which has a central span of 1,114 feet. The cables of the latter structure are of special heat-treated steel, having a minimum ultimate strength of 105,000 pounds per square inch, and a minimum elastic limit of 75,000 pounds per square inch. One of the distinctive advantages of the eye-bar type involving the merging of the cables with the top chords of the stiffening trusses for approximately the centre half of the span, was utilized in this structure. By making the maximum depth of the stiffening trusses at about the quarter point and diminishing the depth therefrom towards mid-span and towards the towers, it was found that, as compared with the parallel chord type of trusses, supported from wire cables, the rigidity was increased four times while the weight of the stiffening trusses was reduced by a third.

Growing out of a number of failures of cast iron arches, it was generally conceded about the middle of last century that further long span arch construction in metals ought to be of either wrought iron or steel. The first notable arch bridge of this new order was the Eads bridge over the Mississippi river at St. Louis, having a central one of three spans 520 feet in length. The construction was carried out from 1868-1874. The chords of the latticed ribs of these arches were of chrome steel staves encased in an envelope of wrought iron. The type was original, but no bridge of any consequence has ever been built since according to this type. Three notable arches in steel have been built across the Niagara gorge, the upper one with a span of 840 feet, having held the record for length of arch span for nineteen years. It was replaced by the 977.5-foot span of the Hell Gate arch at New York city, a structure built of hard steel having an ultimate strength from 66,000 to 76,000 pounds per square inch. The 1,650-foot arch span now being constructed across the harbour of Sydney, Australia, very closely resembles in type the Hell Gate arch. In deciding upon a sudden increase in span limit of 69 per cent, the engineer of the latter structure has exhibited a good deal of boldness.

Trusses in metal are more modern than suspension bridges or arches. The first comparatively long span trusses are the two 455-foot spans of the Saltash bridge, built in 1859 by the younger Brunel. These trusses, as will be recalled, contain each a single elliptical tubular top chord with two eye-bar bottom chords. The limit of span for simple trusses is held by the Metropolis bridge at Metropolis, Ill., 1,720 feet in length, and employing in considerable measure silicon steel.

Continuous bridges, while adaptable to fairly long spans, have not been largely employed in America. The two 408-foot spans of the original Canadian Pacific Railway bridge across the St. Lawrence at Lachine, of course, no longer exist, and the only other notable continuous bridge in Canada is that over the Nelson river at Kettle rapids on the line of the Hudson Bay Railway. The extreme length of span hitherto attained by the type is in the Sciotoville, Ohio, bridge with its two 775-foot spans.

Professor Young expressed the view that having regard to all the circumstances, the Forth bridge is perhaps the most notable cantilever structure ever erected. Built between 1883-1890, it contains two spans of 1,710 feet, only 90 feet less than the central span of the Quebec bridge, which now holds the world's record for span length. The circumstances connected with the two accidents to the Quebec bridge were outlined and the causes explained. However disappointing the two failures were to the engineering profession, there must be a corresponding satisfaction in the successful surmounting of all obstacles and the final completion of the bridge almost wholly by Canadian effort.

Remarkable spans are being attained in reinforced concrete in France by the eminent engineer, M. Freyssinet. The 432-foot span of the St. Pierre du Vauvray arch, with its phenomenally thin box ribs, is the greatest span hitherto attained, but there will shortly be completed at Plougastel an arch having three spans of 590.5 feet each. The speaker described a number of projected bridges of great boldness, for example, the Hudson river bridge with a span of 3,500 feet, which seems likely to reach the construction stage shortly, and the projected bridge for the Golden Gate at San Francisco, with a span of 4,000 feet.

Milton Hersey Company, Limited, has announced the formation of a new company to be known as the Milton Hersey, Ontario, Limited, which will have charge of the design and technical control of asphalt paving work in Ontario which was heretofore done by the parent company, the experience and staff of which will be available to clients, the personnel remaining as in former years. The officers of the new company are:—Dr. Milton L. Hersey, president; Charles A. Mullen, M.E.I.C., vice-president; James G. Ross, vice-president; Robert B. Ross, manager; Roy Geddes, treasurer; Lew R. Hersey, secretary. The head office of the new company will be at London, Ont.

Map of Weyburn and Vicinity

The Topographical Survey, Department of the Interior, Canada, has issued another sheet of the sectional map of Canada known as the Weyburn sheet No. 20, which includes townships 1 to 8, ranges 1 to 15 inclusive, west of the second meridian.

Annual Meeting of American Society for Testing Materials

A provisional programme for the annual meeting of the American Society for Testing Materials, which is to be held at French Lick Springs hotel, French Lick, Ind., June 20th to 24th, 1927, has just been issued. The tentative programme for the five days includes, in addition to the business sessions at which reports of the various sectional committees will be presented and discussed, recreation and entertainment during the meeting.

BRANCH NEWS

Border Cities Branch

C. G. R. Armstrong, A.M.E.I.C., Secretary-Treasurer.

THE MANUFACTURE OF MODERN NEWSPRINT

A regular meeting of the Border Cities Branch was held on the evening of Friday, April 22nd, in the Prince Edward hotel. T. L. Crossley, A.M.E.I.C., vice-president of the Industrial Laboratories, who is a member of the Professional Engineers of the Province of Ontario, and a special lecturer on pulp and paper at the University of Toronto, delivered an address on "The Manufacture of Modern Newsprint."

Mr. Crossley, in dealing with his subject, stated that Canada leads the world in this production, providing 45 per cent of the raw materials and actually manufacturing one-third of the newsprint of the world. He then described in detail the various steps in the process of manufacture from the logging operations to the final production of the paper.

In conclusion, Mr. Crossley again referred to the important place that Canada holds in the manufacture of newsprint paper, and whereas in 1890 the amount of export was $120.00, to-day it is $180,000,000.

Hamilton Branch

W. F. McLaren, M.E.I.C., Secretary-Treasurer.
J. R. Dunbar, A.M.E.I.C., Branch News Editor.

JOINT MEETING WITH A.I.E.E.

There were about one hundred and ninety persons attended the annual joint meeting of the Hamilton Branch of the Engineering Institute of Canada with the Toronto section of the American Institute of Electrical Engineers, held in the Westinghouse auditorium on April 22nd. L. W. Gill, M.E.I.C., as chairman of the Hamilton Branch, called the meeting to order and then turned the meeting over to M. B. Hastings, chairman of the Toronto section, A.I.E.E. Mr. Hastings introduced the speaker of the evening, R. C. Bergvall, of the Westinghouse Electric and Manufacturing Company, East Pittsburgh, Pa., who spoke on "A Mechanical Analogy to the Problem of Transmission Stability."

He showed a very ingenious model having two pivoted arms representing voltage at the sending and receiving ends of a transmission line. The ends of the arms were connected together by a spiral spring which represented the voltage drop in the line. This drop is taken to be entirely due to reactance, the resistance drop and capacity effects being neglected. "Load" was applied to the model by means of weights placed in a pan suspended from a pulley on a continuous cord which was wound in opposite directions around a pulley on each arm of the model, tending to rotate the arms in opposite directions.

As the load was increased the arms separated, the amount of separation depended on the strength of the spring and on the weight in the pan. The electrical analogy for this action is that as the load on the transmission line increases the phase angle between the generator and receiving ends of the line increases, the reactance drop increases. Load might be added until the arms are practically 90° apart, but if any more load was added and the arms pass the 90° position, the model would become unstable and the angle would increase until the arms hit the table or the supports. This condition represents the pulling apart of the two ends of a transmission line.

The effect of short circuits on a transmission could be very readily shown by means of the model and the oscillations resulting from short circuit conditions or from switching operations were very graphically reproduced. It was readily seen, from the model, that when a line is loaded nearly to the pull out point, very light disturbances will cause it to pull apart, but that if it is lightly loaded it will stand very much more severe disturbances and still regain a state of equilibrium.

A condenser at any point on the line was represented by a third revolving arm which did not have any provision for applying a load to it. This was connected to some intermediate point on the spring connecting the arms representing generator voltage and motor voltage. For a condenser of finite capacity, the connection between the condenser arms and the main spring was by an auxiliary spring representing the synchronous reactance of the condenser itself. With the condenser added, it was readily seen how the stability limit of a transmission line is increased.

The effect of parallel lines was readily shown by a second spring in parallel. This, as would be expected, increased the stability limit materially.

The speaker also showed lantern slides illustrating, by curves, the advantages of the high speed of response excitation system in maintaining voltage on the line under disturbing conditions, such as switching, short circuits, grounds, etc. The high speed of response excitation system is being used on the 25-cycle generators of the Gatineau Power Company, which will feed the 250-mile, 220,000-volt transmission line to the Hydro-Electric Power Commission of Ontario in Toronto.

Numerous questions were asked the speaker, after which a hearty vote of thanks was moved by H. C. Don Carlos, of the Toronto section, A.I.E.E., seconded by Hugh Lumsden, M.E.I.C., of the Hamilton Branch, which was carried with applause.

Mr. Gill made a few closing remarks expressing the appreciation of the meeting of the Canadian Westinghouse Company's kindness in arranging the meeting and in serving refreshments, to which Mr. Hart responded.

Executive Meeting

A meeting of the Executive Committee of the Hamilton Branch was held in the office of W. L. McFaul, M.E.I.C., on May 11th, at which six members of the executive were present.

Several recommendations to council regarding changes in the By-laws of The Institute were discussed and some resolutions were passed which are to be referred to the general secretary.

Some discussion resulted regarding another meeting this year, but it was felt that it was too late in the season to arrange one before the summer, and it was decided to hold an executive meeting early in September when an opening dinner-meeting for the next season would be arranged.

Kingston Branch

G. J. Smith, A.M.E.I.C., Secretary-Treasurer.

One of the largest meetings of the branch this year was held in Carruthers Hall, Queen's University, on the afternoon of March 23rd, to hear an address by Prof. C. R. Young, M.E.I.C., of the Department of Civil Engineering, University of Toronto, on "Long Span Bridges." Prof. L. T. Rutledge, M.E.I.C., chairman of the branch, occupied the chair, and the speaker was introduced by Prof. L. M. Arkley, M.E.I.C.

Professor Young sketched bridge history from early times down to the present and even went as far as the consideration of the future possibilities in bridges of long span. In his descriptions of numerous structures of different design and size, he had the details and masses of figures completely at his disposal. A splendid assortment of slides were shown, bringing out many of the salient features peculiar to the particular type of work.

The whole address proved very interesting and was found most instructive by the members of the branch as well as by the large number of engineering students present. An abstract of Prof. Young's address appears on another page of this issue.

At the close a vote of thanks was moved by Prof. A. Macphail, M.E.I.C., and seconded by Prof. W. L. Malcolm, M.E.I.C. The hearty response showed the audience's appreciation of the lecture

Manufacture and Uses of Carbon Dioxide

Attention was called to important developments in the functions and uses of carbon dioxide in an interesting paper delivered at a meeting of the branch on April 4th by J. R. Donald, A.M.E.I.C., consulting chemical engineer of J. T. Donald and Company, Limited.

In introducing the subject the speaker said that of the different gases met with in nature, apart from that of oxygen, there is none more closely identified with our daily life than carbon dioxide.

Until about the beginning of the twentieth century, when more economical processes became available, relatively pure carbon dioxide was obtained by either one of two methods: (1) by contact of sulphuric acid with carbonates, or (2) by heat applied to crushed magnesite or dolomite in closed retorts, both of which produce valuable by-products.

With the growth of the industry another method, known as the coke process, has been developed. In this process a volume of potassium carbonate operates through an absorption tower and a boiler. The carbon dioxide is absorbed from the flue gas passing through the absorption tower and carried to the boiler where it is released under the influence of heat on the bi-carbonate. The efficiency of this process is dependent upon the maximum utilization of heat available in the coke fire.

A more recent process is available in the various fermentation industries where large quantities of by-product carbon dioxide may be obtained economically. Due to contaminating odours, some method of purification is necessary. The most successful, known as the Backhaus process, is dependent upon the ability of activated carbon to absorb large quantities of any gas, and that independent of the amount of another gas already absorbed. In practice, therefore, the gas from the fermenters is passed through towers packed with activated carbon. The mass is quickly saturated with carbon dioxide which thereafter passes through, while the smaller percentage of impurities is retained. When the carbon is saturated with impurities, live steam is blown through the towers to drive them out. It may be said that the economical advantages of this method give promise that it will displace all other processes.

Once the carbon dioxide is collected in the gasometer it only remains to compress it into steel cylinders at approximately 1,000 pounds pressure. At this pressure, the gas at ordinary temperatures becomes liquified and it is thus possible to compress the maximum of gas into the cylinders.

Carbon dioxide has a wide variety of uses. By far the largest market exists in the beverage industry, where it is employed to impart "life" to the drink, improve its appearance and flavour, and give the well known sparkle. It also possesses a valuable preservative action by inhibiting the growth of certain bacteria, a property recognized in the preservation of shredded cocoanut, tobacco, coffee, butter and ice cream.

In refrigeration, due to its non-poisonous and non-irritating properties, it is adapted for use in ships, hotels, stores or other places where ammonia fumes are unpleasant. In the solid form it has the merit of producing fresh, pure dry gas at a low temperature without the formation of a liquid which recommends it for household use.

A new industrial field has recently opened up the development of the use of carbon dioxide for the purpose of fire extinction. Ordinary combustion is inhibited by the presence of 15 per cent of carbon dioxide in the atmosphere. Its use is limited, therefore, to confined areas where this dilution can be maintained. Due to the modification of the containing cylinders and the system of control, it is now possible to release the necessary volume of gas in a few seconds. This application is now finding extensive use in marine, mine, telephone, electrical and inflammable liquid fires, where the presence of the carbon dioxide cuts off the supply of oxygen necessary for combustion.

Other applications are as a source of pressure for clearing pipes, locating leaks, operating paint outfits, inflating tires and as an aid to artificial respiration, removable of boiler scale and the acceleration of plant growth. New uses are developed from time to time, and it seems probable that the next few years will see an increased demand and a consequent increase in its production.

The meeting was presided over by K. G. Cameron, A.M.E.I.C., and a vote of thanks tendered the speaker on the motion of Geo. R. MacLeod, M.E.I.C.

Vallee Street Substation

A distribution substation, which will, when completed, be the latest and largest installation of its type on record, was described at a meeting of the branch in a well illustrated paper on April 21st, 1927, by Humphreys Milliken, M.E.I.C., chief engineer of the electrical department, Montreal Light, Heat and Power Consolidated.

"The 60,000-k.v.a. ultimate capacity of the new substation and its location on Vallee street had been determined," the speaker stated, "after an extensive study of existing and probable future demands for electrical service in Montreal, and by a survey of recent developments in substation practice in American cities."

Following this study a comprehensive construction programme was provided to meet the growth of the city by anticipating the future requirements of each distribution area. The design finally adopted for the central area substation on Vallee street introduced many new and interesting features, principally intended to guard against the spread of operating troubles in so large a plant. These features and the details of design and equipment were fully described by the speaker.

The chairman of the meeting, C. V. Christie, M.E.I.C., presented to the speaker the hearty vote of thanks which was moved by K. B. Thornton, M.E.I.C., past vice-president of The Institute.

Presentation of Gzowski Medal and Students' Prizes

Preceding the paper, J. L. Busfield, M.E.I.C., in the absence of the president, Mr. Decary, and after a brief and commendatory biography of the donor, presented in fitting terms the highest award of The Institute, the "Gzowski Medal," to Lesslie R. Thomson, M.E.I.C., for his paper, "The Fuel Problem in Canada," and the Student Prizes of The Institute to R. G. Beck, S.E.I.C., and B. C. Hicks, S.E.I.C., for their papers on mechanical and electrical engineering subjects.

GATINEAU POWER DEVELOPMENT

An impressive description, beautifully illustrated, of the immense development which has transformed the basin of the Gatineau river in the past year, was given to the members of the branch at the last meeting of the season, April 28th, 1927, by Walter Blue, M.E.I.C., manager of the development department of the Gatineau Power Company.

In the case of the Gatineau river, the manufacture of paper and the development of power are closely associated, for without the power demand of the paper mill there would not be sufficient market available for economic development, and, conversely, without a power supply, it would not be feasible to operate the paper mill.

In quoting a very famous engineer, the speaker said: "As there are opportunities on practically every river for the development of the power placed there by nature, it remains only for man to study the river sufficiently in order to obtain the best solution."

The problem presented by this river has been partly solved by the building of a storage reservoir and three power plants and the proposal to build a fourth. These power plants have been so located that the headwater of one will be approximately the same level as the tailwater of the plant next above.

The plants have been located at Farmer rapids, Chelsea, Paugan falls and Maniwaki. Two units at Chelsea and one at Farmers are already supplying power to the paper mill, where the first unit commenced manufacturing paper last month. The four sites together will develop 370 feet of head in a total stretch of about 80 miles from Ottawa.

The power generated will be distributed as follows:—To the Hydro-Electric Power Commission, 260,000 h.p.; Canadian International Paper Company mill, for steam, 160,000 h.p.; for operation, 40,000 h.p.; Canada Cement Company, 3,000 h.p.

The storage dams at Bitobee, etc., creating the third largest artificial reservoir in the world, were closed on April 1st, and on the day of the meeting had already impounded twenty-five billion cubic feet of water or, approximately, one-quarter of the capacity of the reservoir.*

An interesting feature was the transportation of some 35,000 tons of material by tractors, including the steel hull of a tug weighing thirty-seven tons, which was successfully taken in by one tractor.

A transmission line has already been constructed connecting the Chelsea and Farmers rapids plants and the mill. This is a 110,000-volt line about six miles long. Other transmission lines necessary are: 110,000-volt line about twenty-six miles long from Farmers to Chelsea, to Paugan, and 220,000-volt line also about twenty-six miles long from Paugan to the Ottawa river, crossing near Quyon. This last named line will connect up with the lines of the Hydro-Electric Power Commission of Ontario.

The aerial photographs were found to be surprisingly accurate and greatly aided survey parties in anticipating topography ahead and locating camp sites for the storage survey.

Dr. Arthur Surveyer, M.E.I.C., past-president of The Institute, expressed the appreciation of the meeting, which was presided over by W. C. Adams, M.E.I.C.

* On May 21st the elevation of the water level of the Bitobee storage reservoir was 740.8, there having been stored 56.5 billion cubic feet of water. The reservoir when full will hold 95 billion cubic feet with the water level at elevation 755.

Niagara Peninsula Branch

Walter Jackson, M.E.I.C., Secretary-Treasurer.
C. G. Moon, A.M.E.I.C., Branch News Editor.

VISIT TO UPPER REACHES OF THE WELLAND SHIP CANAL

The spring outing of the branch, which was held on April 27th, was a trip along the upper reaches of the Welland ship canal followed by dinner and an illustrated address by the engineer-in-charge, A. J. Grant, M.E.I.C.

Members from all parts of the peninsula motored to the city of Welland and met about 2.00 p.m. at the headquarters of the Atlas Construction Company, which is building the large inverted syphon to convey the Welland river (sometimes known as Chippawa creek) under the bed of the new canal. Just at present the place presents the aspect of a veritable forest of steel sheet-piling, wooden piles and assembly trestlework, surrounding an excavation approximately 500 feet long, 200 feet wide and 40 to 80 feet deep.

Perhaps the layman will see little to interest him beyond the massive timbering, but an engineer finds features of unusual interest in the foundation work.

The structure, when finished, will consist of six concrete tubes, each 22 feet in diameter and 350 feet long, capable of handling the flood waters of the river, some 10,000 c.f.s., with a loss of about one foot of head. It is being constructed in open cut, in a reddish clay which, when wet, has all the consistency of a good thick soup. Foundation piling is of course carried some twenty feet further to rock but, with this exception, nothing is stable and the present canal carrying navigation adjacent to the east end does not improve the situation. Large circular cut-off cells of steel sheet-piling move two to four feet over night and have to be steadied by gravel backing. The occasional heavy fir strut or waling will crumple or snap like a twig under some intense local pressure and replacements are being made all the time, so that when the concrete is finally poured into another section a sigh of relief is heard.

The superintendent for the Atlas Construction Company, J. A. Grant, M.E.I.C., directed the party on its tour of the work and explained to them some of the difficulties. He appeared quite cheerful and would probably fight shy of anything solid like a rock cut if it was now offered to him.

The steamship A. M. German, with her namesake as master of ceremonies, ran alongside the work and the party embarked for their trip along the canal. First passing through the city of Welland, they then picked up stragglers at the Canadian Dredging Company's wharf, and about two miles further south came in sight of the new vertical lift bridge carrying the Canadian National Railway, Wabash division, over the canal. This bridge is the largest of its type in Canada. The erection has just been completed by the Canadian Bridge Company, but it is not yet in operation, although the lift span has been raised and lowered several times by means of the auxiliary gas engine. Of the twenty-one moveable bridges crossing the ship canal at various points, twelve are to be similar to this vertical lift bridge.

The next ports of call were the two suction dredges belonging to the Canadian Dredging Company, the Tornado and the Primrose. Both were busily engaged in widening and deepening the present canal to the ship canal width of 300 feet on the water line and 25 feet depth.

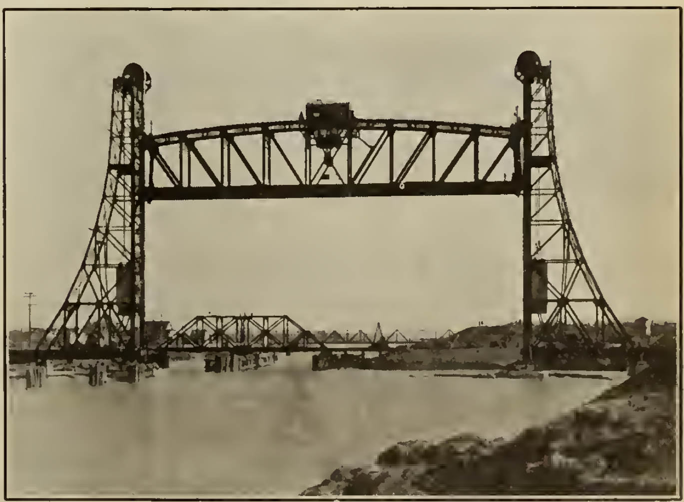
The Tornado impressed the visitors with her spick and span condition, having the advantage over the Primrose in that she was an oil burner. Her engines are directly connected to the large pump and she was gouging into the stiff clay at the rate of about 8,000 cubic yards per day. At the Primrose many of the party availed themselves of the low banks and, headed by the engineer-in-charge, Mr. Grant, scrambled along the pipe line to the discharge end at the spoil grounds.

The party returned to Welland at 6.15 p.m. and sat down to a real and satisfying dinner at the Hotel Dexter.

Right here might be a good place to intimate gently to the members that the secretary admits his secret formula for determining the number of table reservations has fallen down. An excess attendance of 60 per cent has proved it to be a complete failure. In this instance some forty-five members only signified their intention of being present and yet sixty-seven sat down to dinner.

After dinner Chairman Alex. Milne, A.M.E.I.C., formally introduced the speaker, Alex. J. Grant, M.E.I.C., engineer-in-charge of the Welland ship canal.

Mr. Grant gave a brief historical sketch of canal making in Canada starting with a lockless canal at Montreal, commenced by the Seminary of St. Sulpice in the year 1700 but never completed. Coming to the Welland ship canal, slides were presented showing graphically the progress of work up to date, traffic charts, labour and material costs. Then nearly a hundred photographs depicting



Welland Ship Canal—Bridge No. 17.

Vertical lift bridge carrying Canadian National Railways (Wabash Division). Clear span 200 ft., clear lift 122 ft., depth of truss 40 ft., weight of truss 580 tons, height of towers 177 ft.

every stage of the work from Port Weller harbour on lake Ontario to Port Colborne on lake Erie. Dry excavation, dredging, mass concrete work, revetments, wash walls, breakwaters, bridges and many other details.

The inverted syphon, visited in the afternoon, was further described, as well as an interesting method of underpinning an old abutment that was considered unsafe for the newer and heavier bridge loads. Pits were excavated under the toe and the old piles were one by one subjected to the pressure from a 100-ton hydraulic jack and driven to refusal. Extra batter piles, composed of short sections of steel tubing, were then driven in the same manner and filled with concrete.

Details were also shown of the reinforced concrete cribs for breakwaters at Port Colborne and for bridge substructures built in the wet, and in connection with the latter, an ingenious circular saw mounting for cutting the tops off piles at a depth of about thirty-five feet below the surface of the water. Records of pile cutting with this machine show 140 piles in three hours and 260 piles in ten hours.

At the conclusion of the address A. F. Fifield, A.M.E.I.C., moved that a very sincere vote of thanks be extended to Mr. Grant, and also to the Atlas Construction Company and the Canadian Dredging Company for their part in making the outing a success. This was seconded by H. L. Bucke, M.E.I.C., and heartily approved by the meeting.

ANNUAL MEETING—MAY 18TH

New officers:—

C. H. Scheman, M.E.I.C. .... Chairman.
E. G. Cameron, A.M.E.I.C. .... Vice-Chairman.
Walter Jackson, M.E.I.C. .... Secretary-Treasurer.

Executive:—

L. L. Gisborne, A.M.E.I.C. .... R. W. Downie, A.M.E.I.C.
R. H. Harcourt, A.M.E.I.C. .... C. G. Moon, A.M.E.I.C.
(*Ex-officio*), Alex. Milne, A.M.E.I.C. .... E. P. Johnson, A.M.E.I.C.

The annual meeting of the branch was held at the Welland Inn, St. Catharines. Somewhat of an innovation was introduced this year in that the ladies were invited to attend, and judging by the number present there must have prevailed a certain amount of forgivable curiosity as to just what these engineres do and how they conduct their meetings. Mr. and Mrs. Durley were both interested in the experiment, and Mr. Durley promised that on his return to Montreal he would report the matter to Council.

Dinner was interrupted and enlivened by frequent interludes of general sing-song and some extremely good solos were given by Mrs. Malley, of Welland, and S. R. Frost, A.M.E.I.C.

After dinner Mr. Durley gave a brief résumé of The Institute activities and discussed some of the problems which will be dealt with by Council when it meets in October.

The question of relations with the professional engineering associations in different provinces is quite pressing and some set standard of qualification for admission to all is highly desirable. The distribution of prizes is another matter for consideration, as is also the inauguration of better methods for stimulating and developing interest among the members of The Institute and its branches.

Principal Maurice Hutton, M.A., LL.D., of the University of Toronto, was the guest of honour and speaker of the evening. He took as his topic "Some Phases of Present Day Life in America," and dealt with it in a truly scholarly and classical manner tinged with a subtle irony and undercurrents of humour.

At the close of Principal Hutton's address a vote of thanks to the speaker and to Mr. Durley was moved by A. J. Grant, M.E.I.C., and seconded by S. R. Frost, A.M.E.I.C.

A vote of appreciation was also given to R. W. Downie, A.M.E.I.C., for his extremely good work during the last six years as secretary-treasurer of the branch.

Sault Ste. Marie Branch

A. H. Russell, A.M.E.I.C., Secretary-Treasurer.

A regular meeting was held in St. Luke's hall on Friday, April 29th. Owing to the absence of G. H. Kohl, M.E.I.C., chairman, and R. S. McCormick, M.E.I.C., vice-chairman, C. H. Speer, M.E.I.C., took charge of the meeting. For the benefit of the visitors present, he outlined the history of The Engineering Institute of Canada and told how and why it was formed. He then introduced Mr. C. L. Richardson, radio engineer of the Canadian General Electric Company of Toronto, outlining briefly his career and war record, where he was intimately connected with the radio and electrical end of the war work.

Mr. Richardson gave an address on "Radio," which was well demonstrated with slides, showing the design and manufacture of different sets. A film entitled "The Wizardy of Wireless," was also shown in two parts. The first part covered the making of receiving sets and showed the flow or transmission of current through the coils. The second part was a continuation of the first and dealt with the receiving end of the radio and the transmission of the waves through the coils and tubes.

He outlined the early history of radio and the transmission of messages by various methods. The Hindoos and others used drums for this purpose, the Indians used the smoke signs and then followed the flag waving, the semaphore and the heliograph. He demonstrated various types of machines, from the simplest machine up to the present eight-tube machine and gave charts showing their range. He stressed the necessity of using high-power machines to get the best results, as he said more tubes gave more volume.

A hearty vote of thanks was tendered to Mr. Richardson by Mr. Fred Lambert, president of the Sault Radio Club, for his splendid address and was seconded by C. H. E. Rounthwaite, A.M.E.I.C., on behalf of the branch.

Saint John Branch

W. J. Johnston, A.M.E.I.C., Secretary-Treasurer.

The members of the Saint John Branch were addressed on April 21st by J. N. Flood, A.M.E.I.C., speaking on the subject "Engineering in Contracting." As a graduate engineer now engaged in the contracting business, the speaker mentioned many incidents from his own personal experience.

By means of charts the speaker showed the range of bids received on a number of typical jobs, the cost of work, day by day, against monthly progress payments giving an idea of capital required for financing, also the money totals of jobs bid on each year against contracts awarded to a firm, showing the immense amount of work in preparing bids not awarded to a firm. The speaker mentioned the method of calculating by cubic foot or square foot as a basis for approximate bidding, and that this method might also be used as a check on bids made up on the itemized unit price basis. Valuation of property, which is usually figured on its replacement value, was mentioned as one of the fields which contractors are now entering, due to the changing types of construction from residential and apartment to business and office buildings in growing cities.

FOREST FIRE PREVENTION

A feature of the evening was the co-operation of the branch in assisting the work of the Canada Forest Week. A short address on the necessity of forest fire protection was given by H. C. Kinghorn, B.S.F.

A. R. Crookshank, M.E.I.C., acted as chairman and extended a vote of thanks to the speakers of the evening, on motion of F. P. Vaughan, M.E.I.C., and A. Gray, M.E.I.C. The meeting was held in the New Brunswick Telephone Company building.

ANNUAL MEETING

The annual meeting of the Saint John Branch was held at the Admiral Beatty hotel on the evening of May 4th. The business portion of the evening was preceded by a very enjoyable banquet of which thirty-seven partook. Following the procedure adopted last year, only the junior members of the branch, who do not ordinarily take an active part in branch discussions, were chosen to speak on the toast list. The younger men acquitted themselves well and gained thereby additional practice so necessary for ease in public speaking.

The toast to the King was observed in silence. The toast to the City of Saint John was proposed by E. G. Grant, A.M.E.I.C., and replied to by Dr. W. W. White, mayor of Saint John. As the citizens of Saint John had voted on the previous day in favour of harbour nationalization, the remarks of His Worship were devoted largely to this subject and to the part engineers must play in the further development of this port. The toast to the Press was proposed by E. J. Owens, A.M.E.I.C., and replied to by F. X. Jennings, a guest representing the "Telegraph-Journal." F. M. Barnes, A.M.E.I.C., proposed the toast to The Engineering Institute of Canada, which was replied to by W. J. Forbes-Mitchell, M.E.I.C.

At the business session, which followed immediately after the toasts, the reports of the executive and of various branch committees were presented. The reports showed the business of the branch to have been carried on well during the past year, although, due to deaths and removals from branch district, there was a loss of nine members during the year.

J. H. McKinney, A.M.E.I.C., on behalf of the scrutineers, reported that the election of officers for 1927-28 resulted as follows:—chairman, S. R. Weston, M.E.I.C.; vice-chairman, E. A. Thomas, A.M.E.I.C.; members of executive, J. R. Freeman, M.E.I.C., and J. P. Mooney, A.M.E.I.C. One ballot was cast re-electing W. J. Johnston, A.M.E.I.C., to the office of branch secretary-treasurer.

A. R. Crookshank, M.E.I.C., who presided over the meeting, gave an address on "Port Development," as his farewell message as branch chairman.

S. R. Weston, M.E.I.C., newly-elected chairman, was then escorted to the chair and took charge of the meeting.

A vote of thanks to the branch officers for services during the past year and to A. R. Crookshank, M.E.I.C., for his address as retiring chairman was moved by G. G. Murdoch, M.E.I.C., and Geoffrey Stead, M.E.I.C.

A vote of thanks to the Press for courteous treatment in reporting branch meetings, also to the New Brunswick Telephone Company and Saint John Board of Trade for use of assembly halls during the past year, were moved by J. N. Flood, A.M.E.I.C., and E. G. Grant, A.M.E.I.C. O. J. Fraser, manager of the New Brunswick Telephone Company, replied briefly, assuring the branch members of the pleasure of the Telephone Company in making available its assembly hall for branch meetings.

Every feature of the dinner and annual meeting was a success, and while all reports and speeches were well received and comparisons may be out of order, it was generally conceded by all present that the high marks of the evening were the speech of W. J. Forbes-Mitchell, M.E.I.C., on The Engineering Institute, and the address of the retiring chairman, A. R. Crookshank, M.E.I.C., on Port Development.

Victoria Branch

K. M. Chadwick, M.E.I.C., Secretary-Treasurer.

On March 16th members of the Victoria Branch were addressed by Major N. C. Sherman, M.E.I.C., ordnance mechanical engineer, on the subject of mechanical warfare appliances from the early days of the Great War to present day developments. Major Sherman opened his address with a description of various types of field artillery, both mobile and heavy, and outlined the construction of the first tank used in the Great War. He described the powerful machine guns developed in England and United States, which he said were one of the most formidable weapons for combating tank attacks. Major Sherman's address was illustrated by many photographs, principally of tanks developed in Great Britain.

Executive Meeting

At a meeting of the executive committee of the branch, the chairman announced that the local branch had been asked to cooperate with the Oak Bay council in selecting a municipal engineer.

Hydro-Electric Developments at Alouette and Stave Lakes

On April 7th, E. E. Carpenter, M.E.I.C., described to members of the branch the large hydro-electric developments which are taking place at Alouette and Stave lakes.

Following Mr. Carpenter's address, which was illustrated by lantern slides, C. W. Colvin, electrical engineer to the British Columbia Electric Railway Company, described the electrical equipment of the power houses.

Visit to Lithographing Plant

Members of the branch had an interesting visit to the Colonist Lithographing Department on April 22nd, when they were shown the various processes of the work carried on by this organization.

Rainfall and Run-off

At a meeting of the branch on April 27th, at which R. F. Davy, A.M.E.I.C., vice-chairman of the branch, presided in the absence of Chairman E. Davis, M.E.I.C., an interesting and instructive paper was presented by E. G. Marriott, A.M.E.I.C., on the subject of "Rainfall and Run-off." Mr. Marriott illustrated his address with many lantern slides. He referred to records of precipitation on the Pacific coast, explaining in some instances the marked variation in rainfall in various sections of the province. He stated that there were 200 precipitation recording stations throughout the province which were closely linked up with 110 temperature recording stations.

At the close of his address Mr. Marriott was tendered a hearty vote of thanks.

Statistical Year Book of Quebec

The department of the secretary of the province of Quebec, Bureau of Statistics, has issued the 13th Statistical Year Book of the Province, which is for the year 1926. This volume should prove most useful, as it contains in concise form valuable data on a great many subjects. It is introduced by a chronological history of the province from its earliest date under the French regime, followed by a chapter on the physiography of the province. The statistical data is divided under ten principal headings: climatology, population, education, administration of the province, finances, production, communications and transportation, economic activity, organized labour, insurance and mutual benefit associations.

Under the chapter Education is included an interesting section on the cost of education, and under the heading of Production appears sub-sections dealing with the forest, mining and hydraulic electric power and central station industries, with a further section on the manufactures, including a survey of production in Canada. The chapter on Communications and Transportations includes sections on road, railways and automobiles, postal, telegraph and telephone stations and canals, and under Economic Activities appears data on the estimated cost of construction work by provinces.

Trade Publications

Hamilton Gear and Machine Company, Toronto, has issued a second edition of their catalogue of "Speed Reducers, Type T and Q," copies of which are available upon application to the company. The catalogue contains specifications for these speed reducers and also illustrations of the various types, with short descriptions and general data which should prove of value to those interested in such equipment.

Link-Belt Company, Chicago, has issued an interesting booklet entitled "Modern Methods in Coal and Ash Handling," which consists of a collection of five articles previously published separately. These articles are entitled "Coal and Ash Handling"; "Elevators and Conveyors for Coal Handling"; "Belt Conveyors and Skip Hoists"; "Bucket Conveyors and Storage Equipment," and "Equipment for Crushing Coal." This booklet, which is known as No. 530, contains fifteen pages, well illustrated with photographs of actual installations, and should prove of interest to those having to do with the handling of coal and ashes.

The company has issued another booklet, No. 575, entitled "Link-Belt Elevators and Conveyors," which is devoted principally to diagrammatic sketches and photographs of the company's various equipment for handling materials in industrial plants. In the ninety-six pages of this booklet the company has endeavoured to illustrate as many of the applications of elevating and conveying equipment as possible.

Combustion Engineering Corporation, Limited, Montreal has issued an interesting and attractive booklet entitled "An Achievement," which describes the new steam plant which the International Combustion Engineering Corporation of New York has recently completed for the New York Steam Corporation. This booklet gives a series of progress pictures of the construction of this large plant with illustrations of the various equipment installed.

The Westinghouse Electric and Manufacturing Company has just issued leaflets L. 20013-H and L. 20149-C, the first one describing the application, operation and distinctive characteristics of the LV autovalve arrester, and the second leaflet discussing the SV autovalve type. These leaflets may be obtained at any of the district offices of the Westinghouse Company or at the publicity department at East Pittsburgh, Pa.

Irving Iron Works Company announce the change of address of their Montreal office from 402 Coristine Building to 501 McGill Building.

Link-Belt Company, of Chicago, Ill., has issued in booklet form an address delivered before the Chamber of Commerce of the United States by the chairman of the company, Charles Piez, on "Midwestern Industries and the Panama Canal."

Recent Developments in Boiler Furnaces

A Review of the Design of Various Types of Boiler Furnaces

B. N. Broido.

Deceased February 10th, 1927, formerly Chief Engineer, Industrial Department, The Superheater Company, Limited.

Paper read before the Montreal Branch of The Engineering Institute of Canada, January 6th, 1927

Engineering is largely a matter of economies. Its object is to obtain the desired results with the least expenditure of time, labour and money. This is particularly true in connection with the developments in the power plant field.

In the past years many improvements have been made effecting economies in the original cost and in the operation of practically all apparatus constituting a modern power plant, but there was no other problem in connection with power plants in which there was a more urgent need for improvement than in the design and construction of the modern boiler and furnace. The rapid improvement of the steam turbine and the possibility of concentrating more power generators in the large power stations created a demand for increased steam quantities. The logical progress has therefore been towards larger boilers, higher boiler evaporation per square foot of boiler heating surface, and also continuous operation over a long period at high average rating. This has made the problem still broader.

Stoker Development

Ever since the invention of the steam engine, coal has been burned in boiler furnaces. From the crude hand-fired grate type of the early days, the boiler furnace has passed through several stages of development to the modern furnace equipped with automatic stokers. Until 1910, when the automatic stoker began to be the prevailing method of firing, the furnaces were small and there was no serious difficulty or expense in maintaining them and no great loss if they were temporarily put out of service. The automatic stoker involved radical changes in furnace design. Modern stokers have more than doubled boiler evaporation per square foot of heating surface. More complete combustion, higher CO_2, and correspondingly higher boiler efficiencies are also obtained.

Stokers, however, are usually designed to give the best results with a certain grade of fuel, so that there was necessity for a method of combustion which would handle a variety of coals in order to be practically independent as to the kind of fuel.

Introduction of Powdered Fuel

Pulverized fuel was one solution of the problem. In order to reduce the initial installation cost and fixed charges the stoker-fired furnace grew larger and larger and the introduction of powdered fuel was a further step in increasing the size of boiler furnaces, as it was thought that large furnace volume was an inherent necessity for burning powdered fuel.

It was generally accepted that for every horse power generated at least 1½ to 2 cubic feet of combustion space were required, depending on the amount of volatile, moisture, ash, etc., of the coal, large volumes being thought necessary to allow sufficient time in the furnace for better mixing and more complete combustion of the hydro-carbons. The result was that the cost of construction of the large furnaces and the difficulties and expense of maintaining them in operation became exorbitant. Various methods were tried to reduce these difficulties. Air-cooled blocks were developed and used with some success. Hollow air-cooled walls were constructed and are being used advantageously under certain conditions.

Water-Cooled Furnace Walls

It became apparent, however, that in order to eliminate the erosion of furnace walls at the very high ratings, more effective means for cooling furnaces were required or that further steps would be necessary to eliminate the high maintenance cost of the present day large furnace. Attempts have been made before to water-cool furnace walls of water-tube boilers, but no serious consideration was given to them until Thomas E. Murray* decided to provide three additional boilers at the Hell Gate station of the United Electric Light and Power Company with so-called fin walls. These consist of water tubes with thin strips or fins welded to opposite sides. The tubes are located so that the strip on one tube butts on the strip of the next tube, forming a continuous metallic surface. Both side walls of the furnace are equipped with these water-cooled tubes. They have proven conclusively that not only was the maintenance of the furnace decreased but the capacity of the boiler was largely increased. These water-cooled walls have also demonstrated that tubes in a furnace are excellent evaporating surfaces, as they absorb a considerable amount of heat from the gases by radiation.

Particular attention was given to the circulation of the water. It is brought from the mud drum by outside pipes in the lower headers. The circulation in these water-cooled tubes seems to be so rapid that sediment or scale, and the consequent necessity of cleaning the inside of the tubes, is reduced to a minimum. The water-cooled side walls not only replaced practically all the brickwork in these side walls but afforded considerable protection to the front and side walls by absorbing the heat which they reflect.

The amount of cooling surface that can be installed, without lowering the furnace temperature to a point where the combustion would be affected, is dependent on the kind of coal used, particularly upon the kind and quality of volatile matter and ash in the coal, and also on the amount of moisture; all of which are important factors on the ignition temperature and affect the inflammability of the coal. The fusing temperature of the ash is also to be taken into consideration with respect to the slagging of the tubes: with preheated air, the amount of cooling surface can be increased.

Development in Furnaces for Powdered Fuel

The steady increasing pressures and ratings, the development of pulverized fuel burning equipment, water-cooled walls and air preheaters are revolutionizing boiler and furnace design. Since about eight years ago, when the first successful pulverized fuel installation in connection with a stationary steam boiler was put in operation, the furnaces for pulverized fuel underwent extensive developments without affecting the boiler proper.

It was found later, however, that the furnace cannot be separated from the boiler and both should be constructed as one unit. The development of water walls was the first step in this direction. The following requirements of powdered fuel furnaces made this necessary:—

(a) With pulverized coal, the fuel and air must be thoroughly mixed during the process of combustion.

(b) In order to justify the cost of preparing the fuel, the overall efficiency must be higher.

These require a higher CO_2 with correspondingly higher gas temperatures. However, the high temperature and the molten state of the ashes have a very bad effect on the brick walls. With earlier installations for burning powdered coal under steam boilers, which had refractory lined furnaces, considerable difficulties were encountered with the brick furnace from slag and the ash and rapid erosion of the firebrick furnace lining. The ash fused and accumulated in a molten or semi-molten condition at the bottom of the furnace and its removal, either hot or cold, required much hard labour and caused long shutdowns of the boiler.

The fused ash, coming in contact with the refractory, ran down the walls, eroding the brick and washing the slag to the bottom of the furnace. Under such conditions, firebrick lining lasted only a comparatively short time and required frequent repairs. Naturally, the washing away of the brick lining was particularly rapid where the flames were allowed to impinge on it. In order to prevent impingement of the flame, the furnaces were built large enough to keep the walls away from the flame. The furnaces were therefore larger than actually necessary for good combustion. Where this was not the case, the refractory deteriorated after a few months of operation.

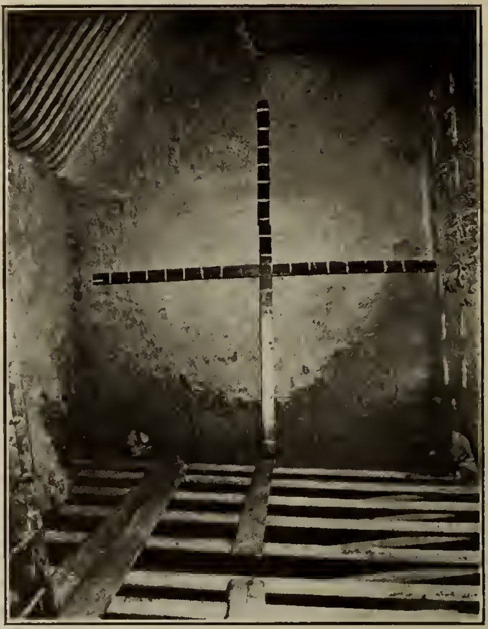

Figure No. 1.—Interior View of Furnace of Semi-Vertical Boiler Fired with Powdered Coal after about Six Months Operation.

Figure No. 1 is a reproduction of a photograph taken in a furnace of a semi-vertical boiler fired with powdered coal after about six months of operation. At the point where the fuel turns and the mixing with the air is completed, rapidly increasing the temperature and volume of the gases, the refractory lining is completely eroded or fused and washed down by molten ash.

It has been stated repeatedly that it is not as hard to burn coal, particularly after it has been brought in contact with air, as it is to bring the necessary amount of air in contact with each particle of coal. In order to burn a particle of coal, approximately fourteen thousand times its volume of air is required. The combustion of a particle of coal can therefore be completed only after this entire amount of air has come in contact with it. From this, it is evident that thorough mixing of coal with air is required for complete combustion. In an effort, however, to prevent the impingement of flames on the firebrick linings, the turbulence of the furnace gases was limited to a minimum. It made the process of combustion very slow, so that only a comparatively small amount of coal could be burned per cubic foot of combustion space. Early installations of pulverized fuel were therefore designed with a maximum liberation of 15,000 to 25,000 B.t.u. per cubic foot per hour. With no means provided for mixing the coal and the air, it was found that even the finest particle of pulverized coal required from one to two seconds in order to be burned completely. Hence, a large furnace was provided to permit these particles of coal to remain in the combustion space from one to two seconds.

* Designing Engineer, New York.

The action of the fused ash, the changing temperature of the flame, and the heat, particularly in the lower part of the furnace, were responsible for the quick destruction of the refractory. Efforts were made to produce refractories that would resist the erosive action and would better withstand the higher temperatures, but as the composition of coal ash varies so much it was extremely difficult to produce a refractory material that would resist all kinds of coal.

Air-cooled hollow walls improved the situation considerably, but did not entirely solve the problem of erosion. Special mechanical means of steel or cast iron construction were designed in order to relieve the weight of the brick upon the lower part of the wall, and to take any of the expansion and contraction due to change in temperatures, but these are very expensive. The above mentioned development of a water-cooled furnace wall was, therefore, at least for certain conditions, the only solution.

Radiation in Boiler Furnaces

A great deal of thought has been given recently to the laws of heat radiation, due to the fact that its importance in furnace design has been recognized. In the modern large furnace, filled with flame or gases of combustion, a great amount of heat can be lost by radiation, not only from incandescent solid fuel but also from the gases of combustion. In a paper presented last year by the writer before the American Society of Mechanical Engineers, entitled "Radiation in Boiler Furnaces,"* it was shown how the experiments of Dr. Shack can be utilized in order to determine the heat radiated from gases of combustion to water-cooled surfaces. It was definitely established that some of the constituents of furnace gases, particularly carbon dioxide and water vapour, radiate heat. Experiments have shown that the radiation of a flame increases with its thickness up to about twenty-four inches. Above that, no increase in radiation takes place. The radiation from a flame with a thickness of twenty-four inches or more is about 7.5 per cent of that of a black body of the same temperature, when the flame contains by volume about 14 per cent of CO_2 and 7 per cent of water vapour. The radiation from a flame in a pulverized fuel furnace is much greater, as it contains, in suspension, a considerable amount of incandescent particles of fuel and hot ashes, both of which are very effective heat radiators.

In the above mentioned paper, the writer pointed out that, assuming a furnace of cubical shape filled with flame and provided with a grate at the bottom, the surface of the flame would be just five times the area of the grate. The radiation from the flame is therefore about 60 to 65 per cent of that of the fuel bed. This shows that the radiation of a flame is an important factor in computing the heat absorbed in a boiler furnace.

In two papers* presented before the American Society of Mechanical Engineers, Professor W. J. Wohlenburg and others have elucidated an elaborate method computing the radiant heat that can be absorbed within a boiler furnace fired with pulverized fuel. They have shown that the radiation from the small particles of coal in suspension in the furnace is still higher than from the gases of combustion. This is probably due to the fact that while a flame, as experiment has shown, becomes opaque to its own radiation at a depth of over three feet, it is apparently transparent to radiation from other bodies even at a considerably greater depth.

* Mechanical Engineering, vol. 48, no. 2, Feb. 1926, pp. 133-137.

* American Society of Mechanical Engineers.—Advance Paper for Meeting Dec. 6-9, 1926.

In order to obtain the highest furnace temperature, and, accordingly, the highest efficiency, it is desirable to have the most rapid agitation and combustion possible. The coal entering the furnace must first be heated, and any moisture in the coal must vapourize, before combustion can begin. At about 400° F. the gases and volatile vapours are given off. After the gases of distillation and the admitted air have reached the ignition temperature the combustion of the gases commences. The burning volatile matter produces water vapour and carbon dioxide, both of which will absorb and radiate a considerable amount of radiant energy. Thus, the combustion process consists of two parts: heat absorption and heat liberation. The time, as well as the space, required for combustion will be less the higher the furnace temperature, the dryer the coal, the higher the temperature of the admitted air and the better the coal and the air can be mixed. Water-cooled surfaces unquestionably reduce the furnace temperature. This can be compensated for, at least to a certain extent, by preheating the air for combustion and by a turbulent mixing of air and fuel in the furnace. The following paragraphs are intended to show the relation between these factors of combustion.

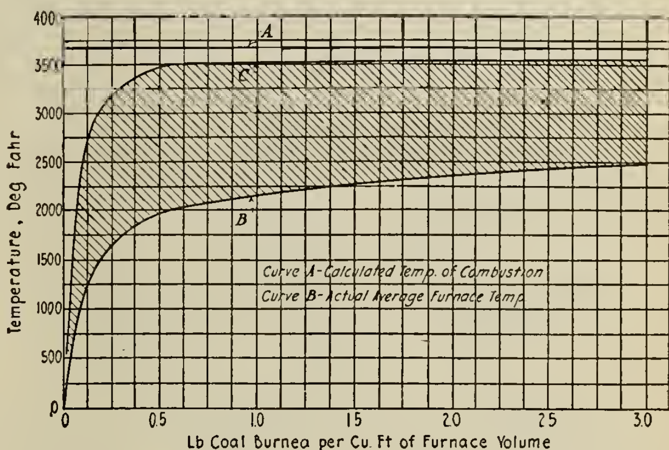

Figure No. 2.—Comparison of Actual and Theoretical Flame Temperatures at Different Coal Rates.

Heat Absorption by Radiation

The heat absorbed by radiation per square foot of surface depends upon the amount of fuel burned and the amount of heating surface that is located in the furnace, both of which influence the temperature of the flame or gases in the furnace.

Figure No. 2 shows how the temperature of the flame varies with the amount of coal burned, also the influence of water-cooled walls upon this temperature. It is based on a furnace 18 feet long, 18 feet high and 24 feet wide, fired with coal having a calorific value of about 14,000 B.t.u. per pound and burned with 14 per cent of CO_2. The first two lower rows of the boiler present about 700 square feet of surface absorbing heat by radiation, and there is also heat-absorbing surface of about 1,000 square feet in the water-cooled walls and bottom.

In figure No. 2, curve *A* represents the calculated or theoretical furnace temperature which would result from combustion with the above coal without any losses. Curve *B* represents the actual average temperatures in the furnace under the above conditions with different rates of fuel consumption. Curve *C* shows what the temperature would be

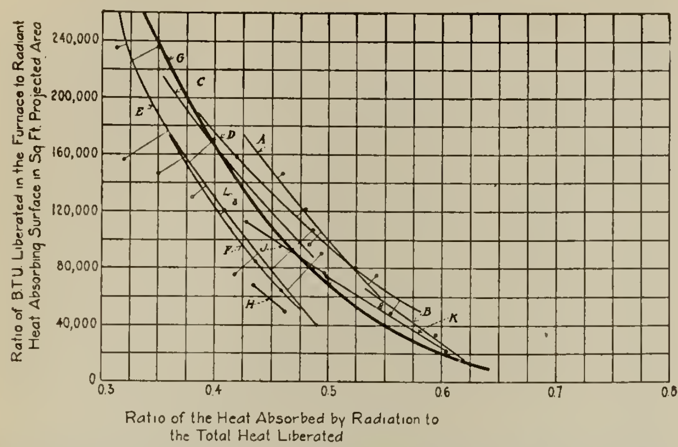

Figure No. 3.—Curve showing Relation between Total Heat Generated in the Furnace and that Absorbed by Radiation.

if no water-cooled radiation surface were present to absorb heat. The shaded portion between curves *B* and *C* represents the temperature drop in the furnace due to heat absorption by radiation. Curve *B* approaches curve *C* as the ratio of combustion increases, which shows that the heat absorbed by radiation does not increase in the same proportion as the fuel burned.

The most important factor in connection with heat radiation is the relation between the total heat generated in the furnace and that absorbed by radiation; in other words, the fraction of generated or liberated energy which is absorbed in the furnace. The author endeavoured to figure this relation for a few cases, either directly where the amount of steam generated by the radiation heat-absorbing surfaces was known or indirectly by comparison with similar cases where water-cooled surfaces are not provided. There seems to be a certain relation between the ratio of the total heat liberated in the furnace to the radiant heat-absorbing surface, and to the heat absorbed by this surface.

Figure No. 3 is taken from the above mentioned paper, "Radiation in Boiler Furnaces." The curves, however, are completed and corrected in accordance with more recent practice. The heavy curve *G*, which represents the average of the others, is sufficiently accurate for practical purposes to be used as a standard on which to base calculations. By means of this standard curve, one can determine what part of the total heat generated will be absorbed by the radiating surface in the furnace for a certain rate of operation of the boiler. This can be found by determining first the ratio of the total heat to the total amount of radiating surface. The total heat should then be multiplied by the figure of the abscissas corresponding to the determined ratio, which gives the total heat absorbed by radiation. This curve can also be used to find the heat transmission by radiation per square foot of heating surface for any given condition of the furnace. Determine the total amount absorbed by radiation as before and divide it by the number of square feet of surface exposed to radiation.

Very often the question arises as to how much steam will be evaporated by the water-cooled surface located in the furnace; that is, the water walls and bottom screen. That this problem can be solved easily by the use of the standard curve *G* of figure No. 3 is evident. The number of B.t.u. absorbed by radiation per square foot of surface should be multiplied by the amount of radiating surface in the furnace in square feet.

The curve *G* in figure No 3 is based on average-sized furnaces of about cubical shape. It can be applied for rates of heat liberation between 8,000 and 32,000 B.t.u. per cubic foot.

Table No. 1 shows the heat transfer per square foot of projected area of the side wall of a standard water-tube boiler of about 1,600 h.p. for different percentages of radiant surface and amounts of coal burned.

Table No.1—B.t.u. transfer per square foot of projected area per hour to furnace-wall surface of standard water-tube boilers.

Millions B.t.u. liberated per hour in furnace	Furnace-wall surface in square feet					
	250	500	1,000	1,500	2,000	3,000
50	29,300	21,800	16,400	13,600	11,400	8,400
100	49,500	41,000	31,000	24,600	20,500	15,200
150	66,000	55,500	42,200	34,200	29,500	22,300
200	77,200	67,300	52,600	43,400	36,700	28,600
250	90,700	79,000	61,800	51,000	44,000	34,000
300	98,600	86,200	69,400	58,500	51,000	39,200

This table is based on boiler having 480 square feet of projected area exposed to radiation in the furnace.

Furnace Temperatures with Water-Cooled Walls

Figure No. 4 is calculated to show what furnace temperature can be expected in a furnace burning pulverized fuel at different rates of heat liberation per cubic foot of furnace volume and for different amounts of water-cooled surface. The method of calculation disclosed in the above mentioned paper by Wohlenburg and others was used. The curves are based on a furnace of about twenty feet on all sides. In accordance with figure No. 4, the furnace temperature decreases rapidly with decreased rate of heat liberation per cubic foot of furnace volume; it also decreases with increased amount of water-cooled surface. It is, however, even with a furnace covered on all sides with water-cooled surfaces, still 2,100° F. when 20,000 B.t.u. are liberated per cubic foot of volume. It should be remembered, however, that figure No. 4 shows average temperatures, and that the gas temperature near the walls is considerably lower. It would be, therefore, hardly advisable, under these furnace conditions, to use certain kinds of coal; for instance, those with a low volatile and high moisture content. It is hoped these curves will be of value in determining the furnace design for a given condition and that it will assist in the determination of the size of the furnace and the amount of water-cooled surface to be installed.

Preheated Air

Preheated air increases the furnace temperature considerably under certain conditions. Figure No. 5 gives the furnace temperatures for various rates of heat liberation, various amounts of water-cooled surfaces and for preheated air of 70° to 570° F. It is based on bituminous coal of about 13,500 B.t.u. heat content, approximately 30 per cent vola-

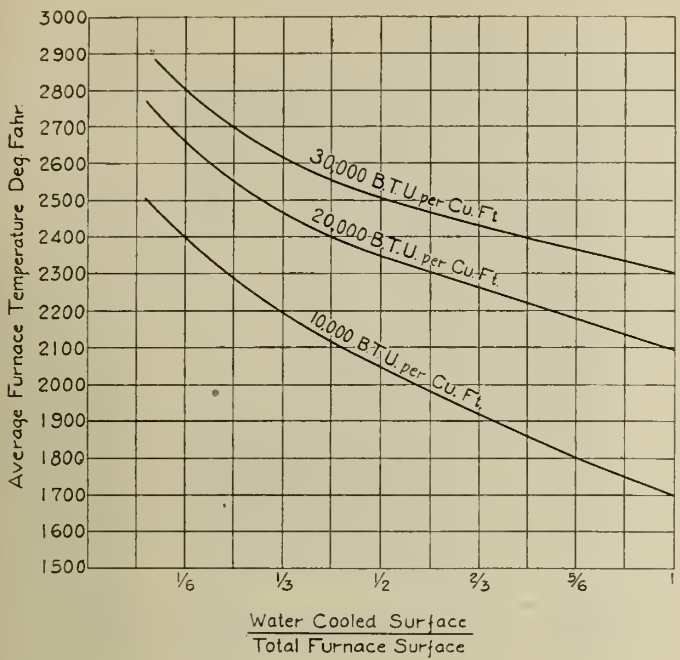

Figure No. 4.

tile and when burned with about 25 per cent excess air. The less the water-cooled surface, the more the furnace temperature increases, with higher temperatures of the air for combustion.

The actual benefit from preheated air is considerably greater than is indicated on these curves. The time and the heat required to bring the air up to the furnace temperature are considerably reduced when the air is preheated. Less space is therefore required to burn a given amount of fuel, or, in the same space, the combustion will be completed earlier.

With preheated air, more water-cooled surface can therefore be allowed and still have complete combustion, without any danger of smoking.

With the present high rates of combustion used in steam boiler practice, there is very little danger that water-cooled furnace walls will cause incomplete combustion by excessive cooling of the flame, particularly when the air is sufficiently preheated. The temperature of the flame is then high enough for anything to burn as long as the supply of air is sufficient and the air mixes properly with the fuel particles.

The fact that air-cooled walls make it possible to use highly preheated air is a very important factor in power plant design. The practice of bleeding turbines for heating feed water is growing rapidly, not only because it is considered a good means for heating water, but because it also improves the thermal cycle of the plant appreciably. The heating of feed water in this way limits the use of economizers; air heaters being used instead. With the use of preheated air, however, when no water walls are provided, the furnace temperature is very high, which increases the wear on the refractory walls.

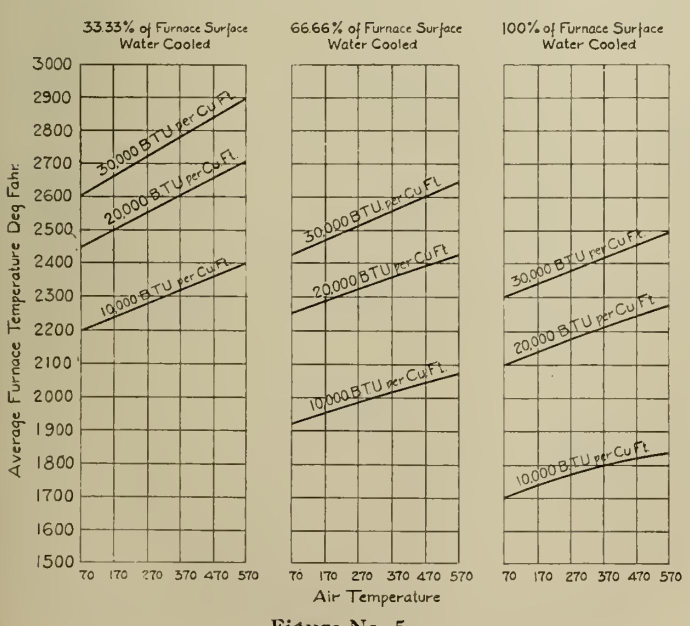

Figure No. 5.

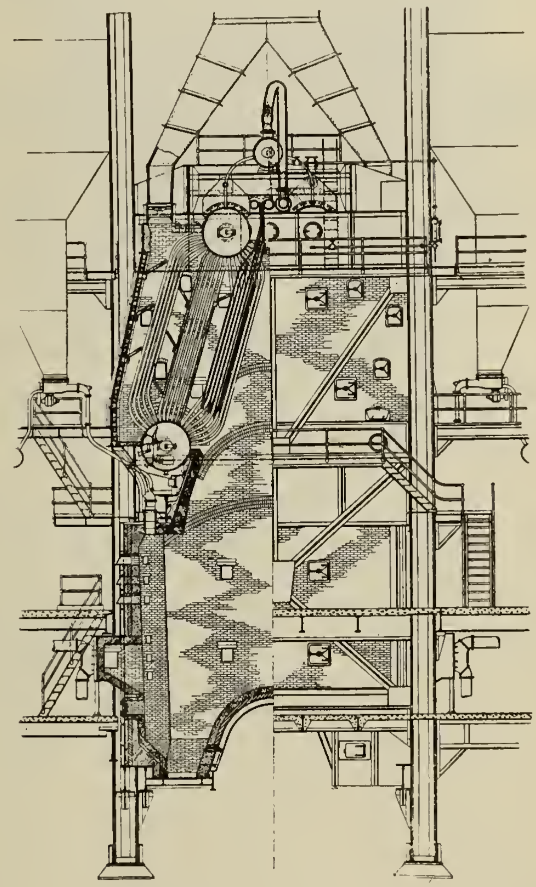

Figure No. 6.—Section of One of Eight Boilers as Originally Installed in Fordson Plant.

Difference in Operation with and without Water Walls

The difference in operation of boilers without and with water walls is admirably illustrated at the Fordson plant, (formerly River Rouge), of the Ford Motor Company. Figure No. 6 shows one of the eight boilers installed in this plant. They are rated at 2,647 h.p. The maximum rating which can be obtained with these boilers, without affecting the brick walls, is 250 per cent.
