Train-Ferry Landings at Port Mulgrave and Point Tupper, N.S.

D. B. Armstrong, A.M.E.I.C.,
Erection Engineer, Dominion Bridge Company, Ltd., Montreal,
and
W. Chase Thomson, M.E.I.C.,
Designer, Dominion Bridge Company, Ltd., Montreal.

Paper to be presented before the Annual General and General Professional Meeting of The Engineering Institute of Canada at Montreal, February 4th, 5th and 6th, 1931.

SUMMARY.—The train-ferry between Port Mulgrave on the mainland of Nova Scotia, and Point Tupper on Cape Breton island, has been maintained since 1901. The landings over which the trains pass from the ferry to the shore are structures which must accommodate the list of the boat, variation of draft, and a tidal range of about 7 feet.

After thirty years' service the demands of heavier and greatly increased traffic required the renewal of the original structures, and the old design was generally followed. Experience has enabled a number of improvements to be incorporated in the new landings, particularly in connection with the method of meeting the severe shocks when the ferry steamer is mooring and with a view of obtaining increased stability and flexibility. Descriptions are given of the means adopted for these purposes, and of the special methods of erection which were necessary in order to avoid any interference with the regular traffic of the Canadian National Railway. The erection programme was also limited by tidal conditions. The actual work of cutting away and removing the old structures and their replacement by the new was done in a period of four months.

All major operations had to be carried out on Sundays, and in the case of some of these it was necessary to select Sundays on which the times and heights of the tide were suitable. The replacement of one apron and its intermediate span involved the handling of more than 450 tons of steelwork, and with the renewal of 300 feet of track, had to be carried out in a period of twenty hours. The total weight of steel in the two landings is more than 1,300 tons. The paper describes in considerable detail the arrangement and operation of the structures, and the erection methods employed.

Historical

Railway traffic between the mainland of Nova Scotia and the island of Cape Breton has been maintained regularly throughout the year since 1901, when a ferry service was provided, capable of transporting an entire train with locomotive engine across the Strait of Canso, a distance of about one mile. The ferry boats are of special construction, having three parallel tracks on the deck, spaced 11 feet 6 inches centre to centre and 260 feet long. (See Fig. 1.)

The landings at Port Mulgrave on the mainland, and Point Tupper on the island, form an essential feature of this ferry service. Their geographical position and the lay-out of the yards are shown in Figs. 2, 3 and 4. These landings must accommodate the list of the boat when being loaded or unloaded, which is about one in ten; variations of light and full draft; and a range in tide of some 7 feet. The original design, which contained many interesting and unique features, was conceived by G. H. Duggan, M.E.I.C., at that time chief engineer of the Dominion Bridge Company, and was worked up under his direction, in consultation with Mr. John Forbes, of the engineering staff of the Intercolonial Railway.

The original structures had for some 30 years been subject to many adverse conditions, including the corrosive action of salt air and sea water, constant racking under heavy traffic, together with the ramming and listing of the ferry boats. Moreover, during the winter season, they had been hampered by floating ice in the slips and by heavy deposits of snow and sleet on the moving structural parts and on the machinery. But they had served their purpose during all these years, without causing serious trouble or delay. Therefore, when the demands of heavier and greatly increased traffic required their renewal, it was decided to follow the old design as closely as possible, making only such changes in detail as seemed to be warranted by past experience, together with increased sections due to heavier loadings. The new ferry landings have been built under the supervision of C. S. G. Rogers, A.M.E.I.C., Bridge Engineer, Canadian National Railways, Maritime Division. Mr. Rogers had carefully studied the condition and behaviour of the old structures; and the modifications and improvements in the new are mostly due to his suggestions. The renewals were carried out by the Dominion Bridge Company during the year 1930.

General Description

An elevation and a plan of one of the new structures are shown in Fig. 5, and transverse sections in Fig. 6. The structure consists essentially of three hinged leaves, supported at the inner or land end on a fixed abutment, and, at other points, by transverse girders, the latter being suspended from gantry frames. At the inner end there is one central track only; from which there are right and left turnouts to 10-degree reverse curves, thus providing three tracks at the outer or sea end, corresponding to those on the ferry boat. Only one of these tracks, however, can be loaded at a time. The spreading of the tracks from a point on the structure, instead of providing for three tracks

Fig. 1—The C.N.R. Car Ferry "Scotia II" approache Point Tupper.

throughout, greatly complicated construction; but this was done in the original design principally to insure that only one track could be loaded at a time. In the new design, there was no option, because the cost of revising the layout of the approach tracks would have been prohibitive.

The ferry landing, which serves as a docking and mooring structure for the vessel, is subject to severe shocks, which must be absorbed by or transmitted through the steelwork to the extreme inner end. In the original structure, the outer longitudinal girders of the apron and the main longitudinal girders of the intermediate and inner leaves were not in continuous lines, but had separate hinged bearings, side by side, on lifting girders *E* and *I*. The inner longitudinal girders of the apron and the end stringers of the intermediate leaf had separate hinged bearings on lifting girder *E*; and the end stringers of the intermediate and inner leaves had separate hinged bearings on lifting girder *I*. Moreover the impact of the vessel, which could be applied to either one of the outer longitudinal girders of the apron, or to all four of its longitudinal girders, in varying proportions, was transmitted by them to lifting girder *E*. At this point, it was taken up and transmitted by the longitudinal girders and the stringers of the intermediate leaf to lifting girder *I*. At girder *I*, a portion of the impact was received and transmitted by the trusses of the inner leaf to the buffers at the abutment; the remainder was received by the track stringers of the inner leaf, and was delivered by them to the top flange of the floorbeams to which they were attached. The latter, acting as horizontal girders, conveyed this portion of the impact to the trusses; thence it was transmitted to the buffers. Some of the shoes on lifting girders *E* and *I* were designed to accommodate girders of adjacent leaves, in which case, the thrust of one of these girders and the resistance of the other tended to twist the shoe about a vertical axis. Other shoes accommodated one member only, in which case, the thrust of the girder or stringer tended to revolve the shoe about a horizontal axis. In consequence, the connections of all the shoes on the lifting girders had become loosened and had partially failed. Furthermore, on the inner leaf, where the stringers were supported on the top flange of the floorbeams and connected thereto by only two rivets, these rivets had been loosened by the impact from the vessel, and permitted sufficient motion between the bearing surfaces to cause serious wear. In some instances, this wear, in combination with the corrosive action of salt water, had practically extended through the bottom flange of the stringers.

In the new structure, the outer longitudinal girders of the apron and the main girders of the intermediate and inner leaves are in continuous lines; for, at lifting girders *E* and *I*, they meet concentrically and are hinged by a pin common to both, thus providing definite and substantial paths for transmitting the thrust or pull of the vessel to the buffers at the abutment, and without tending to twist or to overturn the supporting shoes on the lifting girders. Owing to the comparative rigidity of these paths of resistance, any thrust on the stringers of the inner leaf should be reduced to a minimum.

Inner Leaf

The inner leaf is a pony-truss span of 100 feet, having two parallel trusses 21 feet 6 inches centre to centre, as shown in Fig. 7. It has a single track only to a point near its centre, where there is a three-way switch for the right and left turnouts. The track rails are laid on timber ties, supported by longitudinal stringers, the latter being 8 feet centres under the single track, but spread at the turnouts, where supplementary stringers are also provided. The floorbeams are 12 feet 6 inches centre to centre. The inner end of this leaf is swung by short links inside of steel box pedestals, in which are incorporated steel-spring buffers, to absorb shock from the ferry. A detail of these pedestals is shown in Fig. 8. The other end is hinged in shoes, common to this and the intermediate leaf, on lifting girder *I*. The stringers are supported on the top flange of the floorbeams, as in the original structure; but, to guard against slip from any cause, gusset plates are inserted between the stringers and the floorbeams, and securely riveted. Except for heavier sections, no other improvement of importance has been made to this leaf.

Intermediate Leaf

The intermediate leaf has two 50-foot longitudinal girders, hinged at both ends, and spread from 21 feet 6 inches at lifting girder *I*, to 28 feet 6 inches at lifting girder *E*. Its connections are shown in Figs. 9 and 10. At *I* and *E* respectively, these girders meet concentrically the trusses of the inner leaf and the outer girders of the apron, in shoes and on pins common to both. To facilitate erection, the pin bearings at both ends of these girders are constructed in the form of a hook. It was thus possible to drop the girders into place without disturbing the pins supporting the adjacent leaves. The intermediate leaf carries three tracks, and the rails are laid on timber ties, supported by stringers immediately under the rails. Additional support for the ties is provided by shelf angles on the

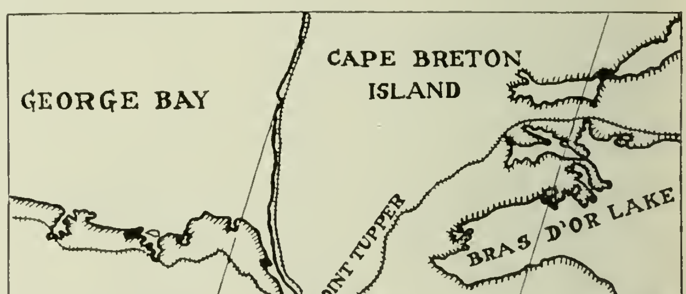

Fig. 2—Geographical Position of Port Mulgrave and Point Tupper.

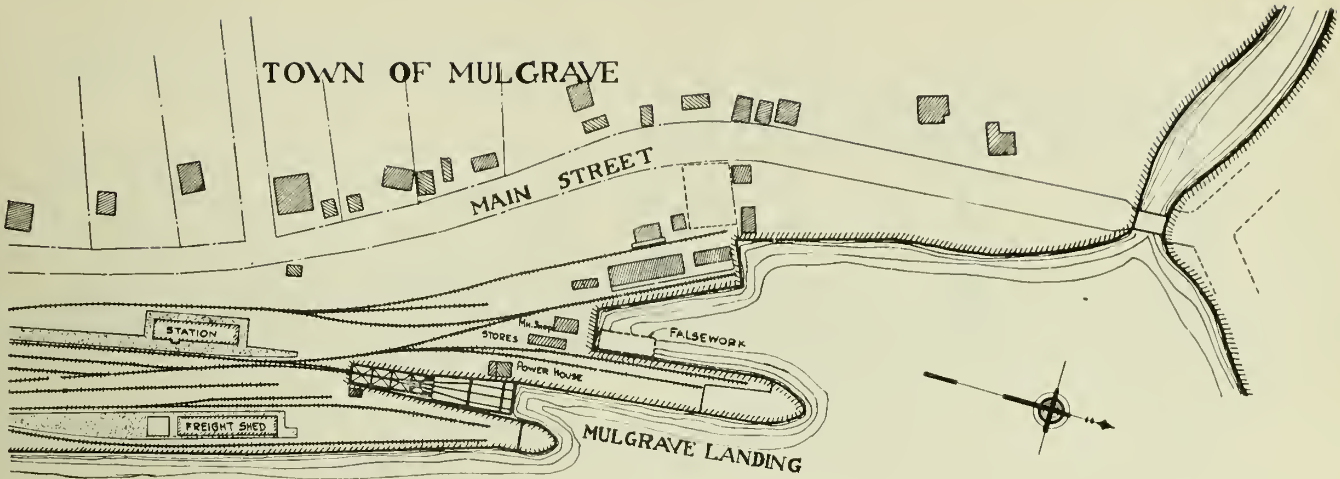

Fig. 3—Location of Yards, Port Mulgrave.

web of the main girders. The stringers on this leaf are connected to the web of the floorbeams, which latter are 12 feet 6 inches centre to centre. The main girders are unusually shallow at their ends; but adequate provision has been made for both vertical and horizontal shear by outside reinforcing plates, covering the vertical leg of the flange angles, and giving to each flange rivet the value of double shear plus bearing on the web. These outside plates were extended towards the centre of the span far enough to splice the web plate.

Apron

The outer leaf, or apron, is 50 feet long and carries three tracks. (See Fig. 11.) It has four longitudinal girders, the two inner being parallel and 11 feet 6 inches centre to centre. At gantry *E*, the two outer girders are 28 feet 6 inches centre to centre, and are hinged in shoes common to these and the main girders of the intermediate leaf; and they are spread to 32 feet 6 inches centres at the extreme outer end of the apron. As shown in Fig. 12, all of the longitudinal girders are supported by ball-and-socket bearings on a transverse lifting girder at gantry *B*, but for dead load only. The live load reactions at the outer end of the apron are taken by the vessel. The rails are laid on ½-inch plates, supported by transverse floorbeams spaced 15 inches centre to centre. In designing the floorbeams, it was assumed that the wheels might either be on the track or at any possible position between the main girders which would produce the maximum shear or moment. All floorbeams, except those at both extreme ends of the apron, were proportioned to carry the maximum wheel concentrations, with impact, uniformly distributed over a length of three feet; but those at both extreme ends were proportioned for the full effect of the wheel loads, with impact.

The excessive listing of the ferry during loading or unloading, to which reference has already been made, affects chiefly the apron; for, while the end supported by the lifting girder at gantry *E* will always be horizontal, the outer end must conform to the deck of the vessel, as indicated in Fig. 13. It was thus necessary to provide a large degree of flexibility in the apron, and without overstraining its main materials or connections. These conditions prohibited the usual and cheaper beam-and-girder construction, with stiff or semi-rigid connections.

To effect the desired flexibility, the end connections of all intermediate floorbeams are provided with universal bearings, as shown in Fig. 14. These consist essentially of steel-trunnion castings, riveted to the ends of the floorbeams. On the trunnions are spherically turned enlargements, which bear on the heavily reinforced web of the longitudinal girders in cylindrical holes. The same general type of bearings was used in the old structure, and provided the necessary flexibility. It was realized, however, that there had been considerable wear on the bearing parts, although the extent of this wear was difficult to determine while the old structure was in service. Accordingly, the diameter of the trunnions and the thickness of web reinforcement were substantially increased in the new structure. On dismantling the old apron, it was found that the wear on these parts had been considerable, as expected; also that it was principally in the holes, rather than on trunnions. With this type of universal bearing, which permits of transverse movement as well as angular, it is necessary to provide some means for spacing the main girders. In the old structure, the spacers consisted of round rods, threaded through wrought iron pipes, and provided with rounded

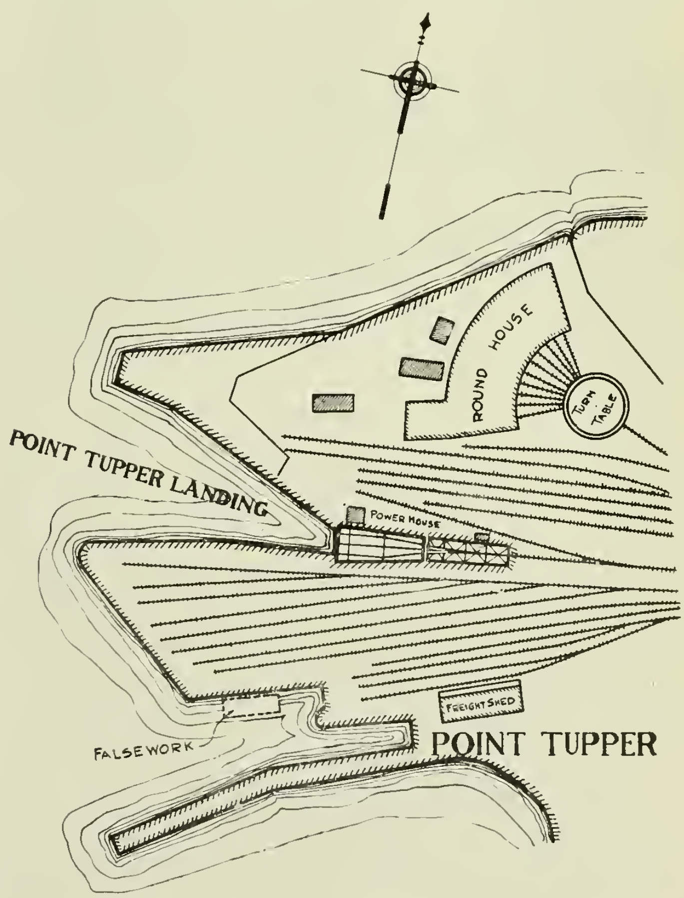

Fig. 4—Location of Yards, Point Tupper.

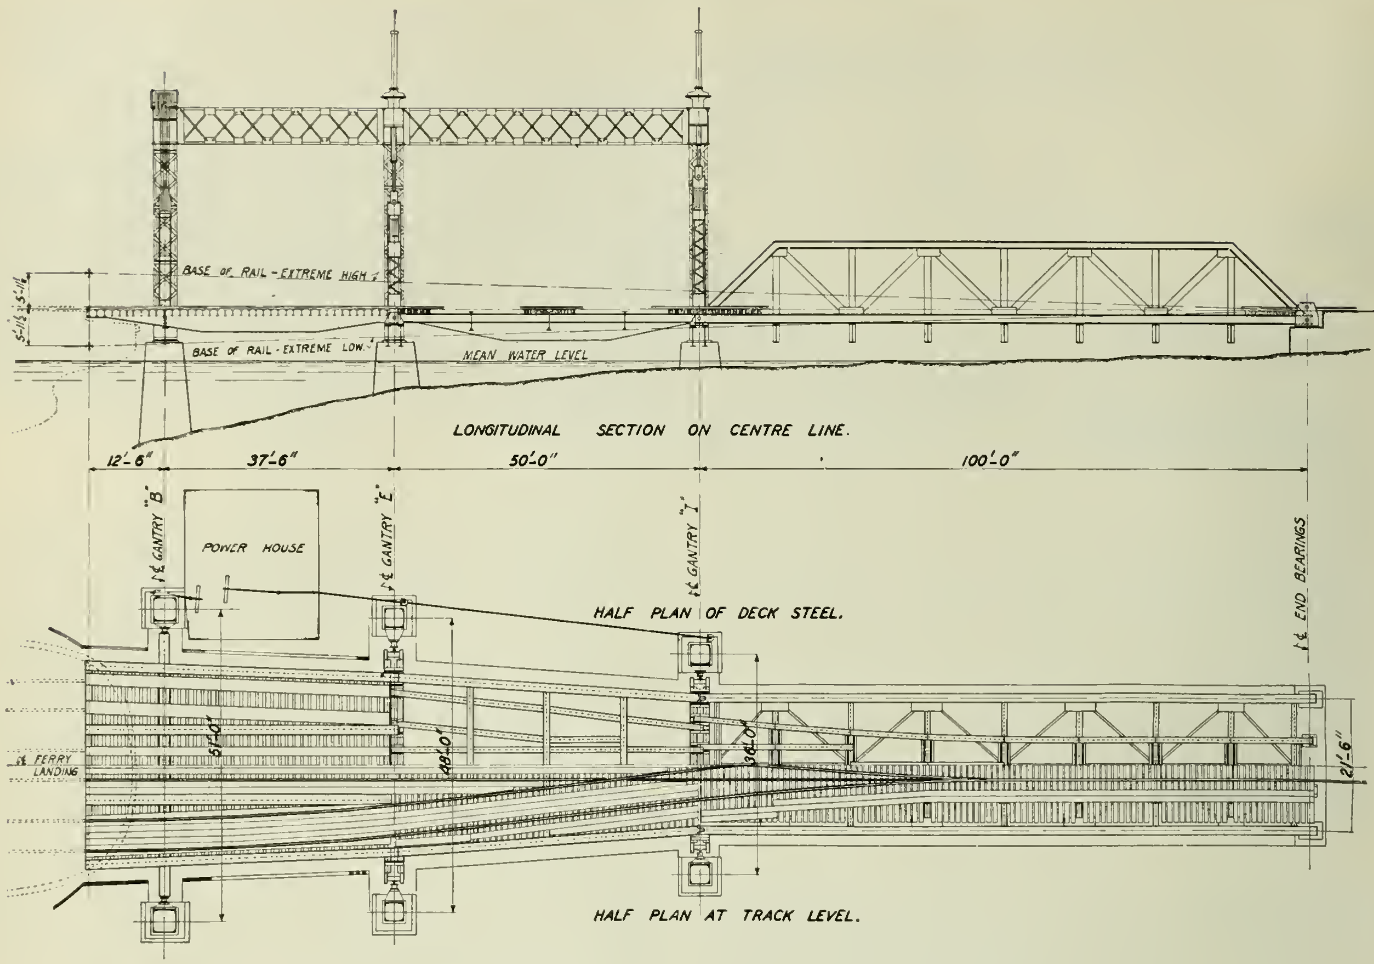

Fig. 5—Plan and Longitudinal Section through Ferry Landing.

castings at the ends, to bear against the web of the girders. They were located between the floorbeams, and spaced 3 feet apart. This construction was unsatisfactory; for many of the spacers had failed and had been renewed from time to time.

To serve as spacers in the new structure, the floorbeams at both extreme ends of the apron are connected by pins to exceptionally heavy stiffener angles, riveted to the web of the main girders. Additional spacers are provided at the middle and quarter points, consisting of substantial I-beam sections, hinged to the main girders immediately below the deck plates.

Further to increase the flexibility of the apron, the track rails are not connected rigidly to the floorbeams, but are bolted to the ½-inch deck plates only. The latter are maintained loosely in position by cleats, riveted to the top flange of the floorbeams, small vertical and horizontal clearances being provided, between the cleats and the deck plates, sufficient to permit of the slight movement between the deck plates and the floorbeams, incident to warping. In the old apron this feature of the design was similar; and the working of the floor plates had caused them to cut into the top flange of the floorbeams as much as ¼ inch. To prevent this wear, it would be necessary to connect the floor plates rigidly to the floorbeams, which was considered inadvisable because it would restrict the warping.

Stability, strength and rigidity are the main governing factors in the design of most engineering structures; but, in an apron of this type, flexibility is an additional requirement, of great importance, and the problem has been to provide a due measure of each of these qualities without sacrificing the others.

In the original structure, the main or longitudinal girders of the apron were found to be lacking in lateral stability. At the outer end, these girders were provided with spherical shoes, bearing on flat bed plates on the deck of the vessel. At the inner end, they had pin bearings in their single web, and were supported in shoes on lifter girder *E*. Owing to lack of definite transverse support, they early developed a tendency to tilt, and anxiety was felt lest they should capsize. To prevent this the railway added, near the hinged end of the girders, deep transverse struts, which were effective in preventing the girders from overturning, but were sufficiently narrow to twist and to permit of the necessary warping of the apron. Even with these struts, the main girders had developed a permanent wind, with their outer end twisted out of the vertical about one in twelve.

In the new structure, some definite measure of stability has been given to the longitudinal girders of the apron by means of double bearings at their hinged end, as shown in Fig. 10. It will be noted that the outer girders are here converted into a box section; and double bearings on the shoe pin, about 20 inches apart, are thus obtained. To serve a similar purpose at the hinged end of the inner girders, where a box section could not be used owing to the interference of the stringers of the intermediate leaf, double bearings on the pin have been obtained by the use of substantial flanged castings, riveted to the heavily reinforced web of the girders. As a result of these improvements, there is thus far no perceptible cant or twist in the main apron girders of the new structure.

The outer end of the apron is exceedingly shallow, to conform to the construction of the ferry; but it has been possible to provide sufficient resistance to vertical and horizontal shear in the main girders by outside reinforcing plates, covering the vertical leg of the flange angles, as explained in connection with the intermediate leaf.

Gantry *B*

The lifting girder at gantry *B* supports only its own weight and the dead load reactions of the apron. It is constructed with a single web, and it is made exceptionally shallow, to keep it as far from the water as possible. In accordance with the requirements of the engineer, allowance has been made for corrosion by substantially increasing its section over that required for present strength. It is entirely suspended from sheaves, carried by the gantry girder above, and is counterweighted for its dead load reactions plus or minus about 25 per cent.

As will be seen from Fig. 13, there are two counterweights for each end of this lifting girder, main and auxiliary. The auxiliary counterweights are above the main counterweights, and are suspended by cables from an operating drum at the centre of the gantry girder, by which they may be raised or lowered, or maintained at any desired height. The function of the axuiliary counterweights is to operate the apron, as follows:—When the outer end of the apron is unsupported by the ferry, the auxiliary counterweights are in contact and acting in conjunction with the main counterweights; and, the lifting capacity of the combined counterweights being greater than the dead load reactions of the lifting girder, the latter will rise when the auxiliary counterweights are lowered, and will fall when they are raised. When the vessel has been brought into position, the apron is lowered to meet the deck of the ferry; and, after the ferry has been secured to the apron, the auxiliary counterweights are raised, thereby causing a positive reaction on the ferry, equal to that produced by the dead load of the apron when supported at both ends only, less a negative reaction due to the upward force at *B* which is exerted by the main counterweights. The resulting positive reaction is sufficient to maintain the longitudinal girders of the apron in contact with the deck of the vessel at all times. The auxiliary counterweights are then raised high enough so as not to interfere with the free working of the main counterweights, which will rise and fall on one or both sides, to accommodate the angular and vertical movements of the ferry while being loaded or unloaded. On departure of the ferry, the end locks are released, and the auxiliary counterweights are lowered as far as necessary to raise the end of the apron well above the deck of the vessel.

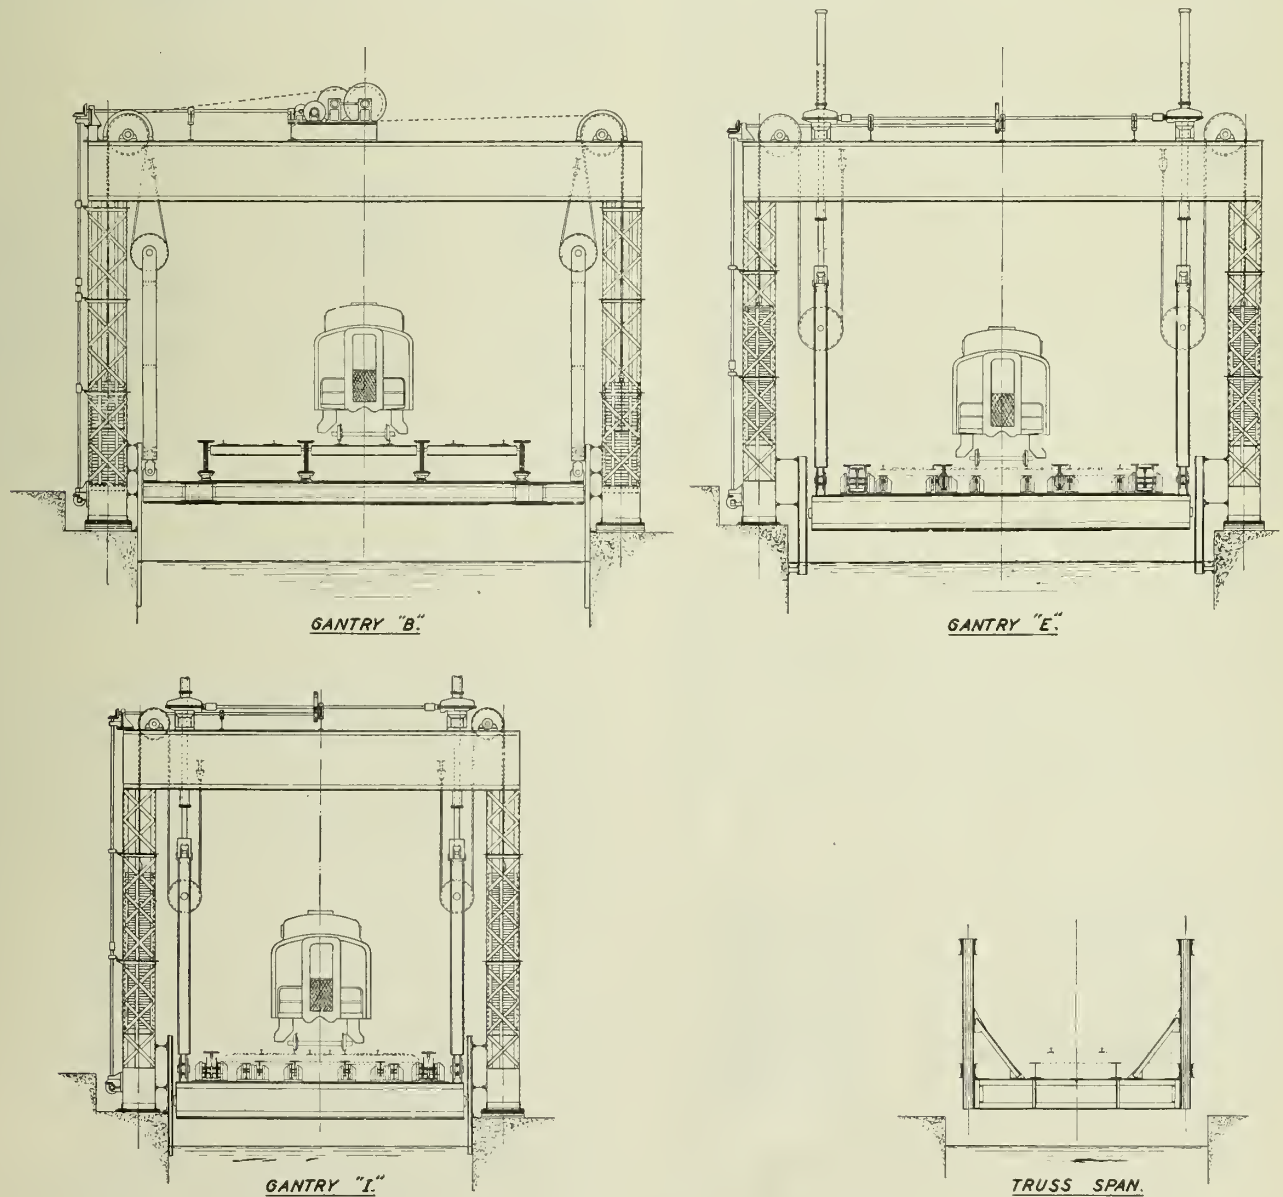

Fig. 6—Transverse Sections of Ferry Landing.

Fig. 7—View of Landing from Shore End—
Inner Leaf in Foreground.

The posts for gantry B are 45 inches square, and are composed of four corner angles with tie plates and latticing on all sides; they serve the double purpose of supporting the gantry girder with its loads and as a guide for the counterweights. The latter are composed of cast-iron slabs, measuring approximately 44 × 44 × 3 inches. The weight of each main counterweight is about 31,000 pounds and that of each auxiliary counterweight about 20,000 pounds. Provision was made for increasing or decreasing both main and auxiliary counterweights. Each main counterweight is suspended by four 1¼-inch diameter wire ropes, which pass through holes in the auxiliary counterweight; and each auxiliary counterweight by two 1¼-inch diameter ropes. The diameter of the sheaves is 48 inches. Fig. 13 is a section at gantry B, showing the inclination of the lifting girder and the deck of the apron at this point, also the relative position of the several counterweights, when the outer end of the apron is supported on the deck of the ferry and the latter is heavily loaded on one side, causing it to list. Furthermore, this view shows the main or longitudinal girders of the apron, in section, with the webs vertical, to which reference has previously been made; and one set of the hinged spacing struts.

Gantries E and I

Gantries E and I, and the lifting girders at these points, are similar to one another. In the original structure, the lifting girders at E and I were of single web design, 42 inches deep, and the flanges of the longer girder E were very heavily plated to resist the large bending moment. In order to provide for the much greater dead and live loads supported by the new structure, and to avoid using a greater depth of web plates, it was decided to use two girders at each of these locations, spaced 24 inches centre to centre, and having flanges 13 inches wide. The girders are connected at the ends by lifting diaphragms, and the top flanges are connected at points of loading. This arrangement permitted of a much better distribution of metal in the flanges, and provides ample space between the girders for inspection and painting. The sections of these girders also were substantially increased to allow for corrosion.

The lifting girders at gantries E and I are suspended by screw shafts and by counterweight cables from the gantry girders above, the counterweights being so proportioned that there will always be a positive dead-load reaction of 10,000 pounds on each screw shaft, thus preventing the possibility of an upward thrust thereon. In addition to this amount of dead-load, the screw shafts support the entire live load reactions of the lifting girders. They are raised or lowered by revolving nuts and bevel gears, but are operated only under dead-load conditions, or a load of 10,000 pounds each, plus friction.

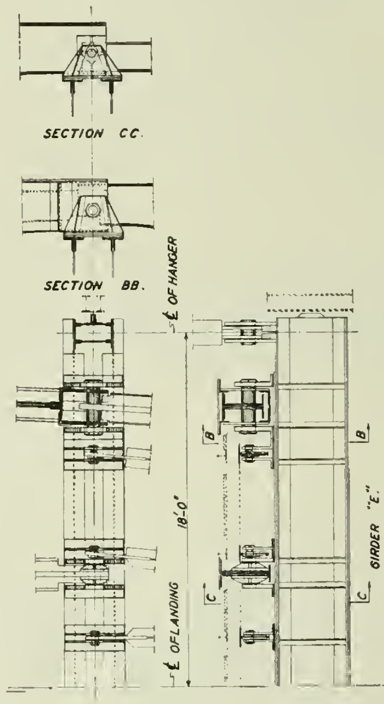

Fig. 9

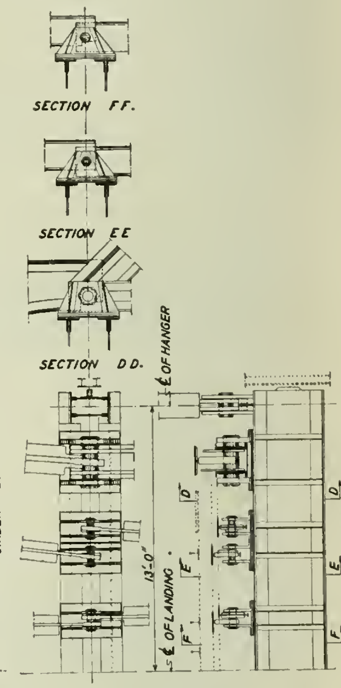

Fig. 10

Connections for Intermediate Leaf, Longitudinal Lifting Girders E and I.

The posts for gantries E and I were made 37 inches square, the same as those of the original structure, in order to use the old counterweight slabs as far as possible. They are composed of four corner angles with tie plates and latticing on all sides. The weight of each counterweight at gantry E is about 45,000 pounds; at gantry I, about 55,000 pounds, and provision was made for increasing or decreasing these weights. Each counterweight is suspended by four 1¼-inch wire ropes. The diameter of the sheaves at gantry E is 48 inches; but, at gantry I, it was impossible to use sheaves of greater diameter than 36 inches, the same as in the original structure. However, the vertical movement of the lifting girder at gantry I is infrequent and small, probably not exceeding 3 feet.

Guide rollers are provided at the ends of all lifting girders; and structural steel guides are attached to all gantry posts and supporting piers.

Mechanical Features

The ferry landing is operated by a steam-power plant, provided for the old structure and located at one side of

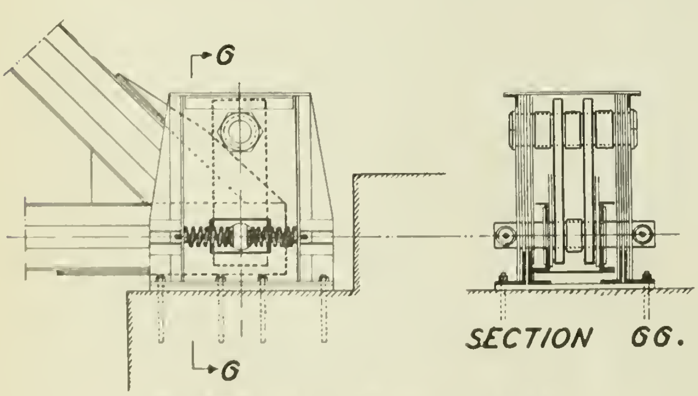

Fig. 8—Truss Span—Shoe and Buffer.

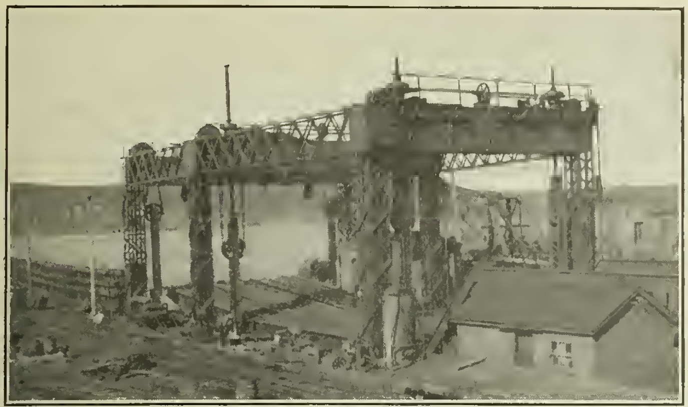

Fig. 11—Point Tupper Landing—Showing Apron and Intermediate Span.

the slip. Power is transmitted by shafting and gears attached to the steel superstructure. The apron, which requires to be raised and lowered much more frequently than the other leaves, is operated independently. On the other hand, adjustments in height at gantries *E* and *I* may be made either simultaneously or independently.

The general principles underlying the mechanical operations are the same as for the original landing, although some details have been considerably improved, due to suggestions made by the Canadian National Railways engineers as a result of their many years experience in the operation of the old structure.

The major mechanical troubles in the old structure were the wearing of the operating nuts on the screw shafts, and the breaking of counterweight ropes.

When in their lowest position, the old screw shafts were exposed to the weather practically throughout their entire length, and were consequently subject to the very bad sleet conditions during the winter, and to a great amount of dirt and grit from passing locomotives, at all times. They were made from vanadium steel, and buttress threads were used in order to avoid the bursting effects incident to the use of V-threads. For the new structure a steel was adopted which would not be so difficult to machine to a smooth surface as vanadium steel; and, because it is a better manufacturing proposition to cut a V rather than a buttress thread, it was decided to use the former. The screws are completely enclosed in an oil-tight pipe case, shown in Fig. 15, which protects them from the weather and all foreign matter. This device was rendered possible

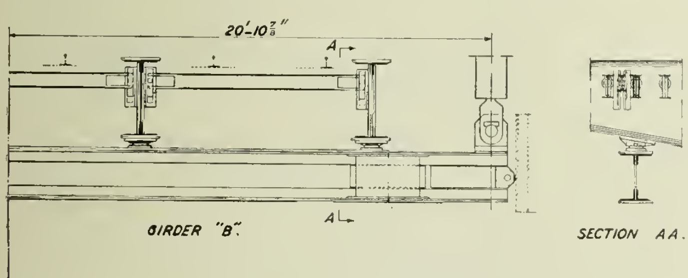

Fig. 12—Details at Apron Girder ***B.***

by shortening the connecting links between the screws and the lifting girders and by lengthening the screws a similar amount.

The new screw shafts were manufactured from a chrome alloy steel, having an ultimate strength of 100,000 pounds per square inch, which, while being reasonably capable of withstanding wear, can be readily machined to a perfectly smooth surface for contact with the bronze nut. The thread is of a modified Acme type, cut rather deeper than the standard Acme thread in order to give as much bearing area as possible on the surface of the thread. Moreover, the thread in the steel screws was made thinner than that in the bronze nuts, in order to make the strengths of these two parts more nearly equal.

The bronze nuts are supported on special bronze and hardened steel thrust washers. Ball bearings were at one time considered for this location, but it was decided that they were unnecessary, because the load under which they would be operated (10,000 pounds) is so small compared with the maximum load of 440,000 pounds which they would be called upon to sustain. Moreover, owing to the high efficiency of the ball bearings, they might revolve automatically under this great load and its vibratory effect, and thus lower the suspended structure inadvertently.

Bronzes were made in accordance with the Canadian Engineering Standards Association Standard Specification for Movable Bridges, as follows:—

Bushings.................	Grade C
Thrust Washers...........	Grade B
Operating Nuts...........	Grade D

The trouble with the breaking of counterweight ropes has been overcome by increasing the size of the sheaves as much

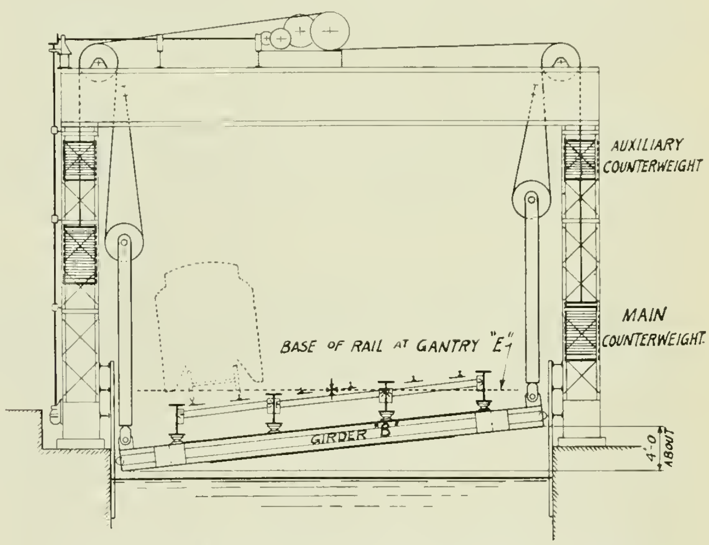

Fig. 13—Diagram showing Warping of Apron when Outside Track of Ferry is Loaded.

as possible, also by increasing the number of parts of rope to each counterweight.

General

The original ferry landings were, to a great extent, pioneers in this type of structure; and, notwithstanding some minor defects in design, they may be said to have given satisfactory service during their long life of 30 years.

The new structures are in principle and general dimensions practically the same as their predecessors; but have been modified and developed in detail where experience has shown this to be desirable.

These structures may be considered essentially as machines, rather than bridges; and, as such, wear and tear must be expected. Moreover, owing to the extremely severe conditions at the sites, corrosion must also be expected, no matter how much care may be exercised in maintenance.

Erection

The ferry service between Mulgrave and Point Tupper constitutes the sole link connecting the railways of Cape Breton island and the mainland; consequently the volume of traffic handled at this point is considerable.

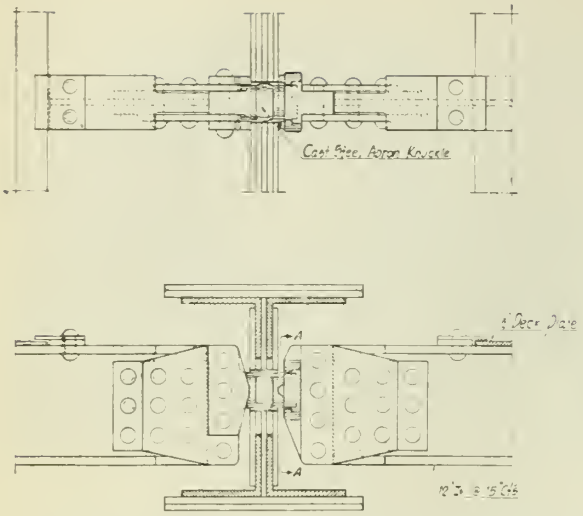

Fig. 14—Connection of Deck Beams to Apron Girders.

The flow of traffic is steady and continuous at all times throughout the week, except on Sundays, when freight movements are restricted to a minimum and no passenger trains are handled between the hours of 3.30 o'clock a.m. and 11.30 o'clock p.m.

It being entirely out of the question to interrupt traffic for any considerable period on week days, all operations which involved the replacement of the deck and floor system of the landings had to be carried out on Sundays. All other work was so planned and carried out that the loading and unloading of the ferry was not interfered with in any way.

The field operations covered a period of four months, work being commenced at Mulgrave on May 14th and the Point Tupper landing being completed by September 17th. The length of time required for doing the work was considerably increased by the requirement that traffic be maintained at all times and by the limited working periods available between trains, which necessitated all major changes being made on Sundays. In the case of the apron replacements, the choice of time was further restricted by having to select Sundays on which the times and heights of the tides were suited to the floating scheme used.

To ensure that the new spans could be speedily erected, one intermediate span was completely shop assembled, together with the apron girders, the adjoining truss chords and the transverse girders *E* and *I*. At that time slight alterations were made to provide increased clearance between some of the members where, it was considered, erection would be thereby facilitated.

Fig. 16 shows the general arrangement of the equipment, falsework and temporary operating devices used in the erection of the Point Tupper landing. As the erection procedure was practically identical for both landings, the following description of the operations at Point Tupper applies to those at Mulgrave as well.

For descriptive purposes the work may be conveniently divided into three stages: first, the replacement of the shore span; second, the replacement of gantries *B*, *E* and *I*, and third, the replacement of the apron and the intermediate span.

Replacement of Shore Span

Advantage was taken of the fact that, with girder *I* fixed in its mean vertical position, the available adjustments of the landing at gantries *B* and *E* were still sufficient to provide for all ordinary tidal ranges and for the loaded and unloaded conditions of the ferry.

Timber blocking was first placed and tightly shimmed under all floorbeams of the shore span, under the stringers adjacent to girder *I* and under the ends of girder *I* itself, as shown in Fig. 17. The operating machinery of gantry *I* was then disconnected, the counterweights were securely blocked, and their load transferred to the blocking by burning through the counterweight ropes.

The dismantling of the trusses was next undertaken, the top chords and web members being burned apart and removed as traffic conditions permitted. In preparation for the replacement of the floor system the rivets in all floorbeam and stringer connections were cut out and replaced by bolts. The bottom chords were partially burned through but sufficient metal was left to ensure lateral and longitudinal stability of the structure under operating conditions.

The actual replacement of the floor steel, bottom chords and laterals was made on a Sunday, work being commenced at 3.30 o'clock a.m., immediately after the departure of the last passenger train. With a locomotive

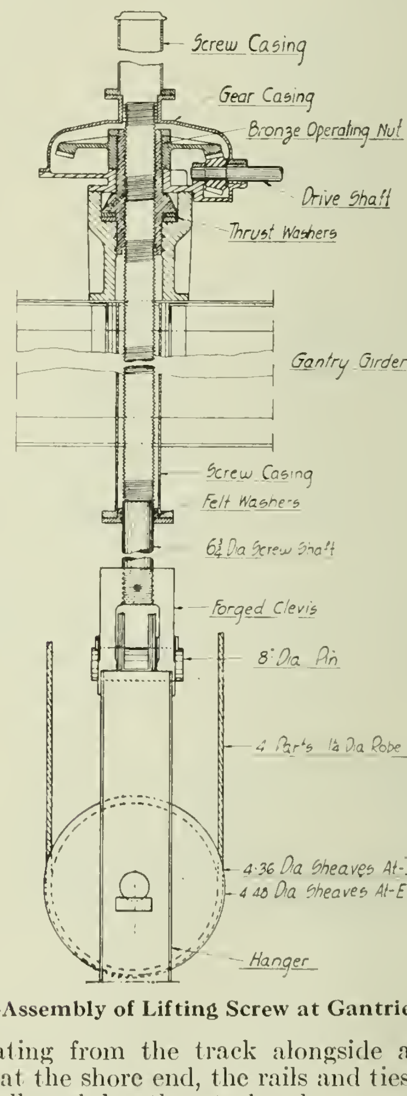

Fig. 15—Assembly of Lifting Screw at Gantries *E* and *I*.

crane operating from the track alongside and a derrick car located at the shore end, the rails and ties were quickly removed, followed by the steelwork, as rapidly as connections could be unbolted or burned apart. No attempt was made to remove the connecting pins at girder *I*, it being found easier to free the members by burning.

The old steelwork having been removed, the height of the timber blocking was altered to suit the new floor steel, which was then erected, followed by the assembly of the new bottom chords and laterals. All stringer connections were fully pinned and bolted, and the ties placed, after which the rails were relaid and connected by the Railway Company's track crew.

At Mulgrave the complete replacement of the floor system and truss chords was made in fifteen hours and at Point Tupper in three hours less, as a result of the experience gained at the former point.

The outer end of the new shore span was at this stage supported entirely on the timber blocking, its only connection to the intermediate leaf being through the track rails, therefore extra precautions had to be taken when mooring the ferry to prevent any excessive shock being transmitted to the landing.

The erection of the shore span was completed by the assembly and riveting of the truss web members and top chords and the riveting of the floor steel, which was done as traffic conditions permitted.

Replacement of Gantries *B*, *E* and *I*

The order of replacing the three gantries was predetermined by the manner in which the existing counterweights were to be utilized in the new and heavier structure.

For the new landing, entirely new counterweights, somewhat different in design from the old, were provided at gantry B, and the old blocks from this point were used to make up the additional weights required at gantries *E* and *I*. As the superstructures of the gantries could not be assembled until the counterweights were in place, it was necessary to dismantle the old gantry *B* to obtain its counterweights, before the new gantries *E* and *I* could be completed.

Gantry *I*, being entirely disconnected from the landing, was first dismantled, and new gantry posts erected and securely guyed in position. The old counterweights were then placed and blocked at a predetermined elevation to provide for the future connection of the gantry hangers to the new girder *I*, which had to be placed under the end shoes of the shore span.

Before gantries *B* and *E* were removed, it was necessary to provide temporary devices for raising and lowering the landing at these points.

As shown in Fig. 18, pile bents were first driven on either side of girder *B* close to its ends. Owing to the limited railway clearance inside the gantry it was necessary to locate these piles close to the gantry posts and in line with the hangers, which prevented the piles being capped until the hangers had been removed. To permit of this being done, the ferry was moored in position and the outer end of the apron lowered on to it. The counterweights were then blocked, and the hanger rods burned through, thereby transferring the weight of the apron to the ferry.

The hangers were then removed and the piles capped, after which heavy tackles (consisting of 5-sheave steel blocks with 9 parts of ⅞-inch diameter wire rope) were suspended therefrom, their lead lines being carried through a series of snatch blocks to a hoisting engine, located alongside the slip.

These tackles were connected by heavy lashings to the apron, which was then raised and the ferry released. During the period necessary for the replacement of gantry *B*, the apron was operated by means of these tackles.

The existing gantries *B* and *E* having been securely shored and guyed for stability, their connecting struts were removed and gantry *B* was completely dismantled. The

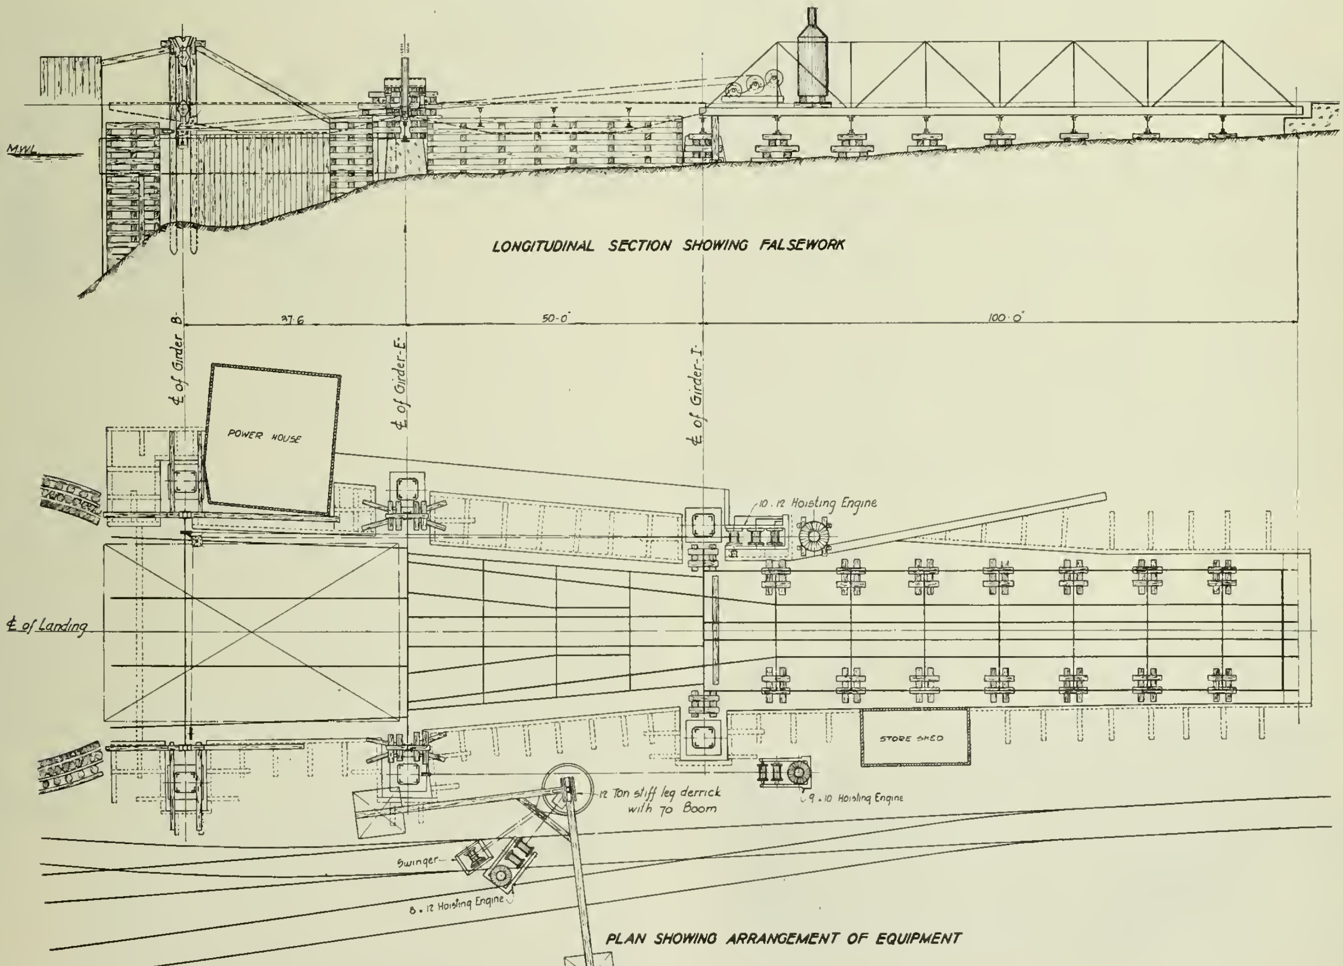

Fig. 16—Plan showing Arrangement of Erection Equipment and Falsework.

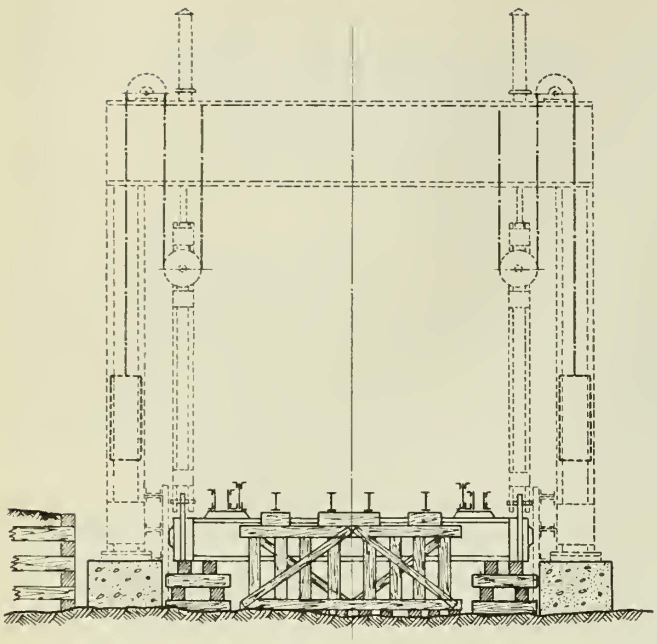

Fig. 17—Temporary Blocking under Girder *I* and Stringers of Truss Spans.

new gantry was then erected, complete with its machinery, hangers and counterweights. The temporary operating tackles were removed and the new hangers connected by means of special links to the old apron, the ferry being again utilized to support the apron during this operation. As the new counterweights were heavier than required to balance the old apron, additional steel was placed on the outer end of the apron to make up the difference, and the apron was operated thereafter through the new machinery.

The old counterweight blocks from gantry *B* being now available, the necessary number were added at gantry *I*, after which its superstructure and machinery were completely erected.

To provide for the raising and lowering of girder *E*, after the gantry at this point had been disconnected, two 50-ton capacity jacks were installed at each end of the girder. This arrangement is shown in Fig. 19. The jacks were set on timber cribbing and operated against temporary jacking girders, which were inserted through the hangers and bolted to them. At these points, timber blocking was also provided to carry both the live and dead

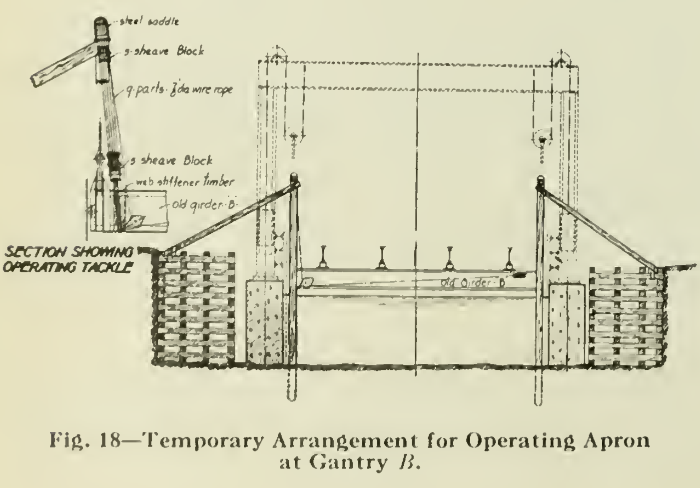

Fig. 18—Temporary Arrangement for Operating Apron at Gantry *B*.

load of the landing when jacking was not actually in progress.

To transfer the load to the jacks, the counterweights were blocked in their posts, girder *E* was jacked up an amount sufficient to release the load on the ropes and the hangers were then burned through immediately above the jacking girder connections.

During the replacement of gantry *E* it was necessary to maintain a jacking gang practically twenty-four hours a day to regulate the elevation of girder *E*, as required. Therefore the old gantry, with its operating machinery and counterweights, was removed and the new one erected as speedily as possible. After the machinery had been placed and tested, the new hangers were connected to the old girder, by means of the special yokes shown in Fig. 20 and the operation of this girder was thenceforth done through the machinery.

Replacement of Apron and Intermediate Span

The replacement of the apron and the intermediate span involved the removal of approximately 200 tons of old steel and the erection of 250 tons of new steel in one day. At first glance, it had appeared advisable to divide this work into two distinct operations to be undertaken on separate days. However, further investigation showed that

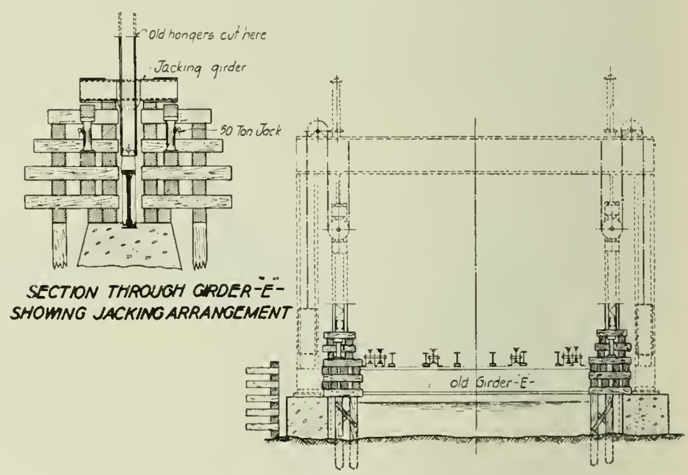

Fig. 19—Temporary Arrangement for Operating Landing Gantry *E*.

the interlocking features of the two spans provided many complications in such a scheme and it was decided to replace the two spans in the one operation.

The apron consists of an intricate structure, made up of a large number of separate pieces whose assembly in place would have proven extremely difficult, if not impossible, in the limited time available. It was therefore decided to assemble it in advance and float it into position as a unit. On this basis, falsework was erected in a nearby slip, alongside of which a railway track was conveniently located. Here the apron, together with girder *B*, was completely assembled and riveted, the deck plates were added and the new track rails placed and bolted in their final positions. To facilitate the connection of the apron to girder *E*, the supporting shoes from the latter were assembled with their pins to the apron girders.

As the replacement of the apron and intermediate spans had, of necessity, to be made on a Sunday, when the heights and times of the tides would be suitable for the floating operations, the actual date was chosen well in advance and all preliminary work was carefully scheduled to ensure its completion before that date. Early in the field operations, tide gauges were installed at the site and regular readings were taken and compared with the available tidal data for that locality. In this way, sufficient information was gathered to indicate clearly in advance what conditions would prevail during the floating operation.

Prior to the date of the actual replacement, all preliminary work was completed. The rivets in all connections of the intermediate span were cut out and replaced by bolts, jacks were installed under the counterweights in gantries *E* and *I* and heavy auxiliary tackles were hung from gantries *B* and *E*, their leads being carried to two steam hoisting engines located nearby. All new steelwork was sorted and carefully checked, the new deck ties were framed and the track spikes of the intermediate span were removed in so far as this could be safely done.

Two days in advance of the replacement, at low tide a scow was floated into position under the new apron, blocking was adjusted and by means of the rising tide the apron was lifted from its falsework. The scow was then moored in the slip and additional weight was added to obtain the desired trim.

Fortunately on the days chosen for the operations, both at Mulgrave and Point Tupper, the weather and tidal

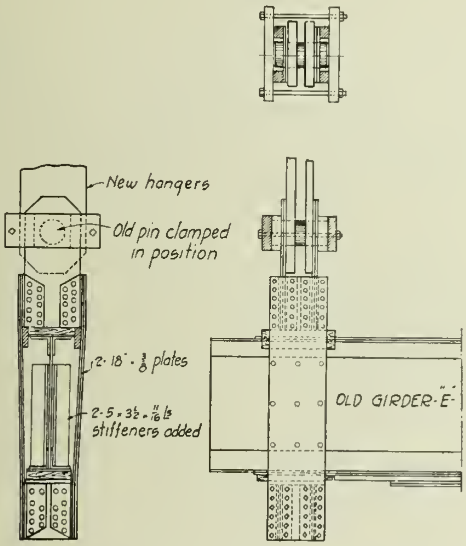

Fig. 20—Temporary Connection between old Girder *E* and new Hangers.

conditions proved to be ideal and the work was commenced at 3.30 o'clock a.m. when the landing was cleared of traffic.

The first operation consisted of bringing the new girder *E* out onto the landing and suspending it by tackles from gantry *E* (as shown in Fig. 21) in such a position that, after the removal of the old steel, it could be lowered and connected directly to its hangers. This procedure was necessitated by the fact that the girder, which weighed 26 tons, was too heavy to be placed by the locomotive crane from any position other than standing on the tracks of the landing itself.

The intermediate span was then quickly stripped of its deck and the existing steelwork, including girders *E* and *I*, removed as rapidly as the connections could be unbolted. Both the locomotive crane and stiffleg derrick were used in this work.

Meanwhile the removal of the old apron had also been commenced. On the rising tide a scow was floated underneath the apron, and blocking was adjusted on the scow.

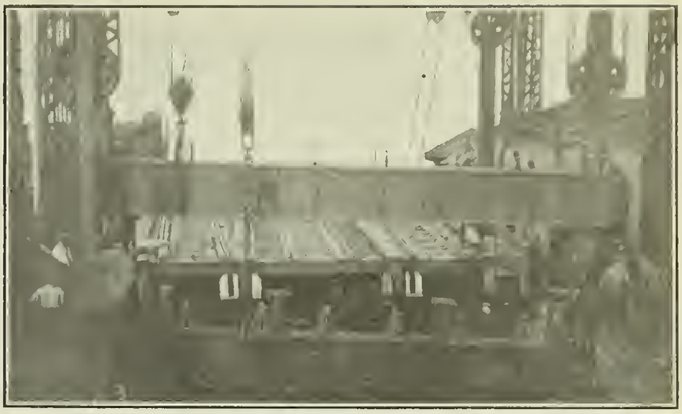

Fig. 21—Removing old Girder *E*. New 26-ton Girder suspended from Overhead Gantry.

The apron was disconnected from girder *E* by burning through the longitudinal girders close to their ends and the transverse girder *B* was disconnected and shortened by burning 5 feet from each end, to permit it to clear the sides of the ferry slip as the apron was being floated out. (See Fig. 22.)

A tug, which had been chartered for the occasion, then took the old apron in tow, removed it from the ferry slip, and shortly afterwards returned with the new apron which was moored in readiness to be connected. The old apron was later transferred to the falsework on which the new one had been assembled and there burned apart for disposal.

The design of the landing is such that it was necessary to connect the apron to girder *E* before the outside girders of the intermediate span could be placed. By the time the old intermediate span had been all removed and the new girder *E* had been lowered and connected to its hangers, the apron was floating in position ready to be connected. So well did the operations coincide with the tide at this stage, that the shoes on the apron girders were within one inch of their correct elevation with respect to girder *E* and it was a simple matter to connect them. (See Fig. 23.)

The length of girder *B* being considerably greater than the width of the ferry slip, field splices had been provided, 5 feet from each end, to permit it to be floated in with the assembled apron. Immediately the apron was floated into position, the end sections of the girder were assembled and the splices fully pinned and bolted.

By the time this work was completed the tide had fallen sufficiently to permit the release of the scow which was done by raising the outer end of the apron on the tackles at gantry *B* and by knocking out the blocking under the shore end.

Fig. 22—Old Apron with Girder *B* being floated out.

Fig. 23—Apron connected to Girder *E*. Note Shoes for connection of Intermediate Span Girders and Springers.

After the removal of the scow, the apron was again lowered, the pins which connect the hangers to girder *B* were driven and the temporary tackles removed from gantry *B*. By means of the operating mechanism, the apron was lowered to release the counterweight blocking which was then removed.

Meanwhile, the old intermediate span having been completely dismantled, the new girder *I* was lowered under the end of the shore span and connected to its hangers, which, as previously indicated, had been set slightly low with respect to the truss span. Girder *I* was then raised by means of the jacks set under its counterweights (at the same time the adjusting screws were slacked off to prevent them from taking any load) until the truss shoes were in contact with the girder. Most of the adjoining members of the shore span were immediately connected to the girder, but as some of the connecting pins also engage stringers of the intermediate span, these were driven later as the adjoining stringers were erected.

As shown in Figs. 9 and 10, the girders of the intermediate span are carried at either end on pins which also carry the outside girders of the apron and the trusses of the shore span respectively. The pin holes of the intermediate span girders are slotted and the details to which they connect are especially designed to permit of the girders being lowered onto their pins after the adjoining members have been permanently connected. After these girders were placed, the remaining steelwork was erected, the floorbeam and stringer connections being fully pinned and bolted. Girder *I* was then jacked up an amount sufficient to release the blocking under the shore span, and then jacked down to transfer the load to the counterweight ropes, after which the jacks were removed. The deck ties were quickly placed and the Railway Company's track crew proceeded to relay and connect the rails.

The replacement of one apron and intermediate span, involving the handling of over 450 tons of steelwork and the replacement of 300 feet of track in a period of twenty hours between trains, was a considerable undertaking but the work was so organized and carried out that the operations were completed well within the time limit.

At Mulgrave, the steel was completely erected in sixteen hours and the tracks were reconnected two and a half hours later. At Point Tupper the steel was erected in twelve hours and the tracks were reconnected five hours before the first train was due.

This operation practically completed the erection, apart from the riveting, painting and other incidental work of a minor character.

Fig. 24 illustrates the progress of the work in this final stage and demonstrates the manner in which the tide was utilized for the various floating operations.

The total weight of steel in the two landings amounts to 1,305 tons, made up of 865 tons of structural steel, 130 tons of machinery, wire rope, etc., and 310 tons of counterweights. Approximately 19,000 ⅞-inch diameter rivets were driven in the field connections.

Erection Equipment

The landings were erected chiefly by means of a 30-ton capacity locomotive crane assisted by a 12-ton capacity stiffleg derrick with 75-foot boom, set up alongside the landing. A 50-foot self-propelling derrick car with two 10-ton capacity booms was used to handle material in the yard and to assist generally in the erection.

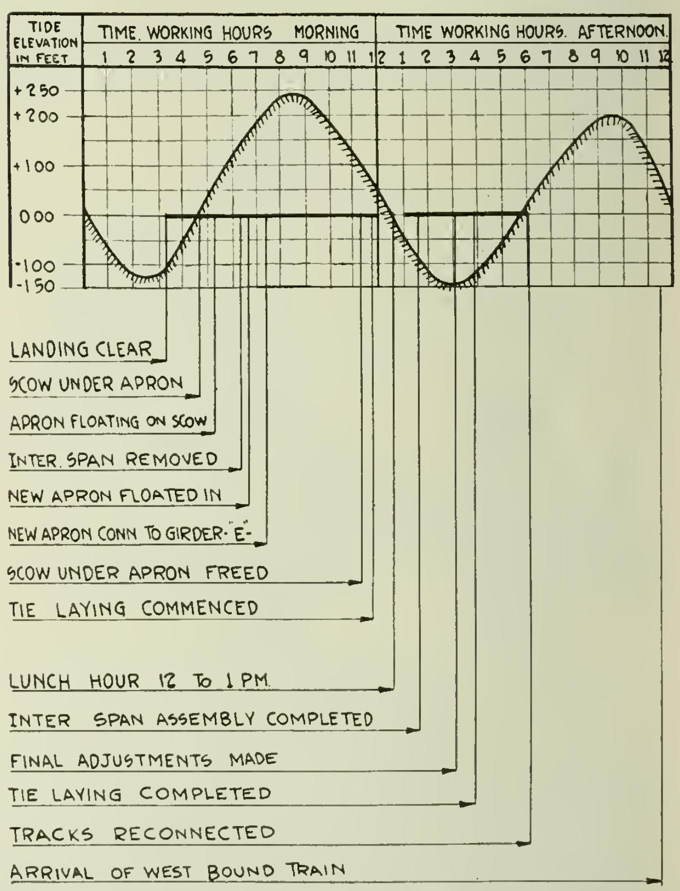

Fig. 24—Diagram showing Progress of Work in Final Stages.

To operate the derrick and the various tackles used, three independent steam hoisting engines of various capacities were provided. The two specially built wooden scows used in the floating operations were each 50 feet long, 30 feet wide and 6 feet deep.

Structure and Oil Prospects of the Eastern Foothills Area, Alberta, between the Highwood and Bow Rivers[1]

Dr. G. S. Hume,
Geological Survey, Department of Mines, Ottawa, Ont.

Paper to be presented at the Annual General and General Professional Meeting of The Engineering Institute of Canada, Montreal, Que., February 4th, 5th and 6th, 1931.

SUMMARY—The Foothills are considered to be an overthrust mass thrust eastward onto the relatively flat-lying sediments of the plains. Low angle faults are known to underlie such structures as Turner valley, Jumpingpound and Wildcat hills and another low angle fault probably underlies the Highwood structure and its extension to the northwest through Waite valley, Fisher creek and the Two Pine area. The Highwood anticline is believed to be too wide and to consist of too many high structural blocks to yield large oil fields although the prospects are by no means exhausted. Fisher creek and the Two Pine structure each containing one high structural area in the central part of the anticline would be expected to cause a much better concentration of gas and oil than a wide structure and are hence thought to be favourable locations for test wells. The whole Foothills belt is considered to be structurally similar to the foothills of the Polish Carpathians where large oil fields have been developed.

The foothills of Alberta occupy a belt of country 12 to 25 miles wide, extending from the international boundary to north of the Peace river. For the most part they consist of parallel ridges trending in a northwest and southeast direction, with elevations increasing from east to west from 3,500 feet to more than 5,000 feet, and with individual ridges rising as much as 1,000 feet above the intervening valleys. The valleys are generally narrow, but fairly flat areas a mile or so in width are not uncommon. The boundary with the mountains to the west is sharp, but the eastern edge is much less clearly defined, and the foothills gradually merge into the gently undulating plains. The main lines of drainage cut across the foothills from the mountains to the plains and in all cases occupy well-defined valleys in which the rivers flow in deeply incised channels, offering many opportunities for the development of water power plants such as have now been constructed on the Bow river at Kananaskis and Ghost rivers.

In order to appreciate fully the geology of the foothills intermediate between the mountains and the plains, it is necessary to understand something of the character of the geological formations and the nature of the geologic processes to which they have been subjected. The following description however, will apply only to that area between the Bow and Highwood rivers (Fig. 1), where in the last few years the writer has been engaged in geological investigations for the Geological Survey of Canada. Briefly the succession of geologic formations in descending order is as follows:

Eras	*Periods*	*Formations*
Tertiary	Eocene	Paskapoo
Mesozoic	Cretaceous	Edmonton
		Bearpaw (not always present)
		Belly River
		Upper Alberta shale (Upper "Benton")
		Cardium
		Lower Alberta shale (Lower "Benton")
		Blairmore
		Kootenay
	Jurassic	Fernie
Palaeozoic		Limestones, dolomites, shales, etc.

All formations here indicated are sedimentary, and no igneous or volcanic rocks occur, although in the southern foothills the latter occur in the Crow's Nest pass area. These sediments were originally deposited in a big basin or geosyncline extending from Manitoba westward and including the Rocky mountains. For long intervals this basin was occupied by an arm of the sea which in certain periods extended from the Gulf of Mexico to the Arctic ocean. The sediments deposited in this sea trough were mainly limestones and shales, and evidences of marine life are found throughout a thick series of limestones and shales in the Palaeozoic, as well as in shales in the Fernie, Alberta shale and Bearpaw formations. At other times the basin was above sea-level and detrital materials consisting of pebbles and boulders (conglomerates) and sand with small amounts of mud (shales) were washed into it by fresh water. These sediments now constitute the formations which we call Paskapoo, Edmonton, Belly river, Blairmore and Kootenay. Undoubtedly during part of this time the basin was occupied by brackish water, and in the swampy shallow lagoons plants grew in great profusion, forming the beds which were later metamorphosed into the coal seams that occur in the Edmonton, Belly river, Blairmore and Kootenay formations and are now extensively mined in Alberta and eastern British Columbia.

The sediments represented in this great deposition are many thousands of feet thick and must have formed a great weight on the earth's crust, eventually weakening it to the point where it was no longer able to withstand the earth's stresses. In the readjustment the pressure was

applied from the west to the east, the western part being uplifted into mountain ranges, and the sediments being broken into large blocks which were thrust over the sediments lying to the east. These in turn were crumpled and broken and forced still farther eastwards. The lines of fracture along which blocks of these sediments moved eastward are known to us as thrust faults, and in many cases the displacement is measured in miles. The Bannock overthrust in southeastern Idaho and Utah for example, has been traced by Mansfield of the United States Geological Survey for a length of 270 miles and has a displacement of 12 to 35 miles. The present mountain front is the result of erosion on a large overthrust of this type and consists of limestones of Palaeozoic age that have overridden younger rocks to the east. East of this mountain front is a crumpled and broken zone which we call the foothills, and it was not until recently that it was realized that the whole foothills area is underlain by a low angle major thrust plane along which the sediments have been pushed onto the relatively flat-lying sediments of the plains. In this movement the strata composing the foothills were highly contorted and were broken into many fault blocks. (Fig. 3.) These fault blocks have in general a westward dip and each succeeding fault block to the west is pushed over the adjoining one to the east. The faults that separate the individual fault blocks are considered to be subsidiary to, and join the major low angle thrust at depth. It is probable, however, that in the foothills there are several major low angle thrusts, between each of which are fault plates of highly folded and faulted strata. This is the type of structure best known in the Alps, but occurring in the Carpathians, in the Highlands of Scotland and in America in the southern Appalachians and Ouachita mountains. The low angle faults are commonly called sole faults in Scotland, and the block between two such faults is known in the Alps as a "decke" or "nappe."

The recognition that a low angle thrust fault underlies the whole foothills belt came from a study of well logs in Turner valley, which is on the eastern edge of the foothills. The Turner valley field is an anticline in which a central valley exposing Alberta shale ("Benton") is bounded by ridges of Belly river strata which on the west and east sides have westerly and easterly dips respectively. This anticlinal structure, however, is in reality a drag fold developed above the low angle thrust plane and was caused by the resistance to eastward movement along the fault plane. The strata of the eastern edge, as the block was shoved easterly along the fault plane, have been buckled under, and the fault plane emerges at the surface at a fairly steep angle (probably 65 to 75 degrees from the horizontal) although the fault plane to the west may have a dip of not more than 20 degrees. (Fig. 3.) The strata west of the line of emergence of this fault are steeply tilted, whereas east of it fairly gentle dips are prevalent. This fault, therefore, may be considered to be the boundary between the foothills and the plains. Several wells in Turner valley have drilled through this fault, two wells after penetrating Palaeozoic limestone for a considerable thickness passed into Cretaceous beds which are much higher stratigraphically. Another low angle fault occurs in the New Black Diamond area a few miles west of Turner valley, and this fault at depth is known from drilling to have a westward dip of about 20 degrees. The area between the low angle fault under Turner valley and the low angle fault under the New Black Diamond area might for convenience be called the Turner valley fault plate or nappe. This nappe is itself folded and faulted and within the width of Turner valley there may be no less than four thrust faults which join the low angle fault at depth.

No discussion can be made here of the relation of gas and oil in Turner valley to this complicated structure, as the object of this paper is to discuss the prospects for gas and oil in the eastern foothills adjoining Turner valley. It is sufficient for this purpose to know that Turner valley is producing large quantities of gas and oil and the question arises: are structural conditions duplicated elsewhere.

The major low angle fault under Turner valley has been traced northwestwards from Turner valley to Bow river where it ends. (Fig. 1.) Another fault to the east of it starts south of Bow river and has been traced northwestward for some miles. To the south of Turner valley another fault west of the Turner valley fault becomes the low angle thrust under the Highwood area. Thus although we are not always dealing with the same fault we are dealing with the same faulted conditions, and the evidence points to the whole foothills belt in this general area being underlain by such a low angle fault. In the area between Highwood and Bow rivers the Turner valley fault passes to the east of the Jumpingpound anticline just south of Bow river and this structure like that of Turner valley is a drag fold developed above the fault plane. Two wells have been drilled on the Jumpingpound structure, starting in strata of the same age as occur in Turner valley. It has been found, however, that whereas the low angle fault in Turner valley cuts below the top of the Palaeozoic limestone productive of gas and oil, the fault in the Jumpingpound wells cuts much nearer the surface, and the wells passed through it without reaching the productive limestone horizon. As this low angle fault is believed to cut lower stratigraphical beds as it passes westwards, there is a possibility that the limestone might be reached above the low angle fault on the west side of Jumpingpound structure. Wells to test this would be very deep and hence may not be justified under present conditions. Of the two wells drilled on the Jumpingpound anticline, one was drilled on the eastern flank and the other about the centre of the structure. Thus although the Jumpingpound anticline is believed to be the same type of structure as Turner valley, it differs in detail sufficiently to cause the eastern and central part to be of no value from the standpoint of gas and oil prospects.

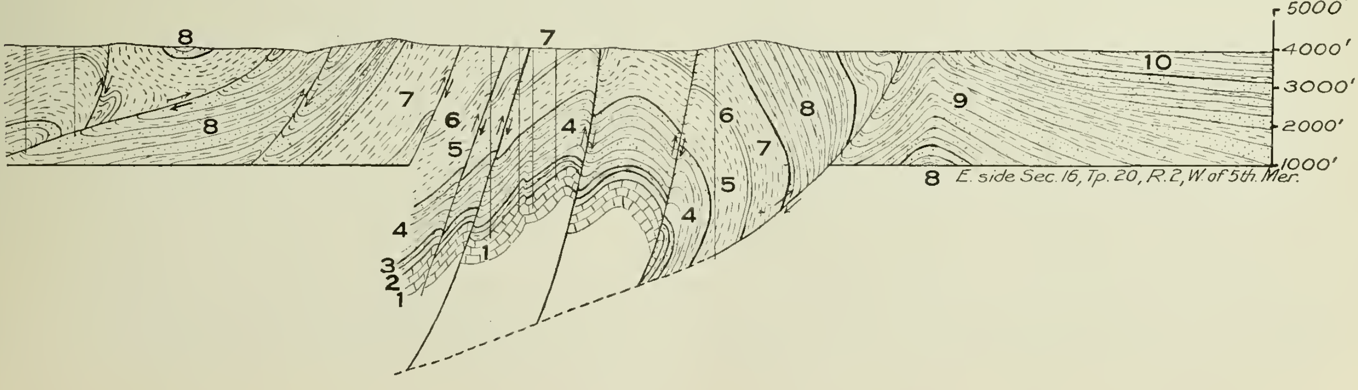
The Wildcat hills anticline to the north of Bow river is outside the area under discussion but here again is a structure similar to Jumpingpound and Turner valley. In this case, however, the fault cuts under the structure even higher than at Jumpingpound and hence prospects are negative.

To the south and west of Turner valley is the Highwood anticline area. A low angle fault cuts under the Highwood area and hence structurally the Turner valley conditions are again duplicated. Erosion over a great deal of the Highwood area has been much deeper than in Turner valley with the result that Blairmore and lower Alberta shales are exposed over wide areas. Four wells have been drilled in the Highwood area and all have penetrated the Palaeozoic limestone, two reaching this horizon at less than 2,500 feet. Three of these wells gave shows of oil but in all three salt water was encountered. Under normal conditions salt water is found in all oil fields underlying the oil and gas on the flanks of the structure. The presence of salt water when studied in reference to the structure in the Highwood area indicates that if commercial oil pools exist here they will be confined to rather limited areas.

In view of all this adverse evidence one may well ask if this area between the Highwood and Bow rivers offers any favourable oil prospects. The answer, in the writer's opinion, is still decidedly in the affirmative and is based on the following considerations.

The Highwood anticline is a very broad structure. Between the flanking Belly river ridges which are considered to be the boundaries in the Turner valley structure the Highwood anticline on Highwood river is 6 miles wide. Within this, faulting has brought to the surface several areas exposing Blairmore strata. Each of these Blairmore areas represents a local structurally high area within the anticline. The shows of oil found in the wells drilled would seem to indicate that the oil may be distributed among a number of these locally high structural areas and there has not been a sufficient concentration in any one area to yield commercial supplies. A narrower anticline where a much better concentration into one high structural area could occur, would, therefore, look exceedingly promising. Between the Highwood and Bow rivers there are two such structures namely Fisher creek and the Two Pine anticline (Fig. 1), both of which were mapped by the Geological Survey and both of which are now being tested. Both of these anticlines are parts of one major anticline which on the Highwood includes the Highwood anticline and extends northwestward for 40 miles to Jumpingpound creek. This anticline is not everywhere of the same structural height. The Highwood area, extending northwest to the south end of Waite valley where the Calgary Development and Production Company's well is now drilling, is structurally high. Waite valley, where several wells were started, all of which are now abandoned or suspended, is structurally low. To the north of Waite valley is the structurally high Fisher creek area. Northwest of the Fisher creek area and south of Elbow river is another structurally low area, and north of Elbow river and south of Jumpingpound creek the Two Pine structure occurs. In the Fisher creek and Two Pine areas the Blairmore formation is exposed mainly in one large block and the anticline between the flanking Belly river is much narrower than on Highwood river. These two areas would seem, therefore, to have the necessary conditions favouring the concentration of any oil and gas that was present and from our knowledge of structural conditions are the most favour-

Fig. 3



able untested areas in the section of the eastern foothills under discussion. Drilling in the Highwood area has yielded shows of oil and the presence of salt water horizons may also be taken as evidences of porosity. If porous rocks that could act as reservoirs for gas and oil are present in the Fisher creek and Two Pine areas (and there is every reason to expect such will be the case) and if the gas and oil is sufficiently concentrated, as would be predicted from the character of the structure, the results of drilling should prove highly interesting. In narrow structures the presence of low angle thrust faults which thrust lower stratigraphic horizons over higher ones is always a menace, but it would appear from present data that the Fisher creek area in particular is fortunate in this regard and is wide enough to avoid striking low angle thrusts of any magnitude provided the wells are properly located. (Fig. 2.) The first location being drilled in the Fisher creek area is on the west side of the structure. If this well should prove to be too far down the west flank and strike salt water, a second well further east and higher structurally will be justified. Four gas seepages occur in close proximity to this well, which commenced drilling on Blairmore beds. It is thought the Palaeozoic limestone will be reached at a depth of 2,000 to 2,500 feet, which contrasts very favourably with wells in Turner valley where the limestone occurs at a depth of 3,500 to 5,000 feet or even deeper.

In the Two Pine anticlinal area Signal Hill No. 2 well is now drilling at a depth of 4,090 feet (October 11th). The well is located at a considerable distance down the west flank of the anticline.

The Calgary Development and Production Company well, the Cottonbelt well in the Fisher creek area and the Signal Hill well are considered to be the most important tests now being made outside of Turner valley in the eastern foothills between Highwood and Bow rivers. It can safely be said that the results of these wells will have a large place in the future of oil prospecting in the foothills.

Oil Fields in Structures Similar to the Foothills

One may well ask, are there oil fields in other parts of the world where structural conditions are similar to the foothills of Alberta. To answer this question reference should be made to Report III of the Federal Oil Conservation Board to the President of the United States, from which the following quotations are taken from the description of the oil fields in the foothills of the Carpathian mountains.

"The Polish Carpathians are characterized by a roughly parallel series of extensive overthrust faults, the overthrust mass of each fault overriding that of the fault to the north. In places the overthrusting has been so intense that two, if not more, overthrust masses lie upon one another. Such intense overthrusting has generally caused intense folding with much minor faulting. The resultant anticline and synclines range from gently symmetrical to highly overturned and recumbent folds, some of which are ruptured along the crest and grade into overthrust faults. In the steep overturned and overthrust folds of the Carpathians with their alternating beds of porous sandstone and impervious shale, petroleum natural gas and mineral wax or ozokerite have been produced in Galicia in a belt about 270 miles long and about 30 miles wide, commencing near Cracow and extending in an arc almost to the eastern boundary of Poland. Over 70 per cent of the oil produced in Galicia, however, has come from an area comprising 9½ square miles. This area includes the Boryslaw-Tustanowice-Mraznica field, which has produced from 1898 to the end of 1927 about 20,517,800 metric tons (approximately 100,000,000 barrels) of petroleum, exclusive of a considerable amount of oil which is burned at the wells for fuel or wasted. The oil-bearing anticlines range from gently to steeply overturned folds, and these may form parts of the overthrust masses at the surface or of the overridden masses lying beneath one or even two or more overthrust faults. The crude oils of Galicia vary in gravity from 53.5 degrees A.P.I. at Bitkow to 25.5 degrees A.P.I. at Harklowa."

From the above description it will at once be evident that the structural conditions in the Polish fields are analogous to the structural conditions found in the foothills of Alberta. The comparison, however, in regard to other conditions should not be carried too far, as the oil in the Polish fields comes mainly from Tertiary strata, whereas the oil-bearing formations of the foothills of Alberta are Mesozoic and Palaeozoic, which might be expected to carry more gas and a higher grade of oil, as is the case in Turner valley.

Acknowledgments and Conclusions

The data for this paper have been collected from several years geological work in the foothills of Alberta and from data collected from many sources of which it has not been possible to make detailed acknowledgments. Much of the data on the results of wells has been secured through the supervisory engineer's office in Calgary, and the comparison with the Carpathian structures was first suggested to the author by T. G. Madgwick. From time to time the problems of foothill structure have been discussed with the geologists of various oil companies drilling in western Canada and particularly with the geological staff of the Imperial Oil Company, to whom as well as to the geologists of other companies the writer wishes to express his thanks.
It seems highly improbable that Turner valley will be the only productive field in the foothills and although the search for oil has been long and expensive it is believed we are approaching the time when the application of our knowledge of the extremely complicated structural conditions will yield favourable results. In comparison with the country as a whole, oil fields are of very limited extent and difficult to locate, and although the results of the many wells drilled in the foothills outside of Turner valley may superficially seem like a condemnation of the oil prospects, it is believed that in selected areas outlined by careful and detailed geological work the search for oil will eventually lead to abundant rewards.

Automatic Block Signalling on the Canadian Pacific Railway

A. J. Kidd,

Assistant to Signal Engineer, Eastern Lines, Canadian Pacific Railway Company, Montreal.

Paper to be presented before the Annual General and General Professional Meeting of The Engineering Institute of Canada, at Montreal, February 4th, 5th and 6th, 1931.

SUMMARY.—Railway signalling, which was originally developed in Britain on the semaphore system, has undergone many changes, largely due to the application of mechanical or electrical power for signal operation. The automatic feature, based on the idea of a track circuit, was conceived in 1872, and from that time the progress in automatic signalling for the control of trains has been continuous. To take full advantage of the track circuit system, power operated signals are a necessity, and these were at first disc or semaphore signals moved by electric magnets and motors. These are now being replaced by coloured light signals, in which the indication is given by a brilliant light both by day and night. Designs have now been perfected so that the beam has an effective range of vision of from three to four thousand feet in bright sunlight.

Modern signalling systems, which increase operating efficiency by speeding up traffic and avoiding collision and other hazards, involve the division of a railway into a series of sections governed by automatic signals. The most recent development of this automatic block system provides for the operation of considerable lengths of track by a centralized traffic control system in which all trains are moved by signal indication at the will of the despatcher, regardless of time table superiority and without train orders. Further developments, such as cab signalling, the automatic train stop, and automatic train control, are briefly touched upon.

Signalling may be said to be as old as man, as there always must have existed the necessity of communication at a distance between primitive man and his companions. A man's arms being the natural medium for giving such signs, it follows that they were probably used as the first semaphores. The semaphore was also used as a method of communication by the warring nations of the Old World before the Christian era and has continued in use, though its form and methods have changed, down to our day of railways.

The name semaphore is derived from Greek words meaning "a sign" and "to bear," and the first record of its application was to a signalling device invented in the year 1084 B.C.

As early as 1794, a practical semaphore was devised in France by three brothers, named Chappe. This semaphore was adopted by the French government; stone towers being erected on the coast and through some of the interior districts, and messages were transmitted from one tower to the other and read by telescope (a similar form of semaphore is in use in the navy today).

Semaphores, as applied to railways, originated in England, as did the railways themselves. After the first railway trains were placed in service the necessity for some form of signal to control their movements was felt, which soon resulted in the use of a large number of kinds of signals for giving information as to the position of switches, location of fouling points and train orders, etc.

One early type of signal was the ball signal, which consisted of a tall pole with two hoods suspended from a yard arm. There were two different coloured balls for the day indications with corresponding coloured lights for the night indications. This signal, shown in Fig. 1, is the one from which the well-known railway term "give 'em a high ball" has come down to us.

The variety of signals on several railways used for similar purposes naturally resulted in confusion, especially in jointly operated properties and numerous accidents resulted, which brought the attention of the operating officers to the necessity of adopting a standard signal. At a meeting held in the year 1841, a Mr. C. H. Gregory suggested the use of the semaphore to replace all other types of signals in use. This suggestion was adopted. The adopted signal gave the following indications: horizontal arm for the "danger" or "stop" indication; downwardly inclined arm for the "clear" or "proceed" indication. No record is found of night indications.

The indications referred to were shown in what became known as the lower quadrant and probably followed the method of hand signalling, which had previously been used to govern train movements. The latter method consisted of holding one or both arms in a horizontal position to stop a train and allowing them to drop to the side in a natural position to allow a train to proceed.

The application of semaphores for the control of trains was for a long time limited to the protection of facing switches, fouling points, railway crossings at grade, etc., due to the fact that these semaphores were mechanically operated by levers grouped together in a frame at some central point and connected, in the earlier days by means of wire, and latterly by pipe. The levers at first were so grouped simply for convenience of operation; then as their number grew and the possibility of clearing conflicting signals at the same time became apparent, interlocking between the levers was introduced; this however is another phase of the protection of train movements which is not included in the scope of this paper.

As the speed and tonnage of trains increased, the need for some means of conveying information to them along their entire route became a necessity and numerous systems were introduced, manual control being of course the only method in the early days. Block stations were established at certain locations along the route of the railway and different methods of conveying the necessary information to the trains were used. In 1851 Charles Minot, then general superintendent of the Erie Railroad, issued the first telegraphic train order for this purpose.

An early system of block signals was put into operation during the year 1863, between New Brunswick and Philadelphia, on the old United New Jersey Canal and Railroad Company (now part of the Pennsylvania system). This consisted of a box at the entrance to each block with a red banner displayed against a white background as a "stop" indication, and the electric telegraph used to keep the block tenders informed as to the arrival and departures of trains.

Following this method track treadles or track instruments came into a somewhat limited use for the control of block signals, but it was not until the year 1872, when Dr. William Robinson conceived the idea of the track circuit, that automatic signalling may be said to have been born, and from that time the progress in automatic signalling for the control of trains has been continuous.

The primary function of the track circuit is to detect the presence of a train within a certain track section. The occupancy of this track section will cause the signal at the entering end of the block to display a "stop" indication for a train which may be following. Incidentally, a broken rail, a misplaced switch, or a car foul at a passing track or siding will also cause a "stop" indication to be displayed, by breaking or short circuiting the continuity of the rail conducting circuit.

Fig. 1.—Ball Pole Signal.

Track circuit protection is accomplished by connecting both rails of a track to the terminals of a battery. At some distance from this battery, determined by the distance between signals, is an instrument which is called a track relay, connected to the rails in a similar manner to the battery. This arrangement is illustrated in Fig. 2. Insulated rail joints are used to confine the circuit to its effective length, the current from the battery flowing along one line of rail, through the relay, back through the other line of rail to the battery, the rails being bonded in a suitable manner to lessen the resistance due to rust in rail joints, etc.

The presence of a train on the rails will short circuit the current from the battery which will cause the track relay to drop, opening or closing auxiliary circuits as desired, and causing the signal in the rear to display the "stop" indication, thus protecting the train occupying the track section.

Coincident with the invention of the track circuit came the demand for a power-operated signal, which was necessary if the full advantage was to be obtained from the use of the track circuit. Various types of power-operated signals were soon on the market, one of the earliest types being the disc signal, similar to that first used on the Pennsylvania already referred, to, but improved and enclosed in a housing and actuated by an electro-magnet to display the required indications; the night indications being given by coloured glasses or roundels, displayed in proper order in front of an oil light, above the banner, (See Fig. 3.) Signals of this type were installed between Windsor Street station and Montreal West on the Canadian Pacific Railway in 1897 and extended to Vaudreuil in 1907. These were removed in 1913 and upper-quadrant semaphore signals installed in their place.

Railway officers however, were still very much in favour of the semaphore, and power operated semaphore signals were soon on the market. Among these were the electro-pneumatic in 1885, which was electrically controlled and operated by air. This signal was not used to any great extent owing to the necessity of air supply for its operation.

With the improvement in small electric motors and primary battery cells, the electric motor semaphore came into prominence a few years after the electro-pneumatic type, made steady progress, and was almost universally accepted as the best type of power signal until the advent of the light signal.

Another type of power operated signal which was put on the market about the same time as the electric motor signal, was the electro-gas semaphore, which was electrically controlled and operated by the expansion of highly compressed carbon dioxide. This signal did not come into general use, as the same objections applied to it, as to the electro-pneumatic, that is, the necessity for a gas supply for operation.

The electric motor semaphore has, since its inception, gone through a number of changes and improvements, and has been brought to a state of high efficiency. In the original signal, known as the "Bottom Post type," the semaphore arm was operated by an electric motor and gear train, which was located in a housing at the base of the mast, the energy being transmitted to the semaphore arm by a rod arranged inside of the hollow iron mast. The Canadian Pacific Railway has some 61 miles of this type of signal in service at the present time, as shown in Fig. 4.

Next in the line of development was the "Top Post type," in which the motor and transmission members were placed in a much smaller housing at the top of the post, adjacent to the semaphore arm.

Coincident with the early development of the power-operated semaphore, the question of the use of the semaphore arm in the lower or upper-quadrant came in for a great deal of discussion, largely due to the fact that owing to the increase of both speed and tonnage of the average train, a further indication other than that of "stop" and "proceed" was desired to give an approaching train advance information when it was approaching a "stop" indication. This led to the adoption of the third or "caution" indication, which in the case of semaphores operating in the lower-quadrant generally meant that a second arm, usually coloured yellow, with a yellow light for night indication, had to be mounted on the signal post in order to show this indication clearly. This second arm is not necessary for a semaphore operating in the upper-quadrant, the three positions of the latter being: arm horizontal "stop" indication; arm 45 degrees above the horizontal position "caution," and the arm 90 degrees above the horizontal, "proceed" indication. Coloured roundels or glasses are carried in the casting which holds the arm, and displayed in front of a light in such a manner to show red for "stop," yellow for "caution" and green for "proceed" indications at night.

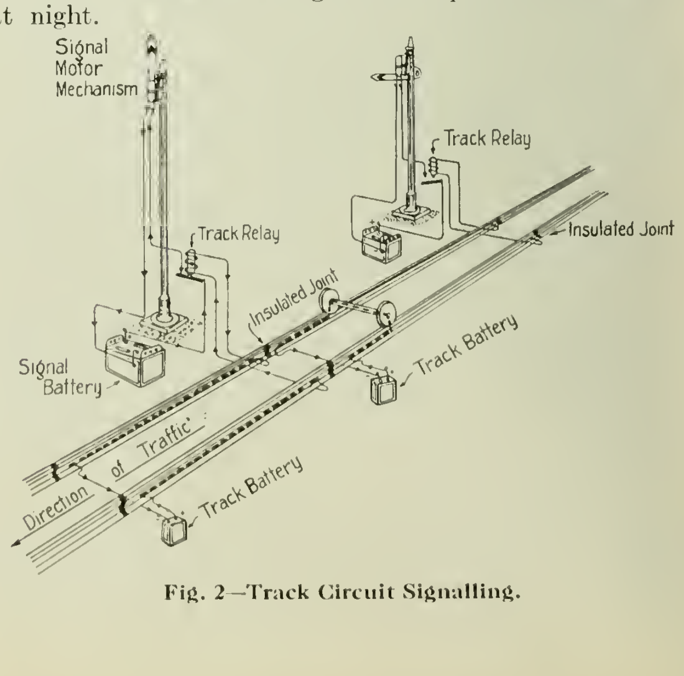


Fig. 2—Track Circuit Signalling.

Fig. 3.—Disc Type Signal.

The upper-quadrant semaphore, shown in Fig. 6, besides being considered more distinctive, has several other outstanding advantages over that operating in the lower quadrant. Among these may be mentioned its inclination to gravitate to its most restrictive position without the use of counter-weights, which had to be employed for this purpose in the lower-quadrant semaphore; also, accumulation of ice and snow on the semaphore arm tended to cause it to assume the "stop" position, which was not the case in those operating in the lower-quadrant.

The similarity of the operation of the lower-quadrant semaphore to the hand signal seemed to be the strongest argument in favour of the downward indication, and was for some considerable time allowed to outweigh the excellent reasons for the use of that operating in the upper-quadrant.

The Baltimore and Ohio Railroad, in 1903, was the first road in America to adopt the semaphore signal operating in the upper-quadrant, and the advantages were so well defined that other railroads were not long in following its example, although there are a number of railways still using the lower-quadrant semaphore.

The present day trend in signalling seems to be towards dispensing with mechanisms to move the semaphore arm (the electric motor and its attendant train of gears), for although they had reached a state of relatively high efficiency, trouble of one sort or another was experienced. This has led to the development of the most efficient signal to date, the light signal. This modern signal is on the market in several forms, but all types rely on light and that alone, the semaphore arm having been eliminated.

Fig. 4.—Lower Quadrant Semaphore Bottom Post Type.

The most popular form of this signal is perhaps the colourlight signal, in which the night indications of the semaphore signal have been used for both day and night, namely: red for the "stop" indication, yellow for the "caution" indication and green for the "proceed" indication.

The Pennsylvania Railroad developed a light signal retaining in effect the positions of the upper-quadrant signal using rows of lights, amber in colour, mounted on a background to simulate the position of the semaphore arm.

The Baltimore and Ohio Railroad has endeavoured to retain both the effect of the semaphore arm and colour of light, having developed what is known as the "Colour Position Light Signal," in which coloured rows of lights mounted on a background simulate the position and colours of the semaphore arm. Other forms of colourlight signals simply make use of the night indication of the semaphore, by means of lights placed behind red, yellow and green lenses, some forms having these lenses mounted in a vertical line, others in a horizontal line, and still others in a triangular form.

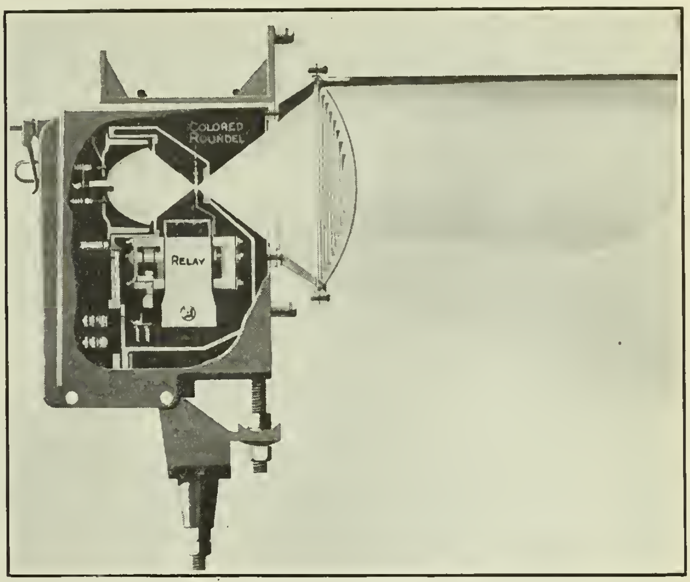

Fig. 5—Searchlight Type of Colour Light Signal.

The particular form of colourlight signal used by the Canadian Pacific Railway is the so called "Searchlight Signal," which was first installed in 1927 on a section of double track between Streetsville Junction and Guelph Junction, on the Ontario district, a distance of 16.5 miles. This signal proved so satisfactory that its use has been rapidly extended, some 355 miles of this type of automatic signal being in service at the present time. No more signals of the semaphore type have been installed on the Canadian Pacific Railway, eastern lines, since that time. As the existing semaphore type needs replacement the searchlight signal is installed in its place. In 1930 this type of signal was made the standard signal on both eastern and western lines.

This signal, shown in Fig. 5, employs a single light unit, consisting of a concentrated filament lamp with the filament located at the focal point of an elliptical reflector, which collects approximately 80 per cent of

Fig. 6.—Upper Quadrant Semaphore Top Post Type.

the light rays emitted by the lamp and concentrates them at the second focal point of the ellipse. At this point, which is coincident with the focal centre of a clear optical lens, the light passes through a miniature coloured roundel, enters the lens and emerges in a substantial light beam, which has an effective range of vision of 3,000 to 4,000 feet in bright sunlight.

The coloured roundels, of which there are three, namely, red, yellow and green, for the "stop," "caution" and "proceed" indications respectively, are carried in a moving member or vane, moving in a plane at right angles with the light beam which is actuated by a standard relay of the three-position type, so arranged that when de-energized it will assume the central position due to gravity and display the red indication. The signal relay also operates contacts from which the three positions of the signal can be repeated, a valuable feature which was present in the semaphore type of signal, but is not present in other existing forms of light signals; the latter depending on auxiliary relays for this purpose.

In the other forms of light signals it is not possible to use a reflector of any kind owing to the danger of an engine headlight having its beam of light reflected to the engineman. This is commonly termed a phantom indication, and may cause confusion and perhaps a false indication. This danger is not present in the searchlight signal, since should it happen, the reflected beam is of the right colour, as it has passed through the proper coloured roundel. The use of a reflector allows the use of a smaller wattage lamp, with no sacrifice of effective range, and it is more economical for that reason.

The Canadian Pacific Railway has at the present writing some 1,210 road miles of automatic signals in service, 855 miles being of the semaphore motor-operated type, and 61 miles being of the lower-quadrant type previously mentioned. The balance of the semaphore type, or 794 miles, is of the upper-quadrant type. The colour-light signal is in service on the remaining 355 miles.

An automatic signalling system involves the division of a railroad into a series of consecutive block sections governed by automatic signals. The length of these block sections and the location of the signals depend upon several factors, such as the density of traffic, and the physical characteristics of the railway, such as grades and curvatures, which affect the ability of a tonnage train once having been stopped by a signal to start again, etc.

The primary purpose of such a system is to increase operating efficiency by speeding up traffic, increasing track capacity, etc. The hazards of collisions (both head-on and rear-end, on single track), broken rails, open switches, cars foul of main track, or other obstructions in the block, are greatly reduced by providing a space interval in the case of the first mentioned and the detection of the others.

Some of the present day methods of control will be briefly mentioned here:

When automatic block signals are applied to double or multiple tracks, protection is generally provided only for trains moving in the established direction of traffic, except in some certain special cases where density of traffic, the peaks of which flow in different directions at different hours of the day, can be facilitated by having one or more of the tracks signalled in both directions. The Canadian Pacific Railway has such a section signalled in this manner between Windsor Street station and Glen Yard, where the third track is signalled for traffic in both directions. This allows the use of this track in either direction as traffic demands.

The application of automatic block signals to a single track presents a more complicated problem than that of double track, in that protection must be provided for train movements in both directions. In the first single track installations the method of control was what is generally known as the "Overlapped Control," in which the "stop" control of the signal was overlapped, that is, the control of a signal would extend to the second signal in advance of it or nearly so. This was necessary in order to give protection against opposing train movements but did not permit following movements from signal to signal. This lead to the development of the "Absolute Permissive Block system" by the General Railway Signal Company. This was a decided step in the advance of single track signalling and the first installation was in Canada on the Toronto, Hamilton and Buffalo Railway.

In the "Absolute Permissive Block system," the train is given an absolute block from passing track to passing track against opposing trains and a permissive block signal to signal

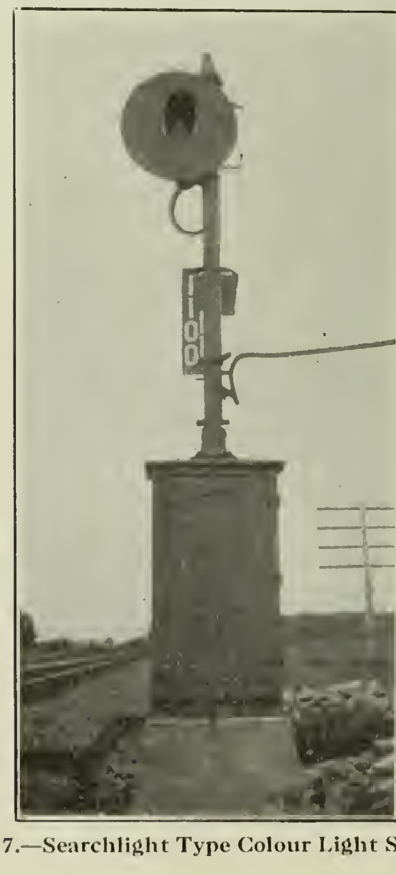

Fig. 7.—Searchlight Type Colour Light Signal.

for following trains. This system permits almost equal facility of operation for following trains as in double track operation, for the reason that the direction of traffic is established by the train that first enters the block. Trains may then follow as if the single track was one of the two main tracks of a double track line. All of these trains must pass out of this section between passing tracks before the signal indications will permit a train in the opposite direction to enter the block. This train will then in turn establish the opposite direction of traffic and trains may follow it, signal to signal, with the same facility as in the first case.

The control circuits are unique and ingenious, but do not require any appliance other than those ordinarily used in automatic block signalling. These circuits are so arranged that the system restores itself to the normal position as soon as the block is clear, regardless of whether or not a preceding train, or trains, have passed through the block. If a train enters an intermediate spur or siding and stands clear of the main track the system restores itself, so that another train could leave the passing track at either end of the block. When the train leaves the spur or siding, it establishes its direction on passing the first signal, the signals governing movements in the direction established display "proceed" or "stop" indications, depending upon the condition of the blocks in advance, and signals governing opposing movements display "stop" indication. The system is flexible and can be easily arranged to provide for any special requirements necessary.

Of the 1,210 road miles of automatic block signals in service on the Canadian Pacific Railway, 212 road miles have double track signalling, while the balance, or 998 miles, is made up of 243 miles of single track "Overlap Control" and 755 miles of "Absolute Permissive Block Signalling."

The use of train orders on automatic signal territory is decreasing and some railways have discontinued the use of "31" orders on automatic signal territory. A step further in the direction has been made by the introduction of the Centralized Traffic Control system, in which the despatcher has direct control of traffic. This system combines all the functions of control into one centralized unit. Protection, direction, and the actual operation of the switches for the passage of trains are brought about by this newly developed system, which is new only in the sense that it co-ordinates various signalling and interlocking functions of proved reliability previously used individually.

Under operation by the Centralized Traffic Control system, all trains are moved by signal indication at the will of the despatcher regardless of time-table superiority and without train orders. Trains are not detained, waiting the transmission and delivery of train orders at points along the railway, the movement of through trains is expedited and local trains can spend a larger proportion of their time in productive work.

Wherever there is a bottle neck on a railway, whether on a stretch of single or multiple track, this system provides facilities that will postpone the building of additional tracks for many years; the cost being but 10 to 15 per cent of what it would cost to build an additional main track.

The operation of the system is simple. The control board or machine, which is small and compact, is located in the despatcher's office and on it is a track model of the territory covered. Immediately below the track model is located a row of small levers for the operation of switches and signals, the position and operation of all switches, and if need be the signals also, being indicated to the despatcher by lights on the control board. The passage of a train in and out of a track section at each end of the passing track is also automatically indicated. This feature is generally used at "OS" points in the territory and is also made to register the time of such passage on the train-graph, which in this system replaces the despatchers train sheets. The Canadian Pacific Railway has four small installations of this system in service at the present time.

Mention should be made in closing of some other developments of the art, such as cab signalling, in which the indications of the way-side signals are repeated in the engine cab, an advantage in keeping the engineman continuously informed of track conditions ahead. Some railways have dispensed with the way-side signal entirely, except where a train is required to stop at a specific location.

Automatic train stop and automatic train control are systems in which the function is to stop or reduce the speed of a train, by applying emergency or service braking in the rear of a "stop" or "caution" signal as the case may be, should the engineman be incapacitated for any reason. The system does not in any way take the control of the brakes away from the engineman should he be alert and able to exercise this control. Space does not permit of a detailed description of these systems. They are comparatively expensive to install and railway officers are largely of the opinion that the money necessary to do this could be much more advantageously spent in other directions, such as extending automatic block signals or centralized traffic control systems and highway crossing protection.

A Method of Laying out Warped Surfaces of Hydraulic Structures

C. P. Dunn, M.E.I.C.,
Chief Engineer, Alcoa Power Company, Arvida, Que.

Paper to be presented before the Annual General and General Professional Meeting of The Engineering Institute of Canada, at Montreal, February 4th, 5th and 6th, 1931.

SUMMARY.—This paper presents a description of the technique of determining and defining in detail the shape of warped surfaces of hydraulic structures. The matter discussed is workmanship in the design officer at her than the scientific or theoretical phases of design. Reference to hydraulic theory and mathematics is omitted, in order to emphasize the one point which the paper is intended to cover.

The designer of complicated engineering works, particularly hydro-electric developments, is of necessity somewhat of a "jack of all trades" and is quite often called upon to do things which he has not done before. It is his regular custom to produce a creditable solution of problems which are new to him, but he cannot hope to be an expert in all of the things which he is called upon to do, and his solutions of many problems fall just a little short of being 100 per cent perfect. It is convenient to be able to find the experiences of others on some troublesome detail recorded in a usable form. Many times in the course of the writer's work, he has been confronted with the necessity of working out a detail on which he had no experience, and concerning which he was unable to find a printed record of what others had done. The failure of engineers to record the methods of working out details is partly due to the fact that those actively engaged in construction are usually too busy to write, and partly because it is natural to choose a big and important subject, neglecting the details. For the above reasons, the writer believes that this paper, covering a relatively minor detail, will be of value.

In almost all hydraulic works there is a necessity for the construction of warped surfaces which it is very difficult if not impossible to define mathematically by curves and straight lines. Surfaces of this nature occur in intake structures, draft tubes, scroll cases, buckets of dams, branches in concrete lined tunnels, manifolds or branches in concrete pipes and in all transitions from one type of conduit to another, such as tunnel to canal, or canal to flume. Speaking in a broad, general way, all of these things might be called hydraulic transitions. The desirability of correctly curved surfaces is not limited to surfaces on which water flows. Under certain conditions there is a requirement for what might be termed a structural transition An illustration of a place where a structural transition might be used advantageously is an arch dam with gravity abutments. A section gradually merging from arch to gravity type with no abrupt change would result in a gradual change of load distribution from full arch action at the crown through partial arch and partial cantilever action to a full gravity dam at the abutment. There are no doubt cases where such construction would result in a more economical, safer and better appearing structure than if the section is changed abruptly from thin arch to heavy gravity abutment.

That the technique of shaping hydraulic transition structures is a matter in which the designer quite often fails to function to perfection, is evidenced by numerous structures which are satisfactory in a substantial sort of way, but which lack the indefinable touch of perfect workmanship. The reason for frequent failure to attain perfection is that the designer, no matter how skilled he may be in mathematics and hydraulic theory, cannot create a perfect hydraulic design until he has mastered the craft, or trade if you please, of the skilful layout of warped surfaces. He quite often attempts to economize by simplifying the shape of the structure, using as many straight lines as possible and making the curves all arcs of circles. This idea may work very well when dealing with something that is confined to a plane surface, but often leads to difficulty and unsatisfactory results when dealing with three dimensions. An attempt to save form costs in a structure like a large draft tube by simplification along the above lines, may actually make the construction more complicated and lead to costs greater than would obtain if the structure were shaped exactly correctly. The reason is obvious. Simplification by using straight lines, angles, and arcs of circles, results in an approximation to the ideal surface, and even though the approximation be fairly close, the departure from the ideal surface causes difficulty in bending, cutting and fastening form boards, which difficulty increases costs, and results in unexpected bumps, depressions and angles in the surface.

Slightly uneven surfaces do not necessarily introduce vital faults into the hydraulic characteristics of a structure, but there certainly is no justification for their existence if they increase costs. An imperfect, crude looking structure is a source of annoyance, while a beautiful structure is a source of pride which increases the pleasure and enthusiasm of all connected with a piece of construction work. Pride and enthusiasm are substantial factors in cost reduction.

The ideal shape of surface for a hydraulic structure may be defined as that surface which will cause the desired change of direction of flow of moving water with the least loss of energy. This definition will apply even to structures which are built for the purpose of destroying energy because we do not really "destroy" energy, we want to divert it away from destructive action on structures and cause it to be dissipated in the form of heat caused by water impinging upon water.

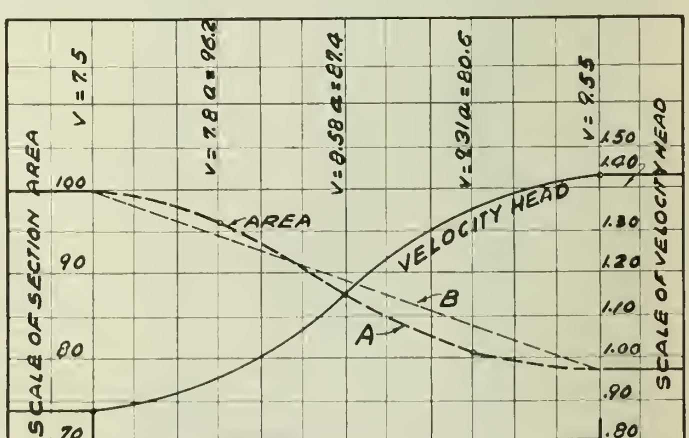

FIG-1
AREA AND VELOCITY HEAD CURVES

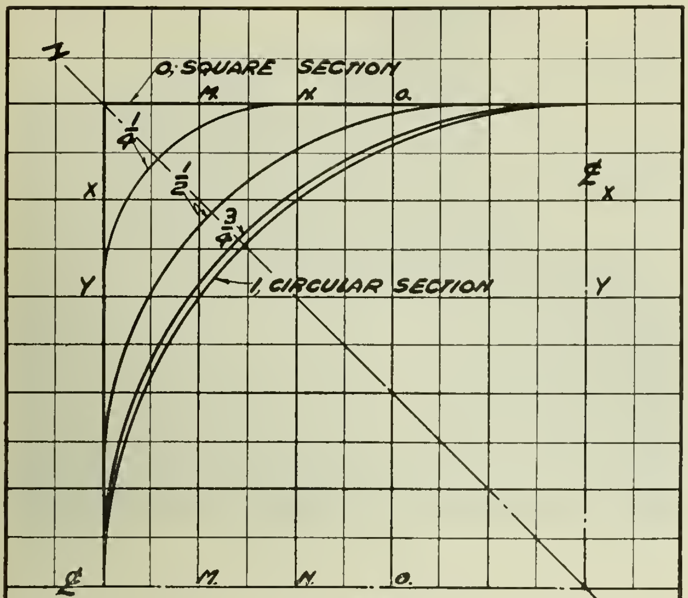

FIG - 2
CROSS SECTIONS

The elements of an ideal surface are composed of long, easy, smooth curves, with no angles and no abrupt bumps or depressions. It is to be noted that almost invariably a surface which is not pleasing to the eye is incorrect hydraulically. The converse is not so invariably true, because it is possible to build a nice appearing surface which is not suitable for the velocities of flowing water which will obtain. The appearance test is a good thing to keep in mind. If a job does not look pretty it is quite likely to be a poor job hydraulically.

An "ideal" surface is a surface the trace of which on a plane cutting it in *any direction whatever*, is a smooth, easy curve, pleasing to the eye. Such a curve need not be a circle or it need not be any curve which can be defined by a mathematical equation.

The method of definition and practical use of curves which are beyond the reach of mathematics and exact dimensions is simple. The procedure to be followed requires skill and practice, but it is not complicated or difficult to understand.

Drawings made with a fine hard pencil may be scaled with an error not greater than one-fiftieth of an inch. If the drawing is made on a scale of say one-half inch to the foot, the possible error is magnified to one-half inch in the finished structure. This is within the allowable error in the curved and warped concrete surface of a large structure, and is closer than forms are usually built.

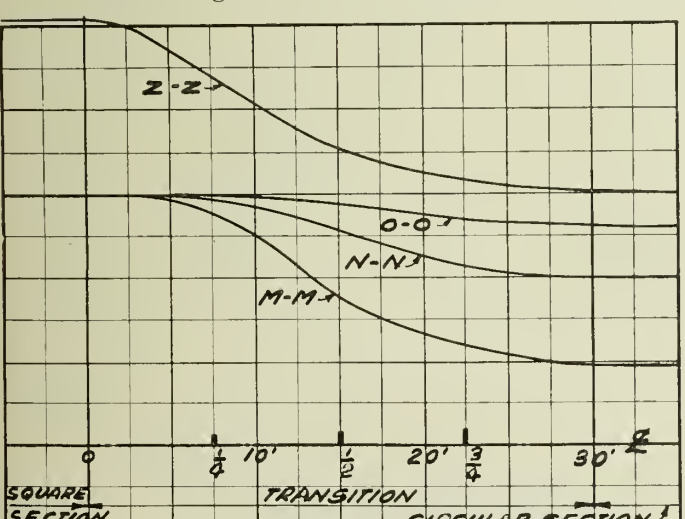

FIG - 3
LONGITUDINAL SECTIONS

The order of procedure is as follows:

First: Determine and fix the limits of dimensions and shape which are required for hydraulic reasons, such as velocity, tendency to scour, etc.

Second: Keeping within the limits defined as above, sketch the desired curves freehand.

Third: Define the curved surfaces exactly, using a spline and weights. In carrying out this process use planes passing in three directions, two series of vertical planes at right angles to each other, and a series of horizontal planes. Intersect the curved surface with a series of parallel horizontal planes at suitable intervals, obtaining a group of horizontal traces or contours. Simultaneously with

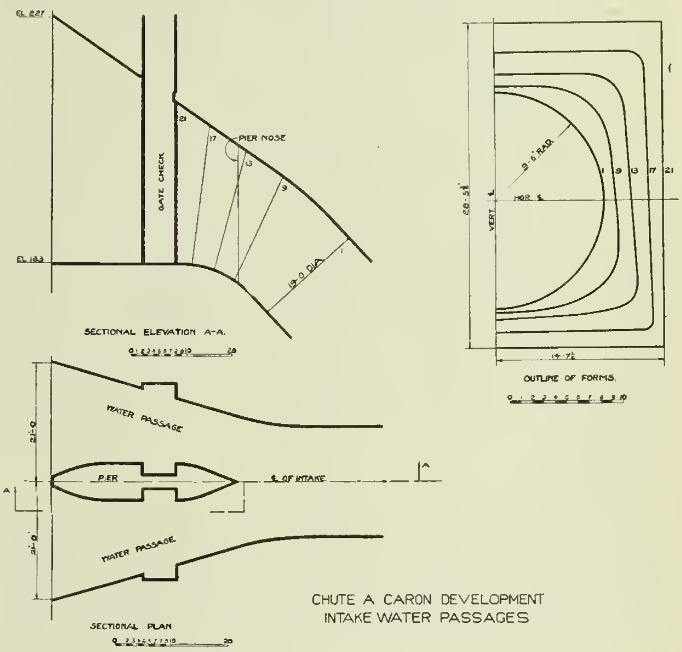

Fig. 4.

the above, obtain two groups of vertical sections on axes at right angles to each other. These three groups of curves should be carried forward on the same drawing, correcting all three sets of curves when a change is necessary at any point, as the work proceeds. Keeping within the limits of the first requirement, the curves should be made to look right to the eye and it should be kept in mind that the trace of the surface on a plane passed through it in any direction should be a smooth, easy curve. Usually the three groups of planes at right angled co-ordinate axes are sufficient, but it is often convenient and sometimes necessary to check up a critical part of a structure by passing a plane through the surface in some inclined direction, observing the appearance of the trace and correcting it if necessary.

As the work proceeds, let us say that one group of curves, say the horizontal ones, have been made to look right. The next step is to draw the intersection of the series of vertical planes with the horizontal sections, and using these points draw the vertical sections. Discrepancies will appear in these vertical sections which must be corrected by using a spline and weights, passing a curve through as many of the points as possible, but eliminating the obviously undesirable bumps and depressions. The newly drawn vertical sections should then be used as the origin of a series of points for the correction of the horizontal sections. A spline should be passed through the revised points for the horizontal sections, eliminating and correcting where necessary. In the above manner, transferring back and forth from one view to another, and carrying all corrections forward simultaneously, the drawing can be perfected to the point where all three views are in agreement, and all are pleasing to the eye. This process appears to be somewhat difficult to understand, but like most manual operations, skill can be quickly acquired by trying it.

Some fundamental points to be observed in the use of a spline and weights are:

First: Three points do not define a curve. Any number of fair, smooth curves may be passed through three given points with a spline. Four or more points are necessary to define a curve.

Second: A spline lies in a fair curve when, it being held in place by a number of weights, any one of the weights can be temporarily lifted without the spline moving.

A simple illustrative example is submitted.

Let us say that we wish to define a transition between a 10-foot square opening in an intake structure and a 10-foot diameter circular concrete lined tunnel. Let us say that the conduit is to carry 750 second feet. Let us say that by experience, judgment, or by the use of a hydraulic model, we have determined that a length of 30 feet will be suitable for the transition. The velocity in the square section will be 7.5 feet per second and in the circular section it will be 9.55 feet per second. A fundamental requirement for efficient hydraulic transitions is that there should be no abrupt change in direction of flow. Another fundamental requirement which is sometimes overlooked is that there should be no abrupt change in velocity head.

To proceed with the example:—

Draw first a curve of velocity heads, (see Fig. 1), which is a symmetrical "ogee" curve passing through the point of half the change in velocity head at half the length of the transition. Choose a number of points on this curve, at each point calculate the corresponding area, and

Fig. 6.—Apron of Chute à Caron Dam—showing warped Surface being constructed without Form.

draw the area curve "*A*." It is to be noted that this curve is an unsymmetrical "ogee" curve, more of it lying below the straight line "*B*" than above it. It is also to be noted that line "*B*" which is a straight line variation of areas, is sometimes erroneously used as the basis of a transition design. This basis of design is to be avoided. Another method which should be avoided in building a transition from a square to a circular section, is the construction of an approximation to a transition by using four quarter cones and four triangles.

The area curve having been fixed, the next step is to sketch, freehand first, sections which will have the required area. For simplicity in this example, the length of the transition is divided into only four equal parts. (For accuracy a finer subdivision is necessary.) Fig. 2 shows the outline of cross-sections at the quarter points which have the required area. Fig. 3 shows the intersection of the curved surface with vertical planes through *M-M*, *N-N* and *O-O*. It is to be noted that in a symmetrical structure such as this example, it is not necessary to use planes in the direction *X-X*, *Y-Y*, etc.,

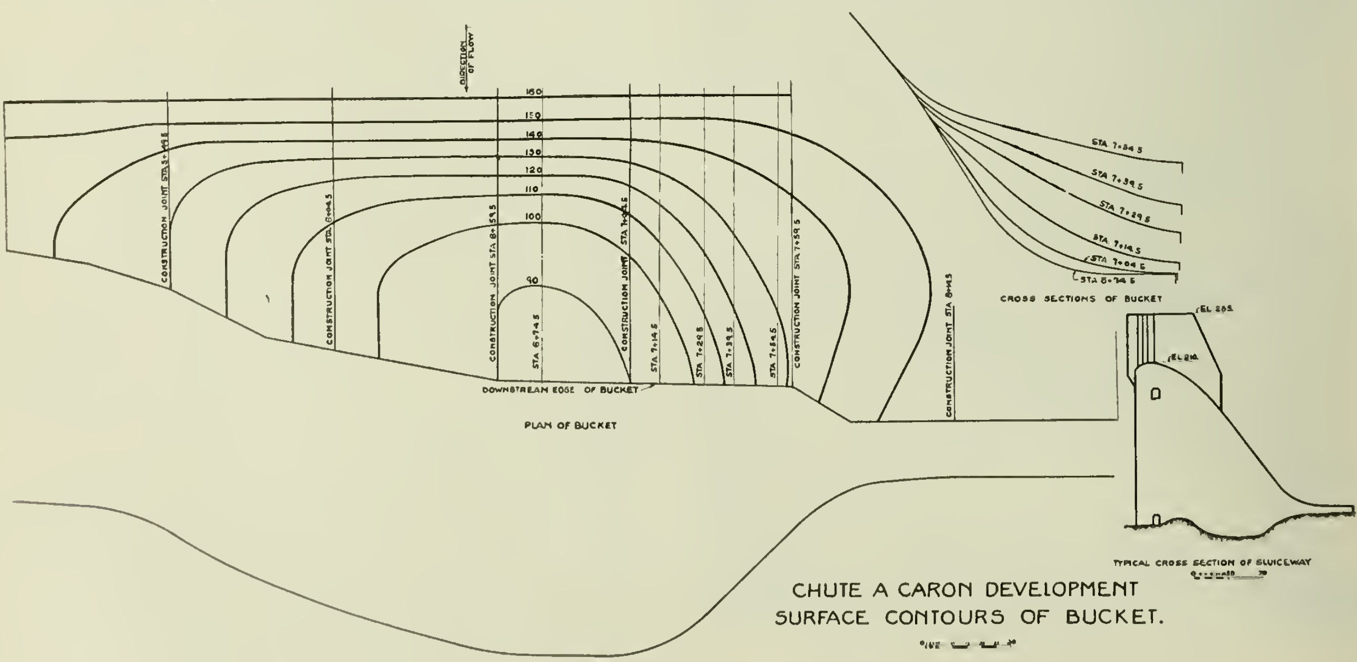

Fig. 5.

because these curves are identical with *M-M*, etc. If the structure were not symmetrical, it would be necessary to intersect the surface with planes in all three directions. Diagonal section *Z-Z* is used as a check on the work and this as well as the other sections is a smooth curve. In Fig. 3 a five-to-one distorted scale is used in order that discrepancies will be magnified and will be more easily and more accurately eliminated.

The foregoing will serve to indicate the method. This method is not original, it is merely the adaptation of the ship-builder's technique in shaping the hull of a ship. A ship is a hydraulic structure, and this method of shaping surfaces, developed by ship designers through a long period of years, cannot be improved upon as a method of shaping the surface of other hydraulic structures.

After the curves are satisfactorily determined on the drawing board, the necessary information is sent to the field for construction in the form of tables of offsets, or co-ordinates, in three dimensions. Quite often the offsets may be laid out full scale on the floor of the carpenter shop, and further refinement made with splines. A small scale wooden model of the surface to be constructed is quite often useful, but it is not necessary unless the surface is very complicated.

Two excellent actual examples in the writer's practice have occurred on the Chute à Caron project in northern Quebec. These are:—

(1) A transition from rectangular to circular section in the penstock intake structure. (See Fig. 4.)

(2) The surface of the bucket of the spillway section of the dam, which is warped to fit the topographic conditions rather than being stepped as is quite often done. This practice on this dam saved a considerable quantity of concrete, and resulted in a better structure hydraulically.

The procedure in this case was as follows:—

(*a*) An outline which looked right was selected by sketching concrete surface contours which followed the general topography of the river channel and allowed sufficient but not excessive thickness of concrete between the rock contours and concrete surface contours.

(*b*) A model was constructed which was tested and the flow of water over it observed. The model was altered several times before a satisfactory shape was secured.

(*c*) The dimensions of the satisfactory model were transferred to the drawing board, and were refined by the methods described in this paper.

The apron of the dam presents a striking and beautiful appearance. (See Figs. 5 and 6.) The accomplishment of this somewhat unusual construction with its attendant saving in cost was made possible by the skill of I. G. Calderwood, general superintendent, and I. E. Burks, concrete technician, and by the fact that substantial encouragement toward working out new and better ways of doing things was given by James W. Rickey, M.E.I.C., and James P. Growdon of the Aluminum Company of America, acting in a consulting capacity.

In conclusion it may be stated that in general, an abrupt change of section, shape or type of construction, in almost any engineering work, be it structural or hydraulic or what not, results in a weak or faulty spot. Abrupt changes seem to be contrary to natural laws, and are therefore to be avoided.

The Water Supply Problem in Southern Saskatchewan[1]

W. A. Johnston,
Geological Survey, Department of Mines, Ottawa, Ont.

Paper to be presented at the Annual General and General Professional Meeting of The Engineering Institute of Canada, Montreal, Que., February 4th, 5th and 6th, 1931.

SUMMARY.—The paper presents the results of recent investigations on the ground water supplies in southern Saskatchewan. This question is largely a geological problem and has been studied not only by officers of the Geological Survey of Canada, but also by a number of independent engineers.

The ground water supply in glacial drift depends largely upon the contours of the underlying bedrock, to which surface topography gives little or no clue. Supplies of water are frequently found in connection with the occurrence of boulder clay sheets or morainic deposits. There are other areas, such as ancient lake basins, where extensive clay deposits yield little or no water. The water supplies found in the district are not as a rule abundant, and vary greatly in mineral character.

In prospecting for ground water consideration must be given to the permeability of surface deposits, and springs are of considerable importance as possibly indicating the existence of ground water reservoirs. Information is also derived from existing wells.

The paper outlines methods used in estimating the quantity of ground water, based on the proportion of precipitation passing into the ground and by comparison with similar areas in which the production is known.

Investigations around Regina have indicated several possibilities for additional supply of water to the city, and additional supplies have also been found for the city of Moose Jaw.

A large artesian area has been located between Moose Jaw and the Southern Saskatchewan river, and the possibilities of this source of supply are briefly discussed.

The problem of obtaining sufficient water to meet the demands of growing cities and towns in southern Saskatchewan is important, for, owing to climatic and other conditions, large supplies of good water are available in only a few places. The average annual precipitation over much of the region is only 10 to 15 inches, the rate of evaporation and transpiration of water by plants in summer is extremely high, and during the winter the ground remains frozen so that comparatively little of the rainfall enters the ground to form ground water. The South Saskatchewan river is the only stream from which large supplies of good soft water may be obtained, but many of the cities are far removed from it. Surface water supplies are made available in places by impounding small streams but the main source of supply is the ground water. Diversion of water from the South Saskatchewan river to supply the cities of Regina and Moose Jaw and surrounding districts was long ago proposed and was shown by elaborate surveys and investigations to be a feasible but costly scheme. The work, however, is not likely to be undertaken for some time, partly because of the large expenditure involved, and partly because there is sufficient ground water in the vicinity of Regina to supply the city for a number of years even allowing for a growth of the city equal to that of the past few years.

The object of the present paper is to describe briefly the mode of occurrence of ground water in southern Saskatchewan, the methods of prospecting for ground water supplies and the results of recent investigations. In 1929 the ground water resources of Regina were investigated by the Geological Survey and in 1930 those of Moose Jaw and the surrounding districts. As the investigation of ground water supplies is largely a geological problem, the work was undertaken, at the request of these cities, in order to aid them in their search for new supplies. The investigation of the ground water resources of Regina by the Geological Survey was done by Dr. Howard E. Simpson, water geologist, University of North Dakota. N. S. Hill, Jr., of New York, and R. O. Wynne-Roberts, M.E.I.C., of Toronto, also made a study of the same problem for the city of Regina. The three reports have been published jointly by the city of Regina. The ground water supply of Moose Jaw was investigated by R. T. D. Wickenden and the author.

Mode of Occurrence of Ground Water

Large supplies of ground water occur in places in southern Saskatchewan both in the unconsolidated surface deposits, largely glacial drift, and in the sandy members of the bedrock formations. It is important in drilling for water and in examining outcrops to determine when the bedrock is reached and to distinguish between the bedrock and the glacial drift, for in many places if the bedrock is reached there is no use in drilling any deeper. The bedrock formations in this region are fairly well known, they are nearly horizontal and extend over wide areas so that it is possible to predict in any particular area the approximate character and thickness of the formations that will be passed through in drilling. But this distinction is not always easily made even by the trained geologist; the upper part of shale beds may be weathered to clay, as for example at the elbow of the South Saskatchewan river, and parts of the glacial drift derived from the shale are nearly similar in character. The glacial drift can be distinguished as a rule by the presence in it of pebbles and stones of granitic and magnesian limestone rocks that are foreign to the district.

The bedrock formations in the vicinity of Regina and Moose Jaw do not yield supplies of potable water, but there is a large artesian water basin in the bedrock in the area about midway between Moose Jaw and the South Saskatchewan river. This basin is referred to in a later part of this paper.

The glacial drift ranges in thickness from a few feet to over 300 feet, and it is impossible to predict at any locality what the thickness of the drift is, for the surface topography gives little or no clue to the contours of the underlying bedrock. An important point in connection with the ground water possibilities of the drift is that there are two or three boulder clay sheets separated in places by stratified sands and gravels and these gravels frequently contain large supplies of hard but usable water. A large part of the drift consists of morainic deposits that were laid down at intervals at the edge of the ice-sheet as it gradually retreated or melted back towards the northeast. These moraines usually have some relief above the surrounding country, are several miles wide and are more porous as a rule than the lake clays and other deposits occupying the intervening depressions, so that they form good catchment areas to supply ground water. In places, for example, northeast of Regina, a large moraine causes a reverse slope towards the west and southwest, and forms the source of an important artesian water area which supplies the city of Regina. The water occurs in sands and gravels between two boulder clay sheets, the upper one forming in places a nearly impervious cover.

A part of the drift consists of glacial lake deposits of sand, silt and clay. One of these ancient lake basins extends southeast through Moose Jaw and Regina nearly to Weyburn. The lake deposits cover a large area and consist very largely of a very fine grained clay that is practically impervious to water. Over a large part of this heavy clay area there is practically no ground water. Numerous wells have been sunk to depths of over 300 feet without finding any water. In places small supplies of

[1] Published with the permission of the Director, Geological Survey of Canada, Ottawa.

water are found in wells located on slight rises in the generally level or slightly undulating plain. It may be that at these places the heavy clay is of small thickness or is absent and the rain water finds access to lower more pervious beds. Over much of the heavy clay area the only source of water is rain water caught in cisterns or in "dug-outs." As the area is a very important one for agriculture and is devoted almost exclusively to grain growing, the domestic water supply problem has not been very acute, but if the farmers are forced by soil drifting and by other factors to undertake mixed farming the water supply problem will be a very important one. The character of the clay plain is such that it is favourable for grain growing, as practically all the rainfall which does not evaporate is used by the growing plants; thus although there is a small precipitation good results in farming are obtained except occasionally in very dry years.

Ground water supplies are also obtained from the alluvial deposits along streams and generally throughout the region except in the heavy clay areas, though these supplies are not as a rule abundant and vary greatly in mineral character.

Prospecting for Ground Water

In examining an area to determine the ground water possibilities one of the first things usually done is to investigate the existing wells and records of wells that have been sunk in search of water, gas or oil. In this connection local drillers can be a great assistance, for though they rarely have complete records of wells drilled, they usually have a good general knowledge of the water possibilities of the districts in which they have worked. The Geological Survey has collected records of wells for many years and these records are available for the use of ground water investigators, but they are far from complete and indeed it would be a hopeless task to attempt to make them complete. They are of value not only to show at what depths water has been obtained by drilling, but to show the areas that have been thoroughly tested by drilling and no water found.

In a region such as southern Saskatchewan, where there is a small precipitation and a high rate of evaporation, a factor of great importance in determining whether there is any large ground water supply in any particular area is the permeability of the surface deposits or of the solid rocks near the surface. The ground water supply comes from the precipitation, and porous beds, which will permit the water to enter the ground, must exist in order to keep the ground water reservoir supplied with water which otherwise would be gradually drained away. Ground water, especially in the sandy beds in the bedrock, may flow for long distances away from its source and even in the surface deposits, for example near Regina, may flow for several miles out under the clay plain. Large areas, however, in which the surface materials are impervious are not likely to contain much ground water. The movement of ground water is extremely slow and the supply of water in artesian basins, such as that near Regina, is only slightly or not at all affected by variations in the amount of precipitation from year to year. The ground water in shallow wells is affected to a much greater extent.

Springs are of considerable importance as indicating possible sources of water not only as direct sources but as possibly indicating the existence of a ground water reservoir at depth from which the water escapes by way of the springs. They are generally of two kinds, one where the water issues at the top of an impervious bed, and the other, like those near Regina, where the water has found a way through an impervious bed along joints or cracks or some other line of weakness. The latter show that a ground water reservoir exists at some unknown depth. In this connection the temperature of the spring waters has some significance. In the Regina district well waters coming from depths of 50 to 150 feet range in temperature from 38 to 40 degrees F.,

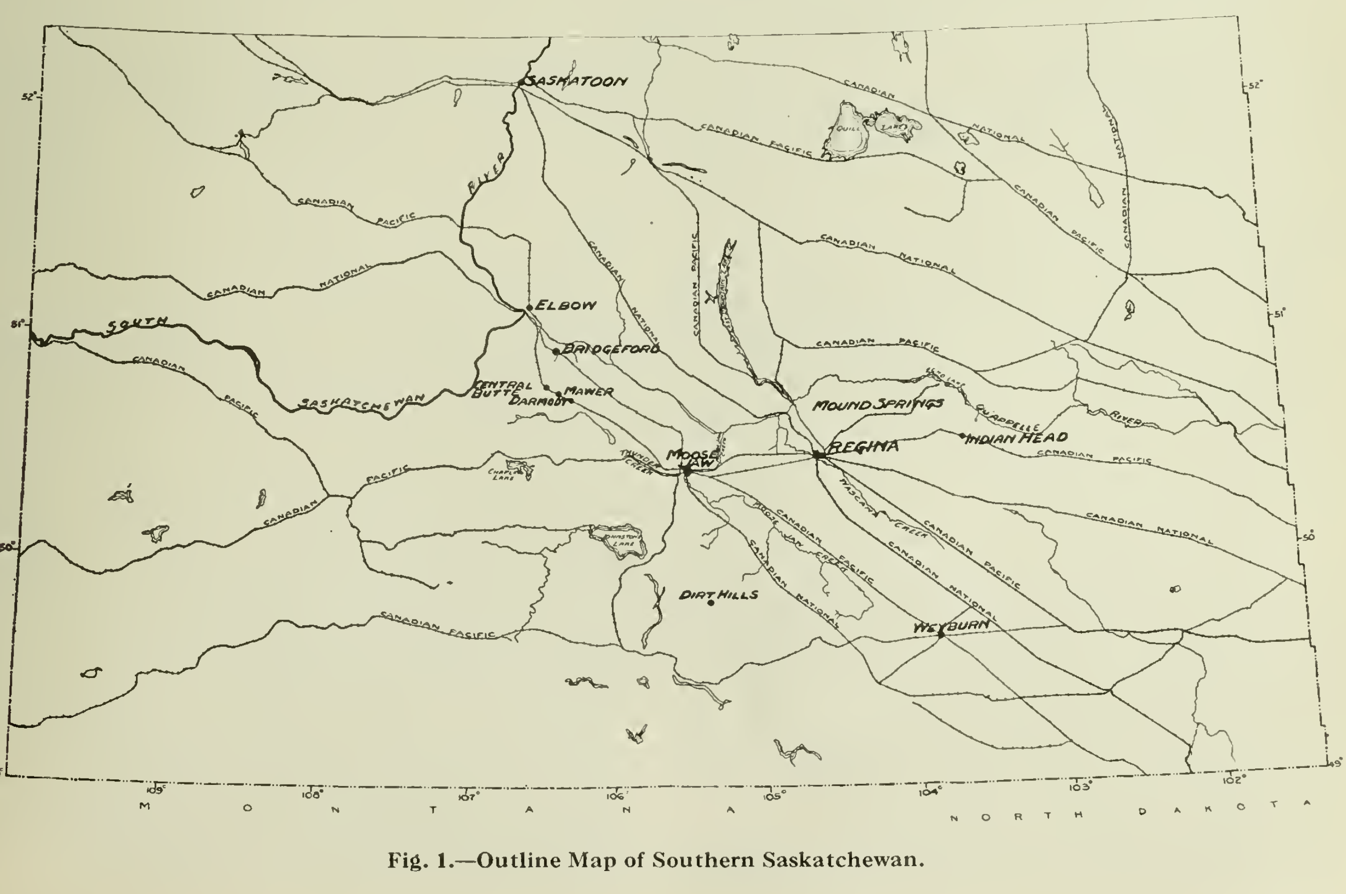

Fig. 1.—Outline Map of Southern Saskatchewan.

the mean annual temperature being 33 degrees, and are fairly uniform in temperature throughout the year. In some areas, for example the lower part of the Fraser river valley, where there is very little snowfall, the temperature of many of the springs is the same as the mean annual temperature. In southern Saskatchewan the blanketing effect of the snowfall and other conditions may cause the spring waters to have a higher temperature. The springs issuing from sandy beds overlying an impervious bed which comes to the surface usually vary in temperature according to the season and in the latter part of the summer have a relatively high temperature. Water coming from wells 400 to 450 feet deep in the area between Moose Jaw and the South Saskatchewan river has a temperature of 48 degrees F. The salty water coming from the deep well at Moose Jaw has a temperature of 60 degrees F. This water probably comes from a depth of about 1,000 feet. The water at a depth of 2,950 feet in this well is reported to have had a temperature of 81 degrees F.

Estimation of Quantities of Ground Water

In order to determine the quantity of water that can be obtained over a period of years from a ground water reservoir without depleting the supply it is obviously necessary to know the rate of replenishment of the reservoir. This rate depends upon the area of the catchment basin and the proportion of the precipitation that passes into the ground to form ground water. But neither of these factors can be readily determined. In the case of an artesian water reservoir the catchment area may be large or small depending upon the surface topography and the character and shape of the underground porous beds through which the water flows from the surface to the reservoir. These buried water-carrying beds may be continuous sheets of porous sand or be narrow ancient stream channels. In areas where a great many wells have been put down to the same water horizon it is possible to obtain from the records of these wells some idea of the character and extent of the water-bearing beds and of the catchment area. In areas where such information is not available there may be no way of determining the size of the catchment area which supplies the artesian reservoir.

The proportion of the precipitation which enters the ground to form ground water in southern Saskatchewan varies greatly depending partly upon the character of the soil. In sandy areas there is a fairly high rate of absorption, for the water left after a rain on these areas quickly disappears, whereas on the heavy clay lands it tends to remain in pools on the surface. Moreover, a part of the water absorbed by the soil descends only to slight depths and is again removed by transpiration by plants and by evaporation. It is held by some investigators that the snowfall adds little or nothing to the ground water supply, as the ground is frozen in winter and, therefore, is impermeable. But in some years the ground late in the autumn is extremely dry and may not readily freeze to any great depth; shrinkage cracks frequently form in frozen ground owing to temperature changes and these may furnish a means of access of melting snow to the ground water. The part of the precipitation which supplies the ground water in artesian basins such as that near Regina must be fairly small, but too little is known regarding conditions affecting absorption of ground water in the region to attempt to estimate what the proportion actually is. That there are very marked differences in the rate of absorption, apparently owing to variations in the character of the soil, is shown by the fact that ground water supplies sufficient for the city of Regina are found in the morainic area northeast of the city, whereas in the heavy clay area a few miles to the south and west there is scarcely any ground water.

Approximate estimates of ground water supplies, however, can be made by comparison with somewhat similar areas in which the production is known, or, better, by actual pumping tests. Measurement of the flow of springs coming from an artesian reservoir and the character of the springs may furnish evidence as to the extent and importance of the reservoir. The springs may vary greatly in flow from time to time owing to changes in atmospheric pressure. Springs that are permanent ordinarily have mounds of calcareous tufa built up around the points where they issue. In places they issue in boggy ground characterized by the presence of numerous 'buffalo' bones and have no mounds.

Results of Recent Work

One of the chief results of the work at Regina was to show that a large additional supply of water is available in the Mound Springs area, 14 miles directly north of the city and 100 feet above the city. This area was recommended for testing by drilling. Nine 6-inch cased wells have been put down and have found water at depths of 50 to 150 feet in the glacial drift. Three of the wells yield flows of between half a million and three quarters of a million gallons a day each, and have a static head of 10 or 12 feet above the ground level. There is little doubt, therefore, that the Mound Springs area will yield at least two million gallons a day and that this area together with other possible new sources will furnish an additional supply nearly equal to that used by the city at the present time which averages about four million gallons a day. The water is hard, but is a good wholesome water free from any possible source of contamination and is similar in character to that used by the city for many years.

The water supply of Moose Jaw is derived from several sources, with no very large supply from any one source, and is partly spring water of good quality derived from sandy beds near the surface and partly impounded water and seepage water from Thunder creek valley. The supply is affected by drought to a much greater extent than is the Regina supply, and during the past two exceptionally dry years there has been a shortage of good water. One of the main sources of supply is Sandy creek about 20 miles west of the city. Water is pumped from a collecting gallery and piped to the city and a gravel walled well recently put down by the Layne Canadian Water Supply Company Ltd. has increased the supply about half a million gallons a day. Another well has also been put down on Forsythe creek about 2 miles south of Caron and will be connected with the pipe line from Sandy creek. With these additional supplies it is believed that the water supply problem of Moose Jaw for the present will be solved.

A ground water supply which may prove to be of importance as a future supply for Moose Jaw and other places in the district is a large artesian area lying about midway between Moose Jaw and the South Saskatchewan river. Comparatively little appears to be generally known about this area although a number of wells drilled 10 to 15 years ago have been flowing ever since. The flowing wells occur in an area extending from Darmody nearly to Central Butte along the Canadian National Railway and north to within three miles of Bridgeford. The wells are 400 feet to 450 feet deep and derive their water from sandy beds that are overlain by shale which forms an impervious cover. Wells sunk to the same horizon are also obtained in the area extending west to the South Saskatchewan river and even beyond the river, but in most of these the water does not rise quite to the surface because of the higher altitudes. The water rises to about 1,987 feet above sea level. The source of the water is not definitely known, but the only possible source appears to be far up the South Saskatchewan river where these sandy beds are exposed along the river and become saturated with the river water.

An analysis of the water from the Canadian National Railways flowing well at Mawer in the artesian area was made by Andrews and Cruickshank, Regina, and is as follows:

Results in Parts per Million	
Calcium bicarbonate (as carbonate)	35.00
" sulphate	...
" chloride	...
Magnesium bicarbonate (as carbonate)	10.00
" sulphate	...
" chloride	...
Sodium carbonate	498.00
" sulphate	789.00
" chloride	163.00
Silica	2.00
Iron and alumina	2.00
Total solids by calculation	1,499.00
" " " evaporation	1,560.00
Temporary hardness	5.00
Permanent "	Nil
Total "	5.00

The almost entire absence of hardening salts in the water is a remarkable feature especially as most of the ground waters found in southern Saskatchewan are objectionable because of their hardness. The water comes from a sand which contains appreciable quantities of green sand, a water softening mineral, and therefore, is naturally softened. Unfortunately the water contains a fairly large proportion of non-hardening salts, is corrosive to some extent, and therefore, is objectionable. It has, however, been used for many years at Mawer as the town supply and at numerous other places with no apparent bad effects. It is possible that the water could be used satisfactorily when mixed with a proportion of hard water. In some of the wells which have a smaller flow than the one at Mawer the amount of salts present appears to be less, but only one analysis is available. Several of the wells flow at the rate of 30 gallons per minute from a one-inch pipe and there is no question that a very large supply of water exists. Further investigation is necessary in order to determine whether water of a more suitable character can be obtained from different parts of the basin or from different depths. The point nearest to the city of Moose Jaw at which the artesian water can be obtained is about 23 miles from the reservoir at the end of the pipe line at Sandy creek and is about 75 feet above it.

THE FORTY-FIFTH ANNUAL GENERAL

and

GENERAL PROFESSIONAL MEETING

of

The Engineering Institute of Canada
Will be held at the Windsor Hotel
Montreal

on

TUESDAY, WEDNESDAY and THURSDAY
FEBRUARY 4th, 5th and 6th, 1931

THE
ENGINEERING JOURNAL
THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XIV JANUARY 1931 No. 1

The Institute's Library and Information Service

The commencement of a new volume of The Engineering Journal gives occasion to direct members' attention to the facilities offered by Headquarters for this work, principally in the form of bibliographies or lists of references to articles in current periodical literature.

Such a service would necessarily be very imperfect were it not for the development during the past few years in Europe and America of a number of indices to scientific and engineering literature, of which the outstanding example is the well-known Engineering Index, issued monthly in card form by the American Society of Mechanical Engineers. To this Index The Institute is now, and has been for many years, a subscriber. Its cards list and classify the titles of current articles in nearly two thousand engineering and scientific periodicals published all over the world, and thus constitute a survey of important communications dealing with every branch of the engineering profession. The items which it publishes are familiar to our members from the selected cards which have been reprinted in The Engineering Journal for the past thirteen years.

In view of the facility with which members, on application to Headquarters, can have prepared for them lists of references and photostats of such articles as they may desire, it has been thought no longer necessary to print in The Journal the list of Index items which has hitherto appeared each month. Members will please note, however, that we continue to receive the complete service at Headquarters, and its information is available for their benefit.

The Institute now possesses a valuable collection of sets of technical periodicals, which are continued and completed as opportunity occurs. Nearly two hundred such periodicals are regularly received, and in some cases the sets are complete for the past fifty years or more. These sets cannot be replaced in case of loss, and are, of course, not permitted to leave the library, but members, on request, are furnished with bibliographies or lists of references on any subjects on which information is available, and, at a moderate charge, can have photostat copies of such articles as they wish to consult at their offices. This service is used to a considerable extent, nearly two hundred inquiries having been received during the last three months. It is felt, however, that our membership at large is perhaps not so familiar with these facilities as it might be, and that the assistance offered by Headquarters in this matter could be utilized to a greater extent than is now the case. No charge is made for service of this kind, unless a considerable amount of clerical work is involved, members being required only to pay for the photostats which they obtain. The subjects on which information is asked from time to time are as varied as the occupations of our members. Inquiries range from a request to be informed as to the design, construction and performance of the steamship Great Eastern, to a question as to the extent to which large generators in Canada are operating with ungrounded neutrals, or an inquiry for a list of the most recent earth-filled dams in Canada.

As regards The Institute's library, it has been for some years the policy of the Library committee to expend the limited funds at its disposal on the maintenance and completion of our sets of engineering periodicals rather than on the purchase of works of reference for the library shelves. The reason for this is, that such books would be of use to a comparatively small number of our members, and many of them soon become obsolete when newer editions appear. The Library committee is, however, always ready to consider the purchase of special textbooks required for reference by individual members, but has not available sufficient funds to make a large appropriation for current technical books.

Textbooks and works of reference in the library are available for consultation, and are also mailed to members on loan for their use for two weeks on payment of a deposit of five dollars, which is repaid when the book is returned to Headquarters. Last year the library accessions, including review copies, books purchased, and books and reports presented, totalled seven hundred and fourteen.

Members may be assured that inquiries or requests for information, for textbooks available, or for bibliographies, will be welcomed, and replies furnished as promptly as possible.

An engineer's work, especially in its early stages, often requires investigation or experiment, and the collection of recent and reliable information as to the experience of others who have dealt with similar problems in the past. Sometimes this information is to be found in text books, but more frequently it is contained somewhere in the mass of technical periodicals, reports, proceedings and so on which cover our reading-room tables and fill our stack-room shelves. Few engineers maintain a large library, nor do they generally subscribe to more than a limited number of periodicals; those papers which do reach their desks are not always preserved for future reference. Thus a real service is rendered by an organization which can furnish promptly references to the titles and sources of scientific or technical papers dealing with any given engineering subject, and can obtain copies of them for consultation by the engineer.

Forty-Fifth Annual General and General Professional Meeting

The Annual General Meeting will be convened at Headquarters, 2050 Mansfield street, Montreal, on Thursday, January 22nd, 1931, at 8 o'clock P.M. After the reading of the Minutes of the last Annual General Meeting, the appointment of Scrutineers to count the Officers' Ballot, and the appointment of Auditors for the ensuing year, the meeting will be adjourned to reconvene at the Windsor hotel, Montreal, Que., February 4th, 5th and 6th, 1931.

Programme of Meeting at Windsor Hotel, Montreal

(*Subject to minor changes*)

Wednesday, February 4th

9.00 a.m. *Registration.*

10.00 a.m. *Annual General Meeting.*
Reception and discussion of Reports from Council, Committees and Branches. Discussions of proposed amendments to By-laws and other matters.

12.45 p.m. *Formal Luncheon.*
Welcome to members by A. Duperron, M.E.I.C., Chairman of the Montreal Branch, who will preside.

2.15 p.m. *Annual General Meeting.*
Scrutineers' report and elections of officers.
Retiring President's address.
Induction of New President.

7.00 p.m. *Annual Dinner of The Institute*, at which Ladies will be present.

9.30 p.m. *Smoking Concert.*
Ladies Bridge.

Thursday, February 5th

9.30 a.m. *Presentation and discussion of papers:*

Room A. *Train-Ferry Landings at Port Mulgrave and Point Tupper, N.S.*—by D. B. Armstrong, A.M.E.I.C., Erection Engineer, Dominion Bridge Company, Ltd., Montreal, and W. Chase Thomson, M.E.I.C., Designer, Dominion Bridge Company, Ltd., Montreal.

The Construction of the Steel Lock Gates of the Welland Ship Canal—by E. S. Mattice, M.E.I.C., Vice-President, National Bridge Company of Canada, Ltd., Montreal. Late Manager and Engineer, Steel Gates Company, Ltd.

Room B. *Breakwater Construction in Port Arthur Harbour*—by F. Y. Harcourt, M.E.I.C., District Engineer, Department of Public Works, Canada, London, Ont.

A Method of Laying out Warped Surfaces of Hydraulic Structures—by C. P. Dunn, M.E.I.C., Chief Engineer, Alcoa Power Company, Arvida, Que.

The Design of the Chute-à-Caron Diversion Canal—by G. O. Vogan, A.M.E.I.C., Chief Designing Engineer, Alcoa Power Company, Ltd., Arvida, Que.

12.45 p.m. *Buffet Lunch* (informal).

2.15 p.m. *Presentation and discussion of Papers:*

Room A. *Structure and Oil Prospects of the Eastern Foothills Area, Alberta, between the Highwood and Bow Rivers*—by Dr. G. S. Hume, Geological Survey, Department of Mines, Ottawa, Ont.

The Water Supply Problem in Southern Saskatchewan—by W. A. Johnston, Geological Survey, Department of Mines, Ottawa, Ont.

Automatic Block Signalling on the Canadian Pacific Railway—by A. J. Kidd, Assistant to Signal Engineer, Eastern Lines, Canadian Pacific Railway Company, Montreal.

Room B. *Alexander Power Development on the Nipigon River*—by T. H. Hogg, D.Eng., M.E.I.C., Chief Hydraulic Engineer of the Hydro-Electric Power Commission of Ontario, Toronto.

4.30 p.m. *Ladies Tea.*

Friday, February 6th

9.30 a.m. *Presentation and discussion of Papers:*

Room A. *Steam Station for the Head Office Building of the Sun Life Assurance Company of Canada, Montreal*—by F. A. Combe, M.E.I.C., Consulting Combustion and Steam Engineer, Montreal.

Mechanical Equipment in the Head Office Building of the Sun Life Assurance Company of Canada, Montreal—by E. A. Ryan, M.E.I.C., Consulting Engineer, Montreal.

The Plumbing Systems Designed for the Head Office Building of the Sun Life Assurance Company of Canada, Montreal—by A. Traver Newman, Consulting Engineer, New York, N.Y.

9.30 a.m.

Room B. *The Structural Engineering of the Head Office Building of the Sun Life Assurance Company of Canada, Montreal*—by A. H. Harkness, M.E.I.C., Harkness and Hertzberg, Consulting Engineers, Toronto.

The Electrical Equipment for the Head Office Building of the Sun Life Assurance Company of Canada, Montreal—by J. H. Mencke, Consulting Engineer, New York and E. A. Ryan, M.E.I.C., Consulting Engineer, Montreal.

12.45 p.m. *Buffet Luncheon* (informal).

2.15 p.m. Arrangements are being made for parties to visit the Sun Life Building and a number of engineering works of interest,

The new Head Office Building of the Sun Life Assurance Company of Canada, which is approaching completion, is designed for a population of 10,000 people, and has the most modern equipment. Its engineering features as regards structural work, heating and ventilation, lighting, sanitation and transportation, are of great interest.

The new shops of the Canadian National Railways at Point St. Charles employ the most advanced methods in locomotive construction and maintenance, and are amongst the most complete on the continent.

The Dominion Engineering Works at Lachine specialize in the construction of large turbines and paper machines.

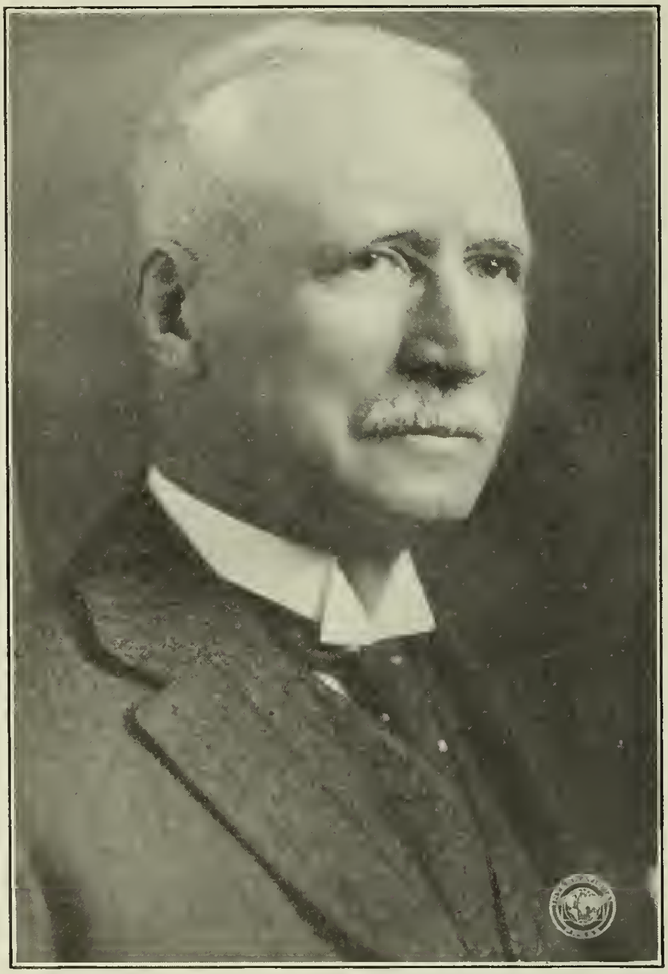
The Dominion Bridge Company, also at Lachine, have the largest bridge and structural shops in Canada.

The new bronze foundry of the Robert Mitchell Company at St. Laurent exemplifies the last word in modern foundry equipment.

9.00 p.m. *Dance and Supper.*

Award of the Sir John Kennedy Medal to George Herrick Duggan, M.E.I.C.

Established in 1928, the Sir John Kennedy Medal is the highest distinction in the gift of The Institute, and commemorates the great services rendered to the development of Canada, to engineering sciences, and to the profession, by the late Sir John Kennedy. It is given, not for the presentation of a paper, but as a recognition of outstanding merit in the profession, or of noteworthy contribution to the science of engineering or to the benefit of The Institute.



GEORGE HERRICK DUGGAN, M.E.I.C.

The first award of this honour was made in 1929, when it was received by Lieut.-Colonel R. W. Leonard, M.E.I.C., whose recent death we now have to deplore. At its meeting on October 17th, 1930, the Council of The Institute decided that the second award of the Sir John Kennedy Medal should be made to Past-President G. H. Duggan, M.E.I.C., to whom the medal will be presented at the Annual Dinner of The Institute to be held on Wednesday, February 4th, 1931.

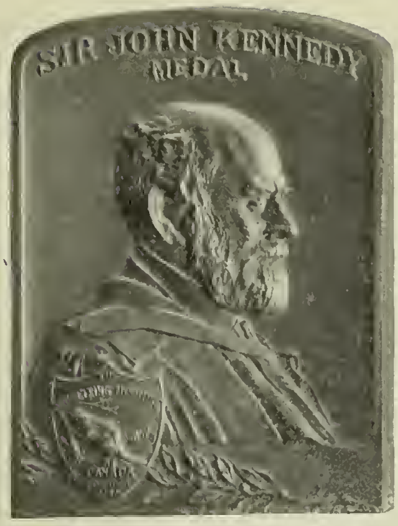
George Herrick Duggan was born in Toronto, in 1862, and was educated at Upper Canada College, and at the University of Toronto, graduating there in 1883, and taking a post-graduate course in 1884.

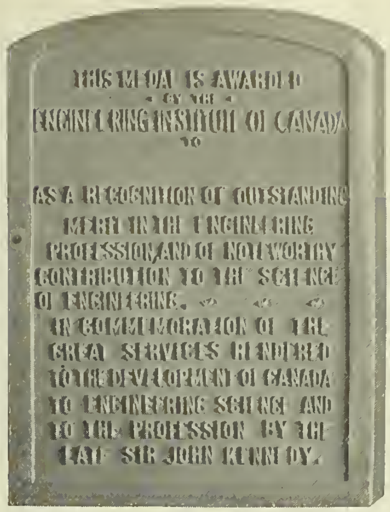
His professional experience began with the engineering department of the Canadian Pacific Railway; in 1886 he joined the staff of the Dominion Bridge Company as draughtsman, and in 1888 became resident engineer in charge of their Lachine works. He was appointed their chief engineer in 1891, and ten years later went to Sydney, Cape Breton, as assistant to the president, and consulting engineer, Dominion Iron and Steel Company and Dominion Coal Company. In 1904 he became second vice-president and general manager of the Dominion Coal Company, remaining in that capacity until 1910, when he returned to the Dominion Bridge Company as chief engineer. After serving as general manager for four years, he was appointed vice-president in 1917, and president of the company in 1918, the position which he still holds.

During his active engineering career he took a leading part in the construction of many outstanding works, among which may be named the Interprovincial bridge at Ottawa, the Quebec bridge, and the Montreal Harbour bridge.

Joining the Canadian Society of Civil Engineers as an Associate Member in March, 1888, during the second year of the Society's existence, he was elected a Member in 1890, serving on the Council for nine years, and as vice-president for five years. He was president in 1916, and has on many occasions since that time rendered valuable service to The Institute.

He is a Member of the Institution of Civil Engineers





(Member of Council, 1918), Member of the Canadian Institute of Mining and Metallurgy (vice-president, 1906; member of council, 1911-1913), and Member of the American Society of Civil Engineers. For many years he has been prominently identified with yachting in Canada, and is an accomplished yacht designer and sailor. He was instrumental in founding the Toronto Yacht Club, the Royal St. Lawrence Yacht Club and the Royal Cape Breton Yacht Club, in all of which he held office.

Mr. Duggan has been chairman of the Quebec division of the Canadian Manufacturers Association, and is a director of the British Empire Steel Corporation, the Royal Bank of Canada, the Montreal Trust Company, and other important industrial and financial organizations.

Meeting of Council

A meeting of Council was held on Friday, December 19th, 1930, at eight o'clock p.m., with President A. J. Grant, M.E.I.C., in the chair, and seven other members of Council present.

The Council noted with deep regret the death of Past-President R. W. Leonard, M.E.I.C., on December 17th, 1930, and on the motion of Fraser S. Keith, M.E.I.C., seconded by George R. MacLeod, M.E.I.C., the following resolution was unanimously passed, the Secretary being directed to send a copy to Mrs. Leonard:

> "On learning of the death of Past-President R. W. Leonard, the Council of The Engineering Institute of Canada desires to express its sincere sympathy and deep regret. Always active in promoting the welfare and advancement of the engineering profession, prominent in educational and philanthropic work, patriotic to a degree, the loss of Reuben Wells Leonard will be keenly felt by the members of The Institute and by the many who benefit from the Foundations he established."

The attention of Council was drawn to the death on November 13th, 1930, of George A. McCarthy, M.E.I.C., an active member of the Toronto Branch, and on the motion of Mr. MacLeod, seconded by J. A. McCrory, M.E.I.C., the following resolution was unanimously passed, the Secretary being directed to send a copy to Mrs. McCarthy:

> "The Council of The Engineering Institute of Canada records with regret the death of George Arnold McCarthy, for thirty-three years a prominent member of The Institute. Active in the affairs of The Institute as a councillor and as an officer of the Toronto Branch, he was always keenly interested in the advancement of the engineering profession. The Council desires to extend to Mrs. McCarthy and to his family its deepest sympathy and condolence."

Consideration was given to the amendments which have been proposed in Council to various sections of the By-laws, and after discussion it was resolved not to put forward this year the proposal to amend Section 34 of the By-laws dealing with the annual fees of members, which was lost on the ballot in May last. It was, however, decided to submit to the Annual Meeting for discussion, and to the membership for vote, the amendments proposed to Sections 66 and 67 dealing with the method of selecting the Nominating committee.

Council took action with regard to a number of members who are in arrears of fees for a considerable period, granting further credit in cases where members had replied to the communications addressed to them, and removing from the list the names of those who had ignored the reminders sent them. Thirty-two members of various classes were thus removed.

Discussion followed on the arrangements for the Annual General Meeting and the Annual Dinner to be held in February, 1931.

The report of the committee on Classification and Remuneration, together with a report on the Tariff of Engineers' Fees, was presented by Mr. Busfield, the chairman of the committee, these reports having been prepared owing to the need of a revision of the reports on these subjects issued in 1922. After discussion, the Secretary was directed to circulate these documents to all members of Council for their comment.

The Treasurer presented a draft budget for 1921, indicating the expenditures considered by the Finance committee to constitute a necessary minimum; additional expenditures approved by the Plenary Meeting of Council; and a further series of items recommended by the Special Committee on Publications. The impossibility of providing for all these was noted, and the matter was held over for discussion at the next meeting of Council.

The newly elected officers of the Kingston and Border Cities Branches were noted as follows:

Kingston Branch

Chairman	A. Jackson, A.M.E.I.C.
Vice-Chairman	L. F. Goodwin, M.E.I.C.
Secretary-Treasurer	L. F. Grant, M.E.I.C.
Executive Committee	A. G. MacLachlan, A.M.E.I.C.
	W. L. Malcolm, M.E.I.C.
	L. M. Arkley, M.E.I.C.
Ex-officio	D. M. Jemmett, A.M.E.I.C.

Border Cities Branch

Chairman	R. J. Desmarais, A.M.E.I.C.
Vice-Chairman	C. G. R. Armstrong, A.M.E.I.C.
Secretary-Treasurer	H. J. A. Chambers, A.M.E.I.C.
Executive Committee	J. D. Cummins, A.M.E.I.C.
	H. J. Coulter, Jr.E.I.C.
	R. C. Leslie, A.M.E.I.C.
Ex-officio	O. Rolfson, A.M.E.I.C.
	L. McGill Allan, A.M.E.I.C.
	A. E. West, M.E.I.C.

The Secretary presented a memorandum received from England regarding the possible terms of agreement with the Institution of Electrical Engineers in connection with the formation of joint radio sections of The Institute's branches, this arrangement being generally similar to that which has been approved by Council in connection with aeronautical engineering and co-operation with the Royal Aeronautical Society. While general approval was expressed the matter was held over for further discussion with the Institution.

The Council received with appreciation a replica of the Fiftieth Anniversary Medal of the American Society of Mechanical Engineers, and transcripts of the remarks of His Excellency Vincent Massey, Minister to the United States, presenting Brig.-Gen. C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C., for the medal, and the citation accompanying the presentation.

Eight resignations were accepted; three reinstatements were effected; five requests for Life Membership were considered, and a number of special cases were dealt with.

A number of applications for admission and transfer were considered, and the following elections and transfers were effected:

Elections		*Transfers*	
Assoc. Members	4	Assoc. Member to Member	1
Juniors	7	Junior to Assoc. Member	3
Students admitted	62	Student to Assoc. Member	5
		Student to Junior	3

The Council rose at one forty-five a.m.

ELECTIONS AND TRANSFERS

At the meeting of Council held on December 19th, 1930, the following elections and transfers were effected:

Associate Members

BICKLE, Warner Pentland, B.A., B.Sc., (Univ. of Man.), supt. of paving, Carter Halls-Aldinger Co. Ltd., Winnipeg, Man.

DREW, Arthur Edward, B.Sc., (Univ. of Sask.), Crystal Springs, Sask.

LEROUX, Louis Joseph, B.A.Sc., (Ecole Polytech.), engr. of bridges and tunnels, City of Montreal, Que.

MANNING, Ralph Clark, B.A.Sc., (Univ. of Toronto), district engr., Canadian Institute of Steel Construction, Toronto, Ont.

Juniors

FRITH, John Rowland, B.Sc., (McGill Univ.), 3429 Peel St., Montreal, Que.

GRIFFITHS, William Eric, 4th year Student, McGill University, Montreal, Que.

HYLLAND, Einar Nyson, C.E., (Tech. Univ. of Norway), designer, Beauharnois Construction Company, Beauharnois, Que.

LALAND, Arne, C.E., (Tech. Univ. of Norway), concrete engr., Messrs. J. M. Eugene Guay, Inc., Keefer Bldg., Montreal, Que.

LARRIVEE, J. Albert Edouard, B.Sc., (Univ. of N.B.), asst. divn. engr. and instr'man., C.N.R., Montreal, Que.

LAURENCE, Emile, B.A.Sc., C.E., (Ecole Polytech.), estimator and sales engr., George W. Reed and Co. Ltd., Montreal, Que.

TRACY, Edgar Herbert, B.Sc., (Univ. of N.B.), student test course, Canadian General Electric Co. Ltd., Peterborough, Ont.

Transferred from the class of Associate Member to that of Member

CIMON, Hector, B.A., B.Sc., C.E., (Ecole Polytech.), engr., Price Bros. & Co. Ltd., Quebec, Que.

Transferred from the class of Junior to that of Associate Member

DYER, Joseph Wilson, B.A.Sc., (Univ. of Toronto), bldgs. supervisor, general plant dept., Bell Telephone Company of Canada, Toronto, Ont.

FRASER, John Douglas, B.Sc., (McGill Univ.), plant engr., Moir's Ltd., Halifax, N.S.

TISON, Maurice, (McGill Univ.), electr'l. engr. in charge of mtce., Electrical Commission of the City of Montreal, Montreal, Que.

Transferred from the class of Student to that of Associate Member

GEALE, Charles Norman, B.A.Sc., (Univ. of Toronto), junior engr., Welland Ship Canal, Port Colborne, Ont.

HENDERSON, Gordon R., B.Sc., (Queen's Univ.), res. engr., Power Corporation of Canada, Ltd., Montreal, Que.

MASSEY, Denton, B.Sc., (Mass. Inst. Tech.), asst. to supt. of Toronto works, in charge of overhead and costs divn., Massey Harris Company, Ltd., Toronto, Ont.

NOTMAN, James Geoffrey, B.Sc., (McGill Univ.), asst. to gen. mgr., Dominion Engineering Works, Ltd., and works mgr., Charles Walmsley and Company (Canada) Ltd., Montreal, Que.

ROSS, Hugh Gordon, B.Sc., (McGill Univ.), design and development engr., Westinghouse Electric and Manufacturing Co., East Pittsburgh, Pa.

Transferred from the class of Student to that of Junior

BUTLER, Ernest W. R., B.Sc., (McGill Univ.), Western Canada manager, Bailey Meter Company, Ltd., Winnipeg, Man.

JOHNS, Charles Frederick, B.Sc., and Engrg. Cert., (Mount Allison Univ.), plant and heating engr., in charge of engrg. dept., Enterprise Foundry Company, Ltd., Sackville, N.B.

MOORE, Alexander Glydon, B.Sc., (N.S. Tech. Coll.), elect'l. engr., underground distribution dept., Montreal Light, Heat & Power Cons., Montreal, Que.

Students admitted

Undergraduates at Dalhousie University, Halifax, N.S.

BACON, Charles Ives, North Tryon, P.E.I.
CORKUM, Philip Byron, 2 Binney Street, Halifax, N.S.
FRAME, George Archibald, Shubenacadie, N.S.
FRASER, Campbell, 3 Payzant Avenue, Halifax, N.S.
FRASER, Innes Martell, 153 Walnut Street, Halifax, N.S.
HAMILTON, William Garrison, 39½ Fenwick Street, Halifax, N.S.
JOST, Burton Norris, Guysboro, N.S.
JOST, Victor Arthur, 3 Coburg Apts., Halifax, N.S.
KELL, Bryce Westhall Thomas, 90 Fraser Street, Quebec, Que.
LLOY, James Murray, 91 Argyle Street, Halifax, N.S.
LODGE, Gomer Angus, King's College, Halifax, N.S.
MACKIE, George May, 306 South Street, Halifax, N.S.
MATHESON, Joseph Silver, 327 South Street, Halifax, N.S.
MENZIE, Harold David, 8 Murray Place, Halifax, N.S.
McCOLOUGH, Edward Pearson, Great Village, N.S.
RIPLEY, Howard Andrew, Fairview, Hfx. Co., N.S.
ROOD, James Lindsay, Berwick, N.S.
WOOD, Albert Lewis, 14 Black Street, Halifax, N.S.
WOODS, William Daniel, Armdale P.O., N.S.
WRIGHT, Charles Abbott, 110 Oxford Street, Halifax, N.S.

Undergraduates at Nova Scotia Technical College, Halifax, N.S.

BAKER, Max Leo, 297 Morris Street, Halifax, N.S.
CAMERON, James Crofton Joseph, Halifax, N.S.
CHANDLER, Edward Sayre, Charlottetown, P.E.I.
CORNING, Keith Welton, 22 Harvey Street, Halifax, N.S.
FRECKER, George Alain, Halifax, N.S.
KEATING, Harold Johnston, 99 Charles Street, Halifax, N.S.
KNODELL, John Frederick, 96 Chebucto Road, Halifax, N.S.
LANG, John Taylor, 13 Mitchell Street, Halifax, N.S.
LEWIS, Daniel Urquhart, 9 Spring Garden Road, Halifax, N.S.
MITCHELL, Lawrence Everett, B.A., (Mount Allison), Campobello, N.B.
PEDDER, Arthur William, P.O. Box 440, Dartmouth, N.S.
RISLEY, Wilfred Cary, Jr., 22 Harvey Street, Halifax, N.S.
ROSS, George Victor, Halifax, N.S.
THOMPSON, Frank Lawrence, 96 Highfield Street, Moncton, N.B.
TIBBITTS, Angus Gordon, Halifax, N.S.

Undergraduates at St. Mary's College, Halifax, N.S.

COLGAN, Patrick, Halifax, N.S.
CONNOLLY, Jack, Halifax, N.S.
FEETHAM, Edward Joseph, Halifax, N.S.
FINLAY, Francis Joseph, Halifax, N.S.
GRANVILLE, Francis X., Halifax, N.S.
HAMILTON, Cecil Roy, Halifax, N.S.
MacDONALD, Leo J., Halifax, N.S.
O'CONNOR, Victor F., Halifax, N.S.
O'LEARY, Edmund C., Halifax, N.S.
SOMERS, John Stephen, Halifax, N.S.

Undergraduates at McGill University, Montreal, Que.

ATKINSON, Thomas Martin, 3637 University Street, Montreal, Que.

BACKLER, Irving Saul, 5331 Mance Street, Montreal, Que.

BLACHFORD, Henry Edmund, 7 Hudson Avenue, Westmount, Que.

CHAMPAGNE, Georges Albert, 6702 de St. Valier Street, Montreal, Que.

GERSOVITZ, Frank, 457 Argyle Avenue, Westmount, Que.

HART, Herbert Trench, 3592 University Street, Montreal, Que.

JOHNSON, Robert Ernest Lacey, 536 Grosvenor Avenue, Westmount, Que.

PHILLIPS, Frederick René, 26 Holton Avenue, Westmount, Que.

EVANS, Edward Norton, 352 Kitchener Avenue, Westmount, Que.

* * *

HYMMEN, Edmond B., (Univ. of Toronto), North House, University of Toronto, Toronto, Ont.

McQUEEN, Duncan R., (Univ. of Toronto), North House, University of Toronto, Toronto, Ont.

SMITH, Henry E., (Univ. of Toronto), North House, University of Toronto, Toronto, Ont.

JACOB, John Kenneth, (Univ. of B.C.), 2978-38th Ave. West, Vancouver, B.C.

SAUNDERS, Arthur Jackson, (Univ. of B.C.), 4501-7th Ave. West, Vancouver, B.C.

BRIDGE, David E., B.A.Sc., (Univ. of Toronto), engrg. ap'tice, Canadian Westinghouse Company, Hamilton, Ont.

LAWRENCE, Stanley Nelson, B.A.Sc., (Univ. of Toronto), test course, Canadian General Electric Co. Ltd., Peterborough, Ont.

ELLIOT, Donald George, B.Sc., (Univ. of Edinburgh), Monsarrat & Pratley, Drummond Building, Montreal, Que.

Reuben Wells Leonard, M.E.I.C.

On December 17th, 1930, death closed the career of Reuben Wells Leonard, M.E.I.C., who leaves behind him a record of outstanding services to his profession, to Canada and to the British Empire.

Born at Brantford, Ontario, on February 21st, 1860, he was educated at the Brantford Collegiate Institute and the Royal Military College of Canada, where he received the silver medal in 1883. His early engineering experience with the Canadian Pacific Railway on surveys and construction in the Lake Superior Division was followed by military service in the North-West Rebellion, as staff officer of transport, and in other capacities. After a further period on the engineering staff of the Canadian Pacific Railway in Manitoba and Ontario, in 1886 he became chief engineer of the Cumberland Railway and Coal Company in Nova Scotia. In 1891 he was engaged on surveys for important branch lines for the Canadian Pacific Railway in Ontario, Quebec and British Columbia, and in 1892-1893 was in charge of the construction of the first hydro-electric power development at Niagara Falls, for the Park and River Railway Company. In 1895 he became chief engineer and manager of construction of the St. Lawrence and Adirondack Railway, occupying a similar position in succeeding years on the Montreal and Ottawa (short line). His next appointment was as chief engineer of the Cape Breton Railway, and later he entered the mining field as engineer for the Lake Superior Corporation in the Sudbury and Michipicoten districts. In 1902 he became engineer in charge of the hydro-electric development at De Cew falls for the Hamilton Cataract Power Co. and later held a similar position at Kakabeka falls near Fort William, Ont., for the Kaministikwia Power Company. Returning to mining work in 1906, he was promoter and president of the Coniagas Mines, and the Coniagas Reduction Company, Limited. He was appointed chairman of the National Transcontinental Railway Commission, Ottawa, in 1911, and in 1918 he became president and promoter of the Electrical Steel and Engineering, Ltd., at Welland, Ont.

REUBEN WELLS LEONARD, M.E.I.C.

Entering the financial field in his later years, he was more particularly interested in mining work and served as a director of a number of important companies.

His work on behalf of the engineering profession was noteworthy. Joining the Canadian Society of Civil Engineers as one of the original members in January, 1887, he served on Council during the years 1905, 1908 and 1909, was elected vice-president in 1910, and became president of The Engineering Institute of Canada in 1919. His untiring interest in its affairs was shown by his activity on its behalf, by his contribution of papers to its proceedings, and by his foundation of the Leonard Medal in 1918. The Council of The Institute recognized his services to the profession and to the science of engineering by the award to him in 1929 of the Sir John Kennedy Medal, the highest distinction in the Institute's gift.

Colonel Leonard was connected with many other engineering and scientific societies, being a past vice-president of the Canadian Institute of Mining and Metallurgy; a corresponding member of the Council of the Institution of Mining and Metallurgy, Great Britain; a Member of the Institution of Civil Engineers, and a Member of the American Institute of Mining and Metallurgy. He found time to devote to educational affairs, serving as a governor of the University of Toronto and of Queen's University, and being associated also with the direction of other educational institutions.

In 1916 Lieut.-Colonel and Mrs. Leonard created the Leonard Foundation for the purpose of establishing Leonard Scholarships in specified schools and colleges of the Dominion of Canada; the scope of this foundation was extended and revised in 1920, at which time the endowment was increased to half a million dollars. Colonel Leonard believed that the stability of civilization and the peace of the world can be best promoted by the education in patriotic institutions of selected and deserving children, and the benefits of the foundation are accordingly available (under certain restrictions) for students who, without financial assistance, would be unable to enter any of the institutions named. The aims and objects of the Leonard Foundation are furthered by an association of past students who have enjoyed the benefits of Leonard Scholarships and who, in their turn, will aid in carrying out the intentions of the founders.

During the Great War, Colonel Leonard gave much of his time and money to patriotic movements and he was enthusiastic in his advocacy of closer union of the various members of the British Commonwealth of Nations. His interest in international relationships was shown by his munificent gift to the British nation of Chatham House, the historic building in St. James's Square, London, which serves as the headquarters of the Royal Institute of International Affairs. This action was received throughout the Empire as a tribute of loyalty from one of the Dominions.

Sensitive and generous in disposition, he was filled with enthusiasm in national or charitable causes, but avoided publicity or self-advertisement. Although suffering severely from illness during the last six years of his life, he retained his interest in Canadian and world affairs. His true worth was realized by those who knew him, but owing to his retiring nature, there has been no adequate general recognition of his services as financier, philanthropist and patriot.

PERSONALS

R. L. Dunsmore, A.M.E.I.C., is on the staff of the Imperial Oil Refineries, Ltd., and is located at Dartmouth, N.S. Mr. Dunsmore was for some years with the International Petroleum Company at Talara, Peru, S.A.

S. Farquharson, A.M.E.I.C., formerly designing engineer with the Alcoa Power Company, Arvida, Que., has organized the firm of S. Farquharson and Associates, industrial consultants, Montreal. Mr. Farquharson was for a time with the B.C. Electric Railway Company, later becoming connected with the Power Corporation of Canada, Ltd., at Montreal.

P. Hughes, S.E.I.C., is now connected with the Dominion Rubber Company, Montreal. Mr. Hughes, who graduated from McGill University in 1926, with the degree of B.Sc., was for a time on the staff of the Bureau of Tests of the International Paper Company at Glen Falls, N.Y. and was later with the John S. Metcalfe Company, Ltd.

W. L. Langlois, Jr.E.I.C., who was formerly assistant engineer in the town department of the Canadian International Paper Company at Temiskaming, Que., has joined the staff of the city engineer at Hamilton, Ont. Following his graduation from the University of Toronto in 1923, Mr. Langlois spent a year in China, and was later engaged for a time on municipal work with the township of Etobicoke, Ont. In 1925 he was in the employ of H. G. Acres and Company at Niagara Falls, Ont., and was later with the Hippo Products Company of Toronto.

J. C. Nutter, A.M.E.I.C., has joined the staff of Price Brothers and Company, Ltd., Quebec, Que. Mr. Nutter, who prior to accepting his present position was superintendent of the Nashwaak Pulp and Paper Company, Ltd. at Saint John, N.B., was at one time electrical engineer with the Groveton Paper Company, Inc., at Groveton, N.H.

M. D. Stewart, A.M.E.I.C., has recently been appointed resident engineer for Lucerne-in-Quebec at Montebello, Que. Mr. Stewart, who was formerly on the staff of the Foundation Company of Canada, Ltd., at Montreal, is a graduate of the University of Toronto of the year 1922. Following graduation he become connected with Bremner Norris and Company, Ltd., as purchasing agent and estimator in charge of construction of warehouse for the Dominion Cartridge Company at Brownsburg. In 1924 he accepted a position with Price Brothers and Company Ltd., at Chicoutimi, Que., remaining with that firm until 1929.

W. H. Greene, M.E.I.C., formerly with the Canada Creosoting Company at Edmonton, Alta. is at present with the Alberta Wood Preserving Company, and is located at Calgary, Alta. Mr. Greene was for a number of years assistant city engineer of Moose Jaw, Sask. He is a graduate of the University of Toronto, having received his degree in 1909, following which he joined the staff of the Teton County Co-operative Irrigation Company as district engineer on irrigation construction in Montana, U.S.A. In 1910 he was appointed by the Department of the Interior as engineer-in-charge of a party investigating the Moose Jaw river as a source of water supply for the city of Moose Jaw, and in the following year carried out, for the same department, an investigation of stream-flow under ice cover in southern Alberta. In 1912 Mr. Greene received his appointment as assistant city engineer of Moose Jaw, and in 1921 was made acting city engineer and also superintendent of waterworks and building inspector. He was later made city engineer, which position he held until he resigned in January, 1929.

An incorrect version of this personal appeared in the November, 1930, issue.

H. F. Bennett, A.M.E.I.C., receives Appointment

Harry F. Bennett, A.M.E.I.C., formerly senior assistant engineer, Department of Public Works, Canada, at Halifax, N.S., has been appointed district engineer for the Department at Sault Ste. Marie, Ont. Mr. Bennett was educated at the University of New Brunswick, graduating with the degree of B.Sc. in 1908. He joined the Department of Public Works immediately after graduation, and served as assistant engineer until 1916, when he was attached to the Canadian Expeditionary Forces, serving in France with the 48th How. Battery, 2nd Brigade, C.F.A. Returning to the Department in 1919, Mr. Bennett remained on the Saint John, N.B., staff until 1924 when he was appointed to the office in Halifax held by him until the present time. Mr. Bennett has taken an active interest in engineering affairs, having served as chairman of both the Saint John and the Halifax Branches of The Institute, as Councillor of both the Association of Professional Engineers of New Brunswick and Nova Scotia, was Maritime vice-president of the Professional Institute of the Civil Service of Canada in 1926-1927, and represented the Halifax Branch on the Council of The Institute for the current year.

HARRY F. BENNETT, A.M.E.I.C.

H. B. Dickens, A.M.E.I.C., is at present reinforced concrete designing engineer for the city of Hamilton, Ont. Mr. Dickens was surveyor and assistant manager at the Amrir tin mine, Nigeria, West Africa, during 1913-1915, and was on active service in the Cameroons and Nigeria, West Africa, from May, 1915, to September, 1919, being in charge of the Mama and Mada patrols in Nigeria for the greater part of 1917-1919. Following the war, Mr. Dickens was engaged on timber limit surveys in northern Ontario, later joining the engineering staff of the Underwriters' Survey Bureau, Toronto. In 1923 he was employed by Frank Barber and Associates; in 1924 he was with the township of East York, and in 1925 with the Welland Ship Canal at Port Colborne, Ont. Later Mr. Dickens was associated with Messrs. Lang and Ross on transmission line survey in connection with the Flin Flon mine, and prior to accepting his present position he was with the Dominion Reinforcing Company at London, Ont.

C. H. Donnelly, A.M.E.I.C., has been appointed technical assistant to the general superintendent of the American Can Company at Simcoe, Ont. Mr. Donnelly is an honour graduate of Queen's University from which he received the degree of B.A. in 1914 and that of B.Sc. in 1919. His first engineering work was with the Donnelly Salvage and Wrecking Company, Kingston, where he was employed during the summer months of his university course. He served overseas with the Canadian Field Artillery from 1915 until the end of the war. From 1920 to 1926 Mr. Donnelly was with the construction department of the Hydro-Electric Power Commission of Ontario as assistant to the superintendent of the Queenston power house, and from May, 1926, to the present time he has been on the staff of the United States Light and Heat Corporation at Niagara Falls, N.Y.

BOOK REVIEW

Estimating Construction Costs

By G. Underwood. McGraw-Hill, New York, 1930, leatherette, 5¾ x 9 inches, 620 pp., figs., charts, tables, $6.00.

The author is already well known in this field, through his work on "Standard Construction Methods," issued by the same publishers.

His new book deals with the art of estimating and gives unit costs for the various classes of work based on the rate of wages, together with the unit cost of various materials based on the price of the materials making up the unit in question. Evidently great care and thought have been used in assembling the information now presented.

It must be borne in mind that estimating cannot be learned from books alone, but requires also practical experience, best gained by working with experienced estimators.

It would seem that the last two chapters of this book should be read before making any reference to those treating of unit costs, as they deal with the important question of overhead charges and the manner of analyzing an estimate, both of which must be clearly understood before attempting to set unit prices in an estimate.

The author bases his costs on practice in New York, where there is small variation in climatic conditions. In the reviewer's experience, with an allowance for heating materials and temporary heat after the building is closed in, work can be done in winter for the same cost as during warm weather. This is probably due to the fact that there is considerably less work being carried out in the winter, when the demand for men is often below the available supply. These remarks, of course, only refer to work in cities, and are not applicable to the same extent to work in isolated localities where the men must be brought from centres of large population. On the other hand it must be remembered that wages are usually lower in the country districts.

In using prices from a book such as this, due allowance must be made for any unusual conditions, and particularly allowance should be made for the cost of installing special plant or machinery, more especially on smaller work where this item may greatly increase unit costs beyond those shown on the charts.

An outstanding feature of "Estimating Construction Costs" is the type of chart used. This chart is of the same form for labour items and for material items, and also the same form of chart is used for the different trades. It is thus very easy to read any chart after the comparatively simple method is understood for any one trade. Each chart is headed by a statement of the basis on which the chart is made up, giving the amount of work that one man can do in 8, 9 and 10 hours respectively, and in the case of materials, the quantities of the various materials required to make one unit. The day's work units would appear to give a very fair average, and should prove most useful in estimating. When the wages of one man for one day are known the labour cost of one unit can be read off the chart for the 8, 9 and 10 hour day. In the same way for materials, when the cost of a unit of the material is known, the chart shows the cost per square yard or cubic yard, etc., as the case may be. It should be noted that some of the information on freight costs is based on rates in the United States, and should therefore be used with caution when dealing with Canadian work. Generally speaking, this book should be very useful to the estimator, but must be used with care and due allowance made for local conditions and for the items of overhead, winter work and the installation of special plant and equipment.

L. H. D. Sutherland, M.E.I.C.,
Engineer,
E. G. M. Cape Company, Ltd., Montreal.

A new principle in automatic control of chlorination has recently been developed by Wallace and Tiernan with their new automatic residual chlorine recorder and controller.

The orthotolidin test, generally accepted as the criterion of correct chlorinator operations, positively controls chlorine flow with this apparatus. The tests are automatically made at ten minute intervals and "residual chlorine" of the treated water recorded on a chart.

Any fluctuations in flow or chlorine demand are reflected in varied "residuals" and immediately compensated for by the automatic controller. Recorded "residual chlorine" curves show no appreciable lag between chlorine demand and automatic adjustment of chlorine flow.

The Association of Professional Engineers of the Province of British Columbia

The Eleventh Annual Meeting of the Association of Professional Engineers of the Province of British Columbia was held at the Hotel Georgia, Vancouver, on December 6th, 1930, with a large and representative attendance. The following were elected as officers and members of Council for 1931: President, Major J. C. MacDonald, M.E.I.C.; Vice-President, A. S. Gentles, M.E.I.C.; Council, W. R. Bonnycastle, M.E.I.C. (President 1930), W. M. Cunliffe, A. G. Langley, J. I. Newell, W. H. Powell, M.E.I.C.

The remaining four members of Council are to be appointed by the government of the province.

At the luncheon meeting the principal speaker was the mayor of Vancouver, W. H. Malkin, and the guests included a number of members of the Education department of the provincial government, officers of the Vancouver School Board, and others interested in educational problems. The visitors were interested in a description by A. S. Wootton, M.E.I.C., outlining the educational requirements and the scheme of study established under the terms of the Engineering Act of the Province of British Columbia for entry into the profession.

At the business session in the afternoon the retiring president, W. R. Bonnycastle, M.E.I.C., gave an account of the Association's activities during the past year. He noted that the Provincial Legislature had now defined the terms Civil Engineer, Electrical Engineer, etc., where these appear in provincial enactments, as meaning engineers registered in these branches under the terms of the Engineering Act of the Province. The retiring president was able to announce that four inquiries had been instituted by the Council of the Association into

J. C. MacDONALD, M.E.I.C.

cases of professional misconduct, and that in two cases the charges originally made in the public press had been completely disproved. In the other two cases the charges had been proved, the license of one engineer had been cancelled and suitable action had been taken in the other case. He would impress upon all members of the Association the necessity of adopting high standards in engineering design and construction. The Council had been active in discouraging the too prevalent custom whereby a consulting engineer is subordinate to or paid by the contractor on an engineering work.

The formation of the Vancouver Professional Engineers Club was noted, and the address also covered the activities of the Association's Board of Examiners during the year. Seventy-two candidates had passed, or, as university students, had been exempted from, preliminary examinations; fifteen non-university candidates had taken the intermediate examination, and thirty-seven had been granted intermediate status on graduation; nineteen non-university candidates had passed their final examinations, and eight graduates' theses had been accepted. After touching on the subject of possible federation among the engineering organizations in Canada, the speaker congratulated the Association on the rapid development of the true conception of professional status in the province.

In the evening the annual banquet of the Association was held, at which about two hundred and fifty were present, and at which a certificate of registration and life membership in the Association was awarded to the guest of the evening, His Honour Robert Randolph Bruce, Lieutenant-Governor of the Province, who received a license to practise Civil and Mining Engineering in the Province of British Columbia, he being a graduate of the University of Glasgow.

BRANCH NEWS

Border Cities Branch

R. C. Leslie, A.M.E.I.C., Secretary-Treasurer.

The May monthly meeting of the Border Cities Branch was held on Friday, May 23rd. On this occasion Mr. Thomas Adams, who has been engaged by the city of Windsor to present a report on the planning of this city, gave an address on "Town Planning," at the conclusion of which he outlined briefly some of the suggestions contained in his report.

The "Town Planner" Mr. Adams stated, is the liaison between the engineer and the architect. He is concerned with the welfare, health and safety of the community and his work includes not only arranging for proper expansion but the correcting of wrong development.

When making a study of the planning of a city, the speaker stated, the three main items requiring consideration are the railways, the highways and streets, and the open spaces. The railways present the greatest difficulties. Not only are railways controlled by a railway company or by the Dominion government and are consequently beyond civic control, but it is difficult to obtain any information regarding what they intend doing in the future. Because of this, the town planner should, after careful consideration and after obtaining whatever information the railway companies will divulge, propose the arrangement which he considers best, this proposal being as adaptable to whatever may arise as is possible.

Highways and streets are within the jurisdiction of the city council. They can, and should therefore, be laid out according to the best possible arrangement. Lanes and streets should be made proportionate to one another, and one should avoid assuming that a city plan is a street plan.

By open spaces Mr. Adams stated that he meant parks, court-yards, gardens, etc. Controlling the open spaces means simply regulating building density, and the allowable building density should be definitely fixed to prevent overcrowding and congestion. Open spaces similarly to highways and streets come within the jurisdiction of the city council and consequently this can be done.

The speaker went on to say that the three needs of any community for its development, are: means of transportation, facilities for development and an adequate supply of labour.

The requirements of any potentially great community, Mr. Adams stated in conclusion, are ample transportation facilities (provided by railways, wide highways and streets and ample sidewalk widths), controlled building heights, segregated building types, a suitable site, a fair administration of justice, uncorrupt political direction, and engineering and architectural leadership.

With reference to the Border Cities, Mr. Adams pointed out that here all these needs were satisfied. The problem of the town planner was, however, made more difficult because of the five separate communities which in reality were one. These five communities, in his opinion, should amalgamate.

The October meeting was held on Friday, October 10th. Before the introduction of the speaker, L. McGill Allan, A.M.E.I.C., gave a verbal report on the Plenary Meeting of Council held in Montreal on September 22nd.

O. Rolfson, A.M.E.I.C., chairman, then introduced the speaker, Mr. W. H. Furlong of the firm Furlong, Furlong, Awrey & St. Aubin, barristers.

The subject of Mr. Furlong's address was "Some Aspects of The Local Improvement Act." Briefly outlined were the changes that have been made in the act since 1852 when sewers were the only construction work which could be done by the municipality. The speaker also interpreted such words as bridge, corporation engineer, frontage, life-time of work, lot pavement, etc. The speaker then went through the Act picking out clauses of importance to the engineer and giving his interpretation of these clauses.

Following the address the speaker was the centre of a barrage of questions regarding the application of the act to the various problems the members had encountered in their work.

Moved by Mr. R. Armstrong, seconded by Ray J. Desmarais, A.M.E.I.C., a hearty vote of thanks was extended to Mr. Furlong by Mr. Rolfson, the chairman of the Border Cities Branch.

The November meeting of the Border Cities Branch was held on Friday, November 14th. The speaker on this occasion was Mr. C. F. Halliday of the General Motors Corporation, who gave an address on the General Motors Proving Ground.

This ground, Mr. Halliday stated, was established in 1924, having been found necessary at that time because of the increased congestion of traffic on the highways. With traffic congestion, accidents more frequently occurred and about 35 per cent of all test cars were wrecked. Not only were these accidents sometimes fatal, but any car which participated in an accident was no longer of use for test purposes owing to the fact that the results obtained from further tests upon it would be unreliable. These test cars were hand-made and the loss of a car meant the loss of a great deal of money. In addition to accidents the congested highways made it practically impossible to duplicate tests and test conditions, and since the testing of motor cars is done chiefly by comparing the test car with other cars under as similar conditions as possible, a specially constructed proving ground was found essential.

Motor cars are compared under four main headings, namely,—performance, appearance, durability and comfort. Performance refers to such qualities as ability to be quickly accelerated or decelerated, to run at very high or very low rates of speed, etc. Apperance means simply style. Durability is defined as the ability of a car to give long service at a minimum cost for repairs. Comfort refers to the riding quality of a car, its freedom from noises, vibrations, etc.

Following his address, Mr. Halliday showed by means of moving pictures the developments in car testing. He showed how standards for performance, etc. were arrived at, and later the means by which it was found how closely a car to be tested approached these standards.

After the motion pictures a lively discussion followed, in which all members present took an active part.

Calgary Branch

A. W. P. Lowrie, A.M.E.I.C., Secretary-Treasurer.
W. H. Broughton, A.M.E.I.C., Branch News Editor.

A general meeting was held in the Board of Trade rooms under the chairmanship of B. Russell, M.E.I.C., at which some twenty-five members and friends were present.

The chairman introduced L. H. Bennett, M.R.A.I.C., who spoke on the "Planning of a House."

The houses, palaces and churches of an era or of a country reflect the economic conditions and state of progress of the inhabitants, and a house reflects the individuality, character and social position of the owner as well as his reaction to the spirit of his time.

There are many factors to consider in planning a house, continued the speaker, climate, site, building regulations, the particular requirements of the family, the exterior appearance, the interior decoration and finish. While some would reverse the order of importance, he thought that the order given was the correct one.

In Calgary a style was being developed, and our existing buildings reflected our history. We had the Colonial, English Cottage, California Bungalow, Elizabethan and others imported from every country in the world in addition to our locally developed "Log Cabin."

In outward effect we aimed either at a symmetrical appearance or one which incorporated a primary mass offset by a less insistent secondary mass and this provided a very pleasing appearance if successfully carried out.

The shape of the land and the orientation of the house to sun and weather often materially affected the shape of the floor plan but convenience should be kept in view in grouping together kitchen and living rooms, bed and bath rooms. These would be better placed on the north or east with living room on the south and west. Large rooms were better than small ones and space should never be wasted in halls that could be used in rooms. There should be sufficient but, in this climate, not excessive window area; about one-tenth of floor area was usual.

There were many different types of construction, but whether frame, concrete or brick is selected, the walls should be insulated by air spaces broken by stops or filled with shavings or other fibrous material. Such filling was an investment that would pay for itself in comfort and should return its cost in five years.

Heating should receive very serious consideration but depended on insulation of building and existence or lack of doors between rooms. The heating and plumbing had an engineering background and was better left to the experts. However, plumbing should never be located in outside walls in this climate.

Interior decoration and lighting should be quiet, restful and subdued. There was, as yet, no measure of agreement, even among experts, as to the best quantity or colour of lights.

There appeared to be a movement towards group dwelling in apartment and duplex houses. The disadvantages of these, however, might outweigh the conveniences and there might yet be a reversion to the individual home.

The address proved the stimulus for a very lively discussion between builders, plumbers, heating engineers and electricians and thereby demonstrated the value of a paper that was not too technical and specialized, and on a subject of which every member, being a home-builder, had some knowledge.

L. A. B. Hutton, A.M.E.I.C., proposed and W. H. Snelson, A.M.E.I.C., seconded, a hearty vote of thanks to the speaker, which was carried with acclamation by the members present.

The opening meeting of the Calgary Branch was held at the Hotel Palliser on October 30th with about one hundred and seventy present. It was ladies' night and quite a few members were accompanied by their ladies.

The speaker of the evening, Dr. T. B. Williams, a prominent local geologist, was introduced by the chairman, B. Russell, M.E.I.C.

Dr. Williams, in introducing his subject of "The Red Coulee Field," spoke of the joys and tribulations of the geologist in the never-ending search for oil. While he encounters much discomfort and hard work in the search, these are amply compensated for by the joy of bringing in a well or a field and by the prosperity thus brought to the district concerned. The curiosity and even suspicion with which he is regarded at first are always forgotten when the oil begins to flow.

The first oil brought in in Alberta was from the foot-hill district near Waterton lakes. In a prairie district the work of the geologist is very different from that in a foot-hill district, yet the proximity of the Sunburst field just south of the International boundary led to the expectation that oil would be found to the north also.

The geologist, continued the speaker, is always hopeful of finding a "structure," a dome or anticline which holds beneath its surface a store of the precious fluid, or at least a sloping plane which has been closed by faults caused by the upheaval of the mountains; it is further necessary that the structure, when found, shall not be at too great a depth.

It is necessary for the geologist to possess himself of such topographical maps as may be in existence or to survey the ground and make them for himself. The character of the structure must also be investigated by the drilling of shallow test-holes. These maps will increase in accuracy from time to time as the result of this more intensive exploration. This work in the Red Coulee field led to the conclusion that the Madison sands, in which production might be expected, would be reached at a depth of about 3,000 feet, a depth well within the powers of modern drilling equipment.

Drilling, continued the speaker, was started in July, 1929, and a flow of 3½ million cubic feet of gas was struck at 2,390 feet below the surface, at 2,466 feet oil was struck in October, 1929, and was thrown clear over the derrick by the force of the gas. Steady production of fifty barrels per day began on January 21st, 1930, which has since increased to 55½ barrels per day and 15,500 barrels at $1.65 per barrel have been sold to the refinery to date. The oil has a gravity of 32 degrees A.P.I. and produces about 27 per cent gasoline and 2½ per cent kerosene. The gas also finds a considerable local market.

Since the oil was struck in the Vanalta No. 1, eighteen wells have been completed as producers, eight as dry holes, and thirteen are still drilling. The present production of the field is about 300 barrels per day on the Canadian side and 500 barrels per day on the United States side of the International boundary.

All indications of the exploration were so promising that the speaker anticipated a renewal of activity in this field in the spring of 1931. The opening out of the field has already resulted in very large growth to the towns of Sweetgrass and Coutts.

The lecture was illustrated by a cinematograph film which was followed by some stills of the district and of the geologist and his crew.

At the conclusion of the address a buffet supper was served, superintended by Mrs. B. Russell and Mrs. T. Lees.

An extremely interesting evening was spent by some fifty members and friends on November 25th in hearing an address by Mr. G. C. Bateman on "Nickel."

The speaker traced the history of the nickel industry from the first discovery of the ore on the north shore of Lake Superior in 1848, its rediscovery in 1856 and again in 1883 when the Canadian Pacific Railway built its line through Sudbury.

The first smelter in Canada was installed at the Copper Cliff mine in 1888 to obtain the copper from the ore.

The Canadian Copper Company was formed with a capital of $2,000,000 in 1886, which acquired large interests in the field, mined copper and shipped it to the United States for treatment. It was impossible to treat the ore so as to separate the copper with the smelters then in use and the trouble was traced to its nickel content. Colonel Thompson tried to treat them at his Orford works with no better success until he obtained particulars of the then secret process used by the H. H. Vivian Company at their smelting works at Swansea, Wales. Finally, after much experimenting Colonel Thompson mastered the process.

The Canadian Copper Company built their first smelter of 100 tons per day capacity in 1888 and their second of 300 tons in 1889. This was the largest smelter on the continent at that time and produced more nickel than the world could use. Mr. Ritchie went to Europe and interested James Riley of Glasgow in the subject. Mr. Riley read a paper on nickel before the Iron and Steel Institute which marked the beginning of the nickel steel industry. This interested the secretary of the United States Navy who had samples of nickel steel armour plate tested against carbon steel with the result that the Congress voted $1,000,000 for the purchase of nickel.

The speaker traced the trials and tribulations of the Orford Company and the Canadian Copper Company up to the formation of the International Nickel Company in 1902. The growing demand for nickel necessitated the development of further supplies and a shaft 2,000 feet deep large enough to handle 10,000 to 12,000 tons per day was proposed. It was found that very high grade ore could be mined at points considerably deeper than 2,000 feet and this necessitated changing their whole plan of campaign.

The company operates the largest smelter in the British Empire and one of the largest in the world, with a capacity of 6,000 tons per day to handle an ore containing 7 per cent combined nickel-copper with substantial values in gold, silver and platinum.

The International Company and the Mond Company subsequently amalgamated as their properties were adjoining and so simplified production and eliminated the necessity for leaving pillars of valuable ore in the workings. The company now produces over 90 per cent of the world's nickel.

Much credit, continued the speaker, is due to the personnel in meeting and solving problems that arise from day to day and are different at one level from those at other levels and even at one stope from those at other stopes in the same level. There is too much talk about the romance and greatness of these mines and too little about the men underground who are daily meeting constantly changing conditions.

Mr. Bateman concluded by making a plea for a better organized and more specific utilization of our greatest natural resource—our young college graduate—who is often left to sink or swim, after obtaining his diploma, entirely on his own resources.

The paper provoked much discussion by the members of The Institute and members of the Calgary Chemical Club who were the guests of the Branch.

A vote of thanks proposed by L. Stockett, M.E.I.C., seconded by F. M. Steel, M.E.I.C., and supported by Mr. Campbell, chairman of the Chemical Club, was very heartily endorsed by the members and visitors present.

Cape Breton Branch

S. C. Mifflen, M.E.I.C., Secretary-Treasurer.
Louis Frost, Branch Affiliate, Branch News Editor.

The scientific application of aerial photography to surveying was the theme of a lecture given by F. H. Peters, M.E.I.C., Surveyor General, Department of the Interior, Ottawa, to a large meeting of members held in the Bank of Commerce building, Sydney, on Friday, November 21st. A. L. Hay, M.E.I.C., Branch chairman, presided.

Introducing the speaker, the chairman referred to the wide present-day application of aerial photography to the pursuit of the economic investigation of the natural resources of this country, and the impetus given by the war to the development of this system, and also the part played by Canadian aviators during that period in the furtherance of scientific research in the realms of aerial photography. The perfection of the present system was in no small degree due to the persistency of research and ingenuity of Mr. Peters, who was a pioneer of this class of work in Canada.

The speaker in his opening remarks brought the members a greeting from the Ottawa Branch of The Institute. He then described the aims of the Department of the Interior in the development of aerial photography, and illustrated his lecture by a large number of slides, which indicated the various phases of aerial photographic surveying in the field and also the subsequent plotting to produce the finished map. The instruments used, which included cameras, range-finders, aneroid barometers, were also shown on the slides.

The object of the Topographical Survey Branch of the department was to produce accurate maps of the Dominion showing the fullest detail upon which engineers and others could base their operations. In the development of railways, waterways, harbours, telegraphic routes and power development sites, accurate topographical data was an absolute necessity, and could not always be obtained by a preliminary survey in regions where the ground was heavily wooded. An aerial photograph, on the other hand, reproduced every feature faithfully with a wealth of detail not otherwise possible, a fact which resulted in material economy in the elimination from later surveys areas which would not be of special concern. As for example in the classification of timber lands for the Forestry Branch of the department, of which a great deal had been done, barren areas which showed up pretty well on the photographs could be avoided, resulting in a great deal of economy.

Accurate maps, indicated the speaker, could not be obtained from photographs alone, sufficient information obtained from ground surveys was necessary to correlate the data obtained by photographs. The work was undertaken in co-operation with the Royal Canadian Air Force who supplied the pilots, while the department supplied the observers. The work of the airmen was exceptionally difficult and required a great deal of courage and fortitude.

Oblique and vertical methods were employed in obtaining photographs, the latter method was used principally when photographing level areas, the oblique photograph was, however, used wherever possible because of the greater areas which could be covered with the same amount of work. The camera used is mounted in the nose of the plane and is automatically operated by electric current, the camera being capable of taking 100 shots without refill.

The general arrangement of the work is to lay out a route in relation to a ground survey for the airmen to follow. They are then instructed to traverse the area by a series of parallel flights about six miles apart, and to maintain a certain elevation and focal angle during the flight. The usual elevation when taking vertical photographs is 10,000 to 12,000 feet and about 6,000 feet when taking oblique photographs. The aeroplane, or hydroplane as the case may be, travels at a ground speed of 80 m.p.h., therefore only exposures of short duration can be tolerated, and to ensure accuracy three sets of exposures are made for each area, and the photographs overlap by as much as fifty per cent in the case of the vertical photograph. When the photographs are completed the ground surveyor locates them in relation to his traverse.

The plotting was somewhat difficult until a method was developed to suit the various focal lengths at which the photographs were taken. In the preliminary work, the photographs are laid out in relation to a general azimuth line. The plotting is then done on squared paper, the photograph being placed under a glass grid chosen in relation to the focal length of the picture.

The lecturer also described the method employed to locate contours when plotting, and indicated upon the screen the wealth of geological and hydrographical data which could be determined directly from the photographs. He concluded the lecture with a series of photographic views of the principal cities of the Dominion.

A hearty vote of thanks was tendered the speaker on the motion of F. W. Gray, M.E.I.C., and seconded by M. Dwyer, M.E.I.C.

Halifax Branch

R. R. Murray, A.M.E.I.C., Secretary-Treasurer.

Minutes of meeting of the Halifax Branch of The Engineering Institute of Canada, held October 15th, 1930, this being the first of the fall and winter programme of 1930-31:

This meeting was held in the assembly hall of the Nova Scotia Technical College and it was called to order at 8.00 o'clock p.m. by the chairman, W. P. Copp, M.E.I.C.

Before the regular programme began, Professor Faulkner called the attention of the meeting to the loss sustained by the Branch and by The Institute in the death of the late Professor W. F. MacKnight. In respect to his memory, all present stood for a minute in silence.

A large number of the engineering students at Dalhousie, St. Mary's and the Nova Scotia Technical Colleges were present as the guests of the branch. For a few minutes, after the meeting opened, the time was spent in singing popular songs.

At the request of the Chairman, H. F. Bennett, M.E.I.C., member of Council for the Branch, addressed the students, pointing out the advantages of membership in the organization and urging that they join as Student members. Mr. Bennett had prepared a sheet on which those who wished to join could sign and later these applicants would be furnished the regular application blank.

The chairman then introduced the speaker of the evening, Mr. McDonald, who gave a most interesting and instructive address on the manufacture and fabrication of structural steel shapes. Mr. McDonald's address accompanied a motion picture film which had been made particularly for showing before engineering organizations and educational institutions. The film showed the ore being unloaded at docks and followed it through a plant until it had been finally turned into rolled steel shapes.

The films were of great educational value, not only to the students but to the older engineer as well, not every engineer having had the privilege of being associated with the steel industry. The various processes of smelting, pouring, soaking and rolling were clearly illustrated, not only in the pictures, but by Mr. McDonald's very clear explanations. He held his audience for nearly two hours.

At the conclusion of the address, a vote of thanks was moved by C. H. Wright and seconded by Dr. F. H. Sexton. Following this part of the meeting, the students and members of the Branch spent a social hour during which light refreshments were served. During this period a large number of students signed the sheet indicating a desire to join The Institute.

On November 16th last, at 1.00 o'clock p.m., a special combined meeting and luncheon was held at the Nova Scotian hotel by the Halifax Branch of The Institute and the N.S. Professional Engineer's Association, jointly.

This was a complimentary farewell luncheon tendered to H. F. Bennett, M.E.I.C., Senior Assistant District Engineer of the Public Works Department at Halifax, who left about November 20th to take over the position of District Engineer at Sault Ste. Marie, to which he had been recently promoted. Professor W. P. Copp, M.E.I.C., chairman of the Halifax Branch, and R. J. Bethune, A.M.E.I.C., president of the N.S. Professional Association, were joint chairmen of the meeting.

Professor Copp explained the reason for the meeting and was glad to see so large a gathering, fifty-three being present, and called on Mr. T. J. Locke, C.E., District Engineer at Halifax, to propose the health of Mr. Bennett.

Mr. Locke, in proposing the toast, said he would not speak in a personal, but in a semi-personal, vein.

He referred with feeling to the high personal qualities of Mr. Bennett; to his professional ability and special fitness for his new position; to his loyalty to his chief and to his duties as senior assistant at Halifax.

Mr. Locke was in a happy mood and invented a few yarns to suit the occasion, completing his remarks by wishing Mr. Bennett much anticipated success and expressing the hope that it may be our pleasure to again greet him from time to time in the old "City by the Sea."

Mr. Bethune seconded the toast to Mr. Bennett and expressed his own pleasure at being present and being able to supplement the good words of Mr. Locke and the same wish for future success.

The toast was enthusiastically drunk by those present, who joined in singing "He's a jolly good fellow," after which Mr. Bethune presented Mr. Bennett with a brass desk reading lamp on behalf of the two organizations.

Mr. Bennett in his reply to the toast was visibly affected by the testimonials to himself, the present tendered him, and the kindly references to Mrs. Bennett.

He said he had been only six years in Halifax but his professional and social contacts had been so enjoyable and satisfying that he found it very difficult to be reconciled to leaving the old city. He also referred to the work of both The Institute and the Professional Association and the advances made by both organizations in the work of forwarding the interests of engineers generally. He thanked all for their kindnesses and assistance and promised to see us all whenever opportunity presents itself.

Professor Copp announced the receipt of a telegram from Moncton, N.B., Branch congratulating Mr. Bennett on his promotion.

Mr. Bennett is a past-chairman of the Halifax Branch and a member of the executive of the Professional Association; he is also a Councillor of The Institute, representing this district.

Mr. Bennett's brother engineers at Halifax are well satisfied that he will be a valuable addition to the Branch at Sault Ste. Marie and are very sure that the loss by Halifax Branch will be the gain to Sault Ste. Marie Branch.

Mr. Bennett was also very active in religious and social work in this city, and contributed largely to any work in which he interested himself and will be much missed by those with whom he was associated, in all quarters.

Lethbridge Branch

Wm. Meldrum, A.M.E.I.C., Secretary-Treasurer.

The Lethbridge Branch held its regular meeting on November 1st, when Mr. R. M. Gourlay of the Canadian Western Natural Gas Co. spoke on "Prevention of Waste of Natural Gas."

One of the greatest problems confronting the operators in the Turner Valley field is the finding of a commercial outlet for the large volumes of surplus gas which comes out of the wells along with the naphtha. Some of the wells have a daily production of about 13 million cubic feet of gas and 150 to 175 barrels of naphtha. In others these figures run up to 45 million cubic feet of gas and 500 to 600 barrels of naphtha. The problem of conserving this large flow of gas which cannot be directly utilized is now engaging considerable attention.

Enough natural gas went to waste in Turner Valley last year to supply the needs of all present Alberta users for 15 years. On a B.t.u. basis compared with coal, enough gas goes to waste in Turner Valley each day to equal 9 train loads of high grade coal, each train having 50 cars and each car containing 40 tons. In other words the equivalent of 18,000 tons of coal goes to waste daily, and in one year this amounts to 3,285 train loads or 6,570,000 tons of coal. With coal at $6.00 a ton, nearly $40,000,000 worth of heat is being wasted each year.

The value of the naphtha and crude oil output in Turner Valley amounts to about $41,000,000 annually. Utilization of this gas would therefore remove a very serious waste.

This brings up the question of repressuring depleted gas fields. The principal requirements in selecting an underground reservoir for this work are: that one company must control the entire field; the depleted gas field must be accessible to the main gas line and the old wells must be reconditioned so as to permit the pumping of gas under high pressure without it again escaping to other sands which are not suitable for gas storage. The gas company selected a field at Bow island for their experiments in repressuring. This field has an area of about 22 square miles. It was discovered in 1909 and 27 wells drilled in the following 10 years having an average depth of about 1,900 feet.

The Bow island field which originally contained 45 billion cubic feet of gas had produced 38 billion feet in 12 years and any further withdrawal would accelerate the encroachment of water and the drowning out of the field.

In 1927 the first repressuring experiments were undertaken by the introduction of gas from the Foremost field 30 miles away. Thirty-seven million cubic were feet introduced into the Bow island sands in five days and the rock pressure raised from 256 pounds per square inch to 286 pounds or slightly less than one pound for every million cubic feet stored. The success attending this experiment led to the decision to carry out further repressuring work. Accordingly, in April 1930, work was started on reconditioning such wells as could be used for storage, some 12 of the 27 original wells still being in the proper condition. To overcome rock pressure and force back the encroaching water having an estimated hydrostatic pressure of 730 pounds per square inch, it was necessary to install compressors capable of high pressures.

The Turner Valley gas used is carried through a 16-inch main for about 150 miles arriving at the plant at 75 pounds pressure and is regulated to 40 pounds for the compressor intake and 15 pounds for fuel gas in the power end. The intake gas is compressed in the low pressure cylinder to 150 pounds and then piped through a series of cooling coils called the intercooler. Then it enters the high pressure cylinders where it is increased to 400 pounds and after passing through another set of cooling pipes it enters the field lines leading to the wells. Since operations started on August 4th, 3 to 5 million cubic feet of gas have been pumped into the field every day.

It might be asked why gas is blowing open in one field and an expensive plant being built to pump it back into the ground in another field 150 miles away. The answer is that anyone may buy petroleum or gas leases from the government and drill for gas and oil. As long as the company is making a commercial success by extracting gasoline it will carry on and the well would not be shut in pending a satisfactory market for the gas which accompanies the crude naphtha. While there is no difficulty in capping in a producing well until the supply is needed, there is no law at the present time to cause the well to be shut in. This waste of gas has been going on for years and should the government desire to conserve the gas, an enormous sum would be required to indemnify the owners for work already done, let alone the value of their acquired leases. The desire for conservation resulting in this repressuring work is based on the generally accepted idea that the generation of gas in a field is negligible and that every foot of gas once used is gone for ever. It is necessary then to conserve all the gas possible to take care of future demands.

Mr. Gourlay, after his address, showed lantern slides of the wells at Turner Valley and of the repressuring plant at Bow island. A vote of thanks was moved by J. A. Carruthers, A.M.E.I.C., after an interesting discussion on the address.

The meeting was preceded by the usual dinner and community singing, music being rendered by the Brown orchestra, a 'cello solo by Mr. Henderson and a vocal solo by Mr. T. Smith.

The Lethbridge Branch held its regular meeting on November 15th at the Marquis hotel. After an excellent dinner, during which orchestral music was rendered by the Brown orchestra, community signing was indulged in and banjo solos by Mr. Solomon and vocal solos by Mr. Stott were appreciatively received.

The speaker of the evening was Mr. E. G. Hazell, proprietor of the Summit Lime Works of Crow's Nest, who discussed the history of the lime industry in Alberta and the uses of its products. It was in 1901 that one Harry Pelletier opened the first lime plant in the Crow's Nest pass two or three years after the railway had pushed its way through the mountains. His plant was literally a hole in the ground cut out of the side of a mountain. He produced 8 cars of lime in his first year of operation. By 1912 the pass kilns were producing 800 cars annually.

In 1902 another plant was opened and the industry grew rapidly. The speaker's plant, which he took over in 1904, consisted originally of one pot kiln 16 feet in diameter and 18 feet high and had a capacity of 150 tons in 9 days. Wood was originally used as fuel, but as the adjoining timber stands were depleted it was necessary to find another fuel supply. A gas producer plant was installed and found quite successful. Steam coal from the adjoining coal mines made a cheap fuel supply possible.

Following 1912 the lime industry declined somewhat due to the growth of the large gypsum and cement companies, but is now on a steady and productive footing. Part of the production at present is pulverized and is blown onto the tunnel walls of coal mines as a means of decreasing fire hazards.

The development of a glass industry in the vicinity of Medicine Hat provides an outlet for a large quantity of lime. Again, the newly established sugar industry in the irrigated area of southern Alberta takes a considerable amount of the lime stone which is burned at the factory, both the gases and the burned lime being used in the sugar refining processes. The growing use of stucco has led to the erection of a stucco plant at the lime works and a market for lime stucco is being built up.

The present kilns used in the Crow's Nest pass are of the upright type, built of steel and lined with fire-brick, and fed continuously from the top. The gas from the producer plant enters a few feet above the bottom, and near the bottom are openings for removing the burned lime.

In the uses of lime in the United States, it is found that 40 per cent is used for construction and agricultural purposes, the remaining 60 per cent being used by chemical industries. In the chemical industry it is used in paper mills, metallurgical processes, tanning, bleaching and so on. It is also valuable in the purification of water for drinking purposes and for water softening.

In agriculture, it is of value in replenishing the lime content of the soil which is heavily depleted by the growth of clover and alfalfa. As a bone builder it is useful in the livestock industry.

Besides its well-known uses in building construction, lime is valuable when mixed with cement for making concrete, producing a more waterproof product.

The Lethbridge Branch held its regular meeting on Saturday, November 29th, at the Marquis hotel. Following the dinner at which 34 were present, a musical programme including selections by the Brown orchestra and vocal solos by Fred Teague was enjoyed.

J. B. deHart, M.E.I.C., drew the members attention to a suggestion that had appeared in the local press that day, that a central organization for administrating unemployment relief in the city be set up and that the usual Christmas cheer funds be consolidated for relief work throughout the winter. The members felt that this was an excellent suggestion, and the meeting went on record as favouring it and requested the city council to call a meeting of representatives of the various organizations to discuss the matter. His Worship Mayor Barrowman, who was present, stated he was personally in favour of such a scheme and would give the matter his full support.

The speaker of the evening was E. E. Eisenhauer, A.M.E.I.C., of the Alberta Wheat Pool, who spoke on "The Alberta Wheat Pool and the Handling of Wheat."

Agriculture, said Mr. Eisenhauer, is Canada's basic industry. In 1929 the total agricultural investment in the country was about $8,000,000,000, and the total revenues about $1,000,000,000. In Alberta, agriculture was responsible for 78 per cent of the total produced wealth of the province in the same year. Agricultural production is necessarily carried on in small units, and the farmers were in the past in a poor position to market their grain to the best possible advantage. To protect their interests they formed their own marketing organization: the Wheat Pool. There were separate pools in each of the three prairie provinces and they have a central selling agency, which handles the marketing of the crop.

The growth of the pools has been phenomenal. The Alberta Pool started operations in 1923 with three country elevators and now owns 439 out of the total of 1,700 elevators in the province. Its investments in the province amount to about $8,000,000. The pool has been instrumental in bringing about many improvements in the design of country elevators, a very important one being the substitution of direct electric drive for the old gasoline engine-operated rope-drive.

With the aid of slides, Mr. Eisenhauer illustrated the handling of the grain crop from the time the farmer delivers his truck loads of wheat at the country elevator. Cars are sampled by government inspectors at Calgary and Winnipeg, and they determine the grade of wheat. At the terminal elevators at the head of the lakes and at Vancouver, the grain is unloaded by machinery, one car being emptied in about seven minutes. Other machinery cleans the dirt and weed seed from the grain which is then stored until ready for transferring to ships, which transfer is accomplished at a great rate of speed, it being possible to load several hundred thousand bushels into a lake boat in the course of a few hours. On arrival of the grain at European ports, it is usually trans-shipped to barges and lighters, which carry it to the mills.

The cleaning operations at the terminals represent a very important part of the work of handling the grain. In 1928 the elevators at Fort William extracted ten million bushels of dirt and weed seeds from the grain they handled. Here, Mr. Eisenhauer drew an interesting comparison, saying that this ten million bushels is equivalent to five years wheat shipment from Vulcan, Alberta, which town ships more grain than any other initial loading point in the world. (Vulcan is about 60 miles north of Lethbridge.)

A lucrative business has been built up lately in disposing of the wild oats which are separated from the wheat at the terminals. Formerly, the farmer was penalized for wild oats, which have, however, a very high feed value. In the last year or two, large quantities have been sold to farmers in Ontario and a substantial profit returned to the western farmer.

Mr. Eisenhauer then touched on some of the economic conditions that have so depressed the wheat market. One of these factors was the Argentine wheat crop of 1928. In most years the Argentine crop grades considerably lower than the Canadian crop and therefore does not command such a good market. However in 1928, the Argentine crop graded just as high as the Canadian product. The Argentine markets its grain on a different basis from Canada. Most of their grain is shipped to England unsold and is purchased on arrival at its destination. The English millers had plenty of wheat on hand and a tremendous amount of Argentine wheat was held under load in English ports. The owners were forced to almost give away this wheat to forestall the rapidly mounting demurrage charges while it was under load. The result was that the English purchasers were able to take delivery of a large quantity of good grade wheat, which was right on hand in their harbours, and available at almost sacrifice prices. So they naturally turned their backs on the Canadian product which was still on the other side of the Atlantic.

A second factor was the decline in the value of silver in the Orient. Oriental countries furnish a large market for the lower grades of Canadian wheat, but the marked depreciation in the value of silver money so reduced the Orient's credit that it was unable to purchase the amount of grain it was accustomed to take.

A third factor was the sudden and thorough raising of high tariff walls in European countries. These countries also compelled their millers to use a high proportion of home-grown grain. This has considerably reduced Canada's market.

A fourth factor is that the world's wheat production has grown faster than the demand, and this year the supply exceeds the demand for the whole world by some 400 million bushels. These four factors together with the general financial depression, have brought about the admittedly serious situation which confronts the pools today.

Following Mr. Eisenhauer's address, a lively discussion took place, numerous pertinent questions being put to the speaker by those present. In fact, the argument waged far into the night, and it was 11.15 o'clock p.m. before P. M. Sauder, M.E.I.C., could get a chance to move a hearty vote of thanks to Mr. Eisenhauer for one of the most interesting evenings the Branch has enjoyed.

The Lethbridge Branch held its regular dinner and meeting at the Marquis hotel on December 13th. It being the last meeting before Christmas, the hotel management served a real Christmas dinner which put the members in the proper shape for the sing-song that followed. Vocal solos by R. S. Lawrence, A.M.E.I.C., and violin solos by G. S. Brown, A.M.E.I.C., were appreciatively received.

The speaker of the evening was J. H. Doughty-Davies, Town Planning Engineer for the city of Calgary, who gave a talk on "Town Planning."

In arriving at a definition of what town planning is, the speaker undertook to outline a few of the things that it is not, and which often cause misunderstandings on the part of the layman. It is not a wonderful and weird new art, nor yet does it consist solely of reams of plans outlining hypothetical ideas, nor is it the idea of tearing down whole portions of a city and rebuilding to a new scheme. Rather is it the listing of common sense information for the purposes of making a constructive plan for the development of a town and for making normal expenditures, when and where the occasion arises throughout the years.

Town planning divides itself into several phases, the first of which deals with major streets and arterial highways. Such streets are necessary for the quick and uncongested movement of traffic from the outskirts to the centre of the city and as by-passes for the purpose of diverting through traffic from the more congested business areas. It is a wise principle to have a system of major streets about half a mile apart throughout the city. These streets are wide and well paved and tend to direct vehicles in certain definite routes. The minor streets within the areas bounded by major streets need not be so wide or heavily paved as their traffic will be more nearly local. The following of such a principle leads to economy in paving programmes.

Another phase is the planning and locating of rapid transit facilities such as street cars, elevated railways and subways. Here topography and population distribution are important factors, as they are in most considerations in town planning.

A third phase is that of transportation and is concerned with the location of railway stations, freight sheds, bus terminals and industrial trackage and convenient interchanges among transportation companies.

Public recreation is another consideration. Playgrounds, playing fields and parks should be located to best serve the people using them and be of proper size to take care of not only the present population but also the prospective increases. For instance, a study of playgrounds has shown that nearly all the children using a particular ground come from within a quarter of a mile radius. This indicates that playgrounds should be about a half mile apart, and suggests that one playground be located nearly centrally in the half mile area bounded by major streets, thus avoiding the necessity of children crossing these busy arteries. Similar studies are applied in the determining of school locations and so forth.

Civic art is a general term applied to the efforts to beautify the community. It includes the studies of the approaches to the town with a view to giving the newcomer a good impression as he enters. Boulevarding is also considered. Another feature is the elimination of unsightly poles and wires from the streets, placing them in lanes and sometimes underground.

Last but not least comes the question of zoning, a matter which has been much discussed in Alberta of late. The intrusion of certain industries or activities into a given area may have a depreciative effect on property values and living conditions. This makes it desirable to guide and direct the various interests into those portions of the town which are best suited for the particular purpose and for the general welfare of the town.

It is necessary to consider the adequacy of street, water and sewer facilities in determining the type of construction to be permitted within these areas.

An interesting discussion followed Mr. Davies' address, and a vote of thanks, moved by A. J. Branch, A.M.E.I.C., was heartily passed.

London Branch

F. C. Ball, A.M.E.I.C., Secretary-Treasurer.
Jno. R. Rostron, A.M.E.I.C., Branch News Editor.

The opening meeting of the 1930-1931 session was held on October 29th, in the Science building of the University of Western Ontario.

The speaker was Dr. R. C. Dearle, B.A., M.A., Ph.D., Professor of Physics, University of Western Ontario, and his subject "Ulta-Violet Light."

E. V. Buchanan, M.E.I.C., presided in the unavoidable absence of the Branch chairman, W. G. Ure, A.M.E.I.C.

A large body of students were present in addition to a fair number of members.

The speaker demonstrated his remarks by various lanterns and instruments for measuring the quantity of ultra-violet rays both in sunlight and artificial light. He also had an elaborate projector which threw on the screen a graduated dial with a registering needle by means of which a comparison of the quantity of ultra-violet light passing through or reflected from various materials could be made at a glance.

Dr. Dearle gave an interesting comparison of the amount of sunlight in each month of the year compiled from observations taken during the last six years. As might be expected July is the sunniest and December the dullest month of the year and as these observations were taken between sunrise and sunset only, they showed that during the hours of daylight the sun is obscured by far the major part of the time, consequently, observations are now being taken daily, and data made, to determine how much ultra-violet light reaches the earth when the sun is obscured.

Demonstrations were made, by means of the projector mentioned, showing the amount of ultra-violet light passing through glass. Ordinary window glass cuts off the ultra-violet almost entirely while various kinds of glass specially made to admit the ultra-violet allowed some of it to pass in varying degrees but the best of these still cut off about 35 per cent. It was obvious that in any room fitted with this special glass unless the reflected light also contained the ultra-violet, the only persons who would benefit from this source would be those directly in the sun's rays and this might be objectionable from other reasons such as heat and the strong light. Experiments were, therefore, being made to determine what kind of materials and colours reflected the ultra-violet the most. Demonstrations were made, with the aid of the special projector, with wood, paper, specially treated paint, etc. Of the various kinds of wood, bass wood was found to reflect the greatest amount of ultra-violet light and was far ahead of most of the others. Likewise, the special mauve-coloured paint was well ahead of the other special paints. The object of these experiments is to find out how hospital sun rooms, classrooms, etc., may best be equipped with materials which will give the occupants the full benefit of the maximum amount of natural ultra-violet light that it is possible to get in an enclosed space. The greatest benefit to be derived from this natural ultra-violet light is, of course, obtained by exposing the nude body to the sun's rays in the open air, but as this is liable to result in severe sunburn, blistering, etc., if overdone, a treatment of five or six minutes daily was recommended. The professor said that undoubtedly the ultra-violet light had been found to be of therapeutic value, yet to just what extent was still uncertain. Another interesting demonstration was made showing the way in which smoke interfered with the passage of ultra-violet light; thus proving that the murky atmosphere over towns and cities where this condition prevails would seriously hamper any benefit derived from the sunlight. Regarding the use of artificial light for this purpose he also stated that it was possible to do more harm than good and recommended the patient to obtain the advice of his physician as to the time of exposure to the rays, if at all.

A hearty vote of thanks to the speaker was proposed by J. A. Vance, A.M.E.I.C., seconded by D. M. Bright, A.M.E.I.C., and unanimously carried.

During the discussion which followed a proposal was made that the students of the university and also of the technical school be invited to attend the meetings of the Branch.

There was also a proposal that the university would provide a special short course of possibly six lectures in co-operation with the Engineering Institute and any other organizations that might be interested. A small fee would be charged to cover expenses and the lectures would cover scientific subjects such as chemistry, physics, botany, zoology, geology, etc. The proposition will be considered by the Executive and it is possible a working arrangement will be evolved.

The regular November meeting of the Branch was held on the 19th in the board room of the Board of Education, Public Utilities building.

The chairman of the Branch, W. G. Ure, A.M.E.I.C., presided, and the speaker was Mr. R. B. Steele, assistant chief engineer of the Canadian National Telegraph System.

The title of Mr. Steele's paper was "The Telegraph—Yesterday and Today," and he opened his remarks by stating that his chief, Mr. J. C. Burkholder, was not able to be present and that he had been requested to convey his regrets.

The definition of the word "Telegraph" before the use of electricity was "A means for conveying intelligence to a distance by means of signs." A later meaning for the word arrived at after the adoption of the electric current was "A means of producing signals visible, audible, or printed at a distant place." The first part of Mr. Steele's paper was devoted to a historical sketch of the means employed in the old days for signalling intelligence such as signal or beacon fires, columns of smoke, light signals, illuminated signs, flags and peculiar windmills with adjustable arms. Flag signals were introduced about the middle of the 17th century by the Duke of York (afterwards James II of England), who was at that time admiral of the English fleet.

This scheme was introduced for directing the manœuvres of the fleet and modifications of it are in use today in practically all the navies of the world. Another outstanding method of signalling in the old days was inaugurated by two French college boys—Claude and Ignace Chappé, and consisted of semaphore arms hinged on a pole and secondary short arms again hinged on the ends of the main arms. These arms could be set at different angles and were capable of conveying nearly 200 distinct signals and by the use of a code conversations could be carried on between any two points where visibility was possible either by the naked eye or the use of telescopes. This was in 1784, and ten years later the French government adopted it and retained Claude Chappé as chief telegraph engineer. This system was in use for many years and a modification of it is still in use today along many railway tracks for conveying a simple set of signals to the locomotive drivers.

This system and that of the flag signals were capable of transmitting about five words per minute but, of course, these messages were entirely dependent on good weather conditions and good visibility.

Coming to the electrical era—Stephen Gray in 1729 discovered that it was possible to transmit electric current to a distance by means of an insulated wire. Between 1767 and 1800 scientists, including Galvanti and Volta, discovered the phenomenon connected with the Voltaic pile and constructed this device for providing a sustained voltage. In 1805, Romagnesi found that a wire carrying an electric current was capable of deflecting a magnetic needle. In 1820, Schweigger discovered that if a coil of several turns of wire carrying a current was employed the deflecting force was increased. In 1825, Sturgeon discovered that a bar of soft iron was rendered temporarily magnetic if surrounded by a coil of wire through which an electric current was passing.

About 1830, Henry worked out the design for electro-magnets suitable for responding to currents received over long telegraph lines and about 1833, Gauss and Weber discovered that they could transmit telegraph signals over a line making use of induced currents produced by the motion of a coil of wire surrounding a bar magnet. These are the fundamental discoveries upon which our present electric telegraph is based.

In 1832, Schilling introduced a telegraph which, with improvements and modifications, is still in use today. Further, this system had the novel feature of using the current reversals, the current flowing first in one direction and then the other to form the signals. In 1831, Henry was first to set up a telegraph system making use of the electric magnetic receiving device.

The first outdoor line was constructed by Webber in 1833. This two-wire line was built at Göttingen using Schilling's system and was eight-tenths of a mile in length. In 1831 Steinheil discovered that a telegraph could be operated by one wire using the ground for the return current. In 1837 Morse patented a form of self-recording electromagnetic telegraph and because of the publicity his invention received he became known as "The Father of the Telegraph." Alfred N. Vail associated with him, and so improved Morse's instruments that they have come down to us today with only minor changes and refinements in design. Vail is also responsible for the code still in use today and known as the "American Morse Code."

The first commercial telegraph was constructed between Washington and Baltimore, financed by the United States government, and built on the lines of the original Morse equipment as improved by Vail. Service was opened on May 24, 1844. The two telegraph companies now in existence in the United States resulted from this venture and a good deal of their business is still handled over the simple Morse circuits.

In England and on the continent the present-day telegraph system is based largely upon Schilling's system with refinements and improvements introduced by many scientists including Cooke and Wheatstone.

The speed of transmission of this period was about 35 words per minute but by the introduction of automatic printing devices, etc., the speed was increased to 360 words per minute by 1900. In 1871, Stearns solved the problem of conveying more than one message at a time over a single line wire and in 1874 Edison devised a method of transmitting two messages in each direction over one wire. Four 50 word a minute messages are now sent each way making a total of 400 words a minute.

In 1909, Major-General Squier of the United States Signal Corps conceived the carrier telegraph system. This, briefly, consists of transmitting low power radio waves through the ether but guided by the telegraph wire and carrying the signal to a much greater distance than would be possible otherwise with the same radio sets. It has also the advantage of not interfering with the direct current messages in the wire itself. This system has been so improved that by using it on a pair of line wires together with the direct current a speed of 4,120 words per minute can now be obtained.

Further developments are still being made and it is impossible to say when the endeavour to obtain greater speed of transmission will cease.

Telephones are now being installed on the main line trains and these will be operated on the carrier system, the radio waves being caught and guided by the telegraph wires paralleling the line.

A hearty vote of thanks to the speaker was proposed by A. H. Smith, A.M.E.I.C., township engineer, and seconded by W. C. Miller, M.E.I.C., city engineer of St. Thomas, and unanimously carried.

The meeting was largely attended, many Bell Telephone employees being present together with a number of technical school students.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

On November 6th, Mr. L. M. Sheridan, chief engineer of the International Nickel Company, described the new Copper Cliff plant of the company to the members of the Montreal Branch.

As this paper was printed in the December number of The Journal, no further description will be given here. However, it is of interest to note that considerable favourable comment was offered during the discussion relating to the successful completion of the work. Amongst those taking part in this discussion were Major J. H. Brace, M.E.I.C., G. H. Duggan, M.E.I.C., C. E. Fraser, M.E.I.C., and D. C. Tennant, M.E.I.C. At the conclusion of the meeting a hearty vote of thanks was proposed to the speaker by Dr. R. A. Ross, M.E.I.C., consulting engineer of Montreal. L. R. Wilson, M.E.I.C., occupied the chair.

Mr. F. A. Hamilton Jr., engineer for the Central Station Department of the General Electric Company, addressed the Montreal Branch on November 13th on the subject "The Practical Aspects of System Stability." Arrangements are being made to have this paper printed in full in a later number of The Journal and therefore no synopsis of it will be given at this time.

Professor C. V. Christie, M.E.I.C., presided.

The Montreal Branch were addressed on November 20th by Wing-Commander L. S. Breadner, D.S.C., A.M.E.I.C., Director of the Royal Canadian Air Force.

Commander Breadner chose as his subject "The Royal Canadian Air Force as a Career," and pointed out the exceptional opportunities offered to young men having the necessary qualifications. These qualifications are that the applicants must be British subjects, holders of a university degree in Applied Science, having the physical fitness and temperament suited to aviation work. It's popularity is attested to by the fact that some 400 to 500 applications for the R.C.A.F. are received every week from young men between the ages of 16 and 20.

This new branch of the Service offers permanent employment with good pay, opportunities for promotion and a pension upon retirement. Commander Breadner stated that officers of the R.C.A.F. were being used, according to their initiative and ability in the various fields, either as pilots, observers, navigators, photographers or in the office or stores. Training is carried out at Camp Borden and a brief description of the life there was given by the lecturer.

Every year a certain number of qualified officers are sent to England for further experience and training, and in addition, the members of the R.C.A.F. in Canada co-operate to fight bush fires, survey new tracts of land, map out mail routes and assist the various branches of the government whenever called upon.

Professor C. M. McKergow, M.E.I.C., vice-chairman of the Aeronautical section, occupied the chair.

On November 27th a very interesting film was shown before the Montreal Branch in connection with a description by M. S. Blaiklock, M.E.I.C., of the Lyon creek trestle fill.

The Lyon creek trestle is on the Canadian National Railways main line between Edmonton and Vancouver about a hundred miles east of Kamloops. The creek is a tributary of the North Thompson river and the trestle itself was 1,500 feet long and 110 feet high. It was constructed in 1914 and the actual fill began in 1925, being finally completed in 1928 after three years of very arduous labour and many severe hardships encountered by the contractor.

The work was carried out in three stages, the two lower sections being filled by dumping from temporary trestles erected a short distance from the main structure and only the third and last section was dumped from the right of way itself.

The film was loaned by the courtesy of the Canadian National Railways, and at the conclusion of the lecture refreshments were served. W. K. McAllister, A.M.E.I.C., presided.

Niagara Peninula Branch

R. W. Downie, A.M.E.I.C., Secretary-Treasurer.

At Bridgeburg, on November 19th, about seventy engineers gathered to hold a dinner meeting and listen to the historical reminiscences and miscellaneous researches of an erstwhile newspaper editor.

It is always a pleasure to listen to Louis Blake Duff, and when lined with a good dinner and properly lubricated, he runs as smoothly and sweetly as one of the immense hydro-electric generators at Queenston. That is why engineers appreciate his utterances probably as much, or more, than the average layman.

Councillor C. H. Scheman, M.E.I.C., and his efficient staff attended to all the details and the success of the party is largely due to their forethought and discrimination.

At the commencement of the programme, Mr. Farnum and Mr. Strickland were invited to say a few words on behalf of the Engineering Society of Buffalo, followed by a "habitant" poem composed and read by Mr. F. S. Drummond of old Niagara. This poem is of such general interest that, through the courtesy of the author, a reprint is given on another page.

Mr. Blake Duff dealt with the early history of Canada, particularly the place-names and their origins, around the Niagara (pronounced Nee-agara) peninsula. The river, with its falls and islands, is full of historical relics. Navy island was a shipyard under the French regime and the vessels that harboured there, or were under construction, when the British took possession in 1759, were towed over to Grand island and burnt in the bay or creek which still retains the name of "Burnt Ship" bay. The same Grand island, with an area of 17,000 acres, was at one time a principality, somewhat of the same nature as Monaco is to-day. After the island was purchased by New York state from the Senacas in 1815, a period of seven years elapsed before full title could be obtained, and it was during this period that the inhabitants established "Prince" Clarke upon the throne and refused to acknowledge other allegiance. In 1825, shortly after Prince Clarke's reign came to an end, a city of refuge for the Jewish people was promoted by one Major Mordecai Manuel Noah, with Grand island for a site, but very little ever came of it and now Buffalo has usurped that honour.

At this point Mr. Blake Duff interrupted his chronological sequence by relating an incident about a vessel named "Le Griffon" which was built at Cayuga creek for trading purposes about the year 1679, when Father Hennepin and LaSalle were exploring these waters. This vessel set out upon her maiden voyage and was never again heard from until this summer, when Harry Tucker of Owen Sound came upon an old wreck which is believed to be that of "Le Griffon," lost for 250 years.

The names of many points and bays along the north shore of Lake Erie give clues to records which reveal secrets of the bygone days. Point Abino was given to a certain Peter Abino by the Jesuit Fathers in 1743. Windmill point was named after Carter's grist mill which existed in 1832 and drew its trade from districts as far west as Simcoe and Port Dover. Sugar Loaf point, so named on account of the peculiar mound or hill of sand, was known as early as 1784 when Henry Zavitz constructed the first flour mill in the district and, in 1787, a survey was made to this point by an engineer, one Phillip Rockwell Frey. It has been seriously suggested on many occasions that this mound was "hand made," but the evidence is not conclusive. Morgan's point was named after a Pennsylvania Dutchman and later the name was officially changed to Point Industry which was suggestive of the character of the inhabitants. Mariners, however, could or would not bend their manner of referring to favourite landmarks at the behest of officialdom and today the locality is again known as "Morgan's point."

John Graves Simcoe was responsible for naming much of the Upper Canada area but for some unexplainable reason he chose names originating in the county of Lincoln rather than from Devon where he was born. At that time, 1791, the county of Lincoln in Upper Canada extended from the Niagara river to beyond Hamilton and it was not until many years later split up into the present counties of Wentworth, Haldimand, Welland and Lincoln.

William Jarvis was an aide of Governor Simcoe and served as the first provincial secretary. Before coming to Canada he was swirled through thirty-two degrees of Masonry in one evening by the Duke of Ancaster, who was at that time Grand Master in England, the object being to allow Jarvis to institute a lodge in Upper Canada similar to that which already existed in the Lower Provinces. Ancaster township derives its name as a grateful recognition of that "swirl."

The township of Sherbrooke was originally known as Wetterburn and was used as a reserve for the Haldimand Indians. A man named Dickson coveted ths piece of property and plotted the acquisition thereof. Bringing the Indian chiefs together at a grand banquet he plied them with firewater, finally succeeding in securing their approval. A rare example of early supersalesmanship, but he forgot to reckon with the squaws. The opinions of these ladies carried considerable weight when opposed to such a transaction as the sale of their homeland, and Mr. Dickson had to go so far afield as Governor Sherbrooke of Lower Canada before he could muster sufficient influence to achieve his desires. Finally however he won and in grateful recognition of the aid thus rendered he renamed the track Sherbrooke township.

Some of the more remote townships had less excuse than a "grateful remembrance of favours received" for their nomenclature. Perhaps in those days they were not considered sufficiently attractive to be considered on the honour list. Perhaps there were not enough influential or notorious names to go around. Be that as it may, it is sad to have to record that three townships will hand down to posterity the names of pet poodles belonging to Lady Maitland, Tiny, Floss and Tay.

Coming to some places of lesser importance or of smaller area, we find Sarnia derived from the early Roman name for the Island of Guernsey, Port Colborne after Sir John Colborne, Port Maitland after Sir Peregrine Maitland, Port Robinson, formerly Port Beverley, after John Beverley Robinson who was attorney general of Upper Canada at the early age of eighteen years. The thriving and striving village of Allanburg was the consequence of another act of gratitude when Sir Wm. Allan allowed the promoters of the first Welland canal to overdraw at his bank. "Amigari" was an error, or the result of an error, made when the county registrar could not decipher the writing of Chris. Bunting, M.P., who wished the name to commemorate the castle of "Amigan" in Ireland.

In proposing a vote of thanks to the speaker, E. G. Cameron, A.M.E.I.C., took occasion to draw a parallel between the hardships which these pioneers had to contend with and the present-day tribulations of a temporary depression.

The meeting was adjourned by chairman Walter Jackson, M.E.I.C. at about 9.30 o'clock p.m.

The "Royal Sauvage"

You lak my ol' stick mistaire. No shes not ash.
Dats a piece from de deck of de "Royal Sauvage."
Never hear of dat ship? Well, long tam it has been
Since shes sunk by de British off ol' Fort St. Jean.

Oui. T'ank you. I'll take a cigar mon ami.
I can tell you de story my grandpere tol' me.
De grandpere of him was de captain in charge,
An' sail to de war on de "Royal Sauvage."

It seems when Napoleon's armies at war
Kept England so busy defending her shore,
De people just South of us thot it good tam
For tak all dis countree, an' over dey came.

But lak all bad causes, our good Curé says
Dey nevaire succeed wit' de one dat is bless.
That numbers don't count when you have a good cause
An' a fas' sailing ship lak de "Royal Sauvage."

Firs' built by de French under Monsieur Montcalm
Shees de bes' of white oak, wit' de fines' of gun.
When war is declare she is sail down Champlain;
Knock down all dere fort an' return home again.

Bye an' bye dey is build dem four ships dat have gun.
An' from dem our ship is pretending to run.
Till strung in a line she halts in her course;
De firs' of dose ship it is nevaire look worse!!

It mak' for de shore, and is sink on de san',
What is lef' of de crew she is manage to lan'.
Den de nex' ship is comin' close up to our gun.
When down comes his mas' and his yards on de run.

De two smaller ship dey is start for de shore
But de "Sauvage" is after dem quickly, encore.
Dey shoot bote together, wit' terrible crash
An' cut de bowsprit from de "Royal Sauvage."

He was Sauvage before but hees Sauvager now
An' waits till he gets dose two ship on a row.
His guns double shotted, he swings in his pride.
Knocks hell out of bote of dem wit' a broadside.

But as time she'll pass on over ten thousand men
Wit' dozens of boat sailed up Old Lac Champlain
De "Royal Sauvage" she is damage dem sure
But what can one do wit' a dozens or more.

She anchor herself by de Fort of St. Jean
But de Garrison leaving, hees spike all de gun.
More sooner be sunk dan an enemy's prize
De "Royal Sauvage" is blow up to de skies.

You know all de res' of it Monsieur Ami
De invaders, defeated, returned dere countree.
We're friends for a century. More I should judge.
Here's a toas' to Kebec, an' de "Royal Sauvage."

An' now when low water and even time comes.
When de girl wit' hees fella walks 'long by de guns.
She sees, near de shore jus' de tip of a beam
Where de bow of de "Sauvage" looks at Fort St. Jean.

F. S. DRUMMOND.

Niagara-on-Lake, January, 1930.

NOTE.—The writer, who took his overseas training at Fort St. John barracks (Que.), has two sticks made from the timber of the "Royal Sauvage."

The December dinner meeting of this Branch was held at the Hotel Reeta, Welland, Ont., on December 16th, but being so near the festive season the attendance suffered accordingly. The guest of the evening was Mr. G. C. Bateman, secretary of the Ontario Mining Association.

As this was the first meeting this season of the Branch that was not a joint meeting with some other association, Walter Jackson, M.E.I.C., chairman of the Branch, took the opportunity of tendering the thanks to the members for his election, afterwards asking A. J. Grant, M.E.I.C., president of The Institute, to make a few remarks on Institute affairs.

Mr. Grant reported that the suggestion of this Branch to have The Journal made 6 inches by 9 inches was not accepted by the Councillors at the last Plenary Meeting.

Mr. Grant also stated that the membership was not increasing at the rate it should, and it was suggested that next year the branches take up a campaign to secure new members.

After Mr. Jackson had asked the members not to lose their ballots for president and local representatives but to turn them in, he introduced Mr. G. C. Bateman to the meeting.

Mr. Bateman said he felt rather nervous in lecturing on "Nickel" as there were two visitors from the International Nickel Company's plant at Port Colborne who knew more about the subject than he did, so he would confine himself to the history of nickel.

Nickel, which had been considered by the general public lately more from a speculative than a practical point of view, has been known since 1700. The first authentic find however was in 1856, by a surveyor named Salter and confirmed by Murray, a Dominion geologist. This find, which subsequently became the Creighton mine, was lost for many years. When in 1883 the Canadian Pacific Railway was constructed through the Sudbury district, a vein of what is now the Murray mine was cut; this property was sold to Vivians of London. This led to prospecting in this district by Frood, Stobie and many others. The original find was rediscovered in 1886 and formed the Creighton mine, the first smelter being erected in 1888.

In 1882 S. J. Ritchie of Cleveland, Ohio, opened up iron deposits in Hastings county and started the Central Ontario Railway, but a shipment of iron to Cleveland proved unsatisfactory. So he then went to Sudbury, acquired large holdings including the Frood, Copper Cliff and Creighton properties, and organized a company with a capital of $2,000,000, the original Canadian Copper Company.

Rich Copper Cliff ore with 15 per cent copper was shipped to smelters who were unable to get any copper out of it. Colonel Thompson found that the difficulty was due to the presence of nickel, and constructed the Orford works, at Bayonne, N.J., but was unsuccessful at first in treating the Copper Cliff ore.

He however experimented with a sodium sulphate salt, which he had found out was used in a secret process by a Welsh firm at Swansea which had solved the problem, and finally solved it himself. He decided then to build a smelter at Sudbury and one capable of dealing with 200 tons a day was erected by Dr. Peters, metallurgist.

Vivian's now came into the field, but, as has often been the fate of Canadian industries managed from London, failed to make a success.

Ritchie at this time was shipping more nickel than was in demand, so he had to find new sources for his output.

Experiments were being made for combatting yellow fever by freezing the germs, a ship being fitted out with refrigerators, but it was found out that cast iron would not hold the ammonia gas, so nickel iron was tried and found perfectly good for the work.

Ritchie went to Europe with Canadian and United States representatives and visited most of the European steel plants, with the result that Riley of Glasgow made a special study of nickel steel and read a paper on it.

Nickel steel armour plates in comparison with compound steel armour plates then in use for battleships were tested on Annapolis proving ground. The nickel steel plates proved so much superior that an order for 1,000,000 pounds of nickel was given by the United States government.

Jules Garnier, a nickel expert from the French mines in New Caledonia, erected a Bessemer converter in Sudbury and refinery in Cleveland but did not make a success of it. Electrolytic refining was also tried but was found to be too expensive.

The Mond process was also tried but was unsuitable for the Canadian climate, and the only economic process the Canadian Copper Company could find was that used by Colonel Thompson.

In 1902 The International Nickel Company was formed taking over four nickel companies and the Orford works.

The Creighton and Copper Cliff mines were well known but on the Frood, the biggest of them all, and staked in 1884, no work was done for 15 years. Then during two years 100,000 tons of ore were shipped. It was afterwards neglected till 1929, and the only ore taken in 45 years would equal what could be done in 45 days if the new plant were operated to capacity.

The reason the Frood was investigated in 1899 is that the Creighton mine was flattening out and thinning, but later by drilling deeper it was found to widen out again and the work on the Frood was stopped.

Mond found that below 2,000 feet there was an increase in the metal contents of the ore and that metals of the platinum group were found. This was also proved on the Frood especially at the 2,800-foot level. An analysis by the Mond Company gave 20 per cent copper, 1½ per cent nickel and ⅔ ounces of the platinum group at that depth.

The shaft on the Frood is sunk to 3,000 feet and between 1,000 and 3,000 feet there are 45,000,000 tons of ore and above the 1,600-foot level, 60,000,000 tons.

Mr. Bateman then gave a short description of the new smelter which will be the largest in the British Empire. The dimension of the smokestack, which is 510 feet high, 60 feet diameter inside at bottom and 45 feet at top with 7-foot walls, gives an idea of the enormous size of the plant.

After giving some details of the method of mining the ore, Mr. Bateman made a plea for the young engineer, and the men who work underground and tackle all the various difficulties incidental to extracting the ore. He expressed the opinion that these men had not been given enough consideration, we had thought more of the speculative side. In this country the importance of the development of natural resources is being continually stressed, but the most important resource is the young engineer who is not enough utilized. In the mines they are replacing the old time shift bosses by young engineers and more should be done to utilize and encourage them.

E. P. Murphy, A.M.E.I.C., proposed a hearty vote of thanks to Mr. Bateman for his very interesting paper, which was passed with acclamation.

W. Seymour, M.E.I.C., of the Sault Ste Marie Branch on a visit to Port Colborne, expressed himself as glad to be at the meeting and enjoyed the talk. This was his first visit to another branch and he wished to offer his congratulations to a live and active branch. They were so far from other centres they had to depend on local industries for papers.

After Mr. Jackson had given a résumé of prospective attractions for the January meeting, the adjournment was made.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Recent Developments in Acoustical Practice

At the noon luncheon on the 20th November, Major G. M. Thomson, Director of Research for Gypsum, Lime and Alabastine, Limited, addressed the meeting upon the subject of recent developments in acoustical practice. John McLeish, M.E.I.C., acted as chairman and was given a special round of applause when he rose to speak as a welcome back after several weeks' illness. Among those at the head table with the chairman and Major Thomson were the following:—L. L. Bolton, M.E.I.C.; Ray Tubman; Victor M. Meek, M.E.I.C.; G. E. Bell, M.E.I.C.; W. H. George; Lieutenant-Commander C. P. Edwards, A.M.E.I.C.; John Murphy, M.E.I.C.; Lieutenant-Colonel C. J. Burritt; Honourable Senator Smeaton White; E. Viens, M.E.I.C.; C. R. Reynolds. Major Thomson in rising to speak said that he felt he was among old friends, for he recognized college classmates, comrades overseas and associates from other walks of life.

Major Thomson characterized any sound that is not pleasant to the ears of the listener as a noise. He stated that noises in general had proved themselves to be among the most insidious and harmful agencies that ever afflicted the human race. We are careful to conserve our eyesight but are not so careful in endeavouring to suppress noises which we dislike.

The recent developments in mechanical transportation that have taken place since the Great War have accentuated the great problem of the evil effects of noise. In fact man, originally silent, is not accommodating himself at the present time to new noises as rapidly as he is adding to them.

In Great Britain there is a commission studying the problem of the abatement of road traffic noises. This problem has also extended itself to the continent. In New York city there is a Noise Abatement Commission and in Germany a Society of Industrial Hygiene which has as one of its problems the cutting down and elimination where possible of unnecessary noise.

Major Thomson quoted authorities with regard to the amount of noise caused by different agencies and the effects of it upon the human system. At a busy New York street intersection, for instance, he stated that trucks were credited with about 40 per cent of the noise to be heard there.

Although engineers have been pioneer crusaders against noise, during the War they missed one of the greatest opportunities to do something really big, by failing to invent a soundproof helmet or protector to cover the ears. Had engineers thought of such a helmet they would have made one of the greatest contributions of the War toward economy of man power. Soundless explosions would not have reduced normally courageous men to a state of nervous collapse.

It is a fallacy that people get used to noise. For executives and those in administrative positions there is likely to be a serious loss or impairment of working capacity operating against their processes of clear thinking, if their offices are so situated that they are subject to the noise of typewriters, adding machines, babble from the outside world, etc. Such noise is in the nature of a constant strain upon the nervous system and ultimately may lead to nervous exhaustion and neurasthenia.

With regard to the prevention of the effects of noise, in such cases three remedies are suggested. The first, the use of some method of preventing noise reaching the eardrum is hardly practicable. Secondly, by mass co-operation it would be possible to reduce or eliminate sounds, whether on the street or in a room or enclosure. And thirdly, it is possible by the use of proper structural means to dissipate unavoidable sounds.

A smooth wall, for instance, may reflect as much as ninety-eight per cent of the sound waves and absorb two per cent. Associated with this is the problem regarding the proper audition in theatre buildings, churches, etc. Sound foci caused by the reflection of sound from domed ceilings may cause interference such that various sound waves neutralize one another giving rise to "dead spots." The remedy for this is the use of felts, carpets, soft materials, etc., to dissipate the sound waves.

With regard to the correct treatment of walls to dissipate sound waves, it has been necessary to expend much effort in order to produce the ideal material for absorbing noise. Such material must be of moderate cost, easy to apply, suitable for decorating, fire-resistant and lend itself readily to cleaning and redecorating. It should also be of some material which will not harbour bacteria, this being particularly true in the case of hospitals. Materials with a mineral content have been worked out and are proving very satisfactory for the purpose.

In the study of noise prevention and abatement Major Thomson paid a great tribute to two men in Canada who had done pioneering work in this regard for many years, one of them for well over thirty years. These men had made available the mental machinery to meet the problem before the engineer of today. They are Professor G. R. Anderson of the University of Toronto and Professor H. E. Reilly of McGill University.

Major Thomson's address proved to be most interesting; it was received with the closest attention by the large gathering present at the luncheon.

Speeding Up Telegraphic Communication

On December 4th, at the regular bi-weekly noon luncheon of the local Branch, the guest speaker was Mr. J. C. Burkholder, Chief Engineer of Canadian National Telegraphs, who spoke upon the subject of "The Telegraph—Speeding up Communication." John McLeish, M.E.I.C., chairman of the local branch, presided and in his introductory remarks stated that engineers were most fortunately situated in that they were constantly being afforded the opportunity for doing something that had never been done before. This applied to the speaker of the day in connection with the work which he had done in instituting a method of telephonic communication from a train in motion.

Mr. Burkholder, in commencing his remarks, stated that the desire of mankind for speed, including speed in methods of communication, was not a new one. He outlined methods of communication from the earliest historic times down to the present, tracing them through the various phases from word of mouth, by the sending of messengers both afoot and mounted often in relays, by the use of signal flags, signal fires, semaphores, and finally by electrically controlled devices.

Flag signals, for instance, were first made use of in the 17th century by the Duke of York, later James II of England, in directing the manœuvres of the English fleet. In a modified form they are still used for certain purposes. Another most successful form of early message system was the invention of the Chappé brothers in France in 1784 who communicated with each other by semaphore signals worked out to a pre-arranged code. In making use of these semaphores some 200 combinations of characters were used. The French government adopted the scheme and extended the system throughout the country, establishing semaphore signalling points upon hilltops. The code, however, was very cumbersome and when a great distance was to be covered it would often take several days to transmit a simple message of only three or four words.

Previous to this, in 1729, Stephen Gray discovered the means of conveying an electric current along an insulated wire and subsequently Galvani, Volta, Schweigger, Sturgeon and their successors in electrical research added their contributions. In 1837, Morse patented a form of self-recording electro-magnetic telegraph. At this time, the Morse code was also developed by Bell who was associated with Morse and two others in certain developments relating to recording and relay systems in connection with the telegraph.

From that time until 1900, practically nothing was done in telegraphic development such as we see it today. In the decade from 1900 to 1910 automatic equipment began to be used. Such equipment allowed a message to be printed out at the receiving end of the telegraph somewhat the same as would be printed on the typewriter. The method was quite satisfactory and by its use 50 words a minute were possible over a pair of wires.

The necessity for further speed was continually being felt. The cost of copper wire—or its equivalent—and the physical limits of construction of the telegraph lines, etc., made it imperative that this speed be attained with the least amount of equipment necessary. Thus development followed along the line of making use of a single wire for operating a number of printing telegraph machines instead of one machine as formerly. At the present time, for instance, with the carrier current system now under development, if multiplex printing telegraph were superimposed, a maximum signal transmission of 6,000 words per minute per wire, or 12,000 words per minute over a pair of wires, would be allowed. Mr. Burkholder stated that it is expected to go even further than this and that within the next decade this figure of 6,000 words per minute should be doubled.

Mr. Burkholder also described the means used to cut down delay or to speed up communication in the matter of handling the messages as they are received at the receiving end of the telegraph line. In each case this is a local problem and may be solved by the use of belt carriers, underground tubes, etc. In Toronto, for instance, a new belt system has recently been installed between the various offices whereby the average time of handling individual messages is cut down some five seconds. Thus it will be seen that the old cry for speed still holds, only today it is a matter of seconds or fractions of seconds whereas formerly it was a matter of minutes, hours or even days.

Toward the end of his address, Mr. Burkholder made a brief reference to the recently developed method of telephone communication from moving trains. He characterized it as being still more or less experimental and he hoped that it would be considerably improved and simplified in the course of time.

Mr. Burkholder's address was listened to with a great deal of interest by those present. At the head table in addition to the chairman and the speaker there were the following:—Brig.-Gen. C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., M.E.I.C., Dean of the Faculty of Applied Science, University of Toronto; Group-Captain F. Lindsay Gordon, A.M.E.I.C.; Dr. R. M. Stewart, M.E.I.C.; T. D. Boomer; T. F. McVeigh; G. J. Desbarats, C.M.G., M.E.I.C., Deputy Minister, Department of National Defence; G. P. Mackenzie; Dr. S. J. McLean; Dr. Chas. Camsell, M.E.I.C.; C. C. Stewart; John Murphy, M.E.I.C.; J. A. N. Cauchon, A.M.E.I.C.; P. H. Holmes; F. H. Peters, M.E.I.C.; J. L. Rannie, M.E.I.C.; A. E. MacRae, A.M.E.I.C., and O. O. Lefebvre, M.E.I.C., chief engineer, Quebec Streams Commission, Montreal.

Saguenay Branch

W. P. C. LeBoutillier, Jr.E.I.C., Secretary-Treasurer.

A meeting of the Saguenay Branch of The Engineering Institute of Canada was held in the United Church of Canada, at Kenogami, Que., on the evening of November 12, 1930.

The meeting was open to member and their friends, and the success of the gathering may be judged by the attendance, which numbered close upon seventy men.

The meeting was called to order by N. D. Paine, A.M.E.I.C., the chairman of the Branch. He introduced the speaker, C. P. Dunn, M.E.I.C., chief engineer for the Alcoa Power Company at Chute-à-Caron, P.Q., and also Mr. George Low, engineer in charge of expropriation claims for the Duke Price Company, who had very kindly consented to show a movie film of the construction and dropping of the obelisk at Chute-à-Caron.

Through the courtesy of the Canadian General Electric Company Ltd., a number of very interesting films on various engineering and scientific topics were shown.

Mr. Dunn started by describing the tests that were carried out in connection with the design of the obelisk. These tests were made, chiefly, to arrive at the cushioning effect the water would have on the block when it was dropped into the river. All models were made to scale and the strength of the concrete was also proportioned according to the size of the models.

In order to determine the shape of the bottom of the obelisk, a hydrographic survey was made under very difficult conditions, but as it proved later, it was done very accurately, as the difference in elevation between the ends of the obelisk, when placed, was only a matter of a few inches.

The mathematics involved in the design were then briefly explained and the speaker concluded his talk by asking Mr. Low to present his film, which proved to be most interesting.

The chairman then closed the meeting by thanking both Mr. Dunn and Mr. Low for a very interesting and pleasant evening.

Saint John Branch

A. A. Turnbull, A.M.E.I.C., Secretary-Treasurer.
(Reported by F. M. Barnes, A.M.E.I.C.)

On Monday evening, November 17th, 1930, at 8 o'clock, the Saint John Branch of The Engineering Institute of Canada inaugurated the regular monthly meetings of the winter programme at the Board of Trade rooms, Prince William street, Saint John, N.B.

F. H. Peters, M.E.I.C., Surveyor General of Canada, gave an address on "Aerial Photographic Surveys" illustrated with lantern slides during the lecture, and followed by motion pictures showing the actual operations of aerial photographing large areas of Saskatchewan.

The meeting was open to the public and members of the Saint John Flying Club were special guests.

W. J. Johnston, A.M.E.I.C., chairman of the Saint John Branch, introduced the speaker. In his opening remarks, Mr. Peters voiced the sentiments of the Ottawa Branch in conveying the greetings of the Ottawa Branch for a successful season.

Owing to the large amount of forest lands in the Dominion of Canada and the great difficulty of making accurate surveys of large areas on foot, the speaker stressed the ease with which large areas of land could be covered by the aeroplane.

To enable the department to decide on the area or section of Canada to be aerially photographed, an index map has been prepared showing the whole of the Dominion of Canada divided into squares of latitude and longitude, scale 16 miles to the inch. Each of these squares is again subdivided into two hundred and fifty-six smaller squares, scale 1 mile to the inch. In each of these squares or parallelograms are numbers denoting certain areas, hence at any time it is desired to designate territory to be surveyed all that is necessary is to point out the locality by the number on the map. The methods used were developed in Canada and worked out by Canadians. There are four hundred thousand photographic prints now in index at Ottawa, and during the year one hundred and twenty-five thousand prints were added to the collection.

The two main methods used in plotting are as follows:

1. Accurate control of major points.
2. In between these points to fill in the topographical details.

The speaker mentioned that it was impossible to make an accurate map from air work alone and that it was necessary to have ground control points. These are first obtained over the areas required to be mapped or surveyed and the aerial work arranged accordingly. In places where lines, fences or concession lines are well defined, the four corners are photographed in correct position. All photographs must be taken with the camera lens at a fixed focal length. The photographic plates are 7 by 9 inches and the magazine of the camera contains one hundred negatives. It is of interest to note that small camera were used many years ago for topographical work in the Rocky mountains. The road and fence lines etc. actually show up on the aerial photographs. From these and the control points you can divide the areas into squares and take off what is necessary.

The two main methods in taking aerial photographs are vertical and oblique. The oblique method is most desirable in that it is possible to cover a larger area of territory, but it is not desirable in hilly country, as the angle of depression which the line of the centre of the camera meets the ground shows that the land in the rear of the hilly country is cut off and its value lessened.

After the location has been decided upon, the area to be aerially photographed is divided into several large strips where control points have been established. These strips are then each separately photographed and overlap each other 50 per cent so that a portion of the overlapping appears on each picture. In the Maritime provinces the vertical method has been chiefly used. On account of the hilly country, the oblique method is not desirable. The use of the stereoscope is of tremendous value in picking out topography and contours.

In the case of the oblique photographs more difficulties are encountered. The first thing to be considered is to try and find the control points as laid down by the surveyor on the ground. The system of squares or grid for plotting is then drawn on the map and must be in the same perspective as the photograph. From this is developed the grid which when plotted converges near the camera and widens out towards the horizon. It is very important to get the horizon in the photograph as from this the tilt of the camera can be measured. If you have chosen the correct grid lines the control points will agree and are easily recognizable on each photograph.

The speaker then illustrated how by a system of base lines, orientation lines and control points, an area of about twenty-five square miles was plotted, after which the preliminary organization of an aerial photographic survey party under the direction of the graphic flying operations in the field, were shown in moving pictures.

A hearty vote of thanks to Mr. Peters for his interesting paper was then proposed by G. G. Murdoch, M.E.I.C., seconded by C. B. Bates, A.M.E.I.C., and carried unanimously by the Branch.

Refreshments were served before adjournment.

On Wednesday evening, November 19th, at 8 o'clock, a meeting was held in the Board of Trade rooms with the Branch chairman presiding.

The speaker of the evening was W. P. Dobson, M.E.I.C., Chief Testing Engineer of the Hydro-Electric Power Commission of Ontario, who addressed the Branch in connection with the work of a modern testing laboratory, illustrating his talk with lantern slides.

Mr. Dobson first touched upon the rapid growth of the testing force from a small to a large force, representing a large investment of capital. The laboratory work covered the preparation of specifications, the testing and inspection of all material entering into a product and the final test of the product itself, such as steels, towers and concrete. Studies were made in great detail of all materials entering into the manufacture of equipment, paint, oils, rubber gloves and numerous other items. He stressed the importance of their contact on this work with the Canadian Engineering Standards Association.

Equipment testing in itself formed an important division of the laboratory. Electrical, mechanical, and chemical tests were applied to household appliances and materials, materials used in wiring, line work and many other items, all with the object of safety. Similar to this work is that of the Underwriters Laboratory in the United States. Approval work undertaken involved the visiting of a large number of cities, both in Canada and the United States, and covered work for about 1,700 manufacturers which in some cases involved 200 items for each manufacturer.

A certain amount of research was undertaken, although not of the fundamental type involving pure physics and chemistry, but of an industrial or engineering nature such as power production equipment and power distribution equipment.

The results of the laboratory work were compared to a sinking fund. All work was undertaken with the idea of improving construction, methods of design and operation. Mr. Dobson stressed the importance of the personal qualities of the staff employed on this work.

Following an interesting discussion, a vote of thanks was extended to the speaker on motion of G. A. Vandervoort, A.M.E.I.C., seconded by G. Stead, M.E.I.C.

Before the meeting adjourned refreshments were served.

A special business meeting was held in the Board of Trade rooms, on November 25th, 1930, with the Branch chairman presiding, at which J. L. Busfield, M.E.I.C., chairman of the Committee on Remuneration of The Institute, gave a very interesting account of the work of this committee, followed by a general discussion of the subject.

On motion of G. Stead, M.E.I.C., seconded by J. L. Feeney, A.M.E.I.C., a hearty vote of thanks was extended to Mr. Busfield.

On motion, the meeting adjourned.

Sault Ste. Marie Branch

A. A. Rose, A.M.E.I.C., Secretary-Treasurer.

The regular October meeting of the Branch was held in the Y.M.C.A., March street, on November 7th, at 8 o'clock p.m.

It was expected that a member of the firm of McLartys, Harten and Wiber would give a talk on the construction of the New Windsor hotel for which they are contractors, but all the members of the firm happened to be out of the city on this date.

In such case the members present engaged in an informal discussion of matters of local interest such as traffic by-laws and unemployment.

On Saturday, November 8th, a number of the members visited the new hotel and were shown through it by the contracting firm. The view from the roof drew special applause.

The November meeting was held on November 28th, at 8 o'clock p.m., in the Y.M.C.A. March street, following a dinner at the Savoury cafe.

The chairman, C. H. E. Rounthwaite, A.M.E.I.C., introduced the speaker of the evening, Dr. Nelson Graham, Branch Director of the Provincial Board of Health, to speak on the subject "Sanitation."

Introducing his subject, Dr. Graham stated that as sanitation problems are present wherever people reside the medical man and the engineer should work together in their solution. The engineer should be consulted regarding their solution more often than he is.

Continuing, the speaker said that of prime importance to the community is the water supply, which is not a difficult one in Sault Ste. Marie. The intake is in the wall of the power canal and contamination is not at all constant. There is no water supply which is safe that is not chlorinated, the only trouble in connection with chlorination being the extra taste on occasion and it is the speaker's belief that this is due to wash water from the coke plant which drains into the river through a creek with very little fall. A solution of this difficulty would be to have the creek drain into the lower river and so below the intake.

The care of garbage and refuse is another problem in a city. Present opinion favours the incinerator for a place the size of the Soo, and it should be placed near the source of the most garbage, which should reach it by the most direct route in water-tight wagons, which could be washed after each load. The incinerator should be sufficiently large to completely burn all garbage at a high temperature to destroy all bacteria. Dumping of refuse along the waterfront is objectionable to the eye, to the water supply, and to fish, and is strictly against the law.

Sewage disposal is a problem; the most approved method being the activated sludge as in Toronto, the cost of equipment being about ten dollars per person. Draining sewage into the river is a real danger—a source of typhoid and other diseases and particularly dangerous to bathers. The use of chemicals has been tried in various places but has proved too costly.

Next to water supply in importance is the milk supply. The milk by-law should be revised to require complete pasteurization and constant inspection by a trained inspector. Without this no board of health can succeed. The board of health should be able to trace and eliminate any epidemic of communicable disease at its start. The key to this is medical inspection of schools which would be much less costly than fighting disease with individual care in homes. A dental clinic is also required in the Soo as the focus of infection in the teeth of a child is a menace to its health. All these things are an absolute benefit to the health of the community.

Discussion followed the giving of the paper, much interest being shown in the way in which these problems are being met in the Soo.

A hearty vote of thanks was tendered Dr. Graham for his most interesting and instructive address, on motion of J. H. Jenkinson, A.M.E.I.C., and F. Smallwood, M.E.I.C.

Toronto Branch

J. J. Spence, A.M.E.I.C., Secretary-Treasurer.
A. B. Crealock, A.M.E.I.C., Branch News Editor.

The first meeting of the Toronto Branch of The Institute for the 1930-1931 season was a joint meeting in conjunction with the American Society of Mechanical Engineers (Ontario section) and the American Institute of Electrical Engineers (Toronto section.) Between the hours of 4.00 o'clock p.m. and 7.00 o'clock p.m. an inspection tour took place and the following places were visited: The Royal York hotel, where the mechanical and electrical equipment was inspected; the steam plant of the Toronto Terminal Railways and the mechanical and electrical equipment of the new building of the Canadian Bank of Commerce. At 7.00 o'clock p.m. dinner was served and following this J. J. Traill, M.E.I.C., introduced J. B. McAndrews, A.M.E.I.C., who spoke on "The Mechanical Features of the Welland Ship Canal." The speaker explained the mechanism for operating the gates, the sluice gate valves, weirs, and gate hoisting derrick, all of which were well illustrated by lantern slides. Following this Mr. L. P. Rundle described the electrical features of the canal, going into considerable detail on the lighting system, bridge operating mechanism, gate equipment, safety devices and the proposed future generating plant. A hearty vote of thanks was tendered to both speakers and expressions of regret were expressed at the unavoidable absence of A. J. Grant, M.E.I.C., our President. R. J. Durley, M.E.I.C., our Secretary, expressed in a few well-chosen words his appreciation of being able to be present on this occasion.

A regular meeting of the Toronto Branch of The Engineering Institute of Canada was held in the Mining building of the University of Toronto on the evening of Thursday, October 30th, 1930. Mr. Traill introduced the speaker of the evening, Dr. H. A. Innis, Professor of Political Science, University of Toronto. Dr. Innis took as his subject "The Hudson's Bay Railway." He described the route chosen from The Pas to Fort Churchill and discussed the advantages pro and con from an economic standpoint of this latest venture in railway activity. By means of numerous slides the speaker showed the right of way, roadbed and equipment of the newly built railway. In additon he took his listeners further on to Chesterfield inlet some 500 miles north of Churchill. Following this address there was an open discussion of the subject and on conclusion a hearty vote of thanks was proposed by L. W. Wynne-Roberts, A.M.E.I.C.

A regular meeting of the Toronto Branch of The Engineering Institute of Canada was held on the evening of Thursday, November 13th, 1930, in the Mining building of the University, with J. J. Traill, M.E.I.C., in the chair. On this evening the Branch was favoured with two speakers, General Sir Charles Delme-Radcliffe and Mr. William Snaith.

Sir Charles spoke first on "Aero Photometric Surveys," in which he described by means of slides a new method in three dimensions by which much greater than usual speed in reduction of results is obtained by a vertical projection of the camera. Pictures are taken from an aeroplane flying at a height of from 2,500 feet to 20,000 feet. By means of the photograph secured a reproduction called a photocartigraph is made to the desired scale by utilizing a special drawing apparatus operated by a draftsman and thus a complete survey of a required area is completed in approximately one-tenth the time required if the same area were gone over by a theodolite and level. Following the paper a discussion took place in which the following members took part: J. R. Cockburn, M.E.I.C., C. B. Hamilton, Jr., M.E.I.C., J. W. Falkner, A.M.E.I.C., J. J. Traill, M.E.I.C., and A. E. Davison.

Mr. Wm. Snaith was the second speaker of the evening. He took as his subject "Industrial Engineering." The speaker went on to discuss the subject and to define the same. He spoke of the relationship of the industrial engineer to the plant management, the bonus system, the study of labour and material, production control, cost system and the part played by the industrial engineer in all these complications. C. B. Hamilton, Jr., M.E.I.C., and J. W. Falkner, A.M.E.I.C., took part in a discussion.

A hearty vote of thanks to both speakers was made by C. S. L. Hertzberg, M.E.I.C., which was seconded by Mr. Hamilton.

On the evening of Thursday, November 27th, 1930, a regular meeting of the Toronto Branch of The Engineering Institute of Canada was held with C. S. L. Hertzberg, M.E.I.C., in the chair. After the minutes of the previous meeting were read and confirmed, the chairman introduced W. F. McFaul, M.E.I.C., city engineer of Hamilton who spoke at some length on "Recent and Projected Improvements to the Waterworks System of the City of Hamilton."

The speaker introduced his subject by citing the expenditures and general layout of the system at the time he took charge in 1913 as manager. In 1923, Mr. McFaul was appointed city engineer and manager of the waterworks system and in this year made many recommendations in a report which involved the expenditure of roughly $2,358,000. Of this amount the ratepayers by by-laws in 1926 and 1928 approved of some $576,000 being spent in the construction of the intake, conduits, screen chambers, an extension to the Beach pumping station and equipment extension of the Ferguson avenue pumping station and connecting main.

In order to relieve unemployment, additions are being made at the present time to various mains and also the construction of a reservoir. In addition to these works his department is preparing plans for a mechanical filtration plant. By means of numerous slides Mr. McFaul explained the many features of the new 48-inch and 60-inch intake pipe and the installation of the same.

Those taking part in the discussion were A. U. Sanderson, A.M.E.I.C., O. M. Falls, A.M.E.I.C., and E. M. Proctor, M.E.I.C. A hearty vote of thanks was tendered to the speaker by Mr. Sanderson.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Vacant

MECHANICAL ENGINEER, university graduate preferred, with at least four years experience in the running, organization and operation of a manufacturing plant, including electric power, high and low pressure steam equipment, heating plant, and motor truck maintenance. A permanent position and good connection with an international company. Apply to Box No. 649-V.

PROMOTION ENGINEER. Graduate engineer to do educational and promotional work with architects and contractors. Must be bi-lingual. Apply to Box No. 650-V.

SALES ENGINEER, University graduate, speaking both French and English fluently, for Montreal firm, preferably not over 35 years of age. Must be a producer and able to get best results from salesmen. Permanent position and salary in keeping with results obtained. Apply to Box No. 651-V.

MECHANICAL ENGINEERING GRADUATE, for steam control and instrument maintenance work for newsprint mill. One familiar with the preparation and analysis of steam reports and the making of necessary efficiency tests. Location, Newfoundland. Apply to Box No. 653-V.

MECHANICAL ENGINEER. Thoroughly qualified mechanical engineer for salesman by large manufacturing plant in Western Canada. When applying give full details, experience, age and salary required. Apply to Box No. 656-V.

MECHANICAL ENGINEER, with some experience in plant maintenance and layout, age from 25 to 30, location Ontario. Apply to Box No. 657-V.

RECENT GRADUATE in mechanical, electrical or civil engineering for development work with an industrial company in Montreal. Young man with one or two years experience required. Apply to Box No. 658-V.

MECHANICAL ENGINEER, with two or three years experience on mechanical draughting, preferably with some paper mill experience. Apply to Box No. 661-V.

THE NATIONAL RESEARCH COUNCIL OF CANADA

The National Research Council of Canada, will shortly proceed to make the following appointments to the staff of the National Research Laboratories:—

1. A physicist or engineer to carry out researches and standardization in the field of wireless telegraphy and telephony.

2. A physicist to carry out researches in the field of optics.

3. A physicist to carry out research and testing on electric meters.

The salaries will depend on the qualifications and experience of the persons appointed. Applications received from former applicants will be reviewed, and new applications are invited for the consideration of the Selection Committee.

Applications should include statements of age, race, nationality, education, technical experience, references. Address applications to:—The Secretary-Treasurer, National Research Council, Ottawa, Canada.

Situations Wanted

CIVIL ENGINEER, A.M.E.I.C., married, desires employment with manufacturer of industrial products, selling to industrial and other markets. His experience includes engineering and building construction, administration and operation of utilities, municipal works, etc. Record of integrity; moderate salary; location immaterial. Apply to Box No. 14-W.

ELECTRICAL ENGINEER seeks connection with Montreal engineer or architect for part time work involving the design and specification for industrial and public buildings. Experienced and capable of complete responsibility. Apply to Box No. 40-W.

CIVIL AND MECHANICAL ENGINEER; aggressive, practical engineer, with background of experience in design, construction, maintenance and operation of pulp and paper mills. Especially qualified to reduce mill costs. Apply to Box No. 53-W.

ELECTRICAL ENGINEER, B.Sc., age 30. Experienced in power distribution and electrical communication, including design of carrier current systems. Apply to Box No. 110-W.

ELECTRICAL ENGINEER, graduate '27, fifteen months students' test course: fifteen months switchboard layout and substation design. Before graduation experience consisted of machine shop practice and electrical construction. Apply to Box No. 132-W.

COLLEGE GRADUATE, age 34, with over ten years experience in power developments and pulp and paper mill construction and maintenance, largely in direct charge of design or construction; desires new connection as chief or assistant engineer or construction superintendent. Apply to Box No. 167-W.

CIVIL ENGINEER, B.Sc., (McGill), M.E.I.C., P.E.Q. and B.C., with broad experience in hydro-electric power investigations, studies and exploration of forest lands, including design and construction driving and storage dams, wharves, flumes, piers and booms and loading plants, as well as general engineering and contracting, is open for engagement. Location immaterial. Now engaged but available on short notice as projects are nearing completion. Speak French fluently, physically fit, active and energetic, and can get results. References can be furnished if required. Apply to Box No. 177-W.

Situations Wanted

CIVIL ENGINEER, A.M.E.I.C., B.A.Sc. and C.E. University of Toronto, with twenty years experience, is open for engagement. Three years railroad construction, one year lake drainage and dam construction, nine years municipal engineering, including pavement and bridges, two years town management, one year paving contracting, and one year resident engineer of highway pavement construction. At present in Maritime Provinces. Apply to Box No. 216-W.

DESIGNING DRAUGHTSMAN, experienee in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing and hoists. Also some experience in ventilating and heating work and calculators. Accustomed to strucural design and details. Good references. Present location Montreal. For interview apply to Box No. 329-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., R.P.E. Ont., with twenty-four years experience embracing dams, wharves, grain elevators, foundations, pile driving, highways, municipal engineering, water power surveys, road locations, inspections and estimating is open for engagement as engineer or superintendent in construction, operation or maintenance. Location immaterial. Apply to Box No. 358-W.

ENGINEER, age 31, married. Experienee includes two years mechanical, two years railway, six years structural and instrumentman and structural engineer on erection, desires position in Toronto. Apply to Box No. 377-W.

CIVIL ENGINEER, A.M.E.I.C., university graduate, O.L.S., married, twenty years experience city surveys, calculations for curved surveys, design, layout and supervision, sidewalks, pavements, sewers and water systems. Acted in capacity of chief engineer for large engineering and surveying firm for five years. Best of references. Available on short notice. Apply to Box No. 413-W.

ELECTRICAL AND MECHANICAL ENGINEER, S.E.I.C., educated Oundle and Manchester, age 24. Student course, Brit.-Westinghouse. Three years design, production, advertising, sales and control of sales force on mechanical and electrical goods. One year outside plant engineering leading public utility company. Desires work in sales, production or engineering capacity. Available immediately. Location immaterial. Apply to Box No. 415-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), graduate. Eighteen years experience in survey and construction, railway, hydro-electric and buildings. Experience comprises both office and outside work. Desires responsible position. Would consider position with commercial or manufacturing firm. Available immediately. Apply to Box No. 425-W.

CIVIL ENGINEER, S.E.I.C., 1930 graduate of Nova Scotia Tech. with experience as plane table topographer, instrumentman and draughtsman and particularly interested in hydro-electric power development and reinforced concrete design, desires position. Willing to go to foreign fields. Available at a few weeks notice. Apply to Box to 431-W.

ELECTRICAL ENGINEER, S.E.I.C., B.Sc., (McGill Univ. '27), age 26. Fifteen months outside plant engineering with large public utility. Twenty months sales engineering experience with electrical manufacturing

The Deterioration of Structures in Seawater

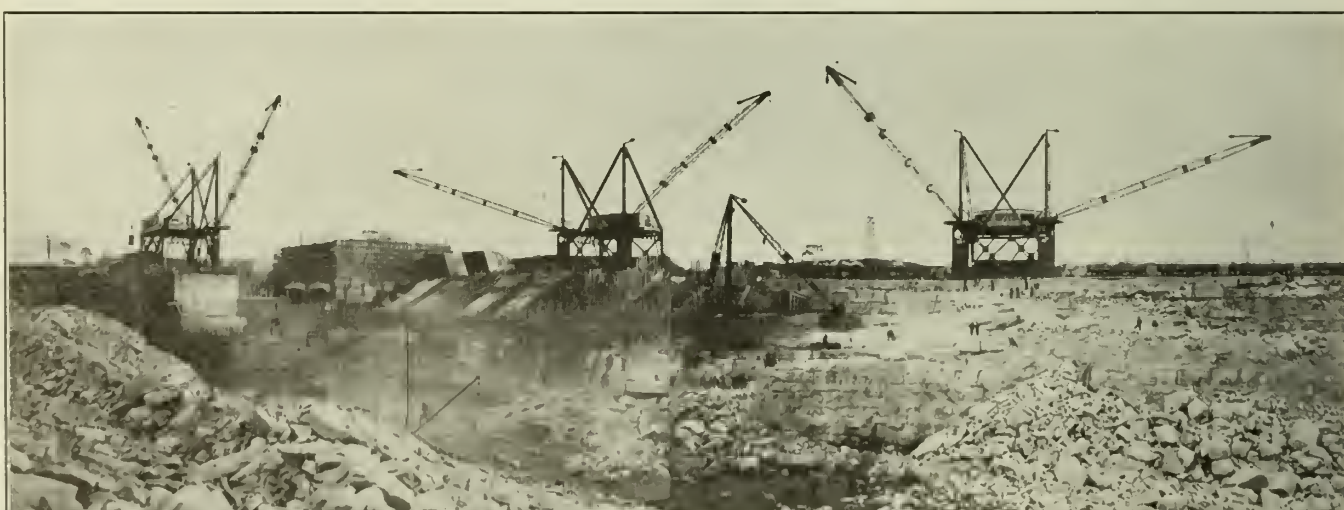
Since 1916 a committee of the Institution of Civil Engineers has been investigating the deterioration of structures of timber, metal, and concrete in seawater. Its first report was published in 1920, and its eleventh (interim) report has just appeared. Whether by coincidence or not, the present report, which now is published without the assistance of the grants that were given by the Department of Scientific and Industrial Research until March, 1928, appears under some headings to be more drastically summarized than its predecessors. In respect, for instance, of the last set of the numerous iron and steel specimens exposed for five years, which consisted of eighteen soft-grade chromium-steel bars, treated in various ways and exposed at Plymouth, Dr. J. Newton Friend, who has carried out this work for the committee, gives no figures of the results he has obtained. Among other results, he reports that, judged by loss of weight and depth of pitting, the resistance of the steel to corrosion by sea action does not appear to be increased by cleaning, whether by pickling or polishing, or by heat treatment. Both in the alternate wet-and-dry and in the complete immersion tests, the heat-treated and cleaned specimens suffered in general more severely than the bars exposed with the skin on. It was found, further, that better results were obtained by quenching followed by tempering than by annealing.

The usual periodical examination has been made, after about eight years' exposure, of the iron and steel bars exposed at Auckland, Halifax, Colombo and Plymouth, showing varying progress of corrosion, but no final dismantling for intimate observation was due to be made in the period under notice.

A progress report for the year was made on the first series of painted steel plates exposed to aerial corrosion at Southampton over five years previously. Of the nineteen types of protection, including galvanizing, none has been absolutely unattacked, but a great many are in very good condition, and deterioration had not proceeded far enough to justify dismantling.

A series of 240 plates, prepared also by Dr. Friend, have been exposed at Southampton and at Weston-Super-Mare respectively for seventeen months and twenty-eight and a-half months. These have been protected by a variety of tars—in some instances with the addition of slaked lime and of paraffin wax. The coating of some plates was applied at 80 or 50 degrees C., and on others the tar was applied at about 200 degrees C. to cold plates, and in one instance to hot plates of the same temperature. Two series of specimens were also treated with white lead in addition to tar, separated from it by several coatings of shellac varnish. In one instance the plates were coated as rolled with the millscale adherent, but in all the remainder they were sand-blasted. The continuously-immersed plates at Weston-Super-Mare broke adrfit and were lost.

At Southampton the completely-immersed plates invariably suffered greater loss through corrosion than those exposed at half-tide level. At both ports the addition of slaked lime to the horizontal-retort tar gave a distinctly better result, both in appearance and in resistance to corrosion, than the pure tar, but the addition to the vertical-retort tar had practically no effect, and, indeed, gave rather worse results than were obtained with the unneutralized tar. The addition of 5 per cent of paraffin wax, on the other hand, made an appreciable improvement in the protective qualities of the vertical-retort tar. Generally the horizontal-retort tar proved to be very much superior to the vertical-retort tar, the latter of which in the series at 80 degrees C. lost three to six times as much in weight as that of the horizontal-retort tar, and when applied at 200 degrees C. lost six to ten times as much. While in general tar applied at 200 degrees C. gave better results than tar applied at 80 degrees C., the application of hot tar to plates at the same temperature was not in general very successful. It is suggested that the plates should only be warm enough to ensure their complete dryness, and that probably about 100 degrees C. is suitable for the tar in most conditions. On the whole, tarring by painting over the millscale was found unsatisfactory. Painting with white lead on top of the tar, with coats of shellac varnish interposed, was very successful.—*Engineering.*



Site of Power-House, Beauharnois Power Corporation, Beauharnois, Que.

Preliminary Notice

of Applications for Admission and for Transfer

December 19th, 1930

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in February, 1931.

R. J. Durley, *Secretary.*

* The professional requirements are as follows—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BARNECUT—REGINALD, of Calgary, Alta., Born at Plymouth, England, Jan. 6th, 1896; Educ., B.Sc., (C.E.), Univ. of Alta., 1923; 1919-22, field dftsman and leveller, D. I. Reclam. Service, Calgary; 1923-24, inspr., C.P.R., Winnipeg; 1924-28, struct'l. dftsman., Worden-Alley Co., Milwaukee, Wis.; 1928-29, struct'l. checker, Dominion Bridge Company, Winnipeg, and at present, struct'l. checker for same company, at Calgary, Alta.

References: R. S. L. Wilson, C. A. Robb, H. B. Lebourveau, H. M. White, R. H. Goodchild, A. J. Dostert.

GREENING—EDWARD OWEN, of Quesnel, B.C., Born at Thames Ditton, Surrey, England, March 29th, 1888; Educ., 1904-07, South Eastern Agricultural College, Univ. of London (Diploma 1906). P.C.E. Assns. of Prof. Engrs. B.C. and Alta.; Capt. C.E. and R.A.F. Reserves; 1907-09, chainman, rodman, etc., Tyrrell & McKay, Hamilton, Ont.; 1908-10, chainman and instr'man., Nat. Transcon. Rly.; 1910-11, transitman, 1911-12, res. engr., 1912-13, locating engr., 1914. res. engr., same rly.; 1914, also res. engr. at Williamstown, Ont., for C.P.R.; 1914-19, overseas., C.E. and R.A.F., Lieut., and Capt.; 1927-28, rly. dftsman., field and office, Edmonton, Dunvegan & B.C. Rly.; 1928, field engr., Calgary Power Company; 1928-29, rly.reconnaissance, 1929, stereoscopic examination of air photographs, and 1929 to date, location engr. in charge of party, Pacific Great Eastern Rly. Lands Survey of Resources, Quesnel, B.C.

Engineering Information Service

Members desiring information regarding specific engineering or technical subjects can obtain from Headquarters lists of references to articles which have appeared in current or past numbers of engineering periodicals. Inquiries should be sent to the **General Secretary, marked "Information Service."**

In writing, please state as clearly as possible the precise subject on which information is desired. It is not sufficient to give a general title such as, for example, Valuation of Public Utilities, or Asbestos Manufacture. The particular features or division of the subject should be given in all cases. This definite information is required so that the investigator may understand clearly what is needed. The lists furnished to members will give in each case the titles of the articles, the authors, the names of the publications in which they appeared, and in most cases, a brief abstract of the contents.

No charge is made for the service unless the inquiry involves prolonged search or office work. Photostat copies (white on a black background) of the articles can be furnished at a cost of thirty cents per page where the size does not exceed 8½ ins. by 11 ins. For larger sizes a slightly higher charge will be made. On receiving the list of references which has been prepared, please select those of which copies are desired, and send a remittance to cover the cost of the photostats needed.

Translations of articles in foreign literature can be made, if desired, at a charge sufficient to cover the cost of the work.

R. J. DURLEY,
Secretary

The Head Office Building of The Sun Life Assurance Company of Canada, Ltd., Montreal

A Foreword by the Architects*

To the series of papers describing the engineering features of the building

The Sun Life building as it stands today covers an area approximately two acres in extent, is 24 storeys high above ground with three basements below grade and has a cubic content amounting to 22,000,000 feet.

To appreciate fully the difficulties faced in designing the building it should be borne in mind that the original building, for which we started preparing sketches some twenty-three years ago, was planned with a height of only 8 storeys, with an area of rather less than one-third of the present site and with no thought of an extension northwards. The problem was to graft on to this comparatively small building, the size and scale of which necessarily governed the much greater final scheme, a structure capable of housing a population of ten thousand people. It is difficult at any time to find the solution of a problem of such magnitude and the restrictions imposed by these governing conditions added greatly to its complexity.

The Corinthian order formed the dominating feature of the original building and it was therefore necessary to continue its use in the extension. This has been done in the lower storeys which form the base of the complete building; colonnades of great Corinthian columns constitute the principal feature of the main facades.

The elements of classic architecture emphasize the horizontal rather than the vertical, and in this building, despite a total height of four hundred feet, it has been possible to preserve those dominating horizontal lines owing to the great breadth of the base from which it springs. The emphasis of the horizontal and the general proportions of the mass are intended to give the building a monumental character in keeping with the dignity of the great organization it houses. The accompanying illustrations show the original building as it was in 1925 and the new building as it will appear when completed.

*Messrs. Darling & Pearson, Toronto.

We have briefly outlined the aesthetic considerations governing the design of the building and these were naturally of the greatest importance to the architects, but there were many other factors to be taken into consideration. The various problems connected with structural design, heating, ventilation, drainage, water supply, fire protection, electrical supply and distribution, vertical transportation and interior intercommunication, all had a profound effect on the architectural design. Each of the engineers had to study the requirements of his particular problem and work out a solution satisfactory not only to himself but also to the other engineers and to the architects, who of course had to co-ordinate the work of all.

Some of the principal requirements which had to be borne in mind by the engineers and ourselves in the design of the building are as follow:—

(1) The complete building, including the old, had to be designed to accommodate a population of approximately 10,000 persons.

(2) Transportation had to be provided to take this large number of people to their various departments within a period not exceeding 45 minutes. To meet this requirement 32 high speed passenger elevators were necessary.

(3) Provision had to be made for serving lunch every day to 10,000 people within a period of two hours.

For this purpose cafeteria and dining room space had to be provided on the 6th floor, the 5th floor and the 2nd basement totalling 44,000 square feet, including 10 fully equipped cafeteria counters each 50 feet in length.

To serve these cafeterias and dining rooms 33,000 square feet had to be provided for kitchens, bakery, serving pantries, dishwashing rooms, dry and cold storage rooms and refrigerating plant.

This lunch room accommodation was required to be divided into three main heads, in each case the sexes being served separately.

(1) General staff cafeterias (6th floor).
(2) Chief clerks' and divisional heads' dining-rooms (5th floor).
(3) Building operating and cleaning staff cafeteria (2nd basement).

Two freight elevators have been provided at the northend of the building for kitchen service only.

(4) Accommodation had to be provided for handling the very considerable shipping and mailing requirements of the company. For this the main shipping department has been located in the 1st basement approached from Mansfield street by means of an easy ramp.

Former Head Office Building.

Two general freight elevators have been provided and located near the shipping department.

Two of the 32 passenger elevators are equipped to serve as postal cars for ordinary inter-departmental communication and for distribution and collection of mail. The main mailing room is in the 1st basement close to these postal cars and to the shipping room.

Provision has been made for a system of pneumatic tubes consisting of 26 stations with possible expansion. This will give rapid inter-departmental communication.

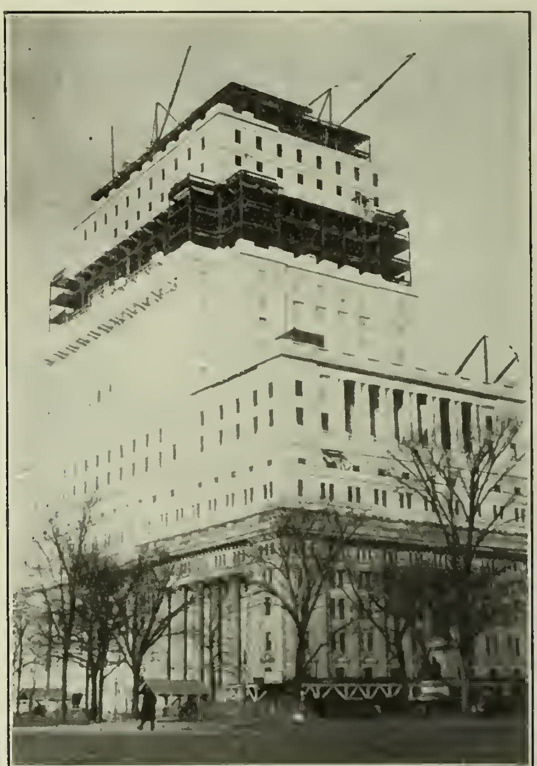
(5) Considerable space was required for the company's medical services, consisting of examination rooms, wards, treatment rooms, X-Ray and dental clinics.
(6) Provision had to be made for a large assembly hall capable of seating approximately 1,000 people, with a fully equipped stage, dressing room accommodation and a projection booth for moving pictures.

Space was also required where badminton, basketball and other games could be played by the staff after office hours. For this purpose a large playroom and several bowling alleys have been provided with fully equipped dressing room accommodation, totalling 17,000 square feet. The playroom is 126 feet by 58 feet and 26 feet 6 inches in height.

(7) Accommodation for the chief executive officers of the company has been provided on the 21st and 22nd floors, together with a board room and committee rooms. Dining rooms for the use of the chief executive officers have been arranged on these floors. They are served by adjacent kitchens entirely independent of the main kitchens on the 6th floor.
(8) Extensive filing accommodation was necessary—the active file room in the 1st basement is 52 feet by 150 feet (7,800 square feet) and the inactive file room in the 2nd basement is 50 feet by 208 feet (10,400 square feet).
(9) The boiler plant, it was early decided, was to be located apart from the building on the east side of Mansfield street at the corner of Cathcart street, but provision had to be made in the building itself for the very considerable mechanical plant necessary to operate it.
(10) The new work had to be arranged so that its execution could be carried on with minimum disturbance of the old building in which the staff were to continue at work during the building operations.

From the number of large units mentioned above and the diverse character of their requirements it is possible to visualize to some extent the highly involved plan layout which had to be worked into one comprehensive whole. When, in addition, it is remembered that the dominating character of the design was necessarily strict classic, requiring absolute symmetry and balance, it will be seen this was no ordinary problem of plan and design.

We hope and believe that the final solution of the problem will be satisfactory, and, if such should prove to be the case, we wish to make it clear that the success attending our labours will, in great measure, be due to the loyal and able co-operation of the engineers who have helped us to create the building, and whose work is described in the papers which follow, contributed by Messrs. F. A. Combe, M.E.I.C., on the boiler plant, A. H. Harkness, M.E.I.C., on the structural features, J. H. Mencke on the electrical equipment, A. T. Newman on the plumbing and fire protection, and E. A. Ryan, M.E.I.C., on the heating and ventilation.



Present Head Office Building.

In closing we wish to take this opportunity of expressing our very real appreciation of the thoughtful consideration and help given us by Mr. D. L. Macaulay, the Assistant Secretary of the Sun Life Assurance Company in charge of building operations, and by the Associate Architect, A. J. C. Paine, A.M.E.I.C., who has worked with us on this building ever since it was originally started in 1913.

The Structural Engineering of the Head Office Building of The Sun Life Assurance Company of Canada, Montreal.

A. H. Harkness, M.E.I.C.,
Harkness and Hertzberg, Toronto, Ont.

Paper presented at the Annual General and General Professional Meeting of The Engineering Institute of Canada, Montreal, Que., February 4th, 5th and 6th, 1931.

SUMMARY—The paper deals with the design and erection of the structural steel work for the new head office building of the Sun Life Assurance Company of Canada, in Montreal. Many interesting features of the work are due to the fact that the original office building, eight storeys in height, had to be incorporated in the new twenty-eight storey building, without interruption to the work of the offices contained therein.

The entire new building occupies a site 214 feet by 428 feet 6 inches, and rises to a height of nearly 400 feet above sidewalk level. The whole work involved the fabrication and erection of more than 18,000 tons of steel. The walls of the building are of granite backed with brick and the floors are of long-span concrete slab construction. Many of the columns in the original building had to be reinforced to take the increased loads, notwithstanding which the work was successfully carried out without interruption to building services.

Special methods of foundation work had to be employed, and a number of the original column bases had to be replaced. The erection of the steel for the new portion of the building presented no unusual problems, but the alterations in the old building involved a large amount of field work, and had to be carried out under difficult conditions.

The original portion of the head office building for the Sun Life Assurance Company is situated on the north side of Dorchester street between Metcalfe street on the west and Mansfield street on the east with a frontage on Metcalfe street of 144 feet 6 inches, on Dorchester street of 214 feet and on Mansfield street of 139 feet, the east end of the building being 5 feet 6 inches narrower than the west end. This building, 144 feet 6 inches by 214 feet, was 8 storeys high with a set back of about 5 feet at the fifth floor level. It was of steel frame skeleton construction, with the columns and footings designed for a 16-storey building. The floors were of tile arch construction with about 6-foot spans. This building was constructed under two different contracts, the westerly 144 feet being finished about 1913 and the easterly 72 feet during 1922. The location and size of the old building are shown on the general foundation plan, Fig. 1.

The new addition to the building extends north between Metcalfe and Mansfield streets, a distance of 284 feet, making the size of the entire building 214 feet by 428 feet 6 inches. Including three duct floors and the pent house, the building is 28 storeys high, rising to a height of 390 feet 11 inches above the ground floor, which is about 9 feet above the level of the sidewalk on Metcalfe street. Three basements, 16 feet, 14 feet and 14 feet respectively, make the lowest basement floor 33 feet below the level of the sidewalk. Up to the eighth floor the building covers the entire area of the lot except for an offset of about 5 feet at the fifth floor. The tower portion starts from the eighth floor and is 16 storeys higher with 3 storey wings up to the eleventh floor extending to the north and south. The main part of the tower is 171 feet by 240 feet up to the nineteenth floor, at and above which two other offsets occur. The outline of the plan of the tower is shown on the foundation plan, Fig. 1.

The walls of the building are of granite backed with brick. The granite facing is in 5-inch and 9-inch thicknesses bonded with 4 inches and 8 inches of brick, the brick backing carried about the steel columns for fireproofing. The walls are furred on the inside with tile furring blocks. The floors are of long span ribbed slab concrete construction, the usual span being about 16 feet. Beams under 18 inches deep are fireproofed with concrete. Those 18 inches deep and over, are fireproofed with terra cotta up to the bottom of the ribbed slabs which are carried on the fireproofing. Generally, the floors are finished with one and one half inches of concrete on three and one half inches of Haydite concrete fill to provide for the electric conduits.

The relation between the new and the old building is shown in the reproduction of the photograph of the west elevation, Fig. 2, the old building being that portion of the elevation on the lower right-hand corner, seven bays wide and 7 storeys high. The south two bays of the tower extend over the north two bays of the old building, so that the north three rows of columns in the old building carry from 22 to 26 storeys of floors and walls instead of the 16 for which they were designed. As a consequence most of the columns and footings of the north three rows required to be reinforced. This photograph shows the offsets in the north and south elevations occurring at the fifth, seventh, eleventh, fifteenth, nineteenth and twenty-second floors. None of these offsets occur at columns so that they all had to be carried on girders. The east and west elevations had corresponding offsets except at the eleventh floor for the tower portion. On these elevations the offsets to the walls of the tower occur at the seventh floor and are to lines of columns. Altogether, there are two hundred and twenty-three beams, girders or trusses in the building carrying columns.

The first contract for the addition to the building covered its construction up to the eighth floor. On account of the Sun Life Company occupying certain buildings on Metcalfe street on the west part of the lot which they could not vacate until new room was provided, the east half of the building was started first, and partly finished before the west half was started. The contract for the tower portion was subsequently let so that the construction of the building has proceeded almost continuously except for a short stoppage in the fabrication and erection of the steel. The steel work in the extension to the building amounts to approximately 16,000 tons and in the old building to 2,550 tons, making a total of 18,550 tons.

The columns in the outer walls for the lower portion of the building, which generally extend only to the seventh floor level, carry moderate loads, the maximum of which is 940,000 pounds. These columns were carried at the street level on concrete piers forming part of the basement walls. They rested on steel slabs figured at a bearing of 600 pounds to the square inch on the concrete. The columns were anchored to the concrete by anchor bolts which extended up through holes in the slabs to the column base. All interior columns rested on a bed of 1:1:2 concrete which was just thick enough over the rock to provide a level bearing at the correct elevation, the rock having been excavated to the nearest seam below. The loads on some of these columns amount to over 4,000,000 pounds. The slabs were designed for a bearing on the concrete of 1,200 pounds per square inch. The tops of the concrete pads were made level, and the bottoms of the steel slabs were planed and set on the concrete without grouting. The slabs were not anchored as they were large enough in area and heavy enough to hold the columns upright during erection, the columns being bolted to the slabs with studs tapped into the tops of the slabs.

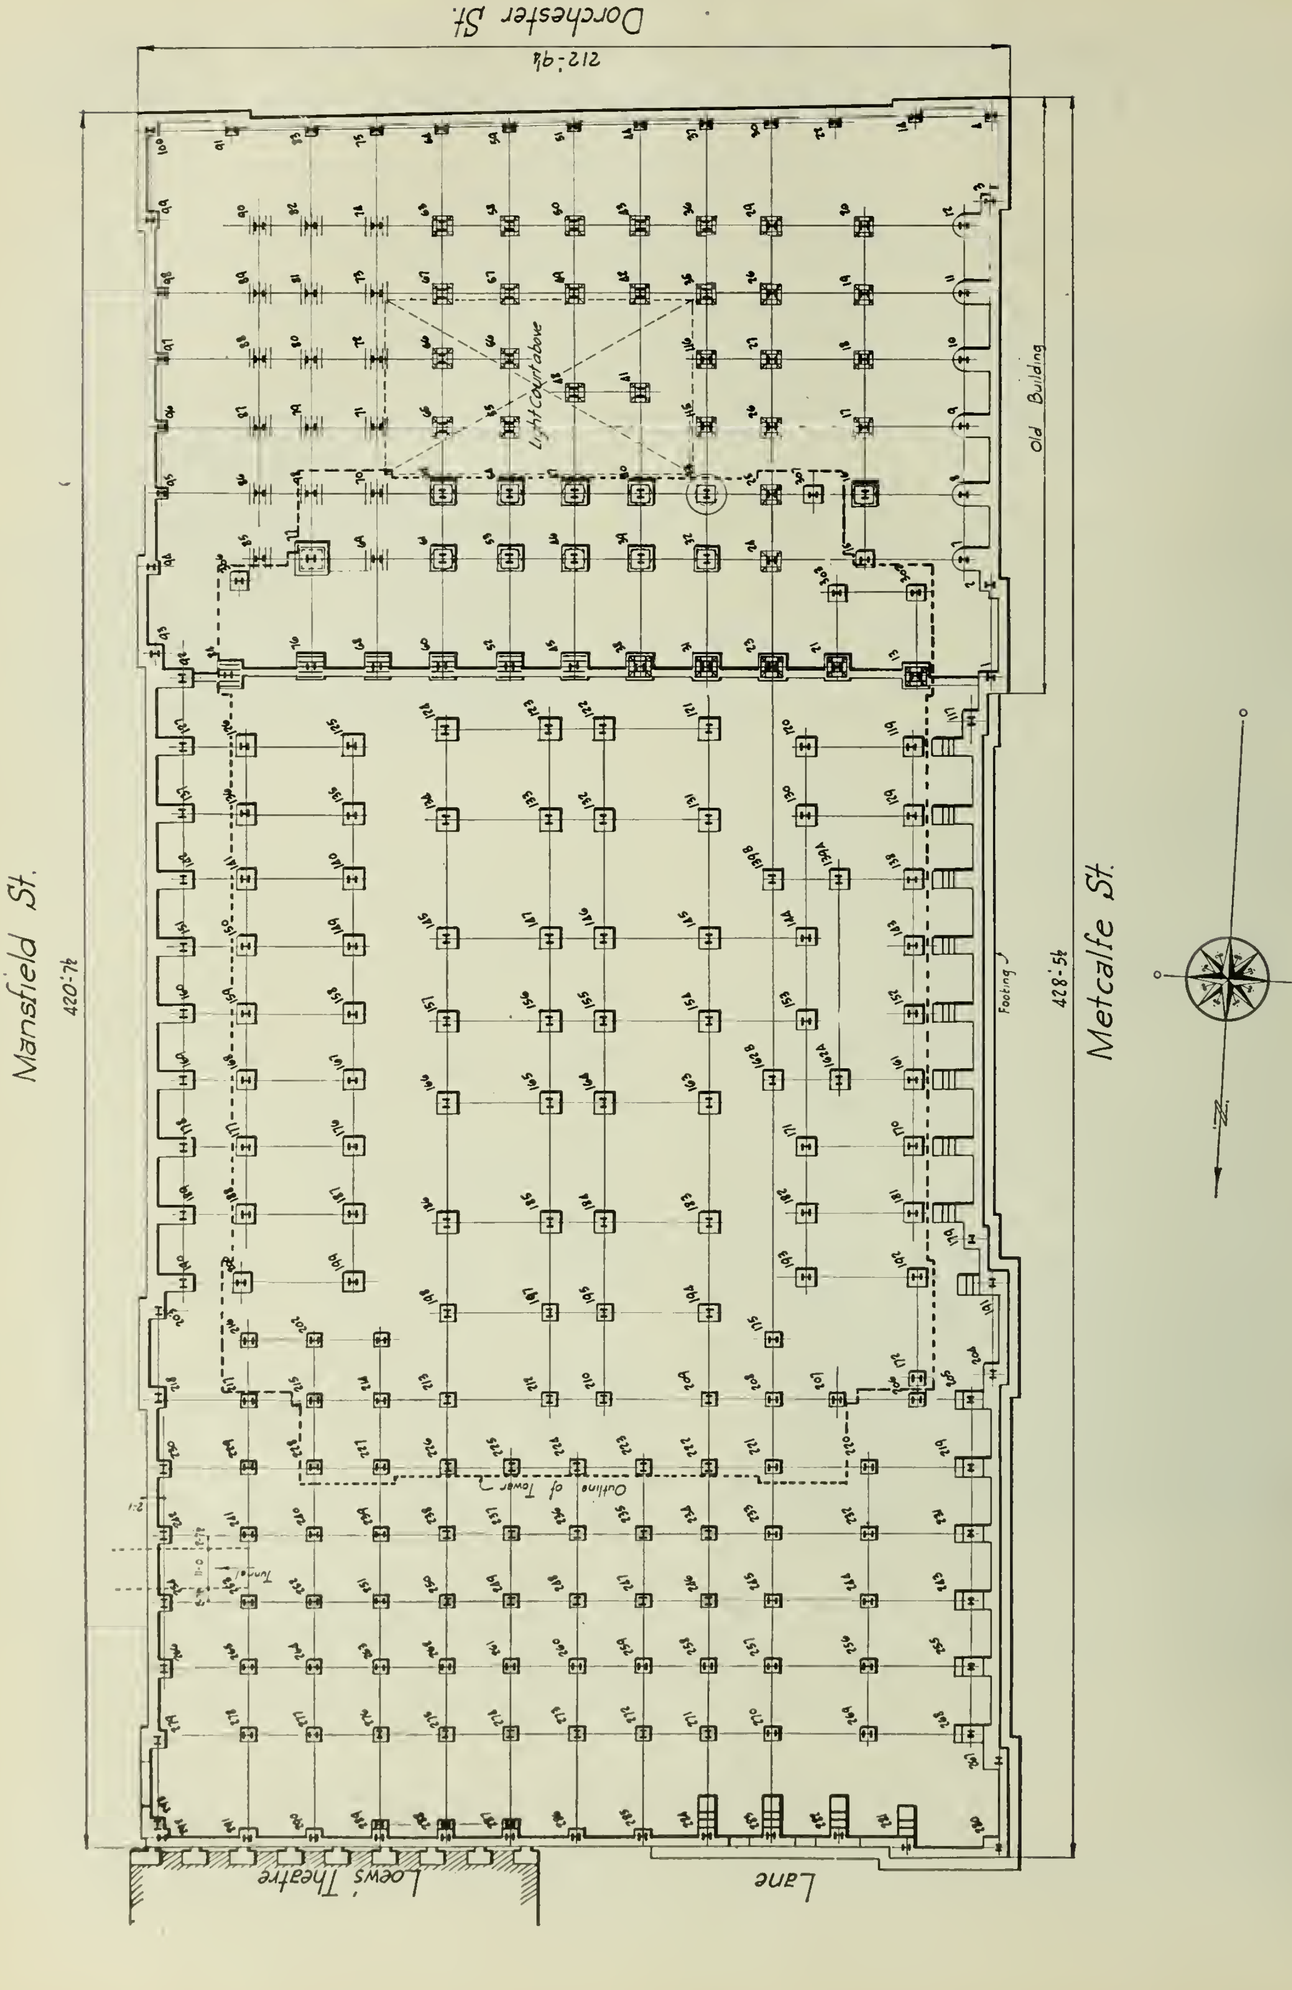


Fig. 1—Foundation Plan, old and new Buildings.

Fig. 2—West Elevation—Building under Construction.

The general excavation for the building extended to a depth of 34 feet below the sidewalk level on Metcalfe street. Approximately 30 feet of this was through a stiff dry clay and the balance through hard rock. For the east part of the building, which was started first, the entire area was excavated to depth and the basement walls and piers constructed as the excavation proceeded. The walls, which were not stable against the earth pressure, required to be shored and the shoring had to be maintained until the westerly portion of the building was constructed. This proved to be difficult and expensive with the full pressure from 35 feet of earth against the walls. To avoid the necessity of shoring the basement walls for the west half of the building they were designed as retaining walls, the piers for the steel and granite columns being given enough projection to provide stability against the earth pressure. (Fig. 3.) This photograph shows the projection of the piers with the offsets at the floor level to take the beams, and the grooves in the sides of the piers and the wall to take the concrete floors. The excavation for this part was done by digging a trench about 20 feet in width along the north and west sides of the lot, to the required depth,

Fig. 3—West Side—Basement Walls designed as Retaining Walls.

the earth being shored directly across the trench until after the retaining walls were constructed. The balance of the excavation for the west half was then finished by the use of steam shovels, a driveway being maintained along the east and south sides of the excavation adjacent to the new east portion already constructed and to the old building for hauling the material to the street.

The sidewalk is constructed of granite slabs from 6 to 7 feet in width, 8 inches in thickness and of a length equal to the width of the sidewalk, 12 to 14 feet. To carry the sidewalk free of the earth a continuous bracket was cast on the outside of the basement wall and a concrete wall was constructed under the outer edge of the sidewalk. Reinforced concrete beams under the joints in the walk spanning from this wall to the bracket on the basement wall were built to take the slabs and also the entrance steps to the building where these projected over the walk. (Fig. 4.)

In the old building there was a basement under the west three bays and a basement and sub-basement under the balance. The steel columns were carried on concrete

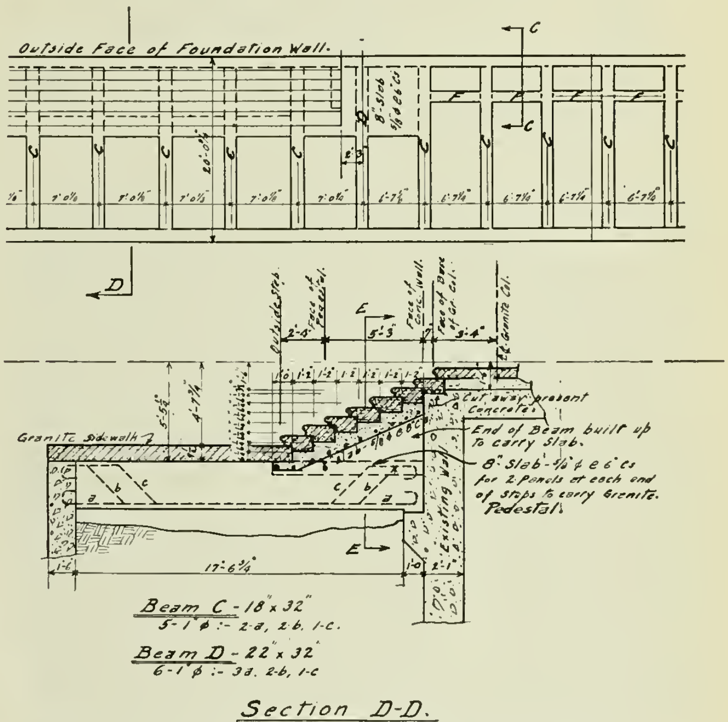

Fig. 4—Plan and Section of Sidewalk and Steps, Metcalfe street.

piers to rock, a distance of approximately 26 feet below the basement and 12 feet below the sub-basement floor. The footings for the columns for the west part constructed under the first contract were circular piers, the columns resting on square cast iron bases. For the east part constructed under the second contract, the piers were square and the columns stood on steel beam grillages. When the north piers of the old building were exposed by the excavation for the extension, it was found that there were thin layers of clay between the upper courses of rock under columns Nos. 52, 60, 68, 76 and 84. After the north wall of the old building was removed and while the columns were shored for reinforcing, the old piers were taken out and the rock underneath excavated to solid material. The steel columns were then extended downwards by the addition of a 12-foot length to each, the old grillage bases being re-used at the lower level. (Fig. 5.) The same condition was found to exist when the rock was exposed under the piers for the west half of this same row of columns

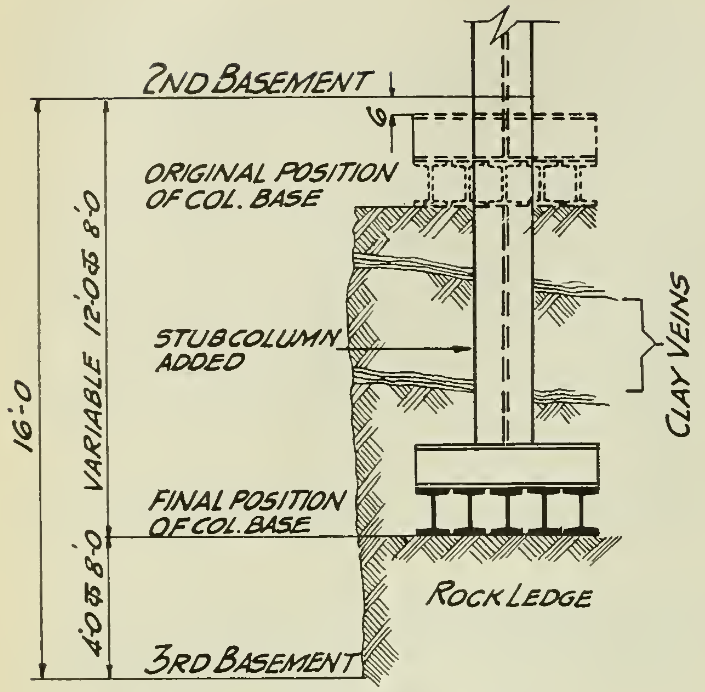

Fig. 5—Downward Extension of Column.

during the excavation for this part of the building. For these piers the columns were shored up, the old piers removed, the excavation carried to solid rock at about the level of the third basement floor and new square piers constructed up to the bottoms of the shored columns.

The old concrete piers for columns Nos. 16, 32, 39, 40, 46, 47, 54, 61 and 62 were 6 feet in diameter and were good for the increased loads on the columns, but the cast iron bases were deficient both in area and strength. These bases were removed, the top of the old pier cut down and replaced with a square concrete cap of 1:1:2 mix to take new steel slab bases. (Fig. 6.) For column No. 33, the final load on which amounts to 2,640,000 pounds, the old pier was increased in area by constructing an annular ring of concrete 2 feet thick about it. The top of the old pier was removed and the total area of the old pier and annular ring covered with a pad of concrete 3 feet thick to take the new steel slab. The footing for column No. 77, which was square, was treated in the same manner. (Fig. 7.)

Practically all the columns in the north three rows of the old building except those in the east and west walls required to be reinforced to take the increased loads from the new addition. These columns were all H-sections, some of which had cover plates. The first ones to be reinforced were columns Nos. 45, 52, 60, 68, 76 and 84 in the north row, which were exposed when the east half of the north wall of the old building was removed. These columns were reinforced by the addition of cover plates to the flanges. This required the cutting out of the old rivets and redriving rivets on the columns which already had cover plates and drilling the flanges of the others. The old spandrel beams carrying the wall were removed, and, after the reinforcing of the columns, replaced by the necessary floor framing. The rest of the columns were reinforced by adding angles or angles and plates to the web as shown in section B-B, Fig. 8. This required the field drilling and riveting of only two lines of holes through the web of a column, instead of four lines through the flanges as would be required for reinforcing with flange plates. The rivets were spaced at 12-inch centres except at connections

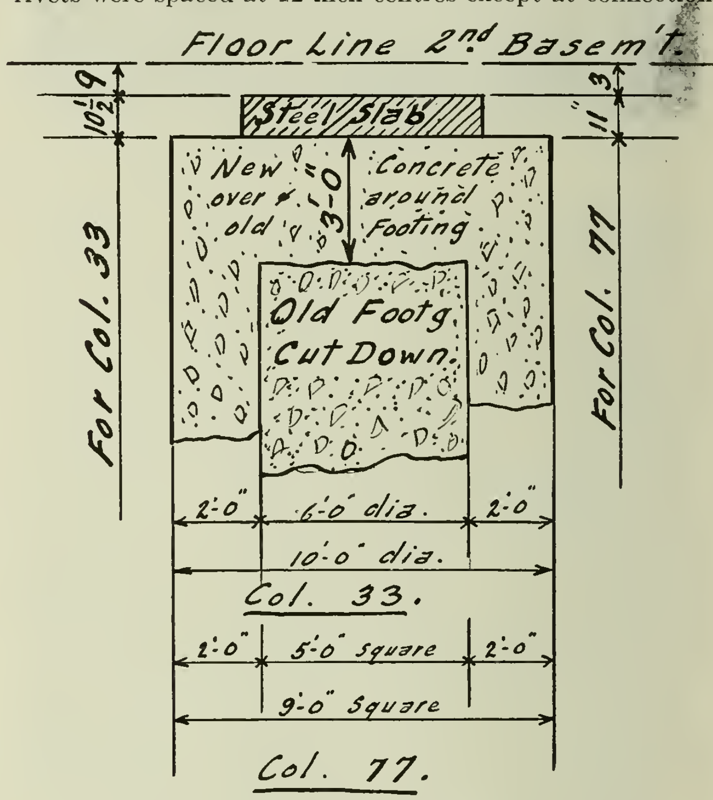

Fig. 7—Section showing addition on to Footings Nos. 33 and 77.

and splices. This method of reinforcing interfered less with the existing beam connections, especially on the columns at the old light court. Beams framing into the web were burned off to clear the projecting leg of the reinforcing angles and were carried on new bracket connections on the flanges of the columns.

At the same time that the eastern portion of the old building was constructed, the light court was shortened by taking a bay off the west end, moving the west wall of the light court one bay east and building in one panel of floors. This wall and the two intermediate columns were carried on a double girder spanning across the light court and framing into columns Nos. 33 and 35 with a span of 48 feet 9 inches. This loaded these columns nearly to the capacity for which they had been designed to provide for additional storeys. These columns were not reinforced at that time for any future additional load such as is now coming upon them, but provision was made for reinforcing for such load by adding reinforcing plates, marked 'A,' Fig. 8, to the flanges of the columns under the connections of

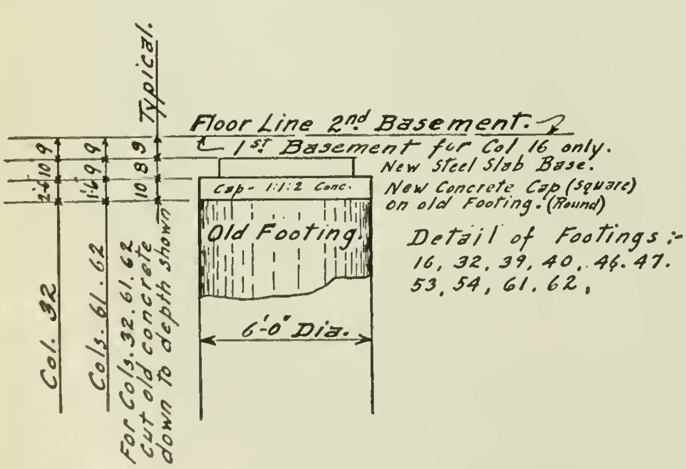

Fig. 6—Reinforcement of Footings in Original Building.

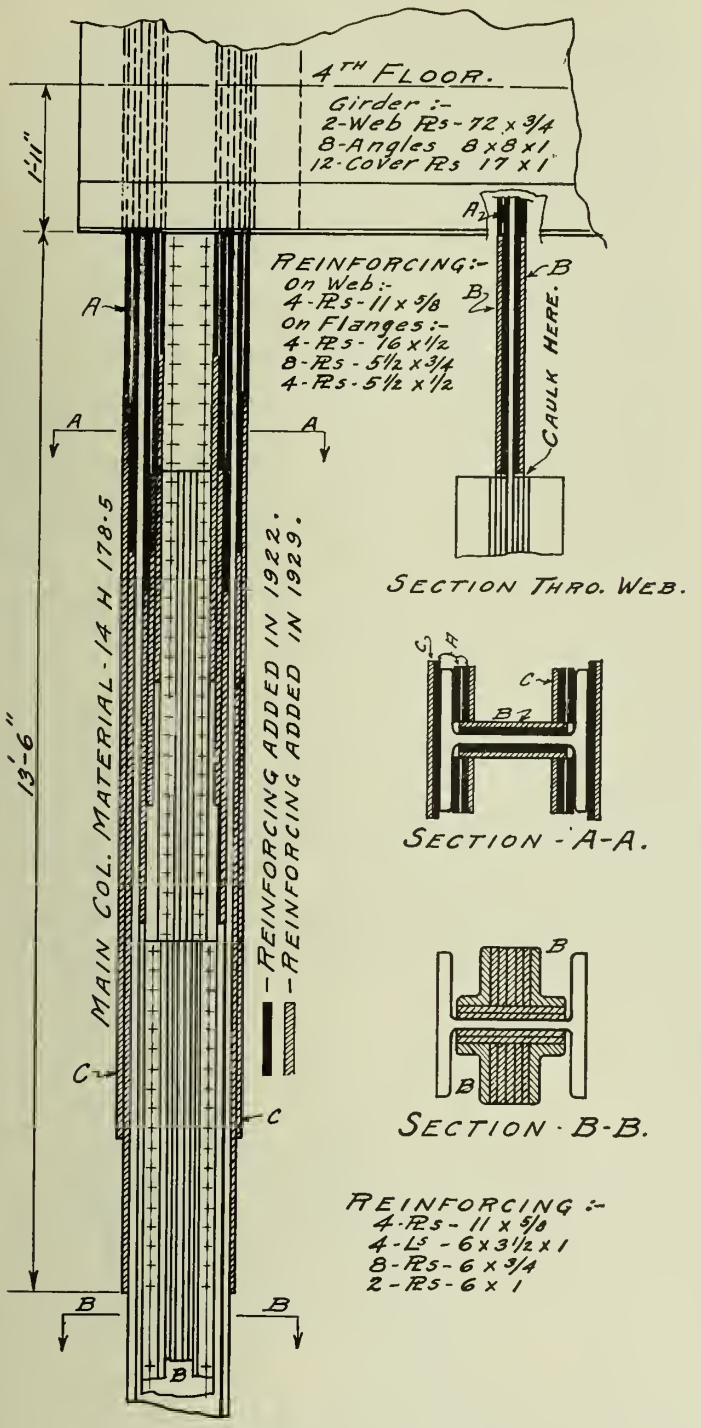

Fig. 8—Reinforcing of Column No. 33.

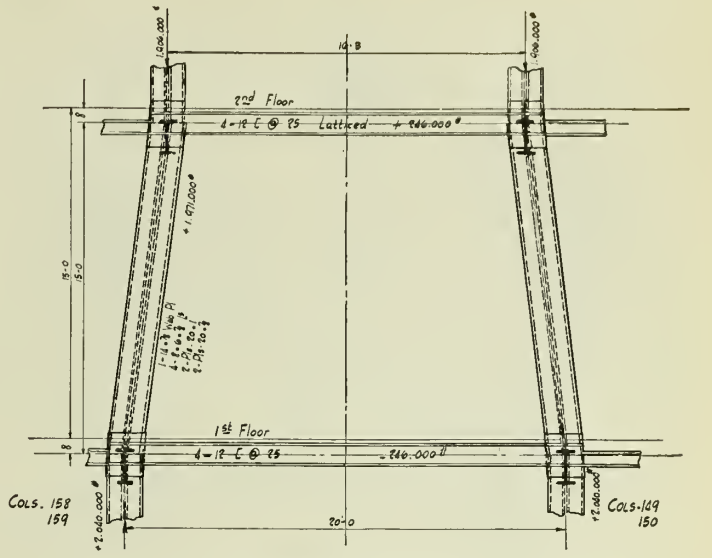

Fig. 9—Details of Sloping Columns Nos. 149 and 158, also Nos. 150 and 159.

the plate girders and to the webs. These plates were staggered in length and faced at the lower ends to bear on reinforcing plates to be added from below from the bottom of the column. The reinforcing used for column No. 33 for the additional load from the tower of the extension consisted of two plates 11 inches by 1¼ inches and four angles 6 inches by 3½ inches by 1 inch on the web with two plates 6 inches by 4 inches between the angles, marked 'B,' instead of plates on the flanges as originally intended. The plates on the webs were brought up to bear under the plates previously provided. New plates 'C' were added to the flanges below the plates 'A' and extended down to lap with the new angle and plate reinforcing a sufficient distance to allow enough rivets to transfer the load from the one reinforcing to the other. As it was impossible to measure and face the web reinforcing plates from below so that they would fit exactly under the plates already on the web, it was proposed to leave these plates about three-sixteenths of an inch short, and caulk the space between the ends of the plates with soft steel wire, then weld over the joint to hold the caulking in place. Before adopting this method a test joint was made in the shop, cut through and planed for inspection. It was found that the round wires had taken a rectangular shape, filling the space perfectly, and it was decided to use this method in the field. The plates, however, came to the field of such a length that they could just nicely be jacked into place making an exact fit so that the caulking was unnecessary.

While a column was being reinforced the stress in it was reduced to zero or near zero by shoring all load off it so that both the old column and the reinforcing would have the same final stress. Otherwise, if the area of the reinforcing were nearly equal to the area of the original column and the original column were loaded nearly to the allowed working stress, the stress in the original column would be 50 per cent. too great and in the reinforcing only 50 per cent. of the allowable stress.

The column spacing in the new building was largely determined by the spacing in the old portion, and as it was impossible to make the spacing in the tower conform to this, there were a great many column offsets. Most of these were made by carrying the upper offset columns on plate girders. There were, however, some exceptions

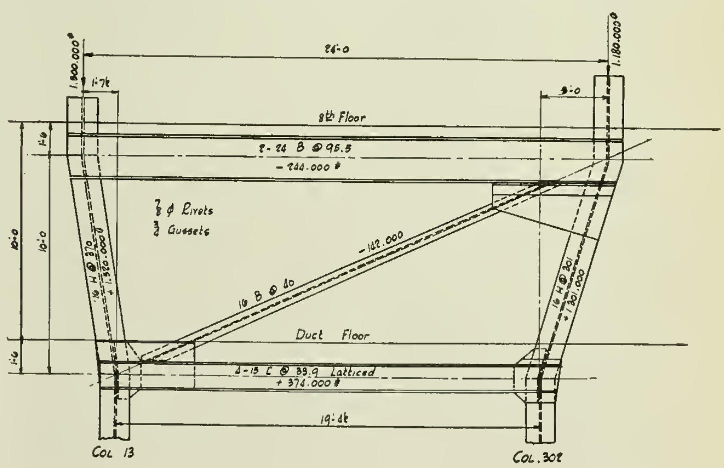

Fig. 10—Details of Sloping Columns Nos. 13 and 302.

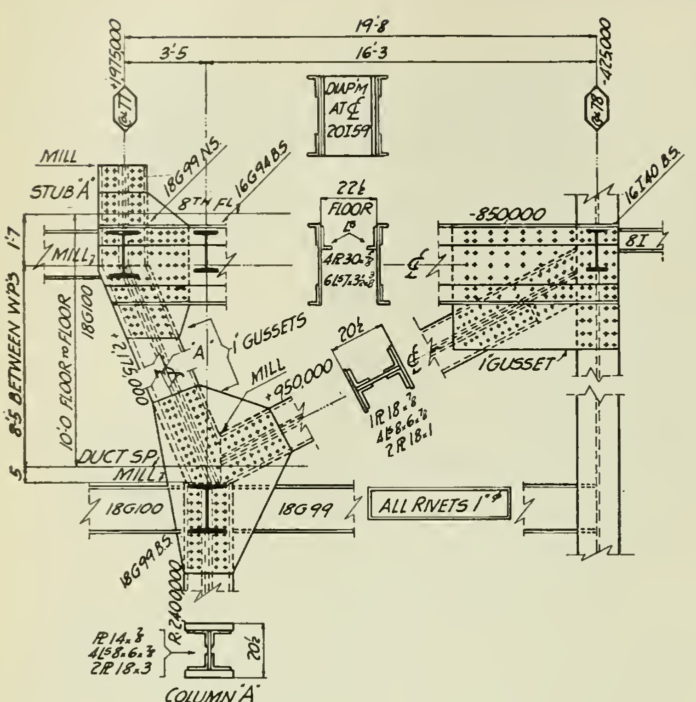

Fig. 11—Truss Between Columns 77 and 78—Duct to Eighth Floor.

to this. Columns Nos. 149 and 158 are spaced at 20 feet centres up to the first floor and 16 feet 3 inches above the second floor. As the loads were the same on the two columns and the construction symmetrical, they were sloped 1 foot 10½ inches towards each other through the first floor, the column splices being faced on the bevel. The sloping columns were tied together across the top and bottom to provide for the horizontal reactions due to the slope. (Fig. 9.) The rigidity of the construction of the building was assumed to be sufficient to provide for any horizontal reactions due to unbalanced loading of the columns. Columns Nos. 150 and 159 are similar.

In the case of columns Nos. 13 and 302 the unsymmetrical conditions, both in regard to loading and spacing, made it necessary to use a diagonal to provide for horizontal reactions. Both columns were carried through the storey height on the slope as shown in Fig. 10, the column splices being faced on the bevel.

Fig. 11 shows a truss construction for columns Nos. 77 and 78 where column No. 77 is cantilevered 3 feet 5 inches in the duct storey height of 10 feet. The direct reactions of the columns are taken by the faced ends, the gusset plates being designed to develop about 40 per cent of the stress. This truss was assembled and riveted up in the shop, the splice for column No. 77 at the eighth floor being provided for by a stub end.

In order to provide a large entrance hall from the Metcalfe street entrance, columns Nos. 144 and 152 of the typical framing were omitted from the ground and first floors. The framing for the second to seventh floors was hung from a double plate girder in the duct space under the eighth floor carried on columns Nos. 139 and 162 with a span of 48 feet 9 inches. The hangers were attached to the girders at the 16-foot 3-inch panel points by plates which form part of the webs and project below the bottom of the girder for riveted connections. These plates pass through slots burned in the cover plates on the lower flange of the girder. The hangers were made of H-column sections and were used as columns for the erection of the floor steel. They also made convenient sections to take the beam connections for the floor framing. Columns Nos. 144 and 156, extending up to the twenty-fourth floor, and each carrying a load of 1,470,000 pounds, stand on this double girder, at the panel points, making the total load at each of these points 2,200,000 pounds. Columns Nos. 139 and 162 which carry the girder stand on trusses at the second floor carried on columns Nos. 139A and 139B and columns Nos. 162A and 162B at the first floor. (Fig. 12.)

In some cases it was impossible to locate girders between existing columns to carry some of the upper columns for the tower over the old building. Four new columns, Nos. 302, 303 and 307 at the west end and No. 306 at the east end, were carried up through the old building from new footings constructed to rock. Column No. 307 stops at the eleventh floor where it takes one end of a girder carrying column No. 16 offset. Columns Nos. 302, 303 and 306 offset in the duct space under the eighth floor, column No. 302 by means of a truss as already shown in Fig. 10, column No. 303 by means of a cantilevered truss in a similar manner to No. 77 shown in Fig. 11 and column No. 306 by means of a cantilevered plate girder. Where the columns pass through floors the existing steel beams were burned off to provide clearance, and the ends carried on brackets on the columns which were erected by being dropped down from above.

The first offset in the old building occurs at the fifth floor, where the walls and wall columns for the fifth and sixth floors are set back about 5 feet from the face of the building. These walls and columns are carried on beams in the fifth floor. Owing to architectural alterations the loads on these beams were increased, making it necessary to reinforce them. Where old columns standing on top of the beams were replaced by new ones the beams were reinforced by adding cover plates to the top and bottom flanges after the old columns were removed. Where the old columns remained in place, making it impossible to

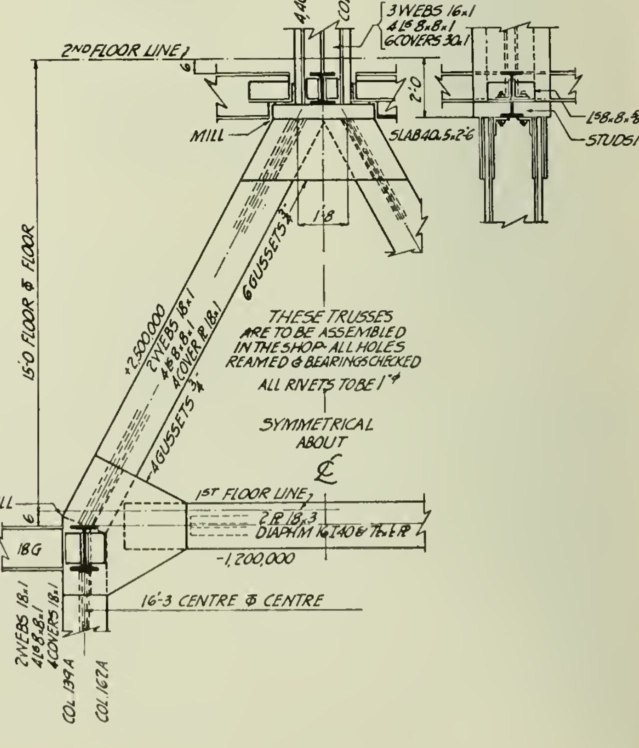

Fig. 12—Truss Carrying Columns 139 and 162.

add cover plates to the top flanges, the beams were reinforced by placing new beams underneath and jacking them into contact throughout their length so that both beams would have the same deflection and each one would get its calculated proportion of the load.

In the erection of the steel for the addition there were no new nor unusual problems. In order to cover the large area of the building, eight derricks were used to erect the steel and spaced so as to accomplish this purpose. The steel was brought to the job only as required for each derrick and immediately erected.

The alterations in the old building, which required the reinforcing of columns, the extension of certain columns downward to new footings, the replacing of old bases by new ones, the removal of steel for the old roof, seventh and part of sixth floors and the reinforcing of the beams over the fifth floor, made a great amount of field work necessary. This work all had to be done while the building was occupied by the staff of the Sun Life Company. For part of the time it was possible to get the use of all floors above the second for the two north bays. Columns which were being reinforced through rooms occupied by the staff were boxed in by sheeting covered with paper.

In order to relieve the column of load so that the stress in the column would be reduced to zero while the reinforcing was being added the floors were carried on vertical posts, one on each side of the floor beam close to the column, and short needles were put across between the posts under the beams. The load from the beams was then taken on the needles by driving wedges between the needles and the bottom of the beams. The shoring was generally carried up five or six storeys. Above this the unit stress in a column was small enough to be neglected. When the shoring was done on the north row of columns the masonry wall had been removed, so that the loads were comparatively small. This method of shoring held the columns while the reinforcing was being added and also while the new footings were being put in place.

It was necessary to replace eleven of the old cast iron bases by new steel slab bases. This operation was one of the most interesting on the building. The columns had to be lifted clear of the old footings, the old cast iron bases

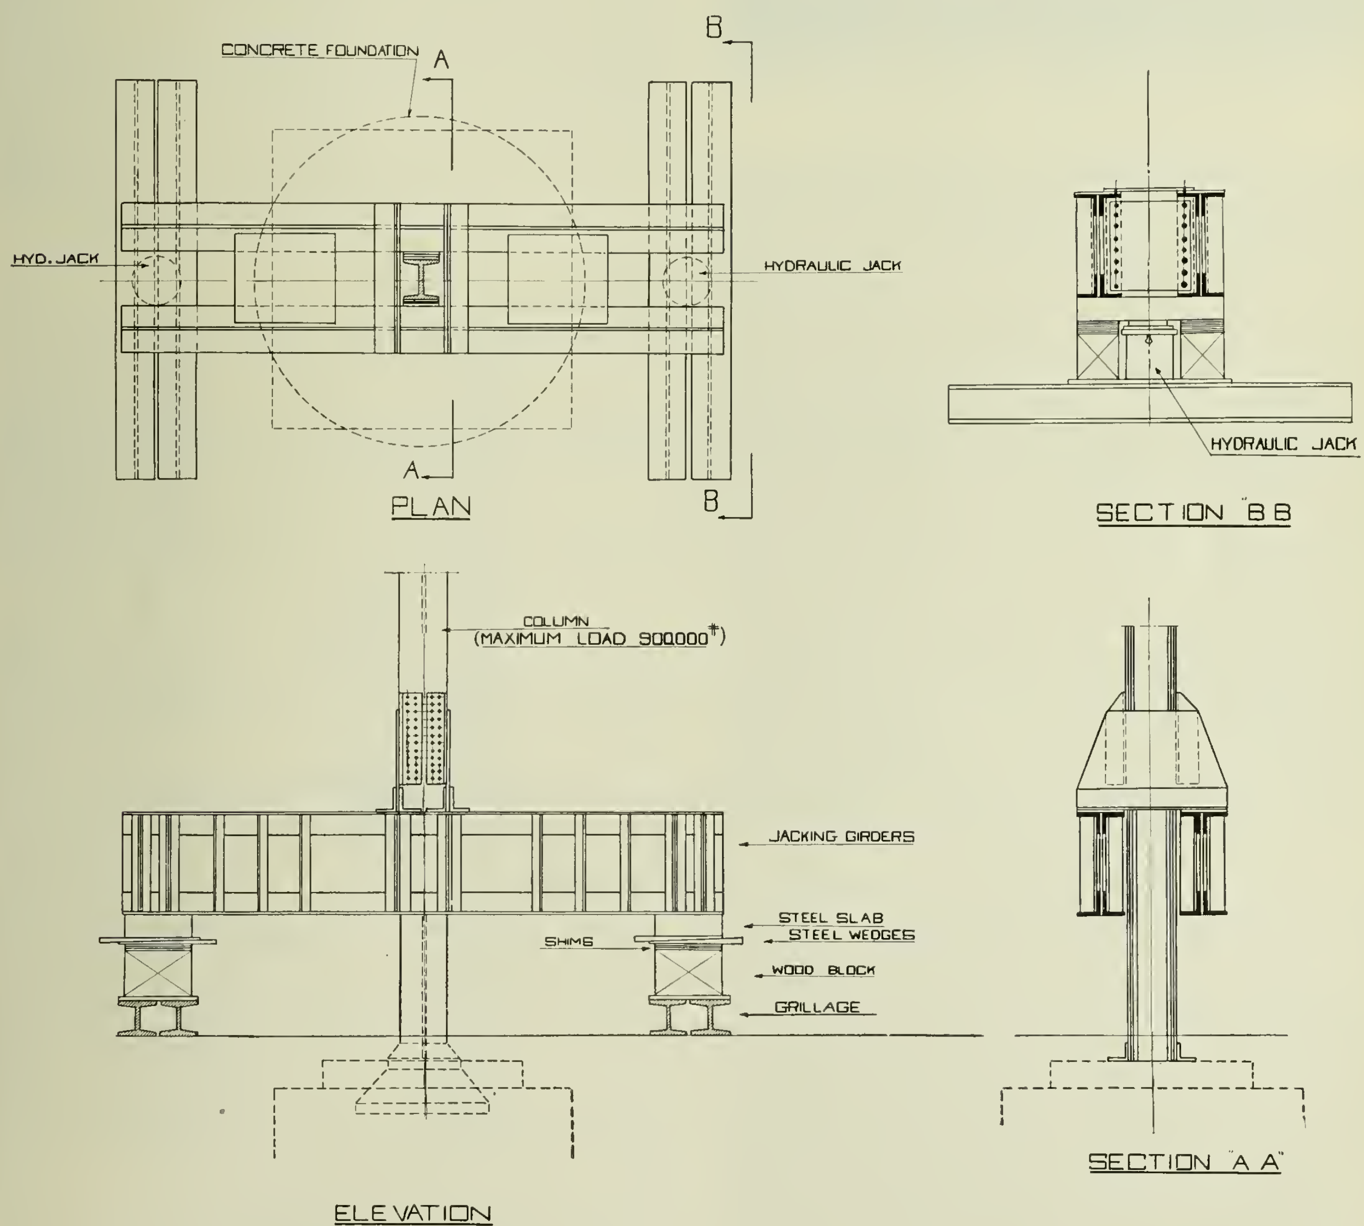

Fig. 13—Arrangement of Girders for lifting Existing Columns.

Fig. 14—Method of Anchoring Top Cornice.

removed, the new concrete footings prepared and the steel slab put in place. On the interior columns, while a portion of the load was removed during this work, such as partitions and the fireproofing on the columns, the loads remaining were still of some magnitude, the maximum being 900,000 pounds. In order to lift a column free from the base ninety-six holes were drilled through the flanges about 8 feet above the basement floor for the connection of heavy steel brackets, the holes in the brackets and the columns being drilled from the same steel templet. The brackets, Fig. 13, bolted to the flanges of the column, projected beyond the column to take the lifting girders. The brackets were made with connection angles on them, with the same spacing of holes as through the web so that they could be bolted to the column with the web plate of the bracket to the flange of the column, or at right angles to this direction with the angles to the flange of the column. This made it possible to connect the brackets to suit the most convenient direction in which to place the girders. The girders were 36 inches deep and 18 feet long, made of silicon steel and designed for a stress of 30,000 pounds per square inch. They were placed one on each side of the column under the brackets, and were carried at each end on a steel slab 24 inches wide, 4 feet 4 inches long and 8½ inches thick planed top and bottom. Each steel slab was carried on two heavy wooden blocks reinforced with heavy angles bolted to each corner. The blocks were spaced far enough apart to allow room for 285-ton hydraulic jacks between them. Steel shims and steel wedges were used on top of the wooden blocks and these were driven tight as the jacks took up their load. The blocks and jack were carried on a base of two 12-inch column sections about 12 feet long laid directly on the concrete basement floor. With the heaviest lift the load on the soil was about 8 tons per square foot. When the column was lifted by the jacks to free the old base, the girders were shimmed up by driving in the steel wedges on the wooden blocks, after which the base could be removed. The old cast iron base was then taken out, the new concrete top to the pier poured, and after setting, the new steel slab was put in place under the column. It was shimmed up tight to the bottom of the steel column and grouted in place, the grout being worked back under the base by drawing a chain back and forth from side to side until the grout showed up in a hole drilled through the base near the centre. After the grout had set, the column was let down on the new base. Most of this work was done in and about the boiler room, a good part of which space was filled with pumping and ventilating equipment, steam mains, water mains and electric conduits, all of which had to be kept in full operation during the progress of the work.

The main stone cornice of the building at the fifth floor level projects about 5 feet beyond the face of the wall. The top course of the cornice is 2 feet thick. The overhanging portion weighs approximately 2,000 pounds per lineal foot and required very secure anchorage. The method of providing this is shown in Fig. 14. The cornice is tied back by 1-inch diameter rounds, and the back is prevented from tipping up by plates bolted to the top flange of the 15-inch channel.

Messrs. Cook and Leitch, who were the general contractors on the building, and the Dominion Bridge Company, who had the contract for the fabrication and erection of the steel, were responsible for the carrying out of this work, and some of the problems presented to them in connection with the shoring of the columns seemed to defy solution. That in connection with the shoring of columns Nos. 33 and 35 was particularly difficult. The space about column No. 35 in the basement was completely filled with pipes, some of which had to be moved before the shores could be put in place. Most of the load came

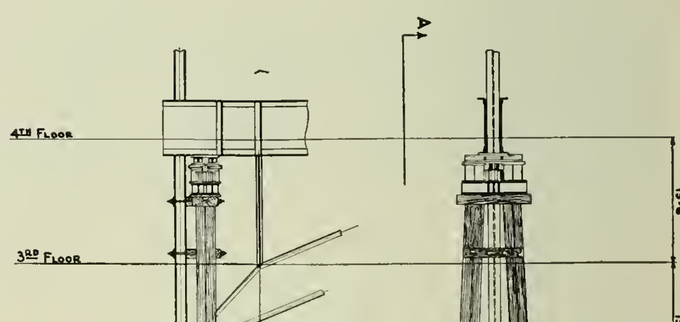

Fig. 15—Method of removing Load from Column 33 during Reinforcing Operations.

on these columns from the large girders on the fourth floor at the west end of the light court. This load was picked up by shoring from the basement floor with a bent under each end of the girder, a distance of approximately 75 feet to the bottom of the girder. Each bent of shoring consisted of two legs, one on each side of the column, each leg built up of four 12-inch by 12-inch timbers bolted together. The legs were tied together by cross braces and the bent anchored to the column as shown in Fig. 15. The end of the girder was then lifted by means of a hydraulic jack on top of the bent, after which the reinforcing was put on the column as previously described.

It is interesting to note the development in the mill, shop and erection practice, as exemplified in this building, between the time when the first portion was designed about 1912 and the present. In 1912 the maximum size of beam obtainable was a 24-inch I-beam at 100 pounds per foot with a section modulus of 198.4. When the design of the final extension was started the maximum size obtainable was a 30-inch girder section at 200 pounds per foot with a section modulus of 617.8. Before the design was completed 36-inch girder sections at 300 pounds per foot with a section modulus of 1103.6 were being rolled. Many of the heaviest weights of beams and girders have been used in this building to carry offset columns which otherwise would have required plate girders. There has been a change in the size and weight of rolled column sections obtainable from a 14-inch H at 287.5 pounds to a 16-inch H at 427 pounds. The change in the design of the cross-section of beams and columns and the addition of new and intermediate weights has resulted in great economy in the design and fabrication of steel. In the first part of the old building cast iron bases were used for the columns, in the second part steel beam grillages and in the new extension rolled steel slabs, the use of each type being the general practice at the time it was used. The use of heavy sections has made it necessary for the shops to resort to drilling to a greatly increased extent and the facilities for this work have been very much improved, so that now there is but small difference between the cost of drilling and punching. The use of electric welding is becoming fairly general both in shop and field and the time may be anticipated when all field work will be welded to avoid the noise nuisance.

In regard to erection much greater attention is being paid to the organization of the work. The fabricated material is carefully assorted in the piling yard so that each tier for each derrick can be shipped in one lot and reach the site just in time to be put in place as arranged according to the erection schedule. The use of stiff leg derricks for the erection of the first portion of the building has given way to the use of guy derricks for the subsequent work.

Mechanical Equipment in the Head Office Building of the Sun Life Assurance Company of Canada, Montreal

E. A. Ryan, M.E.I.C.,
Consulting Engineer, Montreal, Que.

Paper presented before the Annual General and General Professional Meeting of The Engineering Institute of Canada, at Montreal, February 4th, 5th and 6th, 1931.

SUMMARY.—The heating, ventilation and refrigeration equipment of the Head Office building of the Sun Life Assurance Company, Montreal, has been laid out with reference to the services needed in this large 27-storey building used for institutional and office purposes. Forced circulation hot water is employed for heating, with three distinct circulating systems, one for each of the three zones of the building. The building is mechanically ventilated throughout with washed and conditioned air, and in many parts an interesting system of "punkah" inlets has been used, with means for obtaining automatically a periodical variation in the intensity of the air-movement in the office spaces. In this way, through relatively small nozzles, capable of directional control by the room occupants, secondary currents are induced in the air of the room, resulting in thorough mixture. In order to diminish the operating expense for a ventilating system of this magnitude, re-circulation of treated air, and heat interchange between the outgoing warm air and incoming cool air are employed.

There is an extensive ammonia refrigerating plant, principally for the service of the kitchens and cafeterias, the ammonia lines being kept within the confines of the plant proper and the brine circulation being under thermostatic control. Provision is made for complete control and supervision of the mechanical and electrical plants from a central office, with the aid of distant-indicating thermometers, electrical alarms, and remote control switches.

The architectural characteristics, structural features, sanitation and electrical details of this notable structure are being dealt with in other papers at this meeting. The following notes will treat of the mechanical equipment connected with its heating, ventilation, and refrigeration. The building occupies a lot 435 by 220 feet and contains 3 storeys under ground and 24 storeys above ground, together with three full storey duct spaces. Mechanically it may be considered as divided horizontally by the duct spaces into three zones, referred to hereinafter as the low level, intermediate level and high level zones. All of the services in the building have been based on a population of ten thousand persons. As regards the heating and ventilation, the arrangements are unique in many respects, for the building is heated throughout by means of hot water, it is mechanically ventilated throughout, and the systems of air distribution are along lines dictated by the most recent research in this field both in Europe and America. By means of a system of heat recovery the outgoing vitiated air exchanges a portion of its heat with incoming fresh air, and the requirements of a climate peculiar to the locality are provided for in cleansed humidified air by the installation of a special type of air-washer-humidifier. The economical supervised operation of the various systems is assured by the measuring, indicating and control instruments installed for the numerous services which are included in the building.

Finally, the principles underlying the design of the necessary equipment and the restrictions governing the choice of apparatus as to its origin and manufacture are worthy of mention. A sound policy of balancing first cost with operating costs has been followed throughout, and the stamp of "made in Canada" or "within the Empire" marks the structure in many details.

Heating

In the light of the development today of zone and directional control of heat in large buildings, as also vapour heating at sub-atmospheric pressures to meet outdoor conditions of wind direction, temperature changes, the effects of the sun, etc., it is at once evident that the decision of the company to adopt hot water heating under forced circulation in its original structure was a far sighted one. A very thorough investigation into the matter from the several angles of first cost, operating costs, control, results obtained with other systems, and the particular requirements in a building of this kind for the purpose intended resulted in the conclusion to follow the same principle for the greatly enlarged edifice.

The heating is accomplished by three distinct systems—one in each of the zones. Each system is divided into two

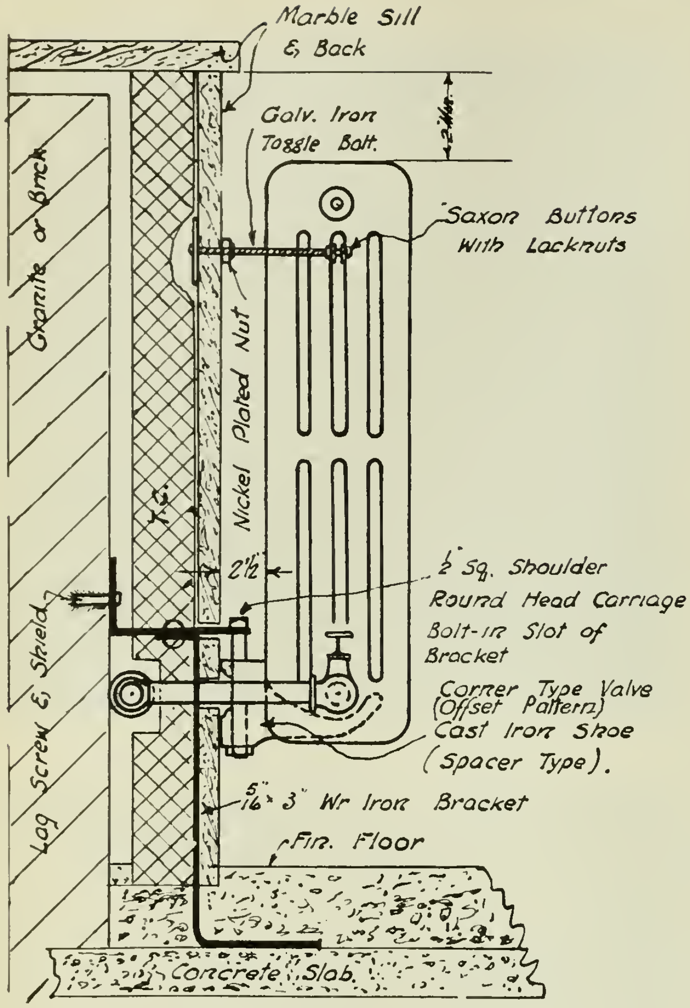

Fig. 1—Typical Detail of Radiator Supports, etc. Lower Zone.

circuits with its own complement of steam heated convertor, pump, control, supply and return main. The distribution is on the overhead main, downfeed principle with supply and return risers. The circuits are so arranged that different water temperatures may be maintained on the wind and lee sides as necessary to meet prevailing outdoor conditions. Hand and remote control of steam to the convertors has been provided. Automatic control of room temperatures is also afforded through a thermostatic system of heat regulation.

In the design of the heating system for the building, because of its proportions, consideration necessarily had to be given to "chimney effect." To this end the floors are cut off one from the other by means of doors at each communicating point, such as stairways, elevator shafts, etc. In determining the heat losses a graduated scale of temperature difference was applied for different levels, and the assumptions for air infiltration through doors and windows were varied according to their elevation. The heating of the entrances on the ground floor gave rise to extensive study because of the many factors involved. Special consideration had to be given to excessive air infiltration at this low elevation as also to the large entry of outside air in certain very short periods of time corresponding to the entry and exit of the large staff. At the same time the architectural treatment imposed restrictions on the arrangements possible of adoption.

In general, the radiation is of the cast iron column type, exposed, except in specially treated rooms where it is concealed. To meet the pressures of water obtaining at certain elevations, the radiators are of extra heavy construction and were subjected to test pressures correspondingly higher than is customary on standard radiation. Thought was given to the use of concealed radiation throughout the building—a practice that has been followed in the case of certain recent prominent buildings, but this was deemed unnecessary because of the low temperatures generally maintained in a hot water system, and the well-known objection to concealment in so far as cleanliness and cost is concerned. In the lower zone the radiators are of the legless pattern, and supported on brackets bolted into the masonry, of special design. (See Fig. 1.) In the upper zones this arrangement was not followed, and the radiators are of the floor standard type with legs of special height to afford easy cleaning. In all cases, how-

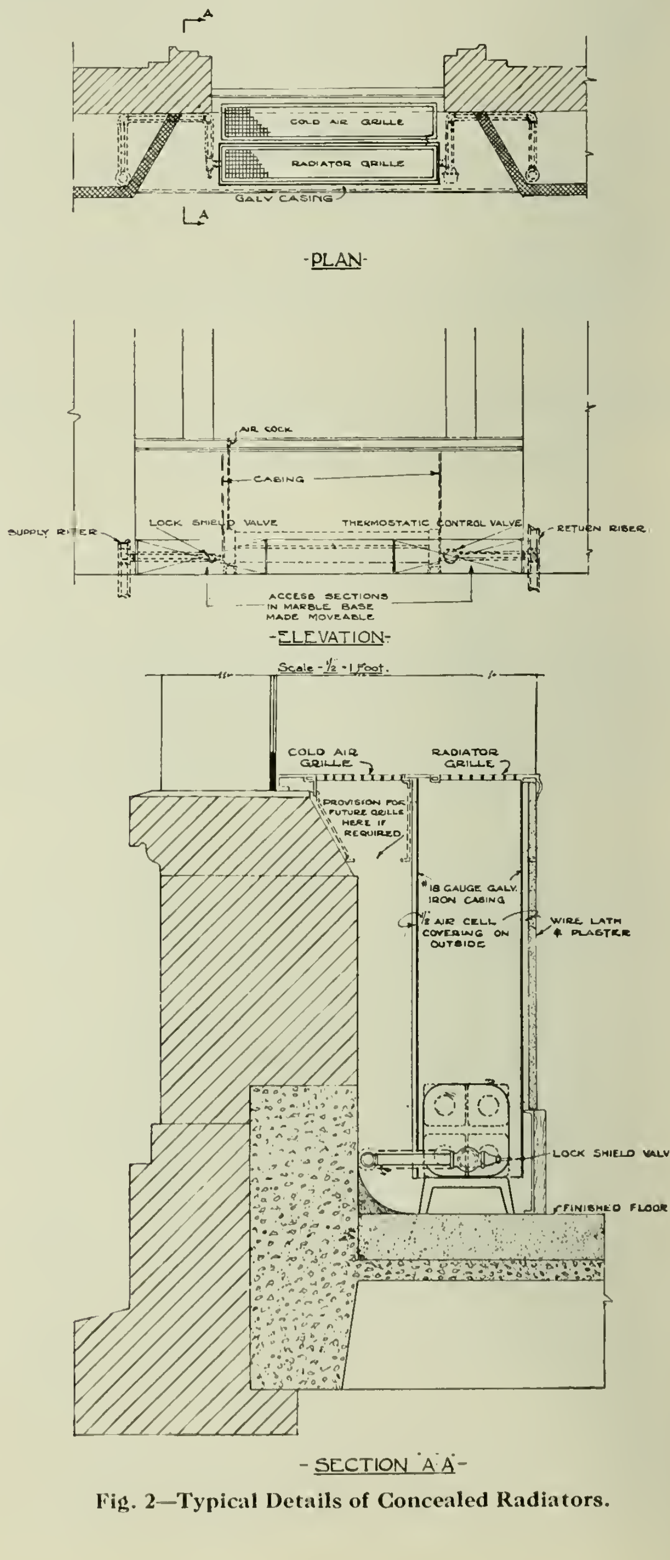

Fig. 2—Typical Details of Concealed Radiators.

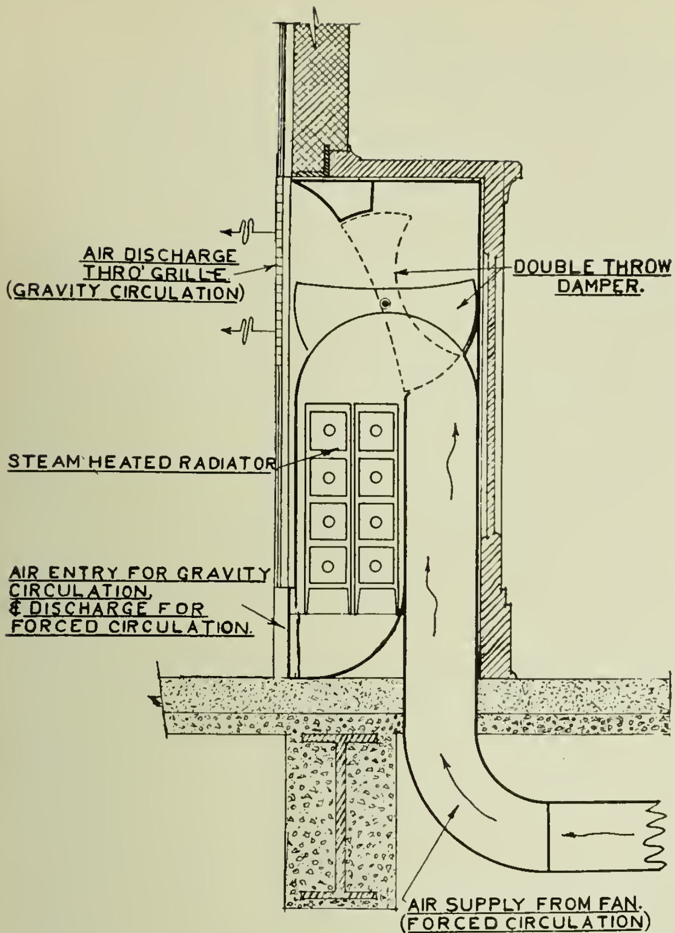

Fig. 3—Typical Detail of Heating Units. Main Entrance Halls.

ever, the radiator connections are brought through from the wall, and not through the floor—as is commonly done.

To meet the conditions arising out of large high windows at certain points, a special design of radiator compartment and baffling was evolved. This employed the combination of cold and hot air compartments with provision to avoid the deflection of cold air currents off the large glass surfaces towards employees occupying positions nearby, as shown in Fig. 2.

The main entrances are provided with individual systems of hot air heating, utilizing re-circulation principles as far as possible. The air is mechanically propelled over concealed steam radiators in enclosures of special design, as shown in Fig. 3. When desired, these radiators may be operated on gravity air circulation.

In order to ensure against sedimentation in the piping systems, which are for the greater part concealed, advantage was taken of the presence of a soft water system in the steam plant. The "make-up" to the heating systems is derived from this source.

Another provision which was made to facilitate rapid emptying of the piping systems is the arrangement of circulating pumps so that they may be used for "pump-out" purposes.

Ventilation

The necessity of comfortable healthy air conditions was appreciated from the beginning by the executives of the company. As a result of years of experience with large staffs they considered it imperative to reduce to a minimum the occasions of "absenteeism" due to necessarily sedentary work indoors. It is believed that this company has given as much, if not more, consideration to this factor than any other institution in the world. The services of its medical officers, engineers and operating staff have been combined in efforts to investigate, determine and maintain the very best working conditions possible. Much experimental work as regards ventilation has been carried out in the original building, careful records have been kept and as a result rules have been laid down for those responsible for the ventilation systems.

Because of the high degree of occupancy, the large interior working spaces distant from outside communication, etc., there was but one available means of fulfilling the requirements,—i.e., mechanical ventilation. The local and very varied climatic conditions make proper humidity control essential, and hence the air circulated throughout is washed and humidified. Owing to the nature of the work performed by the employees, the fixed seating arrangements, etc., the air distribution and circulation had to be arranged in a manner that would avoid noise or draughts. Because of the relation to adjacent buildings or those likely to be erected in the future, great care had to be exercised in the location of intakes and discharges to avoid introducing air already contaminated by smoke or odours and to prevent possible differences with neighbours owing to the emission of vitiated air from certain departments, such as machinery rooms, kitchens, cafeterias, etc. All of these factors had their influence on the architectural and structural features, and necessitated intensive study and scheming.

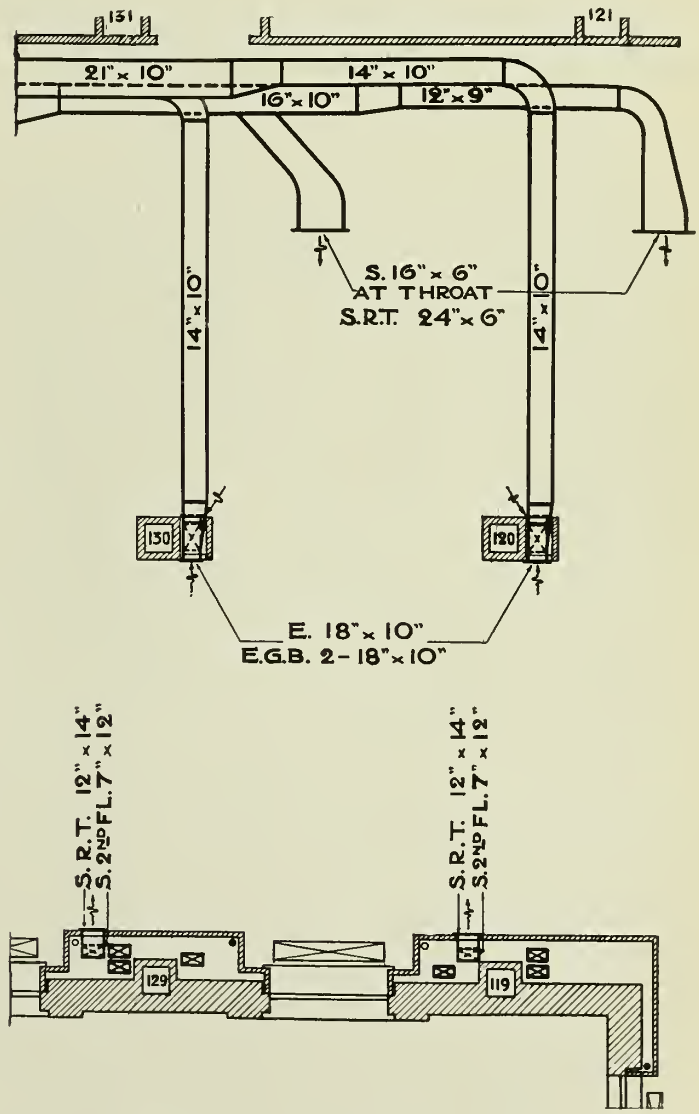

Fig. 4—Part Plan of Typical Floor. Lower Zone.

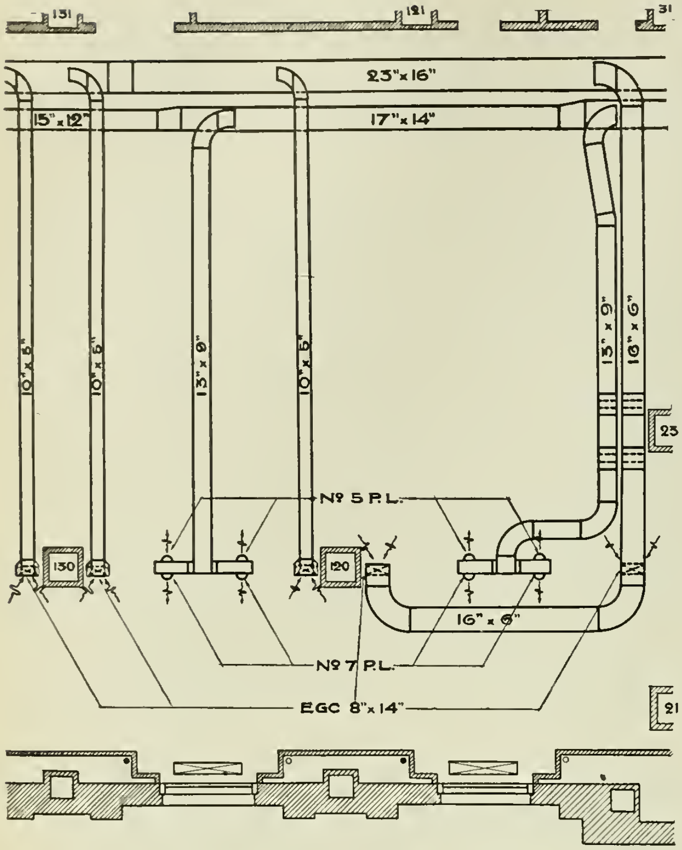

Fig. 5—Part Plan of Typical Floor. Upper Zones.

For years past the need has been recognized of securing better air distribution in ventilated areas. Numerous criticisms have been launched against the systems commonly in vogue, in many instances not without a certain measure of reason. On account of the increasing densities of population in given areas in buildings, engineers have been obliged to increase the hitherto recognized volumes of supply—and this without annoyance from draughts. This requirement resulted in the supply of large volumes at low entrance velocities, and because of restrictions usually imposed by room treatments and design, dissatisfaction or mediocre results ensued, owing to the occurrence of stagnant areas or stratification. Recent research has demonstrated that air motion and turbulence are of greater, or at least of as great, importance as actual change of air.

If asked what constitutes an agreeable condition out of doors in temperate weather the reply of most people will be—a temperature of about 70 degrees with a breeze—not constant, but of *varying* intensity. The breeze may reach a moderate degree of strength, but provided it rises and falls in intensity, it is pleasant. This thought suggested the desirability of varying the static air condition in the occupied areas of the new building, and after various possible methods of obtaining this result were studied, it was concluded that periodic variation of the speeds of the ventilating system fans was the logical solution. This has been accomplished by means of what is termed an "undulating mechanism"—specially developed for the purpose, and, it is believed, used here for the first time. In this mechanism the rheostats of the various fan motors are mounted on a common spindle rotated at slow speed by a small motor, thus varying the fan speeds as the respective brushes make contact with the resistor steps.

In the lower zone of the building the supply and exhaust openings for ventilation have been installed in the well-known way, following standard practice, to meet as far as possible pre-determined departmental and general layouts.

A part plan of a few bays on one of the typical floors of the lower zone is given in Fig. 4. Owing to the depth of the bays at this elevation it is considered necessary to supply air at two points in each bay. Supply and exhaust trunks are carried in a furred down portion of the ceiling kept within the limits of an assumed corridor line. On the office side of this line supply inlets are installed. The exhaust branches are carried over to an intermediate line of columns, with drops extending down to grilles located about 18 inches above the floor, one on either face of the column. Supply inlets also occur along the inner face of the outside walls, at an elevation of about 7 to 8 feet above the floor. This layout affords a very flexible arrangement for extension in the event of subdivisions being made to accommodate departmental heads. Probably there will be very little subdividing of these areas by permanent partitions, as they will be occupied as large departments, and hence the general distribution and circulation of air will be good. It would tend, however, to stratification along defined lines, were static conditions maintained constant. By varying the volumes admitted and the intensity, as is done by the successive rise and fall of fan speeds, and taking advantage of the well-known gravity effects of air motion it is anticipated that stratification will not take place and that the complete areas will be adequately swept. The objections usually raised against annoying air currents of constant intensity along fixed lines are also removed in this way. It must further be remembered that in large departments such as these the locations of desks are fixed, and draughts that will impinge upon individuals along a certain line occasion great trouble. Special care in this respect is required because of the grouping of male and female employees: modern fashions in clothing of the two sexes do not by any means simplify the problem.

When the company decided to proceed with and complete the intermediate and high level zones of the building, further thought and study was given to the subject of air distribution. Several schemes were investigated, following which a decision was reached to adopt a method which has been practised for several years past, with excellent results, in the ventilation of steamships. It is fundamentally the opposite of what has been the conventional practice of delivering large quantities of air into a room at low velocities. Through nozzles of relatively small aperture, capable of directional control at the will of room occupants, air is delivered at high velocities. Secondary currents are thus induced in the air of the room

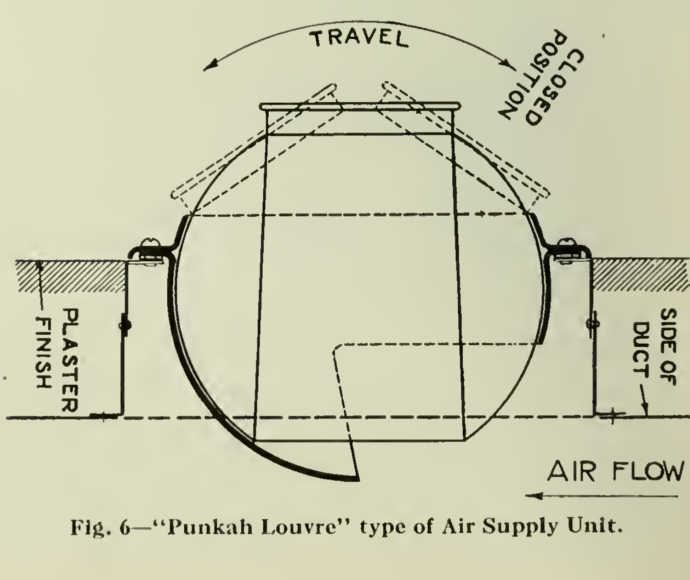

Fig. 6—"Punkah Louvre" type of Air Supply Unit.

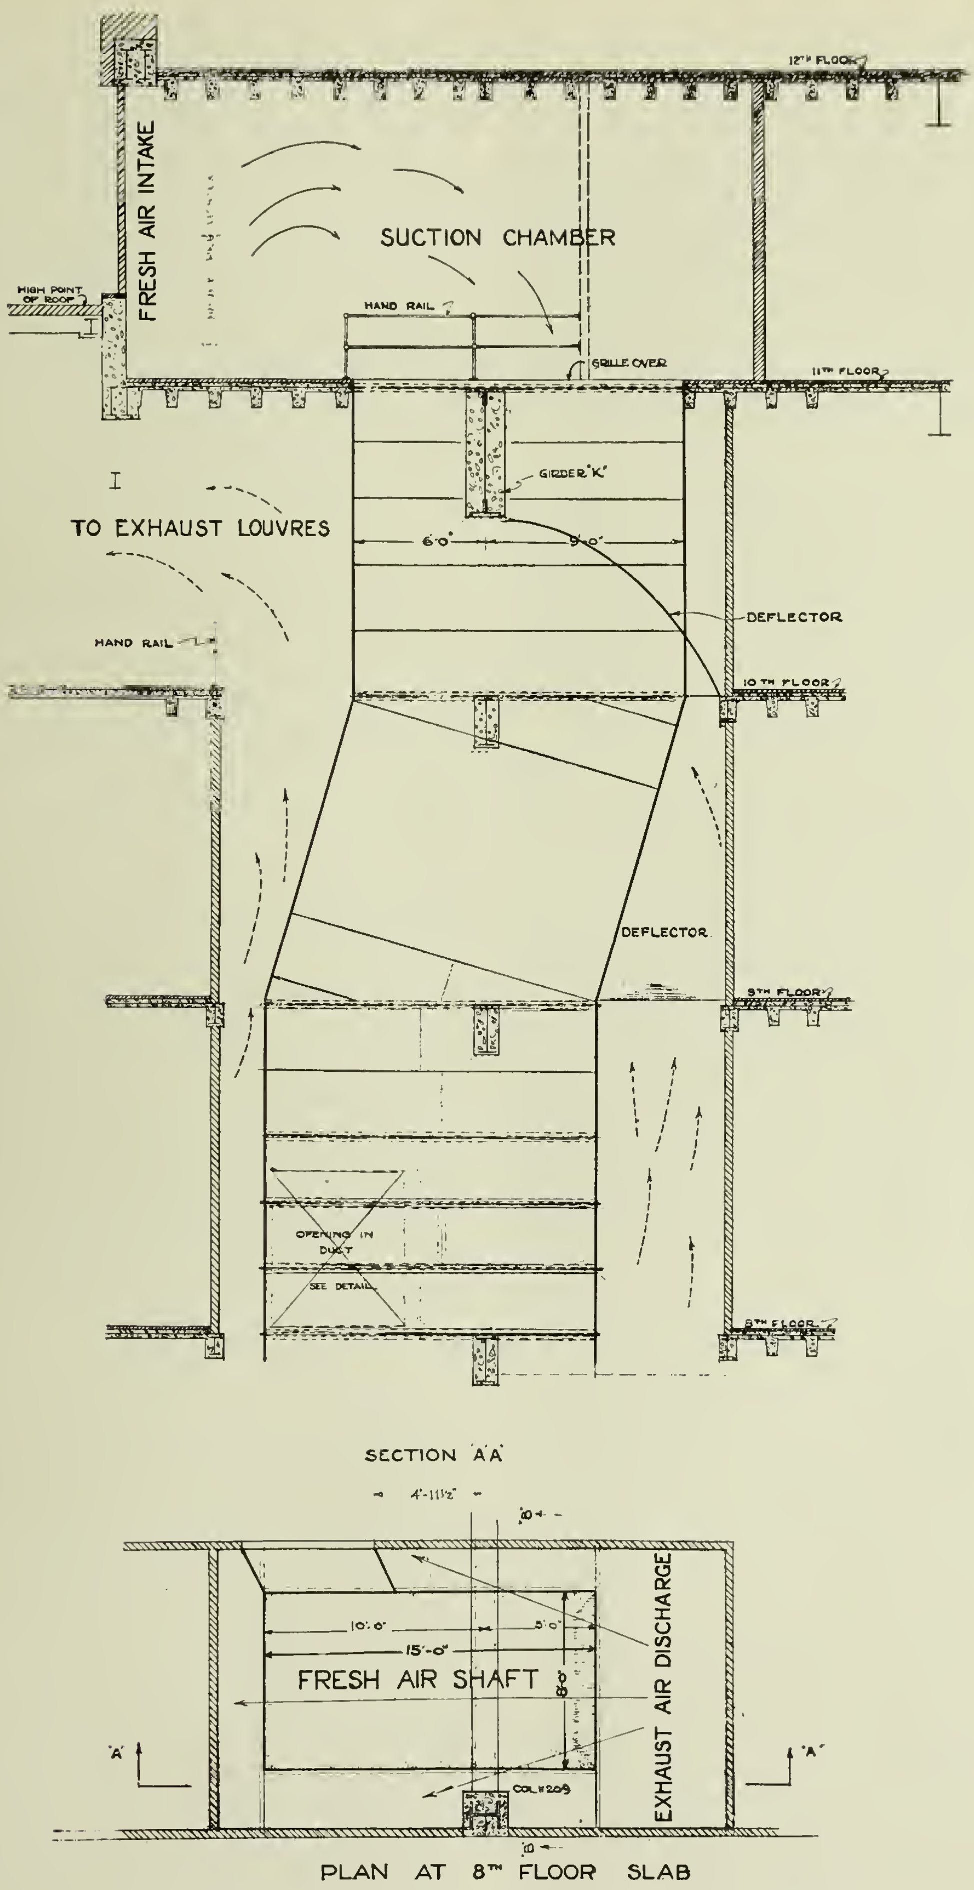

Fig. 7—Section and Plan of Heat Interchanger. Top of Airshaft.

and turbulence ensues, causing a thorough mixture—and without draughts.

A part plan of the layout of a few bays on one fo the typical floors of the upper zones given in Fig. 5 illustrates the arrangement adopted. The exhaust outlets, it will be noted, are along the same line as the supply inlets. A beam is formed in plaster, extending from column to column, which encloses the branch ducts and small plenum chambers. The exhaust grilles are in the soffits of these beams, and the supply outlets on the sides. The distribution will therefore be of the return type, the air sweeping across the ceiling or down at any angle or in any direction desired. Counter currents will also be set up by the convectional effects of the radiators on the outside wall side, and by the inevitable infiltration through windows, and it is anticipated that a thorough admixture will be the result.

A very flexible layout is also afforded permitting of extension or re-arrangement at small cost to permit of sub-dividing should it be necessary. This is very important in the present instance, as the upper part of this building will not be occupied, until required, by the company. For the time being it will be rented and the intention is to furnish space which is either ventilated or not as desired by tenants. Provision is made in the installation of dampers so that sections or units of trunk mains may be served with air as the requirements warrant.

A louvre of the punkah type as used on the supply systems is illustrated in Fig. 6. The outlet consists of a hollow ball capable of rotation in the enclosing socket so that air through the nozzle may be delivered in any direction within a relatively large range. The socket is so constructed that entire cut-off occurs in one position, and partial cut-off at points approaching this.

It is believed that the foregoing method of distribution, together with the undulating control constitute a distinct advance in mechanical ventilation.

Air supply fan rooms are located in the 3rd basement, and on the 9th, 10th and 25th floors to serve the respective zones. In each of these rooms the necessary tempering and heating coils and humidifiers are provided. The last mentioned are of a special design, combining air purification and humidifying characteristics. Atmospheric air first passes through a set of scrubber plates, after which it goes into the spray chamber and then through the eliminator plates to the fan room proper. In each of the fan rooms are the several fan units serving the respective systems. The air throughout these processes is maintained under close control automatically as to temperature and humidity, so that the air condition in the building is kept at all times within fixed limits.

The ventilating systems have been sub-divided into a number of units to provide for the operation of sections of the building independently and for departments such as kitchens, cafeterias, lounge rooms, assembly hall, etc., during short periods, and building service departments throughout the full twenty-four hours. In the interests of economy in space and initial cost, while at the same time serving the requirements fully, a combination system employing but one set of fans, air washer, etc., has been installed for the cafeterias, lounge and assembly rooms. By a series of control levers the fans may be thrown into operation on these rooms separately or together.

Distinct from the basic principles of design of the systems in the occupied portions of the building are those applying in the cooling processes for the removal of heat and vapour from elevator machinery and pump rooms, transformer rooms, etc. In cases such as these the air is cleansed in suitable filters, but not humidified.

A conception of the proportions of the installation will be obtained from the knowledge that the combined capacity of supply and exhaust fans is 1,800,000 cubic feet per minute, in 80 units.

Because of the low average temperature and the extremes that frequently occur in Montreal, with the consequent high cost of heating air for ventilating purposes, economics were given careful study. In addition to the practice of recirculation, whereby a portion of the air in the building is returned to the supply chambers, treated and re-distributed, a principle of heat interchange is followed in one of the large systems. The fresh air for the lower zone is taken in at the 11th floor level, and the vitiated air is discharged at the 10th floor level, in concentric shafts extending from these points to the respective fan rooms in the basement. The thin metal of the duct separates the two and thus heat is transferred from the out going air to the incoming air, thereby effecting a recovery of considerable amount.

A portion of this heat interchanger is shown in Fig. 7 to illustrate its general arrangement and principle.

Steam Services

Steam for the various requirements is generated in a power house separate from the main building and brought in through a tunnel on the Mansfield street side.

At the point of entry is a ring header from which the various distributing lines branch.

In general, high pressure steam at about 100 pounds per square inch is delivered to within close range of the points of usage, where reducing valves are installed to bring the pressure down to that required for the particular purpose.

A main pipe shaft extends through the building from bottom to top which contains main rising steam, hot water heating and domestic lines, cold water services and miscellaneous return lines, vents, etc.

The various steam services have been kept separate for metering purposes so that along main lines the consumption of the chief uses may be definitely determined.

The piping throughout the building both for steam and water has been welded, excepting in the smaller sizes. This has many advantages, the chief of which is the absence of trouble from leaky flanges, threads, fittings, etc. The importance of this is best appreciated when consideration is given to the vast amount of work that is concealed or in places difficult of access. Careful attention was paid to provision for expansion and contraction in the installation of expansion joints and bends. This is particularly necessary in welded construction as there are not the customary threaded connections which otherwise help in caring for this factor.

Refrigeration

A refrigeration plant, located in the third basement, employing ammonia as a refrigerant and brine distribution serves the various storage and refrigerator boxes and cooled drinking water systems. Ice is also manufactured on a small scale for kitchen, laboratory and hospital purposes.

The brine distribution is divided into high and low level systems and sub-divided again into high and low temperature ones, with corresponding coolers and pumps.

Ammonia lines do not extend beyond the confines of the plant proper.

The main compressors are electrically driven by synchronous motors, and the auxiliary compressor by a direct current motor, as is also one of each pair of brine pumps, so that in the event of failure of outside power, advantage may be taken of stand-by power from a storage battery and turbo-generator auxiliary service.

Drinking water for the lower zone is cooled in a cooling tank in the seventh floor duct space and distributed through a ring main with drops to the various units on the different floors.

Brine circulation in the refrigerator boxes is under thermostatic control, so that temperatures may be maintained to suit the nature and requirements of the materials stored. This is considered of great value, not only because of economy in operation of the plant, but also in avoiding waste or deterioration of foodstuffs.

Control Room

The control and supervision of the operation of the mechanical and electrical plants are centred in a control room off the engineer's office in the 2nd basement.

The indicating, measuring and recording instruments are mounted on panels encircling the room and the shift engineer's desk is directly in front. Surmounting these panels are the alarm and "in service" indicators.

The wet- and dry-bulb temperatures of air at different points in the building and the temperature of air, water, brine, etc., delivered to the various systems will be taken at periodic intervals through distance indicating instruments of the pyrometer type by the man on duty. Water temperatures in the hot water heating systems may be varied to meet changed conditions outdoors by means of air switches on the instrument board controlling the steam supply to the various convertors.

Attention is directed to high or low water, excess temperatures or pressures, electrical loads, etc., in connection with sumps, storage and expansion tanks, domestic services, air and refrigeration plants, electric generating and distributing plants by means of an alarm system combined with a series of lamp indicators, whereby the trouble in the affected service and its location is readily detected.

The operation of fans and motor driven pumps is under master control for starting and stopping through remote-control switches having lamp indicators and mounted on one of the panels in this room. Owing to the large number of such units widely distributed over the building, the significance of this feature will be appreciated in saving time when services are interrupted, and also in operating the plant so as to limit the maximum power demand. By studying conditions and staggering certain pumping operations, etc., it will be possible to keep expenditures for power within the most economical limits.

"In service" indicators in the form of lamps back of frosted glass panels bearing the name of the apparatus served show which unit of the more important groups such as boilers, pumps, compressors, etc., is in use.

A feature of the indicator lamp system is the provision made for detecting burnt out lamps and troubles in the control system which would otherwise create false impressions. It consists of a master control switch and wiring whereby all of the indicator lamps may be energized at one time and inspected.

Another item of interest in this room is the "view box" type drawings-cabinet in which are kept transparent records of piping and valve diagrams of the various systems. These diagrams are of standard size and contain complete information as to locations and numbers corresponding with the installation referred to; they may be quickly mounted in a frame holding an illuminated frosted glass panel, through which they are viewed and studied.

Engineering Staff Office

The chief engineer's office and executive department occupy a strategic position in the 2nd basement, adjacent to the control room. From this vantage point, within easy reach of a through service elevator, the many contingencies that arise in operating the building may be expeditiously met. A complete system of house and outside telephones communicates with the various elevator machine rooms, boiler plant, refrigerator plant, pump and heater rooms, etc., and a competent staff will be maintained at this point to carry out emergency repairs or adjustments.

This department also constitutes the centre for fire protection, in that it is the point at which indication of outbreaks of this nature will be registered from the alarm stations throughout the building. From here also the direction of the various trained squads is effected.

The log sheets, records of plant operating results, costs, etc., which will be kept in this department will be complete and up to date. Such records, which are too frequently overlooked, are essential in the successful and economical management of a great building.

In conclusion, the author tenders his most grateful acknowledgement to the Assistant Secretary of the company, officer in charge of building construction, Mr. D. L. Macaulay, for his friendly aid and for suggesting and assisting in the development of the new methods of distribution and control adopted in the ventilating of this building; and to the architects, Messrs. Darling & Pearson, and the associate architect, A. J. C. Paine, A.M.E.I.C., for their hearty collaboration in solving the numerous problems that have been encountered.

The Electrical Equipment for the Head Office Building of the Sun Life Assurance Company of Canada, Montreal

J. H. Mencke,
Consulting Engineer, New York,
and
E. A. Ryan, M.E.I.C.,
Consulting Engineer, Montreal, Que.

Paper presented before the Annual General and General Professional Meeting of The Engineering Institute of Canada, at Montreal, February 4th, 5th and 6th, 1931.

SUMMARY—In designing the electrical installation for an institutional building, provision must be made for changes from time to time in location and requirements as to lighting fixtures, office equipment, telephones, etc. With this end in view, systems of race-ways for electrical conductors have been employed instead of the more usual conduits and wiring to fixed points.

In a building of this type, the electric elevator must receive careful consideration, together with the electrical service needed for ventilation fans, pumps and other auxiliary machinery. Alternating current is supplied from the street mains and is used for most of the building services except the ventilating fans and certain other special purposes.

Three-phase current enters the building at 12,000 volts from underground mains and is transformed to appropriate voltages for lighting, three-phase power, and for the converting equipment. This consists of two synchronous motor generator sets and two 400-kw. power rectifiers.

An emergency storage battery insures against a complete failure of electrical supply and is so connected that in the event of a breakdown, current will be automatically supplied to the drainage pumps, one elevator, and the emergency lighting system. A 150-kw. steam-turbine driven generator set has been installed for the purpose of battery charging.

Inevitable changes in location and arrangement of the various departments are provided for by a special system of ceiling lighting and fixture outlets, and a duct system under the floors provides service for the changing of the location of desks and office machines in office spaces.

Flood lighting has been installed for the outside of the building, stage lighting for the auditorium, radio service in certain areas, and ample provision is made for outside and interdepartmental telephones. Other communication services such as telegraph, teletype, and electrical clocks are arranged on each floor and there is a very complete fire alarm system.

Elevator service is particularly difficult in a building of which the entire population is governed by a single routine. The main elevator equipment of this building includes nine elevators service all floors, nine elevators service to the 5th floor, twelve serving the 8th to 15th, and nine serving the 17th to 27th. In addition to this, there are several other elevators operated for special purposes in other parts of the building.

The primary consideration in planning the electrical equipment of a large institutional building is the space which should be provided to accommodate the various riser shafts, conduits and race-ways. Since the space conditions affect the thickness of floor fill, the type of floor arch and the arrangement of suspended ceilings, the general requirements must be known or assumed before the architectural plans are completed.

Exact requirements regarding the exact locations of the numerous small units of electrical equipment such as lighting fixtures, electrically driven office equipment, telephones and signals of various kinds cannot be determined. Even after the building has been completed there will be a constant change in locations and requirements of this sort. To meet this condition satisfactorily it is imperative that the wire race-ways of various types be so designed and arranged to provide the utmost flexibility. The planning of the electrical installation for this building has been based therefore on the establishment of systems of race-ways for electrical conductors instead of the installation of conduits and wires to fixed points to meet known requirements.

In addition to the electrical facilities the personnel must also be furnished with heat, fresh air and water. To this end various fans, pumps and controls must be furnished with electrical service as most of these are electrically driven. The requirements in this connection are determined within reasonable limits during the preliminary stage and therefore do not present a problem. It was decided that the ventilating fans were to be equipped with direct current motors to provide for a more accurate speed regulation. The electrical service furnished to the building being alternating current and the fan load being of considerable magnitude, the conversion of the alternating current service to direct current for this purpose presented an interesting problem. The various electrically driven pumps are furnished with wound rotor, 3-phase motors and with the elevators constitute the alternating current power load.

The electrical elevator load present and future is made up of thirty heavy duty, high speed elevators and eight smaller elevators of moderate capacity. With one exception all of these elevators are of the variable voltage type and therefore are operated by alternating current service. The only electrical problem in connection with the elevators was to determine the actual loads which would affect the transformer sizes, the feeder capacities and the power factor. The loads were determined by calculation with the co-operation of the elevator manufacturers by applying probabilities to determine the root mean square or heating value of the current. The results were carefully checked by comparison with other installations insofar as this was possible.

For the purpose of insuring continuity of service in so far as this is possible the electric service for the building is obtained from the underground mains of the Montreal, Light, Heat and Power Company, which supplies the building through duplicate three-phase, 12,000-volt, 60-cycle services. The services enter the building at Mansfield street below grade and drop to the service switchboard in the 3rd basement through concrete encased fibre conduit. The two service feeders are arranged so that either may be used to supply the main 12,000-volt switchboard through electrically interlocked oil circuit breakers with suitable pilot lights, etc. The main 12,000-volt switchboard is of the concrete cell type of construction designed after collaboration with the Board of Electrical Examiners of the province of Quebec. By means of remote controlled oil circuit breakers this switchboard (see Fig. 1) controls the current to three groups of transformers, namely the three 12,000- to 115/230-volt, 500 kv.a. transformers for lighting service, three 12,000- to 230-volt, 500 kv.a. transformers for three-phase power service and three 12,000- to 2,300-volt, 500 kv.a. transformers to furnish current for the original building and the d.c. converting equipment. (Fig. 2.)

The three lighting and three power transformers have been located in a transformer room adjacent to the 12,000-volt switchboard, each transformer being placed in a separate concrete cell and supported over a pit, the primaries being fed through fused disconnects. The connections from the lighting transformer bank to the main lighting switchboard and similarly from the power transformer bank to the main power switchboard consist of groups of 2½-inch extra heavy copper tubing hung from the ceiling on insulators.

The main lighting and power switchboards are of the open face type, comprising slate slabs, mounted on angle frame work and providing a lever-type disconnect switch or air circuit breaker on the face of the board for each feeder

Fig. 1—Control Panel and B-16 Oil Circuit Breaker.

and with the feeder fuses or test links arranged on fuse slabs mounted on the rear of the boards. All feeder connections consist of copper bus bars extending to an ample size pull box over each switchboard which forms the terminating point of the feeder conduits and permits the feeders to be carried on racks to the location of the bus bar lugs.

The lighting switchboard is subdivided into three sections, one for each phase, each section being fed through an air circuit breaker and a double throw disconnect switch so arranged that the load of each phase can be transferred to the adjacent phase in the event of failure of one of the lighting transformers. (See Fig. 3.)

The power switchboard together with its transformer bus connections is arranged so that the power transformer bank can readily be operated in open delta in the event of failure of one of the power transformers.

The transformer and switchboard rooms in the 3rd basement have been located as near as practicable to the centre of load. From the light and power switchboard pull boxes, feeders extend across the ceiling of the 3rd basement to each of the four riser shafts, thence upward to the lighting panels and power sub switchboards on the floors above. The horizontal runs of feeder conduits are supported by means of somewhat unusual steel plate hangers wherein the plate is drilled to receive each individual conduit. The riser shafts are of ample size to contain the lighting panel as well as the telephone, signal and miscellaneous distribution boxes feeding the adjacent floor area of each floor. The riser conduits pass through two slots formed in the riser shaft at each floor by special steel framing. The riser conduits are supported at each floor by means of the usual bolted strap hangers resting upon the special steel framing. The cables generally have varnished cambric insulation and are supported approximately every 40 feet by means of special wedge type cable supports located in cable support boxes.

The lighting panel boards are of the three to two wire, open faced type, with a single pole knife switch and fuse for each circuit and with a specially designed neutral bus bar arranged at the top of the panel to which the grounded conductor of each branch circuit is direct connected. The steel panel board boxes are arranged with a hinged door to lock, opening over the entire panel board box including the gutter space but with a small door set in the large door to open over the branch switches and fuses. Each lighting panel is furnished with a main disconnect switch but no main fuses.

The alternating current power feeders extend from the main switchboard to various sub switchboards which in turn feed the individual motors. (Fig. 4.) The relatively low voltage of 230 volts was chosen for the alternating current power supply instead of 440 or 550 volts because of the added complications and increased cost which would result from the necessary segregation of the power feeders from the lighting feeders throughout the entire building. An additional reason is that the kitchen power load included approximately two hundred kilowatts of baking and roasting ovens for which 230-volt service would be required. It was therefore found that the possible saving in feeder sizes or conductor losses was not sufficient to outweight the advantage of the simplicity and safety resulting from the use of the lower voltage.

Two synchronous motor-generator sets originally produced the direct current service for the original building, which occupies the south end of the site. These machines were then fed from a 2,300-volt, three-phase, service entering the original building from Dorchester street, the same service also feeding two banks of transformers, for lighting and power, respectively. Thus there was on the 2nd basement of the original building a complete primary service switchboard, transformer vault, a main switchboard and a direct current generating plant. It was found that it would be inconvenient and costly to dispense with this equipment and it was therefore decided that the original building be left in its existing state and that it be sub-fed from the new Mansfield street 12,000-volt service. It was also found that the bulk of the direct current load was located fairly close to the existing building, and therefore that the existing motor-generator sets could be satisfactorily operated in their existing locations.

The direct current load, however, was so far beyond the capacity of the existing plant that it was decided to retain the motor-generator sets for standby and power factor correction service only, and to install two 400-kw. power rectifiers in the adjacent area. The service for the original building, including the direct current converting equipment, is now obtained from the 12,000- to 2,300-volt transformers located at the main service entrance by means of duplicate 2,300-volt feeders extending through a subway system beneath the floor of the lowest basements to the original building service switchboard. This service switchboard therefore now feeds the light and power transformers serving the original building, the two synchronous motor-generator

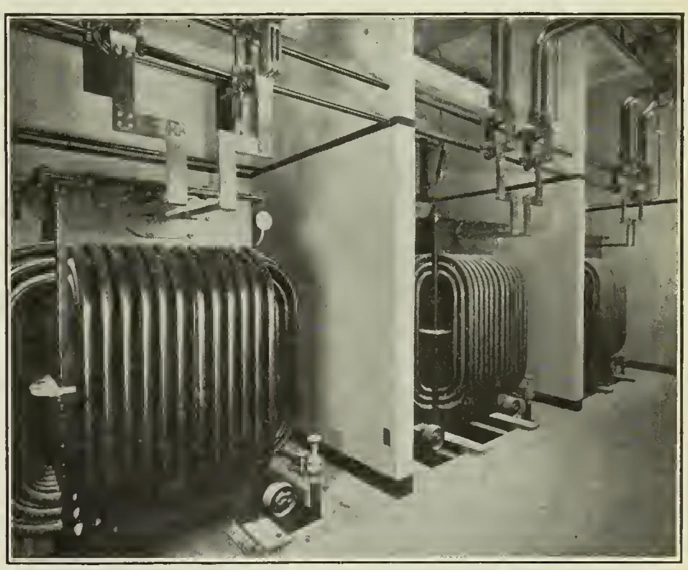

Fig. 2—Three 500 Kv.a. Power Transformer Banks 13,000 to 220 volts.

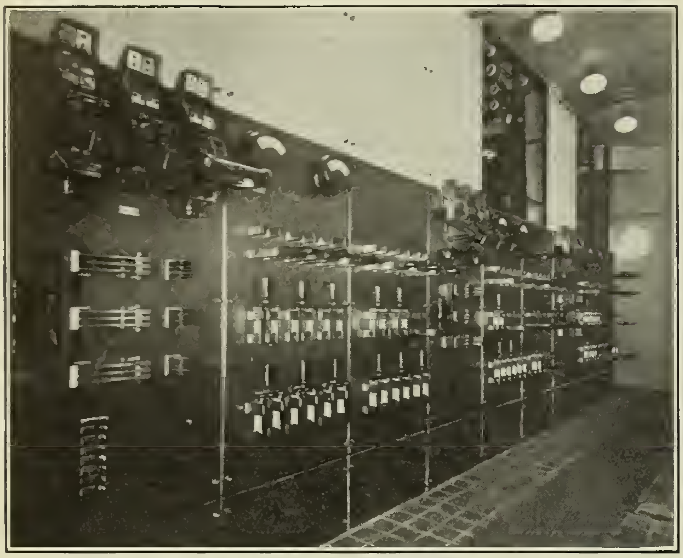

Fig. 3—Main Lighting Switchboard.

sets for power factor correction and standby and two Brown Boveri power rectifiers.

The direct current service for the building is fed and controlled by means of a direct current switchboard located in the rectifier room. The motor generator sets are to be adjusted to operate in parallel with one of the power rectifiers in the event of failure of the other. Additional power factor correction facilities have been provided in the form of two synchronous motor-driven refrigeration compressors.

The building is safeguarded against a complete shutdown of electrical service by means of an emergency storage battery, having a capacity of 600 amperes for one hour at 115/230 volts and so connected through automatic circuit breakers that direct current power will be furnished automatically to certain essential pumping equipment which will serve to prevent a flooding of the basement. The battery will in addition furnish current to one high rise elevator and to stair, exit and skeleton lighting.

A 150 kw. steam-turbine driven generator set has been installed for the purpose of battery charging, as well as to continue the supply of emergency service if the emergency should exist for a period exceeding one hour. During the charging cycle the battery will be split into two sections so that each half may be charged in multiple, thereby permitting this duty to be performed by a 115/230-volt, three-wire generator. The generator and battery connections are so arranged that the battery may be floated in parallel with the generator thereby practically doubling the emergency service supply when required.

While the possibilities of a complete breakdown of electrical service are considered somewhat remote, yet it was felt that a building housing ten thousand people should be safeguarded in every possible way.

It was found that the simplest and most effective method of applying the emergency source of power for lighting purposes was to have this power arranged to serve automatically a special system of exit lights, stair lights and emergency lights. These outlets are fed by separate feeders and panel boards so arranged that the exit and stair lights can be kept burning constantly so that means of exit and the stairways which would carry the occupants to the street are always illuminated. A system of night lights is arranged on separate feeders so designed that the outlets in the daylight areas can be turned off in the daytime by remote control from the engineer's office without affecting the similar outlets in the portions remote from daylight, which will burn constantly. This so-called night light system not only provides skeleton illumination from the general source of supply for the benefit of the watchmen and maintenance staff after hours but will in addition be automatically served by the emergency storage battery in the event of power failure. The night light outlets are strategically located in elevator and circulating corridors, toilets and locker rooms. The departmental areas are served at night by means of outlets placed at long intervals to light the way of the watchmen on their tours of inspection.

In view of the probability of constant growth and therefore the change in location and arrangement of the various departmental areas it became necessary to provide a flexible system of ceiling lighting fixture outlets which would permit relocation of the lighting units with a minimum of cutting and expense. The system adopted comprises a skeleton conduit arrangement wherein rigid conduits form a grid and connect with a permanently fixed pull box with a flush cover set diagonally off one column of each bay. From this pull box flexible conduits are extended above the hung ceiling to the fixture outlets in the bay. Changes in location of the lighting fixtures can therefore be readily made by cutting a hole in the hung ceiling at the location desired, and either fishing a new piece of flexible conduit from the pull box to the new location or by merely swinging the existing outlet to the new location if the length of the existing flexible conduit will permit. By this method changes in the location of ceiling fixtures can be accomplished without cutting a slot in the ceiling. The rigid conduit grid system has been designed to permit changes in the local switch control of the lighting fixtures by merely rearranging the conductors in the conduit.

The problem of providing service to the changing locations of desks throughout the departmental areas has been met by the installation of a fibre under-floor duct system. (See Fig. 5.) This system comprises half round sections of the usual 4-inch fibre conduit thereby producing a duct or race-way 4 inches wide, by 2 inches high, of semi-circular cross section. The ducts are arranged to extend parallel with the outer walls of the building and each run comprises two ducts placed side by side as close as practicable to each other. One duct of each run is utilized for telephone and signal wires and the other for lighting or office machine circuits. These duct runs have been carefully spaced to provide the utmost flexibility of desk location with the minimum expenditure of material. The spacing between duct runs varies from 6 feet to 9 feet, governed by the contour of the walls and the spacing of the building columns.

Although one of the ducts of the double duct, under floor duct system has been described as a race-way for lighting circuits, it is not expected that local or desk lights will be required for ordinary office work. The ceiling light fixtures have been designed and arranged to obviate the

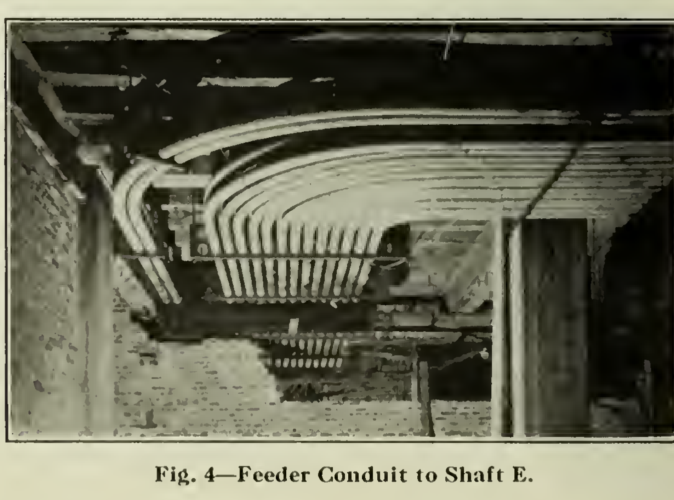

Fig. 4—Feeder Conduit to Shaft E.

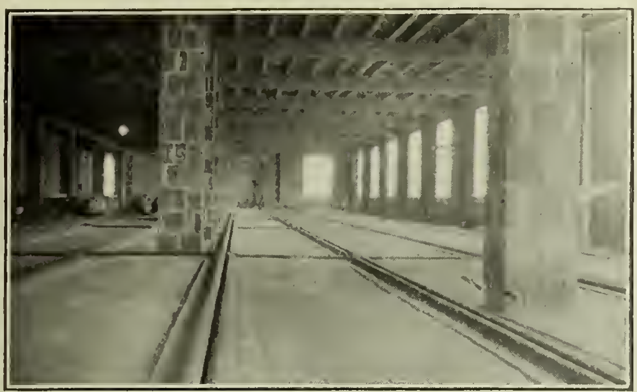

Fig. 5—Typical Under-floor Duct Layout.

use of desk fixtures. The lighting circuit duct will be generally used to furnish electrical service to the numerous business machines which have of late become an important adjunct to modern business methods. The modern office is gradually resembling a machine shop rather than a counting house. Some of these business machines, however, require current characteristics which cannot be served by the ordinary lighting circuit fed from the usual panel board. To meet this need vertical riser conduits extend from the basement and the various intermediate duct spaces to connect with junction boxes on the exterior walls and which form the termination of one end of the under floor duct header.

These exterior junction boxes, designated as auxiliary subjunction boxes, are provided with three distinct and separate sections; one devoted to 115-volt direct current service which is required by tabulating and similar statistical machines, one assigned to 115/230-volt, three-wire service for photostat and other heavy duty machines, and the third section which is connected to the riser shaft at each floor and which has been assigned variously to telegraph, ticker, teletype or telephone P.B.X. requirements. The vertical riser conduits feeding the first two sections obtain their service from a.c. and d.c. loop feeders which form a ring or loop on the duct space floors.

These a.c. and d.c. loop feeders are fed from feeders extending up the riser shaft, the single-phase a.c. service being obtained from the main lighting switchboard and the d.c. loop feeders being fed from a 115-volt storage battery, designated as the service battery, having a capacity of 80 amperes for ten hours. This battery has been so designed that the voltage will be extremely constant to meet the requirements of the direct current tabulating machines. The auxiliary riser conduits will remain empty and conductors for this auxiliary service are installed through these conduits only as required by the needs of each department. As these riser conduits are connected to loop feeders at both their upper and lower extremities, the possibility of congestion and lack of sufficient capacity has been avoided. The service battery in addition to serving the direct current business machines is used to furnish operating current to the remote controlled oil circuit breakers on the 12,000-volt switchboard as well as to the numerous remote controlled automatic panel board switches controlling the flood lighting of the building.

The building has been equipped with a system of feeders, panel board and outlets for lighting the building exterior at night. This exterior lighting, commonly known as "flood lighting," presented somewhat of a problem because it was felt by the architects that merely flooding the exterior of the building would result in the loss of the dominating features of the design. On the other hand, the architectural style prohibited the use of light which would in any way tend toward the modernistic. The problem has been met by the grouping of flood lights in such a way as to silhouette certain of the colonnades and by throwing light at such an angle as would tend to produce the shadows which would produce the results desired. All of the flood lighting groups of outlets are controlled from the engineer's office in the 2nd basement by the use of remote controlled automatic switches in the flood lighting panel boards located on the various floors.

The auditorium on the 7th floor of the building is to be equipped with modified stage lighting equipment comprising a stage switchboard complete with dimmers for the dimming of the various footlights, border strips, etc., as well as for automatically dimming the general lighting of the auditorium. In the rear of the auditorium is located a complete projector booth to accommodate modern motion picture projection and sound equipment for talking movies. The auditorium dimming equipment, as well as the stage curtains, will be under the direct control of the operator in the projection booth. In this booth there will also be

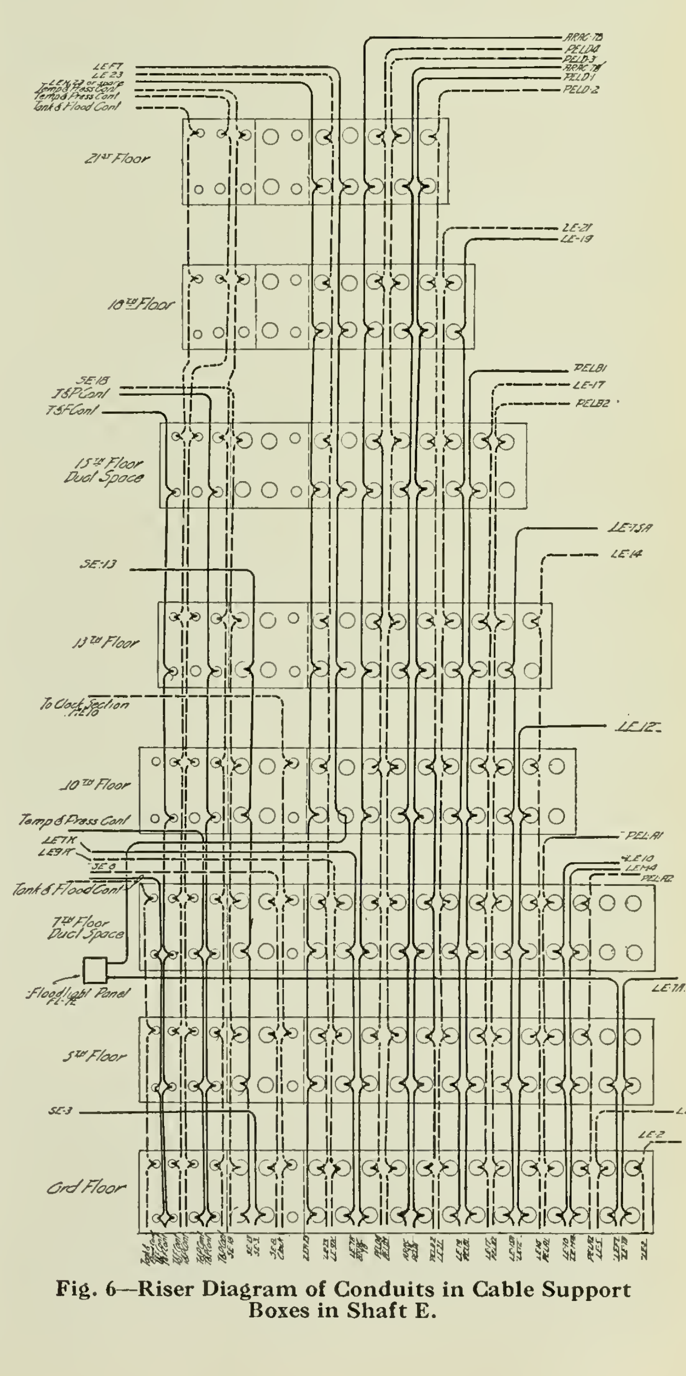

Fig. 6—Riser Diagram of Conduits in Cable Support Boxes in Shaft E.

located the central control board for the distribution of radio or disc record programmes over a two-channel audio distribution system connecting with loud speakers located in the play room on the 9th floor, the main dining room on the 6th floor, the chief clerks' dining rooms on the 5th floor and the officials' dining room on the 22nd floor.

This two-channel system will permit two programmes to be transmitted at the same time so that the choice of either will lie with the persons occupying the rooms in question. In addition this same system will be used upon occasion for the transmission or amplification of public addresses, which may be delivered in either the auditorium or the play room or in fact from the desk of the official delivering the address.

The lighting of the departmental areas is accomplished by the use of a totally enclosed type of lighting fixture, designed especially for the building. The glass enclosing globe is made of semi-daylight, tinted glass of contour determined by collaboration with the architects in an attempt to develop a unit scientifically correct and yet pleasing in form. These ceiling units have been installed on comparatively close centring because of the realization of the fact that uniform lighting as measured by a photometer does not necessarily produce satisfactory lighting conditions when the possibility that the individual will be so located that his body will cast a shadow over his work is considered. The design of the glass unit is such that the absorption of the glass in relation to the size of the unit produces a low brilliancy of light source with an efficient distribution curve. The intensity of light at the working plane in departmental areas will average 8-foot candles, with provision for increasing this intensity to 12- to 15-foot candles where required because of special conditions.

Similar totally enclosed units of smaller size are provided for the illumination of the toilets, locker rooms and general service areas. The main corridors and elevator lobbies throughout the building will be equipped with especially designed fixtures to suit the architectural requirements.

The centre of distribution for all signal services such as Bell telephone, telegraph, etc., is the signal rack room located in the 2nd basement. To this room are extended all of the conduits from the Bell telephone and the Electrical Commission of Montreal service entrances. From this rack room three systems of conduits distribute to each electrical riser shaft, namely, the Bell telephone system, the signal system and the miscellaneous system. The Bell telephone riser cables extending up the shafts are carried on messenger supporting cables and hung in open slots provided for the purpose. At each floor level an ample sized distribution box is provided in the riser shaft space with conduits extending across the ceiling of the floor below to the telephone section of a number of two-compartment subjunction boxes located generally on the wall of the service area and connecting directly with the under floor duct system. Similarly, conduits extend from a signal box in each shaft to the signal section of the subjunction boxes, the shaft signal boxes being interconnected vertically by riser conduits installed in the shaft. The miscellaneous services such as telegraph, teletype and electric clocks are accommodated in the riser shaft by means of a four-compartment distribution box on each floor, each compartment being vertically interconnected with the respective compartment of the boxes above and below. The distribution of wiring for telegraph and similar exterior services will be from the miscellaneous boxes through the signal boxes in the same shafts, thence through conduits provided to the signal sections of the subjunction boxes, to find their way eventually to the location desired through the underfloor duct system. The electric clock wiring is distributed from the shafts through conduits to wall and ceiling outlets spaced uniformly throughout the service areas.

A complete electric clock system has been provided comprising a master clock and programme instrument located in a suitable enclosed cabinet in the generator room in the 2nd basement. Double-faced ceiling type clocks are generally used throughout the departmental areas and chime tone programme bells located in flush containing boxes in these areas are operated by the programme instrument to summon the employees in groups to the dining room during the luncheon period.

A code ringing fire alarm system has been installed comprising approximately six individually coded fire alarm stations on each floor so arranged that the turning in of an

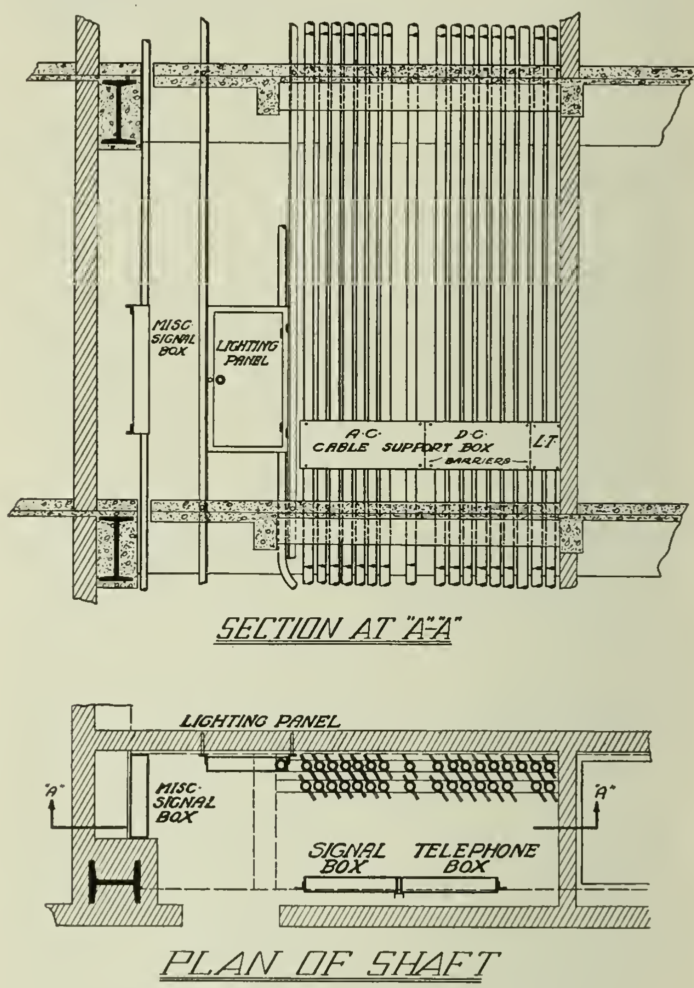

Fig. 7—Details of Typical Electric Riser Shaft.

alarm at one of the stations will cause the code of the station to be run by bells located in the areas generally occupied by the building maintenance staff. The code in addition will be indicated in the chief engineer's office, the boiler room and at the foot of the elevator shafts so that the elevator operators can immediately place their elevators to serve the fire fighting forces of the building. A record of each alarm will be automatically marked on the tape in a fire alarm recorder located in the central watch room.

The central watch room will be the centre of the building watch service as well as the after hour supervisory and inquiry bureau. In this room therefore are located the central control board upon which is indicated the watchmen's progress on their tour through the building in response to the signals despatched from the watchmen's tour stations located on each floor. Communication with the watchmen is arranged for by means of a signal light on each floor controlled from the watch room and located

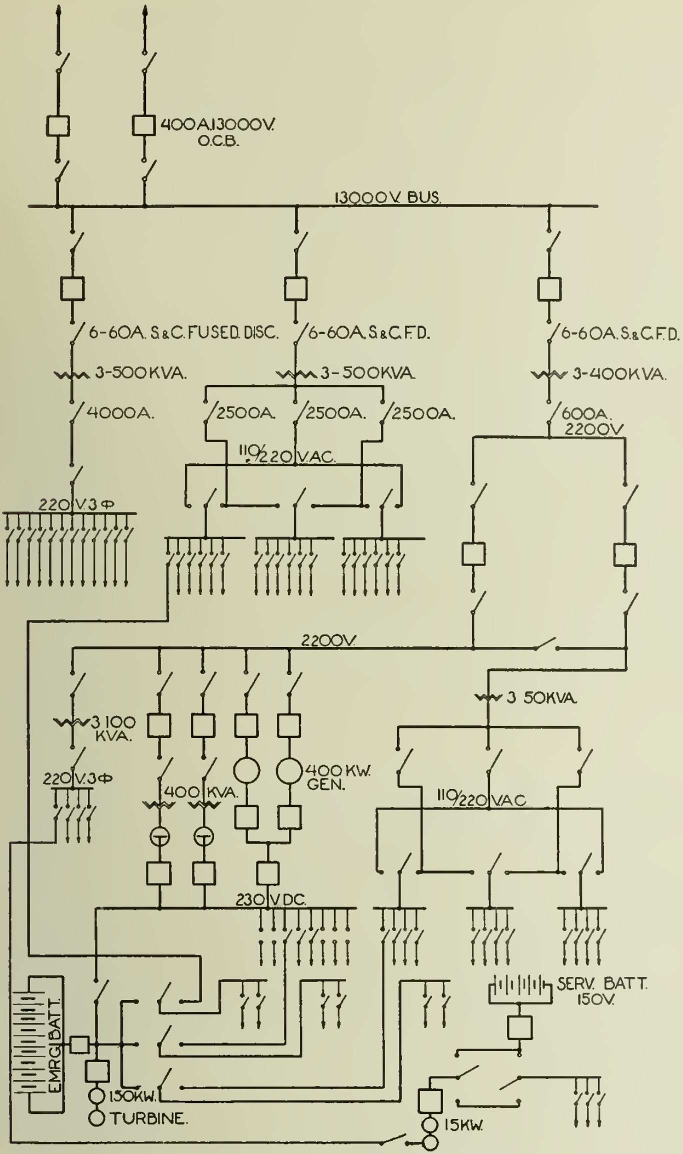

Fig. 8—Single Line Feeder Diagram.

adjacent to an interior telephone instrument. A tape record is made by a recorder of the time and location of each signal received from a watchman.

During the day the same interior telephone system is utilized by the chief engineer for communicating with the various building mechanics by means of signal lights located together with the watchmen's signal adjacent to the house telephone instrument. Each department or trade is assigned one of the seven distinctively coloured lights. Communication from the chief engineer to the various mechanical shops, boiler room, etc., is obtained by the use of the interior telephone system and service is also provided from the chief engineer to each elevator starter in charge of each elevator bank. In addition, each elevator starter may communicate with each elevator under his control or with the elevator machine room by means of a telephone instrument incorporated in the elevator control panel located in each elevator lobby on the ground floor.

Battery service at 24 volts is furnished for the fire alarm, electric clock and interior telephone systems from a signal service storage battery.

Elevators

Probably the most difficult problem that the elevator engineer is called upon to solve is the equipping of an institutional building, such as the Sun Life Assurance Company building, with adequate elevator equipment. The problem is made difficult because the entire population of such a building is governed by a single routine. The population furthermore is found to be more dense because of the large departmental areas with relatively few spaces devoted to private offices.

It will be found that approximately 30 per cent of a population of an institutional building must be transported in five minutes, whereas in an office building, occupied by numerous tenants, facilities for transporting from 15 to 20 per cent in five minutes will be sufficient. Furthermore, the density of population in an institutional building will usually be found to be one person to 80 square feet of net area; whereas in a rented building the density will not exceed 100 to 120 square feet per person.

This peak load of traffic, combined with the density of population produces a peculiar condition, in that if sufficient elevators are provided to meet the morning and evening loads, the space occupied by such an elevator installation will considerably increase the service area or non-productive portion of the building as compared with the useable or productive area. This would therefore result in increasing the cost of the building while at the same time seriously reducing the space which can be utilized for the purpose for which the building is erected.

The mere fact, however, that the occupants of an institutional building are all controlled by the dictates of one institution furnishes the solution. If the peak load is greater than a reasonable amount of elevator equipment can serve, it is quite natural to appeal to the heads of the institution to reduce the peak. The fact that the tramway systems of various cities have been faced by the same problem probably helped toward the conclusion that the hours of arrival and departure should be staggered.

The elevator equipment for this building has been designed on the basis that 50 per cent of the population of the building would commence and end their working day approximately one-half hour earlier than the balance. Even with this subdivision of peak load the elevators will be required to carry twelve to fifteen hundred people in five minutes when the building is fully occupied.

Having thus determined the traffic the next consideration is the size, capacity and number of elevators that will be required. Here again the requirements of an institutional building differ from the ordinary office building in that the large influx of passengers is best served by relatively large cars permitting a comparatively large number of persons to be carried at one time. The capacity of the machine instead of being based upon the usual 75 pounds per square foot of floor area of cab must be increased, because it has been found that the passengers in such a building have a tendency to crowd the cabs to their utmost capacity. The number of young persons that will fit into an elevator cab of ample proportions is sometimes amazing. Numerous tests have proven that the original rule which stated that a person occupies 2 square feet of floor area when standing in an elevator has been completely discarded in favour of a new rule of 1¼ square feet per person. This change in a fundamental rule may have been brought about by the popular fad of dieting for it has been found that each person under the new rule can be assumed to weight 125 pounds instead of the 150 pounds previously assumed. The net result of all of the above, however, is that the elevators for this building have been designed for a carrying capacity of 100 pounds per square foot of cab area. It was furthermore found that the most efficient size of cab would be one that would accommodate approximately twenty-five passengers, provided the cab could be made so that the width would be considerably greater than the depth to facilitate unloading at the various floors. With these conditions established the final arrangement of four banks or groups of 3,500-pound capacity elevators was adopted.

The low rise group known as bank "A," comprising nine elevators operating at 600 feet per minute, serves all floors to the 5th floor with provision for serving the 6th and 7th floors during the luncheon period, the latter floors being devoted almost entirely to this purpose.

Two intermediate groups of six elevators each, serve the 8th to the 12th floor and the 13th to the 16th floor, respectively. The bank "B" group will operate at a speed of 600 feet per minute and the bank "C" group has been designed to operate at a speed of 800 feet per minute, if and when the existing building regulations permit a speed in excess of 600 feet per minute to be used.

The high rise group, known as bank "D," comprising nine elevators, has been designed to operate at a speed of 800 feet per minute and will serve the 17th to the 22nd floor, inclusive, during periods of peak load, but is equipped with hatchway openings on all floors to enable this group to serve for intercommunication during off peak periods. It is expected that most of the elevators of groups "A," "B," and "C" can be shut down during periods of light traffic and that most of the load during such periods will be carried by this high rise group.

All of the elevators in the four groups above mentioned are of the full signal control, variable-voltage, type, wherein the functions of the operator have been reduced to the manipulation of buttons and the closing of the doors, which is accomplished by merely throwing the control lever.

The cab doors and hatchway doors are opened and closed by compressed air engines located above the door opening. The compressed air for this purpose is obtained from a separate compressor plant, located in the 3rd basement.

The elevator cabs are constructed from the architects' design. Each cab of the high rise banks is equipped with a position indicator located over the cab door, which indicates the progress of the cab by means of the successive illumination of glass numerals set in bronze plate. An intercommunicating telephone of the loud speaker type has been provided permitting each operator to communicate with the elevator starter without interrupting his duties. Emergency exit doors have been provided in the cab side which will permit the passengers to be removed to the adjacent elevator in the event of a shutdown.

The elevators are naturally equipped with every modern safety feature and furnished with means to permit the operator to eliminate the automatic features and assume full control of the movements of the car if necessary.

One elevator in the low rise and one in the high rise bank has been designed for freight service while at the same time permitting its use for passenger service when required. These two elevators are each of the same duty and capacity as those of the balance of the bank but each cab is furnished with a rear door opening into a circulating or service corridor to permit freight to be carried direct to the departmental areas without passing through the elevator halls. A special signal system has been provided for freight service only. The cabs of these elevators have been constructed with false tops which can be swung upward when desired to produce a height within the cab of 10 feet 6 inches to accommodate long members of furniture or other equipment.

The motor-generator set of the high rise freight elevator of the bank "D" group is of the dual drive type, having an alternating current motor and a direct current motor both driving the generator. In the event of power failure from the a.c. source, an automatic interlocked circuit breaker on the elevator control panel will immediately close with the result that the generator will be driven by the direct current motor by means of current obtained from the emergency storage battery. Upon the resumption of a.c. power the emergency source will be automatically disconnected and normal operation resumed. This feature will insure that one elevator at least can be operated in the event of a serious interruption of electrical service. It is not expected that this elevator will be of any great assistance in the carrying of passengers in times of emergency but it will permit the building maintenance staff to reach all floors quickly to make emergency repairs or to fight a fire.

Each starter has been furnished with complete indicating and control equipment in the form of ornamental bronze panels which will show him the location of each elevator, the direction of its travel and the floors calling for service. In addition to the usual control equipment one of these panels is equipped with a complete scheduling device which will automatically indicate the proper moment when each car should leave the ground floor on its upward trip and similarly when each car should start on its downward trip from the top terminal landing. The timing device is adjustable so that the headway or operating schedule of the elevators can be changed to meet the varying traffic and the number of elevators in operation.

In addition to the thirty elevators comprising the four main banks there is a group of two manually controlled elevators at the Mansfield street entrance of the original building, a group of two signal control elevators at the Metcalfe street entrance of the original building and an automatic push button elevator located to serve the security vault space and which runs to the 5th floor for the use of officials. The special needs of the cafeteria kitchen, which is located on the 6th floor at the north end of the building, will be served by two moderate duty freight elevators running from the 3rd basement to the 7th floor and thereby providing means of transportation between the cold storage rooms in the basement, the freight service entrance, the kitchen and the auditorium and all intervening floors.

A special automatic elevator will be installed for official use only, to operate between the administrative floors located at the top of the building. All of these auxiliary elevators are of nominal duty and speed to suit the purpose of each and are all equipped with means of telephone communication with the chief engineer's office.

In conclusion, it is perhaps needless to add that the results in this field are due to the efforts of many individuals. The writers wish to particularly express their gratitude to:

D. L. Macaulay, Assistant Secretary of the Sun Life Assurance Company of Canada and Executive Officer in charge of new building construction, for technical advice and assistance in connection with every phase of the electrical and elevator engineering, as well as for his sympathetic understanding of the many problems arising during the course of the work.

The architects for their guidance and for co-operation in providing for the requirements of the installation.

A. J. C. Paine, A.M.E.I.C., associate architect, for the numerous suggestions and the solution of the many problems of installation.

Kenneth T. Cregeen, Jr.E.I.C., engineer in charge of Building Maintenance, for his constant interest and helpful criticism.

The contractors for their intelligent co-operation and excellent work.

Steam Station for the Head Office Building of the Sun Life Assurance Company of Canada, Montreal, Que.

F. A. Combe, M.E.I.C.,

Consulting Combustion and Steam Engineer, Montreal.

Paper presented before the Annual General and General Professional Meeting of The Engineering Institute of Canada, at Montreal, February 4th, 5th and 6th, 1931.

SUMMARY.—This paper gives a general description of the new steam station to serve the head office building in Montreal of the Sun Life Assurance Company of Canada. The station is built below ground level across the street from the main office building with which it is connected by service and pipe tunnels, the intention being to construct a building over the plant which will be used as a service building to the head office. The main floor of the boiler room is 48 feet below street level with ash basement beneath, and approximately one-half of the excavation was made out of rock.

Among the features of special interest in the design of this station may be mentioned:—

(a) The attention given to provide a commodious and well laid out plant, the structural steelwork and braces against earth pressure being arranged for the support of the main pieces of equipment and intermediate floorings. Usually this is difficult to obtain as the engineer rarely has the opportunity to co-operate with the architect on building and structural plans when the steam plant forms the basement of an office building. Study has been given to the appearance by the use of quarry tile flooring, tile dado and tinted walls, and good lighting from large wall brackets around the entire operating floor.

(b) The plant has a capacity of approximately 4,000 boiler horse power. This is exceptionally large for the service of an office building and is due mainly to the very complete system of ventilation and air conditioning that is provided.

(c) As the load is governed in general by the outdoor temperature, the main steam generating units are specially designed for economical operation throughout a wide range of output. In addition to the special setting of the units, with provision for cutting in additional heating surface with auxiliary fans for the higher loads, heat is extracted from the outgoing flues and stack by the incoming air for combustion, so effecting a minimum of heat loss from the fuel burned.

(d) The coal handling system is arranged for fuel to be received either from street level by a covered truckway, or from the underground tracks of the Canadian National Railway's new station development when completed.

(e) A complete installation of instruments, meters and controls furnish full information for the guidance of the operators to maintain efficiency and to indicate and record conditions and results. Distant recording instruments in the chief engineer's office in the main building also furnish essential information and permit general directional control from that point.

(f) Provision is made for the installation of a garbage and refuse destructor furnace, with can cleansing and handling equipment, to burn general rubbish and the waste from the kitchens in the main building. The heat from this furnace will be utilized for the generation of steam in one of the boiler units, as an auxiliary to coal firing.

The steam station to serve the new head office building in Montreal of the Sun Life Assurance Company of Canada is situated below ground level at the corner of Mansfield and Cathcart streets, being connected to the main building by service and pipe tunnels crossing under Mansfield street. It is proposed eventually to erect an 18-storey building over the site of the station, and the structure is designed for the support of such a building which will also be served by the plant. At the present time the chimney, truckway over coal bunker, ash hopper and elevator head above grade are grouped in a brick tower housing which will later be incorporated in the overhead building. The remainder of the site is at present utilized as a covered garage space.

Figs. 1, 2 and 3 show the plan and general sections of the station. The plan dimensions are 117 feet long by 77 feet wide, the main boiler operating floor being 48 feet below street level, approximately one-half the depth having been excavated out of rock. A 12-foot basement below this floor extends over about one-half the area, with a large drainage sump below the basement floor from which all plant drainage is automatically pumped up 60 feet to the Mansfield street sewer.

The enclosing walls are of concrete, the earth pressure being taken care of by a steel bracing framework in conjunction with the main column members for the support of the future building. Provision against water accumulation between the rock face and the outside of the walls is made by vertical ducts draining to pipes or gutters leading to the main sump in the basement.

The spacing and arrangement of columns and structural steel-work is such as to provide a good layout for the boiler plant as well as for the future overhead building. The front ends of the boilers are carried from main cross beam struts, and other cross steels are set at convenient heights to suit the several operating floors and the equipment. The attention given to these features of design has resulted in a commodious well-arranged plant, an important factor for efficient operation.

One main stairway with combined passenger and light freight elevator provides access at the north corner of the station from the covered truck space to all floors, and a second stairway at the south corner leads to the pipe and service tunnels and communicates with the mezzanine floors overlooking the firing floor. Large pieces of equipment are handled through a sidewalk hatchway on Mansfield street with a shaft extending clear down to the boiler room floor. A toilet and locker room with showers is provided for the operating staff and store rooms are conveniently located for ready access.

The main floor is paved with heavy quarry tile of dark brownish red colour and a 54-inch tile dado of lighter colour is carried around the walls, the upper part of the concrete walls being painted. Good lighting is provided by large wall brackets mounted about 12 feet above the floor on each building column around all sides of the main floor.

Boilers

The steam requirements are principally for heating and ventilating and as such the load varies over a wide range depending upon the outdoor temperature. It was decided therefore to instal three main steam generating sets each designed to have an economic range of 10,000 to 40,000 pounds of steam per hour, and also one small boiler of 8,000 pounds steam per hour capacity which was removed from the old boiler-room of the original section of the main office building and re-erected.

Each of these main sets comprises a Babcock-Wilcox and Goldie-McCulloch cross-drum water-tube boiler placed in a specially arranged setting and having an effective heating surface of 4,500 square feet, a large percentage of which is exposed to radiant heat from the furnace, and a Foster-Wheeler economiser or water-heating section of 2,160 square feet heating surface.

The furnace equipment of each boiler consists of a compartment type balanced-draft chain-grate stoker, by the same makers, 9 feet wide by 14 feet long, arranged to operate either on natural or forced draft. Regulated secondary air is provided from the air cooling of the furnace side walls. The grate area and furnace volume allow for rates of burning and heat release which are within the limits of good practice for Nova Scotia coal, for the use of which fuel the plant was designed. This coal analyses approximately 56 per cent fixed carbon, 36 per cent volatile,

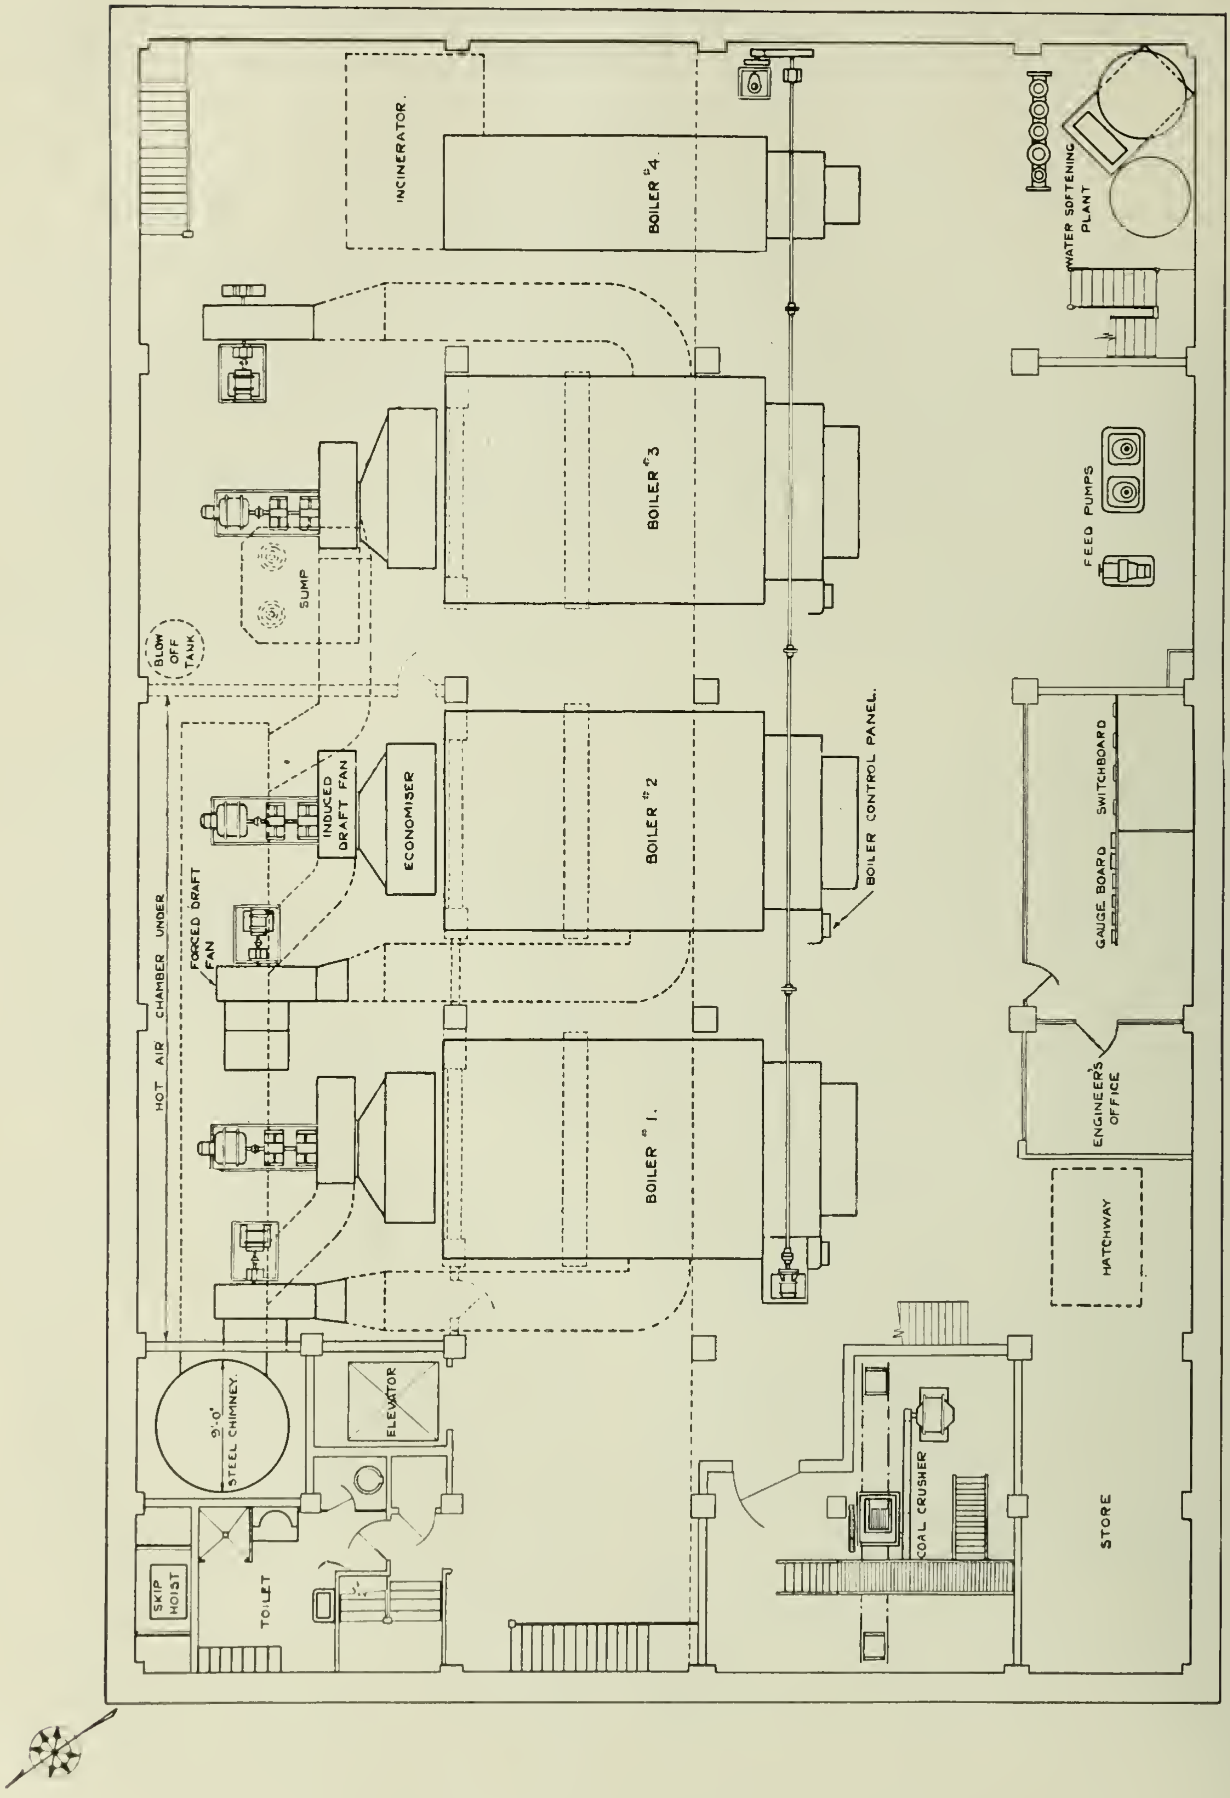

Fig. 1—Plan of Steam Station.

and 8 per cent ash, with 2½ to 3½ per cent sulphur; its calorific value is approximately 13,400 B.t.u. per pound, dry. The iron content is high, the fusing point of the ash being around 2,000 degrees F., and the general characteristics of the coal call for special features of stoker and furnace design to ensure efficient combustion with satisfactory operating and maintenance conditions.

Each steam-generating set has an independent forced draft fan and induced draft fan, connected to variable speed A.C. motors and controlled from an operating panel at the front of the stoker. On this panel are also mounted a Bailey boiler meter and multipoint draft gauge so that the operator can make complete observation and regulation from this point.

The boiler setting is arranged so that under light loads,—up to 15,000 pounds of steam per hour,—the boiler section only will be in service, the gases passing direct to the chimney by an overhead flue. Under such loads the stoker will operate under natural draft. For the higher loads the economizer section is cut into service and the forced draft and induced draft fans operated to maintain a balanced draft condition, the gases being discharged from the induced draft fans to another main flue in the basement leading to the base of the chimney.

Air is supplied to the extent required for ventilation and for light load under natural draft by a main supply fan drawing either from outdoors or from the service tunnel, as desired. When the boiler fans are in use air is drawn in from above street level through windows and louvred openings in the walls over the truckway, down the encasement around the steel chimney stack to a closed compartment in the basement to which the forced draft fan suctions connect. The discharge ducts from the induced draft fans and the main lower flue also pass through this basement compartment and are left uninsulated so that the air for combustion is warmed by heat extraction from the outgoing gas ducts.

The flooring under the rear passes of the boiler is set up 8 feet from the boiler room floor, giving free passage beneath and access all around the furnace walls. This makes for convenient operation and allows for any changes in furnace operation which may be desired or developed in the future, either in the form of pulverized fuel or oil burning. Soot from the rear passes of the boiler is discharged through water jet valves to the sump in basement whence it is pumped in water suspension by the special sump pumps to the street sewer.

Coal and Ash Handling

Coal is delivered in trucks from Mansfield street and after being weighed on a Gurney auto platform scale in the covered truckway is dumped through holes in the floor to the main storage bin below having a capacity of 400 tons. Below this storage is the coal handling floor where the coal is drawn through gates in the bin floor into 1-ton cars and delivered either directly into the stoker hoppers or through a coal crusher to a bucket elevator which raises it to a coal bunker over the firing floor. This overhead suspension bunker has a capacity of 300 tons of coal and is of Allen Sherman-Hoff make, formed of interlocking cast iron plates on steel suspension straps. This construction was considered a desirable one to withstand the destructive action of high sulphur coal. The bucket elevator travels at a speed of 45 feet per minute and is driven through a herringbone speed reducer and chain drive from a 7½ h.p. motor.

Fig. 2—Cross Section of Steam Station.

The low level tracks of the Canadian National Railway Terminal development will be approximately 2 feet below the level of the boiler room floor and provision has been made so that coal may be received from railroad cars on track sidings by an extension of the upper runs of the conveyor through the south wall, while doors at the end of the firing floor will give direct access for loading or unloading equipment.

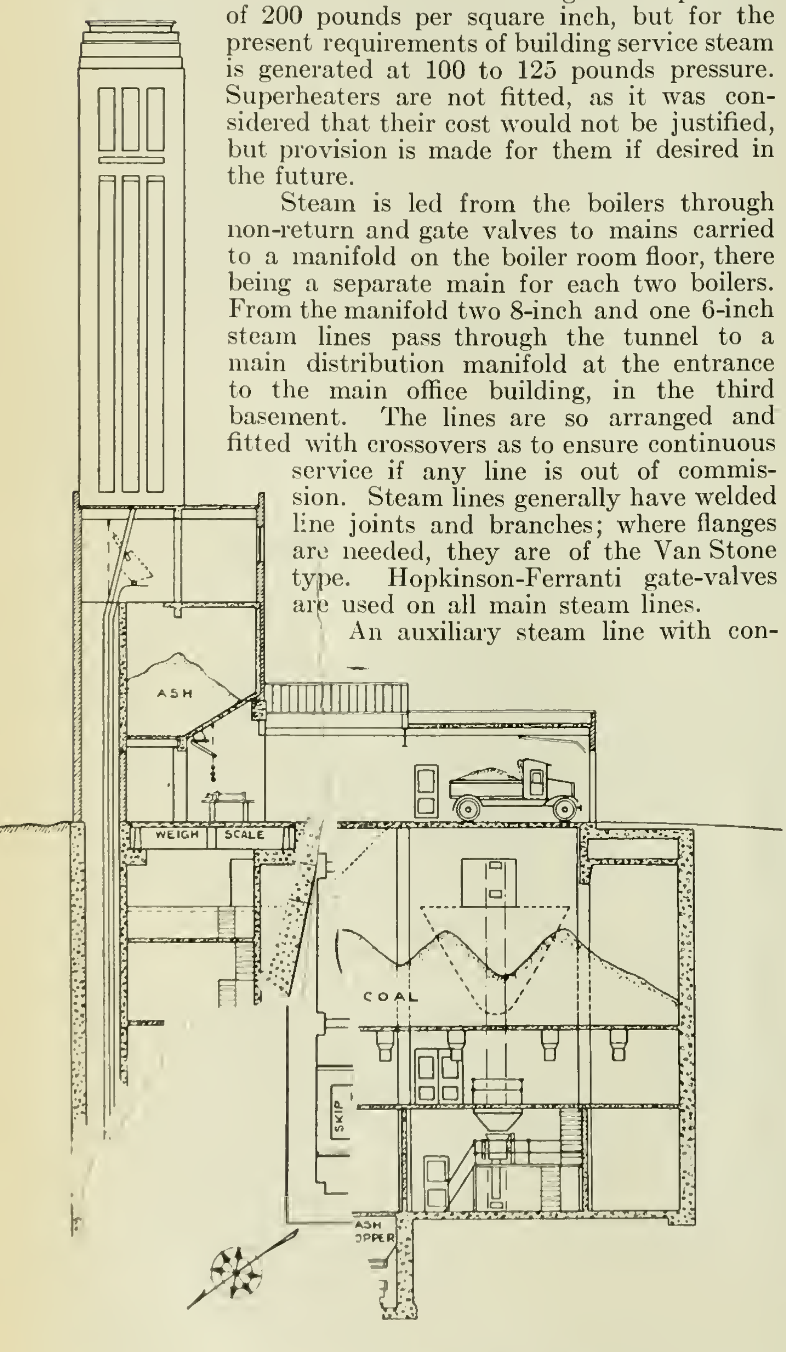
Ashes from the chain grate stokers fall into special tile-lined cast iron hoppers of the same make as the overhead coal bunker and are taken by hand cars in basement to a skip hoist. This hoist lifts the ashes 90 feet to a concrete ash hopper and returns to the basement pit automatically by the action of a single button push. The ash hopper has a capacity of 25 tons and discharges through a roller gate and chute to trucks in the covered way.

Steam and Water Systems

The boilers are built for a working steam pressure of 200 pounds per square inch, but for the present requirements of building service steam is generated at 100 to 125 pounds pressure. Superheaters are not fitted, as it was considered that their cost would not be justified, but provision is made for them if desired in the future.

Steam is led from the boilers through non-return and gate valves to mains carried to a manifold on the boiler room floor, there being a separate main for each two boilers. From the manifold two 8-inch and one 6-inch steam lines pass through the tunnel to a main distribution manifold at the entrance to the main office building, in the third basement. The lines are so arranged and fitted with crossovers as to ensure continuous service if any line is out of commission. Steam lines generally have welded line joints and branches; where flanges are needed, they are of the Van Stone type. Hopkinson-Ferranti gate-valves are used on all main steam lines.

An auxiliary steam line with connections from each main steam line and from each boiler drum supplies the feed pumps and other auxiliary equipment and station heating. As an emergency alternative the steam feed pumps can be fed direct from the main steam manifold.



Handling System.

The water treating and feeding apparatus is placed on two mezzanine floors and at the boiler-room floor alongside the firing aisle. The condensation returns from the building, both under gravity head from the upper zone and from pumps in the third basement, are brought through the tunnel to a 1,500-gallon storage tank on the upper mezzanine floor from which the water passes through a Cochrane de-aerating feed water heater and Bailey V-notch Weir meter on the intermediate mezzanine, and thence to the feed pumps at boiler room floor level. By the use of the full headroom of the boiler plant in this way for the feed water system, a good suction head is maintained on the feed pumps and a simple, accessible and easily visible arrangement effected.

Two Weir vertical feed pumps, removed from the old boiler room, and one Weir steam turbine feed pump of 250 gallons per minute capacity are installed and space is provided for an additional unit. Duplicate feed lines lead to the boilers, either direct or through the economizers, with regulators and pump governors to maintain a constant water level in the boiler drums. A Permutit zeolite water softener supplies soft water to the laundry and heating system in the main building as well as make-up, as required, for the boiler plant.

Instruments and Meters

Complete information for the guidance of the firemen, to indicate operating efficiency, and for record purposes is furnished by numerous meters and instruments. In addition to the water meter measuring the total feed to the plant, the output of each boiler is given by indicating, recording and integrating steam meters and a separate meter shows the steam used by the auxiliaries. Coal fed to each stoker is measured by a Lea coal meter.

As a check on the Bailey boiler efficiency meters, two Republic CO_2 recorders are installed, each one being connected so that gas samples may be read from either of two boilers. Four pen-recording thermometers are connected to each economizer showing the inlet and outlet temperatures of both gas and water, and other instruments are installed to record the temperature and pressure in the feed water heater and at other points so that the condition and efficiency of each piece of equipment may be determined.

Besides the readings given in the steam station, the total feed water will also be recorded on an instrument placed in the central instrument and control room in the main office building, so that the load on the plant can be noted and regulated from this point.

The station switchboard and general gauge board are situated in a glass-fronted instrument room facing the front of the boilers, and adjoining this room is the boiler room engineers' office. A large illuminated master steam gauge is placed on the building wall at the south end of the firing floor and the whole assembly of instruments and controls is in clear vision and convenient for operation from the firing floor.

Incinerator

At the present time garbage from the building cafeteria and kitchens is disposed of by contract, but it is proposed in the future to build a rubbish and garbage incinerator furnace in the basement of the steam station under the rear of the small boiler, the setting of which is arranged so that the heat from the incinerator may be utilized in this boiler. The proposed scheme for garbage disposal includes provision for readily handling the cans and cleansing them before return to the building.

VENTILATION

Previous mention has been made of the air supply for ventilation and for light loads under natural draft. This air is discharged through several ducts down to the firing floor and the warm air from the top of the boiler-room passes up through openings to the space over the suspended coal bunker. The space above the coal bunkers, which is also supplied with a small amount of high velocity air direct from the fresh-air fan to ensure circulation, is ventilated by an exhaust fan which discharges into the chimney enclosure, the air thus joining the circuit to the forced-draft fans supplying the boilers. By this system a general circulation of air is provided and accumulation of dust laden air over the coal bunkers is prevented.

The Plumbing System Designed for the Head Office Building of The Sun Life Assurance Company of Canada, Montreal

A. Traver Newman,
Consulting Engineer, New York, N.Y.

Paper presented before the Annual General and General Professional Meeting of The Engineering Institute of Canada at Montreal, Que., February 4th, 5th and 6th, 1931.

SUMMARY—The paper describes the arrangements and design for the drainage, water supply, fire protection and other allied services in the new head office building of the Sun Life Assurance Company of Canada in Montreal, which will contain a population of ten thousand people. Provision had to be made for an extensive kitchen and cafeteria equipment in addition to the regular sanitary requirements of a large modern office building.

A considerable portion of the drainage has to be carried out by ejectors and pumps, special provision has been made for refrigerated drinking water and hot water supply, and there is a very complete fire protection and sprinkler system.

The fire mains and sprinklers can be supplied from fire engines, from high pressure street mains, from the building steam fire pumps, and from tanks on the 9th, 16th and 24th storeys. Special care has been taken as regards fire hazard from adjoining buildings.

All vent, soil, and relief risers are extended above the main roof level and means are provided to prevent damage to the piping from the fall of storm water carrying grit from the roof drains.

The water supply is drawn from two independent street mains and filtered, the piping being so arranged as to provide for the continuity of service to all of the three pressure zones of the building. There are three electrically operated house pumps with a steam standby pump.

An endeavour has been made to obtain the best in design, material, and workmanship throughout the installation.

The design of the Plumbing System for the Sun Life Assurance Company's head office building in Montreal may be divided into the following groups, each of which will be dealt with individually.

1. Drainage and venting of general fixtures (mezzanine to 24th storey) by gravity.
2. Drainage and venting of general fixtures (ground floor to 3rd basement) by ejectors.
3. Drainage of kitchen fixtures (separate) by gravity.
4. Drainage of laundry fixtures (separate) by ejectors.
5. Drainage of low level fixtures (3rd basement) by ejectors.
6. Drainage of low level floor drains and ground water by sump pumps.
7. Drainage of roof and other exposed surfaces (mezzanine to 24th storey) by gravity.
8. Drainage of other exposed surfaces (ground floor to 2nd basement) by ejectors.
9. Water supply and drainage for drinking fountains.
10. Cold water supply to fixtures.
11. Hot water supply to fixtures.
12. Fire protection supply and sprinklers.
13. Liquid soap supply.
14. Gas (fuel) supply and emergency lighting.
15. Mechanical plant.

These all had to be arranged so as to work in with the existing equipment of the original building on Dorchester street, which was of course much less extensive.

The following sections deal with the above sub-divisions in the order given.

1. Gravity drainage and venting of all plumbing fixtures (except those of kitchens, cafeteria and bakery) from mezzanine to 24th storey inclusive (Diagrams No. 1 and No. 3):

For this service a system of extra strong galvanized, genuine wrought iron piping, with companion main vent risers and branch fixture vents of the same material, was designed, discharging from fixtures to street sewers, entirely separate from the systems taking kitchen waste and storm drainage. In plan the plumbing fixtures were kept as close to risers and as much within a central service area as was physically possible.

Because of plan area (and excluding that part of the building already existing) the gravity sewage drain system, and also the roof drainage by gravity under item No. 6, was divided into four parts, so as to discharge through two separate house drains and house sewers in Metcalfe street, and through two others into the public sewer in Mansfield street. This gives the fixtures and main roof four points of relief, besides reducing the space required for adequate fall in the branch drains.

The house sewers, underground, in the street were designed of extra heavy cast iron soil pipe.

2. Ejector drainage of all plumbing fixtures (except kitchen) from ground floor to 3rd basement inclusive (Diagrams No. 2 and No. 3):

For this service a separate system of drain and vent piping, isolated from the gravity systems, was provided, but of the same material as the gravity drains. These drains discharge into two sets of duplicate Shone ejector pots, operated by compressed air, and discharging through two separate house drains to the public sewers in Mansfield street. The ejector fixture vents of these ejector systems must not be confounded with the ejector air relief risers which are necessarily serving a different purpose.

Inside of the building these ejector discharges were goosenecked or run up vertically to about 7 feet above the highest curb level, then dropped to 1st basement floor level and run thence to the street sewers, in order to prevent any flooding of the building through possible gorging of public sewers under storm conditions, and also to accelerate ejector discharges when public sewers are running full. The sump pump discharges (item No. 5) were similarly arranged. (Diagrams No. 1 and No. 3.)

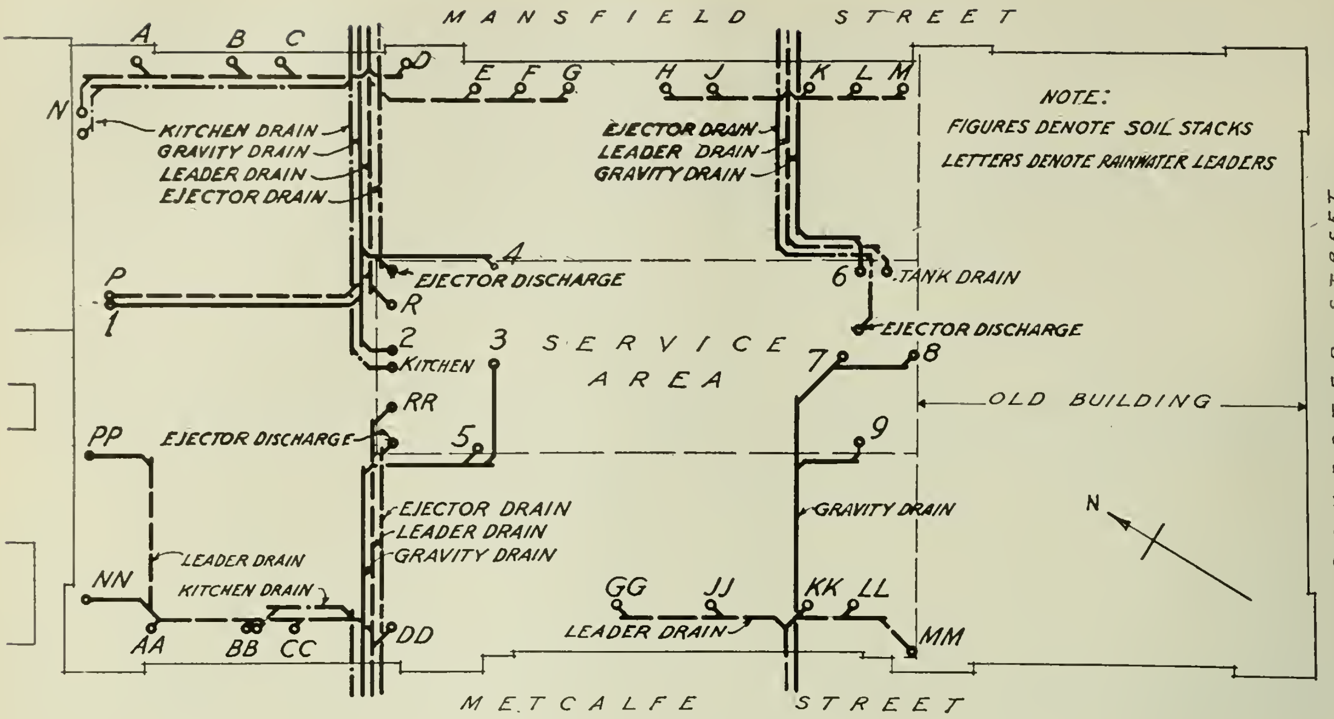


Fig. 1—First Basement Plan.

3. Gravity drainage of kitchen fixtures:

For this service, a separate system of drains was designed, discharging direct to the public sewers from the kitchen, cafeteria and bakery fixtures on the 7th and lower floors. This confines any trouble incident to this type of drainage to its own system of piping. Grease traps of the latest design, without water jackets, were specified to be set on the wastes of all sinks, dishwashers or other fixtures where greasy water is discharged.

The branch vents of these fixtures were designed to be connected with the main vent risers of the system described under item No. 1 where any such risers exist near kitchen fixtures, otherwise into the main vent riser of their own system, but not to the ejector system.

4. Ejector drainage of laundry fixtures (Diagrams No. 1 and No. 3):

From the laundry fixtures on the 3rd basement floor, a separate system of low level drains was designed to discharge to its own unit of two ejector pots delivering through goosenecked discharge mains to the ejector house drains. The branch vents of these fixtures were vented to the high level system of ejector fixture vents. The ejectors used for this purpose (formerly in use in the existing building) were reset in an ejector pit together with a second set of two reconditioned ejector pots for the low level fixtures (item No. 6) all actuated by compressed air.

5. Ejector drainage of low level fixtures (3rd basement) other than floor drains (Diagrams No. 2 and No. 3):

For this service, which includes all general, waste vented and water supplied plumbing fixtures in the 3rd basement, other than floor drains, funnel, trench and other drain boxes, the drainage system was designed to be of extra heavy cast iron soil pipe discharging into a reconditioned set of two ejector pots (mentioned in item No. 4) reset from the existing building in a new ejector pit, and discharging through goosenecks to and through the ejector house sewers to the public sewers.

6. Sump Pump drainage of low level floor drainage and ground water (Diagrams No. 2 and No. 3):

For the drainage of all floor drains, drip and waste funnel drains, the overflow from air moistening and like apparatus together with a few isolated sinks (all in the 3rd basement) plus the overflow from the old sump, another system of extra heavy cast iron soil pipe drains was designed to discharge into a sump pit under the northerly end of the central service area. This sump also receives the overflow from an adjacent interceptor pit which acts as a sedimentation pit for the ground water drainage of the site.

The discharge of the contents of the sump pit was designed to be handled by a set of two submerged vertical centrifugal sump pumps with direct connected electric motors together with a steam standby pump of the duplex piston type, with one emergency suction to the sump pit and one to the open ejector pit. The sump pumps all deliver through goosenecks to the ejector drains and thence to the Mansfield street sewer.

7. Gravity drainage of roofs, loggias and other surfaces exposed to weather (from mezzanine to 24th floor) (Diagrams No. 1 and No. 3):

This system discharges from boxes to the public sewers by gravity, through four separate house drains and house sewers; two to Metcalfe street and two to Mansfield street so as to permit emergency relief of roof drainage if any one drain should be stopped up, and also to prevent the reflection of temporary gorging of house drains on any other system. These rainwater drains join the house drains for sewage from the building foundation wall to the public sewer.

The piping used is extra strong galvanized guaranteed genuine wrought iron screw piping in the building, and extra heavy cast iron soil pipe where buried in street.

Each leader stack is trapped with a double handhole running trap at base. All branches are dropped one storey before joining the leader and all possible bends were eliminated on branches.

8. Drainage of surfaces exposed to weather from ground floor to 2nd basement:

This item is small and after the freight entrance driveway drainage has passed through an oil separator its discharge is delivered to the northerly unit of high level sewage ejectors for disposal to the public sewers.

9. Water supply and drainage for drinking fountains:

For drainage, a system of waste-risers for drinking fountains was designed to discharge with open ends into the large drip funnels. Each single riser was extended to and above the roofs with trapped branches to each fountain.

For supply, the cold drinking water mains connected to the cooling units were designed to distribute in overhead grid form to down supply mains which in turn connect to a return circulation main at their base and thence return without trapping through a single upward return circulation riser to the cooling unit.

Each fountain branch has an individual control valve, and where the pressure will exceed fifty pounds an approved pressure reducing valve is to be installed on the fixture side of the control of each branch supply.

10. Cold water supply to fixtures (Diagram No. 4):

Part of the cold water supply of this building, as is usual with all other high buildings, is supplied under street pressure, and part is pumped to tanks and thence under tank pressure to fixtures above safe street pressure supply level and to all hot water heaters under tank pressure.

Thus to accomplish a golden mean of static pressure on all fixture fittings, this building was divided into three zones, each supplied by house tanks set at such a height above the highest fixtures supplied by them as to give proper working pressure to those fixtures, while at the same time avoiding the use of pressure reducers on the branches to the lowest fixtures in that zone.

This arrangement is typical of the multi-zone building and is applied to the fire protection system as well. The thought can also be applied to the division of carriage of sewage into gravity and ejector systems.

They are, therefore, in the design of water supply for this building, a low level, an intermediate level and a high level zone. In the low level zone the street pressure supply is connected to the base of the cold down supply risers from the low level tank. These risers have dividing valves at the 2nd and 3rd storeys above the fixture branches for those storeys, so that the average street pressure can be made use of up to either level and thus reduce the pumping load. Control valves are placed at the base of each riser so that when desired street pressure can be shut off and the tank pressure supply used.

Water supply can be taken from two separate street mains (in addition to that supplying the original portion of the building) and this applies to fire supply from other high pressure mains as well. Each source of supply is valved and check valved at or near foundation wall and then cross connected to the other supply main. From this cross connecting header, after passing the water through filters, branch supplies are taken to the fixtures and mechanical equipment which require cold water at the average street pressure, and also to a large two-compartment suction tank which forms the normal source of supply to the house and fire pumps. There is also a by-pass to permit of direct supply to the suction of these pumps from the street pressure header if the tanks for any reason should be out of commission.

The electrically operated house pumps, one for each zone, and the steam stand-by pump good for all zones, are planned to draw normally from the suction tank and deliver to a two-compartment house tank and a separate fire tank at the top of each zone. From each tank as before mentioned the cold water is fed down to fixtures and hot water heaters in its zone.

The piping specified is extra strong galvanized guaranteed genuine wrought iron.

11. Hot water supply to fixtures (Diagram No. 4):

For the supply of domestic hot water to the general plumbing fixtures in each zone, a pair of horizontal cylindrical storage hot water heaters are set at the lowest level possible in each zone. Cold water is supplied through a separate down supply main from the house tank to these heaters.

From each pair of heaters the hot supply discharges, properly valved, are combined into one main hot supply riser up to the duct space over each zone, there distributing through a so-called gridiron main without trapping to return circulation supply risers feeding down, from which the supply branches to fixtures are taken. Each of these down supply risers has a check valve set on 45 degree angle where it connects with the branch to the main, and also control valves at top and bottom with a valved drainout at bottom. All such risers connect into return circulation mains and the water returns untrapped to the heaters by gravity.

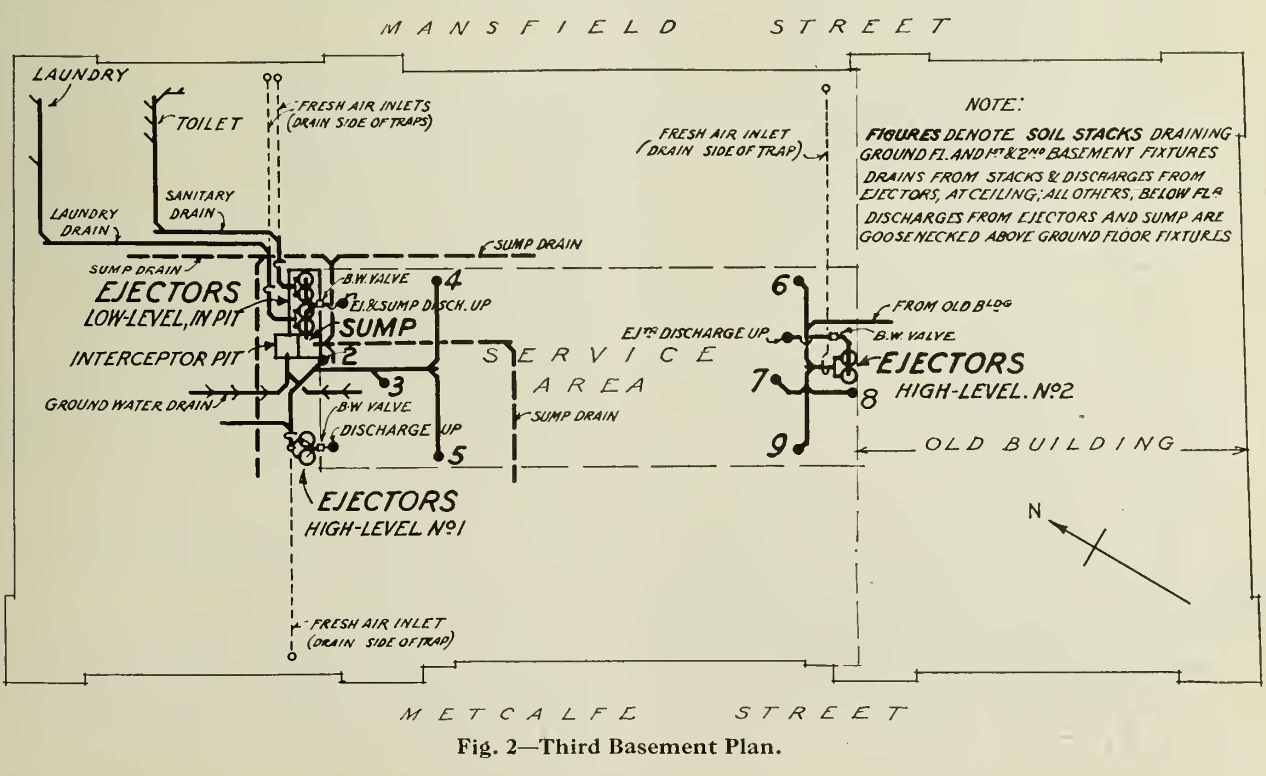

Fig. 2—Third Basement Plan.

In the lower zone are many fixtures for kitchen, cafeteria and bakery service and there is also a considerable amount of laundry equipment. To the general heaters there were therefore added one for kitchen use and one for laundry purposes, all of the same size but all so cross connected and valved that any desired number of units can be valved into any particular service which may at times be subject to heavy draft. It may finally work out that one will be used for laundry, two for kitchen, and one for general service, with hot water at different temperatures. In this zone hot water return circulation pumps, one for each service, are installed to provide efficient circulation in case of any interference with the designed gravity circulation.

In all heaters the water is heated by high pressure steam through copper coils in heater shells, the temperature being controlled by thermostats.

The material originally specified for the hot water heater shells was genuine wrought iron, but owing to difficulties experienced in obtaining this material in Canada of the sizes required, a heavy weight of steel was finally used.

All hot supply and return circulation piping is of 67 per cent copper content brass of extra strong wrought iron sizes and weights, with fittings of 75 per cent copper content.

All hot supply horizontal mains were designed with adequate expansion loops en route and there are loops at top and bottom of all risers. All fixture branches are taken off with six ell expansion loops to prevent rupture by expansion and contraction.

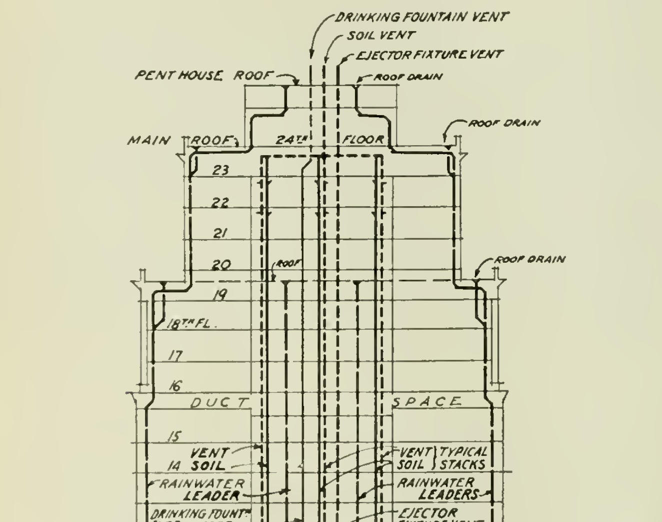

Fig. 3—Drainage Diagram.

On each heater is provided a safety relief valve, and also a free unvalved expansion riser carried up to the house tank of its zone and goosenecked up to an adequate height above the tank water level. From the high point of each hot water heater grid system a free air relief (expansion) riser is taken also goosenecked adequately above the water level in the house tank of that zone. The outlets of all these expansion and relief risers are discharged into drip pans under tanks and not into the tanks themselves, in order to obviate the possibility of scalding any person engaged in cleaning a tank. Drip pans are required under heaters.

12. Fire protection supply and sprinklers (Diagram No. 5):

The system of piping designed for this service consists of a continuous full size, loop fire main header in the 3rd basement, another in the 7th duct space storey and one in the 15th duct space storey. The headers in the third basement and seventh duct space connect to and supply five fire stand pipe risers in the original portion of the building, together with five fire stand pipes in each zone of the new portion. To the 15th storey header are connected four fire stand pipes, all in the new portion of the building, to serve the high level zone.

The header at the third basement ceiling receives its supply as follows:

First: From fire engines through siamese at street level, with check valve opening in on branches from siamese to header.

Second: From high pressure fire mains in Metcalfe and Mansfield streets, through high pressure branch supply mains also provided with check valves opening in. This pressure might serve in the two lower zones in some emergency when fire engines (or pumpers) could not serve through the fire siamese.

Third: From the building steam fire pumps, normally drawing their supply from the suction tank, which tank in turn is supplied from the low pressure water supply mains in Metcalfe and Mansfield streets; the fire pump discharge is also provided with a check valve. As before mentioned an emergency by-pass around the suction tank permits street pressure to be valved direct into suction headers. The two fire pumps can be used either in parallel or in series.

Fourth: From the fire tank in the 9th storey the down supply riser to fire stand pipe No. 1 has a check valve opening down, set in a horizontal position, with an O.S. & Y. controlling gate valve set on each side and sealed open, all located near tank. This tank main down connects into fire stand pipe No. 1 just below another check valve on that stand pipe, which arrangement permits pressure to be pumped up all the way to the main roof or the top of the high level zone, but does not permit the higher tank supply to be drained down to a lower zone than its own. This same principle is applied at connection of tank main down from the intermediate tank to fire stand pipe No. 1 which is the one stand pipe that rises from bottom to top of entire system. All other stand pipes begin in the lowest storey and end at the hose outlet of the upper storey of their zone; in plan they are all one immediately above the other.

We thus have tanks for fire service supply in the 9th storey for the low level zone, the 16th storey for the intermediate zone and the 24th storey (or upper pent house) for the high level zone.

For architectural reasons the pent house roof level was kept down. This brought the high level zone fire tank to such a level in relation to the main roof and attic space hose outlets that an electrically driven booster pump was located in the pent house, to draw from the fire tank down-

main and deliver into the cross header for the outlets mentioned. This pump can be started from the control board in the engineer's room in the 2nd basement, thus permitting a quick rise in pressure at highest hose outlets, until the building fire pumps, or the city fire engines, get into operation.

Dividing valves are placed in each horizontal header so that any one fire stand pipe (in any zone) may be valved out of commission if piping should split or a hose valve burst.

On the 10th storey roofs at the north and south ends of the building, as well as on the main (24th storey) roof, two-way individually valved hose end outlets are provided and at the north end (where buildings either do or may exist quite close to the Sun Life building) there are two swivel-head fire monitors. These can be left in play even though the operators are driven away by heat and they also provide greater force because of their iron pipe connection which obviates the thrashing possible when hose held by hand is in use for such purposes. The water supply to all roof outlets including the monitors is controlled by long stem wheel handle gate valves with the wheel handles well above roof level and adjacent to the outlet served, while the valve itself is protected from freezing. Automatic ball drainouts are also called for, draining down from the outlet side of control valves.

On all the stand pipes, in each storey, there are provided one 1½-inch valved outlet with hose, hose-nozzle and rack, and also one 2½-inch valved outlet, without hose or rack, for the use of the fire department with their own hose. In the 1st, 2nd and 3rd basements the 1½-inch outlet valves are provided with pressure reducers set between valve and hose. These can be reset while in place so as to meet various pressures. Two similar pressure reducers of 2½-inch size are provided and kept at predetermined sites in each of the basements for use by the fire department should a basement outlet have to be put in service while the pumps were providing high service pressure for fire fighting purposes in any of the upper storeys.

The initial service to all fire hose or monitor outlets is obtained under static pressure from the fire house tanks, which tanks in turn are supplied by the house pumps.

From fire stand pipe riser No. 1 a branch emergency supply pipe will be extended to each group of fire and house tanks; namely one in the 9th storey, one in the 16th storey and one in the 24th storey. This affords another means of filling the house tanks and keeping them in service if the normal house pump supply risers to these tanks are rendered useless, which condition actually obtained in one large building some years ago, although heavy rubber lined hose was temporarily used from hose outlets to provide supply to tanks in that case. These permanent emergency branches are out of the way, but the valves at tanks must be sealed shut to prevent draining down the fire stand pipe system and thus defeating its purpose.

As to sprinklers, there are two cases. One valved branch runs from the 3rd basement fire main to sprinkler heads in certain rooms used for such purposes as paper baling etc., and another branch is led from the 16th storey tank fire stand pipe service to an exposed header of brass pipe with open spade nozzles located at the 5th storey level on the north wall of the building above the adjoining Loew's theatre and designed to give additional protection in case of a fire occurring in that theatre. The control valve on this branch is readily accessible inside the building and is sealed closed. It will be manually operated like the valves for the roof outlets, and has the same type of automatic ball drainout, so as to prevent damage from frost.

The valve to the sprinkler head line in basement is to be kept open on a wet system, all heads being factory tested to withstand a pressure exceeding that which would be needed for actual fire service.

Extra strong genuine guaranteed wrought iron pipe is used throughout this system except where brass pipe is noted.

13. Liquid soap supply:

The piping for this service is divided into two down systems in each zone, filling to sub-tanks and from them to faucets on fixtures. The head of each system is provided with valved double offset cross head connection with space and skids for two drums. Easily accessible valves control the supply from drums to sub-tanks.

Isolated fixtures and smaller fixture groups have group tanks rated as sub-tanks, manually filled.

The piping for this system of supply is black full card standard weight genuine wrought iron.

The soap faucets and exposed piping to wall are of non-corrosive mono metal, nickel plated and then chromium plated.

14. Gas supply, fuel and emergency lighting:

Fuel gas supply is connected to all kitchen, cafeteria or bakery fixtures requiring it, and there are also branches to forty emergency lighting outlets in the 3rd basement.

A master emergency shut-off valve for operation by the fire department from the sidewalk was specified but was finally omitted.

The gas piping is black standard weight genuine guaranteed wrought iron.

15. Mechanical plant:

Under this head are the following operative units:

(*a*) Water filter.
(*b*) House pumps................Electric
(*c*) House pump, stand by........Steam
(*d*) Fire pump...................Steam
(*e*) Booster pump (fire system)...Electric
(*f*) Sump pumps.................Electric
(*g*) Sump pump, stand by........Steam
(*h*) Sump and ejector pit ejector...Steam
(*i*) Hot water circulating pumps...Electric
(*j*) Ejectors......................Compressed air
(*k*) Air compressors...............Electric
(*l*) Plumbing fixtures.

Regarding these, the following notes may be of interest.

(*a*) Water filter:

This cast iron shell drifting sand filter has been in use in present building. It will be used until the building population and consumption require the installation of another for which space has been provided.

(*b*) House pumps (electric):

These are three in number (one for each zone) to fill the house tanks and are horizontal multi-stage centrifugal heavy duty pumps, automatically and manually operated by direct connected electric motors.

(*c*) House pump (steam, stand by):

This is a horizontal duplex direct-action piston pattern steam driven pump.

The valved and check valved discharge of this pump is so cross connected to the electric house pump discharge risers as to permit it to be used to supply any house tank at any zone level. This pump will provide an alternative supply in case the electric current is cut off, and will supplement the capacity of the electric pumps if necessary.

(*d*) Fire pump (steam):

This pump was originally specified to be an underwriters horizontal duplex direct action piston pattern steam-driven pump, but later two horizontal multistage centrifugal pumps driven by steam turbines were substituted. These are to be manually controlled in parallel for service on low or intermediate zones and in series for high level zone. They are to operate under an ultimate working pressure of 350 pounds.

Like the house pumps, they will usually draw from the suction tank, but will be connected with the emergency by-pass which, when required, will furnish street pressure supply direct to the pump suctions. The valved and check valved discharge of these pumps connects into the new fire main loop and thence through fire stand pipe No. 1 they will deliver effective fire streams from main roof or any lower outlet. On the pump side of check and control valve there is a valved test end delivering into the suction tank and an unvalved branch with safety relief valve also discharging separately into the suction tank.

(*e*) Booster pump (electric):

This horizontal centrifugal electrically-operated pump has but one source of supply, namely the high level fire tank, and discharges to the highest fire hose outlets direct. It is to be operated from the engineers control board in 2nd basement or at the pump.

(*f*) Sump pumps (electric):

There will be one heavy duty line duplex automatic electric bilge or sump pump unit, submerged in pit, consisting of two pumps direct connected to motors set well above flood level on 3rd basement floor. The pit has an air vent to the outer air and is furnished with a high water alarm. The valved and check valved discharges are delivered through goosenecks to house drains and thence to street sewers.

(*g*) Sump pump, standby (steam):

This is of the same type as the stand by house pump but fitted to handle sewage. Its suction is divided, one leg to draw from the tight sump pit and the other leg from the open ejector pit, each leg being fitted with foot valve, gate valve and priming line. The discharge is the same as for the electric sump pumps.

(*h*) Ejector (steam):

A medium size steam-operated ejector is provided to handle small amounts of drip, thus obviating the necessity of putting the large pump into operation under uneconomic conditions. It draws from the sump or from the ejector pit.

(*i*) Hot water circulating pumps (electric):

There are three of these, of the same horizontal centrifugal type as the cold water house pumps, except that they handle hot water and will be manually controlled. They are placed on valved by-passes from the return circulation main of the system which they are to serve, one for general, one for kitchen and one for laundry service.

(*j*) Ejectors (air operated):

Two reconditioned existing duplex heavy cast iron ejector pot units are reset in the ejector pit, one for general and one for laundry service. Two new duplex pot units are also provided and set on the 3rd basement floor, one at the north and one at the south end of the building; they will serve the general fixtures from 2nd basement to ground floor inclusive. Each pot has its inlet and outlet guarded with a check valve. The moving power is compressed air supplied by motor driven compressors and introduced through an air valve operated by a bell-shaped float so set that the pots alternate in their discharge. Each pot has a silencer, and an adequate size ejector air relief riser run up to and above the main roof.

(*k*) Air compressors:

The existing horizontal direct single action compressors with their belt connected motors, have been reconditioned, and placed at the south end of the 3rd basement, together with one new compressor, one old air receiving tank, and one new tank.

A combined compressed air discharge main will deliver air from the receiving tank to all sewage ejectors.

If compressed air is required later for dental units, small compressors serving one or two chairs will be installed near them.

(*l*) Plumbing fixtures:

These are of normal type, the majority of Canadian manufacture, some from Great Britain and a few of foreign make.

General

It would be well to emphasize the fact that to prevent any possibility of danger or nuisance from vent openings at a low level, all vent, soil and relief risers are extended to end above the main roof level.

All leaders are carefully offset every 8 to 10 storeys to prevent abrasive action at base from fall of storm water carrying grit from roof surfaces. Cushion legs were specified at base of leaders where last drop was ten storeys more or less, but were later omitted.

The flushing rim toilet room floor-drain wastes discharge into large copper funnels, each funnel having a 4-inch trapped and vented waste discharging through the low level drain system to the sump.

No main house traps with fresh air inlets or breathers are permitted by the city of Montreal by-laws, and therefore none have been installed.

No globe valves are used unless they come with some special fixture or apparatus already designed to function with such valves.

In conclusion, the author would remark that in the construction and equipment of this great building, said to be the largest in the British Empire, an endeavour has been made to obtain the best in design, workmanship and material that can be put into its creation, and he believes that no effort has been spared to attain that end.

Report of Council for the Year 1930

In presenting the annual reports for 1930 the Council would point out that although industrial conditions during the year have been somewhat adverse, the activities and services of The Institute have been satisfactorily maintained. The number of branch meetings, and the attendance at them, particularly in the case of the larger branches, has been gratifying, and from the branch news items published in The Journal it is evident that the branches in their activities have well kept in view the acquirement and interchange of professional knowledge, which is one of the main objects of The Institute. But, as will be seen from the committees' reports, it has not been possible to develop the work of The Institute along certain desirable lines, for Headquarters' expenditure has been strictly limited, and in some instances has had to be curtailed.

An outstanding event of the year has been the negotiation of an arrangement with the Council of The Royal Aeronautical Society for co-operation between that body and The Institute. This agreement provides that Aeronautical sections formed by Institute branches will be recognized also as Canadian sections of the Royal Aeronautical Society. Members of these sections will enjoy certain privileges as regards the publications of both bodies, and the arrangement will enable aeronautical engineers in Canada to connect themselves both with their own national organization and with a leading technical society devoted exclusively to the interests of their own branch of engineering work. This constitutes a new and promising departure in Institute policy, for it is hoped that when the scheme has been successfully worked out it may be possible to enter into similarly beneficial relations with other bodies of like standing dealing with other specialized branches of engineering.

A special Committee on the Publications of The Institute was appointed at the Plenary Meeting of Council in October, 1929, and reported at the 1930 Plenary Meeting; a number of its recommendations have already been put into effect, others being necessarily held over for financial reasons. The Plenary Meeting of Council directed the Publication committee to make preparations for the issue of a volume or volumes of Transactions including the principal technical papers contributed to The Institute since the publication of the last volume of Transactions in 1927. It is hoped that funds will be available for this purpose.

The Institute's Committee on Classification and Remuneration, appointed in April, 1930, has continued its work, and has studied the information obtained from some 1,200 of The Institute's members. Their report on this work is now before Council, together with a second report on the question of professional fees; the latter is now presented to the Annual Meeting.

In view of the fact that The Institute's membership during the past five years, while fluctuating, has shown no definite increase in numbers, a Committee on Membership was appointed at the Plenary Meeting of Council in September last, and is now studying the situation, particularly as regards the desirability of co-ordinating the methods of the branches in the recruitment of new members, especially from among recent graduates from Canadian engineering schools. In the opinion of Council a definite policy should be adopted in regard to this important question, which in the past has been left largely to the individual action of the various branch executive committees.

In regard to the relations between The Institute and the provincial associations of professional engineers, a subject which received considerable attention at the last Annual Meeting and at the recent Plenary Meeting of Council, it may be noted that certain suggestions of The Institute's committee as to the formation of a National committee were then outlined, and have been placed before the Councils of the various associations. The governing bodies of some of these have already concurred with the suggestions, and they are still under consideration by others. Pending the formation of the proposed National committee, it is hoped that the associations will permit The Institute's committee to save time by arranging for the collection of preliminary data regarding the present requirements for admission, etc., to the various associations. Progress in this important matter is necessarily slow, as each step involves obtaining the agreement and approval of nine separate bodies.

The work of The Institute's Employment Service Bureau has been actively continued during the year, and would be greatly assisted if a larger proportion of our members would furnish recent particulars of their careers by registering with the Bureau. During the first six months of 1930, employment conditions, while somewhat less favourable than in 1929, were not markedly so, but during the latter half of the year there has been a considerable falling off in the number of placements effected. This is due partially to seasonal causes, but largely also to the reduction which has taken place in the staffs of a number of our larger companies employing engineers.

There has been a gratifying increase in the extent to which members have used The Institute's library and information service at Headquarters. The Engineering Index, to which The Institute is and has been a subscriber for many years, makes it possible to advise members of the latest technical information appearing on any given engineering subject in a list of nearly two hundred technical periodicals in all the principal countries in the world.

The only amendments to the By-laws proposed this year by Council affect sections 66 and 67, dealing with the constitution of the Nominating committee. Council's proposal is intended to make the Nominating committee a more efficient body than at present, and to insure that in every case the Nominating committee, before preparing its list of nominees, shall obtain the opinions of the several branch executive committees as to the nominees they would recommend. The Nominating committee now consists of twenty-six members scattered all over Canada, and under the present arrangement its work must necessarily be carried on entirely by correspondence. Further, it is at present not compulsory for a member of the Nominating committee to consult his branch executive committee when putting forward a candidate or candidates.

The amendment to section 34, dealing with an increase in members' annual fees, which was proposed by Council in 1929 and again in 1930, has twice been rejected by the membership on ballot. Accordingly, while still urging that an increase in members' fees is inevitable if the work of The Institute is to develop as it should, Council has not thought it advisable to present this amendment again this year. There is, therefore, no possibility of increased revenue from members' fees during 1931-1932 unless the number of our members increases.

During the past year the deaths of an unusually large number of The Institute's members have been recorded, the list including no less than eleven of the senior members who joined the Canadian Society of Civil Engineers on its original formation in 1887. The names of such prominent members as C. E. W. Dodwell, Hon.M.E.I.C., Henry Holgate, M.E.I.C., Past-President R. W. Leonard, M.E.I.C., H. M. MacKay, M.E.I.C., W. F. McKnight, A.M.E.I.C., G. F. Porter, M.E.I.C., and F. L. Wanklyn, M.E.I.C., would partially indicate the extent of the loss sustained by The Institute.

The Fourth Plenary Meeting of Council was held at Headquarters on September 22nd, 23rd and 24th, 1930, when an attendance of thirty-three members of Council made it possible to discuss fully many important points of policy. The proceedings are reported in the Engineering Journal for November, 1930, pages 643 to 649

The Forty-fourth Annual General and General Professional Meeting was held in Ottawa on February 12th, 13th and 14th, 1930, and its marked success was principally due to the well organized activities of the Ottawa Branch Executive committee and members.

Canadian engineering achievement was well represented at the Second World Power Conference held in Berlin in June, 1930, and the Dominion was honoured by the selection of Dr. O. O. Lefebvre, M.E.I.C., as chairman of one of the sections. The Canadian contribution to the literature of the Conference consisted of a series of seven papers on Canadian engineering topics, all by prominent members of The Institute. These were published in the July number of The Engineering Journal.

At the Plenary Meeting of Council it was decided to establish eleven Engineering Institute of Canada Prizes, one at each of the principal engineering schools of the country, and these have been gratefully accepted by the governing bodies of the institutions concerned. It is hoped that these prizes will prove of marked benefit to the cause of engineering education in Canada.

Meetings

Annual General Meeting

The Forty-fourth Annual General and General Professional Meeting was held at Headquarters in accordance with the By-laws on Thursday, January 23rd, 1930, at 8 o'clock p.m., with Councillor O. O. Lefebvre, M.E.I.C., in the chair. After the approval of the minutes of the Forty-third Annual General Meeting and the appointment of the scrutineers and the auditors, the meeting was adjourned, to reconvene at 10 o'clock a.m., on Wednesday, February 12th, 1930, at the Chateau Laurier, Ottawa, Ontario.

On February 12th, the adjourned meeting duly took place, with President C. H. Mitchell, M.E.I.C., in the chair. The Nominating committee for 1930 was appointed, and a message from the Hon. Charles Stewart, Minister of the Interior, was presented, inviting The Institute to participate in the Canadian representation at the Second World Power Conference to be held in Berlin in June, 1930.

The medals and prizes of The Institute were then presented to the various recipients, and the meeting proceeded to discuss the Report of Council for 1929, the reports of the various committees, and the branch reports. Prolonged discussion took place on the report of the Committee on the Relations of The Institute with the Provincial Associations of Professional Engineers, outlining a course of action with a view to ultimate confederation of the various bodies concerned. The report was adopted, and the committee was authorized to place the suggestions it contained before the governing bodies of the various associations.

After discussion of Council's proposals for amendments to the By-laws, President C. H. Mitchell delivered his valedictory address, for which he received a hearty vote of thanks. The scrutineers' report was next presented, and the officers for 1930 were declared elected.

The newly-elected President, A. J. Grant, M.E.I.C., was then conducted to the chair, and after a brief address from Mr. Grant, and votes of thanks to the retiring President and Council for their services during 1929, and to the Ottawa Branch for their successful efforts in connection with the Annual Meeting, the business proceedings terminated.

General Professional Meeting

The technical sessions of the General Professional Meeting took place on February 13th and 14th, when a series of papers were presented and discussed, dealing principally with the work of engineers in the government service in connection with communication, transportation and the development of the natural resources of the country. An interesting demonstration of the operation of mechanical transport vehicles across country in snow was arranged by the Department of National Defence. The social features of the meeting included a luncheon on the 12th, at which a vigorous address was delivered by Sir Henry Thornton, M.E.I.C., President of the Canadian National Railways; a luncheon on the following day when Dr. H. M. Tory, President of the National Research Council, spoke on "The Place of Research in Canada," and the Annual Dinner of The Institute on the 14th, at which the principal speakers included the Hon. C. A. Dunning, Minister of Finance, the Hon. Charles Stewart, Minister of the Interior, and the Hon. T. A. Crerar, Minister of Railways and Canals. Through the kindness of the Gatineau Power Company a large party of members and visitors were conveyed to Paugan falls and inspected this very interesting power development. One of the outstanding events of the meeting was the reception and ball held on the evening of the 13th, which Their Excellencies the Governor-General and Viscountess Willingdon honoured with their presence, and which proved perhaps the most popular function of all.

Roll of The Institute

During the year 1930, two hundred and eighty-three candidates were elected to various grades of The Institute. These were classified as follows: nine Members, forty-four Associate Members, forty-six Juniors, one hundred and eighty-one Students, and three Affiliates. The elections during the year 1929 totalled one hundred and seventy-six.

Transfers from one grade to another were as follows: Associate Member to Member, twelve; Junior to Member, one; Junior to Associate Member, fifty-six; Student to Associate Member, forty-one; Student to Junior, thirty-five; Student to Affiliate, two; Affiliate to Junior, one; a total of one hundred and forty-eight.

The names of those elected or transferred are published each month immediately following the election.

Removals from the Roll

There have been removed from the membership roll, during the year 1930, for non-payment of dues, and by resignation, fifteen Members, forty-nine Associate Members, thirty-seven Juniors, ninety-two Students, and two Affiliates, a total of one hundred and ninety-five.

Twelve reinstatements were effected, eleven Life Memberships were granted, and twenty-four members were placed on the Suspended List.

Deceased Members

During the year 1930 the deaths of fifty of The Institute's members have been reported as follows:—

Honorary Member

Dodwell, Chas. E. W.

Members

Armour, Robert	Goulet, J. A. Godefroy
Balfour, Francis Henry	Handy, Henry Francis Troughear
Bowman, Henry Alexander	Hart, Percy Edward

Warren, William Robert

JUNIOR

Williams, Stephen

STUDENTS

Doberer, Cameron
Mules, Nathan Ernest

TOTAL MEMBERSHIP

The membership of The Institute as of January 1st, 1931, totals four thousand six hundred and ninety-one. The corresponding number for 1929 was four thousand six hundred and eighty-three. These figures do not include members who have been placed on the Suspended List, or those who have not yet accepted election.

The details are as follows:

1930		1929	
Honorary Members	9	Honorary Members	10
Members	1,104	Members	1,124
Associate Members	2,309	Associate Members	2,248
Juniors	444	Juniors	468
Students	769	Students	780
Affiliates	56	Affiliates	53
	4,691		4,683

Respectfully submitted on behalf of the Council,

A. J. GRANT, M.E.I.C., *President.*
R. J. DURLEY, M.E.I.C., *Secretary.*

Finance Committee

The President and Council,—

In its report to Council last year your committee pointed out that The Institute's present income per member is much lower than in other technical societies affording comparable services to their members, and that in 1930 The Institute's expenditure would have to be curtailed in certain important respects unless the increase in members' fees, then proposed, received approval. That approval was not given, and, accordingly, it has been necessary to discontinue certain desirable activities. The financial statement now presented indicates the principal items on which money has been saved in this way. The Secretary's visits to many of the branches have had to be omitted, and no professional meetings, other than the general pro-

fessional meeting, have been held. Fortunately, there were no unforeseen expenses of any serious amount during 1930, and the revenue from advertising has been maintained, so that The Institute's total income for 1930 was practically the same as in 1929. There seems no prospect of any material increase of income for 1931.

At its Plenary Meeting in September, 1930, Council directed that certain expenditures be undertaken connected with the issue of Transactions free of cost to members; the establishment of eleven students' prizes to be awarded annually by the principal engineering schools of Canada; visits to branches by vice-presidents; co-operation with the Royal Aeronautical Society, and the work of the Committee on the Relations of The Institute with the Professional Associations. It is estimated that these items will require an expenditure of about $4,000. during 1931.

At the same meeting certain recommendations by the Special Committee on the Publications of The Institute were put in effect, with a view of economizing in the cost of The Journal by omitting the Engineering Index, and augmenting the advertising revenue by an increase in rates. It seems unlikely that these measures will yield more than $1,500 during the year.

Further suggestions by the Special Committee, which were endorsed but not adopted by the Plenary Meeting, recommended the publication of engineering abstracts; additional assistance in the editorial department at Headquarters; the holding of three regional professional meetings each year, and other very desirable features which would require a further outlay of about $10,000 annually.

Your committee draws attention to all these points to show the impossibility of further developing The Institute's work under present financial conditions.

In order to take account of present commitments for 1931 there has been included in the financial statement a reserve of $2,500 against part of the cost of the publication of Transactions, on which preliminary work has already commenced. Apart from this item the statement shows a practical balance between receipts and disbursements.

The accounts of members in arrears have been closely scrutinized, and appropriate action taken in each case, allowance having been made in instances where satisfactory explanations have been furnished. It will be noted that the amount of arrears of fees collected during the year has been less than in 1929, this being in accordance with the estimate in your Committee's report of last year.

Respectfully submitted,
G. R. MacLeod, m.e.i.c., *Chairman.*

Nominating Committee, 1931

Appointments to the Nominating committee for the year 1931 have been made by the various Branches, and the chairman has been appointed by Council, as shown on the following list, which is now presented for announcement at the Annual Meeting in accordance with the By-laws:—

Chairman: P. S. Gregory, m.e.i.c.

Branch	*Representative*
Halifax Branch	H. W. L. Doane, M.E.I.C.
Cape Breton Branch	K. H. Marsh, M.E.I.C.
Saint John Branch	J. P. Mooney, A.M.E.I.C.
Moncton Branch	G. L. Dickson, A.M.E.I.C.
Saguenay Branch	G. F. Layne, A.M.E.I.C.
Quebec Branch	P. Méthé, A.M.E.I.C.
St. Maurice Valley Branch	C. H. Jetté, A.M.E.I.C.
Montreal Branch	P. E. Jarman, A.M.E.I.C.
Ottawa Branch	W. D. McLachlan, M.E.I.C.
Peterborough Branch	A. L. Killaly, A.M.E.I.C.
Kingston Branch	W. L. Malcolm, M.E.I.C.
Toronto Branch	R. O. Wynne-Roberts, M.E.I.C.
Hamilton Branch	W. L. McFaul, M.E.I.C.
London Branch	F. C. Ball, A.M.E.I.C.

Victoria Branch	J. C. MacDonald, M.E.I.C.

Sir John Kennedy Medal

At the meeting of Council held on October 17th, 1930, it was decided to award the Sir John Kennedy Medal for the year 1930 to George Herrick Duggan, m.e.i.c. This distinction is the highest in the gift of The Institute.

Past-Presidents' Prize Committee

The President and Council,—

It is the unanimous opinion of your Committee that the Past-Presidents' Prize for 1929-30 should be awarded to Group-Captain E. W. Stedman, m.e.i.c., for his paper on "Rigid Airships," duly submitted for the prize and published in The Engineering Journal for February, 1930.

Respectfully submitted,
Chas. M. McKergow, m.e.i.c., *Chairman.*

Gzowski Medal Committee

The President and Council,—

Your Committee, having studied all of the papers eligible for consideration for the award of the Gzowski Medal for the prize year 1929-30, has decided to take advantage of the opportunity afforded by the fact that no medal was awarded last year, to award two medals this year, as follows:—

1. To F. M. Wood, a.m.e.i.c., for his paper "A Short Monograph on Nomography."
2. To P. B. Motley, m.e.i.c., for his paper "Reinforcement in Place of the Stoney Creek Arch Bridge."

The decision to make the above noted awards was a unanimous one on the part of the members of the Committee, but it was not arrived at without a considerable amount of discussion with respect to the relative merits of the papers under consideration, among which there were several of outstanding interest.

While this has made the work of the Committee extremely difficult, it is our feeling that The Institute is to be congratulated on the fact that it has been able to publish so many very excellent papers during a single medal year. Furthermore, we feel that The Institute is very much indebted to the authors of these very excellent papers.

Respectfully submitted,
W. C. Adams, m.e.i.c., *Chairman.*

Leonard Medal Committee

The President and Council,—

The proceedings of The Engineering Institute of Canada during the medal year 1929-30 did not contain any suitable papers, leaving, therefore, for consideration only papers presented to the Canadian Institute of Mining and Metallurgy and the Mining Society of Nova Scotia.

Your Committee unanimously recommend the following awards:—

1. The Gold Medal to C. G. McLachlan for his paper on "Twelve Months' Milling at Noranda"—C.I.M.M. Bulletin, February, 1930.
2. A Silver Medal to W. B. Boggs for a paper on "The Noranda Smelter"—C.I.M.M. Bulletin, March, 1930.
3. A third prize of books to A. E. Flynn for his paper on "Anhydrite Plasters and Cements"—C.I.M.M. Bulletin, June, 1930.

Last year your Committee was unable to recommend award of the medal because no paper of outstanding merit had been contributed to either Institute during the period under review; but this year we are glad to be able to avail ourselves of the privilege given by the rules to make the three awards above mentioned.

The Committee desires to express its opinion of the outstanding merit of a paper by the late Walter Herd, M.E.I.C., on "Bumps in No. 2 Mine, Springhill, Nova Scotia," which appeared in the September, 1929, bulletin of the Canadian Institute of Mining and Metallurgy, having previously by arrangement been presented to the American Institute of Mining Engineers.

The Committee also desires to express its regret at the recent death of the distinguished donor of the medal, Colonel R. W. Leonard, M.E.I.C., of St. Catharines, Ontario.

Respectfully submitted,

F. W. GRAY, M.E.I.C., *Chairman.*

Plummer Medal Committee

The President and Council,—

Your Committee, having examined the various papers published in The Engineering Journal during the medal year 1929-30 dealing with chemical and metallurgical subjects, is of the opinion that none of these are of sufficient merit to justify an award of the Plummer Medal for the past year.

Respectfully submitted,

J. R. DONALD, M.E.I.C., *Chairman.*

Students' and Juniors' Prizes

The reports of the examiners appointed in the various zones to judge papers submitted for the prizes for Students and Juniors of The Institute, were approved by Council at its meeting on January 20th, 1930, and make the following announcements:—

H. N. Ruttan Prize (Western Provinces)—No award; one paper received.

John Galbraith Prize (Province of Ontario)—No award; no papers received.

Phelps Johnson Prize (Province of Quebec, English)—To G. B. Jost, S.E.I.C., for his paper on "Steel Mitering Lock Gates on the Welland Ship Canal."

Ernest Marceau Prize (Province of Quebec, French)—No award; no papers received.

Martin Murphy Prize (Maritime Provinces)—No award; no papers received.

Library and House Committee

The President and Council,—

The information service at Headquarters has been well utilized, over eight hundred inquiries having been dealt with during the year. Twenty-eight bibliographies have been prepared, and two hundred and fifty-two pages of photostats have been supplied to members requiring copies of technical articles.

Accessions to the library during the past twelve months number 804, including several valuable sets of early technical periodicals presented by members, all of which have been duly acknowledged.

Necessary minor repairs have been made to The Institute premises, but no extensive work of this nature was needed during the year.

Respectfully submitted,

J. L. BUSFIELD, M.E.I.C., *Chairman.*

Publication Committee

The President and Council,—

The Publication committee wishes to submit the following report:—

In accordance with the decision of Council at its Plenary Meeting to publish Transactions this year, your committee was instructed at the meeting of October 17th to review the papers published in The Engineering Journal during the years 1926-1930 inclusive and to make a recommendation as to their inclusion in the new volume or Volumes of Transactions and as to the arrangements necessary for their publication.

Owing to the amount of material to be reviewed, covering, as it does, publications in The Journal for five years, your committee has not had sufficient time to complete its work but hopes to have its recommendations ready for submission to Council in the near future.

Respectfully submitted,

J. A. McCRORY, M.E.I.C., *Chairman.*

Legislation Committee

The President and Council,—

No questions regarding legislation were submitted during the past year.

In accordance with your instructions, your committee considered and reported upon the changes required in sections 66 and 67 of the By-laws to embody Council's proposal for a modification in the constitution of the Nominating committee, and these suggestions have been duly circulated to the membership.

Respectfully submitted,

J. L. BUSFIELD, M.E.I.C., *Chairman.*

Board of Examiners and Education

The President and Council,—

The results of the examinations held during 1930 for admission to The Institute are as follows:—

	Examined	Passed	Failed
For admission as Student (Schedule A)	1	..	1
For admission as Junior (Schedule B)	2	1	1
For admission as Associate Member (Schedule C):			
Electrical Engineering	3	2	1
Civil Engineering	2	2	..
Structural Engineering	3	2	1
	—	—	—
	11	7	4

While the proportion of candidates who satisfied the examiners is larger than last year, some of them have only succeeded after more than one trial.

Your Board would again draw attention to the difficulty which non-university applicants experience in preparing for The Institute's examinations. Practically all of these men are earning their living, and the opportunities in Canada (even in our larger cities) for obtaining advanced engineering instruction by attending evening classes are almost non-existent. The technical schools in Montreal, Toronto, Hamilton or elsewhere are admirable, but their efforts are necessarily directed along more elementary lines than those necessary for our examinations, and they do not give sufficiently advanced work in mathematics or physics. The various correspondence schools labour under obvious disadvantages and are of comparatively little assistance. There would seem to be a real need in this country for facilities such as are available in Britain, enabling a man, who is willing to give up the necessary time to evening study, to prepare himself for the engineering degrees of universities, such as London, Glasgow, and others.

Cannot The Institute do something to remedy this condition, possibly through the influence of its committee on Engineering Education?

Respectfully submitted,

C. M. McKERGOW, M.E.I.C., *Chairman.*

Committee on Engineering Education

The President and Council,—

Your committee on Engineering Education made specific suggestions in its report of a year ago, which were laid before the annual meeting, adopted with the exception of clause No. 4, and referred back to the committee for action, the committee being requested to give further consideration to this item. These recommendations were:—

1. The formation of a more intimate bond between The Institute and engineering universities throughout Canada, in order that The Institute may be in a position to advise on engineering education through its older and most successful members.
2. That steps be taken whereby The Institute becomes the definite agency—the active connecting medium —between engineering universities and industry.
3. That a study be made by a committee on technical education in its relation to industry and to the engineering profession.
4. That immediate steps be taken by conference with university heads with a view to adopting a six year course for engineers, or a much higher matriculation standard.
5. That the universities be urged to give consideration to giving additional time on the curriculum to public speaking and literature.
6. That immediate steps be taken leading to the formation of student branches of The Institute or student affiliations in every engineering university in the Dominion.

In order that a more definite contact be established with the universities, the committee was reorganized and constituted with the following members:—

Fraser S. Keith, M.E.I.C., *Chairman*
R. W. Brock, M.E.I.C.
C. V. Corless, M.E.I.C.
F. R. Faulkner, M.E.I.C.
E. P. Fetherstonhaugh, M.E.I.C.
A. Frigon, A.M.E.I.C.
W. J. Johnston, A.M.E.I.C.
H. M. MacKay, M.E.I.C.
C. J. Mackenzie, M.E.I.C.
C. H. Mitchell, M.E.I.C.
John Stephens, M.E.I.C.
R. S. L. Wilson, M.E.I.C.
A. R. Decary, M.E.I.C.

Since that time the members of the committee have had under discussion ways and means of putting into effect the recommendations of the previous committee.

Your committee acknowledges with gratitude the action of Council in again selecting as the title for the Past Presidents' Prize "Engineering Education in Canada," and it is the hope of your committee that valuable suggestions will be received. It is planned during the coming year to further discuss the problem and to give more definite effect to the desired end whereby The Institute may achieve a more definite leadership in the realm of engineering education.

Respectfully submitted,

Fraser S. Keith, M.E.I.C., *Chairman.*

Employment Service Bureau

The President and Council,—

The work of the Employment Service Bureau has been actively carried on during the year, but has naturally been affected by the slackening in engineering activity which has made itself felt to an increasing degree during the last six months. Employment conditions for engineers, however, do not appear to have been so unfavourable as in many other lines of endeavour. It is noteworthy that more than fifty per cent of those registering with the Bureau at present are non-members of The Institute, which would seem to indicate either that there are a comparatively small number of our members who are looking for positions, or that members are not so quick as outsiders in realizing the advantages of the service which The Institute offers.

As compared with 1929, there has been a considerable decrease in the proportion of replies received from employers to advertisements in the E-I-C. News, and a similar decrease in the number of positions available.

The number of placements of which definite information has been obtained during the year is 57, but, as pointed out in last year's report, only a small proportion of those obtaining positions notify us of the fact, so that the actual number of men placed must be considerably larger.

Our records are as follows:—

		1930 (12 months)	1929 (17 months)
Number of registrations:			
Members	127		
Non-members	180		
	——	307	345
Members advertisements published in E-I-C. News		160	183
Replies received from employers		70	392
Vacant positions registered		180	486
Vacancies advertised		103	
Replies received to advertised vacancies		754	1,699
Men notified of vacancies		114	347
Records forwarded to prospective employers		190	382

The work has included over 500 personal interviews with members and non-members seeking advice and employment, as well as correspondence with employing firms and others. The principal need of the Employment Bureau is the devotion of more time to its work, and better contact with possible or prospective employers. The E-I-C. News is mailed to a considerable list of employing organizations but this cannot take the place of personal communication which is particularly desirable at a time like the present. The requirements for further development of the Bureau work were clearly described in the report of the Service Bureau Committee for last year, but it has not been possible to provide for them.

Respectfully submitted,

R. J. Durley, M.E.I.C., *Secretary.*

Committee of International Co-operation

The President and Council,—

During the year 1930 there were two important opportunities for contact between members of The Institute and European technical bodies — the meeting of the Second Plenary World Power Conference in Berlin from June 5th to 16th, and the Plenary Meeting of the International Electrotechnical Commission in Scandinavia in July.

More than four thousand delegates attended the first named conference and were welcomed by the German Chancellor on behalf of President Hindenburg, who pointed out that "engineering is about to exercise greater influence than ever upon the economic life of the peoples and to establish a closer connection than ever before between their economic systems." The Canadian delegation included the following prominent engineers:

Charles Camsell, M.E.I.C., Deputy Minister, Department of Mines, Chairman Canadian National Committee.

John Murphy, M.E.I.C., Electrical Engineer, Department of Railways and Canals and Board of Railway Commissioners. Vice-Chairman Canadian National Committee.

F. A. Gaby, M.E.I.C., Chief Engineer, Hydro-Electric Power Commission of Ontario, Toronto.

O. Lefebvre, M.E.I.C., Chief Engineer, Quebec Streams Commission, Montreal.

T. H. Hogg, M.E.I.C., Chief Hydraulic Engineer, Hydro-Electric Power Commission of Ontario, Toronto.

G. Gordon Gale, M.E.I.C., Vice-President and General Manager, Gatineau Power Company, Ottawa.

A. B. Normandin, A.M.E.I.C., Hydraulic Service, Department of Lands and Forests, Quebec.

Hon. F. P. Burden, Minister of Lands, Victoria, B.C.

R. G. Gage, M.E.I.C., Chief Electrical Engineer, Canadian National Railways, Montreal.

G. A. Gaherty, A.M.E.I.C., President, Calgary Power Company, Calgary.

deGaspe Beaubien, M.E.I.C., Consulting Engineer, Montreal.

John Morse, M.E.I.C., Shawinigan Water and Power Company, Montreal.

J. B. McCarthy, Consulting Engineer, Montreal.

J. G. Glassco, General Manager, Winnipeg Hydro System, Winnipeg, Man.

A striking outcome of the conference, perhaps in direct opposition to popular belief, was the contention that the wider development and use of power must eventually reduce unemployment. Officials of the conference issued the following statement:—"Power, from year to year, multiplies the methods by which raw materials are transformed into finished products. New methods create new possibilities of work. New methods require new products for carrying them out, and the markets for the products of labour are thus increased. During the last one hundred and fifty years, 'the machine age,' the increase in the possibilities of work has been much greater than the reduction of the demand for physical labour—if it were otherwise the population of the civilized world could not have increased as it has."

In regard to the conference itself, conference officials said "The most important result of the conference lies in the fact that so many experienced specialists from all over the world have come into personal contact. Quite apart from the value which this has for the individuals and for the organizations to which they belong, it has served to bring the nations into closer touch."

In Scandinavia, the business programme of the International Electrotechnical Commission consisted of an attempt at securing unanimous decisions in regard to the standardization of the following matters, which have been in the hands of the various national committees for many years, namely:—

1.	Nomenclature	United States Committee.
2.	Rating of Machinery	British "
3.	Symbols	Swiss "
5.	Steam Turbines	United States "
6.	Lamp Caps and Holders	Central Office.
7.	Aluminum	Central Office.
8.	Voltages and Insulators	Italian Committee.
9.	Electric Traction Equipment	French "
10.	Insulating Oils	Central Office.
11.	Overhead Lines	Belgian Committee.
12.	Radio-communications	Dutch "
13.	Measuring Instruments	German "
14.	Rating of Rivers	United States "
15.	Shellac	British "
16.	Terminal Markings	Dutch "
17.	Oil Switches	Swedish "
19.	Internal Combustion Engines	United States "

The work of the Committee on Overhead Lines was of special interest. A comparison of practices throughout the world, which was made at Stockholm, showed that in no country was more being done to further the cause of safety than in Canada.

Canada has never taken as much interest in the International Electrotechnical Commission, in its work and its meetings, as her position in the power world warrants. Specialists in the many branches enumerated above should take an active part in the commission's meetings, and aid in the work of the Canadian National Committee.

A memorable opportunity for international contact occurred at the Fiftieth Anniversary celebrations of the American Society of Mechanical Engineers on April 5th to 9th, in New York, Hoboken and Washington. At these, The Institute was represented by Past-President C. H. Mitchell, M.E.I.C., and President A. J. Grant, M.E.I.C., the former contributing a monograph covering the development of engineering work in Canada which formed part of a series covering the humanistic aspects of engineering in all the principal industrial countries in the world. Celebrations of this kind are events of international significance interpreting the social and economic influence of engineering on civilization.

Respectfully submitted,

John Murphy, M.E.I.C., *Chairman.*

Report of the E.I.C. Members of the Main Committee of the Canadian Engineering Standards Association

The President and Council,—

The Institute nominees on the Main Committee of the Canadian Engineering Standards Association are now as follows:—

P. L. Pratley, M.E.I.C., retires March, 1931.
C. J. Mackenzie, M.E.I.C., retires March, 1932.
J. M. Oxley, M.E.I.C., retires March, 1933.

Mr. Oxley has succeeded F. B. Brown, M.E.I.C.

Satisfactory progress has been recorded during the year, one of the chief features being the continuance of financial support from industrial interests. All but two of last year's sustaining members have renewed their subscriptions and seven additional memberships have been listed. The total number of sustaining members is now seventy-five and the total amount subscribed for the year is $6,600. In the face of the prevailing industrial depression this is most encouraging.

Co-operation from the press and technical publications has been very helpful, one of the features being the publication of an article by the Secretary in the special research number of "Industrial Canada." A descriptive article on the Canadian Engineering Standards Association also appeared in the "Commercial Standards Monthly" issued by the Bureau of Standards at Washington.

The sale of specifications is steadily growing and they are being used more and more by different government departments, municipal authorities and purchasing departments of industrial firms. An interesting feature has been the purchase of complete sets of specifications by individual firms.

The fourth Year Book of the association was issued in April and has been widely circulated. The Quarterly Bulletin is increasing in usefulness as a medium of disseminating information on the work of the association.

Six publications have been issued during the year, in all cases revised editions of previous specifications. A description of these publications follows:

B18-1930. This constitutes an Established List of Stove Bolts, similar to the Established List of Machine Screws published in 1929, and is a revision of the old specification B18-1925. The revision consists of a rearrangement of the data and there has been no radical change.

A16-1930, Standard Specification for Steel Structures for Buildings. This constitutes the second edition of the specification which was originally published in 1924. The chief items cover the raising of allowable unit stress for axial tension from 16,000 pounds to 18,000 pounds per square inch; the revising of the column formula, and other revisions to conform with the latest C.E.S.A. Specifications for Steel Railway and Steel Highway Bridges. Provisions for snow load on roofs and wind load have also been revised.

C22-1930, Canadian Electrical Code, Part I. This second edition was issued in January and contains many radical revisions which were made by the Code committee. Section 2, covering general rules, has been rearranged. Section 5, covering wiring methods, has been condensed, and Section 32, covering, hazardous locations, has been considerably rearranged. Section 8 has been expanded to take in additional rules concerning motors. In Section 6, conductors, rules have been added covering demand factors and wattage of outlets. Former Sections 33, garages, and 34, motion picture studios, have now been incorporated in Section 32, hazardous locations. Section 35, motion picture projectors and equipment, has been incorporated in Section 39, theatre installations. Many other revisions have been made and all material in the former edition which was not purely electrical has been deleted as far as possible. The book contains a cross-reference list so that the two editions may be readily compared.

G30-1930, Standard Specification for Billet-steel Reinforcing Bars. G31-1930, Standard Specification for Rail-steel Reinforcing Bars. G32-1930, Standard Specification for Steel Wire for Concrete Reinforcement. These constitute a revised edition of the former specification A9-1923 covering Reinforcing Materials for Concrete. It has been decided to reclassify these under Ferrous Metals, rather than under Civil Engineering and Construction, and a publication has been issued covering each type of reinforcing material. The specifications have been brought up-to-date in accordance with the latest practice and a feature of the first two publications is a supplement covering an established list of sizes for round and square reinforcing bars which provides a practical range of area for use in design. The use of the table by architects and designing engineers is strongly recommended.

Work in Progress

Civil Engineering and Construction

Wood Piles and Wood Pile Driving. The committee has had two meetings and a first draft of a specification is now under revision. It is hoped to include as much educational material as possible in this specification.

Mechanical Work

Cast Iron Pipe. No further progress has been made on this specification, as it has been deemed advisable to await information on experimental work which is now being carried on.

Screw Products. Under the Committee on Screw Products, four panels have been organized dealing with (1) Cap and set screws, studs, etc. (2) Machine, carriage and plough bolts. (3) Machine screw nuts. (4) Binder head screws. Reports from these four panels have been received and discussed at a second meeting of the Committee and it is hoped shortly to get these reports in form for publication. In this work considerable simplification will be accomplished and it is expected that the established lists which will be issued will be of considerable value to both the manufacturers and users of these products.

Standard Colour Scheme for the Identification of Piping Systems. A committee has been organized and has held its first meeting, at which a panel was appointed to consider available data and make a draft specification. Great interest has been aroused in this project and it is hoped that a useful specification will result.

Standard Connections for Cutting Edges and Mouldboards on Road Grading Machinery. A committee is now being organized to consider this question with the object of obtaining uniformity throughout Canada. A tentative scheme has been presented and this will be the basis for the proposed specification.

Electrical Work

Power Transformers. Comments on the second draft of this specification and also a special report from the panel of the committee, have been circulated to the members of the committee, and it is hoped to prepared a final draft very shortly. It has been held in the meantime for a report from the panel which is considering transformer bushings.

Transformer Bushings. A panel of the Committee on Transformers is considering the standardization of transformer bushing connections and held its first meeting during the year, at which the matter was thoroughly discussed. A sincere endeavour will be made to secure uniformity, and it is hoped to have a second meeting of the panel very shortly.

Transformer and Switch Oil. A summary of replies to the questionnaire which was sent out to the committee, asking for information on specifications, was sent out for comment, and a summary of the comments was also sent to the committee, which held its second meeting during the year. After considerable discussion a small panel was appointed, consisting of a representative of the power users, the transformer manufacturers and the oil interests. This panel will endeavour to frame a draft specification which will be duly submitted to the committee for comment.

Lead-Covered Power Cable. A committee is being organized to discuss a specification for this material, and it is hoped to have a preliminary meeting of this committee very shortly.

Canadian Electrical Code, Part II, covering Specifications for Electrical Apparatus. The draft specification covering Power-Operated Radio Devices has been circulated to the members of the Panel on Specifications. A meeting of this Panel was held during the year at which representatives of the Radio Manufacturers Association were present, and many revisions were decided upon. It is hoped to issue a revised draft shortly. A specification dealing with Electric Signs is now being prepared and will shortly be sent to the members of the Panel for comment.

Canadian Electrical Code, Part III, Outside Wiring Rules. Several meetings of the sub-panels have been held during the year, but it has been found rather difficult to make rapid progress. It is now proposed to reorganize the sub-panel on Grounding and Conductive Co-ordination, so that the questions concerning grounding will be assigned to the Grounding Panel which operates under the Code Committee.

Useful contacts have been established with industrial associations, the Secretary having addressed the Kiwanis Club at Lindsay, the Canadian Manufacturers' Association at Toronto, and the Canadian Purchasing Agents' Association at Hamilton. The Secretary also attended, by invitation, conventions of the Canadian Chambers of Commerce at Toronto, the Dominion Fire Prevention Association at Ottawa, American Trade Association Executives at Niagara Falls, the Canadian Electrical Association, and The Engineering Institute of Canada. There is already evidence that these contacts are bearing fruit as some useful suggestions for new work have been received as a result.

Respectfully submitted,

P. L. Pratley, M.E.I.C.
C. J. MacKenzie, M.E.I.C.
J. M. Oxley, M.E.I.C.

Honour Roll and War Trophies Committee

The President and Council,—

During the year 1930 active steps were taken to verify the list of names for the M.E.I.C. War Memorial, covering those who served with units not in the C.E.F. Up to the present, your committee have not been able to verify all the names in connection with the Memorial, but as those on which no confirmation of death is available are now reduced to three, it is the intention to proceed with the construction of the Memorial. It is thought that by leaving space at the bottom of the list of names on the Memorial, arrangements can be made by which a few names can be attached if their confirmation of death is received at a later date.

The total number of names to appear on the Memorial, including the three mentioned above, is one hundred and twenty-two.

Respectfully submitted,

Charles J. Armstrong, M.E.I.C., *Chairman.*

Committee on Tariff of Fees

The President and Council,—

The following schedules have been prepared for the guidance of engineers and clients as a general indication as to what has been found in practice to constitute a reasonable minimum tariff of fees. It is obviously impossible to provide for every contingency, but it is believed that sufficient information is given herewith to enable comparisons to be drawn for situations not actually covered. Judgment must of course be used in application of the various suggestions, as local conditions may quite frequently make desirable and proper serious departures from the schedules.

A:—Per Diem Basis

Ordinary Consultations

For consultations which do not necessitate a written report, the charge to the client shall be established in accordance with the time spent. The basis shall be a professional day of six hours remunerated at the rate of not less than $75.00, although much higher rates may be charged depending on the importance of the work and the standing of the engineer. Charges for fractions of a day shall be made as follows, namely $40.00 for one-half of a day, and for shorter time $25.00 for the first hour or fraction of an hour, depending on the importance of the consultation.

Written Reports, Valuations, Arbitrations, and Expert Testimony

For investigations or study of a project with a preliminary report based on reconnaissance only and not involving detailed surveys and preliminary plans, or for investigations or study of a report prepared by another engineer accompanied by a report on the subject, for study and report on questions in litigations for work as valuator or as arbitrator, or for preparations and depositions before a court of justice or a board of arbitration, or for attendance or evidence in Court during an enquiry, the engineer's fees shall be not less than $75.00 per day although much higher rates may be charged depending on the importance of the work and the standing of the engineer. The client will pay besides the above, all out-of-pocket expenses incurred by the engineer in connection with the work, and shall also pay for all salaries paid for by the engineer to his assistants together with an additional sum equivalent to 100 per cent of the said salaries to cover office and overhead expenses. The client shall deposit with the engineer before the commencement of the investigations an amount equal to the estimated out-of-pocket expenses thereon.

B:—Percentage Basis

The following table and subsequent explanatory remarks outline the recommended minimum schedules for remuneration on the basis of a percentage of the cost of the work.

1	2	3	4	5
Cost of Work not exceeding	Preliminary Work	Preparatory Work	Partial Supervision	Complete Supervision
	$	$	$	$
Minimum fee	100.00	300.00	300.00	700.00
$	%	%	%	%
50,000	2	3	3	7
100,000	1¾	2½	2½	6
200,000	1½	2½	2½	6
500,000	1½	2½	2½	5
1,000,000	1¼	2½	2	4
2,000,000	1	2	2	3½

Explanatory Remarks.

Column 1. The cost of the work shall in the first place be the estimated cost of the project, but in cases where the works proceed to construction the fees shall be in accordance with the total cost of the undertakings, although if a report is made on a major project which finally is only partly completed the fees for all preliminary work shall be based on the estimate of the major project.

Column 2. Preliminary plans, estimates and report. The fees given in this column are for the preparation of a written report on a project with surveys, investigations, studies and conferences, including preliminary plans and estimates of cost.

In addition to the above fees the client shall pay all out-of-pocket expenses incurred by the engineer in connection with the work, and shall also pay for all salaries paid by the engineer to his assistants together with an additional sum equivalent to 100 per cent of the said salaries to cover office and overhead expenses. The client shall deposit with the engineer before the commencement of the investigation an amount equal to the estimated out-of-pocket expenses thereon, and pay to the engineer further sums from time to time as he may request to cover the salaries of assistants actually employed in connection with the project.

Column 3. Preparation of construction plans and specifications. The fees given in this column cover the preparation of construction drawings and specifications necessary for obtaining tenders for the work, and the reporting on such tenders.

Column 4. Partial supervision of construction. In this column are given fees covering partial supervision of the work and comprising consultations at the engineer's office and occasional visits to the works during the normal duration of construction.

Column 5. Complete supervision of construction. The fees in this column cover the complete supervision of the work, comprising consultations at the engineer's office, visits to the works, and in addition the necessary representative of the engineer on the works, the testing of supplies and machinery and the acceptance of machinery or works.

Example. On a project estimated to cost $475,000 the engineer's fee for making the preliminary survey and investigation and reporting thereon will be 1½ per cent of this amount plus the out-of-pocket expenses and overhead referred to above under "Column 1." If the owner then decides to proceed with the work the engineer prepares the construction drawings to enable tenders to be called for, his fee will be 2½ per cent for this part of the work. Finally, if the owner decides to complete the work but only requires a partial supervision from the engineer the fee will be 2½ per cent of the actual cost of the works for this supervision, or, alternatively, if the owner wants the engineer to completely supervise the construction, the fee therefor will be 5 per cent of the actual cost of the works.

This schedule of fees, however, should not be applied to works of the nature of rehabilitation, remodelling, and so forth, as in cases of this sort the actual cost of the works may be a comparatively small amount and yet the engineering work involved may be as great and as responsible as in the original construction of the whole undertaking.

C:—General Conditions

1. A day's work shall be computed as six hours. Nevertheless, when an engineer is obliged to go out of the

city where his office is situated, his fees, when working on the per diem basis, shall be computed for each calendar day at the rate fixed, and each 24 hours or fraction thereof shall be considered as a whole day without taking into consideration the time actually spent on the work each day.

2. The fees of an engineer in case of questions in litigation shall not be contingent on the decisions of the court, and shall be settled by the client immediately after the enquete.

3. For reports, studies, plans and specifications, the client shall pay one-half of the fees of the engineer at the time the engineer will inform him that the preliminary studies have been terminated, and the other half shall be payable upon the delivery of the report or the plans and specifications. Otherwise payments shall be made to the engineer on a monthly basis, and the amount of the payments shall be a reasonable proportion of the estimated monthly proportion of the whole estimated fee based on the estimated length of time for the completion of the works. The balance of any amount due shall be paid promptly by the client on the completion of the works.

4. When it is necessary for special investigations to be made such as borings, tests, soundings, assays or analyses such work shall be carried out at the cost of the client, who shall also pay the engineer the cost of the direction of this particular work in addition to the schedule fee.

5. If the client desires changes in accepted specifications or plans, the engineer shall be entitled to remuneration based upon the necessary delay and time required to alter such plans and specifications either by himself or by his office staff, the said remuneration to be based upon the per diem rates hereinbefore mentioned.

6. In the preparation of specifications and plans or during the supervision of construction, particular problems may arise which may necessitate obtaining additional consulting advice. In such case the fees of the additional consultant, whose engagement must be authorized by the client, shall be directly paid by the client in addition to the fees of the engineer.

7. The actual cost of all travelling expenses and other disbursements incurred by the engineer in connection with the supervision of works, except the salaries, travelling expenses and living expenses of his staff to and from and on the works, shall be paid monthly by the client in addition to the percentage of fees given above.

8. The percentages in the above schedule for supervision during construction are intended to cover the services of the engineer and of his staff during the period ordinarily expected to be covered by such construction, and in the event of delays occurring in the construction, through no fault of the engineer, the engineer's remuneration shall be increased to compensate him for the extra time necessarily spent by him and his staff in supervision, on the basis of the per diem rates for personal services and staff mentioned above.

9. In case of bankruptcy or failure of a contractor on the construction work involving additional works on the part of the engineer over and above that contemplated in his original agreement, or in case any other work may be necessary and not directly relating to the preparation of specifications and plans to the supervision of the work or in case the client and contractor become involved in litigation or arbitration, the client shall reimburse the engineer and his staff on the per diem basis hereinabove mentioned for all additional services required for such purposes.

10. All specifications and plans, and construction documents and data are the property of the engineer. The client is entitled to a copy of plans and specifications for record purposes only and he shall not use any of these for the construction of another project without remunerating the engineer therefor.

Respectfully submitted,

J. L. Busfield, M.E.I.C., *Chairman.*

Committee on Relations of The Engineering Institute of Canada with the Provincial Associations of Professional Engineers

The President and Council,—

During the year the sub-committee appointed to approach the Provincial Associations prepared its recommendations as to the way in which its task should be commenced and these were submitted and discussed at the Plenary Meeting of Council in September last.

In order eventually to bring about a co-ordination of interests and activities of the various professional associations and The Engineering Institute of Canada, the committee were of opinion that a study of the possibilities in this matter should be made by a committee of members nominated by all of the Provincial Associations and The Engineering Institute, and suggested that this committee should be known as "The National Committee." It was felt also that until this National committee could be organized, The Engineering Institute's sub-committee might be permitted to act in making the necessary preliminary arrangements for the collection of data and the mutual interchange of views and suggestions.

It was also proposed that the preparation of an analysis and comparison of the various provincial acts and requirements for admission to membership should be undertaken in so far as they might affect the subject under consideration, and, this analysis having been prepared, it was suggested that three members should be selected by the National committee from among its members, representing respectively the Maritime provinces, Ontario and Quebec, and the provinces west of Ontario, these three members to meet and prepare a draft set of by-laws and requirements for membership that could apply to all the Provincial Associations and to The Engineering Institute of Canada. The committee, further, was of the opinion that when this draft had been prepared it should be communicated to all members of the National committee for their criticisms, and when reasonable agreement had been obtained by correspondence, a meeting of the National committee might be held. It was hoped that such a meeting might agree on a definite set of draft requirements, which could then be submitted to the Councils of the Provincial Associations and The Engineering Institute of Canada.

In so far as The Institute is concerned, this course was approved by its Council, and the sub-committee's proposals have accordingly been forwarded to the governing bodies of the eight Professional Associations for their consideration and criticism. Some of the Councils have already concurred and replies are awaited from the others.

Respectfully submitted,

H. H. Vaughan, M.E.I.C., *Chairman.*

Committee on Membership

The President and Council,—

The Membership committee which was appointed at the Plenary Meeting of Council in October last has endeavoured, in the short period available before the Annual Meeting of The Institute, to make some progress in formulating a policy for increasing the membership and to immediately put into practical effect temporary plans to bring this about.

Your committee "appointed to study the whole question of membership," consisting of Messrs. W. C. Adams, M.E.I.C., H. F. Bennett, A.M.E.I.C., C. J. Mackenzie, M.E.I.C., D. C. Tennant, M.E.I.C., with C. H. Mitchell, M.E.I.C., as chairman, had perforce to carry on its deliberations by correspondence and in doing so considered various methods of procedure to increase membership. Having before them the advantage of the views expressed by fellow members of the Council at the Plenary Meeting, several methods were considered.

One of these methods was that of prosecuting a widespread membership campaign organized on a large scale from Headquarters, in a manner that has commonly been done by other similar societies. Another method was that of a somewhat similar campaign carried out under the direction of a large membership committee embracing representatives of The Institute from coast to coast. A third was a method by which the twenty-five Branches of The Institute would themselves form district or regional membership committees for the purpose.

Your committee has considered that the last method is preferable, for the present at any rate, and has much to commend it. It was felt that a highly organized campaign would, throughout the wide area concerned, prove to be unwieldy and would require very considerable effort and no small expense. On the other hand, with the excellent branch organizations already in existence and desirous of extending the influence of The Institute in their own particular region, the committee considered it most desirable and indeed necessary, to enlist the interest and efforts of the Branches for the purpose.

Your committee, having arrived at this conclusion as a means of serving the immediate situation, recommends that this procedure be adopted in the interval and that it be proceeded with. The committee, however, feeling that no time should be lost in putting some plan into operation in advance of the Annual Meeting of The Institute, took upon itself as a first practical step, communication with the Branches in the hope that they could inaugurate a movement with this in view.

The Branches were accordingly appealed to by letter, the form of which was agreed upon by the committee, and these twenty-five letters were sent out under date of 8th December, signed by the chairman of the committee. These letters placed before the Branches the situation in The Institute with respect to declining membership and while indicating that a general plan for increasing membership was being formulated, pointed out that it was highly desirable to take immediate steps to extend the membership to at least maintain the numbers necessary to meet the normal decreases due to deaths, resignations, and removals.

It was pointed out, and it is for the general interest of the Council and the members of The Institute to note, that during the past five years the annual loss in membership, due to the foregoing causes, has averaged three hundred and thirty-three. It thus appears that in order merely to maintain the membership of The Institute at its present number, it is necessary that annual admissions should be maintained at that number at least or say three hundred and fifty.

In appealing to the Branches, therefore, at this time in presenting these facts and in order to put the situation before them in a practical form, it was pointed out to the individual Branches that, based upon their own proportionate membership, if all uniformly produced an increase, the figure for each would approximately be the following per annum:

Halifax	12	Hamilton	12
Cape Breton	5	London	5
Saint John	7	Niagara	11
Moncton	5	Windsor	9
Saguenay	3	Sault Ste Marie	9
Quebec	10	Winnipeg	20
St. Maurice	4	Lethbridge	4
Montreal	90	Edmonton	6
Ottawa	32	Calgary	10
Peterborough	8	Vancouver	26
Kingston	6	Victoria	4
Toronto	45	Lakehead	4
		Saskatchewan	10

It has been gratifying to the chairman of the committee to receive such hearty responses from so many of the Branches in the short space of time which has elapsed since these letters went out. Over half of the Branches have already replied and are already at work exerting an effort in response to the request, and this with the holiday season intervening.

In the letter sent out to the Branches, certain suggestions were made as to procedure and the difficulties in the way of soliciting new members were pointed out.

One of these suggestions was that individual members should be asked not to go further than to send in to the local committee the names and information concerning prospective candidates, so that later action can be taken by the Branch officials. This suggestion was due to the possibility of embarrassment to the Branch or Council later, should the qualifications of the prospective member prove to be insufficient under the regulations for admission.

It might be interesting at this stage—especially for the information of Branches and the membership generally —to quote a few extracts from some letters the chairman has already received with respect to the efforts being made.

> One Branch, a small one in the Maritime provinces, says, "When a prospective member is discovered, his name is handed to either the chairman or secretary of the Branch, who examines the qualifications of the proposed candidate and advises as to the action likely to be taken by Council. If considered eligible, the prospect is interviewed by a member of the Executive, and urged to send in his application. By following this procedure we avoid, as far as possible, the embarrassment caused by having a man apply for membership, only to be later turned down by Council."

> Another Branch, a small one in Ontario, says, "Your letter—and this step—is very opportune, especially if the several branches will appoint active membership committees, so that the Headquarters committee can issue instructions to them and keep up their interest, at least during one year. In this way we should be able to increase our membership, provided sufficient care is taken by these committees to interest only those we are sure will be elected by Council."

> A small Ontario Branch on the other hand, says, "It was the opinion of this Branch that we had obtained all possible members in this vicinity but that there might be engineers in outlying communities affiliated with this Branch who were not members. We are, therefore, going to get in touch with these communities through members resident there and ask them to give us such information as possible on those who they think are entitled to membership and should be members of The Institute."

> A small Branch in Quebec says, "Campaign for enlisting new members is continuously on in our district and will continue more actively than ever, in accordance with the request of your committee."

A large Branch and the Headquarters office as well, contributes for the committee's information a statement and chart which indicates that "the larger branches are increasing in membership while the smaller branches show a tendency to diminish."

The foregoing outline and activities of your committee and of the Branches are, however, only a beginning. As already stated, the whole question is still under further consideration and your committee would be glad if the Council would arrange to have the membership matter put on the agenda for full discussion so that further views may be obtained. In so far, therefore, this communication forms a progress report in this important matter.

Respectfully submitted,

C. H. Mitchell, M.E.I.C., *Chairman.*

Publicity Committee

The President and Council,—

Owing to the fact that the major suggestion made by your committee in last year's report, which was adopted at the annual meeting, namely:—

> That provision be made in the budget for the engagement of the services of a man familiar with newspaper publicity and capable of carrying out a campaign calculated to bring the engineer more prominently to the notice of the public.

was not possible of fulfilment by the Council owing to lack of funds, your committee has been unable to carry out its previous plans during the past year. It is hoped, however, that during the coming year means may be found of carrying out this proposal, if not in its entirety at least in part, so that eventually this plan may become an integral part of The Institute's functions.

Your committee awaits with interest the reports of the various branches as to the action they have taken in appointing a committee of at least two, as recommended in our previous report, the result of which will no doubt be evidenced in the various branch annual statements.

In connection with the inherent ambition of the engineering profession to be better known and better appreciated, the various articles issued under the direction of the Publicity committee of the Ottawa Branch and published throughout Canada are substantial proof of what can be done in that direction, as they were commented upon editorially in many daily papers and brought to the attention of the public the service the engineer is performing for mankind. The Ottawa Branch is to be congratulated on the good work it has done along this line.

Respectfully submitted,
FRASER S. KEITH, M.E.I.C., *Chairman.*

Committee on Remuneration

The report of this committee is not presented at this time as it is to be submitted for further consideration by the incoming Council.

Branch Reports

Border Cities Branch

The President and Council,—

The work of the Border Cities Branch has been carried on during 1930 by the following committees:—

Papers and Entertainment.......... H. J. Coulter, JR.E.I.C.
Publicity.......................... R. J. Desmarais, A.M.E.I.C.
Membership......................... C. G. R. Armstrong, A.M.E.I.C.
Nominating......................... F. H. Kester, M.E.I.C.
Reception.......................... Fred. Stevens, A.M.E.I.C.
Representative on directorate of the Border Chamber of Commerce... Orville Rolfson, A.M.E.I.C.
Branch News Editor and Assistant Secretary-Treasurer.............. Harold J. A. Chambers, A.M.E.I.C.

The following meetings have been held:—

Jan. 10.—Mr. J. H. Walker, Superintendent of Central Heating for the Detroit Edison Co., spoke on **Central Heating.** We also had a demonstration of rapid calculating by Professor Krieger. Attendance, 50.

Feb. 14.—Prof. W. L. Badger, Professor of Chemical Engineering in the University of Michigan, spoke on **The Use of Diphenyl as a Heating Medium.** Attendance, 20.

Mar. 14.—Mr. S. A. Thoresen spoke on **The Design, Construction and Ventilation of the Detroit and Canada Tunnel.** This was an illustrated lecture. Attendance, 33.

Apr. 11.—Mr. Hugh McIntosh and Mr. Austin Ion of the Bell Telephone Co. spoke on **The Dial System** and the **Mechanics of Automatic Telephone Operation** respectively. Attendance, 29.

May 23.—Mr. Thos. Adams, town planning expert of New York and London, spoke on **Town Planning.** Mayor Jackson of Windsor was a visitor on this occasion. Attendance, 25.

Oct. 10.—Mr. W. H. Furlong, Windsor barrister, spoke on **Some Aspects of the Local Improvement Act.** Attendance, 18.

Nov. 14.—Mr. C. R. Halladay, of General Motors Corporation, Detroit, gave an illustrated talk on the **General Motors Proving Ground.** Attendance, 22.

Dec. 12.—Mr. N. C. Hobson, of Canadian Industries, Ltd., spoke on **The Development of the Salt, Chlorine and Alkali Industry in this District.** Attendance, 27.

This gives an average attendance of 28.

Averages for other years are as follows:—

1926	31	1928	38
1927	20	1929	34

This report would not be complete without some reference to the splendid assistance rendered the secretary by H. J. A. Chambers, A.M.E.I.C., during the past year.

Calgary Branch

The President and Council,—

On behalf of the Executive committee we beg to submit the following report of the activities of the Calgary Branch for the calendar year of 1930:—

MEMBERSHIP

	Dec. 31, 1929 Resident	Non-Resident	Total
Members	22	8	30
Associate Members	49	18	67
Juniors	3	1	4
Students	5	4	9
Branch Affiliates	12	..	12
Totals	91	31	122

	Dec. 31, 1930 Resident	Non-Resident	Total
Members	23	7	30
Associate Members	55	20	75
Juniors	4	1	5
Students	4	1	5
Branch Affiliates	12	..	12
Totals	98	29	127

MEETINGS

The Executive met eleven times during the year to deal with the various questions which arose.

The committee in charge of the Annual Ball met four times. As a result of their efforts a very successful ball was held at the Palliser hotel on Friday, November 22. Four hundred and five guests, including members, were present and it is evident that the affair is growing in popularity and is established as one of the important events in the social life of Calgary.

Ten general meetings were held with a very fair attendance and some excellent papers and discussions.

Details of the meetings and speakers follow:—

Jan. 9.—This meeting was held to consider the question of increase in dues. Attendance, 17.

Jan. 16.—**Things We See** by Dr. H. J. Macleod, M.E.I.C., Professor of Electricity, University of Alberta. Attendance, 49.
Jan. 30.—**Town Planning** by Mr. Doughty-Davis, Town Planning Engineer of the City of Calgary. Attendance, 45.
Feb. 13.—**The Construction of the Ghost Water Power Dam** by H. J. McLean, A.M.E.I.C., Production Superintendent of the Calgary Power Company. Attendance, 64.
Feb. 20.—**The Toronto Water Works System** by W. Gore, M.E.I.C., of Messrs. Gore, Nasmith and Storrie. Attendance, 31.
Mar. 9.—Annual Meeting and Election of Officers. Attendance, 15.
Mar. 9.—Annual Dinner. Attendance, 60.
June 21.—A meeting of the members to visit the Ghost Dam of the Calgary Power Company. Attendance, 30.
Aug. 29.—The Annual Golf Tournament.
Oct. 30.—**The Red Coulee Oilfield** by Dr. P. B. Williams, Consulting Geologist. Attendance, 87.
Nov. 21.—Annual Ball. Attendance, 405.
Nov. 25.—**Nickel** by Mr. G. C. Bateman, Secretary of the Mining Institute of Canada. Attendance, 61.
Dec. 11.—**The Trend of Modern Steam Plants** by W. H. Broughton, A.M.E.I.C., Instructor at the Institute of Technology and Art, Calgary. Attendance, 51.

The average attendance was 45, excluding the Annual Ball and the Annual Dinner.

Cape Breton Branch

The President and Council,—

During the year the Cape Breton Branch held eight meetings at which papers were read and discussed. The average attendance was 68, largely due to the fact that members of the Mining Society of Nova Scotia availed themselves of an invitation to attend. These meetings were as follows:—

Jan. 25.—**Civil Aviation** by J. A. Wilson, A.M.E.I.C., Controller, Civil Aviation, Dept. of National Defence.
Feb. 11.—**Steam—Its Place and Limitations** by M. W. Booth, M.E.I.C., Steam Engineer, British Empire Steel Corporation.
Mar. 11.—**Coal Mining, Past, Present and Future** by T. L. McCall, M.E.I.C., Chief Mining Engineer, British Empire Steel Corporation.
Apr. 8.—**Labour Unionism** by John Moffatt, Safety Dept., Dominion Coal Co.
May 1.—Dinner Meeting, with address by the General Secretary, E.I.C.
Oct. 17.—**Manufacture of Structural Steel and Allied Products** by G. A. Richardson, Technical Lecturer, Bethlehem Steel Co.
Oct. 21.—**Care and Use of Explosives** by E. Godfrey, Technical Representative, Canadian Industries, Ltd.
Nov. 21.—**Aerial Photographic Surveying** by F. H. Peters, M.E.I.C., Surveyor General, Department of the Interior.

The Executive feels that the year was successful from the point of view of meetings held, as all papers were of a high order and the lively discussions which took place were notable.

A Summer Outing and Dance was held at Mira Ferry on Sept. 9 and was well attended.

Halifax Branch

The President and Council,—

We have the honour to submit the following report on the activities of the Halifax Branch of the Engineering Institute of Canada for the year 1930:—

The Executive held several meetings throughout the year at which the routine business of the Branch was attended to, following out the scheme outlined at the last annual meeting arranging the programme of the regular meetings so that only matters of major importance would be taken up.

The membership of the Branch shows a slight increase. Though the Council of The Institute has suspended a number of members for non-payment of dues, the number of new members have more than offset this loss, and the Branch will benefit thereby

The meetings committee arranged for interesting and instructive addresses for each meeting, and their efforts were evidently appreciated by the members of the Branch, as the average attendance at the regular meetings shows a decided increase over last year.

The management of the Nova Scotian hotel approached the Executive regarding the holding of our meetings at the hotel and after considering the proposal it was decided to accept it.

The regular meetings were as follows:—

Jan. 23.—**Progress of Aviation in Canada** by J. A. Wilson, A.M.E.I.C., Director, Department Civil Aviation, Department National Defence.

Feb. 20.—**Sugar** by J. S. Misener, M.E.I.C., Manager, Acadia Sugar Refinery.

Mar. 20.—**The Manufacture of Skates** by Mr. W. L. Davies, Manager, Starr Mfg. Co.

Apr. 24.—**The Electrical Transmission of Speech** by W. A. Winfield, M.E.I.C., Maritime Telegraph and Telephone Company.

May 2.—**The Activities of The Institute** by General Secretary, R. J. Durley, M.E.I.C., Montreal, P.Q.

Oct. 15.—Student's Meeting at Nova Scotia Technical College. Address by Mr. J. A. Richardson, Technical Lecturer of the Bethlehem Steel Corporation.

Nov. 5.—Noon meeting at Nova Scotian hotel in honour of Mr. H. F. Bennett.

Nov. 19.—**Modern Surveying** by F. H. Peters, M.E.I.C., Surveyor General of Canada.

Nov. 24.—**Remuneration and Classification** by J. L. Busfield, M.E.I.C.

The annual meeting was held on Thursday, December 18th, and the following officers were elected for the year 1931:—

Chairman........................J. L. Allan, M.E.I.C.
Executive........................L. M. Allison, A.M.E.I.C.
W. H. Noonan, A.M.E.I.C.
J. J. Sears, A.M.E.I.C.
W. J. DeWolfe, A.M.E.I.C.
A. F. Dyer, A.M.E.I.C.
J. D. Fraser, Jr.E.I.C.
G. S. Stairs, M.E.I.C.
S. L. Fultz, A.M.E.I.C.
J. H. Clark, A.M.E.I.C.
Auditors.........................F. R. Faulkner, M.E.I.C.
G. H. Burchill, Jr.E.I.C.

MEETINGS

The following meetings were held during the year:—

Jan. 14.—**Toronto-Leaside Transformer Station of the Hydro-Electric Power Commission of Ontario:—Electrical Equipment** by C. F. Publow; **Structural Features** by H. E. Brandon, A.M.E.I.C. Attendance, 60.

Feb. 21.—**Engineering in Europe** by Professor R. W. Angus, M.E.I.C. Dinner Meeting. Attendance, 30.

Mar. 19.—**Recent Developments in Arc Welding** by R. E. Smythies, M.E.I.C. Attendance, 40.

Apr. 22.—**St. Lawrence Power** by R. O. Sweezey, M.E.I.C. The Hamilton Branch E.I.C. were the guests of the Hamilton Chamber of Commerce at this meeting.

Apr. 25.—**Lightning Studies and Field Surge Investigations** by E. F. W. Beck. Joint meeting with Toronto Section A.I.E.E. Attendance, 310.

Apr. 30.—**The Hudson River Bridge** by F. W. Skinner. Annual Business Meeting and Dinner. Attendance, 76.

Sept. 11.—**The Future of The Institute and How to Improve Finances and Increase Membership** by A. J. Grant, M.E.I.C., President of The Institute. Several members of the Niagara Peninsula Branch were our guests at this meeting. Dinner Meeting. Attendance, 40.

Oct. 10.—**Mechanical and Electrical Features of the Welland Ship Canal** by J. B. McAndrew, A.M.E.I.C., and L. P. Rundle. The Hamilton Branch E.I.C. were the guests of the Ontario Section A.S.M.E. at this meeting. Joint dinner meeting of Ontario Section A.S.M.E., Toronto Section A.I.E.E., and Toronto Branch E.I.C. Attendance: 113 at dinner; 175 at the meeting.

Oct. 21.—(1) **Illumination of the Endless Caverns of Virginia** by G. F. Foot; (2) **Floodlighting and its Applications** by G. F. Mudgett. Attendance, 60, including ten ladies.

Nov. 4.—**Combustion of Pulverized Fuel** by E. G. Bailey. The members of the Hamilton Branch E.I.C. were the guests of the Engineering Society of Babcock-Wilcox and Goldie-McCulloch Company at this meeting. Attendance, 175.

Nov. 12.—**Weather Reporting to the R100** by J. Patterson. Attendance, 35.

Dec. 10.—**The Telephone Carrier System** by W. A. Dancey. Attendance, 55.

Kingston Branch

The President and Council,—

During the year 1930 five meetings were held by the Branch, as follows:—

Jan. 10.—Address by Mr. J. W. Kelly, of the Portland Cement Institute, on **The Physical Nature of Concrete.**

Jan. 30.—Address by the Branch Secretary on **The Development of Architecture.**

Feb. 20.—Address by C. D. Howe, M.E.I.C., of C. D. Howe and Co., Elevator Engineers, Port Arthur, on **Grain Marketing and Grain Elevators.**

Nov. 6.—Address by Brig.-Gen. Sir Charles Delmé-Radcliffe on **A New Method of Aerial Surveying.**

Nov. 14.—Address by Mr. H. H. Richardson, of the Aluminum Company of America, on **Aluminum as a Structural Material.** This meeting was held jointly with the Engineering Society.

The total attendance at these meetings was 299, giving an average of 60.

The membership of the Branch is as follows:

	Resident	Non-Resident
Honorary Member	1	
Members	12	
Associate Members	9	3
Junior Members	1	2
Students	33	1
Affiliate	1	
Totals	57	6

This compares with 70 at the last annual meeting.

Lethbridge Branch

The President and Council,—

The following report of the past year's activities of the Lethbridge Branch is herewith submitted for your consideration:—

During the calendar year, twelve regular meetings were held with an average attendance of 39, and eight executive meetings with an average attendance of over eight. All the regular meetings commenced with a dinner after which a musical programme was enjoyed.

The subjects and speakers during the year were of a very high order, and the excellence of our meetings has been due, to a very great extent, to the energetic manner in which the Programme committee have handled a problem which is becoming more arduous every year. Mention must also be made of the great assistance towards the success of the meetings rendered by the Entertainment committee whose splendid efforts have been repeatedly acknowledged by the Branch.

The following is a list of the speakers and their subjects since January 1st, last.

Jan. 4—Corporate members meeting. Discussion on report of Councillor G. S. Brown, A.M.E.I.C., on the Plenary Council Meeting.

Jan. 11.—Joint meeting with the Association of Professional Engineers of Alberta. H. L. Seymour, M.E.I.C., Town Planning Commissioner for Alberta. Subject: **A Year of Town Planning in Alberta.**

Jan. 25.—R. S. Trowsdale, A.M.E.I.C., Canadian General Electric Co. Subject: **The Electrical Industry and its Control.** W. P. Campbell, Petroleum Branch, Department of the Interior, Subject: **Water Problems Encountered in Development of Oil Fields.**

Feb. 8.—Dr. K. A. Clarke, Scientific and Industrial Research Council. Subject: **Bituminous Sands of Northern Alberta.**

Feb. 22.—C. G. Childe, A.M.E.I.C., Resident Engineer, Rocky Mountain Parks. Subject: **Highways and Byways in the National Parks.**

Mar. 8.—Dr. R. Neidig, Consolidated Mining & Smelting Co. Subject: **A General Talk on Fertilizers.**

Mar. 29.—Annual meeting.

June 28.—Corporate members meeting. Discussion of Branch activities.

Sept. 9.—Corporate members meeting. Discussion of Plenary Council matters and general business.

Oct. 4.—B. L. Thorne, M.E.I.C., Department of Natural Resources, Canadian Pacific Railway Company. Subject: **Through Oil Lands in Europe and Africa.**

Oct. 18.—Joint meeting with Association of Professional Engineers of Alberta. F. N. Rhodes, A.M.E.I.C., Institute of Technology and Art. Subject: **Efficiency.**

Nov. 1.—R. M. Gourlay, Canadian Western Natural Gas Co. Subject: **Prevention of Waste of Natural Gas.**

Nov. 15.—E. G. Hazell. Subject: **Crow's Nest Lime Works.**

Nov. 29.—E. E. Eisenhauer, A.M.E.I.C., Alberta Wheat Pool. Subject: **The Wheat Pool and the Handling of Wheat.**

Dec. 13.—J. H. Doughty-Davies, Town Planner, Calgary. Subject: **A Talk on Town Planning.**

Most of the addresses were illustrated with lantern slides or motion picture films, which added greatly to the general interest.

At the annual meeting of the Branch held on March 29th, the following officers were chosen for the season 1930-31.

Chairman	C. S. Clendening, A.M.E.I.C.
Vice-Chairman	N. Marshall, M.E.I.C.
Executive	R. F. P. Bowman, Jr.E.I.C.
	N. H. Bradley, A.M.E.I.C.
	R. Livingstone, M.E.I.C.
Ex-officio	J. B. deHart, M.E.I.C.
Councillor	G. N. Houston, M.E.I.C.
Auditors	P. M. Sauder, M.E.I.C.
	C. S. Donaldson, A.M.E.I.C.
Secretary-Treasurer	W. Meldrum, A.M.E.I.C.

The membership of the Branch as at Dec. 31, 1930, is as follows:

	Resident	*Non-Resident*	*Total*
Members	6	0	6
Associate Members	19	5	24
Junior Members	1	1	2
Student Members	1	2	3
Branch Affiliates	30	0	30

London Branch

The President and Council,—

On behalf of the Executive committee of the London Branch we beg to submit the following summary of London Branch activities for the year ending December 31st, 1930:—

Six meetings of the Executive committee were held and seven general Branch meetings.

The annual dinner meeting in January was held at the hotel London. Reports of the year's activities were read and the officers for the year 1930 were elected. Following the dinner Mr. R. L. Stratton, District Superintendent of the Bell Telephone Co., spoke on **The Origin of the Telephone.** In the absence of Mr. W. J. Piggott, Division Superintendent of the Canadian National Railways, his paper on **Phases of Motive Power Development on Railways** was read by J. Ferguson, A.M.E.I.C.. Mr. E. G. Wood rendered appropriate vocal selections.

The February meeting was devoted to land surveying, two papers being presented by Ontario Land Surveyors. The first speaker was W. G. Ure, A.M.E.I.C., and his subject **Land Surveying in Western Ontario.** The second speaker, F. W. Farncomb, M.E.I.C., took as his subject **Early Surveys in the District of London.** The speakers described the methods and difficulties of early surveyors and supplemented these with personal experiences.

The speaker for the March meeting was W. R. Smith, A.M.E.I.C. He gave an illustrated address on **Railway Construction through the Yellowhead Pass.** Mr. W. L. Hill, of the Bitumal Company, showed two motion picture films which illustrated the application of the products of his company in highway construction.

Mr. H. B. R. Craig was the speaker at the April meeting and his subject **Some Aspects of Harbour Engineering.** The paper dealt with the factors that enter into the design of harbour works, and included some notable examples of storm damage.

Branch activities were suspended during the summer, to be opened by the October meeting, held in the University of Western Ontario, in the Science building, with Dr. R. C. Dearle, Professor of Physics, speaking on **Ultra-Violet Light.** Many demonstration were conducted during the evening illustrating the properties and effects of this light.

The Telegraph—Yesterday and Today was the subject and Mr. R. B. Steele, Assistant Chief Engineer of the Canadian National Telegraphs, was the speaker, at the regular November meeting. The paper on the development of the telegraph was supplemented by a description of the train telephone.

The last meeting of the year was held in December and A. B. Crealock, A.M.E.I.C., was the speaker. Mr. Crealock drew from his experiences with the Ontario Department of Highways in describing bridges built by that Department and in giving detailed descriptions of some of the more important structures.

The Branch has been particularly successful during this year in selecting speakers and subjects that drew forth a much larger attendance than formerly, the average being 42.

The membership of the London Branch at the close of 1930 was as follows:—

Members	14
Associate Members	30
Juniors	4
Students	8
Affiliates	2
Branch Affiliates	4
Total	62

FINANCIAL STATEMENT

Moncton Branch

The President and Council,—

On behalf of the Executive committee we beg to submit the eleventh annual report of Moncton Branch:—

The Executive committee held four meetings. There were eight meetings of the Branch held, three of which were supper meetings and two were open to the public.

MEMBERSHIP

Our membership at present consists of forty-seven members, as follows:

	Resident	Non-Resident
Members	10	2
Associate Members	19	8
Juniors	1	1
Students	2	3
Affiliates	1	..
	33	14

OFFICERS

The annual meeting of the Branch was held on June 10, 1930. The following officers were elected for 1930-31:—

Chairman	L. H. Robinson, M.E.I.C.
Vice-Chairman	G. E. Smith, A.M.E.I.C.
Secretary-Treasurer	V. C. Blackett, A.M.E.I.C.
Executive	E. T. Cain, A.M.E.I.C.
	A. S. Gunn, A.M.E.I.C.
	A. F. Stewart, M.E.I.C.

The members of the Executive committee in addition to the above are:—

	T. L. S. Landers, M.E.I.C.
	J. G. Mackinnon, A.M.E.I.C
	C. S. G. Rogers, A.M.E.I.C.
Ex-officio	M. J. Murphy, A.M.E.I.C.

Montreal Branch

The President and Council,—

We wish on behalf of the Executive committee of the Montreal Branch to submit the following report covering the activities of the year 1930:—

During the past year the personnel of the committee consisted of the following:

Chairman	D. C. Tennant, M.E.I.C.
Vice-Chairman	A. Duperron, M.E.I.C.
Secretary-Treasurer	C. K. McLeod, A.M.E.I.C.
Past-Chairman	J. A. McCrory, M.E.I.C.
Executive	A. Cousineau, A.M.E.I.C.
	W. McG. Gardner, A.M.E.I.C.
	N. L. Morgan, A.M.E.I.C.
	P. E. Jarman, A.M.E.I.C.
	J. A. Lalonde, A.M.E.I.C.
	F. Newell, M.E.I.C.
Ex-officio	F. P. Shearwood, M.E.I.C.
	F. S. Keith, M.E.I.C.
	O. O. Lefebvre, M.E.I.C.
	G. R. MacLeod, M.E.I.C.
	P. B. Motley, M.E.I.C.
	F. A. Combe, M.E.I.C.
	J. C. Smith, M.E.I.C.
	J. L. Busfield, M.E.I.C.
	J. A. McCrory, M.E.I.C.

MEMBERSHIP

The membership of the Branch at present is 1,126, which is the largest in its history, comparing with a membership of 1,089 at the end of last year. The chairman of the Membership committee is W. McG. Gardner, A.M.E.I.C., and the standing of the Branch membership reflects credit on his committee.

It is with the deepest regret that we report the deaths of several important members during the past year, and wish to record the following list:—

Henry Holgate, M.E.I.C., died on January 21st. He had been associated with many engineering projects in and around Montreal during his lifetime, and was at different times a Councillor and Vice-President of The Institute.

A. T. Spencer, M.E.I.C., died on January 26th, his engineering work having been associated with the Dominion Coal Company, with the Toronto Transportation Commission and with the Montreal Tramways.

On March 3rd, Henry Irwin, M.E.I.C., passed away. He was at one time Councillor of The Institute and for many years was its Treasurer. He held several important offices with the Canadian Pacific Railway.

C. C. Leluau, M.E.I.C., died on March 10th. His engineering career began in France, where he served in the Franco-Prussian War, being awarded the Decoration of "Chevalier de la Légion d'Honneur." In his latter years he was Professor of Physics and Hydraulics at Laval University, now the University of Montreal.

Geo. W. Thompson, M.E.I.C., died on April 1st. He was best known as the Manager of the city of Westmount, and as such he is greatly mourned.

John J. York, M.E.I.C., died on April 8th. He gave his lifetime of engineering service to the St. Lawrence Sugar Refinery.

On August 3rd, F. L. Wanklyn, M.E.I.C., died at Grimsby, England. He was associated with many railway companies including the Tramways in both Toronto and Montreal, and the Canadian Pacific Railway. He was at one time a Councillor of The Institute.

Arthur A. Mellor, A.M.E.I.C., died in September. His engineering work began in England and later he was with the Milton Hersey Company in Montreal in connection with the Montreal Harbour Bridge.

On October 25th, H. M. Mackay, M.E.I.C., Dean of the Faculty of Applied Science at McGill University, passed away. In his earlier days he was associated with Dr. W. Bell Dawson and also with Messrs. Waddell & Hedrick, Consulting Engineers in Kansas City. He had been a Councillor in The Engineering Institute.

Seldom, if ever, has the Branch in one year mourned the loss of so many important members, notable as they were for their engineering ability, their high type of citizenship and genuine humanity.

Papers and Meetings Committee

The Papers and Meetings committee, under the chairmanship of P. E. Jarman, A.M.E.I.C., deserves special mention. The members of it having worked so well that we think all their names should be mentioned. It is composed as follows:—

Chairman........................P. E. Jarman, A.M.E.I.C.
Vice-Chairman....................H. G. Thompson, A.M.E.I.C.
Ex-officio.......................C. K. McLeod, A.M.E.I.C.
Civil Section, Chairman............R. M. Robertson, A.M.E.I.C.
Vice-Chairman........A. E. Oulton, A.M.E.I.C.
Electrical Section, Chairman........J. L. Clarke, A.M.E.I.C.
Vice-Chairman....H. Milliken, M.E.I.C.
Mechanical Section, Chairman.......L. H. Birkett, A.M.E.I.C.
Vice-Chairman..S. Hermans, A.M.E.I.C.
Municipal Section, Chairman.......C. Jos. LeBlanc, A.M.E.I.C.
Vice-Chairman...F. E. V. Dowd, A.M.E.I.C.
Railway Section, Chairman.........J. W. McAllister, A.M.E.I.C.
Aeronautical Section, Chairman......J. L. Busfield, M.E.I.C.
Vice-Chairman.C. M. McKergow, M.E.I.C.
Student Section, Chairman..........H. W. Lea, S.E.I.C.

It will be noted that during the year there was no lack of papers, in fact, two extra meetings were held in May whereas it is usual to hold the final meeting in the spring in April. The fall programme has also been well filled and for the first session of the year 1931, from January to April inclusive, the committee reports a surplus of papers, which is something almost unheard of here before. That the quality of the papers has also been good, is evidenced by the attendance throughout the year, which has been considerably better than usual. The papers given throughout the year 1930 are as follows:—

Jan. 9.—Branch Annual Meeting.
" 16.—**Process of Zinc Coating Steel Wires** by A. D. Turnbull, S.E.I.C.
" 23.—**Telephone Lines Outside North America** by J. L. McQuarrie.
" 30.—**Scientific Developments Leading to Sound Pictures** by Paul B. Findlay.
Feb. 6.—**Construction of the Sun Life Building in Montreal** by A. H. Harkness, M.E.I.C.
" 13.—No meeting. Supper dance.
" 20.—**Reinforcing Stoney Creek Arch Bridge, B.C.** by P. B. Motley, M.E.I.C.
" 27.—**Transformer Load Ratio Control** by C. E. Sisson, M.E.I.C.
Mar. 6.—**Climatic Cycles as Affecting Water Power** by A. Streiff.
" 13.—**Welded Airplane Structures** by Arthur Piche.
" 13.—**The Problems in Long Distance Telephone** by Messrs. Roll and Rouselle.
" 20.—**Road Building** by E. L. Miles, M.E.I.C.
" 27.—**Toronto Sewer System** by Geo. Phelps, A.M.E.I.C.
Apr. 3.—**Water Power in Brazil** by A. W. K. Billings, M.E.I.C.
" 8.—**The Engineer and Aviation** by J. A. Wilson, A.M.E.I.C.
" 10.—**Point St. Charles New Locomotive Shops and Power Plant** by J. Roberts.
" 17.—**The Hudson River Bridge Span** by F. W. Skinner.
" 24.—**Hydraulic Fill on Ghost Power Development** by W. H. Abbott, A.M.E.I.C.
May 1.—**Electricity in the Eighteenth Century** by Dr. L. E. Pariseau.
" 8.—**The Cottrell Process of Electric Precipitation** by P. E. Landolt.
" 21.—**The Quest of the Unknown** by Harold B. Smith.
Oct. 2.—**The Phenomena of Oil Circuit Breaker Interruption** by J. O. Bason.
" 9.—**Steel Castings** by H. R. Bartell.
" 16.—**Aeronautics as a Branch of the Engineering Profession** by Flight-Lieut. Alan Ferrier, A.M.E.I.C., A.F.R.Ae.S.
" 23.—**Operation of Trains on Single Tracks by Centralized Traffic Control** by C. L. Hacket.
" 30.—**Surveying in the Three Dimensions by a New Photogrammetric Method** by Brig.-Gen. Sir Charles Delmé-Radcliffe, K.C.M.G.
Nov. 6.—**The New Mill at Copper Cliff for the International Nickel Company** by L. M. Sheridan.
" 13.—**The Practical Aspects of System Stability** by F. A. Hamilton, Jr.
" 20.—**Royal Canadian Air Force as a Career** by Wing-Commander L. S. Breadner, A.M.E.I.C.
" 27.—**Filling Lyon Creek Trestle** by M. S. Blaiklock, M.E.I.C.
Dec. 4.—**Recent Investigations at McGill University** by various Members of McGill.
" 11.—**Rapide Blanc Bridge** by Palmer E. Savage, S.E.I.C.; **Steam Distribution and Control in Paper Machine Dryers** by C. B. Charlewood.
" 18.—**Turbo Blowers and Compressors** by John Avery.

It will be noted in the above that an aeronautical section of the Branch is included for the first time. This section, which was inaugurated on April 8th, 1930, had as its principal officers J. L. Busfield, M.E.I.C., and C. M. McKergow, M.E.I.C. This is the first aeronautical section to be formed by any branch of The Institute, and it is already one of our most active sections. The Royal Aeronautical Society has corresponded with The Engineering Institute during the past year expressing its willingness to co-operate in the formation of aeronautical sections and the interchange of technical information between the two societies.

An important change from the regular routine of weekly meetings was that on December 4th, the meeting of the Branch took place at the Engineering building of McGill University where explanations were given by the Engineering Faculty regarding various work done recently in the laboratories, including tests on steelwork and concrete, investigations regarding welding, and also work in the hydraulic, steam, mechanical and electrical laboratories. After the explanations had been given members of the Branch were conducted by the students and staff of the University to whatever portions in the laboratories they were most interested in, and thus a most profitable evening was spent. Arrangements have been made to make a similar visit to the laboratories in the University of Montreal in the next few months and it is hoped that similar visits can be arranged frequently in the future to give the members of the Branch an opportunity of seeing the work in our universities and strengthen in every way possible the bond between the universities and the engineering profession.

Activities with Other Organizations

During the year the Branch has availed itself of several opportunities to co-operate with other organizations. Early last year it was thought desirable, in view of the forthcoming annual meeting of the American Institute of Electrical Engineers in Toronto, to have a visit from their president, Mr. H. B. Smith. It was accordingly arranged, and he addressed the Branch on May 21st, his subject being "The Quest of the Unknown."

During the summer months the Society for the Promotion of Engineering Education held their annual meeting in Montreal, and representatives of the Branch attended the banquet given on that occasion.

The Branch has a representative on the standing committee of the City Improvement League, which is doing a great deal of good work in our metropolitan area.

The Province of Quebec Safety League appointed a sub-committee of their construction division to prepare a safety code for the use of the construction industries in the province. The Branch was asked to co-operate, and appointed a committee under the chairmanship of Geo. Templeman, M.E.I.C., to report on a draft code which had been drawn up. This code has not been approved by the Branch Executive, and it is hoped that further steps may be taken, as your Executive have offered their assistance.

During the year the Branch Secretary has been in communication with several of the other branches in Quebec and Ontario, and the Branch chairman attended the annual dinner of the Peterborough Branch.

Visits

While no extensive trips were taken by the Branch members this year we were fortunate in being able to have two excursions, each of which took half a day only. On August 7th, the members of the Montreal Branch visited the St. Hubert Airport and were privileged to inspect the interior of the airship "R100," which was then at St. Hubert. This trip was very greatly enjoyed by all. About 100 members availed themselves of the invitation.

The Beauharnois Construction Company invited the Branch to visit the work in connection with the construction of the new Beauharnois canal and power house on October 31st. Almost 150 members took in this trip,—transportation from Montreal being provided by private automobiles. The visit proved both enjoyable and instructive.

Annual Dinner Dance

An innovation was made by the Branch this year in holding a dinner dance which took place at the Windsor hotel on February 25th. This proved to be a most successful function and it is recommended that a similar event be held each year, excepting those years in which the annual meeting of The Institute will be held in Montreal, in which case its place would be taken by the activities of the annual meeting.

The Reception committee activities were handled by Mr. J. B. O. Saint-Laurent, A.M.E.I.C., who was always very much in evidence during the year, and to whom the thanks of the Branch should be extended.

In previous years the publicity was taken care of by a Branch reporter. The Executive felt that the most suitable person to act as Branch reporter would be the vice-chairman of the Papers and Meetings committee. The reason for this decision was that he would act as a liaison between the activities of the various sections of the Branch on the one hand, and The Engineering Journal and the public press on the other. Accordingly, H. G. Thompson, A.M.E.I.C., took charge of this work with very desirable results.

An Unemployment committee has been appointed to co-operate with The Institute Unemployment Bureau in trying to help solve, as far as possible, unemployment that may exist amongst members of the Montreal Branch. It is felt that this is a timely move, and it is hoped that the incoming Executive will make of this committee the most effective instrument possible.

A sub-committee on admissions and transfers consisted of J. A. Lalonde, A.M.E.I.C., and N. L. Morgan, A.M.E.I.C., during the past year, and they have made abstracts of the qualifications of the various applicants which have been greatly appreciated by the Executive, and have expedited the Executive committee work in this connection.

ANNUAL GENERAL AND PROFESSIONAL MEETING

In preparation for the Annual General and Professional meeting of The Institute to be held on February 4th, 5th and 6th, 1931, under the auspices of the Montreal Branch, the Executive has appointed the following committee:—

Chairman	D. C. Tennant, M.E.I.C.
Secretary	C. K. McLeod, A.M.E.I.C.
General Duties	A. Duperron, M.E.I.C.
Hotel Arrangements	J. L. Busfield, M.E.I.C.
Luncheons	J. A. McCrory, M.E.I.C.
Registration and Reception	H. Massue, A.M.E.I.C.
Papers and Meetings	P. E. Jarman, A.M.E.I.C.
Inspection Trips	F. Newell, M.E.I.C.
Smoker	C. M. McKergow, M.E.I.C.
Publicity	H. G. Thompson, A.M.E.I.C.
Ladies	W. McG. Gardner, A.M.E.I.C.

This committee has already had quite a number of meetings, and arrangements are well under way.

Respectfully submitted,

D. C. TENNANT, M.E.I.C., *Chairman.*
C. K. McLEOD, A.M.E.I.C., *Secretary.*

Niagara Peninsula Branch

The President and Council,—

The Executive of the Niagara Peninsula Branch present herein the report for the year 1930:—

The Executive held five meetings with an average attendance of 10.4, or 65 per cent.

Nine regular meetings of the Branch and an Electoral meeting were held.

The policy of using our meetings to advertise the profession has been continued. There have been some visitors present at every meeting.

The meetings are listed hereunder:—

Jan. 29.—Dinner meeting at Niagara Falls. **The Future of Engineering** by Professor C. R. Young, M.E.I.C. Attendance, 44.

Feb. 26.—Complimentary dinner to A. J. Grant, M.E.I.C., President E.I.C. Attendance, 169.

Mar. 21.—Joint meeting with Frontier Section American Institute Electric Engineers, at Buffalo. **By-products of Radio** by Dr. Phillips Thomas, Attendance E.I.C., about 50.

Apr. 10.—Dinner meeting at Niagara Falls. **The World Engineering Congress at Tokio** by John Murphy, M.E.I.C. Attendance, 30.

Apr. 29.—Dinner meeting at St. Catharines. **The 3,500-foot span of the Hudson River Bridge, and Comparative Construction Features of Largest Typical Spans.** by Frank W. Skinner, Consulting Engineer. Attendance, 40.

May 22.—Electoral meeting at Lookout Point Golf Club. Attendance, 20.

June 4.—Annual meeting. Dinner meeting and dance at St. Catharines. **Geology from a Motor Car** by Dr. A. P. Coleman, M.A., Ph.D., F.R.S. Attendance, 150.

Oct. 24.—Joint trip and dinner meeting with the Ontario Association of Professional Engineers. **Mechanical and Engineering Features of The Welland Ship Canal** by J. B. McAndrew, A.M.E.I.C., and L. P. Rundle. Attendance, 75.

Nov. 19.—Dinner meeting at Bridgeburg. **The Niagara Area** by Louis Blake Duff, Esq. Attendance, 60.

Dec. 16.—Dinner meeting at Welland. **Nickel** by G. C. Bateman, Secretary, Ontario Mining Association. Attendance, 29.

Total	151	136	16	0

The decrease is due to the approaching completion of the large engineering works in the district.

The most serious item, however, has been the loss by death of E. H. Pense, A.M.E.I.C., and R. W. Leonard, M.E.I.C.

Ottawa Branch

The President and Council,—

On behalf of the Managing committee of the Ottawa Branch we beg to submit the following report for the calendar year 1930:—

During the year the Managing committee held six meetings. In addition the Branch held four evening meetings and fourteen luncheons, one luncheon being a joint meeting with the Ottawa Branch of the Queen's Alumni Association.

The outstanding events of the year were the holding in Ottawa, in February, of the 44th Annual General Meeting of The Institute, and the development of a scheme for co-operation with the Royal Aeronautical Society.

It is with deep regret that we report the loss through death of two members—Colonel S. H. Osler, M.E.I.C., and U. Valiquet, M.E.I.C., and one Branch affiliate, Geo. Mothersill.

PROCEEDINGS AND PUBLICITY

During the year fourteen luncheons and four evening meetings were held as follows:—

Jan. 9.—Annual meeting—Daffodil Tea Rooms.

Jan. 16.—**The St. Lawrence Waterways** by Hon. E. C. Drury; luncheon meeting at the Chateau Laurier.

Jan. 30.—**Impressions of Japan and the Far East** by Tom Moore, President of the Dominion Trades and Labour Congress; luncheon meeting at the Chateau Laurier.

Feb. 28.—**Talking Motion Pictures** by O. R. Harvey of the Northern Electric Company; evening address at the Chateau Laurier.

Mar. 13.—**Darwin** by Colonel Alexander MacPhail, M.E.I.C., of Queen's University; joint luncheon meeting with the Ottawa Branch of Queen's Alumni Association at the Chateau Laurier.

Mar. 27.—**The Technical Service Council and Its Works** by Lieut.-Col. R. E. Smythe, A.M.E.I.C., Secretary, Technical Service Council; luncheon meeting at the Chateau Laurier.

Apr. 10.—**The Engineer's Contribution to Industry** by G. C. Bateman, Secretary, Ontario Mining Association; luncheon meeting at the Chateau Laurier.

Apr. 16.—**A Trip to Japan** by John Murphy, M.E.I.C., Electrical Engineer, Department of Railways and Canals; evening address at the Victoria Memorial Museum.

May 8.—**Industrial Development of Sudbury Area** by E. A. Lapierre, M.P.; luncheon meeting at the Chateau Laurier.

May 22.—**The Arvida Operations of the Aluminum Co. of Canada** by R. E. Parks, A.M.E.I.C., General Superintendent; luncheon meeting at the Chateau Laurier.

Aug. 8.—**The Atlantic Crossing of the R100** by Group-Captain R. B. B. Colmore, O.B.E., and Major G. H. Scott, O.B.E., A.F.C.; luncheon meeting at the Chateau Laurier.

Oct. 23.—**Explorations in Northern Canada** by Major L. T. Burwash, M.E.I.C., Exploratory Engineer of the North West Territories and Yukon Branch, Department of the Interior; luncheon meeting at the Chateau Laurier.

Oct. 30.—**Surveying by a New Photogrammetric Method** by Sir Charles Delmé-Radcliffe, K.C.M.G., Chairman of the Board of Directors of British Cadastral and Topographical Air Surveying Company; luncheon meeting at the Chateau Laurier.

Nov. 6.—**The Engineer in the Nation** by R. W. Boyle, F.R.S.C., M.E.I.C., of the National Research Council; luncheon meeting at the Chateau Laurier.

Nov. 14.—**Dial System Telephony** by C. F. Inglis of the Bell Telephone Co. of Canada; evening address at the Victoria Memorial Museum.

Nov. 20.—**Recent Developments in Acoustical Practice** by Major G. M. Thomson, Director of Research, Gypsum, Lime and Alabastine Canada, Limited; luncheon meeting at the Chateau Laurier.

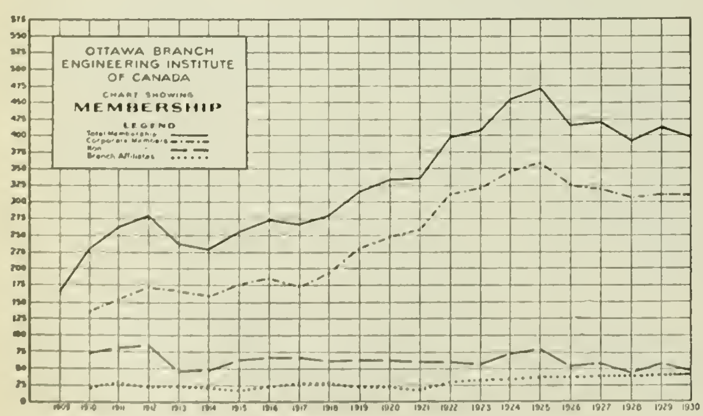
Dec. 4.—**Speeding-up Communications** by J. C. Burkholder, Chief Engineer, Canadian National Telegraphs; luncheon meeting at the Chateau Laurier.

Dec. 18.—**Wolfe's Cove Tunnel, Quebec** by Lieut.-Colonel D. Hillman, D.S.O., M.E.I.C., Engineer of Construction, Canadian Pacific Railway Co.; luncheon meeting at the Chateau Laurier.

The average attendance at the luncheon meetings was 112 and at the evening meetings (including the Annual Meeting) was 154.

In August it was a special privilege to have had as guests Group-Captain R. B. B. Colmore, O.B.E., Director, and Major G. H. Scott, O.B.E., A.F.C., Assistant Director of Airship Development in the Air Ministry, on the occasion of the successful flight of the airship R100 to Canada. These gallant airmen made many friends during their stay in Canada. In consequence it was a matter of intense regret to learn later of their tragic death in the attempt of the R101 to make a trip to India.

The annual ball of the Ottawa Branch was not held on account of a ball being one of the features of the Annual General Meeting of The Institute held in Ottawa on February 12th, 13th and 14th.



MEMBERSHIP

Owing to deaths, resignations and members removed from the roll the membership shows a decrease of 19 for the year. The accompanying chart shows graphically the membership of the Branch from 1909 to date.

The following table shows, in detail, the comparative figures of the Branch membership for the years 1928, 1929 and 1930:—

	1928	*1929*	*1930*
Honorary Members	1	1	1
Members	107	108	107
Associate Members	199	204	202
Affiliates of Institute	7	7	4
Juniors	23	24	17
Students	14	27	22
Branch Affiliates	40	41	40
Total	391	412	393

ROOMS AND LIBRARY

The Branch library is still situated on the third floor of the Stephen Building where it is open to consultation by members under the same conditions as have previously prevailed.

ADVERTISING IN THE JOURNAL

Commissions due for advertising in the Journal during 1929 amount to $29.50, which is approximately equivalent to the rebates from fifteen Associate members.

FINANCES

The statements below of assets and liabilities and of receipts and expenditures show that the Branch closed the year with a balance of $629.10 in the bank, $13.31 cash on hand, and $1,000 in Victory Bonds, a total balance of $1,642.41. In addition to this balance the Branch has assets of $95.76 in rebates due from the main Institute, $29.50 in commissions due for advertising in The Journal, and $201 in furniture, equipment, etc., making a total of $1,968.67, a decrease of $340.15 as compared with 1929. This decrease is due to the expenses incurred in connection with the Annual General Meeting held in Ottawa in February, 1930. The financial standing of the Branch from 1910 to date is shown on the accompanying chart.

The income for the past two years was:—for 1929, $864.67, and for 1930, $1,035.79; the expenditure for 1929, $940.03, and for 1930, $1,249.70. The annual income from Victory Bonds is $52.50.

OFFICERS FOR 1931

The Annual Meeting of the Branch will be held in Ottawa on January 8th when the officers and members of the Managing committee for the year 1931 will be elected.

Peterborough Branch

The President and Council,—

On behalf of the Executive of the Peterborough Branch we take pleasure in submitting the following report covering the various activities of the Branch during the year 1930:—

Meetings and Papers

Jan. 9.—**The Construction of a Modern Locomotive** by W. A. Newman, Chief Mechanical Engineer, Canadian Pacific Railway Company.

Jan. 23.—**Developments in the Mining Industry** by W. R. Rogers, A.M.E.I.C., Ontario Department of Mining and Metallurgy.

Feb. 13.—**The Age of Speed.** Moving pictures shown by the Norton Company of Canada.

Feb. 27.—**Aerial Mapping** by A. M. Narraway, M.E.I.C., Chief Aerial Surveys Engineer, Department of the Interior, Ottawa.

Mar. 13.—Students Papers:
The Diesel Engine by A. E. Jagger.
Power Rectifiers by R. L. Morrison, S.E.I.C.
Forestry in Alberta by J. J. Taylor, S.E.I.C.

Mar. 27.—**Ball and Roller Bearings** by R. F. Runge, Vice-President S.K.F. Industries Inc., N.Y.

Apr. 10.—**Aluminum as an Engineering Material** by H. H. Richardson, Chief of Technical Department of Aluminum Company of Canada.

Apr. 24.—**Rural Power Service** by J. W. Purcell, A.M.E.I.C., engineer, Hydro-Electric Power Commission of Ontario.

May 8.—Annual meeting and joint meeting with the Toronto Branches of the A.I.E.E., A.S.M.E., and E.I.C. held in Peterborough.

Sept. 13.—Annual Picnic.

Oct. 9.—Inspection of plant of the Western Clock Company, with an address by J. H. Vernor.

Oct. 23.—**Canadian Patent and Requisites of a Patentable Invention** by L. C. Prittie, A.M.E.I.C., Patent Attorney.

Nov. 13.—**The R 100 at St. Hubert Air Port** by A. L. Killaly, A.M.E.I.C., and R. L. Dobbin, M.E.I.C.

Nov. 25.—Annual dinner.

Dec. 11.—**Copper in the Electrical Industry** by H. C. Jennison, Assistant Technical Supervisor and Assistant Metallurgist of the Anaconda American Brass Company.

Membership

	Jan. 1, 1929	*Jan. 1, 1930*
Members	20	18
Associate Members	31	30

Students	30	23
Branch Affiliates	25	17
Total	126	108

At the joint meeting held on May 8th, there were present 16 members of Toronto Branches of the American Institute of Electrical Engineers, American Society of Mechanical Engineers and The Institute, and 10 visitors. Tours of inspection were made to the various factories in the afternoon and a bowling tournament and dinner were held in the evening. At the dinner an address on **Water Powers** was given by R. O. Sweczey, M.E.I.C. The attendance at the dinner was 88.

The following members were elected to the Executive committee on May 29th, 1930.

Chairman	W. E. Ross, A.M.E.I.C.
Secretary	F. G. A. Tarr, S.E.I.C.
Treasurer	A. B. Gates, A.M.E.I.C.

ASSEMBLEE ANNUELLE

L'assemblée annuelle de la Section de Québec eut lieu le 26 mai, sous la présidence de monsieur A. B. Normandin, A.M.E.I.C., président; les officiers dont les noms suivent furent élus pour l'année 1930-31.

Président honoraire à vie	A. R. Décary, M.E.I.C., D.A.Sc.
Président	S. L. deCarteret, M.E.I.C.
Vice-président	Hector Cimon, M.E.I.C.
Secrétaire-trésorier	Philippe Méthé, A.M.E.I.C.
Conseillers	F. T. J. King, A.M.E.I.C.
	Alex Larivière, A.M.E.I.C.
	L. C. Dupuis, A.M.E.I.C.
	J. A. Lefebvre, M.E.I.C.
	Louis Beaudry, A.M.E.I.C.
	J. G. O'Donnell, A.M.E.I.C.
Ex-officio (Vice-prés. E.I.C.)	W. G. Mitchell, M.E.I.C.
Ex-officio (ancien président)	A. B. Normandin, A.M.E.I.C.
Ex-officio (ancien président)	E. A. Doucet, M.E.I.C.

ACTIVITES DE LA SECTION DE QUEBEC

Pendant l'année 1930, les membres de la Section de Québec ont eu le plaisir de se réunir et d'écouter les conférenciers suivants:—

Le 27 janvier.—J. E. Noulan Cauchon, A.M.E.I.C., président de la Commission d'Urbanisme d'Ottawa, nous entretient d'urbanisme et expose sa méthode de lotissement hexagonal.

Le 24 mars.—H. R. Wake, A.M.E.I.C., ingénieur préposé aux édifices de l'Aluminum Company of Canada, à Arvida, traite des différents édifices de l'immense usine d'aluminium d'Arvida.

Le 7 mai.—A. A. MacDiarmid, M.E.I.C. et J. S. Bates, A.M.E.I.C., de la Cie Price Bros. Ltd. exposent devant les membres de la Section les propriétés et les procédés de fabrication du Donnacona insulating board, et donnent une description du moulin où il est fabriqué.

Le 3 décembre.—Sir Charles Delmé-Radcliffe, K.C.M.G. expose la théorie et les diverses opérations de l'arpentage aérien par la méthode photogrammetrique de Nistri.

PHILIPPE MÉTHÉ, A.M.E.I.C., *Secrétaire-trésorier.*

Saint John Branch

The President and Council,—

On behalf of the Branch Executive committee the annual report of the Saint John Branch is submitted herewith for the year ending December 31st, 1930:—

EXECUTIVE COMMITTEE

During the year eleven Branch Executive meetings were held. The personnel of the Executive committee to date is as follows:—

Chairman	W. J. Johnston, A.M.E.I.C.
Vice-Chairman	J. N. Flood, A.M.E.I.C.
Secretary-Treasurer	A. A. Turnbull, A.M.E.I.C.
Executive	G. A. Vandervoort, A.M.E.I.C.
	C. C. Langstroth, A.M.E.I.C.
	H. F. Morrissey, A.M.E.I.C.
Ex-officio	E. J. Owens, A.M.E.I.C.

It is with regret that we have to report the death of E. A. Thomas, A.M.E.I.C., who was chairman of this Branch from May, 1929, to January, 1930. He was always a consistant, loyal and active supporter of Branch affairs and his presence is greatly missed by both the Executive and members of the Branch.

COMMITTEES

The chairmen of standing committees of the Branch are as follows:—

Programme and Meetings	S. R. Weston, M.E.I.C.
Entertainment	J. C. Nutter, A.M.E.I.C.
Employment	J. A. W. Waring, A.M.E.I.C.
Membership	Branch Executive.
Policy	Branch Executive.
Salaries	A. Gray, M.E.I.C.
Publicity	F. M. Barnes, A.M.E.I.C.
Natural Resources and Engineering Industries	F. P. Vaughan, M.E.I.C.
Town Planning	A. R. Crookshank, M.E.I.C.
Auditor	C. M. Hare, S.E.I.C.

BRANCH MEETINGS

During the year nine Branch meetings were held including the joint meeting with the Engineering Society of the University of New Brunswick at Fredericton, N.B., the joint meeting with the Professional Engineers of the Province of New Brunswick at Saint John, N.B., and the Branch annual dinner.

PROGRAMME

Jan. 16.—Joint dinner meeting with the Association of Professional Engineers of the Province of New Brunswick. **Progress of Aviation** by J. A. Wilson, A.M.E.I.C., Controller of Civil Aviation, Ottawa, Ontario.

Feb. 20.—**Forestry on the Pacific Coast** by Prof. J. M. Gibson, B.Sc.F., University of New Brunswick, Fredericton, N.B.

Mar. 20.—**Canada** by C. H. Wright, M.E.I.C., District Manager, Canadian General Electric Co., Halifax, N.S.

Apr. 4.—Joint meeting with the University of New Brunswick Engineering Society at Fredericton, N.B. **High Potential and High Frequency Apparatus and Experiments** by F. P. Vaughan, M.E.I.C.

Apr. 17.—**The Evolution of Artillery** by Major E. M. Slader, O.C. 4th Medium Battery, Saint John, N.B.

Apr. 28.—**Annual meeting** held at the Riverside Golf and Country Club.

Nov. 17.—**Aerial Photographic Survey** by F. H. Peters, M.E.I.C., Surveyor General of Canada, Ottawa.
Nov. 19.—**A Modern Testing Laboratory** by W. P. Dobson, M.E.I.C., Chief Testing Engineer of the Hydro-Electric Power Commission of Ontario.
Nov. 25.—**The Work of the Remuneration Committee** by J. L. Busfield, M.E.I.C., of Montreal, Chairman of Remuneration Committee of The Institute.

MEMBERSHIP

A statement of membership as at December 31st, 1930, is as follows:—

	Resident	*Non-Resident*	*Total*
Members	13	7	20
Associate Members	21	16	37
Juniors	2	2	4
Students	6	7	13
Affiliates	1	0	1
Total	43	32	75

Membership at the end of 1929 was 86, making a net loss of 11 for the year 1930.

St. Maurice Valley

Au président et au conseil,—

Nous avons l'honneur de vous soumettre les opérations de la Branche de la Vallée du St-Maurice, de l'Engineering Institute of Canada pour l'année 1930.

La Branche n'a tenu que deux assemblées. La première le 21 juin 1930 au Château De Blois aux Trois-Rivières.

Le conférencier fut A. A. Wickenden, A.M.E.I.C., P.E.Q.Q.L.S., ingénieur en chef du Département forestier de la Canada Power & Paper Company Limited aux Trois-Rivières.

Sa conférence traita du sujet de la construction, des avantages et du maintien des routes à travers les limites de cette compagnie. Cette conférence fut publiée dans les journaux de l'Engineering Institute of Canada au mois d'août 1930. Une discussion s'ensuivit, à laquelle prirent part A. N. Budden, A.M.E.I.C., Elwood Wilson, M.E.I.C., H. Dessaulles, M.E.I.C., et autres.

La deuxième conférence a été tenue au Cascade Inn, à Shawinigan Falls. L'orateur fut Olivier Lefebvre, M.E.I.C., ingénieur en chef de la Commission des Eaux Courantes de la province de Québec, qui parla du voyage qu'il fit avec le Comité International des Pouvoirs d'eau, en Allemagne.

Ce diner était rehaussé de la présence du Docteur A. R. Décary, M.E.I.C., et de R. J. Durley, M.E.I.C., Secrétaire de l'Institut.

Le même bureau de direction a été maintenu en fonction pour l'année 1930 et les membres réélus pour 1931 sont E. Wilson, M.E.I.C., de Grand'Mère comme président et H. Dessaulles, M.E.I.C., de Shawinigan Falls comme conseiller, A. A. Wickenden, A.M.E.I.C., des Trois-Rivières comme conseiller et Bruno Grandmont, A.M.E.I.C., des Trois-Rivières comme conseiller.

Roméo Morrissette, A.M.E.I.C., du Cap de la Madeleine a été réélu secrétaire-trésorier. C. H. Jetté, A.M.E.I.C., a été appointé sur le comité des nominations.

Quoique la Branche n'ait eu que deux assemblées dans le cours de l'année dernière, elles ont été très enthousiastes et avec un grand pourcentage de présences.

La Branche de la Vallée du St-Maurice comprend les ingénieurs, habitants des villes de Grand'Mère, Shawinigan Falls, Trois-Rivières et Cap de la Madeleine. C'est pourquoi les assemblées mensuelles avec un bon pourcentage de présences sont rendues difficiles et le comité de direction a jugé qu'il était mieux de ne faire que deux ou trois assemblées par année avec succès.

Le tout humblement soumis,
ELLWOOD WILSON, M.E.I.C., *Président.*
R. MORRISSETTE, A.M.E.I.C., *Secrétaire.*

Saguenay Branch

The President and Council,—

On behalf of the Executive committee, we beg to submit the following report covering the activities of the Saguenay Branch of the Engineering Institute of Canada during the calendar year 1930:—

MEMBERSHIP

On December 31st, 1930, the membership of the Branch was as follows:—

Members	6
Associate Members	25
Juniors	7
Students	11
	49

This shows an increase of 3 over the total of 46 on December 31st, 1929.

FINANCIAL STATEMENT
(As at December 31st, 1930)

Receipts		
Balance on hand Dec. 31, 1929	$245.30	
Rebates from Headquarters	112.80	
Interest	3.42	
		$361.52
Expenditures		
Stationery and postage	$ 31.44	
Meetings	65.40	
Telegraph Charges	.54	
	$ 97.38	
Balance on hand	264.14	
		$361.52

BRANCH MEETINGS

On February 24th, 1930, N. D. Paine, A.M.E.I.C., Superintendent of the Hydro-Electric Department of Price Brothers and Company Ltd., gave a very interesting lecture on **Electric Drives for Paper Machines.** This meeting was held in Arvida and was attended by thirty-five members.

On June 25th, 1930, the annual general meeting of the Branch was held at Arvida, in the main office of the Aluminum Company of Canada.

The election of officers for the Executive committee of the Branch for the year 1930 took place and resulted as follows:—

Chairman	N. D. Paine, A.M.E.I.C.
Vice-Chairman	J. F. Grenon, A.M.E.I.C.
Secretary-Treasurer	W. P. C. LeBoutillier, JR.E.I.C.
Executive Committee	G. E. LaMothe, A.M.E.I.C.
	G. O. Vogan, A.M.E.I.C.
	G. F. Layne, A.M.E.I.C.
	J. W. Ward, A.M.E.I.C.

H. R. Wake, A.M.E.I.C., the Branch Councillor, then reported the activities of the Council and outlined a few of the more important matters which were discussed at the last Council meeting.

We were also very fortunate in having with us Mr. M. G. Saunders of the Aluminum Company of Canada, who gave a most interesting talk on **Repairs and Maintenance in Plants located great distances from Industrial Centres.**

Previous to the meeting, the group were shown through the aluminum plant at Arvida, a tour which proved to be of great interest to all.

On November 12th, 1930, C. P. Dunn, M.E.I.C., Chief Engineer for the Alcoa Power Company at Chute à Caron, gave a short informal talk on the design, construction and the dropping of the obelisk at Chute à Caron. His lecture was illustrated by a movie film which showed the obelisk at different stages during construction and also dropping it into position in the Saguenay river. The film had been taken by Mr. Geo. Low, of the Aluminum Company of Canada, who had kindly consented to show it to the meeting.

Respectfully submitted,
N. D. PAINE, A.M.E.I.C., *Chairman.*
W. P. C. LEBOUTILLIER, JR.E.I.C., *Secretary-Treasurer.*

Saskatchewan Branch

The President and Council,—

On behalf of the Branch Executive we beg to submit the following report concerning the activities of the Saskatchewan Branch for the calendar year 1930:—

MEMBERSHIP

The membership of the Branch shows an increase of two over last year with the usual fluctuations due to transfers, etc.

The present membership of the Branch is:

	Resident	*Non-Resident*	*Total*
Members	7	11	18
Associate Members	41	39	80
Juniors	5	4	9
Students	3	8	11
Affiliates	1	1	2
Branch Affiliates	5	0	5
Total	62	63	125

MEETINGS

The Executive held seven meetings for the transaction of Branch affairs. There were six regular meetings of the Branch and one special meeting (ladies night) which took the form of a dinner dance at the Champlain hotel, Regina. The Branch meetings in all cases were preceded by a dinner. The average attendance at Branch meetings was 36, and the general interest in the meetings has been satisfactory.

During the year the Association of Professional Engineers of Saskatchewan came into being. The bill for incorporation of the engineers was sponsored by the Saskatchewan Branch of The Institute and the relations between the two bodies are most cordial. This Branch however feels the need for closer co-ordination of the two bodies.

We regret to record the loss by death of one of our members, the late Wm. R. Warren, A.M.E.I.C., Deputy Minister of Telephones for Saskatchewan. Mr. Warren served as chairman of the Branch in 1921 and always took a keen and active interest in the affairs of The Institute.

PROGRAMME

The programme for the year was as follows:—

Jan. 24.—**The Nipawin Bridge** by H. D. Brydone-Jack, A.M.E.I.C., Assistant Engineer, Canadian Pacific Railway Co.

Feb. 14.—Ladies night, dinner dance, Champlain hotel, Regina.

Mar. 21.—Thirteenth annual meeting. Address by Dr. J. S. Huff, Commissioner of Education, on **The New Curricula for Secondary or High Schools.**

May 30.—Address by Prof. Howard E. Simpson, State Geologist of University of North Dakota, on the **Ranco La Brea Tar Pits of Southern California.**

Oct. 24.—Report of Councillor D. A. R. McCannel, M.E.I.C., joint meeting with the Association of Professional Engineers of Saskatchewan.

Nov. 21.—Address by S. R. Muirhead, A.M.E.I.C., on **Experiments in the Transmission of Speech and Music Illustrated with the Aid of Gramophone Records.**

Dec. 12.—Address by E. M. Moore, Engineer, Tri-Cities Utilities Ltd., on **Gas Supply Engineering, with Special Reference to Regina and Other Saskatchewan Cities.**

SCHOLARSHIP

The annual scholarship of $50 offered by the Branch to the most deserving student in the graduating class in Engineering at the University of Saskatchewan was awarded to Mr. B. A. Evans.

FINANCIAL STATEMENT

Receipts		
Balance from 1929	$326.32

Cash on hand	116.20	
		$677.41

Respectfully submitted,

W. G. WORCESTER, M.E.I.C., *Chairman.*

R. W. E. LOUCKS, A.M.E.I.C., *Secretary-Treasurer.*

Sault Ste. Marie Branch

The President and Council,—

There were eight regular meetings and one special meeting held during the year and also one trip of inspection.

The papers and meetings that were arranged for by the Papers committee were much appreciated by all who attended. The difficulty in obtaining speakers seems to be increasing from year to year and the committee for 1930, and particularly the chairman, are to be congratulated.

The meetings held and the papers given were as follows:—

Jan. 24.—**Electro-Chemical Appliances** by Mr. James Kelleher of the Superior Alloys Ltd.

Feb. 28.—**Winter Maintenance of Roads and Sidewalks** by A. H. Russell, A.M.E.I.C., City Engineer.

Mar. 28.—**The Construction of the Michipicoten Coal Dock** by A. M. Wilson, Jr.E.I.C., of the engineering department of the Algoma Central Railway, and **The History of Dam Construction** by L. F. Harza, M.E.I.C., consulting engineer of Chicago, who is associated with the Algoma District Power Company.

Apr. 25.—**Recent Research Studies of Fire, Heat, Sound and Condensation Problems** by Mr. James Govan, Research Engineer for the Gypsum, Lime and Alabastine Co. of Canada.

Apr. 30.—**The Detroit-Windsor Tunnel** by Mr. R. B. Value.

May 30.—**The Steam Engine on the North American Continent** by R. S. McCormick, M.E.I.C., General Superintendent of the Algoma Central Railway.

Sept. 26.—An inspection trip through the store, roundhouse and machine shop of the Algoma Central Railway.

Nov. 7.—**General Discussion of Civic Affairs** in lieu of paper on New Windsor hotel, which was not given owing to unavoidable absence of contractors from the city.

Nov. 8.—An inspection trip of the New Windsor hotel.

Nov. 28.—**Sanitation** by Dr. Nelson Graham, Director of the Local Branch of the Provincial Board of Health.

Toronto Branch

The President and Council,—

The Executive committee of the Toronto Branch respectfully submits the following report for the calendar year 1930:—

The Executive committee holding office during this period is as follows, the present members being elected at the annual meeting of the Branch on April 3rd, 1930:

EXECUTIVE COMMITTEE

January to April, 1930

Chairman	T. Taylor, M.E.I.C.
Vice-Chairman	J. J. Traill, M.E.I.C.
Secretary-Treasurer	J. J. Spence, A.M.E.I.C.
Executive	G. H. Davis, M.E.I.C.
	A. B. Crealock, A.M.E.I.C.
	H. N. Mason, A.M.E.I.C.
	C. S. L. Hertzberg, M.E.I.C.
	J. R. Cockburn, M.E.I.C.
	C. B. Hamilton, M.E.I.C.
Ex-officio	L. W. Wynne-Roberts, A.M.E.I.C.
Councillors	J. G. R. Wainwright, A.M.E.I.C.
	T. R. Loudon, M.E.I.C.
	R. B. Young, M.E.I.C.

April to December, 1930

Chairman	J. J. Trail, M.E.I.C.
Vice-Chairman	C. S. L. Hertzberg, M.E.I.C.
Secretary-Treasurer	J. J. Spence, A.M.E.I.C.
Executive	*F. B. Goedike, A.M.E.I.C.
	*J. W. Falkner, A.M.E.I.C.
	A. B. Crealock, A.M.E.I.C.
	J. R. Cockburn, M.E.I.C.
	C. B. Hamilton, M.E.I.C.
	†G. H. Davis, M.E.I.C.
Ex-officio	T. Taylor, M.E.I.C.
Councillors	J. G. R. Wainwright, A.M.E.I.C.
	T. R. Loudon, M.E.I.C.
	R. B. Young, M.E.I.C.
	L. W. Wynne-Roberts, A.M.E.I.C.

*Elected for period of 2 years.
†Elected for period of 1 year.

STANDING COMMITTEES

The following standing committees, with the chairman of each, were appointed by the Executive:

January to April, 1930

Papers	T. Taylor, M.E.I.C.
Finance	J. J. Traill, M.E.I.C.
Publicity	C. S. L. Hertzberg, M.E.I.C.
Membership	H. N. Mason, A.M.E.I.C.
Meetings	G. H. Davis, M.E.I.C.
Library	J. R. Cockburn, M.E.I.C.
Student Relations	W. B. Dunbar, A.M.E.I.C.
Branch Editor	A. B. Crealock, A.M.E.I.C.

April to December, 1930

Papers	J. J. Traill, M.E.I.C.
Finance	C. S. L. Hertzberg, M.E.I.C.
Publicity	T. Taylor, M.E.I.C.
Membership	G. H. Davis, M.E.I.C.
Meetings	F. B. Goedike, A.M.E.I.C.
Library	J. R. Cockburn, M.E.I.C.
Student Relations	J. R. Cockburn, M.E.I.C.
Branch Editor	A. B. Crealock, A.M.E.I.C.

The Executive committee of this Branch held six meetings during the year for the transaction of Branch business and thirteen general meetings.

The various meetings for the year 1930 were as follows:—

Jan. 9.—**The Internal Structure of Concrete** by J. W. Kelly of the Portland Cement Association, Chicago.

Jan. 23.—**A Pioneer Canadian Industry** by C. E. Macdonald, Assistant to Vice-President, International Nickel Company of Canada, Ltd.

Feb. 6.—**Construction Features of the 220,000-Volt Gatineau-Toronto Steel Power Lines** by A. E. Davison, Transmission Engineer, Hydro-Electric Power Commission of Ontario.

Feb. 20.—**The Petroleum Industry** by A. W. Sime, Technical Engineer, Imperial Oil Ltd., Toronto.

Mar. 6.—**Signalling and its Relation to Speed and Safety of Railroad Operation** by S. J. Turreff, Assistant Resident Engineer, Union Switch and Signal Co. of St. Louis.

Mar. 20.—**The Design and Construction of the Detroit-Windsor Tunnel** by Col. B. R. Value, Executive Engineer of Parsons, Knapp, Brinckerhoff and Douglas, Designers and Engineers of the Detroit-Windsor Tunnel. This meeting was in conjunction with the Association of Professional Engineers of Ontario.

Apr. 3.—**Annual Meeting** of the Branch.

Apr. 17.—**Water Power Development in Brazil** by A. W. K. Billings, M.E.I.C.

Oct. 10.—**The Mechanical and Electrical Features of the Welland Ship Canal** by L. P. Rundle and J. B. McAndrew, A.M.E.I.C. This meeting was in conjunction with the American Society of Mechanical Engineers (Ontario Section) and the American Institute of Electrical Engineers (Toronto Section).

Oct. 30.—**The Hudson's Bay Railway** by Dr. H. A. Innis, Professor of Political Economy, University of Toronto.

Nov. 13.—**Aero Photometric Surveys** by General Sir Charles Delmé-Radcliffe and **Industrial Engineering** by William Snaith.

Nov. 27.—**Recent and Projected Improvements to the Waterworks System of the City of Hamilton** by W. F. McFaul, M.E.I.C., City Engineer, Hamilton.

Dec. 11.—**Arc Welding in Steel Fabrication** by A. S. Wall, M.E.I.C., Dominion Bridge Company, Ltd., Montreal.

MEMBERSHIP

The membership as listed at December 31st, 1930 is as follows:—

J. J. SPENCE, A.M.E.I.C., *Secretary-Treasurer.*

Vancouver Branch

The President and Council,—

We beg to submit the following report of the activities of the Vancouver Branch of The Institute for the year 1930:—

MEETINGS

During 1930 nine meetings of the Branch were held as outlined below:—

Feb. 27.—Student night.

Mar. 27.—H. B. Muckleston, M.E.I.C., on **A Method of Equalizing Stresses in Masonry Arches.**

Apr. 2.—N. C. Stewart, B.C.L.S., on **Modern Methods of Surveying.**

May 16.—W. E. Harper, F.R.S.C., on **Observatories and their Work.**

May 19.—Luncheon meeting. Speaker, Brigadier-General H. St.J. L. Winterbotham, C.M.G., D.S.O.

May 31.—Trip to Ruskin Lake Power Plant.

July 5.—Trip to Pacific Coast Terminals' Cold Storage Plant.

Oct. 29.—Inspection of C.P. S.S. "Empress of Japan."

Dec. 29.—**Annual Meeting.**

In this regard mention must be made of the fact that while the various trips were well attended, the ordinary meetings at which papers were read were not so well supported.

EXECUTIVE

During the year five meetings of the Executive were held to transact the routine business of the Branch and to discuss matters of policy.

Walter Moberly Memorial Prize

The prize for 1930 was awarded to William R. Selby, s.e.i.c., for an essay on "The Sullivan Mine," being the best essay submitted by any student in the senior year of the Faculty of Applied Science at the University of British Columbia.

Library

With the approaching closing of the University Club the problem of the future disposition of the library became serious, and a committee was appointed consisting of a member from each major engineering organization in the city to consider the whole problem of meeting places and the establishment of an engineering library. Discussion soon made it evident that the various bodies were not strong enough financially at present to establish any central quarters, so that the problem of the Branch library was not solved in any way by this committee. Finally negotiations were opened with the Carnegie Public Library and they agreed to take our collection, select what they required and dispose of the remainder as the Branch saw fit. These books taken over by the library would be indexed in the usual manner and made available to the public as reference books. It is the intention of the Public Library to establish a reading room for professional men as soon as funds and space permit, and when this is accomplished, the Branch collection will be placed therein.

The total cost, then, of disposing of the Branch library amounted to $24 for moving the books to the Public Library, of which the Association of Professional Engineers paid $12.

Relations with the Association of Professional Engineers

The relations between the Branch and the Association of Professional Engineers have been very harmonious, and the two bodies have co-operated in obtaining speakers and in the problem of the Branch library.

Relations with Vancouver Section, American Institute of Electrical Engineers

This past year has seen close co-operation between our Branch and the local Section of the American Institute of Electrical Engineers. Two joint meetings have been held to hear papers on topics of interest to both branches and a very valuable precedent has been established in this regard.

Membership

	Dec. 1928	Dec. 1929	Dec. 1930
Branch Resident			
Members	58	59	59
Associate Members	77	79	82
Juniors	11	14	13
Students	61	76	84
Affiliates	2	2	2
	209	230	240
Branch Non-Resident			
Members	16	17	17
Associate Members	40	46	50
Juniors	8	9	14
Students	17	19	16
Affiliates	0	0	0
	81	91	97

Student Section

The Student section of the Branch at the University of British Columbia has had a successful year. In February a very good meeting was held at the university, three excellent papers being given by the students. In addition noon-hour meetings were held during the term where prominent engineers spoke on various topics, technical and otherwise.

Elections

Sixty-seven ballots were returned out of a total of 157 mailed.

Finances

The attached financial statement shows a balance on hand of $181.83 at the end of the year's activities.

Financial Statement

(December 18th, 1929, to December 29th, 1930)

Receipts

Bank balance as at Dec. 18, 1929	$ 81.07		
Cash in hand	9.69		
Rebates from Headquarters, August 1929 to August 1930	379.01		
Library rent (Association of Professional Engineers)	50.00		
Library moving (Association of Professional Engineers)	12.00		
			$531.77

Expenditures

Office Expenses:			
Rent	$ 75.00		
Petty cash	29.69		
Telegrams	3.16		
Stenographer	15.00		
		$122.85	
Meetings:			
Notices and ballots	58.59		
Rent of auditorium	10.00		
		68.59	
Student Section		9.50	
Library:			
Rent	75.00		
Moving	24.00		
		99.00	
Honorarium for Secretary—1929		50.00	
Balance:			
Bank	181.33		
Cash	.50		
		181.83	
			$531.77

Walter Moberley Memorial Fund

(December 18th, 1929, to December 29th, 1930)

Receipts

Bank balance at Dec. 18, 1929	$ 66.19	
City of Vancouver Bond interest 1930	25.00	
Dominion of Canada Bond interest 1930	5.00	
Bank interest	2.46	
		$ 98.65

Expenditures

Bank balance, Dec. 29, 1930	73.65	
		98.65

Library Capital Account

(December 29th, 1930)

	Dr.	Cr.
To loan from Headquarters	$300.00	
By instalment repaid—1927		$ 25.00
" " " 1928		100.00
" " " 1929		50.00
Balance debit		125.00
	$300.00	$300.00

Student Section

The Executive of the 1930-31 session of the Students' section is composed of the following:—

President.....M. C. Nesbitt, s.e.i.c.
Vice-President.....L. F. Swannell, s.e.i.c.
Secretary-Treasurer.....R. V. Anderson, s.e.i.c.
Assistant-Secretary.....P. D. Rossiter.

The work of the section consists mainly in procuring prominent speakers from the various fields of engineering to deliver regular noon-hour talks to the students. The meetings are well attended and thoroughly appreciated.

During the fall term the following papers were delivered:

E. A. Wheatley, a.m.e.i.c., Secretary of the Association of Professional Engineers of B.C., on **The Engineer and The Engineering Institute.**

Mr. E. F. Elderton, the Boeing Aircraft Company of Canada, on **The Design and Construction of Aircraft.**

Patrick Philip, m.e.i.c., Deputy Minister of Public Works for B.C., on **Civil Engineering as a Career.**

J. A. Walker, a.m.e.i.c., Consultant to the Vancouver Town Planning Commission, on **The History of Town Planning in Vancouver.**

F. A. Lazenby, s.e.i.c., B.C. Electric Construction Dept., on **The Ruskin Development.**

Dr. W. E. Cockfield, Geological Survey of Canada, on **The Relation of Geology to the Engineer.**

Mr. W. S. Barwick, Vulcan Engineering Works, on **Foundry Practice in British Columbia.**

A field trip was taken to the Vulcan Engineering Works, located in the industrial section of Granville island. Here the students were privileged to see the actual procedure in foundry practice.

The plant is equipped with two electric furnaces for making cast steel. The melt is "doctored" with ferro-silicon, ferro-manganese, ferro-chrome and carbon to rid it of impurities and give it the required chemical composition. The moulds are prepared from specially selected sand. The entire process of making the cope and drag and preparing the moulds for pouring was witnessed with keen interest. The largest castings in the shop at the time were some gear wheels for use in raising the tainter gates of the new Ruskin dam.

Respectfully submitted.

John C. Oliver, jr.e.i.c., *Secretary-Treasurer.*

Victoria Branch

The President and Council,—

During the year there has been a slight increase in the membership of the Branch and some members have left to take up positions in other places. M. P. Blair, M.E.I.C., has gone to Winnipeg, Engineer-Commander A. D. M. Curry, M.E.I.C., has gone to Halifax and D. K. Penfold, A.M.E.I.C., to Kelowna. We welcome the following Members and Associate Members to our Branch: H. L. Swan, M.E.I.C., Major E. C. G. Chambers, A.M.E.I.C., C. F. Corbett, A.M.E.I.C., A. W. Ferguson, A.M.E.I.C., N. H. Gahan, A.M.E.I.C., J. H. MacIntosh who has been transferred from Student to Associate Member, and M. C. Trueman, Jr.E.I.C., and Wm. Hall, S.E.I.C.

The numbers are as follows:—

	Resident	*Non-Resident*
Members	18	1
Associate Members	25	5
Juniors	2	0
Students	6	4
Affiliates	2	0
Total	53	10

Total membership of Branch 63.

This compares very favourably with a total of 55 last year being an increase of four residents and four non-residents.

The activities of the Branch were much curtailed during the year, though the Branch held a successful dinner at Hamsterley, on March 28th, which was well attended. A complimentary dinner was given to F. C. Green, M.E.I.C., on April 11th to congratulate him on his appointment as Surveyor General. Some visits to construction work are contemplated this coming winter.

The club room with its library and current engineering magazines has been maintained during the year.

Financial Statement
(1930)

Winnipeg Branch

The President and Council,—

The following report for the year ending December 31st, 1930, of the Winnipeg Branch, is respectfully submitted:—

The membership at the end of the year stood as follows:

	Resident	*Non-Resident*	*Total*
Members	41	4	45
Associate Members	96	31	127
Juniors	10	3	13
Students	53	6	59
Affiliates	5	0	5
Branch Affiliates	12	0	12
Total	217	44	261

We regret to report that the Corporate Membership of the Branch was reduced by the death of one of its charter members, the late Captain H. A. Bowman, M.E.I.C., also by the death of the late Captain Charles A. Millican, A.M.E.I.C.

There were eight regular meetings held during the year as tabulated below:

Jan. 9.—R. H. Varcoe, **Talking Pictures.** Attendance, 53.
Feb. 6.—J. C. Burkholder, **Carrier Current.** Attendance, 52.
Mar. 6.—F. Pugh, **Manitoba Limestone.** Attendance, 26.
Apr. 3.—J. C. N. B. Krumm, **Hydro-Electric Power Development at Grand Falls, N.B.** Attendance, 52.
May 1.—Prof. J. J. Hinman, **Treating a Tropical Water Supply in South America.** Attendance, 33.
Oct. 16.—J. Gilchrist, **Forgings for Locomotives.** Attendance, 48.
Nov. 20.—J. C. Davis, **Fire Protection and Fire-Proofing.** This meeting was held jointly by the Branch and Engineering students of the University of Manitoba. Attendance, 150.
Dec. 18.—Prof. Frank Allen, **Physics of the Stars.** Attendance, 31.

The Branch awarded four prizes for Students' papers, two to Students in Civil Engineering, and two to Students in Electrical Engineering.

Eric W. M. James, A.M.E.I.C., *Secretary.*

THE

ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XIV FEBRUARY 1931 No. 2

The Forty-Fifth Annual General Meeting

The last occasion on which the members of The Institute gathered in Montreal at an Annual General Meeting was in 1928, when we were honoured by the presence of His Excellency the Governor-General at the Annual Dinner, a very successful meeting took place, and many pleasant memories were left in the minds of those who attended.

This year the Montreal Branch again sponsored the Annual Meeting and provided an equally attractive programme, both as regards social features, visits to engineering works of interest and the technical papers to be presented and discussed. The Montreal Branch Committee certainly maintained its reputation for organizing attractive Annual Meetings and the efforts of the Branch were fittingly recognized by a cordial vote of thanks at the conclusion of the first day's proceedings.

The Professional Status of the Engineer

It is a commonplace to say that the functioning of the social organization as we know it to-day is only possible as a result of the work of the engineer, using that word in its widest sense as denoting one who by his technical skill has aided in producing the present mechanized system of civilization. But even those who realize that the events of their daily lives are dependent upon the engineer's achievements in power development, transportation, communication or construction, give little or no recognition to engineers as a professional body. Engineers of eminence who have been responsible for great public works, or whose undertakings are in the public eye, are accorded general respect, and "engineering" as a career has a romantic but somewhat indefinite appeal to our boys. The general public, however, knows little, and cares less, about the rank and file of the engineering fraternity. This is largely because the daily work of an engineer, unlike that of a lawyer, doctor or dentist, does not bring him into personal contact with the everyday affairs of the people who benefit from his skill and knowledge. His professional relations are largely with those associated in his work, not with the "man in the street."

It is usual to refer to the typical engineer as inarticulate, but his failure to impress himself upon the public as a professional man is not so much due to inability to express himself as to the technical nature of his work, which has to do with forces and materials much more than with the troubles or difficulties of mankind. The majority of engineers are not voiceless; on the contrary, they have much to say, but their opportunities for expressing themselves freely are usually in connection with professional matters, and therefore they reach only a limited audience.

In a recent address, Professor Wickenden happily defined professional status as "an implied contract to serve society in consideration of the honour, rights and protection society extends to the profession. Through all professional relations runs a threefold thread of accountability, to colleagues, to clients and to the public. The obligations of a profession are so much a matter of attitude that codes alone are not sufficient to sustain them. Equal importance attaches to the state of mind known as professional spirit, which results from associating together men of superior type, and from their common adherence to an idea which puts service above gain, excellence above quantity, self-expression above pecuniary incentives and loyalty above individual advantage. The professional man cannot evade the responsibility to contribute to the advancement of his group. His skill he rightly holds as a personal possession, and when he imparts it to another he rightly expects a due reward in money or in service. His knowledge, however, is to be regarded as part of a common fund; hence the obligation to publish researches and to share advances in professional practice." These are high ideals; how far are engineers putting them into practice?

In the very nature of things, certain professions, for example law and medicine, and to a lesser extent architecture, have been able to form their members into definite groups, increasing their solidarity, raising their standards for admission, and developing adequate methods of governing their members. In these more compact professions there is a clear line of demarcation between the professional man and persons working with him, which can only be crossed by a definite entrance into an organized professional body. No amount of experience in dispensing prescriptions will convert a druggist into a physician. In the case of engineers we are dealing with a calling whose work merges into that of a large number of subsidiary specialists. Engineering organizations contain not only fully qualified engineers, but also draughtsmen, detailers, sales representatives, inspectors, superintendents, and the like, all of whom do some engineering work, and are developed by the experience they obtain. Hence it is increasingly difficult, in many cases, to say whether a man is or is not qualified by experience to enter the professional ranks. Of late years conditions have changed rapidly in another respect. The number of engineers who are doing consulting or advisory work on their own responsibility has greatly diminished, and much of the designing and similar work, which used to be performed by consulting engineers, is now taken care of by corporations organized for the purpose. In fact there is an increasing tendency for engineers to be more and more employees of large industrial or governmental organizations.

Such circumstances go far to explain the lack of recognition of engineering as a definite profession, and the situation is made more confusing in the public mind by the general misuse of the term "engineer," by the lack of a generally understood means of distinguishing between qualified engineers and non-engineers, and by the democratic nature of the engineer's work, which necessarily permits capable men to rise by experience from sub-professional to professional status, engineering thus differing essentially from law or medicine as now organized. Further, it must not be forgotten that the work of all engineers has an underlying economic basis. The undertakings or structures which he plans must pay their way. The expenditure on the apparatus he designs must be justified by its performance and commercial success. This condition recalls the old saying that an engineer is a man who can do for one dollar what any fool can do for two, and in these respects also it is obvious that engineering differs fundamentally from many other professions.

It is essential that a profession govern itself, and it is effective organization for this purpose which really confers professional status. While the conditions which have just been outlined certainly add to the difficulty of the task of maintaining such status, they do not relieve the engineer from the necessity of undertaking it; on the other hand, they render the duty more imperative.

It has long been realized that engineers should themselves take steps to protect the public against incompetent or non-ethical practices, and that such protection necessarily involves to a large extent the protection of the members of the profession themselves. It is therefore interesting to note the methods adopted for this purpose in various countries. In England, for example, it is held that certain grades of membership in one of the principal national engineering societies should be regarded as a guarantee of professional competence and status. Accordingly powers have been obtained in the charters of several of these organizations granting to their duly qualified members the exclusive use of the titles "Chartered Civil Engineer," "Chartered Electrical Engineer," or as the case may be. The privilege of admission to the institutions in question is carefully guarded, and the educational qualifications of those applicants who are not university graduates are tested by means of examinations in general and professional subjects, carried out by the institutions themselves. As a result there is growing up a general appreciation of the status conferred in this way. On the continent of Europe, on the other hand, the great professional schools, such as the Ecole Polytechnique in France, confer by their diplomas the right to use the title of engineer, and their graduates accordingly have a professional status as engineers, as distinguished from that of technicians.

In the United States the policy of state licensing of engineers has been adopted, not without a good deal of argument and discussion. The protection of the public is there a state concern and not a Federal responsibility. Accordingly, in more than twenty states of the Union, licensing boards have been established, deriving authority from acts of the state legislatures, and these bodies examine and license professional engineers quite independently of any membership in national or local engineering societies. This movement has, as yet, not been generally supported in the United States, nor have the various state acts been universally enforced. Further, the necessary methods for co-operation between the voluntary technical societies in the United States, who have no specific educational requirements for membership, and the state licensing bodies, who demand proof of educational qualification before admission, have still to be worked out.

In Canada the majority of engineers seem always to have been in favour of professional registration, which, as affecting the public safety is a provincial and not a Dominion concern. Indeed, the inception of our present registration methods was due to the Canadian Society of Civil Engineers, who, in 1898, obtained in the Quebec Act a definite provincial recognition of the professional status of engineers. From this time on, gradual development took place, and in 1920-1922, owing very largely to the activities of the Council and members of The Engineering Institute of Canada, a policy of provincial registration was definitely embarked upon, so that at the present time Provincial Associations of Professional Engineers exist in eight of the nine provinces of the Dominion. The primary duty of these bodies is, of course, the licensing of engineers for practice; the provincial acts differ considerably in details, but they all recognize this as their main function. Very encouraging success has attended the efforts of most of the Associations, and while in some provinces progress has been slow, the foundations for further work have been laid. Much, however, remains to be done before members of the Associations can have other than a provincial status as engineers, and there is a marked need for concerted action among the Associations with a view to the co-ordination of their special activities and requirements for admission, and with the ultimate aim of conferring upon their members a Dominion-wide rather than a provincial qualification.

The relations of The Engineering Institute of Canada with the Provincial Associations, and the manner in which The Institute can aid those bodies in their work, are naturally of real interest to our members, a very large proportion of whom properly belong to their respective Provincial Associations. As is well known, this subject has been under consideration by an important committee of The Institute for the past three years, and that committee's report was received, and its recommendations endorsed, at the Annual Meeting of The Institute in 1930. The committee is continuing its work under the chairmanship of Past-President H. H. Vaughan, M.E.I.C., and, as will be seen from the report just presented at the Annual Meeting, is endeavouring to aid in the work of co-ordination, while, at the same time, discussing the relationship which an essentially voluntary body like The Engineering Institute of Canada will eventually bear towards the legally constituted Provincial Professional Associations. There is still a long way to travel along the road of professional confederation, but those who remember the years of effort required for the establishment of a Dominion qualification to practise medicine will not be discouraged. In the meantime, it is evidently the duty of all engineers who have the interests of the profession at heart, to comply themselves, and urge others to comply, with the requirements of the existing Provincial Registration Acts, for it is only in this way that definite progress can be made towards consolidation of the profession in Canada.

COMMITTEE

of the

MONTREAL BRANCH

In Charge of Arrangements for

The Annual General Professional Meeting

FEBRUARY 4th, 5th and 6th, 1931

D. C. Tennant, M.E.I.C.,
Designing Engineer,
Dominion Bridge Company, Montreal.
Chairman of
Annual Meeting Committee.

A. Duperron, M.E.I.C.,
Chief Engineer,
Montreal Tramways Commission,
Montreal.
Chairman, Montreal Branch.

J. A. McCrory, M.E.I.C.,
Office Engineer,
Power Engineering Company, Montreal.
Chairman of
Committee in Charge of Luncheons.

C. K. McLeod, A.M.E.I.C.,
Busfield McLeod Limited, Montreal.
Secretary of
Annual Meeting Committee.

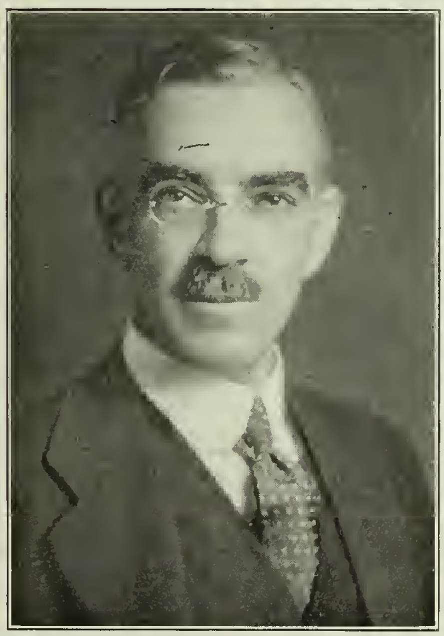
H. G. Thompson, A.M.E.I.C.,
F. S. B. Heward and Company, Ltd.,
Montreal.
Chairman of Publicity Committee.

C. M. McKergow, M.E.I.C.,
Professor of Mechanical Engineering,
McGill University, Montreal.
Chairman of
Smoker Committee.

J. L. Busfield, M.E.I.C.,
Busfield, McLeod, Ltd., Montreal.
Chairman of
Hotel Committee.

H. Massue, A.M.E.I.C.,
Assistant Engineer,
Shawinigan Water and Power Company,
Montreal.
Chairman of
Registration Committee.

F. Newell, M.E.I.C.,
Mechanical Engineer,
Dominion Bridge Company, Ltd.,
Montreal.
Chairman of
Committee in Charge of Visits to Plants.



P. E. Jarman, A.M.E.I.C.,
City Manager,
Westmount, Que.
Chairman of
Committee on Papers and Meetings.

W. McG. Gardner, A.M.E.I.C.,
Principal Assistant to Engineer of
Rapid Transit, Montreal Tramways
Company.
Chairman of
Ladies Committee.

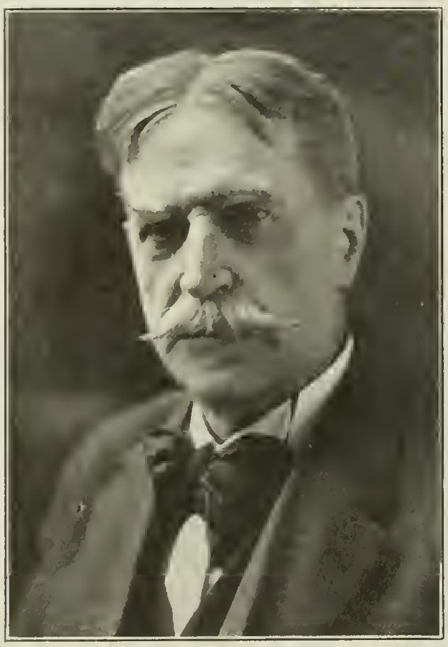
OBITUARIES

Charles Edwards Willoughby Dodwell, Hon.M.E.I.C.

On December 29th, 1930, The Institute lost by death one of its distinguished members, Charles Edwards Willoughby Dodwell, Hon.M.E.I.C., Supervising Engineer for the Maritime Provinces of the Department of Public Works of Canada.

The second son of the Rev. G. B. Dodwell, he was born October 17th, 1853, in Gloucestershire, England, and was educated at New College School, Oxford; Bishop's College School, Lennoxville, Que.; and at King's College, Windsor, N.S., where he graduated B.A. in 1873. Commencing his professional career in railway construction in Nova Scotia, he was assistant provincial engineer under Dr. Martin Murphy, M.E.I.C., until 1881, when he became connected with the work of the Canadian Pacific Railway, and in conjunction with G. H. Massey made the first plans and estimates for the bridge across the St. Lawrence at Lachine. From 1882 to 1885 he was employed on the construction of the line from Toronto to Smith's Falls.

His work was transferred to Montreal in 1885, when he took charge of the construction of the main line from Windsor street to Vaudreuil including the arched stone



C. E. W. DODWELL, Hon.M.E.I.C.

viaduct approach, and the bridges at Ste. Anne's, Stocker's Creek and Vaudreuil. His paper describing the "Foundations of the Ste. Anne's Bridge" appears in the second volume of the Proceedings of the Canadian Society of Civil Engineers.

The firm of Dodwell and Hogg was established in Montreal in 1889, where they carried on a general engineering practice till 1891, when Mr. Dodwell was appointed district engineer of the Department of Public Works of Canada at Halifax, N.S. He held this position till 1922, when he was promoted to supervising district engineer for the Maritime Provinces, an appointment which he retained up to the time of his death.

Associated with The Institute's activities from the very beginning, he was one of the first engineers to be elected Member of the Canadian Society of Civil Engineers on January 20th, 1887, and he continued to take an active and influential part in Institute affairs throughout his life. With Alan MacDougall he was among those who had canvassed the possibilities of the formation of such a Society in 1884-5. This interest he carried with him to Montreal, and was present at the organization meeting held there on March 4th, 1886, when a committee of nine, of which he was a member, was appointed to draft a constitution for the proposed body. This constitution, amended as a result of correspondence between Montreal, Toronto and Ottawa, formed the basis on which the Canadian Society of Civil Engineers was then founded, and as a result of the efforts of Mr. Dodwell and others, the Charter of the new organization received Royal Sanction on June 23rd, 1887.

Mr. Dodwell was a member of Council almost continuously from 1890 to 1910, was a Vice-President in 1904 and 1911, and was honoured by election as an Honorary Member in 1922. He took an active part in the formation of the Halifax Branch in 1918, and was its chairman for two years.

Throughout his connection with The Institute, his guiding principle was the maintenance and development of its status as a professional body, concerned with the high standing of its members, and promoting the interchange of professional knowledge among them. He was equally interested in the possibilities of legislation regulating professional practice, and as early as 1896 was instrumental in presenting a bill to establish engineering as a profession in the province of Nova Scotia, an effort which was almost successful, although perhaps somewhat ahead of the times.

Later, when in March, 1919, The Engineering Institute of Canada invited the various Branches to send delegates to a meeting at Montreal to devise means of creating Provincial Associations of Professional Engineers, Mr. Dodwell was elected chairman of the meeting, and after much intensive work a draft bill was prepared which formed the basis of the acts respecting the Engineering Profession, which have now become law in eight provinces of the Dominion.

Mr. Dodwell was the first President of the Nova Scotia Association of Professional Engineers, holding office for three years, and honoured by all its members for his efforts and the results obtained.

He was for nearly fifty years a corporate member of the Institution of Civil Engineers, having been elected an Associate Member of that body in 1881, and a Member in 1890. He was a member of the board of visitors of the Royal Military College from 1908 to 1911, and a member of the executive committee of the Halifax branch of the British Empire League. He was elected president of St. George's Society, Halifax, in 1908, serving until 1910, and was a vice-president of the Studley Quoit Club from 1909 to 1910 at Halifax.

With two or three others he represented the Dominion government at the twelfth meeting of the Permanent International Association of Navigation Congresses in Philadelphia in 1912, and in 1923 he was the sole representative of the Dominion government and The Engineering Institute of Canada at the thirteenth meeting held in London, England.

A man of wide reading and gifted with a remarkable intellect, his incisive comments on technical matters and questions of the day were always timely and conducive to discussion.

His many friends throughout Canada mourn the loss of a congenial companion, a patriotic citizen, and an outstanding representative of his profession.

Arthur Hutchinson Smith, M.E.I.C.

In the death of Arthur Hutchinson Smith, M.E.I.C., which occurred in his eighty-second year at his home in London, Ont., on October 3rd, 1930, The Institute loses one of its oldest members.

A. H. SMITH, M.E.I.C.

Mr. Smith was born at Shipley, Yorkshire, England, and was educated at Hippersholme school, graduating as a mechanical engineer. He came to this country in 1883 to fill the position of mechanical superintendent of the Grand Trunk Railway, with headquarters at Toronto. In 1885 Mr. Smith organized the first Red Cross train in Canada, one which was sent to the west to take care of men wounded in the Riel Rebellion. He went to London, Ont., in 1890 to take charge of the carshops in that city and of the locomotive shops at Stratford, Ont.

Mr. Smith took an active interest in Institute affairs and was a charter member of the London Branch. He was made a life member of The Institute in 1898.

Mr. Smith joined The Canadian Society of Civil Engineers as a Member of February 3rd, 1887.

PERSONALS

A. N. Ball, A.M.E.I.C., formerly with the McIntyre Porcupine Mines at Timmins, Ont., is now connected with the E. B. Eddy Company at Hull, Que.

W. J. Fuller, A.M.E.I.C., who has, since 1914, been district engineer for the Department of Public Works, Canada, at Sault Ste. Marie, Ont., has been appointed district engineer at Port Arthur, Ont., by the department.

F. A. Crawley, A.M.E.I.C., is at present connected with the Texas Power and Light Company, and is in charge of reconstruction of a hydro-electric plant at Llano, Texas. Mr. Crawley was formerly with the Compania Mexicana de Construccione, S.A., at Torreon, Voahuila, Mexico, as field engineer in charge of transmission line surveys.

A. W. Swan, A.M.E.I.C., has resigned his position as publicity manager of Evershed and Vignoles, Ltd., London, England, after seven years in that post, to accept the appointment of publicity manager of The Brush Electrical Engineering Company, Ltd., Loughborough, Leicestershire, England. From 1919 to 1922 Mr. Swan was assistant editor of The Engineering Journal.

Major L. T. Burwash, M.E.I.C., Exploratory engineer, Northwest Territories and Yukon Branch, Department of the Interior, Ottawa, arctic explorer and discoverer of the remains of the Franklin expedition, was the guest of honour, on December 26th last, at a civic luncheon at the St. Denis Club, Montreal.

F. H. Hibbard, A.M.E.I.C., has recently received the appointment of chief engineer of the Quebec Central Railway Company. Mr. Hibbard has had extensive experience on railway work, particularly with the construction of the National Transcontinental Railway and Saint John Valley Railway. He became connected with the Quebec Central Railway Company in 1913 as engineer in charge of construction, later becoming in turn assistant engineer, engineer maintenance of way, and engineer, holding the last-named office up to the present time.

J. G. Hall, A.M.E.I.C., Receives Appointment

J. G. Hall, A.M.E.I.C., has been appointed general manager of Combustion Engineering Corporation, Ltd. Mr. Hall, who has been with the Corporation since 1924, is a graduate of McGill University of the year 1921, and was for some time in charge of operations in the west. His previous engineering experience includes work with the Grand Trunk Railway, the United States Shipping Board and the Back River Power Company. Mr. Hall is a member of the Associations of Professional Engineers of Quebec and Manitoba.

H. M. LYSTER, A.M.E.I.C.

H. M. Lyster, A.M.E.I.C., has been appointed general manager of the Dominion Welding Engineering Company, Ltd., Lachine, Que. Following his graduation from McGill University in 1913 with the degree of B.Sc., Mr. Lyster was assistant engineer with the Canadian Pacific Railway Company at Bankhead, Alta. In 1915 Mr. Lyster went overseas where he was later attached to the Royal Engineers, and was awarded the Military Cross. He was for a time in charge of explosive railway transport in Yorkshire, England, for the Imperial Ministry of Munitions. He was demobilized in 1920, and returning to this country became salesman and estimating engineer for H. H. Robertson and Company, Ltd., Montreal. He was later connected with

A. C. TAGGE, M.E.I.C.

the Automotive Engineering Company and the Eastern Engineering Company until 1926, when he became Secretary of the Canadian Electrical Association, which position he has held until the present time.

A. C. TAGGE, M.E.I.C., RETIRES

A. C. Tagge, M.E.I.C., has retired from the presidency of the Canada Cement Company, Ltd., which office he has held since 1927. He will, however, remain on the board of directors of the company.

Mr. Tagge was born at Ann Arbor, Mich., in 1870, and received his early education in the public schools of Ann Arbor and his technical education at the University of Michigan, graduating from the latter institution in 1897 with the degree of B.Sc. In 1898 Mr. Tagge was draughtsman with the Link-Belt Machinery Company at Chicago, Ill., and two years later was employed by the Osborne Engineering Company, Cleveland, Ohio. In 1901 he was appointed erecting engineer and superintendent of the Peninsular Portland Cement Company, resigning that position in 1902 to come to Canada as engineer with the International Portland Cement Company at Ottawa. Mr. Tagge remained with this company until 1905 when he occupied a similar position with the Western Canada Cement and Coal Company. Two years later he returned to Ottawa as engineer and superintendent of the International Portland Cement Company, until he accepted the position of general superintendent with the Canada Cement Company at Montreal in the year 1909. He occupied this position until 1919 when he was made assistant general manager of the company.

J. D. JOHNSON, AFFIL.E.I.C.

J. D. JOHNSON, AFFIL.E.I.C., NEW PRESIDENT OF CANADA CEMENT CO., LTD.

J. D. Johnson, Affil.E.I.C., has been elected to the presidency of the Canada Cement Company, Ltd., succeeding A. C. Tagge, M.E.I.C. Mr. Johnson was born at Malagash, N.S., and received his early education at schools in Nova Scotia. In 1903 he joined the staff of the Canadian Portland Cement Company, Ltd., remaining with that company for one year, when he became connected with the Raven Lake Portland Cement Company, Ltd., filling at various times the positions of secretary-treasurer, superintendent and sales manager. In September, 1907, Mr. Johnson became sales manager of the Lehigh Portland Cement Company, Ltd., Toronto, which position he held until October, 1909, when he joined the staff of the Canada Cement Company Ltd., as sales manager of the company's Toronto office. In March, 1919, Mr. Johnson was appointed general sales manager at Montreal, which position he has held until the present time.

T. S. MORRISEY, A.M.E.I.C.

LIEUT.-COL. T. S. MORRISEY, A.M.E.I.C., ACCEPTS NEW POSITION

Lieut.-Colonel T. Sidney Morrisey, A.M.E.I.C., has resigned as vice-president and general manager of Combustion Engineering Corporation Ltd. to become vice-president of United Engineers and Constructors (Canada) Ltd. Lieut.-Colonel Morrisey is a native of Saint John, N.B., and graduated with honours from the Royal Military College, Kingston, in 1910. From that time until the outbreak of war Colonel Morrisey was engaged on the design and construction of various engineering projects. Joining the 13th Battalion the Royal Highlanders of Canada in 1914

GEO. R. MacLEOD, M.E.I.C.

he served continuously for three years in France and later in Siberia, being awarded the D.S.O., the Japanese Order of the Rising Sun and the Czecho-Slovak War Cross, and was demobilized in 1919 with the rank of lieutenant-colonel. Colonel Morrisey joined the staff of the Combustion Engineering Corporation of New York as field engineer during the construction of the steam stand-by plant for the Winnipeg Hydro. In 1926 he was appointed to the position with the Combustion Engineering Corporation Ltd. which he has recently resigned.

Geo. R. MacLeod, M.E.I.C., Receives Important Appointment

Geo. R. MacLeod, M.E.I.C., who was appointed assistant chief engineer of the city of Montreal in May, 1929, has now been entrusted with all questions relating to railways and tramways in that city. He will also supervise the construction of bridges, tunnels and viaducts. Mr. MacLeod thus becomes city railways engineer. This post assumes special importance by reason of the big railway terminal problems confronting Montreal, in connection with which Mr. MacLeod's railway experience prior to his becoming connected with the engineering department of the city of Montreal will be most valuable. From 1918 to 1929 Mr. MacLeod was engineer-in-charge of the Technical Service, a branch of the Public Works Department of the city of Montreal, which was organized in 1918 with the purpose of concentrating in one department all engineering work connected with every branch of the city public services excepting water supply and distribution.

It is also announced that J. G. Caron, A.M.E.I.C., engineer in charge of the Technical Service, will have charge of homolgations, expropriations, etc.

The Lincoln Electric Company of Canada, Ltd., manufacturers of "Linc-Weld" motors and "Stable-Arc" welders, announces a totally enclosed, fan-cooled, induction motor which embodies a number of new and unusual features. This new motor is so designed that its rise in temperature is considerably less than the allowable rise for motors of this type. The design of the motor also includes arc-welded steel construction, double-sealed ball bearings, and a removable cover which facilitates cleaning of the unusually large radiating surface. This new "Linc-Weld" motor has the same mounting dimensions as standard open type, horizontal motors of equal rating, and is manufactured in sizes from 1 to 50 h.p.

BOOK REVIEW

Diesel Engine Operation, Maintenance and Repair

By Charles H. Bushnell. John Wiley & Sons, New York, 1930, cloth, 6 x 9 in., 285 pp., figs., tables, $3.50.

The topics discussed include vapourizing, mixing and ignition systems, fuel injection, governors, indicators and indicator diagrams, lubrication, crankshafts and bearings, knocks, cylinders and pistons, air compressors, joints and packing. The descriptions are clear and concise and are accompanied by numerous drawings which appear to have been specially prepared for the text.

The book is well balanced, emphasis being placed on principles rather than on detailed rules or descriptions of particular machines, and there is a complete absence of padding and introduction of irrelevant material.

Designers and operators will find in this book much valuable information of a practical nature and many useful hints on the design, operation and maintenance of the Diesel and other oil engines.

Professor A. R. Roberts, A.M.E.I.C.,
Associate Professor,
Department of Mechanical Engineering,
McGill University, Montreal.

ELECTIONS AND TRANSFERS

At the meeting of Council held on January 20th, 1931, the following elections and transfers were effected:

Associate Members

MacLEOD, John Angus, designer, engrg. dept., Dominion Iron & Steel Co. Ltd., Sydney, N.S.

THOMPSON, Vincent Swire,(Associate, City and Guilds of London Institute's Technical College, Finsbury), designer, Hamilton Bridge Company, Ltd., Hamilton, Ont.

Transferred from the class of Associate Member to that of Member

CONNELL, Charles Herbert Newton, district engineer, Northern Ontario District (Central Region), C.N.R., North Bay, Ont.

FRIGON, Augustin, B.A.Sc., C.E., (Ecole Polytech.), Grad. E.E., (Ecole Supérieure d'Electricité de Paris), D.Sc., (Univ. of Paris), Director General of Technical Education for the Province of Quebec, Dean, Ecole Polytechnique de Montréal, Chairman, Electrical Commission of the City of Montreal, Montreal, Que.

HARKNESS, Harold Wilson, B.A., B.Sc., (Queen's Univ.), M.Sc., Ph.D., (McGill Univ.), Associate Professor of Physics, Acadia University, Wolfville, N.S.

PERRY, Brian Rhodes, B.Sc., (McGill Univ.), consulting engr., 561 New Birks Building, Montreal, Que.

Transferred from the class of Junior to that of Associate Member

BAILLIE, Edward Leonard, B.Sc., (N.S. Tech. Coll.), asphalt highways engineer, Imperial Oil Limited, Halifax, N.S.

BRICKENDEN, William Thomas, B.A.Sc., (Univ. of Toronto), mech'l. engr., Thorne, Mulholland, Howson & McPherson, Toronto, Ont.

HILL, George Rixon, municipal engr., rural municipalities of Wallace, Pipestone, Sifton, Woodworth, Archie and Miniota, P.O. Box 283, Virden, Man.

LEWIS, James Wentworth, (McGill Univ.), supt., American Concrete Marbelite Co., Chicago, Ill.

MURPHY, Alexander Gordon Silcox, B.Sc., (McGill Univ.), struct'l. engr., Dept. of Railways and Canals, Welland Ship Canal, St. Catharines, Ont.

Transferred from the class of Student to that of Associate Member

SUTHERLAND, George MacKenzie, B.Sc., (N.S. Tech. Coll.), dftsman and designer, engrg. dept., Canadian Ingersoll-Rand Co. Ltd., Sherbrooke, Que.

Transferred from the class of Student to that of Junior

COPPING, Bruce Gray, B.Sc., (McGill Univ.), plant engr., Copper Cliff works, Canadian Industries, Limited, Sudbury, Ont.

DONNELLY, James Henry L., B.Sc., (McGill Univ.), asst. engr., Canada Cement Company, Montreal East, Que.

Students Admitted

Undergraduates at McGill University, Montreal, Que.:
CRAIN, Reginald Albert, 3647 University St., Montreal, Que.
LEA, William Chester, Montreal, Que.
McBEATH, Ernest Harrison, 3592 University St., Montreal, Que.
SANCTON, Richard Arthur, 4643 Sherbrooke St. West, Westmount, Que.
WATIER, Arthur H., 4169 Dorchester St. West, Westmount, Que.

Undergraduates at Nova Scotia Technical College, Halifax, N.S.:
COFFEY, Laurence Edward, Halifax, N.S.
CURRIE, George James, 840 Robie St., Halifax, N.S.
GLOTZER, Samuel, Halifax, N.S.
MUIR, Clarke Bower, Halifax, N.S.
SPENCE, Earl Boyce, 209 South Park St., Halifax, N.S.
SPENCE, Graydon Dill, 209 South Park St., Halifax, N.S.
WEATHERBEE, Weston Ewart, 40 Queen St., Halifax, N.S.

SHEEHAN, John Barry, (St. Mary's College), Halifax, N.S.

SIMONS, Finlay William, (Univ. of Alta.), 11019-80th Ave., Edmonton, Alta.

A new departure in bronze valve design is now being presented by Jenkins Bros. Limited, makers of the well known line of "Diamond" trade marked valves.

This new standard bronze valve is one-piece bonnet construction—assuring unusual ease in removal. The manufacturers state that because of this new bonnet design the valve has a degree of extra strength that prevents springing or distortion even though the bonnet is removed and replaced repeatedly. The heavy proportions of the valve, apparent upon examination, would indicate that it is built for sturdy usage.

Another feature of interest is the slip-on, stay-on disc holder which reduces the matter of disc changing to the very simplest terms. By raising the spindle a turn or so the bonnet may be removed from the valve body without the disc holder slipping off the spindle. When it is desired to remove the disc holder, a turn or two in the opposite direction will cause it to slip off easily.

Jenkins Bros. Limited present these new Fig. 106-A valves for all standard services.

BRANCH NEWS

Calgary Branch

A. W. P. Lowrie, A.M.E.I.C., Secretary-Treasurer.
W. H. Broughton, A.M.E.I.C., Branch News Editor.

About forty members and friends met at the Board of Trade rooms on December 11th, 1930, with B. Russell, M.E.I.C., in the chair, to hear a report by the Branch Councillor, T. Lees, M.E.I.C., of the Plenary Session of Council held on September 22nd to 24th, followed by a paper on "Modern Trends in Steam Power Plant Practice" by W. H. Broughton, A.M.E.I.C., Chief Instructor in Steam Engineering at the Provincial Institute of Technology and Art, Calgary.

Mr. Lees gave a comprehensive report of the proceedings as reported fully in The Journal for November, he having supported the instructions of the Calgary Branch "that any general increase in dues is inopportune under the present depressed condition of industry."

S. J. Porter, M.E.I.C., was accorded a great reception as the official nominee as President for the ensuing year. After thanking the members Mr. Porter briefly reviewed the progress towards closer relationships with the various provincial professional organizations and expressed the hope that considerably more progress might be made during the coming year.

In introducing his subject, Mr. Broughton referred to the modern era as commencing with Savery or Newcomen in the seventeenth or eighteenth centuries relegating the engines of Hero, de Vinci and Branca to the ancient period. After sketching the improvements of Watt, Smeaton, Trethevick, Stevenson, Hornblower, Woolf, Symington, Fulton and Corliss during the eighteenth and nineteenth centuries the speaker projected a comparison of the gain in economy during that period, as follows:

Year	Prime Mover	lbs. of coal per K.W. hr.
1720	Newcomen, condensing beam engine	30
1782	Watt, Double-acting expansion engine	11
1880	Modern Double-acting expansion engine	3
1900	Multiple Expansion, Marine Type	2
1920	Steam Turbine	1.4
1925	Steam Turbine	1.0
1930	Steam Turbine	.86

This shows an almost uniform gain in economy during the past century which apparently has not yet ceased, although we think, as we have thought at each succeeding stage, that finality had about been reached, thus:

From 1880-1900 ..... 33 1/3%
1900-1920 ..... 30%
1920-1930 ..... 38%

These comparisons are for the best prime movers of their respective dates, and tabulations by various eminent authorities were thrown onto the screen supporting them, together with operating figures from individual plants showing that these economies have been realized in small as well as in large plants.

The speaker went on briefly to specify the various improvements that have contributed to the gain during the past ten years. Greater efficiency of combustion because of: improved stokers that will burn coal more economically and burn a wider range of fuels on the same grate; the use of powdered fuel which is economical in itself and has stimulated stoker improvements; zoning of air preventing streamlining in the furnace; increased furnace volume and length of gas travel which has given more time for the completion of the combustion reaction and higher furnace temperatures which increased the speed of reaction; increased turbulence by improved arching and baffling which has increased the intimacy of contact of the combining elements and reduced stack losses by reducing the excess air required. Efficiency gains due to the better collection of the heat generated during combustion by: the use of water-walled furnaces and exposure of boiler tubes to direct radiation thus leaving less heat to be collected from the gases by convection; placing superheaters in positions where they tend to keep the economy curve flat over a wide range of loads; the extraction of a maximum of the heat from the gases by economizers and combustion air preheaters.

Gains in economy in the turbine and auxiliaries by: the use of higher initial pressures and superheats and lower vacua; limiting the moisture in the turbine due to adiabatic heat drop by reheating the steam whenever the moisture reaches 10 per cent; recovery of a maximum of heat rather than power from the steam by bleeding the turbine to heat the feedwater at suitable stages.

History is repeating itself for, as progress during the nineteenth century was delayed by lack of suitable materials and of accurate machining methods, today it is retarded from want of refractories that will stand up to the very high furnace temperature now being developed and of suitable materials for parts of boilers, superheaters, pipe work and turbine blades before still higher steam pressures and temperatures can be used.

Operating technique is responsible for gains due to: keeping the plant more nearly at its initial efficiency by systematic elimination of losses due to such items as dirty tubes in condensers and boilers; the intelligent use of indicating and recording appliances which reflect instantaneous conditions and also allow of comparison with past performance.

The gains, the speaker said, had not accrued without expense. Feed water which was satisfactory at pressures of 200 pounds required treatment for use in boilers at 450 pounds pressure and upwards; larger quantities of condensate must be pumped to obtain the lower vacua and higher wages be paid the higher grade of operator necessary in these modern plants.

The speaker pointed out, however, that these economies have been gained without any, or with very little, increase in first cost of the plant and have been the means of greatly reducing operating costs.

In conclusion the speaker quoted the Vice-President of the Southern California Edison Co. that "With low fuel values the question of efficiency is not so important, but efficiencies have risen so very greatly that the steam plant is much less sensitive to changes in fuel prices than ever before. Under present conditions the cost of steam power is less at all usable load factors than the cost from the cheapest remaining undeveloped hydro-project available to Southern California, not ignoring the results expected from the Boulder dam project," and the Vice-President of the Pacific Gas and Electric Co. who said on the same occasion "By reason of the cheapness of steam-electric power few hydro-electric projects are economically justifiable."

F. N. Rhodes, A.M.E.I.C., moved a vote of thanks to Mr. Broughton for his interesting address, which was heartily accorded by the members and visitors present.

Cape Breton Branch

S. C. Mifflen, M.E.I.C., Secretary-Treasurer.
Louis Frost, Branch Affiliate, Branch News Editor.

The tenth annual meeting of the Branch was celebrated by a banquet at the Isle Royale hotel, Sydney, on the evening of December 16th, 1930. A. L. Hay, M.E.I.C., Branch chairman, presided. The banquet was well attended, over fifty being present.

Following the toast to the King, the chairman appointed scrutineers to count the ballot for the election of officers, and called upon the Secretary to read the minutes of the last regular meeting and the financial report for the preceeding year. The report showed the finances and the membership of the Branch to be in a very healthy condition.

The retiring chairman briefly reviewed the activities of the Branch during the preceding year, paying tribute to the Mining Society of Nova Scotia, jointly with which many of the Branch meetings had been held, and who were equally responsible for the high standard of the papers read during the year.

The scrutineers having presented their report, the retiring chairman introduced A. P. Theuerkauf, M.E.I.C., the newly-elected chairman, to the meeting.

J. R. Morrison, A.M.E.I.C., and W. L. Stuewe, A.M.E.I.C., were elected members of the executive council for the ensuing year.

The toast to sister societies was proposed by Joseph Kalbhenn, A.M.E.I.C., and responded to by T. L. McCall, M.E.I.C. In proposing the toast Mr. Kalbhenn pointed out that the goal striven for by all is happiness. This could only be attained by rational activity in a life free from hypocrisy or formalism and strictly in accordance with principles of pure humanity. The engineer leaving the university sets out to conquer, but soon finds that this is an illusion, and instead of conquering finds himself conquered. He then turns to the technical societies and institutes for guidance, and it is through these institutions that he receives his post-graduate education, fitting him for a more rational acceptance of an engineering future.

This was followed by the main address of the evening on "Sydney—Its place in the Industrial Development of Eastern Canada," by J. W. Madden, Esq., K.C.

Mr. Madden stated that it was wise, at such a period of industrial despondence, to speculate upon the future of Sydney and the province of Nova Scotia. Today, as in times past, Nova Scotia is exploring provincial and federal avenues for the amelioration of its economic burden. Avenues that in perspective appear good, do not, when analyzed, afford the permanent structure upon which the future of Sydney and the province can be built.

Many commissions have investigated the problems that confront us and have passed their recommendations. All that has remained is the agreement or disagreement, whether these recommendations have been implemented. Nova Scotia, and Sydney in particular, have been looking to the west to develop reciprocal markets. Development of the St. Lawrence waterways has been mooted as the channel through which this can be accomplished. Such a channel would also give our competitors to the south equal opportunity to outreach us in economic range. Cheaper rail rates may help to alleviate the situation, but cannot be considered a permanent basis upon which the future prosperity of Sydney can be founded.

Future economic development can only be attained by developing the mineral and other natural resources of the Maritimes, and by looking across the Atlantic to the east, and to the south for reciprocal economic treaties. If, Mr. Madden said, we can persuade the makers of agricultural implements such as the Massey-Harris company, or the larger automobile manufacturers to look over the map of the world and see for themselves our geographical location with regard to South America and the east, and to see how in regard to this we are favoured over the rest of Canada, it would be but a short time before branches would be established right in the province, where steel, coal and timber are available to meet the needs of these industries in the manufacture of their commodities, for which markets are readily available to the east and to the south. Develop the Argentinian, the Australian, and the European markets, and in return obtain leather, and also solve the feed problem in Nova Scotia.

The toast to steel and coal was proposed by Mr. P. J. Lynch, who discussed the present depression in these industries and gave it as his opinion that the local situation could be alleviated by the establishment of finishing mills here to turn out the finished product. This he contended would eliminate the sending of semi-finished products to Upper Canada, there to have them finished and returned to Cape Breton. Such mills as he advocated would do much to relieve the unemployment situation here.

Responding for the coal and steel industry, F. W. Gray, M.E.I.C., reviewed the development of these industries in Cape Breton. Sydney, he declared, is an ideal position for a steel plant, situated as it is close to iron ore deposits and coal mines. The local steel plant is now equipped to roll the largest rails ever made in Canada. Better coke and better steel are now being produced than at any time in the history of the plant.

A new power plant, one of the finest of its kind, has been installed, also new machinery. New mechanized methods of mining are now in use and greater depths have been reached. As a result and despite this time of unparalleled depression, when plants throughout the world are reducing their production, the local plant has worked fairly steadily, and its output compares favourably with the large steel plants of the United States and Europe.

Following several other speakers, the evening's programme was wound up in good style by M. Dwyer, A.M.E.I.C., who gave an address in his inimitable and humorous style.

W. S. Wilson, A.M.E.I.C., was at the piano.

Halifax Branch

R. R. Murray, A.M.E.I.C., Secretary-Treasurer.

The regular meeting of the Halifax Branch was held on the evening of November 19th, in the Nova Scotian hotel, at 6.30 p.m. Professor W. P. Copp, M.E.I.C., presided and there were 32 members present, the meeting being preceded by a supper.

The first business of the meeting was a report from the Nominating committee who gave out their slate of candidates for the various Branch offices. This report was adopted and names ordered placed on the official ballot.

Secretary R. R. Murray stated that he had a message from J. L. Busfield, M.E.I.C., Montreal, to the effect that he expected to be in Halifax and would like to speak before the Branch on the 24th of the month. It was decided to hold a supper meeting on that evening to hear Mr. Busfield on the subject of "Classification and Remuneration of Engineers."

Mr. C. H. Wright, M.E.I.C., president of Halifax Board of Trade, invited all the members to attend a Board meeting on the 25th, to hear a discussion on the "St. Lawrence Waterways" question from the Maritime viewpoint.

Several visiting engineers were welcomed to the meeting.

It was decided to have the executive arrange the details for the annual meeting, which will be held on the third Thursday in December. The chairman was requested to name the scrutineers of the ballots.

The meeting was then adjourned to another room where a very interesting and instructive address was delivered by F. H. Peters, M.E.I.C., Surveyor General of the Department of the Interior, Ottawa. The subject was "Aerial Surveying and Mapping in Canada."

Mr. Peters stated in his opening remarks that he was very pleased to be in Halifax, after which he gave a detailed description of the methods employed in aerial surveying and mapping illustrated by slides of graphs which gave those present an outline of the large amount of work done by the department. It was shown that surveys from photographs were not sufficient in themselves for an accurate map of any territory as it was necessary to lay out control points on the ground. The photographs made in the first instance were skeleton and were afterwards corrected and the details filled in. Old and new types of mapping instruments were also described in detail.

Mr. Peters said that two types of photographs were obtained—oblique and vertical. The oblique method of photography was used over country of low relief and for small scale maps of outlying country where extreme accuracy of detail is not very important. The vertical method is employed where the country presents various types of relief, and for large scale maps. The system used in plotting these aerial surveys was next described, many of the details of which had been developed within the organization itself to suit the particular needs of the area surveyed. To show the value of aerial photography the speaker as an example showed a map having a scale of 4 miles to the inch, an area which was originally very sketchy in detail, a total of nearly 5,000 lakes and more than 6,000 islands, 90 per cent of which were not shown on any previous maps.

Mr. Peters stated that the figures for the work done during 1930-31 were, of course, not available yet but those for 1929-1930 showed that about 125,000 photographs were made, to gather data covering 106,000 square miles of territory. There are in the Index Bureau, at Ottawa, some 300,000 of these photographs of which about 90,000 were secured and completed during the past year. During 1929-30 the field operations were carried into all the provinces, including the Yukon and Northwest Territory. Eighteen separate parties were employed in addition to three survey engineers who acted as navigating officers and technical advisors using planes of the Royal Canadian Air Force. This large complement of men were all engaged in the work of photographing and mapping already referred to. In this work the planes are flown at a sustained altitude of 5,000 feet.

Altogether the address was of great interest, and in conjunction with three reels of films, gave an idea of the magnitude of the work.

W. A. Winfield, M.E.I.C., general plant superintendent of the Maritime Telegraph & Telephone Co., who said that his company had in mind an aerial survey of their transmission lines but no plane was available, moved that a hearty vote of thanks be tendered Mr. Peters.

Mr. C. H. Wright, M.E.I.C., seconded the motion, which was unanimously accorded the speaker.

A special supper meeting of the Halifax Branch of The Institute was held on the evening of November 24th, 1930, at the Nova Scotian hotel. The meeting was presided over by Professor W. P. Copp, M.E.I.C., chairman of the Branch.

Forty or more members were present to greet J. L. Busfield, M.E.I.C., chairman of The Institute committee on Classification and Remuneration, who addressed them on the work of the committee and the conclusion reached in the report to be submitted to the Annual Meeting of The Institute in February.

Mr. Busfield was introduced to the members by Professor F. R. Faulkner, M.E.I.C.

K. L. Dawson, M.E.I.C., congratulated the committee on the vast amount of work done and data compiled, pointing out how well the classification had been worked out. He thought 30 per cent gave a good cross section of members' opinions, but did not feel that personal ability necessarily indicated ability to do; it might refer to ability to organize. However, he did think the average salary as stated to be a good one.

J. H. Winfield, M.E.I.C., also congratulated the speaker on his address, pointing out that such a report is timely because of a feeling among engineers that the remuneration received is not commensurate with the services rendered. He further remarked that personal ability needs opportunity to be able to advance to its proper sphere of usefulness.

Professor R. L. Nixon, A.M.E.I.C., moved that a vote of thanks be tendered Mr. Busfield for his timely address, expressing his own satisfaction and that of members present. J. B. Hayes, A.M.E.I.C., seconded the motion, which passed unanimously.

Mr. Busfield in his reply gave some information regarding the application of averages to salaries paid which do not always indicate the true average. He thanked members for their attention and hoped that the report would be of some value to all, incidentally remarking that he hoped to visit the city again and meet the Branch members.

The annual meeting of the Halifax Branch of The Institute was held on Thursday, December 18th, at the Nova Scotian hotel. Professor W. P. Copp, M.E.I.C., chairman of the Branch, presided and more than 40 members were present.

The meeting was preceded by a supper during which the chairman extended a welcome to those who attended from out of the city and read a telegram from H. F. Bennett, A.M.E.I.C., who has recently been transferred to Sault Ste. Marie, extending his good wishes for a successful year in 1931.

Secretary Murray then read the minutes of the past annual meeting and of the several recent meetings.

The matter of a joint banquet with the Nova Scotia Professional Association was discussed and it was decided to take part. A committee, consisting of J. B. Hayes, A.M.E.I.C., J. D. Fraser, S.E.I.C., and R. R. Murray, A.M.E.I.C., was appointed to represent the Branch in the arrangements.

The Secretary read his report, also the financial report, which was very satisfactory.

J. St.C. Wilson, A.M.E.I.C., chairman of the Papers committee, presented a report reviewing the work of the past year and stated that he expected to have, in the near future, an address on "Gypsum and Allied Products" by a representative from the Canadian Gypsum Co.

J. Lorne Allan, M.E.I.C., chairman of the Membership committee, presented the report from that committee, reviewing the work of the past year and offering valuable suggestions.

W. J. De Wolfe, A.M.E.I.C., chairman of the Publicity committee, reported on the work done during the year, and stated that he hoped for better results next year.

Professor F. R. Faulkner, M.E.I.C., reported, as chairman, for the Prize committee, and some very valuable suggestions were made on making prize competitions more successful and productive, the feeling of his committee being that much good can be accomplished in this manner.

All the above reports were received with enthusiasm and finally adopted.

Professor Faulkner also gave a report on the work of the plenary meeting of Council held in September last. This report was of some length and went into detail on all matters discussed there as affecting the welfare of The Institute generally. The suggestions contained, if taken to heart, could not fail to be of great benefit to all members.

C. H. Wright, M.E.I.C., commended the report for its value and moved a vote of thanks to the committee. This was seconded by J. B. Hayes, A.M.E.I.C., and accepted.

H. W. L. Doane, M.E.I.C., presented a report on behalf of the joint committee on Co-ordination of The Institute and Professional Associations. This was a résumé of the conclusions and work of The Institute committee in that connection. Since the full report of that committee will appear in The Journal it is considered sufficient to state that Mr. Doane was of the opinion that real progress was being made and that the Halifax Branch was not lagging in the effort to find a solution to the question.

The present Branch representatives were asked to continue to function, which they agreed to do.

W. H. Noonan, A.M.E.I.C., for the scrutineers, reported the results of the ballot for Executive for coming year:—

Chairman.......................... J. L. Allan, M.E.I.C.
Council........................... A. F. Dyer, M.E.I.C.
J. D. Fraser, S.E.I.C.
S. L. Fultz, A.M.E.I.C.
J. D. Clarke, A.M.E.I.C.
W. J. De Wolfe, A.M.E.I.C.

Professor Copp, M.E.I.C., next delivered his retiring address as chairman of the Branch for 1930. He thanked all for the honour which had been done him and referred with some feeling to the loss sustained by the deaths of the late Professor W. F. McKnight, A.M.E.I.C., and W. G. Matheson, M.E.I.C., during the year. Efforts had been made to have a Maritime meeting but this could not be carried through. However he hoped for better results during the next year, the probable location being Saint John, N.B. He referred also to the suggested closing of the Technical College in Halifax, and said that, while no definite action had been taken, he was of the opinion that such a retrograde step will not likely be made, at least for some time to come. His opinion was that the earlier meetings of the year had not been as well attended as they might have been but he had noted with pleasure that the later ones had been much better. He suggested greater activity in the affairs of the city and province and looked forward to hearty support of the members to the new executive and to a successful year.

At the conclusion of the chairman's address J. L. Allan, M.E.I.C., was invited to take up his new office.

Mr. Allan was very appreciative of his selection for the office and stated that he would try to make the next year a banner one.

Professor F. R. Faulkner, M.E.I.C., and Professor C. H. Burchell, M.E.I.C., were appointed auditors. H. W. L. Doane, M.E.I.C. was appointed Branch representative on the General Nominating committee.

A letter from Brig.-General C. H. Mitchell, M.E.I.C., re members, was referred to the new executive.

On motion, it was voted that the Secretary receive an honorarium of $50.

A discussion arose as to the best way to stimulate interest in the Students' Prize essays. Various ways and means were thrashed out but no final result was recorded and the matter was given over to the executive to consider several suggestions offered, among which was the offer by Karl Whitman, A.M.E.I.C., to donate the sum of $15 as a first prize open to all students of engineering in the colleges of Nova Scotia.

On motion of G. S. Stairs, M.E.I.C., and Professor W. P. Copp, M.E.I.C., a vote of thanks was tendered to the retiring executive. Thus was brought to a close a very successful year for the Branch.

Hamilton Branch

J. R. Dunbar, A.M.E.I.C., Secretary-Treasurer.
J. A. M. Galilee, Affiliate E.I.C., Branch News Editor.

Executive Committee Meeting, November 21st

A luncheon meeting of the executive committee was held on Friday, November 21st, in the Wentworth Arms.

W. L. McFaul, M.E.I.C., was appointed the branch representative of The Institute Nominating Committee for 1931.

The following branch committees were also appointed.

The branch prize committee:

L. W. Gill, M.E.I.C.
J. C. Nash, A.M.E.I.C.
F. P. Adams, A.M.E.I.C.,

together with the branch chairman and branch secretary.

Scrutineers for branch elections:

J. C. Nash, A.M.E.I.C.,
G. W. Arnold, A.M.E.I.C.

After sundry other details had been discussed and dealt with, the meeting then adjourned.

Branch Meeting, December 10th, 1930
(Reported by J. T. Thwaites, Jr.E.I.C.)

The December meeting of the Hamilton Branch, under the chairmanship of W. F. McLaren, M.E.I.C., was held on the evening of December 10th in the ball room of the Royal Connaught hotel.

Mr. McLaren asked Mr. Knight, engineer of the Bell Telephone Company of Canada, to introduce Mr. Dancey, also of the Bell Telephone Company, the speaker of the evening. Mr. Knight stated that Mr. Dancey had been responsible for a number of engineering developments and was equally at home with explaining the dial system, cable teletype and carrier telephony. He said that Hamilton was the first place in the world to have a telephone exchange, the first to utilize a toll cable, and the first to install the carrier system, namely, between Hamilton and Windsor.

The Carrier System of Telephony

Mr. Dancey, in introducing his subject, explained that he would treat it from a non-mathematical standpoint, even though it is essentially mathematical. He would merely state the assumption and come to a conclusion as a definite fact.

Carrier current consists essentially of substituting one frequency of electric waves for each frequency of sound waves which it is desired to transmit. In ordinary telephony these electric and sound waves have the same frequency, but in the carrier system the electric wave is of a much higher frequency.

Normal speech may be transmitted with commercial clarity if a band 200 cycles per second to 3,000 cycles per second be transmitted. If an oscillatory circuit is set up and made to generate a frequency of 10,000 c.p.s. and this frequency be superimposed on voice currents in a suitable vacuum tube modulator, two bands of frequency are formed, one above and one below the 10,000 c.p.s. frequency. By means of suitable filters the carrier and the lower side band are suppressed.

In this new band of frequency there is an 11,000 c.p.s. current which represents 1,000 c.p.s. in the original, an 11,500 c.p.s. frequency which represents 1,500 c.p.s. in the original, and so on. Thus each frequency in the original has been replaced by a frequency 10,000 c.p.s. higher. Thus speech is transmitted by transmitting a band 10,000 c.p.s. to 13,000 c.p.s. Similarly speech may be transmitted on any band 3,000 c.p.s. wide.

Interference troubles have limited the lower band limit to 6,000 c.p.s. and the upper band limit to 30,000 c.p.s. which allows six bands 3,000 c.p.s. wide with 1,000 c.p.s. spacing between them. These may be sent out over the same wire and sorted out by suitable filter circuits. As sending and receiving must be kept separate, due to the amplifiers being unidirectional, there are only three talking channels.

At the receiving end, these signals, after being sorted by filters, are demodulated by reintroducing the carrier which brings back the original frequencies and these are then intelligible as ordinary speech in the telephone.

Carrier current telephony has given rise to many problems in connection with line transposition and so it is not always possible to make full use of a line already built without considerable expense. Also for carrier telephony there is very expensive terminal apparatus, but for long distances of 200 miles or more, it is to be recommended.

The first commercial carrier current line in Canada was from Hamilton to Windsor and has given complete satisfaction. There are now 17,000 miles of carrier line in Canada and 10,000 more miles are projected for early construction.

At the conclusion of the address, general discussion took place, which elucidated many points.

A hearty vote of thanks was tendered to the speaker by the chairman.

Attendance was 55, a number of engineers from the Bell Telephone Company being present as well as a contingent from Toronto.

The regular monthly meeting of the Hamilton Branch of The Institute took place in the Royal Connaught hotel on January 13th.

After the reading of the minutes J. J. McKay, M.E.I.C., nominated the following for the Nominating committee for the Annual Meeting:

W. L. McFaul, M.E.I.C.
L. W. Gill, M.E.I.C.
H. Lumsden, A.M.E.I.C.
E. M. Coles, A.M.E.I.C.
G. A. Colhoun, A.M.E.I.C.
Branch Chairman
Branch Secretary

The speaker of the evening was W. R. Smith, A.M.E.I.C., of London, Ontario.

Railway Construction Through the Yellowhead Pass

Mr. Smith, at the outset of his lecture, reminded his audience that the pioneer of exploration and surveying of the Rocky Mountains was David Thompson, a man of whom little is known, but through J. B. Tyrrell many interesting facts have come to light.

David Thompson came to Canada when a boy and was apprenticed to the Hudson's Bay Company at York Factory. In 1807 he left for

Western Districts and in 1810 he was at Cumberland House. He travelled up the Saskatchewan river to Fort Augustus (Edmonton) experiencing considerable opposition from the Piegan Indians.

In 1811 he crossed the Athabaska pass and through observations made by J. B. Tyrrell at a later date it was found that a remarkable accuracy was maintained by Thompson, the exception being the altitudes, which were invariably out. Thompson's men mutinied before he reached the coast, but he was able to complete his journey with the aid of a faithful servant, by descending the Columbia river to the Pacific.

At his death he had plotted more Canadian country than any man before or since. It is notable that no memorial has yet been erected to his memory, while his body lies in an unmarked grave in Mount Royal cemetery in Montreal.

The speaker's experience of railway construction occupied a period of ten years and in November, 1909, he was sent out as a resident engineer with eight men to survey a district known as Mile 80 of the Mountain Division.

Mr. Smith gave a good account of the vicissitudes of a resident engineer's life. The conditions of life, though rough, were those experienced in ordinary outdoor life. Accuracy of work was essential: the line was to be constructed on a maximum grade of 4/10 of 1 per cent with a maximum curvature of 6 degrees or a radius of approximately 955 feet. The grade was remarkably low when one considers that around Hamilton grades of 1 per cent are quite common. 0.02 was allowed for grade compensation per degree of curve so that the grade on a maximum curve would be only 0.28 per cent. Searle's spirals were used as easements on all curves over 2 degrees. Embankments were 16 feet in width up to 18 feet, and cuttings 22 feet, allowing for shallow ditches 3 feet in width by 1 foot deep at each side. Rock cuttings were 20 feet in width. Earth slopes were calculated at 1½ to 1, while rock quantities were figured at ¼ to 1 slope.

The duty of the resident engineer was to see that the right-of-way was cleared and then to run check levels and establish bench marks, then pick up the location centre line and re-run the alignment according to the location map supplied. Curves had to close at the tangent points to 3/10 of 1 foot, otherwise they had to be re-run and the errors found and corrected.

In cross-sectioning, the slope was often as steep as 60 degrees, the method adopted for arriving at the horizontal distances was by calculating them from the measured distances along the slope by the medium of the trigonometrical functions of the vertical angles obtained by the use of an Abney hand level. To obtain these measured distances the rodman had sometimes to be lowered by a rope. In many cases the work was done above boiling rapids, where a slip would be fatal. In spite of these hazards, as well as others, the speaker reported that there were no fatalities in his party.

It was the practice to erect temporary trestles, wherever needed, one of the largest being at Big Eddy, where something like five million f.b.m. were used.

As a rule, streams discharge into valleys at the highest parts. This fact made it often necessary to divert mountain streams by means of rock-filled cribs and these diversions were sometimes a cause of much anxiety to the engineer.

Through a certain amount of carelessness typhoid fever attacked the camp in 1910. The Railway Company were very considerate and gave sufferers passes to their homes and full pay during absence.

Considerable trouble through the use of horses in these districts with various diseases was experienced, but it was found that the Missouri mules were practically immune. They were, therefore, used in large numbers towards the end.

An interesting story was told concerning the practice of subletting contracts. A particularly large neck of land, approximately 175 feet deep, had to be moved. Indications pointed to the fact that there was a large amount of rock in this and spectators looked on with amusement when a party of Swedes undertook the job. On digging down, however, the Swedes discovered that the hillside was pure sand and it was an easy matter to tunnel through and operate gravity dump cars and let nature do the work. This good proposition netted the contractors about $1,000 apiece to the 24 men in a little over three weeks.

Hardships encountered at Brûlé Lake district, through blowing sand, caused abandonment of a constructed line. It was impossible to keep the right-of-way clear and fences soon disappeared from sight.

One of the most interesting features of the railway construction in such places was the constant battle against the forces of nature. Human difficulties, through the long distance from the base, the discomforts of living and the monotony of companionship and general isolation were by no means inconsiderable and it is a tribute to those who came through, when they did so, with such cheerfulness.

The party worked all through the winter and temperatures of 40 degrees below zero were often encountered, and contrasting this with a summer temperature of 80 degrees it will be noted how important it was to take temperature into account when using the steel tape. In re-running curves it was possible that very considerable inaccuracies might be encountered.

The speaker recalled seeing a stump on which marks made by Sir Sandford Fleming were discernible. It was found that the elevation of 3,418 feet at this point, made in 1873, differed by only 10 feet, from that of the speaker's measurements. This is a fine tribute to the early surveyors.

At the conclusion of the lecture a number of very fine slides were shown through the courtesy of the Canadian National Railways. These included views of Jasper park and of various trails and mountains and other wild prospects. These slides were beautifully coloured and proved to be a most delightful part of the evening's enjoyment.

At the conclusion H. A. Lumsden, M.E.I.C., made the suggestion that schools should tell their pupils far more about the early discoverers and explorers in Canada so that their exploits might be commemorated.

R. K. Palmer, M.E.I.C., moved a hearty vote of thanks to the speaker for his most interesting and instructing lecture, which was carried with applause.

Lethbridge Branch

Wm. Meldrum, A.M.E.I.C., Secretary-Treasurer.

The Lethbridge Branch held its first regular meeting of the new year on January 10th in the private dining room of the Marquis hotel. The Branch was especially favoured by a visit from Dean C. J. Mackenzie, M.E.I.C., Vice-President of The Engineering Institute of Canada, and sincerely hopes more such visits can be arranged in the future. During the afternoon, Dean Mackenzie attended a meeting of the Branch executive which was concluded in time to attend the usual dinner at 6.30 p.m., the latter being enlivened by Mr. Brown and his orchestra. After dinner, there followed the customary community singing, together with much appreciated vocal solos by Miss Allison and Mr. N. B. Peat. The speaker was then introduced by G. N. Houston, M.E.I.C. Dean Mackenzie took as his subject, his own research work, namely

"URBAN GROWTH IN WESTERN CANADA"

In many cases of civil engineering work in cities, it is necessary to make, as closely as possible, an estimate of the population at some future date. Dean Mackenzie being faced with this problem in regard to some of the cities in Saskatchewan, has made a thorough study of this statistical problem. In the past, many methods of estimating future increase of population have been used, some of these being based on the following methods:

1. Arithmetical progression.
2. Geometrical progression.
3. Second order parabolas.
4. Logarithmic graph.
5. By producing uniformly the curve of the past.

These, however, and all other methods in customary use, fail completely when an attempt is made to apply them to western Canada whose population increase has been so fluctuating that it is impossible to arrive at any reasonable estimate of the future population by any of the past methods in use. Nor, in any of the above cases, are these methods reasonable, because if carried far enough they will continue indefinitely, indicating eventually a limitless population. An engineer's estimate must be based on reason.

Professor Pearl carried out numerous experiments in an attempt to arrive at a solution to the problem. He put two flies in a bottle kept at a suitable temperature and containing an adequate amount of food, i.e. the conditions were ideal for a natural rate of growth of the flies in the bottle. He closely observed their increase and repeated the experiment several times. From the data thus obtained, Professor Pearl was able to plot the population of the flies against time and obtained, in every case, a smooth curve.

This curve belongs to the family of curves expressed by the equation:

$$y = \frac{b}{e^{-ax} + c}$$

Where y = Population
x = Time
e = Natural Base
a, b, c = Constants

Note that there comes a time when an upper limit or asymptote is reached, i.e.

Death Rate = Birth Rate

Then the astounding discovery was made by Professor Pearl that this curve was followed almost identically when he plotted curves for various groups of the states and a number of countries.

When, however, Dean Mackenzie attempted to use these results in western Canada and various places in the United States, he found that there was a discrepancy. However some reasonable basis of estimating the future population had to be found. Professor Mackenzie, after experimenting and studying the problem from all angles, finally discovered the fact that, while the total population of our western provinces followed no apparent mathematical laws, if he divided the population into rural and urban and plotted each separately, they both followed very definite curves. He took as his division point 2,500; that is, cities of 2,500 or over were classed as urban population and all the rest as rural population. On applying the above to numerous states, he was able to show that for rural population an almost exact replica of the "fly curve" was obtained in each case and that for urban population a straight line curve was obtained. He also found that for cities and states in the United States, comparable geographically and economically to cities and provinces in western Canada, that the form of curves obtained were almost identical with each other. In each case the urban population curve showed a decided lag and did not start properly until the rural population curve had reached its upper asymtote and does not start at all until the inflection upwards of the rural population curve begins.

Applying this method to several states it was found that the lag in the urban curve becomes greater and the slope becomes progressively less, as each westward move was made; but the regularity of the curves is most remarkable.

Professor Mackenzie gave as the reason of the lag of the urban curve, the fact that the first people arriving in a new country are homesteaders whose wants and needs are few, hence the needlessness of towns and cities, but once the rural districts begin to fill up, there comes a time when towns and then cities are required with the attending rush of banks and distributors. The urban growth, then, is brought about by the increase in the wealth of the country, and not by industrial production, where the latter is concerned chiefly with production for local consumption.

In all such problems it is necessary to have some secondary proofs. Professor Mackenzie took the records of older cities, especially selected as being similar in type, and compared their records with his estimates for western Canada; taking the per cent of urban to rural population of each and found these percentages not at all unreasonable with his estimates.

A second check was arrived at by taking these comparable cities and plotting their populations on logarithmic graph paper both before and after the population had reached 50,000, using this figure as a common starting point.

Dean Mackenzie illustrated, by lantern slides, all his points and calculations by graphs of numerous cities and states.

Among the conclusions which he drew from his studies, the following are of interest:

By 1955 the urban population of Saskatchewan will be about 300,000 of which 75-80 per cent will be in Regina, Saskatoon and Moose Jaw. Alberta in 1955 should have an urban population of 340,000, about 90 per cent of which will be distributed about evenly between Calgary and Edmonton, each of these cities, therefore, having a population of about 150,000.

A formal vote of thanks was moved by H. W. Meech, A.M.E.I.C., and tendered to Professor Mackenzie through the chairman, C. S. Clendening, A.M.E.I.C. The notable meeting closed at about 11 o'clock p.m. with the singing of the national anthem.

London Branch

F. C. Ball, A.M.E.I.C., Secretary-Treasurer.

John R. Rostron, A.M.E.I.C., Branch News Editor.

The regular monthly meeting was held on Wednesday, December 17th, in the board room of the Board of Education, W. G. Ure, M.E.I.C., chairman of the Branch, presiding.

The speaker was Archie B. Crealock, B.A.Sc., A.M.E.I.C., consulting engineer, Toronto, and his subject "Highway Bridges."

The paper was illustrated by many lantern slides of different types of bridges and details of construction.

Mr. Crealock first explained that although he was now in private practice as a consulting engineer he was formerly engaged for a period of eight or nine years as assistant engineer to the Hon. G. S. Henry, then Minister of Highways, and his remarks were compiled from his experiences during that time. The district covered concerned bridges on the provincial highways of southern Ontario extending from Windsor on the west to the boundary of Quebec province on the east and as far north as Ottawa, the district activities being taken care of by resident engineers stationed at various points.

The old bridges are inadequate for present-day loading and hence the necessity for renewal. The new bridges were mostly built for class "C" loading under the Ontario Highways Specification which provides for 20-ton motor traffic and 40-ton street railway cars. The widths of the bridges were such as to accommodate roadways of from 20 to 24 feet but this had lately been increased to 30 feet in many cases. In and around the large cities the width again increased to 48 and 50 feet roadway accommodation.

Owing to a condition of high flood water which obtained in nearly all the rivers of Ontario, it was necessary in many cases to keep the depth of construction below road level as small as possible and this explained the adoption of the reinforced concrete bowstring arch type of bridge in certain locations. A fine example of this type of bridge exists at Bowmanville and this was shown on the screen—views were shown of many other bridges on the provincial highways and short descriptions given by the speaker. Amongst these were the bridges at Caledonia and Sixteen Mile creek, the prevailing types of bridges being the concrete arch before-mentioned and the steel truss deck bridge. Of the latter type was a bridge on the highway east of Toronto which is built to a 5 per cent grade. This was made necessary by the new bridge being built on a different site from the old bridge in order to do away with the dangerous sharp reverse curves of the roadway at each end of it.

Wherever possible dangerous curves were eliminated, and grade separation adopted to do away with as many level railway crossings as possible. Very considerable expense had been entailed by this work and further improvements along these lines were still being prosecuted.

The steel hog back truss bridge over the north branch of the river Thames at Broughdale in London township has the distinction of being, up to the present, the longest span (194 feet) steel bridge in Ontario. The speaker described the bridge over Hogg's Hollow, North Toronto, in detail and showed many slides of the work in progress. The writer cannot do better than refer the reader to a fully illustrated article written by Mr. Crealock in the Canadian Engineer of December 11th, 1928, for a full description of this work. However, special mention might be made of the difficulty experienced in the foundations of two of the piers where fine sand was encountered. Borings were taken and these showed that the sand extended in some places to a depth of 70 feet before hard ground was reached. This difficulty was met and overcome by the use of Raymond concrete piles, their penetration being 20 feet and the maximum pressure on one pile 39 tons.

The speaker then outlined the supervision necessary to ensure proper maintenance of bridges—under this head he dealt with painting, the cleaning out of bearings, periodical examination of abutments and piers, and scour of the water, etc.

Regarding the first of these—painting—he strongly urged that steelwork should receive at least one coat of paint in time to prevent the necessity of chipping off the rust. As a rule a coat of paint was necessary every two or at most three years and this would be found cheaper than allowing the work to go so long that it would require chipping. He also recommended the use of aluminum paint as it was not much more expensive than the ordinary paint and it stood up better, lasted longer and was desirable from an æsthetic standpoint.

He also stressed the necessity of seeing that men cleaning the roads did not throw the sweepings, etc., over the rails of the bridges as a good deal of this refuse then lodged on the steel and caused corrosion.

The speaker concluded his remarks by giving an outline of prospective work by the department and in this connection the bridge at Paris might be mentioned. This, he understood, was to be of steel arch design rendered more difficult by the fact that it will be on the skew.

A hearty vote of thanks to the speaker was proposed by John R. Rostron, A.M.E.I.C., city bridge engineer, who called attention to many points of similarity between the floor construction of Hogg's Hollow bridge and those of the Victoria and Kensington bridges lately erected in this city. The vote was seconded by W. R. Smith, A.M.E.I.C., vice-chairman of the Branch, and unanimously carried.

There was an attendance of 25 and an instructive discussion was engaged in, many practical questions being asked and answered.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

The aerial photographic methods employed in mapping the vast territories of the Dominion, was the subject of an extremely interesting address delivered before a supper meeting of the branch on November 18th, by F. H. Peters, M.E.I.C., Surveyor General, Department of the Interior, Ottawa. Mr. Peters' address was illustrated throughout by lantern slides, and followed by motion pictures showing the actual taking of photographs from one of the flying boats of the Royal Canadian Air Force.

L. H. Robinson, M.E.I.C., chairman of the Branch, presided.

A feature of the evening was the rendition of several vocal selections by Mr. H. S. Austin, all of which were well received and heartily encored.

Aerial Photographic Surveys

Mr. Peters prefaced his remarks by stating that the system of aerial surveying developed by his department was believed to be the best suited to the needs of this country, although other methods had been devised and were in use in other parts of the world.

Two types of photographs are used, the vertical and oblique. The former is preferable for large scale maps and where there is considerable variety of relief. Knowing the elevation of the plane and the focal length of the camera lens, it is possible to scale distances directly from a vertical photograph. The oblique photograph has the advantage of covering a much greater area and is the one most generally employed. By a most ingenious method of superimposing a perspective grid upon the print, distances can be readily scaled off and plotted. The speaker described, in detail, the system of plotting and of determining compass directions from photographs. He also referred to the technique of the plotting of contours.

The motion pictures showing the daily routine of an aerial survey party, were followed with considerable interest. The planes used are of the pusher type and permit the photographer an unobstructed view ahead. It is usual to fly at an elevation of 2,000 feet and to follow parallel lines about 6 miles apart over the area to be mapped. The personnel of the party consists of three,—the surveyor, in charge, the pilot and the photographer. The two first named sit in comparative comfort in the cockpit of the machine, but the photographer occupies a much more exposed position in the bow and finds it necessary to clothe himself somewhat after the manner of a popular conception of a denizen of Mars, in order that he may withstand the rigours of his breezy perch. Travelling at 80 miles per hour, photographs must be taken every two minutes. Three exposures are made in quick succession—a right, left and centre. The camera is mounted on a curved rail. It is a bulky affair but easily moved about at the will of the operator.

At the conclusion of Mr. Peters' address an argument arose concerning the horizontal grid line which is superimposed upon the horizon of an oblique photograph. A member of the branch contended that this line should not be straight but curved. The natural horizon comprises a circle, and consequently a line made to coincide with this circle or any part of it, must of necessity be curved. The speaker took an opposite view, and although the discussion was prolonged, no satisfactory conclusion was reached.

A vote of thanks moved by Professor F. L. West, M.E.I.C., and seconded by C. S. G. Rogers, A.M.E.I.C., was tendered Mr. Peters by the chairman.

The engineering features of the Allenby campaign in Palestine and the exploits of Colonel Lawrence in Arabia, was the subject of an illustrated address of unusual interest delivered before the Branch, on January 13th, by Major H. W. L. Doane, B.Sc., M.E.I.C., of Halifax. The meeting was open to the public and the attendance was most gratifying. The large audience taxed the combined capacity of the city council chamber and court room and a number were compelled to remain standing. L. H. Robinson, M.E.I.C., chairman of the Branch, presided and introduced the speaker.

In his opening remarks Major Doane stated that owing to the large attendance on the part of the public he would as far as possible avoid technical details. He would say, however, that the final advance against the Turks was really an engineering problem involving the transport of men and supplies. In following up the victorious armies, engineers built a railway on the desert sands at the rate of a mile a day, also an 8-inch water pipe line 147 miles long, with booster stations at intervals to keep up the pressure. With such minor difficulties to contend with as scorpions and centipedes, and with the temperature at 120 in the shade (and by the way there was no shade) the work accomplished by the engineers was truly remarkable. An innovation in the science of road building was introduced when it was discovered that chicken wire netting pegged down to the sand would support guns, tractors, motor cars, etc., and really excellent military highways were built of this material, large quantities of which had been brought out from England for use in trench construction.

It is interesting to note that Major Geo. A. Walkem, M.E.I.C., a past-president of The Engineering Institute of Canada, had charge of the railway work in Palestine.

Turkey was persuaded to enter the war on the promise of the Central Powers that she would get Egypt, Palestine and other adjoining countries in Asia and Africa. At first Britain did not take the Turks seriously as it was believed the great Sinai desert was sufficient barrier to any Turkish advance. However, one of the most amazing feats of the war was the crossing of this desert by the Turks and finally an attack on the Suez canal with an army of 16,000 men.

In 1917, operations having reached a stalemate in France, it was decided to wage a decisive campaign in Palestine, and Allenby was placed in command. This officer had under him troops of seventeen nationalities. One of the most interesting units was the camel brigade, comprising 60,000 camels. Major Doane described in detail the brilliant tactics which resulted in driving the Turks out of Palestine, but which unfortunately was accompanied by heavy loss of life.

Coincident with Allenby's campaign in Palestine, Colonel Lawrence was sent to organize the Arabs, who had revolted against the Turks. In describing the Arab, the speaker declared that he was a magnificient fighter, but generous to a fault in dealing with his friends In war he never harmed women, or children too young to fight. Furthermore, property that could not be carried away was left uninjured. The Arab had a keen sense of humour. During the campaign an Arab king sent the following telegram to King George: "Our troops are victorious everywhere. The truth follows by post."

Lawrence at first did not attempt to drive the Turks out of Arabia, but was content with harassing his lines of communication, thus keeping enemy forces engaged that might otherwise have been used against Allenby in Palestine.

At the conclusion of the address, which was followed throughout with intense interest, a hearty vote of thanks, moved by F. O. Condon, M.E.I.C., was tendered the speaker by the presiding chairman.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

The Montreal Branch spent a most interesting evening on December 4th at McGill University studying and observing the research problems which are being undertaken in the Faculty of Applied Science and Engineering.

Professor Ernest A. Brown, M.E.I.C., Acting Dean of the Faculty, welcomed the visiting members in a short address, during the course of which he paid tribute to the late Dean Mackay through whose efforts the visit of the Branch had been arranged. Professor Brown also outlined the various researches in the different departments after which the members divided into groups. Short descriptive talks were given by various members of the staff, dealing with the particular problems in which they were respectively engaged.

Professor C. V. Christie, M.E.I.C., head of the Electrical Department, arranged for demonstrations of the work in electrical engineering which included acoustic shock absorbers on telephone lines and high voltage testing.

Professor C. M. McKergow, M.E.I.C., and Professor Patten dealt with the work in the Mechanical Department, which included tests of the thermal conductivity of insulating materials as well as heat transfer from radiators.

In the Department of Civil Engineering Professor Brown outlined the study of secondary stresses in riveted trusses, joints and eccentrically connected members as well as the work done by the late Dean Mackay on welded joints in association with A. M. Bain, Jr.E.I.C.

All of the laboratories were open for inspection and proved a source of very great interest to the members who spent considerable time examining the more modern pieces of equipment.

R. S. Eadie, A.M.E.I.C., of the Dominion Bridge Company, moved a vote of thanks to the McGill University authorities and the Faculty of Applied Science for the privileges which had been extended by them.

Two papers were presented before the Montreal Branch on December 11th by students at McGill University.

The first, by P. E. Savage, S.E.I.C., dealt with the construction of a new highway bridge at Rapides Blancs, P.Q. This bridge was built by the Dominion Bridge Company for the Shawinigan Power Company. The location is about 20 miles north of La Tuque in a very rough section of country and over a very rapid stretch of water. Owing to the impossibility of delivering materials on both sides of the river a cantilever design was used which permitted of all erection being carried out from one side only and this feature combined with the fact that erection was completed in the short space of three weeks, made the subject a particularly interesting one. Mr. Savage showed a series of slides covering the various stages in the work of erection.

The second paper was by Mr. C. B. Charlewood on the subject of "Steam Distribution and Control in Paper Machine Dryers." A number of slides were shown illustrating the various arrangements of equipment used in regulating the steam flow in and drainage from the dryer cylinders.

Votes of thanks were moved to the two speakers by F. P. Shearwood, M.E.I.C., and W. McG. Gardner, A.M.E.I.C., respectively, and H. W. Lea, Jr.E.I.C., occupied the chair.

On December 18th Mr. D. Marples presented a paper before members of the Montreal Branch, prepared by Mr. John Avery, of the Brown Boveri Company, on the subject of "Turbo Blowers and Compressors."

Mr. Marples told of the development of the original centrifugal or turbo-compressor by Professor Rateau in 1905 as a machine for compressing air along the same principle as the centrifugal pump. The tests on the first machine were so favourable that in the following year several European firms took up the manufacture under Professor Rateau's patents.

The earliest machines built were for operating pneumatic tools in mines and steel works and, therefore, were for fairly high pressures, i.e., 70 to 100 pounds. These had as many as 20 or more wheels or stages and were usually cooled by water jackets. Later, it was found that a machine built on the same principle but for lower pressures of from 15 to 30 pounds formed an ideal blowing engine for iron blast furnaces. These units were called turbo-blowers as distinct from units for higher pressures. The use of these machines was gradually extended to other uses until the present time, when they are generally used wherever large volumes of air or gas have to be handled under pressure.

In the 25 years which have elapsed since their original conception many changes have been made, mostly along the line of lighter and stronger parts, higher speeds, etc.

Details of the construction of the machines were illustrated and described by the speaker, as well as the theory of operation and an explanation of the phenomenon of "pumping" given. Mention was made of various differences of opinion in connection with minor points of design and also of cooling and regulation.

The speaker finally summarized the advantages of turbo-blowers and compressors over other types of equipment and instanced some points to be guarded against when comparing capacities and efficiencies. Particulars of a number of interesting or outstanding blower installations in Canada as well as other parts of the world were given, two of the largest being the 78,000 c.f.m. unit at 120 pounds for the Victoria Falls and Transvaal Power Company Ltd. and the 130,000 c.f.m. unit at 21 pounds for the Alfred Hutte plant of the Krupp Company in Rheinhausen. In conclusion, Mr. Marples referred to some of the latest fields of application such as supercharging for Diesel and aeroplane engines.

Following the paper a number of interesting points were keenly discussed by several members of the audience, including Messrs. F. S. Winslow, A.M.E.I.C., and J. L. Busfield, M.E.I.C. J. T. Farmer, M.E.I.C., occupied the chair.

Niagara Peninsula Branch

C. G. Moon, A.M.E.I.C., Branch News Editor.

Under the able chairmanship of Walter Jackson, M.E.I.C., the Branch held a dinner meeting on Wednesday, January 14th, 1931, at Niagara Falls.

The guest speaker was Captain A. F. Ingram, Manager of Canadian Airways Limited, and until lately Adjutant at the Camp Borden flying field, consequently numerous members of the local flying club swelled the attendance and assisted the engineers in assimilating facts and disentegrating aero technicalities. Mainly, however, the address was couched in everyday language that could be followed by any layman.

Commercial Flying in Canada

Captain Ingram commenced by referring briefly to the history of his company, of which Mr. James Richardson of Winnipeg is president. The company is an amalgamation of several independent lines which started up soon after the war and served various districts under the stimulus of mail contracts. Western Canada Airways served the prairie country between Winnipeg and Calgary; Canadian Airways had the single route from Montreal to Toronto; other lines ran from Montreal to Moncton, from Edmonton north to Ketchekan and still others had short but dangerous routes to various northern mining camps. All these lines are now under the one management with headquarters in Montreal and have recently received substantial backing from Canada's two great railway systems, thus allowing Sir Henry Thornton, M.E.I.C., and Mr. Beattie to become vice-presidents of the Flying Company; Sir Herbert Holt is also on the board of directors, so that the future promises important developments. Very shortly, continued Captain Ingram, we can promise a trans-Canada quick service, flying by day and reposing more or less restfully during the night in one of the magnificent Pullmans hauled along prosaic rails by an obsolete locomotive. By the way, this is not an exact quotation, as Captain Ingram still has a vast respect for engines and railway companies.

During the War, 62 per cent of the Imperial Air Service was composed of Canadian flyers. This statement somewhat startled the audience, but Captain Ingram explained it by saying that the majority of young Britons had already trained in other branches of the Army and their services were too valuable to allow of any great change while the war was in progress. On the other hand, the Canadian boys were untrained and formed the very best material for this new branch, consequently they were snapped up and given important positions as the Air Service expanded. After the war, from about 1921 to 1926, aviation in Canada was at a standstill. Only about 5 per cent of the returned fliers stayed with the game and earned a precarious livelihood with minor flying units or as forest patrols. Today, there are plenty of pilots available in Canada—the Canadian Airways has a waiting list of fifty names, all eager to take over new routes as soon as they can be opened up. There is a good future ahead for aviators and groundsmen. The Canadian Airways find that it is good policy to pay well for competent pilots; they have fewer mishaps and consequently not only are insurance rates lowered but the public is gradually gaining confidence and using this means of travel to an ever-increasing extent. At present, pilots get a retainer of about $200 to $250 a month plus a flying bonus of 5c. a mile, which amounts to a respectable figure at the end of the year. One thousand to fifteen hundred flying hours is, however, considered low and most of the passenger plane pilots must have more than 2,000 hours to their credit.

Ground crews, naturally, are not paid on such an extravagant scale; air engineers get $150 to $175, mechanics about $100. There are also recorders, radio operators, weather reporters, and many other positions, which are being opened up continuously; also airport engineers have a professional field which has hardly been touched.

Airways in Canada have, so far, had an uphill fight—the Post Office Department has saved the day by means of air mail subsidies but even this has not meant unalloyed bliss. Pressure is continually being brought to bear for uninterrupted service combined with shorter flight timing. On the other hand, insurance companies and the Department of Civil Aviation, combine in insisting upon "Safety First." A hundred successful flights may implant courage into one hesitant traveller but one bad accident will deter many more than a hundred would-be fliers.

Despite these handicaps, aviation in Canada has progressed—the 340-mile air route between Toronto and Montreal was originally flown by Captain Peck in 1918 and his time was about six hours and forty minutes. At present the regular service is three hours.

Accidents are rare: in the last two years there have been 94 forced landings, of which 85 were caused by weather conditions and only 9 due to engine trouble. Forced landing fields are spaced about 30 miles apart where possible; of course, in many of the farmed lands a forced landing can be made almost anywhere but routes such as the one between Montreal and Moncton offer great difficulties on account of its heavily wooded nature. Along this route pilots have orders to fly as close to the Canadian Pacific Railway right-of-way as possible.

The signal service plays a most important part in aviation. Teletype machines are at present employed at all ports between Montreal and Windsor and from Montreal to Halifax ground signals are still in use but these will shortly give way to radio thus allowing the pilot to be in constant communication with both the points of departure and destination.

During the last year Canadian Airways have flown 5,000 passengers in the prairie districts and 1,000 in eastern Canada at rates which are about equal to railway fare plus the cost of a lower sleeper. In eastern Canada the rates are slightly higher than in the west and amount to 5c. a mile. Flying rates in the United States are about double this last figure.

One of the most important of Canadian Airways activities is the mail route to Rimouski and the Island of Anticosti, meeting or overtaking the trans-Atlantic steamers, thus saving some 12 hours' time over the New York service. This route is to be extended another 400 miles to the Straits of Belle Isle with a consequent saving of another 12 hours. Eventually the intention is to extend still farther northward up the coast of Labrador to a junction with the trans-Atlantic service of the Imperial Airways which is even now in process of being established via Greenland. The greatest water-hop is not more than 500 miles and Captain Ingram believes that the next few years will see this project completed and in operation.

In conclusion, Captain Ingram spoke of some of the technical difficulties encountered in flying. Fog is the worst hazard; it is not, at present, possible to complete an entire flight in fog; landing in a ground fog, however, has been proved practicable. The landing field has to be marked by a captive balloon which must be higher than the fog bank; the pilot marks his position and comes down through the muck not knowing just when he is going to strike the ground. However, about 5 feet beneath his plane there dangles a weight carrying an electric contact to a red light on his dashboard. As soon as this weight touches the ground the contact is made and, at the flash of red, he pulls back hard on the stick and lands—very often this gives a smoother landing than with perfect vision because it is automatic and adjusted exactly for every plane. Aquaplanes frequently use this device on glassy water when the distance is almost impossible to judge exactly.

Snow storms do not materially cut down time but they may be very unpleasant to fly in. The present company regulations call for a forced landing whenever the ceiling becomes less than 800 feet and the visibility is less than half a mile. Then the pilot goes forward, or back, to the nearest forced landing field marked on his chart.

Parachutes are going out of use in commercial flying except when pilots are flying at night in single seater planes. Most modern planes are so constructed that it is safer to stay with the plane than risk the jump into the air and the later danger of landing. The bodies or cabins are the strongest part and will resist a crash and protect the passengers when all other parts have crumpled and borne the brunt of the shock.

Following his address, Captain Ingram showed some very good lantern slides of various types of aeroplanes and a motion film sponsored by the N.A.T. lines in the States.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

The Wolfe Cove Tunnel

Lieut.-Col. D. Hillman, M.E.I.C., engineer of construction for the Canadian Pacific Railway, was the speaker at the noon luncheon held at the Chateau Laurier on Thursday, December 18th, his subject being "The Wolfe Cove Tunnel, Quebec." John McLeish, M.E.I.C., chairman of the local branch, presided and other guests at the head table included Major W. E. Blue, A.M.E.I.C., J. E. St. Laurent, M.E.I.C., Dr. J. A. Amyot, Deputy Minister of Pensions and National Health, F. H. Peters, M.E.I.C., Surveyor General, B. R. Riggs, Secretary of United States Legation, C. R. Coutlee, M.E.I.C., Honourable Dr. R. J. Manion, Minister of Railways and Canals, Honourable T. G. Murphy, Minister of the Interior, J. E. Noulan Cauchon, A.M.E.I.C., Irving N. Linnell, United States Consul General, G. J. Desbarats, C.M.G., M.E.I.C., Deputy Minister, Department of National Defence, A. E. MacRae, A.M.E.I.C., and Dr. R. M. Stewart, M.E.I.C.

The Wolfe Cove tunnel now being built by the Canadian Pacific Railway is part of a project relating to the construction of harbour terminal facilities at Wolfe Cove. The systematic waterfront development known as the Wolfe Cove terminal has been brought forward as a result of long and extensive study by the port of Quebec authorities. This project covers the river frontage of the city proper for a distance of about 2 miles, giving a total wharfage of 26,000 linear feet. It consists of a quay wall for the entire length, placed far enough out from the present shore to allow ample trackage together with piers 2,300 feet long and 425 feet wide extending into the river at appropriate intervals. A section of the terminals under construction at the present time consists of 4,300 feet of the above mentioned quay wall and completes the eastern portion of the development.

The tunnel itself when constructed will facilitate the handling of traffic between the new terminal and the Canadian Pacific main line along the St. Charles river. It leaves from a point on the main line about 2½ miles west of the Palais station at Quebec, and passes directly under the ridge which lies between the valley of the St. Charles and St. Lawrence rivers. In its course through the ridge it passes slightly west of the Plains of Abraham and comes out on the St. Lawrence a little to the east of the historic site of Wolfe Landing, the centre line being directly under Belvedere Avenue. The grade on the branch line varies from nearly level at the north portal to a maximum of 0.8 per cent in the tunnel itself. There will be no grade crossings of streets on the branch line. To obviate a grade crossing at Champlain street alongside the St. Lawrence a diversion of the street will be constructed in order to carry it over the tunnel lining which will be extended past the face of the cliff a sufficient distance to accommodate it. The selection of the location of the branch line was influenced by the topographical features, the expected geological formation and the desire to avoid interference with the existing appearance and conditions of the terrain at the historic site of Wolfe Landing. The formation varied from shale to Quebec city limestone, both rocks being quite soft and weathering on exposure. The former has to be supported immediately with timbers while the latter is self-supporting.

The speaker mentioned in some detail the methods used to insure accuracy in the tunnel alignment and also the means taken to hold points of reference both for line and grade.

The location plan, profile and book of reference were approved by the Board of Railway Commissioners July 2, 1930, and the contractor was advised at once to proceed with the work. The time for completion was specified as June, 1931, that is, eleven months only were allowed for the construction of this 1½ mile branch line with one mile of it in tunnel. The date set for the completion will fit in with the date set as the time when the new Canadian Pacific steamship "Empress of Britain" should reach Quebec on her maiden trip, the first steamer to use the Wolfe Cove terminal.

The tunnel is for single track with a clear inside width of 16 feet and a clear height above base of rail on the centre line of 22 feet 6 inches. The side walls are vertical and the top is formed by a semi-circular arch of a radius of 8 feet. The tunnel will be lined with concrete the type and quantity of which will vary according to the class of material through which the bore passes. At three locations in the west wall at equal distances apart refuge bays will be constructed to provide places for the section gang and other workmen to get clear of the trains. In the east wall there will be three conduits for carrying signal and telegraph wires.

The tunnel is being constructed from both portals at the same time and at the time of the address the speaker stated there was still about one-third of the distance to be bored through. Electric power is used for all the plant equipment and lighting on the job and is supplied by the Quebec Power Company. For excavating the tunnel the bottom heading method is used. The heading being driven from each end is taken out about 12 feet high and 14 feet wide. The drilling for this heading consists of about 24 holes 8 feet to 10 feet deep. The work is carried on in two shifts over the 24 hours and each shift generally drill and shoot one round. The shot is arranged in seven delayed actions, the central holes being fired first. About three pounds of powder per cubic yard is used per shot. The advance in each heading averages about 100 feet per week. Further details were given by the speaker with regard to the methods used for handling the muck, the whole operation being very efficiently carried out and running very low in maintenance cost as well as having a low first cost.

After a shot is fired the drillers have been able up to the present time to get back to the heading in about twenty minutes without suffering any ill effects from gas or dust although it is expected that before long blowers for clearing the gasses from the tunnel will have to be put in operation. The spray is turned on the muck heaps after each shot and this tends to expel the gasses and to permit of earlier re-occupation of the heading.

The rock in the tunnel drills easily and shoots small. Many falls of rocks have occurred, fortunately as yet without serious results. These falls have been in the shale only and generally where boulders of foreign rock are imbedded in the shale. No warning, such as small pieces of rock dropping off, occurs prior to such falls and it has only been by careful inspection and from the prompt placing of timbers that serious accidents have been avoided. Where there is an indication of foreign boulders in the shale, breakdown timbers are placed at once.

For the placing of concrete the plant on each end consists of a one-yard mixer with pneumatic placer and necessary pipe. The concrete is mixed in the ordinary way and deposited in a hopper and thence in the pneumatic placer after which a plate is set over it. When the air is turned on, it is caused to flow through a 6-inch pipe and delivered behind the form at the top of the tunnel lining. The placing of concrete will be carried out from the north end and from the south end and from three intermediate stations. At the three intermediate stations within the tunnel the concrete will be delivered through holes that are being drilled from the surface. The placing of concrete will be carried out at the north end and south end on alternate days giving daily progress of about 20 feet at each end.

The rate of progress since this work has started would indicate that the breaking through of the heading will take place in the last half of February. It is expected that the full section excavation will be completed about six weeks later and the concrete lining a month after the full section is completed.

The annual meeting of the Ottawa Branch of The Engineering Institute of Canada was held at the Chateau Laurier on the evening of January 8th. About ninety members were present. John McLeish, M.E.I.C., chairman of the local branch, presided.

The meeting commenced with the reading of the notice of meeting by F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer. The minutes of the last annual meeting together with reports of the various committee chairmen had, previous to the meeting, been prepared in multigraph form so that a copy could be handed to each of the members present. This facilitated the progress of the meeting and on this account a number of the reports were taken as read, thereby allowing a greater length of time to be taken up in discussion.

In the chairman's address, presented by Mr. McLeish, tribute was paid to those who had assisted in carrying out the various duties of the Branch. Reference was also made to various points, most of which were more fully elaborated upon by the committee reports presented later, namely to the extent of membership, the state of the finances, a proposal for the formation of radio and aviation sections, a suggestion for the awarding of prizes to stimulate education in the Ottawa Technical School, and the branch activities in general.

Reports presented at the meeting included that of the Managing committee by E. W. Stedman, M.E.I.C., chairman; the Secretary-Treasurer's report by F. C. C. Lynch; the report of the Proceedings committee by L. L. Bolton, M.E.I.C.; of the Membership committee by J. E. St. Laurent, M.E.I.C.; of the Rooms and Library committee by W. L. Cassells, A.M.E.I.C.; of the committee on Advertising by J. R. Akins, M.E.I.C.; of the Branch By-Laws committee by W. F. M. Bryce, A.M.E.I.C.; of the Reception committee by F. H. Peters, M.E.I.C.; and of the special committee to look after the 44th Annual Meeting of The Institute held at Ottawa on February 12th, 13th and 14th, 1930, by J. L. Rannie, M.E.I.C.

Although the membership of the local branch had fallen off during the year prospects for an increase in 1931 were favourable. There were 393 resident members and 68 non-resident members of the local Branch. The financial statement, according to the Secretary-Treasurer showed that the assets of the Branch were $1,968.67. The cash balance was $1,642.41. The outstanding event of the year had been the 44th Annual Meeting of The Engineering Institute of Canada held under the auspices of the local Branch last February.

The Managing committee's report contained details of a recommendation to the effect that it would be advisable to form professional sections of The Institute; as examples, aviation and radio sections were named. In the discussion which followed, Group-Captain Stedman said that everything was in readiness to proceed with the formation of a local section for aviation. He also said that he understood Colonel W. A. Steel, A.M.E.I.C., who was not present at the meeting, was prepared to organize a radio section.

The report of the Proceedings committee elicited the information that during the year there were 14 luncheons and 4 evening meetings held, with an average attendance of 112 for the luncheons and 154 for the evening meetings. This report contained a recommendation that the local papers the *Journal*, the *Citizen* and *Le Droit*, be communicated with and expressions of appreciation from the Branch sent them for the excellent write-ups which they had given to the luncheon addresses and evening meetings.

With regard to the suggestion put forward that the Branch undertake to donate prizes to pupils of the Ottawa Technical School, the meeting was entirely in accord. In the discussion upon this subject, it was brought out that the prizes should be awarded to both day and night classes. For the latter, particularly, it was considered that the awarding of prizes would afford a stimulus toward the completion of the courses undertaken by those who of necessity had to obtain their technical education in the evenings.

The election of officers for 1931 resulted as follows:—chairman, G. J. Desbarats, C.M.G., M.E.I.C., Deputy Minister of the Department of National Defence; secretary-treasurer, F. C. C. Lynch, A.M.E.I.C., Director of the National Development Bureau of the Department of the Interior; managing committee, R. F. Howard, M.E.I.C., of the Gatineau Power Company, Group-Captain E. W. Stedman, M.E.I.C., of the R.C.A.F., Department of National Defence, C. E. White, A.M.E.I.C., of the Canadian National Railways, J. R. Akins, M.E.I.C., of the Topographical Survey of Canada, and J. E. St. Laurent, M.E.I.C., of the Department of Public Works; the two last named having still one more year to serve in order to complete their term. Ex-officio members of the committee are J. E. Noulan Cauchon, A.M.E.I.C., F. H. Peters, M.E.I.C., and John McLeish, M.E.I.C.

Following the election of officers Mr. McLeish, who had presided up to that time, gave over the chair to Mr. Desbarats, who made a short address.

During the course of the meeting and afterward entertainment was provided by Mr. Roy Wright of Ottawa who contributed several songs and performed a number of sleight-of-hand tricks. Two short moving pictures supplied through the courtesy of B. E. Norrish, A.M.E.I.C., Manager and Director, Associated Screen News, of Montreal, were shown. At the close of the meeting refreshments were served.

Peterborough Branch

F. G. A. Tarr, S.E.I.C., Secretary.
B. Ottewell, A.M.E.I.C., Branch News Editor.

TWELFTH ANNUAL DINNER

The Peterborough Branch held its annual dinner on November 25, 1930, at the Empress hotel, Peterborough, with its usual success, nearly one hundred members and guests being present. Among the prominent guests who honoured the Branch with their presence were A. J. Grant, M.E.I.C., President of The Institute, Colonel R. E. Smythe, A.M.E.I.C., Director of the Technical Service Council, Toronto, R. J. Durley, M.E.I.C., General Secretary, C. E. Sisson, M.E.I.C., Vice-President for Canada of the A.I.E.E., E. G. Cameron, A.M.E.I.C., assistant engineer, Welland Canal, Colonel VanScoyoc, Portland Cement Association, E. A. Peck, M.P., Alderman MacDonald, representatives of the Montreal, Toronto and Kingston Branches and also delegates from the local medical, ministerial and teachers associations.

As a centre piece at the head table a working model of one of the Welland Canal lift bridges paid delicate compliment to our President and several of his engineers who were present.

Chairman W. E. Ross, A.M.E.I.C., proved a capable master of ceremonies and following the banquet he introduced the programme by a brief address in which he reviewed the aims of the Peterborough Branch of The Institute and the possibilities it holds for the profession. The customary programme of toasts followed and addresses were given by a number of guests.

In response to the toast to The Institute, President Grant stressed the necessity for new members and also for closer co-operation between The Engineering Institute and the various Provincial Associations of Professional Engineers.

R. J. Durley in optimistic tone outlined the progress of the work being done towards confederation of these various Associations. Speeches were also given by E. G. Cameron, A.M.E.I.C., Niagara Peninsula Branch, D. C. Tennant, M.E.I.C., Montreal Branch, Colonel E. J. C. Schmidlin, M.E.I.C., Kingston Branch, and J. J. Trail, M.E.I.C., Toronto Branch, and also by members of the sister professions and others.

In deploring the exodus to the United States of a large percentage of the graduates of Canada's universities, which has been checked appreciably by the activities of the Technical Service Council, of which he is a director, Colonel R. E. Smythe, D.S.O., explained that in the past fifty years this exodus from one university alone was approximately 17 per cent. After the War and up to the year 1928, the percentage rose as high as 24 per cent. At that time the Technical Service Council was formed with the intention of increasing the use for technically trained men in Canada and to influence the supply and demand in all branches of the profession; also to establish a clearing house that men of ability could find some opening, where their talents may be used for the good of their own country.

In 1929, 97 per cent of the graduates of Ontario universities put their efforts into Canadian enterprises, in 1930 the percentage rose to 98. "This country needs her engineers," he declared, in making it quite plain that the organization of which he spoke, was in no way antagonistic to the United States. "In 1931," he said, "there will be 38 engineers graduating in Canada for every one million of the population, while in the United States next year, there will be 82 graduates for every million of the populace.

"I believe that in the near future the engineers of Canada are to play a larger part in the wealth of the country than they have done in the past. We still see the demand for engineers, which has kept constant despite the slight depression in most other industries and professions."

The speaker thought The Institute was due for an increase in membership and an increase in influence and strength, and that the quickest way to accomplish such an end was for the A.I.E.E., the Technical Service Council and other kindred organizations to get into harness and pull together, then the engineer of the Dominion would occupy a new status, and commence to play a greater part in the leadership of this country.

Commenting on the immigration situation, Colonel Smythe, while realizing that Canada needs many men of the right stamp and calibre, was nevertheless of the opinion that in times of depression immigration on a large scale should not be encouraged. With this idea in mind the Council had written to the authorities in the preferred countries and had urged them to postpone their impending migration to Canada until trade conditions become more stabilized. The result of this action had been a large falling off in the number of immigrants to this country during the past year; more work for our own engineers and the assurance that these intending migrants, providing they are of the right type, will be needed very shortly.

The musical programme was contributed by an excellent orchestra of piano, violin and 'cello, also a solo by R. J. Cobbold, S.E.I.C. Community singing was led by Paul Manning, A.M.E.I.C., and a skit on the activities of certain prominent members of the Branch on the recent occasion of their visit to the Canada Cement works was entertainingly presented by Student and Junior members.

COPPER IN THE ELECTRICAL INDUSTRY

A well attended meeting of the Branch was held on December 11, 1930, at which an interesting address on the above subject was given by Mr. H. C. Jennison, Assistant Technical Superintendent and Assistant Metallurgist of the Anaconda American Brass Company. Chairman Ross Dobbin introduced the speaker who first showed two reels of moving pictures depicting the plant, equipment and processes of the Anaconda Company. Starting with the mining of the ore and following the progress of the material through crushing, screening, smelting, refining and rolling, the films clearly illustrated modern methods of production. Manufacture of copper sheet, rod and tube was also shown.

Remarking that the production of copper in the United States and Canada in 1929 totalled 1,160,000 tons, the speaker said that approximately half of this was used in the electrical industry, which requires the highest quality in conductivity. A purity of 99.90 per cent was guaranteed and the actual average was 99.95 per cent.

As an example of the ductility of copper mention was made of a 1-inch bar drawn down to .002 inch by special care but without annealing.

Mr. Jennison also dealt at length with copper alloys, of which there are some hundreds, many such as brass, manganese, phosphor bronze, everdur, etc., having valuable properties in the electrical industry.

Incidentally the speaker mentioned that all the Company's mills have been or are changing over to electric drive exclusively with resultant economies. Ninety per cent of the metal is now melted in electric furnaces of the arc, induction and high frequency types.

A very active discussion followed the address, many questions being answered by the speaker. On behalf of those present, H. R. Sills, Jr.E.I.C., moved a hearty vote of thanks.

An exceptionally popular meeting of the Peterborough Branch was held on Thursday, January 8th, 1931, at which Major L. T. Burwash, M.E.I.C., geologist, scientist and explorer, of the Yukon and Northwest Territories Branch of the Department of the Interior, gave an address on the subject of "Exploration in Northern Canada." This meeting was open to the general public and was held in the large auditorium of the Collegiate Institute, the attendance being approximately 800. W. E. Ross, A.M.E.I.C., Branch chairman, presided.

In introducing the subject, Major Burwash stated that the Northwest Territories comprised about one-third of the total area of Canada; He thanked the people for investing money in this and other expeditions. he hoped that further work would not prove too expensive.

The natural resources of this northerly district were pictured as being extensive. A great agricultural area, an extension of the Peace river belt and some of the most fertile land in Canada, stretches northward from the Northwest Territories boundary 300 miles, and east and west 500 miles. This excellent land, the speaker said, is at present very sparsely settled, but promises the sustenance of a large population in the future.

In the Mackenzie river district are extensive mineral and oil deposits. Valuable discoveries were made last year, and this area should become the wealthiest mining district in Canada. Copper ore has been found and this is accompanied by favourable geology. Radium ores, comparing very well with those found in the Belgian Congo, have been discovered, and may furnish Canada with a copious supply of that precious element.

Valuable products such as oil, leather, etc. are furnished by the abundant supply of sea mammals in these northern regions. The country provides good grazing lands for caribou and reindeer.

Eventually Canada will be abundantly repaid by the produce from the northlands, as a result of the investment in exploration and scientific expeditions.

Major Burwash then proceeded to recount the fascinating history of northern Canada, commencing with the discovery of Hudson bay by Henry Hudson in 1603, proceeding with the subsequent expedition of Fox, James and Frobisher, and giving in considerable detail an account of the tragic Sir John Franklin expedition.

The speaker then described his own expeditions and especially those of 1928 to 1930, culminating with a visit to the Franklin camp on King William island.

During these trips Major Burwash took observations of the north magnetic pole, noting a variation of some 7 degrees east and west each day.

Major Burwash's address was illustrated with a very fine series of still pictures and his later expeditions by aeroplane were shown in moving pictures.

At the conclusion of the address the appreciation and thanks of the large audience was ably expressed in a short speech by Judge Huycke.

Saskatchewan Branch

R. W. E. Loucks, A.M.E.I.C., Secretary-Treasurer.

The first regular meeting of the season was held at the Kitchener hotel, Regina, Sask., on October 24th, 1930, at which time Councillor D. A. R. McCannel, M.E.I.C., gave a report on the Plenary Meeting of Council held in Montreal on September 22nd, 23rd, and 24th. Mr. McCannel emphasized the need for additional funds to carry on the work of The Institute and told of the plans which are now under way to bring about closer relations between the various Professional Associations of Engineers and The Institute. He referred to the work of the committee on Publications, committee on Remuneration and Classification, Students Prizes and other matters dealt with at the meeting. He said it was expected that President Grant would make a visit to the western branches during the coming season. Vice-President C. J. Mackenzie, M.E.I.C., Dean of Engineering, University of Saskatchewan, was also present and contributed to the discussion on Institute matters. The meeting was preceded by a banquet held at 6.30 o'clock p.m. at which 40 members and guests were present. At 9.00 o'clock p.m. the meeting adjourned and was followed by a meeting of the Professional Association of Engineers of Saskatchewan, which the majority of the members attended.

Experiments in the Transmission of Speech and Music

At the November meeting of the Branch held at the Kitchener hotel, Regina, on November 21st, 1930, S. R. Muirhead, A.M.E.I.C., gave an address on "Experiments in the Transmission of Speech and Music." This address was illustrated by gramophone records. Mr. Muirhead discussed briefly the principles connected with the transmission of sound, explaining that in telephone work the atmospheric vibrations are transformed into electrical vibrations and vice versa. Due to the characteristics of the electrical circuits and apparatus involved it is impossible to transmit by wire all the frequencies originally present in the atmospheric vibrations but fortunately reasonable results can be obtained by transmitting certain fairly well defined ranges of frequencies. The ranges necessary for satisfactory transmission of speech and music are somewhat different, the requirements for music being more exacting. A number of the records that were played showed the harmful effects of eliminating certain frequency ranges both for speech and music. Other records showed the effect of overtones on the quality of the tones of different musical instruments and gave practical demonstrations of other matters of interest to telephone engineers.

Mr. Muirhead is engineer with the Saskatchewan Department of Telephones. At the conclusion of his address a hearty vote of thanks was tendered him on motion of R. N. Blackburn, M.E.I.C., and H. S. Carpenter, M.E.I.C.

Natural Gas for Saskatchewan Cities

At a largely attended meeting of the Branch held at the Kitchener hotel, Regina, on December 12th, 1930, preceded by a banquet, some 47 members and guests assembled to hear Mr. E. M. Moore, engineer, of the Tri-Cities Utilities Ltd., speak of the proposition which his company has recently submitted to Regina, Saskatoon and Moose Jaw for a natural gas supply.

Mr. Moore traced the development of the use of natural gas on this continent which began in New York in 1832. The first pipe line, having a length of 25 miles from Whitepine to Rochester, N.Y., cost $25,000,000 and was a complete failure.

Engineering schools of that time failed to recognize the value of natural gas and its development was left almost entirely to "wildcatters," who accepted the risks of financing and who are not given all the credit they deserve. Only in recent years has gas supply been recognized as a public utility and to-day we find many prominent engineers connected with the development of oil and gas.

Mr. Moore exhibited a map showing the extent of the development of natural gas in the United States. Within recent years this country has been covered with a net work of lines extending from one end of the nation to the other and the movement is now spreading into Canada.

An investigation of the sources of supply for central Saskatchewan including the cities of Regina, Moose Jaw and Saskatoon, indicates three main fields, Montana, Turner Valley in Alberta and the Kinsella-Wainwright district in Alberta. Mr. Moore stated his reasons for favouring the development of the latter field based on the report of Herbert R. Davis, gas expert of Buffalo, N.Y., recently employed by the cities of Regina and Saskatoon to report on this question. Briefly the Montana field is in shallow sand, under low pressure and it is doubtful whether a sufficient supply of gas could be developed at this point to meet the needs of Saskatchewan. The supply of gas from the Turner Valley field is rapidly being depleted by uncontrolled waste and the gas contains so much sulphur (as much as 700 grains per 100 cubic feet), that it would have to be scrubbed before being fit for domestic use.

The Kinsella-Wainwright field, while not yet fully investigated nor developed, is believed to be eminently satisfactory. Government reports state that wells in the field have from 10 to 30 million cubic feet open flow. The Kinsella well has an open flow of 25 million cubic feet. It is 2,500 feet in depth and has a pressure of 765 pounds per square inch. The Kinsella field has to-day 15 producing wells, including the Hudson Bay well, and the Viking field is only 12 miles from the former. It has been estimated that the Kinsella-Viking-Wainwright field has a sufficient supply of gas already developed to meet the requirements of central Saskatchewan for 11 years, with the probability that this supply can be considerably augmented by the end of that time, either by new wells in that district or by the development of wells in other portions of Saskatchewan.

Mr. Moore recommended the sympathetic support of his audience to the efforts now being made to find supplies of natural gas in Saskatchewan at such points as Simpson, Outlook, Biggar and Pilot Butte, thus encouraging the development of our local resources which in turn would benefit every industry in the province.

Mr. Moore stated that experience shows that not more than 10 per cent to 20 per cent of the open flow of gas wells should be utilized. He further stated that 75 million cubic feet of open flow can be developed from three good wells in the Kinsella field.

The speaker estimated the cost of the proposed development including pipe lines to be $14,000,000. Very few cities on this continent have tried public ownership of gas supply mainly because it embodies an element of speculation, particularly during the first five years of the development. Franchises for the supply of gas usually carry with them provision for control of rates so that the company obtaining a franchise is not allowed over a certain percentage of profit on their investment. These rates are usually adjusted from time to time and at all times the company is forced to maintain rates which can compete with the use of coal as a fuel.

Mr. Moore stated that if his company is granted a franchise, they will introduce a most modern plant and appliances, consisting of mixing chambers, ranges, furnaces, etc., and that a service department will be set up and efficiently manned at all times to advise and inspect the consumers appliances. Gas companies must of necessity give the best of service, since they are in competition at all times with coal and electricity.

Upon completion of the address a general discussion took place.

Sault St. Marie Branch

A. A. Rose, A.M.E.I.C., Secretary-Treasurer.

The annual meeting of the Sault Ste Marie Branch of The Institute was held in the Y.W.C.A. rooms, March street, following a dinner at the Savoury cafe, on December 19th, 1930, at 8 o'clock p.m.

C. H. E. Rounthwaite, A.M.E.I.C, chairman, called the meeting to order and the minutes of the last meeting were read by the secretary and adopted.

On motion of J. W. Le B. Ross, M.E.I.C., and F. Smallwood, M.E.I.C., bills to Cliffe Printing, Barnes Drug Co., and stenographer's salary were passed. An honorarium to the Secretary of $25.00 was passed.

W. S. Wilson, A.M.E.I.C., chairman of the Papers committee, reviewed the year's work and was able to pass on some suggestions to the 1931 committee, regarding prospects for a number of papers. His report was adopted on motion of A. H. Russell, A.M.E.I.C., and Frank H. Barnes, A.M.E.I.C.

In the absence of the chairman of the Membership committee, the Secretary read a summary of the Branch membership, showing a decline of nineteen members for the year. This report was adopted on motion of Messrs. Barnes and Smallwood.

Mr. Barnes reported for the Social committee their efforts to put on a dinner dance which failed to materialize on account of an insufficient number of members being able to be present. His report was adopted on motion of C. H. S. Dennison, Jr.E.I.C., and Mr. Ross.

The Secretary's report for 1930 was read and adopted on motion of Messrs. Russell and Dennison. It showed the Branch in a healthy financial condition. On motion of Messrs. Ross and Barnes, the auditors for 1930, Messrs. L. R. Brown, M.E.I.C., and A. E. Pickering, M.E.I.C., were reappointed for 1931.

As the result of a ballot which was taken, W. S. Wilson was appointed Branch representative on the Nominating committee of The Institute.

Mrs. W. Scott contributed a number of piano solos which were much appreciated by all present.

Mr. Barnes, chairman of Nominating committee, reported the result of the elections as follows:

Chairman: A. H. Russell, A.M.E.I.C.
Vice-Chairman: C. Stenbol, M.E.I.C.
Executive Committee: (2 years)
Resident: W. S. Wilson, A.M.E.I.C.
Non-Resident: C. H. N. Connell, A.M.E.I.C., North Bay.
Executive Committee: (1 year)
Resident: J. W. LeB. Ross, M.E.I.C.
Non-Resident: J. M. Silliman, A.M.E.I.C., Sudbury.
Secretary-Treasurer: A. A. Rose, A.M.E.I.C.

On motion of Messrs. Barnes and Rose, this report was adopted.

In vacating the chair to the new chairman, Mr. Rounthwaite reviewed the work of the year just closing and expressing his hope and faith in the future prospects of the Branch, solicited the support of all the members for the new executive.

In taking the chair Mr. Russell thanked the members for the honour conferred on him and asked the support of all in making 1931 a banner year.

A vote of thanks was tendered the Y.W.C.A. for the use of their room on motion of Messrs. Barnes and Rounthwaite.

The new chairman was instructed to see what arrangements could be made for holding meetings and dinners at the New Windsor hotel.

The meeting adjourned on motion of Messrs. Barnes and Rounthwaite.

Toronto Branch

J. J. Spence, A.M.E.I.C., Secretary-Treasurer.
A. B. Crealock, A.M.E.I.C., Branch News Editor.

The meeting of the Toronto Branch of The Institute held on Thursday December 11th, 1930, was well attended, the speaker being A. S. Wall, M.E.I.C., of the Dominion Bridge Company, Ltd., Montreal. The paper presented was "Arc Welding in Steel Fabrication," and was written from the standpoint of the structural fabricator who in addition to being a manufacturer is a merchant in business to sell fabricated steel, the manufacturer's interest in the sale of fabricated material of welded construction being dependent on whether the use of welding leads to more economical construction or provides means of better design. At the present time and in the near future at least his attitude being that he has a new and very useful tool or process available in addition to his older method; and that he will be prepared to use whichever of the methods that best satisfy the requirements of a particular job. The type of welding discussed was metal electrode arc welding. This process as regards structural steel may be considered as in the earlier stages of evolution, various construction schemes being tried, probably as many being discarded; but the science of welding developed amazingly during the past few years. When welding machines first made their appearance they were used principally on repair or salvage work, but their use grew so that to-day the question is not so much is welding safe but rather the establishment of its economical boundaries. The growth of the practice is evidenced by the fact that while Mr. Wall's company purchased their first single operator machine some ten years ago, to-day the parent plant has 23 manual machines and 2 automatic heads while a dozen or more machines are distributed throughout their various branch plants. Although during this period many types of structures have been fabricated by welding such as tanks, barges, buildings, bridges, etc., it cannot be said yet that the manufacturing of all such structures by welding process has become standard practice, however in some plants there are various structures which are fabricated by welding as a more or less accepted practice. Welding is also used daily for the building up of worn shafts or other parts as the regular or only means, while the formation of loop ends for hangers or bracing rods costs less by the welded process than by the forge method. Vessels built to contain gasoline, caustic liquids and other liquids difficult to hold in riveted tanks give practically no trouble in containers of welded construction, although in this class it is not necessarily a question of reduced cost but rather that welding is more suitable for the purpose.

The speaker described the use of welding for sluice gates, also its advantages for parts made of cast steel and its use in the making of manholes, cleanout doors, machinery bases and bridge pier members. The next part of the paper contained a detailed description of the use of welding in structural work such as trusses, columns, beams and on building work, one of the advantages on the latter being the freedom from noise which is of extreme importance especially in congested districts. Following this Mr. Wall described the development of a system of control for welding operations, so as to ensure the strength of the weld, the training and periodic testing of the operators, the supervision and inspection of the work in order to ensure uniformly reliable welds. The training of the draughting and designing staff and the use of standard instructions were dealt with. Following this Mr. Wall treated on the methods used to provide for general economy in the practice, touching on the use of welding in ordinary shop work and describing how the practice is being studied, stating however that it will be necessary to profit by the accumulated experiences of many companies before a structural steel welding practice can be definitely established.

Then the speaker described the work being done on fundamental research along the lines of stress distribution in welded joints, studies of welded metals under impact and fatigue tests, continuous connections, etc. The need for a method to control the welded structure from distortion under construction was discussed. One of the probable fields for welding is the repair and reinforcing of old structures to allow them to take heavier loadings, but study should precede its employment for this work to ensure that stresses induced by the strains from members subjected to welding will not cause trouble in some plane of weakness. However, because of the rapid development in the art of welded design and operation and the widespread research now in progress, there is good reason to expect that in a comparatively short time there may be a reasonably comprehensive structural steel welding practice paralleling in a measure the older structural steel riveting practice.

Following this Mr. Wall showed some 75 slides illustrating the points covered in his paper. An extensive discussion on the paper took place and the meeting adjourned after a very hearty vote of thanks had been tendered Mr. Wall for his excellent paper.

On the evenings of January 7th, 8th and 9th, the Toronto Branch of The Engineering Institute of Canada in conjunction with the University of Toronto and other engineering societies in the city were again privileged to hear "A Short Course in Concrete," by Mr. R. S. Phillips, of the Portland Cement Association of Chicago. These lectures were given in Toronto two years ago and the interest with which they were received was evidenced by the attendance this year, the lecture room in the Physics building of the University being practically full on each evening.

It is impossible in a review of this nature to treat Mr. Phillips' lectures in detail but the subject was covered in a most thorough and interesting manner. In mentioning some of the highlights of the lectures we might state that the water-cement ratio strength law was the basic theory in both times that Mr. Phillips spoke to Toronto audiences, but whereas two years ago the trend was to get a concrete of a definite strength, to-day the exposure to which the concrete is to be subjected and its durability should be considered. The effect of this in climates such as we have in this locality is that whereas a 2,000-pound concrete (obtained with approximately 6 imperial gallons per sack of cement) might meet our strength requirements the need of producing a concrete that would have the required durability would necessitate a concrete with only 4½ to 5 imperial gallons per sack of cement which would give a strength of 2,700 to 3,000 pounds per square inch. Mr. Phillips pointed out that in cases like this it would probably be better to re-design the work on a basis of using 3,000-pound concrete thus reducing the quantity of concrete needed and obtain a concrete that would meet not only the strength requirements but would provide the durability necessary.

Another point brought out by Mr. Phillips was that the design of a mixture by the calculation method is being superseded by the trial method. An example of the trial method was demonstrated by Mr. Phillips. The essential factors in control such as the selection of materials, effect of size and grading of aggregates, control tests and the placing and curing of the concrete were fully covered, special attention being given to the question of proper curing.

The lectures were of great interest and were thoroughly appreciated by all in attendance, who demonstrated their approval in no uncertain manner.

The Gage Avenue Pumping Station

The Gage avenue pumping station of the city of Hamilton, recognized as one of the outstanding units on the American continent for handling unscreened sewage, consists of four Smart-Turner vertical wood trash pumps, each capable of discharging 15,000,000 Imperial gallons in twenty-four hours (10,416 Imperial gallons per minute) against a head varying from 35 to 49 feet, also one Smart-Turner vertical wood trash pump handling ten million Imperial gallons in twenty-four hours (6,944 Imperial gallons per minute) against a head of 35 to 37 feet.

These vertical pumps are equipped with 16-inch suction and 16-inch discharge, capable of passing a 12-inch sphere, and are installed in the basement, direct connected to motors by flexible couplings and vertical extension shafts to vertical motors mounted on the main floor of the building.

The four larger pumps are driven by 125 h.p. 25-cycle, 3-phase, 550-volt, 360 r.p.m. vertical motors while a 100 h.p. 3-phase, 25-cycle, 550-volt, 360 r.p.m. motor is used for the other unit.

In order to be prepared at all times should electric power not be available, two standby units have been installed, consisting of two horizontal Smart-Turner double suction wood trash pumps, direct connected by flexible coupling through reduction gear to 250 h.p. 8-cylinder gasoline engines.

These pumps are of the horizontal split case type, double suction, capable of discharging 37,500,000 Imperial gallons in twenty-four hours (26,041 Imperial gallons per minute) against a head of 16 feet and each equipped with two 28-inch suction pipes and 36-inch discharge. The speed of each unit is 220 r.p.m. and a sphere 9 inches in diameter will pass through the pump.

The Hamilton Gear and Machine Company, Ltd., Toronto, Ont. have published booklet No. 104, being the fourth of a series of parts of a section catalogue, the three previous parts covering the following subjects: Worm Gear Speed Reducers, Herringbone Gear Reducers and Industrial Cut Gears. The latest part of the catalogue is a twelve-page booklet entitled "Flexible Couplings," containing information regarding, and photographs of, various types of flexible couplings, to enable the engineer to select the correct size and type of coupling for a given service.

The Power Corporation of Canada, Ltd., Montreal, has published a sixteen-page booklet entitled "Power," illustrating and describing briefly some of the activities of the company's engineering, construction and industrial divisions. Among these may be mentioned the Seven Sisters hydro-electric power development of the Winnipeg Electric Company, the Back River power development of the Montreal Island Power Company Ltd., the Upper Notch development of the Northern Ontario Power Company, Ltd., and the Chats Falls Power development of the Ottawa Valley Power Company and the Hydro-Electric Power Commission of Ontario. Copies of this booklet may be secured from the company's offices, 355 St. James street, Montreal.

The Canada Cement Company, Ltd., has recently published two circulars, one of which gives specifications for the use of calcium chloride as an accelerator in concrete and the other gives the results of tests on concrete showing the high early strength when it is so prepared.

Preliminary Notice

of Applications for Admission and for Transfer

January 19th, 1931.

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in March, 1931.

R. J. Durley, *Secretary.*

* The professional requirements are as follows—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

COONEY—RICHARD THOMPSON, Jr., of Newcastle Creek, N.B., Born at Hoboken, N.J., Feb. 7th, 1892; Educ., I.C.S.; A.M., A.I.E.E.; 1909-10, elect'l. helper, Continental Electric Co., Washington, D.C.; 1910-11, elect'n., small power installns., Columbia Pump & Well Co., Washington; 1911-13, elect'l. inspr., Washington & Old Dominion Rly.; 1913-14, supt. of constrn., small power house, Merchant & Evans Co., Philadelphia, Pa.; 1914-16, supt. of constrn., trolley line, North Beach Rly. Co.; 1916-17, asst. operating engr., industrial plant, Baldwin Locomotive Works, Eddystone, Pa.; 1917-18, gen. foreman, shipyard, Amer. International Shiphldg. Co., Hog Island, Pa.; 1918-24, owner, Progressive Electric Co., Maple Shade, N.Y., engaged in house wiring and small power installn. work, contractor and builder on small dwellings; 1924-25, elect'l. foreman, large power plant, Dwight P. Robinson Corpn.; 1926-27, elect'l. supt., large power plant, United Engineers & Constructors Inc.; 1925-26, elect'l. foreman, Byllshy Engineering & Management Corpn., San Diego, Calif.; 1927-28, elect'l. supt., sulphur mining plant, J. G. White Company, New York, N.Y.; 1928-30, elect'l. supt., large power plant, etc., Penn. Rld. for United Engineers & Constructors Ltd.; 1930 to date, elect'l. supt., small power plant for United Engineers & Constructors (Canada) Limited, at Newcastle Creek, N.B.

FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

MORRISEY—THOMAS SYDNEY, of 3275 Cedar Avenue, Montreal, Que., Born at Saint John, N.B., Aug. 30th, 1890; Educ., Grad. with Honours, R.M.C., 1910; 1911, topog'r., Boston & Maine Rly.; 1911-13, junior engr., Montreal Harbour Comm.; 1913-14, principal asst. to A. D. Swan, M.E.I.C., in Montreal and Antofagasta, Chile; 1914-19, overseas, Lt.-Col., D.S.O.; 1924, field engr., Combustion Engineering Corporation, New York, during constrn. at Winnipeg Hydro-Electric Steam Stand-by plant; 1926-30, vice-president and gen. mgr., Combustion Engineering Corporation, Ltd., in full responsible charge of steam plant equipment installed with 39 pulverized fuel units and 150 stoker fired units in Canada. Work ranging from design and installn. of simple stokers to complete plant including boilers, furnaces, burners, mills, air heaters, fans, pumps, etc.; at present, vice-president, United Engineers and Constructors (Canada) Ltd., Montreal, Que. (*S. 1910, Jr. 1913, A.M. 1924.*)

References: C. H. Mitchell, C. J. Armstrong, T. W. Harvie, F. M. Gaudet, J. Stadler, H. O. Keay, F. O. White.

WANG—SIGMUND, of Hawkesbury, Ont., Born at Oslo, Norway, July 7th, 1887; Educ., Chem. Engr., Coll. of Christiana; 1910-11, Univ. of Darmstadt, Germany; 3 years' ap'ticeship, Norwegian sulphite mill; 1912-14, chemist, Oxford Paper Co., Rumford, Me.; 1914-16, chemist, Riordon Pulp & Paper Company, and from 1916 to date, manager of laboratories, now Canadian International Paper Company, Hawkesbury, Ont. (*A.M. 1919.*)

References: C. B. Thorne, W. M. Ketchen, L. S. Dixon, B. Grav, A. K. Grimmer.

WOODYATT—JAMES BLAIN, of 3197 Westmount Blvd., Westmount, Que., Born at Brantford, Ont., July 2nd, 1886; Educ., B.Sc., McGill Univ., 1907; 1904, chainman, Niagara & Welland Power Co.; 1905, topog'r., Toronto and Hamilton Rly.; 1906-08, ap'tice, Can. Westinghouse Co.; 1908-09, investigation of ice conditions in Gulf and River St. Lawrence under Dr. Barnes, for Dom. Govt.; 1909-10, sales engr., Allis-Chalmers-Bullock Co.; 1910-13, supt., Sherbrooke Rly. & Power Co.; 1913 to date, with Southern Canada Power Co. as follows: 1913-16, gen. supt., 1916-20, gen. mgr., 1920-25, vice-pres. and gen. mgr., and 1925 to date, president and gen. mgr., and at present vice-president and gen. mgr., Power Corporation of Canada, Ltd., Montreal, Que. (*S. 1907, A. M. 1916.*)

Claude's Tropical-Seas Power Plant

There are men to whom Kipling's qualification applies most strikingly—

If you can trust your faith when all men doubt you,
Yet make allowance for their doubting too....
You'll own the earth, and what is more,
You'll be a man, my son.

Claude's life is full of instances where he did things that everyone considered to be next to impossible. The creation of the dissolved-acetylene industry was the first of his important achievements. Next came a new method of cryogenation by means of which gases such as oxygen and nitrogen were liquefied by an apparatus in which the energy of the gases was directly consumed in driving a piston. This was followed by the development of a method of producing synthetic ammonia by the use of enormous pressures, by his invention of the neon light, etc.

In all of this work Claude was never afraid of resorting to means beyond anything previously known or considered permissible. His new scheme of producing power by utilizing the comparatively slight difference between the temperature of the surface water of tropical seas and that of the water obtained from a considerable depth belongs to the same category of doing something in a way that no one dared attempt before on a sufficiently large scale.

That the process used by Claude can produce power is beyond doubt. In the first place, the principles lying at the foundation of the Claude development are well-known and recognized, and in the second place, Claude has actually generated power both in his experimental plant in France and in the larger plant on the Cuban coast. The only question that still remains to be solved is whether or not this power can be produced economically—in other words, whether the plant will pay on its investment. From this point of view quite elaborate calculations have been offered showing that it will not pay. The following, however, has to be borne in mind. Claude in addition to being an inventor is an engineer with an excellent mathematical and physical training. He is assisted by Boucherot, a man of recognized engineering ability. The elementary calculations which have been cited against the project are of a kind which Claude himself has certainly made, simply because he could not have laid out his units without some such previous calculations. If, on the face of these he decided to go ahead with an experiment, the cost of which will considerably exceed a million dollars, and when that million has come, not from the sale of stock to the general public, but from the proceeds of his own previous achievements, it behooves the engineering world to refrain from expressing doubt too actively. It is just the ability to see a possible way when every one else says there is no way at all, that distinguishes men like Claude who succeed from those who prove by arithmetical calculation that success is impossible.

Should Claude succeed, he may lay the foundation of an industrial and social revolution in tropical countries. It was only through the application of heat to houses that the temperate and cold zones became habitable, and we know now that with cheap power available the question of cooling houses is no more complicated than that of heating them—and cooled houses would make tropical countries freely accessible to extensive settlement by the white races. If Claude can provide cheap power without resorting to fuel, absent in most cases in the tropics, he may do for those regions what Prometheus of the legend did for the rest of the world.

—*Mechanical Engineering.*

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Vacant

HEATING AND VENTILATING ENGINEER, for investigating and re-designing heating and ventilating system in industrial plant. Temporary position. Apply at once to Box No. 654-V.

MANAGING ENGINEER for construction company in Ontario. Executive business ability of prime importance and prepared to make some investment. Should be energetic young man of good education. University graduate desirable but not imperative. Apply to Box No. 666-V.

PLANT MAINTENANCE ENGINEER, technically trained as mechanical engineer, with at least four years experience in actual charge of gangs. English, speaking French fluently, about thirty years of age. Location, province of Quebec. Apply to Box No. 667-V.

DESIGNING ENGINEER, one familiar with concrete and steel design. Must have had considerable practical experience and also must be capable of meeting public in sales capacity. Permanent position. State salary expected and full details of qualifications. Apply to Box No. 671-V.

CIVIL ENGINEER, with sound technical education, preferably college graduate, with at least ten years experience on general construction work, five years of which has been spent with contractors on road construction as asst. and supt. Apply to Box No. 672-V.

Situations Wanted

CIVIL ENGINEER desires to represent manufacturers of industrial products or specialties selling to industrial and other markets. Experience includes engineering and building construction, municipal works, administration and operation, purchasing and sales, etc. Record of integrity. Apply to Box No. 14-W.

ELECTRICAL ENGINEER seeks connection with Montreal engineer or architect for part time work involving the design and specification for industrial and public buildings. Experienced and capable of complete responsibility. Apply to Box No. 40-W.

CIVIL AND MECHANICAL ENGINEER; aggressive, practical engineer, with background of experience in design, construction, maintenance and operation of pulp and paper mills. Especially qualified to reduce mill costs. Apply to Box No. 53-W.

ELECTRICAL ENGINEER, B.Sc., age 30. Experienced in power distribution and electrical communication, including design of carrier current systems. Apply to Box No. 110-W.

PAPER MILL ENGINEER—Nine years experience with the power and paper industry. Looking for new connection with paper or power company or with firm supplying equipment to this trade. Familiar with cost accounting and executive work, as well as mill practice. Apply to Box No. 115-W.

COLLEGE GRADUATE, age 34, with over ten years experience in power developments and pulp and paper mill construction and maintenance, largely in direct charge of design or construction; desires new connection as chief or assistant engineer or construction superintendent. Apply to Box No. 167-W.

Situations Wanted

CIVIL ENGINEER, B.Sc., (McGill), M.E.I.C., P.E.Q. & B.C., with broad experience in hydro-electric power investigations, studies and exploration of forest lands, including design and construction driving and storage dams, wharves, flumes, piers and booms and loading plants, as well as general engineering and contracting, is open for engagement. Location immaterial. Now engaged but available on short notice as projects are nearing completion. Speaks French fluently, physically fit, active and energetic, and can get results. References can be furnished if required. Apply to Box No. 177-W.

CIVIL ENGINEER, A.M.E.I.C., B.A.Sc. and C.E., University of Toronto, with twenty years experience, is open for engagement. Three years railroad construction, one year lake drainage and dam construction, nine years municipal engineering, including pavement and bridges, two years town management, one year paving contracting, and one year resident engineer of highway pavement construction. At present in Maritime Provinces. Apply to Box No. 216-W.

ELECTRICAL ENGINEER, B.Sc., McGill 1926. Five years experience in the design of switchboards, layouts and wiring diagrams. Considerable experience in high and low tension switchgear design. Fifteen months experience in switchboard estimating. At present employed; available on short notice. Correspondence wanted. Apply to Box No. 247-W.

CIVIL ENGINEER, A.M.E.I.C., of long field experience on reinforced concrete, water purification, steel buildings and bridges, seeks employment on supervision or inspection. Temporary or otherwise. Apply to Box No. 277-W.

CIVIL ENGINEER, A.M.E.I.C., Canadian, R.P.E., Nova Scotia, 21 years engineering experience, both field and office, in railway, highways, foundations, concrete structures, water power and conservation, electric transmission lines, etc., experience comprising both surveys and construction, desires employment. Single. Will go anywhere. Working knowledge of French and Spanish. Available immediately. Apply to Box No. 327-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing and hoists. Also some experience in ventilating and heating work and calculators. Accustomed to structural design and details. Good references. Present location Montreal. For interview apply to Box No. 329-W.

ENGINEERING REPRESENTATIVE. Experienced civil and mechanical engineer wishes to communicate with engineering or equipment manufacturing firm with a view to becoming Ontario or Quebec representative. Apply to Box No. 334-W.

CIVIL ENGINEER, B.SC., A.M.E.I.C., R.P.E. Ont., with twenty-four years experience embracing dams, wharves, grain elevators, foundations, pile driving, highways, municipal engineering, water power surveys, road locations, inspections and estimating is open for engagement as engineer or superintendent in construction, operation or maintenance. Location immaterial. Apply to Box No. 358-W.

Situations Wanted

ENGINEER, age 31, married. Experience includes two years mechanical, two years railway, six years structural and instrumentman and structural engineer on erection, desires position in Toronto. Apply to Box No. 377-W.

CIVIL ENGINEER, A.M.E.I.C., university graduate, O.L.S., married, twenty years experience city surveys, calculations for curved surveys, design, layout and supervision, sidewalks, pavements, sewers and water systems. Acted in capacity of chief engineer for large engineering and surveying firm for five years. Best of references. Available on short notice. Apply to Box No. 413-W.

ELECTRICAL AND MECHANICAL ENGINEER, S.E.I.C., educated Oundle and Manchester, age 24. Student course, Brit.-Westinghouse. Three years design, production, advertising, sales and control of sales force on mechanical and electrical goods. One year outside plant engineering leading public utility company. Desires work in sales, production or engineering capacity. Available immediately. Location immaterial. Apply to Box No. 415-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), graduate. Eighteen years experience in survey and construction, railway, hydro-electric and buildings. Experience comprises both office and outside work. Desires responsible position, would consider position with commercial or manufacturing firm. Available immediately. Apply to Box No. 425-W.

CIVIL ENGINEER, S.E.I.C., 1930 graduate of Nova Scotia Tech. with experience as plane table topographer, instrumentman and draughtsman and particularly interested in hydro-electric power development and reinforced concrete design, desires position. Willing to go to foreign fields. Available at a few weeks notice. Apply to Box No. 431-W.

ELECTRICAL ENGINEER, S.E.I.C., B.Sc., (McGill Univ. '27), age 26. Fifteen months outside plant engineering with large public utility. Twenty months' sales engineering experience with electrical manufacturing company. Available on reasonable notice. Apply to Box No. 463-W.

ELECTRICAL ENGINEER, B.Sc., (McGill), Jr.E.I.C., age 28, graduate Canadian General Electric Company test course, with two years experience in the design of induction motors and direct current machines. Previous experience includes electrical installation in large paper mill, and assistant to engineer in charge of small utilities company. Married. Location immaterial. Apply to Box No. 466-W.

CIVIL ENGINEER, S.E.I.C., 1930 graduate. Experience as instrumentman on city and railroad construction, desires to enter structural or hydraulic field. Available at once. Will go anywhere. Apply to Box No. 467-W.

CIVIL ENGINEER, experienced in road construction, mine surveying, transmission line survey and construction; paper mill construction; age 27. Available on short notice. Apply to Box No. 468-W.

CIVIL ENGINEER, A.M.E.I.C., age 39, with wide experience on design and construction of reinforced concrete structures, desires position. Apply to Box No. 475-W.

DESIGNING ENGINEER, A.M.E.I.C., P.E.Q., with extensive experience in design and construction of power plants, industrial buildings and hydraulic structures, desires position as designing engineer or resident engineer on construction. Apply to Box No. 492-W.

ELECTRICAL ENGINEER, B.A.Sc. (Univ. Toronto '29), S.E.I.C., Can. Gen. Elec. Co. test course. Six months experience in the design of induction motors. Experience in electrical maintenance. Apply to Box No. 494-W.

MANAGING CIVIL ENGINEER, college graduate, A.M.E.I.C., C.P.E.Q., 18 years com-

Situations Wanted

prehensive experience in all lines of architectural engineering and contracting as designing, detailing, quantity surveying, cost estimating, superintending and general business management, desires to change and wants connection with Montreal firm, preferably with chance to share in business. At present in responsible position as engineer in charge and chief estimator, but available on few weeks notice. Apply to Box No. 495-W.

STRUCTURAL ENGINEER, 20 years experience in the design and construction of all types of steel and reinforced concrete buildings. Available shortly. Location Toronto. Apply to Box No. 501-W.

WEST INDIES, Engineer, A.M.E.I.C., etc. Experience with engineers and contractors, railway, harbour and concrete construction, desires position in West Indies. Apply to Box No. 518-W.

MECHANICAL ENGINEER, Jr. E.I.C., B.Sc., '26. Ten months experience in pulp and paper steam control. Four years experience in detail design, in pulp and paper mill, industrial plant and hydro-electric development work. Age 27. Married. Location immaterial. Apply to Box No. 521-W.

CIVIL ENGINEER, B.A.Sc., '29, with experience in supervision of construction and general office engineering, desires permanent position with contractor or engineer. Available at once. Apply to Box No. 524-W.

MANAGER FOR PUBLIC UTILITIES COMPANY, OR INDUSTRIAL PLANT, Mechanical and electrical engineer with wide experience in investigations, reorganizing and improving operating conditions to reduce production costs and increase earnings. Apply to Box No. 525-W.

MECHANICAL, CONSTRUCTION, AND DESIGNING ENGINEER, with special training in hydro-electric power development, underground steam distribution systems, and the operation of large electrical machinery. Active work desired. Apply to Box No. 528-W.

SALES REPRESENTATIVE, civil and mechanical engineer, with office in Toronto, desires to hear from manufacturers of high-grade building materials or industrial equipment, with the view of representing their interests in the promotion and effecting of sales to architects, engineers and contractors. Excellent connection. Apply to Box No. 529-W.

For Sale

One Troughton and Simms theodolite with solar attachments and stiff legged tripod, $70.00; One James Foster Dumpy level with stiff legged tripod, $35.00; Two pairs field glasses, $3.00 each. Apply to Box No. 9-S.

Soft Solders

It is not always realized that of all the common alloys engineers must buy, solders are by far the most costly, and until recently it was no exaggeration to say that all too little work had been done to obtain an accurate knowledge of their properties. Of late years, however, much has been done to fill this gap in knowledge, and in particular the British Non-Ferrous Metals Research Association instituted in 1922 a comprehensive investigation into the jointing of metals. This investigation, which was planned and started in that year by Mr. S. J. Nightingale, included not only soft solders, but also brazing, silver soldering and some aspects of autogenous fusion. The bulk of the experimental work, however, was done on soft solders, partly because soft solder, while easier to work than hard solder, could serve equally well for the determination of principles common to both, but also because in its application to soldered joints it presented an almost untouched field. By the courtesy of Dr. R. H. Hutton, the Association's Director of Research, we are able to give an account of the report on soft solders and soldered joints which was lately issued to the members of the Association. An edition intended for use by practical men has also been prepared.

The base of all soft solders is a series of alloys of lead and tin. The freezing points of these metals when pure and molten are, respectively, 327 degrees C. and 232 degrees C., and the minimum freezing point of any of their alloys is 183 degrees C. At this temperature the eutectic alloy of about 63 per cent tin: 37 per cent lead, passes directly from the liquid to the solid condition, while the other alloys, which begin to freeze at higher temperatures in proportion to their composition, pass gradually from the liquid to the solid state by freezing out solid particles of alloy containing lead or tin as the case may be in excess of the eutectic ratio, until solidification is complete at the eutectic temperature. In the solidification of any of the alloys except the eutectic, there is therefore a plastic range during which the metal is easy to manipulate, and, as Mr. Nightingale points out, plumbers and other craftsmen who use solders have shown an extraordinary acumen in selecting from the infinite number of possible alloys of lead and tin, those few that were best suited to their purpose, and became what he calls the hereditary solders.

Long ago, however, it was found that the properties of solders could be modified by the addition of small quantities of antimony. Whether the modification was beneficial or mischievous appeared to turn very closely on the percentage used, but for the last half century almost all soft solders have contained some of it. In 1925, the British Engineering Standards Association standardized nine different grades of solder for as many different kinds of work, ranging from those, such as steel tube joints, that required a low melting point and used slightly more tin than corresponded with the eutectic composition, down to dipping baths, containing less than some 30 per cent of tin. In each of these alloys antimony was either prescribed or permitted, and it is with these alloys that the present report deals. In an introductory chapter, after showing the equilibrium diagram of the binary (lead and tin) and ternary (lead, tin and antimony) alloys in question, and pointing out their consequences, it indicates the position of the standard solders in the range of possible alloys, and reproduces the analytical limits for each grade defined in the 1925 specification. The grades which throughout the report are used generally for illustrating the application of the results obtained are the four known as A to D, with minimum tin contents ranging from 64 per cent to 29 per cent and minimum antimony from 0 per cent to 2.50 per cent.—*Engineering.*

Combustion Engineering Corporation, 260 Madison avenue, New York, N.Y., has published a new and revised edition of their General Condensed catalogue (GC-6). This 16-page catalogue illustrates and briefly describes the fuel burning and steam-generating equipment manufactured by this company. A complete list of products is included. Individual catalogues are also available on all Combustion Engineering products, and will be sent upon request.

The United States as an Engineering Market

The ties of blood between the United Kingdom and the United States of America are not now, of course, what they were at one time, but the blood is still there, while the common language and almost common weights and measures are appreciable advantages. As a competitor for the trade of the United States, Canada has advantages which we do not possess, but no foreign country has any racial or political advantage over the United Kingdom. Where then do we stand in relation to the American market?

The American engineering market is, without question, the largest and most important of the world. It is not merely that the population of the United States now exceeds 120,000,000, but the people, or a very large proportion at any rate, are the most highly "mechanized" people of the world; that is to say, they use machinery more than any other people. They use it not only in their manufacturing and agricultural industries, but also in their counting houses and in their homes to an extent of which few people on this side can have any conception. This market is not only the greatest of the world, but it is supplied from home sources to a greater extent than, probably, any other corresponding market. Hence, judged by the imports into the States of the engineering commodities with which we are here concerned, it appears only a small market. The grand total for 1928, the latest year for which the details are available, amounted to no more than 13,827,000*l.*; and there are many people who will be surprised that it amounted to so much. In the same year, the corresponding imports into the United Kingdom amounted to over 55,000,000*l.*; even the corresponding imports into British South Africa were double the value of those into the United States of America. This relatively small value of the American imports is due, of course, to the fact that America is one of the most highly protected countries of the world; her "tariff wall" is almost unclimbable. Still the market, as represented by imports, is not a negligible market; it will be noted that of the total of 13,800,000*l.*, iron and steel and manufactures of iron and steel and machinery account for 12,500,000*l.* The other two groups of commodities, electrical and vehicles, make but a small contribution to the total, the duties imposed upon these two classes being almost prohibitive.

Fiscal policy does not account for the fact that out of 354,000*l.* of cast-iron pipes imported by America in 1928 we contributed only 1,244*l.*, while France supplied 280,500*l.* and Belgium 63,000*l.* In other pipes and tubes, we make a rather better showing, with 127,000*l.* out of a total of 847,000*l.*, but even here Sweden beats us with 194,000*l.*, while Germany supplies 365,000*l.*, or 43 per cent. of the total. In round wire we supplied 72 per cent. of the total, but in flat wire and steel strip, out of a total of 363,755*l.*, Sweden supplied 247,850*l.*, while we supplied the rest.

Germany has long been in front of us in America with machinery, and, unfortunately, there are no signs of any recovery on our part. It will probably surprise many people to find that with all her great agricultural experience and her engineering resources, America imports a certain amount of agricultural machinery; she admits agricultural machinery free of duty. Naturally, Canada takes much the larger part of this particular trade, but the United Kingdom comes next, though a very long way behind.

In general machinery we are beaten in every class except textile. America's imports of textile machinery (power) in 1928 amounted to 483,000*l.*, the share of the United Kingdom being 248,000*l.*; of Germany, 132,000*l.*, and of France, 119,000*l.* While we thus had much the larger share of this business as a whole, Germany, for the first time, supplied in this year more cotton machinery to the States than we supplied. In embroidery machinery, the United Kingdom supplied 37,000*l.* out of a total of 38,200*l.*, but in hosiery-knitting machinery, Germany supplied practically the whole of a total of 518,800*l.*, the share of the United Kingdom being 500*l.*—*Engineering.*

SUN LIFE ASSURANCE COMPANY OF CANADA

OFFICE OF
THE PRESIDENT

MONTREAL

January thirtieth
1 9 3 1.

The President and Members,

The Engineering Institute of Canada.

Dear Sirs:-

I have much pleasure in extending to you a cordial invitation to visit our new Head Office Building which stands as a monument to the skill of the Engineers, Architects and Artisans of our great Dominion.

Yours faithfully,

T. B. Macaulay

President.

The Alexander Power Development on the Nipigon River

T. H. Hogg, D.Eng., C.E., M.E.I.C.,

Chief Hydraulic Engineer, Hydro-Electric Power Commission of Ontario, Toronto, Ont.

Paper presented before the Annual General and General Professional Meeting of The Engineering Institute of Canada at Montreal, February 4th, 5th and 6th, 1931.

SUMMARY—The Alexander hydro-electric development came into service in October, 1930, and is the second constructed on the Nipigon river by the Hydro-Electric Power Commission of Ontario. It has a capacity of 54,000 h.p., and, with the existing plant at Cameron falls, supplies the cities of Fort William and Port Arthur, distant about 80 miles. Interesting features in this project include unusual variations in design and construction necessitated by foundation conditions and materials available, the dewatering of the dam site by a diversion channel, the method of closure of the diversion channel, the use of the diversion channel as a power canal in the completed plant, and the provision for distant operation of the plant by supervisory control.

The main dam is of the earth-filled type, this design being adopted owing to the presence of suitable and abundant material and the resulting lower cost. Its maximum height is about 90 feet.

The spillwall has a capacity of 30,000 cubic feet per second, and special construction methods were adopted at the junction of concrete and earth sections. Adequate fishways and log-slides have been provided. The three turbine units, each of 18,000 h.p., are Francis turbines of moderate specific speed, and the generators are of welded structural steel design, each rated at 15,000 kv.-a., 12,000-volt, 3-phase, 60-cycle, 100 r.p.m. Novel arrangements are made for synchronizing.

Power is transmitted by three 110-kv. lines connected direct to the existing transmission lines from the Nipigon station to Port Arthur. The entire switching at the Alexander development will eventually be handled by remote control. The relay protection for the Alexander station consists chiefly of zone protective systems, and special care has been taken to promote system stability.

The Alexander hydro-electric development, on the Nipigon river, came into service in October, 1930. This development is the second constructed on this river by the Hydro-Electric Power Commission of Ontario and, like the first, supplies power to the Commission's Thunder Bay system, the principal market for power being in and near the cities of Fort William and Port Arthur, distant about 80 miles from the generating stations. The new development has a capacity of 54,000 h.p., and the original plant at Cameron Falls 75,000 h.p.

There are certain salient features of this development that warrant the preparation of a descriptive paper thereon. Among these might be mentioned: the unusual variations in design and construction necessitated by the foundation conditions and materials which varied greatly and frequently in adjacent areas; the dewatering of the dam site by a diversion channel to which the configuration of the power site readily lent itself; the method by which the closure of the diversion channel was effected on the completion of construction work; the use of the diversion channel as a power canal in the completed plant; and the provision for operation of the plant by supervisory control from the Nipigon station. In addition to these features, there are a number of other items of interest to which, along with those mentioned, more detailed attention will be given later.

Historical and Geographical

In a description of the Alexander power development, it is desirable that some geographical and historical background be given, so that the reader may better visualize the situation and grasp the significance of the various steps taken. The Thunder Bay system of the Hydro-Electric Power Commission comprises the district in and around Fort William and Port Arthur, and the village of Nipigon. The power for this system is developed by the Commission at its plants on the Nipigon river, that is to say, the Nipigon and Alexander developments, whence it is transmitted by 110,000-volt lines to the Port Arthur and Fort William transformer stations. A map of the district extending from Lake Nipigon to Fort William is shown in Fig. 1.

The Nipigon river from Lake Nipigon to Lake Superior has a total fall of approximately 250 feet, varying with the relative stages of water level in the two lakes. Of this head, the Nipigon development at Cameron falls utilizes 78 feet, and the Alexander power development 60 feet. From the tailrace of the latter plant to the mouth of the river, a distance of 8 miles, there is a normal drop of about 4 feet, which cannot be economically utilized for the development of power. The remaining head of somewhat over 100 feet, between the headwater level of the Cameron falls plant and Lake Nipigon, is as yet undeveloped.

In 1926 the Commission built a control dam at Virgin falls at the outlet of Lake Nipigon, creating thereby the largest storage reservoir in existence, having a capacity of 6,700,000 acre-feet. This control dam consists of a concrete pier and stop-log structure across the main channel, and three concrete sluiceways, also stop-log controlled, in a diversion channel on the left bank. The latter channel, entirely in rock, was used to handle the discharge of the river during construction of the dam in the main channel. The sluiceways in the main and diversion channels have a combined discharge capacity of 10,000 cubic feet per second at minimum regulated lake level.

The catchment area of the Nipigon river above Virgin falls is 9,000 square miles, of which Lake Nipigon comprises 1,700 square miles. The natural run-off in the period of record has averaged 7,600 cubic feet per second, and the storage facilities are such that the whole of this may be made available for generation of power.

The Nipigon development has an installation of six 12,500 h.p. units, of which the first two were installed in 1919, the second two in 1924, and the last two in 1926.

Concurrently with the placing of the last two units in operation, the regulating dam at Virgin falls was constructed.

GENERAL PLAN OF DEVELOPMENT

The growth of load on the system and the prospective load, following the completion of the Cameron falls plant, made it necessary for the Commission to proceed with plans for additional generating capacity. A study of the sites available indicated the advisability of choosing the site at Alexander Landing, about one and one-half miles downstream from Cameron falls. At this location a number of alternative layouts were studied, and estimates prepared, as a result of which the arrangement shown in Fig. 2 was adopted as the most suitable to the site, and at the same time the most economical.

It will be noted that at the power site, two sharp bends in the river, with the resulting backwater pools and narrow peninsulas, form an ideal location for the development of power. By damming a narrow section of the river and diverting the water through a short diversion canal across the adjoining peninsula, it was possible to isolate the two main construction operations of dam and power house with considerable attendant advantage. The diversion canal for carrying the river flow past both structures during the construction period was excavated through the peninsula near the power house. The layout also afforded an opportunity to locate the spillwall well away from the earth dam and from the entrance to the power house. Relatively low dam sections join the spillwall with the main dam and form a cut-off between the power house and the high ground to the west of the plant.

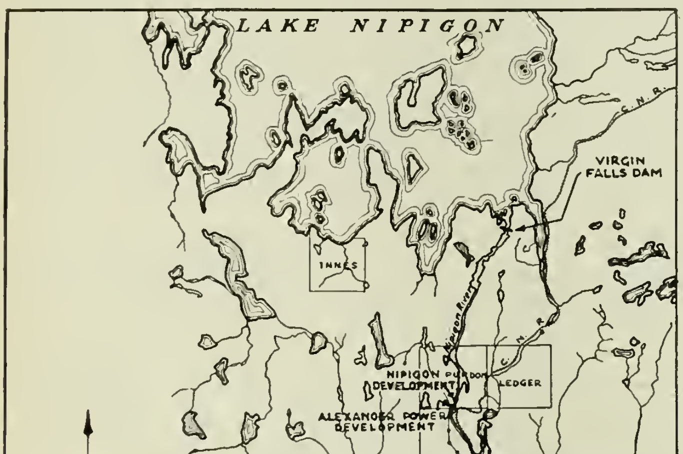

Fig. 1—Map of the District from Lake Nipigon to Fort William to show Location of Power Developments and Transmission Line.

In the preliminary studies, layouts were made in which the power house and dams were located in all the feasible locations available at the site. Comparative estimates of the cost of each layout were prepared, and the most economical arrangement was selected. In considering the economics of the problem, the practical difficulties to be encountered in construction were carefully studied.

In the general plan of the development it will be seen that the main dam extends from the high ground on the east bank of the river to the peninsula upon which the spillway, power house and other structures are located. The earth fill continues for about 400 feet, with a height of only 10 feet across the level ground at the easterly extremity of this peninsula to a junction with a concrete bulkhead section which in turn joined the spillwall. From this junction the spillwall continues for about 500 feet, where it crosses the diversion canal, immediately beyond which are the log slide, fishway and power house. A short concrete bulkhead section unites the northwesterly end of the power house with the auxiliary earth dam, which, although never more than 23 feet high, is 1,800 feet long.

SERVICE CONNECTIONS TO THE CANADIAN NATIONAL RAILWAYS

While the main line of the Canadian National Railways passes a short distance from the easterly end of the main dam on the opposite side of the river from the generating station, yet, in view of the existing connection from that railway to the Nipigon power house, less than a mile away, it seemed advisable to connect the Nipigon station with the Alexander station for convenience in the operation of both plants. Thus, the latter station has its service from the Canadian National Railways by way of Cameron falls.

This involved building two standard type plate girder bridges, designed for E-40 loading plus impact; the one over the Nipigon river a short distance below Cameron falls, and the second over Fraser creek, a small tributary flowing through a wide deep valley not far above the Alexander development.

The location proved of material value during the construction period, in giving access to sand and gravel pits, through which the line passed, and to the old yards of the Cameron falls development, as well as the stone quarry, near the latter plant, from which crushed stone for concrete aggregate and track ballast was obtained.

For permanent service to the new station, spurs have been built at two levels; one into the station at generator floor level, and the second at the level of headworks deck, giving access in the latter case for a locomotive crane to be used for handling head gates, racks, etc.

From the track at the lower level, a short spur serves the transformer station, and from this point to the power house the track is supported on concrete to guard against settlement when transferring the transformers into the power house for maintenance and repair work. The upper track where it joins the headworks is carried by a short girder span from the adjacent rock outcrop to the headworks deck. The maximum grade for the lower track does not exceed 2.5 per cent when corrected for curvature, and that for the upper line is less than 2.5 per cent with correction.

Permanent track throughout is built of 80 and 85 pound rail, with gravel and crushed stone ballast, with the exception of that portion from transformer station to power house referred to above.

Fig. 2—Plan showing Location of Dams and Power House in relation to the Nipigon Development and Transmission Line.

Dewatering by Means of Diversion Channel

The decision to build the main dam of earth, referred to later, necessitated the diversion of the river entirely from the dam site.

Running across the river at the location chosen for the dam, and approximately parallel to its axis, is a relatively narrow ridge of rock. Through a depression or fault in this barrier, the river has in former ages cut its way, and immediately below the dam site turns through almost 180 degrees, creating a narrow peninsula composed almost entirely of rock. This topography at once suggested an efficient method of dewatering, by diverting the river in an open channel cut across the peninsula upstream from the dam site. Here again, the natural conditions in the river, about 600 feet above the dam, were very favourable for a cofferdam location. A low flat point of land projects into the river, where the width of the stream is considerably reduced, creating conditions in which a large part of the cofferdam could be built on dry ground, and requiring a minimum of under-water work.

With the power house located at the downstream end of the cut across the point, the channel for diversion could be utilized for the greater part as the permanent feeder for the development. Thus the actual charges for dewatering were contained in the cost of the cofferdam and the additional depth of diversion channel, which depth was contingent on the height of the cofferdam; the economical balance in costs giving the relative heights and dimensions. The dewatering channel proper as it nears the headworks is diverted away from the feeder canal to the east, and passes through the line of the spillwall in a narrow rock cut. The closure works were located here, and the concrete for this structure ultimately formed the base for that section of the spillwall.

The discharge area actually required for diversion purposes was that necessary to provide for the water passing through the Nipigon station under full load, as the flood stages of run-off for the watershed may, with the flow required for that station, be fully conserved by the vast storage provided in Lake Nipigon by the regulating dam at Virgin falls at the outlet to the lake. Additional discharge capacity was, however, provided for unforeseen conditions of flow.

Where the river was diverted through the spillwall, two water passages were built, each 18 feet wide and 27 feet high, giving ample area with the water at the cofferdam safely below the top to take care of any reasonable contingency in river flow. (Fig. 4.) For closure, each of these areas was provided with checks to receive steel gates in three sections, each 10 feet 4 inches high.

Main Dam

The most suitable site for the main dam was at a point on the river about one and a half miles below the Nipigon development, where the flow passed in a narrow channel flanked by rock on either side. As previously stated, the river made a pronounced bend in its course immediately below the site, creating a point or peninsula, which provides a favourable location for the diversion channel and power canal.

While the sides of the channel at the site of the dam are of exposed rock formation, borings made in the river bed indicated that there was no rock at economic depth for a gravity concrete bulkhead section for the greater part of the length of the dam. This condition narrowed the choice of the type of dam to one of either a reinforced concrete bulkhead or earth section. The presence of suitable and abundant materials for earth fill at elevations well above

Fig. 3—Aerial View of Development under Construction. Nipigon Power House in Background.
(*Photo by Royal Canadian Air Force.*)

the top of the dam on the east side of the river indicated that the probable unit cost for an earth dam would be relatively less than usual, and this, with other considerations, proved the deciding factor in the choice for an earth fill dam.

A typical boring in the bed of the river at the site selected showed at the top, a layer of boulders underlain by a deep stratum of coarse sand, and thence alternate layers of boulders and sand. Soil bearing tests made at a number of points on the proposed site indicated that the bearing value of the soil was well within the margin of safe practice.

The rock walls at the shore ends of the dam were of a naturally rough formation, which, when cleared of all loose and weathered matter, revealed a vertically serrated surface providing a suitable seal for the core and abutments. These rock sides of the channel extended, the one on the east side above the high level of headwater, and the one on the west side almost to normal operating level. A typical section of the dam in Fig. 5 shows excavation for the core and that part of the base upstream from the core to be taken down deep enough to include the deposit of boulders, coarse sand and river silt; this material was used for making the upstream toe of the dam.

Before any earth fill was placed, a heavy rock dump was made forming the toe for the downstream side. This material was excavated from the rock section of the diversion channel and power house substructure. The facts that large quantities of rock had to be disposed of, and that the downstream toe of the dam proved to be quite suitable and economical as a disposal area, made it possible to provide a much more substantial support for the fill on the downstream side than it is usually economical to provide. At the same time, this rock fill provides ample drainage for any seepage through the core or the foundation material underneath the core.

The section chosen had a crest width of 20 feet with downstream slopes of 2.5 to 1 and 2 to 1, and upstream slopes 3 to 1 and 5 to 1. Its maximum height as built is about 90 feet. As the base of the dam is below tailwater level, extra precautions were taken to protect the toes of the slopes. (Fig. 5.)

The section as built is much larger than designed, this being brought about largely by the necessity of keeping dump tracks safely back from the edge of the segregation pool to prevent sliding. The tendency to slide was in turn caused by the very rapid rate of placing fill. The open season for this latitude is short, and the rate of fill was therefore necessarily accelerated.

The total yardage of the dam proper, exclusive of clay blanket upstream, is about 530,000 cubic yards, and from the time the season opened in May up to the end of August, there were 443,000 cubic yards placed in the dam, the rate being greatest in June, when about 159,000 cubic yards were placed. It will be of interest to note that the shrinkage in volume of material as between pit measurement and place measurement was less than 5 per cent.

The nature of the river bed upstream called for a protecting blanket of clay. This was sluiced in from materials on either side of the river to a depth ranging from 4 to 6 feet and extending upstream about 400 or 500 feet to the main cofferdam.

Construction Methods

The dam was built by the "semi-hydraulic" process, the materials being taken from selected borrow pits located on the east side of the river. Some of the borrow pits are in gravel and sand, while others are in pure clay, so that any mix determined to be desirable could be had by regulating the amount from each of the pits.

The output of the shovels in the pits was taken to the dam by trains, and dumped from trestles on either side of the segregation pool for the core, and the fineness of the core was varied at will by controlling the placing of train-loads of selected materials at points where it was sluiced into the pool with the proper grading. The width of the core was controlled by varying the width of the pool to suit.

The excavating plant consisted of five units; one steam-driven dragline with a 3 cubic yard bucket; one railroad type steam shovel with a 2 cubic yard dipper; one full revolving steam shovel on caterpillar tread, with a 1¼ cubic yard dipper; one gasoline-driven dragline on caterpillar tread with a 1¼ cubic yard bucket; and one steam shovel on caterpillar tread with a one cubic yard dipper. They were served by eight locomotives, each with five 16 cubic yard and twenty 20 cubic yard air dump cars. The locomotives ranged from 57 tons to 30 tons in weight. There were no grades against loaded traffic, and the train-weights were limited to the brake controlling capacity of

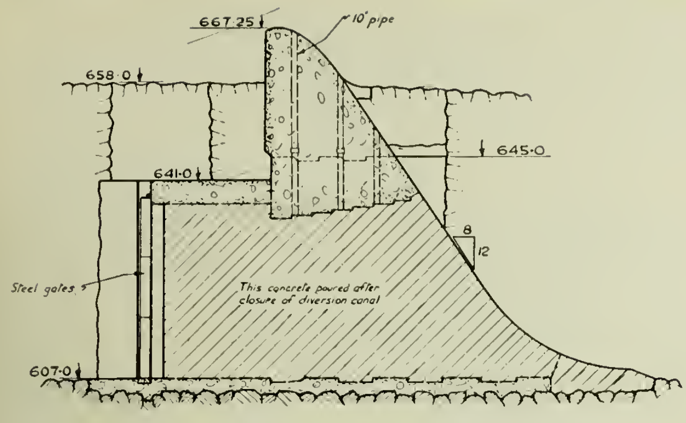

Fig. 4—Section through Sluiceways at Outlet of Diversion Channel.

the engines, as well as by the capacity of the engines to haul empties up the relatively steep grades on the return trip from the dam to the borrow pit.

Sluicing was done by two monitors, each placed on a float in the segregation pool. Pressure was supplied by centrifugal pumps direct-connected to electric motors. Electric power was supplied by special flexible submarine cable suspended on empty oil drums. The pumps were 6-inch by 6-inch two-stage units, equipped with nickel iron impellers to resist the heavy abrasive action of water carrying a large percentage of silt. The pressure at the discharge side of the pumps was 160 pounds per square inch, and the nozzle diameter of the monitor was 2 inches. Each motor was rated at 100 h.p.

Spillwall

The spillwall, as finally located, is 523 feet between abutments, and varies in height from 1 foot to 18 feet, with an average of 7 feet. These heights do not include the depth of section where the diversion channel sluiceways are located. The crest level provides for a maximum discharge head of 6 feet and, according to Bazin's formula for flow over a sharp-crested weir, as modified for this shape and depth, the discharge capacity is 30,000 cubic feet per second. The shape of the crest is shown in Fig. 6, and approximates very closely the parabolic form. Under maximum discharge conditions, the underside of the nappe lies theoretically below the surface of the concrete, so that under no conditions of flow there will be any tendency to produce vacuum. It is not expected that under operating conditions, with the total load for the system proportionately divided between the two plants, there will be any appreciable waste over the spillwall. Only under abnormal operating conditions will there be any overflow, and the possibility of maximum discharge is most remote. With the regulation provided at Virgin falls dam there is little or no waste at week-ends, the pondage of the lake above the Cameron falls plant being ample to balance the fluctuations; this lake providing daily, and to some extent weekly, pondage for both plants.

In constructing the spillwall, the surface of the rock foundation was only roughened, as, with the tilted formation of the beds, ordinary blasting opens seams that would extend to indefinite depths. The natural surface of the rock was for the most part fortunately sloped upwards in the downstream direction, providing a natural resistance against sliding. Dowels were generously provided in those smaller areas where the foundation was not so favourably tilted.

The section of all gravity walls, including spillwall and bulkhead sections, was designed to give ample factors of safety against overturning, sliding and ice action.

Tie Between Earth and Concrete Sections

At the junction of concrete and earth sections for both auxiliary and main dams, specially designed abutments are built in a similar manner to that for a bridge abutment sustaining an earth fill approach. Fig. 7 shows plan, elevation and sections of these. The two wing walls at each abutment are not, however, built to conform to the outer earth slope, but are confined to the core area and are completely enveloped by the less pervious fill which is carried 3 feet higher than the top of the concrete abutment. The sides adjacent to the core are constructed with a batter of 5:12, with the object of compensating for vertical shrinkage in the core material, and the tendency for the core to shrink away from a vertical face. The arrangement provided maintains at all times a tight contact between the earth and concrete. Five vertically placed timbers are embedded to half their depth in the faces of the abutments, to break the seepage plane between the core material and concrete, and these, together with the earth fill completely surrounding the wing walls and extending in front and behind the concrete section of dam, give reasonable assurance against destructive leakage.

The main line of the construction railway serving the mixer plant, boiler house and forebay area had of necessity to be located crossing the line of the auxiliary dam, and, in consequence, a gap through the concrete section was left to permit operation of trains until the last few days before the closure of the sluiceways. The concrete to close this gap was placed about a week before the closure was made, and was sufficiently set to sustain the head of water after the pool had reached its normal level.

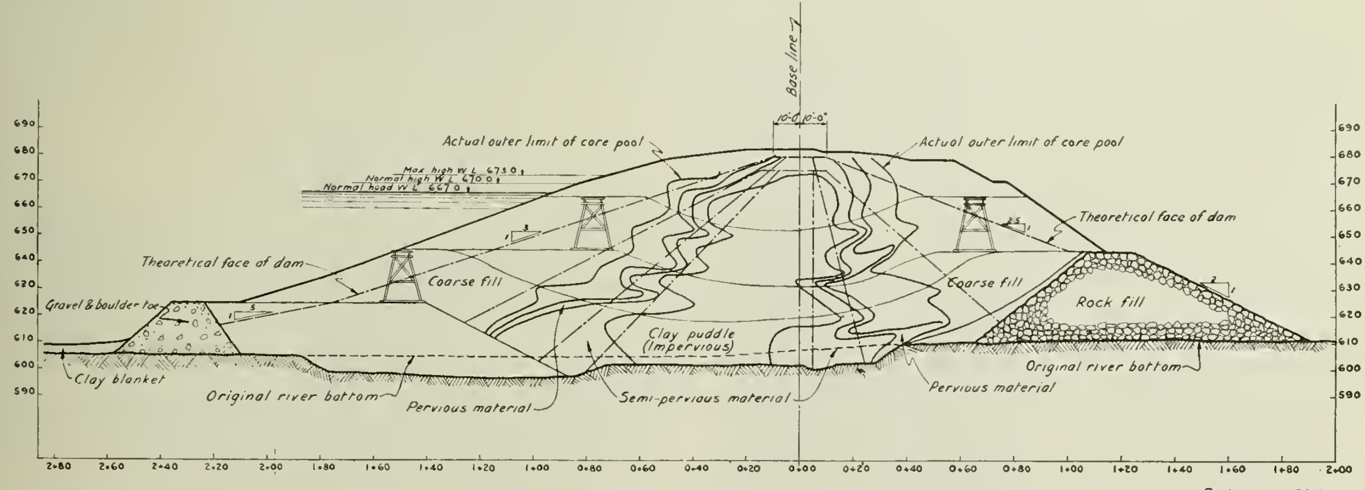

Fig. 5—Typical Section of Main Dam.

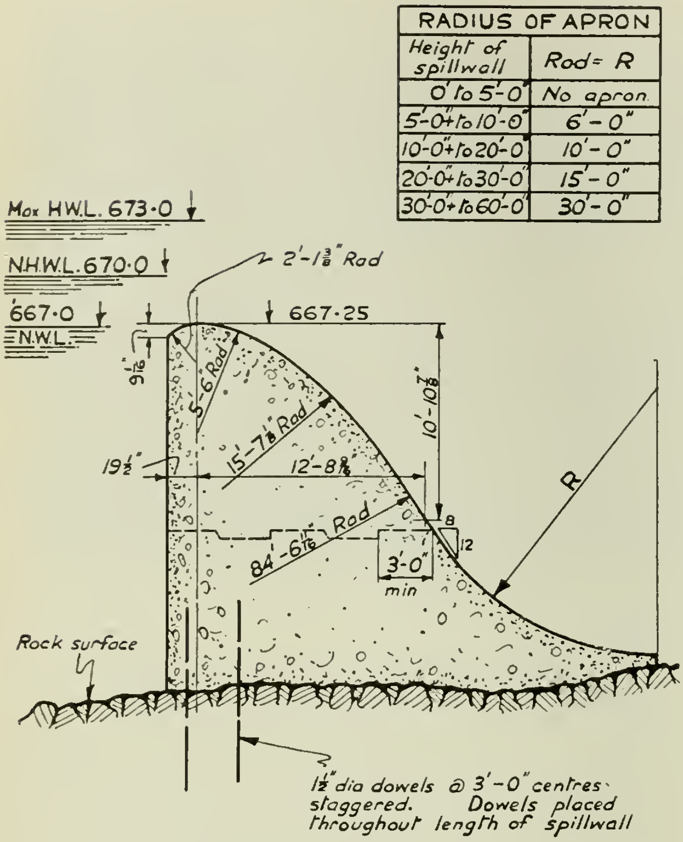

RADIUS OF APRON	
Height of spillwall	Rad = R
0' to 5'-0"	No apron
5'-0" to 10'-0"	6'-0"
10'-0" to 20'-0"	10'-0"
20'-0" to 30'-0"	15'-0"
30'-0" to 60'-0"	30'-0"

Fig. 6—Spillwall.

Auxiliary Dam

The auxiliary dam, running west from the power house was made up of a concrete section tied into an earth dyke. The concrete bulkhead portion of this dam (Fig. 8) is the conventional type, having a 3-foot top width and a batter of 8:12 on the downstream side, and a maximum height of 25 feet.

The earth section of the auxiliary dam was constructed as shown in the accompanying cross section (Fig. 9), having a central clay core supported on either side by pervious material. The central core, it will be noted, was carried to a depth of approximately 5 feet below the base of the dam, and from this point down to impervious material or to the rock, as the case may be, a 5-foot trench was dug between timber sheeting, and back-filled with puddle clay. To date, this dam has proved to be absolutely watertight and satisfactory in every respect.

Power Canal

As previously mentioned, during the construction period the whole of the river was diverted through a channel excavated through the peninsula formed on the right bank by the course of the river. This channel, in rock, is 50 feet in width and about 33 feet deep. The course is straight for about 500 feet, and then deflected to the left through 19 degrees toward the temporary sluiceways used during construction. Downstream from the point at which the course of the diversion channel deflects, and to the right of the channel, the earth overburden was removed to form a forebay. This, and a small amount of rock excavation immediately in front of the headworks, constituted the only additional excavation required for the power canal that was not removed for the diversion channel.

To the left of the power canal, excavation was carried down over the whole of the remaining area to elevation 660, in order to assure free access of floodwater to the whole of the spillway crest, which is at elevation 667.25. To the right of the canal, the original surface is practically all submerged up to the auxiliary dam, so that, under operating conditions, there appears a large headpond having an extreme width of over half a mile, completely submerging the original channels of the Nipigon river, Fraser creek and the diversion canal.

Headworks

Usually, in the design of headworks for a power development in a northern latitude, it has been considered necessary, and until recent years has become customary, to provide a superstructure with travelling crane for handling stop-logs, racks and headgates. A structure of this kind adds materially to the capital cost, as well as the consequential maintenance and operating charges which are of course, reflected in the power costs. In order to eliminate as far as possible this added expense, it was decided to design the headworks without a superstructure.

However, in consequence of the extremes of low temperature and heavy snowfalls prevailing during the long winter periods, certain protective measures had to be incorporated to guard against formation of ice in the rack and gate checks and to protect the headgate hoisting mechanism.

To raise and lower headgates during normal operation, there are provided motors and hoists enclosed in a low-roofed passageway running parallel with the centre line of units, which is about 7 feet high, or sufficient to conveniently house and operate this equipment. Each unit has two gates operated by one motor through disengaging clutches on the main line shaft.

The placing and removal of stop-logs, racks and headgates is done by a locomotive crane operating on a standard gauge track on the headworks deck. The locomotive crane may be used not only for this purpose, but for innumerable other operations in connection with the two developments, including such items as loading and unloading cars in the yards, minor switching service, and the handling of miscellaneous outdoor equipment. Since, in ordinary operation, the headgates are operated by hoists provided for the purpose, any unit may be shut down in an emergency without calling on the locomotive crane, thus permitting the crane to be kept in more or less continuous use, and even at considerable distances from the generating station.

To remove a headgate for repairs or renewal, it is only necessary to hoist the gate with the motor hoist to a height where it may be conveniently transferred to the locomotive crane. The width of the upper portion of the headgate checks is such that when the gate is raised for removal, it may be moved upstream, attached to the locomotive crane, and hoisted clear of the outer wall of the hoist housing. The passageway roof has hatchways, covered with removable concrete slabs made watertight with mastic joints.

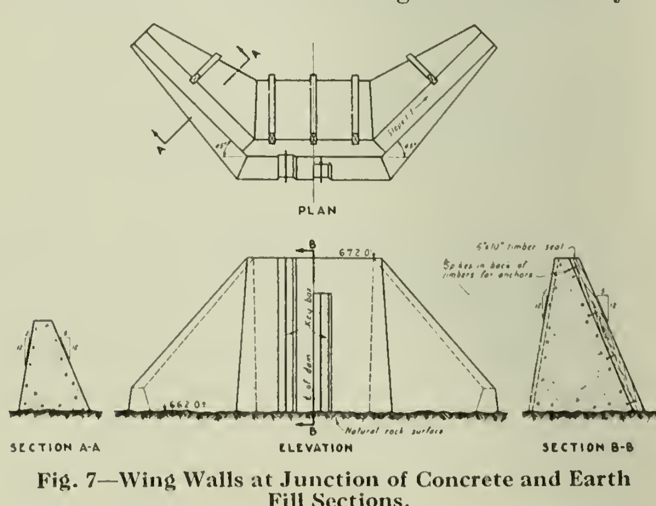

Fig. 7—Wing Walls at Junction of Concrete and Earth Fill Sections.

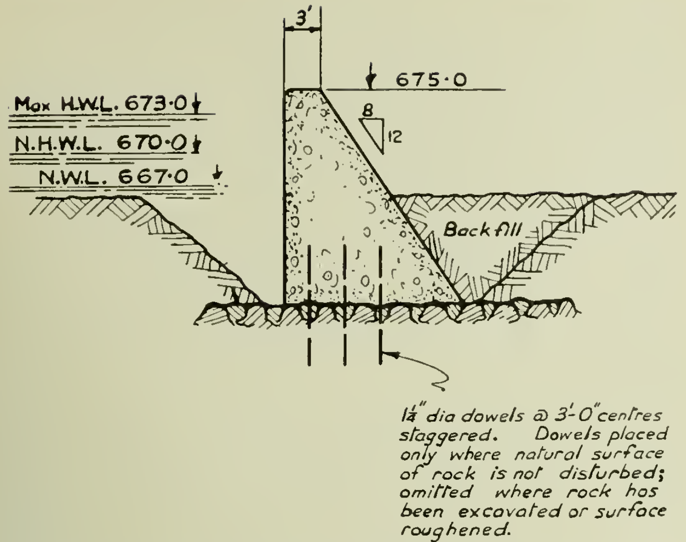

Fig. 8—Typical Section of Concrete Bulkheads uniting Headworks with Auxiliary Dam between Spillwall and Main Dam.

With these various openings available, the removal or replacement of motors and hoists is readily and conveniently effected with the locomotive crane. Removable deck beams carry the entire intake covering and crane tracks.

All openings over the stop-log and rack checks have matched plank covers made in sections fitted for quick handling; so that with the concrete curtain walls extending below low headwater level for each intake, the guide checks are well protected. In addition to this measure of protection, openings are provided immediately behind the guide checks for the headgates, through which heated air has free passage from the generator room. Provision has also been made for the installation of electric heaters, if found necessary.

For storage of the steel stop-log gate sections, two pockets are provided at the west end immediately upstream from the erection bay. These pockets are entirely below the deck level of the headworks, and are also protected with wooden hatch covers. Stop-log gate sections for one unit only are provided at the present time, but when unit No. 4 is installed, and the headgates in place for this unit, there will be released an additional set of stop-log gates, which are now serving as bulkheads in the headworks of this unit.

Racks and Stop-log Gates

The clear width of each of the two intake openings for one unit is 18 feet, and in each one there are three sections of rack panels, 11 feet 8 inches high, with bars 3 inches by

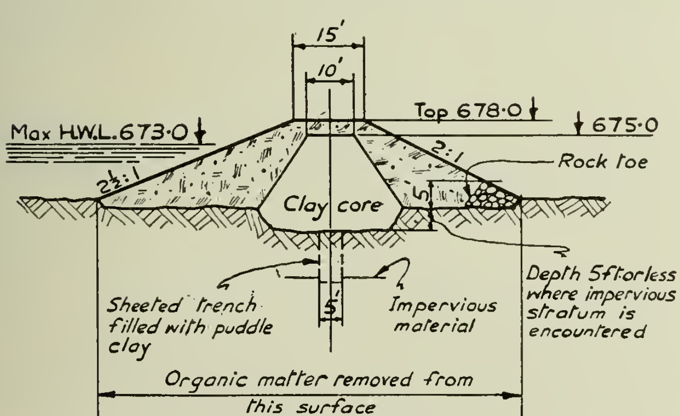

Fig. 9—Auxiliary Earth Fill Dam.

5/16 inch spaced 5⅞ inches centre to centre. The sections are all removable, and, in order that they may be placed in proper vertical alignment, the upstream sides of each section have oak guides fastened full length to the vertical side members of the frame, which ride against the upstream side of the guide check. The total width of I-beam and oak guide is one inch less than the width of the guide check.

The top rack section for each intake opening has a horizontal baffle plate secured to the top beam of the frame and extending upstream nearly to the curtain wall to prevent floating material from passing over the top of the rack, which is below headwater level. The rack sections are designed for a differential head of 10 feet, to allow for the accumulation of ice or debris.

The racks are placed in the checks immediately ahead of the steel stop-logs, and no provision is made for cleaning them in place, except by diver, such a provision having been found unnecessary in the operation of the Cameron falls plant.

To remove the racks, a follower is employed, with hooks near each end, which engage the top member of the rack sections through slots provided for the purpose. The

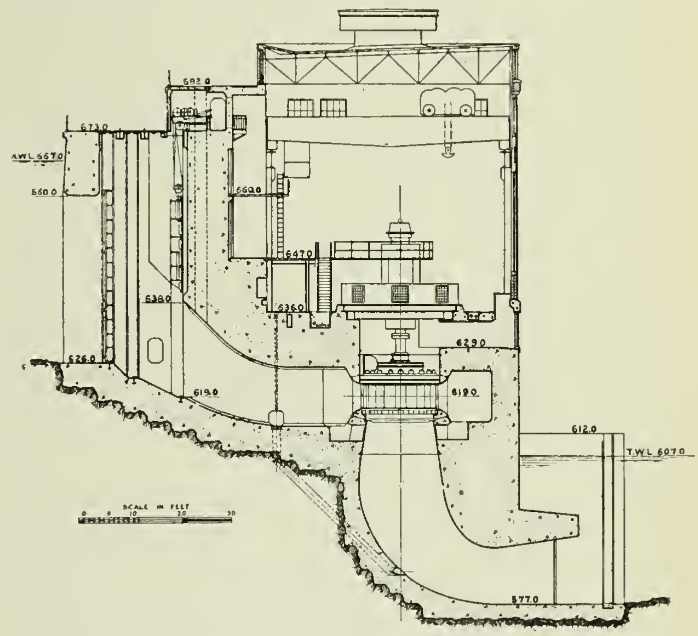

Fig. 10—Section through Power House.

follower is designed to engage or release its load by a line leading to the deck level, and is fitted with two end rollers at either end, to insure freedom from jamming in the checks.

The full depth of an opening to be closed by the stop-log gates is 47 feet, and its width is 18 feet in the clear. The gates for this purpose are in four sections, each 11 feet 9 inches deep, and are made of I-beams covered by ⅜-inch skin plates. The maximum size of I-beams in the lowest gate section is 20 inches at 65 pounds, and the closest spacing is 15 inches. The gross weight of the bottom section is about 18,000 pounds. The top three sections of the gates are adapted for use in the tailrace stop-log checks for unwatering the draft tubes. The same follower is used for handling both stop-log gate sections and the racks.

Fishway and Log Slide

In all the developments on the Nipigon river, present and prospective fishways are essential. Lake Nipigon is a large body of clear fresh water with an established fishing industry. It also lies in a vast area well covered by pulpwood and other timber of commercial value, as a consequence of which it was necessary to provide a log slide at the Alexander plant.

Fig. 11—General View of Forebay and Power House Headworks. Diversion Channel in left Foreground.

In order that fish may have free passage between Lakes Nipigon and Superior by way of the Nipigon river, fishways at both the Cameron falls and Alexander plants have been built according to the requirements of the Department of Game and Fisheries of the Province of Ontario. These are of the ladder type, with the passageways at the intake end spaced to suit varying levels of headwater. This type of fish ladder is very economical in the use of water, the ports supplying the flow being under a head of not more than 18 inches at any time. The velocity through these ports does not exceed 10 feet per second, as this is considered the maximum velocity against with the fish will migrate.

The pulp and paper industry in this district has already grown to considerable dimensions, and is becoming of greater importance, increasingly large quantities of pulpwood passing down the Nipigon to Lake Superior each year. To this end, the shape of the log slide at the Alexander plant is made to give the maximum log transporting capacity for the water used. The trough is "V" shaped, and constructed of timber supported on concrete piers and timber cribs, heavy cribbing having been used at the lower end as protection against ice action.

Hydraulic Equipment

The hydraulic equipment consists of three vertical shaft Francis turbines, placed in reinforced concrete scroll casings. Each is rated at 18,000 h.p. at 100 r.p.m. under a normal operating head of 60 feet. The turbines were manufactured by the S. Morgan Smith-Inglis Company, Ltd., of Toronto. The oil pressure governors and oil pumping equipment were furnished by the Woodward Company of Rockford, Ill. through the turbine contractor. This equipment was placed on order in the year 1927, and, while at that time a number of propeller turbines were in operation under 60-foot head (which, if employed in this case would have reduced equipment cost), the general performance at that time was such that the Commission's engineers did not think it advisable to select propeller turbines for this development. The Francis turbine of moderate specific speed was given preference, and in view of the fact that acceptable part-gate efficiency was anticipated by all competing manufacturers, it was decided to install the above described units.

Fig. 12—View of Power House from Downsteam Side. All River flow Passing over Spillwall.

Furthermore, in view of the fact that improved elbow draft tubes were simple in construction, and as such types showed equally good results compared with other types, decision was given in favour of the elbow draft tubes.

The casings and intake conduits are of reinforced concrete and conventional type and construction, needing no further comment.

The successful bidder of the water wheel contract preferred to furnish the solid type speed ring. This type differs from present-day practice, inasmuch as the stay vanes are integrally cast with upper and lower stay rings. This construction provided a rather simple method of taking care of hydrostatic pressures in the turbine casing, a simple and effective method of connecting reinforcing rods into the stay rings being incorporated in the casing.

Fig. 13—View looking along Main Dam toward Power House.

In general, the turbine consists of a cast iron runner wheel weighing about 95,000 pounds, with fifteen blades cast integrally between hub and crown. It is fastened to the shaft by means of tapered fit and retaining ring. A set of twenty cast steel gates are installed to regulate the flow of water. These gates are cast integrally with the gate stems, which are connected by links and pins to the cast steel regulating ring. This ring, in turn, is connected through adjustable rods to the two servomotors, which are operated through oil pressure. The link connection is of the tension-shearing type, providing protection against distortion of the gate shaft or breaking of gate arms in case of foreign material lodging between the gates.

In order to enable regular inspection of the turbine runner and to repair damaged blades, access is provided through pits and inspection covers placed in the upper draft tube, which is lined with steel plate.

The coupling between the turbine and generator is forged integrally with the shaft. The main guide bearing is of the adjustable water lubricated type, and is bolted direct to the turbine head cover.

Governor System

Each unit is equipped with a governor actuator, sump tank, pressure tank and oil pressure pump.

The governor actuator contains the electric motor driven flyballs, the pilot and main distributing valves, the gate limit device, the restoring mechanism, and the synchronizing gear, which can be operated remotely by electric motor or by hand. The whole governor setting is so arranged as to be compact and yet of easy access to all working parts. The actuator is of the well-known Woodward type, designed so that all parts are enclosed in a dust and oil-proof housing. The operating device consists of one hand wheel placed near the gauges and gate indicators. With this one hand wheel, it is possible to start the unit and bring it into operation, and an immediate shutdown can also be effected at any time.

As a novel feature for synchronizing an automatic speed matcher is furnished, which takes the place of the ordinary synchronizing motor. This speed matcher consists of two special 3-phase electric motors, one of which is connected to the unit which is to be synchronized; the other motor is connected to the bus. These two motors rotate in the opposite direction, and are directly connected to a differential gear which is placed on the synchronizing gear shaft, which, in turn, lowers or raises the pilot valve stem, thus opening or closing the turbine gates as required. When the frequency of the unit and bus is alike, both motors will be operating at the same speed, and the shaft of the differential mechanism will stand still, under which condition the circuit breaker can be closed.

While the oncoming machine is connected to the power system, it is at any time possible to either raise or lower the speed by operating the bus-connected motor. Such procedure will cause loading or unloading of unit.

In addition to all automatic features for synchronizing, a further advantage is introduced by operating the pendulum through a direct-connected electric motor. Such an arrangement eliminates the belt or gear drive, which is necessarily complicated and cumbersome in vertical machines. The current for this flyball or pendulum motor is obtained direct from a pilot exciter mounted on the upper end of the generator shaft. A special protection device is installed to shut down the unit to any predetermined gate or load in case of defect in the connecting wires.

The actuator housing contains the main distributing valves, gate valves and restoring devices, while, as an additional security, a hydraulic hand control is attached. With the hand control, it is possible to start the unit in case no oil pressure or outside current for the pump motors is available.

The oil pressure system is placed on the downstream side of the power house, and so arranged as to enable dismantling of main generating unit without interference with the sump tank, pressure tank or pump.

Construction Joints and Waterproofing

As an aid to the construction forces, detail plans were prepared for their guidance in the placing of concrete. These plans indicated the location and extent of the various classes of concrete going into the structure and the position of the construction joints. There were also shown the necessary cut-off or key trenches and copper bellows where waterproofing conditions indicated the need. With the receipt of weekly and monthly reports of work done, the progress is readily visualized by reference to these joints in the reports.

The location of the construction joints was largely controlled by the capacity of mixing and placing equipment and the restriction in height governed by the strength of forms for green concrete. It is also necessary to place certain joints at definite points where the stresses in the structure may be properly safeguarded and transferred. Wherever joints extend through a comparatively thin wall or pier against which there will be a pressure of water from either side special precaution is taken to waterproof the joint and to place a copper bellows.

The control of the concrete mixing and placing is an important factor in the construction of waterproof walls in that the density, which is a measure of resistance to penetration, may be fixed by the mix, provided it is properly placed in the forms.

To guard against the possibility of seepage damaging the plaster finish on the control room walls subject to water pressure on the upstream side as well as corresponding walls along the upstream side of the power house, a waterproof brick curtain wall was constructed leaving a space of 5 inches between concrete and brick. This space was provided with offtake drains.

Power House Superstructure

The power house superstructure is 52 feet in width and 203 feet in length by 55 feet high, constructed of steel frame with hollow tile walls faced with brick on the exterior and with plaster on the interior. The main generator room is divided into eight bays each 25 feet long, two of which are required for each unit and the two westerly bays for the erection room and control room. Below the erection room is a basement wherein the oil, water and air supply systems for the generators and transformers are located.

The power house is equipped with a four-motor, electrically-operated crane, having a rated capacity of 95 tons on the main hook and 20 tons on the auxiliary hook.

The heat from the generators is utilized for heating the station during the winter months. Five hundred and fifty-volt, 3-phase, electric heaters are provided to heat the control room and certain other sections of the control bay. Provision has been made for the installation of electric heaters in the headworks section should they be required; normally, the warm air from the generating room will be carried into the headworks section.

For cooling each generator a supply of 55,000 cubic feet of air per minute will be required. By a system of dampers, air from the outside may be drawn in through air ducts to the generators and expelled through monitors in the roof, or, if desired, the air may be circulated through the generators from the generator room or partially from outside.

The passages supplying air to the generators are designed for air velocity of 750 lineal feet per minute while the monitors in the roof are designed for an air outlet velocity of 570 lineal feet per minute. There is one monitor for each generator.

Generators

The three generators were purchased from the Canadian General Electric Company and are rated 15,000-kv.-a., 12,000-volt, 3-phase, 60-cycle, 100 r.p.m., 85 per cent power factor. They are of welded structural steel design, only the guide bearings and bearing housings being cast. The generators are complete with spring type thrust bearing and main and pilot exciters designed to give high speed excitation. The thrust collar of the thrust bearing also acts as a guide bearing so that this bearing can be considered as a combined thrust and upper guide bearing. The lower guide bearing is of the usual design, oil lubricated.

A 3-phase tap has been taken from the armature of the pilot exciter of each generator and run direct to supply the governor flyball motor. This eliminates the necessity of step-down potential transformers and connections to supply the flyball motors and supplies a potential direct to the flyball motor as soon as the generator is rotated, whether the 12-kv. connections are connected to the generator or not.

Thermocouples are embedded at different points around the stator windings, also in the upper and lower guide bearings. The leads of these thermocouples are connected to a selector switch which transfers any thermocouple to the temperature indicator or temperature recorder. There is also a Bristol recording thermometer connected to record the temperature of the thrust bearing.

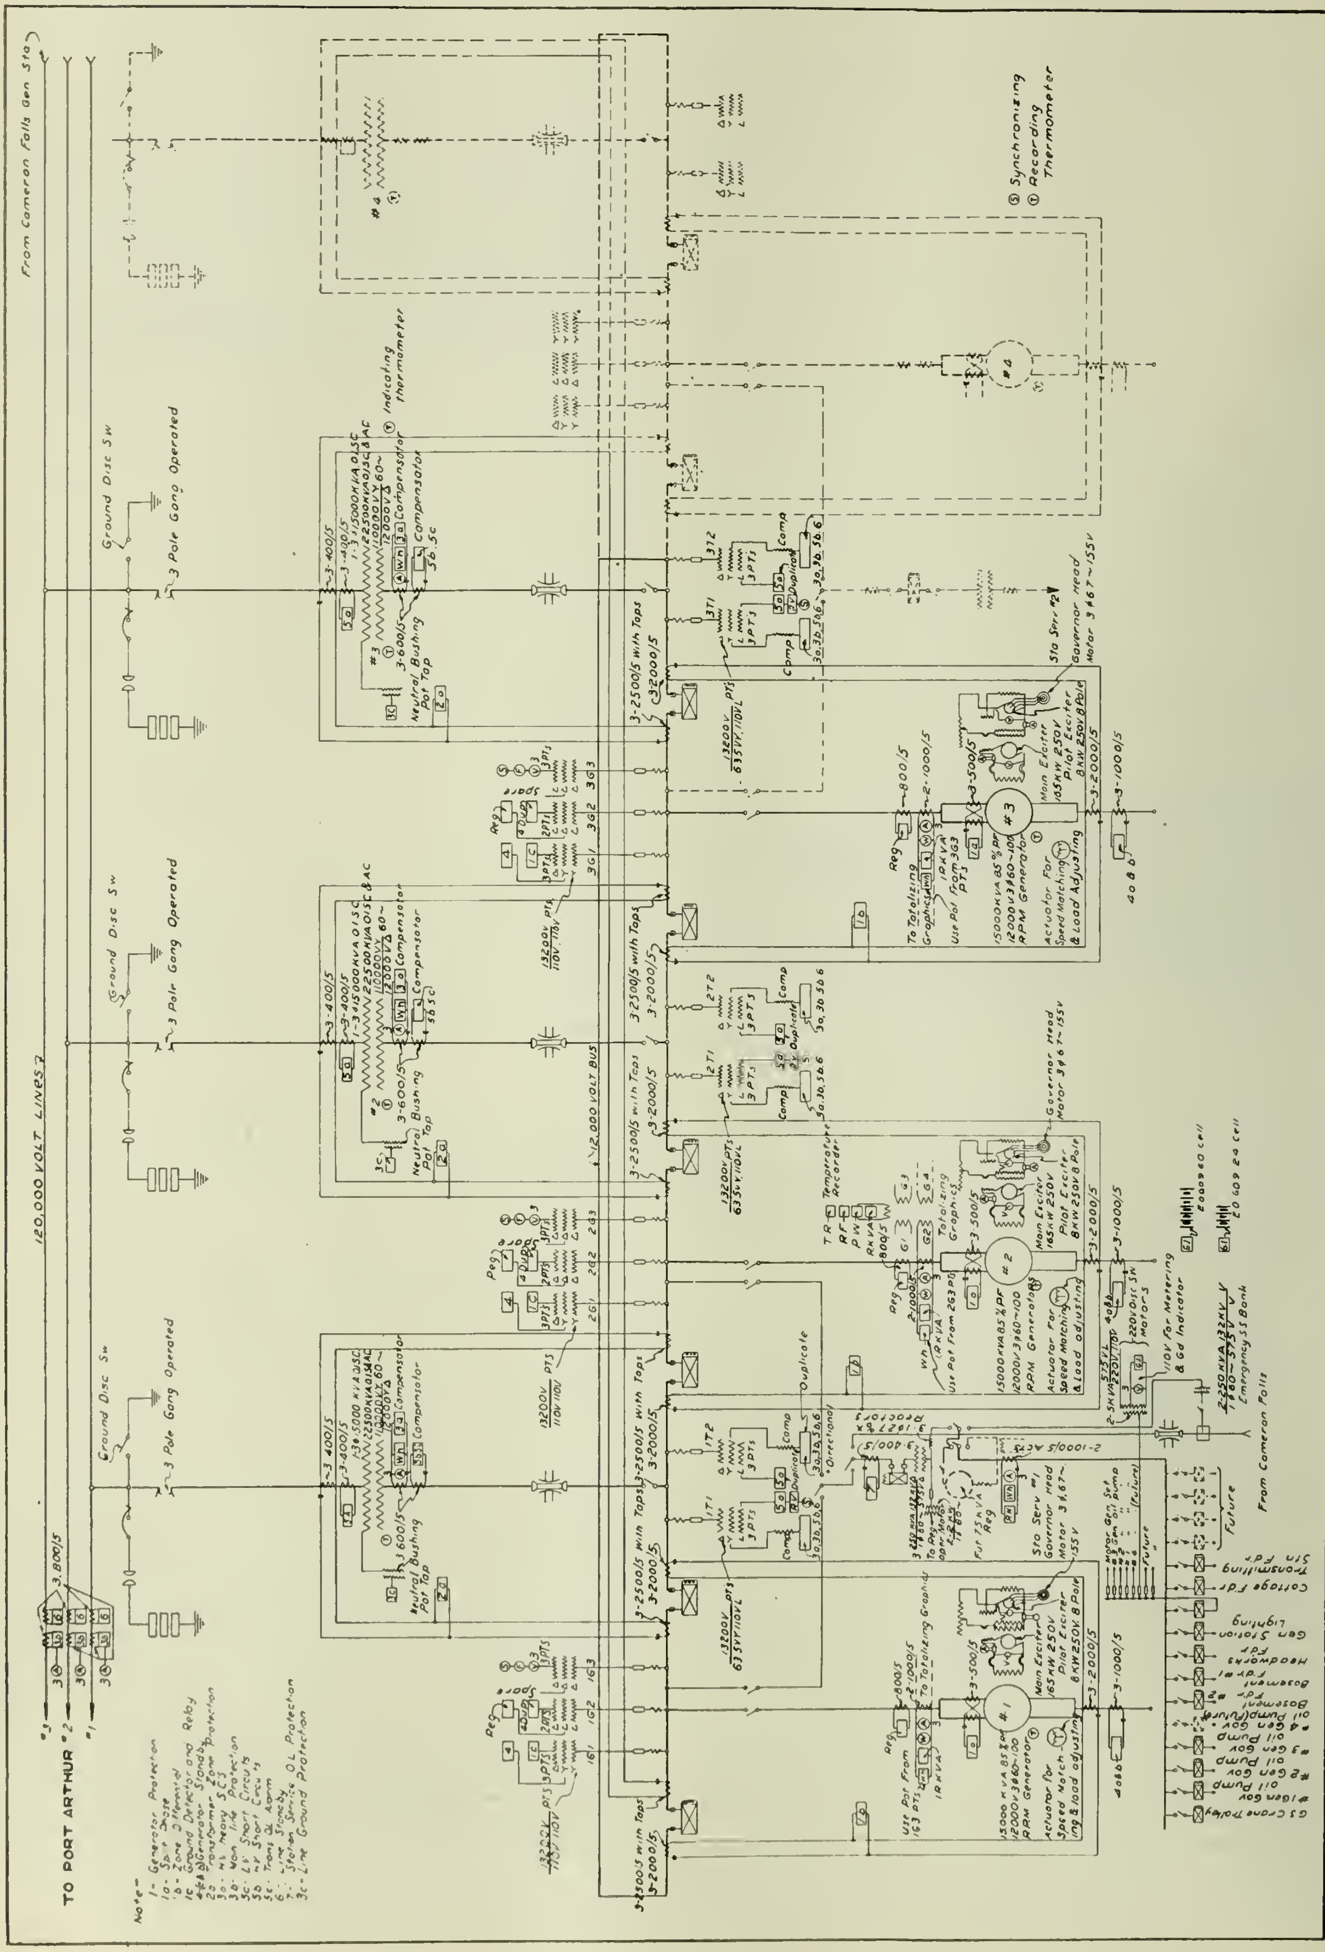

Fig. 14—Line Diagram of Electrical System.

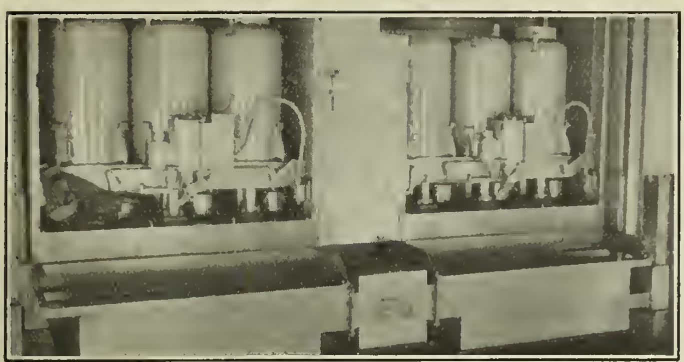

Fig. 15—Metal-clad Circuit Breakers.

Transformers

The power transformers consist of three outdoor, 15,000 kv.-a., radiator type, oil-insulated, self-cooled, 22,500 kv-a. forced air cooled, 80 per cent power factor, 3-phase, 110/12 kv., 60 cycle, 55 degrees rise with four 5 per cent high voltage full capacity taps above 63.5 kv., connected to manually-operated tap changers. The total weight of each transformer is 98 tons.

The transformers are connected 63.5 kv. star 12 kv. delta. The high voltage neutral lead is brought out of the transformer through a 110-kv. bushing of same design as the phase bushings, except that it is equipped with a potential tap device from which potential is obtained for operation of the relays on the ground protection system. This device eliminates the necessity of 63.5 kv. potential transformers.

Ring type current transformers are installed inside the delta in each transformer, also on the high voltage bushings of the transformers for use in conjunction with the protective relay systems. The neutrals of the transformers are not grounded in any manner as will be dealt with more fully later.

No indicating thermometers are provided on these transformers; instead each transformer is equipped with "hot spot" temperature indicating equipment which can be checked by thermocouples whenever desired. The temperature indicators for these transformers are located in the control room so that the transformer temperatures are constantly under observation of the operators on duty.

Electrical Layout

The single line diagram in Fig. 14 indicates the main 110 and 12 kv. switching and connections of this development.

The entire 12-kv. switching and bus connections consist of metal-clad equipment of latest design, so constructed as to fit the various bays in the station and to form a ring bus system. The capacity of the 12-kv. main bus and all oil circuit breakers is 2,000 amps. All breakers are interchangeable and one spare breaker is provided so that a breaker can be removed from service in the ring for maintenance and the spare breaker inserted to keep the ring intact. The breakers are all electrically and mechanically interlocked with the disconnecting switches to guard against faulty operation.

The required ring type current transformers and 3-phase double secondary potential transformers with their primary resistances and protective fuses are all incorporated in the metal-clad structure.

In a bay 21 feet long by 16 feet wide and 12 feet high, a metal-clad switching unit is installed consisting of two electrically-operated, 15,000-volt, 2,000-amps., 3-pole, oil circuit breakers with 12 kv. bus sections, two 3-phase, motor-operated, oil-insulated, disconnecting switches, 12 ring-type current transformers and five sets of oil-insulated, three-phase, double secondary potential transformers with primary protective equipment; this will give some conception of the compactness of this equipment. The equipment is designed for a potential test of 60,000 volts for one minute. It is designed to control the three 15,000 kv.-a. three-phase transformers and station service transformer banks and may be extended at one end in future.

From the ring bus system, six 1,000,000-c.m., 12,000-volt, P.I.L.C. cables are run underground in fibre ducts to each of the outdoor, 3-phase transformers. The connections from the metal-clad service breaker to the outdoor station service transformers are also run underground.

Where the 4-inch ducts are run from below the generator room floor up to the metal-clad structures, a rise of 14 feet 4-inch rubber hose was used instead of fibre or metal conduits. This eliminated the difficulty of fitting fibre duct sections for a vertical spiral run 25 feet long or bending metal conduits to fit properly. The rubber hose was filled with fine sand, capped at both ends and placed in position to which it readily conformed and the concrete poured around it. After the concrete had set the sand was run out and rubber hose joined to the fibre ducts in the main horizontal duct run.

The three 15,000 kv.a., 3-phase transformers are located outdoors approximately 250 feet from the generating station and mounted on concrete foundations. The transformers can be transported between the erection room of the generating station and transformer station by means of a specially designed transfer truck which is run on a standard gauge railway, the rails of which are placed on concrete foundations.

The 110-kv. switching equipment consists of an electrically-operated, 3-pole air break disconnecting switch. There are no 110-kv. oil circuit breakers or bus connections. The arrangement whereby these are eliminated is explained later. The power transformer banks are considered as part of the 110-kv. line and all automatic clearances are cleared by the low voltage breakers in the ring bus system, except infeed faults, in which case the line breakers at the receiving stations operate also. This system of connections involves a considerable saving in the cost of 110-kv. switching and connections.

The three 110-kv. lines from this development are connected at a special line tap steel structure erected on the transmission line right-of-way direct to the three transmission lines running from the Commission's Nipigon development to the Port Arthur transformer station.

The design of this line tap structure is interesting in its simplicity as will be noted from the layout. The structure is designed to accommodate a future fourth line. On the arms of the structure, it will be noted three 110-kv., oil-insulated, double secondary, ring type, current transformers are mounted on each of the three outgoing lines.

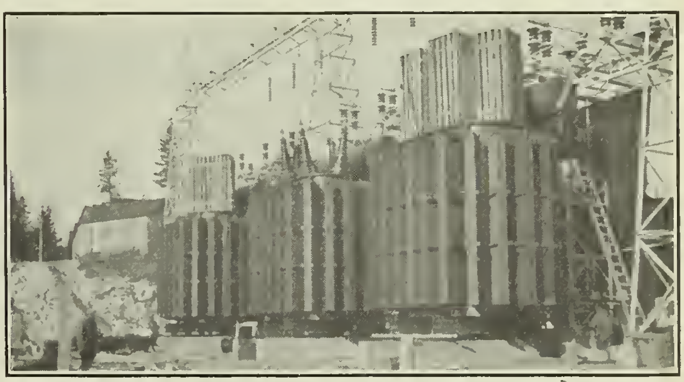

Fig. 16—Transformers.

These current transformers are required for the total line current indication and line protective relay systems.

The current transformers are constructed of two upper sections of oil-filled, 110-kv. porcelain transformer bushings bolted together by a flanged casting at the centre. At the flanged section the current transformers are located and covered with a weather-proof housing.

Control System

The entire station is controlled electrically from a central control desk located in the control room. The miniature type of control equipment is used on this desk, the top of which for the three present and one future unit measures 72 by 30 inches. The control switches are all of the standard telephone type. Forty-eight volts D.C. is used for the miniature control, which in turn connects in 125 volts D.C. for operation of the various switching units.

The synchronizing system consists of synchronizing across any of the 12-kv. breakers in the ring bus system. As there are potential transformers on both sides of each breaker, it is possible to synchronize across each breaker. Automatic synchronizing equipment is being provided, but in case of failure of the automatic equipment a manual synchronizing system is installed as a standby.

None of the 12-kv. oil circuit breakers in the ring bus system can be closed unless first synchronized. By operating a breaker key on the control desk to close a breaker, this key first connects in the speed matching motors of the generator to be connected to the bus, and at the same time selects the proper potential for the automatic synchronizing equipment; the automatic synchronizing equipment is then connected; this functions and when the proper synchronizing point has been established, energizes the control relays which close the breaker.

If a generator is already running and connected to the bus, and it is desired to close in the other breaker, thus completing the ring, the control is so interlocked that the synchronizing system will operate to close the breaker as usual, but the speed matching motors of the unit would not be energized, in such a case the automatic synchronizing equipment checks for voltage difference only and not for phase displacement.

The entire switching at the Alexander development will later be handled by remote control from the Nipigon station.

Protective Relay Systems

The Thunder Bay system has approximately 30 per cent of its connected load as synchronous motor load, which is very sensitive to voltage disturbances. The system is, therefore, being arranged as a series of 110 kv. lines metallically isolated from each other. These are connected to the generating and receiving station transformer banks. There is no essential oil breaker switching at 110 kv., only line disconnecting switches being required.

Parallel is held by the ring bus connections at generator voltage between the groups of units in each generating station and at the receiver station networks.

It is intended to promote stability by a layout of the system such that the effect of a fault on the system voltage will be localized and minimized. In other words, it is necessary to maintain at all times some tie between generators and the bulk of the synchronous load, which will retain some voltage to maintain synchronous torque. In addition, it is also necessary to provide an installation of switching and relaying which will enable any fault to be cleared from the system selectively and rapidly.

The relay protection for the Alexander station consists chiefly of zone protective systems, as will be noted from the single line diagram. The systems consist of the following:—

Generator Protection

Split Phase

This operates on unbalance between the halves of each winding and will operate on a single short circuited coil. This protection is also very sensitive to short circuits in field poles.

Zone Differential

This operates on any unbalance in the phases on any part of the generator circuit from generator neutral to bus side of the 12 kv. breakers in the ring bus.

Generator Ground Protection

(*1*) Heavy range—segregates units.
(*2*) Light range—alarm only.

Transformer Protection

Zone Differential

Covers bank from the H.V. bushings to bank breakers in the low voltage ring bus, including the 12 kv. underground cables.

There are three ranges to this system:
(*1*) Heavy—instantaneous.
(*2*) Medium—time.
(*3*) Light Setting—time, for incipient faults.

As there is no oil circuit breaker on the 110 kv. side of the transformer bank, means must be provided to cause the breakers to trip the line at the other stations. To do this, one phase of the line connected to the respective bank is automatically grounded. This causes the instantaneous ground relays to operate on the line at the other stations. This automatic grounding switch is mounted on one phase of the 110 kv. air 1-break disconnecting switches at the outdoor transformer station.

110 Kv. Line Protection

The line protection differs from the station protection in that distance current potential type relays are used. There are three systems for this protection:

(*1*) Non-directional. Short range instantaneous short circuit protection. Includes transformer bank.
(*2*) Main line protection. Long range S.C.
Short range S.C.
Duplicate.
Directional.
(*3*) Line ground protection.

As the neutrals of the transformer banks at the generating stations are not grounded, a faulty line will first clear on the ground current relays at the transformer station where the bank neutrals are grounded. For a ground detector at Alexander, a tap is used in the transformer neutral bushing with potential network to indicate voltage from bank neutral to ground, this indicating a ground on the line. With this, a ground potential relay is used to trip the line at the generating stations through a line relay, which permits the breaker at the transformer station to operate first.

In addition to the above, there are the standby protective systems and station service bank protection.

Auxiliary Systems

The station service banks consist of three 250 kv-a., oil-insulated, self-cooled, 60-cycle, 12,000/575-volt, single-phase transformers for the main bank, and two 250 kv-a. transformers in open delta for the standby bank.

The main bank can be connected off either of two generators through double-throw, 12-kv. oil-immersed, disconnecting switches. The standby bank can be supplied from the Nipigon station.

The station service banks are located about 100 feet outside the main entrance to the generating station on concrete foundations. The 12-kv. and 575-volt cables from and to these banks are run underground. The 12-kv. and 550-volt structure over the transformers is constructed of 2-inch galvanized iron pipe with standard galvanized threadless fittings.

The secondary cables from the service banks are run to a 575-volt bus in the generating station. Power can be obtained from either the No. 1 or No. 2 banks through selective disconnecting switches. The service power is supplied to the various service mains by underground lead-covered cables, the feeders being controlled by automatic oil circuit breakers with series ammeters mounted on same. All electric motors in the station on the auxiliary equipment are designed for starting at full voltage across the line.

The mechanical equipment comprises air compressing equipment, including a compressor operating at 100 pounds, pressure for general purposes and generator brakes, and a high pressure compressor for supplying air to the governor tanks; these two systems are interconnected. The water pumping equipment includes duplicate pumps for supplying cooling water for the generator thrust bearings and general purposes throughout the plant. A fire pump is also installed and arranged to come into service automatically if a fire line valve is opened.

The generator lubrication equipment consists of a unit oil system for each generator, the pump being driven by a 550-volt motor supplied from the station service system. Connections are run from each unit system to a central filtering and storage system in the station basement.

The transformer oil storage and filtering systems are located in the station basement and can be connected to the main and service transformers by flexible metal hose at the respective outdoor units.

Closure of Diversion Channel

Construction work proceeded rapidly in all sections of the development throughout the summer of 1930. By the third week in September, the fill in the main dam was brought to elevation 681 throughout its length, the head gates were in place in front of each of the turbines, and a week later the gap in the auxiliary dam, through which the construction railway had passed, was closed, and No. 3 generator was completed. By this time also, arrangements had been made for closing the outlets of the diversion channel and raising the headpond to operating level.

For several days before the closure, the headpond levels at the Nipigon station were regulated to meet the period of shutdown without wasting into the Alexander reach, and to allow ample time to draw down the Alexander headwater pool to permit the steel gates to be placed in the diversion sluiceways.

When the time came for making the closure, the gates were assembled above their respective openings, and suspended on "A" frames, in readiness for lowering into the checks. On Sunday, September 28th, at 4 o'clock a.m., the Nipigon plant was closed down, and the flow in the river completely stopped, the forebay at the Nipigon plant receiving and holding the whole flow of the river coming down from Lake Nipigon, this having been reduced by partial closure of the Virgin falls dam. At 7 o'clock a.m. the water in the river below Cameron falls and between the main cofferdam and the earth dam had drained out so that only a very shallow flow was passing through the two sluices. This enabled the gates to be dropped into place without difficulty after the sluices had been thoroughly inspected for any possible obstructions in the way of waterlogged timbers or gravel. Practically no obstructions were found, and the gates were dropped into place and sealed. At 10.25 o'clock the entire closure had been completed, and word was given to the Nipigon operators that that plant could be placed on load again, and at 10.45 o'clock the station was again carrying load. The load during that day proved to be fairly light, and the headpond filled slowly. Early the following morning, water began to flow over the spillwall, and by evening was passing over to a depth of more than 3 feet. With a few minor exceptions, the structures proved to be entirely watertight. A very small leakage through the closure gates was stopped up by dumping cinders against the upstream side and allowing them to be carried into the openings by the current.

The concrete fill or plugs for the water passages behind the gates have been poured, and the upper lift sealed to the lower surface of the existing concrete with grout forced through 10-inch vertical pipes left projecting through the spillwall.

The first unit was turned over on October 1st and the plant first carried commercial load on October 21st.

Personnel

All work in connection with the development was handled by the Commission's staff, of which F. A. Gaby, M.E.I.C., is Chief Engineer. Construction of the plant was carried out by the Commission's Construction Department, of which A. V. Trimble, M.E.I.C., is the head. J. N. Stanley, A.M.E.I.C., was resident engineer and superintendent of construction. The design of all structures, except the power house superstructure and the general supervision of construction was in charge of the writer, chief hydraulic engineer, assisted by Otto Holden, A.M.E.I.C., assistant hydraulic engineer. The power house superstructure and all electrical design was handled by the Electrical Department, under E. T. J. Brandon, A.M.E.I.C., chief electrical engineer. W. S. Lee, M.E.I.C., of New York and Charlotte, N.C., was consulting engineer on the design and construction of the earth fill dam.

The Technique of Placing Concrete on Steep Slopes Without Forms

I. E. Burks,
Concrete Technician, Alcoa Power Company, Kenogami, Que.

Paper presented before the Annual General and General Professional Meeting of The Engineering Institute of Canada, at Montreal, February 4th, 5th and 6th, 1931.

SUMMARY.—A recent advance in concrete construction of portions of structures which are steeply sloped consists in the practice of placing the concrete without top forms. The paper describes the way in which this has been done at Chute à Caron on the curved surfaces of slopes up to 50 degrees. For this purpose somewhat stiff mixtures were used, requiring vigorous tamping when being placed. Preliminary laboratory tests showed that with this character of mixture, properly rammed, the resulting strength was entirely satisfactory. The surface was shaped by the use of screeds placed so that the bottom edges of the screeds represented the finished surface of the concrete; the precautions required to obtain satisfactory results are described. Considerable reduction in the construction cost of gravity type dams can be obtained in this manner.

The practice of placing Portland cement concrete on level surfaces, such as sidewalks and pavements, represents what is probably the most simple method of doing construction work where concrete is the principal material. Pavement sections have been successfully laid on grades up to 15 per cent with little or no difficulty where the workability of the concrete is properly regulated and controlled. Another common type of concrete construction is that of placing the material between vertical or sloping wall forms. The latter named type differs from the first only in the matter of form cost and placing equipment. A third, and rather new development in concrete construction, is found in the recent practice of placing concrete in sections of hydraulic structures having slopes which heretofore were considered to be steep enough to necessitate the use of top forms.

It is the purpose of this paper to describe a method of placing concrete on slopes up to 50 degrees without the use of top forms. Since a discussion or an analysis of the different methods of concrete mixture design is not intended to be within the scope of the paper, as little reference will be made to that phase of the operation as is necessary for a proper understanding of the methods employed. However, it should be stated that the water-cement ratio law was used as a basis for proportioning concrete mixtures on the work where this somewhat unusual method of placement was used. The interpretation of the water-cement ratio law is simply that the compressive strength and other desirable qualities of the concrete are regulated and controlled by the ratio of the volume of water to the volume of cement used in the concrete mixture—as long as the mass is workable and the aggregates are comparatively clean and structurally sound. Since concrete which is called "workable" for one type of construction and placement method might be entirely too soft, or too stiff, for another type of construction or handling method, it appears that the term "workability" is one which might include almost any condition from a soft and plastic mass which would flow easily into place with little or no manipulation, on up to mixtures which appear to be quite stiff and harsh and which require vigorous tamping and ramming to close the air spaces between the particles and compact and solidify the mass. On the work herein described the latter named mixtures were used, i.e., those mixtures which when dumped from a 4-yard concrete bucket stood up and formed a pile of large stones, the voids in which were filled by a quantity of cement-sand mortar appearing to be almost dry. Laboratory tests gave very clear evidence that when this character of mixture was rammed and packed into specimen moulds in a manner comparable to the methods used in the field, the resulting strength was equal to or even greater than the strength obtained from the so-called plastic mixtures having the same water-cement ratio.

In the pages which follow an effort will be made to show that the principal advantages to be obtained through placing concrete on slopes up to 50 degrees without the use of top forms are as follows:

(*a*) A reduction in the cost of forms of at least 25 per cent;
(*b*) A saving in time of about 30 per cent;
(*c*) A saving of about 10 per cent in the quantity of cement used;
(*d*) A higher quality of product in the finished structure;
(*e*) Better appearance of the structure through absolute elimination of any form-marks or honeycombing.

In dams of the gravity type, the downstream face of the spillway section, from the crest of the rollway to the bucket (see Fig. 1), is generally designed to have a slope which when formed causes the placing of concrete to be a slow and somewhat difficult process. The usual placing equipment will not permit the delivery of concrete directly beneath the sloping form therefore it must be dumped at the most convenient point and re-handled by shovels—or, the workability of the mass must be adjusted so as to

Fig. 1—A Section of the Spillway of Chute à Caron.

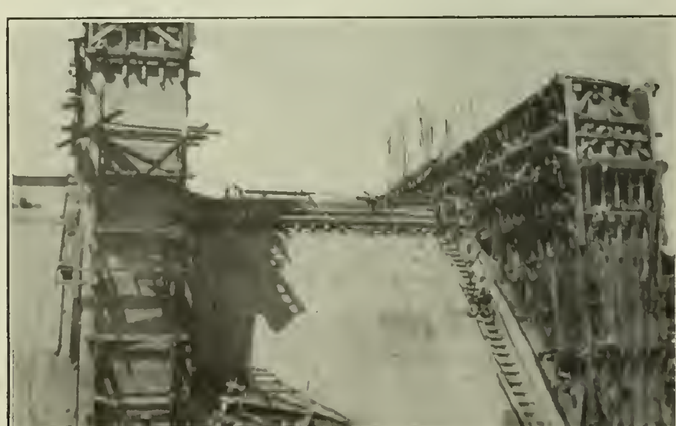

Fig. 2—A Block in the Spillway Section.

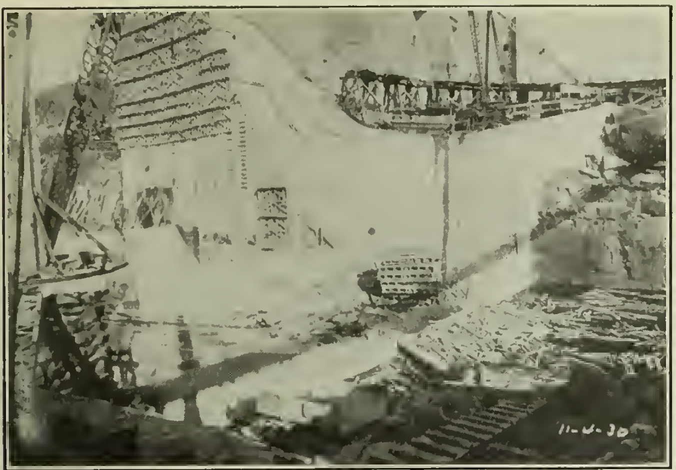

Fig. 3—Warped Surfaces in the Bucket of the Spillway Section.

provide almost fluid consistency. The first method retards the entire concreting operation and consequently increases the cost, and the second results in the two extremes of consistency being used in one form with the very great probability of a large number of shrinkage cracks. In order to place concrete at the toe of this form it must be cast a distance of from 12 to 13 feet with shovels.

In sections where the contour of the spillway is uniform, as is shown in Fig. 2, the cost of making the curved forms is only slightly greater than for the ordinary vertical faces since a large number of standard panels can be made in the shop and used in identical locations—generally throughout the entire job. However, the time required to erect the sloping forms and bring them to the proper line is about 25 per cent greater than for standard vertical forms. In certain sections of the spillway it may be desirable and economical to warp the surface of the bucket in order to fit topographic conditions. Such a situation is shown in Fig. 3. The form-work in a case of this kind becomes a very expensive item of construction cost—the laying out of the work at the shop is a tedious operation, and considerable skill and time is required on the part of the mechanics. Further, such forms can be used only once. The actual erection and proper bracing of warped forms of course requires more time and labour than ordinary vertical work.

The writer's first attempt to dispense with sloping forms was on the top lift of a certain block in the spillway section of Chute à Caron dam. This lift was 43 feet wide by 45 feet long by 13 feet deep, and specifications required that it be placed in one continuous operation. The downstream face was curved on a radius of 83 feet which gave a slope of approximately 25 degrees with the horizontal. Screed guides were set on about 10-foot centres placed at

Fig. 4—Showing Method of Setting Screeds in for a Rollway Lift, also Overhang of Sloping Forms.

right angles with the face of the dam, as shown in Fig. 4. The screed supports were pieces of 2-inch pipe set into holes drilled in the old concrete of the preceding lift. The top of the pipes were cut off about 6 inches below what was to be the finished surface and wooden plugs driven into the ends of the pipe to provide means of fastening the screeds to them. The screeds were 4-by 4-inch timbers cut to the proper radius. These were nailed to the plugs in the pipe supports so that the *bottom* surface of the screed represented the finished surface of the concrete. The straight-edges used to work between the screeds were dapped 4 inches at each end to conform to the depth of the screeds. It is an advantage to set the screeds entirely *above* the finished surface of the concrete for the reason that they can be left in place until the concrete has thoroughly hardened and thus serve as a bridge over which workmen can move, and also there is less difficulty in removing them than if they were imbedded in the concrete. A further advantage of placing screeds in this manner is in the elimination of cracks which invariably occur where screeds have been imbedded in the concrete and later removed and the trenches back-filled.

When the screeds are in position, concrete is delivered to the form in 4-yard buckets which are dumped in the space between the screeds. This operation requires a great deal of care in order not to strike the screeds with concrete buckets. As previously stated very stiff mixtures are used

Fig. 5—Surface being smoothed with Wooden Floats, Straight Edges being pulled forward between Screeds.

and, by using electric vibrators and a certain amount of hand-shoveling, the concrete is spread out in layers between the screeds and compacted so as to conform roughly to the finished grade. The vibrator and shovel-men are followed up immediately by a crew using the dapped straight-edges which are worked back and forth between the screeds and pulled upward along the slope. Fig. 5 illustrates rather well how this operation is accomplished. After the surface has been brought to grade by the straight-edges, it is smoothed off with a wooden float and all small surface voids filled. It should be stated that absolutely no mortar covering is used on the surface other than that found in the regular concrete mixture, and that every effort is made to obtain the greatest quantity of rock possible at the surface. Finishers are cautioned not to remove from the mass any fragments of stone which may protrude slightly above the surface—these are either left in place or are driven down with a small hammer. Obviously, there is no chance of honeycombing or form blemishes in a lift made in the manner just described, and the finished appearance of such a lift is noticeably better than where top forms are used. Fig. 6 gives an idea of the finished appearance of a rollway crest.

Care is taken not to deliver concrete to the screeding crews faster than they can handle it efficiently—however,

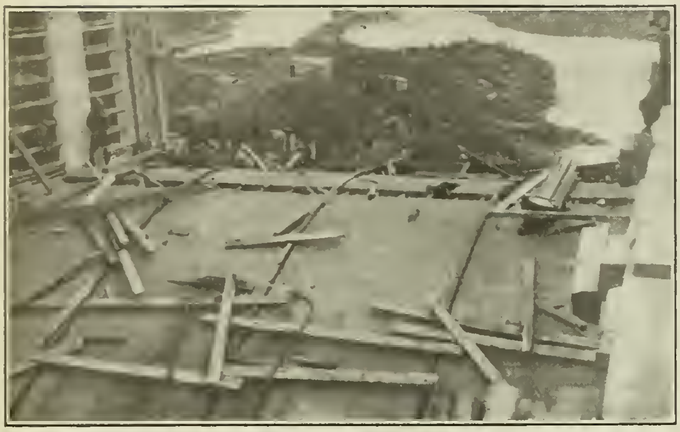

Fig. 6—Rollway Crest finished by Screeding.

with proper supervision the work can be carried on with little or no delay to the placing derricks or transportation system. The interior sections of the form toward the upstream face should be carried up at about the same level as the screeded section, and this provides dumping space for the concrete which the screeders are unable to handle and also permits continuous delivery from the mixing plant.

Five of the eleven rollways of the spillway section of Chute à Caron dam had been built under the old method of top-forming before it was thought feasible to accomplish the work by screeding alone. This offered excellent opportunity for comparison of the two methods. It was revealed that the placing difficulties encountered where top forms were used slowed down concrete delivery to where 22 hours were required to fill the forms of one block and complete the lift. Under the newer scheme of screeding only, the time was reduced to an average of 15 hours—and on one occasion under favourable conditions the lift was made in 13 hours.

The job of screeding the first rollway lift was attacked with a good deal of misgiving on the part of the placing foreman and his crew. The superintendent and engineers on the jobs were also inclined to be "doubting Thomases" and a rather large audience assembled at the forms, apparently to smile at the efforts which were to be made at placing concrete in such an unusual manner. As the work progressed the predicted difficulties turned out to be mere details and when the block was "topped-out" in eight hours less time than was required for the same lift in other locations, there could be no doubt about the success of the new method.

After two or three rollway blocks were successfully placed without top forms the placing crews grew ambitious to try their hand at even steeper slopes. Ample opportunity for a display of their skill was provided in the form of

Fig. 7—Method of Setting Screeds on Warped Surface of Bucket.

certain spillway buckets which, in addition to having slopes slightly steeper than 50 degrees, also had warped surfaces. The placing of this concrete was accomplished in practically the same manner as has already been described for the rollway blocks except that the "straight-edges" were cut on various curves as specified by the engineers. An example of the placing methods used on these steep slopes is illustrated in Fig. 7.

Specifications required that all concrete placed within 6 feet of the exposed surfaces of the dam should have compressive strength of 3,000 pounds per square inch at 28 days. Through previous experience and a knowledge of the characteristics of the materials to be used it was known that a water-cement ratio of 0.9 would produce concrete of approximately the strength specified. With the water-cement proportions set at the figure noted, the workability of the concrete was regulated to fit placing conditions by adjusting the sand and stone quantities.

Where top forms were used the concrete had to be very soft so that it would flow back under the 15 or 16 feet of overhanging form. This meant that the quantities of sand and stone in each mixer batch must be reduced approximately 30 per cent while the amount of cement and water remained constant. From this it follows that the unit cement content of mixtures of given water-cement ratios, increases as the mixture is softened. Where placing conditions allow the use of stiff mixtures, as is the case where top

Fig. 8—Electric Vibrators used to Compact Concrete.

forms are not used, the maximum amount of sand and stone can be added to the designated quantity of cement and water, and the unit cement content is reduced accordingly.

On five rollway blocks the unit cement content averaged 502 pounds per cubic yard of concrete where top forms were used. The average unit cement content on six rollway blocks placed by the screeding method was 449 pounds. This saving of 53 pounds of cement amounts to approximately 31 cents per cubic yard of concrete. Since the top lift in one rollway block only is about 1,000 cubic yards, the saving on the entire job would be very considerable.

The saving in the cost of forms on the regular rollway sections can be safely estimated at 25 per cent since one of the three sides formed under the old method is entirely eliminated except for the comparatively small expense of setting the screeds. However, the saving in form-work on the warped sections of the spillway bucket would be more difficult to estimate—but it would probably be much greater than 25 per cent.

In conclusion it would seem fitting to say that the experience gained on this work warrants the suggestion that the construction cost of gravity type dams can be reduced very materially if the designers of such structures bear in mind the application of the methods described in the foregoing.

The Design of the Chute à Caron Diversion Canal

G. O. Vogan, A.M.E.I.C.,

Chief Designing Engineer, Alcoa Power Company, Ltd., Arvida, Que.

Paper presented before the Annual General and General Professional Meeting of The Engineering Institute of Canada at Montreal, February 4th, 5th and 6th, 1931.

SUMMARY.—The Chute à Caron power development is being carried out on the Saguenay river about 10 miles upstream from the town of Chicoutimi, and the paper describes one of the most interesting features of this work, namely, the diversion and control of the river during the construction period. The discharge of the Saguenay river at this point is affected by the very large storage in Lake St. John, and by the load requirements of the Isle Maligne power plant, about 23 miles upstream. Flood conditions in the river are discussed as they affected the cofferdam and other structures necessary for the diversion work. The diversion canal described was required to carry the flow of the river during the period between the closure of the main channel by the tipping of a concrete "obelisk" and the completion of the closure section of the dam. The "obelisk" was tipped in July 1930, and the final cofferdam closure took place on October 4th, at which time about 150 feet of main dam still had to be completed. The water of the diversion canal was passed under the power house by a tunnel or sluice tube discharging into the permanent tailrace. Hydraulic studies were carried out as to the flow in the diversion canal and in the tailrace, and it was found necessary to line the latter with concrete wherever poor rock or gravel existed. Some difficulties arose in connection with this concrete lining due to the high velocity and turbulent flow in the tail race, but these were successfully met by the methods described. The hydraulic problems in the system were studied by means of large scale model experiments. A description is given of the extensive cofferdam work, the opening at the head of which was closed by means of the "obelisk."

Abnormal conditions during the spring and summer of 1930 affected the programme, as the spring flood was much lower than usual and of short duration, but from August 1st to September 1st flows varying from 70,000 to 100,000 second feet passed Chute à Caron, about 40,000 second feet of which flowed through the sluice tube, while the remainder spilled over the cofferdams, at which provision had been made for dealing with an overflow of this kind. After the final closure of the dams the sluice tube was permanently plugged with concrete, and the dam structure was carried to completion without further difficulty.

Chute à Caron is situated on the Saguenay river in the province of Quebec, about 10 miles upstream from the town of Chicoutimi. At the present time the Alcoa Power Company Ltd. is completing a hydro-electric power development at this point.

This paper is not a description of the entire project, but covers one of the most interesting features of the development, the diversion and control of the river during the construction period.

General Conditions Affecting Diversion and Control of the Saguenay

The Isle Maligne plant of the Duke-Price Power Company is situated on the Saguenay river at the junction of the Grand Discharge and Little Discharge about 9 miles below the outlet of Lake St. John, and about 23 miles upstream from the Chute à Caron plant. The load requirements of the Isle Maligne plant were such that there must be a discharge of about 30,000 to 37,000 second feet on week days and 15,000 second feet on Sundays throughout the entire year. This requirement fixed the capacity of the Chute à Caron diversion works at 50,000 second feet. The normal annual variation of flow of the river ranges between the natural maximum recorded peak of 326,000 second feet and the regulated Sunday minimum of 15,000 second feet. The annual flood peak comes in May or June, but there are frequent flood peaks of a magnitude of 100,000 second feet or more during the summer and fall months, up to December. There could be no assurance of a long uninterrupted period when the flow would be 50,000 second feet or less, hence it was necessary to arrange the cofferdam structures so that intermittent floods of more than 50,000 second feet could be safely passed. Lake St. John storage above the Isle Maligne dam was available to a limited extent as a help in controlling stream flow during the diversion period.

While the Chute à Caron plant was under construction it was necessary to divert the flow of the river only during the period between the tipping of the "obelisk" and the completion of the closure section of the dam. The latter operation entailed the placing of about 120,000 cubic yards of concrete or two and one-half months of uninterrupted work. The use of some 3 feet of storage capacity in the lake resulted in longer and more definite working periods between the intermittent freshets, and reduced the number of times it was necessary to discharge more than 50,000 second feet. The occurrence of flow in excess of this amount would have necessitated stopping work in the river section of the dam and allowing the water to overtop the cofferdams. A detailed description of these cofferdams will be given later. Originally, the construction programme called for this work to be done in the winter of 1930-31 between the periods of fall and spring floods. Later, it was decided to close the cofferdam in the early summer of 1930 and carry the main dam to completion with the exception of two blocks in the deep section of the channel which would be left low to pass the fall flood. Due to adverse flow conditions however, the cofferdam was not closed until September, but owing to a very light fall flood, the main dam was carried to completion in December with only two interruptions due to high flows.

General Description of Diversion Canal, Sluice Tube and Tailrace

Fig. 1 shows the general layout. The diversion is divided into three sections, namely: the diversion canal, the sluice tube and the tailrace. The diversion canal begins at survey station 2 + 00 and continues downstream to survey station 17 + 95, which is the face of the intake, and entrance to the sluice tube. Under the intake and power house on the centre line of number one generator, a tunnel or sluice tube was constructed which connects the diversion canal to the permanent tailrace. The water was taken from the Saguenay at the entrance to the diversion canal at survey station 2 + 00, along the canal, through the sluice tube into the tailrace, and was diverted back into the Saguenay at the end of the tailrace at survey station 45 + 00. The overall length of the excavated channel was about 4,300 feet. The material encountered was rock with no overburden in the vicinity of the power house, and considerable gravel overburden at the upstream end of the diversion canal and the middle portion of the tailrace.

In describing the diversion scheme, it is the author's intention to discuss the different portions of the structure as far as possible in the chronological order of their construction.

The Diversion Canal

The theoretical cross-section of the diversion canal was 40 feet wide at the bottom with side slopes of 1 to 4. The width was set by requirements to operate a shovel and a loading track in the canal bottom. As the excavation proceeded, it was found that this cut was too narrow to handle the work properly, and the channel was widened to provide space for a ramp track on the right bank. A typical cross-section is shown in Fig. 1.

During the late winter of 1927-28 the hydraulic studies of the diversion canal down to the sluice tube were completed. The canal was designed to have a capacity of 50,000 second feet with a velocity of 21.25 feet per second. A roughness factor "*n*" of .045 was assumed as it was considered uneconomical to do any trimming of the sides and bottom.

When the canal was completed, accurate cross-sections of the excavation were taken, and after it was put into operation, profiles of the water surface were obtained for various conditions of flow, with a view to establishing the actual roughness factor. At high flow the section was quite irregular and the sides were partly concrete, partly timber sheeting and the remainder rock. At low flow the canal was rock throughout and it was thought that under low flow conditions, a fairly accurate value of "*n*" could be computed. It was believed from observations and flow measurements that the roughness factor was probably less than the assumed, but it has not been possible to establish the fact mathematically, owing to certain unknown factors such as the time lag of flow changes between Isle Maligne and Chute à Caron and recovery of velocity head at points of variation in section.

The Tailrace

The theoretical cross-section on wchich the hydraulic studies were based was 50 feet wide at the bottom with side slopes of 1 to 4. This section was sufficiently large to keep the velocity within required limits and allow ample width for excavating purposes. In the central portion of the tailrace a heavy gravel overburden was encountered on the right bank which increased the width of the excavation, as the gravel necessitated flatter side slopes. Under these conditions the grade of the tailrace bottom was raised to partially counterbalance the increase in width, and the resulting tailrace, particularly the central portion, does not bear much resemblance to the theoretical. A typical cross-section is shown in Fig. 1.

Hydraulic studies of the tailrace were carried on simultaneously with those of the diversion canal. A roughness factor "*n*" equals .035 was assumed as it was necessary to give more attention to trimming the side slopes and bottom owing to the fact that this portion of the work was to be the permanent tailrace after the diversion was completed. Studies were made with regard to water levels in the channel during the diversion period for various elevations of tailwater. Due to the extremely high velocities in the tailrace during this period, it was necessary to line the canal with concrete where poor rock or gravel existed. The height to which the lining was carried was fixed by the maximum level the water would reach during diversion. Owing to the the type of lining used and the turbulence of the water, it has been impossible to obtain any information of value with regard to roughness factor. The velocities varied from 50 feet per second at the power house to about 30 feet per second in the lined portion of the canal.

Under operating conditions for full plant load of 18,000 second feet and normal tailwater, the average velocity in the tailrace will be considerably higher than ordinary. The size of the tailrace was limited for reasons purely economical as applied to this particular development

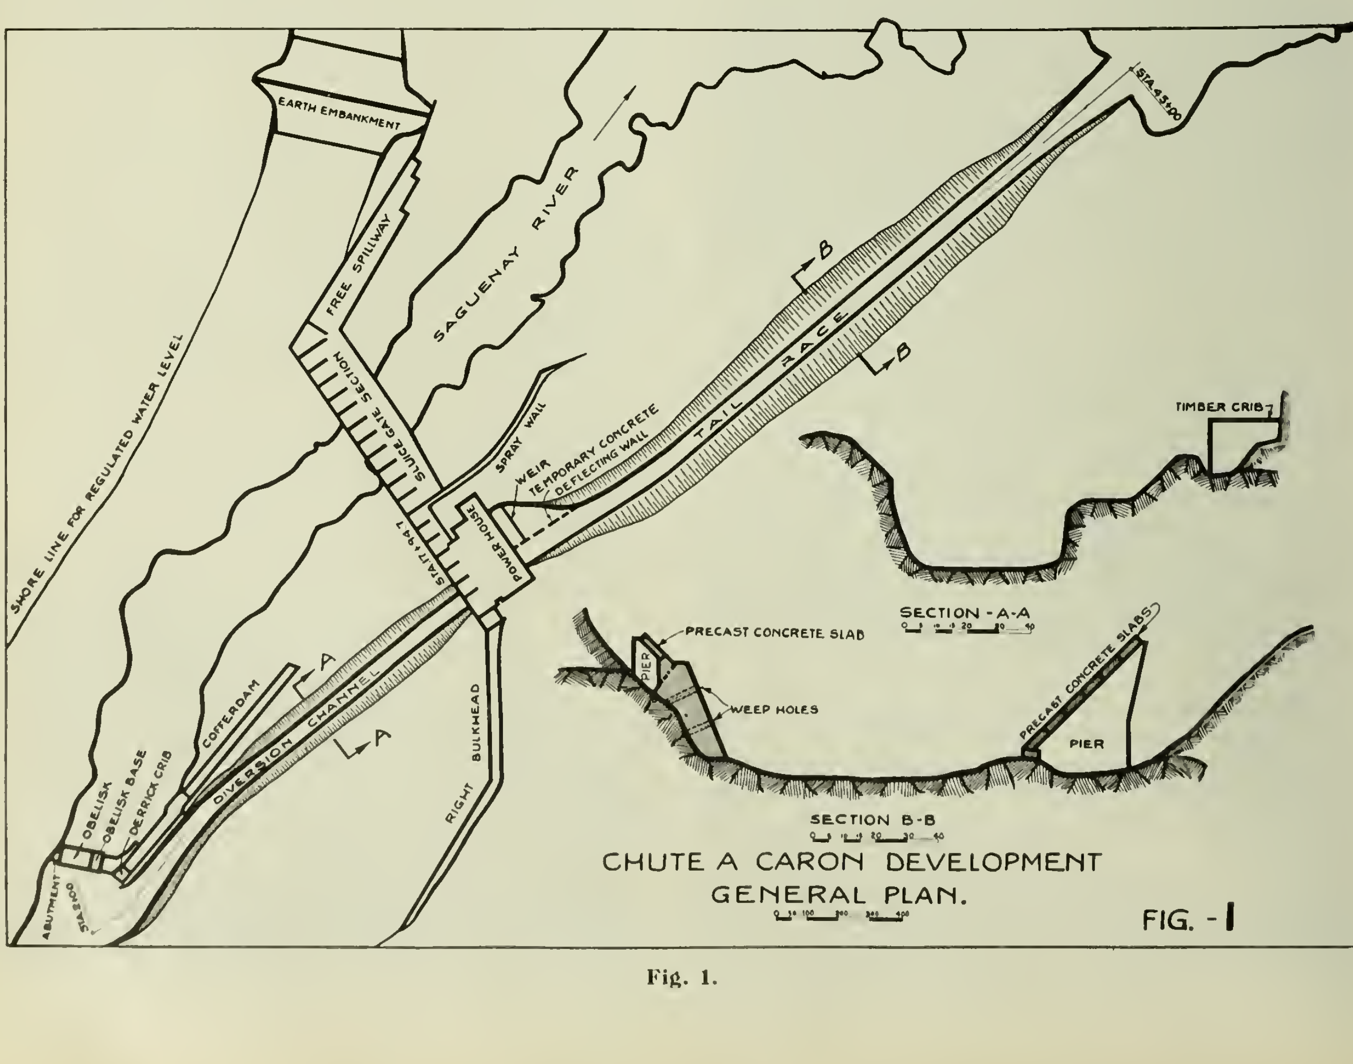

Fig. 1.

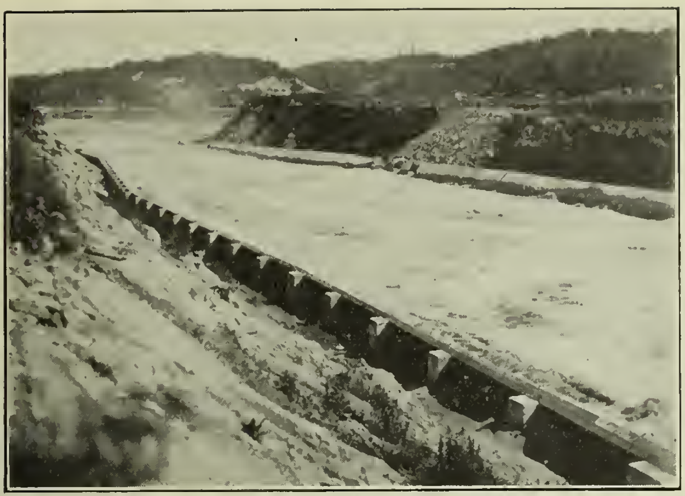

Fig. 2—Slab Displacement in Tailrace due to Gravel Slide.

and which probably would not apply to a development designed to operate under other conditions.

Fig. 1 shows a typical cross-section of the tailrace channel and the concrete lining provided. The rock in the left bank stood at a fairly high elevation throughout, although the quality was poor in places and it was necessary to protect this poor rock from erosion by a concrete slab covering. Weep holes were provided to prevent back pressure, tending to separate the slab from the rock during low flow periods in the tailrace. This portion of the lining was poured in place with the exception of a few precast concrete slabs which were used at the higher elevations. On the right bank the rock was low, with gravel overburden for a considerable portion of its length. This gravel overburden was protected from water flowing at high velocity by precast concrete slabs supported by concrete buttress piers.

The cost of building the lining in place on the right side of the tailrace would have been excessive as it would have necessitated forming the structure on all faces and the concrete quantities involved were small. To reduce the cost of protecting this bank, it was decided to build in place only the piers and low toe wall. The slabs were precast at a location which was easily accessible to the mixing plant, and after completion they were stored for a period of several weeks, and a full supply was available when required for erection. The piers were 3 feet thick, and were spaced at 20-foot centres. The maximum height of pier was about 40 feet. Reinforcing steel was placed in the piers, consisting of three-quarter-inch rods spaced at 18-inch centres both ways, and located 6 inches from the outside faces. Each pier was anchored at the heel by four 1½-inch round rods extending 8 feet into solid rock. The erection of the piers followed closely on the heels of the excavation.

The slabs which span between piers were 19 feet 11 inches long, 8 feet wide and 12 inches thick, and the sides so shaped that a 2-inch wide space existed between slabs when in place, except at the ends. It was assumed that turbulent flow would have practically ceased to exist by the time the water reached the slab structure and that a condition of almost equally balanced pressure would be obtained on the slabs, thus eliminating the necessity for heavy reinforcing steel. Sufficient reinforcing was placed therein only to insure against breakage, when being picked up and put in place by a derrick. Two holes, each 2 inches in diameter, were provided at the end of each slab, extending through its 12-inch thickness, for ease in handling and to facilitate anchoring to the pier. Adjacent to the hole in the slab when in place, a corresponding horizontal hole was provided in the pier and the two were fastened together by means of a three-quarter-inch diameter steel cable through these holes, which was drawn tight and clipped.

After the tailrace had been operating a short time during diversion, some difficulty was experienced with regard to sliding of the clay and gravel bank which caused the loss of a few slabs. This difficulty was overcome by dumping crushed rock on the sloping face of the bank. Fig. 2 shows slabs displaced by a gravel slide and the crushed rock which was placed to prevent further damage.

Several more slabs were lost due to surging in the canal and the cable type anchorage. From observation, it was seen that balanced pressure on the slabs did not exist at all points in the canal, as surges would rush up the sloping face and recede quickly causing practically no disturbance of the water behind the slab. At certain locations where this condition occurred, the punishment to which the slabs were subjected appeared to be increased by the flexible cable anchor. Fig. 3 illustrates the surging of the water in the tailrace.

In all, about twenty slabs were damaged, some of which disappeared. At the end of a month's operation it was decided to close the diversion for two days which would allow inspection of the sluice tube, replacement of the broken slabs and installation of a better type of anchorage for the slabs. The time available to accomplish these repairs was limited and thorough preparations were made for proceeding with the work the moment the sluice tube gates were closed. The missing slabs were replaced and all slabs except those at the extreme top were bolted to the piers by means of 1½-inch diameter anchor bolts and plate washers. When the slabs were designed, a 1-inch space was provided between the abutting ends when in place and this space was utilized for setting anchor bolts which were located on the centre line of the pier face and at approximately the quarter points of the slabs. A rectangular plate washer was then clamped over the ends of the two abutting slabs by means of the anchor bolt. The tension on the bolt was sufficient to prevent appreciable movement in the slabs due to water surges, but still allow slight freedom for expansion and contraction. This work was completed in about one and one-half days and since that time no difficulty has been experienced.

As a matter of fact, the slabs received excessive punishment only at certain points, the location of which varied with the flow and were impossible of predetermination, and it cost much less to replace a few slabs than to reinforce all slabs for heavy unbalanced pressure. On the whole, this construction has been satisfactory and in the light of experience very little change would be made if repeated.

Fig. 3—Flow in Tailrace during Diversion.

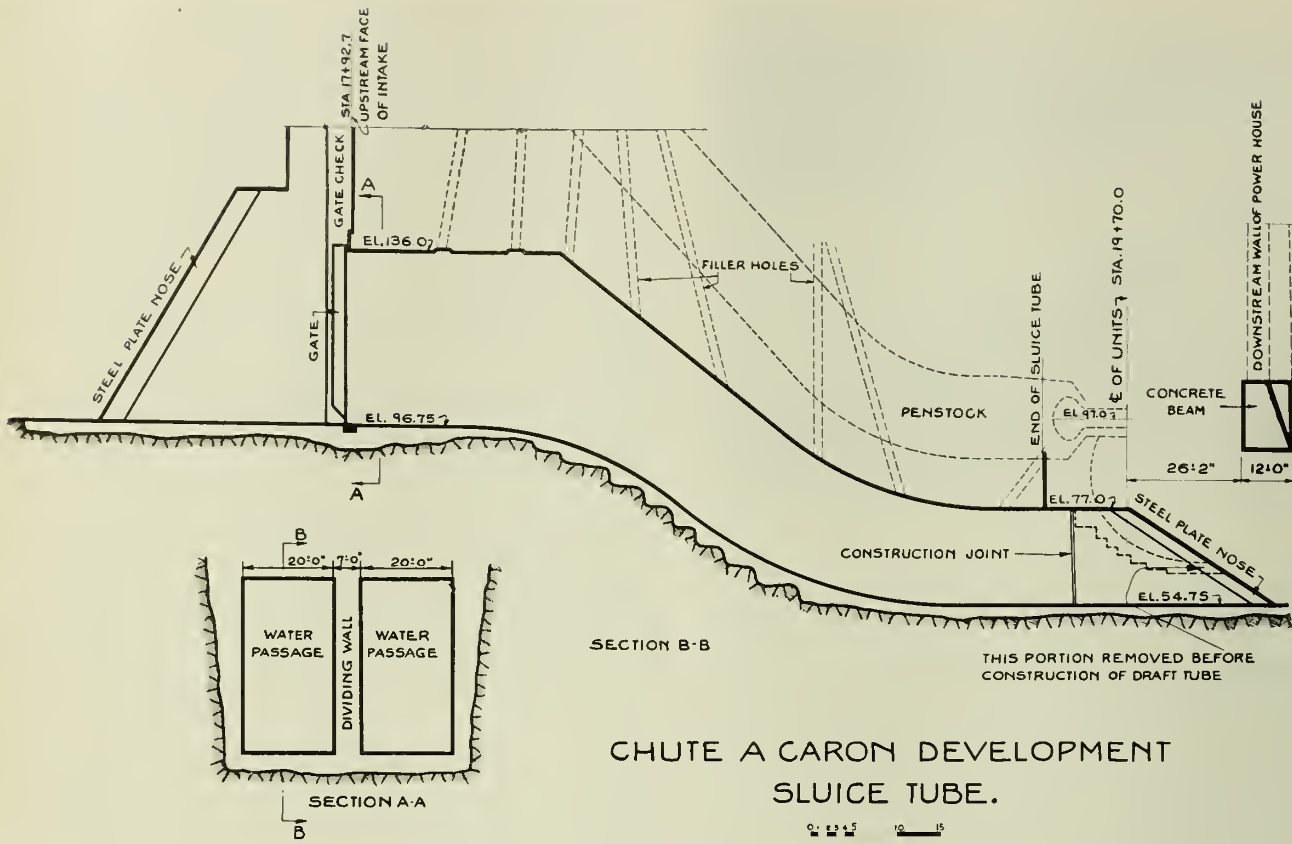

Fig. 4.

The Sluice Tube

The sluice tube, through which the water passed from the diversion canal to the tailrace, is located parallel to No. 1 penstock and under No. 1 generating unit. In the early stages of the design, consideration was given to the idea of excavating a tunnel immediately outside the westerly limit of the power house, but this was discarded for hydraulic and economic reasons. Looking at Fig. 1, it will be noted that the centre line of the sluice tube and the centre line of the tailrace coincide, thus providing direct alignment for high velocity flow.

Numerous hydraulic studies were made of the flow in the diversion canal upstream from the sluice tube, and in the tailrace downstream from the sluice tube, and by means of these studies the heights of the passage-ways were fixed. The elevation of the roof was so fixed that with a discharge of 40,000 second feet the water surface at the entrance would just make contact with the top, while at the outlet the water surface would be several feet below the top of the tube. A hydraulic jump was anticipated, but nothing definite with regard to location or height could be obtained from the computations. As there was very little technical information available on the behaviour of water at extremely high velocities, it was decided that a model should be built in order to verify or refute the computations.

In designing the power house, it was necessary to provide a huge concrete beam spanning the sluice tube at the downstream wall for supporting the columns. This beam was 16 feet deep, 12 feet wide and about 50 feet long. It was located 50 feet downstream from the end of the sluice tube and the bottom of the beam was 13 feet above the top of the tube. A standing wave or jump of any height in this vicinity might seriously damage this beam.

Another point of interest was whether or not an eddy would form in the tailbay and if it would be necessary to provide a temporary deflecting wall between the tailbay and the diversion channel, extending from the downstream power house wall to the throat of the tailbay. (See Fig. 1.)

The model was built of timber in several sections, in the carpenter shop at Chute à Caron, and installed at the foot of the dam adjacent to the Isle Maligne power house, immediately below the trash sluice gate, in the fall of 1928. The model was one-eighteenth full size and was hydraulically similar to the prototype. The length of the model was sufficient to reproduce about 200 feet of diversion canal, 180 feet of sluice tube, and 300 feet of tailbay and tailrace.

The cement mortar lining of the model of the diversion canal and tailrace was roughened before it had received its permanent set, in order to reproduce as closely as possible the friction co-efficient of the rock, and the sluice tube section was cement mortar lined with a smooth finish, with the exception of one side. This side was composed of very heavy plate glass in order that the conditions of flow in the tube might be plainly seen and measurements taken at any point under varying conditions of discharge. At the lower end of the tailrace section, a stilling box and measuring weir were installed. This consisted of a box about 5 feet deep tapering from tailrace width to a width of 8 feet at its downstream end. At the downstream limit of the stilling box, a sharp crested weir and staff gauge were installed. The stilling box contained a system of baffles which reduced the velocity and distributed the flow evenly over the crest of the weir. The velocity of the water was reduced at the entrance to the diversion canal at the foot of the dam by a similar system of baffles.

The model results verified the computations with regard to the water levels at the upper and lower ends of the sluice tube. In addition, it proved beyond a doubt that there would be no hydraulic jump in the vicinity of the beam in the power house wall, except under conditions of very low flow, at which time the jump was small and did not approach the beam. The model also clearly demonstrated that a dividing wall in the tailrace parallel to the canal between units 1 and 2 was essential to prevent an eddy in the tailbay which would seriously decrease the discharge.

It was interesting to note that for low flows, the water rolled back on itself inside the tube near the lower end and with the flow around 5,000 to 8,000 second feet, this backroll pounded the roof of the tube and caused considerable vibration in the model. At the opening of the gates in the power house, the first time water was passed, the same condition existed and although no vibration was noticeable, considerable pounding could be heard until the flow had increased beyond this stage.

At the higher stages of flow in the model, the backroll or standing wave was swept outside the sluice tube into the open canal and the distance downstream of the point at which the standing wave existed varied with the flow.

Inside the tube in the prototype, the flow was fairly smooth, with slight evidence of surging, except at very low stages, when the backroll occurred. For a distance of about 300 feet from the exit the water was relatively smooth considering the velocity at which it travelled. From this point downstream it was very turbulent for several hundred feet to a point where it passed through a transition stage somewhat resembling a hydraulic jump and then became fairly smooth. Fig. 5 shows water surface profiles for two conditions of discharge.

The sluice tube forms part of the power house substructure and is composed of two water passages separated by a concrete dividing wall 7 feet thick. This wall extends 55 feet upstream from the entrance, tapering to a very thin pier nose made of steel plate. At the downstream end it extends 50 feet past the exit, with a similar type of pier nose. An elevation of this wall may be seen in Fig. 4. The upstream and downstream extremities of the wall were designed to offer a minimum of obstruction to flow.

The sluice tube openings were each controlled by a Stoney gate at the entrance. Each gate was approximately 41 feet high and 21 feet 6 inches wide and weighed 72 tons. The gates were suspended from brackets set in the concrete above and operated by a system of sheaves and cables from a double drum winch located on the deck of the dam, about 200 feet distant. They were held in continuous suspension and might be raised or lowered on a few moments notice. The bottom of each gate was tapered to a thickness of about 1 inch at the downstream face, and satisfactory results were obtained while operating in a semi-closed condition, the vibration being negligible.

The water passages are each 39.25 feet high and 20 feet wide at the upper end, tapering to 22.25 feet high and 17.75 feet wide at the exit. Advantage was taken of the fact that the exit could be made smaller than the entrance, due to the increased velocity of the water at the former point. The smaller dimensions at the lower end enabled the building of the sluice tube without increasing the centre line distance between units 1 and 2. The taper also was advantageous in that when the sluice tube was plugged after closure, any movement in the plug would tend to close the joint due to its wedge shape.

The sloping bottom of the sluice tube is similar in shape to a rollway crest on a dam, the concrete projecting well into the under side of the waternappe. For a discharge of 40,000 second feet, the velocity at the upper end is about 30 feet per second, and at the lower end 50 feet per second. The tube has never run full at the lower end even for discharges of well over 40,000 second feet. For the latter discharge, the upper end seals just at the entrance but the water surface quickly drops away and at no time has the top of the tube been under hydrostatic pressure.

After several months operation during the summer and early fall of 1930, the gates were closed for two days and an inspection of the water passages made. No evidence of erosion of the concrete was noticeable and even timber fillers which had been bolted in the keyways on the sides were still in place with the exception of one piece. On December 20th, 1930, however, after the final closure of the gates, it was noted that some parallel grooves of about one-half inch depth existed on the bottom of the sluice tube in the vicinity of the crest. Due to the fact that these grooves existed only on the bottom, it was thought that they were probably caused by the passage of solid matter, such as small and large rocks, the greatest of which would probably weigh some thousands of pounds. For a period of several weeks before final closure, the water level in the diversion channel upstream was very high, which caused a slight amount of sliding of material from the banks and undoubtedly the major portion of this material passed through the sluice tube due to the high velocities in the diversion channel. There was no means of estimating the quantity of this material, but it probably was in the neighbourhood of from two to five thousand cubic yards.

Layout and Manipulation of Cofferdams

Fig. 1 shows the layout of the main cofferdams. A cofferdam 800 feet long was built between the river and the diversion canal and lying parallel to them. At the point where this cofferdam formed a foundation for the derrick crib, two branches were constructed, one of which extended across the entrance to the diversion canal, while the other extended part way across the river to the "obelisk" base. The former extension is not shown on the general plan as it was removed immediately after the completion of the excavation in the diversion canal.

That portion of the cofferdam lying downstream from the derrick crib and the branch across the entrance to the diversion canal was built in the fall of 1929. This was

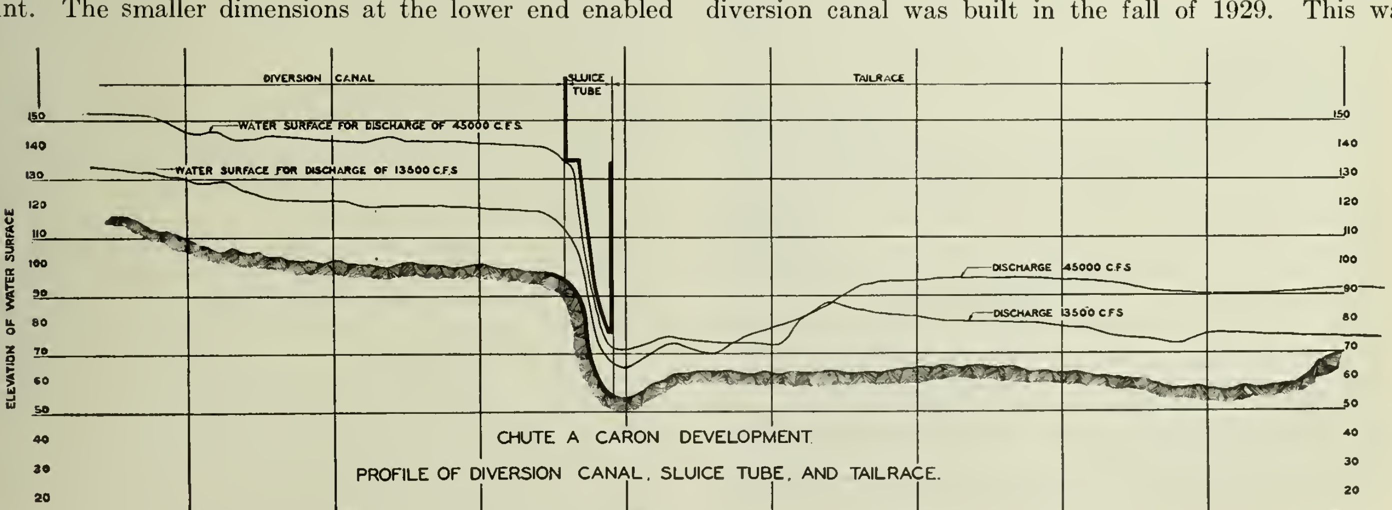

Fig. 5.

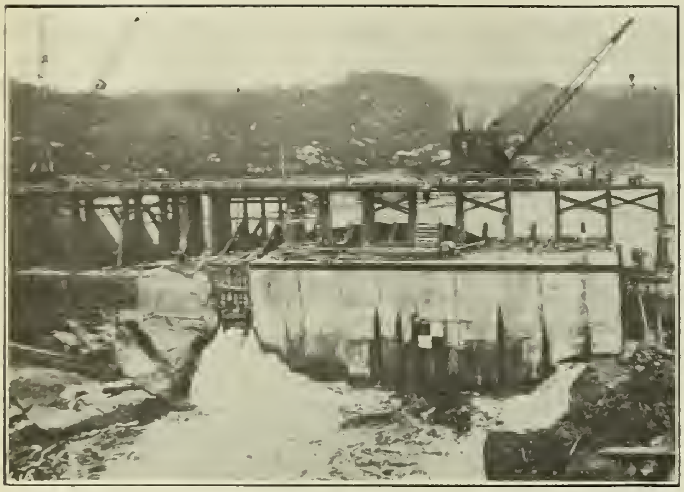

Fig. 6—"Obelisk" in final Position during Construction of Trestle.

necessary in order that the canal might be excavated in the dry, and to provide a track for transporting material to the "obelisk" during its construction. In addition, it was necessary to keep in mind that there must be a minimum of obstruction to flow in the river channel during the spring flood of 1930. As a result of these requirements the cofferdam from the derrick crib to a point downstream 300 feet distant was built to elevation 140, while the remaining 500 feet was carried to elevation 165, which was computed to be above maximum high flood level. Crest elevation 140 was decided upon to satisfy two conditions, namely: it was low enough to allow overtopping during flood periods and thus not unduly obstruct the flow, and it was sufficiently high to be above water level in the diversion canal during low week-end flows.

The Saguenay river was a very difficult stream to cofferdam, particularly in the vicinity of Chute à Caron, as the river channel is comparatively narrow with deep, swift water. The impracticability of constructing the ordinary type of rock-filled timber crib cofferdam in the deep section under such adverse flow conditions led to the development of the "obelisk." In this paper the author will give only a brief outline of the work connected with this huge concrete block. A full account of the design and construction of the "obelisk" is given in a paper by C. P. Dunn, M.E.I.C., chief engineer of the Alcoa Power Company Ltd., in the December 1st issue of "Civil Engineering," published by the American Society of Civil Engineers, New York.*

The method of final cofferdam closure was based on the assumption that the "obelisk" would act in accordance with the computations of design, and that it did so act is clearly indicated in Fig. 6, which shows it in its final position. It came to rest within a fraction of an inch of its computed location and practically no cracks in the block were noticeable.

In the spring of 1930, the river channel was obstructed by the east shore abutment, the "obelisk" pier, the derrick crib and 300 feet of cofferdam immediately downstream from the derrick crib, which was built to elevation 140. For a period of about two months, with the exception of a few days when the discharge from Lake St. John was kept low to enable work to be done at Chute à Caron, the cofferdam adjacent to the derrick crib and the east shore abutment were overtopped from 12 to 16 feet, and no noticeable damage occurred to these structures during that period. The east shore abutment was concrete, while the 300 feet of cofferdam adjacent to the derrick crib was a rock-filled timber crib with concrete caps. The sides of this cofferdam were vertical and the outer vertical surfaces inside the cribbing were concreted to a thickness of 3½ feet. The crest was protected with an 18-inch thick concrete slab placed on top of the rock fill. The top slab provided a smooth surface for the overflowing water as well as a good foundation for the railway trestle which was constructed thereon, and which will be described later.

In years of normal precipitation, the Saguenay river high flow reaches its peak about May 20th, and is down to normal flow about June 15th. The spring and summer of 1930 were not normal in the Lake St. John district. The spring flood was much lower than usual and of short duration, due to the light snowfall during the winter and lack of spring rains. Owing to the unusually low flow during May, there appeared to be a good possibility of tipping the "obelisk" in the latter part of June, which would have made possible the completion of the river section of the dam, with the exception of two blocks, before the fall flood. During the week-end immediately preceding June 18th, construction of the railway trestle previously mentioned was begun, which, when completed would extend from the upstream end of the 165 cofferdam over the 140 cofferdam, the "obelisk" and to the east shore abutment. At this time the trestle could not be completed, as the "obelisk" was still in its vertical position, but was constructed to within a few feet of the "obelisk" pier. The cofferdam, "obelisk" and east shore abutment formed the foundation for the trestle and the sills of the bents were firmly anchored to these structures. The elevation of the bent sills was about 140, throughout, and the base of rail was at elevation 165. The bents were made of 12-inch by 12-inch timber posts with 12-inch by 12-inch sills and caps, and were spaced 13 feet 6 inches centres. The trestle bents not only provided means for transporting material for sealing the "obelisk," but in conjunction with low intermediate bents spaced midway between, formed the support for a timber bulkhead which extended from elevation 140 to elevation 152. The bulkhead was necessary to prevent water overtopping these low structures and flooding out the work in the river section of the dam during a diversion of 40,000 second feet through the canal, because with this condition of flow the water in the canal stood at about elevation 150.

It was necessary to design the bulkhead in such a manner that it could be easily and quickly put in place during the low week-end flow when the crests of the 140 structures were dry. The bulkhead supports were sloped at 45 degrees with the vertical, and the bulkhead was composed of 8-inch by 8-inch timber needles standing on end, side by side, and supported by 12-inch by 12-inch horizontal stringers, which in turn were supported by the trestle and intermediate bents. These 8-inch by 8-inch timber needle beams, of which there were about eight hundred, were not fastened together nor held in place except by water pressure, and for ease in removal, "U" straps were bolted to their upper ends by means of which the railway crane could pull them out while the water stood against them. Canvas was placed over the top of these needles and a very watertight job was obtained. All bents were sheeted on both sides to elevation 154 to provide a smooth surface for the water passing between them when the needles were not in place.

After the completion of the trestle to the "obelisk" pier, flow conditions were such that it was decided to postpone the tipping of the "obelisk" until July. The water level in Lake St. John at this time was near its upper limit but was being lowered slowly by discharging about 170,000 second feet. Any further obstruction in the river channel at Chute à Caron, such as the "obelisk" in its final position, would have seriously decreased the discharge capacity of the river and thereby increased the length of time required to lower the lake for storage purposes. Sufficient lowering of the lake had been accomplished by July 20th, to insure a period of about eight days during which time the flow could

*See also "Engineering Journal," October 1930, page 598.

Fig. 7—"Obelisk" and Pump Crib during Sealing Operation.

be limited to such an extent that it would not overtop the "obelisk" in its final position, and it was decided to take advantage of this period to tip the "obelisk," erect the trestle thereon, and obtain additional information regarding the river bottom.

The "obelisk" was tipped July 23rd, 1930. Work was begun immediately on the closure of the openings at the ends of the "obelisk" and the extension of the railway trestle over the "obelisk," to the east shore abutment. Although no attempt was made to completely seal the cofferdam during this period, the leakage was relatively small (see Fig. 7), which made it possible to extend the main dam toward the river channel a distance of 27½ feet past the previous limit. At the end of eight days the discharge from Lake St. John was increased and the flow allowed to pass over the cofferdam into the river channel

From August 1st to September 1st, flows varying from 70,000 to 100,000 second feet passed Chute à Caron, about 40,000 second feet of which flowed through the sluice tube. The remainder spilled over the cofferdams, through the trestle bents to a depth of about 12 feet without serious damage to the latter, with the exception that two intermediate bents were torn away. One hundred thousand second feet was about the maximum discharge that could be accommodated at this time without serious damage to or loss of the railway trestle. Fig. 8 shows the water passing through the trestle with a river discharge of 80,000 second feet.

On September 1st, the needle beams were installed, as the lake had been drawn down about 3 feet, although the inflow was sufficiently above the discharge to allow a working period of only about fifteen days. The cofferdam in the vicinity of the "obelisk" was sealed at this time. It was thought that this period would allow sufficient time to do the necessary excavation in the deep portion of the channel and allow the placing of a full block of concrete 55 feet long in the main dam to an elevation above interference from the water when it would again be turned into the river. At the beginning of this period, about four days were employed sealing the "obelisk," installing secondary cofferdams, a flume and a battery of pumps to dry the river bottom. When this work was completed, excavating on one side of the river bottom and placing concrete in the 55-foot block on the other side were carried on simultaneously. Owing to a seam of poor rock, which entailed the excavation of some thousands of yards, this part of the work was not wholly completed before the water was again turned into the old river channel, September 16th. One block of concrete, however, had been carried above water level and was continued to the top during the remaining part of September.

While the needle beams were being installed and the cofferdam sealed at the beginning of this closure period, a low cofferdam was constructed across the river about 400 feet downstream from the main cofferdam. The idea was to form a pool from which leakage through the main cofferdam would be handled by a battery of pumps discharging into the diversion canal. Due to an excessive leakage of about 85 second-feet through a rock seam under the cofferdam lying downstream from the derrick crib it was found necessary to build a second low cofferdam immediately upstream from the face of the main dam. Thus two pools were formed, the excess flow over pump capacity in the upper pool spilling into the lower. From the lower pool the leakage was carried by a small timber flume extending across the area of the main dam and discharged at a point several hundred feet downstream.

The final cofferdam closure took place October 4th, at which time there remained to be completed about 155 feet of main dam. Construction was carried on rapidly on both sides of the river extending out toward the centre. By the time the small timber flume began to interfere with the placing of concrete, a small tunnel through the dam about 7 feet by 4 feet had been provided, the flume was dismantled and the water by-passed through the tunnel. Pumping was discontinued at once as the tunnel had ample capacity to handle all leakage. The tunnel entrance was provided with a closure gate which was dropped in place and sealed when the concrete in the last block reached elevation 150. A concrete plug 15 feet long was placed in the tunnel behind the gate by means of filler holes extending through the roof at elevation 150, and after the tunnel was sealed concreting operations on the last block were continued to completion.

Immediately after the final closure of the dam, the control gates in the sluice tube were dropped. During the period required for the water in the forebay to rise from elevation 150 to elevation 210, the crest of the rollway, no flow passed down the river below Chute à Caron. This period was utilized to construct a cofferdam in the tailrace a few feet downstream from the throat of the tailbay. The cofferdam was built to keep the tailbay dry during the erection of the substructure in No. 1 unit, and the extension of the tailbay weir.

The substructure for No. 1 unit was carried to such a height as to form a bulkhead at the exit end of the water passages of the sluice tube and from this point the filling of the sluice tube openings was carried on simultaneously with the concreting operation at No. 1 unit.

Concrete was placed in the sluice tube openings by means of 2-feet square filler holes (shown in Fig. 4) extend-

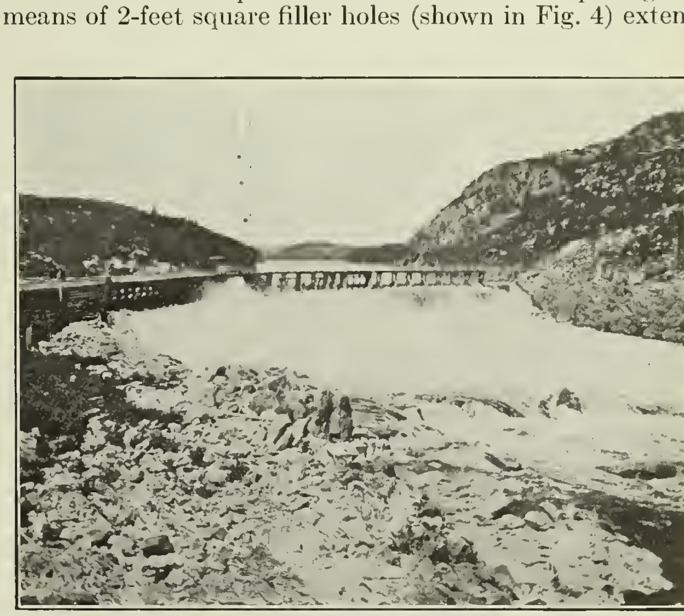

Fig. 8—Water passing through Trestle with River Discharge of 80,000 c.f.s.

ing upward from the roof of the sluice tube and converging to a common point on the downstream face of the intake. A hopper was built over the entrance to these openings, into which concrete was dumped from buckets operated by a traveller and from this point the concrete dropped almost vertically into the sluice tube. It was vibrated and spaded into place until the openings were completely filled. The concrete was then allowed to take its set after which grout was applied under pressure to fill up any space which might exist, due to shrinkage. No attempt was made to salvage the sluice tube gates because the cost of removal would have exceeded their salvage value.

When the substructure of No. 1 unit had been completed to elevation 90, which was 3 feet above normal tailwater, and the downstream face of the No. 1 draft tube sealed by means of the draft tube needle beams, the interesting and very often troublesome problems of diversion were things of the past. No combination of conditions with regard to flow could thereafter cause damage or delay, and the structure was carried to completion without further worry from this source.

No difficulties of any importance were encountered during the construction and operation of the diversion and the essential features of this scheme would be retained were it necessary to accommodate like conditions at any future development.

Personnel

The design and construction of the Chute à Caron project was undertaken by the Alcoa Power Company Ltd., a subsidiary of the Aluminum Company of America. Of the former company, C. P. Dunn, M.E.I.C., is chief engineer, I. G. Calderwood, general superintendent of construction, I. E. Burks, concrete technician, and the author, chief designing engineer.

James W. Rickey, M.E.I.C., chief hydraulic engineer, J. P. Growdon, assistant chief hydraulic engineer, T. J. Bostwick, electrical engineer, all of the Aluminum Company of America, and W. S. Lee, M.E.I.C., are serving as consulting engineers.

Arthur Surveyer, M.E.I.C., of Montreal, Canada, is collaborating engineer.

The Manufacture of Insulating Board at Donnacona, Quebec

Dr. John S. Bates, A.M.E.I.C.,
Executive and Chief Chemist, Price Brothers and Company Limited
and
A. A. MacDiarmid, M.E.I.C.,
Chief Engineer, Price Brothers and Company Limited

Paper presented before the Quebec Branch of The Engineering Institute of Canada on May 7th, 1930.

SUMMARY.—This paper gives a general account of the benefits derived from insulating materials and the use and properties of some that are at present manufactured into a product suitable for thermal insulation and sound absorption purposes in buildings. Particular reference is made to a board manufactured at the mill of Price Brothers and Company, Ltd., at Donnacona, Que., built under the authors' supervision, where sawmill waste and culled wood from paper mills is utilized and manufactured into a fibre board with high insulating properties. A general description of this mill is given, and also a sketch of the various processes in the manufacture of this interesting wood product.

Buildings in Canada are in special need of thermal insulation by reason of our extremes of climate. The public are taking an increased interest in the application of insulation, and there are complete research facilities for the study and development of insulation needs. Canada possesses a wide variety and an abundant supply of raw materials suitable for insulating products and industries are already established to meet the growing need for these products.

Thermal insulation means resistance to transfer of heat thereby offering protection to heat or cold. The fact has been established that the best practical means of obtaining the insulating result is to provide minute, still air spaces not subject to convection currents. In general it may be said that most organic materials of cellulosic composition are more or less equivalent in inherent heat conductivity and are fairly good natural insulators. The manufacture of an insulating product is largely a proposition of disintegrating these cellulosic raw materials into fibrous form and working them up into a porous board or felt for the purpose of producing a large proportion of these minute air spaces. The low density or lightness of the product is therefore a fairly good indication of the insulating quality although the distribution of the air spaces is a vital factor. For instance, dry solid wood weighing 25 to 30 pounds per cubic foot has a heat conductivity of about 1 (in terms of B.t.u's heat transfer per square foot per inch of thickness per degree F. temperature difference per hour), while disintegrated wood fibre in the form of insulating board weighing 15 pounds per cubic foot has a heat conductivity of about 0.33; in other words, the increased proportion of still air spaces has improved the insulating effect threefold with half the weight of material. From the economic point of view it should be noted that one pound of wood material manufactured into artificial lumber in the form of modern insulating board accomplishes six times the insulating effect of the same wood in the form of ordinary lumber.

The mechanics of heat loss in a building has been a subject of considerable study in recent years. The natural tendency for heated air to rise has directed particular attention to roof construction and it is now usually considered that about 50 per cent of the insulating requirements in a house should be provided in the roof. An interesting point is that better roof insulation allows wider scope in style of roof construction and during our Canadian winters by preventing the melting of snow automatically increases the protection during the coldest weather. The outside walls of the building also require adequate insulation to protect against wind and ordinary radiation. Limiting factors of windows, doors and other areas of heat transfer or air infiltration establish a balance making it unnecessary to carry building insulation beyond a reasonable degree. A fortunate factor in connection with building insulation is that the very means which protect our houses from cold weather during winter also guarantee coolness and extra comfort during summer and incidentally preserve quietness by keeping out sound.

The term "insulation" is sometimes also applied to sound absorption and there is a connection between sound insulation and heat insulation. Sound absorption however depends more on surface characteristics, the roughness of fibrous surface and the porous nature of the material creating friction to the air sound waves. New building materials are finding an important place in talking picture theatres, auditoriums, restaurants, offices, etc. for improved acoustics, and special materials are being used more extensively in partitions and walls for sound deadening between rooms of buildings.

Fig. 1—General View of Donnacona Insulating Board Mill.

One inch of wood fibre insulating board has a thermal insulation value equal to approximately 3 inches of lumber, 12 inches of brick or 25 inches of concrete. Reasonable structural strength is needed in insulating board and is well attained by the use of wood fibre. At the same time, the insulating board is manufactured in such a way as to give uniform strength in all directions, thereby eliminating the grain and inequalities of wood. Manufacturing from fibrous raw material also lends itself to special treatments which are impossible with natural building materials. Waterproofing of the fibres is a very valuable result in order to obtain as much protection as possible against humidity and moisture with their tendency towards expansion and contraction of the board. A porous material is naturally difficult to waterproof butwood fibre insulating board can be made more resistant than lumber to moisture absorption when immersed in water. Rotproofing is another desirable treatment to protect vegetable fibre boards from slow decay and thorough treatment can be easily accomplished during the course of manufacture. Absolute fireproofing is almost impossible with organic materials but fire-retarding properties would seem to be most logical for building materials in general. At the present time, there is no insistent demand for the fireproofing of insulating board on account of the quantities of wood and other combustible materials used in ordinary building construction, but it is the desire of insulating board manufacturers to meet the call for increased safety by fireproofing treatments which will give reasonable protection. The colour of the board is a factor for certain uses and the natural wood colour of wood fibre insulating board meets with public favour. Surface finish is another consideration of increasing importance and flexibility of manufacture makes it possible to produce a variety of pleasing surface finishes. The convenience of uniform dimensions of insulating board to suit standard building requirements, large sizes for easy handling, definite thicknesses to meet particular requirements and general control of packaging and distribution are commercial factors which represent improved service to the public.

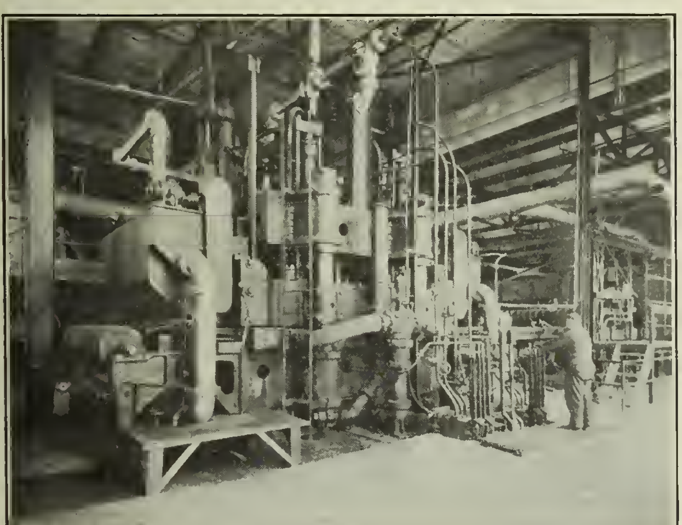

Fig. 2—View of Forming Machine.

Considering the fairly recent development of special insulating materials for building construction it is rather surprising to note the wide variety of products on the market and the extent to which they are used. Rigid insulating building boards are made of vegetable fibre raw materials, such as wood fibre, bagasse or sugar cane, licorice root fibre, cornstalks, etc. Other building boards, such as gypsum, stress fireproofing and smooth finish rather than insulating properties. Cork board is an example of a good insulating product which has practically no virtue as a structural material. Flexible insulation sacrifices structural strength for improved thermal insulation value, the better-known products consisting of dried eelgrass, a blanket of wood fibre between two layers of paper, a blanket of hair felt, a semi-rigid board of flax straw, etc. Loose insulation also finds a place in the air spaces of partitions, and includes wood fibre, gypsum, asbestos mixture, magnesia, diatomaceous earth, slag wool, etc.

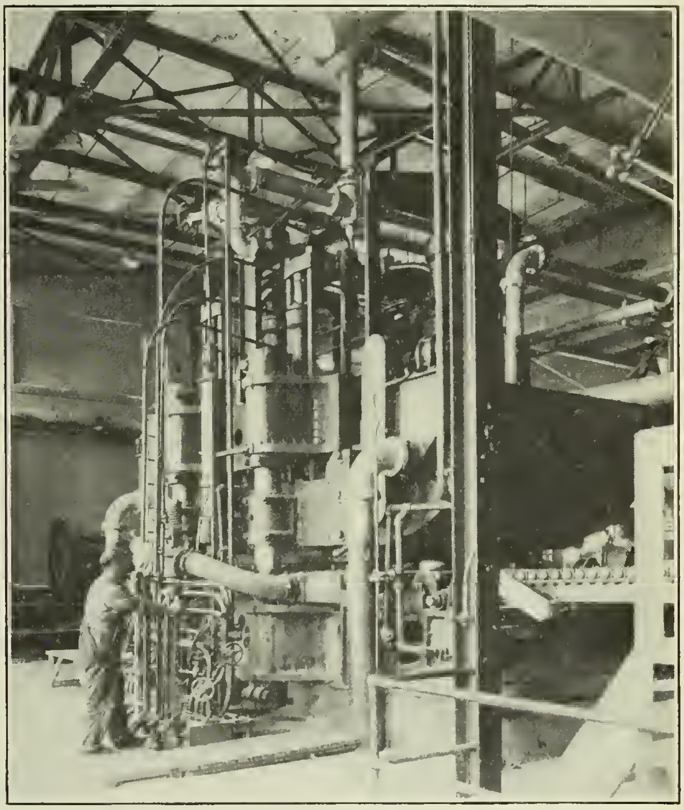

Fig. 3—Forming Machine showing Arrangement of Platens and Hydraulic Press.

As an example of modern methods of manufacture of insulating board, the processes employed at the recently constructed Donnacona mill will be described briefly.

The rated daily capacity of the Donnacona mill is 150,000 square feet on a ½ inch basis.

Fig. 4—Section of Roller Dryer.

The manufacture includes four operations, namely:
1. Preparation of fibres.
2. Forming the fibres into sheets of lumber.
3. Drying.
4. Sawing the lumber into commercial sizes.

1. Preparation of Fibres

The raw material consists of saw-mill slabs and edgings, planer mill shavings, short blocks, and dark or discoloured wood which is unfit for use in paper making, and the coarse fibres rejected in the screening operations in groundwood pulp mills.

The slabs, edgings and blocks are first reduced to chips or chunks of wood by passing them through a suitable type of "hog." This material, with the shavings and groundwood screenings, is then fed to special refiners of different types and reduced in these machines to a mass of fibres of varying size and having a fairly definite viscosity and freeness.

After the refining operations have been completed, various chemicals are added to make the board fire-resisting, water, vermin and rot-proof, and, when these have been thoroughly mixed and the solution adjusted to a definite consistency, the preparation of the fibres is complete.

2. Forming the Fibres into Sheets of Board

The mixture, when ready for forming into sheets, consists of approximately ninety-seven and one half per cent water and two and one-half per cent fibre, that is, the consistency is two and one-half per cent.

The forming machine is a large hydraulic press with platens or pressing surfaces set in a horizontal position. The machine weighs 210 tons and forms a sheet of lumber approximately 8 feet wide by 13 feet long, and in thicknesses from ½ inch to 2 inches.

The bottom platen is stationary, while the top platen is movable vertically and has surrounding it a cast-steel frame (known as a deckle) which also moves vertically and independently of the platen. This deckle is so designed that it makes a water-tight seal with the edges of the top platen and the top of the bottom platen.

Resting on the bottom platen is a fine mesh bronze wire cloth which is wrapped around metal rolls, one at each end of the press. The roll at the discharge end is driven with a motor.

Attached to each end of the cast-steel deckle is a large metal tank or reservoir for holding a quantity of the mixture of fibres and water.

The operating cycle of the machine is as follows:

(1) The top platen is set at a given distance above the bottom one, this distance being determined by the thickness of the sheet to be made.

(2) The mixture of fibres and water is admitted to the head boxes.

(3) The deckle is lowered until it rests tightly on the fine wire cloth which, in turn, is resting on the bottom platen.

(4) The mixture, of definite consistency, is then allowed to flow through gates in the sides of the head boxes and deckle to the space between the two platens and on top of the wire cloth.

(5) Pressure is then gradually applied to the 4 main pistons on the top platen and, as this is done, the water in the mixture is forced out through holes in the platens and to a storage tank. Vents are also provided in the sides of the deckle to allow any entrained air to escape.

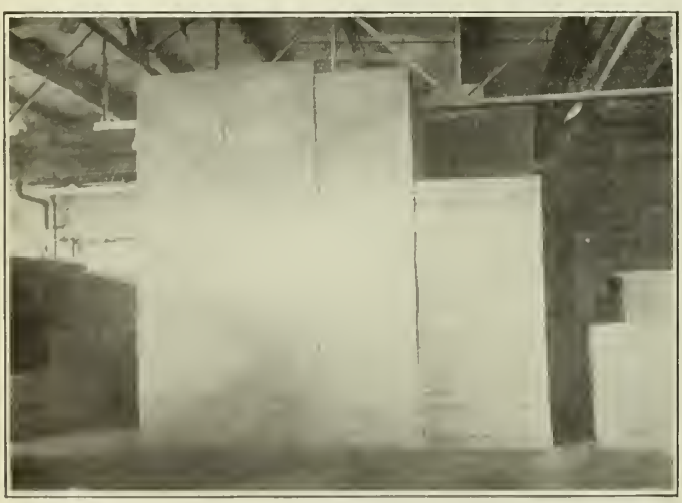

Fig. 5—Board Ready for Packing.

Fig. 6—Insulating Board Packed Ready for Shipment.

(6) The hydraulic pressure (which is 1,500 pounds per square inch) is held on the platen for a definite number of seconds and then released. This hydraulic pressure gives a pressure on the lumber being formed of about 125 pounds per square inch. Afterwards the deckle and top platen are raised and a wet sheet of lumber of a definite thickness remains on the wire cloth.

(7) The motor on the wire cloth roll is put in motion. This forms a conveyor belt of the wire cloth which carries the sheet of lumber out of the press and discharges it on a roller transfer table.

(8) The travel of the wire cloth is then reversed and on its return to the original position the cycle of forming a sheet of board is complete.

3. Drying

The machine used for this operation is known as a roller dryer and consists essentially of a large number of tubular rolls about 3 inches in diameter, spaced closely together horizontally and arranged in eight decks or tiers, one directly above the other. Under each deck of rolls there is fitted in sections a continuous layer of 1-inch return-bend steam coils.

The rollers are all fitted with a central chain drive and the entire apparatus is enclosed in a completely insulated steel casing which is about 300 feet long, 15 feet wide and 15 feet high.

An arrangement of fans and air ducts circulates air through the entire dryer and when this air becomes laden with moisture it is discharged to a heat reclaiming device.

The sheets of lumber are discharged from the transfer table at the forming machine to an automatic push-button-controlled elevator which, in turn, delivers them to each deck of the dryer in proper rotation.

As it requires not less than 3 hours to dry ½ inch thick lumber, the movement through the dryer is comparatively slow—about 1 to 1.5 feet a minute. In order to dry at this rate, a steam pressure of 125 pounds has to be used in the coils and the maximum air temperature in the dryer is held at about 320 degrees F.

4. Sawing the Lumber into Commercial Sizes

After the lumber passes out of the dryer it is conveyed to an automatic saw table that trims the sheets and cuts them into commercial sizes without the aid of attendants. The lumber is then carefully inspected, sorted, graded, wrapped and packed in crates of convenient size for shipment.

VOLUME XIV MARCH 1931 No. 3

The Development of the Aero Engine

Many technical societies commemorate by an annual lecture the life or achievements of some eminent engineer or man of science, after whom the lecture is named. This admirable custom brings yearly to remembrance the career and work of the man in whose memory the lecture is given and affords an opportunity of presenting an authoritative account of progress and recent accomplishment in some special branch of engineering, on which the lecturer is a recognized authority. It is to be regretted that in Canada we have as yet no foundation of this nature, but in Britain and the United States there are several, and the benefits of these discourses to the society and to the engineering public are very evident.

As an excellent example of such lectures we may take the recent Wilbur Wright Memorial Lecture of the Royal Aeronautical Society, an event of international interest. It was founded eighteen years ago as a memorial to the first man who achieved controlled power-driven flight in a heavier-than-air machine.

Last year, recognizing that the internal combustion engine made flight possible as we know it to-day, the Society chose as lecturer a pioneer in research on engines of that type, H. R. Ricardo, F.R.S. Taking as his subject the development of the aero engine, the lecturer discussed recent progress, particularly since the war, and pointed out that the aero engine of to-day is not only an extremely light and efficient prime mover, but also possesses in a high degree that quality of first importance, reliability. Advance during the past twelve years has been remarkable, and during that time the average output of aero engines of given cylinder capacity has been increased by no less than forty per cent, this result having been obtained partly by increasing the rotative speed and partly by increasing the available mean effective pressure, the latter feature having been made possible by a steady improvement in the quality of the fuel available. Mr. Ricardo has himself taken a leading part in research on the latter point and has been particularly associated with the investigation of the phenomena of detonation in engine cylinders. A few years ago hardly anything was known regarding the behaviour of different hydro-carbon fuels, the suitability of gasoline for engine use was judged merely by its specific gravity; no distinction was made between detonation and pre-ignition, and the engine designer was blamed for the troubles which accompanied any increase in speed and compression ratio. Research soon showed that detonation was not a form of pre-ignition but depended primarily upon the composition of the fuel, because some of its constituents, such as benzol and toluene, were found to cause less detonation than other hydrocarbons present. Then came the discovery of the efficacy of certain metals in suppressing detonation and the recognition of the beneficial effects of small doses of metallic dopes, such as lead tetra-ethyl.

Speaking of the concurrent development of both air-cooled and water-cooled types of engines, Mr. Ricardo considers that the obvious advantages of the air-cooled engine as regards lightness, simplicity and freedom from damage by frost, are largely out-weighed by disadvantages which are not so apparent at first sight. Thus, the advantage gained in the way of reduced weight is more than offset by increased head resistance, and in order to obtain effective cylinder cooling without local overheating at any point, the air-cooled engine has to expend more energy in cooling itself, besides requiring more lavish lubrication and working at a somewhat lower efficiency. The question of air versus water cooling, however, is still unsettled, and it is significant that much attention is now being paid to the use of steam cooling for radiators, and the employment of fluids other than water, having a lower freezing point and higher boiling point.

The improvement due to increase in compression ratio seems to have neared its limit, so that further progress in aero-engines of the present generally accepted type must be obtained by increasing the weight of air taken into the cylinder. This can, of course, be done by increase in speed, but this gives rise to difficulties in connection with ignition, carburetion, and distribution. There is no doubt that supercharging at present offers the best means for power increase, but here again development is limited by increase in the heat stresses resulting in valve difficulties and greater tendency to detonation. For supercharging, the exhaust-driven fan has largely been superseded by the gear-driven type and in some cases a pressure as high as 14 pounds per square inch above atmosphere has been maintained in the induction pipe. In the United States very promising results have been obtained by the use of a positive displacement type blower instead of a fan.

The exhaust valve in the four-cycle internal-combustion engine works under very severe conditions as regards temperature and mechanical stresses, and the working temperature of these valves in aero engines is now so high as to require all the skill of the metallurgist and designer to obtain satisfactory and reliable operation. It would, therefore, appear that any substantial increase in performance in the future is dependent upon the substitution of some other form of available mechanism for the time-honoured poppet valve, and in Mr. Ricardo's opinion the use of the sleeve valve opens up possibilities otherwise unobtainable.

In concluding his lecture, Mr. Ricardo directed attention to the promising results already obtained with heavy oil-engines for aircraft. If these can be used, there will result a great reduction in fire risk, much better fuel economy, the use of a cheaper fuel, and the elimination of electric ignition with its sparkplug troubles and interference with radio communication. Many investigators are at work on this problem, and very promising results have recently been obtained. One of the most successful engines of this type, produced by the Packard Company, is said to weigh little over 2¼ pounds per horse-power, a figure only about one-third greater than the weight of a gasoline engine of similar design. In the lecturer's opinion, it will be long before heavy oil engines will supersede the present type of aero engine, while both types will be utilized for many years to come.

Mr. Ricardo also said that in reviewing the progress of engineering in the past, we find that each new line of development starts, of course, with a period of experiment and groping, during which a wide range of types is evolved. By a process of elimination this range is very soon whittled to one or two survivors; in the final choice of these survivors, chance plays often quite as important a part as merit. On the one or more survivors the attention of the whole engineering world is concentrated, with the result that step by step it is improved out of all recognition and reigns supreme until it reaches almost the very limit of its capacity, when a new and fundamentally better type eventually replaces it. Such has been the history of the steam engine which fifty years ago had crystallized into an almost standard design of open-type, double-acting, slow-running engine; for many years this held undisputed sway until it was displaced by the enclosed high-speed vertical type; this again was perfected until it seemed almost final, only to be superseded in turn by the turbine. That this process is so prolonged and that the obsolete so long outlives its day, is due to the fact that in every age the newcomer, in its raw and undeveloped state, is invariably pitted against the champion of the older school and challenged to defeat it in the first round. Allowance is seldom made for the fact that the reigning type has enjoyed the benefit of many years' experience under every conceivable condition, supplemented by the combined skill of the best talent in the country, while the newcomer, of course, lacks these advantages. It is this attitude of mind, this want of imagination, perhaps, which frequently delays progress and allows obsolete types to outlive their day.

Past-Presidents' Prize

Members are reminded that the Past-Presidents' Prize for 1930-1931, value one hundred dollars, is offered for the best paper submitted by a member of The Institute of any grade, on "Engineering Education in Canada." As a guide to authors the following topics are suggested:

(*a*) Engineering Courses at Canadian Universities—Admission standards—Place of cultural studies—Desirability of specialization—Guidance of special abilities in undergraduates.

(*b*) The Need and Opportunity for Collaboration by Practising Engineers and Employers in the Practical Training of Undergraduates and Young Graduates.

Papers to be entered for the competition must be received during the prize year, July 1st, 1930, to June 30th, 1931, by the General Secretary, from whom further information can be obtained.

Students' and Juniors' Prizes

Students and Juniors of The Institute are reminded that five prizes, each of the value of twenty-five dollars, may be awarded to Students and Juniors of The Institute for the prize year 1930-1931 as follows:

The H. N. Ruttan Prize in the four Western Provinces.

The John Galbraith Prize in the Province of Ontario.

The Phelps Johnson Prize for an English Student or Junior in the Province of Quebec.

The Ernest Marceau Prize for a French Student or Junior in the Province of Quebec.

The Martin Murphy Prize in the Maritime Provinces.

Papers in competition for these prizes must be received by branch secretaries before June 30th, 1931. Further information as to the requirements and rules may be obtained from the General Secretary.

Prizes to University Students

At the Plenary Meeting of Council in September last it was decided to offer annually to each of the eleven important engineering schools in the Dominion a prize to be known as "The Engineering Institute of Canada Prize," for competition among the registered students in the year prior to the graduating year. This offer has been cordially accepted by the authorities of the following institutions:

University of Alberta
University of British Columbia
Ecole Polytechnique, Montreal
University of Manitoba
McGill University
University of New Brunswick
Nova Scotia Technical College
Queen's University
Royal Military College
University of Saskatchewan
University of Toronto

and it is anticipated that the first awards will be made this month.

It has been determined that these prizes shall be continued for a period of five years, and it is the desire of Council that the method of their award shall be determined by the appropriate authority in each school or university, so that a prize may be given to the student in any department of engineering who has proved himself most deserving, not only in connection with his college work, but also as judged by his activities in the student engineering organization, if any, or in the local branch of a recognized engineering society.

It is not necessary for the recipient to belong to The Institute, and in this respect the prizes are quite distinct from those offered to Students and Juniors of The Institute, or from the prizes which are offered by a number of our branches to the Students attached to them.

It is felt that the establishment of these prizes will not only aid deserving students, but will assist in developing their interest in engineering societies' work, and in the resulting acquirement and interchange of professional knowledge.

Henry Martyn MacKay Memorial Scholarships

Plans are under way for the establishment of a memorial to the late Dr. Henry Martyn MacKay, M.E.I.C., former Professor of Civil Engineering and Dean of the Faculty of Applied Science, McGill University, who died on October 25th last. Arrangements are in the hands of a representative committee under the chairmanship of Professor Ernest Brown, M.E.I.C., and including Dr. D. A. Murray, J. Colin Kemp, A.M.E.I.C., G. McL. Pitts, A.M.E.I.C., W. E. Cushing, W. Taylor Bailey, Professors C. M. McKergow, M.E.I.C., R. DeL. French, M.E.I.C., and R. E. Jamieson, A.M.E.I.C., and Homer M. Jaquays, M.E.I.C., honorary treasurer. A memorial in the form of undergraduate scholarships in the Faculty of Applied Science has been decided upon as most appropriate, and the committee hopes to secure sufficient funds to permit the endowment of two or more such scholarships. It is estimated that a minimum sum of $10,000 will be required, and it is expected that at least one of these scholarships will be available at the opening of the session next October.

The committee is particularly anxious that the fund shall be fully representative of the large body of friends of the late Dean, and it is hoped that this notice may reach many of those whose addresses are unknown to the committee. Subscriptions should be made payable to "H. M. MacKay Memorial Fund," and sent to room No. 71, Engineering building, McGill University, Montreal.

The Forty-Fifth Annual General and General Professional Meeting

Convened at Headquarters, Montreal, January 22nd, 1931, and adjourned to the Windsor Hotel, Montreal, February 4th, 1931

Annual General Meeting at Institute Headquarters

The Forty-fifth Annual General Meeting of The Institute was held at Headquarters on Thursday, January twenty-second, nineteen hundred and thirty-one, at eight o'clock p.m., with Vice-President George R. MacLeod, M.E.I.C., in the chair.

The Secretary having read the notice convening the meeting, the minutes of the Forty-fourth Annual General Meeting were submitted, and on the motion of H. B. Montizambert, A.M.E.I.C., seconded by C. R. Lindsey, A.M.E.I.C., were taken as read and confirmed.

Appointment of Scrutineers

On the motion of J. B. O. Saint-Laurent, A.M.E.I.C., seconded by W. H. Cook, A.M.E.I.C., Messrs. L. H. D. Sutherland, M.E.I.C., and R. E. MacAfee, A.M.E.I.C., were appointed scrutineers to report the result of the Officers' Ballot.

Appointment of Auditors

On the motion of C. K. McLeod, A.M.E.I.C., seconded by A. Duperron, M.E.I.C., Messrs. Riddell, Stead, Graham and Hutchison were appointed auditors for the ensuing year.

There being no other formal business, it was resolved, on the motion of J. A. Burnett, M.E.I.C., seconded by H. W. B. Swabey, M.E.I.C., that the meeting do adjourn to reconvene on Wednesday, the fourth day of February, nineteen hundred and thirty-one, at ten o'clock a.m., at the Windsor hotel, Montreal, Quebec.

Adjourned General and General Professional Meeting at the Windsor Hotel, Montreal

The adjourned meeting was called to order by President A. J. Grant, M.E.I.C., at ten o'clock a.m. on Wednesday, February 4th, 1931, and the President welcomed the members and guests who were present, particularly F. L. Stuart, M.E.I.C., President of the American Society of Civil Engineers, and W. S. Lee, M.E.I.C., President of the American Institute of Electrical Engineers.

The Secretary having placed before the meeting the letters and telegrams of regret from members and guests unable to be present, the membership of the Nominating committee appointed to nominate the officers of The Institute for 1932, was announced as follows:

Nominating Committee 1931

Chairman: P. S. Gregory, M.E.I.C.

Branch	*Representative*
Halifax Branch	H. W. L. Doane, M.E.I.C.
Cape Breton Branch	K. H. Marsh, M.E.I.C.
Saint John Branch	J. P. Mooney, A.M.E.I.C.
Moncton Branch	G. L. Dickson, A.M.E.I.C.
Saguenay Branch	G. F. Layne, A.M.E.I.C.
Quebec Branch	P. Méthé, A.M.E.I.C.
St. Maurice Valley Branch	C. H. Jetté, A.M.E.I.C.
Montreal Branch	P. E. Jarman, A.M.E.I.C.
Ottawa Branch	W. D. McLachlan, M.E.I.C.
Peterborough Branch	A. L. Killaly, A.M.E.I.C.
Kingston Branch	W. L. Malcolm, M.E.I.C.
Toronto Branch	R. O. Wynne-Roberts, M.E.I.C.
Hamilton Branch	W. L. McFaul, M.E.I.C.
London Branch	F. C. Ball, A.M.E.I.C.
Niagara Peninsula Branch	C. G. Moon, A.M.E.I.C.
Border Cities Branch	J. Clark Keith, A.M.E.I.C.
Sault Ste. Marie Branch	W. S. Wilson, A.M.E.I.C.
Lakehead Branch	F. C. Graham, A.M.E.I.C.
Winnipeg Branch	J. W. Porter, M.E.I.C.
Saskatchewan Branch	H. R. Mackenzie, A.M.E.I.C.
Lethbridge Branch	R. Livingstone, M.E.I.C.
Edmonton Branch	E. Stansfield, M.E.I.C.
Calgary Branch	F. M. Steel, M.E.I.C.
Vancouver Branch	J. C. Oliver, Jr.E.I.C.
Victoria Branch	J. C. MacDonald, M.E.I.C.

Award of Medals and Prizes

The awards of the various prizes and medals of The Institute were next announced, and the President stated that arrangements had been made for their presentation at the Annual Dinner. The prize list was as follows:

The Sir John Kennedy Medal to George Herrick Duggan, M.E.I.C.

The Past-Presidents' Prize to Group-Captain E. W. Stedman, M.E.I.C., for his paper on "Rigid Airships."

Gzowski Medals to F. M. Wood, A.M.E.I.C., for his paper on "A Short Monograph on Nomography," and to P. B. Motley, M.E.I.C., for his paper on "Reinforcement in Place of the Stoney Creek Arch Bridge."

Leonard Medals and Prize—A Gold medal to C. G. MacLachlan for his paper on "Twelve Months Milling at Noranda"; a Silver medal to W. B. Boggs for his paper on "The Noranda Smelter"; a prize of books to A. E. Flynn for his paper on "Anhydrite Plasters and Cements."

The Phelps Johnson Prize to G. B. Jost, S.E.I.C., for his paper on "Steel Mitering Lock Gates on the Welland Ship Canal."

Reports of Council and of Finance Committee

The meeting next proceeded to the consideration of the report of Council together with the report of the Finance Committee, these having already been printed and placed in the hands of members. The reports having been read by the Secretary, discussion followed, during which J. H. Hunter, M.E.I.C., criticized the action of Council in failing to bring forward for the third time the proposal to amend Section 34 of the By-laws so as to provide a much-needed increase in revenue from increased members' fees; he considered the report of Council unsatisfactory in this respect. It was then moved by G. Stead, M.E.I.C., seconded by M. B. Atkinson, M.E.I.C., that the report of Council be received. In support of the motion, Mr. Atkinson thought that Council had been well advised not to bring forward the proposal this year, as he believed that when the membership had had time to consider the situation and when better times arrived, the proposal, if submitted again next year, would have a much better chance of carrying. George R. MacLeod, M.E.I.C., as chairman of the Finance committee, concurred with Mr. Atkinson, and after further discussion, in which Messrs. P. B. Motley, M.E.I.C., and J. L. Busfield, M.E.I.C., took part, Mr. Stead's motion was put and carried; subsequently, on the motion of Mr. MacLeod, seconded by Mr. Stead, the report of the Finance committee was adopted.

Committee on Tariff of Fees

The Secretary having gone over the principal points in connection with the reports of the Library and House committee, the Publication Committee, the Board of

Examiners, the committees on Engineering Education and International Co-operation, the Canadian Engineering Standards Association, the Membership committee, and the Publicity committee, Mr. Busfield gave a brief explanation as regards that of the Committee on Tariff of Fees, pointing out that the report now presented differed from that of 1922, which it superseded, in prescribing a rate of per diem remuneration of not less than $75.00, although "much higher rates may be charged." This, he thought, was quite in accord with present practice.

Mr. Busfield then summarized the work of the Committee on Remuneration, and stated that the report of this committee had not yet been published or presented to the membership, as it was still under consideration by Council.

On the motion of Mr. Busfield, seconded by P. E. Jarman, A.M.E.I.C., the report of the Committee on Tariff of Fees was unanimously adopted.

REPORT OF THE COMMITTEE ON MEMBERSHIP

The Secretary next read the report of the Committee on Membership, and discussion on this was initiated by W. E. Ross, A.M.E.I.C., who pointed out the difficulties arising from the application of the rules regarding The Institute's examinations to men of mature years. Mr. Atkinson referred to the resolution of a meeting of the Montreal Branch regarding this matter which had been presented to Council, and H. B. Montizambert, A.M.E.I.C., thought that if the entrance examinations for the grade of Junior were rigidly adhered to, Council might perhaps be lenient in the matter of requiring examinations when application for transfer from that grade is made. Mr. Busfield pointed out that he had proposed the resolution of the Montreal Branch regarding Council's action on examinations to which reference had been made, and in order to get an expression of opinion on this point from this meeting he would move "that this meeting urges that the Council of The Institute should exercise freely its right under the present By-laws to waive examinations in the cases of applicants for transfer to Associate Membership who show by their engineering record that they have had a reasonable degree of professional experience." This motion was seconded by Mr. Ross.

O. O. LEFEBVRE, M.E.I.C.
Newly-Elected Vice-President.
Zone C.

Mr. Busfield considered that the primary purpose of The Institute was now educational rather than professional, the right to practise as an engineer being conferred by the action of the various Associations of Professional Engineers. He thought that the utility of The Institute would be increased by concentrating on the development of its educational features and by admitting engineers to its advantages on easier terms. He pointed out that the resolution proposed did not change the conditions for admission, but urged Council to use its judgment in applying them.

E. M. Proctor, M.E.I.C., enquired as to the nature of The Institute's examinations, and thought that junior engineers without college training would desire to get qualified by passing them. He did not think that the bars should be lowered.

Mr. Atkinson referred to the action of the Niagara Peninsula Branch in requesting Council to give more consideration to the recommendations of the Branch Executive committees in regard to applications for admission; after which the Secretary, in reply to Mr. Proctor, outlined The Institute's present examination requirements.

H. B. MUCKLESTON, M.E.I.C.
Newly-Elected Vice-President.
Zone A.

Dr. O. O. Lefebvre, M.E.I.C., opposed Mr. Busfield's motion as it would tend to lower the standard of admission to The Institute. He agreed with Mr. Proctor that too much attention was being paid to the question of examinations for non-graduates and pointed out that not enough attention was given to the engineering graduates of our colleges. If the grade of admission were lowered, graduates would no longer think it worth while to belong to The Institute.

S. G. Porter, M.E.I.C., pointed out that the question at issue was closely connected with the relations between The Institute and the various Provincial Associations of Professional Engineers, and remarked that when a close working arrangement had been entered into with these Associations the qualifications for admission to The Institute would be the same as the uniform standard which he hoped would be agreed upon by all the Associations and by The Institute. Such an agreement, however, would no doubt involve some change in the nomenclature of our grades of membership, so that these might correspond to those adopted by the Professional Associations.

After further discussion, Mr. Atkinson expressed the opinion that The Institute should not be bound to take any man because a Provincial Association has licensed him to practise as an engineer in some particular province. He thought that there should be means for admitting into The Institute men of ripe engineering training without the necessity of their qualifying by examination for admission to a Professional Association; such men would enhance the value of The Institute throughout the country.

Mr. Busfield's motion being put, the ayes numbered 20 and the nays 25, and the motion was declared lost.

Mr. Proctor enquired whether the adoption of the report of the Committee on Engineering Education would commit The Institute to all of its recommendations, including that suggesting a six-year course for engineers at the universities. The Secretary pointed out that the recommendation to which Mr. Proctor referred was merely that there should be a conference on the subject.

The President remarked that it would now be in order to move the adoption of the committee reports attached to the Report of Council, with the exception of those which had already been accepted. Accordingly, on the motion of Mr. Motley, seconded by R. L. Dobbin, M.E.I.C., the remaining committee reports were unanimously adopted.

Reports of the Branches

On the motion of Major L. F. Grant, M.E.I.C., seconded by Mr. MacLeod, the Branch reports were taken as read and adopted.

The meeting then adjourned at 12.30 o'clock p.m., to resume at 2.15 o'clock p.m.

Report of the Committee on the Relations of the Institute with the Provincial Associations of Professional Engineers

At the afternoon session the President asked Past-President H. H. Vaughan, M.E.I.C., the chairman of the Committee on the Relations of The Institute with the Provincial Associations of Professional Engineers, to speak concerning his report.

Mr. Vaughan explained that his committee had drafted proposals which had been forwarded to the Councils of the various Professional Associations, suggesting that the first problem to be considered was the establishment of uniform requirements for admission to the various Associations and to The Institute, and proposing the formation of a national committee on which all of the bodies would be represented. This committee hoped to arrange for the preparation of a comparison and analysis of the various present requirements of all the organizations. It was then proposed to select a small committee of three or four members, who would prepare a draft set of uniform requirements for admission, for consideration by the whole committee. The councils of a number of the Provincial Associations had already agreed to this course, and Mr. Vaughan hoped that the others would soon signify their concurrence.

The President thanked Mr. Vaughan for his explanation, and pointed out that the report of his committee had already been accepted by the meeting.

Proposals for Amendments to By-laws

At the request of the President, the Secretary next read the proposals made by Council for amendments to sections 66 and 67 of the By-laws, dealing with the constitution of the Nominating committee. Communications were presented from the Quebec Branch, the Moncton Branch and the Niagara Peninsula Branch expressing disapproval of Council's proposals, and asking that they be withdrawn.

Discussion on Council's proposals followed, during which Mr. Busfield explained the purpose of Council's suggestions, and Dr. Lefebvre pointed out that as there was evidently opposition to Council's proposals, it would be necessary for the chairman to appoint a committee to draft reasons for and against the proposals, such reasons to accompany the letter ballot when sent out to the membership.

Mr. MacLeod remarked that when these communications were received from the Branches named, it was too late to comply with their suggestion that Council withdraw its proposals, particularly as they were based on action taken at the Plenary Meeting of Council.

Messrs. Ross, Hunter and others having spoken, and Mr. Vaughan having proposed an amendment to Council's proposals, which he subsequently withdrew, it was moved by Mr. Proctor that "this meeting go on record as being opposed to the amendments now proposed by Council to sections 66 and 67 of the By-laws."

Dr. Lefebvre opposed this idea, and was of the opinion that it was undesirable when submitting a proposal to the membership to state on the ballot that the Annual General Meeting had declared itself against the measure.

Mr. Proctor's motion not being seconded, the President named as a committee for the preparation of reasons for the proposals, Messrs. J. L. Busfield and R. B. Young, M.E.I.C., and for the preparation of the reasons against the proposals, Messrs. S. L. DeCarteret, M.E.I.C., and W. E. Ross, A.M.E.I.C.

Mr. Proctor expressed a desire that his motion should be voted on, and after being seconded by J. M. H. Cimon, M.E.I.C., it was put to the meeting, and carried by 30 votes to 7.

Retiring President's Address

The President then delivered (in abstract) his retiring address, a masterly description of the great ship canals of the world, with comments on their economic possibilities. This address is printed *in extenso* on pp. 182 to 190 of the March, 1931, issue of The Engineering Journal.

Election of Officers

The Secretary having read the report of the scrutineers appointed to canvass the Officers' Ballot for 1931, the following officers were declared elected:

President	Sam G. Porter, M.E.I.C.
Vice-Presidents:	
Zone A	H. B. Muckleston, M.E.I.C.
Zone C	O. O. Lefebvre, M.E.I.C.
Councillors:	
Halifax Branch	W. P. Copp, M.E.I.C.
Cape Breton Branch	A. L. Hay, M.E.I.C.
Saint John Branch	A. R. Crookshank, M.E.I.C.
Moncton Branch	G. C. Torrens, A.M.E.I.C.
Saguenay Branch	G. E. LaMothe, A.M.E.I.C.
Quebec Branch	J. M. H. Cimon, M.E.I.C.
St. Maurice Valley Branch	B. Grandmont, A.M.E.I.C.
Montreal Branch	C. V. Christie, M.E.I.C.
	D. C. Tennant, M.E.I.C.
Ottawa Branch	F. H. Peters, M.E.I.C.
Peterborough Branch	R. L. Dobbin, M.E.I.C.
Kingston Branch	D. M. Jemmett, A.M.E.I.C.
Toronto Branch	Thomas Taylor, M.E.I.C.
Hamilton Branch	E. H. Darling, M.E.I.C.
Niagara Peninsula Branch	E. G. Cameron, A.M.E.I.C.
Border Cities Branch	A. E. West, M.E.I.C.
Sault Ste. Marie Branch	A. E. Pickering, M.E.I.C.
Lakehead Branch	G. H. Burbidge, M.E.I.C.
Winnipeg Branch	N. M. Hall, M.E.I.C.
Saskatchewan Branch	R. W. E. Loucks, A.M.E.I.C.
Lethbridge Branch	G. N. Houston, M.E.I.C.
Edmonton Branch	R. W. Ross, A.M.E.I.C.
Calgary Branch	R. S. Trowsdale, A.M.E.I.C.
Vancouver Branch	P. H. Buchan, A.M.E.I.C.
Victoria Branch	K. M. Chadwick, M.E.I.C.

The scrutineers reported that in the case of the Councillor from the London Branch, an equal number of votes had been polled by W. P. Near, M.E.I.C., and J. A. Vance, A.M.E.I.C.; in accordance with the By-laws a ballot was ordered to be taken, Messrs. G. R. MacLeod and E. M. Proctor being named by the President as scrutineers.

Induction of Newly-Elected President

Pending the result of the ballot the President asked Past-President J. M. R. Fairbairn and Vice-President O. O. Lefebvre to conduct the newly elected President to the chair, and this was accordingly done.

President Porter, in expressing appreciation of the honour conferred upon him, remarked that he was particularly gratified by this recognition of the western Branches, and he looked upon his election as being an endorsation of the efforts he had sponsored to bring about a more intimate relationship between The Institute and the Provincial Associations of Professional Engineers. He considered this the most important problem now facing The Institute, and believed that nearly all the other questions at issue would be found to be interwoven with it.

Regarding the handicap of distance which would separate him from the Headquarters of The Institute, he nevertheless felt that with the co-operation of the members of Council residing nearer Headquarters, and with well-chosen committees to look after the different phases of the work, there would be real progress in the affairs of The Institute.

The scrutineers next presented their report, and it was announced that W. P. Near, M.E.I.C., was elected as councillor from the London Branch.

Drawing attention to the calls made upon the time of officers of The Institute, Mr. W. C. Adams moved that the hearty thanks of The Institute be accorded to the retiring President and the retiring members of Council, in appreciation of their services during the past year. This motion was seconded by Mr. J. H. Hunter and carried by acclamation.

On the motion of Mr. J. H. Hunter, seconded by Mr. R. L. Dobbin, it was unanimously resolved that a vote of thanks be tendered to the scrutineers for their services in preparing the report on the election of officers, and that the ballots be destroyed.

Mr. E. M. Proctor moved that the thanks of The Institute be conveyed to the Montreal Branch in recognition of their hospitality and activity in connection with the holding of the Forty-fifth Annual General and General Professional Meeting of The Institute in Montreal. This motion was seconded by G. Stead, M.E.I.C., and carried unanimously.

There being no further business the Annual General Meeting then terminated.

Luncheon

On the first day of the meeting, Wednesday, February 4th, a luncheon took place in the Rose Room, at which A. Duperron, M.E.I.C., chairman of the Montreal Branch, presided. Mr. Duperron extended a welcome to the members and guests present, and was followed by Alderman Gilday, who in the unavoidable absence of His Worship the Mayor of Montreal, greeted The Institute on behalf of the city. Dr. Gilday was followed by Mr. B. K. Sandwell, who was introduced by K. B. Thornton, M.E.I.C., and explained that he intended to address the assembly on "Engineering and Morals." Spending most of the time available in explaining to his audience exactly what he thought of them, Mr. Sandwell was obliged to conclude a very entertaining address just as he seemed likely to reach his announced subject.

Annual Dinner

In the evening the Annual Dinner of The Institute was held in the Rose Room, President S. G. Porter in the chair. It was memorable as being the first Annual Dinner at which ladies have been present. After dinner, the prizes and medals of The Institute were presented. In accepting the Sir John Kennedy Medal, Past-President G. H. Duggan, M.E.I.C., expressed his gratification at receiving the honour, and drew attention to the remarkable development of The Institute and its branches since he was first associated with the then Canadian Society of Civil Engineers forty-three years ago. He urged that the engineer best serves his own interests by putting service to the profession first, and by service to the profession he meant giving of his best to encourage the younger members, to promote loyalty to The Institute, and to maintain its ideals. Justly proud of his profession, the engineer's rules of conduct should be based on good citizenship, by observing which he would do his part in maintaining public respect for his profession.

The recipients of the other distinctions, Group-Captain Stedman, Mr. P. B. Motley, and Mr. F. M. Wood, suitably acknowledged the awards they received.

The presentation of the prizes and medals was followed by brief speeches from F. L. Stuart, M.E.I.C., President of the American Society of Civil Engineers, and W. S. Lee, M.E.I.C., President of the American Institute of Electrical Engineers.

After this, Beaudry Leman, A.M.E.I.C., President of the Canadian Bankers Association, delivered a thoughtful address, in which he traced some analogies between the conditions under which engineering and business activities are carried on. He remarked that the factor of safety, which played such an important part in engineering construction, was intended, first, to guard against undiscoverable defects in the structural material employed, which defects reduce the ultimate strength of the material, and second, to provide against the possibility of an unforeseen increase in the load to be carried. The apparent factor of safety was the product of four other factors: the first being the ratio of the ultimate strength of the material to its true elastic limit, the second depending on the character of the stresses produced within the material, the third being affected by the manner in which the load is applied to the piece, and the fourth being the factor of ignorance. Such factors of safety were used by engineers in connection with materials whose resistance and strength had been carefully measured, and yet liberal allowance had to be made for the factor of ignorance. What a lesson for those who, engaging in business, had to build with far less stable materials and to contend with no less powerful forces. The pressure of competition, said Mr. Leman, the breaking strain of taxation, the abrasions made on profits by multitudinous fixed charges, the lack of elasticity in our budgets, the plasticity of politics and the resiliency of our incomes should be figured out in business and large factors of safety applied.

Drawing attention to the disastrous results of modern economic conditions, Mr. Leman pointed out the effect of abandoning factors of safety in business, and the growth of a policy of following the path of least resistance. Why adhere to the gold standard, he observed, when paper is so much easier to procure in abundance? Why practise self-restraint to accumulate capital when credit may easily be made available to all? Why work and toil when it is so much easier to speculate? Why save for the future when it is so much easier for the state to provide for your needs? Why row upstream when it is so much easier to drift? Why have ambition, initiative, forcefulness, when it is so much easier to wait for something to turn up? Why have public spirit and ideals when it is so very much easier to be unconcerned and sceptical?

In concluding his address, Mr. Leman remarked that we are all desirous that our laws should reflect a more advanced civilization, provide more social welfare and extend a more generous hand to those who are handicapped or afflicted, but in so doing we should guard against sapping the very foundation of human progress, which has been private initiative and personal interest. The speaker held the close attention of his listeners throughout.

Smoking Concert

After the dinner a very successful smoking concert was held in the Windsor Hall, and a remarkably good series of turns was presented. C. M. McKergow, M.E.I.C., presided.

Ladies Entertainment

At the same time the ladies listened to an illustrated talk by Miss Amy B. Stone on "Literary Rambles in Southern England," accompanied by folk songs and musical numbers.

First Technical Session

On Thursday, February 5th, the technical sessions began, the papers being presented as follows:—

In the York Room, under the chairmanship of P. L. Pratley, M.E.I.C.:

"Train-Ferry Landings at Port Mulgrave and Point Tupper, N.S.," by D. B. Armstrong, A.M.E.I.C., erection engineer, Dominion Bridge Company, Ltd., Montreal, and W. Chase Thomson, M.E.I.C., designer, Dominion Bridge Company, Ltd., Montreal.

"The Construction of the Steel Lock Gates of the Welland Ship Canal," by E. S. Mattice, M.E.I.C., vice-president, National Bridge Company of Canada, Ltd., Montreal.

In the Prince of Wales Salon, under the chairmanship of J. A. McCrory, M.E.I.C.:

"Breakwater Construction in Port Arthur Harbour," by F. Y. Harcourt, M.E.I.C., district engineer, Department of Public Works, Canada, London, Ont.

"A Method of Laying Out Warped Surfaces of Hydraulic Structures," by C. P. Dunn, M.E.I.C., chief engineer, Alcoa Power Company, Arvida, Que.

"The Design of the Chute-à-Caron Diversion Canal," by G. O. Vogan, A.M.E.I.C., chief designing engineer, Alcoa Power Company, Ltd., Arvida, Que.

"The Technique of Placing Concrete on Steep Slopes without Forms," by I. E. Burks, concrete technician, Aluminum Company of America.

Second Technical Session

At the technical sessions held in the afternoon, the papers presented were as follows:—

In the York Room, under the chairmanship of P. E. Jarman, A.M.E.I.C.:

"Structure and Oil Prospects of the Eastern Foothills Area, Alberta, Between the Highwood and Bow Rivers," by Dr. G. S. Hume, Geological Survey, Department of Mines, Ottawa.

"The Water Supply Problem in Southern Saskatchewan," by W. A. Johnston, Geological Survey, Department of Mines, Ottawa.

"Automatic Block Signalling on the Canadian Pacific Railway," by A. J. Kidd, assistant to signal engineer, Eastern Lines, Canadian Pacific Railway, Montreal.

In the Prince of Wales Salon, under the chairmanship of O. O. Lefebvre, M.E.I.C.:

"The Alexander Power Development on the Nipigon River," by T. H. Hogg, D.Eng., M.E.I.C., chief hydraulic engineer, Hydro-Electric Power Commission of Ontario, Toronto.

Ladies Visit to McGill Library

On Thursday afternoon a visit was arranged for the ladies to the remarkable Gest Chinese Research library at McGill University, and also to the library museum for writing materials of past ages, Japanese prints, illuminated manuscripts and early printed books. Dr. G. R. Lomer, the librarian, gave an explanatory address. Later on the ladies were entertained at tea at the Themis Club.

Third Technical Session

The final technical sessions of the meeting were held on Friday morning as follows:—

In the York Room, with C. M. McKergow, M.E.I.C., acting as chairman:

"The Steam Station for the Head Office Building of the Sun Life Assurance Company of Canada, Montreal," by F. A. Combe, M.E.I.C., consulting combustion and steam engineer, Montreal.

"The Mechanical Equipment in the Head Office Building of the Sun Life Assurance Company of Canada, Montreal," by E. A. Ryan, M.E.I.C., consulting engineer, Montreal.

"The Plumbing Systems Designed for the Head Office Building of the Sun Life Assurance Company of Canada, Montreal," by A. Traver Newman, consulting engineer, New York.

In the Prince of Wales Salon, with W. C. Adams, M.E.I.C., in the chair:

"The Structural Engineering of the Head Office Building of the Sun Life Assurance Company of Canada, Ltd., Montreal," by A. H. Harkness, M.E.I.C., Harkness and Hertzberg, consulting engineers, Toronto.

"The Electrical Equipment for the Head Office Building of the Sun Life Assurance Company of Canada, Montreal," by J. H. Mencke, consulting engineer, New York, and E. A. Ryan, M.E.I.C., consulting engineer, Montreal.

Visits to Engineering Works

Arrangements were made for members to visit a number of new buildings and engineering works on Friday afternoon, and a great many availed themselves of the opportunity offered. Among the places visited were: the new Head Office building of the Sun Life Assurance Company of Canada, which is approaching completion, and is designed for a population of 10,000 people; the new shops of the Canadian National Railways at Point St. Charles, which employ the most advanced methods in locomotive construction and maintenance, and are amongst the most complete on the continent; the Dominion Engineering Works at Lachine, which specialize in the construction of large turbines and paper machines; the Dominion Bridge Company, also at Lachine, with the largest bridge and structural shops in Canada; the new bronze foundry of the Robert Mitchell Company at St. Laurent, exemplifying the last word in modern foundry equipment; the new plant of the Montreal Island Power Company at Bordeaux; the factory of the Canadian Marconi Company, Ltd., which manufactures commercial radio equipment for government and marine use as well as broadcast receiving apparatus, and the works of Canadian Copper Refiners Ltd., the first unit of which will begin operation almost immediately, and which will have an annual capacity of 75,000 tons of electrolytic copper made from blister copper and shipped in the form of wire bars.

Reception and Dance

In the evening the Annual Reception and Supper Dance of The Institute was held at the Windsor hotel, the members and their friends being received by the President and Mrs. Porter. This function concluded a very enjoyable and successful meeting.

Sam Graham Porter, M.E.I.C.

President of The Engineering Institute of Canada

Among the many activities of the Canadian Pacific Railway, none has been of greater benefit to the western provinces than the work of its Department of Natural Resources. Dealing with the development and administration of the company's agricultural and timber lands and its town sites, the exploration and operation of its coal, natural gas and oil properties, and handling also the construction, operation and maintenance of its extensive irrigation systems, the direction of this department gives ample scope for the exercise of administrative as well as of technical ability.

In electing its manager, S. G. Porter, M.E.I.C., as President of The Engineering Institute of Canada, The Institute has chosen a man prominent in both these respects, and has directed attention to the fact that many engineers naturally develop as leaders in the executive as well as the purely technical field. The choice of the new President further recognizes the growing importance to the welfare of the Dominion of the adequate development of the natural resources of the West.

SAM GRAHAM PORTER, M.E.I.C.

Originally of Scottish extraction, Mr. Porter was born September 1st, 1875, and his early education was received at a private school in his native place, Kyle, Texas. Living on a farm and working there during a great part of the year, he gained a practical experience in agriculture and its methods which was later to stand him in good stead.

Entering Baylor University at Waco, Texas, he graduated A.B. in 1898, and, after teaching school for a time, proceeded to the Massachusetts Institute of Technology, receiving there the degree of S.B. in Civil Engineering in 1903. Mr. Porter began his professional career in the United States Reclamation Service, and in 1903, as assistant engineer, was assigned to survey work in New Mexico, Colorado, Nebraska, and Wyoming, having charge of a portion of the construction of the inter-state canal between Wyoming and Nebraska. The years 1905 to 1906 were spent on railway location work, and in 1907 he became chief engineer of the Arkansas Valley Sugar Beet and Irrigated Land Company at Holly, Colorado. In 1913 he came to Canada, entering the Dominion government service, and becoming inspecting engineer in the Irrigation Office of the Department of the Interior at Calgary. He was later promoted to assistant chief engineer and acting commissioner of irrigation. Leaving the Civil Service in 1918, he joined the Canadian Pacific Railway, becoming superintendent of operation and maintenance of the Southern Section of the Canadian Pacific Railway irrigation system, with headquarters at Lethbridge. He retained that position until 1925, when he was appointed assistant manager of the company's Department of Natural Resources, and in 1927, on the retirement of Mr. P. L. Naismith, was promoted to the position of manager of that department, which he still holds.

Mr. Porter's connection with The Engineering Institute of Canada began with his election as Member in 1914. He was active in the affairs of the Calgary Branch, organized the Lethbridge Branch in 1921, and was its first chairman. He served on Council from 1921-23, and was a vice-president in 1927-1928. He is a Member of the American Society of Civil engineers. Always interested in community matters, he is on the Council of the Calgary Board of Trade and on the Board of Directors of the Calgary Rotary Club; he was president of the Lethbridge Rotary Club in 1920 and vice-president of the Lethbridge Board of Trade during 1923-1924. In 1921 he became naturalized as a British subject.

Mr. Porter's interest in the progress of the engineering profession has been evidenced not only by his activities in connection with The Institute, but also by his unremitting efforts in connection with the Association of Professional Engineers of the Province of Alberta and in promoting the movement for the registration and licensing of professional engineers in Canada. For some years a member of Council of the Alberta Association of Professional Engineers, he was vice-president of that organization in 1923-24.

It will be remembered that, following a conference held at Montreal in 1926 between representatives of the various Provincial Associations of Professional Engineers, the Council of The Institute, at its Plenary Meeting in October, 1927, appointed a Committee on the Relations of The Engineering Institute of Canada with the Provincial Professional Associations, of which committee Mr. Porter was a member. He took over its chairmanship in 1928. The committee's report outlined a course of inquiry and negotiation designed to promote uniformity in requirements for admission as regards the various associations and The Institute, and, after approval at the Plenary Meeting of 1929, was adopted at the Annual Meeting in Ottawa, in 1930. At this time, pressure of work compelled Mr. Porter to withdraw from the chairmanship, but he was succeeded as chairman by Past-President H. H. Vaughan, M.E.I.C., and the committee, after further discussion at the Plenary Meeting of Council in October, 1930, is continuing its work and is in communication with the governing bodies of the eight professional associations.

The election of Mr. Porter as President of The Engineering Institute of Canada will be generally welcomed, and will receive special endorsement from those who have at heart the co-ordination of the work of the professional engineering associations throughout the country, by the ultimate federation of these bodies.

Address of the Retiring President

A. J. Grant, M.E.I.C.

Delivered before the Forty-fifth Annual Meeting of The Engineering Institute of Canada, Montreal, February 4th, 1931.

We have listened with interest to the reports of Council and the various committees who have generously given much time and effort throughout the year in assisting Council to manage the business of The Institute, and to them and to all the members of Council, I now desire to express my deep appreciation of the time and thought that they have unselfishly given to the welfare of The Institute. I also desire to record my sincere thanks to our General Secretary for his able assistance throughout the year.

On considering the present status of The Institute, it is sufficient for me to say that its membership is increasing, its financial position is sound and that it is well supported by the members.

It will be noted from the report of the Special Sub-Committee of the Committee on the Relations of The Institute with the Provincial Associations of Professional Engineers, that some progress has been made towards bringing about the co-ordination of the interests and activities of The Institute and those of the Professional Associations and I have no doubt that the new President and Council will very materially advance this work during 1931 and that, in a very few years, a satisfactory working arrangement will be evolved that will make for the mutual advantage of the Professional Associations and The Engineering Institute.

On retiring as President of The Engineering Institute of Canada, custom and not the by-laws of The Institute, requires the President to inflict an address upon the members. Annual presidential addresses have touched upon such a variety of engineering subjects that it seemed difficult to find one that would prove of general interest. After considering the matter for some time, it finally occurred to the writer that as the Welland Ship canal will be officially and formally opened in 1931, that the time was opportune for stating briefly the history of some of the large canals of the world and comparing them with the Welland Ship canal.

The question has recently often been asked:—"Is the Welland Ship canal as large or larger than the Panama canal and other large canals of the world?"

In order that those interested may readily obtain some knowledge on the subject and answer the question for themselves, the histories of the following canals are briefly outlined:—Panama, Manchester, North Sea, Kaiser Wilhelm, Suez and Welland.

THE GREAT SHIP CANALS OF THE WORLD

Panama Canal

History,—The subject of transportation across the isthmus of Panama (or Darien) has intensely interested mankind for the past four hundred and thirty-eight years. Its first highway was a pack mule trail or portage which was superseded after three hundred and sixty-three years by a steam railroad, and sixteen years ago this was replaced by a canal. There is as yet no state, or canal, highway across the isthmus.

As early as 1517 surveys were made for a canal across the isthmus and as late as 1788 Spain surveyed the Caledonian bay route and in 1814 decreed the construction of an isthmian canal, but the independence of her American possessions at the close of the Napoleonic Wars ended for ever her contemplated action.

Many surveys were made and projects put forward for the construction of a canal during the early years of the nineteenth century, but nothing definite was accomplished until May, 1878, when a concession was granted by the Colombian government to French promoters to build a canal across the isthmus. This concession was transferred to the Compagnie Universelle du Canal Interocéanique de Panama, commonly called the Panama Canal Company, chartered under the laws of France, with a capital stock of $60,000,000. The Company turned the first sods for the construction of a sea level canal at Panama and at the famous Culebra cut in January, 1880, under the direction of the company's engineer, Count Ferdinand de Lesseps. In 1889 the company was placed in the hands of a receiver whose report showed a total expenditure of $262,000,000 and that 65,000,000 cubic yards of material had been excavated. The new or reorganized Panama Canal Company, formed in October, 1894, sold all its rights and property in the isthmus and its maps and archives in Paris for $40,000,000 to the United States Isthmian Commission, organized in March, 1904, under the authority of the Act of Congress of 28th June, 1902.

As the work of the Commission proceeded the old question forced itself to the front and stayed there until finally decided by Congress, viz., a sea level canal versus a lock canal. The Act of Congress ordering the construction of a lock canal became effective on the 29th June, 1906. On the 1st April, 1907, the civilian control and management of the Isthmian Canal Commission came to an end when Colonel George W. Goethals became chairman and chief engineer of the Commission. When the military commission took over the work, an effective working organization had been built up and perfected, machine shops erected and equipped, many thousands of employees secured and 80 per cent of the required plant had been purchased or contracted for.

Route of Canal,—The canal connects the city of Colon on the Atlantic ocean with the city of Panama on the Pacific. It is 42 miles long from shore line to shore line or 50 miles long from deep water in one ocean to deep water in the other. The lowest point in the Gaillard (Culebra) cut through the continental divide was 305 feet above sea level when the French began excavation in 1880.

A ship on leaving Cristobal, the Atlantic terminal of the canal, passes through the Atlantic sea level section of the canal in Limon bay to Gatun. This section has a bottom width of 500 feet and is 6⅔ miles long. At Gatun the ship is raised 85 feet to Gatun lake through three twin locks in flight. From Gatun to Gamboa, 24 miles, the ship sails through Gatun lake in a channel varying between 500 and 1,000 feet wide and 45 to 85 feet deep. From Gamboa to Pedro Miguel, 9 miles, it passes through the continental divide in the Gaillard cut, 300 feet wide on the bottom and about 45 feet deep. At Pedro Miguel it enters a twin lock and is lowered 30⅓ feet to Miraflores lake, and sails across it 1½ miles, to Miraflores locks where the ship is lowered 54⅔ feet through two twin locks in flight to sea level. Three twin locks in flight would have been built on the Pacific side if it had been possible to secure a rock foundation long enough to accommodate them. From Miraflores the ship passes through the Pacific sea level section of the canal to Balboa, the Pacific terminal of the canal. This section has a bottom width of 500 feet and is 8 miles long. The axis of the isthmus at the canal zone runs from south-west to north-east, and as the canal is built almost at right angles to this line (north-west to south-east) the Pacific end of the canal is about 27 miles east of the Atlantic end.

Gatun Dam,—The Gatun dam may be called the keystone of the lock canal scheme, for on its stability rests the life and existence of the whole project. The dam forms Gatun lake by damming the flow of the Chagres river. It is situated in a narrow part of the valley 7 miles from the mouth of the river and controls nearly the whole of the drainage area of the Chagres basin, about 1,320 square miles.

The dam is 1½ miles long on the crest, 100 feet wide on the top, elevation 105.0, and about half a mile wide at the bottom. The slope on the upstream side is 1 to 7 below water and on the downstream side the slope varies between 1 to 8 and 1 to 16. The normal water level of the lake created by the dam is at elevation 85.0. The upstream slope is protected by stone rip-rap for a height of 10 feet above and below the waterline. The dam rests on a bed of silted clayey material over 200 feet deep, impervious to dangerous seepage and not soft enough to be pushed aside by the weight of the dam. It is a combination of rock fill and hydraulic fill, the latter consists of a mixture of clay and sand and forms an interior core. The dam for part of the distance across the valley is 105 feet high.

On the axis of the dam, midway across the valley, is a hill of rock, through which a channel 300 feet wide and 1,200 feet long is cut for the regulation of the river. The upper end of the channel is closed by a concrete spillway in the form of a circular arc 808 feet long. The crest of the spillway, elevation 69.0, is divided by piers and two abutments into 14 bays, each 45 feet wide, closed by Stoney valves. A short distance below the apron of the dam, the channel is narrowed to 285 feet wide between side walls. The floor of the channel is at elevation 10.0.

The bottom of the valves when fully open are at elevation 92.0. When the lake is at elevation 85.0 they will discharge 140,000 c.f.s. It is allowed to rise for water storage to elevation 87.0, at which level the sluices will discharge 154,000 c.f.s. The top of the walls and gates of the Gatun locks is at elevation 92.0. If the lake rose to this level the sluices would then discharge 220,000 c.f.s. At the time the dam was built the momentary discharge of the river was calculated to be 182,000 c.f.s. It is apparent therefore that the means provided are ample to control any possible flood.

Gatun Lake,—At elevation 85.0 Gatun lake has an area of 164 square miles. It is kept filled by the Chagres river. For eight months of the year there is a water surplus, during which period the lake is kept constantly filled to elevation 87.0. Water is stored for the operation of the canal during the four dry months of January, February, March and April. The month of least flow is March. The annual rainfall varies from 128 inches at Colon, to 92 inches in the interior and 70 inches at Panama. As navigation can be carried on in the canal when the lake is at elevation 82.0, there will be stored for use in the dry season a depth of 5 feet of water, or sufficient after making allowance for evaporation, seepage and power for about forty lockages daily through the locks, using them at full length.

Pedro Miguel Dam,—At the Pacific end of the Gaillard cut, an arm of Gatun lake, the Pedro Miguel lock and dam hold the waters of the Lake from descending into the Rio Grande. The dam is built in a similar manner to the Gatun dam, but without a spillway, as all regulation is done at Gatun.

Miraflores Lake and Dam,—The small lake about 1½ miles long, between the Pedro Miguel and Miraflores locks, has an area of about 1.6 square miles and is 54⅔ feet above sea level. It is fed by the Pedro Miguel and Grande rivers. The lake is maintained by the Miraflores lock and dam. The latter is built in a similar manner to the Gatun dam and has a concrete spillway with eight sluices each 8 feet deep by 45 feet wide for the regulation of the lake. The spillway is designed to discharge 90,000 c.f.s., the estimated discharge from Gatun lake through one of the Pedro Miguel twin locks should its gates be completely carried out, instead of the small run off from its 38½ square miles of watershed.

Locks,—The Gatun locks including their approach piers are 1-1/5 miles long; the Pedro Miguel locks 5/6 mile long; and Miraflores locks 1 mile long. The Gatun locks have a combined lift of 85 feet (28⅓ feet each); Pedro Miguel 30⅓ feet; and at mean tide the Miraflores have 54⅔ feet lift (27⅓ feet each). The maximum useful dimensions of all the locks are the same, 110 feet wide by 1,000 feet long. The depth of water on the mitre sills is 40 feet in salt water and 41⅓ feet in fresh water. The locks are filled and emptied through culverts in the side walls. As about 95 per cent of the vessels in the world are less than 600 feet long, intermediate gates are placed in the locks, dividing the chambers into two parts suited to vessels 350 and 550 feet in length. The lock gates are the mitering type and are made of steel. They have a uniform width of 7 feet and a length of about 65 feet and vary from 47 to 82 feet high and weigh between 390 and 750 tons per leaf.

Safeguards against Accidents,—On account of the naval importance of the canal to the nation in case of war, the United States has made extraordinary provisions for the protection of the canal against accidents that would make the waterway impassable to ships.

All the locks are double, so that if one lock is temporarily out of commission, navigation can still be carried on through the other. The upper locks of each of the three groups of locks are provided with two pairs of gates at their upper and lower ends. The gates are protected by chain fenders and emergency dams are built at the heads of the locks at each end of the summit level and at the head of the Miraflores locks to cut off the flow between the upper and lower levels, should a stream be accidentally established. In order to protect the lock gates as far as possible from being struck by ships, the latter are towed into and out of the locks by electric locomotives moving on the lock walls. No vessel is allowed to move under her own steam when passing through the locks. The movement of all gates, fenders and valves of each group of locks is controlled from a central control desk provided with an elaborate mechanical and electrical system of interlocking to prevent any of the gates, fenders and valves being operated out of their proper sequence.

Gaillard Cut,—The Gaillard cut through the continental divide is 9 miles long and reached a maximum elevation 312.0 on the centre line of the canal near Gold Hill, north of which the ground surface and slope of the cut intersect at elevation 540.0. On the south side, at this point, elevation 410 was reached. No definite slopes are possible at present on account of slides. At the inception of the work the bottom of the cut was elevation 40.0 but has been lowered since by dredging. The cut has a minimum bottom width of 300 feet. The excavation of the cut was one of transportation and there was for a long time about 70 miles of track in the cut, about one mile of which was moved every day. The average output during the peak years of the work was between twelve and sixteen million cubic yards per annum. Up to the end of 1925 about 148,000,000 cubic yards of rock and earth had been removed from the cut and of this quantity 41,000,000 cubic yards was handled in the wet, due to slides.

Total Quantities,—The total excavation taken out by the United States government for the construction of the canal, up to the end of 1925, was 326,000,000 cubic yards. The two French Panama canal companies excavated 78,000,000 cubic yards, of which 30,000,000 was useful excavation for the canal, as built. In the construction of the locks, dams, docks, etc., about 5,000,000 cubic yards of concrete were required. The daily working force during 1911-1912 and 1913 averaged 45,000 men, of whom 5,000 were American.

Tides,—On the Atlantic side the normal variation between high and low tides is one foot and on the Pacific 12½ feet with occasional ranges of 21 feet. The mean level of the Pacific at the isthmus has been found to be about 8 inches higher than the mean level of the Atlantic. In February the mean levels of the oceans are the same, but throughout the rest of the year, on account of current, tide and wind influences, the mean level of the Pacific is above that of the Atlantic. In October the difference is as much as one foot.

Hydro-electric Station,—The canal has built and maintains at Gatun a hydro-electric station of 13,000 kw. capacity with provision for future extension to 22,000 kw. capacity and uses water from Gatun lake for the generation of electric power. A transmission line crosses the isthmus via the Panama railroad and distributes power to the various canal locks and dams and to the towns in the canal zone.

Cost,—It may be said that the United States built the canal from two motives:—national defence and commerce, and due to these causes the cost has been, for accounting purposes, accordingly separated. The investment charged to national defence is about $125,000,000 and that chargeable to commercial use, $275,000,000. The latter figure may therefore be considered the capital investment in a commercial sense.

Opened,—The first ocean steamer passed through the canal on August 3rd, 1914, and on August 15th, 1914, the canal was opened to commerce. The official and formal opening of the canal was proclaimed by the President on July 12th, 1920.

Tolls,—Tolls are levied on the net tonnage of the ships. For laden vessels the rate is $1.20 per net ton and for ships in ballast the rate is 72 cents per net ton, Panama canal measurement. A net ton is 100 cubic feet. The average cost per ton of bulk cargoes is about 65 cents per ton of 2,240 pounds. The cost of tolls on laden ships is equivalent to about 6 days' operation of the ship at sea.

Sixteen Years' Operation,—The Canal Record states that the canal completed 16 years of operation at the close of business on August 14th, 1930. During the 16 years of operation 60,133 commercial vessels have passed through the canal, aggregating 267,490,045 net tons, Panama canal measurement, on which tolls amounting to $250,660,068.98 were levied and which carried 279,338,333 long tons of cargo. Of these totals, the past ten years have accounted for 82 per cent of the transits, 87 per cent of the net tonnage, 86 per cent of the tolls collected and 86 per cent of the cargo carried.

The canal maintains at Balboa large supply depots and repair shops for the use of the canal and shipping. The repair facilities include a drydock 1,000 feet long and 110 feet wide with a depth of 43 feet over keel blocks at normal high tide. Large quantities of coal are always kept on hand and the coaling plants can load from 100 to 500 tons per hour. The oil tanks operated by the canal and oil companies have very large storage capacity, and the supply of pure water is practically unlimited. The canal stores regularly supply 35,000 people on the isthmus and keep ample reserve stocks of all kinds.

Manchester Ship Canal

History,—The Manchester Ship canal provides water communication for ocean going ships between the sea and the city of Manchester. The city with its suburb Salford has a population of one million and within a radius of 50 miles of the city there live nearly ten million people.

The canal was built by the Manchester Canal Company between 1887 and 1894 and was opened for traffic on New Year's day 1894, and in May, 1894, the waterway was formally opened by Queen Victoria.

Original Cost,—At the opening of the canal it had cost about £15,000,000, including the £1,710,000 for the Bridgewater canal which carried with it the old rights of the Mersey-Irwell navigation. It was not until after the War, which shook shipping out of all the old routes, that the Port of Manchester and the canal began to receive their due. The enforced recognition that the canal then received brought dividends for the shareholders and the past 12 years have brought steadily growing prosperity to Manchester. To date, £18,000,000 have been spent on the project, including its docks, warehouses, grain elevators, etc. that have turned the city of Manchester into one of the ocean ports of the Kingdom.

Description of the Canal,—The canal as built may be briefly described as follows:

The entrance to the canal at Eastham is 19 miles from the bar in the lower estuary of the Mersey. Eastham, Cheshire, is on the south side of the river, 6 miles above Liverpool.

The tides in the estuary are referred to Liverpool bay datum, which corresponds to low water springtide, or 14.8 feet below mean sea level. Ordnance datum is mean sea level. Manchester canal datum is 50 feet below mean sea level.

The lower entrance channel to the Eastham locks has been excavated for a distance of 3 miles to only a depth of 13 feet below Liverpool bay datum. The river from this point to Liverpool has a channel depth of 30 feet at low tide.

The canal from Eastham to Manchester is 35½ miles long and has a total rise of 70 feet between mean sea level at Eastham and ordinary water level at the Manchester docks. The difference in level between Eastham and Manchester is overcome by locks at Eastham, Latchford, Irlam, Barton and Mode Wheel. At Eastham, there are three parallel locks and at all the other places two parallel locks. The lower sill of the large lock at Eastham is 13 feet below Liverpool bay datum, and there is a depth of 30 feet on its upper sill.

Dimensions of Locks

Location	Dist. from Eastham Miles	Lift of Locks Feet	Length Feet	Width Feet	Depth on Sill Feet	Length Feet	Width Feet	Depth on Sill Feet	Length Feet	Width Feet	Depth on Sill Feet
Eastham.....		11.5	150	30		350	50		600	80	30
Latchford....	21	14.5				350	45	25	600	65	28
Irlam........	28.5	16.0				350	45	25	600	65	28
Barton......	30.5	15.0				350	45	25	600	65	28
Mode Wheel.	34.0	13.0				350	45	25	600	65	28
Manchester Docks	35.5										

All the locks, except those at Eastham, are provided with an intermediate gate, that may be used for economizing water. The large locks 600 feet by 65 feet can in this way be made 450 feet by 65 feet and 150 feet by 65 feet. The smaller locks 350 feet by 45 feet, along side the larger ones, can be made 230 feet by 45 feet and 120 feet by 45 feet.

The canal between Eastham and Stanlow oil dock, 4½ miles above Eastham, has been excavated to a depth of 30 feet and from Stanlow oil dock to Manchester the canal is only 28 feet deep.

The standard bottom width of the canal, 28 feet deep, is 120 feet. In the rock cut between Warburton bridge and Millbank wharf it is only 90 feet wide.

Eastham-Latchford Reach,—This reach of the canal, 21 miles long, is tidal and its normal depth is 30 feet as far as the Stanlow oil docks, and for the remaining distance, 16.5 miles, its normal depth is 28 feet. The reach receives a very large flow from the River Weaver, which enters the canal 10 miles above Eastham, and it also receives an influx from the tide during the levelling period. When the tide rises 26 feet 2 inches above Liverpool day datum, the water levels in the river and canal equalize and the Eastham locks are opened and the tide allowed to enter the canal. When a 31.0 feet tide occurs the water level in the canal rises about 5 feet. When the tide is flowing into the canal the current above the Eastham locks is about 2 to 3 miles per hour. The greatest velocity in the reach occurs at Pool Hall cutting, where during the levelling period on certain spring tides the velocity may reach 4.5 miles per hour, which, however, only lasts for a few minutes, and practically causes no hindrance to navigation, as the movement of vessels can be timed to avoid the difficulty. Just before the tide turns the Eastham lock gates are closed and the surplus waters above the normal level (elevation 61.5) of the reach are discharged back into the river under regulated conditions through sluices and side locks.

The Weaver sluices have a total length of opening of 300 feet and are the most important of the regulating works on the canal. The only currents produced in the reach during the operation of discharging the surplus waters back into the river is that adjacent to the sluices and is not detrimental to navigation. The current in the river below the Eastham locks is about 5 knots per hour at half tide, and at the later stage of the river, the elevation of the water is the same for both spring and neap tides.

For a distance of 13 miles above Eastham the canal follows the shore line of the river, and for long distances across bays, etc., the canal channel is only separated from the river by an embankment. The toes of the embankment are made with rock and the hearting with clay from the excavation of the canal prism. The slopes and top of the bank are covered with stone pitching. Where the bank was built on sand beds, timber sheet piling was driven down to a substratum of clay and gravel, along each toe of the bank. Above Runcorn, for a distance of a quarter of a mile, the north side of the canal prism is formed by a concrete gravity section wall instead of an earth embankment.

At low tide the head on these embankments is 24.5 feet. They have given no trouble from settlement, erosion or leakage.

The deepest cutting is near Runcorn where the depth is 66 feet for a short distance. The largest cutting is at Latchford, where it averages 55 feet for a distance 1½ miles. The slopes of the cuttings vary from 1 to 1, to 2 to 1, and in rock cuts the sides are nearly vertical.

Bridges,—The canal is crossed by fifteen bridges, eight being swing spans, and seven, fixed bridges.

The height from normal water level to the underside of the girders in the seven fixed bridges over the canal gives a clear head room of 74 feet 6 inches, except the Runcorn bridge, which is 82 feet 4 inches above normal water level. This head room is however several feet less on the Eastham-Latchford reach at high tides, and in order to avoid detention to ships from this cause, the masts and funnels of ships are lowered to clear the bridges at 70 feet above normal water level.

The five railways that cross the canal are all carried over it by high level bridges. These crossings involved the construction of eleven and one-quarter miles of railway diversion. The question of railway diversion was a formidable one to deal with in the design of the canal, and added greatly to its cost.

The swing bridges are all operated by hydraulic power and with one exception provide a clear waterway of 120 feet.

Barton Aqueduct,—The Barton aqueduct, an iron trough 235 feet long, 75 feet wide, and 6 feet deep, carries the Bridgewater canal across the Ship canal. The trough is supported on a swing bridge, that provides two openings each 90 feet wide. The bridge is operated with hydraulic power. The trough is closed at each end with gates when the bridge is opened for navigation. Similar gates are raised across the ends of the Bridgewater canal to retain the water in it when the bridge is open.

Locks,—All the locks are founded on red sandstone. Their walls are built of concrete throughout with a brick facing above the level of the lower reach. The brick is a hard blue non-absorbent metallic brick, and has stood up very well over a period of 35 years. The width of the centre wall of the two locks at each locality above Eastham is about 30 feet. The locks are fed through culverts in the side walls, which were originally controlled by Stoney sluices. These sluices were taken out some years ago, due to wear and trouble with their roller nests and rails, and replaced with solid greenheart shutters sliding on polished granite. The shutters are operated with hydraulic rams and have given excellent satisfaction and are moreover absolutely water-tight, a very desirable feature in the Mode Wheel and Irlam locks.

Lock Gates,—The upper gates of the locks are placed on a breast wall. The gates are made of horizontal bars of greenheart timber, and sheeted with plank. The original gates are still in use and are in excellent condition. The iron spikes of the planking corroded badly and have been replaced with galvanized iron lag screws and the planking recaulked. The gates are operated by hydraulic machinery.

Preventer Cables,—After the canal had been in use for about 10 years wire cables attached to the gate recess walls and to the tops of the gate leaves at their mitre ends were placed on the gate leaves of all the locks. The object of the cables is to prevent the gate leaves tipping over when slammed against the sills by bad operation and when struck on the upstream side by ships. It is said that these cables have saved gates being knocked out on more than one occasion.

Lighting Canal,—With the exception of the locks, which are dimly lighted, the canal is not lighted. During 1928 the canal authorities were going to experiment with a vessel using a searchlight placed under each end of her bridge to light the cânal banks. When passing another ship the light nearest the approaching ship would be turned out. If this experiment proved unsatisfactory, it was then the intention of the company to light the canal in a similar manner to that of the Kiel canal, by a line of small lamps along each bank.

Water Supply,—As the upper or inland section of the canal, Latchford to Manchester, has taken the place of the Rivers Mersey and Irwell, the canal now acts as the main drain for a large section of country. The Manchester Basin and Mode Wheel locks are supplied with water from the Irwell river. The supply for the Barton and Irlam locks is augmented by some minor streams and a flow of 46 c.f.s. from the Manchester and Salford sewage works, and as the Mersey enters the canal above the Latchford locks, the latter have an unlimited supply.

As the canal above Latchford is a canalized river each lock has alongside it a broad and deep raceway, controlled at its lower end by a battery of Stoney sluices, each 30 feet wide. There are four sluices at the Mode Wheel and Barton locks, five at the Irlam locks and only three at the Latchford locks, as the combined flows of the Irwell and Mersey rivers do not flow all the way down the canal to the Latchford locks, but are discharged into the old course of the Mersey at Rixton Junction and thence through the Woolston weir (opposite Mile 22 above Eastham) and then assist in maintaining the depth in the navigable channel of the river to Warrington, as prescribed by Act of Parliament. The crest of the Woolston weir is maintained at the same elevation (76.00) as the Latchford-Irlam reach, and acts as a spillway for the reach.

Silting,—The Mersey and all its tributaries above Liverpool carry large quantities of silt when in flood, The Irwell is continually filling up the Manchester basin. The Mersey enters the canal at Mile 28, below the Irlam locks, and in heavy flood periods, which last ten to fourteen days, will in that time deposit in the canal as much as 80,000 cubic yards of silt. An ordinary flood deposits in the canal 40,000 cubic yards of silt.

This silting up of the canal reaches and the lower entrance of the Eastham locks necessitates the Canal Company maintaining a fleet of ladder and clam shell dredges constantly at work in the canal.

Use of Canal by Ships,—It took ten or more years for the Canal Company to convince ship owners that the canal could be safely navigated by large ships. The Great War helped materially to break down this prejudice, as many ships were then ordered by the Admiralty to go to Manchester, and during the four years of the War, they learned against their will that the canal could be safely navigated, and today the old prejudice against large ships going up the canal has gone forever.

Draft,—Ships are allowed to load at Manchester to 26 feet and on special occasions may load to 26 feet 6 inches as a maximum. When they reach Stanlow, they may load to 28 feet, which they generally do with bunker coal. The canal operates on the principle that a ship will draw about 6 inches more in fresh water than in salt water. A ship will also on maximum draft go faster in the canal at slow speed than at half speed, as in the latter case she will feel the bottom more and consequently slow down.

Eastham Entrance,—Ships enter the canal at Eastham on ebb tides and leave it on flood tides.

Navigation at Night,—Notwithstanding the fact that the canal is not lighted it is used at night by large and small boats, as it is to their advantage to do so. During certain seasons of the year, fog prevails, especially during the early morning hours and in the forenoon. By sailing at night ships can reach Manchester before fog falls towards dawn, and therefore save 6 to 12 hours delay. The canal is not navigated during foggy weather.

Tolls,—At Liverpool the dock and town dues are paid by the merchant, these are comparable to the wharfage dues and the Ship canal tolls paid on the Manchester Ship canal by the merchant. At Liverpool the ship's net registered tonnage dues are paid by the ship owner, the same as on the canal.

Railways,—The Canal Company have built to date 200 miles of railway on the docks and at many points along the canal, and connect with the railway systems of the Kingdom at several places between Ellesmere port and Manchester. The company's railway rolling stock consists of 54 locomotives and 2,432 cars for hauling freight over their own lines.

Oil Docks,—During 1927 there were imported 304,000 tons of gasoline and 455,000 tons of oils. The latter are chiefly handled through tanks at Manchester, Eccles, Weaste and Barton. The gasoline is handled through tanks at the large oil dock at Stanlow, 5 miles above Eastham.

Canal Docks,—In 1927 nearly 700,000 tons of coal were exported from the Port of Manchester. The coal was largely, if not all, bunker coal. The principal bunkering station on the canal is the Partington coaling basin, which is the nearest port of shipment for the Lancashire, Derbyshire and Staffordshire coalfields. Other coaling facilities are at Haydock coal wharf and at Acton Grange. During 1927 the Canal Company built a $2,000,000 eoal loading plant at Ellesmere port, which will enable the largest outbound vessels to complete their coaling at this point. The plant includes a concrete dock 1,200 feet long, railway exchange sidings and railway storage yard and two coal handling units which under normal working conditions of emptying the railway cars and delivering the coal from them at a continuous and regular rate within the ship's holds or bunkers, has a capacity of 800 tons per hour (or 400 tons per hour per unit).

The Port of Manchester includes the whole of the canal from Eastham to Manchester. The dock estate of the city covers an area of 407 acres. This acreage includes a water space of 120 acres. The dock walls are 5½ miles long. The docks are equipped with hydraulic steam and electric cranes and also with a large coaling crane and a fleet of lighters and floating pontoons. The towns along the canal are also equally well supplied with docks and equipment.

The import and export tonnage of the port amounted for the year 1927 to 6,359,420 long tons and the revenue to £1,576,237.

North Sea Canal

History,—In the delta of the rivers Scheldt, Meuse and Rhine lies the Kingdom of Holland or the Netherlands. Its western eoast line trends south and north and at the intersection of 53 degrees north latitude and 5 degrees east longitude, the cost line turns almost due east along the Frisian islands, slices of the original coast line. Behind the western end of this chain of islands lies the Zuider Zee (Southern sea) which acquired its present shape about 1300 A.D.

The Zuider Zee is mean sea level and has a tidal movement of only 4 to 15 inches. Its bottom is very flat and only over a small area does it exceed 14.5 feet in depth. Its most important ehannel to the North sea is Texel strait between the northern point of the province of North Holland and Texel island. At Den Helder, on the North sea end of Texel strait, the tidal variation is about 5 feet.

Centuries ago, when ocean vessels were no larger than the smaller schooners of to-day, the Amsterdam fleet ruled the seas through the Y and the 14 feet channels of the Zuider Zee. The Y, on which is situated the city of Amsterdam, is a long narrow arm of the bay in the south west corner of the Zuider sea. The silting up of the Y, and the bar outside of it called the Pampus, reduced the Zuider Zee channel to 9 feet, and caused ocean vessels to abandon Amsterdam about the beginning of the nineteenth century.

North Holland Canal,—The first attempt that Amsterdam made to overcome the destruction of its trade wrought by the Pampus sand bar was the construction, in conjunction with the government of Holland, of the North Holland canal during 1818-25, from Amsterdam to Den Helder on Texel strait, at a cost of 11,000,000 guilders. The canal was 49 miles long and 16.5 feet deep. Owing to its shallow draft and tortuous course, and its indirect route for vessels bound south, and the advent of the steamship, and the ever-increasing size of vessels, Amsterdam was soon left as badly off as when the construction of the canal was begun in 1818.

North Sea Canal,—As the city again faced the loss of its ocean trade, an east and west waterway was projected to the North sea, and a company, aided by Amsterdam and Holland, was formed to build it. The new waterway, called the North Sea canal, was located along the axis of the Y for 11 miles to the coastal uninhabited sand dunes at Velsen and through them for 3.7 miles to the coast, where a small town, "Ymuiden" (mouth of the Y) soon grew up at the North sea entrance of the canal. At Ymuiden, ordinary high tide is 2.5 feet above mean sea level and ordinary low tide is 2.8 feet below mean sea level. Storms cause a tidal variation of as much as 12.0 feet above mean sea level and 8.0 feet below it.

All canal elevations are referred to Amsterdam datum (known as N.A.P.) which is approximately mean sea level off the Netherland coast.

The normal water level of the canal between Ymuiden and Amsterdam is 1.5 feet below the datum plane.

Old Locks, 1869-72,—The first North Sea canal was designed for a depth of 23.0 feet below normal water level and a bottom width of 88.5 feet. Through the Y the canal channel was excavated 88.5 feet wide on the bottom, with 2 to 1 slopes, but the banks built along each side of the channel were placed 400 feet apart for future widening of the canal. Two locks and one weir were built at Ymuiden between 1869-72. These structures are still in existence. The larger one is 59 feet wide, 390 feet long, with a depth of 24.5 feet on the sills below normal canal level. The piers of the outer harbour at Ymuiden extend seaward 4,900 feet to the contour of 28 feet below mean sea level, and the channel between them was then dredged to 28 feet at the end of the piers and decreasing to 24½ at the locks.

Orange Locks,—Concurrently with the construction of these works, the Orange locks, weir and dyke at Schellingwoude were built to close the eastern end of the Y at Amsterdam. Storms raise the Zuider Zee at the Orange locks 8.5 feet above its mean level and lower it 7.5 feet below it. The canal was opened for 16.5 feet draft in 1876, and for 21 feet depth in 1877, and was completed for 24.5 feet depth in 1880. The canal was then crossed by three swing bridges, each with a clear channel opening of 62 feet. Two of the bridges were near Velsen and one at Zaandam.

In 1881-83 the depth of the canal entrance from the North sea was deepened to 28.0 feet below mean sea level and the canal to 25.5 feet below normal water level.

Canal Taken Over by the State, 1883,—On account of the financial difficulties that the canal company incurred in the construction of Ymuiden harbour and the enlargement of the canal, the Holland government took over the canal in 1883.

To-day, the state owns and maintains the canal, the Orange locks, weir and dyke at Schellingwoude, but the city of Amsterdam owns and maintains the Port of Amsterdam within the city limits, and as the water level of both are the same, they may be considered as a large wet dock 16 miles long.

About 1760 Amsterdam purchased from the holding company representing the various dock owners and other interests who then controlled the harbour, all their lands, docks, warehouses, equipment, etc. and the municipality also owns to-day all the canals within the city limits and the railway sidings and yards on the docks. Many of these docks are now leased to steamship companies and the railway sidings on the docks to the railway companies.

The Amstel river is now held at the same level as the Port of Amsterdam, and forms one of the many small canals that intersect the city in all directions. These small canals are flushed every night by water from the Zuider Zee, through the weir at Schellingwoude.

Improvements, 1889-1924,—Following the purchase of the canal by the government in 1883, it soon became apparent that owing to the rate at which the size of ships was increasing, it would be necessary to build a new lock at Ymuiden and deepen the canal if the Port of Amsterdam was to retain her foreign trade, and towards this end the following improvements were carried out between 1889 and 1924 at a cost of about 61,000,000 guilders ($24,400,000).

Present Lock (1896),—Between 1889 and 1896 a new lock was built at Ymuiden, north of the old lock. Its dimensions are 82 feet wide, 738 feet long, with a depth on the sills of 32.0 feet below normal eanal level. Concurrently with the construction of the loek, the canal was deepened to 28 feet and the harbour to 31.0 feet below mean sea level.

Between 1897-98 the bottom width of the canal was increased to 118 feet on tangents and to 130 feet on curves.

In 1899 the government decided to enlarge the canal to such dimensions as would accommodate the largest ships that could lock through the 1896 lock at Ymuiden, and in accordance with this decision the following improvements were carried out between 1899 and 1907: viz., the Ymuiden harbour was deepened to 34.5 feet below mean sea level and the canal to 32.0 feet with a bottom width of 164 feet on tangents and 197 feet on curves with slopes 3 to 1. At the same time the two railway swing bridges over the canal were rebuilt so as to give clear navigable openings of 180 feet and the highway bridge at Velsen was replaced by a steam ferry.

Harbour,—The North sea entrance is formed by two converging lines of concrete piers, each about 5,012 feet long, that extend seaward to the contour of 28 feet at mean sea level. At the shore line they are 3,936 feet apart and at the outer ends 853 feet. The latter width is reduced to 722 feet by blocks of concrete placed around the pier heads. The top of the piers vary from 13 to 16 feet above mean sea level.

Lighting Canal,—Along each bank of the canal there is an electric transmission line. The poles are set on a narrow berm at the top of the stone rip-rap of the prism slopes. The canal is lighted by 25 candle power incandescent lamps placed opposite each other and spaced about 800 feet apart on tangents, 400 feet apart on curves and near the locks 300 feet apart. The locks are lighted with clusters of three 50-candle power lamps. The lamps have clear glass bulbs and along the canal are set 45 degrees to the vertical plane on short brackets placed 25 feet above the water. Small reflectors at the back only of the lamps throw the light rays down, which very effectively marks the water line along each bank. The lamps are connected in series of 113 lamps and lighted by single-phase alternating current of 3,500 volts.

Ice Conditions,—The winters in Holland are not severe. January is the coldest month when the temperature may drop to 12 degrees F. for a few days at a time. During many winters there has been no ice in the canal. In the winter of 1927-28, the ice was 6 inches thick, and in 1890, it was about 20 inches thick, and gave a lot of trouble. In the Port of Amsterdam, ice causes very little trouble on account of the large number of small and large vessels that are constantly moving about.

Since the canal was equipped with ice breakers in 1893 it has never been closed by ice. This work is done by a company assisted by the government, the province of North Holland and the city of Amsterdam. The company own two ice breakers, the larger being 141 feet long, 35.5 feet beam with a draft of 17.5 feet and 830 i.h.p.

Drainage and Flushing Canal,—About 1¼ million gallons of water are pumped every 24 hours into the canal from the low-lying lands surrounding the canals. In wet seasons as much as 2 billion gallons are pumped into the canal every day from the polders. The Port of Amsterdam is also flushed every night with about 110,000,000 gallons of water from the Zuider Zee. All this water is discharged into the North sea through the Ymuiden weir at ebbtide. The water level in the canal is maintained as closely as possible at its normal water level, 1½ feet below mean sea level, but may vary from 4 inches below normal to 1½ feet above it during the process of receiving and discharging the foregoing waters. If these surplus waters, on rare occasions, cannot be discharged into the North sea due to storms or other causes they are pumped out of the canal into the Zuider Zee by six steam-power-driven scoop wheels at Schellingwoude.

Silting in Ymuiden Harbour,—The prevailing winds along the Holland coast are southwest to northeast. The greatest storms come from the northwest and cause the highest storm tides.

The tidal currents are parallel to the coast. Flood tides flow northeast and have a velocity of 1.75 miles per hour and the ebb tides flow southwest with a velocity of 1.25 miles per hour. These velocities are 1/5 greater at springtides and 1/5 less at neaptides.

Under normal weather conditions the tidal currents carry very little sand and silt, but give serious trouble from this cause during stormy weather. Flood tides during storms from the southwest silt up the channel beyond the piers and in the outer harbour and make constant dredging necessary. The canal maintains for this purpose a fleet of three suction and three dipper dredges.

As the present breakwaters only extend out to the 28 feet contour at mean sea level, it is considered impossible to maintain a greater depth than 39 feet below mean sea level in the channel beyond the breakwater until a new line of breakwater piers are built out to the contour of 49 feet below mean sea level which it is the intention of the state to do in the future in connection with the canal improvements authorized by the government in 1917. When the new breakwaters have been built it is expected that silting in the harbour channels will be materially reduced.

As very little silting occurs in the canal, only a small amount of dredging has to be done every ten years to maintain the required navigable depth.

Canal Dues,—Since 1890, there have been no canal dues levied; pilot dues are however collected.

Ymuiden Fishing Fleet,—When the North sea canal was opened in 1876 the Dutch North sea fishing fleet sought shelter in Ymuiden harbour and 20 years later (1890-96) a large basin and docks were built for the fleet on the south side of the lock entrance. The basin is 2,300 feet long by 500 feet wide and its docks are equipped with sheds, ice plants, water supply and railway facilities for the fish trade. Today the Ymuiden fishing fleet is one of the largest on the North sea coast.

Rhine Canal,—The port of Amsterdam competes with Rotterdam for the large and lucrative trade of the Rhine valley. Its connection with the river is through the Merwede canal which to-day accommodates barges of 2,000 tons carrying capacity. The Rhine barges are not charged canal or port dues. Amsterdam's trade with the Rhine basin has increased sevenfold during the past thirty years and is therefore of great importance to the port. In order not only to retain this trade, but to enlarge it, Amsterdam contemplates in the near future enlarging and extending the Merwede canal to Tiel on the Rhine, a distance of about 44 miles. Tiel to Rotterdam via the river is about 45 miles. The enlarged Merwede canal will have a bottom width of 164 feet and be 15 feet deep. Its three locks will have a length of 1,082 feet and width of 98.5 feet, and will accommodate 5,000 ton barges. The largest Rhine barges today have a carrying capacity of about 4,300 tons.

1917 Enlargement,—In 1928 there were in operation two locks at the North sea entrance of the canal, the large old 1876 lock, long out of date, and the 1896 lock which can accommodate the largest vessels likely to visit Amsterdam in the near future. The port is however solely dependent upon its continual operation and any damage to it that would necessitate closing it for extensive repairs would react seriously on the trade of Amsterdam. This fact and the rapidly increasing size of ships (in 1925 there were 1,047 ships too large for the lock) determined the government to appoint a Royal Commission in 1909 to investigate the question and to recommend what enlargement of the canal it considered necessary for the preservation and maintenance of Amsterdam's trade.

In 1911, the Commission recommended the construction of a new lock 360 meters by 40 meters and a depth of 14 meters below Amsterdam level (1,180 by 131 by 44.5 below normal canal level), but due to the war and other conditions, it was not until 1917 that an act was passed, authorizing the following enlargements of the canal to be carried out:—

(1) The construction of a new lock at Ymuiden 400 meters by 50 meters by 15 meters below Amsterdam datum (1,312 feet by 164 feet by 47.5 feet below normal canal level).

(2) The enlargement and deepening of the canal to 47.5 feet as and when required.

Cost of Enlargement,—The new lock and its entrance channels is estimated to cost $7,500,000, of which the Dutch government will bear 66 per cent, the municipality of Amsterdam 28 per cent and the province of North Holland 6 per cent.

Canal Enlargement,—In conjunction with the construction of the new lock additional land has been purchased for the ultimate enlargement of the canal to a bottom width of 328 feet and a depth 47.5 feet below normal water level with 3 to 1 slopes, but the canal will only be enlarged for the present to a bottom width of 246 feet and a depth of 39.5 feet below normal water level with 3 to 1 slopes. The curves in the canal will also be reduced to a minimum radius of 9,840 feet and both channels under the swing bridges will be excavated. When these improvements have been completed by 1934, ships like the "Aquitania" (886 feet by 97 feet by 36 feet) can then navigate the canal, as the wetted cross section of the ship and that of the canal will leave a ratio of 1 to 4.3, or slightly greater than the ratio of the wetted cross section of a lake freighter 65 feet beam and 24 feet draft to the wetted cross section of the 25 feet depth of the Welland Ship canal.

Ymuiden Breakwaters,—The ultimate enlargement of the canal to 47.5 feet depth also involves the construction at Ymuiden of a new northern breakwater and the extension of the present southern one at that point. For the present it is only contemplated to excavate the entrance channel to the new lock and the existing harbour entrance channel to 41 feet below mean sea level. If it is found impossible to maintain a channel 41 feet deep beyond the present piers the construction of the new breakwaters will then be proceeded with. It will, however, be a very costly undertaking, as the 49 foot (15 meters) contour at mean sea level is 2 miles or more off shore and the 16 meter contour is more than 3 miles out to sea.

1919-1931 Lock,—The new lock is located north of the present one, but it was not until 1919 that the work of excavating its 2½ miles of approach channels and pit was begun and the placing of concrete was not started until 1922. It is expected that the lock will be completed and placed in commission early in 1931, at which date its approach channels will only have been excavated to a depth of 33 feet.

Gates,—The lock chamber is closed at each end by rolling caisson gates that are moved normal to the axis of the lock. The caisson is supported at each end on two rollers set normal to its axis on two eight-wheel trucks. At the western end of the lock there are two gates, one of which is a spare that can replace either of the service gates as all three are exactly alike. A gate weighs 1,184 tons and its airchamber has a volume of 49,400 cubic feet divided into 16 compartments, each one of which may be filled with water and emptied by compressed air. Under normal working conditions the air chamber is partly filled with water in order to reduce the weight of the gate to 120 tons on its trucks. When empty the caisson has a draft of 12 feet. The gate recesses are designed to be closed with steel bulkheads and unwatered for inspecting, repairing and painting the caissons. The gates were built at Rotterdam during 1928 and were towed to Ymuiden floating in a horizontal position.

Operation of New Lock,—All the gate and valve machinery is erected as far as possible above the top of the lock walls, and will be electrically driven and operated by remote control from an operating cabin built on top of the gate machine house at the eastern end of the lock. There is a cable tunnel at each end of the lock. In the operating room a large wall board will show by small panels and coloured lamps the positions of the valves and gates as they are opened and closed. Sensitive water gauges will also show the water levels in and outside the lock chamber, as the gates can only be operated when the water level on each side of them has been equalized. The operator in the control room will be directed in his operations by men on the lock walls who will communicate with him by phone or electric horn. The latter condition is an inherent defect in a remote control system where the operator is blind and is one that has been eliminated as far as possible in the local remote control system adopted for the locks of the Welland Ship canal.

Conclusions,—At the beginning of the last century the port of Amsterdam faced the Zuider Zee, but in its efforts to keep its approaches deep enough for the largest ships it has been completely turned about and now faces the North sea. During the hundred years struggle to retain its position as one of the great European ports, it has enlarged its North sea entrance three times, and is now engaged on the fourth enlargement which it believes when completed will assure its maritime position for many decades to come. These four enlargements remind one of the hundred years fight that the Welland canal has had to accommodate the largest size of ships, which all over the world appear to be constantly ahead of channel, lock, and port accommodation.

The Kaiser Wilhelm Canal

Entrance to Baltic Sea,—The North sea is separated from the Baltic sea by the Jutland peninsula and up to the time the Kaiser Wilhelm canal (commonly called the Kiel canal) was opened for traffic in 1895 the only access to the Baltic for shipping was via the Skagerrak, Kattegat and the channels between the Danish islands at the southern end of the Kattegat.

The route round the Skaw is 240 miles longer than via the Kiel canal and it is besides very dangerous to shipping, due to bad currents, shoals, reefs, prevailing hazy and foggy weather, and to the want of aids to navigation. The Skagerrak and the Jutland coast have therefore always had a bad reputation among navigators on account of the many shipwrecks that have occurred along these channels.

History,—Towards the middle of the last century an agitation arose for the construction of a ship canal across the southern end of the Jutland peninsula and as Prussia at this time was engaged on the consolidation of the numerous German provinces into a United Empire, she determined to acquire the Danish Duchies of Schleswig and Holstein so that she could control the construction of the projected canal as its construction would place Germany in control of the Baltic and provide a protected base for her contemplated navy.

As the result of the short Danish-Prussian-Austrian war of 1864, Denmark, under the Treaty of Vienna, 30th October, 1864, renounced all her rights in the Duchies in favour of Prussia and Austria, and by the Treaty of Prague, 23rd August, 1866, Austria ceded the Duchy of Schleswig to Prussia.

The formation of the Prussian province of Schleswig-Holstein gave Prussia absolute control of the southern half of the Jutland peninsula and placed in her hands the construction of the projected canal across Holstein from the mouth of the River Elbe on the North sea to Kiel on the Baltic sea.

Baltic Sea,—The Baltic is 960 miles long and has a maximum width of 400 miles with a coast line of 5,000 miles, and is surrounded by Sweden, Russia, Prussia and Denmark. The principal Prussian port is Kiel, the German naval base on the Baltic. At Swinemuende, Prussia, the mean level of the Baltic is 0.22 feet below mean sea level at Ostend. There are no tides in the Baltic but due to storms the water level will fall 6.5 feet and rise nearly 10.0 feet above its normal level.

Proprietor,—The Kaiser Wilhelm canal is owned by the state, which administers it through the Reichs Kanalamt in Kiel. The managing director in Kiel and the port captains at the entrances to the canal are in charge of the shipping and the canal locks under the Reichs Kanalamt. Special officials are in charge of the maintenance of the canal works.

First Canal,—The canal is 62 miles long and traverses the old Danish Duchy of Holstein from Brunsbuettelkoog on the Elbe (20 miles above Cuxhaven and 45 miles below Hamburg) to Holtenau (a suburb of Kiel) on the Baltic. The canal is fairly straight and runs through the west Holstein marshes, the moorland plain of Kudensee and Burg, the watershed between the Elbe and the Eider, and the lowlands of Gieselau, Haarlerau, Luhau and Jevenau. In the vicinity of Rendsburg it follows the valley of the Eider into lakes Audorf and Schirnau which were lowered 6.5 to 8.0 feet, and 8 miles west of Holtenau it crosses Lake Flemhude which was lowered 23.0 feet. From the Rendsburg lake district to Holtenau the land is generally 10 to 40 feet above the water surface of the canal.

Normal Level of Canal,—The normal level of the canal was about 0.2 feet above the normal level of the Baltic, or about mean sea level of the North sea.

Dimensions of Canal Prism,—It was 72 feet wide on the bottom, 220 feet on the surface and had a depth of 29.5 feet. At curves with a radius of 3,280 to 8,200 feet the bottom width was increased to 197 feet.

Cost of Canal,—The first canal was built between 1887 and 1895 at a cost of about 166,000,000 marks ($39,840,000). Of this amount $2,640,000 were spent for the canal right-of-way.

Locks,—The canal was protected at both ends by twin locks that were designed to accommodate ships 475.5 feet long, 75.5 feet beam and a draft of 28.0 feet. The locks were accordingly designed for a usable length of 492 feet, a width of 82.0 feet and a depth on the sills at Holtenau of 31.4 feet and at Brunsbuettelkoog of 32.7 feet. These locks are provided at each end with two pairs of mitering steel gates placed back to back, so that the locks could be used at all stages of the tide. These locks also have a middle pair of gates. A lock 223 feet long, 39.4 feet wide and a depth of 16.5 feet on the sills was built at Rendsburg to connect the Eider river with the canal.

Bridges,—Highway and railway traffic was carried over the canal by two overhead and four swing bridges. The overhead bridges had spans of 515 and 534 feet and a clearance of 137.7 feet above normal water level. The swing bridges had clear openings of 164 feet and were operated by hydraulic power.

The canal was lighted by electricity from power stations at Brunsbuettelkoog and Holtenau.

Second Canal, 1909-1914

Second Canal,—The first canal satisfied shipping requirements for about a decade when it became manifest that it could no longer accommodate the larger ships of the navy and mercantile fleets. The "Deutschland" built at the beginning of this century was 656 feet long and the "Imperator" ("Berengaria") then under construction and finished in 1912 was 884 feet long, 98 feet beam with a draft of 36 feet. On account of these and many other ships of the merchant marine and of the navy not being able to pass through the canal, and on account of the constantly increasing congestion of the waterway, the canal authorities recommended the enlargement of the canal to the German government. The recommended enlargement was approved by the Reichstag in 1907.

Recommended Improvements,—The improvements that were finally decided upon were:—

1. To deepen and widen the prism.
2. To flatten the curves.
3. To rebuild the bridges.
4. To build two new twin locks at each entrance to the canal.

Normal Level of the Canal,—In order to facilitate navigation into the Baltic and North seas, the normal level of the canal, which was then only slightly above the mean level of the Baltic, was raised about 1.1 feet above the normal level of the Baltic or about 0.9 feet above the mean level of the North sea, or about 4.0 feet below the average high tide in the Elbe at Brunsbuettelkoog. Raising the normal level of the canal made it 37.1 feet deep and made the canal 338.0 feet wide at the waterline and provided a wetted cross section of about 9,243 square feet.

The canal was deepened from 29.5 feet to 36.0 feet and the bottom was widened from 72.0 to 144.0 feet. The bottom width was increased at the sharper curves and also at the passing places or sidings.

The curves were flattened to radii of 5,904 to 19,680 feet.

Passing Places or Sidings,—There are eleven sidings where the canal is widened on both sides of the canal prism for ships to pass. The sidings are generally about 440 feet wide and 2,300 feet long. Four of them are 540 feet wide and 3,600 feet long. Each siding is provided at one end with a turning basin 1,000 feet in diameter. Many of these sidings are old ones enlarged. Along each side of the sidings clusters of 7 to 12 timber piles have been driven. The clusters or dolphins are about 50 feet apart. Ships moor against the dolphins with their lines on mooring posts ashore. The dolphins last about 15 years and ships damaging them pay for the damage done.

Bridges,—Although the spans of the fixed overhead bridges were long enough for the enlarged canal, they were replaced with longer and stronger steel bridges. The main span of the new bridges is about 492 feet and the clearance is the same as provided by the old bridges — 138 feet. There are highlevel railway bridges at Hochdonn, Gruenental, Rendsburg and Levensau. The Prinz-Heinrich highway bridge at Holtenau is also a new highlevel bridge and there is a new swing bridge at Rendsburg with a clear opening of 246 feet.

The Rendsburg highlevel bridge is a fine structure 8,200 feet long and contains 18,000 tons of steel. The approaches to the canal span are long curved inclines. The canal span carries a suspended trolley car ferry like the one at Duluth. At Nubbel there is a double swing span highway and railway bridge, whose pivot piers are 308 feet apart. The bridge operates very quickly.

New Locks,—New twin locks were built north of the old locks at Brunsbuettelkoog and south of those at Holtenau. The new locks have an effective length of 1,082.5 feet, a width of 147.5 feet and a depth on the sills of 46.2 feet below the new normal water level of the canal, and 39.4 feet below extreme low water level of the Elbe and 45.1 feet below normal level of the Baltic and 39.4 feet below low level of the Baltic. These dimensions provide for future deepening of the canal and the passing through it of damaged ships. It may be noted that these locks are larger than the Panama canal locks.

Caisson Gates,—The locks are provided with three rolling caisson gates 154 feet long by 26 feet wide. Those at Brunsbuettelkoog are 71.5 feet high and those at Holtenau are 61.0 feet high. The middle gate of each lock divides the chamber into usable lengths of 328 and 725 feet, and it may also be used as a spare gate, as the gates of each lock are interchangeable. The gates are opened and closed in four minutes with an electric current of 50 amperes at 500 volts, but they may be opened and closed in two minutes with double the current.

Remote Control of Locks—The gates and valves are equipped with electric motors that are operated by remote control. The operator's cabin is located at the middle of the centre wall. In the cabin on each side wall there is a board about 3 feet wide by 12 feet long on which are shown by small panels the gates and valves of the locks. The small panels move as the gates and valves open or close. Full open positions are also indicated by green lamps and full closed positions by red lamps. Along the bottom of the boards are the switches for controlling the gates and valves. Water level indicators record the water levels inside and outside of the lock chambers. One operator looks after both boards and performs all operations of opening and closing the gates and valves by directions from men on the lock walls, who transmit their orders to the operator by telephone, or by signals on an electric horn in the operator's cabin. The remote control was designed and installed by the Siemens-Schuckert Werke, Berlin. A similar remote control equipment will be used at the new Ymuiden lock of the North sea canal.

Dates of Construction,—The work of enlarging the canal was begun in the summer of 1909 and completed at the end of 1914. Most of the work was done by contract, but the canal forces unwatered the lock pits and did some of the dredging in the upper Eider lakes, and the canal authorities also built and operated camps and hospitals for the contractors' men employed on the work.

Cost,—The cost of the enlargement was estimated at 223,000,000 marks ($53,520,000). Of this amount, about $5,280,000 was spent for additional right-of-way. The greater part of the new right-of-way was acquired as spoil ground as only a small quantity of the excavated material was required for building embankments and only that adjacent to each end of the canal could be readily disposed of in the sea.

Power and Transmission Lines,—The canal owns and operates Diesel engine driven electric power stations at Brunsbuettelkoog and Holtenau. In each station there are three units — two 340 h.p. and one 180 h.p. unit. During the daytime only the 180 h.p. units are used. There are two transmission lines on each side of the canal—a main supply line and a lamp line. The main supply lines transmit current at 7,500 volts. The lamps are 25 watt in series and are opposite each other across the canal and are 328 feet apart except at sidings where they are 164 feet apart. The lamps are about 20 feet above the water. At the locks the lamps are 100 watt and 75 feet apart.

Time of Transit,—It takes a ship from 6 to 9 hours to make the transit of the canal. The speed limits vary between 6.0 to 9.5 miles per hour.

Fog,—The canal is closed by fog about 10 days or less per year.

Ice,—About every five years ice as thick as 9 inches will occur, but does not close the canal which is kept open by ice breakers. The lowest temperature that has been observed is about 2 degrees below zero F.

Night Navigation,—The canal is navigated at night all the year by large ships. About 50 per cent of the shipping that uses the canal pass through it at night. Steamers following one another must keep 1 km. (0.62 mile) apart. All motor driven vessels and tugs towing barges have to tie up at the sidings after sundown, as they are not allowed to run at night.

Traffic,—In 1900, 8,235 ocean steamers passed through the canal and in 1913, 16,012, and by 1919, owing to the war, the number using the canal had fallen to 6,723, but by 1922 the traffic had again increased to 20,122 ocean ships. There is, in addition, a large traffic of smaller boats and barges passing through the canal.

Tolls,—The Treaty of Versailles, 23 June, 1919, under Articles 380 to 386, lays down certain regulations respecting the Kiel canal. The canal and pilotage dues are limited to rates sufficient to cover the cost of administration, maintenance and improvements. All commercial and naval vessels of nations at peace with Germany have permanent free use of the canal without special permission and on terms of entire equality with those of Germany. Traffic on the canal is subject only to police, customs, sanitary, emigration or immigration regulations and those relating to the import or export of prohibited goods. Goods in transit may be placed in bond and are then not subject to any further customs formalities. In the event of violation of any of the conditions of Articles 380 to 386 or of disputes as to the interpretation of these articles, any interested power can appeal to the jurisdiction instituted for the purpose by the League of Nations. A local German authority at Kiel is qualified to deal with disputes in the first instance.

Supplies,—Shipping may obtain coal, oil, provisions and other supplies at Brunsbuettelkoog, Rendsburg and Holtenau.

Suez Canal

History,—The name of Ferdinand de Lesseps will always be connected with the construction of the Suez canal. When he was the French consul in Egypt in 1830, he began to study the possibility of building a canal across the isthmus of Suez but it was not until 1854 that he obtained a concession to build the canal from the Egyptian Prince Mohammed Said. This concession was however not finally confirmed by the Turkish government until 1866.

In the meantime he succeeded in forming the Compagnie Universelle du Canal Maritime de Suez with a capital of 200,000,000 francs ($40,000,000) to build the canal and in August, 1859; the first sod was turned. The canal was opened for traffic in November, 1869.

Description of Canal,—The Suez canal is a sea level canal, without locks, and is about 102 miles long from Port Said on the Mediterranean to Suez on the Red sea. There are about 88 miles of straight lines and the balance of the distance is curved, with a minimum radius of 2 miles.

The original depth below lowest tide level was 26.3 feet with a bottom width of 72.2 feet. To-day the depth varies between 37.4 feet and 42.6 feet and the width is now 196.8 feet at a depth of 32.8 feet throughout the entire length of the canal, except for a short distance when it is only 147.6 feet wide. This short distance will be widened to 196.8 feet in the near future. The minimum width at the water line is about 345 feet.

Material,—The material encountered in excavating the canal was chiefly sand and sand clay. The maximum depth of cutting at El Gisr was about 90 feet. At Serapeum and Shaluf some rock was taken out. In the early days of construction, excavation was done by Egyptian hand labour and the material was taken away in baskets. At this stage of the work the maximum force was 30,000 men. Machinery was introduced in 1865.

Canal Entrances,—The Mediterranean entrance is protected by piers 1¼ miles long and the Red sea entrance by shorter ones.

Cost,—The canal has cost to date with all improvements about $157,000,000.

Time of Transit,—Before 1886 ships were only allowed to navigate the canal during the day, since then steamships that are provided with the required electric lights are allowed to proceed at night. Prior to 1886 the average time of transit was 48 hours. The time of passage is now about 16 hours. The maximum speed for ships transiting the canal is fixed at 6.5 knots per hour. No ship is allowed to pass through the canal without a canal pilot in charge.

Traffic,—In 1910, 4,533 vessels, with a net tonnage of over 20,000,000, tons passed through the canal. In 1928, 6,084 vessels, with a net tonnage of about 32,000,000 tons, made the transit of the canal. In 1928, 57 per cent of the traffic that passed through the canal was British.

Tolls,—At present ships loaded pay tolls at the rate of $1.34 per net ton. Ships in ballast are allowed a reduction of $0.48 per net ton on the full rate. In addition to the tonnage dues, transit dues are paid on all passengers at the rate of $1.94 per passenger above 12 years of age, and $0.97 per passenger between 3 and 12 years of age.

Levels,—Mean sea level of the Mediterranean and Red sea is about the same elevation. The range of ordinary spring tides at Port Said is 6 to 8 inches and at Suez from 5¼ to 6 feet. The difference in level appears never to be greater than 4 feet at the two ends of the canal which are about 102 statute miles apart.

Currents,—As a result of observations it has been found that between May and October a small current flows in a southerly direction through the canal, and that in winter months southerly winds reverse this condition. A volume of water is consequently moving alternately from sea to sea.

Distance Saved London to Hong-Kong,—From London to Hong-Kong the distance via the Cape of Good Hope is 13,089 miles, and via the canal 9,678 miles or a difference of 3,411 miles. This means a saving of about ten days in the voyage of a fast passenger steamer and indicates the economy of time that is obtained by using the canal.

Welland Ship Canal

History,—The St. Lawrence river canals, including the Welland and Sault Ste. Marie, canals form a great chain of inland navigation, extending from the straits of Belle Isle westward to Duluth at the head of the Great Lakes.

From the days of the earliest settlements on the St. Lawrence down to the present time the Canadian people have looked forward to the day when large ocean ships would be able to sail up the St. Lawrence to the Great Lakes, and towards this end Canada during the past century spent large sums of money improving the ship channel of the St. Lawrence up to Montreal and building canals between Montreal and Sault Ste. Marie.

The largest canal on the route is the Welland, which crosses the Niagara Peninsula 10 miles west of Niagara falls and connects Lake Ontario with Lake Erie. The difference in elevation between the standard low water levels of these lakes is 327 feet. The first canal was built by a private company between 1824-1833. This canal was later taken over by the government of Upper Canada and enlarged between 1841-1850. The completion of the second canal coincided with the completion of the St. Lawrence canals between Montreal and Lake Ontario in 1848 when boats 140 feet long, 26 feet beam and 9 feet draught could then for the first time ascend the river from Montreal to Lake Erie. The construction of the third Welland canal was began about 1873 and completed for 14 feet navigation in 1887, but the enlargement of the St. Lawrence canals for 14 feet navigation was not completed until 1901 when a boat 256 feet long, 43 feet beam and drawing 14 feet could ascend the river from Montreal to the head of the Great Lakes.

Description of Route,—The Welland canal now nearing completion is 25 miles long from the shoreline of Lake Ontario at Port Weller to the shoreline of Lake Erie at Port Colborne and is the fourth canal built by Canada across the peninsula.

From Port Weller it follows the Ten Mile creek to Thorold and between these places it crosses the third canal above lock No. 3 where the water levels of both are elevation 382.0, and between lock No. 7 and the guard gate at Thorold it again crosses the third canal. From Thorold to Allanburg a new channel has been excavated and between Allanburg and Port Robinson the third canal has been deepened and widened.

From Port Robinson to Welland the canal follows the west side of the Chippawa creek valley and is separated from the creek throughout this distance by an embankment 50 feet wide on top. From Welland to Port Colborne the third canal has been deepened and widened, with the exception of a section 2½ miles long immediately north of Lake Erie where a new channel has been excavated through the villages of Humberstone and Port Colborne.

Depth and Width,—The canal has a minimum bottom width of 200 feet and a minimum depth of 25 feet. For a great part of the distance throughout the summit level, Thorold to Port Colborne, it has been excavated to 26.5 feet depth below elevation 568.0 extreme low water level of Lake Erie. All the locks and their entrance piers, bridge piers and the docks at Port Weller and the new docks at Port Colborne have been built for a depth of 30 feet so that the canal at some future date can be deepened by simply dredging the canal prism and harbour entrances.

Locks,—The fall of 327 feet between the lakes is overcome by eight locks. The normal lift of the locks is 46½ feet, except that of the guard lock (lock No. 8) at Port Colborne, which varies with the level of Lake Erie. During the summer months the lift of the guard lock is about three feet. Locks Nos. 1 to 7 are 859 feet long between gates, 80 feet wide, and have 30 feet of water on the sills. These locks have a usable length of 820 feet. Lock No. 8 is 1,380 feet long, 80 feet wide, and has a depth of 30 feet on the sills. It has a usable length of 1,355 feet. Locks Nos. 1 to 7 are located between Port Weller and Thorold. The direct line of the canal down the face of the Niagara escarpment and the slope of the lower plateau permitted the adoption of 46.5 feet lifts for the locks, which constitutes a peculiar feature in the design of the canal and has no precedent in actual construction for locks of their size. Locks Nos. 1, 2, 3, 7 and 8 are single locks. Locks Nos. 4, 5 and 6 are twin locks in flight. The flight is double in order that ships may be passed simultaneously in opposite directions.

About three-quarters of a mile above lock No. 7 a guard gate and weir have been built for safety purposes only, as the water level on each side of them is the same.

The abandoned part of the third canal at Port Colborne is now used as a raceway to feed the new canal, and the flow through it is regulated by a large weir.

As it requires about 70 acre-feet of water to fill one of the locks with a lift of 46½ feet, it is essential that there shall be a large pondage area above each lock, in order to avoid drawing down the canal levels too much when filling the locks. For this purpose lock No. 1 has a pondage area of 107 acres, lock No. 2,200 acres, and lock No. 3,150 acres. Above lock No. 6 a pond of 84 acres has been formed by building an earth dam 3,300 feet long with a maximum height of 75 feet.

Harbours,—Port Weller harbour is situated about 3 miles east of Port Dalhousie and is formed by two parallel earth embankments extending 1½ miles into the lake. The channel between them is 800 feet wide on the bottom, which is narrowed to 400 feet wide at the harbour entrance by two converging lines of concrete cribwork.

Port Colborne harbour is an artificial one, developed in a small bay of the lake to protect the canal entrance and provide shelter for the transfer of bulk cargoes to the government elevator and other industrial plants located on the harbour docks. The outer harbour is formed by two lines of breakwaters placed about 4,400 feet off shore. The entrance, 600 feet wide between the eastern and western breakwaters, is protected against southwest gales by a spur breakwater that extends 2,000 feet into the lake from the eastern end of the western breakwater. Port Colborne harbour is one of the finest harbours on the Great Lakes and has over 5.5 miles of concrete dock walls, 4 miles of which have a depth of at least 25 feet of water in front of them.

Lock Gates,—The gates of the locks are of the mitering horizontal girder type, sheathed on both sides, and are built of steel. The gates at the head of locks Nos. 1 to 7 are 35.5 feet high and weigh 190 tons per leaf. The lower gates of these locks are 82 feet high and weigh 490 tons per leaf. The gates of lock No. 8 and the guard gate are 44.5 feet high and weigh per leaf 240 tons. All the gate leaves are 5 feet thick. The gates were all built at their respective sites in the locks, and will be handled in the future when taken out for repairs, etc., by a pontoon

Table of Ship Canals and Docks

Canals and docks	Year		Canals					Locks

*Longest lock in world. †Largest lock in world.

gatelifter built for the purpose. Spare gates of each size have been built and are stored in the gate dock at Port Weller. For a full description of the gates see the paper by F. E. Sterns, M.E.I.C., in The Engineering Journal, February, 1928.

Safeguards,—All the gates of the locks are provided with safety castings which permit any pair of gates being opened at the mitre about 4 feet without the leaves of the gate losing contact with one another.

Wire rope fenders are being installed above and below the lower gates of a lock, and above the upper pair where no bridge crosses the upper entrance of a lock. The fenders consist of a heavy steel wire rope suspended across the lock chamber at the upper or lower coping level.

For further protection in the operation of the locks, all the control equipment of the machinery operating the gates, valves, fenders and signals is so electrically interlocked that the lock motorman in the operating cabin at each end of each lock can only carry out a lockage by a definite sequence of operations.

Bridges,—There are 20 movable bridges built across the canal:—six are 80 feet Scherzer bascule spans at locks; one is a double leaf Scherzer 200 feet span; two are equal arm swing bridges with channels 80 feet or 100 feet wide under each arm; eleven are vertical lift 200 or 220 feet spans with a clearance of 120 feet under them when raised for navigation. For a description of the bridges see the paper by M. B. Atkinson, M.E.I.C., in The Engineering Journal, February, 1928.

Power,—All the gates and the valves of the locks, the valves of all weirs and all the bridges are electrically operated. The Dominion Power and Transmission Company, Hamilton, is now supplying power for the operation and lighting of the canal until the power plant of the canal is completed and ready for operation. The power house is being built below lock No. 4 and will operate under a nominal head of 189 feet. It will be ready for operation in 1931.

Chippawa Creek Syphon Culvert,—The Chippawa creek was carried under the third canal at Welland by a cut stone aqueduct that is now being removed. It has been replaced by an inverted syphon culvert built of concrete. The culvert consists of six 22 feet internal diameter tubes with vertical shafts at each end, located immediately north of the aqueduct.

The material at this place is a very soft clay 100 feet deep to rock and as the culvert pit was about 82 feet deep, and the bottom of it 75 feet below the water surface of the adjacent canal, the construction of the culvert was a very dangerous and costly undertaking but was successfully carried out. Navigation was diverted across the culvert in December, 1928, and in September, 1929, the creek was passed through it. For a detailed description of the culvert see the paper by the author in The Engineering Journal, February, 1928.

Transit of Canal,—The canal is in continuous operation twenty-four hours per day during the season of navigation, approximately 15th April to 15th December. It is excellently lighted from lake to lake and is easily navigated at night. The time of transit through the canal of a great lake freighter has been estimated at 8 hours. During 1930 the St. Lawrence canals sized ships traversed the canal in 6½ to 7½ hours.

At the opening of navigation in 1930, locks Nos. 1, 2 and 3 were placed in commission and remained in service throughout the season. Locks Nos. 4, 5, 6 and 7 were placed in commission on September 10th, 1930. Lock No. 8 was placed in commission on September 16th, 1929, and has been in use ever since. The whole of the canal was placed in service in September, 1930, and towards the close of the season was available for 18 feet draft by the St. Lawrence canals sized boats. It is anticipated that the canal will be officially and formally opened for use by the great lake freighters sometime in 1931.

On November 22nd, 1930 the last ship passed up through locks 11 to 24 of the third canal. This event may therefore be taken as the closing act in the navigation life of the third canal after an existence of 48 years.

Cost,—The construction of the canal has involved the excavation of about 51,000,000 cubic yards of earth, 9,000,000 cubic yards of rock and the placing of about 3,500,000 cubic yards of concrete, and will cost, including its power house and engineering expenses, about $128,000,000. At the end of October, 1930, the net expenditure on the project amounted to about $120,000,000.

The following table gives the dates of construction, capital cost, and the principal dimensions of the six large canals of the world, and also the dimensions of the Sault Ste. Marie locks and the principal entrance locks of the ports of Liverpool and London.

The construction of a canal not only involves the solution of problems more or less common to all waterways, but also the solution of many problems local to the district through which the waterway passes. In the former category may be placed the width and depth of the waterway and the size of its locks. On the Welland the question was, what size of canal would be required to accommodate the largest ships that would sail the Great Lakes in the future? It was finally determined that a canal 200 feet wide on the bottom and 30 feet deep with locks 800 feet long by 80 feet wide would accommodate the largest vessels that would be built on the Great Lakes for many years to come. To-day the largest ship on the Great Lakes is 633 feet long and 70 feet beam. The present maximum loading depth of the great lake freighter is about 21 feet. The foregoing dimensions would permit of about 65 per cent of the ships that passed through the Panama canal in 1930 to transit the Welland canal. The 3,500,000 cubic yards of concrete required for the construction of the locks and other structures of the Welland canal also compares favourably with the 5,000,000 cubic yards required for the locks, etc., of the Panama canal.

The great rise of the canal and the high lift of its locks is the outstanding feature of the canal. The high lifts is a departure from previous canal practice, and has no equal to-day on any other canal in the world.

As the canal passes through a highly developed agricultural and industrial section of the country many bridges cross it and for safe navigation of the canal by large ships it was deemed most desirable that the canal prism should not be obstructed by bridge piers placed on the bottom of the canal. This decision led to the use of vertical lift bridges over the canal. This type of bridge has proven very satisfactory to navigation, highway and railroad interests, and where movable spans are required has probably forever displaced the old reliable swing bridge.

One of the most important problems connected with the construction of the Welland canal, was the maintaining of uninterrupted navigation in the third canal, while the fourth was being built. The two canals crossed each other seven times and at two places, viz. lock No. 3 and the Chippawa creek syphon culvert, the risks during construction of the fourth canal to the existing canal were very great, but throughout the entire period of construction no delays and very little inconvenience to navigation occurred. At several points the transfer of navigation from the third to the fourth canal was made during the closed season of navigation.

The Welland is and always will remain one of the large canals of the world. The quantities of rock and earth excavation are not as large as those of the Panama canal and several of the other large canals, nor is its cost if compared on a pre-war basis nearly as large as that of the Panama and Suez, but compares favourably with that of the Manchester, North Sea and Kiel canals. The Welland however stands pre-eminently above them all in its total rise and the lift of its locks.

In concluding, permit me on retiring from the position of President to express the hope that the membership and influence of The Institute will continue to grow and that the Council in its labours will always have the unanimous support of the members with the assurance that their actions have only the welfare of The Institute in view and that each member will always feel that The Institute is of real value to him and a benefit to our nation.

Meetings of Council

A meeting of Council was held at the Windsor hotel, Montreal, on Wednesday, February 4th, 1931, at five o'clock p.m., with President S. G. Porter, M.E.I.C., in the chair, and sixteen other members of Council present.

George R. MacLeod, M.E.I.C., announced with regret that F. P. Shearwood, M.E.I.C., who had wished to resign the Treasurership last year, desired his resignation of that office to become effective now. Mr. MacLeod suggested the appointment of W. C. Adams, M.E.I.C. This was unanimously agreed to, and the Secretary was directed to write to Mr. Shearwood expressing Council's thanks and appreciation of his long and effective service as Treasurer, and regret at the necessity for his retirement.

On the termination of his term of office as vice-president, Mr. George R. MacLeod resigned the chairmanship of the Finance committee, and upon his suggestion it was unanimously agreed to appoint J. L. Busfield, M.E.I.C., to succeed him. The other members of the committee were also unanimously appointed as follows:—

W. C. Adams, M.E.I.C.
F. A. Combe, M.E.I.C.
T. J. Lafreniere, M.E.I.C.
F. P. Shearwood, M.E.I.C.

D. C. Tennant, M.E.I.C., was unanimously appointed chairman of the Library and House committee.

It was unanimously decided to continue the following committees, their membership to be decided at the next meeting of Council:—

Board of Examiners and Education
Committee on International Co-operation
Honour Roll and War Trophies Committee
Biographies committee
Engineering Education

and that the following committees should not be re-appointed:—

Classification and Remuneration committee
Committee on Policy
Publicity committee.

Attention was drawn to the retirement from Council of Dr. A. R. Decary, M.E.I.C., after a very long service as Councillor, Vice-President, and President. The President expressed Council's good wishes to Dr. Decary, and pointed out particularly the benefit accruing to The Institute through his sympathetic activity as President of the Corporation of Professional Engineers of Quebec, particularly in regard to the question of the confederation of the various provincial associations.

Dr. Decary expressed thanks for Council's kind wishes. He had had great pleasure in doing what he could for The Institute, and would long retain pleasant memories of his association with the Council and the many members of The Institute with whom he had served. He hoped that the work of unification of the professional associations would continue, and that during Mr. Porter's term of office as President, real definite progress would be made.

The Council rose at five forty-five p.m.

A meeting of Council was held at Headquarters at eight o'clock p.m., on Tuesday, February 17th, 1931, with Vice-President O. O. Lefebvre, M.E.I.C., in the chair, and six other members of Council present.

The minutes of the meetings held on January 20th, and February 4th, 1931, were taken as read and confirmed.

The membership of the following committees was approved as follows:

Finance Commitee: J. L. Busfield, M.E.I.C., Chairman
F. A. Combe, M.E.I.C.
T. J. Lafreniere, M.E.I.C.
F. P. Shearwood, M.E.I.C.
W. C. Adams, M.E.I.C., Treasurer

Library and House Committee:
D. C. Tennant, M.E.I.C., Chairman
H. Massue, A.M.E.I.C.
A. R. Roberts, A.M.E.I.C.
E. A. Ryan, M.E.I.C.
J. H. Trimingham, M.E.I.C.

Legislation Committee:
H. Cimon, M.E.I.C., Chairman
A. Duperron, M.E.I.C.
N. D. Paine, A.M.E.I.C.

Publication Committee:
J. A. McCrory, M.E.I.C., Chairman
F. S. B. Heward, A.M.E.I.C.
C. R. Lindsey, A.M.E.I.C.
G. K. McDougall, M.E.I.C.
H. S. Van Patter, A.M.E.I.C.

Committee on International Co-operation:
John Murphy, M.E.I.C., Chairman
J. B. Challies, M.E.I.C.
H. B. R. Craig, M.E.I.C.
J. M. R. Fairbairn, M.E.I.C.
Fraser S. Keith, M.E.I.C.
H. R. Safford, M.E.I.C.
A. Surveyer, M.E.I.C.
W. F. Tye, M.E.I.C.
H. H. Vaughan, M.E.I.C.

Honour Roll and War Trophies:
Brig.-Gen. C. J. Armstrong, M.E.I.C., Chairman
Col. A. E. Dubuc, M.E.I.C.
Fraser S. Keith, M.E.I.C.
Brig.-Gen. G. E. McCuaig, M.E.I.C.

Engineering Education:
Fraser S. Keith, M.E.I.C., Chairman
R. W. Brock, M.E.I.C.
C. V. Corless, M.E.I.C.
F. R. Faulkner, M.E.I.C.
E. P. Fetherstonhaugh, M.E.I.C.
A. Frigon, M.E.I.C.
W. J. Johnston, A.M.E.I.C.
C. J. Mackenzie, M.E.I.C.
C. H. Mitchell, M.E.I.C.
J. Stephens, M.E.I.C.
R. S. L. Wilson, M.E.I.C.

Membership Committee:
Brig.-Gen. C. H. Mitchell, M.E.I.C., Chairman
W. C. Adams, M.E.I.C.
H. F. Bennett, A.M.E.I.C.
C. J. Mackenzie, M.E.I.C.
D. C. Tennant, M.E.I.C.

The chairmen of the following committees were appointed, and the Secretary was directed to ask them to suggest the names of members of their committees for submission to Council at its next meeting:

	Chairmen
Past-Presidents' Prize Committee..........	C. M. McKergow, M.E.I.C.
Leonard Medal Committee................	F. W. Gray, M.E.I.C.
Plummer Medal Committee................	W. H. DeBlois, M.E.I.C.
Board of Examiners and Education.........	C. M. McKergow, M.E.I.C.

In accordance with the rules governing the awards of the Students' and Juniors' Prizes, the following vice-presidents were appointed chairmen of the examiners in their respective zones:

Zone A—H. N. Ruttan Prize—Vice-President H. B. Muckleston, M.E.I.C.

Zone B—John Galbraith Prize—Vice-President T. R. Louden, M.E.I.C.

Zone C—Phelps Johnson Prize (English)—Vice-President W. G. Mitchell, M.E.I.C.

Zone C—Ernest Marceau Prize (French)—Vice-President O. O. Lefebvre, M.E.I.C.

Zone D—Martin Murphy Prize—Vice-President F. R. Faulkner, M.E.I.C.

Considerable discussion took place regarding the work of the Committee on Biographies, after which F. H. Peters, M.E.I.C., was appointed chairman of that committee.

The budget submitted by the Finance committee was considered, and indicated that in order to maintain the activities of The Institute on the same scale as last year additional funds would be required. The recommendation of the Finance committee was approved, that an effort be made to obtain an increased revenue from Journal advertising to provide the necessary additional sum.

The Secretary read a letter from Past-President A. J. Grant advising of his contribution towards the Past-Presidents' Prize Fund, and expressing the hope that members of The Institute would continue to show great interest in this prize by presenting every year a large number of papers on the subject selected by the Council for the competition. The Secretary was directed to express the sincere thanks of Council to Past-President Grant for his generous gift.

Discussion took place as to the Plenary Meeting for 1931, and the Secretary was directed to obtain written opinions from all councillors regarding its date and location.

A letter was presented from the Toronto Branch asking that arrangements be made to hold the 1932 Annual Meeting of The Institute in Toronto. This invitation was accepted with appreciation.

The newly elected officers of the Cape Breton and London Branches were noted.

A proposed change in the By-laws of the Toronto Branch was submitted and approved.

An invitation was presented from the Royal Institution of Great Britain asking Council to appoint a delegate from The Institute to be present at the Faraday Celebrations which will be held in London on September 21st, 1931, and following days.

A similar invitation was received from the Verein Deutscher Ingenieure to appoint two delegates to represent The Institute at the Seventy-fifth Anniversary Celebration of the Society of German Engineers, which will take place in Cologne in June 1931.

Seven resignations were accepted, one reinstatement was effected, and three special cases were considered.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:

Elections		Transfers	
Members	1	Junior to Assoc. Member	6
Associate members	5	Student to Assoc. Member	1
Juniors	2	Student to Junior	6
Students admitted	35		

The Council rose at eleven thirty p.m.

Address at Annual Dinner of The Institute

By Francis Lee Stuart, M.E.I.C., President, American Society of Civil Engineers, February 4, 1931

To the President and Members of The Engineering Institute of Canada, and guests:

It is a pleasure for me, as president of the American Society of Civil Engineers, to greet The Engineering Institute of Canada at their annual convention and convey to them our best wishes for their continued growth and usefulness.

I am a member of The Institute, have a summer home in Canada, and have been interested in your country for years. I want you to know that as an engineer, when I study your map and statistics, see the wealth of mines and minerals, and the unusual cheapness and quantity of electric power for industry and your abundant agricultural and other products of a self-contained nation, I can not help but feel that the future holds far-reaching surprises for you beyond your most optimistic dreams of today.

At the present moment we are passing through a critical period. Individual reward for initiative and energetic efforts have made both our countries great. This very incentive has been rewarded by such continued prosperity that the herd instinct and avarice of men have run wild with our judgment and greatly aggravated world conditions and brought on us all an unwarranted period of strain and stress, but I believe we are even now beginning to recover.

You have a continent to develop, with potential resources that can hardly be visualized. It offers vast opportunities for pioneering and for attracting additional populations and because it is so sure to respond to well-directed efforts which you will make, it would seem wise to educate the minds of your people as a mass, in the direction of the arts of engineering, so that as your population increases, from the world sources, your sons and daughters will have the education and training necessary for able leadership, as such emigrants are absorbed into your nation.

The Institute, which represents the collective forces of your engineers, is destined to be a great force in the future, and my faith is so great in the importance of the profession in your welfare, that if I were a Canadian I would try to interest every member of my family in the study of engineering, and all the arts pertaining to the developing of the natural resources of your great country, and prepare for coming events.

Let me leave with you the hope that by co-operation with all interested in engineering progress you will co-ordinate your efforts and keep The Institute growing greater and greater, to the mutual advantage of both countries.

Address at Annual Dinner of The Institute

By W. S. Lee, M.E.I.C., President, American Institute of Electrical Engineers, February 4, 1931

Mr. President, ladies and gentlemen, I am here to-night as President of the American Institute of Electrical Engineers to extend my greetings not only on my own behalf but on behalf of the institution to which I belong. We congratulate you gentlemen upon the field you are covering, upon the work you are doing and the magnificent way in which you are doing it. I am a member of your Institute, and have been for several years. Your Institute covers a great number of engineering activities. My dear friends, you can go to this window and look out upon the Sun Life Assurance Building and find more engineering going on in that one building than would have taken place in this entire province two decades ago. The design and lay-out of the modern elevator has more electrical design and more work and detail than many whole buildings designed two decades ago.

It is my business as a consulting engineer to work with various organizations, and I am surprised on many occasions how few men in the different branches of engineering know and come in contact with one another. It is such meetings as you are having here which give us the ambition and inspiration to carry on our work.

Now, ladies and gentlemen, your good President in his talk said this was the first time the ladies had honoured The Institute with their presence. As your speaker at lunch time said, you will never be without them again; I agree with him; they will be here at all times.

I want to say to my friends here that we must keep the ladies with us; you will have more members and better Institute meetings. When I look through your audience and see the men to whom you entrust your engineering work in the Dominion of Canada I must say that they are men of intelligence, they are fine looking men and they are men who are ready to put their shoulders to the wheel and work.

And I say to you that if you cannot win with these men you deserve to lose.

Award of Medals and Prizes

Past-Presidents' Prize

The Past-Presidents' Prize of The Institute for the year 1929-1930 has been awarded to Group-Captain E. W. Stedman, M.E.I.C., for his paper on "Rigid Airships," which was published in The Engineering Journal for February, 1930.

Group-Captain Stedman, who is a Whitworth Scholar and an Associate of the Royal College of Science, London, was for some time engaged in aeronautical research work at the National Physical Laboratory, Teddington, England, and from 1914 to 1919 served in the Royal Naval Air

Service and Royal Air Force. In 1919-1920 he was chief of technical staff with Handley Page, Ltd., of London, England, and coming to Canada in 1920 became director of the technical section at the Air Board, Ottawa. Group-Captain Stedman is at present chief aeronautical engineer, Royal Canadian Air Force, Department of National Defence, Ottawa.

Group-Captain E. W. Stedman, M.E.I.C.

P. B. Motley, M.E.I.C.

F. M. Wood, A.M.E.I.C.

Medallists and Prizewinners for 1930

C. G. MacLachlan

W. B. Boggs

A. E. Flynn

G. B. JOST, S.E.I.C.

Gzowski Medal

Two Gzowski medals have been awarded this year, one to P. B. Motley, M.E.I.C., for his paper on "Reinforcement in Place of the Stoney Creek Arch Bridge," which was presented before the Montreal Branch of The Institute on February 20th, 1930, and published in the May, 1930, issue of The Journal, and another to F. M. Wood, A.M.E.I.C., for his "Short Monograph on Nomography," which was published in two parts, the first appearing in the June, 1930, and the second in the August, 1930, issue of The Journal. Both these papers were considered by the committee as of outstanding merit.

Mr. Motley is engineer of bridges of the Canadian Pacific Railway, having been with that company continuously since 1892, with the exception of a brief period of work with the Dominion Bridge Company.

Mr. Wood graduated from Queen's University, receiving his degree of Master of Arts in 1911, at which time he was awarded the gold medal in mathematics, and taking his degree of B.Sc. with honours in civil engineering in 1914. He served overseas, first in the engineers and artillery, and later for two years as flying officer in the Royal Air Force. For two sessions from 1919 to 1921, he was

lecturer in mathematics at Queen's University, and was subsequently appointed resident engineer on location and construction in connection with the irrigation system of the Lethbridge Northern Irrigation District, which position he occupied until joining the hydraulic department of the Dominion Engineering Works, Ltd., in 1923. In 1925 he became lecturer in civil engineering at McGill University, which appointment he still holds.

Leonard Medal

Three papers were considered worthy of receiving prizes under the Leonard Medal award this year, and presentations were announced at the Annual Meeting of The Institute as follows:

A gold medal to C. G. MacLachlan, for his paper on "Twelve Months Milling at Noranda," which was published in the Bulletin of the Canadian Institute of Mining and Metallurgy for February, 1930. Mr. MacLachlan is connected with Noranda Mines, Noranda, Que.

To Mr. W. B. Boggs, smelter superintendent at the Noranda Mines, Noranda, was awarded a silver medal for his paper on "The Noranda Smelter," which appeared in the Bulletin of the Canadian Institute of Mining and Metallurgy in March, 1930.

A. E. Flynn, professor of mining at the Nova Scotia Technical College, Halifax, received a prize of books, for his paper on "Anhydrite Plasters and Cements," published in the June, 1930, issue of the Bulletin of the Canadian Institute of Mining and Metallurgy.

Students and Juniors Prize

The Phelps Johnson Prize, competition for which is open to Students and Juniors in the province of Quebec, was awarded to G. B. Jost, S.E.I.C., for his paper on "Steel Mitering Lock Gates on the Welland Ship Canal." Mr. Jost is an undergraduate in the civil engineering course in the Faculty of Engineering, McGill University.

OBITUARIES

Ralph Waldo Downie, A.M.E.I.C.

The news of the sudden death of Ralph Waldo Downie, A.M.E.I.C., which occurred on January 21st, 1931, was received with regret by his many friends.

Mr. Downie was born at Melita, Manitoba, on July 7th, 1891 and received his early education at the public school at that place and in Toronto. In 1912 he entered the University of Toronto with the object of taking up a Science Course, but in his second year war was declared and he enlisted as a sapper with the 1st Canadian Engineers. He served eleven and a half months in England and fourteen and a half months in France, receiving his commission as lieutenant on December 22nd, 1916. The following spring he was returned to Canada and was appointed to the staff of C.R.C.E., M.D. 5, May 9th, serving as officer in charge of stores and accounts until his discharge in September, 1919.

Science again engaged his attention and he re-entered the University of Toronto and completed his course, graduating in 1921. During the summer of 1920 he worked in the office of the Canadian Inspection and Testing Company, Toronto, and upon graduation he joined the staff of the Welland Ship canal, in charge of the testing laboratory for cement and building materials, which position he held up to the time of his death.

Mr. Downie had a natural talent towards social organization and was widely known and respected for his untiring work in this direction. While at college he was president of the Engineering Society and shortly after arriving at the Ship canal, he was appointed Secretary-Treasurer of the Niagara Peninsula Branch of The Institute, which office he held for some nine years.

Mr. Downie joined The Engineering Institute of Canada as a Student on April 11th, 1914, and became an Associate Member on June 27th, 1922.

Alexander Brown Neilson, Affil.E.I.C.

Much regret is expressed in recording the death of Alexander Brown Neilson, Affil.E.I.C., which occurred at Winnipeg, Man., on October 19th, 1930.

RALPH WALDO DOWNIE, A.M.E.I.C.

Mr. Neilson was born at Winnipeg, Man., on January 12th, 1881, and received his early education at schools in that city. He was in the employ of the city of Winnipeg from 1904 until the time of his death, having been engaged on survey, well drilling, and in recent years as assistant engineer on maintenance.

Mr. Neilson joined The Institute as an Affiliate on September 20th, 1921.

Louis Gustave Papineau, A.M.E.I.C.

With the death of Louis Gustave Papineau, A.M.E.I.C., which occurred at Montreal on January 17th, 1931, The Institute loses one of its oldest members.

Mr. Papineau graduated in civil engineering from the Polytechnic School of Montreal in 1877, and in 1879 was made provincial land surveyor for Quebec. He was for many years in the employ of the Dominion government, serving with the Department of Public Works, the Department of Railways and Canals and the Department of Marine. From 1908 to 1912 he was in charge of the shipyard at Sorel.

Mr. Papineau joined the Canadian Society of Civil Engineers on February 24th, 1887, and was placed on the life membership list of The Institute on September 5th, 1930.

Paul Emil Mathias Rosenorn, A.M.E.I.C.

The death is recorded, on January 31st, 1931, of Paul Emil Mathias Rosenorn, A.M.E.I.C.

Mr. Rosenorn was born at Fredericia, Denmark, on September 25th, 1882, and received his education at high school and at the School for Officers of the regular army, Denmark, graduating from the latter institution in 1904.

Coming to Canada in 1907, Mr. Rosenorn became connected with the Canadian Pacific Railway Company, and acted as rodman, draughtsman and transitman on the Montreal terminals. From 1910 to 1912 he was transitman on the double tracking of the St. Lawrence river bridge at Lachine, Que., and from 1912 to 1913 was engaged on the construction of the Sortin yard, at Montreal. During the year 1913-1914, Mr. Rosenorn was resident engineer on maintenance of way at Fredericton, N.B. From 1914 to 1917 he was on active service in Canada and France, and returning to Canada in 1917 became supervisor of hydraulic test of h.e. shell for the Imperial Ministry of Munitions at Montreal. In 1919 and 1920 Mr. Rosenorn was again with the Canadian Pacific Railway Company as transitman on the rebuilding of bridges between Westmount and Windsor Station, Montreal; following this, in 1920-1921 he was assistant engineer on the Grand Trunk Railway valuation and in 1921-1923 he was estimator for Messrs. Graham and Windsor, general contractors, at Montreal. From 1923 to the time of his death Mr. Rosenorn was chief draughtsman at Chicoutimi, Que., for Price Brothers and Company Ltd.

Mr. Rosenorn joined The Institute as a Student on January 8th, 1910, and transferred to the class of Associate Member on January 17th, 1922.

Adlard Edward Welby, M.E.I.C.

Members will learn with regret of the death of Adlard Edward Welby, M.E.I.C., which occurred at Banff, Alta., on January 12th, 1931.

Mr. Welby was born at Tollerton, England, on November 10th, 1869, and was educated at Oakham School and the Crystal Palace School of Practical Engineering. Following graduation he was articled from 1887 to 1890 to G. Parry, M.Inst.C.E. From 1890 to 1896 he was assistant engineer on construction with the Great Central Railway, London, extension, and from 1896 to 1901 he was with the Uganda Railway, South Africa. From 1902 to 1907 Mr. Selby was with the East Indian Railway being engaged on construction and later maintenance. Leaving India in 1908 he spent several years in Chile on railroad and mining work for the Arauco Company. In 1911 he came to Canada and joined the staff of the Canadian Northern Railway. During the War, Mr. Welby served with the Canadian Engineers, and was with the Third Tunnelling Company at Ypres.

Returning to Canada after the War, Mr. Welby became connected with the Commission on Irrigation, Department of Interior, with headquarters at Calgary, and in 1921 was transferred to Banff, where he remained in the office of resident engineer with the Rocky Mountain Parks of Canada, until his retirement from active service about three years ago.

Mr. Welby joined The Institute as a Member on November 9th, 1912, and was also a Member of the Institution of Civil Engineers.

PERSONALS

A. E. Stewart, A.M.E.I.C., of the Canadian Pacific Railway Company, has been transferred from Bassano, Alta., to Winnipeg, Man., where he is division engineer of terminals.

E. J. Durnin, Jr.E.I.C., a graduate of the University of Manitoba of the year 1928, is now with the Saskatchewan Power Commission, and is located at Saskatoon, Sask.

H. V. Hagborg, S.E.I.C., has joined the staff of the Detroit Stoker Company of Canada, Ltd., at Toronto, Ont. Mr. Hagborg was formerly with the Detroit Stoker Company at Detroit.

A. G. Patterson, Affil.E.I.C., Works Manager of the Peterborough, Ont., works of the Canadian General Electric Company, Ltd., retired on December 31st, 1930, after forty-two years' service with the company.

Clarke W. Gamble, M.E.I.C., is now assistant district engineer with the Department of Public Works of British Columbia, at Alberni, B.C. Mr. Gamble was for a time with Messrs. Waddell and Hardesty, New York, and later resided at Victoria, B.C.

J. Portas, A.M.E.I.C., has become connected with J. W. Cumming Manufacturing Company at New Glasgow, N.S. Mr. Portas, who is a graduate of the University of London of the year 1921, was formerly designing engineer with Monsarrat and Pratley, Montreal.

A. W. Crawford, A.M.E.I.C., has recently been appointed Deputy Minister, Department of Labour, Toronto, Ont. In addition to his newly assumed duties, Mr. Crawford will continue to look after the welfare of apprenticeship throughout the province of Ontario. He was for five years director of technical education in the Department of Labour, Ottawa, and in 1928 accepted a position with the Ontario provincial government as inspector of apprenticeship, his duties being to administer the Apprentice Act of 1928.

O. A. Barwick, A.M.E.I.C., is leaving shortly on a six weeks trip to England, France and Germany for the purpose of studying architecture and obtaining a vacation. Mr. Barwick graduated from McGill University with the degree of Bachelor of Architecture in 1914. Following graduation he had extensive experience in various architectural works, and for a number of years has been in private practice as architect and structural engineer in Montreal. Mr. Barwick was construction supervisor of the head office building of the Royal Bank of Canada built in Montreal several years ago.

Dr. Ralph Modjeski, M.E.I.C., consulting engineer, New York, is to receive the Washington award for 1931 for his "contribution to transportation through superior skill and courage in bridge design and construction." This award is conferred by the Washington Award Commission, which represents five of the leading engineering societies. Last year Dr. Modjeski was awarded the John Fritz medal for distinguished engineering service. As designer, construction engineer and consultant, Dr. Modjeski has been identified with many of America's most notable bridges, including the McKinley bridge over the Mississippi river at St. Louis, Mo., the Columbia river bridge at Celilo, Oregon, the Keokuk bridge over the Mississippi river, the Ohio river bridge at Cincinnati, the Quebec bridge over the St. Lawrence river, and Manhattan bridge over the East river, New York, and so on.

R. B. Jennings, M.E.I.C., formerly general manager of Robert W. Hunt and Company, Ltd., inspection and testing engineers, has been appointed railroad representative of Crane, Ltd., with headquarters at Montreal. Mr. Jennings received his education at Humberside Collegiate Institute, Toronto, and the University of Toronto. Following graduation, he engaged in railway location and construction, and was appointed resident engineer, Canadian Northern Ontario Railway, in 1909. He served in this capacity on the various lines under construction until 1916, when he enlisted in the Canadian Overseas Expeditionary Force. He was appointed lieutenant and promoted to major in the 10th Battalion Canadian Railway Troops with active service in France and Belgium. On his return to Canada, Mr. Jennings became division engineer, Toronto division, Canadian National Railways, in 1919. In February, 1921, he became division engineer of the Ottawa division and in May, 1922, division engineer of the Montreal division of the Canadian National Railways. In 1926 Mr. Jennings took the position which he has recently resigned.

C. A. MAGRATH, M.E.I.C.

C. A. Magrath, M.E.I.C., Retires

C. A. Magrath, M.E.I.C., has retired from the chairmanship of the Hydro-Electric Power Commission of Ontario, which office he has held since 1925, when he succeeded the late Sir Adam Beck.

Mr. Magrath's professional experience has been varied, and, to a marked degree, of a public nature. In early days he practised the profession of land surveyor in the Northwest Territories, holding the titles of Provincial and Dominion Land Surveyor and Dominion Topographical Surveyor. He was land agent for the Alberta Railway and Coal Company, and later played an important part in the development of the sub-arid districts of southern Alberta as manager of the Canadian North West Irrigation Company. Mr. Magrath entered politics in 1891 as member for Lethbridge, Alta., holding the post of minister without portfolio in the Haultain ministry in Saskatchewan from 1898 to 1901. He also represented Medicine Hat in the House of Commons from 1908 to 1911. From 1911 to the present date Mr. Magrath has been chairman of the Canadian section of the International Joint Commission. This body, which has dealt with many important international questions, such as the Lake of the Woods levels, owes much to his indefatigable energy and executive ability. In 1913 Mr. Magrath was chairman of a temporary Ontario Highways Commission which presented a comprehensive plan of highway expansion for the Whitney government, on which all subsequent highway development in the province has been based.

During the War, Mr. Magrath was a member of the War Trade Board of Canada, and acted as fuel controller from 1917 to 1920. He has been a member of the Federal Advisory Fuel Committee since 1922. In 1920 he performed an important mission in acting as chairman of a commission appointed to investigate agricultural conditions in southern Alberta.

J. H. Wallis, A.M.E.I.C., has relinquished active management of the Dominion Welding Engineering Company, Ltd., Montreal, to become general manager of Dominion Hoist and Shovel Company Ltd. Mr. Wallis, however, retains his interest in the Welding Company as a director. Mr. Wallis has been engaged on engineering work in Canada since 1910, his early work being land surveys, railway surveys and construction. In August, 1914, he enlisted for overseas service as a private with the British Expeditionary Force, and throughout the war served overseas with distinction. In July, 1915, he received his commission as lieutenant, in 1916 that of captain, and in the following year that of major.

Following his return to civilian life in 1919, Mr. Wallis entered the service of the Canadian Pacific Railway Company on maintenance-of-way on the International of Maine division. In June, 1920, he was appointed assistant engineer with the Department of Railways in connection with the Grand Trunk arbitration, and later in that year joined the engineering staff of the Canada Creosoting

J. H. WALLIS, A.M.E.I.C.

Company in Toronto. Subsequently, he was appointed supply engineer with the Riordon Pulp Corporation, Ltd., at Temiskaming, Que., and following the acquisition of this company by the Canadian International Paper Company, he was transferred to the construction department in charge of the purchase of equipment and materials for the extension of the mill. Mr. Wallis was later manager of purchasing for the St. Anne Paper Company Ltd., and the Murray Bay Paper Company Ltd., resigning that position in 1928 to take over the management of the newly organized Dominion Welding Engineering Company Ltd., a company closely associated with the Dominion Bridge Company Ltd., and the Dominion Engineering Works, Ltd.

BOOK REVIEWS

Motor Vehicles and their Engines

By Edward S. Fraser and Ralph B. Jones. 4th ed., rev. by Lee A. Dunbar. Van Nostrand, New York, 1930, cloth, 5¾ x 9 in., 411 pp., illus., figs., tables, $3.00.

Originally written as a text-book for automobile schools, this book is now in its fourth edition. It has been brought up to date and covers the care and operation of the principal accessories of the leading makes of motor vehicles, and is particularly intended for owners, garage-men and chauffeurs who wish not only to understand the elementary principles of motorcar construction but who also desire an intelligent understanding of the operation of the complicated machines with which they are dealing. Although largely illustrated by catalogue cuts, the descriptive matter is well selected and clear, and like its earlier editions, this book will prove very suitable for its purpose. Little or no acquaintance with theory is assumed or required, and the book can be recommended as containing in concise form the information necessary for instruction in the operation and care of motor vehicles.

The Modern Steam Turbine

By E. A. Kraft. VDI-Verlag, GmbH., Berlin, 1931, cloth, 190 x 270 mm., 201 pp., figs., charts, tables, RM. 20.

This is the English translation of the second edition of a well-known German text-book issued in 1926. It consists of two parts, the first giving a general survey of the problems of turbine design and construction in the light of the most recent information, afterwards discussing methods for obtaining improved economy and the technical features limiting turbine design. The second part gives a concise and well illustrated account of modern practice in steam turbines, taken from data furnished by many leading firms. Chapters on turbines for very high pressures and on condensers and their auxiliaries have been added. Special attention is given to the materials now available for steam turbine construction, and to the modern shop processes which have had to be developed to deal with turbine parts, such as blades, labyrinth packing, etc. No attempt is made to expound the theory of steam turbines, for which the reader is referred to standard treatises, such as Stodola.

The book, however, makes available a great deal of very important technical information, and is noteworthy for the absence of redundant matter and for its clear manner of presentation.

Dr. Kraft has not only had teaching experience at the great engineering school of Charlottenburg, but has taken a leading part in the development of the modern steam turbine in his capacity as chief engineer of the turbine works at Berlin of the Allgemeine Elektricitats-Gesellschaft.

The book may be strongly recommended to the engineer or probable purchaser who wishes to familiarize himself with the latest practice in steam turbine construction and to understand the practical value of the new methods and ideas which have developed in recent years. It is admirably illustrated and furnished with a useful index.

The Salt Industry of Canada

By L. Heber Cole, M.E.I.C., Department of Mines, Ottawa, 1930. Paper, 6½ x 9¾, 116 pages, photos, diags. and maps. $0.20.

To meet the demand for information relating to the Canadian salt industry, the Mines Branch of the Department of Mines has recently published a report by L. Heber Cole, M.E.I.C., entitled "The Salt Industry of Canada," this report supplementing and bringing up to date the previous report on the same subject issued by the Mines Branch over fourteen years ago.

The present report consists of 116 pages, and is illustrated with photographs, diagrams, and maps. It covers the salt occurrences throughout Canada, takes up the mineralogy and technology of salt manufacture, and briefly describes the allied industries using salt in their process. A chapter is also devoted to the consumption and marketing of salt and includes general salt statistics.

Copies of this report, No. 716, may be obtained on application to the Director, Mines Branch, Department of Mines, Ottawa.

RECENT ADDITIONS TO THE LIBRARY

Proceedings, Transactions, etc.

ELECTIONS AND TRANSFERS

At the meeting of Council held on February 17th, 1931, the following elections and transfers were effected:

Member

REDFERN, Charles Raimond, B.A.Sc., (Univ. of Toronto), President, Redfern Construction Company, Ltd., Montreal, Que.

Associate Members

BARNECUT, Reginald, B.Sc., (Univ. of Alta.), struct'l. checker, Dominion Bridge Company, Ltd., Calgary, Alta.

LONGSTAFF, John Calvin, C.E., (Univ. of Toronto), designer, Dominion Bridge Company, Ltd., Lachine, Que.

PITTAWAY, George Henry, asst. engr., The Shell Company of Canada, Ltd., Montreal, Que.

ULMANN, Hans, E.E., (Fed. Inst. Technology, Zurich), research engr., development dept., Dominion Engineering Works, Ltd., Montreal, Que.

WHITAKER, Albert William, Jr., B.S. (Chem.), (Univ. of Penn.), works supt., Arvida works, Aluminum Company of Canada, Arvida, Que.

Juniors

KNUDSEN, Sverre, C.E., (Norges Tekniske Hoiskole), dftsman and instr'man., Leonard E. Schlemm, M.E.I.C., Montreal, Que.

MARTIN, Frank John Ellen, B.Sc., (Univ. of Sask.), struct'l. engr., with Frank P. Martin, F.R.A.I.C., Saskatoon, Sask.

Transferred from the class of Junior to that of Associate Member

BOULTON, Beverley Knight, B.Sc., (McGill Univ.), elect'l. engr., Beauharnois Construction Company, Beauharnois, Que.

BURBANK, Jerome Douglas, B.A.Sc., (Univ. of Toronto), engr., Buffalo, Niagara & Eastern Power Corpn., Buffalo, N.Y.

CURRIE, Victor Robert, B.Sc., (Queen's Univ.), asst. engr., Trent Canal, Peterborough, Ont.

HANNA, Harold Benjamin, B.Sc., (Queen's Univ.), plant engr., Canadian General Electric Co. Ltd., Peterborough, Ont.

MARLATT, Charles Ewart, B.Sc., (Queen's Univ.), supt. of safety and fire insurance, Consolidated Mining and Smelting Co. Ltd., Trail, B.C.

MILLER, Wilfrid Laverne, B.A.Sc., (Univ. of Toronto), transformer engr., Canadian Westinghouse Company, Ltd., Hamilton, Ont.

Transferred from the class of Student to that of Associate Member

WEBSTER, Robert Chilion Peter, B.Sc., (McGill Univ.), engr. Canada Power & Paper Corporation, Montreal, Que.

Transferred from the class of Student to that of Junior

BERESKIN, Abraham Isaac, B.Sc. (C.E.), (Univ. of Man.), surveys engr., Topographical Surveys of Canada, Ottawa, Ont.

BLACKETT, Harold Wilfrid, B.A., B.A.Sc., (Univ. of B.C.), engrg. ap'tice., Canadian Westinghouse Company, Ltd., Hamilton, Ont.

DALTON, William Reginald, B.Sc., (Queen's Univ.), P.O. Box 623, Burlington, Ont.

LUSBY, Gerald W., B.Sc. (Mech.), (N.S. Tech. Coll.), mech'l. engr., engrg. dept., Ford Motor Company of Canada, East Windsor, Ont.

PHIPPS, Charles Ferdinand, B.Sc., (McGill Univ.), asst. engr. of transmission line design, Shawinigan Water & Power Company, Montreal, Que.

THICKE, James Ernest, B.Sc., (Queen's Univ.), engrg. dept., Aluminium Limited, Montreal, Que.

Students Admitted

BOWMAN, A. Lorne, (N.S. Tech. Coll.), 190 South St., Halifax, N.S.

CARSON, Mervyn Shannon, B.Sc. (C.E.), (Univ. of Sask.), instr'man., city engr.'s dept., Saskatoon, Sask.

CARSON, Robert Garfield, Jr., B.Sc. (E.E.), (Univ. of N.B.), Saint John Power Commission, Saint John, N.B.

HAMMOND, Rowland Ernest, (Univ. of Toronto), P.O. Box 124, Angus, Ont.

LITTLE, Harry, (Stud. Inst. M.E.), dftsman., Aluminum Company of Canada Ltd., Arvida, Que.

Undergraduates at McGill University, Montreal, Que.

BILLETTE, Roger, B.A., (Univ. of Montreal), 3699 Jeanne Mance St., Montreal, Que.

ELLIS, David E., 3434 McTavish Street, Montreal, Que.

MORRISON, Claude Wilson, 148 Portland Avenue, Mount Royal, Que.

PIMENOFF, Clement John, 2196 Old Orchard Avenue, Montreal, Que.

Undergraduates at Mount Allison University, Sackville, N.B.

ALEXANDER, Robert Lewis, Sackville, N.B.
BARNES, Robert Lockhart, Moncton, N.B.
CAMPBELL, George William, Windsor, N.S.
CURRY, Herbert Nicholas, Windsor, N.S.
DesBARRES, William Frederick Clyde, Sackville, N.B.
ELLIOTT, Roy Chipman, Middleton, N.S.
FIRTH, Angus Theodore, Doaktown, N.B.
FULLERTON, Roland McNutt, Truro, N.S.
GODDARD, Rolfe Alton, Elgin, N.B.
HARDY, William Edison, Sackville, N.B.
HAYMAN, Donald Hood, Moncton, N.B.
HICKEY, Winston Edward, Sackville, N.B.
HOLDER, Allan Scott, 12 Charles St., Truro, N.S.
LIPTON, Samuel, 127 Cottage Road, Sydney, N.S.
MacDONALD, Arden Morris, Londonderry, N.S.
MacLEOD, Bruce Garfield, Moncton, N.B.
MacPHERSON, Arthur Roland, Springhill Jct., N.S.
MURRAY, Robert Leslie, Vernon, P.E.I.
NICHOLS, Judson Timms, 81 Chesterfield Ave., Westmount, Que.
RAMSAY, Donald William, Moncton, N.B.
ROGERS, Carl Lemual, 354½ Cameron St., Moncton, N.B.
SIBLEY, Bertram Charles, Sackville, N.B.
STILES, George William, Matapedia, Que.
SUTHERLAND, William Collie, Westville, N.S.
WASHBURN, Walter James, Saint John, N.B.
WILLIAMS, Thomas Alexander, Sackville, N.B.

The Smart Turner Machine Company, Ltd., of Hamilton, Ont., has recently introduced into Canada the Pacific Deep Well Pump, which has been designed to eliminate the many problems which usually accompany present-day pumping of water from deep wells.

The operation and use of these pumps is described in a number of bulletins issued by the Smart Turner Machine Company, and may be had on request.

Three of the main features of this equipment are pump bearings, line shaft bearings and impellers. The bearings are "Edgewood" and are designed so that water may be delivered absolutely pure and uncontaminated by lubricating oil. The impellers are of the enclosed "Pacific" turbine type and are capable of maintaining high efficiency and high capacity over a wide variation of pumping head, and this without overloading the motor.

The design of these pumps was only adopted after exhaustive research and carefully tested both in the testing laboratories and in the field, and the results have in every way come up to expectations.

Frick Company (Incorporated), Waynesboro, Penn., U.S.A., has recently issued a new 8-page Ice and Frost Bulletin, No. 124-A, describing equipment for making carbonic ice. This bulletin may be secured free of charge by communicating with the company.

The Scientist and the Writing of Good English

Some years ago, the statement was attributed to Sir James Barrie that the man of science appears to be the only man who has something to say just now, and the only man who does not know how to say it. Without verifying the quotation, it may be admitted that it sounds like one of the remarks of that pleasant writer, though it does not seem to lie in his line of country. In the mouth of a literary man, the criticism looks rather as though it ought to have been made by Stevenson, who by his illustrious antecedents would have had the chance of observing any ground for such comments, and by his disposition would have been not disinclined to make it. It is, perhaps, not fanciful to imagine that the reason Stevenson made no such remark was that the scientific writing on which he was brought up did not suggest or justify it. At present, however, taking the statement to refer to the average scientific paper published in the English language, and to exclude some conspicuous exceptions, it cannot be denied that it is substantially true. Probably there is no country in which better scientific work has been done since science emerged from the dark ages than in the United Kingdom. Its quality does not seem to be falling off, and of late years its volume has been constantly increasing. Its immediate value, on the other hand, is suffering from the fact that a large number, and possibly a majority, of those who do the work do not succeed in describing it effectively or clearly.

The rules of good writing doubtless vary with the purpose of the composition. The late C. E. Montague, an admired master of the art, pointed out, for example, that in composition intended to stimulate the imagination of a reader, or perhaps even to persuade his judgment, writing may be too clear, and at its best should suggest a conclusion to the reader, rather than formulate it explicitly. An old advocate's trick is so to shape his argument as to lead the judge to form the desired conclusion for himself, without having the words put in his mouth. There is undoubtedly a pleasure to be obtained from reading such matter, in which the reader is set to co-operate with the author to a modest extent. At all times the writers of speculations upon scientific results have been able to give such pleasure to their readers, and the amazing developments of modern physics give greater opportunity than ever for such composition. It would be unfortunate if scientific men were precluded from publishing more than their definitely ascertained results, and could not communicate also their ideas of possible explanations or extensions before these had been demonstrated conclusively. Even in such writings, needless haziness or ambiguity is undesirable, but such works are to be distinguished from what may be called scientific writing proper, in which the writer is concerned to describe the observations and studies by which he has made additions to knowledge. It is of writing of this class that the present complaints are made, and, even in this primary or proper scientific writing, a distinction may be drawn between what is addressed to workers in the same field, and what is intended for other readers. No such distinction, however, can avoid the fact that in each class, while the primary business of the writer is to be clear, he allows himself too often to be obscure.—*Engineering.*

Sir Charles Algernon Parsons, to whom the development of the steam turbine is due, died on February 12th, 1931, at the age of seventy-seven. He was a son of the third Earl of Rosse, noted astronomer, and was educated at home and at St. John's College, Cambridge, later becoming eminent as a mechanical engineer. The Parsons compound reaction turbine was first introduced in 1884, for the purpose of driving electric generating machinery, and it was afterwards adapted for marine propulsion. Something of a sensation was created at a naval review at Spithead in 1897 when the "Turbinia," the first seagoing vessel to be propelled with turbine machinery, achieved the then almost incredible speed of 32 knots. The success of this small ship of 100 tons, with its 2,100 h.p., led to the general use of the steam turbine for naval purposes. The satisfactory trials in 1904 of the cruiser "Amethyst" demonstrated so conclusively the advantages of the turbine that all subsequent naval craft, from battleships to destroyers, were fitted with that type of engine. To attain the highest efficiency, the turbine should revolve quickly and the propeller slowly. To reconcile these requirements, single reduction and double reduction gearing was interposed between the turbine machinery and the screw shafts. The development of the steam turbine has been, perhaps, the most important step in steam engineering since the time of Watt, and Sir Charles lived to see his original scheme improved upon and utilized in the largest and fastest vessels afloat of 60,000 tons and 100,000 h.p. He died during a cruise to the West Indies on board the Canadian Pacific steamer "Duchess of Richmond," one of the most successful ships of recent design.

A pamphlet has been received from the Ottawa Paint Works Ltd. describing some experiments conducted at their plant on the corrosion of structural steel embedded in concrete, and on the effect of painting such steel. It was desired to ascertain whether paints giving satisfactory results when used upon exposed steel would give good service in contact with concrete. Results indicated that this was not necessarily the case, and that special paints are necessary to exclude moisture, withstand the action of the concrete, and insulate against stray electric currents. Further particulars can be obtained from the company.

BRANCH NEWS

Border Cities Branch

Harold J. A. Chambers, A.M.E.I.C., Secretary-Treasurer.

The regular monthly meeting of the Border Cities Branch was held on January 16th. The speaker of the evening was Captain A. F. Ingram, manager of the Canadian Airways, Limited. His subject was "Commercial Flying in Canada." In his talk, he dealt with the history, the difficulties encountered, the equipment and the prospect for development of air lines in the future.

The pilots and personnel, the speaker stated, were all men of long experience, the majority having served in the Great War. Sixty-two per cent of the Imperial Air Force in the Great War, Captain Ingram stated, were Canadians. At the end of the war 95 per cent of our Canadian pilots went back to their old positions held prior to the war. The remaining 5 per cent entered commercial flying, but not much progress was made until the boom in 1927.

In 1929, many companies amalgamated and the government gave assistance. Planes were given for turning out a certain number of pilots. The Department of Civil Aviation also co-operated. They established lights from Windsor to Toronto for night flying. The railways, namely, the Canadian Pacific Railway and the Canadian National Railways lent assistance in the promotion of flying, seeing the possibility in future air lines.

All the air routes in Canada were established by the giving of air mail contracts, which contracts were of three and four years duration. The difficulties encountered in the formation of an air line, Captain Ingram stated, are: first: To conform to the regulations the government has established to safeguard the public. Second: To meet the rigid requirements and rules of the Post Office Department, and third: To conform to all the requirements of the insurance companies.

The pilots, the speaker stated, have all flown continuously for over ten years and in their work fly approximately 75,000 miles each year. The air engineers must work on aircraft for at least two years and then pass examinations. The staff also includes mechanics helpers and recorders. The recorders are stationed at the various ports along the line. The company in addition has a statistical department. Each district has a district superintendant who must be capable of handling any situation which might arise and who must be a responsible person.

Night flying which is becoming essential is aided by the voice to voice radio and by lighted air ports which are most essential.

The address was illustrated by slides and motion pictures.

A hearty vote of thanks was conveyed to Captain Ingram by the chairman, Orville Rolfson, A.M.E.I.C., on behalf of the members of the Branch.

Calgary Branch

A. W. P. Lowrie, A.M.E.I.C., Secretary-Treasurer.
W. H. Broughton, A.M.E.I.C., Branch News Editor.

The Calgary Branch was favoured by a visit by our western vice-president, C. J. Mackenzie, M.E.I.C., on Friday, January 9th.

Dean Mackenzie met the Executive committee at lunch at the Palliser hotel and took part in a very interesting and informative discussion of Institute business both general and local.

In the afternoon a party, including the Dean, motored to the Ghost river power plant and made an inspection of the plant and dam.

At a special meeting held in the Board of Trade rooms in the evening about forty members and friends gathered and listened to a very interesting address entitled "Estimating Urban Population in Western Canada." As Dean Mackenzie spoke on the same subject at Lethbridge and Edmonton it is understood that a synopsis will appear elsewhere in The Journal.

Dean Mackenzie explained that his visit was arranged in conformity with the new policy of limiting the General Secretary's visits to once every two years instead of annually as heretofore, the vice-president for the Zone to visit in alternate years. The speaker also congratulated the Branch on having one of its members, S. G. Porter, M.E.I.C., elected to the presidential chair and expressed his confidence that the president-elect would prove a worthy successor to some of Canada's most illustrious engineers.

Dean Mackenzie then went on to the theme of his paper and propounded what were to many of the members who have not studied the subject some very novel theories regarding the inevitable limitations to the growth of urban populations in an agricultural country. He produced such a wealth of evidence based on a study of the growth of urban population in the country to the south of us and of some of the European countries as to convert his theories into practical certainties.

It is absolutely necessary, said the speaker, that we should have some basic theory and sound argument with which to curb the money-spending tendencies of the councils of some western cities when swayed by pictures of future populations based, very often, on nothing more solid than western optimism.

The paper was illustrated by a number of slides showing comparative areas in Canada and the United States and graphs of their comparative population growths at various stages of their development.

Town Planning is a subject of very live local interest just now and the discussion might have been expected to have developed along these lines. The inherent subject matter of the Dean's paper, however, was so interesting that this phase of it received scant attention.

A very lively and interesting discussion ensued, taken part in by J. A. Spreckley, A.M.E.I.C., L. A. B. Hutton, A.M.E.I.C., F. N. Rhodes, A.M.E.I.C., F. J. Robertson, A.M.E.I.C., J. H. Ross, A.M.E.I.C., Mr. Turner-Bone and the city planning engineer, among others. A hearty vote of thanks was tendered to the speaker by those present, on a motion by Mr. Porter.

About sixty members and friends gathered at the Board of Trade rooms at a special meeting of the Branch held on Friday, January 16th, to meet D. V. Canning, M.E.I.C.

The speaker gave a brief outline of the history of automatic control pointing out that the first automatic station typical of present design had been put into operation in 1914. Since that time progress along this line has been very rapid until at the present time automatic control has been applied to practically every kind of electrical machinery.

Mr. Canning stated that the rapid development of automatic control had been due to the necessity for finding some economical means of operating the numerous substations and generating stations that are being installed to meet the constantly growing demand for electrical energy.

The devices used in automatic equipments have been developed very carefully to meet the exacting requirements of this service.

The speaker described in detail the operation of several types of automatic equipment.

Synchronous converters require rather elaborate equipment for automatic operation on railway systems. They are usually started on the indication of low trolley voltage or they may be started by time switches or by supervisory control from a remote point. The converters automatically connected to low voltage taps on the transformer and brought up to speed. The field is separately excited to ensure correct polarity. The field is then connected across the converter armature and the polarity is checked. Full A.C. voltage is applied and the brushes are lowered on the commutator after which the machine is connected to the D.C. system through load limiting resistors which are then short circuited.

When the machine is starting and running it is protected against all the usual operating emergencies.

Automatic hydro-electric stations divide themselves into two classes. One class uses self-synchronizing of the unit with the system while the other class uses automatic synchronizing.

Self-synchronizing machines are connected to the system without field at a little below synchronous speed and are pulled into synchronism. This scheme of synchronizing is only used where the capacity of the system is large compared to the machine to be synchronized.

Automatic synchronizing is used in cases where the capacity of the system is too small to allow the use of the other method. In this case the machine is synchronized with the system by means of special relays.

The speaker described the operation of three types of supervisory control equipments, namely, the impulse audible system, the impulse visual system and the direct wire system.

The impulse audible system operates over two line wires, and may be used over comparatively long distances. The system is operated by means of a telephone dial which sends out a code series of impulses to pick up the proper selector relay at the outlying station. Signals are given to the operator by means of a howler located at the dispatcher's station.

The impulse visual system operates over four line wires. It may be used over long distances to control a great number of breakers or equivalents. Indications are given at the dispatchers station by means of indicating lamps and an alarm bell. This system combines accurate selectivity and high speed of operation.

The direct wire system requires a separate wire for each control and another wire for each indication. It is used up to distances up to two or three miles depending on the number of controls and the comparative cost of control cable. Indications are given by means of lamps and a bell at the dispatcher's station.

Mr. Canning said that the installed capacity of automatically controlled equipment has grown from 300 kw. in 1914 to over 2,000,000 kw. in rotating apparatus in 1929. In addition more than 10,000,000 kw. of static apparatus is controlled by automatic switching equipment.

An equally technical discussion ensued, taken part in by Mr. R. A. Brown, city electrical superintendent, F. J. Robertson, A.M.E.I.C., G. H. Thompson, A.M.E.I.C., W. Anderson, A.M.E.I.C., F. N. Rhodes, A.M.E.I.C., and others, at the conclusion of which a hearty vote of thanks was accorded the speaker on a motion by Mr. Brown, seconded by Mr. Thompson.

A general meeting was held in the Board of Trade rooms on Thursday, January 29th, at which about sixty members and friends were present.

The speaker of the evening, M. H. Marshall, M.E.I.C., was introduced by the chairman, B. Russell, M.E.I.C., and proceeded with an address on "The Island Falls Power Development on the Churchill River."

The development was undertaken by the Churchill River Power Company primarily to supply power in bulk to the Flin-Flon mine of the Hudson Bay Mining and Smelting Company Ltd. and the Sherriff Gordon Mine at Cold lake in Manitoba.

The plant itself, said the speaker, is of conventional design, but it has a special claim to interest because of its location in a sub-arctic district and its remoteness from usual means of transportation.

In its total length of 1,325 miles it passes through many lakes which will form excellent storage basins and its total drop of 1,300 feet is concentrated in numerous falls and rapids which make it very rich in power sites but add considerably to the cost of developing them on account of the numerous portages necessary.

Little is known, continued the speaker, of the flow of the river. During 1928-30 a minimum of 10,000 c.f.s. and a maximum of 35,000 c.f.s. were recorded and past high water marks indicate a maximum of, probably, 100,000 c.f.s.

The power site is 70 miles from the mine and a road had first to be constructed over which all material and supplies for construction and machinery could be transported. Summer transportation was by scows on the lakes with portages between them, and winter transportation by 100 h.p. tractors pulling about six sleighs and a caboose. An average trainload of 77 tons and a maximum of 120 tons of material was hauled in an average time of 36-40 hours.

It was necessary, the speaker pointed out, to develop a small power plant of about 2,000 kv.a. capacity at 600 volts to carry the construction load. This load was carried by two 1,250 h.p. turbines and the energy was transmitted about 14 miles to the main construction camp at 26,400 volts.

The general scheme consisted of:

1. A power house of concrete block construction supported by a massive concrete substructure.
2. A main power dam, 90 feet high, spanning the channel, with provision for ice shutes, undersluices and a spillway section.
3. An extension of the power house headworks to provide for additional units in the future.
4. Bulwark dams forming shore connections to the north and south banks.
5. A concrete main spillway dam, 44 feet high, one mile south of the power dam.
6. A number of earth dams or levees to prevent overflow along the margin of the head pond.

The cribs for the six cofferdams were constructed of lumber on shore, shaped to fit the contour of the river bottom, floated and sunk into position and faced with sheet piling and banks of clay.

Three main units of 12,000 kv.a. capacity at 90 per cent power factor, 3-phase, 60-cycle, 6,600 volts, driven by 14,000 h.p. single runner, vertical shaft, propellor type turbines operating at 56 feet head and 164 r.p.m. have been installed and provision made in the dam for three additional units when the load warrants. There are also installed two house turbines of 1,250 h.p. each direct connected to a 1,000 kv.a. 600-volt 3-phase, 60-cycle generator.

Climatic conditions, said Mr. Marshall, are extremely severe, the temperatures falling as low as 55 degrees below zero at times. These low temperatures caused many difficulties during construction and have necessitated the provision of special means for avoiding the formation of ice and of clearing it if it does form. The guides for the stop-logs are electrically heated.

The total length of the power dam is approximately one quarter of a mile with a maximum height of about 120 feet.

Some idea of the magnitude of the job may be gathered from the following approximate summary:

Excavation and earthworks	194,000 c.f.
Rock excavation	63,300 c.f.
Riprap	11,400 c.f.
Concrete	83,700 c.f.
Concrete blocks	134,800 pcs.
Reinforcing steel	11,400 tons.
Structural steel	200 tons.
Cofferdams	17,500 c.f.
Freight handled	35,000 tons.

The whole of the work was completed in two years, concluded the speaker, of which sixteen months was taken in building the permanent works.

The wide appeal of the paper to those present was shown by the large number who took part in the ensuing discussion, including F. J. Robertson, A.M.E.I.C., F. K. Beach, A.M.E.I.C., F. N. Rhodes, A.M.E.I.C., H. J. McLean, A.M.E.I.C. and Mr. Hobson.

A vote of thanks moved by Messrs. McLean and Beach was responded to very heartily by those present.

In the Halifax Branch news for October 15th, 1930, which appeared in the January, 1931, issue of The Journal, it was stated in error that Mr. McDonald was the speaker of the evening. Mr. George A. Richardson, technical lecturer of the Bethlehem Steel Company, addressed the Branch on that occasion.

Hamilton Branch

J. R. Dunbar, A.M.E.I.C., Secretary-Treasurer.
J. A. M. Galilee, Affiliate E.I.C., Branch News Editor.

A meeting of the Executive Committee was held in the Wentworth Arms hotel at 6 o'clock p.m. on February 11th. The chairman and five other members of the Executive were present.

The Secretary-Treasurer reported that two $500 bonds had been purchased.

Formation of an Aeronautical section was discussed but no action was taken.

On the motion of H. A. Lumsden, M.E.I.C., seconded by G. A. Colhoun, A.M.E.I.C., it was resolved that a letter of condolence be sent to the Niagara Peninsula Branch regarding the sad death of their Secretary-Treasurer.

Several applications for admission or transfer were considered.

The Executive committee confirmed their action in endorsing the following resolution adopted at the meeting held in the Engineers' Club, Toronto, on Tuesday, January 20th, 1931, at which were present representatives from the Professional Engineers of Ontario, American Society of Mechanical Engineers (Ontario Section) and The Engineering Institute of Canada (Toronto Branch), and in requesting the Secretary of the Toronto Branch of The Engineering Institute of Canada to transmit their recommendation to the Prime Minister:—

> "That, in view of the impending resignation of the Chairman of the Hydro-Electric Power Commission of Ontario, we, the Engineering Societies of Ontario, respectfully submit to the Prime Minister that the vacancy on the above Commission be filled by the appointment of an engineer of repute.
>
> Also, in the event of this suggestion being favourably considered, that these Societies would be glad to give any assistance in their power to the Prime Minister in this connection."

Immediately following the Executive committee meeting an informal dinner was held in the Wentworth Arms hotel, at which were present H. S. Finnemore, B.Sc., A.M.E.I.C., Canadian National Railways, who was to speak at the Branch meeting immediately following, together with members of the Executive Committee and members of the Branch.

After dinner the meeting convened in the auditorium of the Canadian Westinghouse Company. The chairman asked H. U. Hart, M.E.I.C., to introduce the speaker, who gave an address on the development and operation of oil-electric rail cars on the Canadian National Railways.

The Development and Operation of Oil-Electric Rail Cars on the C.N.R.

Mr. Finnemore prefaced his paper by saying that the unit rail car is not a new development in the railroad field, cars of this kind having been built and used twenty-five years ago.

The unit rail car operates in ordinary railway service by power furnished from a source within itself. This source may consist of storage batteries or some form of generating plant, consisting of a prime mover transmitting power to the wheels through either a mechanical or electrical transmission. The internal combustion engine is now in universal use.

Since the mechanically driven car of large size and weight has poor starting characteristics and involves a somewhat complicated gear shift, it is natural that the next development in rail cars should combine a gas engine with electrical apparatus. This type of car is called gas-electric. This combination gives good starting and an extremely flexible speed control system.

Storage battery cars have been tried for a time but limitations arose which showed conclusively that the car with its self-contained power plant was the solution for light traffic on branch lines.

After investigation and tests, the Canadian National Railways decided to build a number of unit rail cars using a diesel engine. These were the first oil-electric cars ever built for regular railroad operation on this continent. Two sizes of engines were chosen, a four-cylinder and an eight-cylinder. Seven cars were built using the smaller unit, the power plant comprising a Beardmore engine, 200 h.p., direct-connected to a 105 k.w. 600 volt d.c. generator. Two cars using an eight-cylinder Beardmore engine of 400 h.p. were also constructed. The engine is connected to a 200 k.w., 600 volt d.c. generator. These two cars are of the articulated type, that is, they consist of two separate car bodies connected together at one end and supported by a common truck at the joint. This truck contains no traction motors, the motors, four in number, being mounted two on the front truck and two on the rear. The car is 102 feet in length over all, weighs approximately 185,000 pounds and as constructed, seated 126 passengers and provided a large baggage space, as well as a smoking compartment. Since then the baggage space has been increased and the seating accommodation consequently reduced.

The four-cylinder cars are somewhat smaller and consist of the regular type of car body 60 feet over all, seating 57 passengers and with a good sized baggage compartment. These cars have proved especially satisfactory and have not been changed materially, being in service today practically as built.

The next type of car constructed by the Canadian National Railways was 73 feet 9 inches long, weighed approximately 140,000 pounds and seated 37 passengers with a liberal space for baggage. The engine is a Beardmore, developing 300 h.p. at 750 r.p.m. with six cylinders and, like the first two types of engines used, has an 8¼-inch bore by 12-inch stroke. The generator is 198 k.w., 600 volt d.c., with a single sleeve type bearing and is mounted on the same bedplate with and rigidly connected to the engine.

All electrical connections, including engine starting, are established through electro-pneumatic and electro-magnetic contactors from a master controller, which is combined with a mechanically connected engine throttle, and engine starting is accomplished by motoring the generator from a 64 volt storage battery.

After three years' operation with the six-cylinder cars, seven more were placed in service in 1930. These cars are practically duplicates of the first five, with the exception that a Westinghouse engine is used instead of a Beardmore.

A feature of the electrical equipments on all six-cylinder cars is the generator torque control. This device, in the form first developed for oil car application, consists of a small motor, the armature of which tends to revolve against the tension of a spring and whose shaft carries a contact-making arm. The field of this motor is proportional to that of the main generator and the armature is in series through a shunt with the main generator armature.

On future equipments, a more recent development, known as "engine torque control," will be used. This device prevents overloading of the engine by limiting the fuel to each cylinder to the amount corresponding to full load fuel at any one of several working speeds between idling and full speed positions. The engine throttle is mechanically connected to the control for the fuel admission and positively limits the amount of fuel for any given throttle position.

The tests made by the American Railway Association last year on unit rail cars, using gasoline, distillate and fuel oil (Diesel), showed an overall efficiency of the power plants, that is, from the fuel tank to the generator terminals, as follows:

Gasoline and distillate—approximately 12 to 15 per cent.

Fuel Oil or Diesel—23 to 26 per cent.

These tests were made on different railroads and the cars were tested exactly as found, without adjustment or change to any part of the equipment. The operators were told to carry on as usual and endeavour to forget that any tests were in progress. Expressing these results in another way, the output for gasoline and distillate average about 5 kw.h. per gallon, while for fuel oil (Diesel) the output averaged over 10, just double the amount.

A switcher locomotive was shown which proved the adaptability of the Diesel in this exacting service.

At the conclusion Mr. Hart, vice-president of the Canadian Westinghouse Company, pointed out that they had several engineers working on oil-electric cars and it would only be a matter of time when the Beardmore type of engine would be made in Hamilton.

E. M. Coles, A.M.E.I.C., moved a hearty vote of thanks to the speaker for his most interesting and instructive address, which was carried unanimously.

There were 75 present.

Lethbridge Branch

Wm. Meldrum, A.M.E.I.C., Secretary-Treasurer.

The regular meeting of the Lethbridge Branch was held at the Marquis hotel on Saturday, January 24th. There were 28 members and affiliates present. The meeting was preceded by the usual dinner, enlivened by Mr. Brown and his orchestra, following which a musical programme was enjoyed. Besides the community singing of the Branch, vocal solos by Miss J. McIlvena and E. J. Rannard were excellently rendered and enjoyed by all.

The speaker of the evening, N. H. Bradley, A.M.E.I.C., district engineer, provincial government of Alberta, was introduced by the chairman, C. S. Clendening, A.M.E.I.C. Mr. Bradley took as his subject "The Progressive Development of Highways." The speaker illustrated his paper by motion pictures shown with the Branch's new projector operated by Mr. C. M. Watson. The two reels of pictures were obtained from the Ontario Highways Branch.

Mr. Bradley pointed out how, in 1924, the average quantities in earth construction were, approximately, 4,000 cubic yards per mile; while in 1930, the average was approximately 8,000 cubic yards per mile, and not infrequently additional right-of-way is required for the extra material. In 1924 no attempt was made to eliminate sharp turns and corners, while in 1930, 10-degree curves were laid down as standard for all such places. In 1924, diversions in the alignment were resorted to with the idea of saving yardage at hills and coulees, etc. In 1930, a straight alignment was adhered to where at all possible with possibly steeper grades and with the idea that future traffic will warrant hard-surfacing, thereby justifying this additional increase in cost.

In 1924, the gravel placed on roads was the ordinary pit-run gravel passing a 1½-inch grizzly; in 1930, the gravel was crushed to pass a circular screen, with 1-inch round holes.

The maintenance of main highways in 1924 was done by occasional dragging; in 1927 by regular horse patrol on gravelled sections; and in 1930 by regular motor patrol graders. Also the government is now attempting to keep 750 miles of main highway free from snow, as compared with 550 miles during the winter of 1929-1930.

Realizing the comparatively short life and expense of maintaining even the best of gravelled roads, the government has been conducting tests with a number of oil and asphaltic materials.

Mr. Bradley pointed out how Alberta is faced with a tremendous problem in providing highways throughout the province with its sparse population. Alberta has 2.5 people to the square mile, compared with 183 in the New England and mid-Atlantic states and 389 in the British Isles. The rapid advancement of motor transportation and remote scattered settlements has necessitated the building of roads, at times possibly beyond the limit of economic justification.

Alberta by July, 1931, will have a total of 1,875 miles of standard grade road and 1,429 miles of gravelled highway.

The replacement cost of gravel in some sections runs as high as $600 per mile annually, while surface maintenance costs approximately $350 per mile and the laying of an oil coating to settle the dust runs the cost to another $500 per mile.

Gravelled roads differ from the water-bound macadam formerly in vogue, not only in the smaller size of aggregate used, but in the variety of materials utilized, and to secure a compact thickness of road metal, the use of a drag or grader under traffic rather than a road roller. Under constant and intelligent maintenance these roads present a much smoother surface than was formerly the case.

The costly part of the maintenance of untreated surfaces is the replacement of aggregates blown off the road. When traffic increases much over 400 vehicles per day, this item may run so high as to make it advisable to use some sort of a treated surface. The treatment of gravel roads with light oils is economical and can be justified where traffic runs more than 500 vehicles per day. It is known that traffic running 1,000 vehicles per day will throw off the road, as dust, 300 cubic yards of gravel per mile per season. The placing of gravel on roads is costly. Materials must be conserved; to conserve materials they must not be allowed to blow away.

The speaker pointed out that no matter what material is used to surface a road, the major body is gravel or crushed rock—hence the added necessity of conserving our gravel deposits.

The paraffin base residual oils obtainable from Alberta refineries have no intrinsic value for road purposes as they have no adhesive properties. An oil with a tar or asphaltic base is absolutely necessary.

Mr. Bradley's talk evoked quite an interest in his audience which was shown in the lively discussion which followed.

R. S. Winter moved a hearty vote of thanks to the speaker.

The Lethbridge Branch held its regular meeting on February 7th, in the private dining-room of the Marquis hotel, thirty-six members attending. Following the dinner two excellent solos were rendered by Mr. and Mrs. Meldrum much to the delight of those present. Mr. Brown and his orchestra, as usual, were at their best and enlivened the dinner hour with many appreciated selections.

A telegram from The Institute headquarters was received by the Secretary, announcing that two charter members of the Lethbridge Branch, S. G. Porter, M.E.I.C., and Major H. G. Muckleston, M.E.I.C., had been elected president and vice-president respectively of The Institute. The Branch immediately passed a motion that telegrams be sent to these honoured members congratulating them.

The Branch was favoured by a visit from K. R. Jallings, chemical engineer, Maple Leaf Oil and Refining Co., Ltd., Coutts, Alberta. Mr. Jallings took as his subject "The Story of Gasoline," and illustrated his talk by motion pictures of the Standard Oil Refineries of Indiana kindly lent by the Bureau of Mines.

Mr. Jallings said that in order to operate an internal combustion engine in a satisfactory manner a fuel must meet certain requirements. These requirements will vary from year to year as the design of the motor is changed to give greater operating economies. Thus a fuel which gave complete satisfaction when used in the motor of 1910, would be quite unsuited to the high compression motor of to-day. In the early days, specifications were written in a more or less haphazard fashion. At present there is an intensive research programme being conducted, to determine the qualities which are necessary to a good motor fuel.

In the early days of the industry, before the advent of cracked gasoline, the colour of a gasoline was taken as an index of the care used in its manufacture. Mr. Jallings said that as far as he had been able to determine there is no sound technical reason for retaining this specification. Another quaint custom is that of specifying the gravity of a gasoline. The speaker pointed out that there are cracked gasolines on the market to-day with gravities as low as 50 degrees A.P.I. and that they will start a car in any sort of weather.

There are three qualities that do determine the value of a motor fuel that meets the needs of an internal combustion engine. First, the fuel must not corrode any of the metal parts with which it comes in contact. Second, it must have a sufficiently low gum content to prevent the sticking of valves. Third, and most important of all, it must be sufficiently volatile to burn cleanly and start the motor easily without producing vapour-lock at the highest temperature at which the motor will be operated.

There are standard methods of testing a gasoline for these qualities. A freshly polished strip of copper is placed in a test tube immersed with the gasoline to be tested; the tube and contents are then maintained at a temperature of 122 degrees F. for three hours. The copper strip is then examined, and if it only shows a slight discolouration the gasoline is non-corrosive. There are a number of tests for gum, none of which are entirely satisfactory. Hence when the gum content is specified, the method of making the determination must also be specified. The volatility of a gasoline is indicated by the standard A.S.T.M. distillation test.

The principal sources of motor fuel are: first, normal or straight distillation of crude petroleum; second, thermal decomposition or cracking of heavy petroleum hydrocarbons; third, extraction from natural gas; fourth, carbonization of coal; fifth, hydrogenation of petroleum and coal; six, synthesis from carbon monoxide and hydrogen; seventh, retorting of oil shale; eight, the fermentation of carbohydrates. Of these methods only the first three have been of any great commercial importance in the past.

In 1929 the United States produced a total of 434,920,495 barrels of motor fuel. Of this 56.27 per cent was made by the straight distillation of crude petroleum; 33.03 per cent was made by cracking, and 10.70 per cent was extracted from natural gas.

The retorting of oil shale is not at present an economical possibility, save under the most favourable conditions.

A great deal of methyl alcohol is made by synthesis from carbon monoxide and hydrogen. However, a very small amount of it is used as motor fuel because of the relatively high cost of manufacture.

Hydrogenation of coal and petroleum promises to become a very important source of not only gasoline but of kerosene and lubricating oil as well. However, it has still to prove what it can do on a large scale. The carbonization of coal furnished the United States, in 1929, with 2,920,000 barrels of benzole, most of which went into the chemical industries.

The gasoline which is extracted from natural gas is very volatile and as a result finds little or no use directly as motor fuel. It is practically all sold to refineries who blend it with their straight run and cracked products to give them the necessary volatility to render them saleable.

Cracking of petroleum hydrocarbons was developed when the demand for light products became so great that it was impossible to supply it by normal distillation of crude petroleum. In October, 1930, 38.91 per cent of the gasoline produced was made by this method. It has certain properties, due to its chemical composition, which render it especially desirable for use in the modern high compression motor.

Crude petroleum falls naturally into three major classifications. Paraffin base oils are formed largely of hydrocarbons of the paraffin series having the empirical formula C_nH_{2n+2}. Asphalt base oils are composed largely of hydrocarbons having the empirical formula C_nH_{2n} and leave a heavy pitch or asphalt as residue when they are distilled. Mixed base oils, as the name indicates, are a mixture of these two classes of hydrocarbons.

Using the destructive distillation method on a paraffin base crude we obtain as our crude distillates, light naphtha, heavy naphtha, high test burning oil, tar distillate, wax tailings and coke. Such a distillation is usually conducted in a batch or shell still which is a steel cylinder, although sometimes several of these stills are connected in series.

The crude gasoline obtained by these distillation processes have to be subject to a chemical treatment to remove objectionable sulphur compounds. The chief sulphur compounds present in freshly distilled crude gasoline are hydrogen sulphide, mercaptans, alkyl sulphides, disulphides and thiophenes; the type present controlling the subsequent chemical treatment.

In the acid treatment, the crude gasoline is mixed with 66 degrees sulphuric acid, and then neutralized with caustic soda and washed with water. This treatment dissolves out the sulphur compounds. This treatment is objectionable because if unsaturated hydrocarbons are present they are dissolved in the acid and lost; this treatment also lowers the antiknock value of the gasoline.

The doctor or plumbite process is most used. In this method the raw gasoline is pre-treated with a weak solution of caustic soda to remove the hydrogen sulphide. It is then mixed with enough doctor solution to remove the mercaptans. Just enough free sulphur is then added to cause the dark-coloured mercaptides to precipitate out. When the precipitate has settled it is drawn off and the gasoline finished with a water wash and allowed to settle clear. Mr. Jallings illustrated this method on a sample of crude gasoline. He then went into the possible chemical reactions that probably take place in this treatment.

The Edelnau process approached the ideal in that it furnishes a solvent which has a selective action on the sulphur compounds present. The cold distillate is mixed with cold liquid sulphur dioxide which dissolves the most of the sulphur compounds but has no effect on the pure hydrocarbons. However, the cost of installing the process has prevented its general adoption.

The meeting was then thrown open to discussion, after which N. Marshall, M.E.I.C., moved a very hearty vote of thanks to the speaker. The meeting adjourned at 10.30.

London Branch

Frank C. Ball, A.M.E.I.C., Secretary-Treasurer.
John R. Rostron, A.M.E.I.C., News Editor.

A special meeting of the Branch was held on January 15th, 1931, at the London Life Insurance Company auditorium, the speaker being Captain A. F. Ingram, operating manager, Air Mail Division, Canadian Airways Ltd., and his subject "Commercial Flying in Canada."

W. G. Ure, A.M.E.I.C., chairman of the Branch, presided and introduced the speaker.

Captain Ingram's talk was illustrated by lantern slides and a moving picture film.

He said that within three years there should be a trans-Atlantic commercial air line linking North America and Europe, via Greenland, feeding the great territory of mid-western, far-western and southern states. The course will be from Greenland, along the north shore of the St. Lawrence to Montreal and from there to Toronto, London, Detroit and the west.

The British Government is working hard on such a project at the present time, he declared.

By the time the trans-Atlantic line is in operation, however, there should be an all-Canadian transcontinental line.

The northern route as mapped out above is favoured by Captain Ingram for the Atlantic flight ahead of the southern course, via the Azores, as is strongly boosted in the United States.

Developments in this direction mean that great improvement will of necessity be seen in Canadian airports, Captain Ingram said. Night flying was sure to be greatly increased along many sections of the line and for night flying airports must be lighted. He was sorry to say that Western Canadian cities had shown the way to Ontario centres in that respect. At the present time the Government was offering to pay half the cost of installing floodlights at airports; but that offer would not last for ever, the speaker said.

He also predicted a great advance in the equipment and capacity of airports, and said that at the present time Maritime points were showing the way to Ontario cities in upbuilding of their flying fields.

The speaker described how fast mail planes might meet the incoming boats at Father Point, at the mouth of the St. Lawrence, take mail off them and then beat the steamer by almost a day to Montreal. Next year they were going to meet them at Belle Isle straits, almost a third of the distance from Montreal to Europe, and then the saving in time would be increased.

One of the most romantic of Canadian air mail lines is the 1,600-mile journey from Edmonton right up to the mouth of the Mackenzie river. A trip that used to take 72 days by dog team is made by plane in two days. Mail is now delivered to points in Quebec and along the north shore of the St. Lawrence twice a week, where it formerly was not delivered at all during the winter.

Colonel Ibbotson Leonard, M.E.I.C., moved a vote of thanks to the speaker, which was seconded by W. Raywood Smith, A.M.E.I.C.

The annual dinner meeting and election of officers for the year 1931 was held at the hotel London, on Wednesday, the 21st of January, 1931.

The retiring Chairman conducted the proceedings, the speaker for the evening being Dr. A. E. Berry, Ph.D., C.E., M.A.Sc., M.E.I.C., of the Ontario Department of Health.

Dinner was served at 7.15 p.m., to which full justice was done in a thoroughly engineering manner, and was followed by a session of community singing with Mr. Archie McCulloch at the piano.

The first part of the evening was devoted to the business of the Branch and the Secretary's and auditor's reports were read and adopted. W. P. Near, M.E.I.C., Branch Councillor for 1930, who was absent owing to illness, deputed the Secretary to read his report of the discussion and findings of the Plenary Meeting of Council at Headquarters.

This was accordingly done by F. C. Ball, A.M.E.I.C., and the report was adopted without discussion.

The election of officers for the year then took place and the results were as follows:

Chairman	Wm. Raywood Smith, A.M.E.I.C.
Vice-Chairman	D. M. Bright, A.M.E.I.C.
Executive	G. E. Martin, A.M.E.I.C.
	J. Ferguson, A.M.E.I.C.
	John R. Rostron, A.M.E.I.C.
	W. C. Miller, M.E.I.C.
	F. Y. Harcourt, M.E.I.C.
Secretary-Treasurer (Acclamation)	F. C. Ball, A.M.E.I.C.

A pleasing feature during the above business was the presentation by the incoming Chairman, W. R. Smith, A.M.E.I.C., to the retiring chairman, W. G. Ure, A.M.E.I.C., of the silver badge pin of The Institute as a mark of the appreciation and thanks of the Executive and Members for his services during the past year. Mr. Ure in returning thanks also expressed his appreciation of the help given to him by the members of the Executive, particularly Mr. Ball, the Secretary, whose aid had been invaluable. He also called the attention of the meeting to the presence of Robert Angus, M.E.I.C., of London, who at 89 years of age was the oldest living member of the Branch, and said how pleased the Branch was to welcome him. Three hearty cheers were given followed by the singing of "For He's A Jolly Good Fellow."

W. C. Miller, M.E.I.C., city engineer of St. Thomas, then introduced the speaker.

Dr. Berry, in opening his address, said that he proposed to speak of the part played by engineers in public health work. The doctors were chiefly concerned with the cure while the engineers were engaged in the prevention of disease. In the latter class came the control of communicable diseases largely effected by environment and the resistance of the human system. The part of the engineer was seen in the construction and control of healthier conditions of environment, such as the destruction of refuse, proper heating, ventilation and lighting of buildings, sanitary plumbing and drainage and the efficient disposal of sewage; and in the resistance of the human system by the control of supplies, such as water purification, milk and other food supplies.

In the early days organization along these lines was not known nor was the germ theory until this was discovered by Dr. Pasteur.

The Massachusetts Board of Health, in 1876, was the first public body to acknowledge and determine the allocation of the parts played by the medical men and the engineers. That of the former being to cure and that of the latter to prevent.

The efforts of the engineer—civil, mechanical, hydraulic, electric, chemical, etc.—in this direction naturally led to specialization in the various branches and today the term "specialist engineer" is well known in the Departments of Public Health.

Some of the beneficial results from these engineering precautionary measures might be judged by taking the case of epidemics—say typhoid fever, for instance; it was generally known that this disease was largely spread by contaminated drinking water. Before the efforts of the engineer were put forth in the water purification plants and sanitary supplies, forty to fifty cases of typhoid fever occurred to every 100,000 population per year whereas at the present time two to three cases per 100,000 per year is the rate. The waterworks engineer must make the water to conform with three requirements. It must be: 1, safe; 2, palatable; and 3, attractive.

Referring to the organization of the Department of Public Health the speaker referred to the several parts played by the federal and provincial governments and the municipal bodies. The federal government was concerned with pure food and drug supplies and cleanliness in transportation, particularly with regard to vessels and their cargo. The provincial governments, as instanced by Ontario, by engineering in the effort to prevent disease—Child and Mothers' Welfare, Laboratories, Industrial Hygiene (Factory workers), Dentistry, and Vital Statistics. The municipalities appoint a Medical Officer of Health, who is responsible for the administration of all matters pertaining to the health of the community. The city of London, with its activities in these matters, stands second to none.

In the field of nose and throat diseases the engineers' activities were again manifest in such matters as the perfection (not yet reached) of sanitary drinking fountains, swimming pools, sterilization of dishes, etc.

Regarding the milk supply, the speaker, while admitting that the medical man and the veterinary surgeon had their fight to make in the struggle for pure milk, was still of the opinion that the major part of the work came upon the mechanical engineer in perfecting the machinery for the proper sterilization and pasteurization of the milk itself and in the sanitary control and distribution of it. In some of the United States, an engineer was appointed to take charge of this work.

In the matter of vital statistics the engineer was again in the forefront as his training in mathematics, the use of the graph and the slide rule enabled him to deal with statistics in a more efficient way than the doctor, whose training was not so much on these lines.

In conclusion the speaker emphasized the fact that there was a distinct field for health engineers and recommended that more students specialize in this direction rather than that of constructional work, which is overcrowded.

The meeting was well attended and three doctor were amongst those present: Dr. Hugh A. Stevenson (former M.P.P. for London), Dr. A. J. Slack, Dean of the Institute of Public Health of Western Ontario University, and Dr. W. S. Downham, Medical Officer of Health.

All of these gentlemen spoke in approbation and approval of Dr. Berry's remarks.

Dr. Stevenson spoke at length on the germ theory and cited the work of Dr. Pasteur in this direction. He averred that the germs themselves were harmless but they, like other organisms, required food to flourish on and unless they found suitable ground in the animal body on which they could feed no harm would result; on the other hand, if they did find suitable ground the inoculation started and the disease became manifest. In this connection he made the rather startling announcement that if Adam and Eve could come back again and live upon this earth they would be dead in less than a week, his reason for making this announcement being that the various epidemics which had attacked the human race through the ages had rendered the blood of the present generation almost immune to the attack of the germs of many of these diseases.

E. V. Buchanan, M.E.I.C., in proposing a vote of thanks to the speaker, spoke of the broader field which was now open to engineers, such as heating and ventilation, ultra-violet rays, artificial sunlight, town planning and the motor car with the facilities it afforded the people of obtaining the advantage of purer air in the country, etc.

G. E. Martin, A.M.E.I.C., seconded the vote of thanks, which was unanimously carried by all present.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

Commercial aviation was the subject of an extremely interesting address given before a supper meeting of the Branch, on February 18th, by Captain A. F. Ingram, manager of the Canadian Airways, Montreal. In addition to a large attendance of branch members, there were present a number of officials from the local airport and also the chairman of the civic airport committee. L. H. Robinson, M.E.I.C., chairman of the Branch, presided. During the course of the supper, the St. John's male quartette entertained the gathering with several vocal selections.

Commercial Aviation

The close of the great war found Britain supreme in the air, with vast numbers of fighting planes and a large force of trained airmen, over sixty per cent of whom were Canadians. With the cessation of hostilities, however, ninety per cent of the pilots were forced to return to ground occupations, while the remainder earned a very uncertain living with forest patrols or small aviation companies. The reasons for this were that war machines were not suited for commercial use, and the public had not, as yet, become air-minded. Only within the past three or four years has civil aviation come into its own.

In the United States, for example, the country is now covered with a huge network of air lines, whose operation has reached a high state of efficiency. Captain Ingram referred at some length to the American passenger air service as illustrative of what might shortly be expected in Canada.

Passenger planes are of the all-metal, tri-motored type and nothing is left undone to ensure the safety and comfort of travellers. Pilots, during flight, are at all times in two-way radio voice communication with the airports, and are constantly informed as to weather conditions ahead. Planes are equipped with lavatories having hot and cold running water. Regular meals are served en route. Magazines and fruit are supplied free of charge. An individual reading lamp and ventilator is placed above each seat. In order that the most frequently asked questions may be answered at a glance, a speedometer, an altmeter and a clock are mounted within easy view of the passengers. Every plane carries a stewardess, who must be, among other things, a fully qualified nurse. Both a day and night service is maintained. When a passenger wishes to "retire," he is given a pillow and a rug. His chair is then tilted back much after the manner of a barber's chair, and it is remarkable how easily slumber is induced.

In Canada, up to the present time, the progress of aviation has been mostly along the line of the development of a highly efficient air mail service which covers not only the more thickly populated areas but also extends into the northerly regions. Frequently, over these latter routes, mail deliveries are a matter of hours, where months were required in the past. In conjunction with the air mail, a passenger service is now being developed and it is expected that in the course of a very short time it will be the equal of any in the world.

At the conclusion of Captain Ingram's address, he was tendered a very hearty vote of thanks on motion of T. H. Dickson, A.M.E.I.C., seconded by G. E. Smith, A.M.E.I.C.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Joint Luncheon with Queen's University Alumni Association

A joint luncheon meeting with the Ottawa Branch of the Queen's University Alumni Association was held at the Chateau Laurier on Thursday noon, January 29. At this meeting the speaker was Colonel D. S. Ellis, M.A., M.C.E. (Cornell), D.S.O., A.M.E.I.C., head of the Hydraulics Department of Queen's University, Kingston. The subject of the address was "Engineering Methods of Former Days."

In dealing with his subject the speaker made copious references to a rare book published in French in 1729 by an engineer of the name of Belidor under the title of "Engineering Science in Fortification and Architecture." The author of this book, stated the speaker, was a pupil of Sebastian Vauban, Marshal of France, a great engineer and soldier of the time of Louis XIV.

This great engineer and soldier was a builder of fortresses, defender of cities and capturer of both if need arose, builder of canals, harbours and bridges and everything else of the kind. It might well be stated that Vauban was instrumental in lifting the work of engineering from out of the ranks of a very humble pursuit to that of one of the learned professions. In fact, Vauban was one of the great engineers of history and was the leader of an engineering school of thought which continued long after him.

The book, from which Professor Ellis made his own translation, was a very extensive volume and dealt with such topics as elementary mechanics of levers and forces, stability of retaining walls, earth pressure, arches, materials of construction, masonry construction, designing of military buildings, town planning, costs, writing specifications and methods of letting a contract.

The greater part of the address dealt with a brief résumé of the contents of this book. Some very interesting points of difference with present practice were revealed and, on the other hand, in some few features it could be seen that practice has changed but very little up to the present day. Belidor throughout the work emphasizes the value of experimentation for determining methods of procedure and to confirm the results obtained by working out his theories.

In dealing with materials of construction the author of the book did not forget to include human material as well as what is more generally understood by the term. With regard to the physical materials discussed, which included all the masonry material, sand, lime, mortar, various special cements, stone, brick and timber, iron and even glass one could readily realize that the science of chemistry had not up to that time advanced very far. For instance, in regard to stone this was classified as either hard or soft. The former before use was to be left out all winter to see if the frost would chip it. Freshly quarried stone was not to be used as frost would damage it. But frost was not the only destructive agency "for," stated the author, "it is believed that moonlight alters certain kinds of rocks, particles of which the moon rays can dissolve from more compact parts."

A good brick clay was described as one which would stick to one's shoes in ever increasing quantities after the rain. Apparently good brick was made in those days by methods which have only been little improved by machinery, though the author bitterly laments that, due to the decadence of modern times, the brick were not as well made as they used to be.

An interesting comment with regard to the qualities of sand is contained in the statement that "sand should not be left lying around because due either to drying out in the sun or being soaked by rain it will lose its volatile salts and hence be no good."

The oak he characterizes as pre-eminent above all other woods where permanence and strength are desired. The trees should be cut between October and March during the last quarter of the moon so the effect of the humid rays of the moon may be as little as possible. After cutting it should be dried for two years. Iron was of course the structural metal and was used for hinges, bars, tie rods, etc. Of all the iron in France that from the Berry district in the valley of the Loire was most highly esteemed, next to it was that of la Fere. With regard to sheet glass, Belidor mentions a clever means of securing it in a frame which is superior to wedging with paper or using lead. It was by mixing a "pâte" of Spanish white and linseed oil which was pasted around the edge of a frame with a knife and in a day or two set very hard. This seems to be the origin of our putty both in name and in substance.

In describing foundations and mentioning the use of the hammer, the expression "driving to refusal" is given. This indicates that this expression is a very old one and was probably in use much before Belidor's time.

A considerable amount of the address was taken up with the question of construction details, labour, lands and the ethical side of the contractors' part in the work of construction. In carrying out large construction work, three methods were available, namely, the method of a general contract, a special contract, or day labour impressed from the adjacent countryside or by soldiers. This latter was called the corvee. The best means, of course, was a general contract if a competent firm could be found. Failing this the special contract was next to be preferred, and the most difficult manner of doing the work was the corvee.

Among the formalities connected with the awarding of the contract was one which took place after the lowest figure had been reached. Then in succession three tapers or candles would be lighted during the burning of which another contractor could offer a still lower bid.

In concluding his address, Colonel Ellis stated that the practice of engineering has not altered so very much in the past 200 years. The fact that a man wore a tri-corne hat, knee breeches and buckles on his shoes of plain steel did not remove him from his modern counterpart as widely as might be supposed.

The luncheon was very well attended. At the commencement of the meeting the chairman of the local branch of The Engineering Institute of Canada, G. J. Desbarats, M.E.I.C., called upon A. E. MacRae, A.M.E.I.C., chairman of the Ottawa Branch of the Queen's Alumni Association, to introduce the speaker. Among those at the head table were: Victor Meek, M.E.I.C., R. F. Howard, M.E.I.C., W. H. Losee, J. B. Hunter, Group Captain E. W. Stedman, M.E.I.C., C. R. Coutlee, M.E.I.C., Senator Andrew Haydon, A. E. MacRae, A.M.E.I.C., Senator H. H. Horsey, J. McIntosh Bell, Dr. H. M. Tory, John McLeish, M.E.I.C., Professor Kirkpatrick and R. Meldrum Stewart, M.E.I.C.

The annual ball of the Ottawa Branch, always one of the most interesting social events of the winter season, was held in the ball room of the Chateau Laurier on the evening of Thursday, January 29th. Four hundred guests were present at the ball, and the event proved to be one of the most delightful ever held under the auspices of the local branch.

The guests of the evening were received by Mrs. G. J. Desbarats, wife of the chairman of the Ottawa Branch; Mrs. John McLeish, wife of the immediate past-president, and Mrs. J. A. Melville, wife of the chairman of the Committee of Arrangements. Each of these ladies wore a shoulder knot of roses and lily-of-the-valley which had been presented to them by the committee.

Supper was served in the Jasper room at 11.30 o'clock, the long tables being adorned with tall vases of cut flowers. The committee in charge of the arrangements, to whom much of the success of the evening was due, was composed of Colonel J. L. Melville, A.M.E.I.C., chairman, Captain G. A. Browne, A.M.E.I.C., and Philip Sherrin, A.M.E.I.C.

H. D. Henion, of the C. A. Dunham Company, Ltd., of Toronto, was the speaker at the noon luncheon held by the local branch on February 12th at the Chateau Laurier. Mr. Henion spoke on "Developments in Steam Heating," and in the course of his talk outlined the early history of steam heating and the progress made up to the present day.

The luncheon was presided over by G. J. Desbarats, C.M.G., M.E.I.C., chairman of the local Branch, and among those at the head table, in addition to the chairman and the speaker, were R. F. Howard, M.E.I.C.; John McLeish, M.E.I.C.; W. J. Jeffrey; William Gore, M.E.I.C., and Dr. George Nasmith of the firm of Gore Nasmith and Storrie, Toronto; John McKinley; Col. J. L. H. Bogart, A.M.E.I.C., G. A. Gray of the C. A. Dunham Company; Dr. R. M. Stewart, M.E.I.C., Dominion Observatory, Ottawa; A. F. Macallum, M.E.I.C., Commissioner of Public Works, Ottawa; W. E. MacDonald; S. Bray, M.E.I.C., and Group-Captain E. W. Stedman, M.E.I.C.

Before introducing the speaker, Mr. Desbarats, on behalf of the local Branch, congratulated Group-Captain Stedman upon winning the Past-Presidents' prize of The Institute, as recently announced at the Annual Meeting held in Montreal. The paper which was awarded this prize was upon the subject of "Rigid Airships," and was presented at the annual meeting of The Institute held in February, 1930, at Ottawa.

Mr. Henion, in commencing his address, stated that steam heating was first tried out in a more or less experimental manner in the year 1745. In 1890, the one-pipe system came into general use, in which the water of condensation flowed back into the pipe. In order to overcome certain annoyances due to deficiencies in this system, the two-pipe system was invented whereby a separate return pipe allowed the water to be carried away from the radiator. A trouble with this system was that the steam very often was carried off by the return pipe also, and to obviate this the vacuum return line system was designed, steam driven vacuum pumps being employed at first and electric driven pumps later.

In 1903, Dunham invented and produced his first thermostatic trap, a step toward the present-day method of maintaining a positive pressure and of varying the pressure control by different devices, and in 1927, he introduced a differential system of circulation.

Mr. Henion at this point outlined briefly the various steps in a modern steam heating system for maintaining control and for the prevention of excessive fuel waste. Details were given with regard to the construction of control valves for reducing and for regulating pressure, of radiator traps, etc.

An important way of saving fuel and keeping fuel costs down was by the prevention of heat waste. Evidences of inefficiency in this regard could be seen in the large number of windows which have to be opened with some systems when there is a sudden rise of temperature following a period of very cold weather. For about 5 per cent of the heating season the heating systems in Ottawa must be worked at their maximum, and such systems must be designed for a range of radiator temperature extending over about 85 degrees.

An efficient temperature control system, stated the speaker, costs considerably more to instal then other systems but the amount saved as a return on the investment justifies the additional expense of installation.

Saint John Branch

A. A. Turnbull, A.M.E.I.C., Secretary-Treasurer.

A joint dinner meeting was held by the Branch and the Association of Professional Engineers of the province of New Brunswick on Thursday, January 22nd, in the Georgian ball room of the Admiral Beatty hotel.

This dinner followed the Annual Meeting of the Association of Professional Engineers of the province of New Brunswick held during the afternoon. It was largely attended by members of both societies and their guests. A very energetic and capable committee under the chairmanship of J. L. Feeney made excellent arrangements for one of the most enjoyable engineering functions of the season. A very artistic and attractive menu was provided and enclosed in a Polar Forcite gelatin cartridge of the Canadian Industries Ltd., which made a novel as well as an excellent holder. A four piece orchestra supplied music during the dinner interspersed with singing.

The dinner was presided over by W. J. Johnston, A.M.E.I.C., chairman of the Branch. The following toasts were honoured: The King, The Engineering Institute of Canada, The Association of Professional Engineers of the Province of New Brunswick, Our Guests and the Press.

The toast to The Engineering Institute of Canada was proposed by S. R. Weston, M.E.I.C. He recalled the formation of the Canadian Society of Civil Engineers in 1887, which was changed in 1912 to The Engineering Institute of Canada and extended to include all the various branches of the engineering profession. In Canada today, he said, there were over 4,800 members of The Institute, and 3,862 registered engineers. The Association of Professional Engineers in the various provinces was formed at a later date. C. C. Kirby, M.E.I.C., replying to the toast, sought to show the difference between the two bodies of engineers. He stated that The Institute was a body with a voluntary membership organized for the interchange of professional knowledge and interests, to encourage original research and develop and maintain high standards in the engineering profession, extending throughout the Dominion, while the Associations of Professional Engineers were provincial bodies membership compulsory to anyone doing engineering work within the provinces in a professional capacity. The Association of Professional Engineers of the Province of New Brunswick was founded in 1920. It was from The Engineering Institute he said that the first action came toward the creation of the Association of Professional Engineers under government status in the several provinces.

The Institute brought together in 1919 a representative committee from all parts of Canada and charged them with the duty of finding a practical way to bring about a uniform body in the various sections, which resulted in similar legislation being passed in seven of the eight provinces. The form and framework of the bill passed by the various legislatures had been drawn up in New Brunswick and proved itself a model Act used throughout the Dominion.

The toast to the Association of Professional Engineers of the Province of New Brunswick was proposed by the new president of the Association, Dr. John Stephens, Dean of the Engineering Faculty of the University of New Brunswick. He thanked the members for the honour bestowed upon him in being elected President of the Association. The retiring president of the Association, F. P. Vaughan, M.E.I.C., in responding to this toast, reviewed the past year and claimed that the engineer had occupied an enviable position in the large amount of engineering work in progress throughout the Dominion. He expressed the opinion that the engineer had a wonderful heritage in the undeveloped resources of Canada. In reference to power development, he told of projects either under construction or in immediate prospect that would add some 7,000,000 h.p. to the already developed resources of Canada. According to most recent government estimates, he said, it has been shown that of the water power resources in Canada of about 43,700,000-h.p. the existing installation is only slightly more than 13 per cent. The rise of the engineer as a leader in thought development has been rapid and has come through proof of his ability to analyze, deduce and put these findings into action to express energy in terms of fact, he concluded.

The toast to Our Guests was proposed by C. S. G. Rogers, A.M.E.I.C., and replied to by Hon. J. B. M. Baxter, K.C., LL.D., Premier of New Brunswick; His Worship, Dr. W. W. White, M.L.A., Mayor of Saint John; Thomas Bell, M.P., and Hon. L. P. D. Tilley, K.C., president of the executive council. All paid high tribute to the engineering profession and extolled the responsibility shouldered by engineers. They pictured engineers as foremost factors in the advancement of civilization and held out to members of the profession the vision of a great future in Canada through the development of great natural resources.

The toast to the Press was proposed by J. L. Holman, Jr.E.I.C., and responded to by F. X. Jennings, managing editor of the Telegraph Journal and The Evening Times-Globe. Both expressed the need of co-operation in order to reap the prosperity which they believed was in the offing.

Immediately following the dinner, Professor H. W. McKiel, M.E.I.C., Professor of Engineering, Mount Allison University, delivered an excellent address on the "Autobiography of the Earth."

Professor McKiel reviewed various ways and means which have been employed in attempting to determine the age of the earth which can be measured only in hundreds of millions of years. The earth in reaching its present condition has passed through many stages of change in its climatic, geographical and biological relations. These changes have been recorded and preserved in successive layers of rock. It is by a study of these rocks that the history of the past condition of the earth can gradually be obtained. He depicted the many and great changes that have taken place in the globe and its inhabitants during these various stages and illustrated his remarks with many interesting and well prepared lantern slides. The speaker pointed out that of all the animals of unsurpassed ferocity and size that roamed and ruled the earth some millions of years ago, none now remained. All had given way to man, who, while miserably inferior to them in physical strength and stature, had what they had not, superior power of brain, which then as now, was the deciding factor in the struggle for existence. A vote of thank moved by C. C. Kirby, M.E.I.C., and seconded by V. S. Chesnut, A.M.E.I.C., was extended to the speaker for his very interesting address.

Saskatchewan Branch

R. W. E. Loucks, A.M.E.I.C., Secretary-Treasurer.

The January meeting of the Branch was held at the Kitchener hotel in Regina, Sask., on January 23rd, 1931, and was attended by 35 members and guests. The guests included three officials from the General Motors Corporation, Messrs. H. R. Wolf and A. A. Catlin of the Research Department, Detroit, Michigan, and Mr. J. L. Arthur of the Delco-Remy Company of Anderson, Indiana.

General Motors Research Laboratories

Mr. H. R. Wolf of the Research Department of General Motors, in a short address described the work of the research laboratories where some 400 employees are engaged in the operation of a separate unit for the benefit of General Motors alone. Of this number 110 are trained engineers and 125 are engaged purely on research work. Some 5½ storeys of the new General Motors building is given over to the research department, thus providing a floor space of approximately 200,000 square feet for this work.

In this department three general types of work are carried out, viz:—

1. The correction of something that is wrong in methods used in the manufacturing plants, e.g. trouble in drying enamel.
2. The evolution of some new product or an improvement on existing products, e.g. the evolution of a new type of crank shaft.
3. Research as applied to the future progress of the industry, e.g. the production of ethyl gas.

The laboratory is divided into sections dealing with such matters as:—

(a) Chemical research into the physical properties of materials.
(b) Examination of the physical properties of all materials entering into the manufacture of a car, to secure uniformity, etc.
(c) Paint and enamel—the development of duco.
(d) New methods of plating.
(e) The application of rubber mounting.
(f) Fuels—methods of refining and effect on anti-knock properties.
(g) Metallurgical department.
(h) Electrical section dealing with ignition, lighting, etc.
(i) Sound measurements to eliminate noises.
(j) X-ray work examining materials for flaws, etc.
(k) Wind tunnel for the study of fans, radiators, etc.
(l) Head lighting—to conform to various state requirements.
(m) Power plant—to study existing and new types of motors.
(n) Special problems not included in the foregoing such, as balancing of machinery in the car and in the plant.
(o) Machine shop—employing about 200 men in building parts, etc.

Proving Grounds

Mr. Wolf next described the proving grounds operated by General Motors. These grounds consist of some 1,242 acres about 25 miles from Detroit, Michigan, and midway between the various manufacturing plants of that company.

Mr. P. B. McEwen, engineer in charge of specifications at the Regina plant of General Motors, showed a series of moving picture films illustrating the nature, extent and value of these proving grounds.

The proving grounds are situated on property somewhat broken in topography where all types and conditions of roads have been constructed, such as sand, mud, gravel, concrete, macadam, block paving, etc. A total of approximately 60 miles of roads have been constructed and are constantly in use. All traffic is one-way traffic and many of the cars under test are driven 24 hours per day in all kinds of weather, including rain, snow, etc. Hills having standard grades of from 7 per cent to 11 per cent are in use and speedways where the outer edge of the curved roadway allows speeds of from 90 to 125 miles per hour to be attained. These proving grounds exist for two purposes—one to furnish engineering data on the new models of General Motors cars as compared with past models and the other to furnish data on competitors' cars. For this purpose a large number of cars both of their own make and samples of cars from every other manufacturer of cars in Europe and America are purchased from recognized dealers and driven on these proving grounds, where a complete record of their performance is charted. This information is available to the various departments of General Motors corporation but is not made public, neither is it available to salesmen.

The cost of maintaining these grounds amounts to a considerable sum but when distributed over the total number of cars sold by General Motors it is found to add but 45 cents to the selling price of each car.

Discussion

At the conclusion of Mr. Wolf's address a number of questions were asked by the members present.

On the motion of H. S. Carpenter, M.E.I.C., and R. N. Blackburn, M.E.I.C., a hearty vote of thanks was tendered Mr. Wolf and Mr. McEwen for the entertaining and instructive programme of the evening.

The chairman called upon Mr. Arthur and Mr. Catlin for a few words. These gentlemen expressed their pleasure at attending this meeting of the Branch.

On motion of D. A. Smith, A.M.E.I.C., the meeting adjourned at 10.30 p.m.

Sault Ste. Marie Branch

A. A. Rose, A.M.E.I.C., Secretary-Treasurer.

A regular meeting of the Branch was held on January 30th, at 8.30 p.m., following the monthly dinner. The chair was occupied by A. H. Russell, A.M.E.I.C., and the speaker for the evening was Mr. A. H. Sikes, who had taken for his subject, "Natural Gas." Mr. Sikes is connected with the Great Northern Gas Company in Sault Ste. Marie, but has had many years experience in the gas and oil fields. A summary of Mr. Sikes' address follows.

In the earliest beginning of the use of natural gas, it was connected with religious life, the early Greeks seeking omens in the flame of gas escaping from the earth. Similarly in America, burning gas flames played a part in the Indians' religious ceremonies.

The earliest commercial use of gas in America was in Pennsylvania and Virginia, it being piped to Pittsburg, in a wooden pipe line. In these early days piping of the gas was a difficult problem. Many farmers in these regions had gas flares burning day and night in their backyards. Indeed, one of the characteristics of the use of natural gas has been the tremendous waste. During the last century and in particular the last decade, the use of natural gas has grown to a national industry, using billions of feet of gas supplying several millions of consumers and with pipe lines up to 1,000 miles long and 24 inches in diameter.

Natural gas is found in nearly every state of the union, in most of the provinces of Canada and in nearly every large country. In Ontario the flow is not sufficient and so is mixed with artificial gas. In Alberta the Turner field is one of the greatest in the world.

Scientific methods of exploration have been developed, employing the trained geologist. It is believed that gas found at shallow depths is from stray pockets of gas which has escaped through faults in the rock. The deeper wells give a much higher pressure and are more difficult to control. In the control of a gas well the first essential is to extinguish the fire which is done with explosive—the flame is literally "blown out." The second stop to cap the well—a cap with a gate valve being clamped over the casing and the gate valve slowly closed. The life of a gas well depends on its area, thickness and grain of sand from which it comes and the pressure. Its life may be shortened by letting the gas escape into the air, or by going too deep and letting water into the sand. Many wells which give gas with no oil are left to run unstopped.

The largest pipe line in use is 24 inches. The joints are welded and in certain places couplings are used and the pipe is buried to a depth of about 3 feet.

To prevent corrosion, modern practice is to have the soil analysed in order to decide on what treatment to give the outside of the pipe. Pipe lines operate at various pressures and if it is too low pumping stations are put in at suitable intervals. It is difficult to change a line from natural to manufactured gas as the latter dissolves all the tarry matter from the natural gas which has sealed the pipe and leaks are frequent. By-products of gas have the prospects of being a great chemical field as yet undeveloped. In industry gas is used in manufacture of brick, cement, in chemical works and in California it is even being used to dry alfalfa. Residential use alone can never pay without industrial uses. There are about 5,000,000 consumers in Canada and the United States.

Workers in gas and oil fields have a hard life. The speaker related some of his own experiences in the fields of Wyoming and Montana, which most realistically showed how "hard boiled" is the oil man.

Discussion followed, a number of those present being able to give further information on the subject out of their own experience.

A hearty vote of thanks was tendered the speaker for his most interesting address on motion of J. Hayes Jenkinson, A.M.E.I.C., and Wm. Seymour, M.E.I.C.

Institution of Civil Engineers

Address of Sir George William Humphreys, K.B.E., President, at Opening Meeting of Session, November 4th, 1930

At the opening meeting of the Session, on the 4th November, 1930, the President delivered an Address to the Members, of which the following is an abstract. The complete Address will be printed in Volume 231 of the "Minutes of Proceedings."

The President reviewed the activities of the premier municipal body of the Empire from his standpoint as Chief Engineer and Administrator of Housing of the London County Council—a body with which he had been associated for the past 28 years. During this period the population of Greater London had increased from 6,600,000 in 1901 to nearly 8,000,000 to-day, while that of the county had shown a slight but steady diminution. The problems which arose from this growth and redistribution of the population concerned both the administrator and the engineer in close relationship and were of wide interest to every Londoner. In describing what had been done in the past and what remained to be done the address illustrated the dependence of administrative ordinances on the advice and counsel which the engineer alone could give.

The following table illustrated the wide extent of the principal services:

	Sq. Miles
London County contained	117
London main drainage area contained	180
London water area contained	574
London telephone area contained	735
London and home counties electricity area contained	1,797
London traffic area contained	1,820

The principal physical feature, cutting each of these areas in half, was the tidal estuary of the river Thames.

These problems included all the modern requirements of so large a community: adequate means of communication, whether by road, railways or water, water-supply and drainage, refuse collection and disposal, telephone and telegraph services, electricity and gas, housing and town planning, all on a very extensive scale.

The drainage of London presented many remarkable features inherited from the days when sewage was discharged crude into the nearest stream, such as the Fleet, Westbourne, Tybourne or Wallbrook, or direct into the Thames itself. An important factor was that the contents of the tidal river throughout London could not reach the sea on an ebb tide, being met by the incoming tide after a passage of about 12 miles down the river. These conditions, the continual discharge of crude sewage, and the tidal oscillations, in time had their effect until, in the early fifties of last century, the condition of the Thames constituted a nuisance and the Metropolitan Board of Works was created to intercept the London sewage and discharge it by artificial sewers to outfalls beyond London. After much controversy the outfalls were ultimately fixed at Barking and Crossness. At these outfalls the sewage was originally stored in tanks and discharged only on the ebb tide; since 1887, however, it had been sedimented in tanks and the sludge deposited at sea about 48 miles below Gravesend. This system had hitherto proved sufficient, though the increase in volume, and consequent abstraction of oxygen from the river, had directed attention to the necessity of obtaining a better effluent, and it was decided last year to install at Barking an activated-sludge unit to treat a portion of the flow at that station, the construction of which was now proceeding.

The area surrounding the county within a radius of 25 miles of Charing Cross contained as many as 200 separate sewage-works, the effluents from which found their way to the tidal Thames, and the problem of making provision on a comprehensive system for these and additional areas within the catchment-area was now engaging the attention of the Ministry of Health.

To cope with the conditions which arose when very intense rainfalls occurred at about the time of high water, as also to provide for the large areas below high-water level, the county council had carried out a scheme of storm-relief sewers and pumping-stations now nearly completed.

The greater part of the water used in London was drawn from the river Thames, and the remainder from its tributary the river Lee and from wells, by the Metropolitan Water Board, which was constituted in 1903. The Board had to-day available storage-reservoirs of a total capacity of 19,657 million gal., and despite some restriction of use in 1929, it successfully maintained a supply of about 100,000 million gal. of good water a year to a population of about 7¼ millions.

Another authority which literally lived upon the river Thames was the Port of London Authority, constituted in 1908. The capital expended since that date included £17,000,000 spent on improvements, the most notable of which were the King George V dock, the extensions at Tilbury, and alterations at the India and Millwall docks. In addition, systematic dredging of the river had been undertaken, and a channel 1,000 feet wide, giving 30 feet at low water, was being obtained from the Nore to Coldharbour Point.

A brief review of the bridges and later tunnels across the river concluded with reference to the completion, during the present century, of new bridges at Vauxhall and Southwark, a new bridge at Lambeth now in course of construction, and proposals for a new bridge opposite St. Paul's cathedral.

Two vehicular tunnels under the river at Blackwall and Rotherhithe and two tunnels for foot passengers at Greenwich and Woolwich had been constructed in recent years. The development of the internal-combustion engine had produced difficulties in the way of ventilation to a degree not contemplated when the tunnels were made.

Transport was an industry in which a huge amount of public funds was invested in the provision of streets and improvements; only one class of vehicle, however, was administered out of public funds, namely, tramways. It had been announced that a proposal for the pooling of public passenger services was now receiving the renewed consideration of the Ministry of Transport.

There were other services depending upon the work of the engineer in which public funds were concerned. The government was responsible for the network of telephone and telegraph wires and cables, and possessed deep-level tubes for its postal service. The London and Home Counties Electricity area was only surpassed in size by the London Traffic area, and large developments were about to take place in the way of an increase of generating units and transmission facilities. The gas service, on the other hand, was entirely in the hands of private enterprise. The increase in numbers, speed, and weight of vehicles had increased the liability to fracture of both gas- and water-mains, and the advisability of placing gas-mains in subways had been questioned.

A Greater London Regional Planning committee, constituted in 1927, issued its first report last December. The area under the committee's review was the London Traffic area (1,820 square miles). In dealing with the framework of these large conceptions for the future there was scope for the best counsels of the expert and the administrator.

The last activity described in the address was that of housing-accommodation for the working classes. The contributions of the London County Council and the Borough Councils since the war amounted to about 40,000 and 11,000 dwellings respectively. The London County Council since 1920 had been able to create what were small townships, namely:—

	Dwellings
In Lewisham Borough—Bellingham Estate	2,000
" " Downham Estate	6,000
At Hendon—Watling Estate	4,000
Near Morden—St. Helier Estate	10,000
" Dagenham—Becontree Estate	25,000

The St. Helier estate was still under construction, and the figure for Becontree included 6,000 houses for which orders had now been given to the contractor.

The address concluded with observations on the relationship between policy as interpreted by the legislator and administrator, and action, the special function of the engineer; and pointed out that at present there appeared to be a waste and overlapping of effort as far as the labours of the engineer in Greater London were concerned.

Preliminary Notice

of Applications for Admission and for Transfer

February 21st, 1931.

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in April, 1931.

R. J. Durley, *Secretary.*

* The professional requirements are as follows—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BALLARD—BRISTOW GUY, of Ottawa, Ont., Born at Fort Stewart, Ont., June 19th, 1902; Educ., B.Sc., Queen's Univ., 1924; 1924-25, graduate students' course, Westinghouse Engineering School, Westinghouse Electric & Mfg. Co.; 1925-30, heavy traction section, railway motor engrg. dept., Westinghouse Electric & Mfg. Co., at East Pittsburgh. During last four years was asst. to section engr. in charge of design of heavy traction direct current railway motors. Full responsibility for design and constrn. of many types of rotating machines; at present, elect'l. engr. with the National Research Council, Ottawa, directly responsible to the Director for all elect'l. work pertaining to applied science as apart from pure science.

FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

HOLE—JOHN, of 48 Havelock Street, Toronto, Ont., Born at London, England, Jan. 23rd, 1874; 1890-94, 2 years, Finsbury Technical College, and 2 years evening engrg. and bldg. constrn., L.C.C. centres, London; 1892-98, six years prelim. work; 1898-1907, with E. C. Christmas, Forest Hill, London, England, and others, sole charge laying out estates, roads, sewers, and designing and supt'g. bldgs.; 1907-10, subordinate positions with Darling & Pearson, Storey & Van Egmond, architects, and as asst. drainage engr. on road diversions and ditches for P.W. Dept., Sask.; 1910-12, engr. in charge, for the Elias Rogers Coal Co. Ltd., Toronto, remodelling their coal handling plants, also continued to execute all engrg. work required by this firm until 1923 (in addition to salaried positions); 1912-16, asst. chief dftsman., Toronto Harbour Commrs.; 1916-18, asst. supt. of constrn.; 1919-20, arch't. and engr. to Toronto Housing Comm. (City of Toronto and Dominion Govt.); 1920-22, in sole charge of constrn. of Sunnyside Bathing Pavilion and Sunnyside Pavilion, as res. arch't. and engr. for Toronto Harbour Commrs.; 1922 to date, in private practice as architect and engr., specializing on design and superintendence of housing development, designing and organizing for industrial layouts, valuation of bldgs. and supt'g. erection of bldgs., etc. Consultant to Toronto Terminals Railway Co., Property Commission; Assessment Dept. and Parks Dept., City of Toronto, C.N.R. (constrn.), etc. (*A.M. 1923.*)

FOR TRANSFER FROM THE CLASS OF JUNIOR TO A HIGHER CLASS

BURCHILL—GEORGE HERBERT, of Halifax, N.S., Born at Nelson, N.B., May 12th, 1899; Educ., B.Sc., N.S. Tech. Coll., 1923; 1917-19, overseas, C.E.F.; 1923-24, testing dept., and 1924-28, asst. engr., alternating current engrg. dept., Can. Gen. Elec. Co. Ltd., Peterborough, Ont. (design of A.C. generators and synchronous motors); Sept. 1928 to date, asst. prof. of elect'l. engrg., and from Sept. 1930, acting-professor, Nova Scotia Technical College, Halifax, N.S. (*S. 1923, Jr. 1926.*)

References: F. R. Faulkner, C. H. Wright, L. DeW. Magie, B. L. Barns, R. R. Murray.

CAMPBELL—ELLIOT STIRLING, of 92 Beech Street, Halifax, N.S., Born at Moncton, N.B., Sept. 25th, 1897; Educ., 2 years engrg., Dalhousie Univ.; 5 years night classes at Nova Scotia Tech. Coll., 3 in elect'l. engrg., 1 in civil with special cert. of merit, 1 in auto work; 1917, rodman and dftsman on city survey, Pickings & Roland, Halifax; 1917, dftsman., rly. dvn., Halifax Ocean Terminals; 1918, 10th Can. Engrs.; 1918, dftsman.; 1919, asst. on constrn. of dam ($40,000) and flume line power house layout, etc., Halifax Power Company; 1919-26, chief dftsman and purchasing agent, Dept. of Highways, Prov. of Nova Scotia; 1926-29, senior dftsman., supt'g. magazine constrn., and from 1929 to date, asst. engr. in charge of magazine constrn., Mil. Dist. No. 6, Department of National Defence, Halifax, N.S. (*Jr. 1921.*)

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Vacant

CHEMICAL ENGINEER, graduate of a Canadian university, for a pulp and paper mill in the province of Quebec. Apply at once to Box No. 683-V.

INSTRUCTOR. Applications are invited for a position vacant on the instructing staff of the electrical department of an important engineering college. Candidates should be about thirty-five and graduates in engineering, with distinctive scholarship record, some teaching experience of university grade, and practical experience in industry for five or more years in technical and executive capacity. Apply, giving full particulars of education and professional career, to Box No. 684-V.

MANAGER, 28 to 40 years of age, with engineering training and at least five years experience in responsible executive position. Must have excellent character, pleasing personality and plenty of good common sense. Position offers splendid opportunity. State detailed education, experience and references in first letter. Apply to Box No. 686-V.

Situations Wanted

CIVIL ENGINEER desires to represent manufacturers of industrial products or specialties selling to industrial and other markets. Experience includes engineering and building construction, municipal works, administration and operation, purchasing and sales, etc. Record of integrity. Apply to Box No. 14-W.

ELECTRICAL ENGINEER seeks connection with Montreal engineer or architect for part time work involving the design and specification for industrial and public buildings. Experienced and capable of complete responsibility. Apply to Box No. 40-W.

CIVIL AND MECHANICAL ENGINEER; aggressive, practical engineer, with background of experience in design, construction, maintenance and operation of pulp and paper mills. Especially qualified to reduce mill costs. Apply to Box No. 53-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), 15 years experience, available on short notice. Experienced surveys, draughting, reinforced concrete design, municipal engineering, construction work, inspection, estimating. Apply to Box No. 107-W.

ELECTRICAL ENGINEER, B.Sc., age 30. Experienced in power distribution and electrical communication, including design of carrier current systems. Apply to Box No. 110-W.

ELECTRICAL ENGINEER, B.Sc., McGill '27. Experience in the electrical design of power houses and substations. Available on short notice. Apply to Box No. 154-W.

CIVIL ENGINEER, B.Sc., (McGill), M.E.I.C., P.E.Q. & B.C., with broad experience in hydro-electric power investigations, studies and exploration of forest lands, including design and construction driving and storage dams, wharves, flumes, piers and booms and loading plants, as well as general engineering and contracting, is open for engagement. Location immaterial. Now engaged but available on short notice as projects are nearing completion. Speaks French fluently, physically fit, active and energetic, and can get results. References can be furnished if required. Apply to Box No. 177-W.

CIVIL ENGINEER, A.M.E.I.C., B.A.Sc. and C.E., University of Toronto, with twenty years experience, is open for engagement. Three years railroad construction, one year lake drainage and dam construction, nine years municipal engineering, including pavement and bridges, two years town management, one year paving contracting, and one year resident engineer of highway pavement construction. At present in Maritime Provinces. Apply to Box No. 216-W.

ELECTRICAL ENGINEER, B.Sc., McGill 1926. Five years experience in the design of switchboards, layouts and wiring diagrams. Considerable experience in high and low tension switchgear design. Fifteen months experience in switchboard estimating. At present employed; available on short notice. Correspondence wanted. Apply to Box No. 247-W.

CIVIL ENGINEER, A.M.E.I.C., of long field experience on reinforced concrete, water purification, steel buildings and bridges, seeks employment on supervision or inspection. Temporary or otherwise. Apply to Box No. 277-W.

ELECTRICAL ENGINEER. Graduate '25, wide experience in hydro-electric power stations, desires position on power plant design or related work. Apply to Box No. 278-W.

MECHANICAL ENGINEER, B.Sc. Pulp and Paper, hydrometallurgical, design and operation, capable draughtsman, very resourceful in mechanical development. Single. Any locality. Apply to Box No. 306-W.

CIVIL ENGINEER, A.M.E.I.C., Canadian, R.P.E., Nova Scotia, 21 years engineering experience, both field and office, in railway, highways, foundations, concrete structures, water power and conservation, electric transmission lines, etc., experience comprising both surveys and construction, desires employment. Single. Will go anywhere. Working knowledge of French and Spanish. Available immediately. Apply to Box No. 327-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing and hoists. Also some experience in ventilating and heating work and calculators. Accustomed to structural design and details. Good references. Present location Montreal. For interview apply to Box No. 329-W.

ENGINEERING REPRESENTATIVE. Experienced civil and mechanical engineer wishes to communicate with engineering or equipment manufacturing firm with a view to becoming Ontario or Quebec representative. Apply to Box No. 334-W.

CIVIL ENGINEER. Age 48. Married. A.M.E.I.C., R.P.E., Ont. and N.B. 32 years experience in municipal engineering, on roadways, sewers, waterworks and buildings, desires position with either municipality or as engineer supt. with contractor. Ten years with City of Toronto, construction engineer on roadway work. Four years consulting engineer. Three years engineer i/c of construction work. One year resident engineer, Dept. of Public Highways. Available immediately. Martimes or Ontario preferred. Apply to Box No. 336-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., R.P.E. Ont., with twenty-four years experience embracing dams, wharves, grain elevators, foundations, pile driving, highways, municipal engineering, water power surveys, road locations, inspections and estimating is open for engagement as engineer or superintendent in construction, operation or maintenance. Location immaterial. Apply to Box No. 358-W.

CIVIL ENGINEER, grad., age 32, A.M.E.I.C. Ten years experience; seven years on design, construction, erection work and maintenance of paper mill and mine buildings and machinery. Three years on hydro-electric work in charge of surveys and field investigations; associate hydro-electric engineer, U.S. Engineers, on office investigation, design and estimates; desires permanent position in Canada. Apply to Box No. 362-W.

ENGINEER, age 31, married. Experience includes two years mechanical, two years railway, six years structural and instrumentman and structural engineer on erection, desires position in Toronto. Apply to Box No. 377-W.

SCOTS ENGINEER, 28 years old, desires situation as junior executive or some similar situation. Wide experience in mechanical, civil and hydraulic fields and four years as junior executive; A.M.I.C.E., exam., Jr.E.I.C. Will go anywhere. Apply to Box No. 381-W.

CIVIL ENGINEER, A.M.E.I.C., university graduate, O.L.S., married, twenty years experience city surveys, calculations for curved surveys, design, layout and supervision, sidewalks, pavements, sewers and water systems. Acted in capacity of chief engineer for large engineering and surveying firm for five years. Best of references. Available on short notice. Apply to Box No. 413-W.

ELECTRICAL AND MECHANICAL ENGINEER, S.E.I.C., educated Oundle and Manchester, age 24. Student course, Brit.-Westinghouse. Three years design, production, advertising, sales and control of sales force on mechanical and electrical goods. One year outside plant engineering leading public utility company. Desires work in sales, production or engineering capacity. Available immediately. Location immaterial. Apply to Box No. 415-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), graduate. Eighteen years experience in survey and construction, railway, hydro-electric and buildings. Experience comprises both office and outside work. Desires responsible position, would consider position with commercial or manufacturing firm. Available immediately. Apply to Box No. 425-W.

CIVIL ENGINEER, S.E.I.C., 1930 graduate of Nova Scotia Tech. with experience as plane table topographer, instrumentman and draughtsman and particularly interested in hydro-electric power development and reinforced concrete design, desires position. Willing to go to foreign fields. Available at a few weeks notice. Apply to Box No. 431-W.

ELECTRICAL DESIGNER, Jr.E.I.C., age 28, B.Sc., McGill University '26. Five years sales and engineering experience, seeks immediate employment. Apply to Box 436-W.

CIVIL ENGINEER, B.A.Sc., A.M.E.I.C., Jr.A.S.C.E., age 29, married. Experience over the past eight years upon hydro-electric developments in construction, design and reports. Also some experience in railway construction. Permanent work preferred. Location immaterial. Available May 1st. Apply to Box No. 447-W.

Situations Wanted

ELECTRICAL ENGINEER, S.E.I.C., B.Sc., (McGill Univ. '27), age 26. Fifteen months outside plant engineering with large public utility. Twenty months' sales engineering experience with electrical manufacturing company. Available on reasonable notice. Apply to Box No. 463-W.

ELECTRICAL ENGINEER, B.Sc., (McGill), Jr.E.I.C., age 28, graduate Canadian General Electric Company test course, with two years experience in the design of induction motors and direct current machines. Previous experience includes electrical installation in large paper mill, and assistant to engineer in charge of small utilities company. Married. Location immaterial. Apply to Box No. 466-W.

CIVIL ENGINEER, S.E.I.C., 1930 graduate. Experience as instrumentman on city and railroad construction, desires to enter structural or hydraulic field. Available at once. Will go anywhere. Apply to Box No. 467-W.

CIVIL ENGINEER, experienced in road construction, mine surveying, transmission line survey and construction; paper mill construction; age 27. Available on short notice. Apply to Box No. 468-W.

CIVIL ENGINEER, A.M.E.I.C., age 39, with wide experience on design and construction of reinforced concrete structures, desires position. Apply to Box No. 475-W.

CIVIL ENGINEER, B.Sc., six years experience in paper mill and hydro-electric work, desires position with paper or power company. Paper mill experience covers design, layout, some estimating, and construction. Hydro experience covers preliminary and flowage surveys, transmission line location, design, and six months as resident engineer on construction. Available at once. Apply to Box No. 482-W.

DESIGNING ENGINEER, A.M.E.I.C., P.E.Q., with extensive experience in design and construction of power plants, industrial buildings and hydraulic structures, desires position as designing engineer or resident engineer on construction. Apply to Box No. 492-W.

MANAGING CIVIL ENGINEER, college graduate, A.M.E.I.C., C.P.E.Q., 18 years comprehensive experience in all lines of architectural engineering and contracting as designing, detailing, quantity surveying, cost estimating, superintending and general business management, desires to change and wants connection with Montreal firm, preferably with chance to share in business. At present in responsible position as engineer in charge and chief estimator, but available on few weeks notice. Apply to Box No. 495-W.

STRUCTURAL ENGINEER, technical graduate, age 40, married, seeks position with architect or contractor. Fully experienced in design and supervision of all types of office and industrial buildings, structural steel or reinforced concrete. Available on short notice. Apply to Box No. 501-W.

ELECTRICAL ENGINEER, B.Sc., McGill University, Jr.E.I.C., age 32. Five years practical experience before graduating. Since graduation two years course with International Paper Co., including six months as electrical foreman, engineer in charge of installation of electrical equipment for two 28,000-h.p. units. Also electrical equipment for large coal-fired boiler house, designing some of the features. Apply to Box No. 506-W.

WEST INDIES, Engineer, A.M.E.I.C., etc. Experience with engineers and contractors, railway, harbour and concrete construction, desires position in West Indies. Apply to Box No. 518-W.

MECHANICAL ENGINEER, Jr.E.I.C., B.Sc., '26. Ten months experience in pulp and paper steam control. Four years experience in detail design, in pulp and paper mill, industrial plant and hydro-electric development work. Age 27. Married. Location immaterial. Apply to Box No. 521-W.

CIVIL ENGINEER, B.A.Sc., '29, with experience in supervision of construction and general office engineering, desires permanent position with contractor or engineer. Available at once. Apply to Box No. 524-W.

MANAGER FOR PUBLIC UTILITIES COMPANY, OR INDUSTRIAL PLANT, Mechanical and electrical engineer with wide experience in investigations, reorganizing and improving operating conditions to reduce production costs and increase earnings. Apply to Box No. 525-W.

CIVIL ENGINEER, A.M.E.I.C., with twelve years experience embracing survey and construction, railway, hydro-electric and highways, foundations, pile driving, municipal engineering, water power surveys, road location, inspection and estimating, is open for engagement as resident engineer on construction or other responsible position. Experience comprises both office and outside work. Available immediately. Apply to Box No. 527-W.

MECHANICAL, CONSTRUCTION, AND DESIGNING ENGINEER, with special training in hydro-electric power development, underground steam distribution systems, and the operation of large electrical machinery. Active work desired. Apply to Box No. 528-W.

SALES REPRESENTATIVE, civil and mechanical engineer, with office in Toronto, desires to hear from manufacturers of high-grade building materials or industrial equipment, with the view of representing their interests in the promotion and effecting of sales to architects, engineers and contractors. Excellent connection. Apply to Box No. 529-W.

ELECTRICAL ENGINEER, married, graduate of McGill University, desires position in Ottawa, Montreal or Toronto. Experience includes four summers with a building concern as instrumentman and assistant engineer, two and one-half years with the Canadian Westinghouse Co., this time being distributed between tests, design and sales. At present employed but available on short notice. Apply to Box No. 533-W.

CIVIL ENGINEER, B.Sc., McGill University, Jr.E.I.C., age 32. Seven years general experience in hydro-electric power investigations and construction. Has been in charge of high power transmission lines location, also in charge extension surveys. Experience in office and field. Thorough knowledge of French. Best of references from former employers. Apply to Box No. 537-W.

STRUCTURAL ENGINEER, A.M.E.I.C., B.A.Sc. Wishes to join established firm of consulting engineers. Age 37. Married. Ten years experience design of reinforced concrete and steel on buildings. Two years practical contracting experience. Apply to Box No. 540-W.

CIVIL ENGINEER, McGill '20, A.M.E.I.C., P.E.G., age 31, single. Experience includes general engineering, especially reinforced concrete work, and eight years of pulp and paper mill construction and layout. Best of references. Available on short notice. Apply to Box No. 547-W.

The Sampling of Coal

The sample plays a leading part in a large majority of buying and selling transactions. It enables the qualities of the product to be ascertained and the value of the consignment to be deduced in advance, while it also forms a basis of reference, any departure from which is admitted to be good reason for the rejection of the whole or for appropriate compensation. Thus, steel, wheat, tobacco and many other commodities are all bought and sold in this way without difficulty, and any disputes which may arise in dealing with them are easily confined within very narrow boundaries of both fact and opinion. When, however, we come to one of this country's most important natural resources, coal, the position is different and much more complicated. For coal is not a material of simple composition and, in spite of many attempts, it has not yet been possible to isolate more than a few of its constituents. It therefore follows that a condition precedent to the important task of discovering of what coal consists, is some method of ensuring that the samples tested shall bear some definite and fixed relationship to the whole.

A step towards the achievement of this end was taken some three years ago when, at the suggestion of Dr. C. H. Lander, the British Engineering Standards Association convened a conference of bodies interested in coal, with a view to preparing specifications for its sampling and analysis. A Technical committee, together with a number of sub-committees, was appointed and, with the co-operation of the Fuel Research Board, issued draft specifications covering the export and home markets in July, 1929, and August, 1930, respectively. These specifications, which dealt with both sampling and analysis, were widely circulated for criticism and suggestion both at home and abroad, and the latter (No. 404-1930), has now been issued by the Association.

Turning to the specification itself, this lays down that coal shall be divided into five classes, with ash contents of 6, 10, 15, 20 and 25 per cent respectively. The sample taken for consignments of more than 50 tons shall vary from 40 to 925 pounds, according to the ash content, three weights being specified in each class, depending on the size of the coal. The number of increments taken to make up the gross sample is to be 20, 45, 85, 130 and 185 in the five classes, and these are to be collected by plunging a ladle into a flowing stream of coal when it is being discharged from a chute or by careful selection in accordance with specified methods when it is taken from conveyors or wagons. The coal is then to be crushed, so that it will pass through a ¼-inch square mesh aperture, and reduced either in a riffle or by successive manual quartering until about 10 pounds are left. This residue is next to be crushed, so that it will pass through a sieve with an aperture of 0.05-inch and is again to be reduced until about ½ pound is left. This residue is to be ground until it will pass through a sieve with an aperture of 0.0166 inch and reduced to a quarter of a pound. It is then to be ground again so that it will pass through a sieve with an aperture of 0.0083-inch after which it is to be mixed and bottled for testing purposes. Where the consignments are less than 50 tons the weight of the gross sample is to be half the above figures, the subsequent procedure to be adopted being the same. The methods of analysis recommended in the specification are the simple practical ones used in sound commercial practice and do not call for special comment, except to say that alternative ways of determining the moisture, volatile matter and sulphur are included, and that it is recommended that the analysis on the air dry-coal shall be reported—*Engineering*.

The Modern High-Pressure Locomotive

At no time during the history of the steam locomotive have such radical changes been introduced as during the past ten years. These changes have been introduced more or less simultaneously in countries supplying the locomotives of the world, and have no doubt been stimulated by the competition of electricity and oil engines which offered more efficient, and in some cases cheaper motive power. Twenty years ago it was thought that the steam locomotive had attained practically its maximum development, as it had nearly reached the limits imposed by the load gauge. The radical changes necessitated by the adoption of extra high pressures seem to have opened up a new era. Not only do these changes render possible an increase in tractive power, but they should at the same time increase the overall efficiency.

In Great Britain alone there are 23,000 locomotives, and a sum of approximately £45,000,000 per annum is spent on their maintenance, renewal, and running. Of this sum, nearly £12,000,000, or 25 per cent, is the cost of fuel burnt by these locomotives, and another £12,000,000 has to be spent on their maintenance and renewal. The purpose of the novel forms of locomotive which have been introduced during the last five years has been to effect economy principally in fuel consumption, but the author wishes to draw attention to the importance of the cost of maintenance, and the necessity for designers of new and improved forms of high-pressure locomotives to remember that the expense incurred in maintaining locomotives is equal to the cost of the great quantity of coal which they consume. It will be seen what a large field there is for economy if both cost of fuel and maintenance can be reduced, and what an influence such economy can have on the cost of transportation on railways.

From the early days of the locomotive it has been recognized that increase of boiler pressure results in decrease of coal consumption, but with the conventional type of locomotive boiler this has generally resulted in increasing the cost of firebox repairs, and reducing the life of boilers and fireboxes. When the Rocket was built by George Stephenson a boiler pressure of 50 pounds per square inch was employed, and pressures have gradually increased until now there are many engines running in this country with a boiler pressure of 250 pounds per square inch. Pressures up to 325 pounds per square inch have been experimentally tried for locomotives in Germany and America, but 250 pounds per square inch can be looked upon as approximately the maximum pressure which can be carried in a boiler of the Stephenson type, having regard to the cost of boiler maintenance. It has taken 100 years to increase the pressure of locomotives from 50 pounds to 250 pounds per square inch, but during the last five years pressures have leapt up to 450 pounds, 900 pounds, and now to 1,700 pounds per square inch.

The use of pressures above 250 pounds per square inch has necessitated the design of a completely novel form of boiler built up of tubes and circular drums in which, generally, all flat surfaces have been eliminated. Ingenious means have been adopted for transmitting the heat from the fire to the water. The use of very high pressures, and the consequent high temperature, result in conditions which are much more exacting to the materials used in the construction of the boilers. These conditions are aggravated unless the heat transference is very rapid.

In striving for economy by the use of higher pressure, designers of locomotives are only following the lead which has been set by the designers of large stationary plants and marine engines. Their problem, however, has been made more difficult by loading-gauge and weight restrictions, and for these reasons they are unable to take advantage of condensers, and have had to extend the pressure gradient upwards to a greater extent. It does not necessarily follow that the use of high pressures in boilers is more dangerous than that of low pressures. An explosion of a boiler at a presure of 50 pounds per square inch can have disastrous results, and there is no reason, if proper precautions are taken both in design and maintenance, to assume that there is any greater liability to explosion or failure as a consequence of increase in pressure.

Whilst high steam pressure gives greater economy in fuel consumption, it demands complication in design, and care must be taken that the economies in fuel are not absorbed in the increased cost of maintenance of the boiler and of the machine as a whole. Simplicity of design is an important factor, because simplicity generally results in accessibility. Time alone can prove which of the designs, if any, that have been recently produced, will result in such overhead economies as will justify their general adoption. The results which may reasonably be expected from the use of high steam pressures on locomotives are so attractive that encouragement should be given to the production and development of designs by which these results can be attained.—Mr. H. N. Gresley in *Engineering*.

Radio for Air Pilots

Aids to Safety

The high speed of airplanes and their great dependence on weather make it necessary for pilots to have reliable communication with the ground stations. Bell Telephone Laboratories has been a pioneer in developing radio apparatus for this purpose, now standard on several great airlines. To obtain the necessary data on transmission and reception and to test apparatus in flight, two planes are operated by the laboratories.

Radio installations in airplanes presented many difficulties not met elsewhere. First, it was necessary to reduce generators, transmitters, receivers, antennas and other apparatus to light-weight, small volume, and minimum interference with the plane's operating meters and controls. The apparatus must be absolutely reliable, as it is usually out of reach of the pilot, and repairs during flight are out of the question.

Due to the noise on most planes, mouthpieces of special design are necessary. In the hand-type microphone developed for this use, the rubber mouthpiece is held tightly over the lips and practically all noise is excluded from the transmitter. The closed cavity into which the speaker talks is so shaped as to avoid serious distortion of speech. In some planes it is possible to employ transmitters with much less shielding.

Head telephone receivers similar to those worn by telephone and radio operators may be used in airplanes. A more satisfactory headset has been developed, however, employing a phonette type of receiver originally devised for the hard-of-hearing. These receivers, which weigh less than an ounce, are connected with small ear moulds fitted to the ear of the individual pilot.

Another feature of the headset is required for occasions when it becomes necessary for the pilot to leave the plane in a hurry. It would be quite embarrassing to be dangling by the cord of his telephone headset. This cord is consequently attached by means of a plug which will pull out at any sudden jerk and yet will provide good electrical contact.

Power for both filament and plate supply of the radio receiver is produced by a tiny wind-driven generator only three inches in diameter, weighing seven pounds complete with propeller. This generator, in a stream-lined casing, is mounted on a wing or strut. To generate sufficient power, the propeller must revolve one hundred times a second.

Anyone who has heard the noise caused in a radio receiver by a vacuum cleaner or a violet-ray machine will appreciate how necessary it is to shield the ignition system of the plane's motor. Shielding should include the magneto, the low-tension magneto circuits, the high-tension leads, and the spark plugs.

In addition to the shielding, it is also necessary to bond electrically all metal parts of the plane in order to avoid noises in the receiving equipment from intermittent contacts between metal parts of the plane. If transmitting equipment is installed, bonding is necessary to protect against the possibility of high voltages between adjacent parts producing sparks or arcs.

Two types of radio apparatus are used in planes: a long-wave receiver for the weather and radio-beacon signals sent out by government stations on the band between 285 and 350 kilocycles; and a short-wave two-way radiotelephone system for use in the short-wave region between 1,500 and 6,000 kilocycles.

The transmitter developed by the Laboratories is rated at 50 watts, and weighs 32 pounds, while the long- and short-wave receivers weigh about 13 pounds apiece. In both receivers, remote control is accomplished by means of small units within reach of the pilot. This permits the receivers to be as much as 40 feet away.

To operate the transmitter and receiver the pilot uses a master switch having three positions. In the first position everything is "off"; in the second, which is normal during flight, the receiver is capable of picking up messages; in the third, the apparatus is made ready for transmission. In the third position, reception is still possible, but in order to talk, the pilot must press a push-button which starts the oscillations in the transmitter. This button may be in the hand microphone or on the "stick," whichever is convenient to the pilot.

Many installations of this apparatus have been made on airplanes throughout the country. A large number of ground stations also have been equipped with the 400-watt transmitter and its associated receiver.

Breakwater Construction in Port Arthur Harbour

F. Y. Harcourt, M.E.I.C.,
District Engineer, Department of Public Works, Canada, London, Ont.

Paper presented at the Annual General and General Professional Meeting of The Engineering Institute of Canada, Montreal, Que., February 4th, 5th and 6th, 1931.

SUMMARY.—Port Arthur is a harbour of national importance, one of the world's leading grain-handling and shipping ports, and with Fort William, forms the Canadian western terminus of the Great Lakes and St. Lawrence water transportation system.

Two distinct types of breakwater, with their variations, have been constructed at Port Arthur, namely the timber crib and concrete type, and the rubble mound type.

Harbour protection in Thunder Bay began in 1883-1886, when a breakwater of rock-filled timber cribs (a portion of this is still in existence) was built in front of the main part of the town. In 1908 a period of more rapid progress commenced, when a breakwater of similar construction was constructed in the south part of the harbour; this was completed in 1911. At that time a general plan of further development and improvement was prepared and adopted, which will ultimately protect the whole water front from Bare Point on the north to the mouth of the Kaministikwia river on the south, the works constituting a continuous line of breakwaters some five miles in length, with three entrances.

In 1913 the first extension southerly was commenced, nearly 3,000 feet of breakwater being built in that year, and another portion, some 2,500 feet long, in 1914 and 1915. These sections were of the same general type and dimensions as the work completed in 1911 but were placed on a pile foundation. They are not designed as wharves or piers, and vessels do not moor to them.

Later a northerly extension was found desirable and some 7,000 feet of rubble mound breakwater have been built in the northern area of the harbour. This consists of a core of quarry run, covered by an armour course of large trap rock weighing from 4 to 6 tons, an irregularly laid covering which is very efficient in breaking up wave action. A number of settlements have occurred, due to the peculiar formation of the lake bottom, but no serious damage resulted.

The paper gives details of the construction methods employed, both for the timber-crib and for the rubble mound type, and describes the methods of transportation and handling adopted to meet special conditions in the various localities.

One of the chief factors in the growth and progress of a country is the complete scientific and economic development of its natural transportation routes. In this country, the natural advantages of the St. Lawrence river and the Great Lakes, as a means of transporting goods by water, were, partly through necessity, realized from the earliest days. Previous to 1829, the Northwest and Hudson Bay Companies had at least five sailing vessels plying on Lake Superior and trans-shipping cargoes in Thunder bay at the north-westerly end. The first steamer arrived in 1846.

So it may be presumed that, even before the year 1883, when the pioneer cargo of 10,000 bushels of western wheat was loaded on the steamer "Erin" by wheel-barrows and pushcarts, and shipped east, the ultimate possibilities of Port Arthur as a harbour of national importance were to some extent recognized.

Its geographical position on the gently sloping shore of the natural roadstead of Thunder bay near the Canadian western end of Lake Superior, 1,215 miles inland by water from Montreal, was as suitable as could be found, and its location on a slightly crescent-shaped section of water front some 7 miles in length was ideal for the development of the protected type of open harbour.

To afford the required artificial protection, however, extensive breakwater construction has been necessary, and in order that these structures might be intelligently and economically planned, both as to type and location, a thorough knowledge of physical and climatic conditions in the Thunder bay district was a first essential. This knowledge was of great importance also to all those responsibly engaged in their construction.

Physical and Climatic Conditions

Thunder bay itself is a natural roadstead, approximately 15 by 30 miles in extent and capable of providing

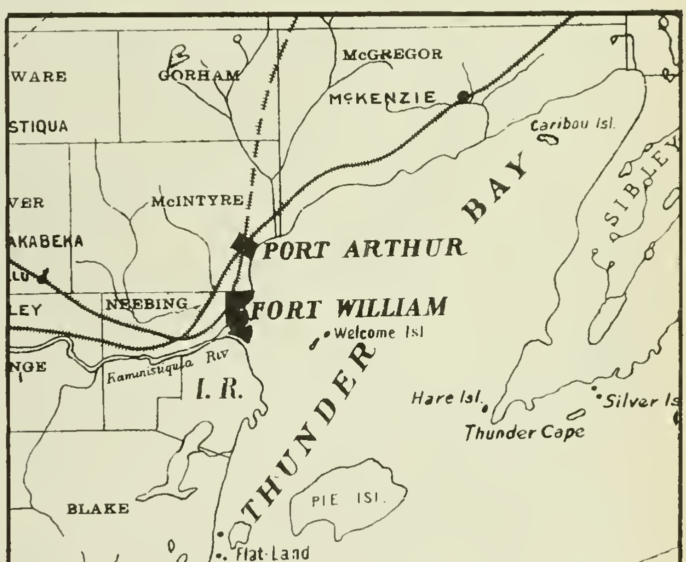

Fig. 1—Location of Port Arthur and Fort William.

secure anchorage for the largest vessels. (See Fig. 1.) The depth ranges from 3 to 49 fathoms. There are no appreciable regular tides, any fluctuations in the water level being the result of rain and snowfall, of heavy continuous winds from one direction piling up the water, and of "seiches" resulting from variations of the barometric pressure on the lake surface. These latter are occasionally of considerable extent, a rise of several feet and a return to normal in a few hours, having been observed at various times.

As the longest effective "fetch" is really only 16 miles, the maximum wave action is not large, 10 feet being the figure that has been used in all breakwater design in the harbour.

The highest recorded monthly level for Lake Superior since 1860 was 604.08 feet above mean sea level in September, 1869, and the lowest 599.9 in April 1926. The average monthly mean from 1860 to 1929, inclusive, varies from 600.10 to 604.08. The greatest annual fluctuation, as shown by the highest and lowest monthly mean of any one year, was 2.67 feet, and the least 0.45 feet.

At present, Canada and the United States, through joint action, by establishing compensating works in the St. Mary's river, at Sault Ste. Marie, at the easterly end of the lake, are endeavouring to control this fluctuation within an ordinary range of 1.5 feet. The highest water usually occurs in the late summer and early autumn months, and the lowest in the spring. The prevailing wind affecting construction during the open season is south-westerly, and often blows with great regularity.

The average navigation season lasts about eight months, opening near the middle of April and closing in December, the earliest opening in recent years being April 7th, 1921, and the latest closing, December 23rd, 1921.

Ice breaking tugs are employed late in the season when the ice is forming, and early in the spring when it is going out, to aid the movement of vessels in the harbour when necessary. The thickness of ice in Thunder bay averages about 36 inches, and depends upon the severity of the winter and the amount of snowfall. January and February are the heaviest ice forming months.

The lake bottom consists of sand, silt and clay overlying rock. Sand, gravel and rock suitable for construction purposes are readily obtainable.

Early Breakwater Construction

Breakwater protection at Port Arthur was considered essential as early as 1883, and in that year the first work of this nature was started. This first structure, completed in 1886, was located in front of the main part of the town at an average distance of one-half mile from the shore, in 11 to 16 feet of water, a location that may have seemed entirely suitable to meet conditions existing and anticipated at that time, but as events have proved, did not provide at all adequately for the future. It was constructed of native timber cribwork, hand-hewn and secured with wooden dowels. The cribs were rock-filled, with a timber superstructure, the whole rip-rapped with large stone on the outer face. It is said that many of these were field stone drawn out over the ice by horses and stone boats. It was built in two sections, the northerly 3,650 feet and the southerly 1,500 feet in length, with an entrance between 350 feet wide. It is still in existence with the exception of the southerly 1,000 feet, which was removed in 1909-1911. The substructure of the section removed was found to be in a good state of preservation. As the remainder is much too close to the harbour line and docks, to meet modern conditions, and as the superstructure is in an extreme state of decay, it will be removed eventually in conformity with the general plan of improvement that has been adopted for the harbour. Its cost was approximately $97.00 per lineal foot.

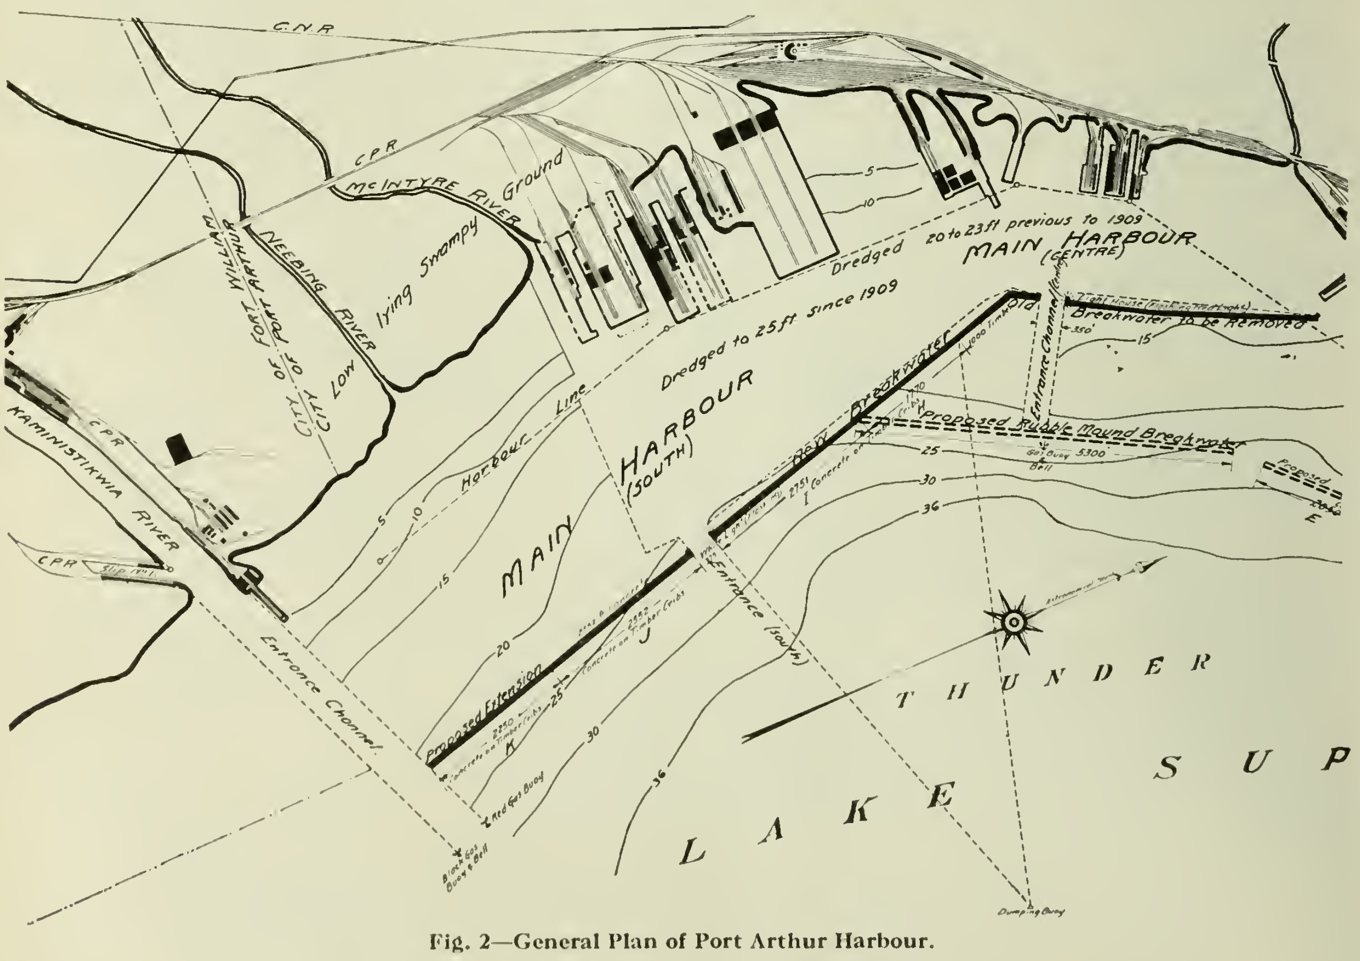

Fig. 2—General Plan of Port Arthur Harbour.

First Breakwater Extension

From 1886, the time when the first or "Old Timber Breakwater" was completed, development at Port Arthur was slow until 1908, when a period of more rapid and extensive progress commenced. As a result, additional breakwater construction was resumed to give protection to industrial plants already located and proposed in the south part of the harbour. This work is 2,780 feet long, 30 feet wide and 8.5 feet above normal water level, with a batter of two to one on the outer face of the superstructure, a slope which experience had indicated as most suitable to meet prevailing wave and ice conditions. The average depth of water was 16 feet. It consists of dimension timber cribwork, stone and gravel filled, with a superstructure partly timber and partly concrete, placed on a natural bottom of sand and clay, after a few feet of the softer overlying material had been removed by dredging to form a crib seat. This foundation was found inadequate, however, as the southerly 600 feet settled considerably, while in course of and immediately after construction. This settlement, besides giving the work a poor appearance, necessitated expensive alterations and repairs. The total cost was over $400,000, or $148 per lineal foot. It was completed in 1911.

General Plan of Development

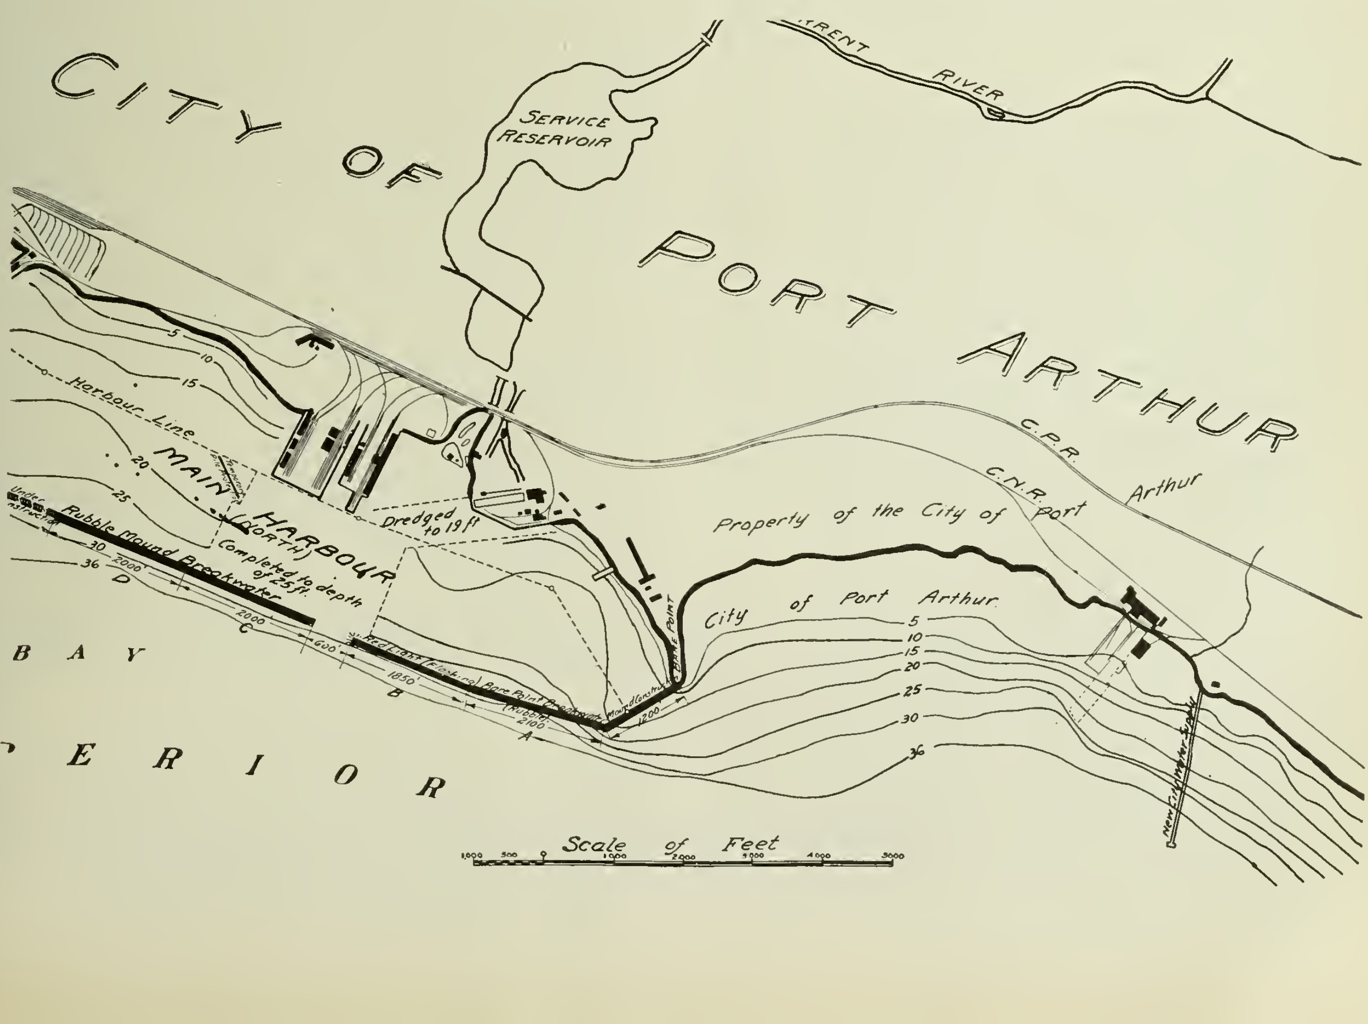
By 1911, it was evident that future harbour work would have to follow some well-defined scheme, and a general plan of development and improvement was prepared and adopted. This plan, in which an endeavour was made to foresee and meet future requirements as far as possible, is intended ultimately to protect the whole waterfront from Bare point on the north, to the mouth of the Kaministikwia river on the south, by a continuous line of breakwaters, with three entrances, as well as the removal of the old timber breakwater, and all dredging necessary for adequate fairways, docks and berths. This means the eventual construction of five miles of breakwater, three of which have been completed. The type chosen was to depend upon the nature of the foundation and prevailing costs of construction.

The general location of the breakwater was governed by the depth of water, for economic reasons, and the distance from the harbour line beyond which no wharf or dock construction is permitted. This harbour line was laid down sufficiently far from the shore line, wherever possible, to allow an industrial and shipping plant of maximum size to be built behind it. In general, an attempt was made to leave at least 1,200 feet between the shore and the harbour line for wharves and docks, and 2,400 feet, or four times the length of the largest vessels, for a basin or fairway between the harbour line and the breakwaters.

The harbour divides naturally into three sections, known as the Main harbour, North, Centre and South, each with its own entrance. It admits readily, in addition, of unlimited future expansion to the north, if and when required. (See Fig. 2.)

Additional Extensions Southerly—Design and Location

As the Main harbour south continued to expand, due mainly to grain elevator construction, the breakwater was pushed rapidly southward, to meet the situation. Two additional sections were built of practically the same general type and dimensions as the one completed in 1911, and on the same centre line, but profiting by previous experience, they were placed on a round timber pile foundation, cut off a few feet above the lake bottom, the cribs having a grillage of longitudinal timbers for bearing, and were riprapped on both sides. One section 2,730 feet in length was built in ten months, February to November, 1913, and the pile foundation was driven and cut off from the ice. The other section, 2,550 feet in length, was built during the summer season of 1914 and 1915, the pile foundation being driven and cut off by a floating plant. The average cost of these two sections was $200 per lineal foot.



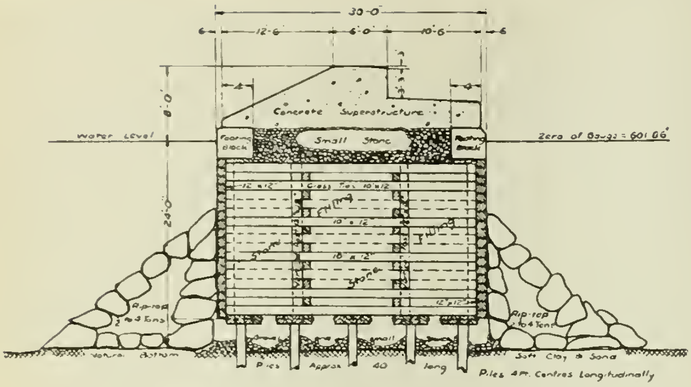


Fig. 3—Typical Section—Concrete Breakwater.

These breakwaters were not designed as wharves or piers, and vessels are not allowed to moor to them.

An additional portion, 2,250 feet long, is still to be constructed before the general plan of development will be completed at the southerly end. The typical section of this part of the work is shown in Fig. 3.

Extensions Northerly—Design and Location

In the meantime a modern ship-building plant and dry-dock was constructed in the Main harbour north, and breakwater extension was consequently necessary there also. The location of the first section having been selected, namely, starting at Bare point and running southerly, the bottom was thoroughly tested by means of wash borings and test piles. These showed that the lake bottom here was particularly unsuitable as a foundation, as it was composed of a thin layer of hard packed sand, a few feet thick, overlying a layer of silt or soft clay, 30 to 60 feet deep, and having no consistency, overlying the rock, as this soft material covered the whole area on which it was possible to locate the work, as it could not be confined, and offered no frictional or lateral resistance for piling, and as unlimited quantities of suitable rock were immediately available, the rubble mound type of breakwater was adopted.

In order to reduce the cost of construction, the design of these structures, which have to withstand only a moderate wave action, but a severe frost action, as well as a heavy scour from the large ice fields moving out and breaking up in the spring, has been made as simple as possible. They consist of a core of quarry run, taking its natural slope, on an average about 1½ to 1, which is covered from below the line of wave and frost action by an armour course of large trap rock, ideal for the purpose, weighing 4 tons and upward on the land side, and 6 tons and more on the lake side, and laid without too much attempt at uniformity provided the core is adequately protected. This irregularly laid armour course has been found to be more efficient in breaking up the waves and withstanding the suction due to recession, than if laid with the uniformity of a pavement, and can be maintained and repaired, if necessary, at much less expense.

The depth of water in which these northerly extensions have been built, with the exception of the first leg 1,000 feet long, connecting with the shore, averages from 24 to 32 feet. In order to reduce the weight as much as possible, the dimensions, particularly in the sections built since 1919, have been reduced to a minimum, a height of 7 feet above normal water level, a top width of 14 feet, and a width at the water's edge of 32 feet, having been found by experience to meet all requirements. A breakwater of this type theoretically, and not taking into consideration the numerous settlements that occurred, has a base of 116 feet in 28 feet of water, and weighs about 110 tons to the running foot, using average weights of approximately 95 pounds per cubic foot of core and 180 pounds per cubic foot of armour stone, weights which were found by actual trial at different times to be fairly representative. Its typical cross-section is shown in Fig. 4.

In practice, this design has been found to be practical and efficient, is permanent, requires little maintenance, achieves its purpose as a breakwater, and considering the very soft bottom the cost is economical.

As had been anticipated, numerous settlements, however, took place, particularly after the core had been brought near to and above the surface. They presented a variety of problems, occurring at times suddenly, so suddenly, in fact, that it was barely possible to save plant and equipment, and at others, slowly. In length, they varied from a few feet to 400 feet, and in depth from 2 to 14 feet. Sometimes the rock went straight down, with a consequent bulge upward and outward at the toe of the slope; at others, it sideslipped to one side or the other, but always with the one inevitable result, namely, more delay to the work and more rock to increase costs. Occasionally they did not take place until long after they were due, which of course compelled the greatest care in carrying on. Usually they gave sufficient warning and could, to a certain degree, be foreseen. If indications pointed to an imminent subsidence, the core was usually constructed higher than grade to make the necessary allowance or to induce the occurrence artificially. Fig. 5 shows a subsidence of this kind.

On one occasion the necessity for doing this formed the basis of a slight but peaceful difference of opinion with the contractors. As a compromise it was agreed to attempt to artificially force settlement by means of a shock representing as nearly as possible natural causes. Accordingly, five cases of 60 per cent dynamite were placed in 16 feet of water at the toe of the slope on each side and immediately opposite each other, and at the station selected, and exploded simultaneously. The results were small and purely local, nor did any settlement occur there at any future time.

From 1911 to 1930, 7,150 lineal feet of this type of breakwater, running in a general southerly direction, to connect with the construction already finished to the south, have been completed. The work has been carried out under contracts let as occasion demanded, to keep pace with the growing demands of the harbour. The cost per lineal foot has varied naturally with the unit prices obtained and the depth of water, and has ranged from $167 to $290.

CONSTRUCTION METHODS—TIMBER AND CONCRETE TYPE—ON PILE FOUNDATION

Foundation—Pile Driving

Before making plans and specifications for a structure of this type, test piles were driven on the centre line of the

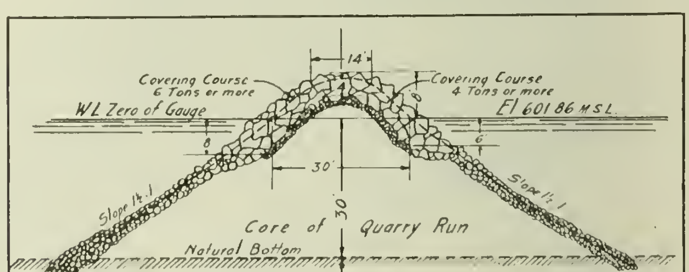

Fig. 4—Typical Section—Rubble Mound Breakwater.

Fig. 5—Settlement—Rubble Mound Breakwater.

proposed location, so that the foundation could be properly designed. The accuracy of the tests was later confirmed by the result of the actual driving. The piles were of spruce, pine and tamarac, varying in length from 30 to 65 feet, and having a least diameter at the cut-off of not less than 12 inches, and at the top, under the bark, a diameter of from 6 to 8 inches, depending on the length. They were driven in bents of five per 30-foot width of crib, the bents being spaced 4 feet centre to centre, longitudinally. They were driven either to refusal or until the final penetration was not more than 2 inches from the blow of a 3,000-pound hammer falling 20 feet. The load per pile was calculated to be 24.5 tons, on the assumption that the timber in the crib supported its own weight and that the stone filling under the cribs and between the bottom chords would support a portion of the weight sufficient to bring the actual loading under 20 tons. The results in any event prove the load was not excessive.

Piles were driven both from the ice in winter, and from a floating plant in summer. Winter work was commenced when the ice had formed to a thickness of 18 inches, and was carried out by three drivers, each capable of a side shift of 15 feet, or sufficient to drive three of the five piles in each bent. Pile centres were marked by 6-inch spikes driven in the ice, but the alignment was carefully checked instrumentally to guard against shifting. Holes for the piles were carefully cut and the latter after being driven to the bottom of the leads, were followed home by a chaser. A minimum length of one foot above the cut-off was left to provide against brooming. An average number of 53 piles, foundation and service, were driven per day. The piling cost from 10 to 14 cents per foot.

Summer work was carried out by one floating driver, and as this plant could only work in comparatively still water, it was used at all times both day and night when weather permitted. The greater part of the work was done from daylight until noon, and from 5 o'clock p.m. to midnight, as the afternoons usually proved too rough. The average day's work was eleven hours, and the average number of piles driven per day was 44. The working hours included towing the driver to and from the work.

Alignment was kept by means of transverse and longitudinal ranges set at sufficiently close intervals and checked by instruments. In all cases a jet was used to start the piles when considered necessary.

Pile Cutting

All foundation piles were cut off on a horizontal plane from 20.5 to 23.5 feet below normal water level, which left the tops projecting from 1.5 to 4 feet above the bottom of the lake. The winter cutting was done by a machine especially constructed for the purpose, consisting of a trussed swinging platform, 14 feet by 55 feet carrying a 30 h.p. boiler, one double drum, double cylinder (8 inches by 10-inches) hoist, one single cylinder (8 inches by 12 inches) driving engine, and vertical leads 40 feet long supporting the shafting and arbor to drive a 40 to 45-inch circular saw. This machine was originally intended to work on bearing timbers laid on the ice, but the ice was so weakened by the pile holes that two rows of service piles had to be driven 15 feet apart transversely and 16 feet longitudinally, to support its weight. The sweep of the saw covered the full width of the foundation.

To place the saw at the proper elevation for cutting, a water gauge was fastened to the arbor, the zero set the cut-off distance from the saw. This gauge was constantly checked.

In order to permit the saw to work, the ice was cut for a width of 27 feet. The removal of the ice presented the greatest difficulty in this operation, the progress being governed by it. The ice breaking was done by means of plows, ice-saws and wedges, the ice cakes being rafted back after enough had been pulled from the water up an inclined platform, by horses, to leave a clear working space. Work was carried on both by night and day shifts, and on an average eleven piles were cut per hour.

Cutting off during the summer season was done by an ordinary scow pile-driver, with one extra single cylinder driving engine, a 3-inch shaft and 12-inch by 15-inch arbor working in the leads to operate a 48-inch circular saw. The saw was kept set to grade by an observer with an instrument mounted on a series of stationary platforms supported on piles, at intervals which gave a maximum sight of 250 feet.

This cutting machine, when operating, was warped lengthwise along a floating fender 110 feet long, anchored longitudinally on the side ranges, and cut twenty-two piles in one move. If it was found that all the piles were not cut, the saw was shifted one foot sideways, and the ground covered a second time. The fender was then moved to the next row of ranges and the process repeated. As the piles were usually all cut in one move, it would appear that they must have been driven with considerable exactness. By

Fig. 6—Finished Portion—Concrete Breakwater.

Fig. 7—Deck Dumping Scow, unloading.

this method, as many as ninety-five piles were cut in one hour, although the average throughout was only sixteen. As absolutely still water was imperative, every advantage was taken of suitable weather conditions during the hours of daylight.

Generally speaking, equally successful results were obtained by the winter and summer driving and cutting, and the respective costs did not vary substantially, although an unusually favourable summer as regards calm weather, undoubtedly contributed to this result.

Substructure

The substructure consisted of dimension timber cribwork, each crib being 100 feet long, 30 feet wide and from 18.5 to 22.5 feet high, with the top 2 to 3 feet below normal summer water level. They were close faced on all sides, with vertical posts or binders, and bottom chords to give a bearing surface on the piles. These chords were so spaced as to allow the crib ballast to run through and fill the space underneath the crib around the piles. All cross ties were through sticks and all longitudinals and cross ties were dovetailed to the face and end timbers. All timbers were thoroughly secured by 1-inch drifts and 1-inch screw bolts of proper lengths. All timber was British Columbia fir, 10 inches by 12 inches and 12 inches by 12 inches in 18-, 20-, 22- and 30-foot lengths.

After the cribs were built on a suitably located platform, to five or six courses, including the binders, and launched, the remaining courses were added, the whole operation taking from three to four days.

As soon as the work permitted, the cribs were towed to position and sunk in place. When light, they floated from seven to eight courses out of water. While being set, they were held in place by means of tackle, controlled from the crib adjacent. They were weighted to their final bearing on the pile foundation, by the concrete footing blocks, approximate weight 9 tons, some 30 to 40 blocks being required for the purpose. In order that the best weather conditions might be obtained, this part of the work was usually done in the very early morning. The operation, on an average, occupied six hours. Very exact preliminary alignment was secured by means of ranges, the final set being checked by a transit. The general result attained was good, as the tops of the cribs were always level, and the driver who made an examination of each crib after it was set, reported that they were all bearing firmly and truly on the piles.

Fig. 8—Rubble Mound Breakwater as Constructed.

The filling consisted of gravel and small stone, the former being put in the bottom to ensure the space around the piles being compactly filled, and on top between the footing blocks to make a good bed for the mass concrete superstructure. Each crib required about 3,100 cubic yards of filling, and it was insisted that each one be at least three-quarters filled before the next one was set. Mass concrete also was not allowed to be placed until there had been ample time for the filling to settle and consolidate.

Superstructure

The precast footing blocks having been placed and lined up, the forms were set for the mass concrete superstructure in 40- and 60-foot lengths, with similar spacing between to ensure breaking joint on the cribs. These forms were in 20-foot lengths, removable without taking down, resting on a waling 8 by 8, secured to the outside of the blocks by bolts running through grooves left for the purpose in the ends. Further, a concrete core, running the full length of the form, approximately 9 feet wide and 2.5 feet high, was first poured down the centre, which had the effect of lessening the quantity and ensuring that each form was poured in one run, of helping to pack the concrete more firmly against the somewhat flat outer slope and of forming a solid anchor to which the forms could be very rigidly wired.

Fig. 9—Dumping Cars from Scow.

The concrete was mixed on a floating plant and placed by means of chutes. The mix was specified as 1:3:5, the sand and gravel aggregates were carefully selected and proportioned, and every effort was made to secure a dense, impervious mixture, a monolithic finish, and a tight bond with the blocks on the outside faces. Considering the difficulty of doing this, without extreme delay and additional cost in a very open and exposed position, the results, for the greater part, were good, as is evidenced by the fact that very little deterioration has taken place since the work was completed. The appearance of a finished portion of the timber and concrete type is shown in Fig. 6.

CONSTRUCTION METHODS—RUBBLE MOUND TYPE

Four different sections of the rubble mound type have been completed from 1911 to 1930, differing considerably not so much in general design, as in the plant and equip-

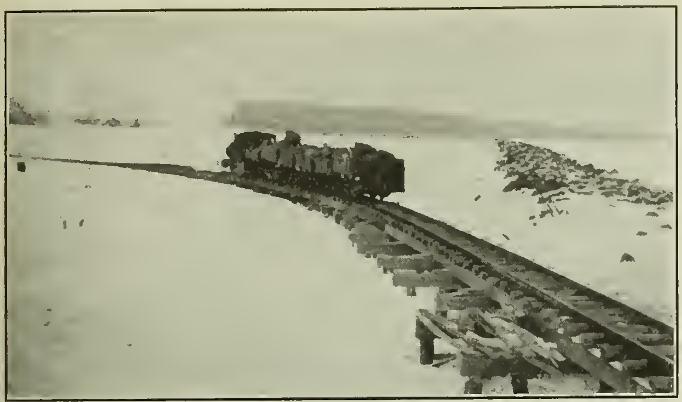

Fig. 10—Work Train on ice.

ment employed, and the manner in which they were constructed. As these changes were the combined result of different conditions, greater labour costs, more modern methods and a species of evolution based on local experience, a brief description of each as a separate unit will be given so as to indicate the difficulties encountered and the results obtained.

The first contract let in 1911 called for the construction of 3,200 lineal feet of rubble mound breakwater, starting at Bare point in the Main harbour north, and running in a southerly direction with an angle 1,200 feet from the shore. The plan and specifications called for a height above low water level of 8 feet, a width at the water line of 48 feet, and side slopes of 1½ to 1, the whole composed of three classes of stone, as follows, paid for at different unit prices:

1. Core of quarry run to 8 feet below water, 50 per cent not less than 1 ton.
2. A protecting course on top and sides of large rubble stone—4 to 6 tons—30 per cent not less than 6 tons.
3. A covering course of 3 to 3½ feet thick over the top, formed of large closely laid stone, 6 to 10 tons, 50 per cent at least 8 tons, and 25 per cent at least 10 tons.

As soon as the first settlement was encountered this classification was found to be impracticable, as the first two classes then merged and as a result the higher price was paid for stone occupying the quarry run position, so consequently, by agreement, the second class was eliminated.

As Bare point, at that time, consisted of rocky bluffs with no buildings adjacent, it was decided to open a quarry there and built the inner half by train-filling from a trestle. Three derricks were set up, and the stone, trap intershot with shale, was chained, shovelled and manhandled, labour being cheaper, into scale boxes, deposited into dump cars having an average capacity of 8 to 10 tons, hauled over a trestle to the work by dinky engines, and dumped. The trestle was kept about 400 feet ahead of the fill. By this means the structure was brought up to approximately the right size and shape, room still being left for the covering course. The average length of haul was 1,800 feet.

The tare of the core rock handled in this way was obtained by passing the trains over a 40-ton Fairbanks scale, sufficient loaded cars being weighed to give a fair daily and monthly average.

At the same time, starting at the outer end, rock was brought and placed in the work by pocket dump scows and side-dumping deck scows. For purposes of alignment over this section, four trestle bents, 130 feet wide, 20 piles to a bent, were driven at right angles to the centre line, approximately 400 feet apart longitudinally. On these, the centre line width at water's edge, and toe of slope, were marked by flags. These bents were carried away by ice each spring and had to be renewed. Heavy concrete anchors were set also at proper distances on each side of the fill and marked by buoys so that the scows, which were equipped with winches at each end, could be placed and held in position while being dumped. The weight of the rock handled by the deck dumping scows was obtained by displacement. In the case of the dump scows, an actual determination on a large scale was made to get a transposition factor from yards to tons. This factor, 2,530 pounds per cubic yard of stone, loose, was satisfactory at this time as the rock in the quarry was very uniform.

The pocket dump scows were of the usual type. The deck dumping scows. meant to handle larger stone, were 110 feet by 32 feet with a draught of 7 feet. They required a depth of from 10 to 14 feet, depending on the load, in which to dump. The decks were protected and friction minimized by strips of iron sheathing running transversely. When the stone was not too small they worked very successfully and dumped rapidly, although some time was occupied in lining them up and securing them in position. (See Fig. 7.)

These scows were built with three compartments running longitudinally. Into either of the side compartments the water could be admitted by two 10-inch pipes located 1.5 feet above the bottom and controlled by valves operated from the deck. The weight of the water when one compartment was filled depressed that side sufficiently to allow the load to slide off, after which the valves were closed and the scow pumped dry. Gauges were set at each end in the centre compartment, and as the scows had been carefully measured and tables prepared, the tare load was easily and closely obtained. As the scow method had to be abandoned when the rock was brought to a depth almost equalling their draught, the work had to be completed by the shore quarry and trestle-fill method. Work proceeded from May to December each year and the contract was not completed until September 1915, a length of 3,330 feet having been constructed in the four years during which operations had been carried on. Fig. 8 shows this type of breakwater.

Extension 1919-22

In 1915, owing to the war, all permanent breakwater construction was suspended until July, 1919, when a further length of 1,600 feet, increased later to 1,850 feet, or to the northerly side of the north entrance, was put under contract. This addition was built in 28 feet of water and had a top width of 16 feet, a width at water level of 48 feet, a height above water of 8 feet, and side slopes of 2 to 1. The cover course extended downward on each side as far as the limit of wave action, or 6 feet vertically on the inside and 8 to 10 feet vertically on the outside or lake face. Both core and cover rock were paid for under one unit price.

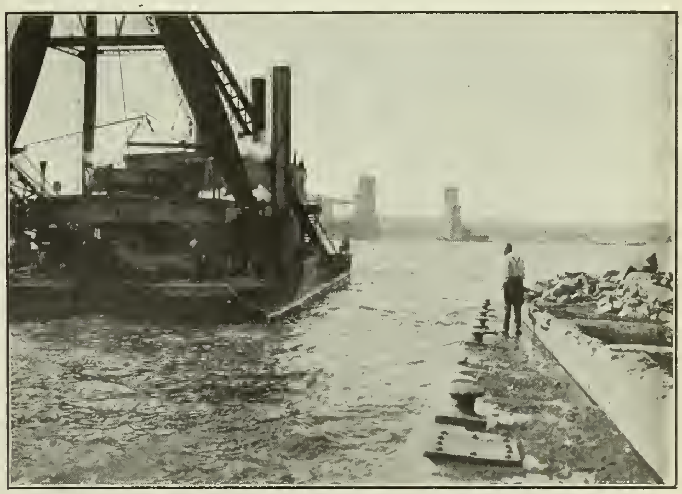

Fig. 11—Derrick Dredge.

Fig. 12—Five-fingered Grabs handling cover rock.

After some investigation, the contractors decided to utilize the partially developed quarry at Bare point, which was the closest available. The rock in the portion of the quarry now brought into use was very heavy trap interspersed in places with thin layers of shale. This shale was always carefully dumped below the limit of frost and wave action. The quarry face varied from 10 to 30 feet, and a level seam or floor of shale, fortunately encountered at a suitable elevation, formed a natural bench as a guide to drilling and blasting.

A portion of the quarry was covered with an earth and boulder overburden varying from 1 to 8 feet thick. This was shot and deposited in the work with the rock, it not being considered necessary to strip it as it was not in sufficient bulk to begin to fill the voids in the core. Care was taken, however, to dump rock containing it in deep water and at spaced intervals so that there would not be any undue accumulation in one place. This overburden was trenched also and cross-sectioned, and the weight of earth deducted in making up quantities for payment.

Drilling was carried on during the winter months in order to have a sufficient quantity of blasted rock on hand in the spring to ensure that the summer drilling could keep pace and allow the work to proceed without interruption from this cause. The whole face was shot at one time and the holes were so spaced and loaded that the rock was broken into a suitable size for handling with a steam shovel. Air drills were used, and the holes, after being sprung, were loaded with about 7 pounds of 60 per cent dynamite to the foot. The cover course was obtained from the talus lying at the foot of the bluffs on Caribou island, some 15 miles distant. This rock was loaded by land derricks onto derrick scows, which after being towed to the work. placed their own loads in position. This placing was done by chaining, the scows working, whenever possible, on the lee side. The tonnage was obtained by displacement and on one occasion when the scales were used as a check, the error was found to be well within allowable limits, or one in one hundred.

The core rock, after drilling and blasting, was loaded on side dumping cars of 6 to 7 tons capacity, by means of a steam shovel with a 2½-yard dipper, and conveyed to the work. This was done by three different methods at different times. During the summer seasons and until the core had reached an elevation that made it impossible, two flat deck scows were used, fitted with tracks capable of accommodating eight cars on each side. A dock, or slip, protected by a temporary pile breakwater, was constructed as near the quarry as possible, and into this the scows were pushed endways. A specially devised drawbridge, adjusting itself to the change in level as the trains were run on the scows, made connection between them and the shore. The cars having been hauled from the quarry and placed on the scows, were chained to the deck and a tug towed the scow to the site of the work. An average net load of rock was 90 tons and the length of tow was less than one mile. The sixteen cars were tripped from the ends towards the centre and both sides simultaneously, as shown in Fig. 9, the whole operation taking about one minute. As this dumping could be performed so quickly, it was found that, under ordinary weather conditions, the scows, once manœuvred into position by the tugs, could be unloaded without anchoring. The whole process of loading the scows, towing to the work, placing in position, dumping and returning empty, averaged twenty-five minutes, or much less time than required to load the two eight-car trains at the quarry.

During the first winter, the experiment of laying a railway on the ice was tried. After the ice had formed to a thickness of 14 inches, some 3,000 feet of steel carried on 12-inch by 12-inch stringers, 20 feet long, with 2-inch by 6-inch cross-ties or sleepers 6 feet long, was laid on the ice from the shore to the work, where it was led on to a pile trestle driven on the centre line. This method was adopted mainly to avoid snow but was difficult to keep in alignment. The snow, however, did not cause as much trouble as had been anticipated, and it would appear that under similar conditions a better method would be to lay the steel on standard ties placed directly on the ice. Trains were run over this track when the ice had thickened to 24 inches, as shown in Fig. 10.

The equipment consisted of four small 20-ton locomotives, 36-inch gauge, and the side dumping cars used during the summer. On account of the grade from the quarry to the shore, which reached 6 per cent in places, each train was limited to eight cars. The gross weight per car was 12 tons, which, with the weight of the engine, gave a total load of 116 tons distributed over a length of 120 feet. This method presented little difficulty, and during forty-six actual days worked between January 27th and March 24th, a very good performance for that time of year, 48,181 tons of rock were placed, giving a daily average of 1,050 tons loaded on 157 cars, or an average net weight of 6.7 tons per car. The best day's work was 206 cars, with a net load of 2,021 tons. As time was not a paramount object, as the number of days the ice was sufficiently thick, in spite of a severe winter climate, was limited, and as extra expense was involved in laying, maintaining and salvaging the track, this experiment, while successful, was not repeated.

After the core had been brought to an elevation 10 to 12 feet below the surface, or a depth in which the scows could not be unloaded with safety, the train-fill from a trestle operation employed on the first section, had to be adopted again and continued until completion. The

Fig. 13—Train loading old Beach Deposit for Core.

Fig. 14—Loading Scows from train by chute.

rolling stock consisted of three engines and 50 cars, a train averaging six cars, with a gross weight of 75 tons and a net weight of 40 tons. A fair daily average was one hundred and seventy cars of 6.5 net tons each, although as many as two hundred and sixty were dumped in one day. The best month's run was 26,000 tons.

About sixty men were employed on an average, about 60 per cent of whom were skilled labour. The items making up the greater part of the actual construction costs, outside of equipment, were coal, powder and labour. This contract was finished in October, 1922, three years having been required to complete it.

Extension 1923-26

The breakwater already constructed at the northern end of the harbour gave fairly adequate protection against the winds from the north and east, but not any against those from the south, which are more prevalent during the open season, consequently it was necessary to continue construction southward, and a new contract was let late in 1923, starting on the south side of the north entrance, and running on the same alignment, for 2,000 feet. Guided by experience, the cross-section was considerably reduced, its general dimensions being as follows:—Top width, 14 feet, width at water's edge, 30 feet, height above mean level, 7 feet with side slopes of 1½ to 1. The general lake depth here was 29 feet. This cross-section, while not so imposing in appearance, answers all requirements.

A new method of obtaining the rock was attempted with success. A dipper dredge working in suitable selected locations in shallow water along the shore, and digging in boulder deposits, or the talus fallen below water from the bluffs adjacent, loaded this material into dump scows, which were towed to the work, lined up and dumped in the usual manner to form the core. The length of haul varied from 7 to 30 miles. The dipper of the dredge was bored and slotted so that when fines or overburden were encountered, they could be washed out by raising and lowering the dipper several times through the water, with a satisfactory result, although the rate of loading decreased.

After the core had reached the elevation above which scows could no longer be used, the method of placing was necessarily different, as the impossibility of bridging the north gap, or crossing the fairway, precluded the use of a train. As a substitute, a powerful clamshell dredge, equipped with spuds and a long boom, was anchored bow on to the breakwater, and working along the centre line, clammed the material placed by the scows in the deeper water left on one side and transferred it to the other, thus building up the core to the section specified. This machine, with its winches and cables, was also used to align the dump scows and hold them securely in position while being dumped. It was employed also to make a berm on each side as a base for the lowest underwater course of covering rock.

As this clamshell or derrick dredge performed so satisfactorily, on this work, in so many different ways, the following general description is given: The hull is steel, 44 feet wide, 100 feet long and 10 feet deep, with a draught of 6 feet and a registered tonnage of 619; the main engines are 16 by 18, the swinging engine 10 by 10. She carries two transferable steel booms 75 feet and 45 feet long, respectively, and is equipped with two Scotch marine boilers 8 feet 6 inches by 12 feet with a steam pressure of 127 pounds. The anchors are 60 feet long and the anchor engines 8 by 8. (See Fig. 11.)

The rocks forming the armour course, which consisted of the larger boulders and larger pieces of talus rock, were collected along the shores within a radius of 75 miles, by a double derricked barge, with specially constructed 5-fingered grabs and whose normal capacity was 630 tons. (See Fig. 12.) The cover rock was unloaded also by means of these grabs, each one being securely placed before being released and very few were lost. All rock was still paid for by one unit price per ton in the work. This contract was completed in September, 1926, an average quantity of 300,000 tons having been placed during each of the two years worked in which work was actively carried on.

Extension 1928-30

The fourth or last extension followed the lines of the previous one, and had the same length and alignment. The following points of difference between it and its predecessors may, however, be given.

The use of an old beach deposit, consisting of small boulders and a very coarse gravel, was permitted as a core, as shown in Figs. 13 and 14. This material was loaded by a steam shovel into trains which were hauled to a chute and unloaded into dump scows, which were towed to the work and dumped. The haul from the quarry to the chute averaged a mile and a half, and the tow from the chute to the work averaged 13 miles. Instead of the clamshell dredge before-mentioned, the core material was rehandled to build up the required section by an ordinary dipper dredge, making transverse cuts and piling up on each side.

The core and the armour stone were paid for under two separate unit prices, the former by the yard and the latter by the ton. Very extensive settlements, greatly delaying the work and increasing the quantities, were encountered. This extension was commenced late in 1928 and completed in 1930.

General

Generally speaking, the situation met with in this north end rubble mound breakwater construction at Port Arthur resolved itself into depositing sufficient rock on a very soft foundation, until the material, after frequent settlements, compacted this underlying material to such an extent that it would bear the superimposed load. No other method seemed feasible. The use of a mattress, while seriously considered, was deemed impracticeable, as the very soft material forming the foundation covered too large an area. The extent of this soft material, both laterally and in depth, and its very soupy nature, also precluded the possibility of dredging to firmer strata.

Outside of procuring, handling and placing the rock, the main features contributing to economy of construction, were the nature of the core material, with due regard to its cost, and the necessity of not leaving any of the smaller rock above water unprotected in the fall, as it would be displaced and lost by the ice. Almost any material not too light, from a coarse gravel up, will do for the core fill below the limits of frost and wave action. Three samples of shale were actually tested, with the following results:—

	No. 1	*No. 2*	*No. 3*
Specific gravity	2.67	2.66	2.66
Weight per cubic foot	165.00	165.00	165.00
Pore space, per cent	3.21	1.46	2.08
Ratio of absorption, per cent	1.22	0.54	0.84
Coefficient of saturation, 1 hour	0.91	0.98	0.82
Coefficient of saturation, 2 hours	0.15	0.01	0.02

0.80 being considered the maximum co-efficient of saturation that could be allowed.

A system of rigid inspection of all phases of the operations, was always maintained, and every effort was made to secure economy, both in material and methods of handling and disposal.

The only description of a similar structure, obtainable when the work began, was a paper entitled "The Breakwater at Buffalo, New York," by Emile Lowe, Member of the American Society of Civil Engineers, contained in the Transactions of that society for 1904.

All the breakwater construction at Port Arthur was carried out by contract, under the supervision of the engineering staff of the Chief Engineer's Branch of the Department of Public Works of Canada, who were responsible also for the design and preparation of all the necessary plans and specifications.

Discussion on "Breakwater Construction in Port Arthur Harbour" Paper by F. Y. Harcourt, M.E.I.C.[1]

G. E. Bell, m.e.i.c.[2]

Mr. Bell observed that the paper had been of great interest to him, because he had had some connection with thd breakwater construction at Port Arthur during the last two or three years. The author deserved a great deal of credit for employing the material that had been used in the last section of the breakwater. The beach deposit to which he referred on the last page of his paper was material readily accessible to the breakwater, and the department had been able to place it in the breakwater at a very economical figure.

The author had made reference to the settlements which had occurred. These settlements were very extensive, both in the last section constructed and the section constructed previously. To anybody familiar with conditions in that locality it would readily be seen why these occurred. The bottom of the lake was of very soft material and the hard material was at considerable depth. Settlements, however, were just about the same in the last section as in the previous one. The actual quantities in the last section did not differ greatly from the estimated quantities, the difference being only about ten per cent. The settlements, occurred altogether during construction. At times the breakwater was brought up practically to completion—for a length of a hundred feet or more—before a settlement occurred. Generally it was found necessary to pile up the core to 5 or 6 feet or more above the surface of the water level to provide for settlement. The general plan was to bring the core up as high as possible to force the settlement, so that the more expensive cover stone would not be lost. There were a few thousand yards of cover stone lost on the last section. Although it was possible to recover some, most of it had settled into the interior of the core and could not be reclaimed. This settlement in some cases amounted to as much as 12 or 14 feet, for a length of perhaps 300 or 400 feet, but this was probably the most extensive. Since the breakwater had been completed no further settlement had taken place.

H. B. R. Craig, m.e.i.c.[3]

Mr. Craig considered the paper an excellent one. There were, however, a few points which might possibly, with profit to other engineers, be somewhat amplified.

(1) Regarding the costs of the various types of breakwaters built, could the author give the detail unit costs and quantities of materials that obtained in the different contracts, with the dates of contracts? The unit costs per foot of completed structures were given only, and the value of the paper to harbour engineers and others would be enhanced in this way. It would be better still if the rates of labour paid on the different contracts could be given, but such data might not now be readily obtainable.

(2) As to the design of the breakwaters, it was presumed that the Stevenson formula for wave-blow was used. It was to be noted, however, that at certain other points on the Great Lakes on both sides of the International boundary, where there was a much greater exposure or fetch, breakwaters of somewhat similar design but of smaller cross-sections had been built and had apparently withstood for years the effects of storm-waves. The first rubble mound breakwater built at Port Arthur was 8 feet high above low water level and 48 feet wide at the water level. Twelve years later the design was changed so as to call for a top width of 14 feet, with width at water level 30 feet, and a height above mean water level of 7 feet. The maximum exposure was about 40 miles, from Isle Royale. An example of a rubble mound breakwater with several times that exposure, was that of the structure completed a year ago at Port Burwell on Lake Erie. This was built of rock of somewhat similar sizes, both armour and core, to those used at Port Arthur, the armour stone being obtained at Milton and Queenston, while the core stone came from the former quarry in part, and also from a softer rock quarry at Beachville, Ont. None of the softer or more friable rock was permitted to be placed above the action of frostline, and then only in the core. The Port Burwell breakwater was built with a top width of 12 feet only and to a height of 9.5 feet above low water level, a settlement of about 1 foot being anticipated. It was built to a slope on the lake side of 1½ to 1, and on the harbour side of 1 to 1. There was at all times, but particularly during storms, a heavy race from the west along the lake face, and it would be interesting to see how this rather smaller section of rubble mound breakwater stood up, as compared with other breakwaters of a similar type of construction, having in mind of course their respective locations with respect to exposure, currents, etc. Possibly, the Port Arthur breakwater sections might have been somewhat reduced from the standpoint of economy, but doubtless the designing engineers took into account the exceptionally soft bottom at Port Arthur together with the fact that

[1] This paper was presented at the Annual General Meeting of The Institute, Montreal, Que., 1931, and appears on page 215 of the April, 1931, issue of The Journal.

[2] Assistant to Managing Director, M. J. O'Brien, Ltd., Ottawa, Ont.

[3] Consulting Engineer, London, Ont.

suitable rock was so conveniently available to the site of the structures. He believed that at no other point on the Great Lakes was suitable rock for harbour works so economically obtainable as in the vicinity of Port Arthur and Fort William.

(3) It would be of interest from an historical standpoint if there were published with Mr. Harcourt's paper a plan showing the harbour as it was before any artificial works were developed.

F. Y. Harcourt, M.E.I.C.

The author, in reply, stated that as regards design, Stevenson's formula had been used. The normal fetch was about 16 miles, causing a wave approximately 6 feet in height. One narrow passage coming from Isle Royale was somewhat over 40 miles in length and when a storm came from this direction, which was very rarely, a 10-foot wave height might be encountered. The formula was of more theoretical than practical interest and really had very little to do with the design.

The rubble mound breakwaters at Port Arthur were built largely with 1½ to 1 slope on both sides, as this was the slope which the rock naturally took when placed in the work. No undue effort was made to keep exactly to this slope. This lowered construction costs. As Mr. Craig surmised, the exceptionally soft nature of the bottom, together with the fact that very suitable rock was conveniently available to the site, covered that phase of the design.

When the paper was written, the question of including details regarding costs was considered, but it was thought that to do so would lengthen it unduly.

The first concrete breakwater built was not a fair example from which to draw conclusions as to costs. The second and third extensions, built in 1913, 1914 and 1915, were of similar construction and the unit costs were very much the same in each case. The second extension was constructed by the Port Arthur Construction Company, during the summer seasons of 1914 and 1915. The piling used in the foundation varied in length from 30 to 60 feet, and the cost from 10 to 14 cents per lineal foot. The contract unit cost for piling, placed, driven and cut, was 35 cents per lineal foot. One hundred and twenty-five thousand lineal feet were driven.

Timber, practically all B.C. fir, 10 × 12 and 12 × 12, and in lengths varying from 12 to 22 feet, cost $26 and $28 per thousand feet, delivered. The iron cost about three cents per pound. Crib-filling, largely coarse gravel, although some small rock was used, came at about 85 cents per cubic yard. Crib-work complete, 60,000 cubic yards, filled and set in place, cost $4 per cubic yard. The unit price for mass concrete was $6 per cubic yard, including cement, which cost $1.70 per barrel. Eleven thousand cubic yards were placed. The cost of concrete aggregate, sand and gravel, approximated $1 per cubic yard. The total cost of this particular section, 2,500 feet long, was $514,000, or an average of $200 per lineal foot.

The figures for the first rubble mound breakwater, commenced in 1911, would not give representative costs, as the first two-fifths was constructed on a hard bottom and settlement did not occur; it was settlement which eventually determined the cost. It was constructed between September, 1911, and October, 1915, at a total cost of $557,000, or $132 per lineal foot for the 3,330 feet. The first extension, built 1919 to 1922, Messrs. Chambers, McQuigge and McCaffrey, contractors, was 1,850 feet long and had one unit price, $1.44 per ton, including cover rock. The final quantity placed was 380,000 tons at a total cost of $531,000 or $287 per lineal foot. The settlement in this case was not so great as had been expected.

The second extension, 1923-26, 2,000 feet in length, was built by the Canadian Dredging Company, at a unit price of $1.20 per ton, including cover rock. The total quantity of rock placed amounted to 620,000 tons and the total cost was $744,000, or $372 per lineal foot. The settlement in this case was very extensive, amounting to 100 per cent. The use of a finer material for the core and the handling of this material by dredge and dump scow, accounted largely for the decreased unit cost.

The last section, also 2,000 feet long, was completed last year by Messrs. Chambers, McQuigge and McCaffrey, contractors, and the unit costs were further reduced by the use of a still finer material for the core, which enabled it to be handled by a steam shovel and dump cars onto the dump scows. Unit prices were $1.12 per cubic yard for core material and $1.75 per ton for the large cover or armour rock. Settlement in this section was very extensive, also over 100 per cent.

H. J. Lamb, M.E.I.C.[4]

Colonel Lamb remarked that the author of the paper was to be congratulated on the clear and concise manner in which he had described the work. It was obvious that the dominating factor in the designing of the breakwater was the extremely soft character of the bottom. Not only was it extremely soft, but the depth of it, sometimes as much as 42 or 43 feet, made it very difficult to estimate with any degree of accuracy what the quantities were likely to be. As the last speaker had said, the settlement was extremely heavy in spots. As a matter of fact, the exact settlement in quantities in the last section of 2,000 feet was between 123 and 124 per cent. In the estimates it was figured that it would be at least double, and as Mr. Bell had said, these were not far out.

In designing the proposed extension southward to the last 2,000 feet, described in the latter part of the paper, it was proposed to construct the core, from a depth of about 6 feet below water level to the cover, of quarry run instead of beach material which was spoken of in the paper, and of which the entire core was built in the last 2,000-foot section. The reason for that was that it was found that should heavy seas arise before the cover stone was placed, the beach material was apt to be washed over. There would be less liability of wash with the use of quarry run. Finally, the best proof that the design had been successful was the manner in which the structure had stood since it was completed.

J. G. G. Kerry, M.E.I.C.[5]

Mr. Kerry asked whether the various designs described by the author had proved satisfactory, and could any useful conclusions be drawn from the experience obtained with them.

A. Gray, M.E.I.C.[6]

Mr. Gray enquired if any damage had been caused by storms. It would appear from the paper that even the portion of the breakwater completed in 1886 was still intact, with the exception of 1,000 feet removed in 1909 and 1911.

The author had placed the longest "fetch" at 16 miles with a maximum wave action of 10 feet. Surely with a storm producing 10-foot waves, considerable damage must, at some time, have been caused to the various structures. The only mention of any serious difficulty was in connection with 600 feet of the portion of the breakwater completed in 1911, which was said to have settled consid-

[6] Chief Engineer and General Manager, Saint John Harbour Commission, Saint John, N.B.

erably in the course of, and immediately after, construction. This evidently was caused by founding the breakwater on a soft bottom of sand and clay.

It would appear that the difficulty in obtaining a suitable foundation for a timber breakwater on piles was the governing factor in deciding on the rubble mound type of breakwater. In constructing a breakwater of such length as that under discussion, it was quite reasonable to expect varying foundation conditions.

In Saint John harbour, the Negro point breakwater, of a length of 2,250 feet, was originally built of timber cribwork, protected on the outer slopes by rubble mound. This was built between 1875 and 1877, and had a full exposure to the Bay of Fundy from the Atlantic ocean; the maximum storm waves, so far as they could be reasonably estimated, never exceeded 10 feet from trough to crest. Observations over a period of years with a dynamometer showed a maximum wave pressure of about 4,000 pounds per square foot.

Thirteen hundred feet of this original breakwater had been carried away by a storm in 1879. The breakwater was afterwards repaired by placing the stone on the seaward side to a uniform slope of three to one. On the top of the rubble mound a concrete superstructure 15 feet in width and of a length of about 946 feet was erected. This was gradually disappearing, both by the action of storms and the gradual disintegration of the concrete. At the end of the breakwater a light-house had been erected and protected by concrete blocks, each weighing 60 to 80 tons. The light-house and all these blocks had now disappeared. Storms had gradually pushed forward the crest of the breakwater at the outer end for a distance of 35 to 40 feet off the centre line. The outer slopes had been raked down and were now standing at a slope of about six to one.

There was also a breakwater within the harbour, protecting the entrance to Courtenay bay, but this did not have the exposure of the outer breakwater.

The first portion of this breakwater, a length of 4,570 feet, was completed in 1916. Covering stones weighing 10 to 12 tons were carefully laid. A storm in October of 1917 displaced quite a number of these, some of them being moved over 50 feet from their original positions. The breakwater was afterwards extended an additional length of 2,500 feet, and the slopes on the outer end on both sides were three to one, laid random. The experience with breakwaters in Saint John had been that heavy stones laid random made a much more economical and efficient covering than if carefully laid on their beds.

The construction of the Port Arthur breakwater would appear to have been favoured with many natural advantages. There had not been very much delay through weather conditions, the work having proceeded through both the winter and summer seasons. More severe conditions, on a sea exposure, such as Saint John has, would undoubtedly add considerably to the cost of the work.

It would be interesting to know if there had been much accretion on the coast line, anf if the breakwater had been designed to prevent this.

F. Y. Harcourt, m.e.i.c.

The author, in reply, said that there had been no accretion at Port Arthur. The 10-foot wave was, of course, an extreme possiblity, while a 6-foot wave was the one to be expected in severe storms. All the concrete structures on a pile foundation, and the rubble mound structures, were still intact, and had never suffered any damage from storms. As a matter of fact, the ice field going out in the spring was more likely to cause damage than wave action.

In answer to Mr. Kerry's question, it could only be said that the structures were still there and were performing very satisfactorily the service for which they were built. Taking everything into consideration, they had been constructed very economically. The intention, so far as was known at the present time, was to proceed with the rubble mound construction as long as the physical conditions remained similar to those described.

Power System Stability

F. A. Hamilton, Jr.,
Central Station Engineering Department, General Electric Company, Schenectady, N.Y.

Paper presented before the Montreal Branch of The Engineering Institute of Canada, November 13th, 1930.

SUMMARY—The ability of synchronous machines to stay in step with each other at all times is becoming a matter of increasing importance to designers and operators of electric power systems. It is to this ability—or to a lack of it— that the terms stability and instability refer.

Associated with the term stability is the term power limit. There is a limit to the amount of power which a system can handle with stability and this varies with conditions encountered in operation. The maximum power which can be transferred from prime movers to load when the load is steadily increased by small increments is ordinarily greater than the maximum power which can be delivered without loss of synchronism in event of a short circuit or other transient condition.

Methods of predicting power limits under steady or transient conditions have been outlined in various publications and are available to system designers. This paper presents in more elementary fashion certain concepts upon which these methods are based. Factors which affect power limits are discussed and their inter-relation illustrated. The factors involved are those which affect the fundamental quantities appearing in the basic power flow equation $P = \frac{E_1 E_2}{x} . \sin \delta$, which is proven in the appendix.

Methods of increasing power limits are discussed, the more important criterion—the transient limit—being stressed. Reducing the duration of short circuits is the most effective single means of increasing transient power limits. The effectiveness of this is compared with the effectiveness of other means. These other means, which should not be overlooked, include prime mover input control; increased machine inertia; reduced machine, transformer, and line reactances; the use of balancing regulators and high speed excitation; the limitation of short circuit currents in various ways; the use of damper windings in synchronous machines; the use of braking resistors; etc.

Introduction

When the contending forces in any organism are so related that the organism functions as a unit in accomplishing in a reasonable manner the purpose for which it is intended we consider the organism to be balanced or stable. Conversely, to organisms which do not function in what we consider a reasonable manner we apply the words unbalanced or unstable.

It requires but little stretching of the imagination to conceive of organisms which function in a balanced manner when subjected to certain conditions, but which do not function in a wholly satisfactory manner under other conditions. For instance, human beings faced with the necessity of suddenly changing their mode of life sometimes cease to carry on in perfectly balanced fashion. But fortunately most of them finally come to accept the new conditions and live and think again in a normal way.

So it is with electric power systems. Although they have operated for a long time in a more or less reasonable manner, changes have occurred with the passing years, and in some instances, when faced with new conditions, systems have been known to lose their equilibrium and to refuse to function in an orthodox fashion. They sometimes exhibit symptoms of instability; their synchronous components, for one reason or another, occasionally break out of step with one another.

The relatively recent and widespread interest in means for circumventing such possibilities is a natural circumstance in the life of the electric power industry. The possibility of instability has been recognized for many years, but through infancy the industry suffered so little from it that its threat was obscured. However, now that the industry has grown up and wishes to do bigger things, the very size of its systems not only favours the occurrence of instability but makes its effects more widely felt. The maintenance of stability in the future will logically require more intensive effort than in the past, and its ultimate consideration is apparently to be forced upon us at times whether we like it or not.

An Early Problem Involving Consideration of Stability

Practical cases involving the problem of keeping synchronous machines in synchronism have cropped up from time to time during the last few years.

For instance, some years ago, perhaps seven or eight, someone proposed the development of a considerable amount of power at a site not far from Montreal and its transmission to New York and New England. The proposal was never carried out and (neglecting international complications) at least one of the reasons was the fact that to make the procedure profitable the amount of power which would have had to be transported, over a circuit 500 or more miles long, was quite a bit more than a circuit of that length could carry with stability, even under steady conditions. Any attempt to steadily transport such a large amount of power over such a long line would have ended in failure since the synchronous machines at the two ends of the line would have refused to remain in synchronism.

Such a recital is perhaps a carrying of coals to Newcastle, but the situation is recounted as one of the early cases in which the question of stability arose.

A More Recent Illustration

Subsequently many other problems of a more or less similar nature have arisen and in more than one instance practical illustrations of the need for considering the stability question have come to light.

One such instance occurred in the south[1] where two systems were tied together by two high voltage circuits, each about 125 miles in length. These were separated by some distance, and were not what are commonly thought of as parallel lines. One of the circuits may be called the north and the other the south line. During the time when the two systems were connected only by these two circuits a drought throughout the territory served by one of them made it imperative to carry most of the load of that system from the plants of the other. At such a time a fault occurred on the southern portion of the system supplying the bulk of the power, and both tie lines tripped open. The fault was not on either of the tie lines, but on another circuit radiating from the generating station where the south line originated. That generating station broke out of synchronism with machines at the load end of the south line and excess currents tripped that line. Other generating stations belonging to the system supplying the bulk of the power also broke out of step with the other system and the north line opened. The disturbance resulted in a total interruption of supply throughout the better part of an entire state, and the fault which initiated it was not on the system requiring the supply, nor even on one of the lines supplying it.

Such occurrences serve to emphasize the necessity for investigating the stability of systems, and are naturally to be avoided if service demands of today are to be satisfied.

Stability Defined

The commonly accepted definition of stability refers to the ability of synchronous machines to remain in synchronism with each other during normal periods, and during and following disturbances of unavoidable nature.

---

(1) Power Limit Tests on Southeastern Power and Light Company's System—S. Murray Jones and Robert Treat—Transactions of A.I.E.E., 1928.

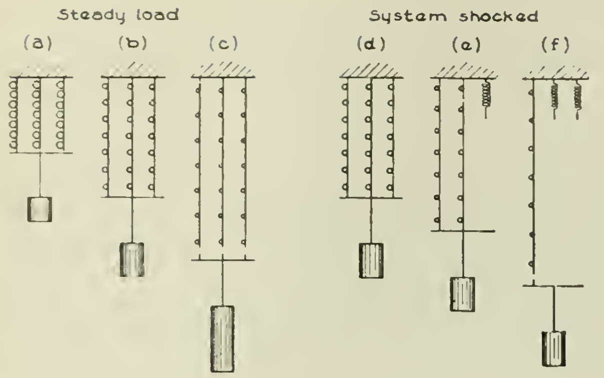

Fig. 1—Analogies of Steady State and Transient Stability.

Power Limit

Associated with the term stability is the term power limit. There is a limit to the amount of power which can be carried with stability, either in normal periods or at times of disturbance.

The power limit is the maximum power which can be transmitted and this differs with the conditions of operation. The maximum power which can be transmitted from generators to load when the load is slowly applied will ordinarily be greater than the maximum power which can be transferred when the load is suddenly applied, and this in turn will be greater than the maximum power which can be delivered without loss of synchronism should a short circuit put in an appearance.

Kinds of Stability

Two kinds of stability are thus distinguishable. They are commonly known as steady state and transient stability. The former refers to the ability to transmit a certain amount of power when the load is steady, or is being applied very slowly. The latter refers to the ability of synchronous machines to remain in synchronism even though some of the conditions of operation are suddenly changed; to the ability of these machines to return to a state of equilibrium after a sudden disturbance has upset, to a certain extent, the state of equilibrium in which they were previously operating.

Stability Calculations

Methods are available for predicting the stability of this or that arrangement of equipment under steady state or transient conditions,(2) and these permit the evaluation of the good and bad points of this equipment, that arrangement of it, etc. In many cases the calculations are long, tedious and involved. At the moment, however, an exact knowledge of the methods of calculation is of less importance than a qualitative understanding of the effect of this thing or that.

A Mental Springboard

As a preliminary step in arriving at an understanding of any complex phenomenon it seems apparent that the vast majority require some sort of mental springboard. Most persons like to conceive of complex things in terms of pictorial analogy. In this case, for instance, an elementary picture of what goes on in an electric power system during steady operation and during transient conditions appears desirable, and a picture of sorts can be drawn.

Consider the various parts of Fig. 1, but remember that the analogy as depicted will necessarily have its limitations.

Examine the spring and weight system shown in (*a*). The position of the springs is governed by the weight. Now if weight is slowly added the springs will take the position shown in (*b*). Naturally if sufficient weight is added the springs will break as in (*c*) even though the weight is applied slowly. This is an incomplete analogy of steady state stability, but if one does not delve too deeply into the whys and the wherefores it will suffice as an illustration—for the moment at least.

Now consider the system shown in (*d*). Then suppose one of the springs is snipped with a pair of shears. The remaining springs will elongate beyond the point shown in (*e*) but will eventually come to rest at that point. Now suppose another of the remaining springs is snipped. In this case the weight (which, if applied slowly, might be successfully supported by one spring alone) may be too much for the one remaining spring with the result that it may break as in (*f*). This is an analogy of transient stability, but again if one should delve too deeply into all of the whys and wherefores it will be found to be an incomplete one. Nevertheless, it also may be defined as a useful picture.

The length of the springs under the various conditions may conceivably represent an angular difference between the machines at one end of a line and those at the other. If the springs are gradually extended,—if the angle is gradually widened as by slowly adding load,—the springs may reach the breaking point,—the machines may break out of synchronism. If the strength of the system is suddenly reduced as by the snipping of a spring,—as with the occurrence of a fault and the consequent opening of a circuit,—the same thing may happen,—the machines may break out of synchronism.

Such an analogy omits many factors, but it provides a starting point,—a useful sort of springboard.

Reactances and Angles

In the analogy just used it has been said that the length of the springs may conceivably represent an angular difference between the machines at one end of a line and those at the other. Now just what is this angle and how does it happen to exist?

When current flows in a circuit containing reactance, such as all power circuits contain, it causes a voltage drop which in effect separates the vector position of the voltage at the load from the vector position of the voltage at the generator end. The more reactance in the circuit, or the more load carried by it, the greater will be the reactance drop and the wider will be the consequent angular separation between the load and generator voltage vectors.

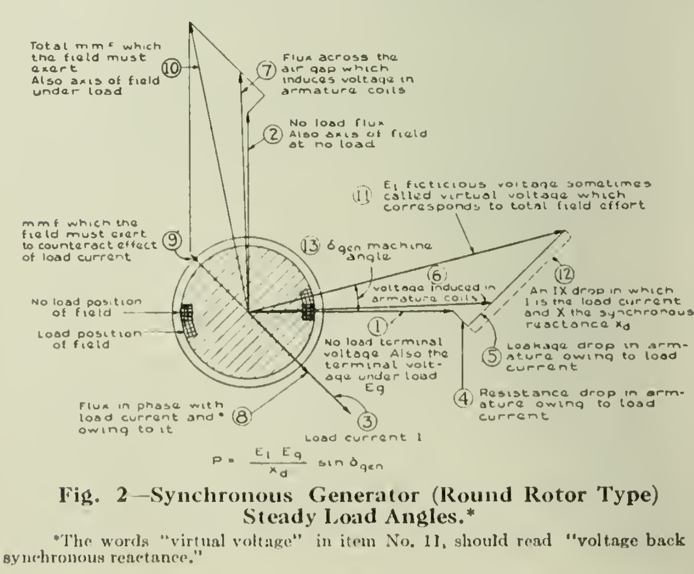

Fig. 2—Synchronous Generator (Round Rotor Type) Steady Load Angles.*

*The words "virtual voltage" in item No. 11, should read "voltage back of synchronous reactance."

(2) Steady State Stability in Transmission Systems—Edith Clarke, Trans. A.I.E.E., 1926; System Stability as a Design Problem—R. H. Park and E. H. Bancker, Trans. A.I.E.E., 1928; Progress in the Study of System Stability—I. H. Summers and J. B. McClure, Trans. A.I.E.E., 1929; The Calculation of Alternator Swing Curves—F. R. Longley, Trans. A.I.E.E., 1930.

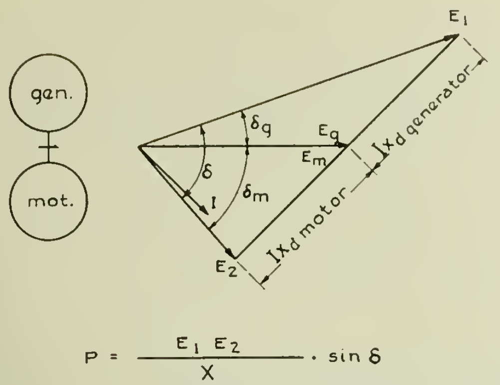

Fig. 3—Synchronous Generator and Motor Steady Load Angles Combined.

If synchronous machines are used at opposite ends of the circuit this angular separation between load and generator voltage vectors cannot be carried beyond a certain point without having the synchronous machines at the two ends of the circuit break out of step with each other.

Thus the power limit of a system is largely a function of certain generator and load voltages, and of the reactance between the points at which these voltages are applied. The question then is, what voltages and reactances are involved, and how are they involved.

Synchronous Machines and Steady State Stability

Obviously some of the reactance involved must be in the rotating machines and, to gain a more complete picture, the simple analogy must be abandoned and the synchronous machine itself must be considered.

Two kinds of synchronous machines are distinguishable: the round or solid rotor type, used largely for high speed turbine generators, and the salient pole type, used for waterwheel generators, synchronous motors, and condensers generally. There are important differences in the characteristics of the two types but for purposes of illustration the simpler theory of the round rotor machine may be selected.

Consider Fig. 2. This is an elementary picture of a simple round rotor machine. Assume that its no load terminal voltage is to be E_g (1) and that the flux producing this is as shown by (2). The axis of the poles at no load is then fixed as shown. Then, keeping E_g at the same value, suppose the machine to be loaded, the current being as shown by (3). There will be a resistance drop in the armature (4), and a reactance drop due to armature leakage (5). Hence the total voltage induced in the armature will be the vector sum of E_g (1), the armature resistance drop (4), and the armature leakage drop (5). This induced armature voltage is shown as (6). This voltage requires a flux crossing the air gap in quadrature ahead of the induced voltage as in (7). The load current tends to produce a flux and this must be counteracted if the machine forces are to remain in equilibrium. An m.m.f. must be produced by the field to counteract the tendency towards production of flux by the load current, as by (9). The total m.m.f. which the field must produce is the vector sum of the m.m.f. required to produce the flux which crosses the air gap (7), and that required to counteract the armature current's flux producing tendency (9). The flux which may be conceived of as corresponding to this is shown as (10). The line in which this acts fixes the position of the field structure under load. Now because it is not convenient to talk in terms of fluxes, some of which do not actually exist, conceive of a voltage in quadrature behind the total field effort as shown in (11). This fictitious voltage which corresponds to excitation, is frequently referred to as the voltage back of synchronous reactance, since the length of the line (12) represents an IX drop, the I being the load current and the X associated with it being defined as synchronous reactance. The usual symbol for synchronous reactance is x_d.

The angle between the voltage back of synchronous reactance and the terminal voltage is the machine angle and the power output (neglecting resistance drop and loss) can be shown to be equal to[3]

$$P = \frac{E_1 E_g}{x_{d_{gen}}} \sin \delta_g.$$

So much for the reactance and angles encountered in a synchronous generator under steady load.

Now refer to Fig. 3 which shows a generator and an equivalent motor closely connected together. In this diagram resistance drops are totally omitted in the interests of simplicity. By symmetry the motor angle appears in the opposite direction and the IX drop in the motor equals that in the generator. The total angle is equal to

$$\delta_g + \delta_m = \delta.$$

The power transferred between generator and motor is

$$P = \frac{E_1 E_2}{x_{d_{gen}} + x_{d_{mot}}} \sin \delta.$$

Synchronous Machines, Transmission, and Steady State Stability

By connecting the generator and motor together by a transmission line through which the load current must pass, an additional angle is encountered as shown in Fig. 4 for two values of load power factor.

---

(3) The extremely useful general relation

$$P = \frac{E_1 E_2}{x} \sin \delta$$

involving any two voltages, the reactance between the points where they are applied, and the angle between their vector positions, is proven in the appendix.

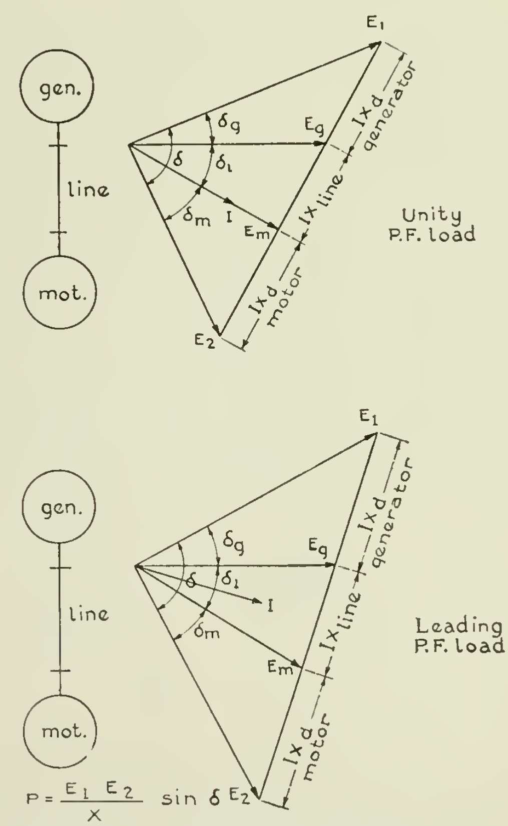

Fig. 4—Synchronous Generator, Transmission Line and Synchronous Motor Steady Load Angles Combined.

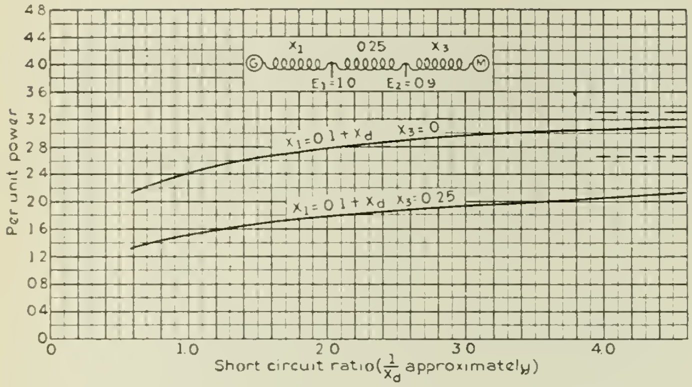

Fig. 5—Short Circuit Ratio, $\frac{1}{x_d}$ approximately.

Again the power can be shown to be a function of the sine of the angle between voltages back of synchronous reactance, and is

$$P = \frac{E_1 E_2}{x_{d_{gen}} + x_{d_{mot}} + x_{line}} \sin \delta.$$

STEADY STATE POWER LIMITS

Since in any of the cases referred to the power transferred from generator to load is equal to

$$P = \frac{E_1 E_2}{x} \sin \delta,$$

it follows that, for given voltages back of synchronous reactances, i.e., for given excitations, the maximum power which can be transferred over a circuit of given reactance is that which is possible when $\delta = 90°$ and $\sin \delta = 1.0$.

In other words the maximum power which can be transferred through a circuit under steady load conditions is given by

$$P = \frac{E_1 E_2}{x},$$

from which it is evident that with given voltages back of synchronous reactances, i.e., with given excitations, the smaller the reactance between the points where these voltages are applied the larger the maximum load which can be steadily carried.

The reactances involved are the synchronous reactances of generators and motors, and the transformer and transmission line reactances, and reducing any one of these will increase the steady state power limit to some degree. The actual increase in power limit will depend upon how much the total reactance is decreased. Thus cutting the synchronous reactance of the generator in half will not double the steady state power limit of a system which includes transformers, lines, and motors as well.

The term used to measure the steady state stability of synchronous machines has come to be called the short circuit ratio and (neglecting saturation and resistance) this is the reciprocal of synchronous reactance. Thus the higher the short circuit ratio the more power can be steadily carried, other things being equal. Possible relations between generator short circuit ratio and steady state power limit are shown by Fig. 5. The top curve applies to a system with characteristics as shown by the small sketch—the load bus being an infinite one.[4] The lower curve applies to a similar system but one in which the load bus is not an infinite one. Interest here is primarily in waterwheel driven generators. The normal short circuit ratio of this type of generator is 1.0 but a ratio of 1.5 can sometimes be obtained (at increased cost) without materially altering overall dimensions. For the particular systems of Fig. 5 the gain in steady state power limit obtainable by using generators with a short circuit ratio of 1.5 instead of 1.0 appears to be only about 10 per cent.

Steady state power limits may be improved to some extent by reducing transformer reactances, but to appreciably reduce these reactances larger than normal transformers are necessary. Roughly speaking normal transformer reactance varies directly with the high voltage rating. For instance a 66 kv. transformer might have a normal reactance of 7 per cent or 8 per cent and a 230 kv. unit a normal reactance of perhaps 12 per cent to 15 per cent as shown by Fig. 6. Transformers of lower reactance are more expensive—they may be looked upon as larger units derated—and their use is not ordinarily warranted. In the systems of Fig. 5 cutting the transformer reactance in half would not increase the steady state power limit more than 1 per cent or 2 per cent.

It goes almost without saying that a reduction in transmission line reactance, as may be accomplished by multiplication of the number of circuits employed in parallel or by the use of higher voltage, is also beneficial in improving steady state power limits.

STEADY STATE POWER LIMITS UNDER HAND CONTROL

Thus far no circumscribing definitions have been used when referring to what has been called the steady state power limit, but actually the power limits under steady load conditions as determined by the relation

$$P = \frac{E_1 E_2}{x} \sin \delta,$$

are those obtainable when the loads are gradually built up in small increments, and excitations changed likewise in small increments by hand adjustment of rheostats while maintaining constant terminal voltage.

The maximum power which can be transferred without voltage regulators is called the steady state power limit under hand control, or frequently just the steady state power limit, since with commercially available regulators and excitation systems the steady state power limit is not likely to be appreciably higher than that obtainable when the excitation is controlled by manual manipulation of rheostats.

The various actions which take place in a system while it is being loaded up to its limit in this fashion are interesting. These will be discussed with the assistance of Fig. 7, which refers to a system comprising a generator and an equivalent motor closely connected together to the same bus.

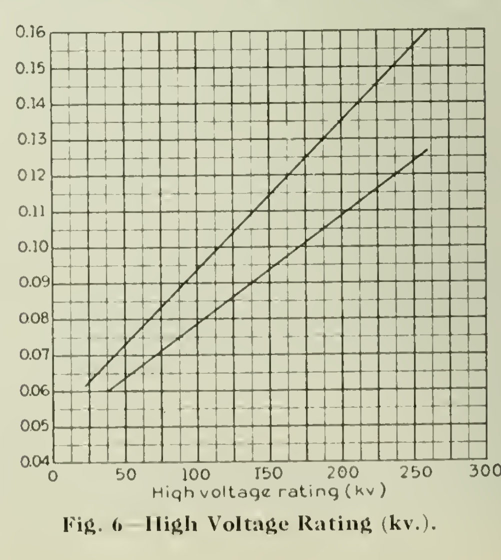

Fig. 6—High Voltage Rating (kv.).

[4] The term, infinite bus, refers to a point where voltage is considered to remain absolutely fixed in magnitude and phase position at all times. It refers to a bus beyond which the system is assumed to have zero reactance. The conception of such a bus is a useful artifice for simplifying calculations. Such an assumption is frequently made when the load system is large with respect to a generating source, the stability of which is under consideration.

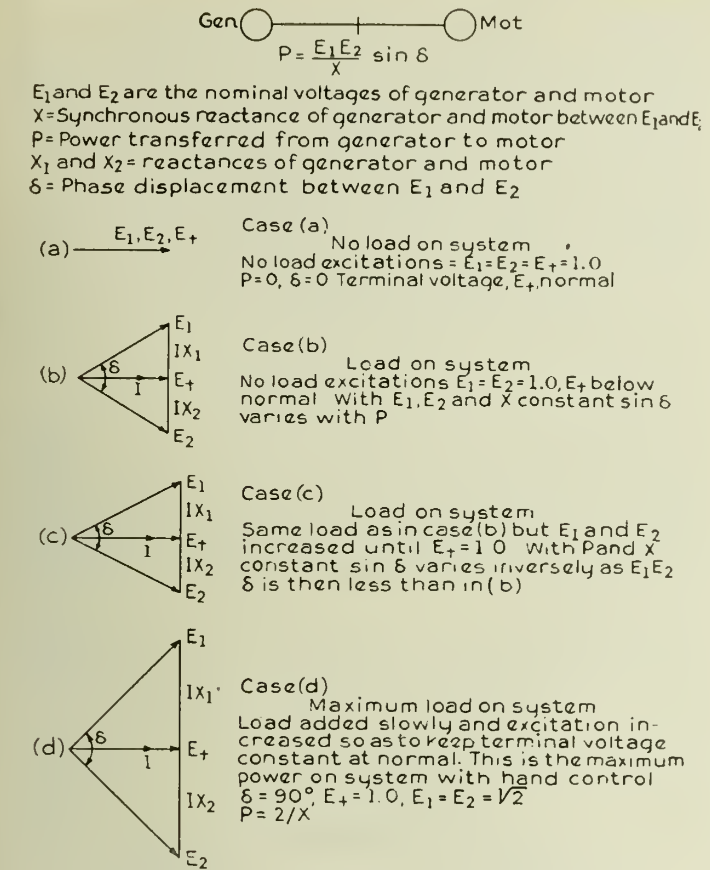

Fig. 7—Successive Steps in Loading a System Comprising an Identical Generator and Motor on the Same Bus.

Note:—In the above figure, the expression $E+$ should read Et

If, in such a system, no load is being transferred from generator to motor (and if no load losses are neglected) the voltages corresponding to excitations can be made to be equal and in phase. And incidentally, the terminal or bus voltage will be equal to and in phase with the voltages which correspond to the excitations. Refer to Fig. 7 (*a*). Now, granting the truth of the statement that

$$P = \frac{E_1 E_2}{x} \sin \delta,$$

it is at once apparent that no load *can* be transferred from generator to motor until E_1 and E_2 cease to be in phase.

Consequently, when a small load is applied to the shaft of the motor, its rotor must temporarily supply the power required by the load by giving up some of its kinetic energy. This causes the motor to commence to decelerate. Thus an angle appears between E_1 and E_2 and power begins to pass from the generator to the motor, which tends to lessen the deceleration.

Prior to this time the generator was operating at no load, and its prime mover was supplying it with but little energy. Now the generator is called upon to deliver more load than is being supplied by its prime mover, so it also begins to give up some of its kinetic energy. It also begins to slow down. Thus it tends to prevent the widening of the angle between E_1 and E_2, i.e., tends to limit the power transferred to the motor. So the motor gives up more of its kinetic energy and continues to slow down.

Now, in response to this slowing down process, the governor which controls the prime mover causes more input to be applied to the task of driving the generator. This causes the generator to accelerate, which tends to widen the angle between E_1 and E_2, and this in turn increases the power delivered to the motor. When the angle becomes wide enough and the power delivered to the motor becomes sufficient for the purpose, it also accelerates and decreases the angle and the power transfer.

Eventually the input to the prime mover equals the generator's output to the motor, and this equals the load demand on the motor. The system will then be in a new state of equilibrium. The generator will be running at its proper speed and so will the motor, but the angle between E_1 and E_2 will remain in a position which satisfies the relation

$$P = \frac{E_1 E_2}{x} \sin \delta,$$

where P is the load demand on the motor, E_1 and E_2 are the excitation voltages, and δ the angle between them.

During all of this time the generator and motor excitations can be assumed to have remained unchanged in magnitude. They have merely moved apart in phase. But the same thing cannot be said of the terminal voltage. It has been reduced in magnitude while remaining unchanged in phase position. See Fig. 7 (*b*). If this terminal voltage is now brought back to normal by adjusting the excitation of generator and motor in like amounts by hand manipulation of rheostats or by voltage regulators, the power transferred from generator to motor will be increased. The motor will use the extra power in trying to accelerate, the generator will begin to decelerate, the displacement angle δ will become smaller, and the extra power will cease to flow until eventually the relation,

$$P = \frac{E_1 E_2}{x} \sin \delta,$$

is again satisfied for the power demanded by the load on the motor and for the new values of E_1 and E_2. The resulting state of equilibrium is pictured in Fig. 7 (*c*).

If this process is repeated, the load being increased by a small amount each time, the two machines can be made to fall out of step. The maximum power will be that which can be transferred when the angle δ is 90 degrees. With E_1 and E_2 separated by an angle of 90 degrees and corresponding to normal terminal voltage, see Fig. 7 (*d*), an increase in load would cause the motor to begin once more to slow down, thus causing E_2 to fall farther back in phase and δ to become greater than 90 degrees. But if the excitation should remain constant at this time, the motor would receive less instead of more power from the generator and would continue to slow down while the generator would tend to speed up.

If the excitations could be increased rapidly enough, the required power might be transferred even though the machines were more than 90 degrees apart. However, with hand control the terminal voltage must drop and this must be observed before the excitations can be increased. It is not practicable, with hand control, to modify the excitations fast enough to keep machines in step when they are more than 90 degrees apart. In fact, as has been said, commercially available regulators are not very effective in taking care of such a situation.

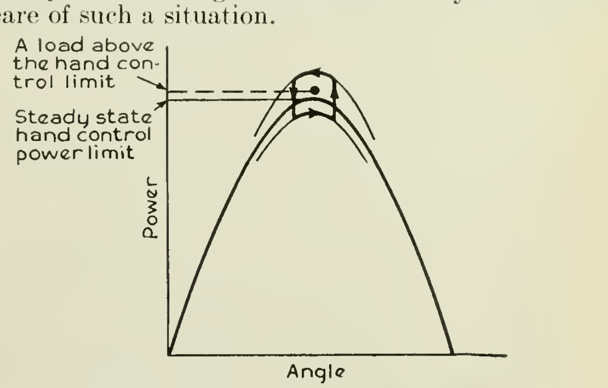

Fig. 8—Power-Angle Curves.

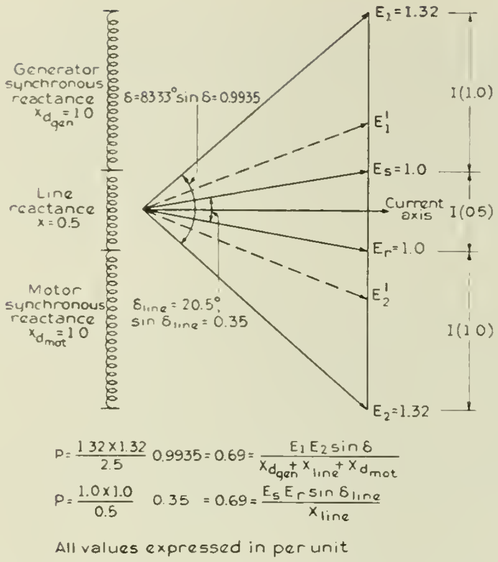

Fig. 9—The Generality of the Expression $P = \frac{E_1E_2}{x}\sin\delta$,

Dynamic Balancing Regulators and Steady State Power Limits

However, by providing suitably responsive regulators and excitation systems the power limits can conceivably be raised above the limit possible with hand control and the system made to operate under a sort of steady state condition which has at times been called the dynamic power limit. The possibility of this has been shown in laboratory tests on miniature systems.

The action of such a regulator may be roughly described by reference to Fig. 8. The heavy curve is one of power versus angle—a sine curve based upon the relation

$$P = \frac{E_1E_2}{x}\sin\delta,$$

where the x includes the synchronous reactance of the generator and motor plus whatever other reactance there is between the two voltages E_1 and E_2 (the voltages back of synchronous reactances).

Assume the system to be operating at the peak of the heavy curve—at the steady state limit with hand control—when a load increase occurs. The increased current widens the angle and since excitations are momentarily fixed (the regulator not functioning for the moment), the system tends to lose equilibrium. The operating point moves to the right and down on the heavy curve. At the same time the terminal voltage decreases, as was discussed in connection with Fig. 7. Assume a suitable regulator and excitation system then come into play to modify the excitation and put the system on the upper light curve. On this curve the system can transfer more than the required amount of power so the angle decreases and the terminal voltage increases. Then the regulator can be assumed to act again to put the system on the lower light curve by decreasing excitation. On this curve the system cannot transfer the required power so the angle starts to widen again and the whole process is repeated time and time again.

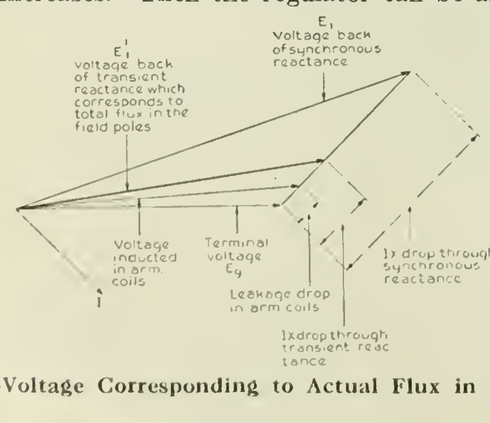

Fig. 10—Voltage Corresponding to Actual Flux in Field Pole.

The average commercially available regulator is believed to possess characteristics of the sort required to provide this dynamic balancing action to but a limited degree on actual systems. However, this is not to be decried at this time. So far operation above the steady state power limit under hand control has not been resorted to on actual systems, and probably it will not be resorted to under ordinary operating conditions, since if a system is to be stable under transient conditions it must ordinarily be operated below the steady state hand control limit.

Transient Stability

The operation of systems under more or less steady conditions has been considered. But it has been said that the maximum power which can be delivered from generators to loads under steady conditions will ordinarily be greater than the maximum power which can be delivered without loss of synchronism should a fault occur somewhere on the system.

Thus it is not ordinarily permissible to load a system to the steady state limit. Ordinarily the amount of power

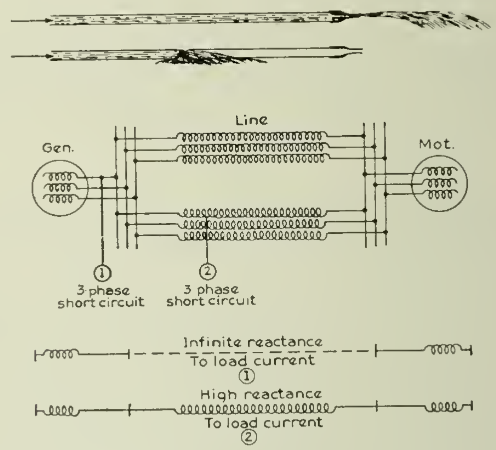

Fig. 11—Transfer Reactance During Three-Phase Faults.

which can be reliably transmitted is fixed by the ability of the synchronous machines to return to a state of equilibrium after a fault has upset the state of equilibrium in which they were previously operating

When a fault occurs the ability of a system to transfer the power which it was handling prior to the fault is momentarily lost. With the occurrence of a fault the power delivered to the motors is suddenly reduced, and as the power delivered is then less than the amount required by their loads, the motors tend to slow down. At the same time the generators at the other end of the system tend to speed up as the amount of power which they can turn out is less than that dictated by the input to their prime movers, this input at the instant after being just what it was at the instant before the fault.

The system is therefore not in a complete state of equilibrium at the instant after the fault occurs,—motors tend to slow down and generators tend to speed up. This means that the motor rotors tend to fall back and that the generator rotors tend to move ahead—the angle between generators and motors tends to widen. The wider the angle gets (up to a certain point) the more power the system can transfer. Hence, as the angle widens, and as the power transferred from generators to motors increases, the slowing down of the motors and the speeding up of the generators is lessened.

If the system is to eventually return to a state of complete equilibrium, the motors must cease to slow down and the generators must cease to speed up; the motors must begin to speed up and the generators must begin to slow down, and this must occur before the angle between them reaches the point beyond which loss of synchronism occurs.

The Cause of the Reduced Power Transferring Ability

It has been said that when a fault occurs the ability of the system to transfer the power which it was handling prior to the fault is lost. It will be of interest to examine the cause of this.

The relation so often referred to previously,

$$P = \frac{E_1 E_2}{x} \sin \delta,$$

is a perfectly general equation. If E_1 and E_2 are any two voltages, x the reactance between the points where they are applied, and δ the angle between the vector position of the voltages, then P is the exact amount of power which is being transferred from one end of the system to the other.

It should therefore be apparent that increasing the reactance between the two voltages E_1 and E_2, without changing either their magnitude or phase position, will reduce the power flow.

This is just what happens when a fault occurs; the same thing happens to a lesser degree whenever a line is switched out, even though no fault exists. When a fault occurs the reactance between certain generator and motor voltages is suddenly increased, and though the reactance is increased, the angle between machines does not instantly change, nor do the voltages themselves change. Thus the power transfer is reduced, and the generators tend to speed up and the motors tend to slow down.

The Machine Voltages Which Do Not Change

Reference must again be made to the relation

$$P = \frac{E_1 E_2}{x} \sin \delta,$$

which has been said to be a perfectly general relation. Its generality may be explained by reference to Fig. 9. This is a vector diagram (drawn to scale) on which the voltages back of synchronous reactances and the voltages at line terminals are shown for a particular load condition on a particular system. The calculations at the bottom of the figure indicate that it makes little difference which voltages are used in calculating the power transfer so long as the proper reactances and angles are used.

Suppose that to calculate the power transfer, voltages designated as E_1' and E_2' had been used in conjunction with the corresponding reactance and angle. The indicated power transfer under the steady conditions for which Fig. 9 was drawn would be the same as shown on the figure.

The voltages designated as E_1' and E_2' are those which might be conceived of as corresponding to the total flux which exists in the field poles of the machines. The total flux in the field poles of a machine is made up of two components—the flux which crosses the air gap to induce voltage in the armature, and the flux which leaks out of the pole faces and back into the field poles without ever reaching the armature. The voltage which corresponds to this total flux is shown again in Fig. 10.

There appears to be a voltage drop between this newly specified voltage and the terminal voltage of the machine. This is an IX drop in which the X is defined as the transient reactance of the machine, (the symbol for which is x'_d). Hence the reason for calling this newly specified voltage the voltage back of transient reactance. This—as in the case of the voltage back of synchronous reactance—is a fictitious voltage, and its significance and usefulness require explanation.

Suppose a fault occurs. When the excess current suddenly starts to flow in the machine armature an induced current automatically flows in the field to prevent demagnetization of the poles. The tendency is for the existing flux to remain constant. Such is the characteristic of all mutually coupled inductive circuits. Now if the total flux in the poles does not change when the generator is short circuited it may be assumed that the fictitious voltage corresponding to this total flux does not change. In other words, the voltage back of transient reactance remains temporarily unchanged in magnitude and the reactance between it and the terminal voltage may be considered as the element which limits the flow of short circuit current.

Actually the flux in the field poles does die away under short circuit conditions but for the first second or so after the short there is some justification (in the interest of simplifying calculations) in assuming that the flux in the poles remains essentially constant and that the corresponding voltage back of transient reactance remains relatively fixed in magnitude.

The die away of flux—the change in voltage back of transient reactance—can be calculated in a given case. The results of such calculations support the principle of assuming this to remain constant during the first second or so of a disturbance. Particularly is this true where a voltage regulator is present. What little decay in flux might take place without it is counteracted by the action of the regulator in increasing excitation. In so far as it does this, the regulator is beneficial from the point of view of system stability, and almost any regulator and excitation system will act to overcome the tendency for the flux to decay, at least during the first second or so after the occurrence of a short circuit.

Consider then that the voltage back of transient reactance remains constant in magnitude for a short time after a fault occurs. The next question is, does it remain fixed in angular position. It does in the first instant after the fault because the inertia of the machine prevents any instantaneous change in angle. Thereafter the angle changes, as will be discussed.

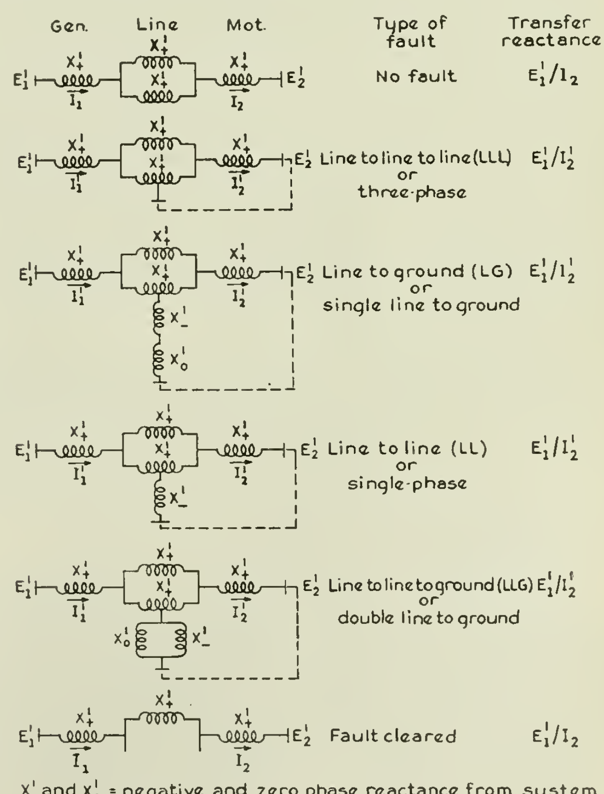

Fig. 12—Transfer Reactance Diagram.

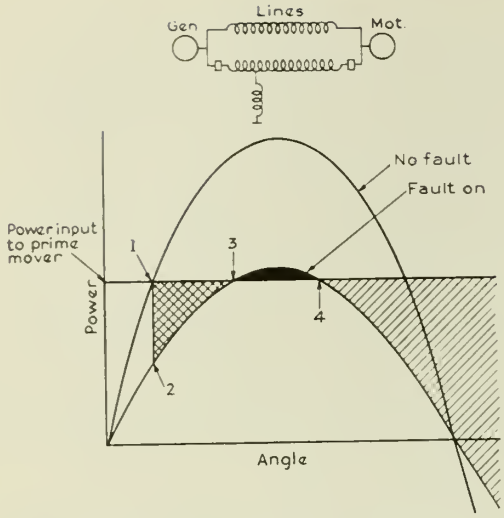

Fig. 13—Instability with Fault Remaining on the System.

The Reactances Which Suddenly Increase When a Fault Occurs

The question now is this: How do short circuits increase the reactances between voltages back of transient reactance? Another simple analogy will help to answer this question.

Suppose water is flowing in a garden hose. The pressure applied at one end causes the flow and water spouts out of the nozzle and performs its appointed task. Now suppose the hose is suddenly chopped apart. The pressure applied at the input end remains and causes a flow out through the place where the hose was chopped apart. But this flow waters the garden in the wrong place. No water goes where the nozzle points. As far as the nozzle is concerned, its applied pressure is zero.

This is what happens in the case of a three phase fault between generator and motor on a simple system as shown at (1) on Fig. 11. As far as the load is concerned, the applied pressure is zero, or the resistance to the efforts of such pressure as is applied is so high that the pressure is of no avail. The condition is thus the same as with infinite reactance inserted.

Should two hoses be used in parallel and should but one of them be chopped open in the middle, the pressure might be able to force some water down the good hose and out the nozzle in spite of the break. The same thing occurs with a three phase fault at the middle of one of the lines as at (2) on Fig. 11. With such a fault the reactance between generator and motor is not infinite and the system retains some of its ability to transfer power, but naturally this is less than the amount which could be transferred with the fault not there.

The amount of power which can be transferred in any case largely depends upon the equivalent reactance between machines and hence the practice of calling these equivalent reactances the transfer reactances. They are obviously values which may be obtained by dividing the pressure (voltage) applied at the generator end by the flow in the circuit at the other end.

Transfer Reactances for Various Kinds of Faults

Faults of other sorts than the three phase variety affect the system similarly but to a lesser degree. These other kinds of faults are not balanced faults, but they may be treated as three phase faults of lessened severity.[5]

Currents which flow in the case of unbalanced faults can be split up into components called the positive, negative, and zero phase sequence components and the reactances encountered by these components can be called the positive, negative, and zero phase reactances. These differ among themselves in different parts of the power circuits, and it is not feasible at this time to consider them in detail. But it is desirable to observe how they are taken into account when reducing an unbalanced fault to its three phase equivalent. This is shown on Fig. 12.

The power being transferred at any instant with or without a fault on the system depends upon the following relation,

$$P = \frac{E'_1 E'_2}{x'_t} \sin \delta',$$

the factors entering the equation being transient quantities; i.e., the voltages back of transient reactances, the angle between these voltages, and the transfer reactance which includes the transient reactances of machines, and is determined in any case by the relation

$$\frac{E'_1}{I'_2}.$$

From an inspection of Fig. 12 and the relations expressed above, it appears that to keep the power carrying ability of the system as high as possible, with or without a fault on the system, x'_+ should be as small as possible and x'_- and x'_0 should be as large as possible, as this is the way to make x'_t as small as possible.

Effect of a Fault Which Suddenly Increases x'_t

When a fault of any sort occurs, the transfer reactance between voltages back of transient reactances, which for the moment may be considered fixed in magnitude, is suddenly increased and owing to the inertia of machines the angle between them remains momentarily unchanged. What happens?

Once more the friendly relation,

$$P = \frac{E'_1 E'_2}{x'_t} \sin \delta',$$

may be called upon for assistance and curves based upon this may be plotted for conditions before the fault and for conditions existing when the fault is on. These are sine curves, as shown in Fig. 13. The peaks of the two curves are inverse functions of x'_t, and hence in the case of the lower curve a function of the type of fault and its location.

At the instant before the fault occurs the system can be assumed to be transferring power of the amount shown at (1); at the instant after, the amount shown at (2).

A Persisting Fault

Assume that the fault remains on the system. Assume also that the input to the prime mover remains unchanged—that in the early stages of the fault the actual speed change is insufficient to affect its governor, this usually being the case. The input is obviously more than the output, so the

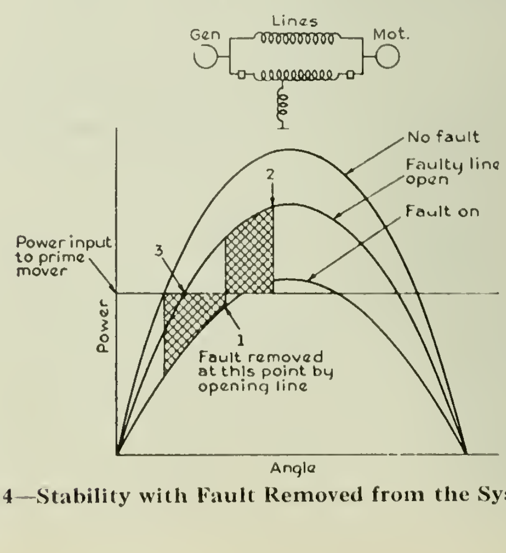

Fig. 14—Stability with Fault Removed from the System.

[5] By applying the symmetrical component method of analysis.

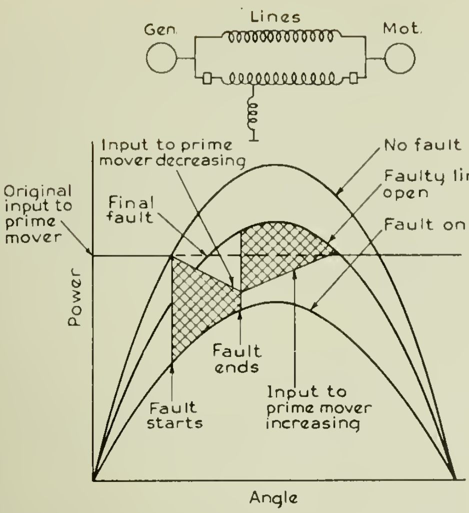

Fig. 15—Effect of Reducing Input to Prime Mover.

generator tends to speed up. The motor tends to slow down. The angle widens—following the lower curve in Fig. 13. The cross hatched area represents the excess of input over output of the prime mover during a period of time. When the angle reaches point (3), the input and output are equal, but during the preceding time the machine has been accelerating and absorbing the excess input in the form of kinetic energy. This must be dissipated, so the angle continues to widen and the output proceeds to grow larger than the input and the excess energy is somewhat dissipated. The amount so dissipated is shown by the solid black area. In Fig. 13 the kinetic energy thus dissipated is not equal to the amount previously stored so the angle continues to widen to the point (4) beyond which the input again exceeds the output. The generator continues to accelerate and finally breaks out of step as the energy represented by the cross lined area is imparted to it. As the energy transferred to the motor continues to decrease, the motor continues to slow down and stalls.

Had the system been carrying less power in the first place, it might have been possible to deliver this even with the fault on the system. But this procedure would not ordinarily be permissible. The power limit would ordinarily be so low as to make operation unprofitable.

Two Things Which Might be Done

Obviously one or both of two things might be done to help the system to deliver the desired amount of power without loss of synchronism incident to short circuits. The fault might be removed from the system and the transfer reactance x'_t thereby decreased, or the input to the prime mover might conceivably be varied in suitable fashion.

The Removal of the Fault

This is illustrated by Fig. 14. When the fault is removed as at point (1), the transfer reactance is decreased but not to its original value, since one of the two lines originally in service is now disconnected. After its removal, the angle continues to widen from (1) to (2) following the middle curve until the previously acquired excess kinetic energy is used up in reaccelerating the motor. This is commonly called the first swing of a disturbance. Then the angle proceeds to decrease and eventually return to the point (3) where the system continues to operate in a stable manner. That is—it will eventually come to rest at the point (3) if there is anything to damp out its swinging. And there usually is. What happens is that the angle decreases along the middle curve to a point below point (3), stops, and increases to a point above point (3), but not as high as point (2), stops, and decreases to a point which is still below point (3), but not so much as before, etc. Eventually it stops at point (3).

Obviously the quicker the fault is removed, the better; the quicker it is removed, the smaller the accelerating energy imparted to the generator rotor and the quicker this is applied to the job of reaccelerating the motor; the quicker it is removed, the smaller the angle to which the machines must swing, and the sooner they will return to a state of equilibrium. The quicker it is removed, the greater the permissible input to the prime mover.

The effect of various switching times on the power limits of systems will appear in various figures to be referred to later.

Varying the Input to the Prime Mover

That this means might be used to increase the power limits of systems has been demonstrated on at least one system where the generators are driven by steam turbines—where it is possible to cut off the steam supply with the required speed without damage.[6] In water wheel installations this has not been practicable since the sudden stoppage of water flow endangers hydraulic structures. However, it is not wholly inconceivable that by-pass mechanisms may be designed in the future for use on water wheel installations. These might be operated by quick acting relays responsive instantaneously to the occurrence of faults. Such a relay was tested on the steam turbine generator system mentioned.

The effect of such devices might be as illustrated in Fig. 15. When the fault occurs, the action of relay and by-pass mechanism might immediately (without waiting for an observable speed change) start to reduce the input to the prime mover, and with the opening of the faulty line, these could start to increase the prime mover input to its initial value. This would limit the widening of angles and permit the raising of power limits to some degree.

However, the advantage to be gained by this procedure is at the moment believed to be quite overshadowed by the efficacy of quick switching and fault limitation.

Transient Power Limit Versus Switching Time

Where a system can be considered to comprise a generator and motor connected together by a transmission system (the simple sort of system which has been used as the basis of discussion thus far), it is possible to prepare curves of the power which can be carried as a function of fault duration. The method used is based upon power-angle curves such as are illustrated by Figs. 13, 14 and 15.

Consider the power angle curves shown in Fig. 16. If the fault is not cleared at all, some power (P_a) can be carried through it without loss of synchronism. If the fault is cleared after the angle has had time to widen as in (b),

(6) Governor Performances During Systems Disturbances—R. C. Buell, R. J. Caughney, E. M. Hunter, V. M. Marquis—Trans. A.I.E.E., 1930.

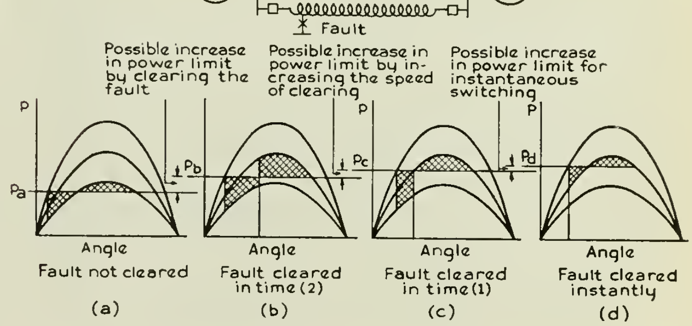

Fig. 16—Variation in Power Limit with Switching Time.

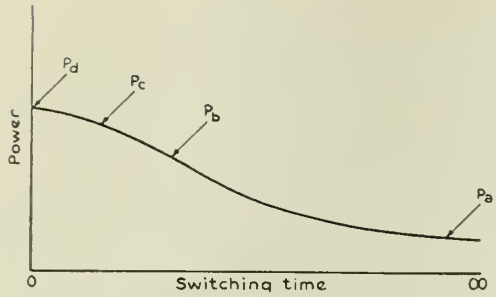

Fig. 17—Power-Switching Time Curve.

the power which might be carried is (P_b); if the fault is cleared faster, as in (c), the power limit is (P_c); and if the fault is cleared instantly (which is the same thing as merely opening a line), the power limit is (P_d).

These various power limits can be plotted against the switching times corresponding to the angular swing which takes place between the starting of the fault and the opening of the breakers. Such a curve would have the shape shown in Fig. 17.

The Effect of WR^2

The rate at which the angle between generators and motors changes during disturbances—the time consumed in changing the angle a given amount—depends upon the inertia of the rotating parts. The heavier these are, the longer the time consumed in widening the angle a given amount, and for a given time of fault duration, the smaller the angle to which machines will swing; in other words, the higher the power limit for the particular fault.

Now, how much can power limits of a given system be increased by increasing the WR^2 of the generators? Fig. 18 shows the gain obtainable for a particular system. The lower curve is based upon normally designed machines. The upper curve is based upon similar machines having approximately 30 per cent more WR^2 than the normal machines. This represents the extra WR^2 which might be added to otherwise normal machines without seriously increasing their dimensions. Adding even this increases costs somewhat. To get more WR^2, machines of greater physical dimensions and considerably higher cost must be used.

The system chosen—the system of Fig. 18—consists of a generator which is relatively small with respect to the system which it feeds. The gain obtainable by increasing the WR^2 is about 7 per cent if the switching time is .3 seconds. The gain obtainable by reducing the switching time from .3 to .2 seconds without changing the WR^2 is of the order of 23 per cent or more than three times the gain obtainable by increasing the WR^2 by 30 per cent.

The gains obtainable by increasing WR^2 are not in all cases so small (for instance, in the system of Fig. 18, much larger machines might be used with further gain). On the other hand, increasing WR^2 will not in all cases result in gains of the order indicated by Fig. 18. The gains depend upon inertias at both ends of the system. In general, the nearer the inertias at the two ends approach each other the smaller the good effect which can be obtained by increasing the smaller inertia. In most large systems the generating end has the smaller inertia. The curves indicate the best gains possible without resort to abnormally large machines, since the system of Fig. 18 consists of a generating station with a finite inertia and a system having infinite inertia.

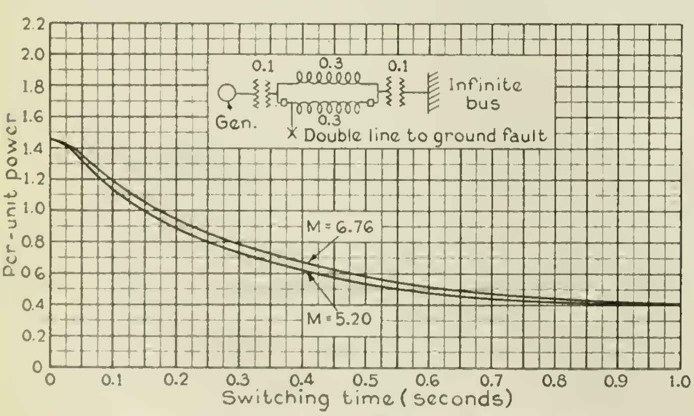

Fig. 18—Effect of Changing Generator WR^2 30 per cent.

Further Comments Concerning Quick Switching

The effect of reduced switching time appears to be of very material advantage as a means for increasing transient power limits. Hence, it is perhaps pertinent to inquire whether such high speed switching can be obtained.

High voltage breakers which will open in as short a time as .133 seconds are now on the market, and breaker and relay combinations which will act in conjunction to remove faulty lines from service in .167 seconds under favourable conditions are available. Fig. 19 is a picture

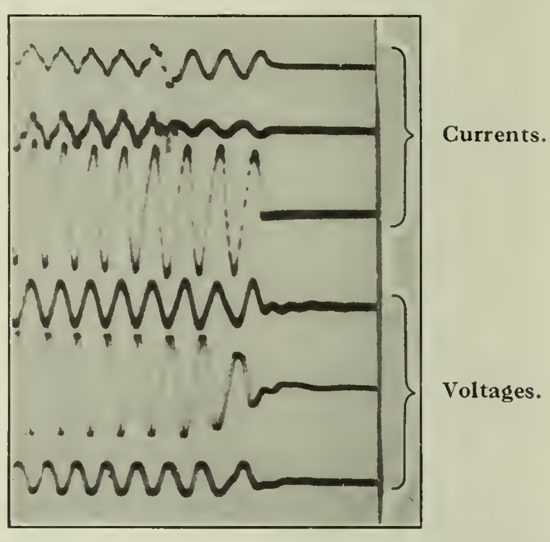

Fig. 19—Opening of a 220 kv. oil circuit breaker as recorded by a new type of automatic oscillograph.

of voltages and currents which indicate the opening of 230 kv. breaker in .133 seconds—8 cycles on a 60-cycle basis—which in this case includes the relay time. However, such fast operation can not yet be relied upon under all conditions and .2 seconds may be considered as a reasonably average lower limit in fault clearing time at the moment.

Should quick switching be relied upon to prevent loss of synchronism, persons reponsible for system operation must assure themselves that the switching equipment remains always capable of clearing faults in the short times relied upon. So, there seems to be some need for a transient recorder to provide data concerning the behaviour of breakers and relays under actual operating conditions. The record on Fig. 19 was obtained with such a recorder. This recorder was started automatically by the fault which it records. It is a relatively inexpensive oscillographic device which starts in less than a half cycle after the beginning of a disturbance and so permits the accurate determination of the number of cycles used by the relays and breakers in clearing a fault from the system.

Incidentally the record shown was obtained during short circuit tests on an actual 230 kv. system. In these tests arcs were initiated across strings of insulators. Observations of these arcs were quite interesting. With quick

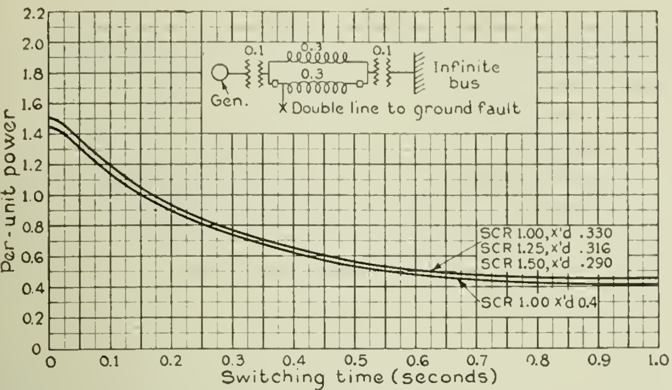

Fig. 20—Switching Time Curve Showing the Effect of x'_d and SCR on Transient Stability.

switching in use the arcs did not blow away from the arcing rings on the insulators. Apparently quick switching is likely to be of benefit by preventing single line to ground faults from becoming more serious—by preventing arcs on one phase from blowing into other phases.

At the moment high speed breakers are somewhat more expensive than slower speed breakers, but recent advances in breaker design justify the hope that this condition may not persist indefinitely.

Other Things Which Increase Transient Power Limits

The effects of quick switching, prime mover input control, and increased WR^2 have been briefly discussed but there are other things which may help to increase the amount of power which systems can carry through short circuits. Some of these will now be taken up, but before doing so it is advisable to recall once more the friendly relation

$$P = \frac{E'_1 E'_2}{x'_t} . \sin \delta',$$

since the efficacy of these other things depends upon their effect upon the various factors included in this equation.

Short Circuit Ratio and Transient Power Limits

The effect of increased short circuit ratio on steady state power limit has been discussed. But it has been said that the transient power limit ordinarily fixes the amount of power which can be dependably transferred. Now the short circuit ratio of a synchronous machine is a measure of its synchronous reactance, not of its transient reactance, and transient reactance is the thing which affects transient power limits. In spite of this, machines with high short circuit ratios are sometimes specified with the expectation that the operation of the system under transient conditions will thereby be measurably improved. The expectation is not always likely to be fulfilled. It should be interesting to examine the effect of short circuit ratio upon transient power limits.

What normal relation exists between short circuit ratio and transient reactance? Interest here is primarily in waterwheel driven generators so the following tabulation pertains to the relations which might be made to exist in a typical waterwheel driven generator of given dimensions.

SCR....................	1.00	1.25	1.50
x'_d....................	.33	.316	.29

The range of transient reactance shown is quite small and it is not always possible to obtain even this range in a machine of given dimensions. Furthermore where the lower reactance can be obtained some increase in cost is likely to be incurred since increases in short circuit ratio are obtained at the expense of higher field currents owing to wider air gaps. To obtain a lower transient reactance than shown in the tabulation it would ordinarily be necessary to increase the size of the machine. This would quite naturally increase the cost, perhaps in an unwarranted fashion. How much then can transient power limits be increased without greatly increasing the size and cost of machines?

This is illustrated by Fig. 20. On the particular system considered the power which might be carried through a fault seems to be just about the same regardless of the generator short circuit ratio assumed. On systems employing shorter lines of the same or higher voltage the advantage of using generators having the higher short circuit ratio might become more noticeable. But in general increasing the short circuit ratio of generators will result in but small improvement in transient power limits.

The improvement is obviously small when compared with the gain which can be obtained by speeding up the opening of faulty lines.

Transformer Reactance and Transient Power Limits

The effect of decreasing transformer reactance was discussed in connection with steady state power limits. There is a limit to which these reactances can be decreased without seriously affecting costs. To take advantage of economically permissible reductions in transformer reactance would help to increase transient power limits, perhaps to a greater degree than in the case of steady state power limits, but the improvement would in any case be quite small.

The Relation Between Steady State and Transient Limits

It might at this time be interesting to compare the amount of power which can be carried by a given system in steady state and in case of short circuits. Fig. 21 will help.

Note the case of the stub feeder fault. The fault is cleared without interrupting a line, both lines remaining in service after the fault has been cleared. The maximum power which can be carried with instantaneous switching can be calculated to be higher than the maximum amount which can be carried in a steady state condition. This is because in applying the general relation

$$P = \frac{E_1 E_2}{x} \sin \delta,$$

synchronous values are used in one case and transient values in the other. Now, it is not possible to start out by carrying more than the steady state limit so even with instantaneous switching the higher limit cannot be taken advantage of.

However, this is nothing to worry about. Fast switching times can be obtained, but truly instantaneous switching is out of the question. For that matter, switching

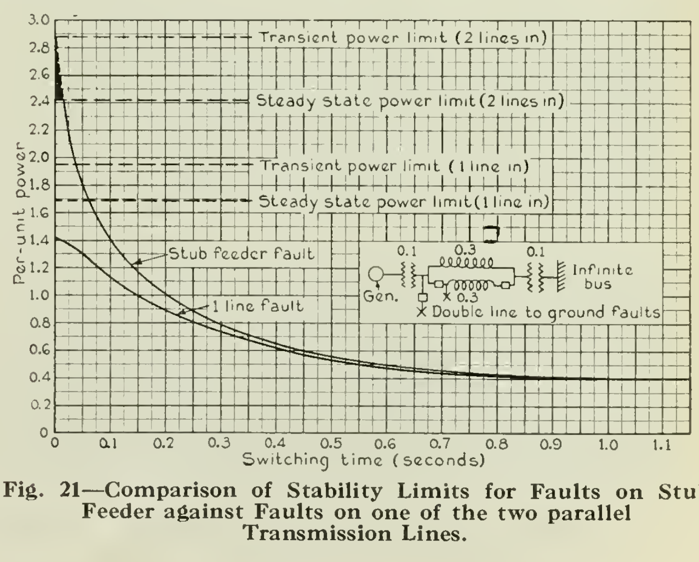

Fig. 21—Comparison of Stability Limits for Faults on Stub Feeder against Faults on one of the two parallel Transmission Lines.

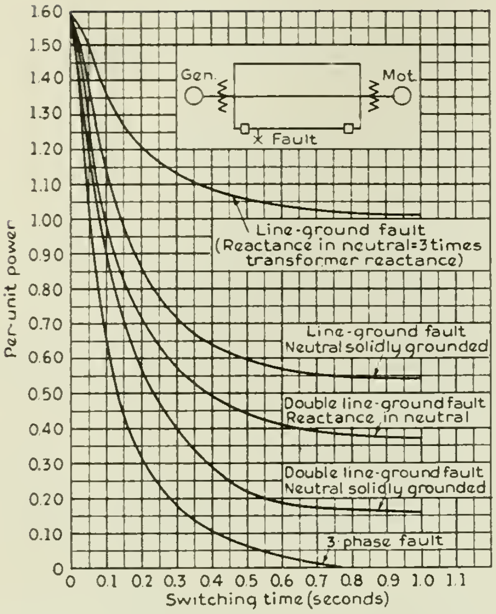

Fig. 22—Power-Switching Time Curves for various Kinds of Faults and the effect of Neutral Reactance.

times which would permit carrying the steady state limit without instability in case of the stub feeder fault shown are unobtainable.

Incidentally, assume for the moment that instantaneous switching could be obtained. Then, if some means for carrying more than the steady state limit to begin with were available, the power which could be carried through a short circuit of the sort shown could be increased. That is where the dynamic balancing regulator would come into the picture. But since such fast switching is impossible, a dynamic balancing act on the part of the regulator would be useless.

Now, forget the stub feeder fault for the moment and consider a fault on one of the lines which means that the line must be opened. The power which can be carried through such a fault with stability is shown by the lower curve. These are the faults which must ordinarily be considered.

Compare the amount of power which can be carried through such a fault which is instantly cleared with the amount which can be carried steady state with both lines in—or, for that matter, with but one line in service. If an attempt should be made to carry the maximum power which could be carried steadily, even with but one line in

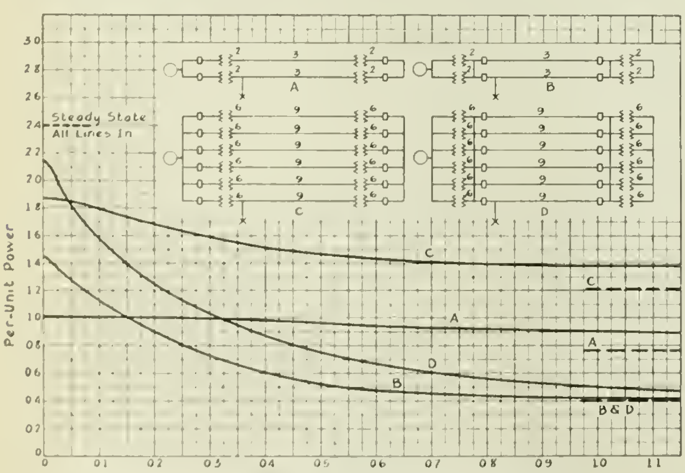

Fig. 23 Comparison of Switching Arrangements for Double Line to Ground Faults.

service, the system would certainly suffer from instability in the event of a line fault. And since switching times as fast as .05 seconds are unattainable, synchronism would be lost even in event of a stub feeder fault.

So once again the present need for a dynamic balancing is not apparent.

These curves, as those previously shown, indicate the gain which may be accomplished by decreasing the switching time from .5 seconds (which was once considered good enough) to .2 seconds which is not at all out of the question now.

Excitation Systems

While the subject of regulators is still in mind, it is desirable to consider the subject of excitation systems generally. It has been said that most of the regulator and excitation systems being applied at this time are capable, to all intents and purposes, of acting with the induced field current at time of short circuits to maintain constant flux in the field poles. Now suppose it were possible to obtain some sort of a system which would act quickly enough to actually increase the flux—and the voltages back of transient reactance—when a fault occurs. Were such a scheme available, it would be possible to raise all of the transient power limit curves bodily and carry more power through short circuits. But just what sort of a scheme would be needed, and what would it do?

Since the flux in the field resists any efforts to change it in the first place—since it refuses to die away when short circuits occur—how then increase it short of treating the field more violently than the short circuit itself treated it? To get any increase in flux—to increase voltages back of transient reactance—exciter voltages would have to be

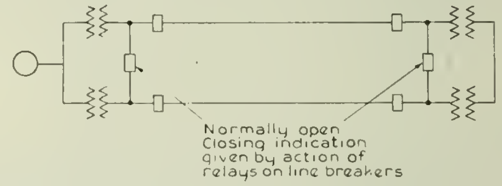

Fig. 24 Combining the Effect of Low Voltage and High Voltage Switching.

increased in tremendously rapid fashion and go to a high value. Some factor such as volt seconds might be used to indicate the tendency of the excitation system to increase flux. There would be little use in having a rate of exciter voltage rise of the order of 1,000 volts per second if the voltage is permitted to increase but a hundred volts. So high voltage exciters or their equivalent would be required.

By such means breaker interrupting duties would be increased and when a fault was cleared from the system, serious overvoltages would result. And unless the flux could be made to die out again in a proper manner, loss of synchronism might occur after a fault is cleared, i.e., on some swing other than the first one.

So extra high speed excitation is viewed with a certain disbelief that it would do much other than increase the costs of installations. The subject will doubtless receive more attention as time goes on, and may show ways to increase power limits. At the moment, however, such installations are not being seriously considered.

At present commercially available rheostatic regulators and exciters, having an average build up rate of perhaps 200 volts per second plus a reasonable maximum voltage are considered suitable from the standpoint of transient stability.

Increasing Transient Power Limits by Fault Current Limitation

The power-switching time curves thus far shown have been based upon double line to ground faults. If three phase faults are excepted this is the most severe type of

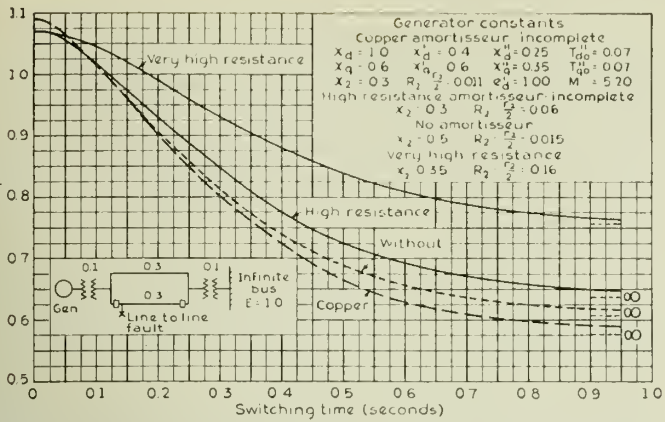

Fig. 25—Power that can be carried through the first Swing with a Line-to-Line Fault by a Water-Wheel Generator with and without Amortisseur Windings.

fault which can occur as might have been surmised from inspection of Fig. 12. Now, referring again to that figure, some conclusions can be drawn concerning the effects of various sorts of faults and means for reducing their severity.

It has been said that it is desirable to keep x'_- and x'_0 as high as possible since in this way x'_t can be kept at the lowest possible value.

The x'_+ and x'_- of such equipment as transformers, series reactors and lines are equal, so if x'_- is increased x'_+ is also increased, which is undesirable. Furthermore, x'_+ and x'_- of generators and motors are so related that it is difficult to increase x'_- without increasing x'_+ in the same proportion. For instance, in the system of Fig. 22 it would be impossible to increase x'_- for a fault at the generating station high voltage bus without also increasing x'_+.

This is not the case with x'_0. This is the reactance encountered by the current which flows in the ground in case of a ground fault. This can be arbitrarily increased by inserting reactance or resistance between transformer neutrals and ground so that the ground current must flow through the added reactance or resistance. This in no way increases x'_+ since it is not in series with the conductors between generator and motor. Thus it is an effective way to limit increases in x'_t during line to ground faults—an effective way to keep the system on a higher power-angle curve during the fault. It is not quite as effective for double line to ground faults since in this case the negative and zero phase reactances act in parallel and increasing one of them does not proportionally increase their parallel value. The degree to which reactance in the neutral increases power limits for line to ground and double line to ground faults is shown for one system on Fig. 22.

If all faults were line to ground, problems of maintaining stability might be largely solved by the use of reactance or resistance in neutral connections together with suitable arrangements for removing the faults in a reasonable time—and this reasonable time might be relatively longer than is now considered desirable in certain cases. It might even be possible to operate with infinite impedance in the neutral—if it were not for arcing grounds.

Unfortunately however, many faults are double line to ground or even three phase and these must be considered if a system which will be stable under any short circuit condition is to be attained. Reactance or resistance in the neutral will help solve the problem where double line to ground faults are concerned, but will not limit increases in x'_t in case of three phase faults. Power limits for three phase faults are lower than for any other sort of fault as shown on Fig. 22.

The Effect of System Arrangement on Transient Power Limits High Voltage Versus Low Voltage Busses

Sometimes a reasonable neutral reactance and reasonably quick switching may fail to provide freedom from instability for double line to ground and three phase faults. In such cases other methods may be of assistance. For instance, low voltage busses may be used instead of high voltage busses. This is advantageous in some cases though not in others, the relative effectiveness varying with the number of lines and their reactance. To make the system's power transferring ability high while the short is on, it is better to bus the transmission lines on the low sides of the transformers at both ends of the line rather than on the high sides, but when the line with the fault is switched out, the transformers connected to that line will be out of service. The transfer impedance will be higher after the fault is cleared than it would have been if the lines had been bussed on the high sides, at the two ends. The length of time the fault remains on the system will determine which of the two arrangements is preferable for a given system. If the short could be switched off instantly, high voltage busses would be better than the low voltage ones, but if it takes a longer time to clear the fault, low voltage busses are often more desirable.

Fig. 23 partially illustrates this. Two systems are shown with high voltage busses, and two are shown with low voltage busses. The steady state power limit is the same in all cases, the difference between systems being that the six line systems have lower voltage lines.

For long lines such as those used in the systems of Fig. 23, the advantage of the low tension switching is apparent. Very fast switching times would be necessary to take advantage of the high voltage switching schemes, and short enough switching times to get above the limits set by low voltage switching schemes for these systems are not now available. If the systems comprised shorter lines, where the terminal equipment reactances might be a greater percentage of the total than in the case of long line systems, the reverse might be true—relatively higher limits with reasonable switching times might be obtained by using high tension busses.

By providing additional high voltage breakers and arranging these as shown by Fig. 24 the advantages of the low voltage and high voltage switching schemes may be combined to some degree. In such an arrangement the transfer reactance during the fault is maintained at the same value as in the low voltage switching arrangement of Fig. 23. Subsequently, when the fault has been cleared and the tie breaker has closed, the transfer reactance

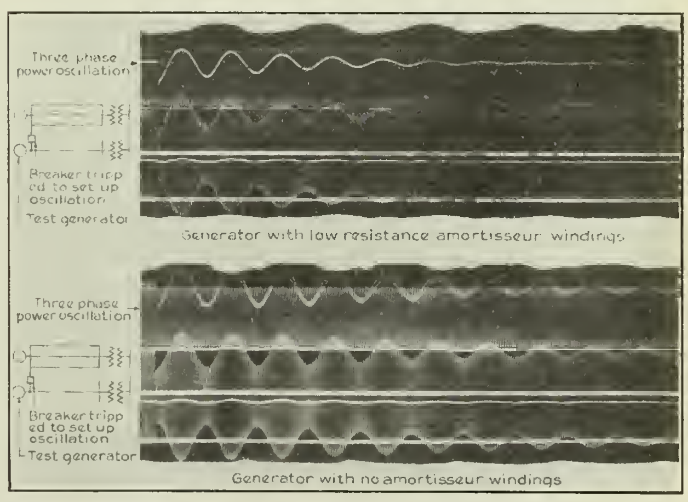

Fig. 26—Effect of Low-Resistance Amortisseur Windings in Damping out Three-Phase Oscillation.

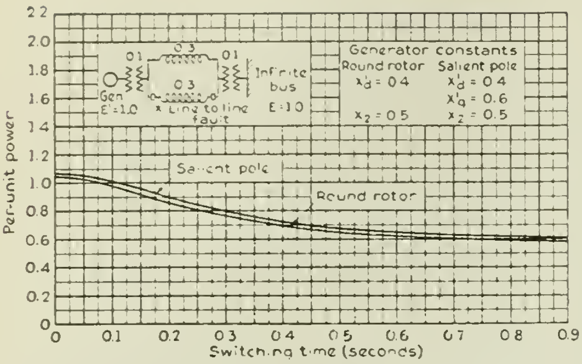

Fig. 27—Switching Time Curve Comparison of Salient Pole and Round Rotor Synchronous Machine Calculations.

becomes the same as in the high voltage switching scheme of Fig. 23 when one line is out of service.

The Effect of Amortisseur Windings on Transient Power Limits

The desirability of damper windings in waterwheel generators has been the subject of some controversy and in recent months a great deal of study has been given to the subject. Although the problem is not completely solved, it is now generally agreed that a damper winding produces three principal effects. These can be discussed most conveniently with the assistance of Fig. 25.

The first effect is called the damping effect. This opposes all speed changes and is always beneficial. The greatest amount of this effect can be obtained by using suitably designed low resistance damper windings.

The introduction of damper windings reduces x'_- of the generator and (remembering the way in which this enters into transfer reactance during faults) it will be seen that this increases the severity of all faults except the relatively infrequent three phase variety. This effect is in the wrong direction.

Since the damping effect of a low resistance damper winding is always beneficial it follows that if the fault were to be instantly removed the power limit with a low resistance amortisseur would be higher than without it. If the fault were removed instantly the evil effect of the lower x'_- of the generator would not be felt. However, as time of clearing faults is increased the tide turns the other way and the power which can be carried, with machines provided with low resistance amortisseur windings, through faults lasting more than about .1 seconds (and they usually do) is less than the amount which might be carried without them. However up to .3 seconds or more the difference is rather insignificant.

Now the third effect of damper windings is also quite important. Under all conditions of unbalanced faults—in case of any but three phase faults—double frequency currents are set up in the damper windings and if these have sufficient resistance the I^2R loss in them produces a braking effect on the machine. It adds a load, the amount of which depends to some extent upon the type and location of the fault, and this partially offsets the difference between power input to the shaft and power output to the load. Thus it limits the tendency of the machine to speed up. So when unbalanced faults are prolonged a gain in power limit can be obtained by using high resistance damper windings.

The curves show the relative advantage of three types of machines. One with no damper, one with low resistance damper, and one with high resistance damper.

On the face of these curves it might be concluded that the high resistance damper is the thing to use. However, the system used as a basis for calculations and the type and location of the fault considered are more favourable to the high resistance winding than otherwise. Furthermore the amount of resistance which can be used and the loss which can be permitted is limited by the ability to design machines so that heat may be dissipated; by the risk which one is willing to take on overheating due to possible unbalanced loads or faults which may accidentally persist too long. Hence the permissible gain might not be more than that shown by the curve marked high resistance (not by the curve marked very high resistance). In this case the gain in power limit for say .2 seconds switching times is not very great—perhaps 3 per cent.

The curves shown are based on line to line faults. Normally it is possible to ride through these with little difficulty anyway and on double line to ground faults the advantage of high resistance damper windings fades some more. For three phase faults high resistance damper windings would not be effective at all. In the cases of three phase faults the x'_- does not enter the picture in any way so all the damping action of low resistance dampers would be effective.

The low resistance winding is effective in damping out oscillations after a fault has been cleared. It is effective in case of balanced three phase oscillations. It is effective in preventing hunting between machines in the same or closely adjacent stations which might be initiated by faults and continue after the faults had been cleared. It is effective in case of large load changes or on systems where the load fluctuates widely. It helps the steadying down process after synchronizing machines. That these things are so can be shown by Fig. 26 which includes the records of two commercially used machines, identical except that one has a low resistance damper and the other none, for identical balanced three phase disturbances. In the case of the machine with the amortisseur winding the disturbance was damped out at least twice as fast as in the case of the machine with no damper winding—and for such disturbances a high resistance damper winding would have behaved just as though there were no damper winding present.

Hence the use of low resistance damper windings is generally desirable on account of their favourable action on all system disturbances, particularly those incident to the worst kind of faults—the three phase sort—though their overall effect on stability limits is small. The use of high resistance damper windings may occasionally be justified but the actual gain in stability obtainable is small if quick

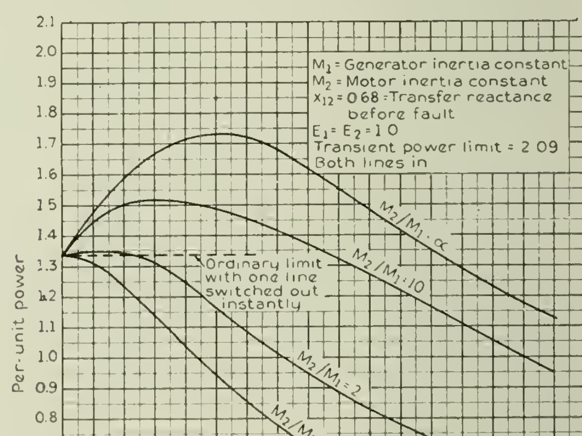

Fig. 28—Per-Unit Power that can be carried through the first Swing with instantaneous Switching using a Series Braking Resistor.

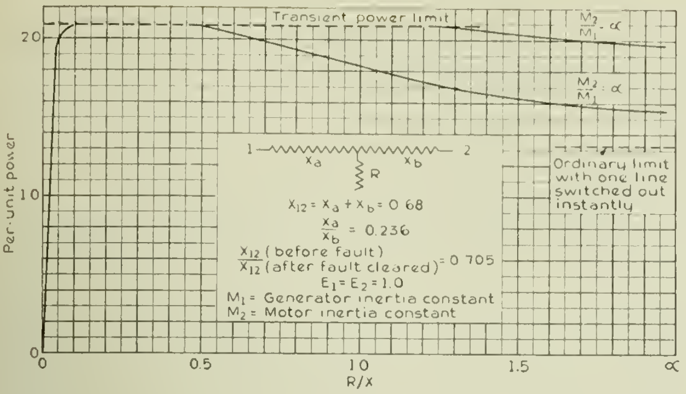

Fig. 29—Power that can be carried through first Swing with instantaneous Switching using a Shunt Braking Resistor.

switching is used while the risk of overheating on persistent unbalanced loads is incurred.

Either low or high resistance damper windings give an important reduction in recovery voltage on clearing faults, and hence a reduction in the duty imposed on oil circuit breakers.

ROUND ROTOR VERSUS SALIENT POLE CALCULATIONS

Earlier in this discussion there appeared a statement to the effect that it is usually justifiable, in the interests of simplifying calculations, to use round rotor theory even though the machines involved should really be salient pole machines. In certain cases however it is not possible to obtain truly comparable results by the use of round rotor theory. The curves shown by Fig. 25 are a case in point. In order to obtain true comparisons of the various kinds of damper windings and their effects it was necessary to use salient pole theory.

However, in the case of the curve showing the action of a machine with no damper winding, approximately the same result might have been obtained by using round rotor theory.

In Fig. 27 is shown the curve previously shown in Fig. 25 for the case of no damper winding and superimposed is a curve based upon identical conditions but calculated according to round rotor theory instead of salient pole theory. The discrepancy between the curves represents the error involved in using round rotor theory instead of the more rigid salient pole method. What error there is, is in the right direction. By using round rotor theory something of the nature of a factor of safety is inserted.

BRAKING RESISTORS AS A MEANS OF INCREASING TRANSIENT POWER LIMITS

Now recall the damper winding question again for a moment. A statement has been made to the effect that high resistance damper windings in reality add a load (in case of unbalanced faults) which partially offsets the difference between the power input to the generator shaft and the power output from the generator to the load. This, it has been said, helps to limit the generator's tendency to speed up.

The same result might be accomplished, perhaps to better advantage, in another way. For instance, a temporary load might be deliberately applied to the generator during times of disturbance. The effect of deliberately applying a resistance load has been recently investigated, and the investigations will doubtless be continued. Two general schemes are under consideration.

The next two figures illustrate graphically the results of calculations made to determine the effect of series and shunt braking resistors on the transient power limit of a particular system. The results, though applying to a particular system, are of such a nature that they may be used as basis for a few general conclusions concerning the effectiveness of such braking resistors.

Fig. 28 shows a series resistor which may be inserted in the circuit by the opening of a shunting breaker.

In preparing the accompanying curves instantaneous switching was assumed. It was assumed that a faulty line might be isolated in zero time and the resistor inserted coincidentally with the opening of the line breakers. The curves indicate the increase or decrease in the amount of power whigh might be carried through the first swing of such a disturbance without loss of synchronism. In other words, the curves illustrate the variation in the starting point of power-switching time curves, such as those previously shown, for various values of inserted resistance and for various ratios of inertia at the two ends of the system. It is apparent that the transient power limit for the first swing could be increased by the insertion of a proper series resistance if instantaneous switching were possible—but only if the ratio of generator inertia to motor inertia is quite large. In general this ratio is not likely to be larger than 4 or 5 and therefore the possible gain owing to the use of series resistors is not likely to be very great in the average case. However, where the inertia ratio is large, say of the order of 10, the maximum gain with instantaneous switching may be of the order of 12 per cent to 15 per cent. As line and resistor switching times become coincidentally greater the percentage gain becomes greater, and if the resistor could be inserted before the fault is cleared the gain might be somewhat further magnified.

Fig. 29 shows the effect of adding a shunt resistance load. As before, instantaneous switching was assumed and the curves illustrate possible increases in transient power limit for the first swing under such conditions. The curves indicate that amount by which the zero switching time transient power limit can be increased by the application of various values of shunt resistance. The curves apply to the system used in the preparation of Fig. 28. Observe that regardless of the inertia ratio some increase in the zero switching time transient power limit can be obtained for the first swing. The maximum gain with instantaneous switching appears to be of the order of 60 per cent. As before, the percentage increase in transient power limit for the first swing may become larger as the switching time is increased.

The effectiveness of methods employing temporary series or shunt resistance loads appear to be beneficial enough to warrant their consideration in special cases where ordinary methods seem likely to fail of accomplishing the desired results,—for instance, where the fastest switching obtainable will not increase transient power limits to the

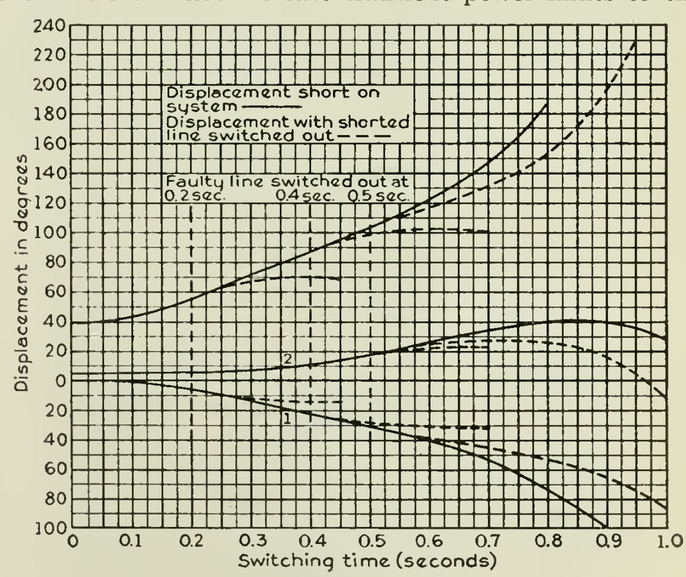

Fig. 30—Swing Curves Double Line to Ground Fault three times Transformer Reactance in Neutral.

desired point. Although at the moment the shunt resistor scheme appears to hold an advantage over the series braking method, both methods seem worthy of further examination.

A word of caution is nevertheless desirable. The use of loading resistors is accompanied by a certain amount of danger. Unless the removal of the resistance load is properly controlled synchronism may be lost on other than the first swing. This phase of the situation will doubtless receive further attention in the future, as will the matter of costs.

The Dynamic Balancing Regulator Again

Now remembering for a moment what has previously been said of the dynamic balancing regulator an interesting conjecture can be drawn.

Were it possible to raise the transient power limit of a system for faults on one of a pair of parallel lines to a point which is above the steady state power limit of the system with one line in service, as by using braking resistors of the shunt type, some benefit might conceivably be obtained from the dynamic balancing regulator.

The system might be operated below the ordinary steady state power limit with two lines in service, but above the steady state power limit of the system with but one line in service. Then with both lines in service stable operation might be provided in case of line faults by using braking resistors, presupposing of course the use of breakers of the proper opening speed. The dynamic balancing regulator might then permit operation under a dynamically stable condition until the faulty line could be replaced in service.

This sort of operation does not at the moment appear to be necessary nor does it at the moment appear to be practical because of breaker speed and regulator limitations. But conceivably the future may indicate the possibility of some gains in this direction. As better regulators and faster switching schemes are developed this sort of operation may occasionally become useful. The vacuum tube regulator, which possesses the dynamic balancing possibilities of the best of vibrating regulators, is showing commercial possibilities and improvements in breaker design indicate that the hope of obtaining even faster switching times may be realized.

Other Things

The discussion of the effect of this or that on the stability of systems might be carried much further. But this discussion has gone far enough to illustrate that every case is unique unto itself and therefore the more interesting. The conclusion may be drawn that there is no complete panacea for instability.

The effect of quick switching has been shown and this seems to be the most practically effective way of increasing system stability. The effect of controlled input to prime movers may come to be of some benefit in the future. A proper excitation system is necessary at least to keep the flux in machines constant and it is rather impractical to try to do much more than that with excitation systems. The effect of limiting faults by neutral impedance and by segregation of the system, which is beneficial at times, has been discussed. Other means, such as changing WR^2 have been mentioned.

But the possibilities are not exhausted. The effect of synchronous condensers has not been touched upon. Sometimes these help to maintain stable operation, although they have a habit of adding to the general confusion amongst machines at times of faults and after. Series capacitors have not been referred to. These counteract the effect of line reactance, but they must be taken out of service during faults or they would break down due to the voltage drop across them with heavy current flow through them. They improve steady state limits, but chief interest is in transient limits. Nothing has been said of the effectiveness of adding lines, but obviously these help to increase power limits up to a certain point. Synchronized at the load schemes have not been discussed and these are sometimes effective.

Complex Problems

In all of this discussion, simple two machine systems involving round rotor machines have been assumed to facilitate the discussion. Obviously such a simple method of analysis cannot always be applied, and where it is applied it is usually necessary to make certain simplifying assumptions.

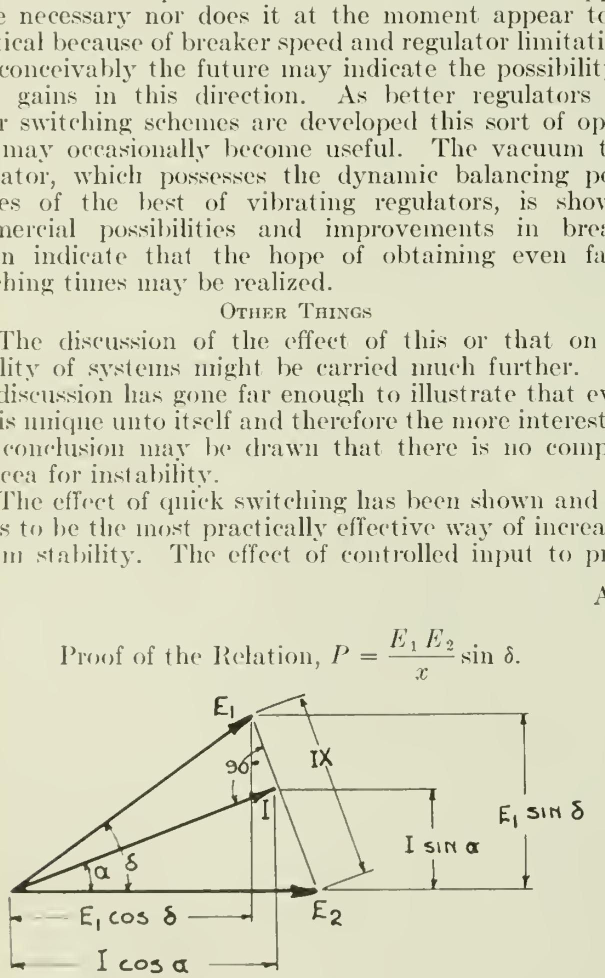
Where system components cannot be lumped together and a two machine problem set up, then the calculations may become truly burdensome. Step by step calculations of the angular position of three, four, or more equivalent machines must be made, the resulting curves being called swing curves. An example is shown by Fig. 30. Moreover, where salient pole machine theory must be employed the calculations become still more complicated. But it is beyond the present scope to discuss these more intricate details. Suffice it to say that methods are available for analyzing most of the problems which arise, and that these methods are being extended as occasion demands.

Conclusion

In conclusion the author wishes to express his appreciation of this opportunity of discussing some of the phases of a problem which is becoming of increasing importance, and also to express the hope that he has usefully explained the fundamental considerations involved. He also wishes to express his appreciation of the assistance furnished by his associates, without which this discussion could not have been so fully prepared.

APPENDIX

Proof of the Relation, $P = \dfrac{E_1 E_2}{x} \sin \delta$.



Vectorially,

$$j(x\dot{I}) = \dot{E}_1 - \dot{E}_2 \quad \ldots\ldots (1)$$

$$\dot{I} = \frac{\dot{E}_1 - \dot{E}_2}{jx} \quad \ldots\ldots (2)$$

Now take the position of E_2 as the vector of reference. Then,

$$I \cos \alpha + jI \sin \alpha = \frac{E_1 \cos \delta + jE_1 \sin \delta - E_2}{jx} \quad \ldots\ldots (3)$$

Simplifying the right hand side of (3),

$$I \cos \alpha + jI \sin \alpha = \frac{E_1 \sin \delta}{x} + \frac{j(E_2 - E_1 \cos \delta)}{x} \quad \ldots (4)$$

Equating the real parts of (4),

$$I \cos \alpha = \frac{E_1 \sin \delta}{x} \quad \ldots\ldots (5)$$

Power being the in phase product of volts and amperes,

$$P = E_2 I \cos \alpha \quad \ldots\ldots (6)$$

Substituting (5) in (6),

$$P = \frac{E_1 E_2}{x} \sin \delta \quad \ldots\ldots (7)$$

Direct Method for Normal Thrust and Moment Influence Lines for Fixed Arches

Alfred Gordon,
Canadian Pacific Railway Company, Montreal.

Paper presented before the Montreal Branch of The Engineering Institute of Canada on February 19th, 1931.

SUMMARY—The determination of influence lines for fixed arches can be performed by the aid of models, or by a standard method of analysis which necessitates a great deal of laborious calculation. The author in this paper sets forth a method of analysis involving no more difficulty than in the case of a two-hinged arch. It is based on the ellipse of elasticity.

It has been shown in recent years that the assumption, in the standard analysis of the reinforced concrete spandrel arch, of knife-edge application of the load by the spandrels to the rib is not warranted; and that the stiffness of the frame formed by the spandrels and deck slab should be taken into account.

A strict mathematical treatment of such a structure, dealing with it as it is, a stiff frame composed of straight and curved members, would need a prohibitive amount of labour. For example, an arch with nine spandrels would have eighteen joints, at each of which there would be an unknown angle of rotation, an unknown vertical displacement, and an unknown horizontal displacement; and these fifty-four unknowns would have to be found for nine positions of a unit load.

In order to meet this situation, the aid of cardboard models has been invoked, and it has been shown that reliable influence-lines may be obtained by observing the distortion of such models. This apparatus is, however, quite costly.

For these reasons, therefore, it seems probable that many arch ribs will yet be designed in accordance with the standard texts.

Now, even the standard method at present necessitates a great deal of work; and the object of this paper is to set forth a method which makes the analysis of the fixed arch, on the usual assumptions, at least no more difficult or laborious than that of the two-hinged arch. It is based on the ellipse of elasticity, and it is presumed for the nonce that the reader is familiar with its theory. This presumption may not be warranted, but seems advisable. The spiders' webs of funicular polygons hitherto associated with the ellipse of elasticity have been sufficient to make it a thing abhorred; but let it be seen, as it were, in its untrammelled beauty, and it may come to be desired, when, if this devoutly-to-be-wished-for consummation be brought to pass, the anatomy of its art may not be so distasteful.

Accordingly, the constructions themselves will first be given, for their simplicity is such, that it is scarcely conceivable anyone would afterwards gainsay the pleading of their *raison d'être*.

Fig. 1 shows the influence-line for the normal-thrust at panel-point 2 of the arch-rib analysed in Hool and Kinne's "Movable and Long-Span Bridges," sections 9-21, and is described and constructed as follows:

(1) The numbers denote the centres of 32 equal "voussoirs," each being 156.4″ long ($ds = 156.4$).

(2) "G" (see Table) is the "elastic weight" (ds/I) of each "voussoir."

(3) "O" is the "elastic centre" of the arch, i.e. the C.G. of the "elastic weights."

(4) X-X and Y-Y are the co-ordinate axes for all subsequent calculations.

(5) The "ellipse of elasticity" is not drawn, but is indicated by its major and minor circles, the radius of the former being given by $a = \sqrt{\Sigma Gx^2/\Sigma G}$, and of the latter by $b = \sqrt{\Sigma Gy^2/\Sigma G}$.

(6) The point $P2'$ is the "antipole of the normal to the arch axis at the point $P2$." If x_p and y_p be the intercepts of this normal upon the X and Y axes, then the co-ordinates of $P2'$ will be given by $x = a^2/x_p$ and $y = b^2/y_p$.

(7) The line M-M is drawn through O and $P2'$, the lengths "m" are scaled, and the products "Gm" are computed, completing the Table.

(8) The "Gm's" are then considered as vertical loads applied at the centres of their respective "voussoirs," and force- and funicular-polygons are drawn for them, using scales as hereafter indicated. The funicular-polygon so obtained is the desired influence-line.

(9) Scales: These may be best represented by the formula:

$$\text{Pole Distance} = \frac{\Sigma Gy^2 \cdot \cos\phi}{\cos\theta} \cdot \frac{\text{Scale of Drawing} \times \text{Scale of } Gm\text{'s}}{\text{Desired Scale of Influence Line}}$$

thus, in the present example, ΣGy^2 was 2191, $\cos\phi$ was virtually unity, $\cos\theta$ was .7864, the scale of the Drawing was $1/180'' = 1''$, the scale of the Gm's was $1/.36'' = 1$ (Gm), and it was desired that an ordinate of 10″ on the influence diagram should represent a normal thrust of 1 lb., so that the pole-distance was

$$\frac{2191}{.7864} \times \frac{\frac{1}{180} \times \frac{1}{.36}}{10} = 4.3''$$

It should also be noted that the pole is taken opposite the load-divide-point, Ga.

Fig. 2 shows the influence-line for the moment at panel-point 7 of the same structure. Here the line M-M is the "anti-polar of the point $P7$ with regard to the central ellipse of elasticity." It may be determined by the construction shown (and treated more fully later), or analytically, thus: its intercept, OG, on the Y-axis is given by $OG = b^2/y$ (for $P7$); and its inclination, ϕ, by $\tan\phi = b^2x$ (for $P7$)$/a^2y$ (for $P7$). The remainder of the procedure is the same as for the normal-thrust influence-line except for the pole-distance and the setting off of the force-polygon. Commencing with ab, set off the loads in the usual manner up to the panel-point; then, G being coincident with a, set off the loads GF, FE, etc., up to the panel-point, with sign reversed. Take the pole itself opposite the load-divide point, Ga. These precautions ensure the funicular polygon, which is the desired influence-line, having a horizontal base so that it is immediately available for use. With regard to the scale: if the pole-distance had been made the same length as the load-line, the ordinates on the influence diagram would have been to the same scale as the arch-rib. Thus, in the present example, the scale of the rib was $1'' = 180''$, so that had the unmodified length of the load-line been used, then an ordinate of 1″ would have represented 180 in. lbs.; but the pole-distance was made 100/180 the length of the load-line, so that an ordinate of 1″ represented 100 in. lbs.

Fig. 1.

The explanation of these constructions is based on the well-known fact that the influence-line for any reaction, shear, bending moment or stress is identical with the deflection diagram produced by a unit displacement at the point of application and in the direction of the desired reaction, shear, bending moment or stress.

From the principle of consistent elastic distortions, the relation between load, reaction and deflections for an indeterminate structure is governed by the law of the lever, so that (see Fig. 3) we have at once $TD = Wd$, whence, if D and W be made unity, $T = d$, and the curve of vertical displacements due to a tangential displacement of unity at P will be the influence-line for T due to a moving vertical load of unity. Similarly, the curve of vertical displacements due to an angular displacement of unity at P will be the influence-line for the moment at P.

Now, consider (see Fig. 4) the skew-backs connected by a rigid bar, the rib fixed at the panel-point in question and cut immediately to the left of it, the free end being connected to the elastic centre by another rigid bar. (These rigid bars leave the elastic properties of the system unaffected.)* Then, according to the properties of the ellipse of elasticity, a force acting along the line M-M in Fig. 1 will displace the elastic centre in a direction parallel to the tangent to the arch axis at the cut section, that is, will displace the free-end, connected thereto by the rigid bar, tangentially; whilst a force acting along the line M-M in Fig. 2 will produce a pure rotation of the elastic centre, and of the free end connected thereto by the rigid bar, about the panel point.

Let the force acting along M-M, producing this desired displacement or rotation, be unity, then the moment at each voussoir due to it will be "m," and, by the method of moment-areas, the curve of vertical displacements due to it will be given by loading the cantilever (with support and free end coincident) with the several products Gm and obtaining the bending-moment diagrams therefor. The funicular-polygons corresponding to the force-polygons having for their loads these products are these bending-moment diagrams, or curves of vertical displacements, or required influence lines.

The chain of argument will now be completed by proving the statements in the penultimate paragraph, that a force acting along the line M-M in Fig. 1 will produce the desired tangential displacement of the elastic centre; and a force acting along the line M-M in Fig. 2 will produce the desired pure rotation of the elastic centre.

As a preliminary to the proofs of these two statements, there will now be presented such geometrical properties of the ellipse as are germane to them.

(1) If there be a point, P_m (Fig. 5a), and from P_m there be drawn secants, and tangents to the ellipse at the

*See final note.

points of intersection of the secants with it, then each pair of secants intersects on a line M-M, and the point, P_m, and the line, M-M, are said to exist in the relation of pole and polar, while the point, P'_m, (symmetrical with P_m) is said to be the antipole of the line M-M. It may be shown that $(r_m)^2 = m'\overline{m}$.

(2) Any line passing through the centre of the ellipse is called a diameter. The pole and antipole of any diameter, such as AB (Fig. 5b), lie at infinity on a line parallel to the tangents at its extremities. Since two diameters, each parallel to the tangents at the extremities of the other, such as AB and CD, are called conjugate diameters, therefore the pole and antipole of a diameter fall upon its conjugate diameter at infinity. It may be shown that

$$\tan\theta_1 \tan\theta_2 = -a^2/b^2.$$

(3) Consider the line M-M (Fig. 5c). As it moves, parallel to itself, to the position qrs, its pole moves from P_m to the point r, so that the point r is the pole of the tangent qrs parallel to M-M. Now, from the previous paragraph, the pole and antipole of PC, a diameter, lie on the diameter conjugate to PC, that is, on a diameter parallel to the tangent at r, that is, parallel to M-M, that is: the pole and antipole of any line lie on a diameter whose conjugate is parallel to the given line, or: any line joining a pole or antipole to the centre of an ellipse is conjugated with a diameter parallel to the corresponding polar, e.g., rr' is conjugated with PC.

Consider Fig. 6a, the fundamental formula for the deflection of curved beams being $\delta = \int Mm\, ds/EI$, in which M is the moment due to the applied loads, and m the moment due to an auxiliary force applied at the point of which the deflection is desired, and in the direction of the desired deflection: the vertical deflection of B is therefore $\Sigma Fx \,.\, 1 \,.\, x \,.\, ds/EI = F/E \,.\, \Sigma Gx^2$, and the horizontal deflection is $\Sigma Fx \,.\, 1 \,.\, y \,.\, ds/EI = F/E \,.\, \Sigma Gxy$. If the origin of co-ordinates be taken at the elastic centre, or C.G. of the elastic weights, G, then the term ΣGxy becomes zero, so that the vertical deflection is $F/E \,.\, \Sigma Gx^2$. Similarly, if F were horizontal (Fig. 6b), we should have the horizontal deflection due to F given by $F/E \,.\, \Sigma Gy^2$, and the vertical deflection would be zero.

Next consider a force, Q (see Fig. 7), so applied that it causes a displacement of B (connected to O, the elastic centre, by a rigid bar) $= \delta_\theta$.

Resolving Q into its horizontal and vertical components, the horizontal displacement of O will be $x = Q/E \,.\, \cos\phi\, \Sigma Gy^2$, the vertical displacement $y = Q/E \,.\, \sin\phi\, \Sigma Gx^2$; and the tangent of the angle of the resultant displacement will be $y/x = \tan\phi \,.\, \Sigma Gy^2/\Sigma Gx^2$. If an *ellipse* be drawn with half its major axis, $a = \sqrt{\Sigma Gx^2/\Sigma G}$, and half its minor axis, $b, = \sqrt{\Sigma Gy^2/\Sigma G}$, the expression for this tangent becomes $\tan\phi \,.\, a^2/b^2$.

Now, from section (2) of the paragraph dealing with the properties of an ellipse, this indicates that the resultant displacement is at right-angles to the axis conjugate to the direction of Q, i.e., that Q must be applied along the axis conjugate to the diameter parallel to n-n, n-n being at right-angles to δ_θ, to effect the displacement δ_θ.

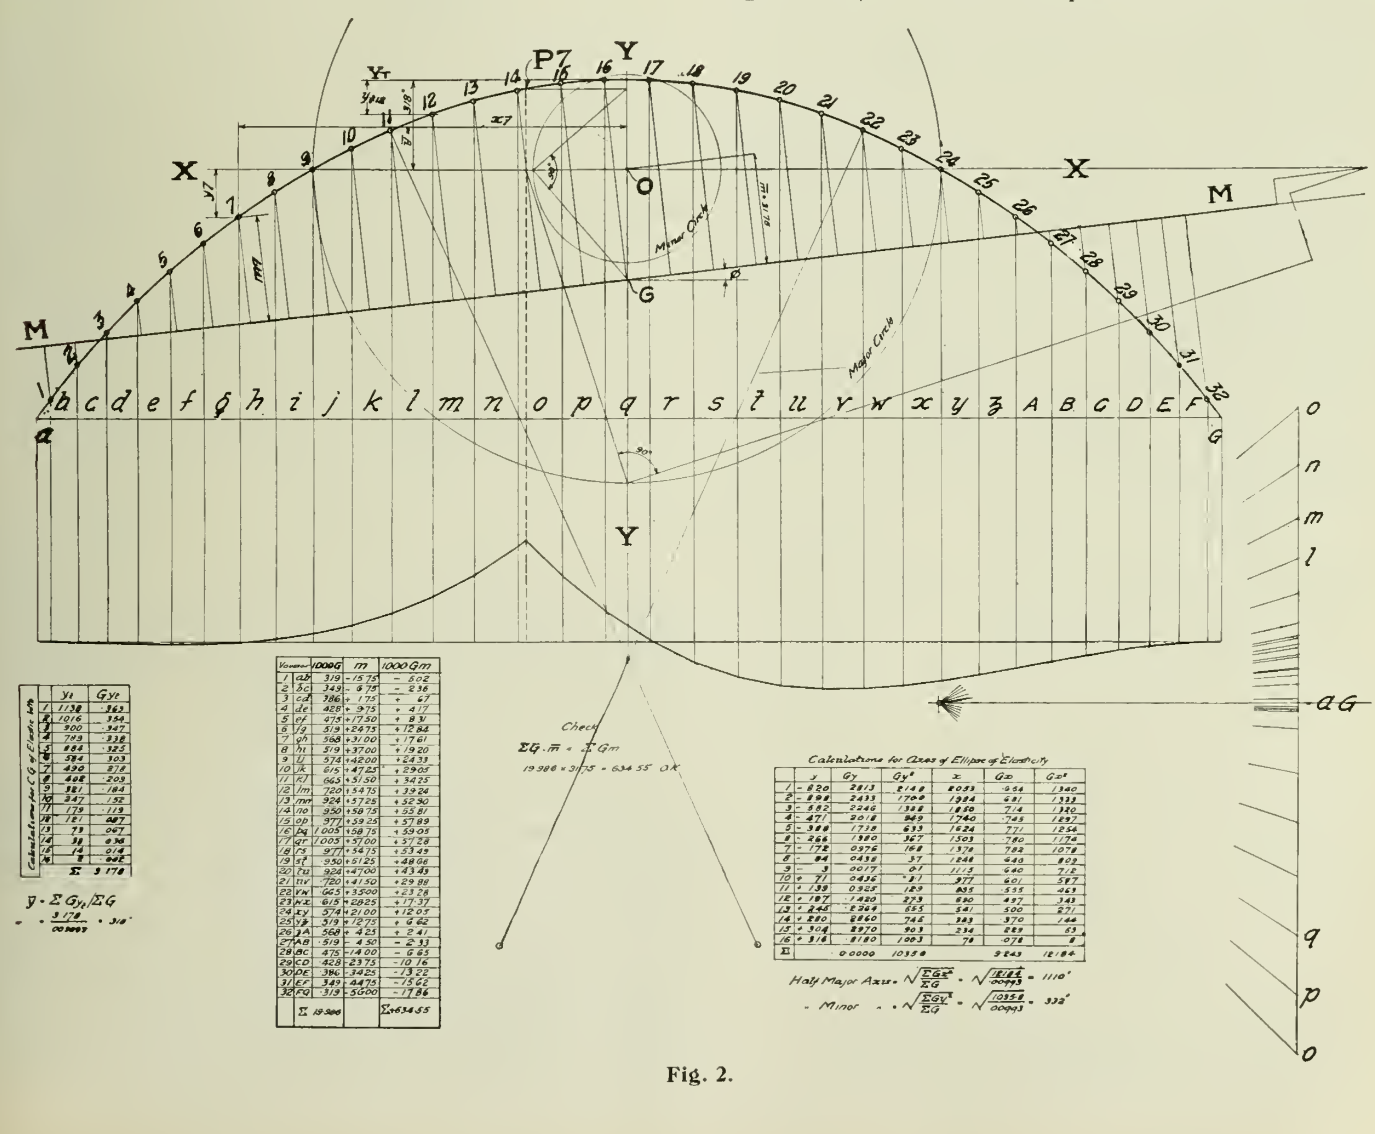

Fig. 2.

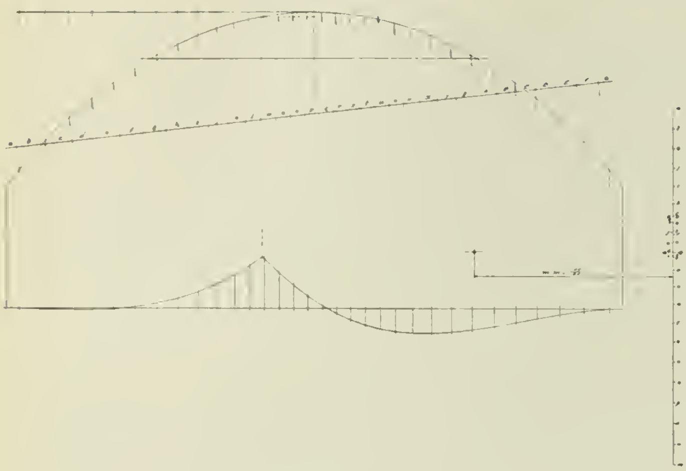

Fig. 2 a.

Again, because the axis M-M (Fig. 1) is a diameter drawn through the antipole of the normal, n-n, to the arch-axis at P, therefore, in accordance with section (3) of the paragraph dealing with the properties of an ellipse, it *is* conjugate to n-n, and any force acting along it *will* produce a displacement of the elastic centre at right-angles to n-n.

Finally, the displacement

$$\delta_\theta = x/\cos\theta = \Sigma Gy^2 \,.\, \cos\phi/\cos\theta = \frac{b^2 \Sigma G.\cos\phi}{\cos\theta}$$

(E and Q being taken as unity), from which follows the pole-distance used in the construction of the thrust influence lines.

Again, consider Fig. 8. The point B will rotate, due to the force F, about some instantaneous centre, C, yet to be determined, through an angle $\alpha = F \,.\, \Sigma Gm$ (from the fundamental formula $\alpha = \int Mm \,.\, ds/EI$, in which M is the moment due to the applied loads, and m is the moment due to an auxiliary couple applied at the point of which the rotation is desired, thus $\alpha = \int Fm \,.\, 1 \,.\, ds/EI = F \,.\, \Sigma Gm$—hence the pole-distance used in the construction of the moment-influence-lines).

Drawing through B the rectangular axes X-X and Y-Y, we have

$$\Delta_x = \rho_x\alpha = \rho_x F \Sigma Gm; \quad \Delta_y = \rho_y F \Sigma Gm \qquad \text{(1a and 1b)}$$

and, applying a unit force first along X-X, and then along Y-Y,

$$\Delta_x = F \Sigma Gmy; \quad \Delta_y = F \Sigma Gmx \qquad \text{(2a and 2b)}$$

Equating, there result

$$\rho_x = \frac{\Sigma Gmy}{\Sigma Gm}; \quad \rho_y = \frac{\Sigma Gmx}{\Sigma Gm} \qquad \text{(3a and 3b)}$$

If the elastic moments, Gm, be regarded as weights, the coordinates of their C.G. will be

$$x_m = \frac{\Sigma Gmx}{\Sigma Gm}; \quad y_m = \frac{\Sigma Gmy}{\Sigma Gm} \qquad \text{(4a and 4b)}$$

giving

$$x_m = \rho y; \quad y_m = \rho x \qquad \text{(5a and 5b)}$$

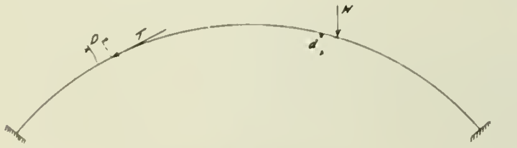

Fig. 3.

Fig. 4.

whence: The instantaneous centre for any terminal point of an elastic system under the action of a force acting along any line M-M is coincident with the C.G. of the elastic moments, Gm.

Continuing, the displacement of B along M-M is $\Delta_m = F \Sigma Gm^2 = F \Sigma G\ (m' - \overline{m})^2 = F \Sigma Gm^2 + F \Sigma Gm'^2$ since $2 \Sigma Gmm'$ is zero due to O being the C.G. of the elastic weights, or

$$\Delta_m = F\overline{m}^2 \Sigma G + F \Sigma Gm'^2 \qquad (6)$$

since $\overline{m}$ is constant.

Also, just as, above,

$$x_m = \Sigma Gmx / \Sigma Gm,$$

so $\qquad m_m = \Sigma Gmm/\Sigma Gm = \Sigma Gm^2/\Sigma Gm,$

or $\qquad \Sigma Gm^2\ (= \Delta_m/F) = m_m \Sigma Gm = m_m\overline{m}\, \Sigma G$

(since O is the C.G. of the elastic weights), that is

$$\Delta_m = Fm_m\overline{m}\, \Sigma G = Fm'_m\overline{m}\, \Sigma G + F\overline{m}^2 \Sigma G \qquad (7)$$

Equating (6) and (7), we obtain

$$m'_m\overline{m} = \Sigma Gm'^2/\Sigma G.$$

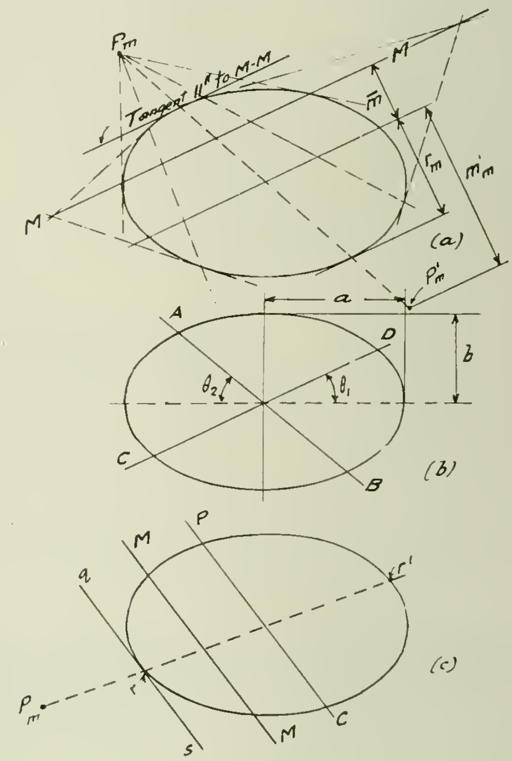

Fig. 5.

Let the ellipse be drawn as before. It is clearly nothing more than the ellipse of inertia of the elastic weights, from the familiar properties of which it follows that their radius of gyration about M-M will be

$$r_m = \sqrt{\Sigma Gm'^2/\Sigma G,}$$

giving $\qquad r_m{}^2 = \Sigma Gm'^2/\Sigma G = m'_m\overline{m}.$

We have seen, however, in section (1) of the paragraph dealing with the properties of an ellipse, that this is the relation between a polar (M-M) and its antipole (P'_m). Accordingly, the instantaneous centre of a force acting along M-M; the C.G. of the elastic moments (Gm); and the antipole of M-M—are all identical.

It should be remarked that the pole, as well as the antipole, is related to the line M-M by the same formula, since the pole and antipole are symmetrical; but the pole cannot be the instantaneous centre of a force acting along M-M. If this were so, then, in Fig. 5c, if the force were acting along the line qrs, of which the pole is r, then its

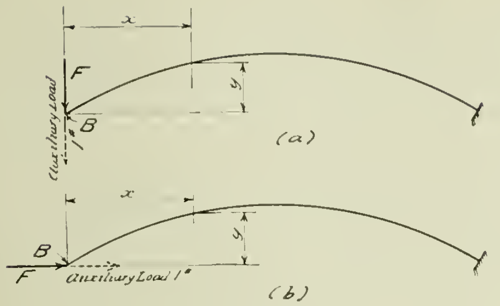

Fig. 6.

instantaneous centre would fall on its line of action, which is impossible. The instantaneous centre is coincident with the antipole, r'.

A simple graphical construction enables us, given the ellipse and the line M-M, to find the antipole—even without drawing the ellipse. It is shown in Fig. 9.

Join the intersection, P, of M-M with the major axis, to the intersection, Q, of the major circle and minor axis. Draw QR at right angles to PQ, cutting the major axis at R. Join the intersection, S, of M-M with the minor axis, to the intersection, T, of the minor circle with the major axis. Draw TU at right angles to ST, cutting the minor axis at U. Then OR and OU are the co-ordinates of the antipole P'_m. The inverse process enables us to find M-M, given P'_m.

Thus the antipole $P2'$ of the normal n-n was found in Fig. 1, and thus the polar M-M corresponding to the antipole $P7$ in Fig. 2; and since the antipole $P7$ is the instantaneous centre for the terminal point of the system, i.e. the elastic centre, under the action of a force acting along M-M, therefore this force will cause the elastic centre to rotate about $P7$ as was stated at the outset.

Thus the critical statements, that a force acting along the line M-M in Fig. 1 will produce a tangential displacement of the elastic centre, and a force acting along the line M-M in Fig. 2 will produce a rotation, have both been proved, and the chain of argument is complete.

Before drawing to a conclusion, since the explanation of these influence-lines has unavoidably necessitated, in turn, an explanation of the ellipse of elasticity, the treatment of the latter may here be completed by one or two notes which, if they had been inserted earlier, would have broken the march of the main argument.

It should be observed that in equations (1a) and (1b), since $\Sigma Gm = \overline{m}\Sigma G$, the displacements along the axes X-X and Y-Y are

$$\Delta_x = F\rho_x\overline{m}\Sigma G \quad \text{and} \quad \Delta_y = F\rho_y\overline{m}\Sigma G$$

respectively.

These expressions for the displacements along X-X and Y-Y, together with the expression for the displacement along M-M, $\Delta_m = Fm_m\overline{m}\Sigma G$, in equation (7), may all be expressed in words, as follows: the displacement of the terminal point of an elastic system under the action of a force in any direction is given by the equation: Displacement = Force × Perpendicular Distance of Antipole of Line of Action of Force to Line along which Displacement takes place × Perpendicular Distance of Line of Action of Force to Centre of Ellipse (of elasticity) × Sum of Elastic Weights.

This equation, of course, as we have seen, does not, however, apply when the line of action of the force passes through the elastic centre. The displacement then, it has been shown, is along the diameter conjugate to the line of action of the force, and is given by the equation

$$\vec{d} = Fb^2\Sigma G \,.\, \cos\phi/\cos\theta.$$

The proved statements in the last two paragraphs, and the demonstration that a force applied along a polar will cause a rotation of the elastic centre about the corresponding antipole, in amount equal to $F\Sigma Gm = F\overline{m}\Sigma G$, summarize completely the fundamental theory of the ellipse of elasticity.

These influence-lines have the advantage that it is very easy to check their construction. For example, in the normal thrust influence-line there is a step at the vertical under the panel-point in question, and this step must be, to scale, sine θ, since this is the vertical component of the assumed unit tangential displacement at the panel-point; whilst the moment-influence-line consists, as may be seen, of two curves starting tangentially from the two ends of the rib, and the cusp formed by their intersection must fall on the vertical through the panel-point in question, and, furthermore, the sum of the Gm's must be equal to the product of the antipolar force, unity, acting along M-M, and its perpendicular distance from the elastic centre.

The moment-influence-lines, it should be said, are of greater importance than those for the thrust, as in practice it will be found best to draw two sets of them, the one for the upper "core-points," the other for the lower, thus giving the extreme fibre stresses directly, and rendering the thrust-influence-lines superfluous.

It may also be remarked that, strictly speaking, the Gm's should be applied as vertical loads *not* at the centres of their respective "voussoirs," but at the antipoles of the ellipse of elasticity of each voussoir with regard to the line M-M, thus taking account of rib-shortening. This is, however, a super-refinement; and, further, it seems desirable, with the tendency to compensate for rib-shortening by the use of hinges, to compute this separately.

A still greater simplification of the work may be effected by dividing the arch-axis into sections such that ds/I is a constant. Fig. 2a shows the same construction

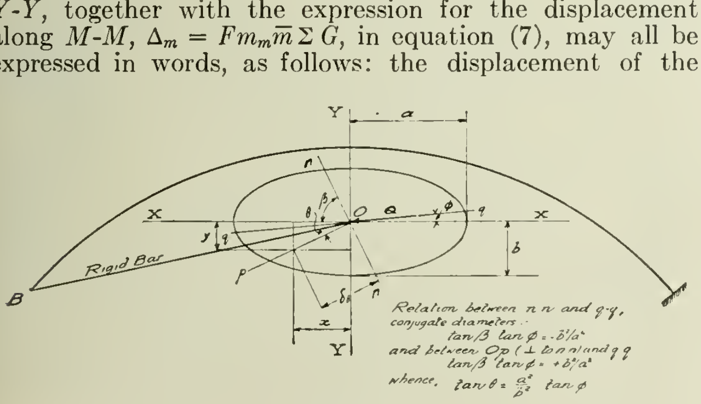

Fig. 7.

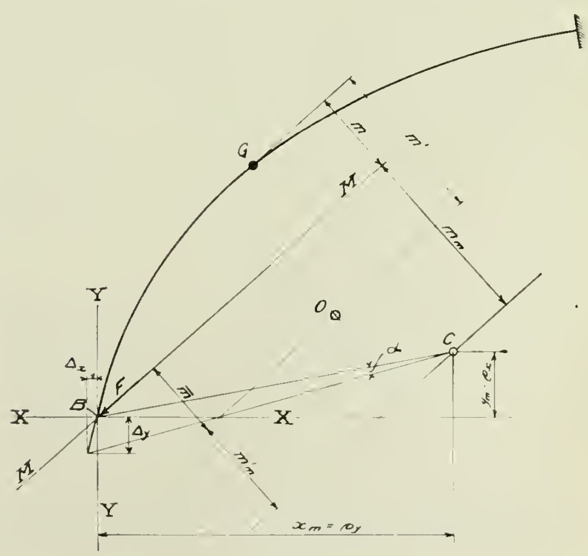

Fig. 8.

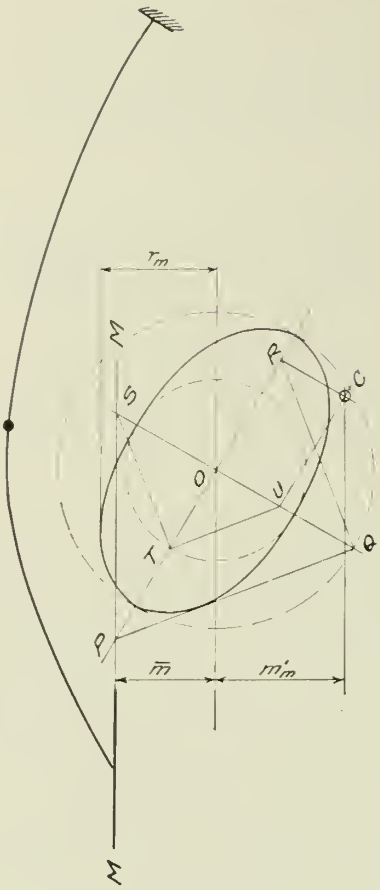

Fig. 9.

as for Fig. 1, with this modification. The arch-rib was divided into 32 such sections, the work of computing the C.G. of the elastic weights and semi-major and minor axes of the ellipse being thereby greatly reduced, and the tabulation of the products Gm being rendered unnecessary, it being only required to lift the lengths, m, off the main figure with proportional dividers, and thus obtain the load-line at once. The location of the elastic centre is given by the mean of the ordinates, k; the radius a is $\sqrt{\frac{\Sigma x^2}{32}}$, and the radius b is $\sqrt{\frac{\Sigma y^2}{32}}$.

With a table of squares these calculations are a bagatelle and after they have been made the work is as easy as the drawing of a bending-moment diagram, with which, in fact, it is identical. In this figure, by intention, only essential lines have been shown, and it is itself more eloquent than anything that can be said on its behalf.

It is true that there would have been more complications had an unsymmetrical arch been selected for an example; we should had to "conjugate" its axes; and there would have been still more complications had arches on elastic piers been selected; we should have had to combine the ellipses of the arches and piers

Had an unsymmetrical arch been selected, we should have had to assume temporary axes H-H (horizontal) and V-V (vertical). The principal axes X-X and Y-Y of the ellipse would then be at an angle with the temporary ones such that its tangent would be given by the expression

$$\tan 2\phi = \frac{2\,\Sigma\,Ghv}{\Sigma\,Gh^2 - \Sigma\,Gv^2}.$$

Had arches on elastic piers been chosen, it would have been necessary to supplement the present treatment of the ellipse of elasticity by practically a repetition of Mr. Janni's treatment of the same problem in section 48 of Professor Hool's "Reinforced Concrete." As that section does not involve any of the "spiders' webs" by which it is there preceded, and as it may readily be understood with the introduction here afforded, it seemed better to indicate it than to resort to bare quotation.

In brief, the simplifications effected by considering the most elementary example, a symmetrical arch, are not responsible for the elegance of the diagrams. The complications mentioned pertain only to the determination of the ellipse of elasticity, the slope and length of its axes. These having been determined, the procedure would be as straightforward as here shown for the symmetrical arch.

This directness arises from the physical concepts which lie behind it. Whereas in the standard method we consider the horizontal, vertical and angular displacements of the elastic centre, from which we are able to evaluate influence lines for the horizontal thrust, vertical reaction, and moment, from which in turn we can obtain expressions for the normal thrust and moment at any section; in the method presented we are able, through the properties of the ellipse of elasticity, to apply a *single* force in such manner that it will produce *any* desired displacement or rotation of the elastic centre. This fact, coupled with the law of consistent elastic distortions and the principle of moment areas, virtually reduces the analysis of the fixed arch to the same order as that of a structure which is indeterminate in but a *single* degree.

Because of the directness of the method in application, it has seemed imperative to re-present the ellipse of elasticity, shorn of its usual festoon of spiders' webs of funicular polygons, in its essence, as simply a geometrical means of locating a force that will produce a desired displacement or rotation. There is, it must be admitted, no originality in the proofs offered; but it may be claimed that there is some originality in the shearing of these festoons. It is surely no more than the truth to say that the existing examples of arch-analysis by means of the ellipse of elasticity are enough to make any average engineer, with the normal moment of inertia in respect to new methods, wish the whole subject to Hanover.

Finally, certain acknowledgments must be made. The method just completed was in part indicated by D. B.

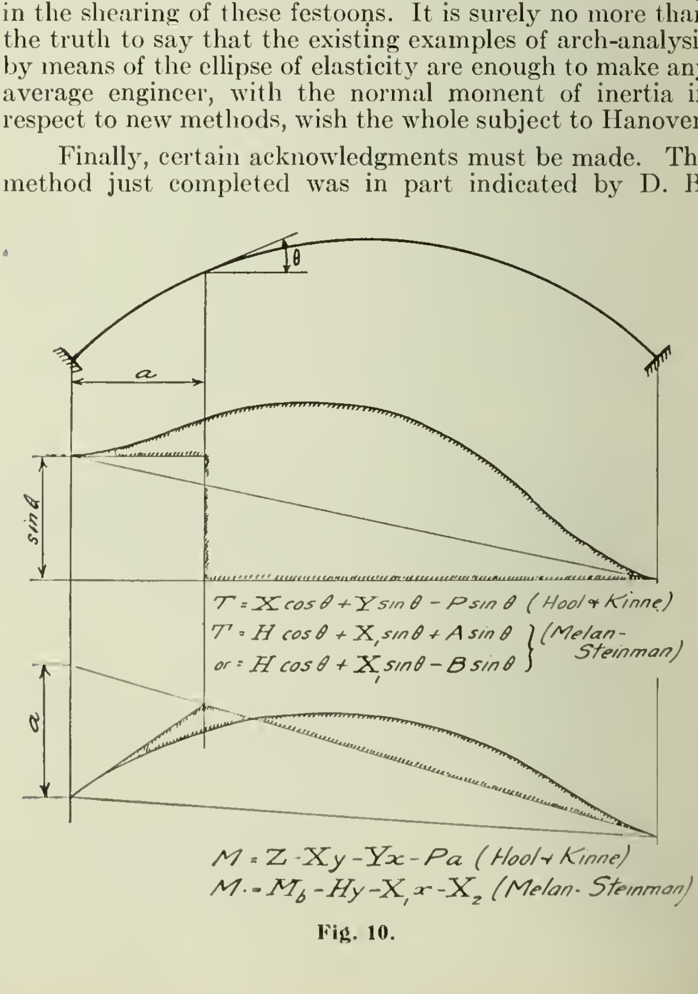

Fig. 10.

Steinman, M.Am.Soc.C.E., in the discussion of the paper by A. C. Janni, M.Am.Soc.C.E., "The Design of a Multiple-Arch System and its Permissible Simplifications" (Trans. American Society of Civil Engineers, vol. 88), where he barely stated the method for the moment-influence-line. The remark seems to have passed unnoticed for five years.

It was a corollary that the same idea should apply to the normal-thrust-influence line, but it was not so clear just how the application should be made. Eventually the problem was solved as shown; and when the solution was found, it appeared to have been anticipated in Johnson, Bryan and Turneaure's "Modern Framed Structures," Part III, Appendix C, section 8, on the "Deflection of Beams Under Unsymmetrical Bending." This seems to have passed unnoticed for fourteen years.

A good text, therefore, for this sermon, would be "The stone which the builders rejected, the same is become the head of the corner."

Of course, the whole method is implicit in the ellipse of inertia; but, as Professor Swain remarked, when it was contended that his formula for computing rotation in elastic distortion was "implicit" in Castiliagno's work-equations, the whole of modern dynamics is "implicit" in Newton's laws of motion, but this does not detract from those who have made those implications explicit

It is hoped that it will be considered of some service to the profession to have made explicit, in these constructions, what has hitherto either been merely implicit or else brushed on one side into possible oblivion through its practical utility having been under-estimated.

Note: The introduction of the rigid bar connecting the skew-backs, and cutting the ring thus formed so that it becomes a cantilever with free end and support coincident, are not mere tricks. Otherwise, we should run into all the complications of "residual" cantilevers or beams. That is, dealing with the thrust, we might load the arch as a straight cantilever beam, supported at the left-hand end, with the same elastic weights, Gm, and from the moment-diagram thus obtained deduct $\sin\theta$ between the left-hand end up to the panel-point considered. Or we might load the arch as a simply supported beam with the same elastic weights, Gm, and combine the moment-diagram thus obtained with the influence-line for shear at the panel-point considered due to a moving load of $\sin\theta$. The first alternative would correspond to the equation $T = X\cos\theta + Y\sin\theta - P\sin\theta$ used in Hool and Kinne, Q (see Fig. 7), multiplied by a constant, replacing $X\cos\theta + Y\sin\theta$. The second alternative would correspond to the equations $T = (H\cos\theta + X_1\sin\theta) + A\sin\theta$ (loads to right of P) and $T = (H\cos\theta + X_1\sin\theta) - B\sin\theta$ (loads to left of P), in which $X_1 = (M_L - M_R) \div$ span, and A and B are the reactions of a simple beam, as in "Plain and Reinforced Concrete Arches," Melan-Steinman. The same reflections apply to the moment-influence-lines. The method adopted avoids all these complicated equations, and is consistent with Fig. 3 and the simple $TD = Wd$, enabling us to deal with the influence-line for T or M directly, as well as giving it to a straight-line base ready for use without re-plotting. The only use of the "ellipse of elasticity" is to locate the line M-M, along which a force will produce the tangential displacement, D, or a simple rotation. Fig. 10 is added to show the complications, both in theory and practice, avoided.

Discussion on "Direct Method for Normal Thrust and Moment Influence Lines for Fixed Arches"

Paper by Alfred Gordon[1]

J. F. Brett, A.M.E.I.C.[2]

Mr. Brett remarked that the author's method of stress calculation, applied to arches, although not new, had as yet received only limited attention in text books, its treatment consisting usually of the bare statement of the underlying formulae. He considered that the author's amplification of the subject was original and of real practical value to the profession.

At the outset it should be noted that the fundamental problem in arch design, after the selection of the proper type of arch, consisted of the design of the axis, the determination of the rib thickness and the reduction of the elastic stresses due to deformation.

The checking of the stresses by the Elastic Theory in one form or another was only the last step, and was quite distinct from the design, because it had not been found possible, so far, to obtain an exact solution of the fundamental problem directly through the Elastic Theory.

Arches might be classified according to their various characteristics, such as span length, span to rise ratio, arrangement of ribs and spandrels, manner of putting the rib under load, etc. The characteristics of the several classes were so different that it was not possible to analyze them all by any single method.

The method of analysis discussed by the author assumed that the ring or ribs would not be seriously affected by the deformations of the spandrel supports and the deck framing. This was only true when the rigidity of the latter was quite small compared to that of the arched member, or when the spandrels were provided with some form of hinged connection.

A rigidly connected stiff deck framing might displace the neutral axis of an arch as much as several feet from the position it would occupy if this influence were non-existent, and at certain points along the rib the stresses might be increased.

Again, if it were desired to make use of the spandrel superstructure to assist the arch, as is done quite often in the case of bridges with a rise to span ratio in the neighbourhood of 1 in 10, the structure would become in reality a Vierendeel truss and could be analyzed by the original method of Professor Vierendeel, or more simply, if it were assumed that the points of inflexion are located at mid-panel for the chords and at mid-height for the vertical web members.

If it were further assumed that the moment of inertia of all the members is the same, the problem became one of simple statics. It was claimed that the values obtained by the approximate method did not differ by more than ten per cent from those of the exact analysis.

This short discussion of the effect of the spandrel superstructure upon all arches would show the necessity of considering the problem of arch design in the light of the true structural conditions existing, rather than as a problem of pure mathematics. In the process of solving the structural problem, method of stress analysis must not restrict the designer's ingenuity and understanding, but

(1) This paper is published on page 243 of the April, 1931, issue of The Journal.

(2) Designing Engineer, Montreal Water Board, Montreal.

should merely indicate to him the factor of security of his structure.

This statement did not detract from the mathematical accuracy of the form of analysis under discussion, but visualized it only as a tool usable in certain specific cases.

The mechanical analysis of indeterminate structures of the use of small models, referred to by Mr. Gordon, was most certainly a decided advance in structural engineering, and even if used only to establish an outline of the elastic line, it furnished a most valuable guide through the maze of computations.

Mr. Brett believed that the cost of the necessary apparatus and models would be fully justified even for modest undertakings. In extreme cases of interaction between rib and spandrel framing the use of models was indispensable.

A case in point was the 311 foot arch over the Rhone river near Chambery. In this intricate case, the results obtained from the mechanical analysis showed the necessity of modifying the analytical computations and the final design was based on the co-ordination of both methods.

His understanding of the author's direct method of influence line determination was, that the usual computations for moment and thrust at points along the rib and the construction of the load polygon would not be required. The influence lines would be used for the dead as well as for the live loading and seemingly the claim of time saving advantage of the method could only be based on these premises.

In so far as monolithic arches without flexural connections were concerned, the usual case in the United States, it was overhelmingly against established practice to discard the load polygon properly located by means of the elastic analysis. Apart from the approximate direct method of Strassner, the load polygon was the only means whereby the shape of the arch axis corresponding to the most effective elastic equilibrium could be determined. This determination must proceed through successive trials and adjustments, and it might be based on the dead load alone or include a part or all of the live load, depending on the rise-to-span ratio, the length of the arch and individual judgment.

If flexural connections were used, then in so far as the dead load and a substantial portion of the rib deformations were concerned, the structure would be a three-hinged arch whose axis coincided with the mechanical load curve in contradistinction to the elastic load curve of the monolithic arch. In this case the direct determination of the influence lines would be an advantage, although it must be noted that the elastic calculations for that part of the deformations stresses occurring after the closing of the flexural connections must still be made.

To sum up, Mr. Brett agreed with the opinion most generally held to-day, that the introduction of the ellipse of elasticity in arch analysis is only necessary in case of multi-span continuous arches on elastic piers when the arches and the piers have a varying moment of inertia between the points of support. The only other practical way to obtain an exact solution for this type of structure would be through the original method of Ritter, as extended by Professor Suter and others. Of the two methods, possibly that based on the ellipse of elasticity was the shorter, though both these methods were a combination of analytical and graphical processes, and were to be preferred in practice as a rule to a purely analytical or graphical process.

He regretted that he could not agree with the claims as to the simplicity of the mathematical processes involved in either of these methods of solution, contending that the exact analysis of this type of structure was one of the most delicate problems of structural engineering.

P. L. Pratley, M.E.I.C.[3]

Mr. Pratley referred to the paper as being a very interesting description of a mathematical "stunt" and admitted that he had not had occasion to apply this method in his practice up to the present. He was rather of the opinion that the author had begun in the middle of his subject from the point of view of the listeners and that a little more elementary explanation of what the method sought to accomplish by means of the particular mathematical "stunt" involved would be of assistance in a general appreciation of the work. It would be interesting to know whether any member present had had an opportunity of comparing the proposed method with the more usual and better established methods in respect of time and labour involved. He remarked that on general principles he was inclined to avoid the use of terms and quantities which had no corresponding physical interpretation. For instance, the "Elastic Weights" ds/I did not represent any physical or tangible feature and the peculiar cantilever arm was of course not an actual fact. He preferred, as a rule, methods of analysis wherein the engineer could be constantly reminded of the basic principles upon which his analysis was based. For instance the method of least work always appealed to him as being one where every step in the mathematical procession was related to the fundamental fact that nature would comply with the principle of the conservation of energy and would perform the necessary work of support or resistance with the least expenditure of this energy. Consequently by expressing the work function in terms of the unknown elements such as moments, or thrusts, or shears or reactions, and differentiating in turn to each of these unknowns, one was actually conscious at all times of the principle that all of these unknowns would so arrange themselves that the differential of the work function to any one of them would become zero in order to keep the work down to a minimum. It was perfectly true that the author suggested that Castigliano's equations and Maxwell's reciprocal theory were actually the basis of all these enquiries, but the chairman felt that normally there was more advantage in adopting methods that kept this fact before the student or practising engineer. He thought that if the author would, in reply to the discussion, make a short explanation as to what the immediate object was of the mathematical treatment presented and the purpose of introducing the ellipse of stress, the theory of poles, polars and anti-poles, it would be a welcome addition to the paper. The mathematics in itself was of course quite simple, but he felt that the object of this mathematics needed to be made clearer, particularly to those who had not previously dealt with this type of analysis.

Conservation of Natural Gas

Robert M. Gourlay,
Canadian Western Natural Gas, Light Heat and Power Company, Calgary, Alta.

Paper presented before the Lethbridge Branch of The Engineering Institute of Canada, on November 1st, 1930.

SUMMARY—Conditions in the Alberta oil fields where the product is largely wet gas and an estimate of the value of the gas at present going to waste. A description of the repressuring of the Bow Island field is included.

The storage of natural gas in underground reservoirs has become very important because of the peculiar conditions existing now in Turner valley. We are aware of the various negotiations on foot to save the tremendous waste of gas by sale to cities in Saskatchewan. While it is known in a general way that the storing of natural gas in depleted fields has been carried on in the United States we have heard little about it, and the work done this year at Bow island may prove of some interest. Turner valley is still something of a puzzle to geologists and operators, though a number of problems incidental to drilling and production have been defined and overcome. The major problems confronting the operators at present are those of finding a commercial outlet for the surplus gas and on the other hand solving the problem created by the freezing in of deep lime producers. A small outlet for the gas is provided by the Gas Company's storage project at Bow island and the problem may be solved in the long run by the proposed pipe line to Regina. The freezing problem still baffles the operators. It is due to the sudden release of gas under a pressure that has probably never been equalled in any other field. The large volume of wet gas encountered under exceptionally heavy pressure in the lime, have however revived the original theory of an underlying reservoir. So far no tests in the large producing area of Turner valley have been carried through the lime. Although in the extreme south Sterling Pacific No. 1 met a shale strata after drilling through a great thickness of lime, McLeod No. 4 drilled about 1,400 feet in the lime and got a second producing horizon but did not go through the formation. Whether an underlying reservoir exists and whether it is within reach of an exceptionally deep test are questions that only the drill can answer.

Recent developments in Turner valley were featured by the bringing in of three new producers in the deep lime horizon. The most important of these are apparently East Crest and Mayland No. 2, the latter with about 13,000,000 feet of gas and 150 to 175 barrels of naphtha per day. It is quite evident that the daily open flow is increasing monthly and regardless of the waste it is allowed to blow open in order that the gasoline content may be extracted. This brought the Gas Company's attention to the matter of seeking some means of conserving a portion of the gas, which cannot be distributed.

The origin of gas and oil has been made the subject of much debate by geologists and chemists. The most generally accepted belief, is, that they have been formed by chemical action induced by heat and compression acting upon animal matter buried in the sands at the time when they were deposited along a sea shore in ages past. These sands subsequently settled very slowly, being overlaid by other deposits, sometimes hundreds of feet in depth. As the overburden increased, compression and heat consolidated the sands and the overlying materials as rock formations. Ages afterwards other deposits were formed including strata which contained sufficient remains of various organisms to form another gas or oil sand. These upheavals and settlements were repeated many times over a period of millions of years. The sand or gas-bearing stratum must be covered by an upper layer of hard non-porous rock, commonly called the "shell" which holds the gas down, something in the same way that warm air collects and is held under a gable roof. Without this, the gas would sooner or later seep upward even to the outer air. Although these theories leave some problems without satisfactory explanations they partly explain why some small portions of the earth contain gas.

Enough natural gas went to waste in Turner valley during the past year to supply the needs of all present Alberta users for fifteen years. Assuming that Saskatchewan was to use 8,000,000,000 cubic feet of gas a year as compared with Alberta's 7,000,000,000 cubic feet of gas per year, enough went to waste in the year to supply Saskatchewan for twelve years. Figures are staggering when we reduce them to something within the scope of the mind. On a B.t.u. basis compared with coal, enough natural gas goes to waste every day in Turner valley to equal nine trainloads of high grade coal, each train being of 50 cars and each car containing 40 tons; in other words, the equivalent of 18,000 tons goes to waste daily; multiply that by 365 for the total wasted each year, this means that the equivalent of 3,285 trainloads or 6,570,000 tons of coal burned as waste in Turner valley each year. Therefore with coal at $6 a ton nearly $40,000,000 worth of heat is being wasted every year. Naphtha and crude oil output in the valley at present approximates $4,000,000 in value annually. Utilization of the gas lost in the process of this reclamation of oil would remove a cardinal waste and would place the natural gas industry on a firmer footing. It is generally known that storing of natural gas in depleted fields has been done in the United States and the experiment of repressuring the Bow island field this year may prove of value. There are several requirements that are essential in selecting underground reservoirs and one of them is, that the Gas Company must have control of the entire field. The depleted field must also be accessible to the main gas line and the old wells must be reconditioned so as to permit the pumping of gas under high pressure without it again escaping to other sands which are not suitable to gas storage. The field at Bow island covers an area of about 22 square miles and was discovered in 1909, and over a period of ten years, 27 wells were drilled to the gas horizon at an average depth of 1,800 to 2,000 feet. The boundaries of the field were defined by the drilling of either dry holes or water wells. The wells as drilled proved, that the gas sand body is entirely surrounded by water and one of our problems will be to control the encroachment of this edge water so that the flooding of the gas sands will be prevented. Early in 1927 the Gas Company realizing that the Bow island field which originally contained approximately 45,000,000,000 cubic feet of gas and over a period of twelve years produced approximately 38,000,000,000 cubic feet of gas reached the stage whereby the withdrawal of more gas would accelerate the encroachment of water and the drowning out of the whole field, decided to carry out experiments of repressuring the field by the introduction of gas from the Foremost field 30 miles away; 37,000,000 cubic feet of gas from this field was introduced to Bow island sands over a period of five days.

Bow Island Repressuring Plant.
Canadian Western Natural Gas, Light, Heat and Power Company.

This small amount of gas had the effect of raising the rock pressure from 256 pounds per square inch to 286 pounds or a trifle less than 1 pound per 1,000,000 cubic feet stored.

The removal of water from gas wells is one of the most serious problems in the production of natural gas. Usually the problem of water removal increases in importance as the production of gas declines. Frequently the condition of wells is such that water occurring in the formation penetrated by wells and in the producing gas sand cannot be satisfactorily shut off and operators are compelled to remove water by pumping, bailing or swabbing or by employing a syphon after it is entered. The cheapest way of removing water is by means of a syphon where applicable. The term syphon as used in a natural gas industry is applied to a pipe or tubing installed in a gas well to remove water. Its operation depends upon the expansion of gas within the eductor pipe and the fact that the rising gas bubbles decrease the density of the column of water in the syphon line. Usually the pressure of gas in the well suffices to start the syphon.

The first experiment of repressuring from the Foremost field being successful it was decided to carry out further work of introducing gas for a longer period of time and using some of the waste gas from Turner valley. In April of this year work was started in the Bow island field of cleaning out and overhauling such wells as could be used for storage. Of the 27 wells in the field possibly not more than 12 will be suitable for repressuring purposes. When these wells were drilled twenty years ago upon completion to the gas horizon, some of the strings of casing were pulled for use in drilling additional wells. The cementing process was little used or practically unknown at the time and the casing left on the top of the gas horizon was therefore uncemented. It is estimated that it will take two years

Intake Scrubber.

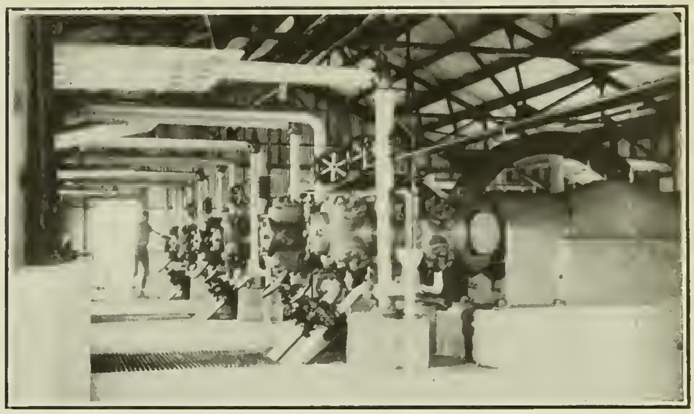
work of reconditioning the wells, and 15 or more of these wells will be abandoned and the water shut off completely by the use of cement or mud fluids. At present we are repressuring through three wells Nos. 4, 7 and 8. No. 3 well had to be cemented off on account of perforated casing and No. 6 well abandoned in the same way on account of tools lost in the well many years ago. Additional wells will be reconditioned from time to time and connected to the main repressuring line. To overcome rock pressure in the existing wells and ultimately to force back encroaching water having an estimated hydrostatic pressure of 730 pounds per square inch, it was necessary to install compressors capable of handling high pressures. This summer three, two-stage 200 h.p. direct driven gas engine compressors manufactured by Clark Brothers were installed, having a combined capacity of 3,000,000 feet per day at 800 pounds discharge pressure, or, 5,000,000 feet delivery at 400 pounds discharge pressure. The intake gas from Turner valley reaches the plant at a pressure of 75 pounds per square inch and is regulated to 40 pounds for the compressor intake, and 15 pounds pressure for the fuel gas in the power end. The intake gas in the low pressure cylinder is compressed to 150 pounds and piped through cooling coils called the inter cooler. It then enters the high pressure cylinder where it is increased to 400 pounds pressure and piped through another set of cooling coils called the after

Cooling Coils.

cooler before it enters the field lines to the wells. The arrangement of the piping is such that the gas can be reversed and sent out of the field when required. Before starting the compressors wells 4, 7 and 8 were turned into the main repressuring line and registered a pressure of 264 pounds. After 24 hours repressuring the compressors registered on the discharge side 270 pounds indicating that the wells were offering but slight resistance. The original rock pressure of the field was 730 pounds. The compressors have been running almost continually since August 4th and the quantity of gas pumped into the sand through the three wells has varied from 3,000,000 to 5,000,000 cubic feet of gas every day.

The auxiliary equipment installed in conjunction with the compressors consists of a 90 h.p. direct driven gas engine and generator which supplies electric light and also power to three motor driven centrifugal pumps. Two 10-inch water intake lines were laid from the bed of the Saskatchewan river to a settling well. The pumps have a capacity of 200 gallons per minute each. The engine end of the compressors require 12 gallons of cooling water per horse power hour and about the same amount is required for the compressor cylinders or a total of 240 gallons per minute for the three machines. The cooling coils in warm weather will require about 100 gallons per minute. A total of 340

Compressor Building, showing Intake Lines.



Interior of Compressor Building.

gallons per minute for the plant. One pump can therefore be held in reserve in case of emergency. The engines are of the two cycle type and very economical. The gas consumption is only 10 cubic feet per horse power hour. The success of the storage of gas in Bow island field will not be determined until the plant has been operating about six months, when sufficient data can be gathered to warrant a definite decision being made on additional expenditure and enlargement of the present plant. In the meantime the repair and inspection of the gas wells will continue until it is felt that the main gas bearing sands within the boundaries of the encroaching water are fully protected. After all it might well be asked why the gas is blowing open in one field and a costly plant installed to pump it back into the ground in another field 150 miles away. The answer may be this, that in this province anyone can buy petroleum and natural gas leases from the Dominion government and drill for gas and oil. As long as the company can make a commercial success by the extraction of gasoline it will carry on, and the well will not be shut in pending a satisfactory market for the gas which is most decidedly not a by-product. There would however be no difficulty in capping the wells until such a time as the supply was needed. Once they purchase their lease and continue under the present government requirements there is no law at the present time to cause the well to be shut in. This has been carried on for many years and should the provincial government desire now to conserve the gas an enormous sum would be required to indemnify the owners for work already done, let alone the value of their acquired leases. Such a sum would be prohibitive. The situation is also complicated by the divided ownership of the mineral rights. That the natural gas supply is unlimited or that new gas is being formed by nature is an opinion that is not accepted so generally as it was a few years ago. The most exhaustive study of gas fields has shown that whatever gas is being generated underground is negligible. When any gas is removed from a sand there is no new gas takes its place as proved by the silent evidence by abandoned wells and fields. When some of the gas is removed from a sand the pressure is lowered in much the same way that the pressure in an automobile tire is reduced when air is removed, for the space occupied by the gas is generally a definite or fixed container. There can be no natural gas supplied to consumers except as it comes from the wells which have tapped nature's limited store house and it is this fact that differentiates the natural gas business from that of supplying manufactured gas or electric service where the sources of supply are so unlimited that the undertaking may sell fuel service guaranteed to be unlimited in time and volume. Each sale of a cubic foot of natural gas is a sale of the nonreplaceable part of the gas operators capital. Our great coal areas may lie in reserve for years to come and wheat may be grown from year to year but natural gas can never be reproduced.

Note: Since the above paper was written, it has been decided not to construct the pipeline to Regina as proposed, and other means for the conserving of gas are being considered.

Discussion on "The Water Supply Problem in Southern Saskatchewan" Paper by W. A. Johnston[1]

Dr. J. A. Dresser[2]

Dr. Dresser remarked that he would like the author to enlighten him on one point.

For a few years while working on a certain oil and gas problem in the Peace river district, it was often necessary to cross a wide syncline between the Rocky mountains and the lower country on the east, by boat on the Peace river. The country to the south was suffering from a lack of water. The rocks along the Peace river appeared to have a slight inclination towards the south. Would there be any possibility of obtaining water within the strata to the south of the Peace river by borings to a reasonable depth? That is, was there a possibility of water entering the strata which were inclined only very gently to the south but which might be reached at a depth of one thousand or fifteen hundred feet for some miles south of the Peace river in a country which was otherwise desirable, but which definitely lacked a water supply?

W. A. Johnston[3]

Mr. Chairman and gentlemen: Regarding the question Dr. Dresser has raised, I must say I do not know anything about the area, but if Dr. Dresser thinks there is a very good chance, I fancy he is right, because he is a pretty good geologist.

Dr. F. D. Adams, Hon.M.E.I.C.[4]

Dr. Adams considered that the paper was one of much interest and value. What the northwest needed more than anything else was water, and any area which could be freshened with a supply of good water, becomes more fruitful and therefore much more valuable not only to the province in which it existed, but to the Dominion as a whole.

Some seventeen years ago when the Research Council of Canada was started by Sir George Foster, the question came up as to whether there were any ways in which research could be applied with advantage to big problems in connection with mining, agriculture, and so on, in the Dominion, and the problem of securing additional supplies of water by artesian wells in the western provinces presented itself at once. A gathering at Ottawa of persons who were especially competent to deal with this question at the time discussed the matter, the consensus of opinion including that of the Geological Survey was that one could scarcely hope to find any considerable supply of fresh water under the great plains. Water had indeed been obtained by boring in many places but it was too saline for common use, so nothing further was done with reference to the matter.

The author must therefore be congratulated and also the Geological Survey for assigning him to make a more careful investigation of the water conditions in the provinces. It was very satisfactory indeed to know that his work had already been rewarded by the discovery of areas underlain by strata carrying fresh water and perhaps there are other areas, still more extended, in which such water could be obtained by boring.

J. W. D. Farrell, A.M.E.I.C.[5]

Mr. Farrell stated that the paper was a very useful contribution to the available information on underground water supplies in the prairie provinces. Economically the subject was one of prime importance to a large portion of the population of those provinces and it was to be hoped that the investigations such as the author had been engaged upon would be continued by the Geological Survey and the results made available from time to time through papers and reports. In prospecting for ground water supplies geological assistance was of the utmost value for the correct interpretation of drillers' logs, surface indications, and topography.

Southern Saskatchewan was not without its lakes and surface streams but these were principally located in deep valleys in cases like the Qu'Appelle lakes or up a hill in cases like the Carlyle lakes on Moose mountain. The centres of population, on the other hand, had been established at locations suitable for distribution along the main railway lines, which had been kept to the general prairie level. The result had been that cities like Regina and Moose Jaw had been compelled to develop underground sources for their water supplies.

In southern Saskatchewan natural conditions did not favour surface streams. The annual precipitation was small and the rate of evaporation was high. Those conditions made underground storage appear to be a wise provision of nature. Underground waters as they occurred in southern Saskatchewan had some advantages over surface supplies. They were usually of excellent potability, clear and free from contamination, requiring neither filtration nor sterilization. The temperature had a very small variation throughout the year. Regina tap water, for instance, had a temperature range of from 39 degrees to 45 degrees F. On the other hand, there was the disadvantage of comparatively high mineral content, usually hardening salts of calcium and magnesium, with a fair amount of sodium sulphate, which was not hardening, but was corrosive. The hardness and mineral content usually increased with the depth from which the supply was obtained. At Boggy creek, water obtained from a shallow deposit contained 280 p.p.m., while deeper waters ran as high as 1,160 parts per million in mineral content. A similar occurrence had been noticed about the water from test wells at Mound springs but location seemed to influence the amount of mineral content more than depth. The water in the wells along the south boundary of the field were considerably softer than the water from wells one-quarter to one-half a mile north. Another disadvantage of an underground source was the difficulty of knowing its capacity. Here again the opinion of a geologist based on field work was of great value.

Where underground waters were found in regular formations such as the sandstone of North and South Dakota, the prospecting for and locating of a supply did not appear to offer serious difficulties. When the underground source was that very heterogeneous formation known as glacial drift, the problems connected with prospecting and locating a source and estimating the capacity were extremely difficult and often baffling to waterworks engineers and well drillers.

Mr. Farrell observed that it had been his good fortune to be in touch with the author who had been sent by the Geological Survey to assist in the solution of water supply problems as they affected Regina, and he was able to observe portions of the investigations. From this association much disconnected data had been gradually combined into a useful working knowledge and familiar topographical features took on a new significance. It had turned out that

[1] This paper was presented at the Annual General Meeting of The Institute, Montreal, Que., February, 1931, and published in the January, 1931, Journal.
[2] 437 St. James Street West, Montreal.
[3] Geological Survey, Department of Mines, Ottawa, Ont.
[4] Montreal.
[5] Superintendent of waterworks, City of Regina, Sask.

the inconsistent glacial drift did have some regularity and its formations had been laid down to some extent at least in accordance with laws that could be deduced by trained observers. The author attributes the geological work at Regina to Dr. Simpson, but as Dr. Simpson had pointed out, his report was based on the co-operative work of the entire party and he made special reference to the survey and mapping of the Pleistocene deposits by the author.

The Regina supply was developed at two locations, known as Boggy creek and Mallory springs. The Boggy creek source was in the valley of Boggy creek, 5 miles northeast, and the Mallory springs source 4 miles east, of the centre of the city.

Both the Boggy creek and Mallory springs sources were initially developed as artesian fields with the exception of one well at Boggy creek which was pumped intermittently. Under this development, the combined yield averaged a little over 3 m.g.d. At both sources it had been found that increasing the number of wells did not permanently increase the yield, that is, after an optimum number of openings had been made to the water bearing layers, additional openings did not produce an additional flow.

In 1928, Regina experienced a considerable increase of population and indications pointed to this growth being continued in 1929. In January, 1929, the demand had overtaken the maximum artesian production at the sources. The city was thus faced with the necessity of immediately increasing its water supply and also of making plans for a supply that would be in excess of consumption for some years to come. It had been recognized that the solution of the problem of immediate supply lay in forcing the yield of the existing sources beyond their artesian flow. This was an engineering problem and while simple in statement, its achievement was accomplished with sufficient speed only by the united effort of almost all the city's engineering resources both human and material.

The second phase of the problem, that of providing a permanently increased supply, involved a study of local underground sources both developed and to be developed, and of more distant surface supplies.

To advise on this problem, Mr. Nicholas S. Hill, Jr., of New York, and R. O. Wynne-Roberts, M.E.I.C., of Toronto, were chosen as consultants, and to assist in the geological studies, the Geological Survey was appealed to for aid. This aid was very effectively given by Mr. Johnston and his party, and resulted in a clearer understanding of the geology of the recent deposits in the district and their relation to underground water supplies.

The information provided from the geological studies indicated that it was reasonably safe to provide permanent equipment for developing Boggy creek and Mallory springs to yield considerably more than their artesian flows. An independent study by Mr. Wynne-Roberts indicated the same conclusion. Mallory springs was now entirely a pumped supply, yielding on the average 1 m.g.d., as compared with its former artesian flow of 0.3 to 0.4 m.g.d. At Boggy creek, the artesian flow was still the main contribution to the supply but equipment had been installed for increasing the yield to 5 m.g.d., as compared with a former yield of 2¾ m.g.d. The effect of prolonged pumping on the artesian flow at Boggy creek had yet to be ascertained, but present indications were that the artesian flow would be reduced. The developed supply at present was 6 m.g.d. and capable of expansion for short periods to 7 m.g.d., which compared favourably with an average consumption of 3.8 m.g.d., and peak demands on a few days in summer of 5 m.g.d. Steps were being taken to connect the Mound springs field to the city in the near future and develop a supply estimated at not less than 2 m.g.d.

The new type of well put down was quite a departure from the old meta cased wells of 5-inch and 6-inch diameters, without screens. The two wells at Mallory springs and one of the wells at Boggy creek were put down by the Kelly Well Company of Grand Island, Nebraska. These wells were cased with a column made up of 3-foot sections of precast concrete casing, and screened with the required number of 14 inch sections of precast concrete screen. Both casing and screen were 18 inches inside diameter. While under construction the well was temporarily cased with steel casings larger than the outside diameter of the concrete casing. When the well was dug to its final depth the sections of concrete screen and casing were lowered to their proper locations. As the temporary steel casing was being withdrawn, gravel of suitable size was packed around the outside of the screen sections thereby increasing the effective diameter of the screen. The other pumping wells at Boggy creek were lined with 10-inch cast iron pipe and provided either with brass Cook screens or with concrete Kelly Junior screens. All the pumped wells were equipped with Pomona deep well turbine pumps driven by electric motors.

The artesian field in the neighbourhood of Mawer should prove of interest in the future to both Moose Jaw and Regina. The size of the field and its source as described by the author indicated a very considerable capacity. As this was close to the proposed route of a pipe line from the Saskatchewan river, the development might form part of the early stages of a plan for bringing water from the river. The mineral content of the water suggested the need for investigation as to the effect when used for human consumption, the effect on plumbing and the result obtained when mixed with the water now available at Moose Jaw and Regina.

R. O. Wynne-Roberts, M.E.I.C.[6]

Mr. Wynne-Roberts thanked the author for the information on hydro-geology in the paper, as a supply of water in the territory referred to was of vital importance for the general welfare of the people. Mr. Wynne-Roberts had been instructed by Regina in 1911 to advise on the question of a more adequate supply of water for the city, and on that occasion the first task was to study the geology as there was no information available.

There had been a number of invasions of ice sheets of tremendous thickness and width which had passed over this territory carrying with them hard rocks which had acted as huge abrasures, to grind and level the earth surface. When the ice had receded towards Hudson Bay, enormous volumes of water which came from the melting ice discharged mud which formed the plains: boulders which formed tesselated moraines and sand, gravel and other material which filled the depressions and built up hills in different places. Hence, it was often difficult to diagnose the underground formations. When recognized geologists undertook to reveal the secrets the problem became more clarified and the public should be grateful to the author and those associated with him for presenting information of such great value.

It was found in Boggy creek area (72 square miles) that a substance known to well drillers as hardpan overlay the main water bearing strata. This substance in general had a fairly uniform grade and thickness for some miles to the southwest, and when it was tapped on the city's quarter section of land about 8 miles northeast of the city, over forty gushing wells were struck by 1914. These continued to overflow for many months but eventually as the number of wells were increased (now 73) the underground pressure diminished and the water subsurface flows yielded about 3 to 3.5 million gallons per day. His estimate

[6] Wynne-Roberts, Son and McLean, Toronto, Ont.

of 1911 for the ultimate yield of the Boggy creek area was about three million gallons daily, which had been more than realized. The water rose in 1912 to a height of 35 feet above the ground and it now flowed into the collecting lines.

Mallory springs were located about 5 miles east of the city and about 2½ miles south of the quarter section above referred to. These wells were drilled about two years ago and there were now two Kelly wells with deep well pumps.

The maximum daily safe yield from Boggy creek and Mallory springs had been estimated at about six million gallons.

The geological formation of the Flying creek area, which was about 14 miles north of Regina and included Mound and other springs, appeared to resemble that of Mallory springs area more than Boggy creek, inasmuch as the underground water-bearing strata were irregular in depth. He had reported on Mound springs, etc., in 1911. The author was correct in stating that there were now nine 6-inch cased wells sunk to a depth of 90 to 200 feet, tapping water at 50 to 155 feet below the ground surface, with static heads of 10 to 24 feet. These wells had been tested individually to ascertain the flows. The effect of the flow of one well on another had been observed in three instances but the aggregate yield had not yet been ascertained. It should be borne in mind that the water-bearing strata were now under the same condition as the Boggy creek wells were in 1912, that is, it was practically under virgin pressure, and it would be instructive to know what the author anticipated the ultimate aggregated flows from the nine Mound wells would be.

He acknowledged that there were other potential small sources in the area, which might be eventually developed. The question which engineers would have to consider and advise the clients was to what extent the other sources could be relied upon in time to supplement the supply for a growing city.

The total annual precipitation ranged from 9.53 inches to 24.53 inches. The average of 39 years was 12.62 inches of rain and 4.41 inches snow, or rain, making a total of 17.03 inches. Precipitation and evapo-transpiration in southern Saskatchewan might be divided into three divisions:

1. Snow, the most of which fell upon frozen ground. There were exceptions but these might be set aside in most years. The melted snow drained away to streams or into sloughs before the ice was out of the ground.
2. Rain which fell during the growing season between April and August inclusive was usually consumed by plant growth, together with loss by evaporation.
3. Rain which fell in the fall after the harvest and before May in the spring and more or less percolated into the ground. Some of it was lost by evaporation.

Government investigations in western Canada and elsewhere showed that very little underground water was derived from snow. Others contended that some snow when melted drains into earth shrinkage cracks. This depended upon the character of the early winter and whether water from snow got in them and became frozen thus preventing further flows. Most of the sloughs had water-tight floors. When farmers desired to drain any of them they drilled holes to permit the water to pass out to the underground beds.

The crux of the problem was how long the water bearing strata would continue to yield water and in what quantity without depleting the wells sunk into the higher reaches. When the rain averaged only 7.93 inches during three years and much of this was consumed by plants and lost by evaporation it would be observed that the problem was one of very great importance.

The subject of evapo-transpiration had become an important one in the discussion on matters of water supply in relatively dry territories. The yield of crops was dependent on the quantity of rain and the roots absorbed with avidity any moisture available in dry growing seasons. In years of relative abundant rainfall crops in the west were plentiful. In more humid eastern Canada the conditions were somewhat different. The striking feature of certain western crops was the depth to which roots actually extended in the search for water.

The water which replenished the underground sources in southern Saskatchewan was therefore mostly derived from rains falling in the spring and fall, less the evaporation which occurred. The withdrawal of water in large quantities must ultimately affect the storage capacity of the underground sources necessary to sustain such heavy droughts, especially if the dry season was a prolonged one, and unfortunately such events were not unknown.

The work done by the author and his collaborators was most acceptable, as it would be of value to all concerned in the problems of water supply in the west. If underground water could be found south of Regina and Moose Jaw down south to the neighbourhood of Weyburn it would enable the district to prosper beyond imagination. There were also other areas in southern Saskatchewan where the services of the Geological Survey would be of great advantage.

It was gratifying to learn that a large artesian area of about 40 square miles lay between Darmody and Central Butte and northwards to within 3 miles of Bridgeford. It would be of interest if the author could give some idea what the probable aggregate yield from this area would be. The author stated that the source of the water to this area appeared to be far up the South Saskatchewan river. This was somewhat difficult to understand as the elevation of the river north of Swift Current was about 1,744 as compared with 1,987 where the well water rose near Mawer.

It might be stated that R. O. Wynne-Roberts was instructed in 1928 to extend his investigations and in this connection he had the collaboration of Mr. W. A. Johnston, Professor Howard E. Simpson and Mr. Nicholas S. Hill, Jr. As would be expected in a district like southern Saskatchewan certain areas which gave promise of water supply, proved on testing to be inadequate in quantity or unsuitable in quality.

W. H. Powell, M.E.I.C.[7]

Mr. Powell stated that he had read the paper with a great deal of interest.

In Vancouver, with over 400 million gallons a day available within from 6 to 10 miles from the centre of density of population, the difficulty of the Saskatchewan problem was amazing.

The study of the conditions by geological engineers foretold with a considerable degree of accuracy the probability of a ground water supply. But the quantity and quality always seemed to be a matter of more or less conjecture.

It would be interesting to know the cost of the wells in the Regina field and the quantity of water supplied. It was probable that the statistics of cost and quantity over a large number of wells would show only the vaguest relation existing between them.

A very excellent report by Dr. Adams some years ago on the ground water supply of Montreal discussed both characteristics.

The South Saskatchewan seemed to be the natural source of any large quantity of water for the Moose Jaw-Regina district. The problems was too large for any one

[7] Engineer, Greater Vancouver Water District, Vancouver, B.C.

city. The author referred to the water requirements of mixed farming. Could not the South Saskatchewan scheme be made to serve a very large agricultural development? It would appear that a water district such as Winnipeg or Vancouver should be created to attend to the requirements of the area. Now that pipe could be fabricated and installed so economically by the welding process and its hydraulic qualities were so much superior to the older fashioned riveted pipe even 100 miles of pipe line was not the financial matter that it was only a few years ago.

Professor J. A. Allan [8]

Professor Allan observed that the author, who was regarded as an authority on the subject, had described a problem of most vital importance to many parts of western Canada. The area discussed in the paper was not unique in western Canada; in fact, there were other areas, at least in Alberta, where the water problem was more acute and difficult of solution than it was in southern Saskatchewan.

He stated that too little attention has been given in the past to water supply problems in Canada, for there were districts in western Canada where settlers were compelled to haul water 10 or 15 miles or even a greater distance, and where many have been compelled to abandon their farms. There are towns where all the water required is brought in by tank cars on the railway. There are other districts where there is abundant water, but on account of dissolved salts the water is unusable.

During the past ten years he had had to give considerable attention to water supply for domestic and industrial purposes in central and parts of northern Alberta. Due to the attention given to the water problem by the Geological Survey of Canada, under the field direction of the late Dr. D. B. Dowling, an artesian area was defined in southeastern Alberta where water of local origin was lacking. In this case the observations of the field geologist were confirmed and the presence of artesian water from artesian sands determined by the drilling of a number of test wells, by the Federal government under the direction of Dr. Dowling. The policy of determining the water horizons by drilling can be highly commended, and similar methods should be followed in other parts of western Canada, where the source of underground water was in doubt, and where the depth entails too great a cost to be undertaken by the individual farmer or by the small town.

When investigating possible water supplies, it had been necessary to convince many individuals that the recommendations given them by operators of the divining rod were unsound and not based on geological facts. In deprecating such methods of finding water, many kinds of instruments in use to-day were not included, as some of these were based on scientific principles, and have been referred to as geophysical methods of locating underground fluids. There are geophysical methods, based on the conductivity and density of the rock, used to-day for locating rock structures or porous horizons suitable for water or other fluid horizons, or for indicating the depths to the contact between unconsolidated material and bedrock, that should be considered worthy of consideration in water supply surveys.

In the third paragraph he believed the author had not made it clear why in many places if the bedrock was reached there was no use drilling any deeper. Also why does the bedrock not contain water in the vicinity of Moose Jaw, where there was a large artesian water basin in the bedrock in the area midway between Moose Jaw and the South Saskatchewan river. To the geologist the explanation might be quite evident, but this was not true in the case of the engineer who did not know the stratigraphic succession in southern Saskatchewan? Even in the Regina district might not the lower formations in the Cretaceous contain water sands as is the case west of Cypress hills?

In the fifth paragraph the association of ground water with morainal deposits was considered. There were marked limitations to a supply of water from this class of unconsolidated material and the origin of such deposits naturally gave irregular distribution of porous and impervious material, unless the glacial deposits had been resorted by water and bedding had resulted. The contact between glacial deposits and the bedrock was a common source of water in many parts. Again, if the glacial deposits contained soluble salts, such as sodium or magnesium or aluminum sulphates or chlorides, these might contaminate water supplies in the glacial deposits over large areas.

Professor Allan observed that he must express difference of interpretation of the meaning of the term "artesian water" as used by the author. The commonly accepted usage of the term artesian water was that the water was not of local origin, but had entered the water-bearing strata some considerable distance, possibly upwards of a hundred miles from the point where the water was obtained by drilling. Artesian water in southeastern Alberta had entered the strata in the foothills over 100 miles to the west, while in the central United States, artesian water had entered the outcrop of porous strata several hundreds of miles to the west. It did not seem appropriate to designate as "artesian" water of meteoric origin in glacial gravels and of comparative local origin and dependent upon local precipitation. Underground water associated with irregularly sorted morainal deposits was not artesian water.

In districts where rock outcrops were scarce, the geologist must seek evidence in underground water from all wells drilled, bored or dug in the district. It was the rule rather than the exception that records were not kept of wells for future use. The Geological Survey of Canada was rendering a real service in collecting drilling records in many parts of western Canada, but there was urgent need of governmental regulations, both Federal and provincial, whereby complete and accurate records would be made of all wells at the time when the operations are under way. There were districts in Alberta where water was scarce but where complete records of wells already drilled would enable the geologist to determine water horizon, whereas now it was necessary to drill a series of test wells before a solution to the water problem could be anticipated.

It was to be hoped that the paper would stimulate interest among the engineers in the water supply problem. In the past the engineer in locating transportation lines and even towns, considered, primarily, the surface features, accessibility and lowest grades between various points, forgetting, it would seem, that a water supply was also of vital economic importance. It was not necessary to go far afield to see that there are towns where a slightly different location would have obviated the water supply problem.

Engineering Standardization—Its International Aspect

During the years which have elapsed since the War there have arisen a great number of international problems, all difficult of solution. Many of these have been of vital moment to the peace and prosperity of the world; others, fortunately less pressing and of a non-political character, have afforded opportunities for the friendly interchange of views between national bodies of delegates. Such international discussions, involving personal contact between the representatives of national organizations, even if they do not succeed fully in their objects, are nevertheless of great benefit in bringing about a better mutual understanding of the various national points of view, characteristics, and mentalities and the difficulties which have to be faced before agreement is possible.

As an example of such discussions we may take those on engineering standardization, considered from the international point of view. The growing recognition of standardization as an important factor in economics and industry has led to the establishment of national standardizing bodies in all of the more highly industrialized countries. The movement commenced in Great Britain before the War by the formation of the British Engineering Standards Association in 1901, and this example has now been followed by more than twenty other countries. The Canadian Engineering Standards Association was established in 1919. The need for some co-ordination of the methods of working of all these associations soon made itself felt, and, largely as a result of conferences of their secretaries which were held in London in 1921 and in Zürich in 1923, a new organization, known as the International Standards Association, was established in 1929; the following eighteen countries now belong to it:

Austria	Italy
Belgium	Japan
Czechoslovakia	Norway
Denmark	Poland
Finland	Roumania
France	Russia
Germany	Sweden
Holland	Switzerland
Hungary	United States

Its executive offices are in Switzerland, and its objects are, to interchange information on the standardization work accomplished in the various member countries, to assist and co-ordinate the work of the national standardizing bodies, and to avoid conflict between the standards they adopt.

The work of The International Standards Association is supplemented as regards certain subjects by that of one or two other organizations. For example some of the work of the International Electrotechnical Commission has to do with engineering standards as applied to electrical problems. Co-operation between these bodies, however, seems to be adequately provided for. It may be noted that the list of adherents to the International Standards Association does not at present include either Canada or Great Britain, their abstention being due to reasons which it is hoped will not be of permanent effect.

The subject of international standardization has not received the attention it deserves from engineers in general, and as a result there has been considerable misapprehension as to the extent and scope of the movement and as to its possible effect on the industrial relations of the various countries.

Some who regard engineering standardization as a great benefit for the industry of their own country hold a different view as to international agreement on engineering standards. They are inclined to fear that such agreement may actually re-act injuriously on their own industrial progress by furnishing to outsiders confidential or detailed information otherwise not available, and by intensifying international competition. Such an outlook would seem to indicate that its holder cannot rely entirely upon his own efficiency and the excellence of his product to maintain his place in the world markets, and loses sight of the many opportunities for sales abroad which compliance with international standards of quality, dimensions or workmanship would afford. This view, however, is not generally held, and it is difficult to see, for example, why, if international agreement on sizes of nuts enabled British spanners to fit American as well as British nuts, this would cause the British purchaser to buy more American and fewer British machines than is now the case. Actually the relative merit and price of the two machines would still be the deciding factor, while there would be greater opportunity for the sale of British wrenches.

The report for 1930 on the progress of the International Standards Association has just been issued, and indicates considerable and growing activity and a gratifying measure of practical success. The work of the association is carried on by twenty-nine technical committees, each dealing with some specific subject of international interest and sponsored by one of the national standardizing bodies. Their proceedings are circulated in the three official languages of the association, English, French and German, and a working agreement has already been reached in connection with a number of important subjects. Several standards have already acquired definite international status, thus, for example, the British Whitworth screw-thread is now a national standard in eleven countries; the nominal dimensions of the most important series of radial ball bearings have practically become a world standard, and agreement on their tolerances is expected to be reached very shortly.

Another subject of primary importance now being dealt with by a number of continental countries with a view to international agreement is the problem of limit gauging, both as regards a standard reference temperature and the question whether tolerances should be applied primarily to the plug or to the hole. It is encouraging to note that the leading German engineering firms are now willing to abandon their own national system of limits and fits, at considerable sacrifice, in order to work in agreement with the other countries represented in the International Standards Association. Negotiations on this extremely contentious subject began in 1923 and were continued at meetings held in Zürich in 1925, New York in 1926, Prague in 1928, in Paris and Cologne in 1929 and in 1930 in Stockholm and Prague, a list which will give some idea of the lengthy discussions which are needed before effective international agreement on an important subject can be reached.

A considerable measure of agreement has been attained in connection with the standardization of paper sizes, the object being to facilitate trade by the use of the same series of sizes for cut papers in various countries. Ten countries have now agreed on the same size for business letter paper and proposals are being considered for standard sheet sizes for other kinds of paper for printing and other purposes, the general adoption of which would lead to marked economy both for the paper manufacturer and for the user.

From the long list of subjects which are being handled by the International Standards Association, a few further examples may be selected at random. Obviously convenience and economy would result if it were possible to obtain international agreement on the leading dimensions of certain fittings of ships, so that, for example, a British vessel entering a German port could obtain without delay and at reasonable cost replacements for such accessories as bollards, port-lights and the like, without sending to a long distance for such replacements. Again it would be of advantage if the authorities of all industrial countries were agreed on the same pressure tests for the acceptance of steam boilers; if shafting, keys and couplings could be made in a series of sizes or shapes which would permit of practical interchangeability, and there is, of course, an enormous field for international standardization in connection with automobile parts. The supply of replacement parts for agricultural machinery affords another wide opportunity for international standardization, particularly as regards ploughs, mowers and harvesting machines, and if there were international agreement on highway signals they would be far more readily understood by automobile drivers of all nations. The list of such topics might be extended indefinitely.

The undoubted economies resulting from the work of the International Standards Association, and its beneficial effect on international trade, would alone justify the time and effort expended upon it, but, in addition, it leads to an exchange of engineering information and experience which tends to place the construction and manufacture of engineering equipment upon a sound and uniform international basis. This is of continually increasing value in eliminating unfair competition and misunderstanding, in simplifying specifications, insuring adequate quality and in affording increased opportunities to all countries for commercial activity in engineering products.

Address by Beaudry Leman, A.M.E.I.C., at the Annual Dinner of The Engineering Institute of Canada, February 4th, 1931.

Mr. Chairman and Gentlemen,

I had prepared a very elaborate and almost eloquent introduction to this talk, wherein was expressed my pleasure in meeting my fellow engineers of bygone days, but it suddenly dawned upon me that I was not here with you for that purpose, that your President and Secretary had in view a much more important object lesson, so far as you were concerned, and that their motives and designs when inviting me to this dinner were darker and more sinister than you and I had thought. They were not content with modern forms of torture, which have become more humane as civilization has progressed; even the middle ages did not offer any form of punishment that would satisfy their refined cruelty; they sought their inspiration in ancient history and renewed a practice resorted to only in extreme cases, by the most rigid and stern inhabitants of Greece: the Spartans. When a Helot, the underdog of those days, had been derelict in his duty, the leaders of Sparta would feed him well, oversaturate him with wine, and then bring him before the populace to stand, as best he could, as an example that would impress the younger generations and keep them in the path of righteousness. I have been brought before you tonight under similar conditions, for I have wandered away from the avenues of pure and disinterested science, and, unpardonable crime, I have worshipped the golden idol. As president of the Canadian Bankers' Association I can offer no alibi before this jury. I stand before you, in shame and in confusion. Now let whomsoever has never sinned throw the first stone. I must confess I feel a certain sense of security as I turn towards your President, and we all know how forbearant is Mr. Durley. I do believe, gentlemen, that these cruel ordeals should cease and that in future you should be satisfied with the incentive provided by the rewards given to merit and abstain from asking an engineer who became a banker to talk when he should be delving into simple arithmetic to figure out the value of his collateral security.

I understand that it is not good form to talk "shop" after dinner. This eliminates matters that would be of interest to you and questions that I might happen to know something about.

And yet, it should be possible to find a common denominator for engineering and business. May I suggest that investigations be made in the direction of ascertaining if the formulae used in the determination of the "factor of safety" in engineering could not be made to extend to business problems. There is a marked tendency nowadays to unify all fundamental laws and I read lately that Professor Einstein had developed an algebraic expression that would apply to gravity, light and electro-magnetism. The old belief in the possibility of transmuting metals one into another, which was discarded for many centuries, is now not only an accepted theory, but an accomplished fact. Why, even the old time nursery rhymes are applicable to present economic conditions, for we all know too well that "Jack Commodity and Jill Security went up the hill lured by a silver quarter; Jack fell down and broke his crown and Jill came tumbling after."

Let us make a superficial inquiry in the realm of "safety factors" and investigate if there is any likelihood of bringing more closely together engineering and business, as their present divorce has been a cource of great mental agony to one who is deeply interested in the welfare of both. The engineer approaches the problem as follows: in order that the safety of a structure shall be assured, there must be no danger of rupture in any of its members. To secure this assurance of safety the stress induced in any member by any load which the member will be called upon to carry must never approach the ultimate strength of the material. The working stress for any material is the unit stress which by experiment has been found safe to allow in that material and still give a proper degree of security against rupture and is the unit strength to be used in determining the sizes of structural members of that material. The factor of safety is the number by which the ultimate stress must be divided to give the working stress. The purpose of the factor of safety and the working stress is twofold: first, to guard against undiscoverable defects in the structural material employed, which defects reduce the ultimate strength of the material; and second, to provide against the possibility of an increase in the load to be carried due to unforeseen circumstances. Let us see how this last sentence would read if applied to business: "The purpose of the factor of safety and the working stress is twofold: first, to guard against undiscoverable defects in the organization, which defects reduce the ultimate strength of the undertaking; and second, to provide against the possibility of an increase in the load to be carried due to unforeseen circumstances." I submit that so far the formulae seem to fit in very satisfactorily. But you know that engineers would not be satisfied with a general factor of safety, even if it should run from one hundred per cent to four thousand per cent; they have torn it apart, analysed it and weighed its component parts. They have found that the apparent factor of safety is the product of four other factors: the first is the ratio of ultimate strength of the material to its true elastic limit; the second depends on the character of the stress produced within the material; the third depends upon the manner in which the load is applied to the piece (for a load suddenly applied the factor is greater); the fourth is the "factor of ignorance." The first three of these factors provide for known contingencies; the fourth provides against the unknown, such as excessive or accidental overload, unexpectedly severe service, unreliable or imperfect materials and all unforeseen contingencies of manufacture or operation. This "factor of ignorance" may become as great as one thousand per cent. Again we are compelled to acknowledge that the various elements to be considered when determining the factor of safety applicable to engineering materials must also be taken into account in business, for the same reasons and almost in the same proportions.

Let us bear in mind that these factors of safety are used by engineers not in connection with unknown untested or untried materials, but with bronze, nickel, steel, cast iron, granite and the like whose resistance to compression, tension, flexure, torsion and shear, have been measured most carefully, under practically all conditions, with the best instruments that can be built and under the supervision of the most experienced and capable men. And yet, after human intelligence and ingenuity have forced back the borders of the unknown, liberal allowance is made for the "factor of ignorance." What a lesson and what an inspiration for those who, engaging in business, whether it be commerce, finance or industry, have to build with far less stable materials and to contend with none the less powerful forces. No engineer has encountered more unreliable quicksand or gumbo to build upon than the shifting sands of popular whims, fancies or fashions upon which many a business rests. The pressure of competition, the breaking strain of taxation, the abrasions made on profits by multidinous fixed charges, the lack of elasticity in our budgets, the plasticity of politics and the resiliency of our incomes should be figured out in business and large factors of safety applied.

Whilst engineers were actively engaged in improving the quality of the materials used in their structures by seeking proper alloys that would strengthen the fibre of these materials, have we witnessed any great improvement in the moral fibre which makes up the elements entering in our social fabric? The most conspicuous new alloy developed during the recent years in business appears to have been "ease," in place of the old-fashioned "effort" which was renowned for its toughness. "Ease" has found its application in a great many ways and we all know how widespread has become its use: easy work—easy money—easy payments—easy credit—easy living—easy profits—finally, easy come easy go. I am afraid "ease" is not as good an alloy as many were led to believe and that our economic structure has not been strengthened thereby. Great hopes were founded on the use of this "easy metal" and it was suggested that it would do away not only with the cumbersome "safety factors" but even with the time-honoured safeguards which a few still remembered and called prudence and thrift. Why! if this policy of ease had kept its promises, you engineers would have had to invent some new material endowed with supernatural qualities, at the risk of being hopelessly outdistanced on the road to progress. I may be out of touch with modern engineering development but I am not aware that you have as yet been successful in devising motors without brakes, or steam engines without fly-wheels, or hydro-electric generators without governors. This "easy fabric" would do away in economics with all the regulators, which would become useless impediments. Why adhere to the gold standard, when paper is so much easier to procure in abundance? Why practise self-restraint to accumulate capital when credit may easily be made available to all? Why work and toil when it is so much easier to speculate? Why save for the future when it is so much easier for the State to provide for your needs? Why row upstream when it is so much easier to drift? Why have ambition, initiative, forcefulness, when it is so much easier to wait for something to turn up? Why have public spirit and ideals when it is so very much easier to be unconcerned and sceptical?

Please do not believe I am suggesting a doctrine of pessimism, reaction and retrogression. Engineers have experimented in many fields and on many materials; these tests have not all been successful and many a promising discovery has proved impracticable. When stumped in one direction they have sought a solution in another, always benefiting by the investigations they have made. The "easy alloy" could not give business all that an unbalanced optimism had dreamt of, but it does not mean that all the elements entering in the alloy should be discarded and abandoned. Because too much credit has been used in the alloy does not imply that credit is not capable, when used in proper proportions, of rendering very extensive and efficient service. Because gold is no longer a fetish and we have learned to carry on financially with a smaller ratio of the precious metal should not mean that we may with impunity disregard its function as a lever, a brake and a regulator. The stock exchanges have been instrumental in gathering small and scattered amounts of capital and in welding them into strong, progressive organizations, and they are not solely to blame if their activities have occasionally been turned into mere gambling operations. We are all desirous that our laws should reflect a more advanced civilization, provide more social welfare and extend a more generous hand to those who are handicapped or afflicted, but in so doing we should guard against sapping the very foundation of human progress, which has been private initiative and personal interest.

We hear a great deal nowadays about the Russian five-year plan and we are prone to believe that something new has appeared under the sun. The "people's commissars," Messrs. Lenine and Trotsky, strove, conformably to their own words: "when they had reached a more advanced stage of socialistic development, to direct all enterprises from a central point, having in view a rational plan of distribution of the available energies and resources co-ordinated along the lines of pre-established national progress." These words and this programme merely carry us back four or five centuries when the common law of the middle ages, or the edicts and decrees of kings, or the corporate regulations of manufacturers and traders, or the by-laws of the chartered boroughs or towns tried to regulate production and to force a rigid discipline upon industry, commerce and agriculture. This method has been tried, has been found wanting and, to the honour of humanity, has not stifled personal liberty. Personal liberty is a condition which has been achieved and secured through age-long struggles and is one of the proudest adornments of our civilization; its life-long enemies have been license and easy-going habits. From time to time it becomes necessary to fight to preserve personal liberty and these battles have to be waged against the foes that are within as often if not oftener than against the foes that are without. May I conclude by quoting Doctor Nicholas Murray Butler in a lecture on Nation-Building and Beyond:—"The path of civilization through the ages is littered with splendid but wasted ideas. The largest visions, the deepest insights, the most compelling arguments, have been spread before the minds of men by prophets and by seers, by statesmen and by nation-builders and then let fall into the darkness of forgetfulness. Nearly everything that man has ever said well was best and most finely said by those ancient Greeks and Romans who, after 2,500 years, still rule the mind of the western world. Material waste is as nothing compared with the intellectual and moral waste which follows upon our not heeding the counsels that have been offered us from generation to generation and from century to century."

OBITUARIES

Pamphile P. V. DuTremblay, A.M.E.I.C.

The death is reported, at Ste. Anne de la Perade, on February 24th, 1931, of Pamphile P. V. DuTremblay, A.M.E.I.C.

Mr. DuTremblay was born at St. Paul's Bay, Que., on November 17th, 1844.

He commenced to practice as a provincial and Dominion land surveyor and civil engineer at Ste. Anne de la Perade in 1874, and has since remained there. He took an active interest in municipal affairs and was the first mayor of Ste. Anne.

Mr. DuTremblay joined The Institute as an Associate Member on May 10th, 1898.

Gustavus Adolphus Bernasconi, M.E.I.C.

Deep regret is expressed in recording the death of Gustavus Adolphus Bernasconi, M.E.I.C., which occurred at Granville Ferry, N.S., on January 12th, 1931.

Mr. Bernasconi was born at Chiasso, Switzerland, on September 18th, 1844. Graduating from the Ecole Polytechnique at Zurich in 1865, he came to Canada in 1871, In 1872 he entered the service of the Department of Public Works, Canada, at Saint John, N.B., and remained with the department until he retired in 1923, his last appointment being that of resident engineer in charge of the public works in Cape Breton, with headquarters at North Sidney.

Mr. Bernasconi joined The Institute as a Member on December 9th, 1897, and was placed on the Life Membership list in September, 1923.

NORMAN M. McLEOD, M.E.I.C.

Norman M. McLeod, M.E.I.C.

Members will learn with much regret of the death of Norman M. McLeod, M.E.I.C., which occurred at Montreal on February 23rd, 1931. Mr. McLeod, who was the son of the late Professor C. H. McLeod, was born at Montreal on September 13th, 1877, and graduated from McGill University in 1899 with the degree of B.Sc.

After graduation Mr. McLeod spent a year with the Dominion Bridge Company at Lachine as structural draughtsman. In 1900 he joined the staff of the Canada Foundry Company, where for the first two years he was engaged in structural design with supervision of shop and field work. From 1902 to 1910 he was in charge of the Bridge Department of this company

In 1910 Mr. McLeod left the Canada Foundry Company to engage in engineering contracting, and was associated with the late Mr. F. H. McGuigan, the first contract of any size being the Queen street viaduct in Toronto.

In 1913 he formed a company in Toronto which operated under his own name, and amongst some of the works completed were some sixteen theatres for Jules and J. J. Allen, and the Famous Players; the Bank of Commerce book vaults; the Oriental Textile plant at Ottawa; the Cadillac building for General Motors at Oshawa; the Durant Motor factory, and several large bridges for the Ontario Department of Highways. During the last two years he was general manager for the Frontenac Dredging Company, doing dredging and general contract work.

John William Astley, M.E.I.C.

It is with much regret that the death of John William Astley, M.E.I.C., which occurred at Victoria on February 28th, 1931, is recorded.

Mr. Astley was born at Barrie, Ont., on June 26th, 1845. He received his early education at the Barrie Grammar school, and from 1865 to 1869 was articled to the Northern Railway Company, Toronto. He was soon promoted to the direction of important survey work in northern Ontario for the Canadian Pacific Railway. In 1900 he became chief engineer of the Klondike Mines Railway, and since that time has directed much railway construction in central and western Canada. Mr. Astley was appointed engineer of construction for the city of Winnipeg in the year 1908, which position he occupied since that date. He was an acknowledged authority on railway engineering subjects, and constantly contributed to Canadian newspapers, mining and railway journals and other periodicals. In the Northwest Rebellion of 1885, Mr. Astley joined the special constabulary attached to the Northwest Mounted Police.

Mr. Astley joined The Institute as an Associate Member on April 8th, 1892, and was transferred to full Membership on June 10th, 1911. He was made a Life Member in 1923.

PERSONALS

J. B. P. Dunbar, A.M.E.I.C., since 1925 district engineer, Military district No. 12, at Calgary, Alta., has been transferred to military district No. 5, at Quebec, where he will again fill the office of district engineer.

C. C. Parker, S.E.I.C., is now with James, Proctor and Redfern, Toronto, Ont. Mr. Parker, who graduated from the University of Toronto in 1929 with the degree of B.A.Sc., was formerly with the engineering department of the Manitoba Bridge and Iron Works, Ltd., Winnipeg, Man.

H. A. Gregory, S.E.I.C., who was formerly attached to the control department of the Anglo-Canadian Paper Mills, Ltd., at Limoilou, Quebec, is now on the staff of the Aluminum Company of Canada, and is located at Shawinigan Falls, Que. Mr. Gregory graduated from McGill University in 1927, with the degree of B.Sc.

W. G. Worcester, M.E.I.C., professor of ceramic engineering at the University of Saskatchewan, Saskatoon, Sask., has been made a fellow of the American Ceramics Society. Professor Worcester, who is on the staff of the Department of Labour and Industries, has been very active in the development of the clay industries of Saskatchewan. In 1930 he was given an honorary degree by the University of Ohio, Columbus, Ohio, from which college he graduated.

J. R. Holmes, S.E.I.C., has been appointed branch manager at Montreal for the Robbins and Myers Company of Canada. Mr. Holmes graduated from McGill University in 1929 with the degree of B.Sc., and was for a time in the eastern division plant engineer's office of the Bell Telephone Company of Canada, Montreal. Prior to accepting his present position, Mr. Holmes was on the staff of the Canadian Ingersoll-Rand Company, Ltd., Montreal.

John Grieve, M.E.I.C., Receives New Appointment

John Grieve, M.E.I.C., who has since 1928 been general industrial sales manager of Brandram-Henderson, Ltd., has been appointed sales promotion manager of the Imperial Varnish and Color Company, Ltd., Toronto. In addition to successful paint sales operation on many of the largest engineering works in Canada and the United States, Mr. Grieve has had long experience in research work. He is an Associate Member of the American Society of Civil Engineers, a member of the Architectural League of New York, of the Arts Club of Montreal and of the Engineers' Club, of both Toronto and Montreal.

J. A. L. Waddell, M.E.I.C., consulting engineer, New York, has been awarded the first Clausen Gold Medal by the American Association of Engineers. The Clausen gold medal is to be awarded annually to the citizen of the United States (engineer or otherwise) who has during the preceding year performed the most distinguished service for the social or economic welfare of engineers. The medal is not awarded for engineering or scientific achievements unless they have served very definitely and directly to promote the social and economic welfare of engineers. Dr. Waddell enjoys an international reputation as an expert in bridge design and economics, having to his credit in Canada and the United States hundreds of bridges of all kinds. He has also designed and constructed many important and difficult bridge structures in Mexico, Japan, New Zealand, Russia and Cuba.

Joseph H. Wallace, M.E.I.C., has become connected with the Black-Clawson Company, Hamilton, Ohio. Mr. Wallace graduated from the Worcester Polytechnique Institute, department of civil engineering, in 1892 with the degree of B.S., and received the degree of C.E. from the same institution in 1899. From 1892 to 1894 he was connected with the United States Lighthouse Establishment, being assigned in 1893 to conduct experiments for the improvement of fog signals under the direction of Major W. R. Livermore, U.S.A. From 1894 to 1897 Mr. Wallace was constructing engineer with A. B. Tower and Company, Holyoke, Mass., and from 1897 to 1901 was a partner in the firm of Tower and Wallace, mill and hydraulic engineers, New York, N.Y. Mr. Wallace has for a number of years been a member of the firm of Joseph H. Wallace and Company, industrial engineers, New York.

R. W. Mitchell, A.M.E.I.C., who has for some years been engaged in private practice as a consulting engineer in Montreal, specializing in reinforced concrete work, water and filtration works, sewerage works, bridges and dams, and the investigation of centrifugally cast concrete pipe and coal handling problems, has been elected president of Consolidated Pipe Company, Ltd., Montreal. Mr. Mitchell received his early training in the office of Messrs. Crouch and Hogg, Glasgow, Scotland, where he served an apprenticeship of five years. On coming to Canada in 1911, he joined the staff of the resident engineer on maintenance of the Grand Trunk Railway, in Montreal. In August of the same year he was on the staff of the resident engineer of the Montreal filtration works, and later in the capacity of chief assistant supervising the work. In 1913, when the Montreal main water supply conduit burst, he designed and supervised the construction of the emergency works from the Lachine canal. From 1920 to 1922 Mr. Mitchell was designing engineer with the Montreal Water Board. His overseas service dated from September, 1914, when he enlisted with the Royal Engineers as a sapper. He was commissioned in the field and retired with the rank of major.

BOOK REVIEWS

The Principles of Coal Property Valuation

By A. W. Hesse. Wiley & Sons, New York, 1930, leatherette, 5 x 7½ in., 183 pp., figs., tables, $3.00.

This book covers in a very comprehensive way the whole field of coal property valuation from the undeveloped coal rights holding to properties equipped with the most modern devices for coal winning and preparation.

It is divided into three major sections: virgin coal lands, operating properties and appraisals and valuations.

Under the first head are included geological examinations, topographical surveys, preliminary investigations as to the character of the coal seams, estimation of probable recoverable coal of commercial grade, accessibility of property to markets, including transportation facilities. Methods of investigation to be followed are outlined and the writer draws special attention to the necessity of giving close study to the local characteristics of the field under investigation. This is particularly applicable to practically all of the coalfields of western Canada, where the assumption of conditions found in older and more regular fields resulted in the loss of much capital in the earlier days of development.

Under operating properties valuation of equipment and consideration of its adaptability to the working conditions in the mine are set forth. Costs of production and the effectiveness of mining systems followed are considered, as well as methods of preparation necessary in order to obtain markets and best prices.

Under appraisals and valuations consideration of financial factors entering into successful operation is given. A number of very useful formulae and tables are included, which may be used in arriving at present values of equipment and property.

This book is a valuable work of reference in engineering economics for all those called upon to value or advise in connection with the operation of coal properties.

B. L. Thorne, M.E.I.C.,
Mining Engineer, Dept. of Natural Resources, Canadian Pacific Railway, Calgary, Alta.

Mercury Arc Power Rectifiers: Theory and Practice

By Othmar K. Marti and Harold Winograd. McGraw-Hill, New York, 1930, cloth, 6 x 9 in., 473 pp., figs., tables, $6.00.

Existing literature on the subject of mercury arc power rectifiers has not been readily available to Canadian power and traction engineers; much of it has been written in German and a large proportion of the remainder has been put out in the form of articles in electrical journals; technical matter in this form is scattered and inconvenient to refer to. This book covers all phases of the subject with clarity and completeness. The authors of this treatise have been associated with the development of the mercury arc power rectifier from its earliest beginnings and the information is based on a very extensive background of experience.

The book opens with a story of the various steps which marked the evolution of the mercury arc power rectifier.

The fundamental theory of arc rectifiers is explained in a very complete and lucid manner. The mathematical development of the expressions describing the wave shape, power factor and other features of the rectifier is given in full, and numerical results are obtained using the basic physical constants appertaining to mercury vapour.

The book proceeds to show how these scientific deductions are applied in the practical development of a power rectifying device. Back-fires and the methods of overcoming these troubles are discussed. The effects of different types of load and the behaviour of the rectifier under short circuit conditions are covered very completely, and a number of oscillograms are given to illustrate these points. Special types of transformers and certain auxiliary power equipment are required to supply A. C. power to these rectifiers. The theory and design of these transformers is set forth at considerable length. Another chapter covers the mechanical design of the rectifier itself and describes the auxiliary apparatus, vacuum pumps, automatic equipment for the maintaining of the vacuum, water cooling systems, etc. Special attention is given to operating matters, such as voltage control, regulation, and all the details which require to be taken care of in a substation which is supplying D.C. power continuously. Power panel arrangements and protective apparatus are described and their functions explained very fully.

Inductive interference with communication circuits and the methods which can be adopted for the prevention of any difficulties of this kind, form the subject matter of another chapter.

The testing of rectifiers and performance rating of rectifier substations is adequately covered.

The volume is well supplied with illustrations and a very complete bibliography is included in an appendix.

As a work of reference and a text book of engineering data on rectifiers, this work is probably the most comprehensive that has appeared; but it might have been made more complete if some reference had been made to expected service life on this type of plant.

ELECTIONS AND TRANSFERS

At the meeting of Council held on March 24th, 1931, the following elections and transfers were effected:

Member

HARRISON, Albert Dex, (Sheffield Univ.), mech'l. engr., Harland Engineering Co. Ltd., Montreal, Que.

Associate Members

COONEY, Richard Thompson, Jr., asst. supt., United Engineers and Constructors (Canada) Limited, for the New Brunswick Electric Power Commission, Newcastle Creek, N.B.

GARNETT, Charles Ernest, (Manchester Coll. of Technology), engr. in charge of all engrg. sales and installations, and vice-president Gorman's Ltd., Edmonton, Alta.

GREENING, Edward Owen, location engr. for P.G.E. Rly. Lands, survey of resources, Quesnel, B.C.

McWILLIAM, Archibald, (Royal Technical College, Glasgow), struct'l. designer, Canadian Bridge Company, Ltd., Walkerville, Ont.

TYRER, Thomas George, Sask. land surveyor and asst. field inspr., Surveys Branch, Land Titles Offices, Regina, Sask.

WIGMORE, Roy Douglas Hazen, B.Sc., (Acadia Univ.), asst. dist. highway engr., Prov. Dept. of Public Works, Saint John, N.B.

Juniors

HOLGATE, William Thomas, B.Sc., (Univ. of Alta.), students' test course, Canadian General Electric Co. Ltd., Peterborough, Ont.

PALMER, Frederick Ernest, (West Kensington Tech. Coll.), engrg. dftsman., Riverbend mills, Price Bros. & Co. Ltd.

THOMSON, William John, B.Sc., (Queen's Univ.), chemist, Abrasive Company of Canada, Hamilton, Ont.

Transferred from the class of Associate Member to that of Member

MORRISEY, Thomas Sydney, Lt.-Col, D.S.O., (Grad. R.M.C.), vice-president, United Engineers and Constructors (Canada) Limited, Toronto, Ont.

WANG, Sigmund, Chem. Engr., (Coll. of Christiana), manager of laboratories, Canadian International Paper Company, Hawkesbury, Ont.

WOODYATT, James Blain, B.Sc., (McGill Univ.), president and general manager, Southern Canada Power Company, Ltd., and vice-president and general manager, Power Corporation of Canada Limited, Montreal, Que.

Transferred from the class of Junior to that of Associate Member

COMEAU, Jules, B.A.Sc., C.E., (Ecole Polytechnique), asst. to engr. in charge, Technical Service, City of Montreal, Que.

JICKLING, Robert William, B.Sc. (E.E.), (Univ. of Man.), transmission and distribution engr., Saskatchewan Power Commission, Regina, Sask.

MILNE, Oswald, (Barrow Technical College), chief engr., Peabody Limited, 161 Victoria St., London, S.W.1, England.

OLIVER, Cuthbert Jack, B.Sc., (McGill Univ.), overhead distribution engr., Rio de Janeiro Tramway Light and Power Co. Ltd., Rio de Janeiro, Brazil.

Transferred from the class of Student to that of Associate Member

BRIGGS, Herbert Lee, B.Sc. (E.E.), (Univ. of Man.), relay engr. and asst. to chief operator for system, City of Winnipeg Hydro-Electric System, Winnipeg, Man.

Transferred from the class of Student to that of Junior

WRIGHT, Harold Sinclair, B.Sc. (Mech.), (N.S. Tech. Coll.), chief engr., steam power plant, Demerara Electric Company, Ltd., Georgetown, British Guiana.

Transferred from the class of Student to that of Affiliate

MacINNES, Donald Alexander, (Grad. R.M.C.), B.Sc., (McGill Univ.), advertising manager, Lake of the Woods Manufacturing Co. Ltd., Montreal, Que.

Students admitted

CAMERON, Hoyes Alexander, (Mount Allison Univ.), Sackville, N.B.

CARTER, John Russell, (Univ. of Toronto), designing dftsman., struct'l. dept., H.E.P.C. of Ontario, Toronto, Ont.

EVANS, George Egerton, (Univ. of B.C.), Wellington, B.C.

GREEN, John Scott, (Univ. of Toronto), 59 St. George St., Toronto, Ont.

HULL, Roland Street, (N.S. Tech. Coll.), Woodstock, N.B.

JARVIS, Gerald Walter, B.Sc., (Queen's Univ.), demonstrator in mech'l. engrg., Queen's University, Kingston, Ont.

MacDONALD, John Winston, (N.S. Tech. Coll.), 72 South St., Halifax, N.S.

MARTIN, Reginald Lee, (McGill Univ.), field engr., Lucerne-in-Quebec, Monte Bello, Que.

McLACHLIN, Hugh Frederick, (Grad. R.M.C.), ap'tice, Canadian Westinghouse Company, Hamilton, Ont.

RALSTON, William Pasmore, (R.M.C.), Hill and Dale, Port Hope, Ont.

ROY, Leo, B.A.Sc., C.E., (Ecole Polytechnique), ap'tice course, Shawinigan Water & Power Company, Montreal, Que.

SMITH, Ralph Rolland, (Mount Allison Univ.), Sackville, N.B.

SMITH, William Stanley, (Univ. of Toronto), Toronto, Ont.

WATSON, Dalton H., (Univ. of B.C.), 1826-13th Ave. West, Vancouver, B.C.

Undergraduates at the University of Saskatchewan, Saskatoon, Sask.

ANDERSON, Gordon Stuart, Theodore, Sask.
CLARK, Ralph William, 818-14th St. East, Saskatoon, Sask.
DOUGLAS, Arnold Howard, Saskatoon, Sask.
FOWLER, Joseph Sims, 1005 Melrose Ave., Saskatoon, Sask.
MOLLARD, John Ellis, Watrous, Sask.
McGOWAN, Edwin Archibald, Officers' Mess, R.C.A.F., Camp Borden, Ont.
OLSON, Arthur Bishop, 1036 College Drive, Saskatoon, Sask.
SCHNEDAR, Clarence Christopher, 715-12th St., Saskatoon, Sask.
WOOD, Donald Waldron, 1036 College Drive, Saskatoon, Sask.

Undergraduates at Queen's University, Kingston, Ont.

CONN, Hugh Gordon, Kingston, Ont.
LaFONTAINE, Daniel Joseph, Tweed, Ont.
RICHARDS, Victor Lloyd, 29 Clergy St. West, Kingston, Ont.
THOMAS, Charles Edwin, 47 Delaware Ave., Hamilton, Ont.
TURNER, Alex. John, 119 Maple Ave., Hamilton, Ont.
WAITE, Matthew J., 21 L. Albert St., Kingston, Ont.

Undergraduates at the University of New Brunswick, Fredericton, N.B.

HURLEY, Joseph Louis, 456 George St., Fredericton, N.B.
MACREDIE, John Robert Calderwood, 752 King St., Fredericton, N.B.
PARLEE, Rutherford J., Lower Millstream, N.B.
WILLIS, Ralph Richard, Youghall, N.B.

Undergraduates at McGill University, Montreal, Que.

CHARLEWOOD, Charles Benjamin, 2664 Orchard Ave., Oak Bay, Victoria, B.C.
DOBBIN, David Crawford, 2095 Grey Ave., Montreal, Que.
HENNIGER, Charles Freeman, P.O. Box 886, Smiths Falls, Ont.
MARKEY, Henry Toller, 2133 Dorchester St. West, Montreal, Que.
PARISH, Charles Ernest, 3434 McTavish St., Montreal, Que.
PRICE, Harold Buchan, 3566 Lorne Ave., Montreal, Que.
ROGERS, Howard W., 1174 St. Mark St., Montreal, Que.
WARNOCK, Robert Nicholson, 344 Metcalfe Avenue, Westmount, Que.

Wm. Kennedy and Sons, Ltd., of Owen Sound, Ont., announce a new standardized line of right angle speed reducers having a remarkable power transmission efficiency. The new reducers, which were developed by the Falk Corporation, are built up with spiral bevel gears, combined with single helical gears for the final reduction when more than a single speed reduction is necessary. Wm. Kennedy and Sons are distributing bulletin No. 210, a 48-page booklet, which describes and illustrates these speed reducers. This booklet may be obtained upon request from Wm. Kennedy and Sons.

BRANCH NEWS

Border Cities Branch

Harold J. A. Chambers, A.M.E.I.C., Secretary-Treasurer.

MANAFACTURE OF REFRACTORY MATERIALS

The February meeting of the Border Cities Branch was held on February 20th, 1931.

Messrs. Ted. F. Stockslager and W. G. Sinn, of the Harbison Walker Company, the speakers on this occasion, were introduced by H. J. Coulter, Jr.E.I.C., and by means of motion pictures they proceeded to illustrate the processes of manufacture of the various refractory materials used in commerce today.

First among these processes to be illustrated were the methods of manufacture of firebrick. Fireclay, from which firebrick is made, is mined in numerous widely distributed places in the United States. It is quite hard and flinty as found in nature and it is necessary to crush and grind it, after which it is graded and then ground again to a certain fineness and a measured quantity of water added until the required consistency for moulding is obtained.

Firebrick was up until quite recent times, and for some special types and shapes still is, hand made, but for the most part is machine made. The clay is fed into the moulds of the brick making machines from overhead hoppers, and then pressed into shape and placed on drying racks after which it is burned in either periodic or continuously operating ovens.

Periodic ovens are of the ordinary dome type and bricks burned have to be graded according to hardness. In the continuously operating ovens the brick is placed in racks on trucks and these trucks move continuously through the ovens, the time of burning being about one hour and a half.

The manufacture of silica brick is very similar to that of fireclay brick except that the chief constituent, silica, is a rock. This necessitates considerably more work in crushing and grinding and because of the dry nature of the crushed material, it is necessary to add a certain quantity of lime to the silica. This mixture is then dried and burned, the burning requiring a somewhat higher temperature than fireclay.

Magnesite and chrome refractories are also manufactured. These require even more careful handling in moulding and also require a higher temperature for burning than silica brick.

Fireclay, silica, chrome and magnesite brick each have their uses in commerce. In the lining of boilers, cupolas, furnaces, converters, etc. one or the other plays its part. The research carried on by refractory manufacturers has been for the purpose of obtaining practically insoluble refractories for the various slags found in smelting of metals and the success achieved along these lines is greatly due to their efforts.

Calgary Branch

A. W. P. Lowrie, A.M.E.I.C., Secretary-Treasurer.
W. H. Broughton, A.M.E.I.C., Branch News Editor.

ARTIFICIAL REFRIGERATION

A general meeting, held in the Board of Trade rooms on the evening of Thursday, February 20th, was attended by about sixty-five members and friends to hear a paper by Kenneth Moodie, B.Sc., M.E.I.C., on the subject of "Artificial Refrigeration."

Mr. Moodie was introduced by J. A. Spreckly, A.M.E.I.C., and traced the development of artificial refrigeration from the early days when food was kept cool in running streams, through the evaporation dish and the "chattie," or evaporation bag, used in the eastern countries, to the elaborate and highly specialized systems now in use.

The speaker showed how dependent we are upon the transfer of heat; in cooking and preserving our foods, in heating our homes, to melt metals and temper tools. All these, however, utilize the absorption of heat, while this most modern use of heat transfer—refrigeration—deals with the removal of heat, and it is fast developing from a luxury into a necessity.

He traced the rapid increase in the consumption of ice in the United States since the installation of the first ice plant built in America in 1805 until today the consumption is about 60,000,000 tons per year in that country.

We are only at the beginning of the use of mechanical refrigeration in the home; undoubtedly it will extend to house cooling, especially in the warmer climates.

The speaker outlined the principle of the modern refrigerator in liquifying vapours under high pressure and allowing them to absorb their heat of vapourization at a low pressure and pointed out that these principles were stated by Dalton in 1801, and in 1823 Faraday produced, first liquid chlorine and then a number of other liquids from gases (or vapours) which were previously considered as permanent. This may be considered as the beginning of mechanical refrigeration.

The speaker defined the unit of heat and the commercial unit of refrigeration, the latent heats of the various refrigerants, their vapourization temperatures at the pressures generally used, and discussed their suitabilities from their relative refrigerative effects, pressure required and volumes occupied. He also outlined the cycle in the modern refrigerating machine.

Refrigerating machines, stated the speaker, may be divided into two groups:

1. Air, which is not condensible.
2. Vapours, which are condensible.

and the second group into three classes:

1. Machines in which the refrigerant is lost.
2. Machines in which the refrigerant is recovered by absorption into a liquid, usually water.
3. Machines in which the refrigerant is recovered by compression and condensation.

He outlined the principle of absorption and rejection of heat and the essential parts required for each type of machine. Air and carbon-dioxide are used in ships, carbon-dioxide and ammonia in abattoirs and ice-plants, while the domestic machine uses sulphur-dioxide, ethyl-chloride or methyl-chloride as the refrigerant.

It appears possible, said Mr. Moodie in conclusion, that solid carbon-dioxide may become more used as a refrigerant during transportation of goods and it may be that the day is not far distant when a solid block of CO_2 will be left each morning at the householder's door instead of a block of ice and so dispense with the necessity of turning on the refrigerator or filling the ice-box.

The interest of the sixty-five members and friends who heard the address was evidenced by the live discussion which ensued; unfortunately Mr. Moodie could not see any prospect of recovering and selling the enormous quantities of CO_2 resulting from the burning of some 300,000,000 cubic feet of natural gas per day which is being wasted in the Turner valley oil field.

A hearty vote of thanks was accorded the speaker following a motion by P. Turner-Bone, M.E.I.C.

ANNUAL DISTRICT DINNER MEETING OF PROFESSIONAL ENGINEERS OF ALBERTA

The Association of Professional Engineers of Alberta held its Annual District Dinner Meeting in Calgary on Saturday, February 7th, at the Renfrew Club. All local members of The Institute were invited to attend, and a majority of about sixty present were also members of the latter organization.

The chair was ably occupied by Dr. J. Allen, Professor of Mining and Geology at the University of Alberta.

Dr. Allen briefly reviewed the legal developments during the past year. Steps are being taken, for the first time, to prevent a non-professional from advertising, or to bring him into the Association.

Mr. B. F. Hake was introduced by the chairman and gave a splendid address on "The Age of Specialized Engineering." He traced the influence of the engineer on the development of the race and the progress of civilization from ancient times up to the present and showed how dependent our present civilization is upon work of an engineering nature. The speaker went on to show that it is impossible for any one individual to comprehend the whole of engineering knowledge at the present time and how the field has been subdivided into many highly specialized branches; he gave some very interesting comparisons of ancient and modern ideas of speed in transportation of people and goods and transmission of speech, of the problems arising from the displacement of labour by machinery and of new jobs continually being created.

The outstanding problem facing the professional classes—engineers, teachers, doctors and lawyers—is to prevent the world from becoming excessively materialistic.

B. L. Thorne, M.E.I.C., gave a résumé of the progress to date towards closer relationship between the various Provincial Professional organizations and gave much credit to The Institute and to S. G. Porter, M.E.I.C., for the efforts being made towards this end. He expressed the hope that considerable progress would be made under Mr. Porter's presidency of The Institute during the present year and he though, that the overtures of The Engineering Institute should be sympathetically received in promoting this object.

B. Russell, M.E.I.C., spoke along the same lines as the chairman of the Calgary Branch.

Mr. R. A. Brown, superintendent of utilities of the city of Calgary, released his usual collection of humour, this year largely at the expense of the geologists, who have quite recently considerably swelled the membership of the P.E.A.

Mr. R. A. James gave an interesting address on "Russia," which was a summary of conditions in that country and of the aims and progress of the "Five Year Plan," as reported in current literature.

The Secretary, Mr. Debney, gave an account of the membership and finances, which showed that a very healthy condition exists in the organization of the P.E.A. of Alberta.

A. Griffin, M.E.I.C., gave an interesting address on some of the problems of "Irrigation."

Hamilton Branch

J. R. Dunbar, A.M.E.I.C., Secretary-Treasurer.
J. A. M. Galilee, Affil.E.I.C., Branch News Editor.

The first students' meeting ever held by the Hamilton Branch took place in the Royal Connaught hotel on March 10th, 1931, with W. F. McLaren, M.E.I.C., in the chair.

Before calling on the Student and Junior members who were presenting the papers, the chairman outlined briefly the history of the various prizes offered by The Institute, and then called upon the Secretary to outline the conditions under which the Branch Student prizes are offered.

The three speakers drew lots to see who spoke first. The papers presented were as follows:—

P. R. Adams, S.E.I.C., "A Brief Résumé of the Development of the Air Brake and its Relation to Transportation."

D. E. Bridge, S.E.I.C., "Electric Furnaces as Applied to Industrial Heating."

H. W. Blackett, Jr.E.I.C., "The Power Supply of Southern Vancouver Island."

Air Brakes

The first speaker was P. R. Adams, S.E.I.C., who dealt with air brakes. He pointed out that starting and stopping of any type of transportation agent are complementary factors in the problem of making time between stations. Therefore, it is evident that the best results can only be obtained where both factors are given due consideration.

A practically perfect brake must be automatic, durable, simple, always ready, responsive and flexible.

The first steps toward the complete solution of braking problems were taken in 1869 by George Westinghouse, who patented his non-automatic air brake, since known as the "Straight Air Brake." This apparatus had many good qualities but nevertheless shortly afterwards gave way to the "Plain Automatic Brake." This type was almost immediately superseded by the "Quick Action Automatic Brake" which was a very decided improvement, chiefly from an emergency standpoint. By using this equipment, the time taken to apply the brakes fully on a fifty-car train was reduced to one-sixth of what was formerly necessary.

The air brake has played an important rôle also, in the development of our electric railway systems. The complete "Air Brake and Safety Car Control Equipment" must be given credit for the prominent part it has taken in the remarkable success of street railway transportation. The fast schedules, short headway, and elimination of one man could not have been possible, with safety, without this equipment.

The air brake has also invaded another division of transportation and is being associated with highway traffic, and it wields as potent an influence here as in the railway field.

The Automotive air brake is a power braking system which delivers a maximum braking force much greater than that which can be produced by the ordinary foot brake. Consequently, the high power, extreme flexibility, absolute equalization, and the fact that it operates without physical exertion, stamps it as an outstanding contribution to motor vehicle transportation.

Electric Furnaces as Applied to Industrial Heating

The second speaker was D. E. Bridge, S.E.I.C., who took up the subject from an engineering and technical standpoint, reviewing some of the fundamental principles which should be considered in the design and construction of electric furnaces of various kinds; also giving a brief description of the construction and application of the more important types of furnaces.

The early progress of electric heating was retarded by the high cost of electricity, the low price of fuel and the lack of stable apparatus to which it could be applied. These handicaps have been largely overcome due to the increased cost of fuel, to the rapid development of water power which has greatly reduced the electrical rates, and to the development of dependable and efficient heating devices.

In an electric furnace the electrical energy is converted to heat for industrial purposes by:

(a) The Resistance Method.

(b) The Electric Arc Method.

Both of these methods have their applications with some overlapping, for example the resistance method operates more satisfactorily for temperatures below 2,000 degrees F. while the electric arc is used for high temperatures.

The resistance method includes all applications of electric heating where the heat is produced by an ohmic resistance. The heating may take place by direct resistance or indirect resistance.

For direct resistance heating the current flows in the material itself and is more or less limited to material of uniform cross-section. For induction heating the heating currents are induced in the material to be heated. The distinctive advantage of this type of heating is that the heat is developed within the material to be heated without a transfer of the heat across space and without terminals attached to the material being heated. The material in this case acts like the secondary of a transformer. Should the material being heated not be a conductor of electricity, the walls of the container may form the secondary of the transformer, thus producing the heat.

In the indirect resistance class of electric heating the material to be heated is independent of the resistor and heat has to be transferred across space to the surfaces to be heated either by conduction, by convection, by radiation or by a combination of any or all three methods.

The arc furnace is of two types, single-phase and 3-phase. The former is extensively used for the melting of non-ferrous metals and is of cylindrical shell construction with a refractory lining and having horizontal electrodes along the axis of the cylinder. Carbon electrodes are usually used as they produce the hottest arc although tungsten iron and nickel may be used.

The heat given to the charge is chiefly by radiation from the arc, although a part is by re-radiation and also conduction from the walls of the furnace. The transfer of heat is at a rate proportional to the difference of the fourth power of the absolute temperature of the hot and cold surfaces.

A homogeneous metal is obtained by stirring the alloy during the melting process. To do this the cylinder is rotated, thus exposing all parts more directly to the arc, washing the inner surface of the walls, cooling the refractory lining and preventing excessive volatization of the metal.

Due to the fact that the arc dies to zero every half cycle, and a considerable value of voltage is required to start it again, the current fluctuates. Stability of the current is obtained by placing a reactor in the primary side of the supply transformer.

The 3-phase arc furnace is quite similar to the single-phase furnace except that the electrodes are in a vertical position and in a triangular arrangement. During the melting the slag forms at the surface and serves as a shield to protect the molten metal from the high temperatures of the arc, thus limiting the volatization of the metal and acting as a temperature equalizer.

The essentials for an arc furnace are a transformer, a reactor, a circuit breaker in the primary circuit, an indicating wattmeter, a watthour meter, a motor for rocking the furnace, and a motor for the automatic adjustment of the electrodes.

A description of each type of furnace was given pointing out the application of each with its distinctive advantages and disadvantages from an engineering viewpoint.

Furnace atmospheres were discussed, especially the normal atmosphere, and the application of hydrogen, carbon dioxide, and methane atmospheres, at varying pressures.

The chief advantages of electrical heating were shown to be:

(1) Improvement of the quality of the product.
(2) Closer regulation of the temperature.
(3) Heating becomes. an exact science, no combustion temperatures entering into it.
(4) Elimination of rejects and the increase in production.
(5) Better conditions for the operators to work under.
(6) Reduction in fire and explosion risk.
(7) Perfect automatic control.

The Power Supply of Southern Vancouver Island

The last speaker of the evening was H. W. Blackett, Jr.E.I.C., who dealt with the power supply of southern Vancouver island.

The period of greatest expansion of the use of electricity in the city of Victoria and the neighbouring municipalities dates from 1902 when the total connected load was 500 h.p. By 1927 this had increased to 28,000 h.p.

At the present time, southern Vancouver island is supplied with power by two hydro-electric plants and one steam plant; the combined capacity of the former being 44,000 h.p., while the latter has a capacity of 6,000 h.p., and is used mainly as a standby to take care of peak loads.

Of the three plants, the first to be installed was that at Goldstream, some 13 miles from Victoria. The original installation consisted of two 600 h.p. Pelton wheels direct connected to 350 kv.a., 3-phase, 60-cycle, 700-volt generators. The powerhouse was subsequenly enlarged and the original equipment supplemented by a 1,000 h.p. single-runner Pelton wheel and a 2,000 h.p. double-runner machine driving a 500 kv.a., and a 1,000 kv.a., generator respectively. The power is transmitted to Victoria at 17,000 volts, two banks of 400 kv.a., air-cooled transformers being used to effect the transformation.

At the steam plant at Brentwood bay, water tube boilers are used supplying steam turbines direct connected to two 2,000 kv.a., 3-phase, 60-cycle, 2,300-volt generators. The plant is tied in to the 60,000-volt Jordan river network.

The source of the water used at the Jordan river plant is Jordan meadows, the area of the watershed being some 82 square miles. The water is conserved by means of two dams, one on Bear creek and the other on Jordan river itself. The dam on Bear creek is 55 feet high and 1,150 feet long, flooding an area of 285 acres. The diversion reservoir on Jordan river is of the Ambursen slab and buttress type, 128 feet high and 860 feet long, with a crest elevation of 1,286 feet above sea level. At the west of the dam are the outlet gates through which the water passes into the surge chamber and thence to the flume.

The flume follows the Jordan river valley a distance of about 5.3 miles to the forebay which acts as a balancing reservoir between the flume discharge and the intakes of the pipe-lines. The difference in elevation between the powerhouse and the forebay is 1,145 feet, giving a pressure of 497 pounds per square inch at the needles.

Two pipelines conduct the water from the forebay to the powerhouse. The first, 48 inches in diameter, extends part way down the hill to a "Y" piece whose outlets are 36 inches in diameter. From the "Y," two pipes proceed to the powerhouse with a diameter of 31 inches at the lower end. The other pipe is a single one from the forebay to the powerhouse. Of the three pipes entering the powerhouse the first two feed the 6,000 h.p. Pelton-Doble water wheels driving the two 4,000 kw., 3-phase, 60-cycle, 2,300-volt generators which comprise the original installation. The remaining large pipe feeds a double-runner 13,000 h.p. Pelton wheel direct connected to an 8,000 kw. machine of the same characteristics as the original units. The voltage is stepped up to 60,000 volts for transmission to Victoria.

During the past two years a fourth unit of 13,000 h.p. has been added to the main plant and a small plant of 2,000 h.p. has been installed at the diversion dam.

After the speakers had finished they were requested to withdraw while those present decided on the order of merit of the oral presentations. The vote put H. W. Blackett first and P. R. Adams second. All three papers are now being judged by the Branch Prize committee for subject matter and style. The prizes will be presented at the annual meeting of the Branch on May 6th.

The meeting was very successful but should have been better supported by the senior members, there being only twenty-five present, which included a large number of students. Those who were not present missed a very interesting and instructive meeting.

Lethbridge Branch

Wm. Meldrum, A.M.E.I.C., Secretary-Treasurer.

The Story of Steel

The Lethbridge Branch held its regular meeting on February 21st in the club dining room of the Marquis hotel, when Mr. G. B. Davies, Manager of the Lethbridge Iron Works, was the speaker of the evening.

A special musical programme was arranged and greatly enjoyed during the dinner hour, the programme being broadcasted over CJOC for the benefit of the radio fans. Miss J. McIlvena gave a very entertaining monologue, while Master George Brown and R. S. Lawrence, A.M.E.I.C., gave vocal solos. Master Clifford Palmer also gave a violin selection. Mr. Brown and his orchestra were in attendance.

During the evening the balloting for election of chairman, for the ensuing year, resulted in the very popular choice of Nat Marshall, M.E.I.C., provincial government boiler inspector.

The chairman, C. Clendening, A.M.E.I.C., then introduced the speaker, who gave a brief introduction to the six-reel motion picture on "The Story of Steel, from the Ore to the Manufactured Product." Mr. Davies pointed out that next to aluminium, iron forms the largest percent of the earth's crust of all the other elements. The many iron ore and limestone deposits and coal fields in America made it one of the largest producers of steel in the world. The early methods used to wrest iron from its ores were very crude, fuel and ore being piled in a heap in alternate layers, the fuel ignited and the wind acting as an artificial blast. There followed many contrivances for producing a blast until the building of the first furnace with tuyeres in Spain. From that time on there has gradually developed, by natural stages, the large blast furnace of the present day. The speaker drew special attention to the rapid progress that has been made in the mechanical inventions used for the handling of the iron from the time it is mined as iron ore through its long journey to the time it becomes a finished manufactured product.

The motion pictures of the United States Steel Corporation's plant at Gary, Indiana, illustrated the many mechanical devices that were used in the manufacture of steel products and the handling of ores, including underground and open pit mining.

At the smelter the ore and flux, limestone usually, and coke are charged into the blast furnace through a hopper at the top. The coke and limestone forms one layer, the ore forming another layer, the whole is supplied with air, under pressure, necessary for the combustion of the fuel, at the bottom. The speaker then described the modern blast furnace, its function and operation.

The handling of the blast furnace products was also described and a short account given of the Bessemer and open hearth processes, the materials used and the tests made on the resulting products.

The electrolytic purification of cast iron was briefly described and the method of rolling and forging steel ingots.

Rolling mills have undergone much development, with resultant increase of output and elimination of hand labour and consequently a greater safety to labourers.

Most standard sections—rails, I-beams, channels, angles, round and square bars, etc.—are produced in three-high mills with rolls of fixed centre distances and grooved to the special shapes.

Specialized lines of manufacture include plates, sheets, lap-weld pipe, barbed wire, woven-wire fences, cable, nails, tin-plate and galvanized iron, and a brief description was given of the methods used in manufacturing these.

The Branch was very fortunate in being able to obtain these most interesting and very educational pictures, and in having Mr. Davies to answer the many questions that naturally ensued.

A vote of thanks was tendered by G. S. Brown, A.M.E.I.C., to Mr. Davies and the programme committee.

Engineers' Close Season Meetings

On Saturday night at the Marquis hotel the members and affiliates of the Lethbridge Branch of The Engineering Institute of Canada held the last meeting of the season, under the chairmanship of C. S. Clendening, A.M.E.I.C. The meeting commenced with the usual dinner at 6.30 p.m. at the Marquis. During the dinner Mr. Brown's orchestra very ably entertained with appropriate music. The 46 present were also quite evident in the vocal attempts in community singing with a welcome variety put in by the solos of Mr. G. Evans and Mr. W. Meldrum.

The reading of the minutes of the last meeting, and the reading of the annual Secretary-Treasurer's report by Mr. Meldrum, was very well received and appreciation of Mr. Meldrum's splendid work for the season was shown by the hearty applause and unanimous passing of the report.

The chairman reviewed the progress during the past season, mentioning the excellent work of the various committees and the result of the purchase of the projector.

At 8.15 the meeting was addressed by Mr. Cottam, of the Baalim Motor Company Limited, on the modern gas engine. Mr. Cottam very ably reviewed the progress of the gas engine from the original one-cylinder 4-cycle type to the present day including 2, 3, 4, 6 and 12 and 16 cylinder engines. He also indicated the reason for the increase in the number of cylinders whereby the increase of overlap of the power stroke due to the increase of all cylinders gave smoother operation.

Moving picture reels operated on the new projector by Mr. Cyril Watson showed very clearly the manufacture of the 6-cylinder motor from pig iron to the finished product. The moulding, casting, boring and honing of the cylinder block was shown in a very clear manner. The stamping of oil pans and forging of crank shaft and timer shaft all showed the effect of modern heavy presses and forging machines enabling manufacturers to produce cars at prices decreasing much more rapidly with average commodities prices.

The unceasing inspection was shown to be necessary to control the sizes and weights of the parts of the modern motor including the cylinder, crank shaft, drive shaft, connecting rods, pistons, etc. A number of questions were asked Mr. Cottam, and after able answers, G. N. Houston, M.E.I.C., moved a hearty vote of thanks.

Due to recent bereavement, the recently elected new chairman, N. Marshall, M.E.I.C., was not present and the meeting was presided over by Mr. Clendening, the retiring chairman. The result of the ballot gave the new Executive as Messrs. J. Haines, A.M.E.I.C., R. Livingstone, M.E.I.C., J. B. de Hart, M.E.I.C., N. H. Bradley, A.M.E.I.C. In addition the executive would be ably assisted by the retiring chairman, Mr. Clendening, the Councillor, Mr. Houston, and the Secretary-Treasurer, Mr. Meldrum.

It was not expected that any regular meetings would be held until the fall, but mention was made by Mr. Sauder of two or three construction jobs in the vicinity which might profitably be visited by members of the Branch in summer field tours.

London Branch

Frank C. Ball, A.M.E.I.C., Secretary-Treasurer.
John R. Rostron, A.M.E.I.C., Branch News Editor.

Railway Signalling

The County Council chamber, where the regular monthly meeting was held, was crowded to capacity to hear Mr. C. H. Tillett, Signal Engineer, Central Region, Canadian National Railways, speak on the subject of "The Purposes of, and Methods Employed in Railway Signalling."

The meeting was held on February 18th, under the chairmanship of the newly elected Branch chairman, W. Raywood Smith, A.M.E.I.C., and was attended by members of the Branch, C.N.R. officials, and a large body of electrical students from the technical school.

The chairman, in opening the meeting, pointed out that as this was the first meeting over which he was to preside he would like to make a few remarks with regard to his proposals for the year's programme. Under the regime of former chairmen, papers had been given and engineering works visited more or less synchronizing with the particular branch of engineering in which the various chairmen had been engaged. In his case, as township engineer, he was very much interested in re-afforestation and he proposed to promote interest and advancement along these lines during his term of office. He pointed to the present condition of Middlesex county where many wells were dry and the farmers were put to great expense in transporting water—sometimes of doubtful quality—from the nearest river or stream. This condition, he maintained, could largely be prevented by the proper proportion of bush and undergrowth and it would also have the effect of promoting an increased yield from the surrounding land. He quoted figures to show that while 10 per cent of bush land was considered ideal with 5 per cent the minimum, Middlesex had less than ½ of 1 per cent of bush land. He gave instances to show where land which was sheltered from the dry arid winds of summer in this manner yielded richer and larger crops than land not so protected and furthermore the ground supply of water was conserved. Of course, the undergrowth in the bush should be preserved by keeping cattle out. After these remarks, Mr. Smith called upon Mr. J. Piggott, Superintendent of the London Division, C.N.R., to introduce the speaker.

Mr. Tillett commenced with an illustrated description of the old mechanical means of operating the signals and switches by wires and rigid rods from signal cabins. The distance from the cabin at which signals and switches could be worked was of course limited, but it must not be supposed that these systems were obsolete; on the contrary, they were still in operation in many places. However, they were gradually giving way to the electrically controlled and automatic devices, as the facility and reliability of the latter are being demonstrated.

The whole principle of the automatic control was based on what is called the track circuit in which the electric current travels along each rail in the section or area desired and the circuit is completed by the contact of the wheels and axle of any vehicle entering the section.

On the completion of the circuit an electro-magnet becomes active and attracts a small relay switch which sets the machinery in motion for the operation of the semaphore arm, or the light, or switch as the case may be. As the train passes out of the section the circuit is again broken and the original order resumed. At junctions, crossings, passing sidings, etc., complications and duplex situations arise but the track circuit is the fundamental principle of operation. The power machinery for operating the various units is of various types, electric, pneumatic, and in some cases soda-water gas. The two former are most generally used but the electric motor was, he thought, coming into more general use. Views were shown of different types of semaphore arms with their attendant light arrangements for night time. However, these are now being replaced by lights only, as by means of special lenses these can be made sufficiently powerful for use in the daytime even in the strongest sunlight. Views were given showing the various systems of light signals, some with three lights—green, yellow and red, alternately—and others (and newer types) of only one light which gave the necessary colours as required.

In the former there are three lenses with the separate colours to each while in the latter only one lens with the operating automatic device simply controlling the colour elements and the light. Views were shown of the motors controlling these operations which, in turn, were controlled by the relay switch formerly mentioned; also illustrations were given of the machinery—mostly compressed air—for operating the ground switches of the tracks and electrically controlled either from the track circuit or a distant station. Regarding the latter, cut-out systems were shown by which, if necessary, the switches could be operated by hand. Also interlocking devices were shown, which make it impossible to operate a switch when a train is too near or passing over it. The speaker outlined the next advance in automatic signalling, viz. that of having the light signals in the engine driver's cab instead of or in addition to the fixed signals by the track side. These are in use at present, but not extensively, and views were shown of the attachment on the engine which is operated by a device connected with the signal control and which is situated close to the rails and with which contact is made by the attachment on the engine. Should the signal be at danger this machine also puts the brake in action on the train and so automatically stops it, or puts the driver on guard.

This electrical operation of signals and switches had the effect of greatly extending the mileage of track under the control of one despatcher and illustrations were given of the modern despatcher's board. Lengths of track of 40 or 45 miles are controlled by one despatcher, the position and direction of each train being indicated on a diagram on the board and the signals and switches operated by the control levers on the same board.

When the new Brantford cut-off on the main line of the C.N.R. has been completed a central traffic control station will be erected at Paris junction and switches and signals of the double track at either end of the cut-off will be operated from this central signal station and in this way the movements of all trains controlled from it.

As many as 37 units, signals, switches, etc., can be controlled over two wire lines by what is known as the codal system. Many of the installations shown were located on various railways in the United States and in this category the speaker gave an illustrated description of what is known as "hump" shunting into sorting siding yards. In this process the cars are shunted over a high spot on the tracks and run by gravity into the sidings, laid out fanwise, on the lower level. Again this operation is electrically controlled; at the neck of the fan-shaped group of sidings a control cabin is situated and all the switches into the numerous sidings are controlled from it. As each car or group of cars is shunted by the engine past this cabin the operator sets the various switches which will take the unit into its proper siding. It will be understood that in many cases these cars gain too much momentum by gravity and would run out of the siding at the bottom end if not slowed down. This operation was formerly accomplished by men stationed at various points who, when necessary, applied the brakes on the cars in motion. This was a dangerous operation, but it is now done away with and the cars are slowed down by "retarders" which are electrically operated from the control cabin. These retarders consist of solid strips or plates of metal fixed on each side of the rail and extending for a considerable distance along it. They may be said to form a jaw for the whole length of the plates and standing a few inches above the rail. When in action these jaws grip each side of the rims of the wheels of the cars and so retard them in passing.

The latter part of the speaker's talk was devoted to the matter of level crossing protection. He favoured the wig-wag system and gave a detailed description, with the aid of blackboard sketches, of the automatic operation of these signals by means of the track circuit.

He strongly stressed the necessity of motorists waiting till the wig-wag signal stopped before attempting to cross the tracks, particularly where there was more than one track. If a motorist started up immediately the train had passed there was always the danger of another train or engine approaching unseen and unheard.

In the discussion, many points were brought up showing the interest which the subject had aroused. One of these points was the possible derangement of the electric equipment through flooded tracks after heavy rainfall. The speaker admitted that this contingency was a source of trouble but it was gradually being overcome. He stated, however, that there was no danger from this cause, but only possible delay, inasmuch as when any derangement of the apparatus occurred from this or any other cause the signals affected reverted to danger and traffic was stopped.

Chas. Talbot, A.M.E.I.C., county engineer, stressed the need of adequate level crossing protection and in his opinion "Stop" signs should be provided and fixed on the highways at all level crossings. In furtherance of his argument he cited the case of side roads leading on to through roads where by the sign the motorist was compelled to stop (although he could see there was nothing coming on the highway) or run the risk of being hailed up by some police officer. The railway was a through road just as much as any highway and a far more forcible one in the sense that a motorist on the highway might be able to avert a collision while the engine driver on the railway was unable to do so. He also advocated special measures for removing obstacles at these crossings which interfered with clear visibility.

Several others commended the speaker for his discourse and a hearty vote of thanks was ably proposed by D. M. Bright, A.M.E.I.C., consulting engineer, London, and seconded by G. E. Martin, A.M.E.I.C., assistant engineer, department of Public Works, western Ontario.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

Annual Meeting

On January 8th the annual meeting of the Montreal Branch was held. The reports of the retiring Chairman, D. C. Tennant, M.E.I.C., and of the executive were read. Then following the report of the Nominating committee the new Chairman, A. Duperron, M.E.I.C., took over the chair.

J. L. Busfield, M.E.I.C., then introduced a motion covering a recommendation to Council that they should exercise more freely their power to waive examinations in the case of applications for Associate Membership. After considerable discussion pro and con the motion was finally put and carried by a vote of 36 to 31.

After the meeting was adjourned refreshments were served in the reading room.

Diesel Electric Suction Dredge

Mr. B. G. Flaherty, chief engineer for the General Dredging Contractors Limited, addressed the Montreal Branch on January 15th on the subject of the new Diesel electric suction dredge—"General Brock."

In describing the equipment of this most modern dredging plant Mr. Flaherty pointed out that with the existing low first cost of Diesel engines it was now found more economical to use this form of motive power in place of steam engines for requirements below 5,000 h.p. The power plant on the "General Brock" consisted of Diesel engines direct connected to D.C. electric generators which in turn supplied the necessary current to D.C. motors driving the pumps and other equipment.

I. J. Tait, M.E.I.C., occupied the chair.

The Lighthouse Service of Canada

A most interesting address was presented before the Montreal Branch on January 22nd by J. G. Macphail, M.E.I.C., Commissioner of Lights in the Department of Marine at Ottawa. His subject was "The Lighthouse Service of Canada" and with the assistance of slides and moving picture films, Mr. Macphail presented a most realistic picture of the wonderful work carried out by this branch of the service.

Most of us, no doubt, consider, that we have a fair realization of the size of this vast country of ours but even so it must have come as something of a surprise to learn that Mr. Macphail's department was responsible for the protection of no less than 50,000 miles of coast line extending from Sable island on the east to the Queen Charlotte islands on the west. The aids to navigation which number over 12,000 comprise lightships, lighthouses, buoys of every description and fog signals. In this connection Mr. Macphail paid tribute to the pioneer work done by Canada in the invention and development of the diaphone, a siren used for giving warnings through fog which was now in service in practically every country in the world.

The personal side of the work was not overlooked and a very sincere tribute was paid by the speaker to the honesty, devotion and fortitude of the hundreds of men, women and children who are engaged in the lonely and arduous tasks of the service.

The Chairman of the Branch, A. Duperron, M.E.I.C., presided.

The British Grid

The January 29th meeting of the Montreal Branch marked a unique and most interesting development in engineering achievement when a capacity audience was addressed by Mr. Clifford C. Patterson, O.B.E., President of the Institution of Electrical Engineers, speaking from London, England.

Unfortunately a severe atmospheric disturbance earlier in the week made reception very difficult. However, with the assistance of printed copies of the paper and the slides it was possible to follow the speaker's remarks throughout. The two-way communication established between the headquarters of The Institute in Montreal and Mr. Patterson in London was made possible through the co-operation of the British Post Office, Imperial and International Communications Ltd., Canadian Marconi Company and the Bell Telephone Company of Canada.

Mr. Patterson chose as his subject for this important paper, "The British Grid," and was introduced to the audience by Julian C. Smith, M.E.I.C., who occupied the chair. The greetings of his organization and colleagues were first conveyed by Mr. Patterson, after which he referred briefly to the Faraday Centenary to be celebrated in London next fall.

Acting upon the authority of the Parliament of Great Britain, a committee headed by Lord Weir had organized a scheme for the national supply of electricity. Under this arrangement the generation of electrical energy was concentrated in some 130 selected stations each supplying the area in which it was located and all connected together by means of a complete system of transmission lines into a network or "grid" covering the whole country. This "grid," it was explained, was not so much a huge transmission line as a system of bus-bars, through which the generating stations are kept running in synchronism and in parallel with each other and through which equalization of load could be effected.

At the close of the paper the thanks of the meeting were conveyed to the speaker by Mr. Smith and brief discussions were offered by Messrs. R. A. Ross, M.E.I.C., and John Morse, M.E.I.C.

Niagara Branch

Paul E. Buss, A.M.E.I.C., Secretary-Treasurer.

One of the regular dinner meetings was held at the Leonard hotel, St. Catharines, on Feb. 26th, with Dr. R. W. Boyle, M.E.I.C., of Ottawa, as the speaker. About thirty members and guests were present.

The Engineer in the Nation

Dr. Boyle, who is Director of the Physics division of the National Research Council at Ottawa, has had ample opportunity for the study and analysis of the engineering complex. The theme for his address was the result of close analytical studies made into the life, manner and habits of engineers—both embryo and mature. His opportunities for these studies were wide and varied and he had come to the conclusion that engineers were psychologically different from the rest of mankind. Science students were characterized by soundness, sanity and common sense but they did not appear to take a great part in the social life of the university. They preferred to delve into the origin of things and discover fundamental truths. In consequence of this concentration they became retiring and lost much of that faculty of oratorical expression which is so highly recognized and rewarded by the present-day world.

All of the great advances in civilization have been made in the realms of pure and applied science, so that engineers have no cause to be ashamed of their profession. Art, philosophy and law have barely moved since the Grecian era and politics, ethics or economics have retrogressed if anything. The half-truths with which these pseudo-sciences deal and are largely based upon have no place among the exact values which are demanded by the true engineer.

Such being the case it is the engineer's own fault if he is not recognized. He is very often over-trained and under-educated and if he wants to succeed as a world-builder he must forsake the straight, narrow path and be content with the half-truths which were formerly scorned. (See page 713 Eng. Journal, Dec. 1930).

Dr. Boyle did not follow his remarks to the logical conclusion and state just what might happen to science if it's devotees forsook intensive training for worldly pursuits. Probably he preferred his hearers to figure that point out for themselves.

At C. G. Cline's suggestion, Dr. Boyle gave a short resumé of the Research Council's activities. Plant pathological studies were centred in Alberta, timber researches in British Columbia and T.B. studies in Quebec. The new building in Ottawa will house four main divisions, namely the Bureau of Standards, Department of Inventions, Industrial research and lastly pure science.

A Journalist on the R 100

At the meeting of the Branch held at St. Andrews Hall, Thorold, Ont., on March 6th, Mr. Thomas Wayling, free lance journalist of the Press Gallery at Ottawa, was the speaker, the subject of his address being "A Journalist on the R 100."

Mr. Wayling gave a most interesting description of life on board the R 100 from the time the ship left St. Hubert, Que., on August 13th, until it reached Cardington, England, fifty-seven hours later.

Prior to the address a dinner was served, the attendance being about seventy-five, and many others attended the lecture. Members of the flying club were also present.

Walter Jackson, M.E.I.C., was in the chair, and John C. Moyer, A.M.E.I.C., introduced the speaker.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Joint Meeting With United Service Institute

At the Chateau Laurier on March 12th a noon luncheon was held under the joint auspices of the local branch of The Engineering Institute and the United Service Institute of Ottawa, at which Commodore W. Hose, C.B.E., R.C.N., spoke upon the subject of "Naval Conferences in the Scheme of Armament Reduction and Limitation." The meeting was presided over by G. J. Desbarats, C.M.G., M.E.I.C., chairman of the local branch of The Engineering Institute, who called upon Colonel J. G. Rattray, president of the United Service Institute, to introduce the speaker. In addition, at the head table there were the following guests: Major G. H. Brown; Major K. Stuart, A.M.E.I.C.; Dr. J. A. Amyot; John McLeish, M.E.I.C.; Dr. R. M. Stewart, M.E.I.C.; Group Captain E. W. Stedman, M.E.I.C.; F. H. Peters, M.E.I.C.; Commander C. T. Beard; Admiral Sir Charles Kingsmill; Commander H. B. Hynes, R.N.; L. B. Pearson; Lieut.-Col. H. D. G. Crerar; Dr. Charles Camsell, M.E.I.C.; Colonel J. L. H. Bogart, A.M.E.I.C.; D. Barry, A.M.E.I.C.; V. Lawson.

Commodore Hose in his address briefly outlined the various efforts made by the great powers since the armistice toward working out the problem of naval limitation. "The avowed object," he stated, "of all governments since the armistice has been the production of a system for the settlement of international disputes which will eliminate war as a final recognized arbiter."

Complete disarmament is impracticable at the present time. Nations, for their own security, must retain sea, land and air armaments, but these should be reduced to figures essential to self-preservation only, until such times as the international machinery of investigation, discussion and, if necessary, economic and military assistance can be brought to bear by other powers.

In his address Commodore Hose endeavoured to show where the various naval conferences and discussions have been of practical value in the naval sphere towards attaining the main objective—security against the scourge of war. He characterized security as of two kinds: first, "preventive"—security against the possibility of war breaking out; and second, "bellical"—security of a nation already embroiled in war. The real difficulty has been to strike a true balance between these two types of security.

The speaker stated that the years from the armistice to the present day, so far as naval limitation was concerned, could be divided into three periods, these periods being marked with four special major obstacles to the attainment of mutually agreed naval limitation. They were, first, the period up to the Washington conference; second, that between the Washington conference and the London Naval conference of January, 1930; and, third, the period subsequent to the last mentioned conference. The four problems were: the problem of the first period of "bigger and better battleships"; second, the problem relating to parity with the United States resulting from the terms of the Washington conference; third, the question of limitation of naval forces by their "global" or total aggregate tonnage and their global tonnage subject to categorical designation. The fourth problem was the matter of parity between France and Italy which has more recently come to a head.

A brief résumé of the efforts toward limitation during these three periods was then given. The five great naval powers—Great Britain, United States, Japan, France and Italy—attended the Washington conference and arrived at a ratio in actual capital ship allotment, which in brief was fixed as follows with the powers in order as named—5: 5: 3: 1⅔; 1⅔; the actual tonnage allowed Great Britain being 525,000 tons. An important political result was also attained in the "Quadruple Pacific Treaty" whereby the four powers interested in the Pacific ocean agreed to respect each others' insular possessions there, and to meet in joint conference in the event of any controversy arising which could not be satisfactorily disposed of by arbitration.

Following the Washington conference there was much in the way of conversations carried on between the powers relating to the question of the interpretation of its provisions. The obstacle mentioned above as the second of the four problems, namely the matter of parity between the naval forces of the British Empire and the United States, came to a head. The question of respective relative strengths in capital ships and aircraft carriers had been arrived at, but agreement as regards cruisers, destroyers and submarines was unattainable at the time.

The next particular naval phase was the third session of the Preparatory commission for the Disarmament conference. At this third session the third big obstacle to agreement came to a head. This difference of principle was found to be irreconcilable and the session terminated after an unacceptable measure of compromise was put forward.

The next naval conference was the Coolidge Naval Conference at Geneva in June, 1928, which lasted six weeks. Of the five powers, France and Italy declined to participate, although they sent observers.

This conference was not entirely successful and as an aftermath Great Britain "marked time." The United States introduced a bill which, after modification, was passed by the Senate on February 15, 1929, and which provided for the construction of fifteen big cruisers.

What the fate of this bill would have been had it not been for another set of negotiations which were going on in Europe, can only be left to speculation. By these negotiations between Great Britain and France an agreement was reached which settled between themselves the fundamental difference between global and categorical systems of limiting naval armaments. This agreement was communicated to Washington, Rome and Tokyo in July, 1928.

The London Naval Conference was called for January, 1930, at which the five naval powers attended. It lasted three months. An immense amount of technical detail was discussed, and agreement reached as to the classification, definition and individual limitation of the various types of warships. At this conference a general agreement extending to the five powers was also reached regarding global and categorical systems of limitation. Mutually agreed total tonnage figures for each and every category was accepted and inserted in the treaty for the three powers of Great Britain, United States and Japan.

Unfortunately, however, the problem of Franco-Italian parity was still left over, and consequently actual tonnage figures to be inserted in the accepted table of naval strengths were unobtainable from France and Italy.

Within the past few days the text of the Franco-British-Italian naval accord has been published, and all the world has been led to hope that this difficulty need no longer be a bar to the efforts being put forward toward naval limitation.

Peterborough Branch

F. G. A. Tarr, S.E.I.C., Secretary
B. Ottewell, A.M.E.I.C., Branch News Editor.

Research Problems in General

The ever-interesting subject of research, with particular reference to the work of the Ontario Research Foundation, was presented to the Branch in a very able address by Mr. O. W. Ellis, on the evening of January 22nd, 1931.

In introducing the speaker, chairman W. E. Ross, A.M.E.I.C., mentioned that he received his early training in England, with the Great Western Railway. He was a graduate of Birmingham university, and first came to this country in 1910. Mr. Ellis was for some time a professor of engineering at the University of Toronto, and subsequently with the Research department of the Westinghouse Company. He received his present appointment as director of metallurgical research, Ontario Research Foundation, Toronto, some two years ago, when it was established under the chairmanship of Sir Joseph Flavelle, with Dr. H. B. Speakman as director.

Research on such widely different subjects as packing house problems, chemical engineering, the woollen industry, farm economics and metallurgy, is carried on by the Foundation.

The metallurgical division co-operates with a group of manufacturers known as the Ontario Metal Industries Research Association, and as the results obtained are available to the members of the Association only, Mr. Ellis explained that he was not permitted to describe them in detail.

Referring to the work of this division up to the present as having been mostly for the purpose of locating the source of trouble rather than fundamental research, the speaker stated that during 1930 some forty-four problems and eighty enquiries had been handled.

As particular examples of some of the investigations carried out, Mr. Ellis mentioned the effect of nickel on bronze, on the improvement in yield point with the somewhat erratic tensile strength; and also the increase in the strength of metals, particularly copper and steel with cold working.

Another interesting subject dealt with was tin base bearing metals, extensive tests being made in compression, microstructure, Brinell hardness, etc., for a wide range of alloys.

Other investigations included the brittleness of silicon steel sheet, and the effect of oxide in brass on the mechanical properties. The many interesting methods employed and the general results obtained were described and well illustrated by diagrams and slides.

After answering a large number of questions following his address, Mr. Ellis was accorded a very hearty vote of thanks.

Water Supply and Sewage Treatment

On several previous occasions the Branch has been favoured with addresses by William Gore, M.E.I.C., of Messrs. Gore, Nasmith and Storrie, consulting engineers, Toronto, and was therefore prepared for an interesting talk on the above subject at the regular meeting on February 13th, 1931.

Ross Dobbin, M.E.I.C., as chairman, introduced Mr. Gore.

With the aid of a large number of fine lantern slides, the speaker described modern trends in construction of works for water supply and sewage treatment. He emphasized the similarity in processes and that both branches are intimately related to health and to each other.

The stream, river or lake drainage systems of the country are the sources of municipal water supplies and such waters after use are again returned to the drainage systems possibly to be used again for water supplies. For this and other reasons the safeguarding of streams from excessive contamination is a public charge of considerable importance.

It is realized, however, that surface waters at least cannot be secured entirely free from contamination and purification processes, sometimes very elaborate, are essential to treat modern water supplies in order to secure waters that are clear, sparkling, safe and palatable. This can only be provided if the sources are relatively pure; otherwise the purification processes may become over-loaded and the filtered water unsafe. Generally speaking the larger the works the greater the difficulties experienced.

Sewage treatment works are required so that the streams and other surface waters shall not become heavily contaminated and otherwise objectionable in odour or appearance. In this connection great difficulties have been experienced in preventing such treatment works from becoming nuisances in themselves and intelligent, scientific operation is required to prevent this as well as to prevent stream contamination.

An active discussion followed, and the speaker was tendered a cordial vote of thanks.

Radio Direction Finding as an Aid to Navigation

One of the most interesting and entertaining addresses ever given to the Peterborough Branch was presented by Commander C. P. Edwards, A.M.E.I.C., Director of Radio Service, Department of Marine, Ottawa, on February 26, 1931. The speaker was introduced by W. E. Ross, A.M.E.I.C., chairman of the branch, who in stating that this was the Commander's first visit to Peterborough was, strictly speaking, not making allowance for the fact that the lecturer passed over the city in the British dirigible, the R 100, on the occasion of its Canadian tour last summer. Commander Edwards' style of narrative is conversational and extremely humorous with nothing suggestive of the professional lecturer.

The address was illustrated by a large number of slides and was followed by a showing of some fine moving pictures of the visit of the R 100 to Canada last year.

By way of emphasizing that navigation is not an exact science and that even with the best of instruments and most skilled navigators ships occasionally go ashore, a number of photographs of wrecks were first shown. The speaker then proceeded to outline the development of radio direction finding as an aid to navigation. The ordinary straight aerial being non-directional is useless for this purpose hence the early use of the loop aerial, giving the "figure 8 diagram" or signal strength proportional to the cosine of the angle. The ordinary small movable loop was however at that time, some 20 years ago, not sensitive enough, and to overcome this Bellini and Tosi invented a large antenna with two fixed loops at right angles from which the signals were transferred to a small movable loop beneath.

Other difficulties encountered were the "vertical antenna effect" of the loop aerial, overcome by the shielded transformer and balancing methods, and the direct reception effect of the set itself, now eliminated by enclosing all parts in metal boxes.

The determination of the sense of direction, while not necessary for land stations, is important for ships receiving at sea, and is accomplished by the use of an auxiliary vertical antenna or its equivalent. This combination produces the "heart" shaped diagram, with minimum signal strength shifted 90 degrees, from that of the "figure 8" diagram.

Errors due to refraction as the radio waves pass over land near coast stations were illustrated by diagrams for typical Canadian stations on the Atlantic coast, the necessary correction factors being determined by transit.

Reflection from the "heaviside layer" at night is another disturbing element, which can however usually be detected by skilled operators.

Ships bearings determined by the intersection of lines from two radio stations, known as the "cocked hat," are guaranteed within plus and minus one degree and usually come much closer than this.

In the early days of direction finding, D.F. instruments aboard ships were not as accurate as those on shore, but of late years tremendous improvements have been made in this apparatus and the whole trend of the art for the past few years has been the use of ship direction finders in conjunction with automatic radio beacons on shore. These beacons might be described as 75 mile lighthouses. The Canadian type work automatically once an hour for six minutes in fine weather and once every three minutes in thick or foggy weather. They are located at strategical points and ships can take their bearings therefrom at any hour of the day or night long before they are in sight of land. Seventeen of these automatic beacons have so far been established in Canada.

Commander Edwards stated that the first D.F. station was erected in Canada in 1917 and there are now twelve such stations with some sixty operators. On the Hudson Bay route navigation is entirely dependent on D.F. stations, as there are no lighthouses or fog alarms.

The great value of this work in assisting navigation and consequently as a means of saving life, was stressed by the speaker. Thousands of bearings annually are given by stations such as Saint John, N.B., and Cape Race, Nfld.

At the conclusion of his talk Commander Edwards showed several reels of moving pictures of the R 100 during its landing at Montreal last summer and gave a fascinating personal account as a passenger, of its voyage over Ontario.

A. B. Gates, A.M.E.I.C., moved a vote of thanks to the speaker which was heartily endorsed by all present.

Students and Juniors Meeting

A very successful "Students' and Juniors' night" was held on Thursday, March 12th, the arrangements being in the hands of D. J. Emery, S.E.I.C., who also acted as chairman for the meeting.

Papers were presented by H. Ainsworth, non-member, H. E. Barnett, Jr.E.I.C., and T. Woodhall, S.E.I.C., and are summarized as follows:—

Synchronized Sound and Screen, by H. Ainsworth

A short résumé of the principles of sound, involving the loss of energy, pitch or frequency and resonant frequency as important features in the production of "talkies" was given.

The equipment was divided into two parts, the recording and reproducing equipment. Each part consists of two corresponding types, namely disc and film systems.

Disc recording was dealt with first. The pickup is effected through a capacity microphone, amplified and recorded by an electro-magnetic recorder on records. Characteristic curves for recorders were shown. The film recorder, using similar pickup and amplifiers, was described in more detail, and characteristic curves and a comparison of the two types was made. The different systems of monitoring the two recording systems was dealt with.

The reproducing equipment was next described, including the various integral parts. The record was discussed giving reasons for its size and speed of rotation also curves showing the effect of successive playings. After discussing the magnetic disc pickup, the characteristic curves were shown for various types in use. The film pickup equipment and its characteristic curve was then dealt with. The last individual part of the equipment was the horn receiver, types and characteristic curves of which were described. Mention was made of the types of screens and horns that are used.

The theatre installation as a unit was then discussed and a wiring diagram of a typical theatre installation was shown.

Selectivity Without Distortion Using Band-Pass Filters,
by H. E. Barnett, Jr.E.I.C.

One of the main advantages of radio communication is the ability of the transmitting medium — the ether — to carry a large number of messages simultaneously. This is essentially due to the fundamental properties of the tuned circuit.

To obtain undistorted reproduction, a certain band of frequencies must be amplified and transmitted from stage to stage of the receiver in equal proportions. It is usually considered that if frequencies within five kilocycles of the carrier frequency are equally reproduced the quality of reproduction will be good. To pass this band of frequencies, using simple tuned circuits the resistance of the circuit must be considerably above the minimum, limiting amplification, and to obtain adequate selectivity several stages of radio-frequency amplification are necessary.

Now that transmissions are becoming more powerful and more numerous and their carrier frequencies are closer together—it may often happen that an unwanted signal produces a greater first stage voltage than the signal to which the set is tuned. If the wanted signal is fully loading the first valve, the unwanted signal will in part be taking the first valve off the straight portion of its characteristic. Then partial rectification of the unwanted signal ensues, and the desired signal has impressed on it an audio-frequency modulation, which is unaffected by successive tuned circuits and is amplified with the desired signal.

Under such conditions the only satisfactory solution is to use a tuning arrangement in the first circuit having a response curve with a fairly flat top over the 10 K.C. band to be transmitted and steep sides.

Coupled tuned circuits, variously known as pre-selectors, band-pass filters, or 3-circuit tuners, have a characteristic response curve with two resonant frequencies. The coupling impedance may be capacity, inductance, mutual inductance, or any combination of these. To obtain constant peak separation (constant width of band of transmitted frequencies) the coupling impedance must vary with frequency in a definite manner. The speaker showed that, excluding mechanical devices to this end, which have practical disadvantages, this condition cannot be fulfilled by capacity or inductance, alone, or in series or parallel, but a combination of capacity in series with negative mutual inductance, can, for very definite values of its constants, depending on the other constants of the coupled circuits, give almost constant peak separation over a wide range of carrier frequencies.

The disadvantages of the double-humped response curve in actual use, can, if desired, be corrected by the use of a tuned anode stage following the first valve, without impairing quality of reception.

The use of reaction with this type of tuning does not introduce high-note loss as in ordinary circuits, but accentuates the high notes, making reproduction more than usually brilliant. It also increases selectivity to a certain point by increasing the steepness of the sides of the response curve, but if used to excess would separate the tuning peaks so much that low notes would be badly reproduced and selectivity would be impaired by making the transmitted band too wide.

Photo-Electric Cells, Their Theory and Application,
by T. Woodhall, S.E.I.C.

The subject was introduced through reference to the wider field of electronic cells including both the thermionic and light-sensitive type. The law governing the liberation of electrons from a material was reviewed with reference to Einstein's equation. The effect of the wave length of the light energy on the response of the material was discussed, only the alkali metals being responsive in the visible spectrum.

Photo electronic cells were classified under the following types: Photo Conductive, Photo Voltaic, Phototube, with a short description of each.

The phototube was then enlarged upon as the most used at the present time. The sensitive material of which the cathode is made was discussed as to its requirements and the means of meeting these. The effect of filling the cell with gas was also considered. The amplifiers used with the photo tube were stated to be of two kinds, those employing the 3-electrode vacuum tube and those employing the grid glow tube, the characteristics of each being given.

The ideal properties of a photo electric cell were outlined as: Sensitivity, Speed of Response, Linearity of Response, Reproducibility, Colour Sensitivity.

A short reference was then made under these heads to the present day type of cells.

In reviewing the industrial applications the following classifications were made, with reference in each case to the type of cell used.

(1) The control of a process and the indication of an event or condition; as in automatic manufacturing methods, traffic control, smoke detection, burglar alarms, etc.

(2) The quantitative translation of variation of light intensities into corresponding variation of current in an electrical circuit; reference being made to the talking picture and television field.

(3) The replacement of the human eye in the evaluation of light intensity and colour determination; as exemplified in photometry and colour standardization.

In concluding, the wide field open to the application of the photo electric cell was stressed, with a prediction that human operators would in the future be relieved of routine work dependent on the eye.

An active discussion took place on each paper, after which the thanks of the Branch were tendered to each of the speakers by B. L. Barns, A.M.E.I.C.

Saint John Branch

A. A. Turnbull, A.M.E.I.C., Secretary-Treasurer.
(Reported by F. M. Barnes, A.M.E.I.C.)

AIR TRANSPORTATION

The regular monthly meeting of the Saint John Branch of The Engineering Institute of Canada was held at the Admiral Beatty hotel, Saint John, N.B., February 18th, 1931, at 8 o'clock p.m.

W. J. Johnston, A.M.E.I.C., chairman of the Branch, presided. The meeting was open to the public and there was a large attendance of members of the Branch, also the Saint John Flying Club and the Civic Division of the Board of Trade, to hear Captain A. F. Ingram, general manager of Canadian Airways Limited, give a talk on "Air Transportation."

The address was broadcast from Station CFBO, Saint John, N.B.

Captain Ingram in his opening remarks mentioned that Great Britain, at the end of the war, was supreme in the air, and that over 60 per cent of the British Air Force were young Canadians, 90 per cent of whom gave up flying at the end of the war because commercial aviation in Canada had not come into its own and there was insufficient capital available to promote aviation companies. There were, however, small companies endeavouring to operate at this time, but eventually these succumbed and went into liquidation. A few of these pioneer companies did very well in the north country carrying freight and passengers for mining and prospecting companies in remote districts.

During the last few years the Dominion government has inaugurated air mail routes, competing against competent rail service in populated districts where difficulties were met with in endeavouring to improve the service. This was not the case in remote districts. Take, for instance, mail service along the north shore of the gulf of Saint Lawrence, which by the old method required about one month, is now accomplished in three and a half hours flying time. Also the case of the Magdalen islands. The people on the islands were, previous to the advent of air mail service, practically isolated during the winter months, due to ice and storm conditions. The Christmas mail for 1930 was delivered February 18th, 1931, the mail plane taking off from the Moncton airport and making two trips on February 18th and 19th, the delay being due to bad weather and the inability to land. In order to expedite this service, night flying is now being carried on between Winnipeg and Calgary, a distance of 1,200 miles.

During the transition period of freight carrying by the railways of the Dominion and the inauguration of the motor truck as a competitor on the highways, the railway companies did not appreciate the effect motor transport would have on their freight business and neglected taking part in the advancement. This was not the case in air transportation. The railways were not going to miss the opportunities offered by air transportation. When the merger of the several companies were brought under one control, the two large railways in Canada took an equal share in the company with President James Richardson, Winnipeg, and Vice-Presidents E. W. Beatty of the Canadian Pacific Railway and Sir Henry Thornton, M.E.I.C., of the Canadian National Railways. Many prominent financial and business men in most of the large cities throughout the Dominion are on the directorate, the real object being to put aviation in Canada on a sound basis and ultimately to have a transcontinental air mail service from Halifax to Vancouver; also during the season when the straights of Belle-Isle are open to navigation to have especially designed aeroplanes meet the mail steamers at Belle-Isle, take on mail and passengers and save at least two days time between Belle-Isle and Montreal.

Captain Ingram spoke inspiringly of the efforts made to build a civic airport at Saint John, portions of which have actually been carved out of solid rock, abundance of which is prevalent in this locality.

Lantern slides of an educational character were then shown on the screen which had been taken in a number of the larger aviation centres of the United States.

Maps of Canada and the United States showing air mail routes were also shown. Chicago and Montreal appear to be the centres of aviation in North America at this stage of development. Moving pictures were then screened, showing some wonderful scenic views of the Rocky mountains and flying above the clouds.

A hearty vote of thanks was then proposed and carried unanimously by the Branch to Captain Ingram for his splendid address.

Sault Ste. Marie Branch

A. A. Rose, A.M.E.I.C., Secretary-Treasurer.

Manufacture of Refractory Materials

The regular monthly meeting of the Sault Ste. Marie Branch was held on Friday, February 27, at the Y.M.C.A. The speaker of the evening, Mr. F. B. Cornell, was entertained at dinner previous to the evening programme.

Mr. Cornell is the district sales manager at Detroit for the Harbison-Walker Refractories Company of Pittsburgh, whose products are largely used by the industries of Sault Ste. Marie. He showed moving pictures illustrating the manufacture of their refractory materials, in particular fire-clay and silica brick.

In his introductory remarks he pointed out how closely refractories are connected to everyday life, through processes of manufacture; as, for example, the metals in an alarm clock, table knife, or an automobile. Some of the commonest refractories are fire-clay, silica, magnesite and chrome and their use depends on chemical conditions of the product, fire-clay being used for acid and magnesite and chrome for basic materials.

Consideration of refractories is important in the design of a furnace, as special shapes are expensive. The operator of a furnace can prolong the life of the bricks by careful operation. Bricks should be carefully handled when being placed as breaking and chipping decrease the efficiency of the furnace.

The picture showed the improvement that is taking place in methods of manufacture. As far as possible errors due to human elements are eliminated. For example, the moisture of the mix is not now tested by feel but by weighing. The screened size of flint-clay and plastic materials is also emphasized.

Bricks are burned at a temperature of about 2,400 degrees F. and the time of burning is from three to three and a half weeks. Tunnel kilns with oil or gas fuel are replacing the periodic or down draft kilns.

The company are carrying on extensive laboratory research work in an effort to give greater service and a better product to their customers.

Following a short discussion of the paper, a very hearty vote of thanks was tendered Mr. Cornell on motion of W. Seymour, M.E.I.C., and L. R. Brown, A.M.E.I.C.

Toronto Branch

J. J. Spence, A.M.E.I.C., Secretary-Treasurer.
A. B. Crealock, A.M.E.I.C., Branch News Editor.

Grain Elevators

On the evening of Thursday, January 22nd, the members of the Toronto Branch were privileged to hear C. D. Howe, M.E.I.C., of Port Arthur, who spoke on "Grain Elevators." Mr. Howe's vast experience as consulting engineer for many grain boards, wheat pools and Canadian National Railway placed him in a most advantageous situation in order to give his most interesting paper before this Branch.

The speaker introduced his subject by explaining the function of the five thousand town elevators scattered throughout the west, and the part they play in rushing the grain to the outlet ports of Vancouver and Fort William for export. He discussed the total world's crop and compared the Canadian production to this, giving carry-over figures for the Canadian grain production for several years back. To-day the surplus is about 540,000,000 bushels on the North American continent but by the end of the present year this figure, according to the speaker, will probably be cut in half.

Although the North American continent has more carry-over wheat in storage at present than Canada would produce in a normal year (about 400,000,000 bushels), and although Russia is preparing to make a larger bid for world markets by introducing bulk handling methods, the outlook for the grain trade in this Dominion is improving. Mr. Howe illustrated his paper with slides showing the primitive country elevator of years gone by and the progressive development arising out of this by what is known as the following types, crib, steel, tile and the latest construction, concrete, as used in the terminal elevators. Among the slides was one of the terminal elevator at Port Churchill. Among those taking part in the discussion which followed were J. M. Oxley, M.E.I.C., J. W. Falkner, A.M.E.I.C., Mr. Wyman, Mr. Bennett and A. T. Perrin, M.E.I.C.

Alexander Power Development

The meeting of the Toronto Branch, held on Thursday, February 19th, was addressed by Dr. T. H. Hogg, M.E.I.C., chief hydraulic engineer of the Hydro-Electric Power Commission of Ontario, on the Alexander Power Development on the Nipigon river.

The speaker commenced by outlining briefly the power development on the river, where the Commission now has two plants. The first of these at Cameron falls, which has a capacity of 75,000 h.p. under a head of 76 feet, was commenced in 1919 when the first two units were installed, and completed in 1926. In October of 1930, the second development at Alexander Landing, a mile and a half downstream from Cameron falls, commenced operations. This development has a capacity of 54,000 h.p. in three units of 18,000 h.p. each, under a head of 60 feet. The principal market for power is in the cities of Port Arthur and Fort William, about 70 miles distant.

Dr. Hogg also described the possible future developments on the Nipigon river, stating that there remained undeveloped a head of about 110 feet between the headwater of the Cameron falls plant and Lake Nipigon. Lake Nipigon has been developed as a storage basin by the construction of a control dam at Virgin falls at the outlet of the lake.

Going on to a description of the Alexander development, Dr. Hogg described the conditions at the site of the main dam, which necessitated the use of a structure of the earth fill type and complete dewatering of the main channel of the river by means of a diversion channel. The main dam was built by the semi-hydraulic fill method, material for construction being deposited by train fill at the sides of the central pool, and the impervious core was then formed by sluicing material from the sides to the centre part of the dam. An unusually heavy rock toe was placed, excavated material from the diversion channel and the power house site being available for this.

The author also described special features of construction; as, for example, in the tie between the earth and concrete sections of the dam, where the structures were designed to prevent leakage due to shrinkage of the earth fill away from the concrete. In the design used, as shrinkage occurs a close contact will always be maintained between earth and concrete. Another feature of interest is the omission of a headworks structure. A low extension, close to the power house wall, houses the winches for the head gates, but, aside from this, there is no construction above the headworks deck. The headworks deck is closed by close-fitting covers, and provision is made for the admission below the deck of warm air from the power house, in order to prevent freezing of head gates and racks.

A moving picture film, illustrating the events during the closure of the diversion channel and the succeeding period when the headpond level was raised, was shown, and interesting explanatory comments during its showing were made by Otto Holden, A.M.E.I.C., assistant hydraulic engineer of the Commission.

Vancouver Branch

W. O. Scott, Jr.E.I.C., Secretary-Treasurer.

The annual dinner of the Student section of the Vancouver Branch was held on Wednesday, January 21st, 1931, at 7.30 p.m.

The purpose of this dinner was to bring about a better acquaintance of the younger and older members of the Branch.

Following the dinner short talks were given by the Chairman, H. B. Muckleston, M.E.I.C., Dean R. W. Brock, M.E.I.C., of the University of British Columbia, Mr. A. H. Findlay also of U. B. C., Major G. A. Walkem, M.L.A., M.E.I.C., and John C. Oliver, Jr.E.I.C.

The speakers touched on early engineering, modern engineering, the outstanding bridges constructed or under construction 1928-1930, and the value of The Engineering Institute of Canada to the student, engineer and public.

There was an attendance of thirty-one, about twenty-two of which were students.

Forest and Game Conservation in Canada

On Wednesday, February 18th, Mr. A. V. Ablett, of the Canadian Forestry Association, gave a very interesting talk accompanied by motion picture illustrations on "Forest and Game Conservation in the Dominion of Canada."

One film gave a very interesting review of the logging and lumber industry from the cutting of the raw material (under the modern system) in the woods, to the finished product in the mill.

The attendance was disappointingly small, possibly due to a large extent on the inclement night on which it happened to be held.

Annual Meeting of Students' Section

The Student section held their annual meeting at which the Student members read a paper or gave a talk, on Wednesday, February 25th, in the University Science building at Point Grey.

W. Hall, S.E.I.C., in fourth year forestry, gave a very educational talk, accompanied by slides, on "Mapping from Aerial Photography." Mr. Hall has had some experience in this line of work with the Pacific Great Eastern Railway and presented actual photographs to illustrate the methods of transferring to paper the results recorded on the film or plate.

H. L. Thorne, S.E.I.C., in fourth year geology, spoke on "Oil and Gas Wells of Commercial Importance in Alberta." He traced the early developments and concluded with the output of the various fields at the present time. He is confident that there is a big future for the oil and gas industry in that province.

R. V. Anderson, S.E.I.C., in fourth year civil, took as his subject "Problems and Characteristics of the Modern Skyscraper." This talk was also accompanied by slides illustrating all the newer skyscrapers of the United States and included such places as New York, Chicago, Detroit, etc.

Mr. Anderson stressed the need of further co-operation between architects and structural engineers. He touched on wind stresses, foundations, trend of modern design, elevator systems, by-law restrictions, traffic congestion and so forth, points which arise in this connection, showing a very thorough knowledge of the subject.

Following the talks, the chairman, H. B. Muckleston, M.E.I.C., moved a vote of thanks to the Student section for the very educational and entertaining evening and at the same time complimenting the speakers for their very able presentations; W. H. Powell, M.E.I.C., seconded.

The attendance totalled about thirty-four, of which eleven were members of the parent branch.

Preliminary Notice

of Applications for Admission and for Transfer

March 21st, 1931.

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in May, 1931.

R. J. Durley, *Secretary.*

* The professional requirements are as follows—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ANSON—CLEMENT MATTHEW, of Sydney, N.S., Born at Rotherham, England, Sept. 9th, 1901; Educ., B.Sc., McGill Univ., 1925; 1915, quick test helper, Sydney, Australia; 1916-19, open hearth helper, G. C. Hoskins, Ltd., Lithgow, Australia; 1919-20, supt., elec. furnace dept., Commonwealth Steel Products Ltd., Newcastle, Australia; 1926-28, asst. supt., blast furnaces, 1928, asst. supt., mills, 1928-30, asst. gen. supt., Dominion Iron & Steel Company, and from 1930 to date, asst. gen. mgr., Dominion Iron & Steel Divn., Dominion Steel & Coal Corpn., Sydney, N.S.
References: A. P. Theuerkauf, K. H. Marsh, T. L. McCall, F. W. Gray, W. L. Stuewe, W. E. Bown.

CARRIERE—JEAN PAUL, of 77 Laurier Ave., Hull, Que., Born at Hull, Que., Nov. 15th, 1907; 1922-23, Ottawa Univ., Ottawa. 1923-24, LaSalle Academy, Ottawa; 1924-25, Hull Tehcnical School; I.C.S. diplomas, Surveying and Mapping, and Civil Engrg.; 1924-26, chainman and rodman, and 1926-28, asst. engr., Corpn. of City of Hull; Nov. 1928 to Mar. 1929, asst. engr., E. B. Eddy Co., Hull, Que.; at present, dftsman, chief engr's dfting room, Dept. Public Works Canada, Ottawa, Ont. (1931, Jan.-Mar., asst. engr., Corpn. of City of Hull, by special permission of Deputy Minister.)

INGRAM—ARTHUR FERGUSON, of Montreal, Que., Born at Standish, England, Sept. 17th, 1892; Educ., 1916, course in Aeronautical Engrg., Reading Univ., England; July 1916. passed British Air Ministry Exam. obtaining Commission in R.F.C.; 1919-20, undergraduate (medicine), Queen's Univ., Belfast; 1915-16, early training under British Air Ministry in aeronautical engrg.; 1916-18, Flt.-Commdr. No. 27 Squadron on active service in France and Egypt; 1918-19, in charge of flying school at Fowlmere, Cambridge, England, including flying instruction and other aeronautical subjects; 1919-25, transferred to School of Army Co-operation and responsible for Air Force co-operation with the Army in aeronautical matters; 1925-28, transferred to Air Force Training Camp, Uxbridge, England, as Adjutant in Charge of Instruction; 1928-29, Flt.-Commdr., Adjutant in charge of Canadian Air Force Training, Camp Borden, Ontario, and Flying Instructor; 1929 to date, operating manager of flying operations, Canadian Airways Limited, Montreal, in charge of all air mail operations in Eastern Canada from Windsor, Ont., to Halifax, N.S.
References: J. A. Wilson, R. H. Mulock, E. W. Stedman, L. S. Breadner, J. L. Busfield, A. Ferrier, C. K. McLeod.

JACOBS—MILTON, of Montreal, Que., Born at West Stewartstown, N.H., May 14th, 1891; Educ., B.S. in C.E., Norwich University, Northfield, Vt., 1912; 1912-14, dftsman., pulp and paper mill extensions and mtce., Burgess Sulphite Fibre Co., Berlin, N.H.; 1914-16, field engr., grade crossing elimination, Pennsylvania R.R., Cleveland, Ohio; Feb. 1916 to Aug. 1920 (except Mar. 1918 to Jan. 1919, 2nd Lieut., C.A.C., U.S. Army), constrn. engr., pulp and paper mill extensions and hydro-electric developments for International Paper Co., Berlin, N.H.; 1920-21, asst. engr., hydro-electric development, Brown Company, Berlin, N.H.; 1921-23, designing engr., pulp and paper mill developments, Fort William Paper Co., Fort William, Ont., Provincial Paper Co., Port Arthur, Ont., and Mead Fibre Co., Kingsport, Tenn., with Management Engineering and Development Co., Dayton, Ohio; Feb. 1923 to May 1924, res. engr., paper mill extensions, Sonoco Products Co., Hartsville, S.C., with H. S. Taylor, M.E.I.C., consltg. engr.; May 1924 to Feb. 1931, Montreal manager and chief designing engr., with H. S. Taylor, M.E.I.C., consltg. engr., and at present, associate engineer and member of firm, H. S. Taylor and Company, Consltg. Engrs., Montreal, Que.
References: H. S. Taylor, D. C. Tennant, B. R. Perry, R. E. Chadwick, E. P. Cameron, F. O. White, S. J. Fisher.

LUDGATE—JAMES VERNON, of 188 William St., Kingston, Ont., Born at Parry Sound, Ont., Jan. 30th, 1901; Educ., B.Sc., Queen's Univ., 1923; 1923-25, asst. to manager, Schroeder Mills & Timber Co., Pakesley, Ont.; 1925-27, res. engr. for same company; 1927-28, woods engrg. dept., Canadian International Paper Co., Montreal; 1928-30, manager, Tudhope & Ludgate, Ardkeg, Ont.; 1930 (7 mos.), land surveys and topographic surveys, Parry Sound, Ont.; at present, inspr. for Canadian Terminals System on constrn. of transfer grain elevator, Kingston, Ont.
References: J. A. H. Henderson, T. A. McGinnis, W. P. Wilgar, A. Macphail, D. S. Ellis.

McFARLAND—WALTER IRVING, of Beauharnois, Que., Born at Havelock, N.B., Nov. 10th, 1902; Educ., B.Sc. (E.E.), Univ. of Alta., 1929; 1927 (5 mos.), electrn's. helper, 1928 (5 mos.), night electrn., Marlboro Cement Works, Marlboro; 1929-30 (8 mos.), student ap'tice, Canadian Westinghouse Company; Feb. 1930 to date, elect'l. engineering dept., Beauharnois Construction Company, Beauharnois, Que.
References: B. K. Boulton, R. G. Watson, J. A. Knight, C. A. Robb, R. S. L. Wilson.

PRENTICE—WILLIAM RAMSAY, of Hawkesbury, Ont., Born at Edinburgh, Scotland, Jan. 21st, 1895; Educ., Toronto Public and High Schools. Three or four years evening classes, mech'l. drawing and applied mechanics, Toronto Technical School; 1911-16, articled student, Geo. M. Miller & Co., Architects, Toronto; 1916-21, gen. dfting, Fairbanks Morse Co., Toronto; 1921-22, gen. dfting, Massey Harris Co., Toronto; 1922-25, chief dftsman., Canada Foundries and Forgings Co. Ltd., Brockville, Ont.; 1925-29, research lab. engr., and 1929-31, asst. mill engr., Canadian International Paper Co., Hawkesbury, Ont.; at present, machine designer, Geo. J. Manson, A.M.E.I.C., Consltg. Engr., Hawkesbury, Ont. (Design of special pulp products machinery).

References: C. B. Thorne, S. Wang, A. K. Grimmer, G. J. Manson, J. Tomkins, C. B. Shaw.

RYBKA—KAREL R., of Montreal, Que., Born at Vienna, Austria, Jan. 28th, 1900; Educ., Mech. Engr., States Colleges at Bruo and Prague, Czechoslovakia, 1923; 1924 (Jan.-Nov.), junior dftsman., M. Becker machine shops, Prague; 1924-25, dftsman., W. Merlet foundry and machine shops, Prague; 1926 (Jan.-Oct.), field supt. and dftsman., T. Kozeluh, consltg. engr., Prague and Dresden; 1926-28, heating engr., Emile Stohr, heating, plumbing and ventilating contractor, Prague and Vienna; 1928 to date, designing dftsman., engrg. dept., Ross & Macdonald, arch'ts., Montreal.

References: W. J. Armstrong, G. S. Townsend, G. L. Wiggs, A. H. Ross, A. C. Fleischmann.

YATES—JOHN MUNRO, of 18 Grafton Avenue, Toronto, Ont., Born at Toronto, June 24th, 1905; Educ., Diploma in Arch'ture and Bldg. Constrn., Technical Institute, Toronto, 1927; 1925-30, dftsman., with the following firms: Browne & Cavell, Willis Chipman, C.E., Bell Telephone Company of Canada; at present, dftsman., Dept. Public Highways Ontario, Port Hope, Ont.

References: A. M. Reid, R. E. Smythe, A. A. Smith, R. M. Smith, A. Hay.

YOUNG—JOHN DOUGLAS, of Montreal, Que., Born at Boston, Mass., Nov. 30th, 1900; Educ., B.Sc., Queen's Univ., 1927; 1922-24, operator, marine gas engine, Upper Ottawa Improvement Co., also marine diesel operator; 1925-26, steel detailing, Chelsea power house, Gatineau Power Company; 1927 to date, sales service engr., Bailey Meter Co. Ltd., Montreal, Que. Work includes sales with service requirements on equipment, consisting of installation, repair, recalibration and combustion test work for meter adjustment purposes, also considerable consulting work as to best methods of handling power and process flow sheets.

FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

HALL—JOHN G., of Montreal, Que., Born at Cornwall, Ont., Sept. 2nd, 1891; Educ., B.Sc., McGill Univ., 1921; 1911-12, G.T.R. shops, Pt. St. Charles; 1914-16, G.T.R. shops, Chicago; 1917-19, U.S. Shipping Board, Montreal and Cleveland; 1921-24, engr. and asst. supt., Back River Power Co., Montreal; 1924 to date, with Combustion Engineering Corporation Ltd., as follows: 1924-27, manager, Winnipeg office; 1927-30, in charge of sales, prairie provinces and from Montreal to maritimes; and at present, vice-president and general manager, Montreal. (*S. 1919. A.M. 1924.*)

References: J. T. Farmer, C. M. McKergow, J. W. Sanger, E. V. Caton, K. Moodie, J. Haddin, T. S. Morrisey.

MacAFEE—RALPH EVANS, of 4156 Dorchester West, Montreal, Que., Born at Newton, N.B., April 15th, 1887; Educ., B.Sc., McGill Univ., 1910; 1909 (Apr.-Sept.), Angus shops, elect'l mtce., C.P.R.; 1910-11, ap'tice course, Canadian Westinghouse Co. Ltd., Hamilton, Ont.; 1911-13, with same company, correspondence dept., Hamilton and Calgary; 1913-15, with McMullen Riley & Durley, Consltg. Engrs., preparation of plans and specifications including designs covering elect'l and heating systems for large buildings; 1915-19, overseas, Capt. Can., Engrs.; M.C. and mentioned in Dispatches; 1919-23, steam power plant engrg. contracts and sales, Babcock & Wilcox Ltd., Montreal; 1923-29, steam power plant engrg. contracts and sales, Babcock-Wilcox and Goldie-McCulloch, Ltd., and from April 1929 to date, manager, eastern branch (covering Quebec and Maritime Provinces), for same company. (*A.M. 1920.*)

References: C. V. Christie, F. A. Combe, R. J. Durley, S. J. Fisher, C. M. McKergow, E. J. C. Schmidlin.

FOR TRANSFER FROM THE CLASS OF JUNIOR TO A HIGHER CLASS

MARCHAND—EUGENE F., of St. Jerome, Que., Born at Ottawa, Ont., May 28th, 1897; Educ., 1914-16, Ottawa Collegiate Institute. Passed maths. exam. for D.L.S., Ottawa, 1916; 1917-19, overseas; 1919-20, with P. E. Marchand, Ottawa, Ont., on transmission lines and small power plants; 1920-21, Bathurst Company, steel transmission line, contractors, Morrow & Beatty, Peterborough; 1922, in charge of constrn. for Rockland Electric Light Plant and lines; 1924-27, in charge of finishing constrn. and also operating of system and plant for Laurentian Hydro-Electric Ltd.; 1927 to date, manager of Laurentian division, Gatineau Electric Light Co. Ltd., St. Jerome, Que. (*Jr. 1925.*)

References: F. B. Brown, G. G. Gale, J. S. Parker, J. E. Woods, H. B. Fisk.

FOR TRANSFER FROM THE CLASS OF STUDENT TO A HIGHER CLASS

BELL—HARRY HEARTZ, of Calgary, Alta., Born at Halifax, N.S., Nov. 9th, 1906; Educ., B.Sc., Dalhousie Univ., 1927. B.Sc., N.S. Tech. Coll., 1929; 1924-25, marine surveyor, Biological Board of Canada; 1927 (2 mos.), instr'man., Anglin Norcross Ltd.; 1928 (June-Sept.), ap'tice, industrial control, Can. Gen. Elec. Co., Peterborough; 1929-30, technical work, mech'l. and elect'l., on 132,000 v. transmission line, and 1930 to date, load and voltage survey of system, Calgary Power Company, Calgary, Alta. (*S. 1928.*)

References: W. P. Copp, F. R. Faulkner, K. L. Dawson, R. E. Heartz, H. B. Sherman, G. H. Thompson, W. Anderson.

EVANS—JOHN MAURICE, of Outremont, Que., Born at London, England, Oct. 7th, 1905; Educ., B.Sc. (Hons. in E.E.), McGill Univ., 1929; 1925-27, test engr. and research, 1928, shift operator, Marconi beam system, Canadian Marconi Co.; 1927 (5 mos.), forest cruise and transitman, International Paper Co.; 1929-30, (1 year), special engrg. problems and system planning, and from 1930 to date (9 mos.), industrial engr., Shawinigan Water and Power Co., Montreal, Que. (*S. 1929.*)

References: F. S. Keith, J. Morse, S. Svenningson, P. S. Gregory, R. H. Mather, C. V. Christie.

LOCHHEAD—STUART GEORGE, of 309 Brock Ave. North, Montreal West, Que., Born at Montreal, Que., May 18th, 1905; Educ., 1924-27, McGill Univ. (completed all but one course in second year); 1926 (summer), chainman, C.N.R.; 1927-28, dftsman., Dominion Bridge Co.; 1928-29, chief of party and instr'man., Canada Power & Paper Corpn.; April 1929 to date, junior engr., City of Westmount. (*S. 1928.*)

References: F. F. Clarke, D. C. Tennant, P. E. Jarman, P. G. Delgado, S. E. Oliver, A. Peden.

WARDLEWORTH—THEOPHILUS HATTON, of 168 Cote St. Antoine Road, Westmount, Que., Born at New Brighton, Cheshire, England, June 7th, 1903; Educ., B.Sc. (Civil), McGill Univ., 1925; 1924-30, with Fraser Brace Engrg. Co. as follows: 1924 (summer), rodman, Deer Lake, Nfld.; 1925-26, estimator, Montreal; 1926-28, instr'man., Colombia, S. A.; 1928-29, estimator, Montreal; 1929-30, instr'man., Copper Cliff, Ont. (*S. 1923.*)

Meeting of The Joint Committee on Concrete and Reinforced Concrete

The Joint committee on Specifications for Concrete and Reinforced Concrete met in Chicago, on February 27 and 28, 1931. This committee, which is made up of five representatives each of the American Society of Civil Engineers, American Society for Testing Materials, American Railway Engineering Association, Portland Cement Association, and the American Concrete Institute, is a reorganization of the committee that made reports on concrete specifications in 1921 and 1924.

A number of developments since the 1924 report makes certain changes in the specification desirable. Among the advances which have been made, relating to concrete as a material in recent years, the most significant are the developments in cement, use of ready-mixed concrete, and a more widespread understanding of the design of mixtures with increasing attention to field control.

In the field of design, an outstanding development which should be covered in future reports of the committee is the tendency towards the greater use of rigid frame construction.

All these developments are to be given consideration by the reorganized committee in addition to a general study of the 1924 report with a view to improving its presentation and widening its scope.

The committee proposes in its report to separate portions which are in the nature of specifications and those which are in the nature of recommended practice. It is planned also to add as an appendix the technical data upon which the recommendations of the report are based. The committee is considering the necessity of distinguishing between the requirements for so-called outdoor concrete and concrete in locations such as heated buildings not exposed to the effect of weather. Water-tightness as an element of durability will be recognized as one of the essentials of concrete for outdoor exposure. The necessity for this has been brought about by the recent development of generally higher strengths in portland cements. Following the practice which has become quite general of designing concrete for a given strength requirement, it is possible with these newer cements that mixtures will result which are too lean for proper durability. Some limitation will, therefore, be placed upon the cement content to avoid this difficulty.

In the field of design of reinforced concrete, the committee proposes to present the recommendations in regard to moment coefficients by putting primary emphasis on the general case of unequal spans, thus reversing the arrangement in the 1924 report in which the emphasis is placed on a series of equal spans. Moment coefficients will be given only for the case of equal spans and these will be presented with separate coefficients for live and dead load.

The American Institute of Steel Construction, Inc., has published a 48-page booklet entitled "True Economy in Highway Bridge Design," by T. W. Dodd, with a discussion by J. G. Greiner. This booklet contains a comprehensive treatment of the economics of the small highway bridge, and includes many diagrams and illustrations. It is obtainable gratis upon application to the offices of the American Institute of Steel Construction, Inc., 200 Madison Avenue, New York, N.Y.

The Burlington double-leaf bascule bridge being built by the Hamilton Bridge Company will be the largest of its kind in Canada, and the second largest on the continent. Each leaf measures 160 feet long and weighs 600 tons. The primary power is supplied by two Canadian Westinghouse 125 h.p., 100-kw., 550-volt, D.C. motor generator sets. There are four 48 h.p. motors, which act as main lifting motors, and there are two 5 h.p. motors, which drive the locks into the bridge.

The Dominion Oxygen Company Limited have this winter opened a new training shop in their Toronto plant, offering greatly increased facilities for giving instruction to their customers' welders. For some years instruction has been given in the various applications of the oxy-acetylene process to welders employed by users of Dominion Oxygen products, but the value of this service to the users of the process has taxed to capacity the facilities available.

This training shop, is equipped so 15 to 20 welders can receive instruction at one time. Pipe lines distribute the gases to each welding and cutting table and a straight line cutting machine, capable of cutting and bevelling plate up to 12 inches in thickness, has been installed for preparing material. The shop is completely equipped with oxy-acetylene welding and cutting blowpipes for sheet metal, aircraft, pipe and general repair welding. A tensile machine for testing welds assists greatly in the instruction of welders who can be shown the results of improper handling of the blowpipe by destructive testing of their own work.

This shop is operated five days and five nights a week for welders employed by customers of the company and special instruction is given in automotive repair work, aircraft welding, pipe welding and the fabrication of pipe fittings, as well as general instruction in welding cast iron, malleable iron, steel plate and castings, aluminum, monel metal, brass, bronze, copper and the various alloys and other metals used in industry.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Vacant

ELECTRICAL OR MECHANICAL ENGINEER. A young electrical or mechanical engineer with some experience in statistics. Application should state fully education and experience. Apply to Box No. 693-V.

BUYER required by large corporation in Eastern Canada. Applicant must be graduate engineer and have had at least three years practical experience. Should not be over 30 years of age. Apply to Box No. 697-V.

SALES REPRESENTATIVE. Young engineer with about two years experience required for sales work in Ontario and Quebec. Apply giving full particulars as to training and experience to Box No. 698-V.

PARTNER wanted with $3,000 to further develop exclusive agency for British product of engineering nature, in good demand. Location Montreal. Apply to Box No. 701-V.

YOUNG ENGINEER, as sales representative for industrial and building products, with some experience on general contracting estimating. Location central Ontario. Apply at once to Box No. 703-V.

MECHANICAL ENGINEER. Technically trained engineer, fully familiar with modern shop practices and costs. Experience in coal mining, oil well and miscellaneous mechanical equipment and repair work desirable. Splendid opportunity. Location Western Canada. Apply, giving full information regarding education and experience, to Box No. 704-V.

GENERAL SHOP SUPERINTENDENT. Familiar with modern shop practice in modern shop, foundry and miscellaneous iron and steel construction. Must be hustler and able to handle men. Location Western Canada. Apply, giving full information regarding experience, to Box No. 705-V.

WANTED, engineer with good knowledge of combustion principles, to organize and carry on sales of automatic stokers. Must be energetic, have good personality, with executive ability. Apply to Box No. 706-V.

PARTNER WANTED. Engineer with extensive construction and mechanical experience, speaking French and English, desires to make connection with engineer or firm engaged in engineering work. Will make investment. Apply to Box No. 708-V.

Situations Wanted

CIVIL ENGINEER desires to represent manufacturers of industrial products or specialties selling to industrial and other markets. Experience includes engineering and building construction, municipal works, administration and operation, purchasing and sales, etc. Record of integrity. Apply to Box No. 14-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), 15 years experience, available on short notice. Experienced surveys, draughting, reinforced concrete design, municipal engineering, construction work, inspection, estimating. Apply to Box No. 107-W.

ELECTRICAL ENGINEER, B.Sc., age 30. Experienced in power distribution and electrical communication, including design of carrier current systems. Apply to Box No. 110-W.

ELECTRICAL ENGINEER, B.Sc., McGill '27. Experience in the electrical design of power houses and substations. Available on short notice. Apply to Box No. 154-W.

ELECTRICAL ENGINEER, B.Sc., McGill 1926. Five years experience in the design of switchboards, layouts and wiring diagrams. Considerable experience in high and low tension switchgear design. Fifteen months experience in switchboard estimating. At present employed; available on short notice. Correspondence invited. Apply to Box No. 247-W.

CIVIL ENGINEER, A.M.E.I.C., of long field experience on reinforced concrete, water purification, steel buildings and bridges, seeks employment on supervision or inspection. Temporary or otherwise. Apply to Box No. 277-W.

ELECTRICAL ENGINEER. Graduate '25, wide experience in hydro-electric power stations, desires position on power plant design or related work. Apply to Box No. 278-W.

MECHANICAL ENGINEER, B.Sc. Pulp and paper, hydrometallurgical, design and operation, capable draughtsman, very resourceful in mechanical development. Single. Any locality. Apply to Box No. 306-W.

CIVIL ENGINEER, A.M.E.I.C., Canadian, R.P.E., Nova Scotia, 21 years engineering experience, both field and office, in railway, highways, foundations, concrete structures, water power and conservation, electric transmission lines, etc., experience comprising both surveys and construction, desires employment. Single. Will go anywhere. Working knowledge of French and Spanish. Available immediately. Apply to Box No. 327-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing and hoists. Also some experience in ventilating and heating work and calculators. Accustomed to structural design and details. Good references. Present location Montreal. For interview apply to Box No. 329-W.

ENGINEERING REPRESENTATIVE. Experienced civil and mechanical engineer wishes to communicate with engineering or equipment manufacturing firm with a view to becoming Ontario or Quebec representative. Apply to Box No. 334-W.

CIVIL ENGINEER; age 48; married; A.M.E.I.C., R.P.E., Ontario and New Brunswick; 32 years experience in municipal engineering, on roadways, sewers, waterworks and buildings, desires position with either municipality or as engineer superintendent with contractor. Ten years with City of Toronto, construction engineer on roadway work; four years consulting engineer; three years engineer in charge of construction work; one year resident engineer, Dept. of Public Highways. Available immediately. Maritimes or Ontario preferred. Apply to Box No. 336-W.

Situations Wanted

CIVIL ENGINEER, S.E.I.C., graduate '29, desires engineering position with possibilities of advancement. Past experience consists chiefly of survey work and municipal construction. Location in western provinces preferred. Apply to Box No. 338-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., R.P.E., Ont., with twenty-four years experience embracing dams, wharves, grain elevators, foundations, pile driving, highways, municipal engineering, water power surveys, road locations, inspections and estimating is open for engagement as engineer or superintendent in construction, operation or maintenance. Location immaterial. Apply to Box No. 358-W.

CIVIL ENGINEER, graduate, age 32, A.M.E.I.C. Ten years experience; seven years on design, construction, erection work and maintenance of paper mill and mine buildings and machinery. Three years on hydro-electric work in charge of surveys and field investigations; associate hydro-electric engineer, U.S. Engineers, on office investigation, design and estimates; desires permanent position in Canada. Apply to Box No. 362-W.

ENGINEER, age 31, married. Experience includes two years mechanical, two years railway, six years structural and instrumentman and structural engineer on erection, desires position in Toronto. Apply to Box No. 377-W.

SCOTS ENGINEER, 28 years old, desires situation as junior executive or some similar situation. Wide experience in mechanical, civil and hydraulic fields and four years as junior executive; A.M.I.C.E. exam., Jr.E.I.C. Will go anywhere. Apply to Box No. 381-W.

ELECTRICAL AND MECHANICAL ENGINEER, S.E.I.C., educated Oundle and Manchester, age 24. Studied course, Brit.-Westinghouse. Three years design, production, advertising, sales and control of sales force on mechanical and electrical goods. One year outside plant engineering leading public utility company. Desires work in sales, production or engineering capacity. Available immediately. Location immaterial. Apply to Box No. 415-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), graduate. Eighteen years experience in survey and construction, railway, hydro-electric and buildings. Experience comprises both office and outside work. Desires responsible position. Would consider position with commercial or manufacturing firm. Available immediately. Apply to Box No. 425-W.

CIVIL ENGINEER, S.E.I.C., 1930 graduate of Nova Scotia Tech. with experience as plane table topographer, instrumentman and draughtsman and particularly interested in hydro-electric power development and reinforced concrete design, desires position. Willing to go to foreign fields. Available at a few weeks notice. Apply to Box No. 431-W.

ELECTRICAL DESIGNER, Jr.E.I.C., age 28, B.Sc., McGill University '26. Five years sales and engineering experience, seeks immediate employment. Apply to Box No. 436-W.

CIVIL ENGINEER, B.A.Sc., A.M.E.I.C., Jr.A.S.C.E., age 29, married. Experience over the past eight years upon hydro-electric developments in construction, design and reports. Also some experience in railway construction. Permanent work preferred. Location immaterial. Available May 1st. Apply to Box No. 447-W.

ELECTRICAL ENGINEER, S.E.I.C., B.Sc., (McGill Univ. '27), age 26. Fifteen months outside plant engineering with large public utility. Twenty months sales engineering experience with electrical manufacturing company. Available on reasonable notice. Apply to Box No. 463-W.

Situations Wanted

CIVIL ENGINEER, s.e.i.c., 1930 graduate. Experience as instrumentman on city and railroad construction, desires to enter structural or hydraulic field. Available at once. Will go anywhere. Apply to Box No. 467-W.

CIVIL ENGINEER, experienced in road construction, mine surveying, transmission line survey and construction; paper mill construction; age 27. Available on short notice. Apply to Box No. 468-W.

CIVIL ENGINEER, a.m.e.i.c., age 39, with wide experience on design and construction of reinforced concrete structures, desires position. Apply to Box No. 475-W.

CIVIL ENGINEER, b.sc., six years experience in paper mill and hydro-electric work, desires position with paper or power company. Paper mill experience covers design, layout, some estimating, and construction. Hydro experience covers preliminary and flowage surveys, transmission line location, design, and six months as resident engineer on construction. Available at once. Apply to Box No. 482-W.

DESIGNING ENGINEER, a.m.e.i.c., p.e.q., with extensive experience in design and construction of power plants, industrial buildings and hydraulic structures, desires position as designing engineer or resident engineer on construction. Apply to Box No. 492-W.

STRUCTURAL ENGINEER, technical graduate, age 40, married, seeks position with architect or contractor. Fully experienced in design and supervision of all types of office and industrial buildings, structural steel or reinforced concrete. Available on short notice. Apply to Box No. 501-W.

ELECTRICAL ENGINEER, b.sc., McGill University, jr.e.i.c., age 32. Five years practical experience before graduating. Since graduation two years course with International Paper Co., including six months as electrical foreman, engineer in charge of installation of electrical equipment for two 28,000-h.p. units. Also electrical equipment for large coal-fired boiler house, designing some of the features. Apply to Box No. 506-W.

WEST INDIES, Engineer, a.m.e.i.c., etc. Experience with engineers and contractors, railway, harbour and concrete construction, desires position in West Indies. Apply to Box No. 518-W.

MECHANICAL ENGINEER, jr.e.i.c., b.sc., '26. Ten months experience in pulp and paper steam control. Four years experience in detail and design, in pulp and paper mill, industrial plant and hydro-electric development work. Age 27. Married. Location immaterial. Apply to Box No. 521-W.

CIVIL ENGINEER, b.a.sc., '29, with experience in supervision of construction and general office engineering, desires permanent position with contractor or engineer. Available at once. Apply to Box No. 524-W.

CIVIL ENGINEER, a.m.e.i.c., with twelve years experience embracing survey and construction, railway, hydro-electric and highways, foundations, pile driving, municipal engineering, water power surveys, road location, inspection and estimating, is open for engagement as resident engineer on construction or other responsible position. Experience comprises both office and outside work. Available immediately. Apply to Box No. 527-W.

MECHANICAL, CONSTRUCTION, AND DESIGNING ENGINEER, with special training in hydro-electric power development, underground steam distribution systems, and the operation of large electrical machinery. Active work desired. Apply to Box No. 528-W.

SALES REPRESENTATIVE, civil and mechanical engineer, with office in Toronto, desires to hear from manufacturers of high-grade building materials or industrial equipment, with the view of representing their interests in the promotion and effecting of sales to architects, engineers and contractors. Excellent connection. Apply to Box No. 529-W.

ELECTRICAL ENGINEER, s.e.i.c., about to graduate (1931), desires to become associated after graduation with some branch of electrical engineering offering good opportunity for advancement. Sixteen months experience in draughting of electrical apparatus with large manufacturing concern; including layout work, and making of detail working drawings. Bulk of experience with industrial control apparatus. Apply to Box No. 532-W.

ELECTRICAL ENGINEER, married, graduate of McGill University, desires position in Ottawa, Montreal or Toronto. Experience includes four summers with a building concern as instrumentman and assistant engineer, two and one-half years with the Canadian Westinghouse Co., this time being distributed between tests, design and sales. At present employed but available on short notice. Apply to Box No. 533-W.

CIVIL ENGINEER, b.sc., McGill University, jr.e.i.c., age 32. Seven years general experience in hydro-electric power investigations and construction. Has been in charge of high power transmission lines location, also in charge extension surveys. Experience in office and field. Thorough knowledge of French. Best of references from former employers. Apply to Box No. 537-W.

STRUCTURAL ENGINEER, a.m.e.i.c., b.a.sc. Wishes to join established firm of consulting engineers. Age 37. Married. Ten years experience design of reinforced concrete and steel on buildings. Two years practical contracting experience. Apply to Box No. 540-W.

CIVIL ENGINEER, McGill '20, a.m.e.i.c., p.e.q., age 31, single. Experience includes general engineering, especially reinforced concrete work, and eight years of pulp and paper mill construction and layout. Best of references. Available on short notice. Apply to Box No. 547-W.

UNDERGRADUATE ENGINEER, s.e.i.c., junior year standing (Sask.), desires work to complete course. Electrical or mechanical work preferred. Apply to Box No. 553-W.

A.M.E.I.C., graduate of University of Toronto, 1915. Building engineer and superintendent, with considerable experience as installation, sales and promotion engineer. Present connection, four years in responsible position with large utility corporation. Open for immediate connection where he can use his past experience. Location immaterial. Apply to Box No. 560-W.

ELECTRICAL ENGINEER, a.m.e.i.c., university graduate 1924. Experience includes one year test course and five years on design of induction motors with large manufacturer of electrical apparatus. Four summers as instrumentman on highway construction. Several years experience in accounting previous to attending university. Available at reasonable notice. Apply to Box No. 564-W.

CIVIL ENGINEER, s.e.i.c., graduating this year. Experience in railway maintenance, and instrumentman on location and construction. Desires to enter any branch of civil engineering or industrial work affording technical experience and an opportunity for increasing responsibility. Will go anywhere. Apply to Box No. 567-W.

CIVIL ENGINEER, a.m.e.i.c., ten years experience as mining engineer of a colliery, six years railway construction, including location, construction, bridge construction, and maintenance. Also one year on hydro transmission lines; one year government land surveys. Would consider position in any branch of construction, as resident engineer or instrumentman. Apply to Box No. 569-W.

CIVIL ENGINEER, b.sc. McGill Univ., jr.e.i.c. Five years experience along the lines of general construction, including structural steel. Available at once. Apply to Box No. 570-W.

YOUNG ENGINEER, jr.e.i.c., experienced in design, details and erection of steel and concrete structures. Also a good theoretical and practical knowledge of steam, hydraulic and I.C. engine power plant. Good practical mechanical and electrical engineer, able to operate and maintain any type of machinery or power plant. At present in England on visit, returning in May. Location immaterial. Apply to Box No. 572-W.

CIVIL ENGINEER, jr.e.i.c., b.a.sc. (Toronto), 1928, age 25, married. Experience in field and office of surveying, general structural design, hydro-electric structures. Present location Montreal. Apply to Box No. 576-W.

MECHANICAL ENGINEER, s.e.i.c., b.a.sc., (Univ. of B.C. '30), Undergraduate experience in pulp mill. One year's experience, Canadian General Electric Co., mech. dept. Single. Age 24. Desires position in technical design or sales. Location immaterial. Available on short notice. Apply to Box No. 577-W.

For Sale

FOR SALE. Gurley transit, without tripod, in good condition. Price $150. Can be seen at Institute headquarters. Apply to Box No. 9-S.

It is announced that the Montreal offices of Affiliated Engineering Companies, Ltd., have removed from the Southam building to suite No. 1606, University Tower, 660 St. Catherine Street, west. The following is a complete list of the accounts now held by Affiliated Engineering Companies: American Engineering Company, Taylor Stoker Company, Ltd., Bernitz Furnace Appliance Company, Coppus Engineering Corporation, Andale Engineering Company, Allen and Billmyre Company, Inc., James MacIntosh and Company, Victory Valves Ltd., Thomas Clarkson, Ideal Commutator Dresser Company, Ernst Company, National Company, Ellis Drier Company, Keystone Refractories Company, Inc., Terminal Engineering, Inc., Frank H. Paquin Company, Rolland Gardner and Company, Vulcan Soot Cleaner Company, Canadian Kellog Company, Ltd., B. G. Carpenter Company, Inc., Troy Engine and Machine Company.

Wm. Kennedy and Sons, Ltd., Owen Sound, Ont., announces that it is now manufacturing the first "made-in-Canada" convertible gasoline shovel and crane. The "Beaver" shovel, as it has been named, is of three-eighths yard capacity and is a remarkably adaptable piece of equipment. It is completely mobile, running on caterpillar treads, has a high road speed of 4½ miles per hour, and easily climbs a slope of 40 degrees. The total weight, including shovel, is 21,800 pounds, and it has a maximum digging radius of 20 feet.

SECRETARY
R. J. DURLEY, Montreal, Que.

OFFICERS OF BRANCHES

HALIFAX
Chairman, J. L. ALLAN
Sec-Treas., R. R. MURRAY, 87 Cambridge St., Halifax, N.S.
Executive, L. M. ALLISON, G. S. STAIRS, W. H. NOONAN, S. L. FULTZ, J. J. SEARS, J. H. CLARK, W. J. DeWOLFE, A. F. DYER, J. D. FRASER
(Ex-Officio) F. R. FAULKNER, W. P. COPP

CAPE BRETON
Chairman, A. P. THEUERKAUF
Vice-Chair., Y. C. BARRINGTON
Sec.-Treas., SYDNEY C. MIFFLEN, Dom. Coal Co. Ltd., Glace Bay, N.S.
Executive, J. A. FRASER, J. R. MORRISON, W. L. STUEWE
(Ex-Officio) A. L. HAY

SAINT JOHN
Chairman, W. J. JOHNSTON
Vice-Chair., J. N. FLOOD
Sec.-Treas., A. A. TURNBULL, 348 Douglas Ave., Saint John, N.B.
Executive G. A. VANDERVOORT, C. C. LANGSTROTH, H. F. MORRISSEY
(Ex-Officio) E. J. OWENS, A. R. CROOKSHANK

MONCTON
Chairman, L. H. ROBINSON
Vice-Chair., G. E. SMITH
Sec.-Treas., V. C. BLACKETT, Eng. Dept., C.N.R., Moncton, N.B.
Executive, E. T. CAIN, T. L. LANDERS, J. G. MacKINNON, C. S. G. ROGERS, A. S. GUNN, A. F. STEWART
(Ex-Officio) M. J. MURPHY, G. C. TORRENS

SAGUENAY
Chairman, N. D. PAINE
Vice-Chair., J. F. GRENON
Sec.-Treas., W. P. LEBOUTILLIER, Price Bros. & Co Ltd., Kenogami, Que.
Executive, G. F. LAYNE, J. W. WARD, G. E. LAMOTHE, G. O. VOGAN
(Ex-Officio) R. E. PARKS, H. R. WAKE

QUEBEC
Hon. Chair., A. R. DECARY
Chairman, S. L. De CARTERET
Vice-Chair., HECTOR CIMON
Sec.-Treas., P. METHE, Ecole Technique, Blvd. Langelier, Quebec, Que.
Executive, F. T. J. KING, J. A. LEFEBVRE, A. LARIVIERE, L. BEAUDRY, L. C. DUPUIS, J. C. O'DONNELL

HAMILTON
Chairman, W. F. McLAREN
Vice-Chair., F. P. ADAMS
Sec.-Treas., J. R. DUNBAR, Can. Westinghouse Co., Ltd., Hamilton, Ont.
Executive, J. B. CARSWELL, H. S. PHILIPS, E. M. COLES, G. A. COLHOUN
(Ex-Officio) H. A. LUMSDEN, E. H. DARLING

LONDON
Chairman, W. R. SMITH
Vice-Chair., D. M. BRIGHT
Sec.-Treas., FRANK C. BALL, City Engr's Dept., London, Ont.
Executive, J. FERGUSON, F. Y. HARCOURT, G. E. MARTIN, W. C. MILLER, J. R. ROSTRON
(Ex-Officio) W. P. NEAR, W. G. URE

NIAGARA PENINSULA
Chairman, WALTER JACKSON
Vice-Chair., E. P. MURPHY
Sec.-Treas., P. E. BUSS, P.O. Box 35, Thorold, Ont.
Executive, C. W. WEST, F. L. HAVILAND, J. C. MOYER, W. R. MANNOCK, C. G. CLINE, N. BATES, H. D. DAVISON
(Ex-Officio) A. J. GRANT, C. H. SCHEMAN, M. B. ATKINSON, E. G. CAMERON

BORDER CITIES
Chairman, R. J. DESMARAIS
Vice-Chair., C. G. R. ARMSTRONG
Sec.-Treas., H. J. A. CHAMBERS, Canadian Bridge Co. Ltd., Walkerville, Ont.
Executive, J. D. CUMMINGS, H. J. COULTER, R. C. LESLIE
(Ex-Officio) ORVILLE ROLFSON, L. McG. ALLAN, A. E. WEST

SAULT STE. MARIE
Chairman, A. H. RUSSELL
Vice-Chair., C. STENBOL
Sec.-Treas., A. A. ROSE, 34 The Drive, Sault Ste. Marie, Ont.
Executive, W. S. WILSON, C. H. N. CONNELL, J. W. LeB. ROSS, J. M. SILLIMAN
(Ex-Officio) A. E. PICKERING

LAKEHEAD
Chairman, C. B. SYMES
Vice-Chair., D. G. CALVERT
Sec.-Treas., GEO. P. BROPHY, P.O. Box 86, Port Arthur, Ont.
Executive, D. C. CHISHOLM, J. C. MEADER, W. H. SOUBA, G. R. DUNCAN
(Ex-Officio) H. S. HANCOCK, G. H. BURBIDGE

WINNIPEG
Chairman, C. T. BARNES
Sec.-Treas., E. W. M. JAMES, 255 Balfour Ave., Winnipeg, Man.
Executive, W. E. HOBBS, J. M. MORTON, R. W. MOFFATT, A. L. CAVANAGH, F. G. GOODSPEED
(Ex-Officio) J. W. PORTER, N. M. HALL

SASKATCHEWAN
Chairman, D. A. R. McCANNEL
Vice-Chair., J. D. PETERS
Sec.-Treas., S. YOUNG, Director of Town Planning, Regina, Sask.
Executive, D. A. SMITH, R. A. SPENCER, G. M. WILLIAMS, J. M. CAMPBELL, W. H. HASTINGS
(Ex-Officio) W. G. WORCESTER

LETHBRIDGE
Chairman, N. MARSHALL
Sec.-Treas., Wm. MELDRUM, Galt Mines, C.P.R., Lethbridge, Alta.
Executive, N. H. BRADLEY, J. B. deHART, J. HAIMES, R. LIVINGSTONE
(Ex-Officio) C. S. CLENDENING, G. N. HOUSTON

EDMONTON
Chairman, JULIAN GARRETT
Vice-Chair., C. A. ROBB
Sec.-Treas., W. E. CORNISH, University of Alberta, Edmonton, Alta.
Executive, T. W. BROWN, R. M. DINGWALL, R. J. GIBB, H. J. MacLEOD
(Ex-Officio) R. W. ROSS, E. STANSFIELD

CALGARY
Chairman, R. C. HARRIS
Vice-Chair., F. M. STEEL
Sec.-Treas., A. W. P. LOWRIE, Dom. Water Power & Hydrometric Bureau, Southam Bldg., Calgary, Alta.
Executive, H. J. McLEAN, L. A. B. HUTTON, F. N. RHODES
(Ex-Officio) B. RUSSELL, T. LEES, R. S. TROWSDALE, S. G. PORTER

VANCOUVER
Chairman, H. B. MUCKLESTON
Vice-Chair., P. H. BUCHAN
Sec.-Treas., W. O. C. SCOTT, 930 Birks Bldg., Vancouver, B.C.
Executive, F. P. V. COWLEY, A. S. WOOTTON, A. C. R. YUILL, R. J. LECKY, J. C. McKENZIE, J. C. OLIVER
(Ex-Officio) A. D. CREER, A. K ROBERTSON

VICTORIA
Chairman, A. L CARRUTHERS
Vice-Chair., I. C. BARLTROP
Sec.-Treas., K. M. CHADWICK, 1827 Chestnut Ave , Victoria, B.C.
Executive, F. C. GREEN, F. G. ALDOUS, H. L. SWAN, E. C. G. CHAMBERS
(Ex-Officio) F. M. PRESTON

Volume XIV — Montreal, May 1931 — Number 5

The National Electricity Supply Scheme of Great Britain

C. C. Paterson, O.B.E.,

Director, Research Laboratories, General Electric Company, Ltd., Wembley, England,
President of the Institution of Electrical Engineers of Great Britain.

Presented before the Montreal Branch of The Engineering Institute of Canada, January 29th, 1931

SUMMARY.—In this address Mr. Paterson points out that in Great Britain the control of the supply of electricity has now been placed in the hands of the Central Electricity Board, a body receiving its authority and constitution from Parliament, but which is financially self-supporting and which has all possible freedom and independence in the handling of its policy and administration. The board is appointed by the Minister of Transport, and administers the Electricity Supply Act of 1926, schemes for the local supply of electricity being submitted by the Electricity Commissioners for the approval of the Board. Such schemes can only become effective when adopted by the board after full consideration by the parties affected. The board, whilst controlling and administering the generation of electricity, has no jurisdiction over its distribution to the ultimate consumer. The centralized authority of the board has been a great advantage in rendering possible the replacement of the individual schemes of some 580 local electricity authorities by a comprehensive supply system known as the Grid. This now includes some 3,000 miles of 132,000 volt transmission, which enables all the connected stations to be operated at good efficiency under a central control authority.

The paper describes briefly the constructional details of the main network and points out the many advantages of this bold scheme of nationa electrification.

Foreword.—The delivery of this address in Montreal by wireless from London on January 29th, 1931, marked the first occasion on which two-way radio communication overseas has been used at a meeting of one of The Institute's Branches. While atmospheric conditions were by no means favourable, transmission both ways was effective, and the thanks of The Institute and congratulations were duly accorded to the President of the Institution of Electrical Engineers and to the following organizations whose co-operative effort made the transmission possible:

The British Post Office—Office of the Engineer-in-chief;
Canadian Marconi Company, Montreal;
Imperial and International Communications, Limited, London, Eng.;
Bell Telephone Company of Canada, Montreal.

Great Britain is a small country measured in square miles, and when the almost limitless tracts of Canada are contemplated it causes wonder as to what are likely to be the respective futures of these countries, as the two wonderful agencies of electric power transmission and electric communication exert their inevitable and complete influence on the social and industrial evolution of Canada and Britain. For this new electrical age has just been entered and no one can predict what it will be when it comes to its maturity.

Michael Faraday discovered exactly one hundred years ago next August, those secrets of electromagnetic induction which are the basis of electrical engineering, and in this time the world has been establishing fundamentals in electrical engineering, and evolving through study and experience, systems and methods which are worth perpetuating and such as can be handed on with pride to our successors.

The problems peculiar to each country are handled in different ways and the solution is not and should not necessarily be the same for different countries. This should be emphasized because, while the people of Great Britain are in doubt as to what systems are best for Britain, they are far from suggesting that they would therefore be applicable elsewhere. Thus some thirty years ago the Engineering Standards Association was started in Britain and while this has been a most successful agency in establishing a high and uniform standard for products made by a number of competing concerns, its precise form has been the result of spontaneous evolution under British conditions, and has required modification to make it suitable in other countries.

In the early days of broadcasting, as suited conditions, a central nationally organized authority was established which was made responsible for the administration of the broadcasting service and for establishing such a system of radio stations that the whole country would be efficiently served. It was a type of organization with state authority but designed to be without those trammels which are so often liable to lead to official lethargy, and lack of business enterprise.

It is always valuable to study such systems in another country provided one is equally careful to study the institutions and the mentality of the nation for which the system has been evolved. Great Britain has had in the past two generations or more, every kind of control for public services—from the purely private concern to the completely state owned and controlled service. But there has been a marked tendency during recent years towards a type of organization which receives its authority and constitution from Parliament, but which has a maximum measure of freedom and independence in the handling of its policy and administration, and furthermore which must be financially self supporting.

In broad terms, this is the authority which has been set up by Parliament, following the recommendations of

Lord Weir's committee, for unifying, developing and lowering the cost of production of electricity in Great Britain.

The authority consists of a Central Electricity Board of eight members appointed individually by the Minister of Transport for a period of years. The members are mostly business men detached from politics and chosen on account of the confidence which they enjoy of different sections of industry. The board is in no sense a government department nor is it subject to any more control than any other statutory body which receives its power from Parliament. The members are paid a small salary and their duties encroach but to a limited extent on their business time.

There is a whole time chairman, Sir Andrew Duncan, and the board appoints its own chief engineer, secretary and staff.

The Electricity (Supply) Act of 1926 which is the Charter of the board has a good many references to the Electricity Commissioners, a body of five in number three of whom are experienced electrical engineers of the highest standing, established in 1920 for the purpose of promoting, regulating and supervising the supply of electricity. The commission prepares district schemes and submits them to the board. After giving opportunity for full consideration by the parties affected these schemes are adopted by the board with any amendment which may have been found necessary.

The work of the commission is mainly, however, concerned with the administration of the electricity supply statutes, it has certain judicial functions and in this connection the board, as an executive force, has to obtain the consent of the commissioners in compliance with the statutory provisions and regulations. The commission also advises the government on electrical matters and acts in accordance with the general directions of the Minister of Transport.

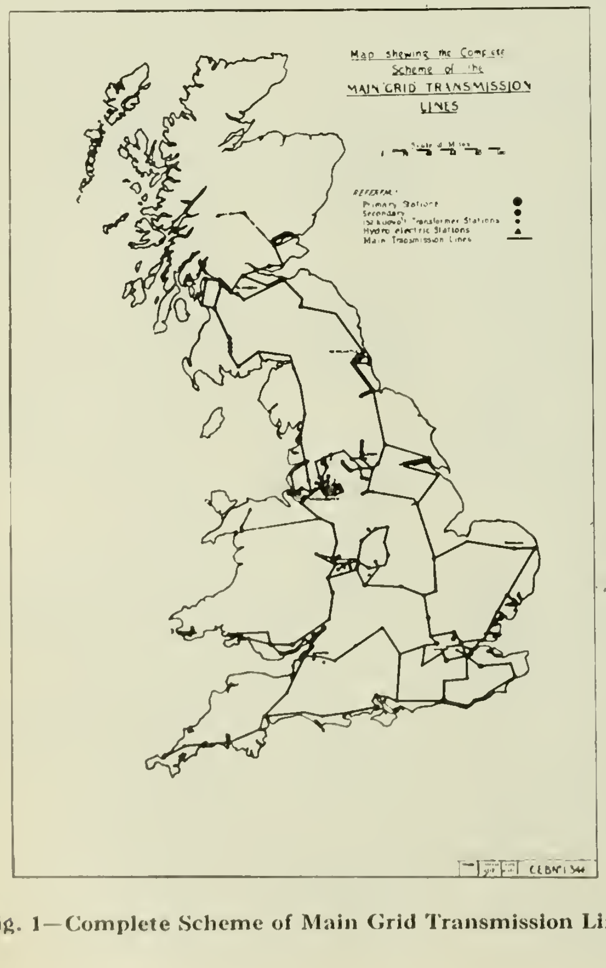

Fig. 1—Complete Scheme of Main Grid Transmission Line.

This machinery may appear somewhat complicated but in practice it works very well and it is an advantage to have within the government service a small independent court of trusted engineers. Their presence ensures that the uninstructed critic who tries to impose on the non-technical official or member of Parliament has little chance of causing mischief.

The Central Electricity Board whilst controlling and administering the generation of electricity has no control over its distribution to the ultimate consumer. That part of the service is still to be handled by the companies and municipalities who have hitherto been the bodies to deal direct with the public. These numerous distribution concerns are to buy their power from the central generating authority.

You will see at once what are the advantages of such a centralized authority to a country like Great Britain. Hitherto there have been some five hundred and eighty electricity authorities, each with its own city or area to supply. Most of these authorities have been self-contained units each with its own spare generating plant, and its generators of a size to suit its own limited requirements.

If this should be surprising, it must be remembered that Britain has no huge water power resources which would tend to concentrate generation in a few centres, and occur throughout the country. This facility,—of being able to set up a fairly economical generating station in almost every town of the country where there is suitable water for condensing purposes,—was an asset up to a point, as pioneer work was stimulated. But the arrangement has its disadvantages, for, as the uses of electricity extend, the lack of unification and of standardization becomes serious. It was therefore realized some fifteen years ago that some change would eventually have to be made.

The legislation, the negotiation and bargaining which took place before the present clean cut and statesmanlike plan was evolved were considerable, as the process of securing the support of powerful companies and municipalities to a scheme which puts the whole control of the generation, transmission and sale of bulk supply into the hands of one authority was not easy to obtain. This was finally achieved in 1926—and to-day the enormous system is well on the way to completion. The instigators are convinced of its suitability for existing conditions and this is shown by the fact that $250,000,000 are being spent on the system—of which some $95,000,000 is for standardization of frequency. The capital charges of the major part of this expenditure (i.e. on the "Grid") are to be borne by the Central Electricity Board and paid for out of the generation economies which will result under the new system.

The Electricity Supply System in Great Britain—The Grid

In designing a unified system of electricity generation for Great Britain, those responsible did not discard the advantage of the widely scattered coal resources which Great Britain enjoys and they have decided to concentrate the generation of electricity in approximately one hundred and thirty selected stations. The position of each selected station has been chosen so that it can feed direct to the city and area near which it is situated. It was not, however, possible to find all the desired resources amongst existing stations, and at upwards of twelve additional centres, new generating plants are being erected.

The second portion of the scheme consists in the interlinking of all these one hundred and thirty generating stations with a complete system of transmission lines which

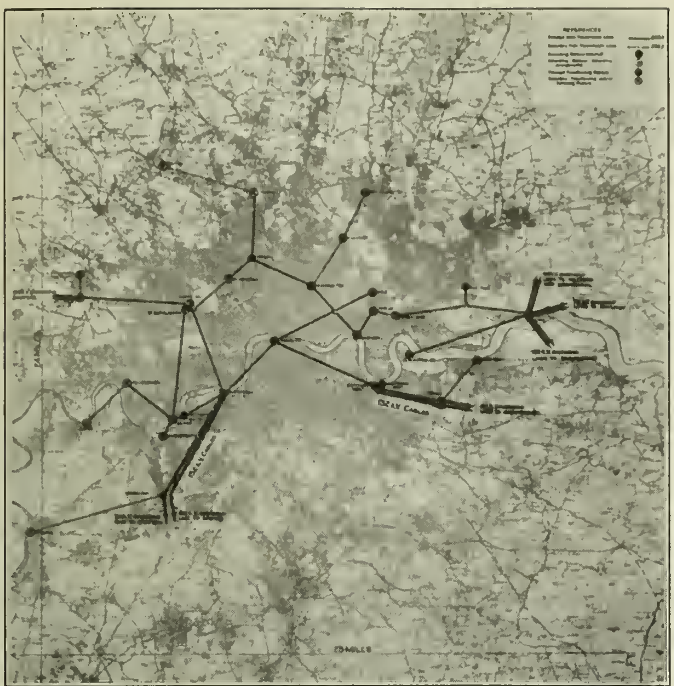

Fig. 2—London Cable Grid.

will form a network or "grid" over the whole country, and give supply to the less important intermediate towns. It will thus be apparent that this "grid" is not so much a huge transmission line, as a system of bus-bars through which all the generating stations are kept running in synchronism and in parallel with each other, and through which equalization of load can be effected.

The complete system of primary overhead transmission lines (Fig. 1), comprise about 3,000 miles of 132,000-volt 3-phase transmission. A steel core aluminium cable 0.77 in diameter is used—the resistance being equivalent to that of a 0.175 square inch copper conductor, and capable of transmitting up to 50,000 kilowatts. It will be seen from Fig. 1 that the system covers the whole country with the exception only of one or two sparsely populated areas which are also mountainous. The system is also to be extended to the north of Scotland but details are not yet settled.

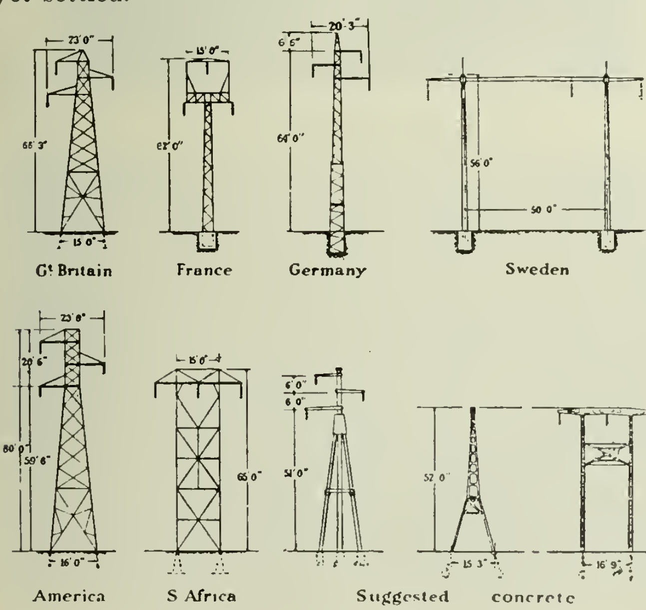

Fig. 3—Single-Circuit Towers.

One of the reasons for the choice of 132,000 volts is the probability of the experimental work on cables for operation at this voltage proving successful. Such cables involve very large expense but it is particularly desirable that they should be available when circumstances warrant their adoption. Oil-filled cables of this class are being tested on three sections of the grid in the London area.

Method of Operation of the Grid

The first function of the network is to enable all the connected stations to be operated at their best efficiency and to ensure the use of the spare plant throughout the country to its maximum extent. The power stations are divided into two main categories "base load" and "peak load" stations. The base load stations operate continuously, and the peak load stations operate for two shifts or for one shift. The choice of any station for one category or the other, depends on its operating costs and its capacity. Power will flow in any direction over the grid according as the requirements of economic running may demand—for the relatively short lengths of transmission line between stations makes the interchange of energy a simple matter. There is no intention or need to interchange energy over extreme distances. For convenience, therefore, in administration and in arranging operating programmes, the system is divided into ten sections which largely depend on the geography of the country.

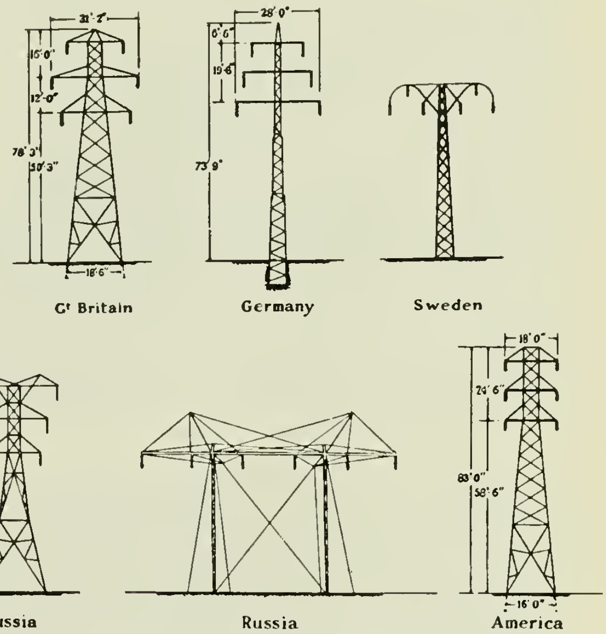

Fig. 4—Double-Circuit Towers.

The central authority controls and administers the generation and transmission of bulk supply, but this does not prevent the generating stations remaining the property of, and being manned by the body who distributes to the public. All that the central board requires, is power to dictate what stations shall run and how much energy they shall deliver at any time to the grid. The central board pays to the owners of a station all the costs of running it, including interest on its capital; and the board becomes the owner and seller of all the electricity generated. It is the deliberate policy of the board not itself to own and man generating stations.

A good deal of interest will attach to the scheme which is being evolved for the technical control of so large a system. Each section has its area control engineer, whose control station is in communication with each power station in his area, through special lines which are part of the general telephone system of the country. He will have

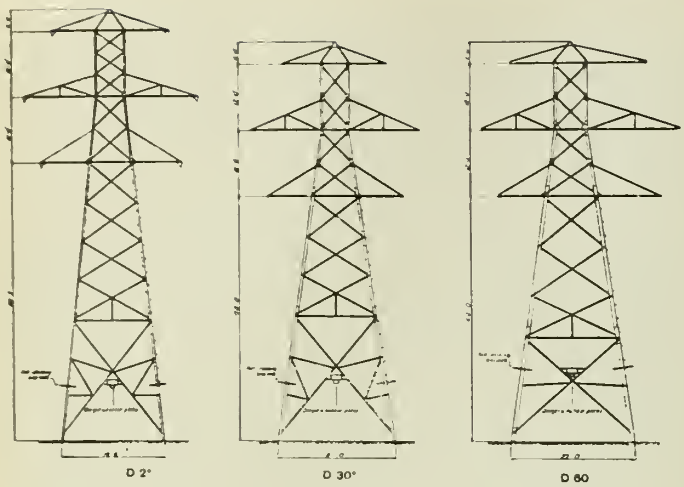

Fig. 5—Types of Double-Circuit Towers.

continuous automatic indication of five of the principal operating data of each station—including its power output, circuit breaker connections and such like.

Each station will adjust its generator voltage to suit the needs of its local supply, and the voltage at which it supplies the grid will be regulated by a ratio changing gear incorporated in the main transformers.

It is the intention to maintain the frequency of the whole network rigidly to a constant figure of 50 cycles per second, and the load exchanging throughout the system must be carried out without disturbing this.

The neutral point of the high voltage 3-phase system of the network is earthed at each transformer—a decision which has been the result of careful investigation of the conditions calculated to cause least interference with the communication circuits of the country.

The line protective gear for automatically isolating a faulty section is based on the use of pilot wires for short distances of the order of 10 miles, and on "distance impedance protection" without pilot wire for long distances. The maximum time of operation for clearing a fault in the case of the latter is two seconds.

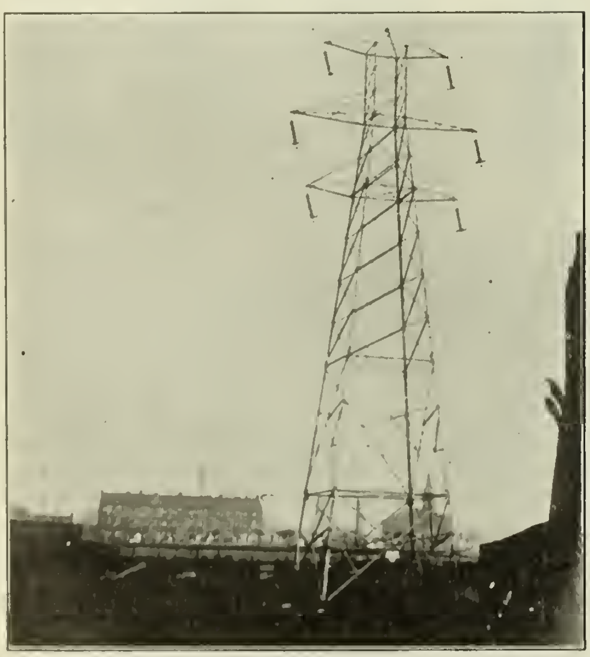

Fig. 6—Overhead Grid Passing Through an Industrial Part of the City of Glasgow.

The large number of existing generating stations which will not ultimately form part of the electricity supply system of the country are not to be rapidly eliminated. They will serve to supply the peak load to their local areas until it ceases to be economically sound to run them for this purpose. This will take a number of years and therefore the capital value of a large proportion of this plant will not be lost.

The London Grid—and the Secondary Network

London cannot be crossed by overhead lines, and the grid system for energy equalizing and transfer in London, is being arranged by a system of some 300 miles of 3-phase cables (Fig. 2). These cables have to be carried through the existing highways, and are at the moment in the process of being laid. Fifteen miles are for 132,000 volts and 285 miles are mainly for 66,000 volts. The principles of control and operation for London are to be identical with those for the rest of the country. Fig. 2 shows the London area and the positions of the selected stations and their connecting cables. The width of this area from border to border scales about 24 miles.

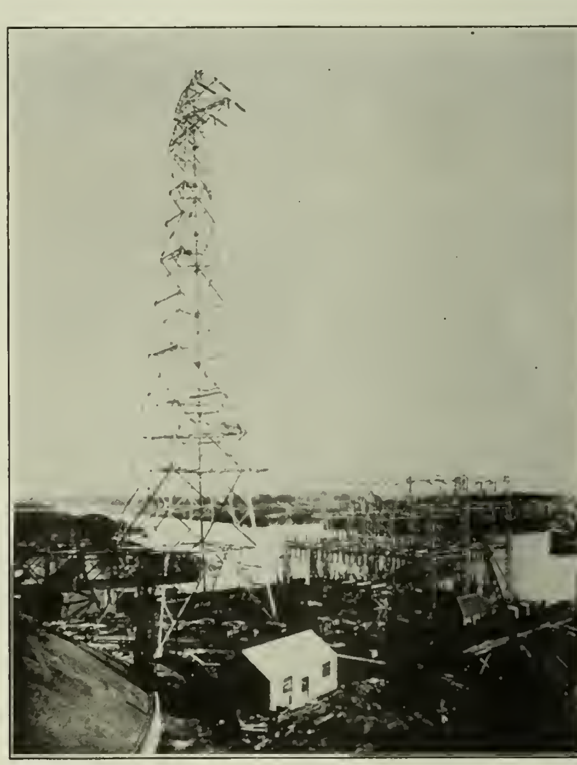

Fig. 7—Crossing the River Clyde.

Before illustrating constructional details of the 132,000-volt network, the explanations given above will not be complete without a mention of the secondary network. This is to transmit energy from the primary network to transforming centres at a distance from the primary lines. There will be upwards of 1,200 miles of such secondary transmission lines completed by 1934. The voltages will generally be 33,000. These lines will form regular distribution networks and will not be used so much for the purpose of load transfer and equalization, which is the principal function of the primary lines. There is, of course, already a large mileage of this kind of line which will now be incorporated in the main system.

The whole of the plant has been designed and manufactured in Great Britain and the opportunity of manufacturing so much high voltage large capacity plant has been warmly welcomed by engineers and manufacturers in this country.

Fig. 8—Crossing the River Forth.

CONSTRUCTIONAL DETAILS OF TOWERS, ETC.

The outline of the towers used on the British grid is the same throughout, this being determined so far as aesthetic considerations were concerned after a consultation with an eminent academician. The engineers were very pleased to be able to pass on to other shoulders this burden of responsibility, for there is a numerous and influential body of people in this country who fight hard, and rightly so, for the preservation of the beauty of the countryside in England.

Fig. 3 is reproduced from a recently published paper by Wright and Marshall, and shows typical constructions used in different countries.

In Fig. 4 are similar designs for double-circuit towers, and whether the British designs are considered more attractive than others is a matter of opinion.

Altogether there are eight standard types of single-circuit towers and eight types of double-circuit towers.

One example will suffice, showing respectively the 2 degrees, 30 degrees and 60 degrees double-circuit towers, these designations implying the maximum combined angles which the arrival and departure cables may make with the straight-through line (Fig. 5).

Fig. 6 shows the overhead grid line passing through an industrial part of the city of Glasgow,. This gives an idea of the appearance of the 132,000-volt transmission as now erected.

Fig. 7 shows the crossing of the River Clyde. The span is 960 feet, the heights of the towers are 270 and 283 feet, and the clearance at the lowest point of the span wires is 228 feet.

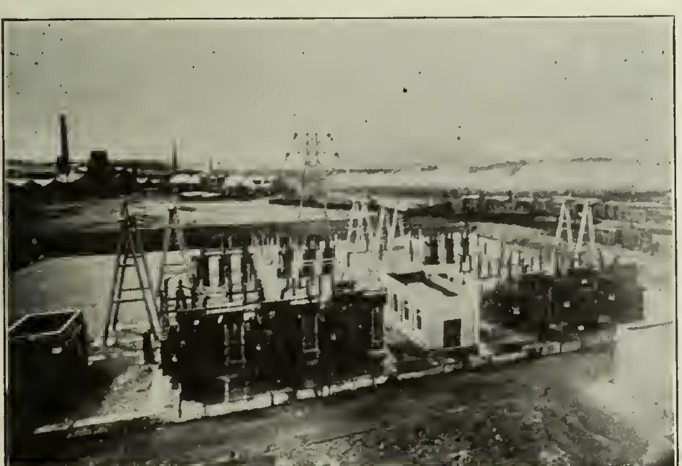

Fig. 9—Sub-station "Low" Type.

Fig. 8 is of the crossing of the River Forth. Here the towers are 3,050 feet apart, 338 feet high, and the clearance at the lowest point of the conductors is 158 feet.

The transformers for feeding the grid are of the 3-phase type, having capacities of up to 75,000 kv.a. in one unit. The ratio changing gear for adapting the station voltage to that of the grid is incorporated in each transformer.

Fig. 9 illustrates a "low" type of transformer and switch station, designed for places where land is cheap. It avoids the elaborate overhead gear of the more usual "high" type and is in itself inexpensive and has a low maintenance cost, and Fig. 10 one of the more usual design of "high" type transformer and switch stations.

STRENGTH AND TESTING OF TOWERS

The testing of the towers to withstand any load which could come on them accidentally has been carefully worked out, and Fig. 11 shows a tower testing plant at Wembley. The towers must have a factor of safety of 2.5 when, with unbroken conductors there is a wind pressure of 8 pounds per square foot on the conductor when coated with ice, and a wind pressure of 25 pounds per square foot on one and a half times the projected area of one face of the tower. The factor of safety must be 1.5 under the above conditions

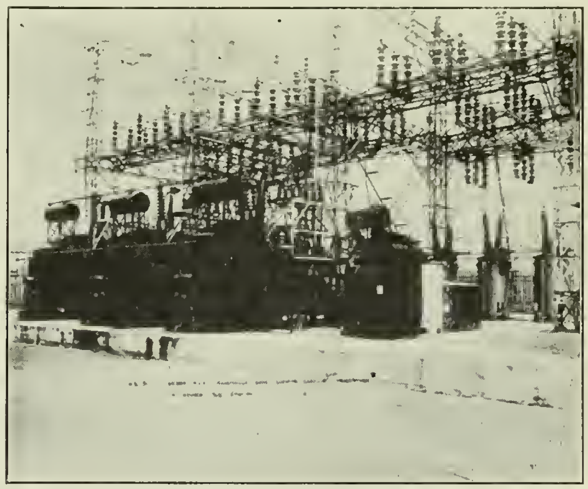

Fig. 10—Sub-Station "High" Type.

when two-thirds of the conductors are broken. These conditions involve applying loads at the top of the towers which may reach 70 tons. All the tower designs are type tested to ensure that they comply, and they are then tested to destruction to ascertain their ultimate strength.

Fig. 12 shows a tower after being tested to destruction. Usually, when carrying out this test, one of the members is observed to buckle and the load can then be released before complete collapse takes place. In the instance illustrated here, the collapse was too sudden for this to be done.

CONCLUSION

In conclusion, and quoting from the inaugural address of a predecessor in the presidential chair of the Institution of Electrical Engineers—Sir Archibald Page, who is chief engineer of the Central Electricity Board. In enumerating the advantages to be obtained from this bold scheme of national electrification, he stated:—

(*a*) It will constitute, with the selected stations, a complete system for the production and transmission of electricity on a wholesale scale, and thus enable full advantage to be obtained from the diversity of loads, from the correct apportionment of the total load between stations of varying efficiency, and from the elimination of obsolete and unsuitable plant.

Fig. 11—Tower Test Plant.

Fig. 12—Tower Test to Destruction.

(*b*) It will enable the capital cost per kilowatt installed in the selected stations to be kept down, owing to it being possible to use the largest and most efficient plant. This can be done because the stations will form part of a really widespread system.

(*c*) It will be possible for these stations to be correctly located away from the centres of population, thus reducing the railway congestion caused by the carriage of coal to them and ensuring all the other advantages which accompany freedom in the choice of site.

(*d*) It will enable individual stations to be employed of larger output than would otherwise be possible; and extensions to be co-ordinated in accordance with a plan, which will both avoid premature expansion and at all times closely relate the plant capacity to the actual load.

(*e*) It will allow the aggregate amount of spare plant to be considerably reduced.

(*f*) It will enable "blocks" of waste heat or energy from blast furnaces, coke ovens and other sources to be transformed into electricity and thus usefully employed.

(*g*) It will level up (without levelling down) the efficiency of generation throughout the country.

(*h*) It will enable such water power resources as we have, to be tapped, and thus supplement the energy from coal in a more complete and less costly manner than would otherwise be possible.

(*i*) It will facilitate railway electrification by reducing the capital cost of the necessary transmission lines, since the "bars" of the grid will follow the railway routes to a considerable extent.

(*j*) It will reduce the cost of secondary or regional transmission by increasing the number of points at which the supply can be taken; and, for the same reason, it will encourage the opening up of new areas of supply in rural and agricultural districts.

These are all factors which will make for financial gain. But there are other considerations which may ultimately mean more than the financial ones.

(*k*) The existing population and industries in the rural districts of England would not have obtained supplies for many years, and the establishment of new industries in such districts would have remained very difficult.

(*l*) The general availability of electricity for domestic and industrial use in such districts will undoubtedly help to make country life more attractive and should help to check the drift of the population towards the larger towns and cities which has been a marked tendency in the past.

(*m*) The scientific use of coal in large electric generating stations instead of its crude consumption in smaller plants and in the domestic grate, should help the movement towards purification of the atmosphere in large cities.

Great Britain undertook the pioneer work in high tension distribution, when in 1887 Ferranti laid his 10,000-volt transmission from Deptford power station to the west end of London, and supplied energy over these mains before there was any high tension transmission elsewhere. The comprehensive national system of electric trunk mains which have been described is another piece of pioneer work of a similar kind. Whether or not the idea is applicable to other countries remains to be seen, but the result will be worth careful study by those in all communities who believe that electricity has but just begun its great social and civilizing work in the world.

DISCUSSION

Julian C. Smith, m.e.i.c.[1]

Mr. Smith remarked that there was a possible danger in such a comprehensive development, that lines would be built and equipment installed that could not be justified by immediate economic considerations. If those in charge of such a development allowed themselves to be carried away by the magnitude and perfection of the plan, it might be found in later years that a plant had been installed that was not properly located to give maximum service and that money had been spent that was not giving a maximum possible return. Experience in a rapidly expanding industry in Canada had taught the wisdom of not making commitments for expansion too far in advance.

John Morse, m.e.i.c.[2]

Mr. Morse, while appreciating that the electric power problems of Great Britain and Canada are vastly different, observed that in the past we had been in the habit of considering a transmission system as essentially for the transmission of power. The Grid included all the elements of a transmission system, but he understood that its purpose is not to transmit large amounts of power, but to act as a system bus bar through which all the generating units will be held in synchronism, regulating the frequency, permitting the equalization of load, and facilitating the better utilization of the higher efficiency plants. It seemed rather surprising that under these circumstances such a high line voltage was used. It would be interesting to know what the maximum transfer of power would be between some of the larger stations where load transfer takes place.

Tap changing under load would appear to have decided advantages on a system such as the Grid.

He had noted that in many cases small banks of 10,000 to 20,000 kv.a. transformers connect the lines to a station, thus forming part of the lines, and these banks were paralleled on the low voltage side. This would appear to

(1) Vice-President and General Manager, Shawinigan Water and Power Company, Montreal.

(2) General Superintendent, Shawinigan Water and Power Company, Ltd., Montreal.

indicate that the lines, which were designed to carry upwards of 50,000 kv.a., would be limited in load to the capacity of the connecting banks.

The author had stated that the neutrals of all power banks are solidly earthed on the 132 kv. side, and that "this decision was the result of careful investigation of the conditions calculated to cause least interference with the communication of the country." This was a particularly interesting point in Canada, as interference with communication has been quite a problem in this country.

He noted that pilot wire protection is being used on 132 kv. lines up to 10 miles in length. It would appear that this would be rather an expensive protective scheme for such distances.

The number of generating stations in the country was given as 580, but there were only 130 selected stations in the Grid, 12 of which were being newly built. It might be interesting to learn what would become of the remaining 462 generating stations.

Mr. Morse felt that with regard to certain features of this system further information would be of interest, and desired to ask the following questions:—

(1) Has any difficulty been experienced with regard to the stability of the system, when a three-phase short-circuit has been cleared on the longer relay times?
It would appear that with so many generating units in parallel, certain stations might go out-of-step with the main system during an extended short-circuit, and result in faulty relay action, possibly at remote parts of the system.
(2) If a loop is broken by the automatic clearing of a faulty line, is there any fear that any of the smaller banks in the loop will become seriously overloaded due to the redistribution of the loads?
(3) When a by-pass breaker is closed between two lines, making a metallic connection between these lines, will the impedance type of line protection used function with equal effectiveness as for the normal method of operation?
(4) Has it been necessary to resort to directional or (reverse power) relays in connection with the distance impedance protection? If so, has this feature proved successful in operation?
(5) Is overhead or underground construction used for the pilot wires, and would it be possible to give approximate cost per mile?
(6) Is the tap changing on power banks under load done by remote manual control, and what provision is made to insure that taps are also changed on the potential transformers used for relay protection?
(7) Have any interference problems been experienced with the star, solidly earthed method of operation of the 132 kv. lines?
(8) Are there any separate generating systems in the Grid area not connected to the Grid, and if so, will these be included eventually?

Mr. Morse expressed the hope that Mr. Paterson at some future time would add to his kindness by contributing a paper on the actual operating experience on the completed scheme.

C. C. Paterson, O.B.E.[3]

The author replied that Mr. Morse had raised some most interesting points regarding the features of the British Grid and that he would deal with each of his questions as far as was possible, though one would appreciate that as the grid system was not yet complete, and that the part now in commission had been working for only eighteen months, operating experiences particularly concerning abnormal conditions, was somewhat meagre at present.

With reference to the stability of the system on short circuit, the author observed that so far there had been no 3-phase short circuits directly on the 132 kv. system. Repeated 3-phase short circuits had, however, occurred on the lower voltage systems without causing instability.

Regarding the opening of ring main loops, the design of the grid system was such that it should be possible to open any loop under normal load condition without causing serious overloading.

[3] Director, Research Laboratories, General Electric Company, Ltd., Wembley, England.

In reply to the question regarding bypass breakers and impedance protection, the normal method of operating the lines was with the section switches closed, and the impedance protective gear was designed for operation on the assumption that all the 132 kv. lines were directly connected.

Directional relays were incorporated in the impedance protective system. Up to the present, no faults had occurred on the lines so that no experience was available to state whether the scheme of protection was effective or not.

Under pilot wires were generally used, drawn into existing ducts where possible. Pilot protection was usually associated with sections of transmission line in the densely populated areas. The pilot routes were determined by the duct and other facilities available, and did not necessarily follow the routes of the power lines. The approximate cost per mile of the pilots was $4,000.

In connection with the tap changing gear control, the ratio changing gear on the power transformers had a remote electrical control which was worked by the operating engineer. Provision had been made for a later addition of automatic gear should this be found necessary. The taps on the potential transformers were changed automatically by auxiliary switches to correspond to the taps on the main power transformers.

No interference troubles had so far been experienced due to the use of a solidly earthed system of 132 kv. lines.

There were still a few privately owned generating systems in operation which were not connected to the grid. Since the inception of the grid system, however, many of the companies owning these generating stations had been considering the advisability of connecting up to the grid system. It was anticipated that in the long run practically every generating station of importance would be directly or indirectly connected to the grid system.

The author stated that he would like to add a few words about other points mentioned by Mr. Morse. Regarding the adoption of 132 kv. for a system in which transmission of power was not necessarily the main object, this voltage was chosen after careful consideration of the required power interchanges, the maximum load interchange per line being estimated at 50,000 kv.a. In fact, the actual costs of 110 kv., 132 kv., and 150 kv. systems were investigated and compared before making a decision, the 132 kv. scheme proving to be the most economical.

The load capacity of the lines was not affected in any way by the connection of transformer banks of only 10,000 or 20,000 kv.a. for as well as these being parallelled on the low voltage side, the high tension section switches were normally kept closed and the lines were therefore unbroken.

To refer again to pilot wire protection, this scheme was admittedly expensive, but the cost of the protective system was, in the opinion of the engineers, fully justified by the fact that the lines protected pass through densely populated industrial districts, and it was of great importance to ensure that adequate protection was afforded to the properties over which the lines pass, as well as to ensure continuity of supply.

Of all the generating stations in the country worked by the 580 electricity authorities, 8 per cent of the stations alone had between them half of the total plant, while 40 per cent of the stations—the smaller ones—aggregated less than 2 per cent of the total capacity. The largest, most economical and most conveniently situated of the stations would be included in the 130 selected to be developed for base load supply. Of the remainder, a proportion would be kept for peak load and emergency supply purposes, whilst some of the smaller and less efficient plants would be shut down, or used only as distribution centres.

Predicting Future Population in Western Canada

C. J. Mackenzie, M.E.I.C.,
Dean of Engineering, University of Saskatchewan, Saskatoon, Sask.

Original version presented before the Saskatchewan Branch of The Engineering Institute of Canada, in March, 1929.
Revised version of paper presented before the Edmonton, Calgary and Lethbridge Branches of The Institute in January, 1931.

SUMMARY.—Predictions of the probable future growth of population are necessary in many branches of engineering work, and in this paper the author has developed a method of estimating the future population in western Canada based on the separate consideration of urban and rural areas. Light is thrown on this question by a study of records for comparable districts and cities in the United States in the past, and the conclusion is reached that while the urban population in Western Canada will probably grow substantially in the next twenty-five years, it is not likely that under the present fundamental conditions there will be any marked increase in rural population over a large portion of the prairie provinces.

Introduction

This paper is the result of a study made in 1929 to answer an ordinary engineering question. There is nothing unusual in the question, but it is felt that some novel features and methods were developed out of the resulting study. The question was: "What is a reasonable assumption as to the population of Saskatoon, Saskatchewan, in 1955 for purposes of engineering planning and design?" The bare answer to that question is, of course, local in interest, but the investigation brought out facts and relationships which it is felt will be of interest to every one concerned about the future of Canada.

It is desired to emphasize the problem before the solution is offered. The question is not "What *will* the population be in 1955?" but "What is a reasonable assumption for purposes of design?" There is obviously a great difference between the two questions, and the writer is not so much concerned with the ultimate correctness of his estimates for one particular city as with the reasonableness of his method. In the case of a particular and phenomenal growth, a reasonable estimate is bound to be wrong and a correct guess must have been unreasonable when made. An engineer's estimate is soundest when it will approximate closest to the truth in the greatest number of cases. The writer is also fully aware that the problem is scientifically indeterminate and that nothing in the nature of a logical proof is to be found in this paper, but he also feels that the evidence submitted is very convincing and until more impressive proof to the contrary is submitted or until time itself reveals the truth, the estimates made, as a result of the following study, must be considered as reasonable.

Estimating Future Populations Not New

Estimating the future population of countries and cities is not a new problem: extrapolation however has always been recognized as uncertain and only when the growth curve is regular and of great length compared with the extrapolated portion can the method be considered reliable.

Extrapolation between census years has long been a necessary practice in most countries of the world, and the larger and well established cities have also been able to do this with satisfactory results.

The methods in most common use are:—

(*a*) Arithmetic Progression, i.e., assuming that the growth in actual numbers per year will continue as for the past census period.

(*b*) Geometric Progression:—i.e., assuming that the rate of growth per year will continue as for the past census period.

(*c*) Graphical Extrapolation:—i.e., plotting a curve of past growth and extending it by eye.

(*d*) Derivation of a formula:—i.e., fitting a higher order parabola, logarithmic or other curve to data of past and then extending it.

As already inferred some of these methods give very reasonable results when used in connection with older countries and larger cities and for periods of ten years and even longer, but when it becomes necessary to estimate population over much longer periods and especially where the history of growth is both brief and flashy, none of these methods as ordinarily applied to individual cities can be used with confidence. This is the case in western Canada as the following table will illustrate.

Table I

Method	Year of Estimate	Census Data Used	Estimated Population for 1936	
			Edmonton	Calgary
Arithmetic Progression	1916	1906–1916	133,000	142,000
" "	1926	1916–1926	76,000	74,000
Geometric Progression	1916	1906–1916	770,000	980,000
" "	1926	1916–1926	80,000	75,000

Take as an example the case of Calgary with a present population of from 85,000 to 90,000—the arithmetic method if used in 1916 would have given for 1936 an estimate double the figure obtained if applied in 1926, and both will be wrong by perhaps 50 per cent. If the geometric method be used the 1926 calculations give an estimate for 1936 which is about 20 per cent below the present (1931) population and the 1916 estimate of 980,000 is as ridiculous as the real estate boom of twenty years ago when land was subdivided and sold in quantity and price in all western cities on some such geometrical assumption. What has been shown to be the case for Calgary and Edmonton is true for all western cities. Fig. 1 which illustrates in graphical form the growth of Calgary, Edmonton, Saskatoon and Regina, will show that extrapolating any of these curves by eye is out of the realm of reason and that trying to fit a mathematical curve would be futile even if possible.

It is obvious then that ordinary methods cannot be used for estimating the future of cities in western Canada with any confidence. But estimates had to be made and one solution worked out is presented below.

Biological Theory of Growth

Professor Raymond Pearl, in his book "Studies in Human Biology" under the heading of Population Studies,

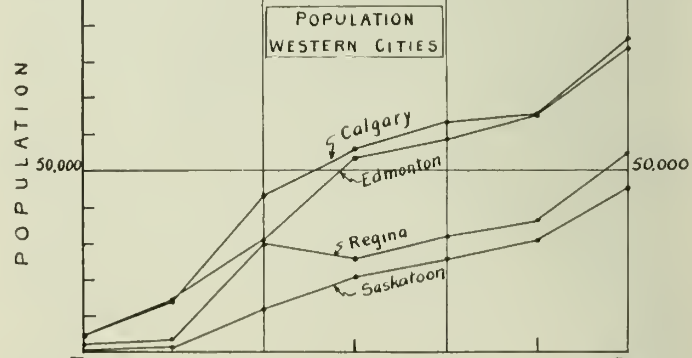

Fig. 1—Population of Western Cities.

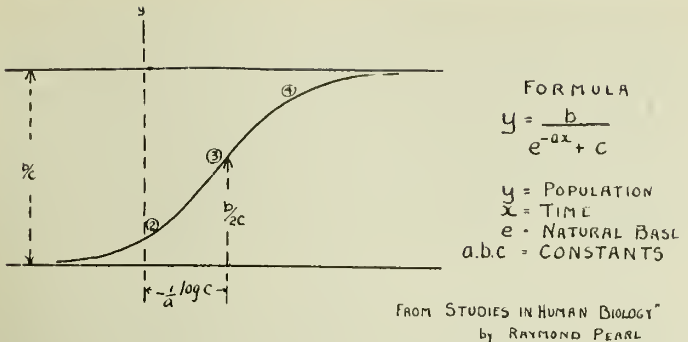

Fig. 2—Pearl's Curve.

offered several years ago some very pertinent observations on current methods of predicting population. He pointed out that most formulae for population curves take no account of the obvious truth that, in any prescribed area, the population can not increase indefinitely. He consequently sought a curve formula which he hoped would be comprehensive enough to cover the entire life history of large economic states. In discussing population growth he cited some interesting laboratory experiments made by him. Two flies were put in a bottle which was both comfortable in temperature and provided with an adequate and agreeable food supply. In this miniature garden of Eden the mathematical story of world population growth is, he contends, roughly paralleled. Fig. 2 shows graphically how the increase took place and indicates the suggested formula for the resulting sinusoidal curve.

It will be noted that for a while at first, the flies being only two in number, the increase, though large on a per capita basis, was actually small; shortly after, the increase, following the law of geometric progression, became very rapid (2-3); the reason being that the food was plentiful, the living conditions comfortable, the birth rate high, the death rate low and therefore the natural increase large. At the inflection point (3) a change occurs, although not abruptly, the curve of increase first straightens out and then begins to decrease, first slowly (3-4) then rapidly, until finally a stationary population is reached. The reasons are clear; with increasing numbers the strife for food becomes greater, living conditions become more cramped, the death rate increases; in general human terms, the economic pressure becomes great and the increase stops.

Professor Pearl suggested that for any country with definite boundaries the population increase would follow a curve of the form shown in Fig. 2, providing the basic form of civilization was not changed by any fundamentally

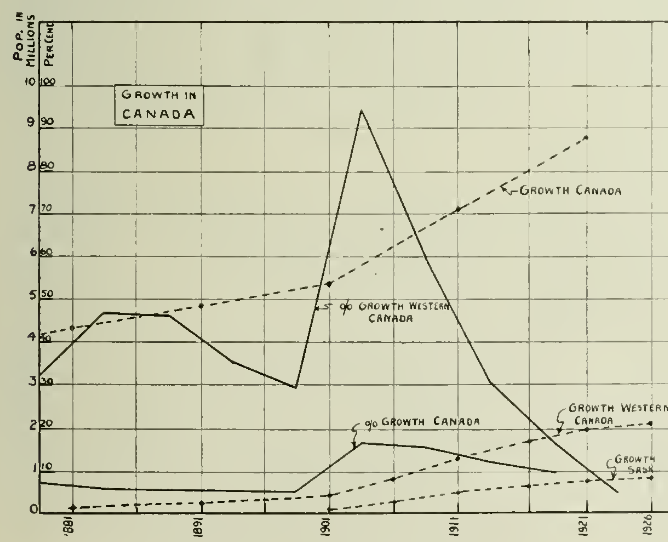

Fig. 3—Growth in Canada.

new factor or forces such as those which changed the culture of countries from the pastoral to the industrial stage. He successfully fits such curves to the growth data of over fifteen countries including the United States and most of the European nations. If one tries, however, to fit such a curve to Canada he will probably come to the conclusion that the theory is not sound, as it does not appear to be mathematically applicable, and Fig. 3 also seems to indicate that there is little regularity, rule or order to Canada's growth, and that there is little if any direct connection between the growth of the western provinces and that of Canada as a whole.

The writer is not advocating or concerned with the general mathematical correctness or applicability of Professor Pearl's formula but he does feel that from a qualitative viewpoint this theory of population increase is very suggestive. It must also be quite clear to thinking people of this day that Canada is not and probably never will be an economically confined bottle in the sense of the above experiment. To-day Canada grows enough food to supply well over 20 millions of people which means that over 10 million of Canada's human flies are living in other and foreign bottles. Western Canada, where the major portion of our exportable food stuffs are grown, is thus really more dependent upon conditions outside of Canada for its growth and prosperity than upon strictly Canadian conditions. Incidentally this may explain in part why the

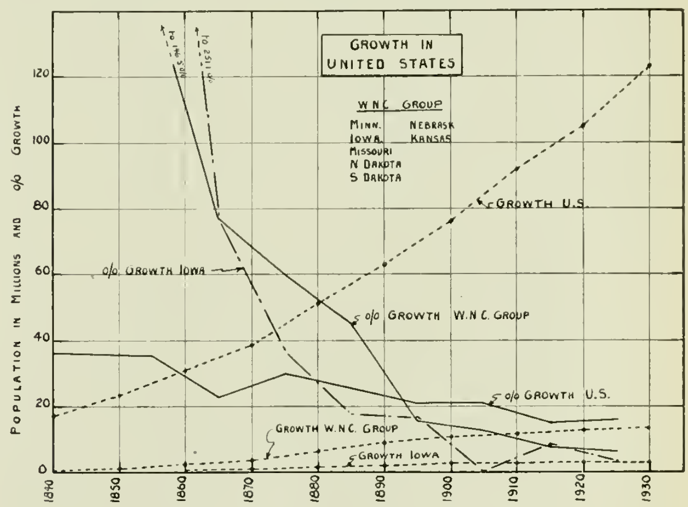

Fig. 4—Growth in United States.

common people of western Canada have on the whole been given to a more than usual interest in international considerations.

The study of the growth of Canada does not throw much light on the growth of Saskatchewan, but it is interesting to note that while western Canada was being filled up rapidly from 1905 to 1915, the urban centres in Ontario alone, which had been growing very slowly before 1900, increased by one man for every man placed on a western farm. While the writer feels that little guidance to western population problems is to be had from a study of the growth of eastern Canada, he does feel that those interested in the growth of eastern cities as a whole should consider as one of the many factors involved, the future growth of western Canada.

Comparison With Western States

It seems, then, that little help can be found in a study of general Canadian conditions, but it was felt that a study of the western agricultural states of the United States might throw light on our problem.

Fig. 4 shows the growth of the United States as a whole, the west north central group of agricultural states and the individual State of Iowa, which for reasons to be given later

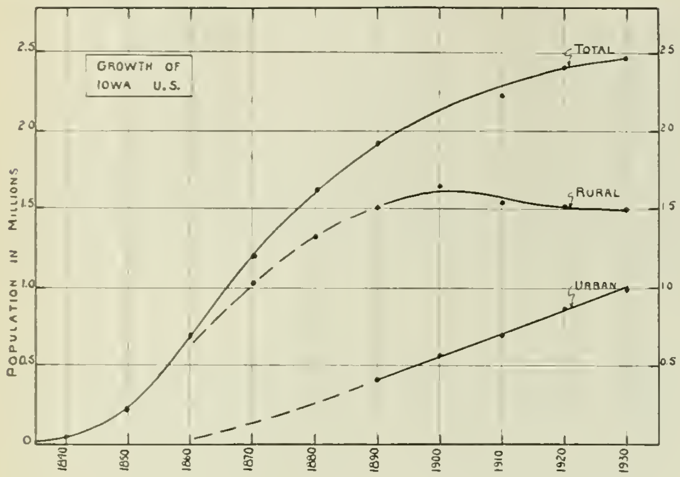

Fig. 5—Growth of Iowa.

seemed to offer the best comparison with Saskatchewan. It will be noted that, as was the case in Canada, the growth of the western agricultural states is not related even approximately to the general growth of the United States. The growth in the latter has increased from about seven millions during the 1860-1870 decade to about seventeen millions during the 1920-1930 decade while the rate only decreased from about 23 to 16 per cent. While in the former the actual growth decreased from 1.7 million during 1860-70 decade to about 0.7 million during the 1920-1930 decade and the rate decreased from 78 per cent to 6 per cent. It was concluded then that a general study of the western agricultural states should be undertaken and a detailed study of Iowa as the state most comparable to Saskatchewan in its economic setting. The following facts indicate the similarity of these two areas:

(1) Iowa is about 300 miles west of Chicago, the great regional city of the American states.
Saskatchewan is about 400 miles west of Winnipeg, the great regional city of the Canadian west.

(2) Iowa is cut off from a distributing standpoint on the north by Minneapolis-St. Paul, Minnesota, on the south by Kansas City and St. Louis, on the west by Omaha, Nebraska.
Saskatchewan is cut off on the north by a barren area, on the south by the international boundary and on the west by the cities of Edmonton and Calgary.

(3) Iowa is essentially an agricultural state.
Saskatchewan is essentially an agricultural province.

(4) The urban centres of Iowa, generally speaking, are state cities and see the needs of the area within the state, and do not partake of the nature of Chicago and Minneapolis and St. Paul which serve as manufacturing and distributing centres of many states. Likewise the cities of Saskatchewan, generally speaking, will serve the people of the province only and thus are dependent on the development of the local resources.

Rural and Urban Growth in United States

Fig. 5 illustrates the growth of Iowa. The curve showing the total growth is not illuminating but when the rural and urban curves are separated a very striking and novel generalization occurs to one. Namely "In agricultural states the rural population seems to grow according to a sinusoidal curve similar to that suggested by Pearl. The urban centres on the other hand get their greatest growth after the agricultural land has filled up." In the case of Iowa the rural population apparently reached the saturation point about 1890, while the urban population has increased from 400,000 to nearly 1,000,000 since that date, and it should be remembered that these cities are serving generally only the State of Iowa. Obviously a generalization based on one observation is questionable, the writer has, however, found a similar condition for nearly every state of the Union. Fig. 6 gives the curves for a few states and indicates that, as far as the United States is concerned, the above generalization seems to be reasonably sound. Many interesting points arise from a careful study of Fig. 6.

Rural

Considering rural growth first, it is seen that the group of old New England states, Maine, New Hampshire and Vermont, which are not excessively industrial in aspect, approached rural saturation in 1850, and while records are not available to plot the complete curve it apparently is of the sinusoidal type. In Ohio the country started to fill up rapidly about 1820 and reached rural saturation about 1880. Coming still farther west, Illinois started later than Ohio but grew faster, then still farther west Iowa started after Illinois was nearly filled up, and Minnesota lags behind Iowa in a similar manner. The curves of the Dakotas, which are not shown, in turn lag behind that of Minnesota. We have here in these curves of rural growth, each lagging behind the other as we proceed westward from the Atlantic coast to the far west, a graphic picture of the history of rural settlement in the United States. What the writer believes, however, has never been pointed out in this form before, is the very important fact that the rural growths follow curves of approximately sinusoidal form, differing of course in total height and steepness but nevertheless of the same general form. Naturally, with the great changes that have taken place in the mechanization of agricultural and other processes, the curves are not perfect, especially on the top asymptote, but no one can deny the general nature of the curves, and the reasons are, in the writer's opinion, to be found in the operation of general economic laws of international scope as already suggested.

Urban

Now consider the urban development. From the figures of Ohio the cities of Cleveland and Cincinnati have been deducted, also Chicago from Illinois and part of the twin cities from Minnesota. This was done because these cities are regional or national in character and it was desired to get a picture of the growth of the urban centres which were more dependent on the local conditions, although of course in the more eastern states this can be done only approximately.

In every case it will be seen that the urban growth did not really start until rural saturation was approaching; that in Maine, New Hampshire and Vermont the urban growth has continued for nearly 80 years after rural saturation, and in Iowa for about 40 years to date with no indication of decreasing, that in Minnesota rural saturation seems to be approaching while urban growth is still showing no sign of diminishing.

A significant observation is that in the more industrialized states the urban curves are steeper and tend, up to the present at least, to be concave upwards, while in the agricultural and less highly industrialized states the urban growth has more closely followed a straight line of more moderate slope.

One readily sees the economic history written in these curves. As settlement worked westward each new agricultural state was rapidly filled up by pioneers; at first the country was unproven, the settlers usually had little capital, their purchasing power was limited. What supplies they used were brought in from urban centres in established eastern states and the total urban centres usually were small trading centres. As the settlers became established and prosperous their purchasing power increased, manufacturing and distributing companies, realizing that a prosperous and permanent market was being built up which could be served more economically at close range, opened up wholesale houses and branch factories in local centres: to this impetus to urban growth was added the need and opportunity for financial institutions, professional services, governmental departments, printing establishments, industries using the local products as raw materials, and the many other activities of advancing civilization. Unquestionably with the shifting westward of branch factories, etc., many eastern centres were deprived of past business, but with the general advance in mechanization and new development, which has marked this century, new fields have been constantly opening up so that up to the present the losses in some fields have generally been more than counterbalanced by newer activities and markets.

If we study in detail the urban basis of Iowa we find that, in what is probably one of the most essentially agricultural states of the Union, the gross value of manufactured products is nearly double the gross value of the agricultural products, that the industrial activity is not centred in a few large plants producing a national product, but over 50 per cent of all employees are in small and diversified plants, employing fewer than one hundred men. The first ten principal industries in order of value of products are slaughter and meat packing, butter making, food preparation, railroad shops, glucose and starch, flour mills, printing and publishing, bakeries, foundries, and engine shops. It will be seen that most of these activities are either founded on the natural production or on the needs of an essentially agricultural state, and we know that the urban development of Saskatchewan will be founded upon a similar basis.

Urban and Rural Growth in Canada

In western Canada since 1905 settlement and development have taken place qualitatively as described in the preceding paragraphs. At first all manufactured articles came in from the east or south and for a while Winnipeg was the only distributing and manufacturing centre of the three prairie provinces, but gradually manufacturing is becoming a real factor in the west, and branch factories and distributing agencies are rapidly increasing in the larger urban centres in all three provinces. Fig. 7 shows in graphical form the past growth of western Canada and suggests future trends. The Canadian census data have been adjusted so as to be comparable with those of the United States, in which urban includes all towns of 2,500 population and over, while rural includes all towns and villages below that figure as well as the actual farm population, which in the United States amounted in 1920 to about 60 per cent of the total rural. However, if this adjustment be not made, the general shape of the curves will be the same and the conclusion reached about urban growth will also be the same.

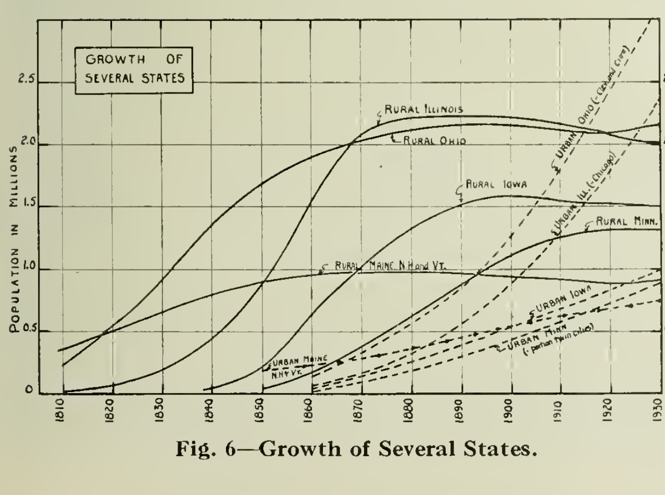

Fig. 6—Growth of Several States.

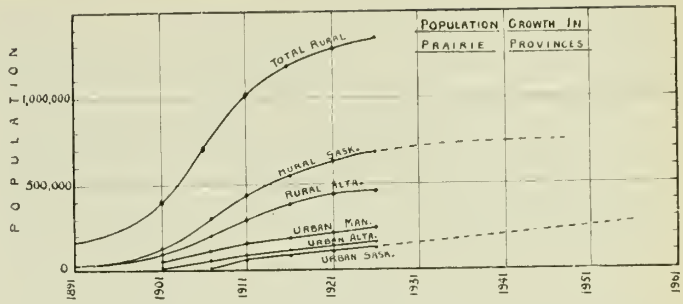

Fig. 7—Population Growth in Prairie Provinces.

Rural

From Fig. 7 the conclusion is reached that under the present fundamental conditions we can expect little more rural growth in Saskatchewan or in the other parts of western Canada. This statement when first made by the writer during the buoyant and prosperous days of 1929 was severely criticised but to-day when a more thorough appreciation of the effects of international economics on the value of exportable products is the order, it does not meet with the same reaction. However, to estimate that the future rural population of Saskatchewan will become stationary around 700,000 to 800,000 is novel, and can not be accepted lightly. The writer realizes that although a formula may be and has been fitted to the existing curve, according to methods explained, that is only evidence and not a proof. In addition, however, a general study has been made of the probable density of western agricultural areas by assuming that the rural population density economically suited to any of the western agricultural lands is a function of the quality of the soil, the yearly rainfall (between obvious limits) and the reciprocal of the freight rate to the European market, and such a method was applied to the western states of Iowa, Kansas, North Dakota and South Dakota. Using Iowa as a base, the calculated densities which the other states should have on that basis checked out quite well with the prevailing densities. When this method was applied to Manitoba and Saskatchewan the densities per square mile of usable agricultural land worked out to 15 and 7 respectively which correspond well with existing conditions. As there are about 105,000 square miles of such land in Saskatchewan, by this method an ultimate rural population of about 735,000 is indicated. While it is admitted that the second method is approximate only and can not be accepted as a proof, it at least reassures one in the general conclusion drawn from the curves. It will be protested that no account has been taken of the vast mineral possibilities of northern Manitoba and Saskatchewan, but the reply is that even admitting great potential developments in mining, the present portion of Saskatchewan will probably be no more affected than was Iowa with the development of Minnesota mines, or the farmer of Ontario with the mineral development in the north of that province. On the other hand Alberta offers a somewhat different situation; the Peace river district, if given a short outlet to tide water and thus a cheaper freight rate to world markets, would probably grow for reasons just given, but as far as the present settled portions of Alberta are concerned little effect would likely be felt in rural or urban centres. It is assumed then, that over the settled portions, rural western Canada is approaching saturation, that future growth will be slow and no more large immigration movements may be looked for.

Urban

Even although it is admitted that there will be little tendency towards increase of rural population, one concludes from a study of the curves of the western states that the urban population will grow substantially within the next twenty-five years. If the rural population does not increase greatly in numbers, this does not mean that business will not increase. In the nature of things (unless the present exceptionally severe depression completely ruins the west) as time goes on the wealth and purchasing power of the country will gradually increase; this taken into consideration with the definite movement, evident to-day, towards establishment of branch and moderate sized industries serving local needs will assure a healthy urban growth for some time.

At what rate will that growth take place? As was pointed out, in agricultural states of the Union the total urban growth taken over a number of years approximates a straight line. Fig. 7 indicates that a similar growth has been taking place in urban population in Manitoba, Saskatchewan and Alberta. Will this continue for twenty-five years? When will the curve for total urban growth begin to flatten out like the rural curves, as they, of course, must eventually? These are questions that cannot be definitely answered, but in western Canada the writer feels that this will not occur for at least twenty-five years, his reasons being as follows.

First, the 1930 census data show that the curve for total urban population of the United States as a whole is still slightly concave upwards but is approaching the point of inflection. Fig. 8 shows that in the old industrial state of Massachusetts there is a falling off, while the middle Atlantic states of New Jersey, New York and Pennsylvania are still increasing in a straight line, as also are the Dakotas, Iowa, Minnesota and the north west central group as a whole. The rapid growth of urban population in California and Florida has done much to keep the curve of total urban population from falling off, but the growth of these two latter states is of a type foreign to the economic considerations of this paper. The sharp increase in population of the southern states is due to the gradual industrialization

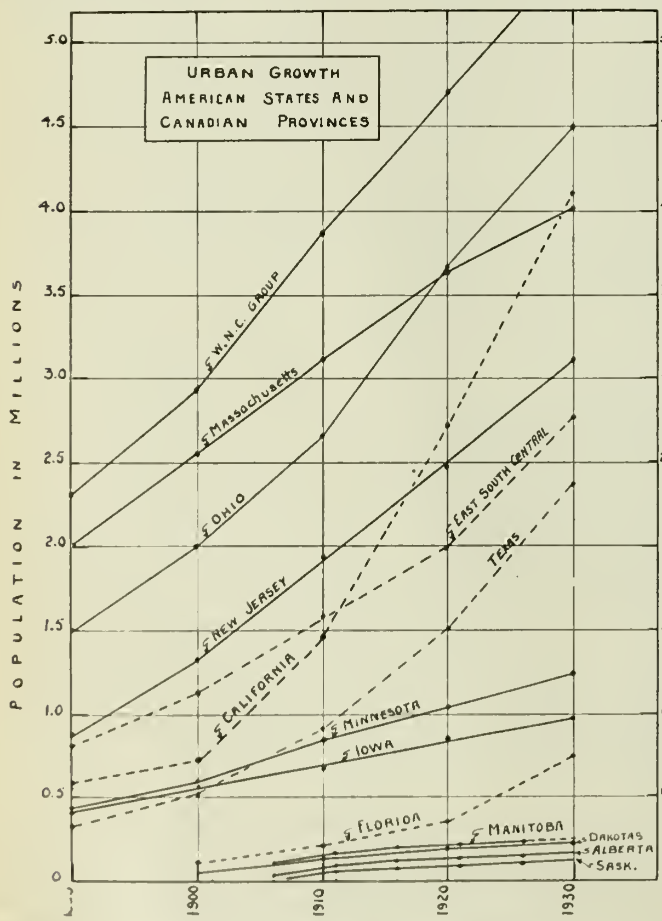

Fig. 8—Urban Growth in American States and Canadian Provinces.

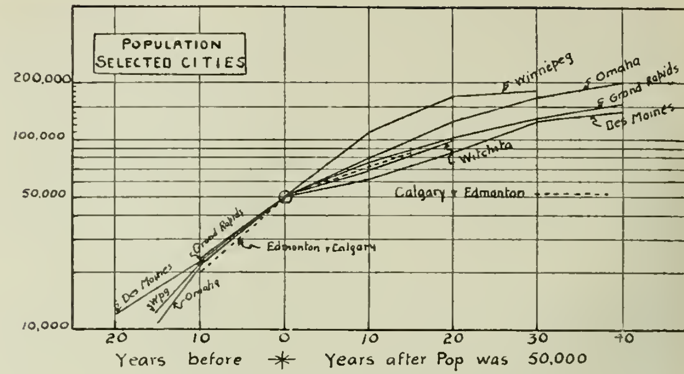

Fig. 9—Populations of Selected Cities.

of the southern states (probably at the expense of the New England states) and of course Texas has soared skywards on oil. It is seen then that generally speaking in the United States the increase in urban population as a whole has not yet started to decline, although there are indications of a general tendency in that direction.

Secondly, even if the turn in the United States is imminent, it seems reasonable to assume that in Saskatchewan there will be a considerable lag, and even after the inflection point is passed the decline will not be rapid for some years. Again, if we produce the Saskatchewan curve for twenty-five years we find that the ratio of that urban population, i.e., 290,000 to the assumed rural maximum of 750,000, is not greater than is to be expected from a study of similar ratios in comparable states. It is therefore concluded that in Saskatchewan the total urban population will continue to grow for at least twenty-five years in a straight line and in 1955 will amount to from 290,000 to 300,000.

The next question is: How will that population be distributed? For the purpose of answering that question a detailed study of the provincial conditions was made, in which the extent and productivity of the distributing areas served by each urban centre, the natural trade barriers such as rivers, and the existing trade routes such as railways and highways, were considered. At present, besides the small towns and villages which are merely local trading centres and for this study are classified as rural, there are two urban classes, larger or primary distributing centres and the secondary smaller centres. The development brought about by modern rapid transit facilities has tended to concentrate the major part of the urban population in a few larger centres. In Saskatchewan these are Regina, Saskatoon and Moose Jaw. Regina and Moose Jaw are relatively close together and their contributing areas largely overlap and it appears that the growth of each will affect that of the other. If we take Regina and Moose Jaw together as one urban unit, Saskatoon as another and all the other secondary centres as a third, Table II shows the relative trend in growth.

Table II
Percentage of Total Urban Population in Each Unit

	Regina and Moose Jaw	Saskatoon	Secondary Centres
1916	52 per cent	25 per cent	23 per cent
1921	51 "	24 "	25 "
1931 (estimated)	52 "	28 "	20 "

Saskatoon appears to be increasing its percentage, which is to be expected, as the northern parts of Saskatchewan, especially the more broken country, develop slower and the farmers have less capital. In twenty-five years it is estimated that Saskatoon will have about 33 per cent of the total urban population of 290,000 or about 96,000, while Regina and Moose Jaw combined will have about 54 per cent or about 160,000. This estimated relationship checks fairly well with the present rural population and areas of field crop contributary to each group.

Tentative studies only have been made for Manitoba and Alberta, but, by extending their curves, a total urban population of about 420,000 and 330,000 are respectively indicated. In Alberta, Calgary and Edmonton, which are approximately the same size, constitute about 90 per cent of the total, and in Manitoba, Winnipeg with its suburban centres represents about the same proportion. If these percentages are maintained, both Calgary and Edmonton should have in 1955 populations of approximately 150,000 and Winnipeg with its environs about 380,000.

As a further check on the above conclusion Fig. 9 was made, in which the curves of growth for several American cities of comparable character were plotted showing the population at various years after the population had reached 50,000. Des Moines is the largest and most rapidly growing city of Iowa; Wichita, Kansas, a very progressive prairie city; Grand Rapids, a progressive industrial city in Michigan; Omaha, Nebraska, a large distributing centre and for many years a jumping-off place for the territory to the west, somewhat similar to winnipeg in the Canadian west. If Des Moines, Grand Rapids and Wichita be assumed to represent the growth of active and progressive cities, and if the present population of Saskatoon be taken as 45,000 and Calgary and Edmonton as 85,000, it will be seen that additional support is given to the above estimates.

Conclusions

While the primary conclusion is, that, for purposes of design, it is reasonable to assume that the population of Saskatoon will be about 96,000 in the year 1955, it is felt that this study brings out many facts of general interest and that the method worked out might well be developed to serve as a guide for the laying out of long term programmes for provincial and national highways, railways, other utilities and public measures in western Canada.

Discussion on "The Structural Engineering of the Head Office Building of the Sun Life Assurance Company of Canada, Montreal"

Paper by A. H. Harkness, M.E.I.C.(1)

D. C. Tennant, M.E.I.C.(2)

Mr. Tennant remarked that at the meeting of the American Society of Civil Engineers held recently in New York two buildings were described—one was the Empire State building, and the other the Manhattan Company building. The Empire State building was of course a very large structure. The offsets in that building were attained by making them exactly conform to the panel lengths, so that it had not been necessary to carry the load from upper columns by girders to other columns down below. It had been aptly remarked that largely as a result of this arrangement, the steel work on the Empire State building was majestic in its simplicity. On the other hand the Manhattan Company building had a great many girders carrying columns above, also trusses and all sorts of troublesome details due to architectural requirements. It would be agreed, he thought, that the Sun Life building was more like the Manhattan building in this respect than like the Empire State building; that is, there had been a great many unavoidable architectural requirements in connection with the Sun Life building which caused difficulty in the structural features. These had been pointed out in the paper, but in his opinion, the author's modest disposition had prevented him from emphasizing them as he might have done. In many cases the columns had to be carried on girders because of the size of the set-backs. Then, again, there were cases where trusses in the building carried upper columns and certain columns had been splayed out. These things are not easy to arrange in connection with structural steel.

However, there was another feature about the Sun Life building which the author had also mentioned, making it even more remarkable, the transition from a small to a much larger building. In the first place there had been a very beautiful but comparatively small building. But when built it was not intended to become the large and wonderful building it was to-day. The design of the original building had been covered by specifications and plans; the design of the final building was similarly covered. Yet there were scarcely sufficient rules for making the transformation from one building to the other. This made the Sun Life building a special problem and the transformation was the most interesting feature to engineers.

In connection with the transformation some of the columns had to be reinforced. It was not sufficient merely to add the new steel to the columns. There had to be some way of taking the load off the steel already in place before the new steel could be added. That was done by shoring and jacking. In many instances considerable new material had to be added to an existing column. It was necessary to consider whether extra stiffening was required in these cases. Most of the columns in the Sun Life building were comparatively short for their sections, and therefore the consideration of the factor $\frac{l}{r}$ did not come into account. There were however some of the columns so reinforced which were very long, and it was thought advisable that this reinforcing should be stiffened in some way. Actually those reinforcing sections were put on in lengths of about eight or ten feet and in order to provide stiffness squares had been welded on to the outstanding legs of the reinforcing angles. Again, in the jacking up of the columns to replace the bases by stronger bases, as described by the author,—the loads which were to be lifted were very carefully calculated. It was calculated how much load was on each floor at the time the operation was done. After all the calculations had been made the jacks were chosen with considerable excess strength and the columns had to be actually lifted until there was a very slight crack appearing at the bottom of the column, between the column and the base upon which it rested. It was fortunate indeed that these jacks did have excess strength, because it was found that the load that was actually lifted, in order to bring the column clear, was greater than had been calculated. The reason was obvious, for in addition to the calculated load it was necessary to overcome the resistance or stiffness of the floors, and the stiffness of the beam connections made it harder to lift the columns than had been figured. Such problems, he thought, made this transformation the most interesting part of the whole construction. In such work, engineering showed itself, as the author said, in a venturesome light, and appeared as an art as well as a science.

(1) This paper was presented at the Annual General Meeting of The Institute, Montreal, February, 1931, and appears in the February, 1931, issue of The Journal.

(2) Designing Engineer, Dominion Bridge Company, Montreal.

C. J. A. Cook[3]

The following statement was presented by Mr. C. J. A. Cook of the firm of Cook and Leitch, general contractors for the building. It covers a number of points of interest regarding the quantities of materials, the rate of construction, and the contractors' equipment.

The building was constructed in three units, namely, the eastern portion facing Mansfield street, the westerly portion facing Metcalfe street, and the tower portion from the eighth floor to the pent house.

The following list gives the start and finishing dates of the main structure on the three units:—

	Easterly		Westerly		Tower	
	Start	Finish	Start	Finish	Start	Finish
Excavation..	May 1927	Dec. 1927	Jan. 1929	June 1929	..	..
Structural Steel.......	Jan. 1928	Apr. 1928	May 1929	Oct. 1929	Jan. 1930	July 1930
Floor Slabs..	Apr. 1928	June 1928	Sep. 1929	Oct. 1929	Mar. 1930	Aug. 1930
Granite and Brick Backing....	May 1928	Oct. 1928	Aug. 1927	Dec. 1929	May 1930	May 1931

The first excavation amounted to 40,000 yards earth and 8,000 yards rock; the main feature of this excavation was the underpinning of Loew's theatre on the north end of the property.

The second excavation amounted to 40,000 yards earth and 6,000 yards rock, making a total of 80,000 cubic yards earth, and 14,000 cubic yards rock. With the 20,000 yards excavated for the original building there is a total of 114,000 yards excavation.

It may be noted that the total weight of structural steel is 18,550 tons.

The floor construction which is of the concrete joist type was about 300,000 square feet for the easterly portion, done in three months, and the same area for the westerly portion which was completed in two months. The 650,000 square feet of floors in the tower section were completed in about six months, and with 200,000 square feet in original building, made a total floor area of 1,450,000 square feet.

The granite on the easterly portion, about 7,000 tons, was set in six months, on the westerly portion the same tonnage was set in five months, and on the tower portion a tonnage of 16,000 tons will have been set in less than twelve months.

All materials, including the structural steel for the tower section, were delivered and raised from the Mansfield street side and passed over at the various floor levels above the eighth floor to the Metcalfe street side.

The following is a list of materials estimated as being required for the construction of this building:—

	Tons
Cement in Bags (500,000)	25,000
Sand	40,000
Crushed Stone	40,000
Brick (3½ million)	9,000
Terra Cotta Partition Blocks, 2 inch, 3 inch, 4 inch and 6 inch (1½ million square feet)	12,000
Terra Cotta Beam and Girderfireproofing (176,443 square feet)	1,000
Reinforcing Steel	1,400
Plaster Material	2,000
Metal Lath (150,000 yards)	220
Metal Corner Beads (200,000 lineal feet)	20
Angles and Furrings	500
These figures total	131,140
Add 12½ per cent for original building	16,390
	147,530
Add structural steel	18,570
	166,100
Add granite	35,000
	201,100
Add for 2,650 Doors, 1,963 Windows, Marble Stairs, Plumbing equipment, Heating equipment, Electrical equipment, Elevators, Ventilating equipment, and Roofing	50,000
Grand Total	251,000 Tons

Total Floor Area .... 1,450,000 square feet
Total Cubic Contents .... 21,750,000 cubic feet

A few special details on the granite will finish this statement:—

Total number of courses in height	270
Total lineal feet of courses	237,156 or 45 Miles
Number of stones over 5 tons	818
Number of stones over 10 tons	53
Number of stones over 17 tons	2
Number of freestanding columns	114
Total length of columns	4,260 lineal feet
Total weight of columns	5,600 Tons
Total number of openings in granite windows and doors	1,963
Total weight of granite	35,000 Tons

Average stone weighs 1,000 pounds and is 4 feet in length.

In the setting of this granite stiff leg derricks were used. The following number of derricks may yet be seen on the job:—

2—15 ton all steel, stiff leg.
1—10 ton steel boom and mast, sill and legs on wood.
2— 5 ton all wood stiff leg.
1— 3 ton all wood stiff leg.
1— 1 ton all wood stiff leg.
3—Top point setters, 3,000 pounds capacity.
12—Circle swing, 2,500 pounds capacity.

During the year 1930, on the tower section about 100,000 tons of material were handled. This includes structural steel and granite, with an average of 750 men for 300 days; that means each man took from the street and put in place 1,000 pounds per day.

Professor E. Brown, m.e.i.c.[4]

Professor Brown inquired what clay pressures had been used in the design of the shoring for the basement walls, and also what main considerations had led to the extension of the steel columns, as shown in Fig. 5, when clay veins were encountered, instead of placing the concrete down to solid rock.

In shoring the floor beams to take the stress off the columns when the columns were reinforced, how were the loads determined? The author had explained how the whole column was shored, but he was not clear as to the extent to which the load was taken off a column, when the separate floor beams were shored.

A. H. Harkness, m.e.i.c.[5]

The author replied that there was no earth pressure directly against the walls, except that of back-fill, and that was of loose material which was there for only a short time before it was supported by the floors. A horizontal pressure of about 35 pounds had been assumed. Once the floors were in everything was secure.

In regard to the extension of the steel columns downwards for the east half of the north wall, rather than concrete piers, the Sun Life Company wished the second basement floor to open through between the old and new buildings, and concrete piers would have cut off too large a proportion of the space. This did not apply to the west half.

[3] Cook and Leitch, Montreal.

[4] Professor of Applied Mechanics and Hydraulics, McGill University, Montreal.

[5] Harkness and Hertzberg, Toronto.

The more heavily loaded columns were lifted with hydraulic jacks. The two posts with needle beams and wedges were used only for the lighter loads. The wedges were driven to lift the columns free at the base.

F. P. Shearwood, M.E.I.C.[6]

Mr. Shearwood observed that in connection with the jacking operations on the columns one of the greatest troubles was to get the load properly transferred to the blocking from the hydraulic jacks. It was necessary to grease the steel wedges very liberally so as to get them in and relieve the heavy load on the jacks. Again, the wooden blocks taking the load on the inside of the jacks were intended to carry 1,200 pounds per square inch, which they should have supported easily. As an extra precaution angle irons were placed on each side of the blocks and bolted through and it was fortunate that this was done, as when the load came on the blocks, shakes in the wood began to show up quite prominently.

E. V. Gage, A.M.E.I.C.[7]

Mr. Gage understood that the height of the building above sidewalk level would have been 399 feet 11 inches, if it had not been for the strain in the columns, which amounted to 2 inches. Observing the construction he noticed that a portion of the building was built and plastered, after which the additional weight of the tower was placed above. He would ask if any precautions were taken to keep the plaster from cracking down below. Did the plaster on the lower floor crack when the weight was put on the upper floors?

A. H. Harkness, M.E.I.C.

The author stated that the plaster on the lower floors did not crack as there was enough elastic deformation in the partitions to take compression without cracking.

[6] Chief Engineer, Dominion Bridge Company, Montreal.
[7] A. F. Byers Company, Ltd., Montreal.

In regard to compression of the steel columns in buildings, there is an interesting point in connection with the Empire State building. The steel was erected, and the mail chutes were put in alongside the elevator shafts, in their usual position. The columns were loaded afterwards by the construction of the concrete floor and compressed, there being no corresponding load and compression in the mail chutes. The angles and plates of the chutes buckled and became crooked. The contractors had to go over the mail chutes and ease them up so as to get clearance at the splices. There was a total of about 6½ inches compression at the Empire State building.

To get the level of the window sills a bench mark was taken at the centre of the building by which to fix the elevation. As the exterior walls were built the contractor noticed the tops of the window frames got closer and closer to the beam above. The engineer was asked what the matter was and he found that it was the load on the outside columns which was causing the trouble. The columns compressed and lowered the spandrel beams in relation to the interior of the building. That is, when the interior of the building was loaded with the concrete floors the outer bays sloped inwards a little, and after the wall was built it became level again.

Professor E. Brown, M.E.I.C.

Professor Brown observed that the amount of steel in the building was about the same as the Chrysler building. The cubic capacity of the building had just been quoted. What was the capacity of the Chrysler building?

A. H. Harkness, M.E.I.C.

The author replied that there was not much difference. The lower columns ran heavier in this building and there was some very heavy masonry that they had not on the Chrysler building, and the Chrysler walls were lighter. It would be noticed also, that there was a magnificient colonnade around the twenty-second floor, each pair of columns of which weighed about 300,000 pounds.

Discussion on "A Method of Laying out Warped Surfaces of Hydraulic Structures"

Paper by C. P. Dunn, M.E.I.C.[1]

James W. Rickey, M.E.I.C.[2]

Mr. Rickey stated that the paper was one of great interest and though as the author had said the method might be the ship builder's standard technique, he had no doubt it was as new to the majority of engineers as it was to him. It should prove very useful to hydraulic engineers in particular and he could think of many instances in his own practice when he would have greatly appreciated something of the sort.

The author had defined the ideal shape of the surface in terms of hydraulic efficiency and then proceeded to say that the elements of this ideal surface would consist of smooth easy curves and that the trace of a plane cutting it in any direction would also be a smooth easy curve. This premise was obviously correct.

Having determined hydraulically or by model (and the value of models in this connection was to be emphasized) the approximate ideal surface, this method of refining and obtaining the ideal surface would unquestionably result in the easiest form work. Of course, there might be circumstances where transitions could not be justified economically on the basis of hydraulic efficiency alone, but structural efficiency, i.e., resistance to erosion and avoidance of cracking must also be considered. In concrete it was elementary that cracks tend to form at any abrupt change of section.

He had seen the intake and bucket on the spillway section of the dam. Both were impressive. The latter in particular was a beautiful piece of work and its hydraulic performance fully bore out the theory back of the author's method. The combination of this method of design and construction without top forms had resulted: (1) in a structure ideally shaped; and (2) in a surface texture which should be far more resistant to erosion than that of the usual surface obtained by placing concrete against forms.

In his opinion, the paper was both excellent and timely and merited very close study by the hydraulic engineer.

[1] This paper was presented at the Annual General Meeting of The Institute, Montreal, Que., in February, 1931, and published in the January, 1931, Journal.
[2] Chief Hydraulic Engineer, Aluminum Company of America, Pittsburgh, Pa.

Frederick B. Brown, m.e.i.c.[3]

Mr. Brown stated that the paper was an example of one of the many problems which occurred in construction practice and which, unfortunately, were too seldom recorded. This type of paper was undoubtedly of great value to the field engineer, and particularly to those in junior positions who were likely to advance in their profession and who also had the ability to think for themselves.

It was undoubtedly true that the busy man in the field considered that he had no time to write about what he considered ordinary routine in the solving of field problems. It was also true that the busy man could always find time for additional activities if he considered them sufficiently important. Many a good field engineer and superintendent knew short cuts, stunts, kinks, gadgets or whatever one wished to call them, which could save his working brothers many an anxious hour and many personal energy units, if he only realized that the benefit of his experience would be valuable to himself and his juniors if he could present them in a form which could be readily understandable, and available.

Each item of valuable information such as given in the paper, added to the sum total of the knowledge of how and why to use the working tools of the art. In his experience, several men had taken the attitude that the knowledge gained by them in the exercise of their profession constituted a personal asset to be jealously guarded and used for their own direct benefit, but his opinion was that the dissemination of such knowledge was of more value to the man who discovered the particular item and to the profession at large than if he had kept it to himself.

The author was therefore to be congratulated for having set forth in such clear and concise language one of those items of information, and it should cause stimulation of thought and save time and money for others when they had to handle similar problems.

The technical aspects of the paper were sound and the exposition of methods was clear and concise. The use of models was of very great importance in checking paper calculations and Mr. Brown had found that in every case where a model had been recommended, the cost had been more than repaid in the results obtained.

F. W. Caldwell, m.e.i.c.[4]

Mr. Caldwell asked whether the energy function would not fit in with a case like this better than the velocity function. A change in energy should of course include all losses in a section, and there would not appear to be very much practical difference in a case such as that chosen. He wondered, however, if anyone had had any experience with this method of attack.

C. P. Dunn, m.e.i.c.[5]

The author replied that he had thought of this thing several times in terms of energy function, and in trying to get the mental picture of it the question which came to mind was: An attempt is to be made to set up a curve for the energy content of this water. Then came the question: The energy content of what water? How much water? Would the lineal foot be taken and the energy content computed and then the energy content be taken at another place where the conduit was small, or would the energy in one cubic foot of water be measured and followed through the transition?

The latter idea was carried out when the velocity head was used. That was the thing on which his mind was not settled. It was done this way and it seemed to work—but it might not be right, and it was not certain that this was the best way to do it.

J. J. Traill, m.e.i.c.[6]

Mr. Traill remarked that there was a minor point in the paper to which he took exception. It was not one perhaps of any particular importance in connection with transitions in which the velocity was increased as it was in the structures described in the paper. In Fig. 1 there was a curve showing the rate of increase in the velocity head in the transition. In the case of a transition in which the velocity was increased he did not think it mattered greatly at what rate the velocity was increased, whether it was increased as a direct function of the velocity with respect to distance, or the velocity-squared with respect to distance, or somewhat irregularly as was shown in the present case. When he considered the case of a transition in which the velocity was being reduced he found there were definite experimental data which indicated that the change should take place as a function of velocity-squared with respect to distance. A straight conical tube was the simplest expanding section that could be made. But that tube did not recover as much energy as one in which the change took place by a uniform rate of reduction in the square of the velocity. The change he suggested in the author's case was instead of using a curve to determine the rate of reduction of the velocity head a straight line should have been used. Experimental data indicated that such a type of transition, at any rate for an expanding section, was the most efficient.

C. P. Dunn, m.e.i.c.

The author, in reply, stated that in setting up the illustration referred to in the paper he had shaped a curve of velocity-head through the transition so that it would be a smooth curve, and believed this to be approximately right because he had used it successfully, although the experimental data available to him were not sufficient to convince him fully that the assumption was absolutely correct. It appeared reasonable to believe that a transition designed on the variation of velocity-head would be more nearly correct than a design based on simple area or velocity variation, because it would be more nearly a correct expression of the energy content of a given quantity of water. It seemed reasonable that the energy loss in a transition would be a minimum if the energy content in an assumed quantity of water, say one cubic foot, followed through the transition, were changed from one amount of energy to another with a minimum abruptness of variation in rate of change. A straight line variation of velocity-head, such as that suggested by Mr. Traill, would produce an abrupt variation of rate of change at the beginning and end of the transition.

Discussion on "Automatic Block Signalling on the Canadian Pacific Railway"

Paper by A. J. Kidd[1]

W. M. Post[2]

Mr. Post observed that the paper on "Automatic Block Signalling on the Canadian Pacific Railway" covered the history and development of automatic block signals quite fully and the description would apply to most railroads which had used automatic block signals to any extent over a period of several years.

The author had stated that electro-pneumatic signals were not used to any great extent owing to the necessity of air supply for its operation. The Pennsylvania Railroad used electro-pneumatic automatic signals quite extensively east of Pittsburgh for twenty-five years prior to 1910. There was a 2-inch pipe line over the entire New York division between Philadelphia and Jersey City, 90 miles, conveying compressed air for the automatic signals and electro-pneumatic interlockings. There were altogether about 335 road miles, or 1,060 track miles equipped with electro-pneumatic automatic signals. These electro-pneumatic signals were very reliable in their operation and gave excellent service. They were of course rather expensive to instal and to maintain and the development of the top post motor signal, and later the position light signal, made it advisable to discontinue the installation of electro-pneumatic signals. As an illustration of the rapid changes in signalling which had taken place in the last twenty-five years, there were today only 29 road miles, or 76 track miles of electro-pneumatic automatic signals on the Pennsylvania system.

The impression was also given that lower quadrant signals had to be two-arm signals if the third or caution indication was displayed, the second arm being used to give this indication. It might be interesting to know that on the Pennsylvania lines west of Pittsburgh there were several hundred miles of automatic lower quadrant three-position signals in service prior to the development of the upper quadrant three-position signals.

The author had also stated that in other than searchlight signals, it was not possible to use a reflector of any kind owing to the danger of a phantom indication. A reflector was used in the position light signal for close-up indication, i.e., a reflector was so placed that the beam of light was reflected downward so that an engineman standing close to the signal will get the indication. The shape of the cover glass on the position light signal prevented the possibility of a phantom indication, as the rays from a headlight, or from sunlight, when the sun was near the horizon, were deflected in all directions except towards the engineman.

A. J. Kidd[3]

In connection with Mr. Post's remarks the author felt that perhaps he should admit that the title of his paper was somewhat of a misnomer and should perhaps have been called "An Historical Sketch of the Development of the Automatic Signalling Art in General and Latterly on the Canadian Pacific Railway in Particular." His remarks in connection with the use of electro-pneumatic signals were intended to note in passing a very interesting phase of the development of the art, and while he knew that the Pennsylvania Railroad and he thought the Central Railroad of New Jersey, had at one time installed a considerable mileage of this type of signal he did not have the exact mileage and he thanked Mr. Post for the information. The idea he meant to convey was that their use was not as general for instance as the use of the electric motor signal and that the use of the second arm on lower-quadrant signals became the general practice, although some roads were using a three-position lower-quadrant signal; the objection to this however was the difficulty of distinguishing the 90-degree position when given in the lower-quadrant.

When describing the use of a reflector in other than the searchlight type of colour-light signal the author had referred to the main light beam of signals and not to the "close-up-indication," and perhaps he had not been very explicit in this particular. The reflector Mr. Post mentioned was placed at an angle to the lamp in the top of the case and directed the light downwards, so that the engineman can obtain the signal indication when close up to, or more or less under the signal if mounted on a signal bridge.

F. O. Condon, M.E.I.C.[4]

Mr. Condon stated that the paper covered concisely the history of the signalling branch of railway work and described the different methods which have been tried from time to time as well as the changes and modifications made down to the present.

The different types and systems in use on the Canadian Pacific Railway were duplicated to a large extent on the Canadian National Railways; the only point of difference being the use of direct colour-light signals in the later installations in preference to the "searchlight" with moving roundels inside the lamp hood as used on the Canadian Pacific.

In place of the coloured, movable roundels to provide the colour indication, there were three separate lamps having coloured lenses which gave the required indication.

The lamp case was blackened at the rear of the lamp so that there was no possibility of a "phantom" indication, which seemed to be the principal reason for the "searchlight" type. In that type of signal there was no relay and all moving parts were done away with.

The centralized traffic control system had not yet been tried out on the eastern lines of the Canadian National as there were no locations where, with present traffic conditions, it would be justified.

The author had given a very comprehensive description of the signalling methods in use on the railways of North America and had handled his subject in a most creditable way.

A. J. Kidd

The author thanked Mr. Condon for his kind remarks in connection with his paper; he would like however to point out that the colour-light signals using three lights placed behind the necessary coloured lenses do use a relay, although the relay is housed somewhere else than in the signal head. It is felt that by placing this relay in the signal head and obtaining the ability of repeating this signal from the point where the indications are given to the engineman a very valuable feature is secured, especially in interlocking territory.

Discussion on "Direct Method for Normal Thrust and Moment Influence Lines for Fixed Arches"

Paper by Alfred Gordon[1]

Alfred Gordon[2]

The author, in reply to Mr. Brett, observed that the method presented presumed that influence-lines were required. This having been granted, let a comparison be made between Fig. 2a of the paper and Fig. 72 of Hool and Kinne's "Reinforced Concrete and Masonry Structures," or the calculations in Section 9-21 of the same authors' "Movable and Long-Span Bridges": if this were done, there should be no doubt as to the simplification effected. Mr. Brett was, of course, quite correct in pointing out that the effect of the spandrel supports and deck framing, unless flexurally connected to the arch-rib, would render the method nugatory; but this was anticipated in the introductory paragraphs. The paper was, essentially, a "computer's," rather than a "designer's" paper. The art of computation, however, was not to be despised. In another type of structure, the continuous bridge, the simplification of this art, together with the correction of some erroneous views as to the quantitative effect of a settlement of the supports upon the stresses (this effect, measured as a percentage of the total stress, becoming almost negligible in long spans), had resulted in more and more of such spans being built. In this connection the possibilities of the fixed steel arch were not to be overlooked, although at present it was rare; but for such a structure the method would be quite valuable.

Replying to Mr. Pratley, the author said that there had been added to the paper a note which, it was hoped, would answer the question as to the object of introducing the "ellipse of elasticity." As there stated, its only use was to locate the line *M-M*, after which everything was as simple as Fig. 2a. With regard to "elastic weights" versus "method of least work," the former amounted to no more than finding the deflection of a beam through loading it with its M/EI diagram, hence the pictorial term "weight"; and it might be contended that this graphical way of evaluating an integral (i.e., in this case determining a deflection, since $\delta = \int Mm\, ds/I$), coupled with the generalization that every deflection-diagram was also an influence-line, was as "physical" and "tangible" as the "conservation of energy." As for the rigid bars, since to some they were evidently confusing, they might be set in yet another light. The one connecting the cut section to the elastic-centre simply corresponded to the analytical procedure of taking the centre of co-ordinates so that all terms containing $\int \frac{ds}{I} xy$ vanished. The other, connecting the skew-backs, converted the structure into a ring, cut at the panel-point considered. Because a force acting along the line *M-M* would produce a pure rotation or tangential displacement, as desired, the problem then became as simple as, say, that of a beam continuous over two supports, in which, as was well known, the deflection-curve due to a vertical load at the left-hand support (the support being removed) was itself the influence-line for the left-hand reaction due to vertical loads. It was unfortunate that the *proof* of the fact, that by means of the ellipse of elasticity the force which would deflect the end of the curved cantilever or cut ring in any desired direction could be located, was so tedious; but, the proof being accepted, the method for the curved rib, or ring, was just the same as for the continuous beam cited,—and it was to be remarked that, shorn of the simple, but tedious, mathematical proof, the whole method was set forth in four short paragraphs, commencing at the words "The explanation of these constructions is based on the well-known fact . . ." down to "The chain of argument will now be completed."

The only difference between the two cases was, that whereas in the continuous beam the vertical load at the support (the support being removed) deflected the beam vertically, a load applied to the end of the cantilever or cut ring deflected it, not in the direction of the force, but in a direction at right-angles to the axis conjugate to its direction. It was hoped that this argument by analogy would be to some more convincing than the mathematics.

[1] This paper was presented before the Montreal Branch of The Institute on February 19th, 1931, and appears on page 243 of the April, 1931, issue of The Journal.

Discussion on "The Design of the Chute a Caron Diversion Canal"

Paper by G. O. Vogan, A.M.E.I.C.[1]

J. B. Macphail, a.m.e.i.c.[2]

Mr. Macphail stated that the author's account of the results of operation of the sluice tubes was most welcome in its justification of the methods customarily used in the computation of such a case. Some calculations, necessarily rough because they were based only on the small scale drawings of the paper, showed that one could independently make a reasonable estimate of conditions which would actually occur. The model tests seemed to have had their greatest use in the removal of that doubt, which often occurred in the period between the design and the final operation of hydraulic works, as to the extent of the correlation between the physical facts and the assumptions on which calculations must be based. They must also have been useful as a reminder of the fact that the temporary deflecting wall in the tailrace east of unit No. 1 would be needed to remove an unsymmetrical channel condition which would be likely to cause unpredictable eddies in place of the jump desired.

It was perhaps a little ungrateful to wish that the author had ventured a little further into those regions which were at present beyond our mathematical reach, such as jump in abrupt channel enlargements of various proportions, and the jump in channels with sloping bottoms. Again there were cases of submerged sluices where the flow would be expected to be not in proportion to the square root of the net head if there was a possibility of a jump being formed: there was the case of the jump forming in the sluice tube itself; and there was the determination of the conditions just at the point when the proportionality of the square root of the net head begins or fails. Some information on all these points would have been very welcome, and it was to be hoped that others who might have had an opportunity of making some useful observations, either on models or on a full scale, would take the trouble which the author had in collecting and communicating his data.

Aerial Cameras and Photography

Flight Lieutenant J. R. Cairns,
Staff Officer Photography, Royal Canadian Air Force, Ottawa.

Presented on March 24th, 1931 ,before the Aeronautical Section of the Ottawa Branch of The Engineering Institute of Canada (Ottawa Section, Royal Aeronautical Society).

SUMMARY.—This paper outlines the development of aerial photography, first as a war-time development in Europe and later as applied for special purposes in Canada. The equipment and methods are considered for oblique and vertical aerial photography and in Part 2 descriptions are given of some of the early cameras used during and since the War and many of the latest developments in hand and multiple-lens cameras.

Application of Aerial Photography in the Great War

There is no authentic information as to where the first aerial photographs were actually taken; it is definitely known, however, that aerial photographs had, to a limited extent, been taken from balloons, dirigibles and kites previous to the great war, and were used for various purposes, but during the war aerial photography was greatly developed and its scope widened through the taking of photographs from airplanes.

Little information can be obtained as to how the aerial camera was first used for military and naval reconnaissance; the credit, however, for a great deal of the pioneering work in aerial photography is given to, at that time, Lieutenants Campbell and Moore Brabazon. During the early part of the war flights had been made and photographs taken with ordinary ground cameras, usually of the press type, and although the results obtained by these early cameras were anything but perfect, sufficient information was obtained from the photographs to warrant further experimental work being carried out to secure better results.

Hazy and vague negatives had to be improved upon and lack of contrast had not only to be eliminated but contrast if possible emphasized. Better results were eventually secured by the use of filters and proper developers, etc., and with such success that roads, trenches, paths, etc., showed up clearly on the photographs as white lines against a dark back-ground and guns camouflaged to deceive the human eye could not deceive the all-seeing eye of the camera.

By this time it was thoroughly appreciated by the authorities that a new field of operation of enormous value in warfare had been discovered, and steps were taken to secure a camera better suited for this type of work. This matter was put in the hands of Lieutenant Colonel Moore Brabazon who was later founder and chief of the Photographic section of the Royal Air Force. He was sent from France to London, where in conjunction with the Thornton Pickard Company, Ltd., he designed and produced the first practical aerial camera used by the Air Force.

The value of aerial photography during the war cannot be over-estimated. It completely changed the tactics of war, as the all-seeing eye of the camera revealed information which would otherwise have been hidden, and complete records and maps were made of enemy territory and kept up to date by frequent photographic flights over the line and comparison of photographs previously taken, and the work of interpreting these photographs and making them into mosaic maps became a highly specialized study, making this branch of the Service one of the most important and valuable in the war.

Application of Aerial Photography to Survey Work in Canada

After the world war was ended aerial photography still continued to make headway, although it is only within recent years that it has been applied to any great extent for commercial purposes. In Canada, however, it was felt by engineers and surveyors alike, that its application to topographical surveying and mapping could be used to great advantage and experiments in this work were carried out in 1918-19 when the Air Board was formed and wonderful progress was made yearly in the development of air survey by improvement of equipment and methods.

War-time aircraft and cameras were at first used, but these were gradually replaced by more up to date equipment until today the best types of aircraft and most up to date cameras and photographic equipment procurable are used for air survey work.

Canada with its vast tracts of unexplored territories was in need of accurate maps as these vast tracts of land were only known to Indians and a few white trappers, and any maps which might be available were inaccurate and unreliable.

As the natural resources of the country opened up, the demand for more accurate maps grew greater yearly, and the increase in the taking of air photographs developed accordingly. The percentage of this increase can best be judged by the following figures. In 1921-22 the total area covered by air photography in Canada was 280 square miles which involved the taking of 7,984 negatives; in 1925-26, five years later, 49,170 square miles were photographed and involved the taking of 24,248 negatives, and during 1929-30, 74,655 square miles were photographed, the number of negatives taken being 97,742.

This great work was first carried out by service and ex-service personnel under the Air Board, then by the Royal Canadian Air Force, and within the past three years by Royal Canadian Air Force officers and personnel under the Directorate of Civil Government Air Operations, each working in conjunction with the Topographical Survey of Canada.

Oblique Aerial Photography

There are two methods of photography used in these operations, vertical and oblique. The oblique photographs are taken from Vickers Vedette flying boats and the verticals from Fairchild cabin monoplanes and Bellancas which can be equipped with landing wheels, pontoons or skiis depending on conditions under which they may be operating. The photographic detachments which carry out the work consist of two aircraft with cameras and full camping equipment, etc., so that they can be operated away from a base. The personnel consists of two pilots and three other ranks who in addition to being qualified air engineers are trained as camera operators. When the detachment is operating away from civilization a cook is also included in the establishment. A suitable base is selected within or near the area to be photographed and the detachment remains there until the operation is completed.

For the purposes of mapping by aerial photography the country is divided into sheets covering 1 degree latitude and 2 degrees longitude, or approximately 70 by 90 miles. These sheets are marked and flown in strips 6 miles apart and photographed obliquely. For this purpose a Fairchild model fully automatic K.3 or F.3 type camera is mounted in the front cockpit of a Vedette flying boat and suspended in a special anti-vibration mount which can be tilted or depressed to any desired angle; it can also be rotated so that the horizontal axis of the camera can be kept parallel with the horizon.

The mount in turn is attached to a carriage which slides on a semi-circular track on the rim of the cockpit in order that the camera can be swung around to an angle of 45 degrees either side. The sight which can be readily attached to the top of the camera consists of a rectangular negative lens with a vertical and horizontal cross hair mounted in a moveable frame and supported by trunnions, to which is attached a quadrant marked in degrees; a foresight is also provided which is detachable. The camera is fully automatic and is operated electrically, current being supplied through a switch-board from an engine driven generator. From four to six camera magazines are carried, each of which hold a roll of film 75 feet in length and sufficient to take 112 exposures, the negatives being approximately 7 by 9 inches. The focal length of lens used in oblique photography for mapping is usually 8 inches with apertures of F6.8 or F4. Twelve-inch lenses are also carried for the taking of scenic photographs; the types of lenses used are Ross Xpres, Goertz Dagor and Zeiss Tessar.

Oblique photographs are taken from a height of 5,000 feet and it is essential for mapping purposes that the horizon line be clearly shown parallel to and 7/10ths of an inch from the top of each photograph. For this purpose the camera operator sets the camera sight to an angle of approximately 18 degrees on the quadrant, then by sighting on the horizon and having the cross hairs on the negative lens and foresight in alignment, the camera is given the correct angle of depression to show the horizon the correct distance from the top of each photograph. Bayonet type optical flat filters are used on the front of the camera lens to penetrate haze and give a clear horizon line. A set of three photographs are taken every mile and a half, one being taken directly on the line of flight and one on either side at an angle of 45 degrees from the centre of the first one taken; this ensures a side as well as a front overlap. Inside the cockpit and underneath the track on which the camera is mounted there is a scale marked in degrees and when the aircraft is crabbing or drifting the centre photograph is deflected through the drift angle and the others accordingly.

On completion of a photographic flight the exposed rolls of film are packed up and forwarded to the Photographic section, Ottawa, for developing and printing and enclosed with each roll of film is a report and record giving particulars of weather, light condition, exposure, altitude, temperature before taking off, and at height chosen for photography, altimeter readings at the commencement of and end of each photographic line and on landing. Copies of these reports are forwarded to the Topographical Surveys for their information, where they are used in plotting to determine the exact scale of each photograph.

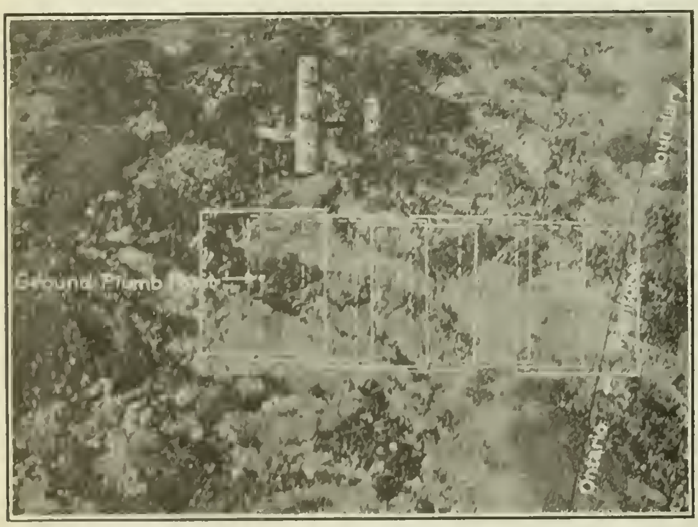

Fig. 1—Overlap of Vertical Pictures on a Strip.

Fig. 2—Installation of F.3 type Camera in Fairchild Cabin Monoplane for Vertical Photography.

Immediately the exposed films are received at the Photographic section, Ottawa, from photographic detachments on operations, they are developed and examined and a telegraphic report is sent back to the detachment giving them information regarding the quality of the film, overlap, crab, etc., and advising whether it is necessary to refly any line. After the films are dry, prints are made and forwarded to the Topographical Surveys where they are used in the making of the maps.

Prints which are required for mosaic purposes are corrected for scale and tilt and are also carefully matched to colour tone. Prints for filing are also supplied as a complete library and index is kept by the Topographical Survey department of all aerial photographs taken on government operations.

Vertical Aerial Photography

In the vertical operations carried out by the detachments of the Civil Government Air Operations the same type of cameras are used as in oblique photography, namely the Fairchild K.3 and F.3. As already mentioned, the camera platform used is a cabin type of plane, which can be fitted with either wheels, ski or floats. The camera is mounted vertically, that is, with the lens pointing vertically towards the earth's surface through a hole in the floor of the aircraft. The mount used is an adaption of the Fairchild gimbal mount which (in place of being suspended on rubber cushions to two cross bars placed above the hole in the floor of the aircraft through which the cone of the camera projects) fits into a circular metal container with sponge rubber to prevent vibration. This metal container fits around the edge of the hole, and is more or less a permanent fixture in the aircraft, being protected by a lid or cover which fits over the hole when the aircraft is not being used for aerial photography. The mount has a scale marked in degrees and the camera can easily be turned in either direction, through any angle of drift which may occur through crabbing of the aircraft.

The camera is electrically operated through a switch board as in oblique photography, but in addition an electrical timing device known as an intervalometer is used. This device automatically trips the camera shutter at predetermined intervals so as to ensure an overlap on each photograph, the interval being set by means of a dial on the intervalometer which is graduated in seconds. To obtain this interval accurately, which is most important in the taking of vertical photographs for mapping purposes, a special type of viewfinder is used which is really nothing more or less than a small camera having a ground glass on which a clear and distinct image of objects beneath the aeroplane are projected by means of a lens. Each viewfinder is provided with two or more ground glasses having lines engraved on them to correspond with the different focal lengths of lenses used on the camera. The viewfinder is operated on a ball and socket joint and has a scale marked in degrees to compensate for drift or crabbing of the aircraft.

In practice the finder is rotated on its ball and socket joint until an image of some object below the aircraft is travelling in a direction parallel to the lines which are ruled half an inch apart on the ground glass; these lines determine the true direction of flight and the amount of degrees the camera mount must be rotated to correct for crabbing. Two engraved lines at right angles to these drift lines are used to determine the exposure interval necessary for a 60 per cent overlap. The exposure interval is found by carefully noting the time this object (projected by the lens on the ground glass) takes to travel between the two engraved lines, this being the correct exposure interval for a 60 per cent overlap.

As already mentioned extra ground glasses are provided for different focal length lenses which must be changed to correspond with whatever lens is being used at the time. The sight is also provided with a level so that it can be kept on a vertical plane when timing the interval. Having determined the time interval, which is obtained by taking the mean of several trials, it is only necessary to set the dial on the intervalometer or electric timing device to the required number of seconds to operate the camera automatically.

In vertical photography the responsibility for keeping the machine on a level keel and flying straight lines rests entirely with the pilot. On reaching the height at which the photographs are to be taken, the camera operator levels his camera and determines the time interval through the sight so that the photographs will have the correct amount of overlap. The camera is then clamped and it is entirely up to the pilot to keep his machine flying level. The time interval is checked at various intervals throughout the flight and any variation is corrected on the intervalometer. A small light bulb on the pilot's dash board and one fixed near the camera operator flashes on a few seconds prior to each tripping of the camera shutter, and gives the pilot sufficient warning to keep his machine perfectly level during the period of exposure.

Fig. 3—Fairchild K.3 Camera Mounted in Vedette flying boat for Oblique Mapping Photography.

Eight, ten, twelve and twenty-inch cones are used in vertical photography depending on the nature of the operation being carried out, and optical flat filters are provided for the elimination of haze which is mainly caused by reflected light from water vapour, dust, smoke, etc.,

Fig. 4—Oblique Aerial Mapping View.

Fig. 5—K.3 Camera with 8-inch, 12-inch and 20-inch Cones.

suspended in the atmosphere, or by dry mollecules of the air itself; if filters are not used under these conditions this reflected light makes the first impression on the highly sensitive emulsion of the film and tends to reduce the necessary contrast in the negatives thereby producing flat indistinct photographs.

The same careful records are kept with reference to altitude and temperature readings, etc., as applies to oblique photographs.

In addition to this, where location of detachments permits such being done, prints of each roll taken by the detachment are returned to them for indexing and error tabulating. By means of special gauge cards made for this purpose the personnel of the detachments calculates the altitude percentage of overlap and degrees of crab and tilt of each photograph, and also keep an index map giving full particulars of each operation; this data is later sent to the Topographical Surveys department and is used by them in plotting the photographs.

During the operational season 1929-30, 26,130 square miles of vertical photographs were taken and 48,525 square miles of obliques. During the past summers operations 21,300 square miles of vertical photographs were taken and 32,800 square miles of obliques, or within the past two, a total area of 128,755 square miles have been covered by oblique and vertical photography.

Part II

A description of some of the early cameras used during and since the Great War and some of the latest developments in aerial photographic equipment.

C. Type

One of the first aerial cameras designed and used by the British during the war was the Model C. type. This camera, manufactured by the Thornton Pickard Company, was made entirely of wood and built to take plates not larger than 5 by 4 inches and lenses of not more than 12 inches in focal length. The plates were inserted in metal sheaths or septums and loaded one on top of another in magazines, each magazine holding from 12 to 18 plates. The shutter was of the simple focal plane type with a variable slit for different exposures and controlled by a spring with variable tensions. The lens, screwed into a flange in the cone of the camera, was of fixed focus and usually had an iris diaphram. The loaded magazine was locked on top of the camera and pulling out the sliding lid which was jointed and could be folded and locked on top of the magazine, allowed the plates to drop into position ready for exposure. By means of a sliding handle on top of the camera, the shutter was set and a sliding plate operated by gears pushed the exposed plate over into the other end of the camera where it dropped into an empty magazine. During the re-setting of the shutter curtain an opaque slide attached to the handle was drawn between the lens and the variable opening in the shutter blind and prevented the other plates becoming fogged; a tubular view finder with cross wires was attached to the side of the camera for sighting. This type of camera was adapted for vertical photography only, and was attached to the side of the aircraft by means of brackets; at a later period of the war it was used for training purposes in England, Canada and the United States.

E. Type

The E. type camera, an improvement on the C. type, was similar in many respects. It was made entirely of metal, however, and was less bulky owing to replacement of the opaque safety slide by a lens flap which worked automatically with the shutter. In place of the handle as used on the C. type camera, to change plates and re-set the shutter, provision was made for distance control by means of cords, and release of the shutter by means of a bowden wire.

L. Type

A further improvement in the last two types of cameras, which were non-automatic in their action, was the semi-automatic L. type. The same principle was used of carrying the unexposed plates in a magazine on top of the camera and pushing the exposed plate along on a horizontal plane until it dropped into an empty magazine. The principal difference was the addition of a mechanism whereby it could be connected up through a flexible cable to a wind driven propeller; provision was also made for attachment to an electric motor.

The focal plane shutter used in this camera was of the variable aperture type with a flap behind the lens to cap it during the setting of the shutter. The greatest fault in the cameras already mentioned was the frequent jams that occurred through bent plate sheaths or cracked and chipped plates, but despite these faults the L. type camera was used during the last two years of the war, and it was not until the closing months that an improved model, the L.B. type was constructed.

L.B. Type

The principal change from the L. type was the introduction of several interchangeable cones of different focal lengths. The focal plane shutter was also made removable and self-capping; the slit was variable from ¼ to 1½ inch to give various speeds. The changing of the plate and setting of the shutter could be done in a single movement by hand or by a wind-driven propeller; a bowden wire release of any length was also provided so that the operator could release the shutter at some distance from the camera. The gear driving mechanism, plate changer, and removable focal plane shutter was contained in the body of the camera; the lens was contained in the cones which as already stated were interchangeable and of various focal lengths, and were attached to the camera body by means of a bayonet type joint arrangement. A small wind-driven propeller, held by brackets in the slip-stream, and connected by a flexible drive to the camera, furnished the driving power. After an exposure the exposed plate was moved in a frame along the overhanging body extension to fall into the receiving magazine at the same time the shutter was re-set ready for the next exposure.

A. Type Hand Held Plate Camera

The types of cameras already described were used for vertical photography only and were not adaptable for oblique work. One of the earliest types of cameras used by the British during the war, and adapted for both oblique and vertical photography, was the A. type hand held plate camera, manufactured by the Thornton Pickard Company. It was made of wood and had a lens of 8-inch to 10-inch focal length and a focal plane shutter. It was adapted for 4 by 5 plates and was provided with a tubular view finder.

P. Type Hand Held Camera

Another type of hand held camera used during the war was the P. type which was made of metal with a fixed cone and lens of 8½ to 10½ focal length. It was provided with a variable slit focal plane shutter with fixed tension and was made for 4- by 5-inch plates; a handle and strap

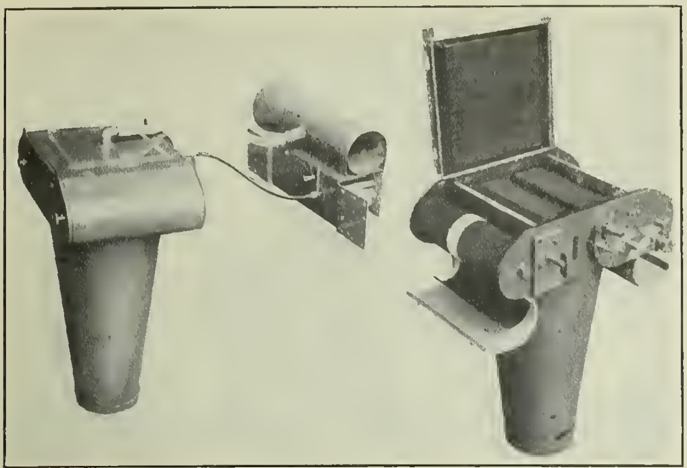

Fig. 6—Eastman K.1 Type Camera.

were provided to hold the camera, and a direct vision open sight was attached to the body and could be folded back when not in use.

THE GERMAN ICA HAND HELD CAMERA

This camera used during the war was fitted with a special type of removable shutter; four slits in the shutter provided four speeds varying from 1/90th of a second to 1/750th of a second. The shutter blind could be set at any slit to give the speed desired and an indicator was provided showing the speed markings. A capping device protected the plates when the shutter blind was being re-set. The magazines carried six plates 13 by 18 cm., the exposed plate being changed by withdrawing and pushing back the end of the magazine; handles were provided to hold the camera and an open vision view finder with fore-sight which could be folded back when not in use was also provided.

SOME LATER TYPES OF HAND HELD CAMERAS

EASTMAN A.1 TYPE FOR PLATES AND CUT FILM

This type of camera is made entirely of aluminum; it is fitted with a 10-inch Hawk Eye lens with an aperture of F4.5 and of fixed focus. The shutter is a focal plane type with a fixed slot and variable spring tension, and exposures can be made varying between 1/120th to 1/435th of a second. The camera body is adapted to take Graflex plate magazines, Graflex cut film magazines or Graflex roll film magazines of 4- by 5-inch size. The plate and cut film magazines have a light-proof leather bag attached into which the exposed plate or film is pulled by means of a metal slide; the bag is then gripped and the exposed plate or film is pushed back into the magazine behind the unexposed ones, this operation being carried out until all twelve exposures are made; an indicator on the side of the magazine records the number of exposures. The sight is of the tubular variety fitted with cross wires and is readily attached to the body of the camera. This type of camera was used in early operations carried out by the Air Board and a few of these cameras are still in use for scenic oblique work by the Civil Government Air Operations.

EASTMAN K.1 CAMERA

This type of camera, of metal construction, is made to take rolls of film 75 feet in length and sufficient for a hundred exposures of a size of approximately 7 by 9 inches. It is automatic in its action, the motive power being derived from a wind motor box which is attached by brackets to the side of the aircraft. A rotary paddle wheel is contained in the lower half of this box which is connected to a gear box on the camera by means of a flexible drive. The upper half of the box contains the venturi tube which is connected by rubber tubing to a suction head on top of the camera body. A graduated quadrant, with a lever to which a metal shutter is attached inside the box, controls the passage of air through the tunnel and acts as a damper control by which intervals between exposures may be governed. The body of the camera, which is also the film magazine, is equipped with a fixed aperture focal plane shutter with varying exposure from 1/90th to 1/310th of a second. Cones of varying focal lengths, and equipped with Hawk Eye lenses, with apertures of F4.5 can readily be attached to the camera body and are interchangeable with other cameras of this type. The film is held flat during exposure by means of a vacuum back which opens up on top of the camera body. The inside of this vacuum back has a perforated platen connected up by a suction head to the venturi tube in the wind motor box, the film being held flat against this platen by suction during exposure.

This type of camera was used in government surveying until 1923-4, when it was replaced by the Fairchild "between the lens shutter" camera.

THE WILLIAMSON PISTOL GRIP CAMERA

The camera body is made entirely of aluminum and is fitted with a Ross Xpres lens of 5-inch focus and an aperture of F4.5. The shutter is a sector type fitted between the lens combination and is adjustable for speed and aperture, the maximum speed being 1/100th of a second. The camera body is adapted to take plate holders, film pack adapters or roll film holders. A focusing screen with hood is also provided. The size of the picture taken is 2¼ by 3¼ inches. A brilliant view finder is built into the top of the camera which gives the correct view when the eye is approximately 6 inches from the back of the camera.

FAIRCHILD MODEL F.4 AERIAL CAMERA

This is a late type semi-automatic hand operated camera. It is equipped with a focal plane shutter of constant speed which tends to prevent distortion. The shutter speeds are adjustable and range from 1/75th to 1/225th of a second. A capping device for the lens works in conjunction with the shutter inside the cone. The lens is a 12-inch Zeiss Tessar F4.5 and is fitted with a diaphragm and focusing mount so that the camera can be used for taking ground pictures. The lens is provided with a locking device and can be locked at infinity when taking aerial views; lenses of various focal lengths can be interchanged with the standard cone of 12 inches supplied with the camera. Interchangeable magazines are provided for this camera which takes a roll of film 75 feet long suf-

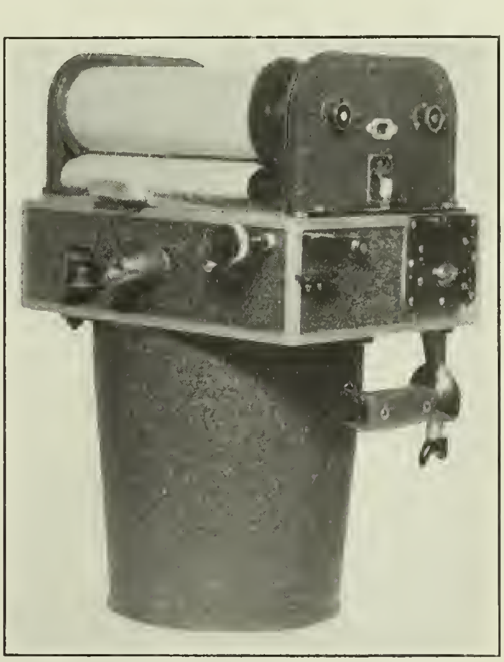

Fig. 7—Fairchild F.4 Type Camera with Magazine Cover Removed.

ficient for a hundred and twelve exposures, each exposure being 18 by 24 cm., or approximately 7 by 9 inches. The magazine is the standard Fairchild K.3 pattern with an automatic spacing unit which spaces the exposures equally throughout the entire roll, and an optical flat glass through which the pictures are taken; an automatic pressure plate holds the film securely and firmly against this glass during exposure and releases when the film is being wound for the next exposure. The camera is hand operated but is so constructed that it can be used for vertical as well as oblique photography. A negative lens sight is provided which can readily be attached to the body when used for oblique work.

French Aerial Camera Type Planiphote

This camera has been designed for the French Air Service and can be operated either automatically or semi-automatically. It is fitted with a Labrely shutter. The shutter consists of a number of very thin steel blades about 1 cm. wide. These blades operate like the slats in a Venetian blind, but only cut off a very small portion of light when they are stationary and parallel to the optical axis. There are eight blades pivoted on their longitudinal axis. All of the blades are connected together and operated by rods at each end. The rods in turn are operated by a cross shaft with a maltese cross shaped cam engaging with a second shaft, carrying a cam with two merging arms, which makes a three-quarter turn for each exposure During the three-quarter turn the shutter blades open, remain stationary, then close. The next exposure is precisely the same, but made in the opposite direction. This shutter is claimed to pass 80 per cent of the possible light; the exposure can be changed but is usually 1/150th of a second.

In the Planiphote magazine the film is stretched like a drum skin at the moment of exposure. This action is obtained by locking the winding reels and lowering a frame against the back of the film. This frame stretches the film and is claimed to give a plane surface as good as is obtained with plates. After exposure the frame is raised and the winding reels unlocked. The magazine is made for two hundred exposures on film 18 by 24 cm. A counter is provided for registering the exposures.

The cone of the camera carries a motor of 1/25 h.p. at 24 volts, driving gear, regulator for intervals varying from 5 to 60 seconds, shutter, lens focal length 30 cm. f.5.7., diaphragm, gear connecting shutter and magazine, suspension frame and a yellow screen.

French Military Type Camera by Demaria-Lapierre

This type of camera is used by the French Military Air Service. It uses a plate or film 18 by 24 cm., and a lens of 30 cm. focal length; magazines for 12 or 24 plates, or for a film of two hundred exposures are used. The shutter is of the focal plane type with ball bearings. The lens has an iris diaphragm and provision is made for a yellow screen. The body of the camera is entirely metallic in the form of a rectangular pyramid. A lens cover in the form of a metal flap open during exposure is used which can be fixed to remain open if desired. The shutter and lens cover are operated by a bowden control, and the speed of the exposure can be regulated. The plate magazine is of the sliding drawer type and the film magazine is of the same type as used on the Labrely camera.

Eagle Camera Type F.8 Mark II

This type of camera is used by the Royal Air Force and can be operated either manually or automatically by mechanical or electric controls which can be placed at a distance from the camera.

The camera is made entirely of metal and has interchangeable cones with lenses of various focal lengths. Interchangeable magazines are provided which take a roll of film sufficient for one hundred exposures, the size of each photograph measuring 7 by 8½ inches.

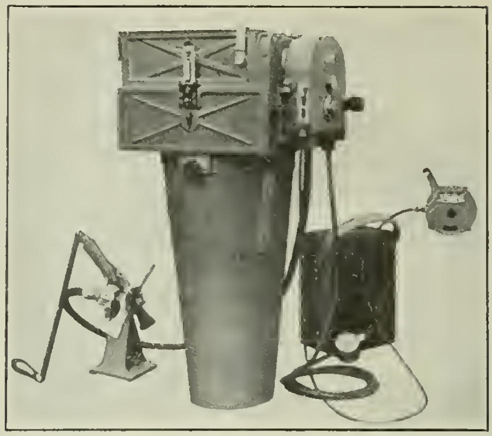

Fig. 8—Williamson Eagle Camera.

The body of the camera contains an optical flat glass through which the photographs are taken, the film being held flat against this glass by means of a pressure plate inside the magazine. The top surface of the casting surrounding this glass is in the plane of the focal register and therefore ensures the retention of the lens in correct focus. The shutter is of the focal plane type and operates close up to the focal plane glass in the camera body thereby providing greater efficiency than in the ordinary type of focal plane shutter. The shutter is also equipped with a braking device which ensures an even exposure over the whole photograph; it has a fixed speed of 1/90th of a second but interchangeable shutters can be provided with speeds varying from 1/40th to 1/120th of a second. All units of this camera are interchangeable and can readily be replaced if necessary. The camera can be operated by hand, electrically or by a wind-driven propeller and the timing between exposures can be controlled automatically by an electric control box which also shows the exact number of exposures taken; warning lights are also provided to enable the pilot to level his machine prior to an exposure being made.

Eagle Camera, Mark I

Another model of this camera, the Mark I, is identical in design but the body of the camera is constructed to take an instrument box containing a Veeder counter aneroid registering from 0 to 15,000 feet, two-way spirit level, a thirty-hour watch and an ivorine tablet on which useful data can be written; instruments are illuminated by small electric lamps and wide aperture lenses automatically records an image of these instruments on the side of every photograph taken by the camera.

Wilde Air Camera

This camera, manufactured by the Henry Wilde Surveying Instrument Supply Company, Switzerland, is built along precision lines for accurate aerial survey work. It is adapted for plates only and made entirely of metal, the body being a one-piece casting. The shutter is a between the lens type consisting of two blades only and one speed, a 1/100th of a second. The frame top of the camera body against which the plates are pressed during exposure has markers in the centre of each side and by intersecting lines through these markers the principal point can be obtained on each photograph. A stencil in one corner of this frame shows the camera number on each exposed plate while a set of small glass wheels in the lower left corner automatically register a reference number. The shutter is set by pushing down on this frame, the frame automatically springing back again into its former position after each exposure.

The magazines are of the drawer type and hold ten plates in metal sheaths of a size approximately 5 by 5 inches. To change a plate after exposure the drawer with all the unexposed plates is pulled out by a handle, the exposed plate remaining in place on the camera frame. When the drawer with the unexposed plates is pulled out far enough to clear, the exposed plate is snapped to the top of the magazine by two strong springs which come into play by the withdrawl of the drawer. A numbering device on the side of the magazine registers the number of plates exposed. When the magazine is in place, pushing it down on the camera body sets the shutter. A special locking device prevents the magazine drawer being pulled out after the tenth exposure thereby preventing exposing the plates twice over. Another device prevents the magazine being removed from the camera body before the magazine light slide is closed.

Special sights are provided on the camera and an elaborate camera mount with scales for drift, depression, etc., for accurate surveying work. Two rigid handles on the sides of the camera provide an excellent grip when the camera is being hand held for oblique pictures; a direct vision cross-wire sight, attached to the body, can be locked back when not in use.

Fairchild Model K.3 and F.3 Type Cameras

The K.3 and F.3 type of cameras are used on all photographic operations carried out by the directorate of Civil Government Air Operations. The principal difference, apart from minor changes in the two types, is the position of the focal plane glass plate. In the K.3 camera this plate is contained in the camera magazine, whereas in the F.3 type it is contained in the camera body, the latter type being considered the more accurate for topographical mapping.

The two types of cameras, which are fully automatic, consist of three principal parts: the magazine, the camera body or case, and the cone.

The magazine, which is built to take a roll of film 75 feet long capable of making 112 exposures, approximately 7 by 9 inches, contains the magazine drive, the pressure plate, the focal plane glass plate (in the K.3 type of camera), the light slide and a dial which shows the approximate amount of film exposed. The magazine drive spaces the film between exposures and automatically raises and lowers the pressure plate thus ensuring perfect contact of the film with the focal plane glass plate during exposure, and preventing movement or distortion.

The camera body or case contains a 12-volt motor, the main camera drive, exposure counter, levels, shutter speed adjusting dial, electrical connections, winding handle, trigger and magazine locking bar. The functions of the main drive mechanism, which is driven by the motor, is to control the motor circuit, re-wind the shutter after each exposure, and wind the magazine drive which is connected to the main drive when the magazine is locked in place on the camera body.

The cone, which is attached to the camera body by four screws, contains the adaptor for holding the shutter which is the Fairchild "between the lens" type consisting of five blades linked to a cam operating between the lens elements. A positive inertia retarding device provides three shutter speeds, 1/50th, 1/100th, and 1/150th of a second. This device comes into operation only when the shutter leaves are fully open, and disengages before they start to close, which gives the shutter a high efficiency. Attached to the sides of the cone are two trunnion arms for supporting the camera in the vertical mount.

Multiple Lens Cameras

Fairchild Model T3A 5-Lens Camera

This camera is one of the latest developments of the Fairchild Aerial Camera Corporation, New York. It consists of five separate chambers each with its own lens and magazine containing separate rolls of film. The camera is operated by hand, a turn of the handle winding

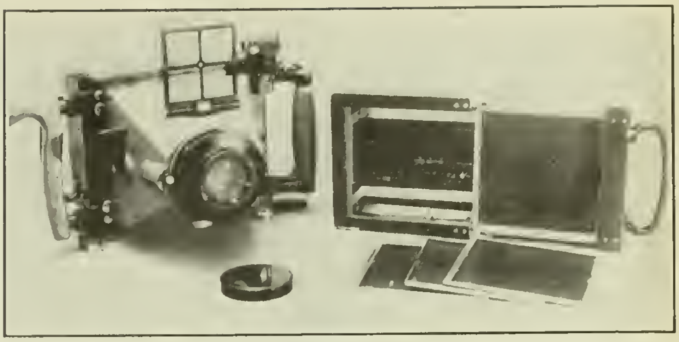

Fig. 9—"Wilde" Air Camera.

all five shutters simultaneously and bringing fresh film into place in the magazines ready for exposure. The centre lens is set vertically the other four being set at an angle so that the full coverage angle of view is approximately 86 degrees. The size of pictures taken by the centre lens is 5½ inches square; the side pictures are 5½ by 6½ inches. The lenses used are 6-inch Goertz Dagor F6.8, each lens being fitted with an Ilex shutter which is tripped simultaneously by a single tripping lever. The film is held flat in the magazine by means of a special vacuum back. A stop watch is built into the body of the camera for timing overlapping photographs; also a circular bubble level. In the camera mechanism a special spacing device spaces each film automatically and 190 exposures can be made at one loading. A special mount is provided for suspension of the camera in aircraft.

Automatic Interval Finder

Another recent development in aerial photographic apparatus is the Fairchild automatic interval finder. This instrument is a combination view finder and intervalometer and is somewhat similar in design to the Fairchild's vertical view finder previously described.

The timing mechanism operated by a small motor is contained on the side of the cone or body of the instrument which also contains the lens and ground glass screen and operates a wire which travels directly under and close to the ground glass screen. The speed of this wire is controlled by a rheostat so that it can be synchronized with some picked object on the ground, an image of which is thrown on the ground glass screen by the lens.

As soon as the speed of the wire coincides with this object, the camera is automatically tripped by means of an electrical control to ensure a 60 per cent overlap on every picture taken, the wire springing back to commence its travel over again after each exposure.

A dial on top of the instrument is engraved with different focal lengths of lenses and when set to whichever focal length lens is being used on the camera controls through the mechanism the length of travel of the wire.

Signal lights which flash on a few seconds prior to every exposure give warning to the pilot and camera operator to keep the camera on a level plane during exposure.

The ground glass screen on this instrument is engraved with drift lines half an inch apart; also a line at right angles to the drift lines marks the commencement of travel of the automatic wire. A wire on top of the ground glass is also provided and can be set to correspond with whatever focal length of lens is being used on the camera, the elapsed time as object takes to travel between the engraved line at right angle to the drift lines, and this wire can be taken by stop watch to insure an additional check of the time interval where necessary. The finder is operated on a ball and socket joint and is provided with a scale marked in degrees to compensate for drift; a circular level is also provided.

VOLUME XIV MAY 1931 No. 5

The Engineer and Economic Problems

It is generally agreed that in the more civilized portions of the world, at any rate, the last half century has been remarkable for a general improvement in the physical well-being and standard of comfort of the average citizen, a development that has perhaps been more marked in North America than elsewhere but has also taken place in most of the European countries. Based originally on the work of the early inventors and the development of the steam engine, and carried forward with increasing speed as soon as the inventor joined hands with the man of science and the trained engineer, the movement has now enabled industry to furnish mankind with facilities for communication and transportation and with material comforts undreamed of fifty years ago. Better living conditions now exist; people are better housed and fed; control has been established over many diseases; education has advanced, and the distribution of wealth, with the material advantages it brings, has become more general.

For many of these changes the engineer is given credit, and rightly so, but if he leaves for a moment his preoccupation with the material requirements of mankind and begins to look round, he is struck with the fact that our industrial and scientific advance has not been accompanied by an equally satisfactory development of our economic organization. While it is true that the general standard of comfort has improved and that great changes have taken place for the better in working conditions in all lines of industry, it is evident that much still remains to be done. The factory or office worker still fears unemployment. The farmer has no assurance that he can sell his produce when he has harvested it, the investor feels insecure. At the present time there are people in need of food, while quantities of food-stuffs are available which cannot be sold for want of purchasers. Millions of men are anxious to work, capital and well-equipped factories are ready for them, but things do not move, and so they are not earning the money with which they could buy the products of the industry of others. Sooner or later, no doubt, our economic system will begin to function again with some approach to its former efficiency, but no one seems able to tell us when or why this will take place. Our social system has developed and improved, but apparently not along lines which are controllable.

Of late years there has been a tendency on the part of some to blame the engineer for such unsatisfactory happenings as business depression, unemployment and the like, presumably on the ground that as the industrial revolution and our mechanized civilization are largely the engineer's work, he should take the responsibility for their unpleasant as well as their pleasant results. It has even been suggested that the engineer, who has already accomplished so much, ought to organize the economic development of humanity and employ his analytical skill to plan all the readjustments necessary to make the future secure. But is this really his job? What about the statesmen, economists, sociologists, financiers, bankers and industrialists? It is true that in turn all of these experts have been struggling with the problem, have put forward many explanations and suggestions, and so far, while more or less unanimous in destructive criticism, have failed to agree on any constructive course of policy which will remedy our troubles. After all, should they not really take the lead as being best acquainted with the situation? They are in fact the persons most closely concerned in finding answers to these pressing questions and by training and experience should be best qualified to deal with them.

These reflections are suggested by the encouraging fact that leading engineering societies on both sides of the Atlantic are welcoming communications on economic topics. It is most desirable that engineers should apply themselves seriously to the consideration of economic problems as they affect industrial work. Two thoughtful addresses (*) on this subject delivered at a recent meeting of the American Society of Mechanical Engineers will repay careful study. One was by a prominent engineer, the other by an eminent economist. The former propounded some of the questions which suggest themselves to anyone concerned with the improvement of social conditions in connection with industry, and the latter explained the very serious difficulties standing in the way of providing answers to them. "How far are our present troubles due to speculation," asked the engineer. "Should people be thrifty or should they spend freely? What hinders industrial activity when everybody concerned is anxious to resume production?" Such problems as these will not settle themselves, and it is somewhat discouraging to find that the professional experts either cannot reply to such questions, or, if they do, show a hopeless diversity of opinion. But why should not a new profession arise, employing the engineer's methods of basic research and analysis and applying them in this new field? Its practitioners would deal with the action of economic forces on humanity rather than with the effects of physical forces upon materials, and as a result of their investigations, the problem of economic control would be attacked with extended knowledge and

*Mechanical Engineering, Feb. 1931, pp. 99-110.

from new viewpoints. If we accept this suggestion, it is evident that the engineer can help in this great task, and the question arises, how can he best do so.

The economist whose address followed that of the engineer naturally stressed the difficulties presented by economic problems, and while admitting the progress already made in social well-being, painted rather a discouraging picture of the complicated workings of the present economic machine. In his opinion the mystery is, not that our economic system now and then gets badly out of order, but rather that most of the time it actually runs after a fashion. Speaking for the economists, he admits that hitherto they have been critics rather than constructors, that they have not as yet sufficient knowledge of human behaviour to predict accurately the result of any given policy, and that up to the present, their theories have commanded very little support from people who are in a position to apply them. They can, in fact, "make headway with economic reforms only so fast as a large part of the public gets enlightened enough to sustain us or we get enlightened enough to carry a large part of the public with us."

Before an economist's proposal for a major change in economic method can even be tried in practice, it is necessary to persuade, not merely the management of a single business enterprise, but governments, politicians and millions of individuals.

For example, take the views expressed by a noted British economist, who states that the present industrial depression, unlike those which have preceded it, is principally due to the four years' cessation of production during the war. At that time, vast credits were established, on which the world has been living, and which are now exhausted, so that debtor countries are no longer able to finance their purchases. Tariff barriers almost everywhere prevent the debtors from making payment to the creditor countries otherwise than in gold, which they do not possess, and in consequence world commerce is paralysed. We are told that our only salvation is the universal abolition of these tariff barriers, thus providing all possible facilities to help the debtors to pay their debts. This is the considered recommendation of an economist, and the reception it is likely to get from the world at large may be judged from the fact that the tariff structure of which he complains has been built up everywhere in the face of the unanimous and continuous opposition of economists. Its demolition then would involve a complete change of heart on the part of almost all the leading countries of the world. Evidently we have not yet arrived at the point where economists alone can produce schemes which will meet with adoption in a reasonable time. For progress we must depend upon the co-operation of the economist with the financier, the business man and the industrialist.

The engineer can aid in this great task by convincing the public that it is physically possible to increase production, communication and transportation facilities to any extent required for the world's material welfare, and by pointing out that the difficulties which stand in the way of a world-wide rise in the level of material comfort for mankind are not technological, but depend on the peculiarities of human nature. Next, the engineer must aid the economists and other experts in the educational programme which is needed to give the average citizen, business man, or investor a better knowledge of the possibilities of industrial production, a more altruistic outlook, a greater readiness to study any proposals which appear to offer adequate solutions, and a more constructive attitude of mind.

Report of Committee on Classification and Remuneration of Engineers

Approved for Publication by Council at its Meeting held on March 24th, 1931.

The President and Council,—

Following instructions to prepare a revised edition of the 1922 report on classification, remuneration and tariff of fees of engineers, your committee issued a questionnaire to all corporate members and juniors requesting information regarding their education, engineering experience, and remuneration. There were 1,135 replies received to this questionnaire, representing 30 per cent of the number sent out, and your committee has made a complete analysis and study of all the information obtained in this manner, and the complete record of data and analysis is forwarded in the form of an appendix hereto.

The definite impression was obtained that the replies gave an excellent "cross-section" of conditions regarding remuneration in the engineering profession. They were uniformly distributed on the basis of years of experience from three years up to twenty-seven years. Beyond this point, say up to forty years' experience, there were still quite a large number of replies.

Of the total replies received it was found that 80 per cent came from college graduates and 20 per cent from non-graduates, and broadly speaking, the studies were made on the basis of keeping these two classes separate.

The conclusions of your committee are as follows:—

(*a*) That no useful purpose could be served by the preparation or repetition of a classification system. This conclusion was reached after careful study of the existing classification, but it was felt that in an organization representative of so many different branches of engineering endeavour it would be impossible to prepare a classification system without going into volumes of comparisons, definitions, and so forth, and that as soon as the classification became lengthy it would lose its value. As a basis of comparison therefore, years of experience were used throughout the analysis.

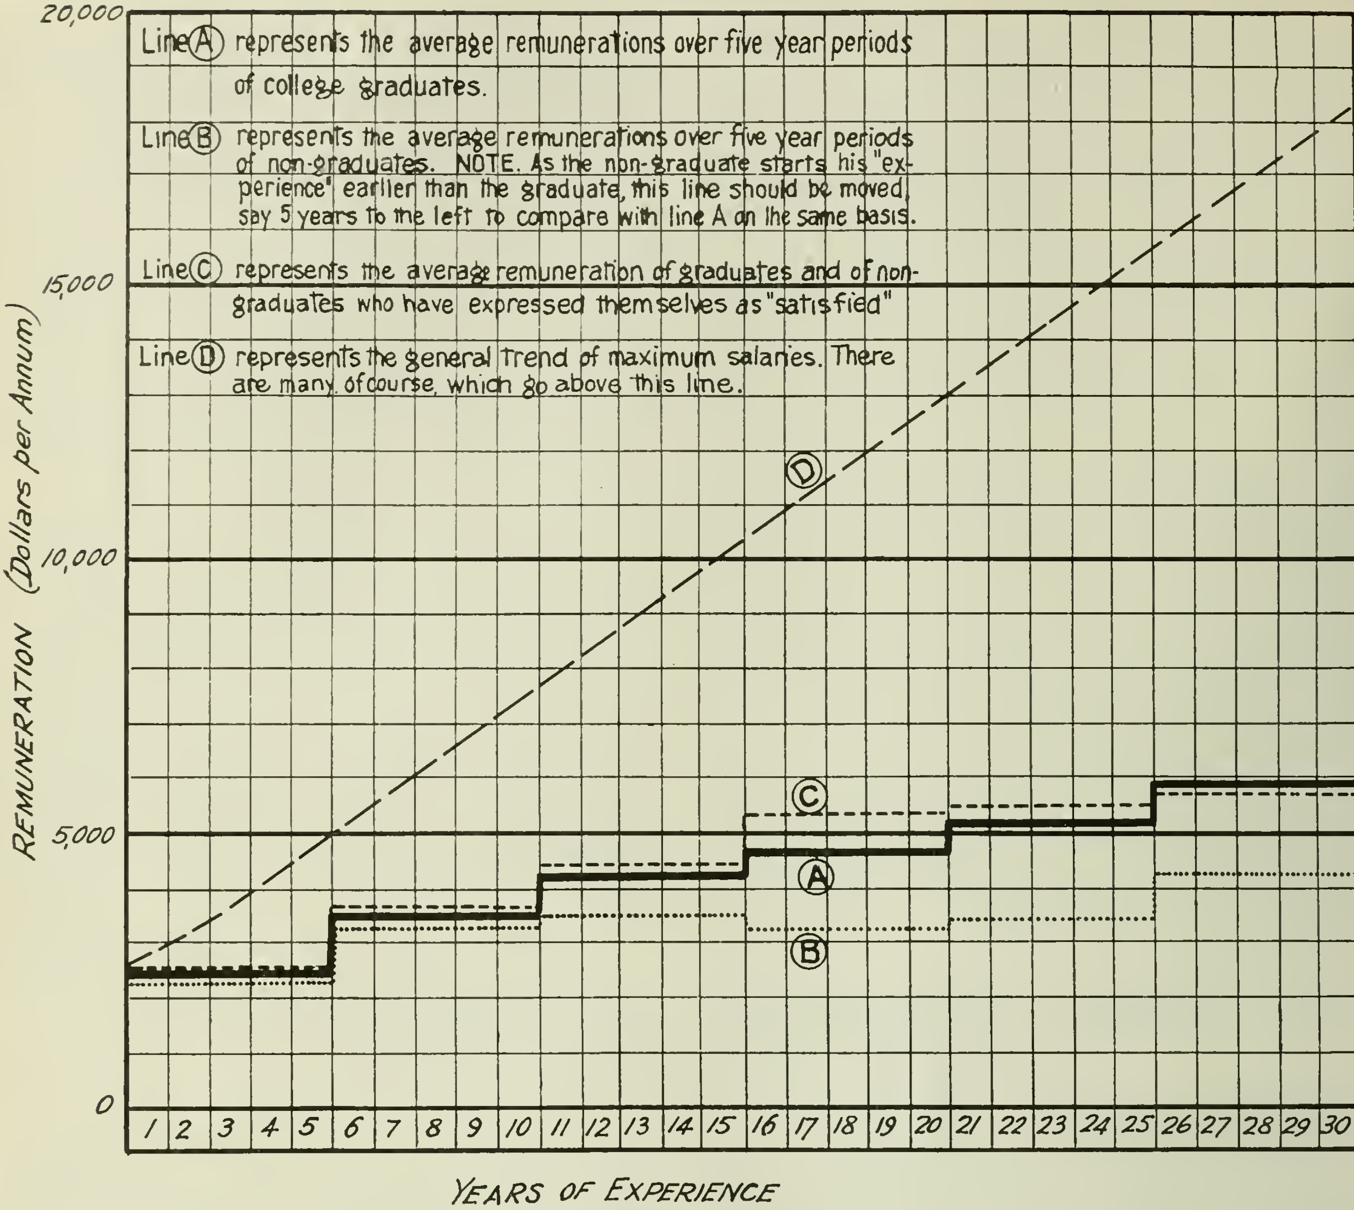
(*b*) That college graduates earn more than non-graduates.

(*c*) That the majority of college graduates express themselves as being satisfied with their remuneration, while in the case of non-graduates the opinion was equally divided between those who were satisfied and those who expressed the opinion that they were underpaid.

(*d*) That 5.4 per cent of the replies to the questionnaire reported remunerations exceeding $10,000 per annum, and the following table gives the nature of positions held by recipients thereof:—

Consulting Engineers	20
Executives	12
Chief Engineers	8
Contractors	5
Construction Engineers or Superintendents	5
Research Engineers	3
Not Stated	3
Sales Engineers	2
Plant Superintendents	2
College Professors and Consultants	1

It may be of interest to note that more than half of this group have had at least twenty-five years' experience since graduating.



(*e*) That graduates and non-graduates on the average earn the following remunerations:—

Years of Experience	Average Remuneration of Graduates	Average Remuneration of Non-Graduates	Average Remuneration of all Engineers who Expressed Themselves as Being Satisfied
1- 5	$2,462	$2,160	$2,587
6-10	3,410	3,151	3,486
11-15	4,138	3,415	4,341
16-20	4,674	3,113	5,343
21-25	5,094	3,344	5,496
26-30	5,963	4,132	5,740
31 and over	6,645	6,062	9,595

In explanation of the foregoing figures, it might be mentioned that in order to obtain representative figures, one extreme high and one extreme low remuneration in each year was eliminated before computing the average of the remainder. The average is really a weighted average in that it represents the summation of all salaries divided by the number reporting.

Attached hereto is a diagram on which is indicated in graphic form the average remunerations of graduates, non-graduates, and of those engineers who have expressed themselves as satisfied. In addition, a line in shown indicating the general trend of maximum salaries—this line, of course, is purely arbitrary, and there were a great many reports received of remunerations considerably above this line.
