Attention is drawn to the fact that the foregoing figures are actually a fair application of the law of supply and demand; in other words, they definitely represent the ordinary market conditions as far as engineering services are concerned.

(*f*) That the order of the different branches of the profession from the best paid to the lowest paid is as follows:—contracting, industrial, electrical, mining, mechanical, civil.

(*g*) That the order by nature of employment from the best paying to the lowest paying is as follows:—consulting, sales, companies, teaching, municipal, government.

(*h*) That the majority of engineers do not reach the highest positions until they have had at least twenty-five years' experience.

(*i*) That the presentation of the facts regarding actual remunerations will be of greater value than any arbitrary recommended schedule of salaries.

Respectfully submitted,

Dec. 17th, 1930. J. L. Busfield, M.E.I.C., *Chairman.*

Meeting of Council

A meeting of Council was held at Headquarters on Tuesday, April 21st, 1931, at eight o'clock p.m., with Vice-President O. O. Lefebvre, M.E.I.C., in the chair and five other members of Council present.

On the suggestion of F. H. Peters, M.E.I.C., it was arranged that a copy of the report of The Institute's Committee on Remuneration should be forwarded for the confidential information of the Royal Commission which, under the chairmanship of Mr. E. W. Beatty, is investigating and reporting upon Civil Service matters.

Further discussion took place as to the date of the Plenary Meeting of Council, representations having been received from some members that the dates selected are not the most convenient. The Secretary was directed to communicate further with councillors regarding this matter. Discussion also took place regarding the best means of defraying the expense of this meeting.

Following the suggestion of Fraser S. Keith, M.E.I.C., chairman of The Institute's Committee on Engineering Education, the Secretary was directed to communicate with the various universities to ascertain whether they would take part in a conference on Engineering Education to be held in Toronto in February next at the time of the Annual General Meeting of The Institute.

The membership of the Leonard Medal Committee was approved as follows:

F. W. Gray, M.E.I.C., Chairman
F. D. Adams, Hon.M.E.I.C.
L. H. Cole, M.E.I.C.
S. C. Mifflen, M.E.I.C.
W. S. Wilson, A.M.E.I.C.

It was noted that K. L. Dawson, M.E.I.C., had accepted membership on the Papers Committee to represent the Maritime branches.

The examiners for the Students' and Juniors' Prizes, as submitted by the chairmen in the various zones, were approved as follows:

Zone A	Vice-President H. B. Muckleston, M.E.I.C.,	Chairman
H. N. Ruttan	Councillor R. W. Ross, A.M.E.I.C.,	Edmonton
Prize	Councillor N. M. Hall, M.E.I.C.,	Winnipeg
Zone B	Vice-President T. R. Loudon, M.E.I.C.,	Chairman
John Galbraith	Councillor D. M. Jemmett, A.M.E.I.C.,	Kingston
Prize	Councillor L. W. Wynne-Roberts, A.M.E.I.C.,	Toronto
Zone C (English)	Vice-President W. G. Mitchell, M.E.I.C.,	Chairman
Phelps Johnson	Councillor F. A. Combe, M.E.I.C.,	Montreal
Prize	Councillor J. A. McCrory, M.E.I.C.,	Montreal
Zone C (French)	Vice-President O. O. Lefebvre, M.E.I.C.,	Chairman
Ernest Marceau	Councillor Hector Cimon, M.E.I.C.,	Quebec
Prize	Councillor B. Grandmont, A.M.E.I.C.,	Three Rivers
Zone D	Vice-President F. R. Faulkner, M.E.I.C.,	Chairman
Martin Murphy	Councillor G. C. Torrens, A.M.E.I.C.,	Moncton
Prize	Councillor A. L. Hay, M.E.I.C.,	Glace Bay

J. A. McCrory, M.E.I.C., the chairman of the Publication Committee, presented that committee's report regarding the publication of a volume of Transactions. This report, which recommends the inclusion in this volume of twenty-six papers selected by the committee, was approved, and the Secretary was directed to prepare for the publication of the volume and to submit prices to the Finance Committee. The volume will be forwarded to the members free of charge, bound copies being available at cost of binding.

It was unanimously resolved that Messrs. W. McG. Gardner, A.M.E.I.C., H. Massue, A.M.E.I.C., and H. G. Thompson, A.M.E.I.C., be appointed scrutineers to canvass the ballot for the amendments to the By-laws, returnable on May 4th, 1931.

The Council noted with regret the death on March 30th, 1931, of R. W. E. Loucks, A.M.E.I.C., for many years secretary-treasurer of the Saskatchewan Branch of The Institute, and recently elected to represent that branch on Council. The following resolution was unanimously passed, the Secretary being directed to send a copy to the family:

"The Council of The Engineering Institute of Canada has learned with deep regret of the death of Roy William Egbert Loucks, so recently elected councillor by the Saskatchewan Branch. Always actively interested in Institute affairs, his valuable services for many years as Secretary-Treasurer of the Branch are gratefully recognized. The Council desires to record the loss sustained by The Institute and to express sympathy with his family on their bereavement."

In connection with the presentation of the first awards of The Engineering Institute of Canada Prizes the following were nominated to represent The Institute at the convocations of the various universities:

University of Alberta	R. W. Ross, A.M.E.I.C.
University of British Columbia	P. H. Buchan, A.M.E.I.C.
Ecole Polytechnique	O. O. Lefebvre, M.E.I.C.
University of Manitoba	J. G. Sullivan, M.E.I.C.
McGill University	D. C. Tennant, M.E.I.C.
University of New Brunswick	W. J. Johnston, A.M.E.I.C.
Nova Scotia Technical College	J. L. Allan, M.E.I.C.
Queen's University	Major L. F. Grant, M.E.I.C.
Royal Military College	D. M. Jemmett, A.M.E.I.C.
University of Saskatchewan	J. E. Underwood, A.M.E.I.C.

It was noted that at the University of Toronto no formal presentation of prizes is to be made.

The newly elected officers of the Toronto and Lethbridge Branches were noted.

Four resignations were accepted; two reinstatements were effected, and three special cases were considered.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:

Elections		Transfers	
Associate Members	5	Assoc. Member to Member	1
Juniors	3	Junior to Assoc. Member	4
Students admitted	5	Student to Assoc. Member	3
		Student to Junior	7

The Council rose at ten forty-five p.m.

OBITUARIES

Roy William Egbert Loucks, A.M.E.I.C.

It is with deep regret that the death is recorded of Roy William Egbert Loucks, A.M.E.I.C., which occurred at Regina, Sask., on March 30th, 1931.

Mr. Loucks was born at Meaford, Ont., on October 31st, 1884, and was educated at the public schools there, later teaching for two years prior to taking a course in civil engineering at the University of Toronto, graduating in 1908 with honours.

Mr. Loucks was a Dominion, Saskatchewan and Alberta land surveyor, and for some time in 1909-1910 he did mining prospecting in the north of Saskatchewan and also surveying work in the extreme north. In 1911 he was assistant to L. W. Brown on Saskatchewan land surveys and general engineering for municipalities. Later he organized the Northwest Construction Company at Saskatoon, and in 1913 established the engineering firm of Brown and Loucks in that city.

Mr. Loucks became a Student of the Canadian Society of Civil Engineers on June 12th, 1909, and transferred to Associate Membership on September 19th, 1916. He took an active interest in the affairs of The Institute and was for a number of years Secretary-Treasurer of the Saskatchewan Branch. Mr. Loucks was the representative of the Saskatchewan Branch on the Council of The Institute for the year 1931-1932.

Joseph William Hayward, M.E.I.C.

The death is recorded at Ste. Anne de Bellevue, Que., on April 14th, 1931, of Joseph William Hayward, M.E.I.C.

Mr. Hayward was born at Winchmore Hill, England, on January 24th, 1875, and was educated at Manchester University, graduating with the degree of B.Sc. with honours, in 1895, and securing the degree of M.Sc. in 1898.

During the years 1898-1902 he was engineering laboratory assistant at Armstrong College, Newcastle-on-Tyne, and in 1902-1906 he was chief engineering laboratory assistant at Central Technical College, South Kensington, London. Coming to Canada, Mr. Hayward was appointed assistant professor of mechanical engineering at McGill University, Montreal, and remained in that position during the years 1906-1908. In 1911-1912 he was engaged on a report on the harbour at Fanning island in the Pacific ocean for Mr. C. N. Armstrong, of Montreal, and in 1915-1916 he was chief assistant resident engineer for Sir Douglas Fox and Partners during the construction of the Royal Naval Cordite Factory, at Holton Heath, England. Returning to this country in 1916, he was engaged until 1918 as engineer of design and construction with British Acetones, Ltd., at Toronto, and later was designing engineer for the Canadian and American Electro Products Factories at Shawinigan Falls, Que. In 1921-1924 Mr. Hayward was instructor in machine design with the College of the City of New York, New York. In 1925 he collaborated with Professor Howard T. Barnes, M.E.I.C., in the preparation of a report upon the formation and movement of ice in the St. Lawrence river for the Hydro-Electric Power Commission of Ontario. For the past few years Mr. Hayward has been engaged in educational work.

He joined The Institute as an Associate Member on May 2nd, 1907, and transferred to full Membership on September 15th, 1925.

Mike Dmytro Olekshy, Jr.E.I.C.

Regret is expressed in recording the death at Wetaskiwin, Alta., on March 10th, of Mike Dmytro Olekshy, Jr.E.I.C.

Mr. Olekshy was born in the Western Ukraine, Europe, on September 12th, 1902, and, coming to this country in 1907, received his education at the Victoria High School, Edmonton, Edmonton Normal School, and the University of Alberta, graduating from the last-named institution in 1930 with the degree of B.Sc. In 1930 he was engaged as an instrumentman on Alberta Main Highways at Bassano, Alta., and in 1931 was with the Department of Public Works, Edmonton, Alta.

Mr. Olekshy joined The Institute as a Student on December 2nd, 1927, and transferred to the class of Junior on April 18th, 1930.

PERSONALS

Major R. D. Thexton, A.M.E.I.C., who has, for a number of years, been in Nigeria, B.W.A., is at present district engineer in charge of construction, Nigerian Railways, Kaduna Junction, Nigeria, B.W.A.

W. H. Hooper, Jr.E.I.C., is now connected with the Canada Wire and Cable Company, Ltd., at Leaside, Ont. Mr. Hooper, who graduated from McGill University in 1927 with the degree of B.Sc., was for a time with the Canadian General Electric Company at Peterborough, Ont., on a test course.

Dr. Charles Camsell, M.E.I.C., Receives Award.

Charles Camsell, B.A., LL.D., F.R.S.C., F.G.S.A., M.E.I.C., Deputy Minister of Mines, Department of Mines, Ottawa, has been awarded this year's gold medal by the British Institution of Mines and Metallurgy. Dr. Camsell has been selected for this honour "in recognition of his untiring zeal and great ability in promoting the development of the natural resources of the Dominion, and in furthering the general interests of the mining industry." The gold medal is the premier award of the Institution and was first presented in 1901. It is presented once each year "in recognition of eminent services rendered by the members of the Institution and others in the advancement of the technology of mining and metallurgy and for the improvement of various processes for the extraction of metals from their ores."

G. S. Clark, A.M.E.I.C., who was formerly with the Donnacona Paper Company, Ltd., Donnacona, Que., is now with Molsons Brewery, Ltd., Montreal.

H. T. Crosbie, M.E.I.C., is at present with the Department of Northern Development. Mr. Crosbie had been town engineer of Kenora, Ont., since 1927, and was for some years town engineer of Yorkton, Sask.

R. M. Doull, S.E.I.C., is now connected with Construction Equipment Company, Montreal. Mr. Doull, who is a graduate of McGill University of the year 1929, was formerly with the Dominion Engineering Works, Lachine, Que.

G. D. Durham, S.E.I.C., who has been located at Kenogami, Que., since January, 1930, is now with the Shawinigan Engineering Company, at Rapide Blanc, Que. Mr. Durham graduated from Queen's University in 1929, with the degree of B.Sc.

R. J. Fuller, A.M.E.I.C., has entered practice at Toronto, Ont., as a structural engineer. Mr. Fuller graduated from the University of Toronto with the degree of B.A.Sc. in 1912. In November, 1912, he entered the department of the city architect and superintendent of building, city of Toronto, where he remained until 1917, when he was appointed chief engineer of the John V. Gray Construction Company, Ltd. In 1927 he became connected with Mr. Roy. H. Bishop, architect, at Oshawa, Ont.

John E. Jackson, A.M.E.I.C., is at the present time employed with the Surveys department of the Department of Public Highways of Ontario, and is located at Riverside, Ont.

J. W. Lucas, S.E.I.C., has joined the staff of the Testing Laboratories of the Department of Public Works, Ottawa, Ont. Mr. Lucas, who was formerly with the Beauharnois Construction Company at Beauharnois, Que., is a graduate of the University of Alberta of the year 1930.

Major P. J. Jennings, M.E.I.C., who since 1928 has been Reclamation Engineer, Water Power and Reclamation Service, Department of the Interior, Calgary, has been appointed acting superintendent of Banff National Park. From 1911 to 1920 Major Jennings was connected with the Irrigation Branch, Reclamation Department of the Interior, with the exception of the period 1916 to August, 1919, when he was on active service, serving in British and German East Africa. Major Jennings takes a keen interest in Institute affairs, and is a charter member of the Calgary Branch. He represented that Branch on the Council of The Institute in 1928.

T. H. NICHOLSON, A.M.E.I.C.

T. H. Nicholson, A.M.E.I.C., is the head of a new company formed under Dominion charter at Montreal for the distribution through Canada, Newfoundland and the British West Indies of domestic electrical devices. Mr. Nicholson was formerly engaged as vice-president and general manager of the Compania Nacional de Electricidad, operating the principal electric light and power, telephone and tramway properties in Costa Rica. He was at one time consulting engineer with the Brazilian Telephone Company with headquarters at Rio de Janeiro, Brazil, and was for a number of years on the engineering staff of the Bell Telephone Company of Canada, Ltd., at Montreal.

T. S. Scott, M.E.I.C., who for the past year has been town engineer of Port Colborne, Ont., has received the appointment of Commissioner of Works for the township of York, Ont. Mr. Scott graduated from Queen's University with the degrees of B.A. and B.Sc., and was, for a time, professor of civil engineering at that university. In 1922 he became city engineer of Niagara Falls, Ont., and was later appointed city manager.

F. K. Beach, A.M.E.I.C., is now attached to the Petroleum and Natural Gas Division, Department of the Interior, Edmonton, Alta. Since 1927 Mr. Beach has been assistant engineer, office of the mining engineer, North West Territories and Yukon Branch of the Department of the Interior, located at Calgary, Alta.

F. C. Wightman, A.M.E.I.C., who has since 1927 been county engineer, Department of Highways, Truro, N.S., is now town manager of Kentville, N.S.

C. W. Justice, Jr.E.I.C., is electrical engineer with Noranda Mines, Ltd., Noranda, Que. Mr. Justice, who was formerly electrical demonstrator at the University of Manitoba, Winnipeg, Man., graduated from the university in 1926, with the degree of B.Sc., following which he took a test course with the Canadian General Electric Company at Peterborough, Ont.

BOOK REVIEWS

Airplane Structures

By Alfred S. Niles and Joseph S. Newell. Wiley & Sons, New York, 1929, cloth, 6 x 9 in., 413 pp., figs., charts, tables, $5.00.

In such a profession as aeronautical structural engineering, the necessity of designing structures as light as possible and yet adequate to withstand any probable load is essential; for upon this a large measure of the success of the aircraft depends. This book, which is for the most part intended to meet the needs of both student and practising engineer, deals with the more common problems encountered in this branch of aeronautical engineering. The problems at the end of each chapter are particularly useful to the student, and in fact could have been made more numerous with beneficial results. Being of American origin, the book is more particularly concerned with current American practice.

The book opens with a discussion of specification, a general description of loading conditions and the various forces applied to the aeroplane structure. Fundamentals in bending moments, shear, forces, etc., and methods of expressing them both in analytical and graphical form are reviewed.

The usual beam theory, the equations of three moments with various load distributions, and the effect of offset moments are discussed at some length. Detail design of simple beams with remarks on horizontal shear and allowable stresses are also dealt with. One chapter is devoted to torsion in various cross sections and allowable torsional stresses, with a description of how torsional stresses are combined with bending and axial stresses in practical design.

Then follows a dissertation on trusses and analytical methods of solution with examples included. The elementary principles of graphical truss analysis are explained fairly fully with the help of an illustrative problem.

The design of axial loaded members in both metal and wood with various tables, nomograms and charts appended, forms a very valuable part of this book. The effect of end fixity of columns is discussed at some length for the various materials in common use in aircraft work. Examples include various forms of joints used in aircraft construction with their relative merits and limitations and are commented upon with illustrative examples of design.

Considerable space is allotted to a treatise on members subjected to combined lateral and axial loads. The American methods adopted from British and German sources are discussed fully in general form and for several particular cases. The numerical examples given greatly facilitate the application to practical problems. Tables of the necessary functions are included. Mention is also made of special computation devices, approximate methods, secondary shear, special use of the precise formulae, and graphical solutions, with several numerical examples. This part of the book is probably the most valuable to the practical designing engineer.

Allowable stress grading for wood and metal according to the form of member involved, is explained quite fully. Useful charts are appended.

Deflections and various methods of obtaining them are fairly well discussed as applicable to both beams and trusses. Redundant structures and the method of least work applied to axial and bending conditions of loading together with many useful suggestions for practical use are explained.

Towards the end of the book, the writers return to the subject of weights and weight control with its many ramifications. Tabulated data directly useful to the designer are included with an attempt at detailed classification. A very useful bibliography and a good index complete this volume, which, without doubt, is one of the most useful books to those engaged in aeronautical engineering whether as students or as designers.

A. O. Adams, Flying Officer,
Civil Aviation Branch,
Department of National Defence, Canada,
Ottawa.

Automobile Steels

By A. Müller-Hauff and K. Stein. Translated from the German by H. Goldschmidt. Wiley & Sons, New York, 1930, cloth, 6 x 9 in., 219 pp., illus., figs., charts, tables, $3.50.

The book was written with the object of supplying a practical manual for designer, automobile plant manager, steel plant manager, business man and mechanic. With this purpose in view the authors have brought together a mass of widely scattered material to which they have added data and observations of their own.

The subject has been treated from many angles such as testing, metallography, manufacture, types of steel used, the selection of steel for various parts, and standards. A chapter on failures, consisting of photographs of broken parts, and one, consisting of thirteen tables showing the analysis and properties of steel used for the various parts by leading American and European manufacturers, were added in the translation. These may be considered by many to be the most valuable portion of the book.

Brevity is always desirable, but the reviewer feels that the authors have carried this too far. In chapter II the metallography of steel has been treated in about twelve pages. These contain some inaccurate statements which possibly result from the desire for brevity. In the effort to obtain brevity and simplicity the iron-carbon diagram is shown with a solidus curve but with no liquidus curve. The subsequent discussion of the changes which occur on cooling the alloys will probably leave an incorrect impression in the mind of the reader who is unfamiliar with this phase of the subject.

While the authors may not agree, the reviewer believes that the book would have been improved by the total omission of chapter II as it is too brief to be of any use to the technical man and will only add to the confusion of the non-technical reader.

Probably due to the attempt at a literal translation some of the terms are not used in their generally accepted sense. This is particularly true of the term "annealing."

The following typographical errors were noticed in chapter IV: 650° C. (840° F.) for 450° C. (840° F.), 7 per cent carbon for .7 per cent and Mi for Ni.

The comparison of German and American standards and practice will be found interesting, as well as the great mass of tabulated data on compositions and properties of the various steels. To those interested in automobile steels, the large amount of data contained in this book will make it of value as a reference.

Queen's University,
Kingston, Ont.

American Sewerage Practice

Volume 1 — Design of Sewers

By Leonard Metcalf and Harrison P. Eddy. McGraw-Hill, New York, 1928, cloth, 6 x 9 in., 759 pp., photos, figs., tables, $5.00.

It may truthfully be said that this volume, first published in 1914, constitutes an excellent work of reference. First editions are often subject to considerable revisions and additions and this book is no exception. The present edition represents the best thoughts devoted to the design of sewers, which design, however, is still regarded by not a few municipal authorities as an ordinary undertaking. Actually the function of the engineer is one of considerable importance when due regard is paid to his duty to his employers and to himself in the matter of reasonably economical designs.

Whilst the principles and theories appertaining to the hydraulics of sewers are dealt with fully, their application is described in such detail that the engineer is afforded ample opportunity of selecting the information which best suits the particular local conditions. In the chapter on precipitation the subject is dealt with in twenty-eight pages, and storm-water occupies another eighty-four. The term "rational method" of estimating the quantity of runoff does not seem to be logical: what is rational to one engineer may not be so to another. A term such as "synthetic method" seems to be more appropriate since it is a process of building up information, because the computations are started at the distant end of the sewer and each branch is added in orderly sequence. In other words the design is synthetically built up.

The numerous illustrated examples of masonry sewers will be of great value to engineers engaged on larger sewer schemes.

The section dealing with analysis of stress in sewer sections is a carefully prepared thesis on the subject.

The sections on junctions, siphons, bridges, flushing devices, and regulators, overflows, outlets, etc., are instructive and many examples are given of each.

The chapter on pumps of different kinds is interesting. Non-clogging impellers originated probably by Wood, of New Orleans, are described but no reference is made to the stereophagus pumps designed by Parsons.

Finally, the usefulness of a volume of this kind is greatly enhanced by a good comprehensive index, to which, in this volume, thirty-nine pages are devoted. This volume should be in the library of every municipal engineer.

City Noise

Report of the Noise Abatement Commission of the Department of Health, New York City. Edited by Messrs. Brown, Dennis, Henry and Pendray, 1930, paper, 6 x 9 in., 308 pp., photos, diagrs., tables.

In the foreword Dr. Shirley W. Wynne, Commissioner of Health, New York city, remarks in regard to the Noise Abatement Commission appointed in October, 1929:

> "Eight months ago I appointed a commission to study city noise and map out the means of abating it. This is the report of its work . . . " "This volume is the record of the generous contribution of time and talents by the members of the commission to their city. They have laboured with no hope of reward other than to make New York a peaceful, healthful place in which we can live."

In the list of commissioners appointed there are found several prominent physicians and professors of neurology, otology, etc., accoustical and other engineers, and executives of companies manufacturing sound deadening materials, as well as the Commissioner and Deputy Commissioner of Health for the City of New York.

Of especial interest to those who view city building and civic affairs in the light of the science and art of city planning is the fact that Lawson Purdy, LL.D., well known for his work in taxation and city planning is also a member of the commission.

A classification of the various city noises is made and their effect from the standpoint of health is analyzed. It is, of course, not within the scope of this review to go into details and the report is recommended to all readers who view community betterment as one of their main considerations, whether it be in New York where the first Noise Abatement Commission has been appointed, or in other less populous centres.

It seems to be quite clearly proved in the report that noise may destroy health and efficiency and cause economic loss.

There are many simple ways in which noise abatement may be carried out. As indicative, however, of some of the difficulties in the way and as to the attitude of the commissioners, the following extract in regard to radios may be quoted:

> "The commission has had cases called to its attention where these loudspeakers in residential neighbourhoods poured forth their intolerable clamour all day long and far into the night. Protests to the owners were useless; they refused to be reasonable or courteous, maintaining that every man has a right to operate his business and its advertising as he pleased—a specious argument which, if carried to its logical conclusion, would make the city uninhabitable!"

To those who see in the unlimited erection of skyscrapers an entire lack of scale between the height of such buildings and the open spaces around them there will be found another argument against the high building with the attendant noises after erection and the roar of the riveting machines during erection. Incidentally, the information is of value that the Pacific coast cities allow in their building codes for noiseless arc welding instead of riveting and some of the eastern United States cities may follow suit.

The appointment of such a commission and the publication of such a report is another indication of the regard that is being given to matters which in the past through lack of study and of thought were considered to be merely matters of individual whim and not of community concern. It is another illustration of our growing consciousness "that individual rights should cease when they become public wrongs."

Horace L. Seymour, m.e.i.c.,
Director of Town Planning,
Dept. of Municipal Affairs, Alberta,
Edmonton, Alta.

High Speed Steel

By Marcus A. Grossman and Edgar C. Bain. Wiley & Sons, New York, 1931, cloth, 6 x 9 in., 178 pp., illus., diagrs., charts, tables, $3.50.

The book is in two parts, the first dealing with melting, casting, working, annealing, hardening, tempering and inspection, the bearing of each step on the quality of the finished product being clearly discussed. The second part deals with the constitutional diagrams, the microstructures developed at various stages in the manufacture and heat treatment and their relation to the ultimate mechanical properties of the material.

High speed steel, an alloy of iron, tungsten, chromium, vanadium and carbon with or without some cobalt and molybdenum, has been considered an exceedingly complex alloy which bears little resemblance to ordinary carbon steel. However the authors have presented their work in a manner which shows clearly that the metallurgy of high speed steel is analogous to that of the simple carbon steels. By the assumptions that each per cent of Cr, V, and Mo may be considered as equivalent, respectively, to 0.5, 4.0 and 1.3 per cent of additional W, that the carbide exists as Fe_4W_2C and that cobalt may be treated as iron, a pseudo-binary diagram for the system $Fe - Fe_4W_2C$ is constructed and used to give a very satisfactory explanation of the heat treatment. The diagram bears a marked similarity to that for the $Fe - Fe_3C$ system, and any one with an understanding of the heat treatment of ordinary hypereutectoid carbon steels will readily follow and remember the heat treatment of high speed steel.

The book contains a considerable amount of valuable data and many micrographs. In the final chapter some excellent X-ray crystallograms (diffraction patterns) are reproduced. It is an excellent and authoritative technical treatise and will eliminate much of the existing confusion regarding high speed steel. The book has been written chiefly for the metallurgist, but the facts and principles have been expressed so clearly and simply that any one will find it easy to read and digest.

In the opinion of the reviewer the book will form, both as a text and a reference, a valuable addition to the libraries of all those who are at all interested in high speed steel.

Kingston, Ont.

Modern Diesel Engine Practice

By Orville Adams. Henley Publishing Co., New York, 1931, cloth, 6 x 9 in., 656 pp., front., photos, figs., tables, $6.00.

This volume consists of 656 pages of material excellently printed and profusely illustrated and is intended to be a comprehensive treatise for the student and practical engineer, covering fully, theory, practical applications, operation, maintenance and repairs. It includes instructions suitable to the owner, operator, repairman, and engine salesman in addition to being valuable to students.

Within its covers there is a vast amount of general and detailed information regarding Diesel engines, their applications, operations, costs and so forth, dealing principally with American engines and practices. It might have been better, however, to have concentrated more on one phase of Diesel engineering rather than to attempt to include everything. For example, there is much in the book which the "practical Diesel engineer" will not read—and there is a great deal that the Diesel owner will not read. It is difficult to see the value of inserting into a book of this nature pages—nay, chapters, of material which can readily be obtained from the manufacturers' catalogues—in fact possibly more advantageously—as catalogues are kept up to date—whereas many manufacturers' practices described in this volume may be altered or obsolete in a very short time—Diesel practice is passing through many changes.

This very fact, however, gives merit to the publication, because it is at least an up-to-date review of the subject, of which there are not too many available.

The book has many illustrations, but it is very hard to see the purpose of some of these—unless merely to give a pictorial effect—and others have apparently been inserted without regard to the adjacent text.

These are, of course, minor criticisms and there is no doubt but that the volume would make a worth-while addition to the bookshelf of any engineer—even one with only a remote interest in Diesel engines or plants.

J. L. Busfield, M.E.I.C.,

The Herbert Morris Crane & Hoist Company, Ltd.:
Book 30 [252 pp.].

The Ferranti phase rotation indicator has met with considerable favour from various operating utilities, and the company announce that they are extending its range to 600 volts. This is being used primarily as a convenient means of checking phase rotation for synchronizing when connecting up new installations for the first time, or when a line or apparatus has been disconnected for repairs. It is more convenient than the familiar lamp and reactor connection. It is also used in checking meter and relay potential transformer connections.

Link-Belt Company, Chicago, Ill., announces a new design of heavy-duty manganese steel apron feeder. The new feeder is suitable for handling either abrasive or non-abrasive material, containing lumps of ¼-inch size, and smaller, up to 6-foot dimensions, being especially well adapted to the handling of extremely heavy, large, lumpy and abrasive materials. Full details, data and illustrations of this new apron feeder and its component parts, as well as installation views, are shown in Folder No. 1251, which is being distributed by Link-Belt Company, 300 West Pershing Road, Chicago, Ill.

ELECTIONS AND TRANSFERS

At the meeting of Council held on April 21st, 1931, the following elections and transfers were effected:

Associate Members

BALLARD, Guy Bristow, B.Sc., (Queen's Univ.), elec'l. engr. with National Research Council, Ottawa, Ont.

BARTEAUX, Ross M., B.Sc. (Elec. and Mech.), (N.S. Tech. Coll.), asst. to gen. supt., Nova Scotia Light & Power Co. Ltd., Halifax, N.S.

BIZIER, Joseph Lionel, B.A.Sc., C.E., (Ecole Polytech.), dredging engr., Quebec Harbour Commission, Quebec, Que.

GEROW, Carlyle, B.Sc., (Queen's Univ.), asst. gen. mgr. and technical advisor, coal sales dept., Dominion Coal Company, Limited, Montreal, Que.

POUNDER, Thomas James, B.Sc. (Eng.), (Univ. of Man.), asst. dist. engr., Dept. of Highways of Saskatchewan, Yorkton, Sask.

Juniors

GOODMAN, James Edward, (Queen's Univ.), research work for Dept. Public Highways of Ontario, Kingston, Ont.

GUDMUNDSON, August Evert, B.Sc. (Elec.), (Univ. of Alta.), Canadian Utilities Company, Calgary, Alta.

WRANGELL, Kjell Frederick, (Horten Tekniske Skole), mech. engr., E. B. Eddy Co. Ltd., Hull, Que.

Transferred from the class of Associate Member to that of Member

WHITTAKER, David, (Univ. of Liverpool), asst. hydraulic engr., Dominion Water Power & Hydrometric Bureau, Dept. of the Interior, Edmonton, Alta.

Transferred from the class of Junior to that of Associate Member

BURCHILL, George Herbert, B.Sc., (N.S. Tech. Coll.), acting professor of elect'l. engrg., Nova Scotia Technical College, Halifax, N.S.

HEATLEY, A. Harold, B.A.Sc., M.A., (Univ. of Toronto), chemist, John Walter & Sons Ltd., Kitchener, Ont.

KINGSMILL, Charles Grange, B.A.Sc., (Univ. of Toronto), res. engr. on portion of canal, Beauharnois Construction Company, Beauharnois, Que.

KIRKPATRICK, Harold Thompson, B.Sc., (McGill Univ.), Parrsboro, N.S.

Transferred from the class of Student to that of Associate Member

CAMPBELL, Wilfred John, B.A.Sc., (Univ. of Toronto), elect'l. engr., Detroit Edison Co., Detroit, Mich.

DILWORTH, Edwin L., B.Sc., (Queen's Univ.), heating and ventilating engr. in charge of Montreal sales office, Canadian Blower & Forge Co. Ltd., Montreal, Que.

THOMPSON, Harry Alexander, B.A., B.Sc. (C.E.), (Univ. of Sask.), constrn. engr., Morrow & Beatty, Fitzroy Harbour, Ont.

Transferred from the class of Student to that of Junior

ALLISON, Jesse Graham, B.Sc., (Univ. of So. California), estimator, H. C. Johnston Co. Ltd., Montreal, Que.

GRANT, Alex. James, Jr., B.Sc., (McGill Univ.), field engr., Dominion Bridge Company, Ltd., Montreal, Que.

GRANT, Wilfrid John, B.A.Sc., (Univ. of Toronto), teacher, dept. of physics, Central Technical School, Toronto, Ont.

MOOGK, Ernest George, B.A.Sc., (Univ. of Toronto), asst. in supt.'s office, University of Toronto, Toronto, Ont.

PATTERSON, Ian Stewart, B.Sc., (N.S. Tech. Coll.), industrial control specialist, Canadian General Electric Co. Ltd., Montreal, Que.

TAYLOR, Frank Denzil, B.Sc., (McGill Univ.), mill chemist, Brompton Pulp & Paper Co., East Angus, Que.

TIMLECK, Curtis James, B.A.Sc., (Univ. of B.C.), in charge of contract service dept., Canadian Ingersoll Rand Co. Ltd., Montreal, Que.

Students Admitted

BLAIR, James, (Univ. of Alta.), Hanna, Alta.

BROWN, William Boughton, (N.S. Tech. Coll.), Clark's Harbour, N.S.

CRAIG, Carleton, (McGill Univ.), 3433 Peel St., Montreal, Que.

FORSBERG, Clarence Rudeford, (Univ. of Sask.), Dunblane, Sask.

HEWSON, Edgar Wendell, (Mount Allison Univ.), Amherst, N.S.

Twelfth Annual Meeting of the Corporation of Professional Engineers of Quebec

A. R. Decary, D.Sc., M.E.I.C., Superintendent Engineer for the Province of Quebec, at the Department of Public Works of Canada, was re-elected for the twelfth time president of the Corporation of Professional Engineers of Quebec, on March 25th, at the headquarters of The Engineering Institute of Canada, Mansfield Street.

The following engineers attended the meeting: Messrs. Geo. E. Reakes, A.M.E.I.C., E. S. Holloway, M.E.I.C., Huet Massue, A.M.E.I.C., Charles Taschereau, J. A. McCrory, M.E.I.C., O. Graham, A. Leduc, E. Duval, Geo. K. McDougall, M.E.I.C., J. Chas. Legendre, Chs. A. Cousineau, M.E.I.C., Herbert Cantwell, A.M.E.I.C., N. L. Morgan, A.M.E.I.C., A. B. Normandin, A.M.E.I.C., C. E. Olive, J. M. Robertson, M.E.I.C., A. R. Decary, M.E.I.C., Frederick B. Brown, M.E.I.C., J. B. Macphail, A.M.E.I.C., J. A. Beauchemin, A.M.E.I.C., J. Raoul Julien, Gaston Labelle, Edmour Chauret, Emile Labay, Hector Cimon, A.M.E.I.C., R. J. Durley, M.E.I.C., J. M. Portugais, A.M.E.I.C., Ch. Godin, A.M.E.I.C., Walter Manning, S.E.I.C., Walter Clerk, Paul de Guise, P. E. Bourbonnais, A.M.E.I.C., J. B. O. Saint-Laurent, A.M.E.I.C., Y. Marchand, Adrien Genest, Réal Bélanger, S.E.I.C., Adrie Barrette, A.M.E.I.C., Martin Wolff, A.M.E.I.C., Wallace Dickson, M.E.I.C., M. A. Downes, A.M.E.I.C., J. C. Chagnon, C. A. Mathieu, H. Carignan, W. H. Benne, F. A. Combe, M.E.I.C., R. A. Vincent, A.M.E.I.C., J. N. E. Bélanger, K. B. Thornton, M.E.I.C., G. C. Bastien, M. Cailloux, H. Labrecque, A. Duperron, M.E.I.C., R. Langlois, A.M.E.I.C., Wm. McG. Gardner, A.M.E.I.C., N. Dozois, C. Valiquette, Jr.E.I.C., F. W. Caldwell, M.E.I.C., Teles. Toupin, J. P. Lalonde, S.E.I.C., Francis J. Hoar, S. F. Rutherford, A.M.E.I.C., A. Mailhiot, C. G. Porter, A.M.E.I.C., W. E. Lauriault, A.M.E.I.C., Jean M. Forget.

Mr. Frederick B. Brown, Secretary-Treasurer of the Corporation, read the reports from Council, from the Treasurer and from the Board of Examiners. All these reports show that the Corporation of Professional Engineers of Quebec is doing efficient work in the way of protecting its members, and that the law governing the engineering profession in the province of Quebec is helping greatly the members of the profession. Not less than forty-four cases of illegal practice and advertisement were reported settled during the past year.

The Treasurer's report shows a surplus for the year 1930.

Several questions of interest to the profession were discussed by the engineers present. Among these, the question of temporary licenses granted to engineers residing out of the province of Quebec was fully explained by the President of the Corporation, Dr. A. R. Decary. Several committees were nominated to study ways and means of improving the act governing the practice of the profession, and of giving more publicity to the work of the engineer for the welfare of the community.

The President read the report of the scrutineers, and the following members of Council were declared elected: For the district of Montreal: Dr. Olivier Lefebvre, M.E.I.C., and Messrs. Geo. K. McDougall and J. M. Robertson; for the district of Quebec: Mr. Hector Cimon.

At the close of the meeting, the Council met and elected officers as follows: President, Dr. A. R. Decary; Vice-President, Mr. J. M. Robertson; Secretary-Treasurer, Mr. Frederick B. Brown. The other members of Council are: Messrs. Olivier Lefebvre, C. N. Monsarrat, M.E.I.C., Geo. K. McDougall, A. B. Normandin and H. Cimon.

Mr. Adhémar Mailhiot was reappointed as Registrar of the Corporation.

The Garlock Packing Company have recently developed a new gasket material which is called "Button Hole Tape." On account of its unique construction and method of application it has many advantages for certain jobs. The Garlock button hole tape is made up of two parallel courses of high grade folded asbestos cloth joined together by a single ply of bonding fabric. As shipped from the factory it contains no holes. The insertion of a knife blade between the two parallel sections of the tape cuts the bonding fabric, forming a button hole which slips readily over the bolt or stud. With no tools, other than a knife, any workman can quickly make a perfect gasket which will remain in place, fit correctly, lie flat and form a positive seal around every bolt.

Jenkins Bros. Limited announce the election at the recently held annual meeting of the company of Mr. Herbert H. Gee as a director. Mr. Gee, who has been connected with the company for some twenty-three years, is Ontario manager.

The Herbert Morris Crane and Hoist Company, Ltd., Niagara Falls, Ont., have recently published Book 30, the company's latest general catalogue, which illustrates and describes in concise form the complete range of Morris material handling equipment.

BRANCH NEWS

Border Cities Branch

Harold J. A. Chambers, A.M.E.I.C., Secretary-Treasurer.

The regular monthly meeting of the Border Cities Branch was held on Friday, March 20th. The speaker of the evening was Mr. R. C. Manning, district engineer for the Canadian Institute of Steel Construction. The subject of Mr. Manning's address was steel; its growth as an industry, its importance, properties and uses in our modern civilization. Also, he outlined the work accomplished by the institute which he represented. At the close of his talk, motion pictures were shown illustrating the rolling of structural steel shapes in mills. An interesting film of the construction of the Empire State building, New York city, was also shown.

Steel

Iron, the speaker stated in opening his address, is one of the oldest and most useful of our known metals. Steel, however, which may be termed a refinement of iron, does not date far back, being discovered in England by Bessemer.

Trains, airplanes, automobiles, sky-scrapers and other features of our modern civilization, often termed the steel age, then only became possible. Since the discovery of steel, the growth of that industry has indeed been great. It has grown by leaps and bounds until now it is one of our leading industries and is widely used in building construction.

Structural steel is made by three important processes for commercial use, namely: the Bessemer, open hearth and the electric furnace. The open hearth is the most common process because it gives a better heat control. The electric furnace process is as yet very expensive. It yields a very pure product, but is not used to any great extent.

The physical and chemical properties of structural steel in process are under accurate scientific control and test. Great care in the selection of the flues and the furnace linings is necessary. Tests for phosphorus are taken for each melt. Consequently we are certain of a material of pre-determined analysis. The next step in the manufacture of structural steel shapes, rolling, is also carried out with great precision. Knowing the analysis of the steel, the ultimate strength and the cross section to be accurate, the designer can work intelligently and accurately. The detailer and fabricator also play their part, with the result that the completed structure is known to bear out the design. Material in building which takes up the least room is the material most desired. Steel insures strength and security. Steel bridges can be readily reinforced or altered to suit new conditions. They have a long life and the maintenance cost consists of painting every five or six years.

Steel can be erected in any weather and is self-supporting during erection. The erection is fast. Obsolete steel can be re-erected in a different location or it can be sold for scrap. Generally other building materials can not be sold or re-used. In steel, tension, compression and shear are all resisted to the same degree. The material is perfectly elastic and the deformation is proportional to the stress. The steel completely recovers its original volume and form if not stressed above the elastic limit. The yield point is never equalled by the working stress, a certain factor of safety always being used. Steel is not subject to fatigue. It fails slowly by bending and elongation. It is fabricated by standard methods. It is quickly erected and does not suffer damage from the weather. The above are some of the many advantages that steel has over other building materials.

Arc welding in steel structures is a comparatively new method of fabrication. As yet it is only used in secondary members. The first all-welded structure was erected by the Canadian Bridge Company, Ltd. during the summer of 1930. It was of the mill building type and was built for the Canadian General Electric Company at Peterboro, Ontario.

The purpose of the Institute of Steel Construction, the speaker stated, was to establish standard specifications and standard practice. In this direction, the first step was accomplished in 1923 by the American Institute of Steel Construction when they established a set of standard specifications. In 1924 a code of standard practice was drawn up. Later a handbook of standard sections was compiled, and following that specifications for fire proofing were established. This information was obtained from steel manufacturers, fabricators, architects and engineers.

At the conclusion of the address a hearty vote of thanks was conveyed to Mr. Manning by the chairman, R. J. Desmarais, A.M.E.I.C., on behalf of the members of the Branch.

Hamilton Branch

J. R. Dunbar, A.M.E.I.C., Secretary Treasurer.

J. A. M. Galilee, Affil.E.I.C., Branch News Editor.

Joint Meeting with A.S.M.E.

(*Reported by E. B. Scott*)

On April 2nd a joint meeting was held with the Ontario and Buffalo sections of the American Society of Mechanical Engineers and the Niagara Peninsular Branch of The Engineering Institute of Canada. At 1.00 p.m. approximately sixty members of the joint organizations met for luncheon at Cecil Roberts' restaurant, Hamilton.

Visits to Plants

Immediately after lunch this original party was supplemented by thirty additional members for visits to various factories in Hamilton. The members had their choice of going to the Canadian Westinghouse Company Ltd., the Firestone Tire and Rubber Company or the Steel Company of Canada, after which everyone went to the Dominion Glass Company. At the Canadian Westinghouse Company, motors, transformers, circuit breakers, generators, meters, relays, air brakes and all the more interesting electrical equipment were seen being made and tested. At the Firestone Tire and Rubber Company, the manufacture of tires and inner tubes was followed from the bulk gum rubber direct to the finished product. At the Steel Company of Canada the manufacture of steel in all its different stages was followed through systematically from the raw materials, mixing, heating, pouring, blooming, drawing and cutting, to the finished product. At 4 o'clock the different parties met at the Dominion Glass Company and were shown through the plant. The Glass Company were manufacturing bottles alone. The large furnaces and automatic blowers were the main points of interest.

Dinner

At 6 o'clock an enjoyable dinner was held in the ball room of the Royal Connaught hotel. Seated at the head table were Alex. J. Grant, M.E.I.C., St. Catharines, Past-President of The Institute, J. P. Wys, Toronto, E. H. Darling, M.E.I.C., Hamilton, W. F. McLaren, M.E.I.C., chairman, Hamilton Branch of The Institute, Prof. C. E. Harrington, Buffalo, Walter Jackson, M.E.I.C., St. Catharines, S. L. Fear, Toronto, Prof. E. A. Alcutt, M.E.I.C., Toronto, E. G. Cameron, A.M.E.I.C., St. Catharines, W. H. Taylor, Buffalo, and Dr. L. G. Hector, Buffalo.

After dinner Mr. McLaren introduced Alex. J. Grant, M.E.I.C., Past President of The Institute, who welcomed the visitors from the American Society of Mechanical Engineers. He spoke of the advisability of having as many joint meetings as possible between Canadian and American branches of engineering associations, because the development of the prosperity of our respective countries was principally in the hands of engineers and that we should advance together.

Mr. McLaren then introduced Professor Harrington from the University of Buffalo, who remarked upon the number of associations represented, Buffalo, Toronto, Galt and Hamilton, and the similarity between the Canadian and the American engineer.

Flow of Air Past Stationary and Rotating Aero Foils

Professor Harrington then asked Dr. Hector to say a few words explaining the photographs which were to follow. Dr. Hector explained that most of the motion pictures to follow were taken in Japan at the University of Tokyo and that the films dealt mostly with the flow of air past rotating and stationary aero foils. He said that Mr. Taylor would explain the aero foil and that he would deal with the construction of the camera. To obtain from 1,000 to 40,000 exposures per second a spiral film was wound on a fast moving drum. After the film has been taken, the film is cut along the spiral and made into a straight film which is enlarged to camera size. The photographs are taken in a dark room with light from an arc appearing from 1,000 to 40,000 times per second with total darkness in between. No shutter is needed. An entirely different scheme may also be used by the use of continuous illumination and make the object travel with the film. This is done by using 120 mirrors revolving as the film revolves with the mirrors reflecting the object. Perfect synchronism between speed of mirrors and speed of film must be obtained. Using 120 mirrors, 20,000 exposures per second were obtained. Later the number of mirrors was increased to 160 and 40,000 exposures per second was the result. In future it is hoped to obtain 80,000 exposures per second by still further increasing the number of mirrors.

Mr. Taylor then gave an explanation of the pictures. He asked the meeting if they had ever seen air and then asked if they had seen the air above a heated stove. That is how the action of air around air foils was studied. The foil was placed in a tunnel and heated air passed through. The use of smoke was also very common in studying the air disturbances around an aero foil.

The films were then projected on the screen. The first reel showed aero foils stationary and rotating and the disturbance of the smoke or air was very clearly seen. The foil was placed in all positions and rotated. At the end of the first reel a bullet was shown fired from a gun and entering a glass bulb (electric light bulb of ordinary size). The bullet seemed to enter one side and then bulge the opposite side before the glass shattered. This was very clearly seen and the bullet seemed to move very slowly.

The second reel showed aero foils of single motor aeroplanes and biplanes being rotated and their consequent air disturbance. Also in this reel were shown the disturbances caused by rotating spheres and semi-spheres.

The third reel dealt mostly with sound waves. A noise was created by an instantaneous arc inside a circle and the sound waves were seen to hit the circle and rebound, focusing in the centre, being sent out again and rebounding till the sound died away. The sound waves were also shown in a triangle and in an ellipse.

The pictures were very interesting and very amazing, but the steady advance of science and engineering was making many things possible.

Steam Storage

Mr. S. L. Fear, chairman of the Ontario Branch American Society Mechanical Engineers, then introduced the speaker of the evening, Mr. J. P. Wys, chief engineer of the Ruths Steam Storage (Canada) Limited, who gave a very interesting address on "Steam Storage."

Mr. Wys defined storage as "A method of putting something aside at a time when not needed in order to have it readily available at a time of want." This applies to steam as well as to any other product of manufacture.

In the average steam plant, such as dye, brewing, bleaching and evaporating plants, a large amount of steam is required to bring the process to a start, thus causing a heavy peak in the steam consumption which usually occurs at starting time in the morning. Following this peak period there is a period of low consumption which may continue through the day or there may be another peak before the process is finished. The power generation is in most cases entirely independent of the steam demand but the turbine or engine supplying steam cannot be regulated according to available steam. The steam has to be supplied at a rate corresponding to power requirements. It may easily be seen that the demand for steam in all plants varies greatly.

To flatten out the steam demand curves the first method is to distribute the peaks over the working hours, never allowing two peaks to occur at the same time. This method calls for rigid schedule which is not successful even at part time operated plants.

Steam storage is the next method. The first successful attempts to store steam were made in connection with mine hoisting and rolling mill machines. The exhaust from their engines at atmospheric pressure was put into constant volume accumulators and was then withdrawn for use in a turbine at a constant rate. This method was not so successful as steam could not be withdrawn unless the same amount of steam was entering.

Several methods of steam storage have since been invented but the one with the most general application at present is the Ruths system. The principle of this system is to supply the boilers with hot feed water during a peak load and to prepare such hot feed water during slack demand. If the boilers are fed with water at saturation temperature, the latent heat of the steam and the superheat has still to be supplied by heat transfer through the furnace. With the Ruths system feed water is supplied at a constant rate and high temperature and the steam production is therefore always equal to the maximum output. The feed pump must have a capacity of about six times the normal feed to supply sufficient water to condense all excess steam in case of heavy off peaks in steam demand.

Mr. Wys went on to explain the method of construction of the accumulators and the rigid tests they underwent. Illustrating with slides he showed a number of practical applications of the Ruths steam storage system in Canada and European countries.

Mr. Darling moved a vote of thanks to Mr. Wys for the very interesting lecture.

Professor Harrington thanked the Hamilton Branch on behalf of the Buffalo Branch for their hospitality and Mr. MacLaren then adjourned a most successful meeting.

The attendance at dinner was 100, and at the meeting following dinner, about 120.

London Branch

F. C. Ball, A.M.E.I.C., Secretary-Treasurer.
J. R. Rostron, A.M.E.I.C., Branch News Editor.

Fuel Burning Equipment for Modern Steam Plants

The regular monthly meeting of the Branch was held on March 17th in the County Council Chambers and W. R. Smith, A.M.E.I.C., Branch chairman, occupied the chair. The speaker was Mr. J. H. Schofield, of the Combustion Engineering Corporation Ltd., Toronto, Ont., and his subject was "Fuel Burning Equipment for Modern Steam Plants."

Mr. Smith first called upon Mr. Ball, the Secretary, to read to the meeting the pamphlet issued from Headquarters setting forth the aims and objects of The Engineering Institute of Canada and showing the reasons why membership in that body was desirable and even necessary from the viewpoint of engineering qualification.

D. M. Bright, A.M.E.I.C. who was called upon to introduce the speaker, said he had pleasure in stating that Mr. Schofield was an authority on all kinds of mechanical stokers from the smallest to the largest installations and he would show how to economize and yet obtain the highest amount of efficiency in the combustion of fuel with various boiler installations.

Mr. Schofield's talk was illustrated by means of lantern slides and he began by stating that the equipment in the first place must be designed to suit the particular kind of fuel it was proposed to use, whether bituminous coal, coke breeze or anthracite.

By means of illustrations he showed the variation in the size of lumps of coal and pointed out the desirability of having the lumps uniform in size in order to insure complete and efficient combustion. It was obvious that smaller pieces burnt through first and then hindered the combustion of the larger ones. Run of mine coal only gave an efficiency of from 40 to 50 per cent and this can be increased from 50 to 60 per cent. Again mechanical stokers increased the efficiency from 65 to 75 per cent and pulverized coal burnt in suspension still further increased the efficiency from 75 to 85 per cent according to the fineness of the pulverization.

Views were shown of several types of underfeed stokers, one designed for smaller boilers, others for boilers from 100 to 200 h.p., 125 to 650 h.p., and a multiple retort stoker designed to take care of boilers about 500 h.p. up to any required size, most of these being of the ram feed type. Chain grate stokers were then shown and described by the speaker. These included the Green chain grate stoker—natural draft and forced draft, and were followed by the Coxe travelling grate stoker—forced draft. The working of these units was fully explained by Mr. Schofield with particular attention to the action of the draft and the advantage of each type under certain conditions.

The speaker next turned his attention to the powdered coal applications and illustrated his remarks by views and diagrams of the Raymond roller mill, the Raymond hammer type mill and mention was made of a ball type mill. These mills can be regulated to give the desired degree of fineness and are situated directly in front of the boilers. The speaker pointed out that when these mills were in full operation the process of grinding the coal into dust was noiseless.

The moisture content of coal should not exceed 8 per cent before entering the furnace.

This was followed by a description of the designs of several air preheaters, water walls and water screens.

Mr. Schofield's talk was much appreciated by those present and followed with lively interest, as was evidenced by the number of questions asked and by the discusssion which followed.

One question was "When does pulverized coal become economical?" The answer was—In plants requiring from 600 to 700 h.p. or over and when the operation is continuous day and night.

Another question was "What is the principal cause of explosion with pulverized coal?"

Answer—Poor operation or control. If the gases are allowed to escape before ignition at the burner there is no danger.

In answer to another question it was stated that 30,000 B.t.u.'s can be obtained from a cubic foot of coal and about 25,000 B.t.u.'s from a cubic foot of pulverized coal.

A hearty vote of thanks to the speaker was proposed by H. B. R. Craig, M.E.I.C., and seconded by John R. Rostrom, A.M.E.I.C.

About thirty-five members and other persons interested were present.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

Sackville Visit

On March 17th a joint meeting of Moncton Branch and the Engineering Society of Mount Allison was held in the Science building of the University at Sackville. George Campbell, President of the Engineering Society, occupied the chair. The speaker of the evening was J. D. McBeath, B.A.I., chief engineer of the city of Moncton, who gave an address on Municipal Engineering. Mr. McBeath described in detail the various engineering services of Moncton and also referred to the local air-port, the design for which he is responsible. The address was illustrated with maps and plans. At the close of his remarks a hearty vote of thanks was tendered Mr. McBeath by the presiding chairman.

Recent Research Developments in Building Materials

(Reported by G. E. Smith, A.M.E.I.C.)

A very pleasant gathering composed of the engineers and friends in the building fraternity gathered at the Y.M.C.A. building for the regular monthly meeting of the Moncton Branch on March 18th.

This took the regular form of dinner and lecture combined, and after musical numbers by local artists, the speaker of the evening, James Govan, M.R.A.I.C., of Toronto, was introduced. Mr. Govan took for his subject "Recent Research Developments in Building Materials."

The speaker dealt with his subject from the view point of fire, fire resistance, insulation, acoustics, building materials and orientation of buildings.

In speaking from the fire point of view the speaker showed that in adapting Fire Underwriter codes and Building codes a very careful study should be made to note their adaptability to Canadian conditions.

During the lecture lantern slides and moving pictures were shown. The first group of pictures showed the construction of a fire test building, the building constructed with frame work of wood covered inside and outside with Gyproc, and spaces between joists, studs, and rafters filled with insulex. An additional layer of Gyproc board was applied to the inside of the building and combustible material placed and ignited. Recording thermometers showed that in twenty minutes time the inside temperature had risen to 1,930 degrees, while the outside temperature of the wall remained below 80 degrees. At no time during the test did the exterior of walls become too hot to place the hand thereon.

In dealing with insulation of buildings various tables were shown indicating the time required for passage through walls of a fixed amount of heat. Tests had been conducted whereby the amount of radiation had been reduced by 55 per cent and the desired inside temperature steadily maintained. These tests showed that the present standard practice of figuring radiation was in error, in that the temperature difference used was too high and not sufficient allowance given for insulation.

In the acoustic field the speaker stated that Canadian research indicated that some of the data presented by the authorities in other countries is not in accord with results obtained in actual practice. Very careful deliberation was now being given to the matter with a view of obtaining more reliable data as to the acoustic properties of various building materials.

One slide showing the results of tests made in Norway with various forms of wood wall construction showed a wall filled with shavings and heat resistance qualities very high. This was particularly interesting in that this has been the type of wall used for ice house construction for many years and is still in practice. The test showed that the breaking up of the air spaces and consequent reduction in air motion was the chief agent in providing high insulating qualities.

In speaking of the placing of buildings with regard to the sun's rays, Mr. Govan said that this is causing not only a needless waste of fuel but also discomfort in Canadian buildings. These conditions he said could easily be remedied by a greater attention to the principle of orientation of buildings.

C. S. G. Rogers, A.M.E.I.C., brought up the question of the corrosive action of gypsum composition on steel and the speaker showed that if the material was allowed to dry and was kept from further moisture there was no danger of the action being carried beyond the initial stages similar to that obtaining with concrete.

H. J. Crudge, A.M.E.I.C., brought up the question of vibration in buildings with light steel framing and thin partition walls, etc. He felt that this was a question which was causing some very serious thought in some structures now in place. Mr. Govan said he realized this very much and mentioned work where such disturbances had been foreseen, but the methods adopted to overcome same had not proved satisfactory.

The chairman tendered Mr. Govan a very hearty vote of thanks on motion of H. J. Crudge, A.M.E.I.C., seconded by C. S. G. Rogers, A.M.E.I.C.

Montreal Branch

C. K. McLeod, A.M.E.I.C., Secretary-Treasurer.

The New Viau Bridge

On February 12th, L. J. Leroux, M.E.I.C., engineer of bridges and tunnels for the city of Montreal, delivered a paper before the Montreal Branch on the new Viau bridge across the Back river at Ahuntsic.

At first it was undecided whether the bridge should be constructed of steel or concrete but the latter was the final choice of those responsible for the work. The main section of the bridge was 1,050 feet in length divided into five unequal spans and in addition there were the approaches on each side, 150 feet and 250 feet in length respectively. The old bridge constructed in 1885 was only 16 feet wide and had no sidewalks while the new one is 54 feet wide with two 6-foot sidewalks and provision for street car tracks if same should ever be needed.

Steel caissons were used for piers and these had to be sunk to depths of from 22 to 32 feet to reach solid rock. At the water line the piers were protected with granite blocks. As the piers were completed, a very substantial trestle was erected to carry the formwork for the concrete. The bed of the river was cleared of obstructions and irregularities and the trestle supported on the bottom. B.C. fir to the value of over $100,000 was used in the construction of the trestle work.

The bridge was hinged at three points, namely on each of the central piers, and amongst the many interesting slides which were shown were several illustrating very clearly the detail of these hinges. In all some 176,000 bags of concrete were used in the bridge and the work which started in May, 1929, was completed in October, 1930.

Dr. O. Lefebvre, M.E.I.C., occupied the chair.

The Art of Telegraphy

Mr. J. C. Burkholder, chief engineer of the Canadian National Telegraphs, addressed the Montreal Branch on February 26th on "The Art of Telegraphy and other forms of Railway Communication."

The earlier forms of communication were first described, commencing with the semaphore system built by the Chappe brothers in France followed later by the Morse telegraph, the telephone invented by Alexander Graham Bell, the printer telegraph, and finally the carrier system in use at the present time.

The carrier current principles were discovered in 1886 by Elisha Gray and later, with the development of the telephone, it was found possible to combine telephone and telegraph circuits. This led, Mr. Burkholder said, to the production by the Canadian National Telegraphs of the "Jitney Carrier telegraph system."

Amongst the many applications of communication used by the Canadian National Railways at the present time are the use of both telephone and telegraph for train dispatching; two way telephone service from moving trains; radio broadcasting network with 41 broadcast control stations and 78 individual amplifiers. By means of carrier currents it is possible to transmit telegraph and telephone messages over 24 current channels on one pair of wires, and Mr. Burkholder indicated that its maximum possibilities had not yet been reached.

J. L. Clarke, A.M.E.I.C., presided.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Island Falls Power Development

N. J. Kayser, M.E.I.C., a director and assistant to the first vice-president of the Fraser-Brace Engineering Company, was the speaker at the noon luncheon held at the Chateau Laurier on February 26th. G. J. Desbarats, C.M.G., M.E.I.C., chairman of the local branch, presided at the meeting. At the head table in addition to the chairman and the speaker there were the following guests: Honourable T. G. Murphy; Honourable Charles Stewart; R. A. Gibson; J. T. Johnston, M.E.I.C.; V. Meek, M.E.I.C.; N. Marr, M.E.I.C.; J. Murphy, M.E.I.C.; K. M. Cameron, M.E.I.C.; Colonel A. E. Dubuc, M.E.I.C.; Noulan Cauchon, A.M.E.I.C.; O. B. Lefebvre, M.E.I.C., chief engineer of the Quebec Streams Commission; F. S. Small, M.E.I.C., resident engineer on construction at Island Falls; and Dr. G. Malcolm, resident physician on construction at Island Falls.

Mr. Kayser in his address, supplemented by the use of lantern slides, outlined the steps taken in the construction of the Island Falls power development from virgin wilderness to its present state whereby it is producing power for the Flin Flon and Sherritt-Gordon mines.

Island Falls is located about 15 miles west of the Manitoba boundary in latitude 55°32′. It is the first hydro-electric development to be built in Saskatchewan and the most northerly one of its size in Canada.

Power for the operation of the construction machinery for the main plant itself was obtained from a temporary hydro-electric plant located about 13 miles northeast of Island Falls at the outlet of a chain of lakes having an area of about 100 square miles. This temporary plant had a 38-foot head and consisted of a crib dam 30 feet long with a maximum height of 20 feet with two wood stave penstocks 8 feet in diameter and 90 feet long to convey the water to two 1,250 h.p. vertical shaft turbines which were direct connected to 1,000 kv.a. generators.

The development at Island Falls itself consists of a main dam with power house and intake works located in the main channel, a spillway dam containing 46 stop log sluices located in an old channel of the river, and seven earth-fill cut-off dams. These dams completed the structures necessary to confine the water in the head pond which is 56 feet above the original river.

The present installation consists of three 14,000 h.p. units and the two smaller units previously mentioned. Provision is allowed for the building, when required, of an additional three large units. The current is generated at 6,600 volts and is stepped up to 110,000 volts and transmitted to Flin Flon over a double-circuit steel tower transmission line. Power was delivered to Flin Flon on June 12, 1930, a few days less than a year from the time the first concrete was placed in the power house foundations.

The main power plant being 68 miles by winter road and 72 miles by summer route from Flin Flon, the nearest railway station, the matter of transportation was, of course, a very serious one.

Both routes followed the same chain of lakes, the summer route occupying the higher ground on the portages (of which there were six totalling 17½ miles), while the winter road followed the muskeg. Due to the flat nature of the country the winter road had a maximum grade of only 4 per cent against the north bound traffic and very little grading was necessary.

For summer freight, barges of 15 tons capacity were built at each lake. Each barge was fitted with two 15 h.p. outboard Johnson motors and a third was kept aboard as a reserve. When loaded they travelled about 6 miles an hour. However, only a very small proportion of the total freighting was done by this method, some 1,500 tons being taken in during the summer out of a total of 35,000 tons transported altogether.

The main winter's hauling was done by eleven 100 h.p. Lynn tractors carrying a 6-ton load as ballast and pulling from three to five sleighs and a caboose. The crews worked in eight-hour shifts, the spare crews living in the caboose, and the tractors worked continuously. The switching at each end was done by Holt-60 tractors, two at the railway head and one at Island Falls.

The average load for the first winter was 67 tons, and this varied with the thickness of the ice. In February the maximum was 112 tons with 32 tons on one sleigh. The speed of the tractor trains loaded varied from 2½ to 5 miles an hour and when empty 7 miles an hour.

Tank sleighs were used to ice the portages and each Lynn tractor carried a snow plow. Crossing some of the wind swept lakes where the snow drifted badly, as many as four parallel roads were plowed—the outer ones acting as snow fences and intercepting the drift.

An interesting feature of the construction programme was the manner of arranging for the transportation of food stuffs for the eight hundred men who were employed on the construction. Practically all the food was hauled in during the winter, this item amounting to 1,380 tons, of which 250 tons were meat. Fresh vegetables, canned goods and eggs were placed in heated vans. The meat was allowed to freeze and upon its arrival was put in a frozen storage room. A 10-ton ice machine maintained the meat storage room at a temperature of 10 degrees above zero. A cold storage room with a temperature of slightly above freezing was also operated by the ice machine.

STRUCTURAL ENGINEERING IN LARGE BUILDINGS

At The Engineering Institute luncheon which was held at the Chateau Laurier on March 27th, 1931, A. H. Harkness, B.A.Sc., M.E.I.C., president of the Association of Professional Engineers of Ontario, spoke on the interesting technical details of the new Canadian Bank of Commerce building in Toronto. Among those at the head table with the chairman, G. J. Desbarats, C.M.G., M.E.I.C., and Mr. Harkness were L. L. Bolton, M.E.I.C., John McLeish, M.E.I.C., A. W. Mattice and F. H. Peters, M.E.I.C.

CANADIAN BANK OF COMMERCE BUILDING, TORONTO, ONT.

This building, the tallest in the British Empire, rises 35 storeys or $472\frac{1}{2}$ feet above the street level. The depth of the foundation is 62 feet and embodies 4 separate basements while some of the columns in the building support a weight of 4,400,000 pounds.

Mr. Harkness said that while there are other lines of engineering work in which development has been equally great, and perhaps, in some respects even greater, there is no development in modern civilization quite so spectacular as tall buildings. Dwelling for a few minutes on the importance of each specialized engineer's work to the whole, he pointed out that while structural engineers might build sky scrapers, the latter would not be of much use unless the electrical engineers and mechanical engineers installed elevators, lights, bells, heat and so forth, thus stressing the interdependance of these professions.

A short description was given of the various operations after the architect had submitted his plans—how "loads" were calculated, the different steps in making plans, from pencil sketches to the actual working blue prints. While the Canadian Bank of Commerce building did not present any features different from those met from time to time in equally tall or taller buildings some of the column loads reached magnitudes that have not very often been exceeded, on account of the heavy masonry walls and pilasters. The loads standing on the plate girders were also placed in this category.

Mr. Harkness illustrated his points with lantern slides of the building itself showing various features of interest from the excavation to the completed job; technical details, coal-bins, banking-rooms, walls, frame-work, spacing, tower and graphs of calculations.

CORROSION OF METALS

Dr. A. Stansfield, M.E.I.C., professor of Metallurgy at McGill University, Montreal, was the guest speaker at the noon luncheon held at the Chateau Laurier on April 9, his address being upon "The Corrosion of Metals." Dr. Stansfield was introduced by the chairman, G. J. Desbarats, C.M.G., M.E.I.C. In addition, the following were at the head table: R. F. Howard, M.E.I.C.; W. B. Timm; Colonel Mulock; Dr. R. W. Boyle, M.E.I.C.; R. J. Durley, M.E.I.C., General Secretary of The Engineering Institute; Dr. Chas. Camsell, M.E.I.C.; F. H. Peters, M.E.I.C.; F. E. Lathe; John McLeish, M.E.I.C.; R. Meldrum Stewart, M.E.I.C.; J. L. Rannie, M.E.I.C.; and B. Stuart McKenzie, M.E.I.C.

Dr. Stansfield remarked that while prehistoric articles of copper or bronze have come down to us with comparatively little corrosion, there are very few relics to-day of the iron age, iron being acted upon more rapidly than bronze when exposed to moisture. The question of the corrosion of metals had thus been one of considerable importance from early days. Such corrosion was due to the combination of a metal with oxygen or some other non-metallic element, and the corrodibility of metals could be measured by their tendency to combine with oxygen. The action of water or corrosive agents upon metals was greatly affected by the purity or otherwise of the metal, and as a rule material which was shown on microscopic examination to consist of a mixture of a number of different compounds, as in the case of cast iron or steel, showed more tendency to rust than pure electrolytic iron. By means of X-ray spectra it was now possible to study the atom arrangement in metals, and this had thrown much light upon the causes of corrosion.

Metals or alloys which were comparatively free from corrosion were those in which the various elements existed as a solid solution, as, for example, in copper-steel, where the atoms of copper were distributed throughout the mass of iron and did not cause electrolysis.

Discussing the action of various liquids, Dr. Stansfield pointed out that in the case of water corrosive action on a single piece of metal might be produced if the amount of oxygen dissolved were different in different parts of the solution. Thus, for example, the action of moisture upon iron was largely due to the difference in oxygen content of the water at different places where it was in contact with the iron.

When corrosion had occurred, the resulting film of oxide or other product of corrosion might or might not protect the metal beneath it. In aluminum the oxide film prevented further corrosion, while with iron this was not the case.

Dr. Stansfield's address was illustrated by slides and was listened to with the greatest of interest by his audience. Toward the conclusion of the meeting the chairman took the opportunity to extend congratulations to Dr. Charles Camsell for being awarded the medal presented by the Institute of Mining and Metallurgy of Great Britain for achievement of outstanding importance in connection with the sciences of mining and metallurgy. The award went to Dr. Camsell this year for his work in connection with promoting development of the mineral resources of the Dominion. Dr. Camsell responded briefly and stated that the award, in his opinion, was not so much a personal one as a recognition of the work being done in Canada by Canadians.

Peterborough Branch

S. O. Shields, Jr.E.I.C., Secretary.
B. Ottewell, A.M.E.I.C., Branch News Editor.

AUTOMOBILE BODY DESIGN

At the meeting of the Peterborough Branch of The Institute held on March 26th, 1931, the speakers, Messrs. J. E. V. Shortt and Charles Smith, both of the General Motors Company of Canada, were introduced by the chairman, W. E. Ross, A.M.E.I.C.

The numerous tests to which automobiles are subject to ensure the utmost of performance was explained and illustrated by films, which proved most informative and unfolded facts unknown to the average automobile owner.

For instance, the General Motors Corporation maintain an immense proving ground some 1,245 acres in extent a short distance north west of Detroit, wherein are built roads of every type and description and where a scientifically banked speed loop, one of the finest on the American continent, is constructed, and where General Motors products are run against those of their competitors without prejudice or favour.

In this proving ground are roads constructed of gravel and concrete, dust roads, rutty roads, water-logged roads and miry roads; there are also service stations run and operated by almost every car manufacturer on the continent, living quarters for resident and visiting engineers and a lecture auditorium.

Before going out on test the cars are each measured and every specification duly noted by competent engineers—nothing is left to chance or taken for granted. The automobiles are then started out on a 2,000 mile running-in test, during which they are held at specified speeds. At 2,000 miles the cars are tuned-up for the more gruelling engineering tests, after which they are subjected to over 100 different scientific and mechanical examinations covering speed, safety, riding comfort, performance and durability.

A detailed record is kept of the performance of each car, so that comparisons can easily be made at any time between two automobiles of different makes, while any part of the mechanism which gives way under the strain which is imposed upon it, is sent to the laboratories for scientific investigation as to the underlying cause for that breakdown.

Mr. Smith traced the growth of the bodies from the time when they first take shape in full size chalk drawings, which after approval by the designers and artists, takes more concrete shape in the form of clay models, from which wooden patterns are made. He went on to describe the construction of the steel panels of the body which are made from the wood patterns, and how each part is carefully woven together. Tests are conducted on the finished body to prove its roadibility, freedom from vibration, its comfort and ability to withstand the weather, etc.

He averred that the present trend in automobile body design is for speed, and consequently lighter bodies, in other words a decrease of weight and increased strength.

Both speakers were accorded a hearty vote of thanks.

Quebec Branch

P. Methé, A.M.E.I.C., Secretary-Treasurer.

HISTORIC BUILDINGS AND EARLY INDUSTRY IN QUEBEC

On April 9th, 1931, the Quebec Branch held a well attended meeting in a seventeenth century setting, the vaults of the old Boswell brewery, which formerly were part of the Intendant's palace. The building was originally constructed in 1668 as the Brasserie du Roi by Jean Talon, the first Intendant of New France, and later, after the return of Talon to France about 1675, was purchased from Talon by the government and became an official residence and the meeting place of the SovereignCouncil.

The Intendant Bégon had hardly taken up his residence there when in 1713 the building was destroyed by fire, a fate which overtook it again in 1726. In 1775, the building, then abandoned as a seat of government, was occupied by the Americans, and was greatly damaged by the bombardment it received from the Garrison of Quebec. Later its ruins formed the basis on which the present Boswell brewery was established, the original vaults being incorporated in the more modern building, and reverting to their original purposes.

At the meeting, Hector Cimon, M.E.I.C., gave an interesting historical résumé of the development of early industry in Quebec, of which the following is an abridgment.

AUX CAVES DE TALON

Les voûtes hospitalières qui nous abritent ce soir, furent construites au XVIIe siècle, par Jean Talon, premier Intendant de la Nouvelle-France, un homme d'une grande valeur qui fit des sept années de son séjour au Canada (1665-72) une des périodes les plus intéressantes de l'histoire de ce pays.

La plaque de bronze que l'on voit sur la façade de l'édifice actuel, rue St-Nicolas, rappelle aux passants qu'ici fut érigée en 1668, il y a 263 ans, la première brasserie, la Brasserie du Roi et qu'elle fut transformée après quelques années en "palais de l'Intendant."

En 1665 s'ouvrit une ère nouvelle pour le Canada. La France alors prospère et glorieuse après une série de victoires, suivie des traités avec l'Allemagne et l'Espagne et d'une période de paix et de prépondérance dans les affaires de l'Europe, était à l'aurore du grand règne de Louis XIV qui affirmait sa volonté de gouverneur lui-même dès l'âge de 23 ans. Les requêtes des pionniers de la Colonie auprès du trône de France allaient enfin trouver une oreille bienveillante et les secours depuis si longtemps attendus allaient être effectivement donnés à sa jeune France d'outre-mer.

Le développement du pays avait jusqu'ici été laissé aux soins de Compagnies plus intéressées dans la traite des fourrures que dans la colonisation et la mise en valeur des autres ressources naturelles. Aussi, depuis bientôt 60 ans que la nation Canadienne était née, le jour de la fondation de Québec, en 1608, et qu'il y avait eu résidence en permanence sur les bords du St-Laurent, la population s'était-elle accrue bien lentement au faible chiffre total d'environ 3,000 âmes.

En 1668, Talon avait fait passer par le conseil une ordonnance très importante concernant l'importation des boissons alcooliques et l'établissement des brasseries.

Talon voulait en même temps créer un marché pour le surplus des grains et ainsi engager les gens à se livrer à la culture.

Prêchant d'exemple, il construisit lui-même la première brasserie—où nous sommes réunis.

Commencée en 1668, elle était en opération 2 ans plus tard et en 71, Talon écrivait dans un mémoire: "Elle peut fournir 2,000 barriques de bière pour les Antilles, si elles en peuvent consommer autant, et en travailler autre 2,000 pour l'usage du Canada, ce qui donnera lieu à la consommation de plus de 12,000 minots de grain par chaque année."

Quoiqu'elle fut connue dans le temps par les habitants comme la Brasserie du Roi, cette première brasserie appartenait à l'Intendant personnellement et elle figurait dans la liste de ses biens, d'après son estimation personnelle, à 43,192 livres ($9,000, environ).

Après son retour en France, Talon négocia pour la vente de ses propriétés du Canada. Mais, le roi, satisfait des services de Talon, priait le gouverneur de s'intéresser aux propriétés de l'ex-Intendant, spécialement à la brasserie dont on projetait l'acquisition pour des fins publiques et, finalement, le marché se conclut pour une somme de 30,000 livres ($6,000), en 1685.

Le palais de l'Intendance, qui servirait de résidence à l'Intendant, aussi bien que de lieu de réunion pour les séances du Conseil Souverain, de prison et de magasins de l'état, allait succéder à la première brasserie du Canada.

Un incendie désastreux ravagea une première fois le Palais, le 5 janvier 1713. L'intendant Bégon s'y était installé l'automne précédent avec un mobilier et un équipage des plus magnifiques. Le palais fut immédiatement reconstruit aux frais du Roi et Bégon vit à ce qu'il fût bien plus somptueux qu'auparavant. En 1726, le feu visita de nouveau le Palais qui fut restauré l'année suivante.

Le fameux Bigot fut le dernier Intendant qui présida, et, pendant les 11 années de son séjour, le palais fut témoin d'une force et d'une splendeur sans précédents.

Vint la Conquête (1759) et sous le régime anglais le Palais fut négligé comme résidence officielle. Enfin, au cours de l'invasion Américaine, 1775, un détachement de l'armée d'Arnold s'étant retranché dans ses murs, le Palais fut soumis au bombardement de la garnison de Québec et détruit en grande partie.

En fin de compte, les extrêmes se touchent parfois puisque des ruines de la Brasserie du Roi surgit la Brasserie Boswell dont nous apprécions la bonne et hospitalière courtoisie en ce moment.

Une tannerie fut aussi établie près de Québec, et l'Intendant sut développer diverses industries domestiques et autres, les plus nécessaires à la colonie, si bien qu'il écrivait dans un mémoire en 1671: "J'ai fait faire, cette année, de la laine, qu'ont portée les brebis que Sa Majesté a fait passer ici, du droquet, du bourocan, de l'étamine, de la serge de seigneur; on travaille des cuirs du pays près du tiers de la chaussure et, présentement, j'ai des productions du Canada de quoi me vêtir du pied à la tête.

D'autres industries ayant pour vus de venir en aide à la colonisation furent celles de la fabrication de la potasse et du goudron.

La potasse canadienne devait être employée soit pour lessiver le linge, soit convertie en savons mous, pour nettoyer les soies et dégraisser les draps et devait affranchir la Mère-Patrie du tribut qu'elle avait à payer à la Moscovie pour ses potasses et à l'Espagne pour ses soudes. Par ailleurs, cette industrie favorisait le défrichement des terres canadiennes en fournissant un moyen de rétribuer ce travail. L'entreprise fort avantageuse pour les habitants ne devait cependant pas survivre bien longtemps après le départ de Talon.

Le goudron devait aussi être tiré de nos arbres par distillation et servir tant aux chantiers maritimes du Canada qu'à ceux de France. Talon avait fait venir des experts pour organiser cette industrie et enseigner aux habitants la méthode de la faire. Il en fut fabriqué de très bon, paraît-il, mais le sort de cette initiative devait être la même que celui des potasseries.

Il convient aussi de noter que la construction des navires à Québec, industrie qui fut si active ici pendant de nombreuses années est due à la sagacité de Talon dont le but était d'obtenir des moyens d'échange commerciaux et des débouchés pour les produits du Canada. Il fournit ainsi des vaisseaux de tous tonnages pour les communications fluviales de la colonie, la pêche et surtout en circuit canadien de navigation d'ici aux Indes Occidentales et en France. Prenant toujours l'avant et réalisant par ses actes ce qu'il prêchait aux autres, on le vit s'associer à un marchand local pour expédier aux Antilles sur des vaisseaux Canadiens, une des premières cargaisons de produits canadiens consistant en saumon, anguille, morue sèche et salée, pois, huile de poisson, douves, madriers et petits mâts.

La prospective des mines reçut aussi une attention particulière. En 1666 un ingénieur, M. de la Tesserie, rapportait qu'une mine de fer très abondante gisait à la Baie St-Paul et qu'il espérait y trouver aussi du cuivre et peut-être de l'argent. Un autre ingénieur, Sieur de la Potardière, vint de France l'année suivante pour examiner cette mine et celle des environs des Trois-Rivières que l'on venait de découvrir et déclara qu'il n'était pas possible de trouver du meilleur fer et en plus grande abondance.

Saskatchewan Branch

Stewart Young, A.M.E.I.C., Secretary.

Annual Meeting

The annual meeting of the Saskatchewan Branch of The Engineering Institute of Canada was held in the Kitchener hotel at 6.30 p.m. on Friday, March 27th, the meeting being preceded by a banquet at which there were forty-nine guests present.

The meeting was presided over by the branch chairman, Professor W. G. Worcester, M.E.I.C., of the University of Saskatchewan. After the toast to the King, the minutes of the previous annual meeting together with the minutes of the last regular meeting were read by the acting secretary, S. Young, A.M.E.I.C. There being no objection to the minutes these were duly confirmed.

There then followed an explanation of the necessity for a substitute to take the Secretary's place, and on motion of Messrs. MacKenzie and D. A. McCannell, M.E.I.C., the acting Secretary was instructed to convey the sincere regrets of the meeting to Mrs. Loucks at the inability of R. W. E. Loucks to be present, also best wishes for his speedy recovery.

The acting Secretary then read letters of good wishes for a successful meeting from W. T. Thompson, M.E.I.C., Cranberry Portage, Man., M. Sinclair, A.M.E.I.C., Yorkton, and J. W. Hamilton, Dauphin, Man.

On behalf of the legislative committee, P. C. Perry, A.M.E.I.C., reported that the committee had no report to submit, there being no activity in legislation this year.

J. W. D. Farrell, A.M.E.I.C., reported on behalf of the Papers and Library committee. This report, on motion of Messrs. Farrell and Ritchie, was adopted.

The report of the Executive committee was then read by the acting Secretary, and on motion of Messrs. McCannell and MacKenzie was adopted.

Messrs. Kirkpatrick, Laird, Sergeant Day and Corporal Leatham, R.C.M.P., entertained the guests during the banquet.

The Financing of Canadian Engineering Projects

The chairman then called on Mr. W. L. Gilliland for his address on "The Financing of Canadian Engineering Projects." Mr. Gilliland, the manager of the local branch of the Imperial Bank of Canada, and an authority on the subject, defined engineering and traced the development of engineering science from very early times to its present high standards. He stated that to-day engineering is one of the outstanding professions. The profession had advanced until at the present time marvellous feats such as the Suez, Panama and Welland canals have been carried out. The transcontinental railways were another marvel, and from these examples, he stated, it was obvious that the activities of the engineer are among the greatest factors in modern life.

All these projects cost money and it therefore is the duty of the engineer to see that they are successfully put across. Mr. Gilliland divided engineering projects roughly into two classes according to authority: (*a*) Government, (*b*) Private capital.

Under the heading of government activities he cited canals, power plants, highways, public buildings, stating that for these projects it was the custom to issue bonds which become a general charge on the public domain. With respect to private capital he divided the activities into two groups according to the nature of the investment: (1) highly speculative, (2) more nearly a project of safe investment such as a government bond.

In the first group he stated that mining claim development would be a fair example. A group of men would at first finance the project, later selling stock to the public, which is willing to speculate, thus the capital for development is obtained. In the second group as an example he cited a power development. A few men would organize a company, subscribe an amount to start, then an engineer would make an investigation. On the strength of his report if favourable, the group would go to a banker, who in turn would retain an engineer. If his report is favourable, the financier would put out a bond issue. A trust company would take a mortgage to cover the assets and thus the bond holders were protected, interest being payable at stated periods for definite amounts. In the event of failure to meet the interest charges the trust company could take charge of the plant for the bond holders. Usually the company was obliged to create a sinking fund to retire the bonds. In an organization of this nature there must also be a capital structure;

this is termed usually the common stock. These are the controlling owners. Finally the bond holders must be paid off and often this is done through common stock. The initial expenditures also often take common stock and are thus reimbursed.

Mr. Gilliland's address was productive of considerable discussion, a number of questions being asked and answered.

On motion of J. D. Peters, A.M.E.I.C., and A. C. Garner, M.E.I.C., a hearty vote of thanks was tendered to Mr. Gilliland and to the entertainers.

The scrutineers then reported for the ensuing year reporting a tie between Messrs. W. H. Hastings, A.M.E.I.C., and S. R. Muirhead, A.M.E.I.C., as members of council. On the tossing of a coin Mr. Hastings won the toss.

The officers for the ensuing year were then declared by the Chairman to be D. A. R. McCannell, Chairman; J. D. Peters, Vice-Chairman; S. Young, G. M. Williams, A.M.E.I.C., W. H. Hastings, Executive committee.

The nominating committee for the ensuing year is A. P. Linton, A.M.E.I.C., A. R. Greig, M.E.I.C., E. H. Phillips, A.M.E.I.C., M. B. Weekes, M.E.I.C., J. R. C. Macredie, M.E.I.C.

On motion of Messrs. Peters and Houston the meeting adjourned at 10.30 p.m.

Saint John Branch

A. A. Turnbull, A.M.E.I.C., Secretary-Treasurer.

A meeting of the Branch was held in the Saint John Board of Trade rooms on Thursday, March 19, 1931, at 8 p.m., with the chairman, W. J. Johnston, A.M.E.I.C., presiding.

Experiences of an Oil Geologist in India

The speaker of the evening was Dr. W. J. Wright, provincial geologist, of the Department of Lands and Mines, Fredericton, N.B. Dr. Wright is also professor of mineralogy at the University of New Brunswick. Dr. Wright gave a very interesting address on the "Experiences of an Oil Geologist in India" and "The Great Vale of Kashmir," illustrating the address with many excellent lantern slides depicting the country and the inhabitants.

Following the illustrated address on India, Dr. Wright spoke of the geological conditions in the Province of New Brunswick. He deplored the fact that New Brunswick people were not "prospecting minded" enough and stated that in his opinion the future of the mineral wealth of the province depended upon non-metallic minerals such as coal, gypsum, salt and building stone. Providing the minerals are there, the geological formations would indicate that there is no reason why New Brunswick should not have as great mineral development as Ontario. He urged that all prospects be fully investigated before extensive operations were undertaken. If there was a decent showing there would be no trouble in obtaining money for testing. He spoke of the fine new laboratory which the Department of Lands and Mines had fitted up in Fredericton for the purpose of helping mining in the province and of conducting researches into mining prospects. Prospecting in New Brunswick, he claimed, was difficult because of the "drift" that in many parts was overlaying the stratified or other rock formations.

Sault Ste. Marie Branch

A. A. Rose, A.M.E.I.C., Secretary-Treasurer.

The regular monthly meeting of the Sault Ste. Marie Branch was held in the Y.M.C.A., on Friday, March 27th, following a dinner.

Atlantic Outports of Canada

The speaker of the evening was H. F. Bennett, A.M.E.I.C., district engineer, Department of Public Works. He had taken as his subject "Atlantic Outports of Canada," and as Mr. Bennett has but recently come to Sault Ste. Marie from Halifax, where he was assistant engineer for the department, and as he was also for a number of years at Saint John, he had a first-hand knowledge of his subject.

Introducing his subject Mr. Bennett mentioned a few of the almost innumerable harbours of Nova Scotia and New Brunswick. In general these harbours may be classed as fishing harbours, harbours of safety and national harbours.

Of the hundreds of fishery harbours, the speaker described in some detail two, Cove Harbour on Grand Manan island and Lunenburg, famous as the home of the "Bluenose" and those other boats that fish "The Banks."

The two most important harbours of safety are Sydney and Louisburg in Cape Breton. Sydney is very large and well protected and easy of approach. Louisburg, the winter port of Sydney, is open the year round.

The national ports of Saint John and Halifax were described in considerable detail. Saint John, the mouth of a river, has its own peculiar problems due to its being situated on a soft soil instead of rock and to the tides, there being a range of 28 feet at the spring tide. Saint John is open the year round, is the winter harbour of the Canadian Pacific Railway of whose main line it is the eastern terminal. It gives freight service to almost any port in the world, and in the speaker's opinion its freight service is due for a large development.

Halifax harbour is the great naval base of the north Atlantic and an extremely well protected harbour. In contrast to Saint John it is situated on rock, is not a river mouth and has a tide range of about 4½ feet. It is a "port of call," being near the lane from New York to Liverpool and is specially equipped for passenger service, in which line it is likely to increase.

The address was appropriately illustrated by maps, lantern slides and photographs.

Following an interesting discussion, a vote of thanks was tendered Mr. Bennett for his most interesting and instructive address on motion of Messrs. C. H. E. Rounthwaite, A.M.E.I.C., and R. S. McCormick, M.E.I.C.

Toronto Branch

W. S. Wilson, A.M.E.I.C., Secretary-Treasurer.

The Civil Government Activities of the Royal Air Force

On the evening of March 5th the Toronto Branch was privileged to hear an address on "The Civil Government Activities of the Royal Air Force" by Wing-Commander G. O. Johnson, A.M.E.I.C., officer in charge of Flying Operations Branch, Department of National Defence. Commander Johnson's paper was very interesting to all present. In introducing his subject the speaker told how the application of aircraft to civil government work, in an experimental way, was originated by the Air Board in 1920. By 1923 when the Air Board was merged with the Department of Militia and Naval Service in the Department of National Defence, civil government air operations were deemed essential by the various departments concerned and the work was continued by the Royal Canadian Air Force. By 1927, 48 officers and 206 airmen of the Royal Canadian Air Force were employed on civil government work. The foundation of the civil government organization was a forest protection service in Manitoba, Saskatchewan and Alberta which expanded from year to year until it reached a peak in 1927. Gradually, however, other classes of work were developed and extended until they have become more extensive than the forest protection service.

The methods employed in the forest protection service vary with the nature of the country. The east slopes of the Rockies have been patrolled since 1920 but as the areas are mountainous and devoid of places to land the service is primarily a detection service corresponding to a city fire alarm system. On the other hand, the forest areas of Manitoba and Saskatchewan include numerous lakes and rivers on which seaplanes can alight. In these areas the air service not only locates fires in their early stages but also transports men and fire-fighting equipment to nearby lakes and rivers. By placing crews on fires promptly, most of the fires are prevented from spreading to any serious extent.

A large part of the civil government activity is photography, the type of photograph varying with the purpose for which it is to be used. The late Dr. Deville, former Surveyor General of Canada, devised a method of mapping with a reasonable degree of accuracy from photographs taken obliquely at an altitude of 5,000 feet with the horizon showing in each exposure, the method being applicable only to areas in which the variation of ground elevation is relatively slight. Weather permitting, one aeroplane can take photographs in a 4-hour flight to map more than 1,000 square miles.

Another activity is that of reconnaissance flights over large areas to determine hill tops suitable for observation posts, for the forest service to investigate timber resources and for the geological survey to locate rock and outcroppings and geological formations. Transportation of survey and investigation parties proceeding to northern points is another activity, thus increasing the working time of these parties. Some years ago the Department of Agriculture called upon the Air Force to assist in developing methods of combating insect and fungus pests. Experimental work is still being carried on to perfect a dusting apparatus from an aeroplane to combat the spruce bud worm and the hemlock luper which completely destroy an area of timber in which they get established. It has also been proven that wheat rust can be combated by dusting a crop two or three times at intervals of one week during the first three weeks in July, provided that the dust is not washed off by rain, but at the present price of wheat the process is not economically worth while.

The organization of the directorate of the civil government air operations is centred at Ottawa, Winnipeg, High River and Vancouver, and the work is carried out from these bases. The speaker then described the activities of the service in 1930 showing the great amount of work that is being done. In conclusion Wing-Commander Johnson stated that the function of the Civil Government Air Operations is in applying aircraft to assist in the administration and development of Canada's resources in such a manner as to expedite development and effect economy. The lecture was illustrated by slides and on conclusion a hearty vote of thanks was tendered the speaker for coming from Ottawa to address the Toronto Branch.

Structural Engineering in Some Recent Buildings

The speaker at the meeting of the Toronto Branch on March 19th was Mr. A. H. Harkness, M.E.I.C., of the firm of Harkness and Hertzberg, consulting engineers, who presented a paper on "Structural Engineering in Some Recent Buildings." Mr. Harkness gave a very interesting and instructive talk on structural engineering as applied to the modern tall building and dwelt particularly on the Canadian Bank of Commerce Building in Toronto and the Sun Life Building in Montreal. In opening his remarks the speaker mentioned the importance of the work and how spectacular is the construction of this type of building, possibly because of its conspicuous position. In describing the evolution of the skyscraper Mr. Harkness stated that the first work done towards its construction falls to the architect who will probably spend months preparing sketch plans and in consultations with the owner, keeping in mind the engineering possibilities. Following this the general plans are submitted to the engineer who prepares a preliminary lay-out of the steel framing to see that no unreasonable or unsurmountable difficulties are met with. After the plans including elevations have been fully decided on the engineer proceeds with his design. Different firms have different methods and Mr. Harkness described the one used by his firm which is as follows: Pencil plans of all floors are made locating the columns, beams and girders, arranged with regard to floor construction, elevators, stairs, etc. A preliminary investigation is made of wind pressures and the best method of providing for it is decided on. The direction in which the columns will stand is then determined having respect to beam connections and resistance to bending from wind stresses. Next all loads are carefully calculated for live and dead loads, for beams and fire-proofing of same, piers, column fire-proofing, elevator machinery, water tanks, and these are noted on the floors on which they occur. The column loads are individually tabulated on column sheets and the total loads are transferred to another sheet from which the columns are designed, additional areas due to bending on account of eccentric loading and wind being added as required. The columns so designed are then tabulated on the column drawings. After the beams have all been designed the floor plans are traced off and special drawings made of girders, trusses and special details.

The new Bank of Commerce which at the present time is the tallest building in the British Empire, did not present any features different from those met with from time to time in equally tall and taller buildings in the United States. However on account of the heavy masonry walls and pilasters and the off-set columns, some of the columns reached magnitudes that have not often been exceeded and neither have the loads standing on plate girders.

Mr. Harkness then showed a considerable number of slides describing the Bank of Commerce building. This structure has 35 storeys with 4 basements, and has a height of 472 feet 6 inches. The first storey is 33 feet, the second and third are 18 feet, the fourth and fifth are 15 feet, the sixth is 14 feet and the balance are generally 12 feet, thus making the building equivalent to a 39-storey building having 12 feet storey heights. The exterior is of Indiana limestone backed with brick, the walls being 14 inches in thickness. The floors are of long span ribbed slab reinforced concrete. The banking room at the south side has a width of 85 feet with a ceiling about 60 feet high. The general excavation for the building was carried 47 feet below street level and for the boiler room 63 feet.

The slides shown covered the building in detail and they were fully explained by Mr. Harkness. A feature was the extremely heavy column sections and girders that were required. The wind pressure was figured for a load of 30 pounds per square foot with 25 per cent overstress allowed. This took care of the stresses down to the 26th floor while below the 26th floor they were carried in the outer wall columns.

Following Mr. Harkness's address a moving picture was shown of the construction of the Empire State building in New York, the tallest building in the world. This film was shown by courtesy of the Canadian Institute of Steel Construction. A general discussion followed and it was easily seen that the lecture had been well received by the members of the Toronto Branch.

Annual Meeting

The Annual Branch Meeting of the Toronto Branch was held on Thursday evening, April 2nd, 1931. During the evening the reports of the various committee chairmen were received and R. J. Durley, M.E.I.C., who was present, spoke on Institute affairs. Following the counting of the ballots the scrutineers reported the election of the following officers.

Chairman	C. S. L. Hertzberg, M.E.I.C.
Vice-Chairman	J. Roy Cockburn, M.E.I.C.
Secretary-Treasurer	W. S. Wilson, A.M.E.I.C.
Committee	G. H. Davis, M.E.I.C.
	W. W. Gunn, A.M.E.I.C.
	R. E. Smythe, A.M.E.I.C.

The scrutineers also reported that the change in the Branch by-laws which allows a continuity of service for the secretary-treasurer had passed. Following this Mr. Hertzberg was conducted to the chair and after speaking briefly declared the meeting closed.

Winnipeg Branch

E. W. M. James, A.M.E.I.C., Secretary-Treasurer.

Annual Meeting

The annual meeting of the Winnipeg Branch of The Institute was held in the Engineering building of the University of Manitoba on February 19th.

Colour

On this occasion the speaker of the evening was the Right Reverend Monsignor Morton, who delivered an extremely interesting address under the title of "Colour," which was defined as a sensation produced on the retina by means of energy impulses which occur with varying frequencies up to 763 grand billion per second. Monsignor Morton's address was illustrated by lantern slides and experiments which the speaker performed with great dexterity. An interesting fact was brought out, viz. that perception of red and green is very poor in an astonishing number of persons (from 1 in 80, to 1 in 20), and that perception of orange and blue is almost universally good. This provides a strong argument in favour of substituting orange and blue for the conventional red and green in traffic signals.

Retiring chairman J. W. Porter, M.E.I.C., read the report of the Executive committee, and remarked that apparently there is a tendency for small attendance, when meetings are held monthly, as compared to that when meetings are held fortnightly; and as the Branch has decided in favour of continuing fortnightly meetings, it is hoped that the desired effect upon attendance will be produced.

The report of the committee on Students' Prizes was read by Dean E. P. Fetherstonhaugh, M.E.I.C. The prizes were awarded as follows:

- 1st prize Civil Engineering, $25 to L. E. Jones, S.E.I.C., for a paper entitled "Track Realignment."
- 2nd prize Civil Engineering, $15 to W. E. Morden, for a paper entitled "Open Pitwork at Flin Flon."
- 1st prize Electrical Engineering, $25 to G. M. Bell, S.E.I.C., for a paper entitled "Arc Welding, its Principles, Control and Application."
- 2nd prize Electrical Engineering, $15 to H. A. Park, for a paper entitled "Preparing High Tension Transmission Line Foundations."

The report of the scrutineers was presented, showing the election of the following:

Chairman—Charles T. Barnes, A.M.E.I.C.

To the Executive Committee—W. E. Hobbs, A.M.E.I.C., J. M. Morton, A.M.E.I.C.

Chairman, Nomination Committee—F. H. Martin, M.E.I.C.

Auditors—R. H. Andrews, A.M.E.I.C., D. N. Sharpe, M.E.I.C.

Chairman, Library and Publication Committee—J. F. Cunningham, Affil.E.I.C.

Chairman, Legislation and Public Affairs Committee—D. L. McLean, A.M.E.I.C.

Chairman, Advisory Committee—E. P. Fetherstonhaugh, M.E.I.C.

" Remuneration Committee—C. H. Fox, M.E.I.C.

" Students' Prize Committee—E. V. Caton, M.E.I.C.

" Programme Committee—A. E. MacDonald, Jr.E.I.C.

" Research and Investigation Committee—C. A. Clendening, A.M.E.I.C..

Nominees for Councillors—J. N. Finlayson, M.E.I.C., J. W. Porter, M.E.I.C.

Secretary-Treasurer—E. W. M. James, A.M.E.I.C.

Preliminary Notice

of Applications for Admission and for Transfer

April 18th, 1931.

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in June, 1931.

R. J. DURLEY, *Secretary.*

* The professional requirements are as follows—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ALEXANDER—DAVID TASKER, of Sandwich, Ont., Born at Dundee, Scotland, Jan. 14th, 1885; Educ., 1901-04, Dundee Technical College. I.C.S. Struct'l. Engrg. and Bldg. Constrn. courses; 1909 to date, with the Canadian Bridge Co. Ltd., Walkerville, Ont., as follows: 1909-14, detail drawings of bldgs. and bridges; 1914-16, checking bridge drawings; 1916-19, asst. supt. of munitions plant; 1919-22, squad foreman in charge of dfting-room work on bridges; 1922-23, design of bridges; 1923 to date, chief dftsman. in charge of all dfting-room operations.

FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

DuCANE—CHARLES GEORGE, of Rickmansworth, Herts., England, Born at Willingale, Essex, England, Mar. 20th, 1879; Educ., B.A. (Mech. Sci. Tripos), Cambridge Univ., 1900; 1900-01, pupil in Crompton & Co.'s works, Chelmsford, England; 1901-02, pupil to Sir John Wolfe Barry and Partners, acting as junior asst. in London office, and until 1910 with same firm as follows: 1902-05, asst. to res. engr., and 1906, res. engr., Middlesborough Dock Extension; 1907, asst. on general work in London office; 1908-10, mainly occupied as chief asst. in connection with design and contracts for the Kowloon Canton Railway (British Section) for constrn. plant, bridges, permanent way, repair shops, equipment, etc.; 1911-12, chief engr. for Western Canada for Norton Griffiths & Co. (Canada) Ltd.; 1912-14, partner in firm, DuCane, Dutcher & Co., consltg. engrs., Vancouver, B.C.; 1914-19, on active service with Royal Engineers, in Russia and France. Lieut.-Col., O.B.E.; 1919, in India as representative of Sir John Wolfe Barry, Lyster and Partners, in connection with report on Madras minor ports; 1920, in charge, for A. J. Barry and Partners, of Kent Portland Cement Works (Dartford), also parliamentary and general work; 1921-22, partner in firm A. J. Barry and Partners; 1922 to date, partner in firm, Sir John Wolfe Barry and Partners, Consltg. Engrs., London, England. (*A.M. 1912.*)

FOR TRANSFER FROM THE CLASS OF JUNIOR TO A HIGHER CLASS

DUNCAN—JAMES EDGAR, of 215-6th Ave. West, Calgary, Alta., Born at Vankleek Hill, Ont., Apr. 7th, 1897; Educ., B.Sc. (E.E.), Univ. of Man., 1923; 1916-18, army signal work, C.E.F.; 1923-24, equipment engrg. (machine switching telephone work), and 1924-25, magnetic materials research, Western Electric Co., Hawthorne, Ill.; 1925-26, field work on development of apparatus for picking up seismic waves and transmission of radio time signals, and 1926-27, development of seismic reflection waves and charge of seismic crew using refraction method, for Geophysical Research Corporation, 65 Broadway, New York; 1929 to date, geophysical prospecting using magnetic variometers and electrical apparatus in Alberta for possible gas structures, for Canadian Western Natural Gas, Light, Heat & Power Co. Ltd., Calgary, Alta. (*S. 1922, Jr. 1925.*)

References: R. W. Boyle, C. A. Robb, E. P. Fetherstonhaugh, C. J. Yorath, J. Garrett.

FOR TRANSFER FROM THE CLASS OF STUDENT TO A HIGHER CLASS

ABBOTT—ARTHUR CALDWELL, of 435 des Forges St., Three Rivers, Que., Born at Senneville, Que., Jan. 27th, 1904; Educ., B.Sc. (Mech.), 1925, B.Sc. (E.E.), 1926, McGill Univ.; 1926-28, ap'tice course with Shawinigan Water & Power Company; 1928-29, asst. supt., and 1929-30, supt., Beauharnois Electric Co. Ltd., in charge of operation and mtce., responsible for plant and equipment, ordering of all material, formation of power contracts, etc.; at present, distribution engr., Commercial and Dist. Dept., Shawinigan Water & Power Company, Three Rivers, Que. (*S. 1925.*)

References: C. V. Christie, E. Brown, G. A. Wallace, P. S. Gregory, R. H. Mather.

ANGUS—FREDERIC WILLIAM, of 3450 Drummond St., Montreal, Que., Born at Montreal, Feb. 19th, 1904; Educ., B.Sc., McGill Univ., 1929; 1927, Montreal Armature works; 1929, toll estimating, 1929 to date, dial engr., dial division and equipment engrg. dept., Bell Telephone Company of Canada, Montreal. (*S. 1929.*)

References: G. A. Wallace, C. V. Christie, C. M. McKergow, W. F. Angus.

CLANCY—JOHN, of Montreal, Que., Born at Mulgrave, N.S., Oct. 5th, 1903; Educ., B.Sc. (Elec.), Nova Scotia Tech. Coll., 1928; 1928 (May-Nov.), inspection engrg. dept., and from 1928 to date, telephone systems equipment, engrg. dept., Northern Electric Co. Ltd., Montreal, Que. (*S. 1928.*)

References: A. J. Lawrence, N. L. Dann, N. L. Morgan, W. B. Cartmel, B. B. Shier.

DURLEY—THOMAS, RICHARD, of Westmount, Que., Born at Montreal, Aug. 7th, 1905; Educ., B.Sc. (E.E.), McGill Univ., 1928; 1925-26 (summers), installn. dept., Northern Electric Co.; 1927 (summer), dftsman., Dominion Bridge Co.; 1928-29, test dept,. General Electric Co., Schenectady and Philadelphia; 1929 (6 mos.), switchboard engrg. dept., Can. Gen. Elec. Co.; 1930, in charge elect'l. installn. Plant No. 1, and from Feb. 1931 to date, asst. supt., Plant No. 1, Montreal East, Canada Cement Company. (*S. 1926.*)

References: F. B. Kilbourn, S. Barr, W. G. H. Cam, A. B. Gates, C. V. Christie, W. M. Cruthers, L. DeW. Magie.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Vacant

MECHANICAL ENGINEER. Technically trained engineer, fully familiar with modern shop practices and costs. Experience in coal mining, oil well and miscellaneous mechanical equipment and repair work desirable. Splendid opportunity. Location Western Canada. Apply, giving full information regarding education and experience, to Box No. 704-V.

Situations Vacant

GENERAL SHOP SUPERINTENDENT. Familiar with modern shop practice in modern shop, foundry and miscellaneous iron and steel construction. Must be hustler and able to handle men. Location Western Canada. Apply, giving full information regarding experience, to Box No. 705-V.

WANTED, engineer with good knowledge of combustion principles, to organize and carry on sales of automatic stokers. Must be energetic, have good personality, with executive ability. Apply to Box No. 706-V.

Situations Vacant

PARTNER WANTED. Engineer with extensive construction and mechanical experience, speaking French and English, desires to make connection with engineer or firm engaged in engineering work. Will make investment. Apply to Box No. 708-V.

ELECTRICAL AND RADIO ENGINEER, must be able to understand the uses of paper dielectric and all other types of static condensers in the electrical and radio industry and also able to sell fixed condensers. Apply to Box No. 713-V.

Situations Wanted

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), 15 years experience, available on short notice. Experienced surveys, draughting, reinforced concrete design, municipal engineering, construction work, inspection, estimating. Apply to Box No. 107-W.

Situations Wanted

CIVIL ENGINEER, university graduate 1926, desires employment as junior engineer or instrumentman on construction work. Experience, resident engineer on railway construction, miscellaneous surveys. References. Available any time. Apply to Box No. 149-W.

ELECTRICAL ENGINEER. Graduate '25, wide experience in hydro-electric power stations, desires position on power plant design or related work. Apply to Box No. 278-W.

CIVIL ENGINEER, A.M.E.I.C., Canadian, R.P.E., Nova Scotia, 21 years engineering experience, both field and office, in railway, highways, foundations, concrete structures, water power and conservation, electric transmission lines, etc., experience comprising both surveys and construction, desires employment. Single. Will go anywhere. Working knowledge of French and Spanish. Available immediately. Apply to Box No. 327-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing and hoists. Also some experience in ventilating and heating work and calculators. Accustomed to structural design and details. Good references. Present location Montreal. For interview apply to Box No. 329-W.

CIVIL ENGINEER; age 48; married; A.M.E.I.C., R.P.E., Ontario and New Brunswick; 32 years experience in municipal engineering, on roadways, sewers, waterworks and buildings, desires position with either municipality or as engineer superintendent with contractor. Ten years with City of Toronto, construction engineer on roadway work; four years consulting engineer; three years engineer in charge of construction work; one year resident engineer, Dept. of Public Highways. Available immediately. Maritimes or, Ontario preferred. Apply to Box No. 336-W.

CIVIL ENGINEER, S.E.I.C., graduate '29, desires engineering position with possibilities of advancement. Past experience consists chiefly of survey work and municipal construction. Location in western provinces preferred. Apply to Box No. 338-W.

CIVIL ENGINEER, graduate, age 32, A.M.E.I.C. Ten years experience; seven years on design, construction, erection work and maintenance of paper mill and mine buildings and machinery. Three years on hydro-electric work in charge of surveys and field investigations; associate hydro-electric engineer, U.S. Engineers, on office investigation, design and estimates; desires permanent position in Canada. Apply to Box No. 362-W.

SCOTS ENGINEER, 28 years old, desires situation as junior executive or some similar situation. Wide experience in mechanical, civil and hydraulic fields and four years as junior executive; A.M.I.C.E. exam., Jr.E.I.C. Will go anywhere. Apply to Box No. 381-W.

CIVIL ENGINEER, S.E.I.C., 1930 graduate of Nova Scotia Tech. with experience as plane table topographer, instrumentman and draughtsman and particularly interested in hydro-electric power development and reinforced concrete design, desires position. Willing to go to foreign fields. Available at a few weeks notice. Apply to Box No. 431-W.

CIVIL ENGINEER, B.A.Sc., A.M.E.I.C., Jr.A.S.C.E., age 29, married. Experience over the past eight years upon hydro-electric developments in construction, design and reports. Also some experience in railway construction. Permanent work preferred. Location immaterial. Available at once. Apply to Box No. 447-W.

Situations Wanted

CIVIL ENGINEER, experienced in road construction, mine surveying, transmission line survey and construction; paper mill construction; age 27. Apply to Box No. 468-W.

CIVIL ENGINEER, A.M.E.I.C., age 39, with wide experience on design and construction of reinforced concrete structures, desires position. Apply to Box No. 475-W.

CIVIL ENGINEER, B.Sc., six years experience in paper mill and hydro-electric work, desires position with paper or power company. Paper mill experience covers design, layout, some estimating, and construction. Hydro experience covers preliminary and flowage surveys, transmission line location, design, and six months as resident engineer on construction. Available at once. Apply to Box No. 482-W.

STRUCTURAL ENGINEER, technical graduate, age 40, married, seeks position with architect or contractor. Fully experienced in design and supervision of all types of office and industrial buildings, structural steel or reinforced concrete. Available on short notice. Apply to Box No. 501-W.

ELECTRICAL ENGINEER, B.Sc., McGill University, Jr.E.I.C., age 32. Five years practical experience before graduating. Since graduation two years course with International Paper Co., including six months as electrical foreman, engineer in charge of installation of electrical equipment for two 28,000-h.p. units. Also electrical equipment for large coal-fired boiler house, designing some of the features. Apply to Box No. 506-W.

MECHANICAL ENGINEER, Jr.E.I.C., B.Sc., '26. Ten months experience in pulp and paper steam control. Four years experience in detail and design, in pulp and paper mill, industrial plant and hydro-electric development work. Age 27. Married. Location immaterial. Apply to Box No. 521-W.

CIVIL ENGINEER, B.A.Sc., '29, with experience in supervision of construction and general office engineering, desires permanent position with contractor or engineer. Available at once. Apply to Box No. 524-W.

CIVIL ENGINEER, A.M.E.I.C., with twelve years experience embracing survey and construction, railway, hydro-electric and highways, foundations, pile driving, municipal engineering, water power surveys, road location, inspection and estimating, is open for engagement as resident engineer on construction or other responsible position. Experience comprises both office and outside work. Available immediately. Apply to Box No. 527-W.

ELECTRICAL ENGINEER, S.E.I.C., about to graduate (1931), desires to become associated after graduation with some branch of electrical engineering offering good opportunity for advancement. Sixteen months experience in draughting of electrical apparatus with large manufacturing concern; including layout work, and making of detail working drawings. Bulk of experience with industrial control apparatus. Apply to Box No. 532-W.

CIVIL ENGINEER, B.Sc., McGill University, Jr.E.I.C., age 32. Seven years general experience in hydro-electric power investigations and construction. Has been in charge of high power transmission lines location, also in charge extension surveys. Experience in office and field. Thorough knowledge of French. Best of references from former employers. Apply to Box No. 537-W.

Situations Wanted

CIVIL ENGINEER, McGill '20, A.M.E.I.C., P.E.O., age 31, single. Experience includes general engineering, especially reinforced concrete work, and eight years of pulp and paper mill construction and layout. Best of references. Available on short notice. Apply to Box No. 547-W.

UNDERGRADUATE ENGINEER, S.E.I.C., junior year standing (Sask.), desires work to complete course. Electrical or mechanical work preferred. Apply to Box No. 553-W.

ELECTRICAL ENGINEER, S.E.I.C., graduating 1931, desires employment in electrical engineering. Sixteen months draughting experience on electrical machines with a large manufacturing company. Work included making of layouts and detail working drawings. Available immediately. Location immaterial. Apply to Box No. 555-W.

A.M.E.I.C., graduate of University of Toronto, 1915. Building engineer and superintendent, with considerable experience as installation, sales and promotion engineer. Present connection, four years in responsible position with large utility corporation. Open for immediate connection where he can use his past experience. Location immaterial. Apply to Box No. 560-W.

CIVIL ENGINEER, S.E.I.C., graduating this year. Experience in railway maintenance, and instrumentman on location and construction. Desires to enter any branch of civil engineering or industrial work affording technical experience and an opportunity for increasing responsibility. Will go anywhere. Apply to Box No. 567-W.

CIVIL ENGINEER, A.M.E.I.C., ten years experience as mining engineer of a colliery, six years railway construction, including location, construction, bridge construction, and maintenance. Also one year on hydro transmission lines; one year government land surveys. Would consider position in any branch of construction, as resident engineer or instrumentman. Apply to Box No. 569-W.

CIVIL ENGINEER, B.Sc. McGill Univ., Jr.E.I.C. Five years experience along the lines of general construction, including structural steel. Available at once. Apply to Box No. 570-W.

CIVIL ENGINEER, Jr.E.I.C., B.A.Sc. (Toronto), 1928, age 25, married. Experience in field and office of surveying, general structural design, hydro-electric structures. Present location Montreal. Apply to Box No. 576-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., (Univ. of B.C. '30), Undergraduate experience in pulp mill. One year's experience, Canadian General Electric Co., mech. dept. Single. Age 24. Desires position in technical design or sales. Location immaterial. Available on short notice. Apply to Box No. 577-W.

ELECTRICAL ENGINEER. College graduate with about seven years designing experience with large manufacturer of electrical apparatus; would consider junior partnership with electrical contractor or electrical repair firm. Could invest several thousand dollars. Correspondence invited. Apply to Box No. 579-W.

TEMPORARY EMPLOYMENT FOR SUMMER MONTHS wanted by an engineer with wide experience in the design and operation of steam power plants and heating systems. Apply to Box No. 584-W.

Power Development at Island Falls, Churchill River,

M. H. Marshall, M.E.I.C.,

Dominion Water Power and Hydrometric Bureau, Department of the Interior, Calgary, Alta.

Paper presented before the Calgary Branch of The Engineering Institute of Canada, January 29th, 1931

SUMMARY.—The hydro-electric power plant at Island Falls on the Churchill river is the first development of this nature in Saskatchewan. The 44,000 h.p. developed will be used for mining purposes at the Flin Flon and Sherritt-Gordon mines.

The paper describes the Churchill river basin and storage conditions. The construction of the plant presented considerable difficulty as a transportation system had to be provided. Forty-three miles of road had to be built and scow transportation arranged for on the lakes. In winter the material was handled by trains of sleighs hauled by 100 h.p. tractors, and carrying about 77 tons per train. The total freight dealt with during construction was 35,000 tons. Power during construction was supplied by a temporary hydro-electric plant developed at a site 14 miles from the job.

Three main turbine units are installed, each giving 14,000 h.p. under a 56-foot head at 163.6 r.p.m. The three vertical generators are rated at 12,000 kv.a., 3-phase, 60-cycle, and generate at 6,600 volts, the voltage being stepped up to 110,000 kv. for transmission over the 58 miles to Flin Flon and the 45-mile branch line to Sherritt-Gordon.

The power dam spans the river channel and has three ice chutes, four under sluices, and a spillway section with thirteen openings. There is a separate concrete spillway dam and a number of earth dams along the margin of the headpond to prevent overflow.

The total construction period was some two years, but power was supplied twelve months after first breaking ground.

The completion of the Island Falls power plant on the Churchill river marks the entrance of the province of Saskatchewan into the field of hydro-electric development, as this is the first plant of that nature to be placed in operation in that province.

The plant has been constructed mainly for industrial purposes by the Churchill River Power Company Ltd., and will not be used for the distribution of electrical energy for municipal purposes, as there is no market at present available for sale of the power, other than the mines in the vicinity of the plant. The power being developed, which amounts to 44,000 h.p., is used by the Flin Flon mine of the Hudson Bay Mining and Smelting Company, Ltd., and by the Sherritt-Gordon Mine at Cold lake in Manitoba.

Before proceeding with a description of the construction of the plant, it may be of interest to give some particulars of the source from which this hydro-electric energy is produced.

Churchill River

The Churchill river basin lies in the central and northern parts of the provinces of Manitoba and Saskatchewan and extends into the province of Alberta. The greater part of the area is included in the Pre-Cambrian peneplain of northern Canada and has a gently rolling surface characterized by rounded outlines that have resulted from long continued and profound erosion. The river is peculiar in that it is composed of chains of lakes connected by falls, rapids and stretches of swift water which makes it difficult to navigate and numerous portages are necessary to pass these points. In earlier days the river was used to a considerable extent by the fur traders, but traffic has practically ceased since the advent of railway transportation.

The river rises in Churchill lake in western Saskatchewan, but some of the tributary head waters are in Alberta, and the total length from Churchill lake to Churchill, where it enters Hudson bay, is approximately 1,325 miles. In this distance there is a fall of over 1,300 feet which is well concentrated in the numerous falls and rapids along its course, making it a very valuable stream for power purposes, particularly so as the large lakes in the drainage basin and extensive areas of swamp and muskeg afford means of natural regulation. The total drainage area is about 114,500 square miles of which possibly 80,000 square miles is above the power site. There are excellent facilities for storage as the drainage basin contains several large lakes of which Reindeer lake, Lac la Ronge and Ile à la Crosse lake may be mentioned, and it would be a comparatively simple matter to dam the outlets of these lakes and impound large quantities of water.

In the drainage basin above the power site the rock formations consist mainly of granite or gneisses which are exposed along the river channel. In the areas away from the river the rocks are covered with glacial drift, sometimes to considerable depths, and these consist of till, clay and sandy formations; where suitable cover exists the country is covered with thick growths of poplar, spruce, birch and jack-pine. Some good stands of merchantable timber are to be found in the valley bottoms, but most of the timber is too small for commercial use.

At present little information has been obtained as to the flow of the stream, but a minimum of 10,000 c.f.s. and a maximum of 35,000 c.f.s. was recorded during the years 1928-1930, and there is reason to believe that a much higher maximum flow has been attained at some time in the past, which may have amounted to as much as 100,000 c.f.s., judging from old high water marks.

Preliminary Investigations

The Flin Flon mine was first discovered in 1915 and some efforts were made to develop the property, but little

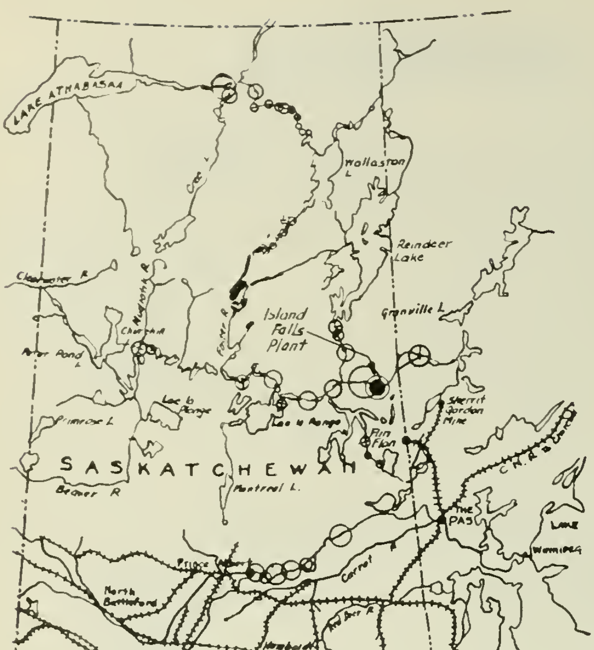

Fig. 1—Location of Island Falls Plant.

success attended these efforts owing to lack of transportation facilities and a successful method of treatment of the ore. Sufficient work was, however, done to reveal the presence of a large body of copper-sulphide ore and an option on the property was secured by the Whitney interests in 1925. Experimental work was carried on during the years 1926-1927 and the results were sufficiently encouraging to warrant the purchase of the property. Arrangements were immediately concluded for the construction of a railway from The Pas to Flin Flon and investigations of possible water power sites were started. A considerable amount of study was given to the power possibilities of both the Churchill and Nelson rivers and the site at Island falls was finally selected as the one most suitable to the needs of the company.

Preliminary Construction

The location of the power site was in a region remote from the point where power was to be used and the only means of access was by canoes with frequent portages between lakes. No roads existed in this area and the distance from the mine to the power site was about 70 miles.

It was therefore obvious that a transportation system would have to be built to connect the job with railhead, which would be capable of handling the large amount of material and supplies needed by the construction crews, during both the summer and winter seasons, and this work was started during the summer of 1928 and completed the following winter. During this period a total of 43 miles of forest road had been cleared and graded. Camps were established along the route, docks built at the end of each lake, and several large scows of 20 to 30 tons capacity had been constructed. A bush telephone line connected the camps and terminal points.

Winter transportation was handled by trains of sleighs hauled by tractors of 100 h.p. Each train was made up of about six sleighs, tractor and heated caboose, and operations were carried out on a definite running schedule, the time for the round trip varying from thirty-six to forty hours. The average load per train was 77 tons, but loads up to 120 tons were hauled.

The total amount of freight handled during the construction period was 35,000 tons, 70 per cent of which was handled during the first winter.

The work of erecting the construction camp was started during the winter. Operations were also commenced in connection with the location and clearing of the transmission line.

The permanent camp buildings were erected during the winter of 1928-1929, and the two sawmills were busily engaged in preparing lumber for building and construction purposes.

Power for construction purposes was first supplied by portable engines, but a small power site had been located at Spruce falls, about 14 miles from the job, and a temporary power plant was constructed at this point, with a transmission line to Island falls. Power was transmitted at 26,000 volts and stepped down at a substation to motor and lighting voltages.

This small plant was in operation for over a year and supplied 4,700,000 kw.h. of electrical energy. The dams and power-house were of timber construction and the plant consisted of two 1,250 h.p. units coupled to 1,000 kv.a. vertical type generators, 600-volt, 3-phase, 60-cycle, speed 400 r.p.m. 40-foot head. The transformers were located apart from the building and consisted of a bank of three 667 kv.a. units 600 to 6,600/26,400 volts with lightning arresters for protection purposes.

Construction and Design

The design of the plant was based upon the use of local material as far as was possible, in order to save transportation of structural material, and the layout of the plant was so arranged that space was also economized so as to keep the cost of construction within reasonable limits.

The general layout may be briefly described as follows:—

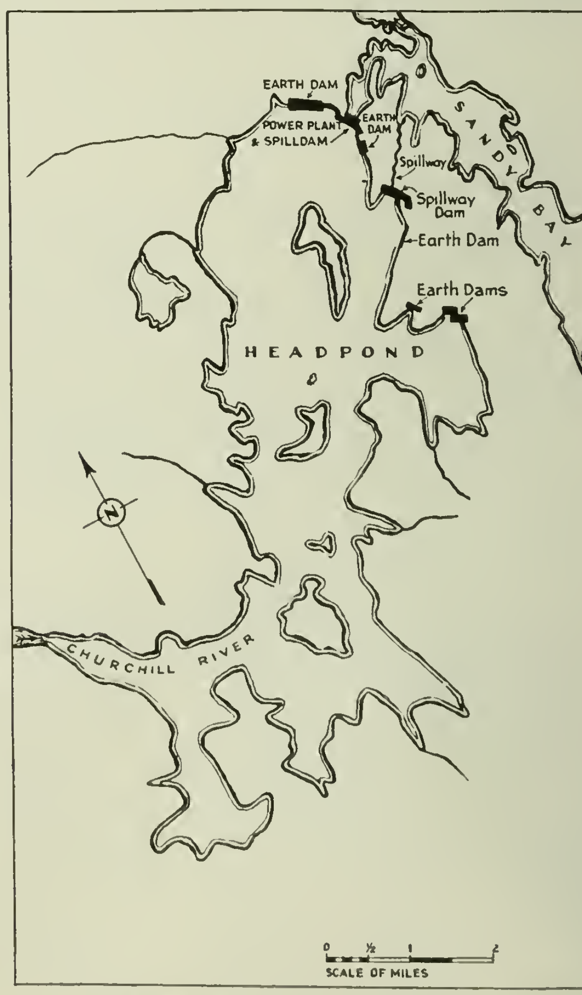

Fig. 2—Plan of Power Development.

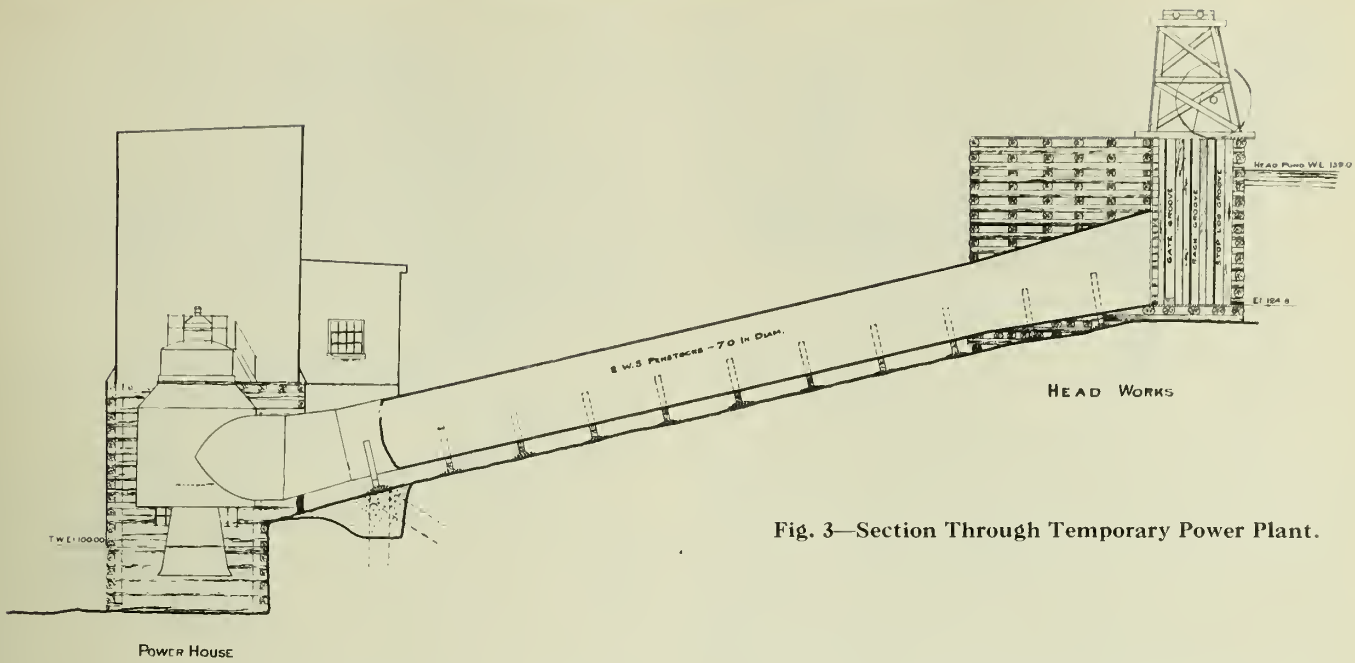

Fig. 3—Section Through Temporary Power Plant.

1. A power-house of concrete block construction supported by a mass concrete substructure.
2. A main power dam spanning the river channel with provision for ice chutes, undersluices and spilldam section—maximum height 90 feet.
3. An extension of the power-house headworks to provide for additional units in the future.
4. Bulwark dams forming shore connections to the north and south banks.
5. A main spillway dam of concrete construction situated one mile south of the power dam—maximum height 44 feet.
6. A number of earth dams or levees along the margin of the head pond to prevent overflow.

Cofferdams

To unwater the sites of the main dam and tailrace it was necessary to construct six cofferdams; these were of crib construction filled with rock and sheet-piled on the water face. The south channel closure was first made, building out from the river bank and a small island in midstream, the dam being closed by a key section. A side dam was built on the island and the downstream end closed by another dam, when the water was pumped out by two 12-inch centrifugal pumps. The tailrace was enclosed by one dam following the line of the south bank, and the north channel by two dams from the island to the north shore.

The cribs were constructed of rough lumber, squared on the connecting face and were built on the shore or existing cofferdam, and then launched and floated into position, being held by cables until ready to sink. Soundings were taken from projecting timbers and the bottom crib was then shaped to fit the river bottom. The sheet-piling in face of the dams was set by divers, three crews being employed, and upon the completion of the dams a banquette of clay was deposited on the water face, which made them practically water-tight.

Power-House

The power-house is of concrete block construction with overall dimensions of 203 feet by 112 feet and has a maximum height of 125 feet. The initial development provides for three main units and two auxiliary units which are contained within the present building. A temporary wall is placed at the south end with a view to further extension to provide for three additional units. The superstructure is supported by a mass concrete substructure,

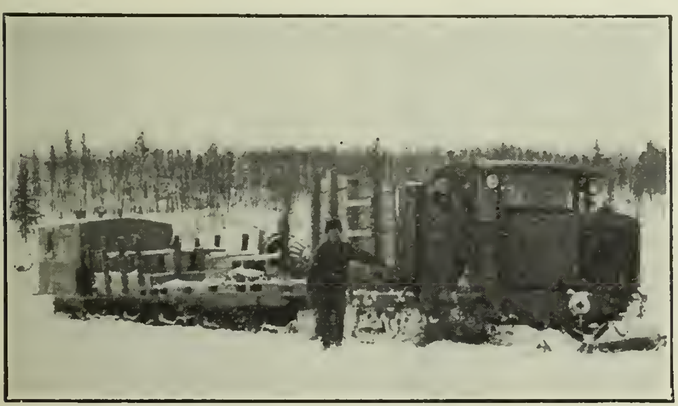

Fig. 4—Small Tractor Train—Winter Transportation.

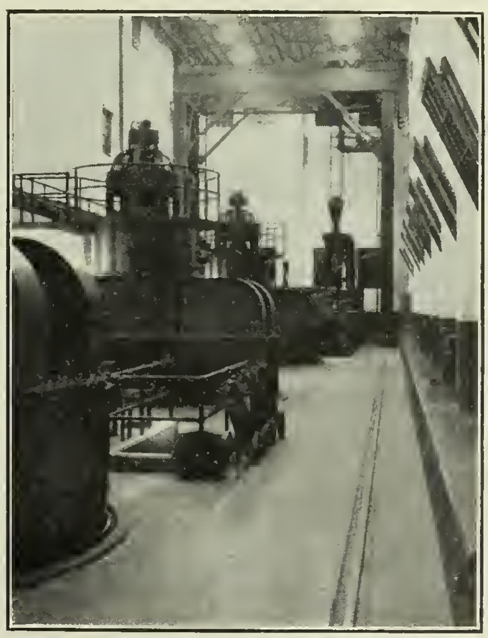

Fig. 5—Generator Room.

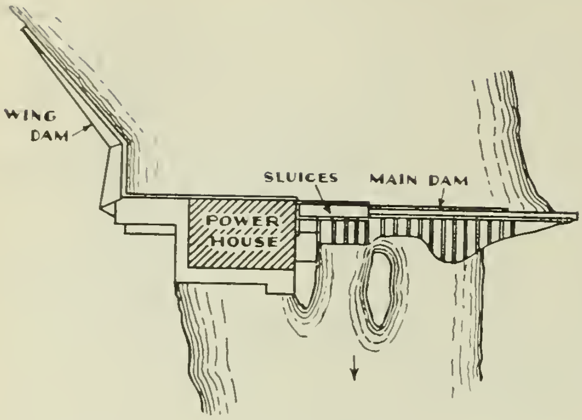

Fig. 6—Plan of Island Falls Power Dam.

which contains the turbine intakes, wheel pits and draft tubes for the units at present installed.

There are two gate openings for each of the main units, with areas of 293 square feet, and these are separated by piers six feet in width, the piers between the intakes being one foot wider. The gates are of the fixed roller type operated by electric hoists placed below the floor of the gate-house, wire rope being used for hoisting. Trash racks and emergency gates are provided in front of each inlet and are handled by a 40-ton gantry crane. The gates are equipped with a water seal, and seat on steel sills let flush into the floor of the intake; steel guides are placed in all gate openings and checks for stop-logs, to facilitate operation.

The auxiliary units have only one opening, and are equipped with gates similar to the main units.

The fixed roller type of gate has given no trouble in operation and seems to give better results than the type with the loose roller train when working under fairly high heads. The gates were loaded with concrete to overcome the pressure head. All the gate operating mechanism of the power-house is enclosed within the gate-house.

Initial Installation

The initial installation consists of three main units and two auxiliary units as previously stated. The hydraulic equipment includes the turbines, governors and pressure tanks, and a pumping plant for water supply and fire protection purposes is provided. The electrical installation includes generators, transformer banks and the necessary switching equipment for delivering power at 110 kv.a. to the transmission line.

The turbines which are of the single runner, vertical shaft, propeller type are capable of developing 14,000 h.p. when operating under a head of 56 feet and running at a speed of 163.6 r.p.m. The maximum expected efficiency of the turbines is 92 per cent.

These machines are direct-connected to conventional vertical shaft two-bearing generators with thrust bearing of the Kingsbury type located above the stator. The casing is formed in the concrete and is of the spiral type. Separate casing stay-vanes are set around the outside of the movable guide-vanes, and these carry the supporting ring to which the turbine head cover and pit lining are secured. These stay-vanes are designed to withstand the bursting pressure of the water in the casing and transmit the superimposed loads of concrete and machinery to the sub-structure.

The draft tube is of the Moody spreading type, formed in the concrete, with symmetrical collection chamber and a hydracone extending up to the runner, which is set to clear it. The upper parts of the draft tube and cone are protected with cast steel plates and semi-steel supporting vanes set around the draft tube carry the superimposed weights of concrete and machinery.

The runners are of cast steel of the diagonal flow propeller type, with six vanes, the shaft being fitted with cast steel sleeves where it passes through the guide-bearing

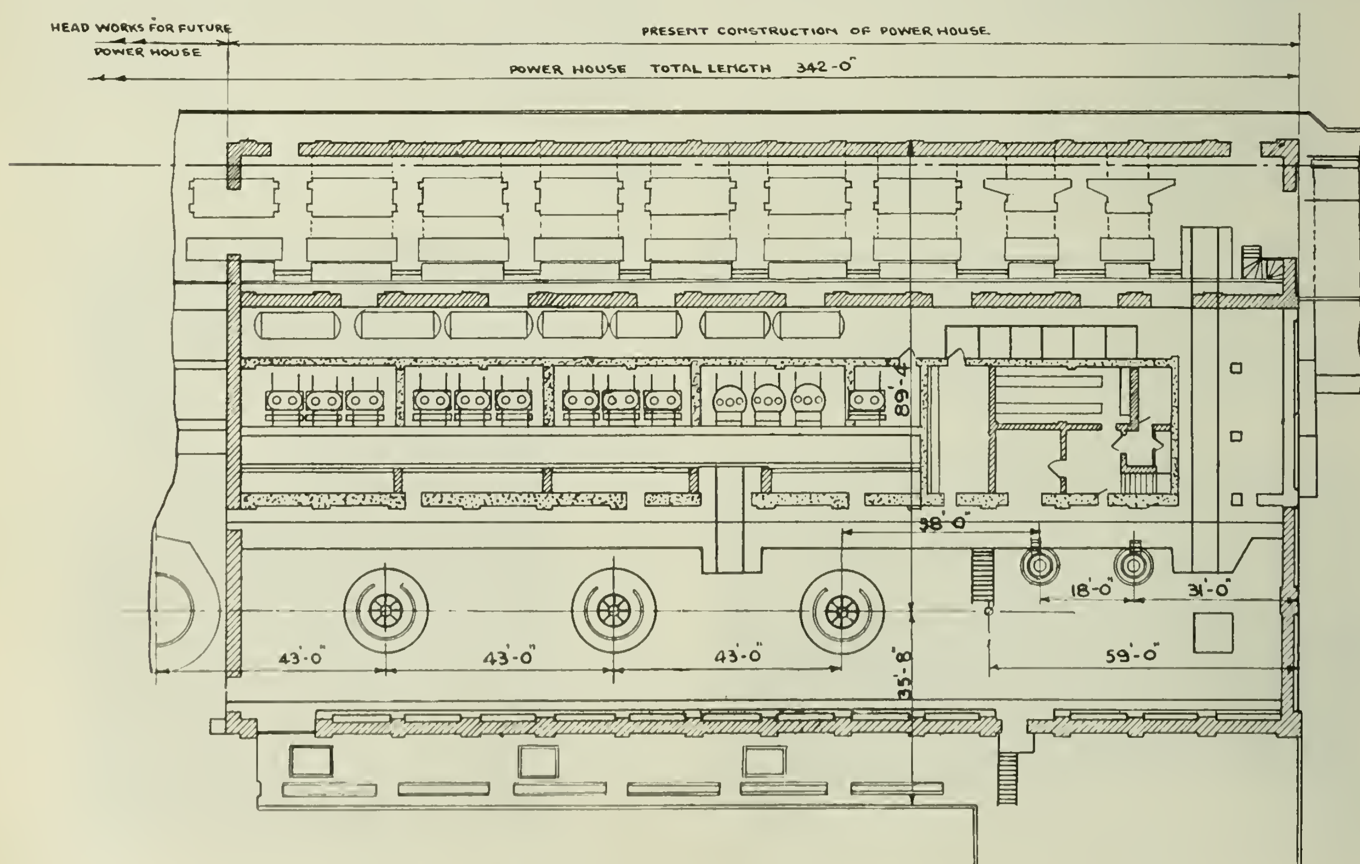

Fig. 7—Layout of Power House.

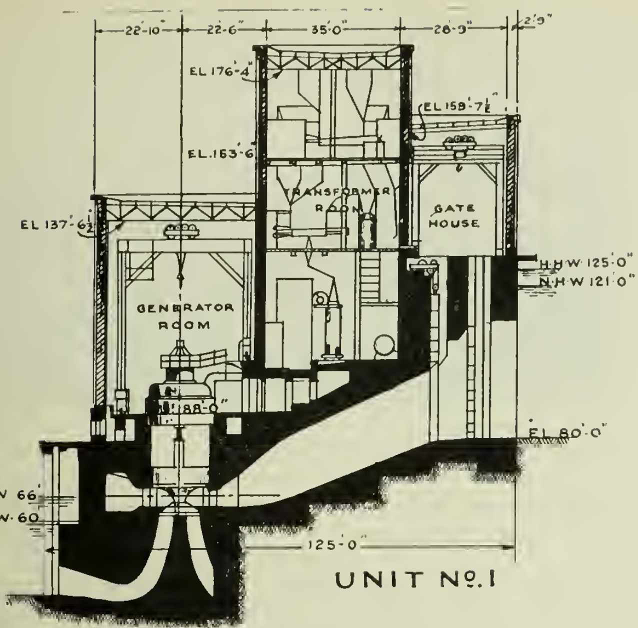

Fig. 8—Cross Section of Power House.

and stuffing box. The guide-bearing is lined with strips of lignum vitae and is water lubricated.

The operating mechanism consists of two cast iron servo-motors which are connected to the operating ring and supported by the pit liner. A governor actuator of the Woodward type is set alongside the generator and is arranged to use oil as the pressure medium and equipped with electrical motor-driven mechanism. Each unit is equipped with a pressure system which includes oil pumps, accumulator tank, sump tank and compressor plant, and the systems for each unit are interconnected.

The generators are of the revolving field vertical shaft type rated at 12,000 kv.a., 3-phase, 60-cycle, speed 163.6 r.p.m., power factor 90 per cent. Current is generated at 6,600 volts. Excitation is provided by a 100 kw. 250-volt main exciter and a 2½ kw. pilot exciter both direct connected, and a 100 kw.-250-volt station exciter is also installed. Each generator is connected directly to the low tension side of the transformer bank.

The two small auxiliary units are of the vertical water wheel type rated at 1,250 h.p. each and are direct connected to 1,000 kv.a., 600-volt, 3-phase, 60-cycle generators which supply current for station services.

Three banks of main transformers and one spare are provided, also one bank of transformers for the auxiliary units. The main transformers are of the oil-filled, water-cooled type rated 4,000 kv.a., single-phase, 60-cycle, 6,600/110,000 v., D/Y with grounded neutral. Taps for 112,750/107,250/104,500/101,750 volts, full capacity. The auxiliary transformer bank consists of three 667 kv.a., single-phase, 60-cycle, 600/6,600 volt D/D oil insulated self-cooled transformers, with grounded neutral. All transformers are mounted on steel trucks and can be readily moved as required.

Current and potential transformers are installed in fire-proof compartments opposite the main transformers.

The high tension oil circuit-breakers connecting the transformers to the high tension bus bars and outgoing lines are of the solenoid operated type, 125 volts, 3-pole, single-throw, 400 amperes, 110,000 volts, with automatic overload trip. The three individual poles of the breaker are entirely insulated from one another. The disconnecting switches are of the three-pole, single-throw, gang operated type, 600 amperes, 110,000 volts, and operation is effected by means of hand levers.

The transfer bus is located on the floor adjoining the breaker rooms, immediately above the main transformer bay, and the main disconnects and high tension busses are on the top floor of the building. The 110 kv. busses are of 1½ inch copper tubing and low tension busses of copper bars.

The main and auxiliary switchboards, relay panels, rheostats and voltage regulators are placed in the control room from which the operation of the station is directed by a complete signal system.

A small motor generator set in duplicate is installed for charging batteries used in connection with the emergency lighting system and other purposes and the building is heated throughout by electrical heaters. A complete machine shop is provided at the north end of the building for repair work and an electrically operated 75-ton gantry crane is placed in the generator room to handle the heavy equipment.

The pumping-plant is located in the basement below the machine shop, and water for fire protection and operating and domestic purposes is taken direct from the river, the domestic supply being chlorinated.

Main Dam

The main dam, which occupies the river channel, adjoins the power-house on the north side and contains

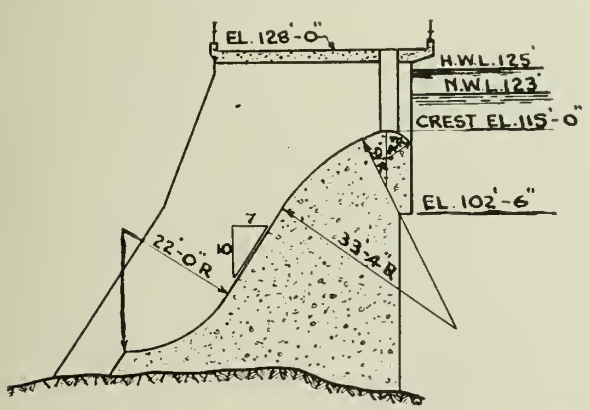

Fig. 9—Section Through Ice Sluice.

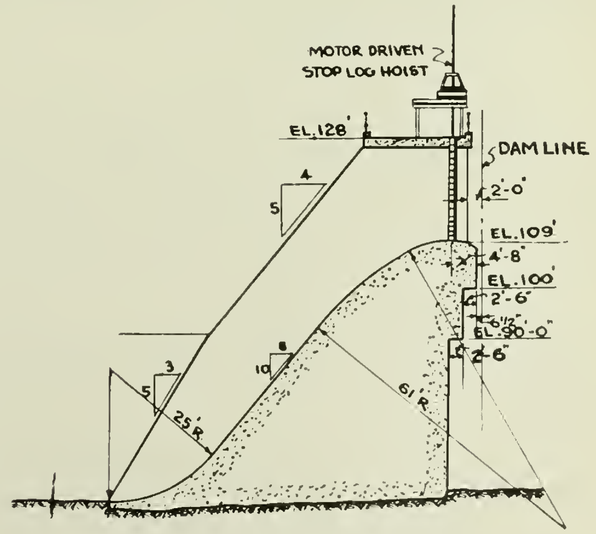

Fig. 10—Section Through Spillway.

three ice-chutes with stop-log control, four large undersluices with submerged gates and a spillway section with thirteen openings fitted for stop-log regulation. The guides for the stop-logs are electrically heated to facilitate winter operation and a stop-log machine is placed on the deck for placing the logs in position or withdrawing them. The undersluice gates are of the fixed roller type, loaded with concrete and raised or lowered by a 30-ton gantry crane with link connections to the gates.

The rollways are of mass concrete and are separated by piers, extending to the river level. The crest is of a compound curve section and is connected by tangents of varying lengths to a reversed curve at the bucket. The north shore connection is made by means of a mass concrete bulwark dam and the overall length of the combined structures from the power-house to the north bank is 468 feet.

The headworks extension south of the power-house is similar in design to the existing works at the power-house and has a length of 139 feet. The south shore connection is an extension of the headworks and is a mass concrete bulwark dam 497 feet long. The proportions for plain concrete were 1:2½:5 used in dams and mass work and 1:2:4 for reinforced concrete with a minimum mixing time of 1½ minutes. The total length of the power dam from shore to shore is approximately one quarter of a mile.

Main Spillway

The main spillway dam is located about one mile to the south of the power dam and is a concrete structure of about 1,000 feet in length with a maximum height of

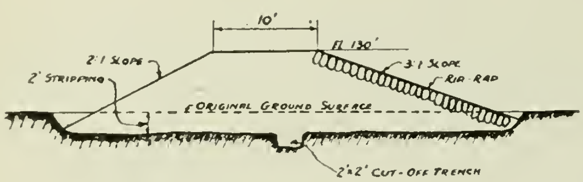

Fig. 11—Typical Section Through Earth Fill Dam.

approximately 40 feet. The rollways are of mass concrete separated by piers which support the operating deck. Forty-six openings 15 feet 6 inches in width are provided to pass the main flow of the river, which is diverted into a spillway channel discharging 1½ miles below the power-house. The deck is 18 feet wide, of tee beam construction, and carries two stop-log machines, and a compressed air system is installed to agitate the water in front of the dam during the winter months. Power is brought from the main plant by a 6,600-volt pole line and is stepped down at the dam to operating voltage.

Cut-off Dams

Nine cut-off dams were constructed at various points along the river bank to prevent the escape of stored water. The dams were made of clay obtained from borrow-pits located away from the dams, and excavated by machine shovels or other means. The dams varied in height from 5 to 20 feet, had 10-foot crests and side-slopes 2:1, 3:1 with benches on the slopes of the larger dams. The slopes were riprapped on the water side, and a rock-filled toe placed on the dry side with suitable drainage.

In constructing the dams the surface soil was stripped to a solid bottom, longitudinal drains were excavated, and the filling material brought up in layers of about eight inches, with a slope rising from the water side, when the whole surface was rolled and sprinkled. The larger dams were constructed from trestles and the material dumped from side cars, after which it was spread by teams and scrapers. Cut-off trenches were excavated wherever a

Fig. 12—View of Power House and Dam.

porous substratum was encountered, and refilled with impervious material.

Transmission Line

The main transmission line to Flin Flon is 58 miles in length with 125 feet cleared right-of-way. The branch to Sherritt-Gordon mine is about 45 miles in length and is of pole construction. The main line is carried on suspension type double circuit towers set in concrete foundation or grouted into rock, and is strung for two 3-phase circuits. A lightning arrester is provided at the power-house end of the line, located on the tailrace operating platform.

Plant Layout

The majority of the plant used on the job was electrically operated. Several miles of standard gauge track were laid and equipped for use of electric locomotives of which five 8-ton and four 20-ton were in use. Material was hauled in side-tip wagons of five cubic yards capacity and flat cars. Two gasoline motors were also used at outlying points.

The mixing and crushing plant was very complete and operated on the gravity system. Two one-yard concrete mixers, a jaw crusher and a cone crusher were installed in this plant and also a plant for making concrete block for the power-house. Concrete was placed by the tower and chute system. An air compressor station containing two 600-cubic foot air compressors and some smaller machines supplied air for the drills and other purposes. Electrical shop, machine shop and carpenters' shop were located adjacent to the power-house, also a plant for welding and general repair work.

The quantities of work comprised in the development exclusive of the transmission line, are indicated by the following figures:—

Excavation and earthworks	194,000	cubic yards
Rock excavation	63,300	"
Riprap	11,400	"
Concrete	83,700	"
Concrete blocks	134,800	pieces
Reinforcing steel	1,140	tons
Structural steel	200	"
Cofferdams	17,500	cubic yards
Freight handled	35,000	tons

From start to finish the whole of the work was completed in a little over two years, but actual construction of the permanent works was completed in sixteen months, and power was being supplied to the mine twelve months after the first ground was broken.

Construction of the works was carried out by the Fraser Brace Engineering Company Ltd., of Montreal, who were also responsible for the general design, and the cost of the undertaking was approximately $7,100,000.

Topographical Study of a Hidden Bedrock Surface by Resistivity Measurements

E. G. Leonardon,
Schlumberger Electrical Prospecting Methods, Toronto, Ont., and New York, N.Y.

SUMMARY.—This article describes the results of an electrical exploration carried out in 1929 for the Department of Railways and Canals, in connection with the study of a dam site at Morrisburg, Ont., to obtain further data on the underground contours of the bedrock. The method adopted was developed by Professor Schlumberger, and depends on the measurement of an electrical field set up in the ground by current passed between two electrodes at the ends of a known base line. Several series of measurements are taken with different lengths and directions of base line, thus determining many equipotential curves from which the average resistivity of the sub-soil can be deduced. Most rocks have resistivities of 1,000 to 2,000 ohms per meter-meter square, while clayey formations give corresponding figures of 10 to 400 ohms.

The necessary apparatus is described, and results given for a large series of measurements carried out on both sides of the St. Lawrence river at Morrisburg. Good agreement was obtained between the depths calculated by the electrical method and those measured by actual drilling.

Introduction

The object of the present paper is to discuss the results of an electrical exploration which was carried out in 1929 at a dam site located on the St. Lawrence river, near Morrisburg, Ont. The work consisted of determining at numerous places, by means of electrical measurements performed at the surface, the thickness of an unconsolidated overburden and thus establishing a topographical map of the bedrock.

The electrical process employed was the "resistivity method." Before describing the field survey, the elementary principles underlying the measurements of the specific resistance of large volumes of the ground will be discussed briefly.

Principles of the Resistivity Measurements

The geophysicist and the geologist are, by now, well acquainted with the resistivity method, which they have known for many years[1] and are well aware of its efficacy in supplementing stratigraphical and structural researches. The civil engineer, however, is less familiar with it, since its application to the study of foundation problems is quite recent. The first experiment in this direction was performed on the Connecticut river in spring 1928 near Littleton, N.H.[2]

The principle of the method lies in the fact that the various formations constituting the underground possess different electrical conductivities. Therefore, if a current is sent into the ground by means of two electrodes A and B (Fig. 1), it will create an electrical field, which will be a regular one, provided the ground is homogeneous. If this is not the case, and if there is a buried mass in the area of the electrodes A and B, possessing a conductivity different from the encasing material, the electrical field will be distorted at the surface. The object of electrical prospecting is to interpret such distortions. This simple method of exploration was discovered in 1912 by Professor C. Schlumberger, and was named by him the method of the "Map of the Potentials."[3] Fig. 2 is a diagram representing the Schlumberger field in the case of a homogeneous, isotropic medium. Such a field will be designated later on by the abbreviation: S-field.[4]

It must be pointed out that this figure not only gives the picture of the equipotential curves at the surface of the soil in the area of the two earth contacts A and B, but its lower part (under the line AB), also represents a cross section of the equipotential surfaces in the interior of the soil. The lines of current going from A to B are shown in dotted lines. The numerals 1, 2, ...10 marked on the lines of current, outline the tubes of current containing one-tenth, two-tenths, etc., of the total current sent into the soil through the contacts A and B. This figure clearly shows that there exists a definite relation between the distance AB of the electrodes and the depth of penetration of a certain ratio of the current (1/5 or ½ for instance). This leads to the concept of the depth of investigation of a pair of electrodes A and B located at a given distance apart. This point will be developed in greater detail later on.

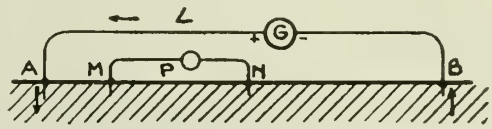

Fig. 1—Measuring Arrangement for Resistivity Measurements of the Underground.

Tracing equipotential curves is a slow process of exploration. As early as 1913, it was evolved by Professor Schlumberger in the measurement of the resistivity of the ground. The computation of this parameter results from a simple formula which applies to the S-field in homogeneous ground. If i is the intensity of the current passed between the two grounds A and B (Fig. 1), if ΔV is the difference of potential recorded between two searching electrodes M and N at the surface, and if R is the resistivity of the ground, we have, with the normal S-field, the equality

$$\frac{1}{R} = \frac{i}{2\pi\Delta V}\left(\frac{1}{AM} - \frac{1}{AN} - \frac{1}{BM} + \frac{1}{BN}\right)$$

In an isotropic homogeneous medium the value obtained for R is the specific resistance of the medium under consideration. This evidently is not the case if the ground is heterogeneous, and the S-field abnormal. The formula will then give for R a figure representing the average resistivities of the subsoil down to a certain depth. The thickness of the layer taken into consideration by the electrical measurement depends, as previously stated, on the distance existing between the pair of electrodes A and B. Experience and theoretical considerations have

---

(1) Resistivity measurements of the subsoil were made by Professor C. Schlumberger as early as 1913. The first resistivity patent is chronologically the French patent which is dated September 25, 1925. In 1920 and the years following important commercial surveys have been carried out by Professor Schlumberger and his associates, some of them covering very large areas. Part of this work has been made public. Refer in this connection to:

(4) This abbreviation was first used by S. S. Stefanesco in his mathematical discussions of the Schlumberger field:

Sabba S. Stefanesco—Etudes Théoriques sur la Prospection Electrique du Sous-sol. Institut Geological Romaniei, Vol. XIV, Fasc. 1.

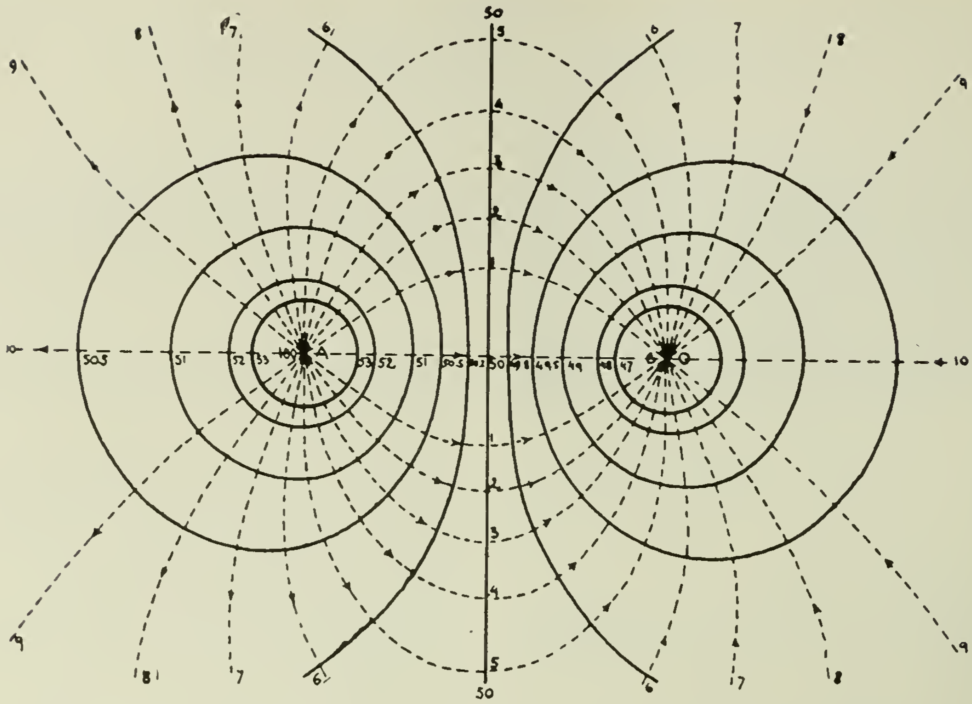

Fig. 2—Electrical Field at the Surface of a Homogeneous Isotropic Ground.

shown that, for practical purposes, the average resistivity obtained with a distance of electrodes AB corresponds to a thickness of the soil of $\frac{AB}{4}$. In other words, the depth of investigation of a certain length of line is practically one-fourth of this line.[5]

It is now easy to imagine a procedure which will investigate the constitution of the subsoil at a given place. It will suffice to carry out at this place a series of resistivity measurements with different lengths of line AB and to compute the average resistivity of the ground for different depths of investigation, thus realizing a "vertical electrical drilling." This "vertical electrical drilling" may be recorded by means of a diagram showing the depths plotted in abscissae against the resistivities in ordinates. The interpretation of the diagram will consist of establishing a correspondence between the variations of the resistivities and certain changes occurring in the constitution of the rocks at depth.

Such a prediction, of course, will not always be possible, and the problem of the interpretation will not lend itself, in all instances, to a satisfactory solution. Sometimes numerous heterogeneities occur in the ground and affect, at the same time, the surface measurements. Some of them are located near the surface, others are deeply buried. They may be very irregular and complicated in shape. Finally, nothing is known about them. The result is that the geophysicist will have no means of differentiating them and will not be able to predict the underground conditions because the latter are not simple enough.

However, among the cases amenable to practical exploration there is the problem of the "horizontal layers," which can be treated mathematically and which is very often encountered in nature, in a more or less ideal form. This problem consists of the case of several parallel, horizontal, homogeneous and isotropic layers possessing distinct electrical conductivities. In this instance, the resistivity measurements depend entirely on the resistivities and positions of the different layers. No other perturbation affects them. This problem has been solved and its solution is of considerable moment in applied geology, since it makes possible the approach to numerous problems concerned with the structural study of horizontal formations.

This study of horizontal, parallel layers also finds its application in civil engineering. For instance, in the preliminary investigation of a dam site or of a tunnel line, it is very important to ascertain whether or not there exists, underground, a solid rock upon which the dam can be built or through which the proposed tunnel can be safely bored. If the surface formations are made up of unconsolidated terrains, as is frequently the case (glacial or alluvial overburden, in particular), it will become necessary to investigate by drill holes, test pits, or other means, the depth at which the bedrock lies. The electrical method is very appropriate for an exploration of this kind, provided that the surface and the bedrock topography are not exceedingly rough and are somewhat parallel. If this is the case, the overburden constitutes a layer of more or less uniform thickness and it is possible to measure this thickness at numerous points at the surface. The electrical measurements provide, then, the data necessary for the preparation of a topographical map of the bedrock. If the overburden is constituted of several layers electrically well differentiated, it will even be possible, in many cases, to give an idea of their respective thicknesses.

It is evident that, in order to solve this problem satisfactorily and with great accuracy, the theoretical conditions of the parallel, homogeneous and isotropic layers must be approximately realized. This however, does not occur entirely in practice, because most of the time, some of the conditions are lacking. Either the surface and the bedrock topography are decidedly irregular or quite non-parallel; or the layers are lenticular; or they lack uniform electrical properties. In all these instances, the electrical diagrams will, then, be more or less altered and sometimes difficult to interpret.

It is, therefore, interesting, in the case of a practical problem to obtain a rapid idea of the accuracy of the

[5] C. and M. Schlumberger—Depth of Investigation Attainable by Potential Methods of Electrical Exploration. American Institute of Mining and Metallurgical Engineers. New York, February, 1929.

measurements. This will be achieved by the means of a few depth determinations on the field. The resistivity curves corresponding to the measurements will be traced and compared with the theoretical diagrams. Their form, the order of magnitude of the discrepancies observed between the two kinds of curves, etc., will make it possible to see to what extent the problem is amenable to electrical prospecting.

Experience has proved that most dam site or tunnel problems can be satisfactorily studied by the electrical method. In the first place, a considerable difference between the electrical properties of the bedrock and of the overburden generally exists. The bedrock is, as a rule, a compact and solid formation, where there are few open spaces or pores. Since the electrical current is transmitted mainly by means of the water which is contained in the rocks, this material is highly resistive. On the other hand, the overburden is frequently composed of unconsolidated material like clays, sands, glacial drift with a high water content and a comparatively good conductivity. For instance, granite, gneiss, marble and in general all metamorphosed rocks possess easily resistivities of 1,000 or 2,000 ohms per meter-meter square, whereas clays and clayey formations, clayey-calcareous soft terrains show corresponding figures of 10 to 400 ohms.

Another point in favour of the method, which should be mentioned here, is the fact that the depth determinations remain quite satisfactory, even in those cases where the surface and the bedrock topography are not parallel and make quite large angles (up to 15 degrees). Under such circumstances, the accuracy of the results will be appreciably improved by performing several series of measurements with the line AB running in different directions. This same procedure also applies when it comes to the elimination of local disturbances due to the lack of homogeneity of the overburden or of the bedrock.

To substantiate these general considerations, it may be mentioned that in the study of more than twenty dam sites or tunnel problems, but one case was encountered which was entirely uninterpretable.

Exploration of a Dam Site on the St. Lawrence River Near Morrisburg, Ontario, Canada

The survey of the dam site near Morrisburg, Ontario, may now be discussed.

This survey was performed in spring, 1929, for the Department of Railways and Canals of Canada, who were studying the location of a dam site on the St. Lawrence river. The results are given with the Department's permission.

Several tentative locations had been chosen for the dam along the river, from Cardinal to Cornwall, and the preliminary study of the project was to be accomplished with all possible speed, so as to take full advantage of the summer season. Therefore, an electrical survey, for the purpose of obtaining a rapid and broad outline of the bedrock conditions and orienting the subsequent drilling exploration was quite justified. A considerable area was systematically covered with electrical measurements at Morrisburg, Ont. and on Ogden island, N.Y. From the data gathered the topographical map of the bedrock shown on Fig. 3 was prepared.[6]

[6] Electrical exploration was also carried out on the Canadian shore at Cardinal, Williamsburg and Cornwall, but much less extensively. These limited surveys are not discussed here.

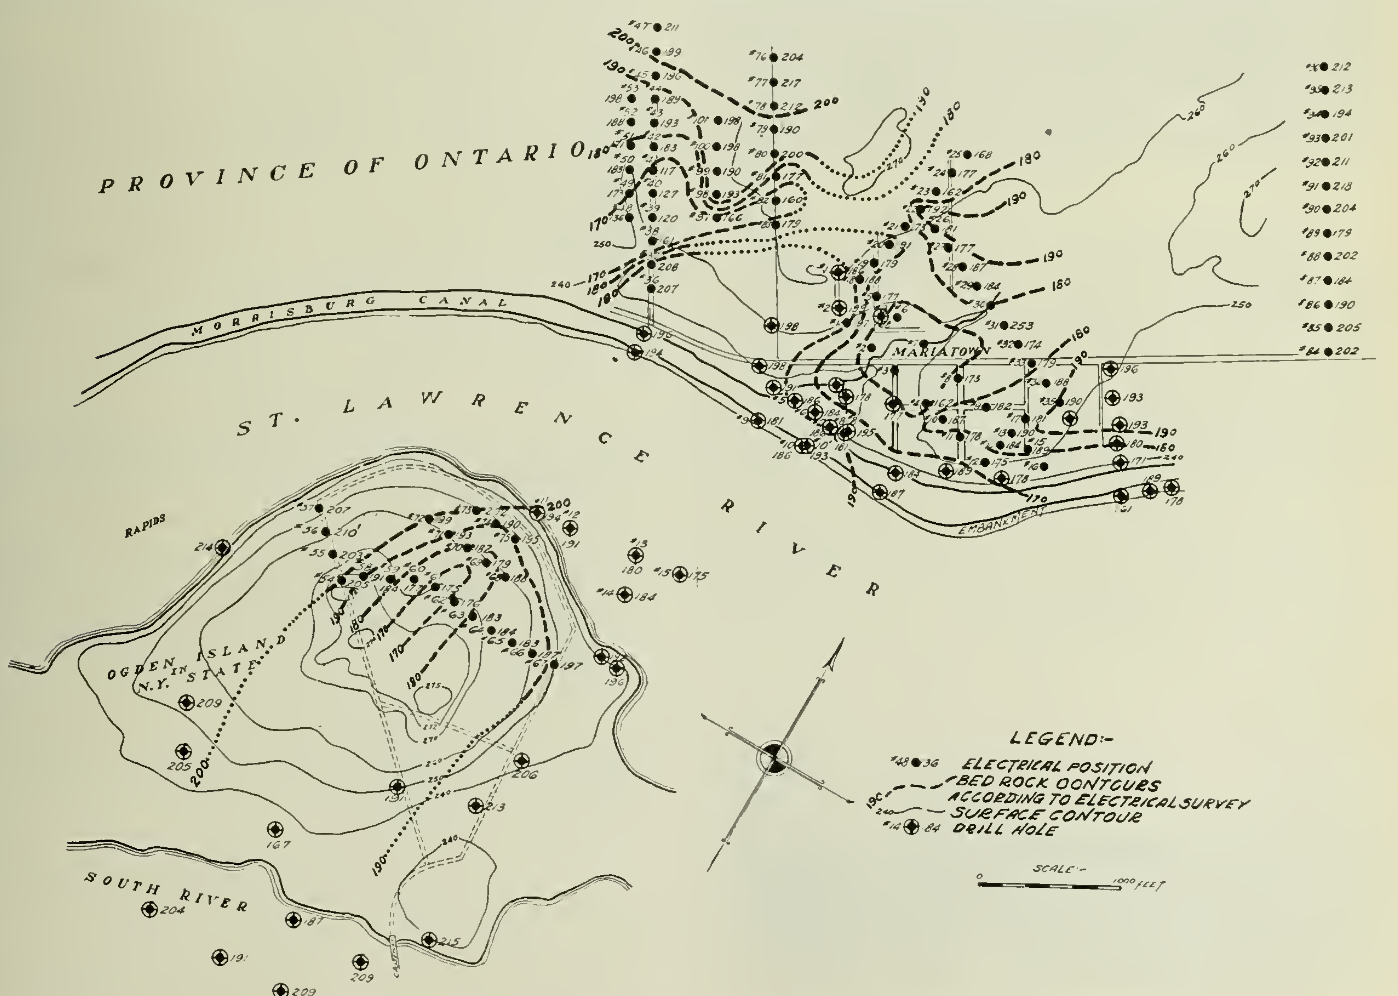

Fig. 3—Topographical Map Showing Exploration at Morrisburg.

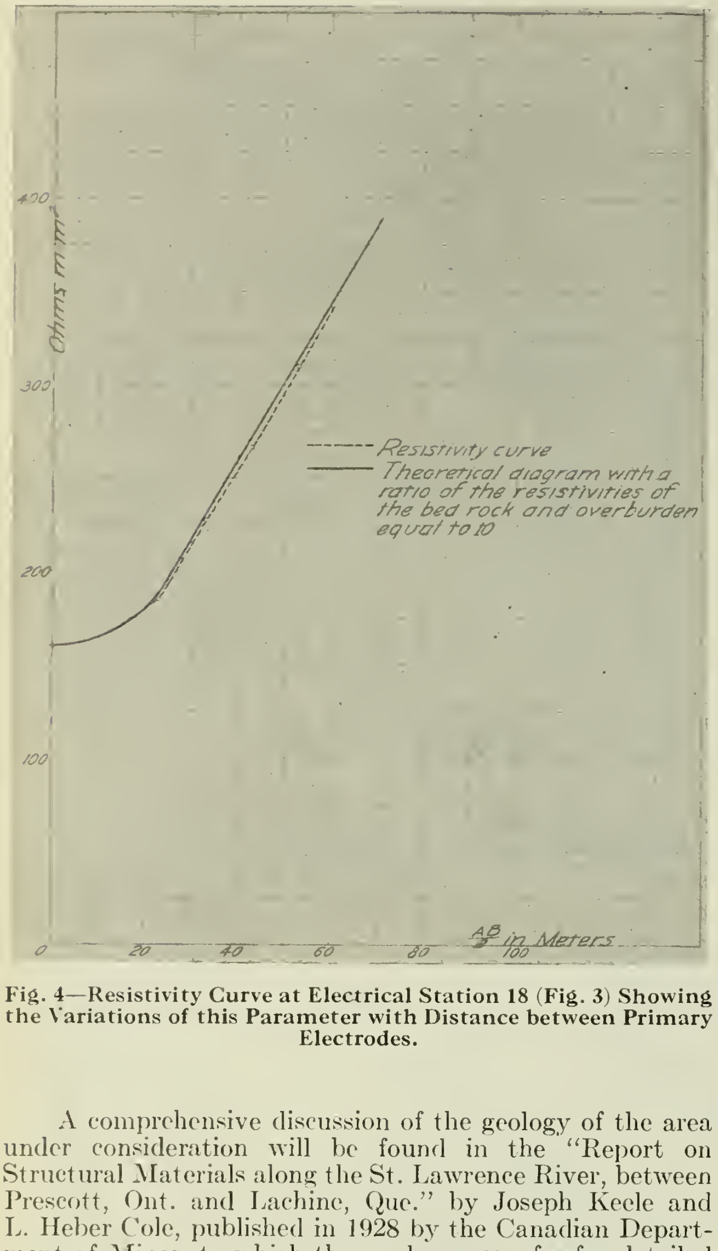

Fig. 4—Resistivity Curve at Electrical Station 18 (Fig. 3) Showing the Variations of this Parameter with Distance between Primary Electrodes.

A comprehensive discussion of the geology of the area under consideration will be found in the "Report on Structural Materials along the St. Lawrence River, between Prescott, Ont. and Lachine, Que." by Joseph Keele and L. Heber Cole, published in 1928 by the Canadian Department of Mines, to which the reader may refer for detailed information. The bedrock in this portion of the St. Lawrence valley is made up largely of nearly flat lying beds of more or less pure limestones, magnesian limestones, dolomites, and shaley limestones, with a minor amount of shale. At Morrisburg the bedrock is composed of dolomites and magnesian limestones with a few narrow beds of dark grey shale, and thin films and layers of shale scattered through two of the dolomite beds. The overburden is composed principally of boulder clay.

Under such circumstances, it was to be expected that the electrical conductivities of the two formations (bedrock and overburden) would be quite different, the bedrock showing much higher resistance than the overburden, and that the problem of the determination of the thickness of the overburden would be amenable to the electrical process. In fact, this is what actually occurred on the field, since the resistivity of the overburden was found to be very uniform and of the order of 150 to 200 ohms, while the bedrock showed everywhere a resistivity 8 to 10 times larger. Fig. 4 represents the resistivity curve registered at station 18. In order to demonstrate how closely the experimental curve checks with the theoretical diagrams, there is also shown on the figure the theoretical curve corresponding to a depth to bedrock of 75 feet (23 meters) and to a ratio of the electrical conductivities (bedrock and overburden) of 10.

All the electrical stations, amounting to 101, are plotted on Fig. 4. With the help of these numerous depth determinations, as well as the results of some drill holes located in the area, it was possible to prepare a topographical map of the bedrock with contour lines at ten-foot intervals, covering an area of more than 100 acres. After the electrical exploration was completed, 15 new holes were drilled. They are marked on the map and numbered 1 to 15. Some of them are located outside of the area covered by electrical measurements and therefore cannot be utilized to determine the precision of the results. This is not the case however, with drillings 1, 2, 3 and 11, which can be used to this effect and give the results contained in the table shown below.

The biggest error is 9 per cent at drill No. 2 and the average error 6.6 per cent. This result is quite remarkable, and even more satisfactory than could be expected, considering the fact that the surface of the bedrock is not at all regular. This point seems evident from the results obtained at drill holes 8 and 8′ and 10 and 10′. Drill holes 8 and 8′ are located a few feet apart; yet they give depths to bedrock of 57 and 47 feet. The discrepancy between the two figures is 37 per cent. At drill holes 10 and 10′ depths of 52 and 45 feet were recorded; the discrepancy between the two figures amounts still to 15.4 per cent. Under such circumstances, the electrical measurements will give an average value of the depth to bedrock in the neighbourhood of the station. This will not necessarily check very closely with the figure obtained by a single drilling, but will, nevertheless, furnish quite a true picture of the underground conditions.

Field Material

The field apparatus is not at all cumbersome. The equipment required for an electrical exploration is shown in Fig. 5, and it comprises a potentiometer, some electrical batteries and two reels of insulated cable. With this very limited amount of material, investigations up to a depth of 300 feet can easily be carried out. If a greater depth of investigation is necessary, the observer need only increase his supply of insulated cable accordingly. Each piece of

Fig. 5—Apparatus used for Field Measurements.

the equipment has been built so that it can be handled conveniently by a single individual, even under the most trying conditions. No car, no roads, no special preparation of the terrain is necessary for the performance of the survey. Thus the electrical method is especially valuable when the place to be investigated is difficult of access, as is often the case in a preliminary study. Under such circumstances an electrical work will often result in an appreciable saving of time and money.

Conclusions

The practical work described in this paper shows how the geological study of the bedrock conditions at a dam site can be efficaciously supplemented by an electrical survey. When the bedrock and the overburden possess different electrical conductivities, such a survey makes it possible to determine the depth to bedrock at a given place from electrical measurements carried out at the surface. Since the procedure is rapid and cheap, very large areas can be systematically covered, thus enabling the preparation of a veritable topographical map of the bedrock. Such a document is evidently very valuable because it gives a general picture of the underground conditions and can be used to orient any kind of subsequent exploration.

The possibilities of the process are not by any means limited to the study of dam sites, since the measuring of the thickness of an overburden is a problem which is frequently encountered in civil engineering as well as geological work. For instances, the same technique can be utilized in the survey of a tunnel line in order to ascertain whether or not the proposed tunnel will have a safe cover of solid rock all along the line. In mining exploration the outlining of a buried channel carrying high values in gold and silver, or the location of mineralized superficial pockets in a rocky formation, constitute structural studies of the same kind.

The electrical method is advantageous because of its rapidity and economy. This makes its application especially valuable at the beginning of a preliminary survey, at which time heavy expenditure can be avoided by carefully planning the exploration by drill holes, test pits and other expensive means. In particular, if the electrical survey demonstrates that the underground conditions are not favourable to the construction of the proposed engineering work, further unnecessary expense will be avoided. That the process is rapid and economical is shown by the fact that the work described above was performed in 30 working days. During this length of time, 101 depth determinations were made, which cost the Department of Railways and Canals less than $4,500. This is a very small sum for the amount of information gathered. The figures also show that the cost of a depth determination was less than $45 and that an average of 3.4 depth determinations was made per working day. It is evident, that for surveys of a very short duration expenses will be proportionally higher, although not to any considerable extent.

Pont Viau

Construction of a Five-Span, Three-Hinge Arch Bridge, at Back River, Montreal

L. J. Leroux, A.M.E.I.C.,
Engineer of Bridges and Tunnels, City of Montreal.

Paper presented before the Montreal Branch of The Engineering Institute of Canada, February 12th, 1931.

SUMMARY.—The paper describes a five-span reinforced concrete bridge over the Back river at Ahuntsic, Montreal, built to replace a steel bridge erected in 1865,quite unsuitable for motor traffic.

The new bridge provides for six lanes of traffic, and is 1,050 feet in length, with arches 56 feet wide. The spans are two of 202 feet, two of 212 feet, and a centre span 222 feet, all being three-hinged arches. The hinges consist of steel castings abutting on centre pins placed in the line of the neutral axis of the arch. Special reinforcement was provided at the hinges. The three-hinged arch was decided on as involving simpler calculation and avoiding indeterminate stresses. The pier foundations were sunk to rock by means of pneumatic caissons, and the bedrock surface was from 22 to 32 feet below water level.

Construction lasted from May, 1929, to October, 1930.

The old Viau bridge was built in 1885 and consisted of four through spans 220 feet long and three pony truss spans about 50 feet long alternating with the long spans. These spans rested on six river piers and two abutments all built of stone masonry. The trusses were pin connected, 19 feet centre to centre leaving a clear roadway of 16 feet with no sidewalk. The floor-beams consisted of old 14-inch I-beam sections suspended by U-bolts passing over the pins of the bottom chord of the truss.

This bridge was built some time before motor cars came into use and had been protected by load restrictions since 1914. In late years the traffic loads had been limited to four tons, at four miles an hour.

Two years ago, in view of the constantly increasing volume of traffic, the city administration decided to rebuild the bridge and gave instructions to prepare plans and specifications.

It had previously been decided that the bridge would be erected in prolongation of Lajeunesse street as this had been widened a few years before with this in mind. After consulting a number of authorities with reference to the provisions which it would be necessary to make for traffic in the future it was deemed reasonable to build a structure capable of handling six lanes of vehicular traffic. The design was prepared for a structure carrying a 54-foot

Fig. 1—Viau Bridge, June, 1930.

Fig. 2—New Viau Bridge.

roadway and two 6-foot sidewalks. In the centre of the roadway a depression was left in the structure to permit the laying of tramway tracks if these were required in the future. The lamp posts were the same as those used elsewhere in the city of Montreal and were erected on the edge of the sidewalk.

There was considerable controversy with regard to the type of bridge to be adopted and whether it should be of steel or concrete. It was finally decided to prepare designs and to call for tenders on both the steel and concrete types.

The steel project was designed with seven spans in groups of two spans continuous over two piers and with expansion joints at the centre of every second span which corresponded to the junction between two groups. Each span was composed of two trusses 40 feet centre to centre, of deck type with arched bottom chords.

The floor was a reinforced concrete slab with cantilivered sidewalks and the surface of the roadway was composed of sheet asphalt three inches thick.

The concrete bridge which has now been completed is composed of five spans of unequal length symmetrically distributed over the river and covering 1,050 feet between abutments. The two shore spans are 202 feet, the two intermediate spans are 212 feet and the centre span 222 feet long. The south approach is 350 feet long and the north approach 150 feet long and both are built of reinforced concrete and designed to match the general aspect of the bridge proper, but with this difference that the approaches are of plain continuous beam design whereas the bridge proper is designed with reinforced concrete arches and open spandrels.

The plans were prepared with three principal considerations kept in mind: strength, appearance and minimum cost. To take care of these three considerations the three-hinged arch design was decided on as this had the advantage of being simpler to calculate, and did not involve extensive research covering indeterminate stresses. Another immediate advantage of the hinged arch is the elimination of the clumsy sections required at the skewback in the case of the fixed arch and necessary on account of temperature stresses. This also made it possible to design a thin arch which is an element of beauty. This is also the reason for the choice of a barrel arch. Again, in distributing the stresses on every foot in width the thickness of the rib can be decreased to a minimum.

Another element of beauty is the departure from the horizontal line for the deck. The bridge is designed with the deck in a vertical parabolic curve ending with a tangent on a 4 per cent grade at each approach. This curve explains the variable length of the spans of the bridge. There are three different arches but they all have the same character, same curve and same proportional rise which is about one-tenth of the horizontal distance between lower hinges.

The arches are designed with no particular geometric curve, they are not circular, nor elliptical, nor parabolic but are designed with a curve which gives moments that equal zero at every concentration under the dead load. The only moments which the arches would have to take if their

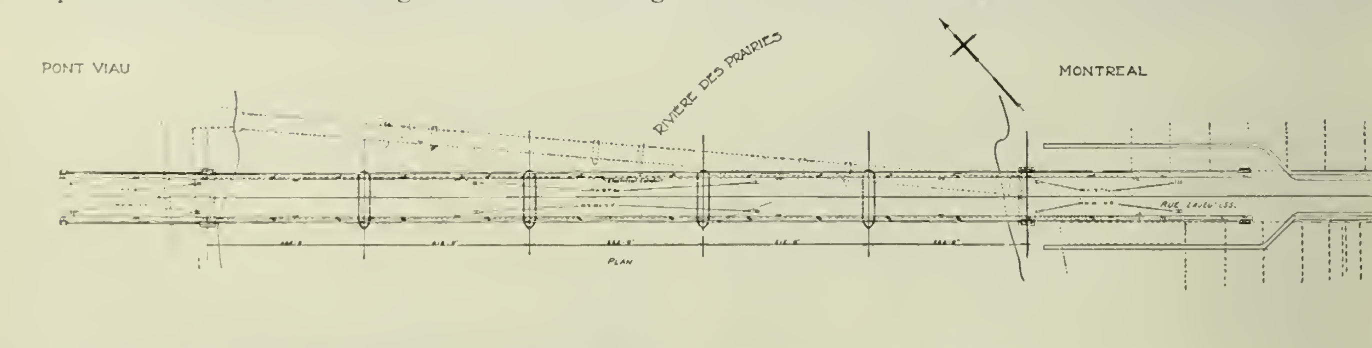

Fig. 3—Plan and Elevation of Bridge.

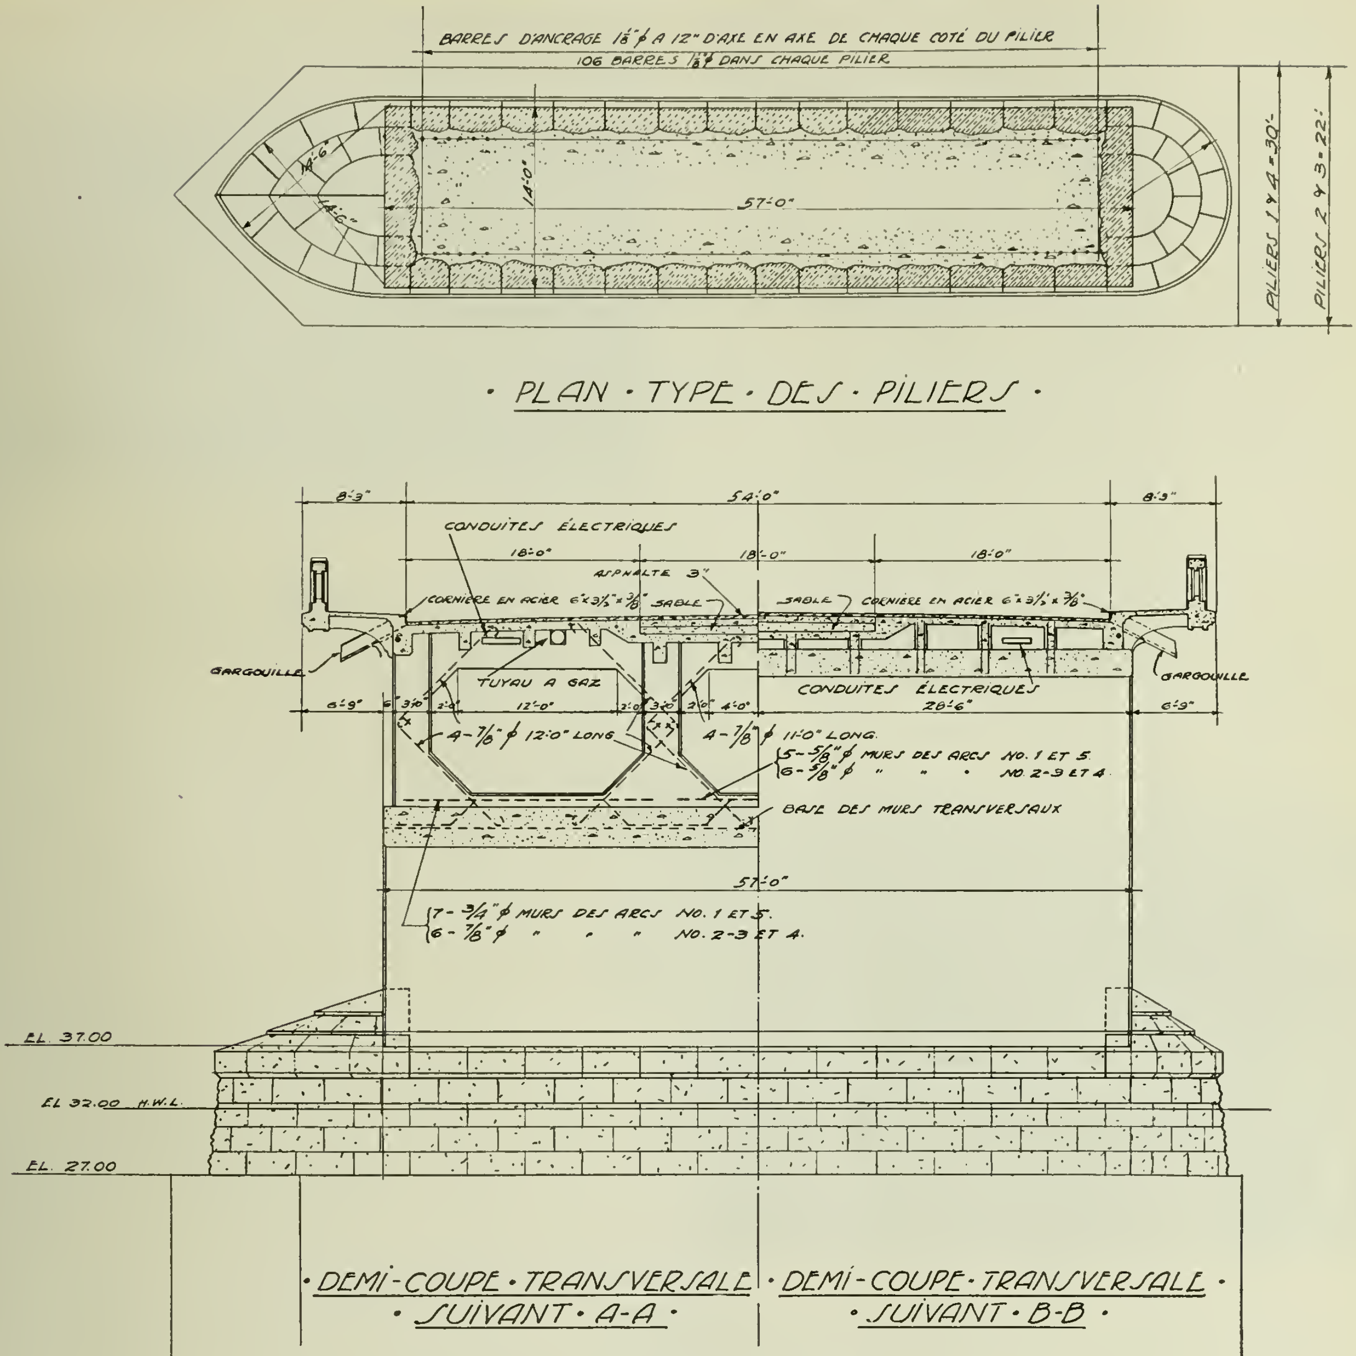

Fig. 4—Plan and Elevation of Pier.

neutral axis after construction followed exactly the curve of the design, would be those produced by the live load. This proves that the bridge should be safe as long as there is no live load on it! The main difference between a truss bridge and an arch bridge lies in the fact that in the former the reactions on the piers are vertical whereas in the latter they are inclined and tend to overturn the piers.

In the case of the Ahuntsic bridge special calculations were made for each abutment and each pier as no two adjacent arches were the same and the resulting thrust on the piers was different for the abutment and the first two piers on each side of the river. Moreover a special study was made for each pier due to the varying depths of the rock on which they were located and this affected the moment of stability.

The largest horizontal component thrust was produced by the shore arch, on account of its smaller proportional rise, although this was the shortest. This amounted to 184,600 pounds per lineal foot of width of the arch which was 57 feet wide. The centre arch produced a horizontal thrust of 168,000 and the intermediate arch was the least in importance with only 165,700.

These figures in each case were the result of the dead load and the combination of live load which produced the maximum stresses on the piers. With these figures it was found that in order to have a proper coefficient of stability the pier between the first and second span required a base 30 feet wide, and yet, with two feet of eccentricity in a direction away from the shore, the pier between the second and third span needed only 22 feet width for base and no eccentricity.

The abutments which received no counter thrust have a base 50 feet wide, that is, in the direction of the thrust, by 82 feet in the other direction.

All these foundations were sunk to rock by means of pneumatic caissons and keyed to the rock by means of a block of concrete which projects downward into the rock,

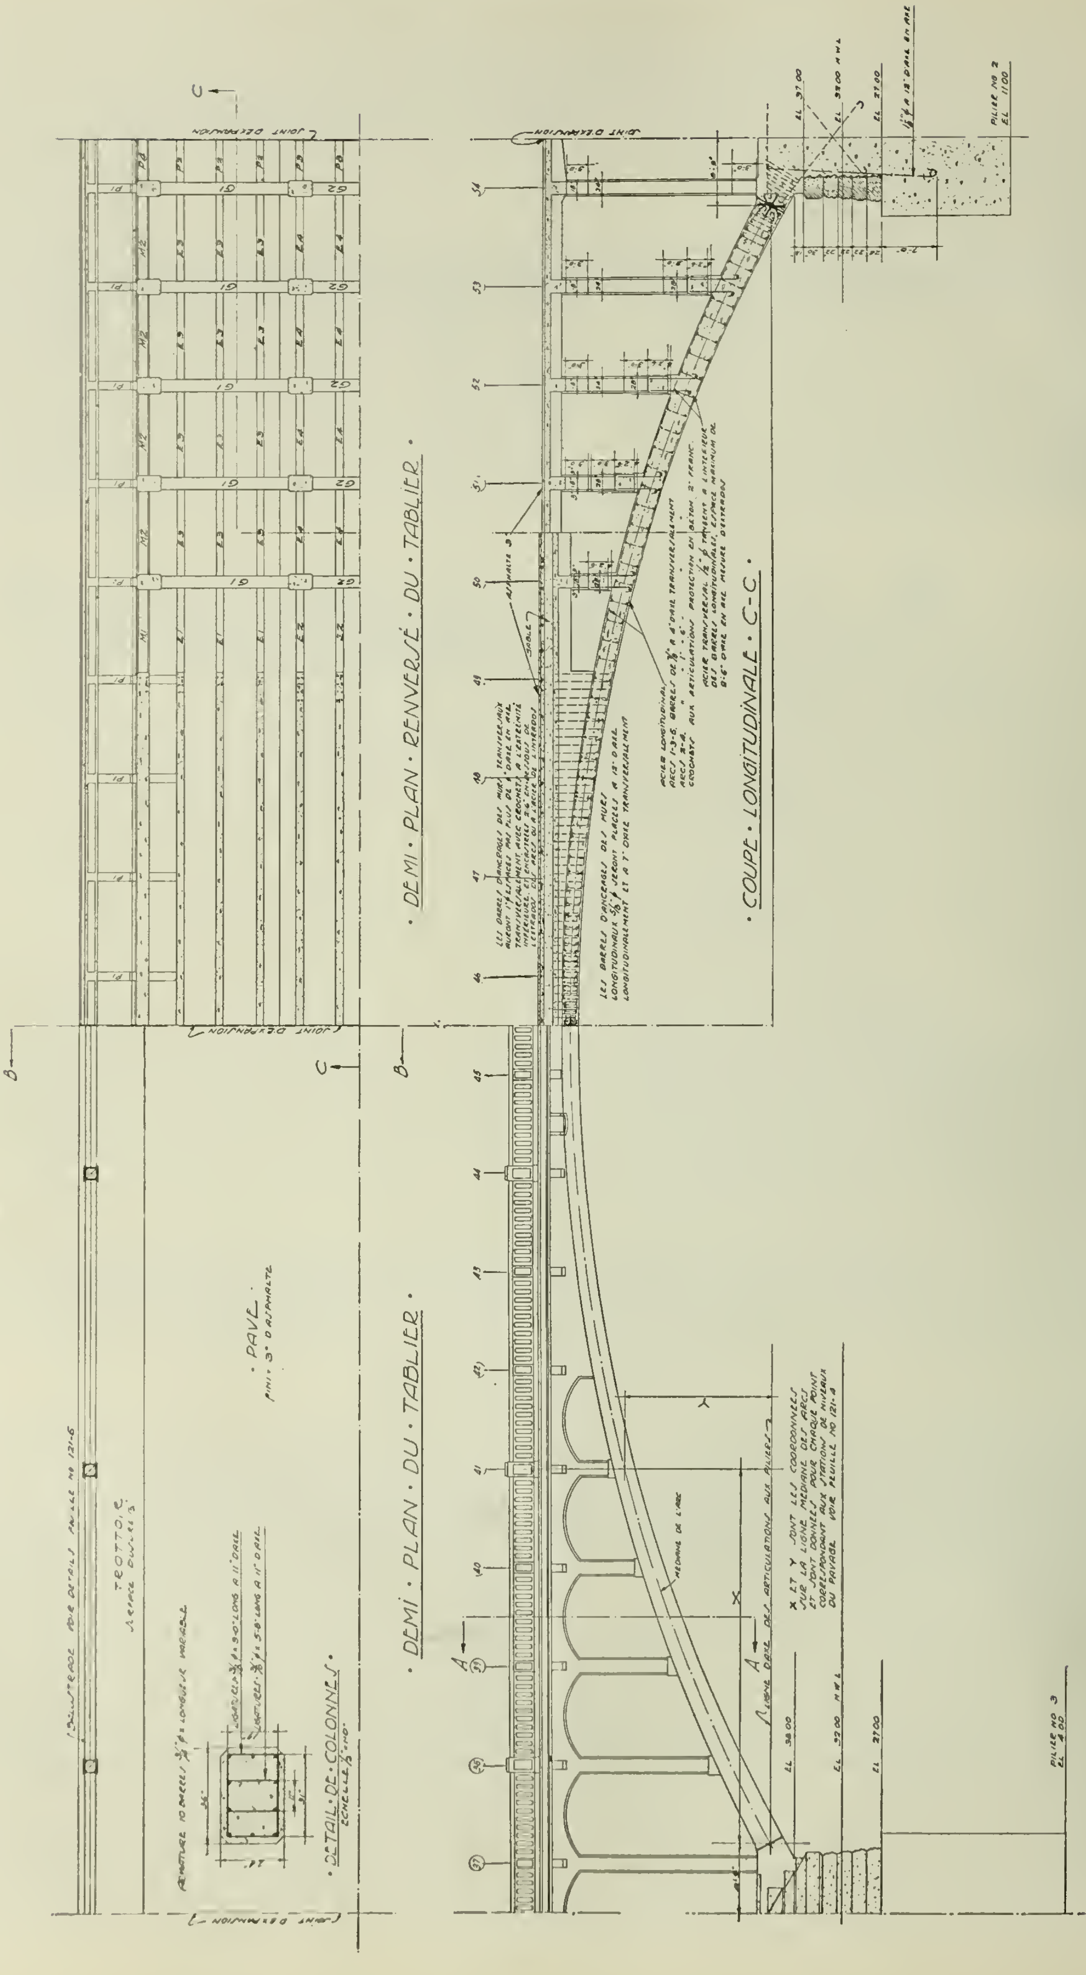

Fig. 5—Elevation and Plan of Arch.

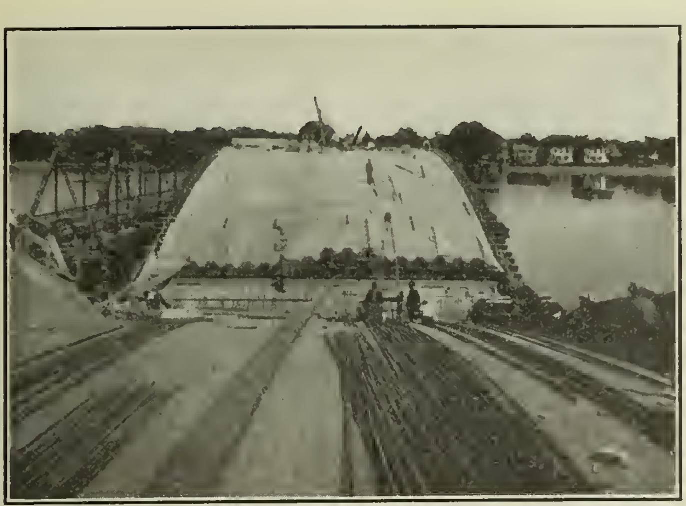

Fig. 6—Forms for Concrete Arches.

the dimensions varying for each pier. Solid rock was found at a depth varying from 22 to 32 feet below water level. The contractor used steel caissons for the river piers and the abutments were made with reinforced concrete caissons, the cutting edge only being steel. No particular difficulty was experienced in sinking these caissons except in the case of two of the piers where it was necessary to cut through old wooden cribs and these had to be destroyed with dynamite and picks or bars under the cutting edge.

The tops of the pier bases were left at elevation 27.00, that is five feet below the proposed water level which the Montreal Island Power Company intends to maintain by regulating the flow at the power house. Above the base the piers all have the same dimensions. They are built of concrete keyed in the base for horizontal shear, reinforced and anchored to the base for the overturning moments which had to be taken care of during erection as well as in the finished bridge.

To remove the shoring from under the first span so as to use it again at the other end of the bridge, all four piers had to take a share of the thrust coming from the swung span. In the finished bridge the five arches rest against one another and this will explain why such expensive centring was built under four of the five spans. Over $100,000 worth of timber, mostly 12 by 12 (and 12 by 16) B.C. fir was used to construct this centring and shoring, which was composed of five longitudinal rows of posts, 13 feet centre to centre, each carrying a truss-like wooden frame whose top chord members were shaped to receive the forms of the intrados of the arch in their erection position. The design of these frames determined the longitudinal spacing of the posts which were located at each bottom intersection of the diagonal members of the frame. Some of these posts had over seventy tons to carry. All were made of two 12 by 16 timbers bolted together and driven with a 3½-ton steam hammer after the resting place on the bed of the river had been prepared by divers. These posts varied in length from 12 to 30 feet. For adjustment and also for uncentring facilities a 12 by 12 short block was introduced on top of hard wood wedges at each point of support. Also all centring was adequately braced transversely and blocked against the piers longitudinally.

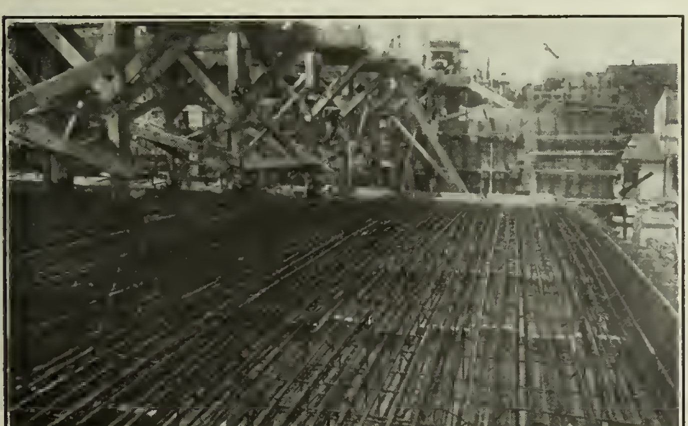

Fig. 7—Arch Reinforcing in Place.

The erection position of the intrados of the arches was determined after taking into account the following factors: temperature, shrinkage of concrete and settlement of the shoring under the load of the fresh poured arch. This settlement was arbitrarily assumed to be one inch. The deflections due to temperature and shrinkage were calculated with the ordinary formula assuming that with a 45-degree drop in temperature the arch would deflect to its geometrical position which corresponded to the zero moment curve.

Observations taken during construction show that these assumptions were not entirely correct. A few of the shoring posts settled as much as one inch more than expected but on the other hand the larger number settled only one-quarter to three-quarters of an inch. The deflection due to shrinkage was also less than expected by about an inch. As a matter of fact when the arches were swung to take stress they dropped only about one and a half inch at the crown, when the calculated figure was two and three-quarter inches, consequently the crown of the arches at the present time is about one and a quarter inch too high. However, this is trifling and does not affect the strength, if anything it improves the coefficient of safety in the event of the temperature falling to 40 degrees below zero.

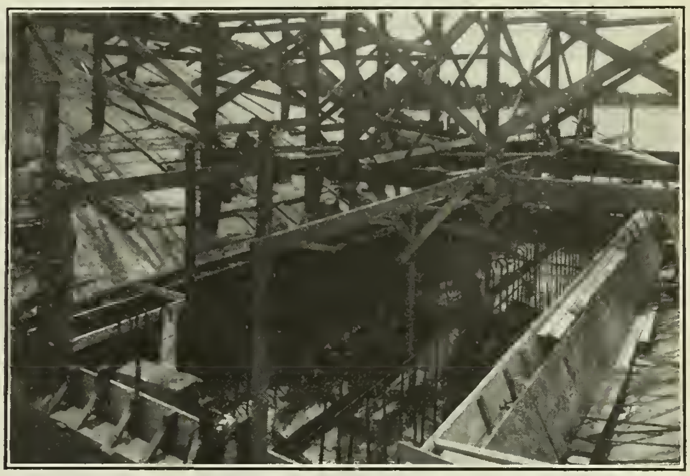

Fig. 8—Forms and Reinforcing, Pier No. 3.

Construction of the Arches

The piers have all been brought to the same elevation, and the intersection of the intrados with the face of the pier is also at the same elevation for all arches. The elevation of the lower hinge pin varies on account of the special curvature of each arch. The hinges are composed of twin steel castings designed to distribute the load from the full thickness of the concrete arch to a centre pin located in the line of the neutral axis of the arch. These were cast in lengths of 3 feet 9 inches and placed end to end fifteen in a row thus covering the 56 feet of width of the arch. The pins were put in place with a graphite coating, carefully aligned and levelled, and the closing row of castings then put in place and bolted tight to those of the first row, the whole resting on three-inch concrete blocks in order to have the castings completely embedded in the concrete of the arch.

Fig. 9—Bridge in August, 1930.

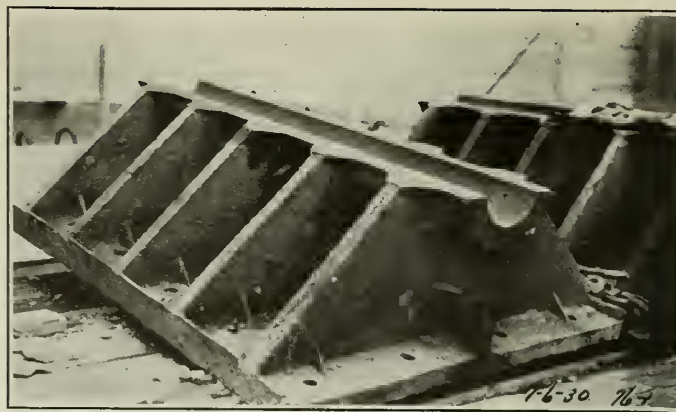

Fig. 10—Steel Castings for Hinges.

The bearing dimension is three feet for the lower hinges and two feet for the crown hinges, the thickness of the arches being 3 feet 6 inches at the springing line and 2 feet 6 inches at the crown.

The calculated unit stress in the concrete was close to 450 pounds per square inch at the lower hinges and 950 pounds at the crown. Special reinforcement was provided at these points through the use of stirrups on close spacing to tie the top and bottom longitudinal reinforcement and make the arch work somewhat in the manner of a spiral hooped column. The arches are reinforced at 0.61 per cent with plain round bars of intermediate steel. It offered quite a network of steel which made it a problem to pour the concrete in voussoirs as was the first intention.

This idea was therefore abandoned and it was decided to concrete each half arch in one continuous operation. This took slightly over twenty-four hours. The concrete plant consisted of a Blaw Knox one yard mixer equipped with inundator and two high speed motor trucks travelling on top of the works to deliver the concrete through portable steel chutes wherever it was wanted.

The specifications called for 3,000 pound concrete in the arches and all test reports which came regularly from the inspectors, J. T. Donald and ,Company Ltd., showed that the twenty-eight day tests gave results well over that figure.

The deck is supported on the arches by means of columns and walls which were designed to obtain a uniform distribution of the stresses across the arches, otherwise the construction does not differ from that of an ordinary viaduct, built of columns, beams and slabs. Reference should also be made to the expansion joints, as in order to allow for the free movement of the arches through temperature variation, the floor is provided with an expansion joint over each crown and each pier. This is a two-inch gap across the deck and is covered with a steel expansion plate.

The deck structure was concreted before any of the centring was removed, and although this precaution was not required, it nevertheless saved the trouble of determining the safe distribution of the deck loads and did away with the necessity of symmetrical pouring which otherwise would have been required in order to avoid dangerous moments in the arches.

The author would express his appreciation of the good spirit showed by the Dufresne Construction Company, contractors, all through the execution of this important enterprise, and for the excellent co-operation received from all the representatives of the company and also from the representatives of J. T. Donald and Company Ltd., who had been appointed inspectors for testing materials and concrete.

It may be interesting to know that 176,000 bags of cement were used in the construction of this bridge and 19,600 cubic yards of concrete were required for the piers and abutments, 5,500 cubic yards for the arches, 4,400 cubic yards for the deck and spandrels, 2,300 cubic yards for the two approaches, and also some 1,000 tons of steel reinforcing.

The air plant used by the Dufresne Construction Company, Ltd., consisted of two low pressure units of about 1,500 cubic feet each and one high pressure unit of about 1,000 cubic feet. All were mounted on a large concrete base, and the three compressors were electrically driven by 150 h.p. motor. There was also a battery of ten portable gasoline air compressors.

Construction started on May 23rd, 1929, and was completed on October 31st, 1930.

Discussion on "Train-Ferry Landings at Port Mulgrave and Point Tupper, N.S."

Paper by D. B. Armstrong, A.M.E.I.C., and W. Chase Thomson, M.E.I.C.[1]

C. S. G. Rogers, A.M.E.I.C.[2]

Mr. Rogers stated that the authors of the paper had performed a real service to The Institute in placing on record a clear description of the design of the ferry landings, for they were structures of a type concerning which there was little literature available.

The paper rightly pointed out that they were more than bridges. The floor systems carried train loads just as did the floor systems of bridges, but otherwise the landings were machines and their operation as machines was the governing factor in their design. Mr. Rogers observed that together with the landings on the Prince Edward Island ferry service there was to his knowledge no other railway ferry landing, in Canada at least, that demanded such strength combined with such flexible construction as to permit of the warping of the end apron leaf to conform to simultaneous list and change of draught in the boat itself while in process of loading, and also to adapt itself to the change of grade on the apron due to these same causes and to the varying tide.

The complexity of the Mulgrave-Tupper landings was due to several conditions. In the first place they carried

[1] This paper was presented at the Annual General Meeting of The Institute, Montreal, February, 1931, and appeared in the January, 1931, issue of The Engineering Journal.

[2] Bridge Engineer, Canadian National Railways, Moncton, N.B.

three tracks; next they must provide on the side tracks for a range of 5 feet 6 inches above and 5 feet 6 inches below mean level for the extremes of tide, listing and draught; finally they must carry train loads equivalent to Cooper's E 60.

These heavy train loads were, of course, due to the coal and steel industries of Cape Breton Island. Thirty years ago when the landings now renewed were built it was felt that the future was well provided for when the structures were designed to carry theoretical locomotives weighing 314,000 pounds. Now on both sides of the straits there actually were locomotives weighing 558,750 pounds. Those weights were not direct indices of the strength of the structures required as the lengths of engines were not the same, but they did represent on the one hand the train loads originally designed for and on the other hand the actual results after thirty years of life.

Mention had been made in the paper of the corrosion of the steel work and Mr. Rogers thought that this condition was to be expected. Parts of the floor system such as the suspended cross girders were seldom dry. What with actual submersion, with wave action and splashing from propellers, combined with the eroding action of ice and water shot against the steel, one would think no severer agents of corrosion could be found. But moist sea air was an even more active re-agent in inducing rust than the salt water. In fact in the old structures, whereas the flange angles on the main outside cross girders which were most constantly wet were reduced fairly uniformly in their long life from five-eighths inch thick to one-quarter inch thick, the overhead bracing which was subject to the salt laden damp sea air had completely rusted away in several places. A little reflection would show these as the natural results. Rusting of course was just a changing of iron to iron oxide by the combination of the oxygen of the air, and/or oxygen from the chemically broken up water, with the iron in the structure; and those parts of the structure actually immersed were insulated by the water itself from contact with the oxygen of the air so that the steel below the water line had not the doubly available oxygen to attack it. In the port of Halifax a like condition was found a few years ago. At Pier No. 2 the windows in the ventilator tops had metal sash. These were replaced with wood sash as they had completely rusted away though only exposed to damp salt air. Another contributing factor in this result was of course that intensely active oxygen in the form of ozone was always present in sea air. This did not suggest that water was a preservative, for steel must be kept dry to preserve it and this could be done by means of painting frequently where the steel was above the water line. That in the water was subject to erosion as well as rusting and was very difficult to protect.

It might be interesting to know that several rust-resisting compounds had been tried on the landings, with little difference in results. Some of them wore off quickly; others were pulled off by ice which formed on the steel in periods of quiet, only to be broken away with the protective coating under propeller or wave action; others were just poor paints. The problem of rust-prevention therefore still remained.

Special care was taken in the new installation to avoid water and dirt pockets and to clean and paint thoroughly all steel-work with good red lead and good graphite paints prepared according to the railways' own standards and experience showed that this was the best that could be done.

The authors had referred to the "first" landing at the site, but of course this meant the first landing of a similar type. From 1892 till the completion of the steel landing just replaced, cars were transported on two scows on either side of a ferry steamer, the cars being loaded on the scows by means of timber aprons which required no warping but merely adjustment to suit tide and the changing draught of scows.

Mr. Rogers wished to comment on the high calibre and engineering efficiency of Canada's bridge building companies. During the course of the renewal of the landings 1,300 tons of steel were placed and 750 tons of old steel removed during construction, four regular first class passenger trains were transported across the straits daily, except Sunday, and the ferries made ten to fifteen trips daily. Yet in spite of that the landings were completely renewed without delay to train service.

F. O. Condon, M.E.I.C.[3]

Mr. Condon remarked that the authors had given a very complete account of the reconstruction of the ferry landings in 1930, and he desired to pay his tribute to the ability and ingenuity displayed by the engineers of the Dominion Bridge Company in carrying out this very difficult undertaking. The paper had referred to the old structure erected in 1901 by the Dominion Bridge Company for the Intercolonial Railway. At that time W. B. MacKenzie, M.E.I.C., now retired, was the chief engineer, and the late John Forbes was bridge engineer, the latter working in very close touch with the engineers of the bridge company. This work, like that now described, required long discussions and studies, with close consideration of each detail, but he would point out that in the structure now described even more careful preparations had to be made, as it was of the utmost importance that traffic should be maintained without interruption. With the original installation this factor did not exist.

P. L. Pratley, M.E.I.C.[4]

Mr. Pratley observed that the use of burning was becoming an important factor where demolition of structures was involved, and he was sure the bridge company would have found it much more difficult to remove the old structure in the twenty hours at their disposal if it had not been possible to use the torch to advantage. One of the detailed points which had occurred to him was the stiff shape of the gantry frames which consisted of two vertical posts each composed of four angles latticed and a double webbed girder placed across them. With a fairly stiff anchorage this constituted a rigid frame and under the live load conditions there would arise a certain bending moment at the top of the vertical posts and at the end of the gantry girder. He therefore wished to inquire whether this moment was calculated, whether it amounted to very much, and whether it called for any modifications in the section such as the increase of the internal over the external angles, and whether the shear was of sufficient amount to affect the dimensions of the latticing.

P. B. Motley, M.E.I.C.[5]

Mr. Motley desired to ask what precautions were taken to safeguard projecting pieces of steel from floating ice. The approach span on the landing seemed to have its floor beams below it, and if the waterline were somewhere near the floor beams, it was possible that ice would find its way in. He would also ask why it was necessary to employ such an elaborate and long apron for an extreme rise and fall of tide of ten feet. It would be interesting to know what was the worst grade that could occur when a train was coming on or off a ship. Mr. Motley did not know whether these questions had to be solved by the engineer in charge of the work or not. They were, however, general questions

[3] Principal Assistant Engineer, Canadian National Railways, Moncton, N.B.

[4] Monsarrat and Pratley, Montreal.

[5] Engineer of Bridges, Canadian Pacific Railway, Montreal.

which were usually decided by the railway company's engineer. Insofar as the Canadian Pacific Railway Company's experience was concerned, a difficult condition existed in Ladysmith, B.C., where there was a tide of 16 feet. The maximum grade at which cars would uncouple was the ruling factor and this had been found to be about 6 per cent, this being the maximum at which any car would stay coupled when passing over the vertical kink in the track at the end of the apron.

D. B. Armstrong, A.M.E.I.C.[6]

Mr. Armstrong, in reply to Mr. Motley, said that in order to give protection from ice, wooden fenders were fitted across the slip to keep the ice from piling in the slip, when the ferry churned up the water. This fender was located about in line with the front girder *B*.

As regards the grade of the apron, he would point out that the gantry *I* was very seldom operated, and five feet plus or minus was probably the maximum ever called for. This, in 100 feet, the length of the outer half of the landing, would give about a 5 per cent grade. The total length of the landing being about 200 feet, there would be about a 2½ per cent grade, providing everything were in a straight line.

W. Chase Thomson, M.E.I.C.[7]

In reference to Mr. Pratley's comment, Mr. Chase Thomson stated that the gantry posts were not figured for bending moment due to continuity.

The load on the track itself would have little or no lateral effect on the gantry because the track was suspended by hangers, and was simply steadied by guides attached to the posts and the masonry below.

C. M. Goodrich, M.E.I.C.[8]

Mr. Goodrich remarked that there were one or two notes which he would like to present, after adding his compliments to those already paid the authors for so excellent a paper.

In connection with secondary stresses in the lifting frames, Professors Van den Broek and Timoshenko of the University of Michigan, and Professor Kist of the University of Leyden, and a number of others had pointed out that steel is not only elastic, but is ductile; the gentlemen who had spoken so earnestly about secondary stresses for so many years had omitted to consider the matter of ductility, and if this were looked into it would be found that in steel we had a material which would stretch a little and then after distributing stresses more favourably, be perhaps 20 per cent stronger than it was before.

Mr. F. C. McMath had stated that one could assume any reasonable distribution of stress for a structure and proportion it to carry the resulting stresses, and if the structure did not want to carry them that way, it would carry them in some other easier way. This was a very pleasant and very true way of putting the thing.

Mr. Goodrich referred to the three-track ferry apron at Mackinac. This was composed of the usual number of girders for three track aprons, held at the rear by pins which were held horizontally by rather heavy springs. There was the usual gantry, and a stiff transverse member at this point. The top flanges of the longitudinal girders were of angles and plates and the bottom flanges of plates only; the plane of the top flanges was accordingly stiff and yet it could warp because of the flexibility of the bottom flanges.

The first apron of this type had been constructed about five years ago, and had had rough treatment, yet the only maintenance had been painting; previous to this installation the maintenance cost had been very heavy. Thus, a stiff and yet readily warping floor seemed to be a good solution.

H. S. Grove, A.M.E.I.C.[9]

Mr. Grove referred to the angle between the pins and apron stringer, and remarked that the outer ends of the apron stringers would ordinarily move in planes at right angles to the axis of the pins, but warping of the deck would tend to cause the outer ends to deviate from these planes.

Was this deviation sufficient to make special clearances or curved bearings necessary?

P. L. Pratley, M.E.I.C.

Mr. Pratley also noticed the inclined position of the stringers of the intermediate span resting on the cross girders and asked whether there was any motion laterally on the cross girders.

D. B. Armstrong, A.M.E.I.C.

Mr. Armstrong pointed out that on the shore span and intermediate span there was no tilting whatever. The transverse girder *E* and the girder *I* always remained horizontal. The only tilting occurred in the apron. Of course, there would be a slight tilt in the shore end of the apron stringers, but this required a very small play on the pins. As far as he knew, there was no adverse effect.

W. Chase Thomson, M.E.I.C.

Mr. Thomson also explained that the stringers were not supposed to tilt. In fact, they were stiffened at the girder *E* with a box section to prevent them from tilting.

Hinged spacer struts had been put in at the ends to prevent the girders from spreading, but that had a very slight effect on the width.

P. L. Pratley, M.E.I.C.

Mr. Pratley thought Mr. Thomson had misunderstood the question, which referred to the longitudinal tilting of the apron in respect to the intermediate span; the stringers being longitudinal would tilt in longitudinal planes, and therefore, as these longitudinal stringers tilt, and as they are on an incline to the pin axis, there must be some movement laterally. What provision had been made for that movement?

H. B. Blackman[10]

Mr. Blackman was interested in the same question, and noted that in Fig. 9 the longitudinal girders were apparently secured so that when the apron tilted the four longitudinals remained vertical. What would prevent them tilting at the outer end where there was nothing to support them?

W. Chase Thomson, M.E.I.C.

Mr. Thomson replied that the strength of the inner end, that is, the torsion value of the girder itself, was the only thing that held them; they did not tilt.

Referring to Mr. Pratley's suggestion that there should be some provision for lateral movement due to the fact that the longitudinal girders are inclined to the axis of the pins, he explained that bevelled steel fillers had been riveted to the ends of these girders, providing vertical bearing surfaces parallel to the longitudinal axis of the structure. Thus the ends of the girders are, in effect, perpendicular to the axis of the pins.

Discussion on "Structure and Oil Prospects on the Eastern Foothills Area, Alberta, Between the Highwood and Bow Rivers"

Paper by Dr. G. S. Hume[1]

J. A. Allan[2]

Professor Allan remarked that a few years ago the geology of the foothills of Alberta was considered to be moderately simple. Most geologists having a knowledge of Alberta geology would have agreed with this statement. Structures suitable for oil accumulation were then believed to be extensive and widespread within the foothills.

Fortunately for Alberta, and possibly for the investing public of Canada, the Geological Survey of Canada had assigned the colossal task of detailed geological investigation in Alberta to one so able as the author, who had shown, as a result of his extended detailed surveys, that the foothills of Alberta really contained the most complicated geological structures. If this statement were doubted, he would advise inspection of the author's advance issue of his maps of Turner valley and the Fisher creek sheets, west and northwest of Turner valley. Faults were so numerous and "nappes" so narrow that there was little room for petroleum accumulation. This was one reason why more oil pools had not been encountered in Alberta foothills, and was also a reason why the outside public should be careful to consider the geological position and the structure before paying fabulous sums for ridiculously small blocks of acreage. Ignorance of these facts too frequently produced the inevitable results. Had the detailed structure along the Highwood and northwest or Turner valley been known even a decade ago, many would be better off financially to-day, but blame for this could not be attributed to the author.

Professor Allan did not wish to give the impression that all foothills structures were unsuitable for oil accumulation. It was only necessary to examine Figs. 2 and 3 in the paper to arrive at the conclusion that certain areas were more favourable than others, and furthermore that the Turner valley structure was more favourable as to depth than most other positions on the lines of his sections.

In 1914 the Turner valley structure seemed quite regular and moderately simple. As drilling continued, the structure proved to be progressively more difficult of interpretation. However, even though Turner valley was classed as a gas field, from which over 60 billion cubic feet of gas had been produced from a block of 1,000 acres, yet that gas had produced a barrel of naphtha from every 25,000 to 60,000 cubic feet of gas, worth about $3.50 per barrel. The Turner valley structure had produced a valuable product, whatever it might be called.

Referring more specifically to the paper, Professor Allan noted that Fig. 1, apparently through lack of space, had been turned sidewise. There was no north sign and unless acquainted with Alberta, it would be difficult for the reader to get orientated geographically.

Although all the formations were of sedimentary deposition, as noted by the author, there were pyroclastics, in the form of volcanic ash beds in the Cretaceous sedimentary formations. The author had omitted to note a rapid variation in the thickness of the formations in an east-west direction, and also from north to south along the strike of the foothills. A formation 2,000 feet thick on one part of the foothills might be two or three times as thick fifty or a hundred miles away, or vice-versa. The formations were of both marine and fresh or brackish water origin. The marine members tended to thicken to the southeast and the latter to thicken towards the northwest. Even the Belly River formation was in part of brackish or marine origin, especially in the southern foothills.

The changes in the interpretation of the Turner valley structure had been marked in the past five years, as a result of more extended drilling, and there was no doubt that as additional drilling was completed, structural details as now recognized might have to be revised. This was to be expected where complicated structures existed such as those in this part of the foothills of Alberta. In this change the number of faults would be more apt to increase than to diminish.

In spite of the complicated system of faulting which the author had indicated, he had sounded an optimistic note in stating that there were favourable prospects of petroleum accumulation in certain parts of the foothills. This optimism on his part was to be commended, for a study of Dr. Hume's sections might cause the reader to conclude that oil prospects in this part of the foothills of Alberta were poor. Professor Allan agreed with the author that there were structures in the foothills worth testing by drilling, but at the same time would point out that these structures were not of wide extent, and drilling sites should be selected only after all available geological facts had been obtained. A mistake of even a few hundred feet in the location might result in failure instead of success. If a number of engineers would take the author's hints as to favourable structural conditions, then we might expect increased drilling activity in the foothills of Alberta in the near future, on locations outside the bounds of Turner valley.

Professor Allan remarked that he was very grateful to have had the opportunity of discussing Dr. Hume's lucid, informational, and at the same time, technical paper.

B. F. Hake[3] and Robin Willis[4]

Messrs. Hake and Willis stated that the paper appeared to them to be the best exposition of the geologic structure of the Alberta foothills which had thus far been published. The facts as presented were in close conformity with their own observations. The author's estimates of the oil and gas possibilities of the region seemed reasonable. They wished, however, to invite attention to a few points of interpretation concerning which they were not in agreement with him.

Noting the statement in the summary that "the foothills are considered to be an overthrust mass thrust eastward on to the relatively flat-lying sediments of the plains," Messrs. Hake and Willis, observing the eastern margin of foothill folding from Waterton river northward as far as Peace river, had failed to find evidence which would confirm this statement. On the contrary, their observation was that this margin almost everywhere consisted of a pronounced east dip involving a thick section of rocks and merging to the eastward into the undeformed sediments of the plains.

They found that where relationships were clear, the outcrops of the most easterly major faults lay west of this east dip, their character suggesting faults developed as a result of folding rather than faults which were primary features and which controlled the folding. Speaking of Turner valley, Dr. Hume had said "this anticlinal structure, however, is in reality a drag fold developed above the low

(1) This paper was presented at the Annual General Meeting of The Engineering Institute of Canada, held in February, 1931, at Montreal, and appeared in the January, 1931, issue of The Engineering Journal.

(2) Professor of Geology, University of Alberta, Edmonton, Alta.

(3) and (4) Nordon Corporation Ltd., Calgary, Alta.

angle thrust plane and was caused by the resistance to eastward movement along the fault plane." The cross section of Turner valley shown in Fig. 3 was a representation of structural conditions with which they were in close agreement. It did not, however, appear to them as a picture of a drag fold on a sole fault, but rather a primary anticline which had passed into a thrust fault.

The method used by the author in projecting the cross sections below the observed surface information appeared to be somewhat illogical and to give too optimistic results in the light of drilling experience in the foothills. Although Dr. Hume's surface observations showed closely compressed folds with sharp axes of the similar type, he had not projected this type of fold in depth, but had used the concentric construction which rounds off and broadens the synclines and flattens out the anticlines. This gave a minimum depth below the surface for any given horizon at any point in the cross section. Numerous disappointments and failures to reach the limestone at estimated depth had indicated that the similar type of construction should be carried to depth and that estimates of the position of the limestone should be made in a much more conservative manner.

Specifically, in Fig. 3, five miles from the west end of the cross section, the northern extremity of the Highwood uplift was shown as having a minimum drilling depth of 2,200 feet and a maximum depth, for a width of a mile, of 3,000 feet. In this locality the Highwood uplift plunged to the north, and therefore drilling depths south of the author's cross section should be less than those indicated by him. In contrast to this the No. 1 well of the Calgary Development and Production Company, located along the strike of the uplift about one and one-half miles south of the cross section, was now drilling below 3,700 feet and had not yet encountered the limestone.

They would ask Dr. Hume how the second principal fault from the west end of Fig. 3 happened to be a thrust fault with a large throw at the surface, although at the same time it had a normal displacement in the opposite direction at a depth of 2,500 feet.

They were of opinion that the names "Upper Alberta Shale" and "Lower Alberta Shale" proposed by the author to replace "Upper Benton" and "Lower Benton" would add unnecessarily to our profusion of formation names and would themselves be subject to at least some of the objections inherent in the older terms. In a more northerly portion of the foothills, Malloch* had described the unquestionable equivalents of these two formations and had given to them the names Blackstone shale (lower) and Wapiabi shale (upper). They favoured the acceptance and general use of these names, which had priority and referred to definite lithologic units and definite type localities. The identity of these with the author's Upper and Lower Alberta shales had been established by several workers, including Messrs. Hake and Willis themselves, both by tracing out the outcrops and by collection of fossils.

T. A. Link[5]

Mr. Link observed that the paper under discussion dealt with an area which was intimately known to him, and that the stage had now been reached with respect to the foothills structure when various theories and ideas were being put forth in print with some degree of confidence. As stated by the author, many of these ideas had been developed in the geological department of Imperial Oil Limited, where much first hand sub-surface and detailed surface geological information had been assembled.

The paper presented, quite definitely, some of the current conceptions regarding foothills structure, and should serve to give one not familiar with the area a good picture of these conditions. There were however minor details of structure which would, no doubt, be interpreted in a different manner by those familiar with these details.

The incorrect orientation of the map in Fig. 1, was unfortunate and might give rise to confusion.

Mr. Link further remarked that since the Jumping Pound structure was generally recognized as the fold indicated by No. 2 on that map, it was to be regretted that the author had termed the Highwood-Waite valley uplift the "Highwood-Jumping Pound Anticline." This would lead to considerable misunderstanding. He would suggest that the author should retain the locally used and established names in the government publications which would follow on this area.

The author's contention that the Highwood structure is too large to effect "sufficient concentration in any one area" recalled remarks of a similar nature made regarding the Big Sweet Grass Arch before commercial production was obtained there. In Mr. Link's opinion the Highwood structure was sufficiently cut by faults and was composed of enough subsidiary folds to afford plenty of opportunity for local concentration.

He pointed out that the Fisher creek structure was underlain by what appeared to be a very low-angle overthrust fault and that the topographic expression of this major fault was such that the Fisher Mountain uplift appeared to be a thin overthrust sheet of considerable areal extent. If the Palaeozoic limestone were not encountered at a depth shallower than 3,000 feet it appeared highly probable that it might never be reached, on account of the presence of this low-angle sole fault. The several high-angle slice faults above the sole might cause enough repetition of beds to prevent reaching the limestone before the major sole fault was encountered. In view of these facts Mr. Link believed that the author's statements regarding the test on the Fisher creek uplift were somewhat too optimistic.

The substitution of the name "Alberta Shale" for "Benton Shale" had caused considerable discussion among geologists working in western Canada. The general consensus of opinion was that the introduction of the new term "Alberta Shale" was unnecessary, because it did not offer any solution of the problem of a Colorado and Montana fauna in the Benton shales. It was felt that there were at the present time suitable names available which had priority over "Alberta Shales." He considered that since the province of Alberta covered a rather large area, of which only a narrow belt exposed Benton shales, it seemed inadvisable to employ the name "Alberta Shales."

T. Madgwick[6]

Mr. Madgwick observed that the paper presented a valuable résumé of certain aspects of the author's work on the geology of the oil and gas fields of western Canada. The final word both as regards tectonics and economic prospects was a matter for the not-immediate future, but, as regards the particular area covered by the paper a considerable step forward had been made.

There were two striking points, first, the complexity of the structures with which oil and gas are associated in the foothills, and second the confidence with which the writer regarded the future of the oil and gas industry. Mr. Madgwick thought that a certain degree of caution was advisable as to exactly *how* these minerals did occur.

As a result of drilling it had been demonstrated that a low angle thrust fault underlies Turner valley. Fig. 3 represented the utmost that could safely be drawn at present to illustrate this. As to the exact nature of that

*G. S. Malloch, "Bighorn Coal Basin, Alberta," Geol. Surv. Can., Memoir 9-2 (1911).

[5] Geologist, Imperial Oil Limited, Calgary, Alta.

[6] Petroleum Engineer, Department of the Interior, Ottawa, Ont.

thrust fault opinions were divided, as a recent discussion in Calgary had clearly shown. Curiously enough, in spite of the much greater drilling activity which had taken place in Turner valley compared with the adjacent New Black Diamond section, there would appear to be less unanimity regarding the kind of thrust faulting in the two areas. This, he supposed, was due to the fact that the flatter part of the Turner valley fault was deeper and that as yet but few wells had reached it, neither was their interpretation agreed upon. The deep well shown in the east of the section might be taken as representing certain wells which had failed to meet not merely the limestone but some overlying formations. They entered a formation at about a mile depth, which owing to lithological similarities between various Cretaceous sandstones had not been definitely tied up with any, but may have been Belly River. But a quarter of a mile west the limestone was struck at 3,800 feet.

The few wells that had actually passed through the fault from the limestone had entered beds in regard to which controversy also existed. One well might have struck Benton, another Blairmore, whereas some observers would regard both as in Belly River. A recently published section definitely showed Belly River.

The distinction was important, for if the latter were the case, then the hypothesis of a bedding plane fault along the Belly River or the overlying Bearpaw would be tenable, whereas if Benton or Blairmore were there encountered, then the faulting might be subsidiary to the folding and the limestone not have been torn so completely from its roots and perhaps translated a considerable distance eastwards into the bargain. In the first case there was shear thrusting, in the second break thrusting. The difference was not merely of academic interest, for it must have a bearing on our ideas of the size of the reservoir from which the wet gas is coming.

Before leaving the subject of the interpretation of subsurface structure by means of boreholes Mr. Madgwick referred to a divergence of opinion current amongst geologists in the west regarding the reliance to be placed on information thus acquired, owing to the crookedness of holes. It was only during the last three or four years that petroleum engineers had become interested in the verticality of their holes, although the results of crookedness had long been known. Various methods of surveying boreholes were in existence, but most engineers would agree that although the angle of inclination from the vertical is relatively easy to determine, the direction is much more difficult. A number of holes had been surveyed in Turner valley and it had been found that rotary drilled holes are worse than those drilled with cable tools, particularly where there had been an attempt to rush a rotary hole down. Looking at Fig. 3 and the more western wells shown in Turner valley, it was clear that the possibility of the deflection of a hole several hundred feet either way might have an important bearing on the interpretation of the log geologically.

Some would consider that the results are so vitiated by this uncertainty that it is inadmissible to publish any section of the kind here shown. Such meticulous precision to his mind was absurd. Nobody who took the trouble to study all the well logs in Turner valley would interpret the information blindly. Such a section as the author had given supposed the drawing of many other sections and the elimination of much doubtful information.

To look at things in a more general way, he noted that in Fig. 1 the author had the system of thrust faults arranged "en coulisses." Mr. Madgwick suggested that this might favour a moderate amount of thrusting, on the lines of A. J. Goodman's recent paper, rather than a too definitely pronounced type of sole fault. It would be difficult to picture sole faults with great displacements without introducing tear faults between the ends of these separate sections, and even then it would be hard to reconcile the results with the mapped longitudinal continuity of the outcrops of strata in the foothills. Tear faulting was another vexed question in the foothills. By introducing smaller thrusts these difficulties were largely removed. Thrusts could give place to folding laterally, and new thrusts could come in to take up the stress in the same way.

There was great reluctance on the part of western geologists to admit evidence of flowage in the Alberta shales. It would of course be necessary to suppose something of this sort if Turner valley were to be accepted as showing break thrusting. Elsewhere in the foothills where cores of Alberta shales had been taken, whole zones were characterized by slickensiding and the development of an incipient schistose appearance, in which sandstone bands pinched out, apparently by compression. It was worthy of note that in Fig. 3, beneath the little syncline in front of the New Black Diamond well (on the left hand side of the section) flowage was indicated. Although such shales could hardly be expected to behave like rock salt, the Menelite shales of the Polish Carpathians, a region to which the writer made reference, very similar in texture, undoubtedly exhibited the flow. Whilst referring to the Carpathians, Mr. Madgwick mentioned that in the case of Boryslaw, the principal field, the analogy with which must not be stressed too far, there is a flattening in the drag fold towards the southwest, so that productive wells extend as far as Mraznica. It had not yet been proved that something similar does not occur at Turner valley.

Although the author did not specifically say so, Mr. Madgwick imagined that he regarded the Palaeozoic limestones as being the competent beds through which the thrust had been transmitted from the west. Was it not true that where visible the limestones tended to form structures with decreasing thrust from the southwest to the northwest? In Mr. Madgwick's opinion the Lewis thrust represented something quite different from the structures now considered. He must confess that he had not yet found any reliable theory of the mechanics of this kind of thing. He did not decry the interesting work done experimentally, but felt that the conditions which one ought to take into consideration in this particular case were quite impossible to reproduce in a laboratory, such conditions being the loading, ratio of thickness to area involved, lateral variation both in thickness and lithology and complexity of floor and incidence of thrusting forces. An incalculable factor, but one which might have played an important role in Turner valley, was the resistance of the autochthonous beds to the east. These had probably been thickened in the process and he thought that the rapid rise in the surface from the Bow river towards Turner valley in part expressed this.

Coming now to the oil and gas prospects, he believed that the author had given a correct picture, on the conservative side if anything. The exact manner of occurrence of the wet gas had yet to be determined and as usual it would fall to the driller to help out in this respect. The amount of drilling accomplished, even in Turner valley, was small. Elsewhere, particularly in view of the tectonic problems requiring solution and the area to be prospected, drilling had been insignificant. All the same, the results measured on this scale had been very good. It would be altogether unprecedented were the whole of the author's Highwood-Jumping Pound Anticline to prove oil or gas productive, and Dr. Hume had rightly called attention to certain sections of it where the drilling would be watched with interest. If the analogy of the Polish Carpathians were pressed, we might expect to find many fields with varied structure and grade of oil, not all equally productive, and it must not be forgotten that Boryslaw-Tustanowice, like its Albertan parallel, lies on the outer margin of the foothills. The area so far studied in detail was tiny compared with that over which oil is known to occur. The oil and gas industry of western Canada had made a good start; it had a long and very promising life before it.

J. B. Webb*[7]

Mr. Webb, referring to the structural conditions along the eastern border of the foothills in the vicinity of Highwood river, observed that his interpretation of the geology would lead to conclusions at variance with those expressed by the author.

In his paper, Dr. Hume had emphasized the undoubted presence of a major low-angle thrust fault plane beneath the outermost foothills folds and had made the statement that "the whole foothills area is underlain by a low angle major thrust plane along which the sediments have been pushed on to the relatively flat-lying sediments of the plains." The inference would be that one continuous fault is found along the eastern edge of the foothills, but this first statement was later qualified in the paper as follows:—"To the south of Turner valley, another fault west of the Turner valley fault becomes the low angle thrust under the Highwood area. Thus although we are not always dealing with the same fault, we are dealing with the same faulted conditions, and the evidence points to the whole foothills belt in this general area being underlain by such a low angle fault." The author, referring further to the Highwood structural conditions, had written "To the south and west of Turner valley is the Highwood anticline area. A low angle fault cuts under the Highwood area and hence structurally the Turner valley conditions are again duplicated."

Mr. Webb stated that he had spent considerable time in detailed mapping of the Highwood river and Bull creek sections and the outer hills of the Highwood district. The conclusion he had reached was that definite surface evidence of an overthrust of major proportion in the east flank of the outer Highwood folds was lacking. Furthermore, the subsurface evidence provided by four deep wells drilled in this territory did not indicate the presence of such a fault.

On Highwood river there existed outcrop evidence of a displacement, with a stratigraphic throw believed to be less than 400 feet. This break occurred about due south of the Imperial Highwood well, and had been regarded by some geologists as the surface expression of a great sole fault, which had been extended far to the south along the east front of the Highwood-Pekisko hills. Such an interpretation was seriously questioned, on the basis of surface evidence alone, and was practically disproved by the log of the Imperial Highwood well.

If, then, this structural break were regarded as of comparatively minor proportions, where did the hypothetical major thrust plane appear at the surface? If the Highwood river were followed eastward, it would be found that successively higher (younger) formations appeared in an east dipping series, until the coal-bearing beds in the basal portion of the Edmonton formation were reached. There followed a broad zone, about 1½ miles in width (measured normal to the strike) in which the basal part of the Edmonton and the Bearpaw formations are extremely contorted, folded and slightly faulted, but without indication of any major displacement. On the east side of this belt the beds again had a regular east dip. If the Highwood thrust fault existed it must be present in this highly distributed zone, but, as stated above, no large thrust fault had been observed. However, a tremendous amount of east-west foreshortening was still expressed in the contorted belt of Edmonton and Bearpaw strata.

*Discussion published by permission of Hudson's Bay Oil & Gas Company, Ltd.

[7] Geologist, Hudson's Bay Oil and Gas Company, Ltd., Calgary, Alberta.

In Mr. Webb's opinion, southward from Highwood river to the Pekisko creek district there was no more conclusive evidence of a great overthrust in front of the Highwood anticlinal area than had been found on the Highwood river section. The strip of territory between the basal Belly River sandstone in the east flank of the Highwood structure and the most easterly outcrops of the Blairmore formation was sufficiently wide to accommodate the entire section of Benton shales. At several localities along the east flanks of the hills the top sandstone of the Blairmore, displaying an east dip, emerged from beneath the Benton shales. There was no indication of over-riding by the Blairmore rocks on to the younger formations to the east, except on a comparatively minor scale.

The subsurface information obtained from the four wells drilled between Highwood river and Pekisko creek did not establish the existence of what could be regarded as a major fault. The deepest of these holes (Imperial-Highwood No. 1, depth 4,525 feet) which was located on the east flank of the structure, encountered the top of the Palaeozoic limestone at 4,229 feet, but passed through a minor overturned fold in this formation and ended in Fernie shale. It was believed that the limestone would have been re-encountered at greater depth. The other three wells were located on either the axial portions or the west flanks of outer folds and did not meet with any recognizable repetition of strata. The deepest of these three wells (Hudson's Bay Oil and Gas Co., Highwood No. 1) reached the limestone at the shallowest depth, 2,156 feet, and was drilled to 4,067 feet without encountering any evidence of faulting.

In conclusion it might be stated that there was a considerable amount of surface and subsurface information available in the Highwood river area which was contradictory to the existence of a major thrust fault plane beneath the outer folds, as postulated by the author.

F. D. Adams, Ph.D., Hon.,M.E.I.C.[8]

Dr. Adams, while not prepared to discuss the details of the complicated sections which had been prepared by the author and presented with his valuable paper, called attention to the great strides which had been made by geologists within the last few decades in unravelling the exceedingly complicated structures presented by many of the mountain ranges of the world. These studies had commenced in the Alps, which, running through the centre of Europe, were early made the subject of investigation by the geologists of the several countries traversed by these mountains.

Some of the individual peaks in this range offered to the geologists of those days veritable geological riddles. One of these was presented by the twin peaks of the Greater and Lesser Mythen near Brunnen on the Lake of Lucerne. This massif rose abruptly from an area of relatively level land which was underlain by flat stratified rocks. The rugged massif itself was clearly seen to be composed of three sets of stratified rocks overlying one another which could be distinguished even from the plain by their differences in colour. They were in the form of a syncline or downward bending fold. Not only was this sharply folded mountain mass superimposed upon a plain composed of strata which had not been folded, but the clear evidence of the fossils in the rocks of the mountain showed that the lowest of the three sets of strata of which it was made up was the newest, while the strata forming the summits of the mass were the oldest. The mountain had been turned upside down and was in fact standing on its head. No one could then understand what had happened, but the facts were incontrovertible.

[8] Montreal.

Dr. Adams remembered showing the section of this mountain, given in Gredner's Geology, to one of the older geologists under whom he was working in those early years, who informed him that any one who drew such a section showed thereby that he knew nothing of geological science, because such a structure could not exist.

The study of the Alps had now been continued by a host of geologists for three generations, and the mountain range had been mapped in great detail foot by foot. The knowledge thus gained enabled one to understand what had really happened, not only in the Alps but in other great folded mountain ranges of the world, including the Rockies.

The tremendous lateral pressures to which the mountains had been submitted and which in fact had brought them into being, were so intense and long continued that the strata had not only been thrown into great folds but these folds had been overturned and bent back upon, and even forced over one another again and again, while in other cases great faults had been developed and one great mountain block had been shoved bodily over the other, the process often being repeated again and again as shown in the author's sections.

The Mythen was merely a fragment of a great overturned fold carried by a horizontal fault, upside down, over a tract of level country and then cut off by erosion from the rest of the range, in which the continuation of its structure could now be traced.

S. G. Porter, M.E.I.C.[9]

Mr. Porter did not feel competent to discuss the geological problems involved, but thought it would be of interest to give some information as to what had been done in the way of development and to what extent production had been secured.

Drilling and production operations had been carried on in the field from 1914 to date, and in 1924 the horizon of high pressure gas and naphtha was discovered in Royalite No. 4 well, which had led to the intensive developments set forth in the tabulated statement shown below of the results obtained in the Turner valley.

[9] Manager, Department of Natural Resources, Canadian Pacific Railway Company, Calgary, Alta.

Dr. G. S. Hume[10]

The author, in reply, pointed out that the geological structure of the foothills was so complicated that it was not surprising to find a divergence of opinion as to its interpretation. As new data became available from drilling, certain modifications of present ideas would be inevitable and the present discussion was a welcome contribution toward the solution of this difficult problem. The admission that low angle faults occur in such structures as Turner valley, New Black Diamond, Jumpingpound, and Wildcat hills had served to direct attention to this important feature of foothills structure and it was obvious that locations for new test wells would be made with much more care than had been the case in many instances in the past. Certain objections had been made to the author's interpretation of local structure. He realized that various interpretations were admissible on account of the relatively small amount of data available at the present time and that no one opinion should be accepted as final until more information had been acquired.

In regard to the use of the name "Alberta Shale," a new name had some objections on account of the common use of the old. The name "Benton," however, was objectionable because the strata included in that formation are not the same age as the Benton in the type section, and hence the use of the name assumed a correlation that did not exist. The formational names applied in the more northerly parts of the foothills could not be used where the Cardium member of the so-called Benton could not be recognized, and a general formational name seemed desirable, hence the name Alberta shale had been introduced.

The author wished to thank those who had contributed to the discussion, which had been very helpful in trying to solve many difficult problems.

Discussion on "The Alexander Power Development on the Nipigon River"

Paper by T. H. Hogg, D.Eng., C.E., M.E.I.C.[1]

J. T. Johnston, M.E.I.C.[2]

Mr. Johnston remarked that the engineers of the Hydro-Electric Power Commission appeared to have thoroughly appreciated the possibilities of the site and to have fully availed themselves of the opportunity, both to secure excellent construction conditions and to save expense at the same time. This same foresight was evident in the utilization of surplus rock to obtain so satisfactory a downstream toe-wall and in the manner in which the fill was placed. The securing of a satisfactory dam at the rate of construction necessitated by the shortness of the season was in itself an achievement.

He had been greatly interested in the methods used to secure a satisfactory junction between concrete and earth sections for both auxiliary and main dams. Another matter of interest was the design worked out for headworks which could be operated satisfactorily under severe winter conditions without the provision of an expensive superstructure; engineers would be anxious to hear whether the methods adopted had come fully up to expectations.

W. S. Lee, M.E.I.C.[3]

Mr. Lee observed that in every power house certain power was dissipated as heat, and that this heat must be disposed of through ventilating fans, ducts or by some other method. The hot air coming from the generating room could be passed through ducts and utilized to keep the bulkheads, gate housing and gate apparatus in proper working condition, and also to free the bulkhead entrances from ice. The author adopted this system, which had also been used at Isle Maligne on the Saguenay river. There the hot air went through tunnels to the bulkhead and entrances and under no weather conditions was there ice interference, although this station had been operating in a severe climate for a number of years. This same scheme was being incorporated in the Beauharnois station.

There was another feature at Alexander which he considered an excellent one. For the operation of the gates or other machinery on the bulkhead there was a standard gauge railway track with a locomotive crane, thus providing not only a locomotive crane for the bulkhead, but also a useful piece of apparatus which could traverse various yard tracks and serve the entire power plant.

A most interesting feature of the Alexander plant was the method of building the earth dam. He might add one or two features to the author's explanation. The lower part of this dam was a rock fill, approximately 45 feet high. That amount of rock would not have been placed in the toe, but the stone was available and instead of wasting it it was dumped into the river, before the river was diverted, forcing the river to a narrow channel on the opposite side which was closed with stone just before the dumping of earth began. The rock foundation beneath the earth dam was probably 150 to 200 feet below the bed of the river. This area was filled with debris, gravel, sand, laminations of clay and perhaps some broken stone that had been weathered off the rocky sides. They had expected it to leak, and the next problem was to devise some plan to seal the flow of water and prevent it from flowing under the dam, and out below the rock toe. It was decided that the proper procedure was to seal or caulk this gravel drain under the dam. If a very fine clay were dumped in a quiet pool of water in one spot the clay would flow and spread itself out under the water. He had seen fine clays in solution dumped in this way into a quiescent pool, flow as much as 1,000 feet and there would not be over five-tenths of a foot variation in the top elevation of the layer of clay. It seemed to flow like heavy oil or molasses. Accordingly three or four feet of impervious clay were deposited between the upstream toe of the earth dam and the cofferdam.

The author had stated that in the construction of the Alexander plant his superintendent and his resident engineer were the same man, Mr. Stanley. That was an excellent practice when installing any piece of work built by the owner. In this case the Commission built the plant. One of the most important points in the construction of any engineering work was to co-ordinate the construction with the design. When an engineer could be used both in the capacity of engineer and that of superintendent a great step had been taken towards co-ordination. By that plan it was possible to cut the costs and speed the work very materially. Personally he would like to see many more engineer-superintendents than in the past, because the superintendent should be a well-educated engineer in order to cope with some of the intricate problems which the author had outlined.

R. C. Flitton, A.M.E.I.C.[4]

Mr. Flitton desired to ask the author what was the reason for deviating from the previous practice of operating the flyballs from the generator leads through step-down transformers.

B. Ottewell, A.M.E.I.C.[5]

Mr. Ottewell believed that so far as Canada was concerned this was the only installation having this type of pilot exciter, but there were several instances in the United States. He would suggest that before dropping the scheme some further investigations should be made.

G. A. Gaherty, A.M.E.I.C.[6]

In regard to Dr. Hogg's design for the transition section between the concrete and the earth fills of the Ghost dam, Mr. Gaherty stated that no leakage whatever had developed at this point in the dam, although the dam had now been in service for over a year. This was the case notwithstanding that there had been considerable settlement in the earth fills themselves. Some slight leakage had shown up through the earth fill hydraulically placed, but strangely enough it was all near the top of the core. This was attributed to the difficulty in the placing of the hydraulic core of preventing layers of sand from extending across the core where it was narrow. There was also some slight seepage through the rock foundation of the fills.

M. V. Sauer, M.E.I.C.[7]

Mr. Sauer asked whether any special provision had been made to consolidate the clay in the pond above the dam so that later velocities which might occur when the dam is discharging would not stir it up?

F. W. Caldwell, M.E.I.C.[8]

Mr. Caldwell enquired whether the fineness of the material which was used in the clay core of the dam had been specified. Was the fineness about 200 mesh? In regard to the material underneath the clay core of the dam, were borings taken so as to obtain samples of it, and were any tests made as to the amount of water flowing through the material below the core?

He had had the opportunity to look over a clay dam on the Sacandaga river in the state of New York, which was very similar to the case described in the paper. There, the rock fill had been used for the toe, and that material had been obtained from the spillway which was excavated in the rock ledge on one side. The material in the stream bed was gravel, but on excavating a key section 30 feet deep a tight clay blanket several feet deep was found, although there was material below that which would leak. It was not necessary to place a clay blanket above the dam. The general construction of the work as a whole was semi-hydraulic. The clay was obtained locally.

T. H. Hogg. M.E.I.C.[9]

Amplifying the geographical notes in the third and fourth paragraphs of the paper, the author stated that the distance between Lake Superior and Lake Nipigon was about 22 miles. The Alexander development was about eight miles from Lake Superior, and utilized a head of 60 feet. The Cameron falls plant, a mile and a half farther upstream, utilized 78 feet. Lake Nipigon ranged in elevation from 846 to 855 feet above sea level, and as the average level of Lake Superior was about 604, the fall in the river was about 250 feet. Of this, 138 feet was utilized at Alexander and Cameron falls, and there remained about 112 feet of fall at present unused, of which about 108 feet occurred in the twelve miles of the river between the Cameron falls plant and Lake Nipigon, and four feet below the Alexander development.

The Hydro-Electric Power Commission had made surveys of the power sites between Cameron falls and Lake Nipigon, and while there was a possibility of developing the available power in this part of the river in two stages, it was also quite feasible to utilize the whole of the available head of 100 to 105 feet in a single development at Pine Portage. Thus ultimately, perhaps in another eight or ten years, the whole head from Lake Nipigon to Lake Superior would be in use, and of the whole fall, probably only five or six feet would not be concentrated at the power sites, the major portion of which would be between the tailwater of Alexander development and Lake Superior.

Referring to Fig. 9, in the paper, it would be noted that the auxiliary dam, which ran from the west side of the river to the power house, was also an earth fill structure, with a clay core. At one point a difficult situation had been found, extending for a distance of about 300 feet, where there was gravel lying on the rock, some 12 or 15 feet in depth. The question arose as to how this was to be cut off, the choice being between steel or wood sheeting, or a cut-off of clay. The author did not favour the use of steel or wood sheeting, if it were at all possible to avoid it, and resort was had to trenching such as is employed in bad ground on sewer construction. The trench was sunk 12 or 15 feet to rock, and filled up with clay, which resulted in very satisfactory freedom from leakage.

The author also drew attention to a method of construction which was used for the first time by the Calgary Power Company on the Bow river in connection with the attachment of concrete walls to earth fill. Those who had had experience in this type of work would know that danger always existed at the contact of the earth fill and concrete structure, and that it was exceedingly difficult to avoid the possibility of leakage developing there. The earth fill invariably shrank away from any vertical face of concrete as the fill dried, and before it became saturated again it would leak. The scheme adopted at the Alexander dam was shown in Fig. 7. At the end of the concrete buttressed sections, two wing walls had been splayed into the earth fill, forming a U section, and these wing walls had not in any respect any vertical face. They were sloped in every direction, so that the earth fill, when sinking, would flow around or be compressed around the concrete. Thus in shrinking, it remained in contact with the concrete.

As regards the installation of a fourth unit, he would point out that the three units installed were quite able to take care of the flow available from the present drainage area, since there was a very high load factor on the Thunder Bay system. Pulp and paper plants used large amounts of power, and the grain elevators provided a summer load, which tended to compensate for the winter peak. Three units thus were ample to use the present flow of the river.

However, it must be noted that there was a possibility of a dam being placed on the Ogoki river at some later date. This river drained the area west and north of Lake Nipigon, and, swinging to the east around the north part of Lake Nipigon, joined the Albany river, which flowed into James Bay. By a dam placed easterly of Lake Nipigon on the Ogoki river, the drainage from 6,000 square miles could be diverted across a height of land from the James Bay watershed into the Great Lakes watershed. A dam, 50 feet high, involving an expenditure of probably one and a half million dollars, would throw an additional 4,000 or 4,500 cubic feet per second through the Jackfish river into the north end of Lake Nipigon, increasing the flow of the Nipigon river by 60 per cent. It was very probable that this would be done in the future, and for that reason space had been left in the station at Alexander for the installation of a fourth unit.

J. H. Hunter, M.E.I.C.[10]

Mr. Hunter inquired whether there was any possibility of a dam across the Albany river.

T. H. Hogg, M.E.I.C.

In reply, the author stated that there was a possibility, but not an economic probability, of a dam across the Albany river, which would throw the Albany, as well as the Ogoki, down through Lake Nipigon. If that were done, it would bring down an additional 12,000 cubic feet per second, but the topography was not sufficiently favourable to justify such a structure. It would also be possible to dam the Albany above the junction point between the Ogoki and the Albany, thus diverting part of the Albany water into the Ogoki and thence into the Nipigon. That, however, was remote. A dam across the Ogoki would not involve the flooding of territory to any great extent, as would the damming of the Albany, and would probably produce only about one hundred square miles of lake area. A dam, 50 feet high and about 500 feet long, would be required. The cost had been estimated at about $400,000 or $500,000; but the site was very inaccessible, some fifty miles from the Canadian National Railways, and material would have to be brought in.

The author would refer to the arrangement described in his paper for driving the governor flyballs, as follows:

> "A three-phase tap has been taken from the armature of the pilot exciter of each generator and run direct to supply the governor flyball motor. This eliminates the necessity of step-down potential trans-

[8] Consulting Engineer, Montreal.

[9] Chief Hydraulic Engineer, Hydro-Electric Power Commission of Ontario, Toronto, Ont.

[10] General Superintendent and Chief Engineer, Canada Starch Company, Montreal, Que.

formers and connections to supply the flyball motors and supplies a potential direct to the flyball motor as soon as the generator is rotated, whether the 12-kv. connections are connected to the generator or not."

The standard practice which had developed in the last few years, and had now become almost universal, was an electrical drive for the flyball head, instead of the mechanical belt drive or gear drive. Such electrical drives had been installed in some fifteen units in the Commission's systems, and had worked very satisfactorily and without any interruption. In these cases, energy for the flyball drive was supplied from the generator leads.

Any change in the speed of the unit would be mirrored at once in the speed of the flyball head. But the difficulty with that arrangement was that until the generator was excited the flyball motor would not rotate. That was not a serious matter, because before the machine reached full speed the generator would be excited. Again, by this arrangement, the governor would operate in accordance with the speed corresponding to the bus frequency and not the speed of the unit, and although these speeds were identical under normal operating conditions, it is conceivable they might be greatly different, in which case the governor would not function properly to perform its duties. In the Alexander plant, this difficulty had been avoided by driving from the pilot exciter with a low frequency drive, thus obtaining generator speed on the flyball head, and this as soon as the machine started to operate.

For steady operation, this was probably satisfactory, but with sudden changes of load, results had not been good; there had been hunting and oversurge. The pilot exciter connection was therefore being replaced by a connection to the main leads.

In reply to Mr. Flitton and Mr. Ottewell, the author pointed out that the reason for making the change was perhaps more of an academic than a practical nature. With the governor drive hitherto in use, the flyballs did not begin to turn until the generator was excited. This did not matter so long as there was excitation before reaching the point of synchronization of the machines. The governor should be operating before the machine got up to speed, and usually there was enough residual magnetism in the machine for this purpose. Thus the objection was more or less academic, as long as all protective equipment operated properly and there was no practical objection to coming off the main leads.

Nevertheless he was heartily in favour of driving the flyball from the pilot exciter if it were possible to do so; perhaps it could be done by getting a higher frequency. But in this particular case a change was being made. There were several other plants using the pilot exciter drive; he believed there were fifteen developments of the International Paper Company, and the Chute à Caron also had it. He considered it a very proper method of handling the matter; it had advantages. But he was not prepared to leave it in Camp Alexander under present conditions, as satisfactory results were not being obtained.

In reply to Mr. Sauer, the author remarked that the clay blanket would not be affected by any discharge through the dam, because the cofferdam which had been put in ahead of the construction of the earth fill dam provided a dead pocket of water. There would be no flow beyond the cofferdam, because the earth fill was a dead structure.

In reply to Mr. Caldwell he stated that there were rigid specifications for the quality of the material to go into the core, and the average on the core ran about 95 per cent through the 200-mesh sieve. As regards the borings, test pits had been put down some 20 feet, so as to get a cross section, in addition to the wash-borings that were made over the area. The results plainly indicated that while there was gravel and sand, it was not in continuous layers; it was in lenses, in which the fine material segregated, which of course was favourable. There was a great deal of clay material below the dam, but it was broken up.

Discussion on "The Technique of Placing Concrete on Steep Slopes Without Forms"

Paper by I. E. Burks [(1)]

J. A. McCrory, M.E.I.C.[(2)]

Mr. McCrory stated that he knew of no industrial organization which had given more practical study to the placement of concrete than that with which the author was connected. Developments along the line which they had finally worked out and had used on the work described constituted a distinct advance.

There were one or two points upon which the author's paper did not touch which should be of interest. One of these concerned the class of concrete that is used in mass work. He understood that in the heavy mass construction, two classes of concrete were used designated as classes "A" and "C." Class "A" concrete, which was placed on the two faces of the dam, tested out to a minimum of 3,000 pounds per square inch compression, and had a water-cement ratio of about 0.9. Class "C" concrete was placed in the interior and was there solely for the mass that it gave to the structure and the strength did not exceed 1,500 to 1,800 pounds per square inch, and he thought had a water-cement ratio of 1.2. The separation of these two classes of concrete was rather easy considering the extremely dry concrete which was used but it would be more difficult in the ordinary type of construction. He believed however that it resulted in a very distinct economy in the structure, and in cases where a large amount of concrete was used, such as the case in question where there was something like 500,000 yards, the saving in cement bulked very largely in the total cost.

Mr. McCrory remarked that another point that impressed him when he first saw photographs of it was the screeding of the concrete on the steep slopes.

He was under the impression that a layer of mortar was spread on the surface in order to obtain a smooth face with the straight edges when screeding. However he had been informed by the author that this was not the case, as the action of the vibrators was depended upon to work the mortar in the concrete to the surface, with the result that the aggregate was close to the surface and the concrete very dense.

Some Problems Connected with Fluid Motion

J. J. Green, A.R.C.Sc., Ph.D., B.Sc., D.I.C.,
National Research Council, Ottawa, Ont.

Presented on April 10th, 1931, before the Aeronautical Section of the Ottawa Branch of The Engineering Institute of Canada (Ottawa Section, Royal Aeronautical Society).

SUMMARY—Theories of fluid motion which have been practically useful in aeronautics assume that the air is frictionless and devoid of viscosity, but model work and the interpretation of results in wind tunnels involve the consideration of viscosity.

The paper first sketches the development of the theory of fluid flow and notes the important results following from Prandtl's hypothesis postulating the existence of a thin layer of fluid close to the body in which the frictional force between adjacent fluid layers is proportional to the velocity gradient normal to the direction of motion.

Starting with the Eulerian equations, the author shows the result of the addition of the viscous term by Stokes and then of Prandtl's modification for the boundary layer, and applies these considerations to the case of two-dimensional flow around circular cylinders.

The author, in his work on this subject at the Royal College of Science, obtained results which show a considerable measure of agreement between the observed boundary layer velocities around a cylinder and the theoretical distribution. From photographs of the air flow around the cylinder it is evident that there is at one point a complete change of flow, and a sheet of discontinuity is formed which breaks up into eddies. This is also in agreement with the mathematical results.

The paper points out that in addition to the consideration of viscosity it will probably be necessary, in dealing with aircraft of a very high speed, to take into account the compressibility of air. This may be ignored as long as the speed is not comparable with the velocity of sound in air, but aeroplanes have already reached a speed of one half that amount and in the operation of high speed air screws it is quite possible to have tip speeds of this order.

The subject of fluid motion, in common with many other fields of human endeavour, has aroused a great interest in the minds of men who have had widely different training.

The mathematician is interested in fluid motion from a philosophical point of view, and in consequence, he has been more engrossed with the behaviour of perfect fluids, which are devoid of compressibility and viscosity, rather than with the real fluids of everyday life which exhibit these properties. It is to be understood that air is included, and, in fact, all gases, in the category of fluids. This attitude of the mathematician need cause no alarm; it is customary for him to amuse himself with the manipulation of quantities which are themselves nothing but mathematical abstractions, having no real existence. In the same way, his perfect fluid has no actual reality, apart from its existence in his own mind, but yet the results deduced from the theory of perfect fluids are of great value when we come to consider the motion of bodies through real fluids, like air.

The physicist, displaying a profound interest in matter in all its forms, has been intrigued by fluid motion and the forces arising in virtue of that motion. He has been able to formulate a theory of viscosity, based on the kinetic theory, which gives a mechanical picture of the way in which viscous forces are generated by the fluid motion, and on the practical side, the exact measurement of the coefficient of viscosity has caused him no little difficulty.

Last of all, we have the engineer, turning a practical eye on the progress of science; he too has been drawn into the problems of fluid motion, in the hope of increasing the efficiency and reducing the running costs of the many devices he has which depend for their action on the flow of fluids.

It is customary, in a paper of this nature, to give a brief history of the subject, and it is necessary to go back nearly two hundred years in order to do this. In the study of fluid motion, the mathematician was the first man in the field, beginning in 1755 and doubtless, as usual, he will have the last word to say in the matter. The physicist was not far behind.

The aeronautical engineer has just got there, and is still somewhat breathless with haste. To him, the problems of fluid motion are of vital importance; the very fact that his aircraft do fly, that his airscrews develop thrust sufficient to overcome the resistance to motion of his aeroplanes, the existence of this resistance itself, are all consequences of the properties of viscous fluids. His task today is not one of producing more stable aeroplanes, for the modern machine does not leave much to be desired as regards stability and manœuverability. His chief problem now is the reduction of head resistance, and the consequent decrease in the minimum horsepower required for flight, together with an increase in top speed. This cannot be achieved until there is a full understanding of the manner in which this resistance arises, and it is here that the mathematician may prove useful to the aeronautical engineer.

The resistance is a direct outcome of the viscous property of fluids, but it is indeed strange that the only theories which can be applied practically to aeronautics assume that the air is frictionless or inviscid, and no theory of viscous fluids is at present useful to us. All model work, however, and interpretation of results in atmospheric wind channels, compressed air tunnels and water tanks depends on the theory of "dynamical similarity" and this involves a consideration of viscosity which is very important in these cases.

Euler gave the first theory of inviscid or perfect fluid flow, in his contribution to the memoirs of the Berlin Akademie in 1755. In the development of the theory of fluid motion, a mathematical definition of viscosity was necessary in order to account for the forces that arose from shearing both in the main mass of the fluid and also where it approached the surface of solid bodies placed in its stream. The mathematicians guessed that viscosity is directly proportional to the shear in fluids and this was subsequently verified by Poiseuille in his well known work on the flow of fluids through tubes.

It was in 1845, nearly a hundred years later, that Sir George Stokes contributed the viscous term to the equations of motion as given by Euler, and thereby established the three equations which imprison the secrets concerning the complete behaviour of real fluids. Since 1845, the equations have existed in unaltered form to the present day, their complexity has baffled mathematicians and in their entirety no solution to them has, as yet, been found.

To return to the perfect fluid theory of the mathematician, it yields the very surprising result that a body in motion through it experiences no resultant force whatever; there is no lift or drag on an aerofoil moving in a perfect fluid. If however, the fluid is endowed with a tendency to circulate round the aerofoil section, a lift force can be developed and the results of the theory based on this conception of the origin of lift agree fairly closely with wind channel experiments. But we still have to explain how the circulation is developed, and further, the theory is incapable of yielding any drag force on the aerofoil. In a real fluid we can look to viscosity for our answers: the viscosity is probably responsible for the circulating tendency and is undoubtedly the factor which governs the creation of the drag force.

It was in 1904 that the next step forward was made in the investigation of these phenomena. Professor Prandtl(1) at Göttingen advanced the hypothesis that there can be no relative motion between a solid and the fluid immediately in contact with it, in other words, the fluid sticks to the surface of the body. This was not generally accepted at first, and a slipping coefficient was suggested but was finally abandoned. The Prandtl hypothesis postulates the existence of a thin layer of fluid close to the body, in which there is intense shearing due to the influence of the solid surface, where the fluid velocity is reduced to zero. Since the frictional force between adjacent fluid layers is proportional to the shear or velocity gradient normal to the direction of motion, it follows that in this thin film of fluid the viscous forces are relatively large, but that outside this "boundary layer" the fluid can be sensibly assumed frictionless, being sufficiently remote from the surface for the shearing to be negligible. This hypothesis presents a revised view of what is happening when a body is moving in a real fluid, and it is seen that there are now two distinct regions in which the conditions existing, and the type of flow resulting, are both dissimilar. At some distance from the body the viscous forces are small, due to the comparative absence of shearing, but the dynamic forces, which depend on the square of the velocity, are large. Without serious error, the fluid in this region can be treated as a perfect fluid—the limiting case of a real fluid whose viscosity has been reduced to zero. Close to the surface of the body is a thin layer where the viscous forces are of the same order of magnitude as the inertia forces.

It has already been stated that viscosity is the responsible factor as far as the creation of drag is concerned and if it is assumed that the viscous forces are confined to the boundary layer, it becomes evident that any search for the mechanism which creates resistance will have to be made in the boundary layer itself.

Not only did Prandtl's theory narrow down the field of enquiry, it also enabled him to simplify the three viscous fluid equations when considering the flow in close proximity to a solid surface. This simplification(2) of the equations when applied to the region known as the boundary layer, stimulated the efforts of mathematicians to find a solution to them, but although twenty-seven years have elapsed since Prandtl first advanced his theory, there are but few solutions existing today, simply because the application of these equations to the flow past a body leads to unmanageable difficulties except in a few special cases. Blasius(3) has solved the equations for the flow along a flat plate where a further simplification can be made in virtue of the fact that the pressure gradient along the surface of the plate can be assumed negligible. Some work also has been done on the flow through pipes. Around curved bodies, the flow conditions are more complex; at least one attempt to perform the solution for the motion of a fluid round an aerofoil has met with failure and efforts have therefore been concentrated on the more simple shape of the circular cylinder. It is some of these attempts to solve the boundary layer equations for two-dimensional flow round circular cylinders that will now be discussed.

The three equations of Eulerian flow(4) which refer to a perfect fluid can be written thus:—

$$\frac{\partial u}{\partial t} + u\frac{\partial u}{\partial x} + v\frac{\partial u}{\partial y} = -\frac{1}{\rho}\frac{\partial p}{\partial x}$$

$$\frac{\partial v}{\partial t} + u\frac{\partial v}{\partial x} + v\frac{\partial v}{\partial y} = -\frac{1}{\rho}\frac{\partial p}{\partial y}$$

$$\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} = 0$$

u and v are the components of velocity parallel to the X and Y axes respectively, ρ is the density of the fluid and $-\frac{\partial p}{\partial x}$; $-\frac{\partial p}{\partial y}$ are the components of pressure along the X and Y axes respectively.

The left hand side of the first two equations has the dimensions of an acceleration, and the right hand side has the dimensions of a force divided by a mass, so that the first two equations are statements of Newton's Second Law of Motion applied to a fluid element. The third equation is the equation of continuity, and depends on the fluid being incompressible; it expresses the fact that there can be no increase or decrease in the quantity of fluid contained in any elementary volume chosen at random in the fluid.

The next step was the addition of the viscous term by Stokes. Consider motion of the fluid parallel to the axis of X. The velocity of a fluid layer relative to a parallel layer unit distance away will be $\frac{\partial u}{\partial y}$ and hence the frictional force between them will be $\mu \frac{\partial u}{\partial y}$ per unit area of the layers, where μ is the coefficient of viscosity. Now consider the viscous forces on an element of fluid $ABCD$ of unit depth normal to the XY plane. At AB (Fig. 1) the shearing is given by $\frac{\partial u}{\partial y}$ and hence at CD its value is

$$\frac{\partial u}{\partial y} + \frac{\partial}{\partial y}\left(\frac{\partial u}{\partial y}\right) . \delta y$$

and the corresponding frictional forces on each face will be

$$-\mu\frac{\partial u}{\partial y} . \delta x \quad \text{and} \quad \mu\left(\frac{\partial u}{\partial y} + \frac{\partial^2 u}{\partial y^2} . \delta y\right) . \delta x$$

since the area of the faces AB and CD is δx .

Hence the resultant force on the element due to viscosity will be

$$\mu\left(\frac{\partial u}{\partial y} + \frac{\partial^2 u}{\partial y^2} . \delta y\right)\delta x - \mu\frac{\partial u}{\partial y} . \delta x = \mu\frac{\partial^2 u}{\partial y^2} . \delta y . \delta x = \mu\frac{\partial^2 u}{\partial y^2}$$

per unit volume or $\frac{\mu}{\rho}\frac{\partial^2 u}{\partial y^2}$ per unit mass, but $\frac{\mu}{\rho}$ is the kinematic coefficient of viscosity ν .

A similar force $\nu \frac{\partial^2 u}{\partial x^2}$ will be experienced by the element due to variation of u with x and in addition there will be similar forces depending on motion parallel to the Y axis.

Hence the total force on the boundaries of the element due to viscosity will be

$$\nu\left(\frac{\partial^2 u}{\partial x^2} + \frac{\partial^2 u}{\partial y^2}\right) = \nu \nabla^2 u \text{ in the } X \text{ direction}$$

and $\nu \nabla^2 v$ in the Y direction.

The three viscous fluid equations as given by Stokes are then

$$\left.\begin{aligned}
\frac{\partial u}{\partial t} + u\frac{\partial u}{\partial x} + v\frac{\partial u}{\partial y} &= -\frac{1}{\rho}\frac{\partial p}{\partial x} + \nu\nabla^2 u \\
\frac{\partial v}{\partial t} + u\frac{\partial v}{\partial x} + v\frac{\partial v}{\partial y} &= -\frac{1}{\rho}\frac{\partial p}{\partial y} + \nu\nabla^2 v \\
\frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} &= 0
\end{aligned}\right\}$$

In steady motion, the terms $\frac{\partial u}{\partial t}$, $\frac{\partial v}{\partial t}$ are zero. Before imposing Prandtl's modification for the boundary layer on a cylinder, it is convenient to put the equations in a non-dimensional form by dividing lengths and velocities by representative values of length and velocity.

If lengths are all expressed as fractions of 'd' the diameter of the cylinder, velocities as fractions of the channel speed 'V', and if pressures are all measured as fractions of ρv^2, the equations become

$$\left.\begin{aligned} u\frac{\partial u}{\partial x} + v\frac{\partial u}{\partial y} &= \frac{1}{R}\nabla^2 u - \frac{\partial p}{\partial x} \\ u\frac{\partial v}{\partial x} + v\frac{\partial v}{\partial y} &= \frac{1}{R}\nabla^2 v - \frac{\partial p}{\partial y} \\ \frac{\partial u}{\partial x} + \frac{\partial v}{\partial y} &= 0 \end{aligned}\right\}$$

where $R = \frac{Vd}{\nu}$ = Reynold's number.

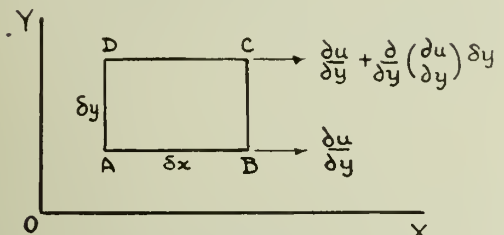

Fig. 1.

In the case of a circular cylinder it is more convenient to express these in curvilinear co-ordinates. With the axes as shown in Fig. 2, s denoting distance round the cylinder, r distance normal from the surface, and velocities w and q signifying radial and tangential velocities respectively, the equations transform to:—

$$\left.\begin{aligned} &-q\,.\frac{\partial q}{\partial s} - w\,.\frac{\partial q}{\partial r} - w\,.\,q\,.\frac{\partial \alpha}{\partial s} \\ &\quad = \frac{1}{R}\left\{-\frac{\partial^2 q}{\partial s^2} + q\,.\left(\frac{\partial \alpha}{\partial s}\right)^2 - 2\frac{\partial w}{\partial s}\,.\frac{\partial \alpha}{\partial s} - \frac{\partial q}{\partial r}\,.\frac{\partial \alpha}{\partial s} - w\,.\frac{\partial^2 \alpha}{\partial s^2} - \frac{\partial^2 q}{\partial r^2}\right\} + \frac{\partial p}{\partial s} \\ &q\,.\frac{\partial w}{\partial s} + w\,.\frac{\partial w}{\partial r} - q^2\,.\frac{\partial \alpha}{\partial s} \\ &\quad = \frac{1}{R}\left\{\frac{\partial^2 w}{\partial s^2} - w\,.\left(\frac{\partial \alpha}{\partial s}\right)^2 - 2\frac{\partial q}{\partial s}\,.\frac{\partial \alpha}{\partial s} + \frac{\partial w}{\partial r}\,.\frac{\partial \alpha}{\partial s} - q\,.\frac{\partial^2 \alpha}{\partial s^2} + \frac{\partial^2 w}{\partial r^2}\right\} - \frac{\partial p}{\partial r} \\ &\frac{\partial q}{\partial s} + \frac{\partial w}{\partial r} + w\,.\frac{\partial \alpha}{\partial s} = 0 \end{aligned}\right\}$$

These look very formidable, but fortunately Prandtl's approximations greatly reduce this complexity. His first condition is that R is supposed large compared with unity. This is usually true in wind channel work with cylinders where R is of the order of 100,000.

His second assumption is that q is large compared with w the normal velocity, and is true if the motion is laminar. Lastly derivatives with respect to r are supposed large compared with those with respect to s. This is experimentally satisfied.

With these assumptions, the equations reduce to

$$\left.\begin{aligned} -q\,.\frac{\partial q}{\partial s} - w\,.\frac{\partial q}{\partial r} &= -\frac{1}{R}\,.\frac{\partial^2 q}{\partial r^2} + \frac{\partial p}{\partial s} \\ 0 &= \frac{\partial p}{\partial r} \\ \frac{\partial q}{\partial s} + \frac{\partial w}{\partial r} &= 0 \end{aligned}\right\}$$

The second equation states that the boundary layer transmits normal pressures on it unaltered and we can therefore assume $\frac{\partial p}{\partial s}$ to be sensibly independent of r.

These then, are the equations to be solved, and the solution will give the tangential velocity q in terms of r and s for all positions round the cylinder, and will indicate the value of w the normal velocity.

Dr. Thom[5] at the University of Glasgow attempted a step by step solution, but after the first twenty degrees round the cylinder, an examination of his results suggested a new method of attack. He noticed that at any definite distance from the surface of the cylinder, the ratio $\frac{q}{v}$ was nearly independent of s, the distance round the cylinder, where v denotes the velocity just outside the boundary layer at the section being considered.

As a first approximation then, he assumed that $q = vx$ where x is a function of n only, n denoting values of r beyond the surface of the cylinder, that is, distances measured normal to the surface through the boundary layer. Also in his first approximation he neglected the term $w\,.\frac{\partial q}{\partial r}$ since w the normal velocity is a small quantity.

Then if, $q = vx \qquad \frac{\partial q}{\partial n} = v\,.\frac{dx}{dn}$

$$\frac{\partial^2 q}{\partial n^2} = v\,.\frac{d^2 x}{dn^2} \qquad \frac{\partial q}{\partial s} = x\,.\frac{dv}{ds}$$

and by differentiation of Bernoulli's equation for constancy of total head we get

$$\frac{dv}{ds} = -\frac{1}{\rho v}\,.\frac{dp}{ds}$$

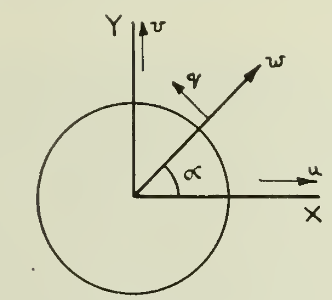

Fig. 2.

Substituting these values in the dimensional form of the first boundary layer equation, remembering that

$$\frac{\partial}{\partial r} = \frac{\partial}{\partial n}$$

and dividing by v yields

$$\frac{dv}{ds}x^2 - \frac{dv}{ds} = \nu\frac{d^2 x}{dn^2}$$

This can be integrated twice to give a relation between n, and x or $\frac{q}{v}$, the boundary conditions giving the appropriate constants of integration. Hence the solution gives the distribution of velocity through the boundary layer at the various positions round the cylinder. It was found that this did not give as good agreement with experimental observations of boundary layer velocities as the original step by step method of solution, but this was only to be expected from the nature of the initial assumptions. Thom therefore examined the neglected terms and modified his solution to make allowance for the errors involved in his first assumptions. The term $w \frac{\partial q}{\partial n}$ was included, and also a term $\frac{\partial x}{\partial s}$ to allow for variation of x, and hence q, with s.

His final solution appears in the form

$$n = \sqrt{\left(\frac{r\nu}{\sqrt{h}}\right)}\, F(x)$$

where $F(x)$ is a complicated function of x, r is the radius of the cylinder, V is the channel speed, and h is an expression involving $\frac{dp}{ds}$ the pressure gradient. This solution agrees well with experimental measurements over its range of application. The thickness of the boundary layer is given in the form $\delta = c \sqrt{\dfrac{\nu}{\frac{dv}{ds}}}$ where c is the value of $F(x)$ at the outside edge of the layer.

It is evident that where the velocity gradient $\frac{dv}{ds}$ becomes small or negative the solution is no longer valid, since this quantity appears under the root sign, and this occurs in the neighbourhood of 55° to 60° round the cylinder for $R = 10^5$.

In solving the equations it is necessary to make some initial assumption concerning the character of the velocity q. Thom suggested q a function of n only, and later modified the assumption to q a function of n and s. Falkner and Skan[6] have derived a particular solution of the boundary layer equations for the case where the tangential velocity outside the boundary layer can be expressed as $v = ks^m$

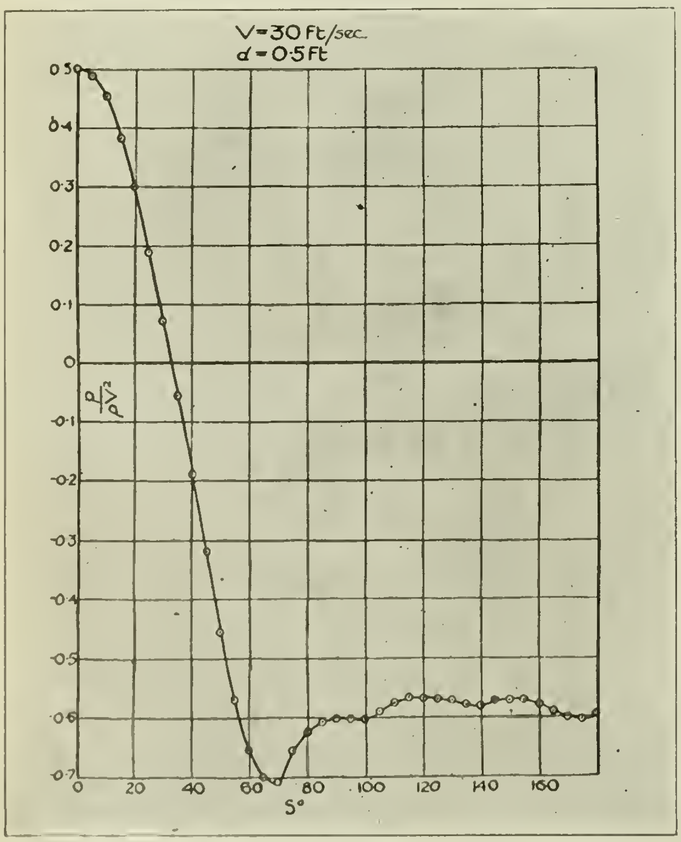

Fig. 3.

where k and m are constants. They showed that Blasius' solution for a flat plate is a particular case of this solution when $m = 0$. For a circular cylinder they claim that m is unity at the stagnation point and very nearly unity over a considerable range on the front portion of the cylinder. The particular solution is used as a basis for two approximate solutions of the boundary layer equations in the general case and comparison between experiment and calculation is made for a plate, circular cylinder and an aerofoil.

A method tried by the author at the Royal College of Science[7] was to assume a solution which expressed q as a power series in n and s and by substitution in the equations evaluate the coefficients.

The initial assumption was that

$$qR = nf_0 + \frac{n^2}{\lfloor 2}f_1 + \frac{n^2}{\lfloor 3}f_2 + \ldots\ldots = \sum_{\alpha=1} \frac{n^\alpha}{\lfloor \alpha} f_{\alpha-1}$$

R = Reynold's Number, f_0, f_1, etc. are functions of s only and n represents values of the radial co-ordinate measured from the surface out into the boundary layer. By differentiation of this equation, at the surface of the cylinder we get $f_0 = R\left(\frac{\partial q}{\partial n}\right)_{n=0}$ and since $\left(\frac{\partial q}{\partial n}\right)_{n=0}$ is the velocity gradient at the surface, f_0 is a measure of the skin friction.

Combining the initial assumption with the equation of continuity yields

$$\frac{\partial}{\partial n} wR = -\frac{\partial}{\partial s} qR = -\sum_{\alpha=1} \frac{n^\alpha}{\lfloor \alpha} \cdot \frac{\partial}{\partial s} f_{\alpha-1}$$

hence

$$wR = -\sum_{\alpha=1} \frac{n^{\alpha+1}}{\lfloor \alpha+1} \cdot \frac{\partial}{\partial s} f_{\alpha-1}$$

and

$$\frac{\partial}{\partial n} qR\ ;\ \frac{\partial^2}{\partial n^2} qR,$$

can be got from the initial assumption by directly differentiating.

Multiplying the first boundary layer equation throughout by R^2 gives

$$-qR \cdot \frac{\partial}{\partial s} qR - wR \cdot \frac{\partial}{\partial n} qR = -\frac{\partial^2}{\partial n^2} qR + R^2 \frac{\partial p}{\partial s}$$

and substituting the various values derived from the initial assumption yields an expression which ean be written as

$$-\sum_{\alpha=2} n^\alpha \sum_{\beta=1} f_{\beta-1} \cdot f'_{\alpha-\beta-1} \cdot \frac{\alpha - 2\beta + 1}{\lfloor \beta \cdot \lfloor \alpha-\beta+1} = \sum_{\alpha=0} n^\alpha \cdot \frac{f_{\alpha+1}}{\lfloor \alpha} + R^2 \cdot \frac{\partial p}{\partial s}$$

The dashes denote differentiation with respect to s. The coefficients in the equation for qR are then easily deduced by giving α and β successive values in this expression, thus:

$\alpha = 0$ gives $f_1 = R^2 \cdot \frac{\partial p}{\partial s}$

$\alpha = 1$ $\quad f_2 = 0$

$\alpha = 2$ $\quad f_3 = f_0 f_0'$

$\alpha = 3$ $\quad f_4 = 2f_0 f_1'$

$\alpha = 4$ $\quad f_5 = 2f_1 f_1'$

$\alpha = 5$ $\quad f_6 = 4f_0^2 f_0'' - f_0 (f_0')^2$

⋮

etc.

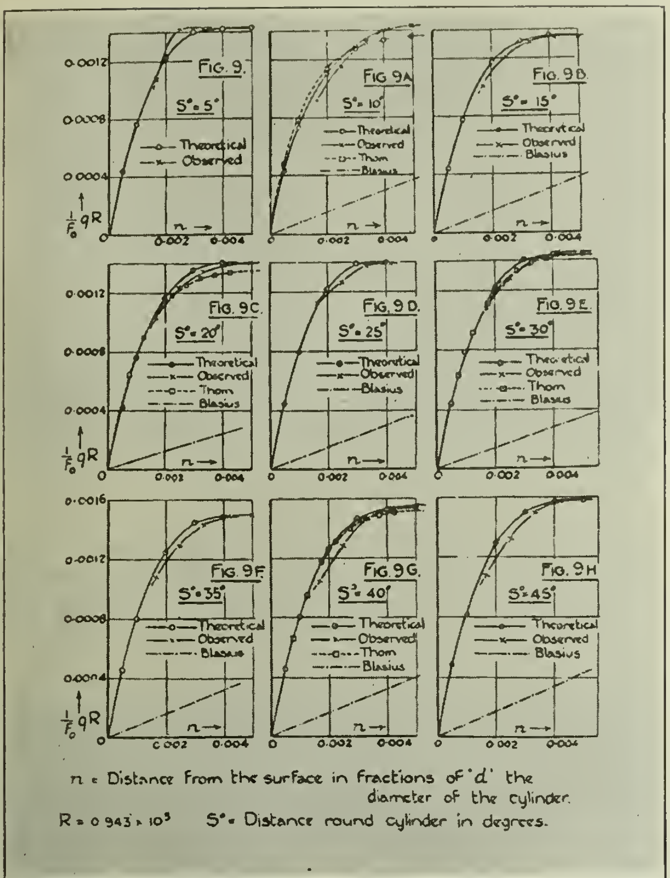

Fig. 4.

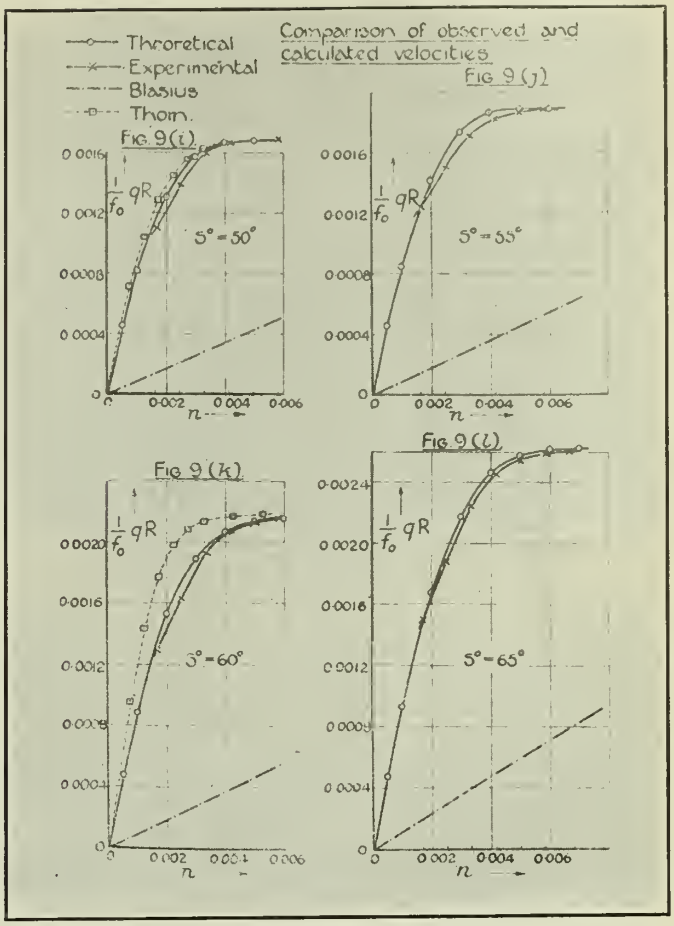

Fig. 5.

The last term employed was

$$f_9 = 7f_0{}^3f_0{}''' - 24f_0{}^2f_0{}'f_0{}'' + 27f_0(f_0{}')^3 + 40f_1{}^2f_1{}'' - 16f_1(f_1{}')^2$$

Hence all the coefficients needed in the solution are expressible in terms of f_0, f_1 and their derivatives with respect to s. Inserting these values in the expression for qR and differentiating gives

$$\frac{1}{f_0}\cdot\frac{\partial}{\partial n}\,qR = \left(1 + n\,.\frac{f_1}{f_0}\right)\left(1 + \frac{n^4}{\lfloor 5}\,.\,2f_1{}'\right) + \frac{n^3}{\lfloor 3}\,.f_0{}' + \frac{8n^4}{\lfloor 5}f_1{}' + \ldots\ldots$$

The method of solution was then to evaluate the f coefficients, which are now known in terms of f_0, f_1 and their derivatives, for each step round the cylinder, insert in this last equation, plotting the values of $\frac{1}{f_0}\,.\,\frac{\partial}{\partial n}\,qR$ for various values of n. Integration would then yield $\frac{1}{f_0}\,.\,qR$ giving the theoretical velocity distribution through the layer for that position on the cylinder.

The above analysis revealed that $f_1 = R^2\frac{\partial p}{\partial s}$, and $\frac{\partial p}{\partial s}$ the pressure gradient round the surface of the cylinder was derived experimentally by measuring the pressure distribution. This was done in the usual way using a micromanometer. Only one pressure hole was drilled in the cylinder at its mid section, and rotation of the cylinder on the trumpet of the wind channel balance enabled the pressure to be measured at any desired position round the cylinder. Fig. 3 shows the pressure plotted as fractions of ρV^2 against S. It will be noticed that the pressure falls to a minimum value, after which there is a reversal in the direction of the pressure gradient. The values of the functions f_1, $f_1{}'$ and $f_1{}''$ are obtained by successive differentiation of this curve employing a graphical method and it only remains to evaluate f_0 and its derivatives before the solution is complete.

Near the stagnation point or 0° position it is easy to obtain a close approximation to the value of f_0 by restricting the number of terms in the series value of qR. Similarly it was possible to obtain two approximations for $f_0{}'$ the first derivative at this position, which agreed quite closely; $f_0{}''$ at this position was deduced in a more laborious fashion which will not be discussed here.

Having obtained approximate values for the f_0 coefficients at 0° their values at 5° were deduced by a Taylor's expansion

$$(f_0)_{s+ds} = (f_0)_s + ds\,.\,(f_0{}')_s + \frac{ds^2}{\lfloor 2}\cdot(f_0{}'')_s + \frac{ds^3}{\lfloor 3}\cdot(f_0{}''')_s + \ldots\ldots$$

Similarly the values of $f_0{}'$ and $f_0{}''$ at 5° were extrapolated and the nature of the method was such that the error in the values of the functions was reduced at every step made round the cylinder.

It was necessary to guess a value for $f_0{}'''$ at each position round the cylinder. In practice three different values are guessed, which it is hoped will enclose the correct value. These guesses are arrived at by inspection of the f_0 and $f_0{}'$ curves which are known up to the preceding point. For

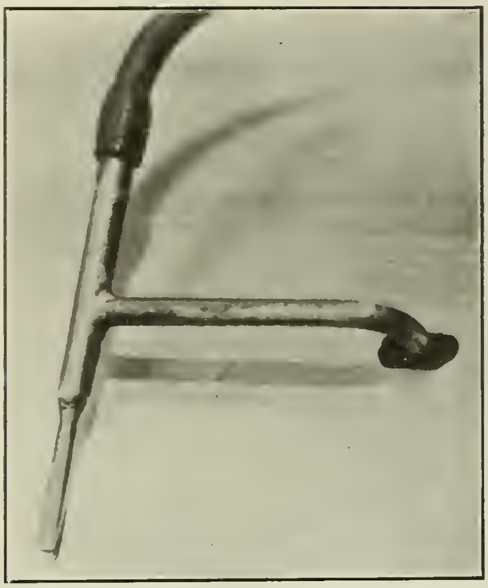

Fig. 6.

each of the guessed values, the entire number of f coefficients are evaluated and the equation for $\frac{1}{f_0} \cdot \frac{\partial}{\partial n} qR$ solved for f_0. The three values for f_0 are then compared with the initial assumed values, and the correct value of f_0''' is that which makes the initial and final values of f_0 the same. The usual method was to plot the two values of f_0 against the corresponding values of f_0''' and the point of intersection of the two curves gives the true value of f_0''' with considerable accuracy.

Having determined the correct value of f_0''' the computation is repeated to give the correct solution, and the distribution of velocity through the boundary layer is plotted before advancing to the next point round the cylinder.

Figs. 4 and 5 show comparison between observed boundary layer velocities and the theoretical distribution, and it will be seen that on the whole the agreement is good.

The small pitot tube which was used for exploring the velocity distribution experimentally is shown in Fig. 6. It consists of a one-half inch length of hypodermic syringe needle let into a one inch length of larger bore tube. The finer tube was flattened at the end, to yield a slot of an approximate width of one-fiftieth of an inch.

It was found that the solution entirely failed at 73° round the cylinder. The skin friction was found to be falling

Fig. 7.

rapidly from about 50°, likewise a very rapid reduction in the value of q, the tangential velocity, was found to exist over the same range. The normal velocity w had been steadily growing until finally it was comparable with the falling value of q, which indicates a failure of Prandtl's second assumption. The mathematics indicates a change of flow at this point. Prandtl's hypothesis no longer holds, and the fluid, ceasing to flow along the surface, is tending to flow away from the surface. The boundary layer is breaking away.

The fluid near the surface is moving very slowly, but whilst the pressure gradient is in the direction of main stream flow, it will continue to move in that direction. After the point of minimum pressure (69°), the speed of the fluid is reduced owing to the reversal of the pressure gradient, acting in conjunction with the viscosity, and further round the cylinder there is a tendency to back-flow, the effect of which is to force the forward flowing layer to leave the surface and a sheet of discontinuity is formed which ultimately breaks up into eddies.

Fig. 7 shows a closeup of the breakaway of the boundary layer and the formation of a sheet of discontinuity.

Fig. 8 shows back-flow along the surface of a cylinder behind the point where the boundary layer breaks away.

Both of these two photographs were secured with the aid of titanium tetrachloride smoke.

Fig. 8.

In conclusion, the fact should be stressed that the effects of viscosity are twofold and the hope of future advancement is based on the possibility of controlling this duality. The direct effect of viscosity is that it induces a viscous drag over the surface of bodies in motion through the fluid: this is usually referred to as skin friction and is not of very great magnitude. The indirect effect of viscosity is to cause complications of the flow pattern past bodies, which greatly affects their resistance. As has been seen, the viscosity, by slowing up the fluid particles, causes the boundary layer to leave the surface, resulting in a stagnant wake and two sheets of discontinuity which, being unstable, break up into a succession of eddies, forming what is known as a Kármán vortex street, named after von Kármán who studied this type of flow[8]. Figs. 9 and 10 show the formation of a vortex street behind an elliptic cylinder moving in a water channel, the flow being rendered visible by a suspension of white particles, obtained from a mixture of condensed milk and alcohol which was poured into the water. Now the drag due to these eddies is called the form drag, which, together with skin friction, makes up the profile drag of two dimensional motion. The form drag depends on the shape of the body, being negligible for a well streamlined body like a good aerofoil, where the vortex wake is small; in such a case the profile drag is composed mainly of the skin friction. For a bluff body, the vortex

Fig. 9.

wake is strong and hence the form drag, which depends on the energy dissipated in the vortices, is very much larger than the skin friction. Once more the mathematician is able to chime in and calculate the form drag, from a knowledge of the strength of the eddies and the width of the vortex street, but this again is based on the assumption that the fluid is perfect or frictionless.

It is not always possible so to streamline bodies that the form drag is negligible. We are still a long way from the streamlined aeroplane of theory. In a perfect fluid there is no drag, the stream divides at the nose of a body, flows smoothly round the contour of the body however bluff, and rejoins at the tail. If the breaking away of the boundary layer could be prevented when dealing with the fluids of everyday life, if it could only be coaxed, however unwillingly, to stick closely to the contours of bodies that are not well streamlined, the vortex street would be eliminated in those cases, and the resistance would be enormously reduced. The viscous drag would still be left, but viscosity would have been robbed of its trigger action in setting up the larger eddy resistance. Thus it is now a problem to discover means of restraining the contrariness of the boundary layer in its efforts to break away. One method of controlling the breakaway of the flow which has been more or less successful is to suck away air at suitable points near the tail of bodies, thus causing the flow to collapse back on to the surface. The principle has been demonstrated, but the method is doubtful as a practical means of reducing head resistance. The Handley Page slot and the Townend ring are two successful inventions which do actually prevent the breakdown in flow in special cases, and doubtless more devices of this nature will be forthcoming. A field of research still exists for the further examination of the flow conditions at the point of breakaway as well as those existing in the wake of bodies, in order to understand fully the breakdown in flow, and what possibilities there are of preventing it.

The large part played by viscosity in the behaviour of real fluids as compared with the perfect fluid of the mathematician has been indicated. With the growth of aeronautics, a new problem has arisen. It is enough at present to consider the air as a viscous incompressible fluid as far

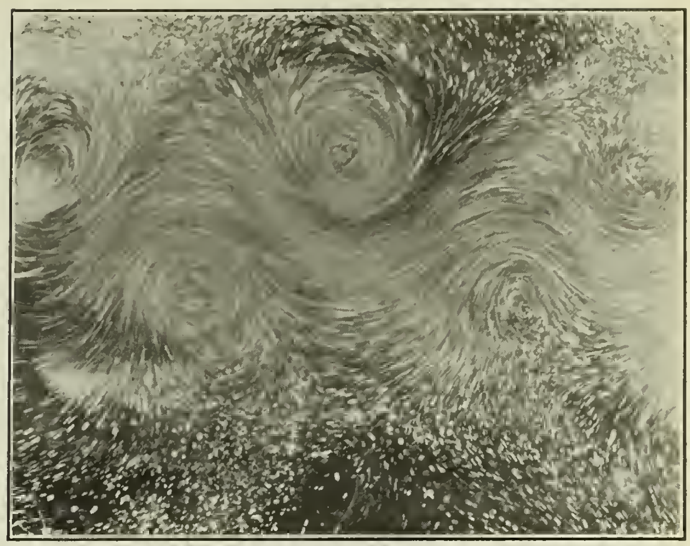

Fig. 10.

as aircraft are concerned, but with the rise in top speed of these machines, it seems reasonable that the compressibility of the air will have to be taken into account in our fluid theory. It is well known that the compressibility may be ignored as long as the speed is not comparable with the velocity of sound in air, but already a speed one half of that value has been reached, and nobody would suggest that this is the limit. Further, in the operation of high speed airscrews, it is quite possible to have tip speeds in the neighbourhood of the velocity of sound, in which case the air flow round the blades will be complicated by the rising significance of compressibility, and a detailed study of high speed air flow cannot fail to be beneficial to design. Work on these lines is already in progress in England and a number of new problems are facing the research worker in the realms of fluid motion. It is to be hoped that the solution of these problems will not only be of academic interest, but will prove useful to the aeronautical engineer.

VOLUME XIV JUNE 1931 No. 6

The National Research Council of Canada

The Thirteenth Annual Report of the National Research Council for 1929-1930 has just been issued, and gives an interesting review of the Council's activities. During the early period of its existence, from 1916 to 1924, the work of the Council was mainly directed towards relieving the shortage of scientifically trained men which the country was then experiencing. This was done by the establishment of post-graduate research scholarships in the universities, while at the same time advisory committees were appointed in some of the more important branches of science and technology in order that the Council might have the benefit of their advice in extending its operations.

Since 1924 a large number of associate research committees have been appointed, directing investigations on major problems of importance to the country, and in addition, pending the provision of accommodation for national research laboratories, arrangements have been made for assisting co-operative research in the laboratories of federal and provincial government departments and the universities.

As at present organized, the National Research Council reports to a special Committee of the Privy Council, and, while continuing the support of assisted researches and more than sixty post-graduate scholarships at the universities, is building up its own staff of investigators, which is at present organized under three main divisions—Physics, Chemistry, and Agriculture.

It is expected that the laboratories and offices of the Council will be transferred shortly to the new building now approaching completion in Ottawa on Sussex street, the accommodation in which will be supplemented by the space already available in the aeronautical and other laboratories now existing in the older buildings on the Edwards property in John street.

The Council's revenue of less than $500,000 a year is very modest compared with the sums available for research in other countries, the United States Bureau of Standards, for example, having expended nearly three million dollars during the year 1929-30.

The Council has at present over one hundred assisted researches in progress, dealing with such varied topics as catalysts, the utilization of natural gas, the chemistry of fish curing, the chemical control of weeds, the cross-breeding of sheep, and the continuity of welded steel beams, taking half a dozen titles almost at random. To this work the Council has been devoting the greater part of its expenditure (about $220,000 in 1929-30), and the co-operation of twenty-eight associate committees, acting in an advisory capacity without remuneration, whose membership includes the best available industrial and scientific authorities. These associate committees, in their turn, co-operate with industrial and other organizations interested in their special subjects.

One branch of the Council's work which is of special interest to The Institute is that of the committee which is carrying on and continuing investigations on the constitution of Portland cement, and the deterioration of concrete in alkali soils. It will be remembered that this work was taken over by the Council from one of The Engineering Institute committees in 1929, and that it deals with a very pressing problem for western Canada where the losses due to the deterioration of concrete are so serious. Gratifying progress has been made in the last two years, as may be seen from the report.

The Research Council is also greatly interested in engineering standardization work, the Canadian Engineering Standards Association ranking as one of its associate committees. Engineers are, in fact, largely indebted to the National Research Council for the possibility of carrying on the work of the Canadian Engineering Standards Association in its present effective form. In a country like Canada, where many industrial concerns are branches of non-Canadian companies, and therefore carry on their industrial research elsewhere, it is particularly important to have a Canadian organization with the staff and funds to undertake the investigation of purely Canadian problems. Until the establishment of the National Research Council this task fell upon individual government departments, the already overworked staffs of our universities, or upon individual investigators, for whom adequate support was lacking. This condition has now been removed, and it is indeed encouraging to note the continued expansion of the Council's external activities, which are proving increasingly beneficial both from the industrial and scientific points of view.

Proposed Amendments to Sections 66 and 67 of the By-laws

The report of the scrutineers on the ballot closing May 4th, 1931, on the amendments proposed by Council to Sections 66 and 67 of the By-laws, was presented to Council at its meeting on the 19th instant, and showed that of 729 valid ballots, 257 were for and 472 against the proposal.

The amendments in question, dealing with the constitution of the Nominating committee, were therefore declared lost.

Aeronautical Sections of Institute Branches

On the completion of the arrangements with the Royal Aeronautical Society which were described in the Engineering Journal for December, 1930, page 696, notifications were sent to a large number of engineers interested in aeronautical work throughout Canada, and over five hundred and fifty replies were received, indicating a widespread interest in the proposal to organize aeronautical engineers in Canada in this way.

Aeronautical sections have now been formed in connection with the Montreal and Ottawa Branches, and these will probably be followed by others. Such sections, in accordance with the agreement with the Royal Aeronautical Society, will be recognized as Canadian local sections of that body, and their members will have access to the Royal Aeronautical Society publications, and an opportunity for obtaining wider publicity for papers which they may contribute than can possibly be afforded in the columns of any Canadian publication.

Members of The Institute of all classes will wish success to this new undertaking, which marks a new and promising development in the policies of The Institute and of the Royal Aeronautical Society.

Engineers in Russia

The remarkable industrial experiment which is being tried on such a vast scale in Russia is of great interest to engineers, for it has been found necessary to enlist the aid of a large number of technically trained men from capitalist countries to plan and operate various engineering projects in the U.S.S.R.

The employment of engineers in the development of the resources of foreign lands is not uncommon, but, as a rule, when leaving their own countries, they go to others where living and employment conditions are known, and where social institutions are more or less similar to those to which they are accustomed. This is not the case at the present time in Russia. The many reports and articles which have appeared in the public press on conditions in that country leave the impression that non-Russian engineers are meeting there with considerable difficulty and hardship.

Recognizing the general interest in this matter, the national engineering societies in the United States have recently devoted attention to a study of the conditions under which professional and technical men are employed in Russia, and statements have now been issued containing valuable information for the guidance of those contemplating employment there. In these reports stress is laid on the fact that the form of government in Russia is different from that of any other country, and that the vast mass of Russians are living, and have been living for some years, under conditions with which few residents of other countries would be content.

A very interesting report on engineering employment in Russia, prepared by a committee of the American Society of Civil Engineers, appears in the May issue of "Civil Engineering" and is based on the personal experiences of engineers who have worked in the U.S.S.R.

A somewhat similar report, drawn up by a committee appointed by the American Institute of Mining and Metallurgical Engineers, appears in the April issue of "Mining and Metallurgy," from which the following significant extracts are reproduced here by permission:

Living Conditions

a. Food, generally speaking, is scarce; some of very poor quality. It is extremely expensive unless bought at government stores with a government food card. While conditions are not uniform throughout Russia, in Moscow and Leningrad long lines of people are obliged to stand in front of these stores waiting to enter.

In certain places the government has opened special stores for foreign employees. Accounts differ as to how satisfactory conditions are in these stores. Undoubtedly these vary in different districts.

The importation of food as a general proposition is forbidden unless it is agreed upon in the employment contract or arranged for by the contractor or the head of a group. Here again, opinions differ as to whether importation of food is feasible even if agreed upon. This apparently indicates the advantage of employment of engineers by large American engineering firms or contractors, rather than the taking of independent employment.

b. Housing conditions. In cities such as Moscow there is a great shortage of accommodations. In other districts there is said to be no shortage.

c. Articles of clothing, shoes, etc., are difficult of purchase, of poor quality and expensive, throughout Russia.

d. Other conditions, such as medical attendance, hospitals, etc., vary greatly in different parts of Russia, but nowhere are these facilities said to be good, except possibly those provided by some American contractors or engineering organizations operating on a large job.

Without question, an engineer should not take children into Russia. Most people familiar with conditions there strongly advise against the taking of wives, unless they be strong, healthy, robust individuals, accustomed to discomforts and inclined to enjoy overcoming difficulties and the fighting of adverse conditions.

Legal Status and Personal Safety

a. An individual accepting employment under the Soviets must appreciate that he is working for an autocratic government.

Adequate reasons may develop for the breaking of a contract, but still the government has the arbitrary power to take away passport and food card, and/or prevent the employee from leaving the country. In such case great difficulty may be experienced in subsisting. The engineer may be fined or forced to do menial work in punishment for alleged breaking of his contract.

b. Fear is entertained that, if the five-year plan should not eventuate as represented to the people, or if some plant or installation should fail to deliver anticipated results, the Soviets will seek a "scapegoat." If so, who would be more suited to the role than the foreign engineers in charge of that particular piece of work? Many people have been executed or imprisoned as "scapegoats."

Recommendations in the Event of Accepting Service

If he decides that his particular situation is such that he must accept Russian work regardless of the known unfavourable conditions, then he should if possible give preference to employment with some large American contractor or engineering firm, rather than attempt an individual contract with the U.S.S.R.

While the matter of performance of an employment contract by the Soviets is a matter of faith, on account of the impossibility of bringing any dispute before an American court, still as far as we know they have thus far shown a disposition to live up to the letter of the contract. This being so, it becomes important that the contract terms should embrace every possible contingency. No dependence whatever should be placed on verbal statements or assurances. It has been found repeatedly that assurances made here have no force whatever when the employee arrives in Russia.

Whether going as an individual or as a member of a group, one should see that the following points, among others, are provided for:

a. Adequate provision for first-class transportation and expenses from America to place of employment and return.

b. The extent to which payments will be made in dollars in the United States and rubles in Russia. He should insist on receiving as large a portion as possible, certainly not less than 50 per cent of his remuneration, in dollars, to be deposited or paid as directed in the United States. It must be remembered that foreign money can be brought out of Russia only to the extent to which it was taken in, less the amount the authorities decide he should have spent while in Russia. After residing in Russia for a certain length of time, no foreign money can be taken out. While a certain amount in Russian currency can be sent out, it has only a greatly depreciated value in foreign countries.

c. Amount of money the engineer will be required to spend in Russia. Visitors to Russia are required to spend a certain minimum per day, and the engineer should inform himself to what extent these regulations apply in his case.

d. A non-resident citizen is subject to our Federal income tax, but should be free from taxation by the Soviet government on amounts deposited in this country to the citizen's credit. A definite understanding should be had as to the amount of taxes on salaries paid in Russia as well as on all other taxes.

e. Provision of living quarters, domestic servants, water, heating, light, cooking and sanitary arrangements, either free of charge or at a definite price.

f. Fuel for heating and cooking and price thereof.

g. Supply of food and privilege of purchasing food, clothing and other supplies at commissaries established for foreign diplomats and engineers.

h. Privilege in regard to taking in and importing into Russia later, foodstuffs, clothing, toilet articles, etc., free of duty, coupled with guarantee of arrival.

i. Outlining of duties and responsibilities of service to be rendered.

j. The conditions under which employees are privileged to resign with safe conduct and expenses back to the United States, etc.

k. Discontinuance at one job not to give Soviet the privilege of transference to another.

l. Various Soviet industrial organizations operating through Amtorg Trading Corporation in New York, engage American engineers and technicians to work in Russia. As there are no relations between the government of the United States and that of the Soviet Union, the signature of the Amtorg for itself as an American corporation should always be obtained to any contract.

The thanks of the engineering profession are due to the societies responsible for these reports, which should be carefully studied by anyone who thinks of proceeding to Russia in the near future.

Meeting of Council

A meeting of Council was held at Headquarters on Tuesday, May 19th, 1931, at eight o'clock p.m., with Vice-President W. G. Mitchell, M.E.I.C., in the chair, and six other members of Council present.

The early part of the meeting was taken up with discussion regarding the formation of specialized sections of Institute branches in connection with military and radio engineering, representations being made in connection with these subjects by Lt.-Col. W. L. Malcolm, M.E.I.C., and Lt.-Col. W. A. Steel, A.M.E.I.C., who attended by invitation.

Attention was drawn to the satisfactory working of the arrangement already concluded with the Royal Aeronautical Society, and it was decided to place the whole subject in the hands of a committee for study, the committee's report, if possible, to be available for consideration at the Plenary Meeting of Council in September. It was decided that the committee should be asked to study the general question of co-operation or affiliation with other technical societies with a view to the adoption of a uniform policy in dealing with problems of this kind.

It was decided that the Plenary Meeting of Council for 1931 should be held on Monday, Tuesday and Wednesday, September 21st, 22nd and 23rd, 1931.

The report of the scrutineers appointed to canvass the ballot for the proposed amendments to Sections 66 and 67 of the By-laws was received, from which it was noted that the proposed amendments in question were lost by a considerable majority.

The membership of the Past-Presidents' Prize committee of The Institute for the year 1931 was approved as follows:

C. M. McKergow, M.E.I.C., Chairman
F. A. Combe, M.E.I.C.
E. F. Fetherstonhaugh, M.E.I.C.
T. R. Loudon, M.E.I.C.
J. B. Porter, M.E.I.C.

The Finance committee submitted a memorandum pointing out the unsatisfactory results of the present procedure with regard to members in arrears of fees. The Finance committee suggested that this question should receive early consideration from Council and that it should form one of the subjects for discussion at the Plenary Meeting.

The subjects proposed for the Past-Presidents' Prize competition for the prize year 1931-1932, as submitted by the various branches, were considered, and after considerable discussion it was resolved that the subject for the above named prize year, ending on June 30th, 1932, should be "The Effect of the Development of the Electronic Valve on Electrical Engineering and Industry."

Recommendations for the award of the Sir John Kennedy Medal for the year 1931 were presented from five of the branches of The Institute, and, after discussion, it was unanimously resolved that no award of the medal should be made this year.

In accordance with Section 13 of the By-laws, on the recommendation of the Executive committee of the Saskatchewan Branch, it was unanimously resolved that Dean C. J. Mackenzie, M.E.I.C., be appointed as Councellor from the Saskatchewan Branch until the next annual election, replacing the late R. W. E. Loucks, A.M.E.I.C.

The newly elected officers of the Saint John Branch were noted.

The report of the Board of Examiners on the May, 1931, examinations of The Institute was submitted and approved, from which it was noted that three candidates out of six had satisfied the examiners.

Four resignations were accepted and three Life Memberships were granted.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:

Elections		*Transfers*	
Member	1	Assoc. Member to Member	3
Associate Members	5	Junior to Assoc. Member	2
Juniors	7	Student to Junior	4
Students admitted	4		

The Council rose at twelve twenty-five a.m.

OBITUARIES

Gordon F. Cairnie, A.M.E.I.C.

Regret is expressed in recording the death of Gordon F. Cairnie, A.M.E.I.C., which occurred at Montreal, Que., on May 5th, 1931.

Mr. Cairnie was born at Melbourne, Que., on March 17th, 1864. From 1881 to 1882 he was engaged as a rodman on a survey of the Trent canal from Trenton to Georgian Bay and from 1882 to 1886 he was engaged as a junior assistant engineer on the construction of the Fenelon Falls canal and locks, Buckhorn canal and lock, and the Burleigh canal locks and dams. From January to July, 1887, Mr. Cairnie had charge of harbour improvements, piling, wharfing and dredging at Midland, Ont., and later in the year was in charge of the construction of the Peterborough and Chemong lake railway. During the years 1888-1892 he was assistant engineer on the Midland division of the Grand Trunk Railway, during which period he had special charge of bridge construction, culverts, bridge and elevator foundations, location surveys, etc. In July, 1892, Mr. Cairnie entered private practice.

Mr. Cairnie joined the Canadian Society of Civil Engineers as an Associate Member on February 14th, 1887, and was made a life member of The Institute on January 22nd, 1929.

Edward Parke Cameron, A.M.E.I.C.

We regret to record the death at Montreal on May 11th, 1931, of Edward Parke Cameron, A.M.E.I.C.

Born in London, Ont., in 1893, Mr. Cameron was educated at the Ottawa Collegiate Institute, and at McGill University, where he took the degree of B.Sc. in chemical engineering in 1920.

Mr. Cameron's professional career has been almost entirely with the Dominion government in the Forest Service of the Department of the Interior. Entering the service as technical assistant in the Forest Products Laboratories of Canada in Montreal shortly after graduation, he was promoted to chemist and chief of the division of pulp and paper in 1923. Since that time he has been acting as the director of the Division of Pulp and Paper under the co-operative research agreement between the Canadian Pulp and Paper Association and the Dominion government. Just about the time that he was given charge of this work, the project inaugurated by the Pulp and Paper Association for a pulp and paper building with facilities for research work, put upon Mr. Cameron the major responsibility for the design and equipment of the semi-commercial pulp and paper mill. One of the important results of the work done under his direction was the perfection of apparatus for the control of pulp mill operations in the form of a freeness tester. Mr. Cameron served with distinction in the Canadian Expeditionary Force as a Captain in the artillery during the War.

Mr. Cameron became an Associate Member of The Institute on April 27th, 1926.

Sydney Stuart Gear, A.M.E.I.C.

The death is recorded at Bridgeburg, Ont., on March 22nd, 1931, of Sydney Stuart Gear, A.M.E.I.C.

Mr. Gear was born at Fort Erie, Ont., on January 19th, 1884, and graduated from the University of Toronto in 1908.

Following graduation he joined the engineering staff of the Bethlehem Steel Corporation at Buffalo, N.Y., and during the years 1914-1916 was connected with the Donner Steel Company, Buffalo, as a draughtsman. In 1921 Mr. Gear joined the Horton Steel Works, at Bridgeburg, Ont., as sales engineer, and in 1922 was appointed contracting engineer for the company, which position he held up to the time of his death. Mr. Gear took a keen interest in the activities of the Canadian Water Works Association and was the Association's president for the current year.

He joined The Institute as an Associate Member on May 18th, 1928.

PERSONALS

George R. Revell, S.E.I.C., who graduated from Queen's University in 1930 with the degree of B.Sc., has been appointed assistant research fellow in fuels by the Ontario Research Foundation, and is located at Toronto, Ont.

B. B. Hogarth, A.M.E.I.C., is now employed by the Department of Mines and Natural Resources of the province of Manitoba, and is at present acting as resident inspecting engineer on the Slave Falls power development on the Winnipeg river. Mr. Hogarth was formerly connected with the Dominion Water Power and Hydrometric Bureau at Winnipeg, Man.

Nicol MacNicol, Jr.E.I.C., was recently appointed as engineer of Forest Hill Village, Ont. Mr. MacNicol graduated from the University of Toronto in 1919, with the degree of B.A.Sc., and for the last seven years has occupied the position of engineer of Etobicoke township. He also spent two years on the staff of James, Proctor and Redfern, Ltd., as resident engineer.

G. S. Walker, A.M.E.I.C., is at present employed as county road engineer for Lanark county, and is located at Perth, Ont. Mr. Walker, who is a graduate of Queen's University of the year 1922, was for a time with the London and Pacific Petroleum Company, Ltd., at Negritos, Talara, Peru, and was later connected with the Border Construction Company, Ltd., at Walkerville, Ont.

G. E. Booker, A.M.E.I.C., formerly with the Power Corporation of Canada at Montreal, Que., is now with the Wabi Iron Works at New Liskeard, Ont. Mr. Booker was for a time with the Riordon Pulp Corporation at Temiskaming, Que., and later acted as office engineer for the James Ruddick Construction Company at Quebec, Que. In 1928 he was connected with the Metabetchouan Sulphite and Power Company, Ltd., at Desbiens, Que.

F. A. Macpherson, M.E.I.C., is resuming his former position as office engineer, Highway and Utilities Office, Department of Public Works of British Columbia, at Vancouver, B.C. For the past year Mr. Macpherson, who has been on the staff of the department since 1917, has been acting as highway traffic and utilities engineer, being in charge of the offices opened up to take care of all work connected with the licensing and control of the operation of public passenger and freight vehicles under the Public Carrier Regulations.

J. H. Ings, A.M.E.I.C., has joined the staff of the Beauharnois Construction Company, and is located at Beauharnois, Que. Mr. Ings, who is a graduate of the University of Toronto of the year 1925, was for a year resident engineer on the construction of Section 7 of the Kapuskasing-Smoky Falls Railway with Messrs. Morrow and Beatty, Ltd., he later became connected with the Spruce Falls Power and Paper Company at Kapuskasing, Ont., and in 1930 was with the Gatineau Power Company at Ottawa, Ont.

H. W. B. Swabey, M.E.I.C. has been appointed a director of J. T. Donald and Company, Montreal and Toronto. Mr. Swabey has been associated with the Donald organization since 1926. He was supervising engineer on the construction of the Atlantic, Quebec and Western Railway, resident engineer for a time on the construction of the Quebec and Saguenay Railway, and served the Canadian Pacific Railway Company as resident engineer on construction of the Campbellford-Lake Ontario and Western Railway. During the War, as chief inspector of steel, he had charge of the inspection of all steel and forgings for shells manufactured in Canada for the British government.

J. A. Burnett, M.E.I.C., consulting engineer, Montreal, has been appointed by the city council of Lachine, Que., to make an appraisal of an electric light and power plant owned by the city. Mr. Burnett has had a wide experience with the Royal Electric Company, Canadian General Electric Company, the construction of a large sub-station for the Montreal Light, Heat and Power Company, the construction of the Montreal and Southern Counties Railway, and the appraisal of all the electrical equipment on the Grand Trunk System for the government arbitration. In 1930, he made a physical appraisal of the manufacturing plants in the town limits of Lasalle, Montreal. Mr. Burnett took over the office of M. A. Sammett, A.M.E.I.C., in 1922.

S. J. Fisher, M.E.I.C., formerly Mill Manager of the Lake St. John Power and Paper Company Ltd., at Dolbeau, Que., has recently moved to Montreal, and is now residing at 4997 Grosvenor avenue. Mr. Fisher was for six years sales and service engineer for Babcock and Wilcox Ltd., and from 1916 for three years was engaged in mechanical engineering work at Ottawa for the Canadian and British governments. At the close of 1921 he entered the news print field with the E. B. Eddy Company Ltd., at Hull, Que. where he was woods manager for four years, and also supervised the engineering, installation and start of operation of the new Eddy newsprint mill. In 1926 he joined the staff of John Stadler, M.E.I.C., in charge of the drawing office of the Lake St. John Power and Paper Company Ltd. After supervising the installation of the machinery in the new newsprint mill at Dolbeau, he was appointed mill manager, and started up and operated the mill for over three years.

R. A. Logan, A.M.E.I.C., has recently returned from South America, where he was associated with the Pan American Airways Extension and Development Department in connection with air mail routes, and is located at Ship Harbour Lake, N.S. In the past fifteen months, Major Logan travelled over fifteen thousand miles of air routes between Porto Rico, Miami, Fla., Panama, Peru, Santiago, Chile, Buenos Aires and Rio de Janeiro. In 1927 he joined an aerial survey expedition for the Aircraft Operation Company Ltd. in Northern Rhodesia, and in 1928 was manager of an African expedition for the same company at Bulawayo, Southern Rhodesia. Major Logan is a graduate of Nova Scotia Technical College, of the year 1911, and was also a student at the University of Alberta. In 1915 he was appointed aeroplane pilot and engineer in the Royal Flying Corps, and became flight commander in 1917. Subsequently Major Logan was appointed officer in charge of ground instructional section, Canadian Air Force, Camp Borden, and since September 1st, 1921, has held the rank of squadron leader (major). In 1922 he was engaged on special investigation of flying conditions in the Arctic regions with the Canadian Arctic Expedition of that year. Later he was appointed manager of the mapping division of the Fairchild Aerial Camera Corporation in New York.

CORRESPONDENCE

40 Lorne Avenue,
St. Lambert, Que.
April 23rd, 1931.

The Secretary,
The Engineering Institute of Canada,
2050 Mansfield Street,
Montreal.

Sir:—

After listening to Mr. Busfield's exposition of the work of the Committee on Remuneration, the writer carried away with him the idea that there was present in the meeting a feeling that Mr. Busfield was right, and that he had said all there was to say, when he told us that the average engineer was quite satisfied with his remuneration, and that his financial rewards were quite as large as those of either the lawyer or physician. There was too much complacency altogether about the question of remuneration; it was regarded as a purely personal matter, instead as it should be, a question of solidarity.

The one place where engineers should receive due recognition is in communal affairs, for there in contact with his immediate neighbours, he can deal with matters on which he, above all others, is best fitted to express an opinion, but unfortunately, a man's standing in the community is not determined by his knowledge or by his outstanding ability in some certain line, but by the amount of wealth he displays; and the vast majority of people place most weight on what an affluent person says. If that affluence be reinforced with ignorance, that very fact will enable him to express definite opinions so easily absorbed by the average mind.

If the engineer was consulted more, 90 per cent of the world's business would be immeasurably better, but what is the use of knowing this and not doing anything, and how can we raise our standing to a greater height in the community if we ignore the measuring stick which the man in the street uses. We must get out of the vicious circle of supply and demand into an increasing spiral where increased remuneration will give increased recognition, and with increased recognition, an opportunity for increased service; then, when we arrive at the second turn of the spiral, it will be the time to see if we are aiming too high. As has been said many times before, the engineer is an inarticulate being; that he does his work, and does not like to talk about it; but there is a worse state than being merely dumb, that is, to be blind as well: there is some hope for a person who cannot express himself, but who has aspirations for the future; his very work will gain him recognition at last: but to be blind as well as dumb, to be inarticulate and without vision, can only result in degradation.

Consider what the medical and dental professions have done during the past twenty years and are still doing, with such marked success that they have even persuaded the government to pay a large part of the cost of their advertising, as was to be seen on a large bill-board in Montreal some weeks ago where it said in effect "If your child is backward at school, consult a physician, there may be some hidden trouble." A most clever example of practical psychology, for it stands to reason that any person who is interested in his children's welfare would gladly pay for advice, and the point to be noted, Sir, is that you and the rest of us are paying for thus advertising the medical profession.

If such advertising raises the general standard of public health or relieves some suffering individual, more power to it, but we cannot hide the fact that it is advertising. We all hear over the radio that we should use Tompkin's tooth paste and see our dentist twice a year; we all read directions for hygiene and first aid, with instructions to consult our physician every time; in fact, in spite of the restrictions against personal use, the medical and dental professions are the best advertised in the world.

Lawyers and physicians are in direct touch with the individual person. Everyone requires the services of a physician at some time of their lives, and many are glad to avail themselves of the advice of a lawyer, but the engineer and his work are practically unknown to the great mass of people; they know that a physician's business is to restore health, that a lawyer knows the law, but to them the engineer is the man in the cab of the locomotive or the man who runs the boilers and looks after the pipes in the apartment house; so while it is comforting to know that we are riding in the same priced car as the members of the other professions, it is rather disturbing to find out that we are sitting back and driving our car around in fancy curves and circles, while the physician is going somewhere, and we engineers are not.

The question of paramount importance is, not whether the engineer is better paid than other professional men, but whether the engineer obtains from the public a just appreciation of his services, which may be expressed in terms of wealth, honour or place; but it must ever be kept in mind that the vast majority of people, especially those who take an interest in mundane affairs, are all admirers, if not worshippers, of the great international god Mammon, and are therefore always especially respectful to those on whom the god has showered favours, looking up to them as benefactors, or possible dispensers; the engineer having nothing to give, need not be considered.

The above is a statement of the standing of the engineer in the community. Doubtless many are quite satisfied, but for those who are not, the writer proposes next month to outline a scheme of advertising.

Yours truly,
C. D. NORTON, A.M.E.I.C.

BOOK REVIEWS

Canadian Trade Index, 1931.

Compiled and published by Canadian Manufacturers' Association, Inc., Toronto, 1931. Cloth, 6½ x 10½ in., 884 pp., tables, $6.00.

This is the seventh annual issue of the Canadian Trade Index. The special feature is the inclusion of a 54-page special export section, provided by the Department of Trade and Commerce of the Dominion government, and giving an analysis of Canada's trade, with data designed to aid in the further development of our exports.

The present edition contains an alphabetical and classified directory of over 10,000 Canadian manufacturers and their products; a produce section giving the names of producers of a variety of agricultural products; and a complete survey indicating those firms interested in and prepared to do export trade. The lists are not limited to members of the Association.

This work is very valuable as a reference aid, and is the only comprehensive book of its kind published in Canada.

Applied Aerial Photography

By Capt. Ashley C. McKinley. Wiley & Sons, New York, 1931, cloth, 6 x 9 in., 341 pp., front., photos, figs., tables, $5.00.

Those interested in modern aerial photography will find this book of great help and benefit, as it gives a compact outline of this comparatively modern science in a clear and concise form without going into long technical detail.

The author has had considerable experience in aerial photographic work with the United States Air Service, and was the official aerial surveyor with the Byrd Antarctic expedition. His book is divided into three parts — taking aerial photographs, finishing the photographs, and mapping with or from the photographs. It also contains a chapter on oblique aerial surveys by A. M. Narraway, M.E.I.C., chief aerial surveys engineer, Department of the Interior, Canada, which is devoted to a description of the grid method used in Canada in mapping from the oblique photographs which are taken by the Civil Government Air Operations Branch, Department of National Defence.

Part I deals with the methods employed in taking aerial photographs, the duties of the pilot and camera operator, different types of aerial photographs and their uses, instruments used in navigation and modern types of aerial cameras and accessories; there is also a chapter on the essential features of lenses used in aerial survey work.

Part II is devoted entirely to laboratory work in aerial photography and contains some interesting and instructive sections on the construction ofa photographic laboratory and photographic chemistry; it also covers fully the processing of the aerial film, developing, printing and copying, etc.

In Part III the methods employed in constructing maps from aerial photographs are fully described, special chapters being devoted to types of aerial photographic errors, maps and map readings, relief, control, methods of assembling mosaic photographs and line maps, etc.

The volume contains a great deal of valuable and instructive information usually only found in technical bulletins published by the Air Services. It is well illustrated and could be used at all times as a work of reference.

The reviewer would recommend the book to all readers of The Engineering Institute of Canada.

J. R. C.

Wind Stresses in Buildings

By Robins Fleming. Wiley & Sons, New York, 1930, cloth, 5¾ x 9 in., 193 pp., illus., figs., tables, $3.50.

John Portas, A.M.E.I.C.*

The publicity which has been given to the many conflicting theories and specifications dealing with the action of wind on tall buildings has roused widespread interest in this major problem of modern engineering. Mr. Fleming's valuable contributions to the development of modern structural steel practice have earned for him an international reputation, but it is to be feared that those who take up his book, in the search for enlightenment on the subject of wind stresses, will be somewhat disappointed.

The first part of the book contains much irrelevant matter regarding the classification of winds. A chapter on the "Relation of Wind Pressure to Velocity" describes at some length various types of anemometers and discusses the well known formulae of Hutton, Duchemin, etc.

The hackneyed subject of wind stresses in mill buildings is treated in the conventional manner and is followed by an exposition of the well-known methods for analysing wind stresses in tall buildings, which have been associated with Mr. Fleming's name for some years.

In the application of these methods a sense of humour is of more value than a knowledge of mathematics and those who, like the reviewer, have indulged in the undignified chase of refractory points of contra flexure all over an unsymmetrical building, have probably emerged with little faith in approximate solutions. Some reverence, however, is due to those methods by which the majority of tall buildings have been designed.

Mr. Fleming places emphasis on the importance of measuring actual deflections of tall buildings subjected to high winds; surely it is empirical data thus obtained, rather than mathematical gymnastics, which will ultimately lead to rational design of these complex structures. If, as is suggested, the "architectural clothing" increases the rigidity of the frame "300 to 400 percent," we need not mourn too deeply our inability to find an accurate and practical method of stress determination—based on quite irrational assumptions.

The remainder of the book deals with details for connections, windload distribution in the Lincoln building, and a chapter on earthquakes. These last chapters strike a familiar chord, consisting as they do of reprints of articles by various writers from current engineering literature.

Mr. Fleming's book may be helpful to students desirous of delving into history, but perhaps its chief value lies in the many references to a wide range of periodicals and books dealing with wind and its effect on buildings.

Union-Management Co-operation on the Railroads

By Louis A. Wood. Yale University Press, New Haven, 1931, cloth, 6 x 9 in., 326 pp., $4.00.

John E. Armstrong, A.M.E.I.C.†

This book is an impartial presentation of the facts in regard to Union-Management Co-operation, a comparatively recent development in the trend of industrial relations toward industrial democracy by means of which organized workers share in managerial responsibility. It deals principally with experience on the Baltimore and Ohio Railroad since 1923, on the Canadian National Railways and the Chicago and Northwestern Railway since 1925 and on the Chicago, Milwaukee, St. Paul and Pacific Railroad since 1926, in connection with maintenance of equipment.

The introductory chapters explain the economic compulsion generally applicable and the legal compulsion specifically applicable in the United States and Canada, respectively, to maintain equipment, outline the industrial processes involved and the organization for doing the work, cite the organization and jurisdiction of the several labour organizations concerned, and review the historical background culminating in the shop men's strike of 1922.

The following chapters deal with the origin of the co-operative plan, the developments leading to its adoption by the railways, the technique of co-operation, the attitudes of management and labour toward it, and in some detail the types of matters co-operatively considered. There is also discussion of the resulting improvement in morale and its effect upon the worker, the work and the employer, the problems of measurement of co-operative gains, including stabilization of employment, and the difficulties involved in the fair sharing of these gains between workers and employers.

In the concluding chapters such matters as apprentice training under co-operation, the relation of incentive wage payments to co-operation and the adoption fo co-operation in other railway department and in organizations other than railways are considered.

The text throughout is fully referenced to original sources of information and the subject is handled in a clear, concise and non-technical manner, the author consistently drawing attention to both sides of all controversial matters.

The book should prove both interesting and instructive to the general reader and particularly so to anyone concerned in recent developments in industrial relations. To the student of industrial relations in those departments of railways concerned with maintenance of equipment it should prove invaluable.

*Chief Engineer, J. W. Cumming Manufacturing Co. Ltd., New Glasgow, N.S.

†Assistant Chief Engineer, Canadian Pacific Railway, Montreal.

ELECTIONS AND TRANSFERS

At the meeting of Council held on May 19th, 1931, the following elections and transfers were effected:

Member

JACOBS, Milton, B.S. in C.E. (Norwich Univ.), associate engineer and member of firm, H. S. Taylor and Company, Consulting Engineers, Montreal, Que.

Associate Members

ANSON, Clement Matthew, B.Sc., (McGill Univ.), asst. gen. manager, Dominion Steel and Coal Corpn., Dominion Iron and Steel Divn., Sydney, N.S.

DUNN, Harold Stewart, res. engr., C.N.R., New Glasgow, N.S.

*KERSON, Morris William, designer and dftsman., T. Pringle & Son, Ltd., Montreal, Que.

*MILLAR, Peter, squad leader, Dominion Bridge Company, Limited, Lachine, Que.

STOREY, Gilbert Calder, B.A.Sc., (Univ. of Toronto), secretary-manager, City of Windsor Water Commissioners, Windsor, Ont.

Juniors

*CYR, Séraphin Adélard, asst. to supt., Eastern Steel Products, Limited, Montreal, Que.

DWYER, Thomas Edward, B.Sc., (N.S. Tech. Coll.), Masson, Que.

FERGUSON, John Henry, B.Sc., (Univ. of Man.), Flying Officer, R.C.A.F., Ottawa, Ont.

McFARLAND, Walter Irving, B.Sc., (Univ. of Alta.), engr., elect'l. engrg. dept., Beauharnois Construction Company, Beauharnois, Que.

McPHERSON, Alexander Ferrier, B.Sc., (Univ. of Alta.), engrg. dftsman., Canadian Westinghouse Company, Limited, Hamilton, Ont.

STEWART, Charles John Raphael Barnewall, B.A. (Eng.), (Cambridge Univ.), dftsman., Dominion Construction Company, Ltd., Fraserdale, Ont.

YOUNG, John Douglas, B.Sc., (Queen's Univ.), sales service engr., Bailey Meter Company, Montreal, Que.

Transferred from the class of Associate Member to that of Member

HALL, John G., B.Sc., (McGill Univ.), vice-president and gen. mgr., Combustion Engineering Corporation, Ltd., Montreal, Que.

HOLE, John, (Finsbury Tech. Coll., London), consltg. engr. and architect, Toronto, Ont.

MacAFEE, Ralph Evans, B.Sc., (McGill Univ.), mgr., Eastern Branch, Babcock-Wilcox and Goldie-McCulloch Ltd., Montreal, Que.

Transferred from the class of Junior to that of Associate Member

KINGSTON, Thomas M. S., B.A.Sc., (Univ. of Toronto), city engr. and supt. of waterworks, City of Chatham, Ont.

LAURIE, William Little, B.A.Sc., (Univ. of Toronto), Capt., Royal Canadian Signals, in charge Air Mail Radio Stations, Ottawa, Ont.

Transferred from the class of Student to that of Junior

BELL, Harry Heartz, B.Sc., (N.S. Tech. Coll.), engr., Calgary Power Company, Calgary, Alta.

EVANS, John Maurice, B.Sc., (McGill Univ.), industrial engr., Shawinigan Water and Power Company, Montreal, Que.

GOBY, Thomas, B.Sc. in C.E., (Tri-State Engrg. Coll.), sales engr., W. Q. O'Neall Co., Crawfordsville, Indiana.

WARDLEWORTH, Theophilus Hatton, B.Sc., (McGill Univ.), 168 Cote St. Antoine Road, Westmount, Que.

Students Admitted

MacDONALD, Murray Vickers, (Univ. of Sask.), Swift Current, Sask.

ST. JACQUES, Jean, C.E., (Ecole Polytech.), (McGill Univ.), 386 St. Catherine Road, Outremont, Que.

SCOTT, Edward Beresford, (Grad., R.M.C.), ap'tice, Canadian Westinghouse Company, Limited, Hamilton, Ont.

KETELSEN, Carsten, 1431 Metcalfe Street, Montreal, Que.

*Has passed Institute's examinations.

BRANCH NEWS

Border Cities Branch

Harold J. A. Chambers, A.M.E.I.C., Secretary-Treasurer.

Cyanamid and its Derivatives

The regular monthly meeting of the Border Cities Branch was held on April 10th. The speaker of the evening was S. R. Frost, A.M.E.I.C., of the American Cyanamid Company, Niagara Falls, Ont. The subject of Mr. Frost's address was "Cyanamid and its Derivatives."

Limestone for the manufacture of cyanamid is obtained from Beachville, Ont., where the company own and operate their own limestone quarry. A year ago a plant was built to take care of the fine screenings from the limestone from which agricultural limestone, mineral fillers and calcium carbonate as an ingredient for stock foods are produced.

The limestone is shipped to Niagara Falls where it is burnt in seven or eight large rotary kilns to form lime. This lime is then mixed with coke of a special grade and the two materials are processed in electric furnaces at 4,000 degrees F. Calcium carbide is formed. The nitrogen for cyanamid is obtained from the air by the liquid air process and fractional distillation. This nitrogen is placed in contact with the carbide which has been pulverized and the reaction is started by the application of intense local heat, the carbide burns actively in the atmosphere of nitrogen, with the result that calcium cyanamid is formed.

Cyanamid is lifted from the retort in which the reaction takes place in the form of an ingot, weighing approximately five tons; it is cooled, pulverized, treated with water and oil and packed in bags for shipment. This cyanamid is about 23 per cent nitrogen.

Cyanamid is exported for a great many purposes. It is used as a fertilizer for sugar cane, cotton, corn and fruits, as an ingredient to mix fertilizers, and also as a neutralizing agent and a conditioner.

A large percentage of cyanamid manufactured at Niagara Falls is used to make cyanide. This cyanide is used in the reduction of gold and silver ores in what is known as the "Cyanide Process" and is shipped to South Africa, Mexico, Australia, United States, Formosa, Nicaragua and Honduras.

A large amount of this material is shipped as cyanogas, which is powdered cyanide, and is used for rodent extermination.

Cyanamid has a very great number of derivatives which are practically all made at the American Cyanamid Company's plant at Warners, N.J. Aqua ammonia is produced from cyanamid by autoclaving, or treating under high pressure steam in a closed vessel. Some of this ammonia is sold direct and some is combined with phosphoric acid brought from Florida in the form of phosphate rock. These two chemicals properly combined make ammonia phosphate, the trade name of which is "Ammo-Phos." This is a comparatively new high analysis fertilizer and because of its high analysis it can be shipped long distances. Ammo-Phos has about 50 per cent plant food in it, ordinary fertilizer having only about 15 per cent. This product is used to fertilize bananas in Central America, mulberry trees in Japan, coffee in Java, olives and oranges in Greece and Spain, cocoanuts in the Philippines, pineapples in Hawaii, tea in China, in addition to numerous uses on this continent. In the process of manufacturing this high analysis fertilizer, there are two by-products derived from the waste black sludge. These are gypsum, which is made into structural gypsum blocks, and graphite. Some of the other derivatives of cyanamid are rubber accelerators used in automobile tires to increase the mileage, also rezyls, which are used in lacquers and modern quick drying paints.

The address was illustrated by motion pictures showing the manufacture of cyanamid and ammo-phos.

A hearty vote of thanks for the very interesting address was conveyed to Mr. Frost by the chairman, R. J. Desmarais, A.M.E.I.C., on behalf of the members of the Branch.

Calgary Branch

A. W. P. Lowrie, A.M.E.I.C., Secretary-Treasurer.
W. H. Broughton, A.M.E.I.C., Branch News Editor.

Annual Meeting

The annual meeting and election of officers was held in the Board of Trade rooms on the afternoon of Saturday, March 14th, 1931, when the following officers were elected to carry on the business of the Branch for the year 1931-1932.

Chairman	R. C. Harris, M.E.I.C.
Vice-Chairman	F. M. Steel, M.E.I.C.
Secretary-Treasurer	A. W. P. Lowrie, A.M.E.I.C.
Executive Committee	F. N. Rhodes, A.M.E.I.C.
	L. A. B. Hutton, A.M.E.I.C.
	H. J. McLean, A.M.E.I.C.
	S. G. Porter, M.E.I.C.
	B. Russell, M.E.I.C.
	R. S. Trowsdale, A.M.E.I.C.
	T. Lees, M.E.I.C.
Auditors	K. Moodie, M.E.I.C.
	W. H. Broughton, A.M.E.I.C.

The Secretary-Treasurer reported a net increase of six corporate members and two affiliates since the last annual meeting, made up of the gain of eleven by transfer and two by affiliation and the loss of three members by transfer, two by resignation and one by death. There are a number of applications for membership now in the hands of Headquarters or of the Application committee and a further number of application forms in the hands of prospective members.

During the year, ten meetings were held at which the average attendance was forty-nine. In addition there were four hundred and five present at the annual ball and eighty-seven at the annual dinner.

The Branch had somewhat over-expended its income during the year because of two annual dinners falling in one financial year but had just about broken even when this expenditure was allowed for.

Before vacating the chair, Mr. Russell thanked the officers and the members of the various committees, particularly the Secretary-Treasurer and attendance committee, for their cooperation throughout the year. After congratulating the incoming officers, he retired in favour of the newly-elected chairman, R. C. Harris, M.E.I.C.

Mr. Harris thanked the members for electing him as chairman and felt sure he could look forward to the same spirit of co-operation and support that had always been accorded to his predecessors in that office. He strongly endorsed a recommendation that the Programme committee should set up small committees of experts to consider and prepare papers on individual technical subjects, especially those which are matters of live interest to the city or province. This recommendation had previously been referred to the incoming Executive and Programme committees with instructions that it be given very careful consideration.

On a motion by Messrs. R. S. Trowsdale, A.M.E.I.C., and J. J. Hanna, A.M.E.I.C., a very hearty vote of thanks was accorded the retiring officers for the excellent work they had done for the Branch.

Annual Dinner

The annual dinner was held in the Palliser hotel on the evening of Saturday, March 7th, 1931, with Ben Russell, M.E.I.C., in the chair. Invitations had been sent to all professional engineers in the city who were not also members of The Institute and about ninety attended the dinner.

Mr. Andrew Halkett, general superintendent, Canadian Pacific Railway, in proposing a toast to the "City," pointed out that Calgary citizens had taken high honours in the life of the Dominion during the past year: R. B. Bennett as Premier of Canada, R. G. Hutchings as president of the Canadian Manufacturers Association, Col. J. H. Woods as President of the Associated Boards of Trade, and S. G. Porter, M.E.I.C., as president of The Engineering Institute. Andy Davison, Mayor of Calgary, replied in lighter vein and paid tribute to the loyal service given by the professional employees of the city.

"The Institute" was proposed by H. S. Patterson, K.C., with reminiscences of college and city life, and was replied to by the newly-elected president of The Institute, S. G. Porter, M.E.I.C. Before calling on Mr. Porter for his response, Mr. Russell rose to perform a very pleasing, and judging by the prolonged applause, a very popular duty, to present to him an illuminated address on behalf of the members of the Calgary Branch on his election as president of The Engineering Institute of Canada.

The president gracefully expressed his appreciation of the honour done him. In addition to the honour, said the president, he felt it was a call to a wider field of service. His election, he thought, might be taken as a request by the members to finish the work of unifying the various engineering organizations in the Dominion and so enable the members of the profession to give better service to the public and perhaps receive more adequate recognition for their share in the development of the Dominion. It is but natural, he said, that men with similar aims should get together for the advancement of the practical application of scientific attainments and to advance the standing of the profession.

While the advancement of civilization, continued the speaker, is largely due to the engineer, far too often he shrinks from taking his proper place in the councils of the city, the province or the Dominion. One half of all scientific advance has occurred during the past twenty-five years, the engineer is the man who applies this scientific knowledge to industry and he should take a larger share in the manner of its application because he understands better the problems involved in the development of the country than does the member of any other class in the community.

The engineer's duties are patriotic as well as professional, they are not wholly for material gain but for the development of the Dominion and the conservation of its natural resources.

Mr. Porter briefly reviewed the inception of The Engineering Institute of Canada and its expansion to include all branches of engineering, and voiced its present hope to be the means of bringing about closer union between the professional bodies of the various provinces during his term of office.

T. Lees, M.E.I.C., proposed the toast of "Our Guests," which was responded to by R. S. L. Wilson, M.E.I.C., Dean of Applied Science, University of Alberta, and John Allan, D.Sc., Professor of Mining and Geology, University of Alberta.

Dr. Allan very strongly asserted the intention of the Council of the Professional Engineer's Association and of the senate of the university to maintain the standards set for admission to the Association of Professional Engineers of Alberta and to prevent unqualified people practising as professional engineers within the province. He hoped that, in the near future, there would be one act governing the practice of engineering from coast to coast and the Association of Professional Engineers of Alberta is out to see that all qualified engineers become registered under the Alberta Act. There were in our ranks the material and the brains to take a leading part in the government of the city, the province, and the nation, and he agreed with Mr. Porter that it is time for professional engineers to take their proper places in public affairs.

Musical numbers between the toasts, by Messrs. Plesner, Lydiatt, Walrod and G. H. Patrick, M.E.I.C., under the direction of the latter, were very much appreciated.

The Tar Sands of Alberta

A general meeting of the Calgary Branch was held in the Board of Trade rooms, Calgary, at 8.00 p.m. on Saturday, March 21st, when about forty members and friends gathered to hear Dr. K. A. Clarke, chief engineer, Roads Materials Division of the Research Council of Alberta, speak on "The Tar Sands of Alberta."

Dr. Clarke reviewed the early development and experiment carried out jointly by the federal and provincial governments and independently by various commercial interests. Interest in the field and its possibilities, he said, seemed to receive renewed vigour in cycles of about ten years duration.

When the Research Council of Alberta entered the field they concentrated on the separation of the oil from the sand—the sand being too far from all possible fields of utilization to be able to carry transportation costs. Their experiments were at first confined to shipments brought down to Edmonton, but in 1929 a plant of small commercial size was erected at the field in order to test the results of the experiments on a larger scale.

The principal difficulties encountered were to separate the oil from the water used, to remove the oil from the sand; to separate the last residue of the sand; and to separate large flat stones from the mixture so as to avoid damage to pumps and machinery. These have all, except the last, been overcome on a small scale and the provincial government now feels that further development should be left as a commercial project while the energies of the department should be concentrated in finding uses for the products after recovery.

Some experimental stretches of road, he continued, have been laid down and have proven very satisfactory but the amount required for road building and oiling is small and the cost of mining prohibits its use for this purpose in competition with petroleum refinery products.

Dr. Clarke illustrated his talk by a number of slides of the district and of the separation plant.

The very interesting nature of the subject was proven by the lively discussion that ensued and by the hearty manner in which the vote of thanks, moved by Messrs. A. S. Chapman, A.M.E.I.C., and Graves, was received by the assembled company.

Louis Frost, Branch Affiliate, Branch News Editor

Geological Exploration Work on the Labrador

An interesting lecture describing a number of years of geological exploration work on the Labrador was given by John Wightman, A.M.E.I.C., before a large gathering of members of the Cape Breton Branch at their regular meeting held in Sydney on Friday, April 16th; A. P. Theuerkauf, M.E.I.C., chairman of the Branch, presided.

The lecturer, following a short review of the history and early settlement of the Labrador, referred to the many disputes between the companies operating in that country, and to the territorial argument between Canada and Newfoundland, the culmination of which was the now famous Labrador boundary question settled in 1927, wherein the Dominion of Canada claimed the whole of the Labrador with the exception of a narrow strip on the coast line.

The Privy Council, to whom the matter was referred, rendered a decision in favour of Newfoundland and confirmed Newfoundland's charter of 1763. The boundary line between the Labrador and Quebec, the lecturer indicated, was now a line drawn due north from the eastern boundary of the Bay of Blanc Sablon as far as the fifty-second degree north latitude and from thence westward along that parallel until it reaches the Romaine river and then northward along the east bank of that river and its headwaters to their source, and from thence due north to the crest of the watershed or the height of land there, and from thence westward and northward along the crest of the watershed of the rivers flowing into the Atlantic ocean until it reaches Cape Chidley.

The superficial area of Labrador has been computed at about 110,000 square miles, or approximately three times the area of Newfoundland, and having a population of less than 5,000 people.

Speaking of the geological formation, the lecturer stated that the southern part of the coast from the strait of Belle Isle to Nain, is low-lying and indented with numerous fiords wherein are innumerable islands. There is everywhere evidence of profound glaciation, and in sheltered places and on high land snow lies throughout the year. Most prominent along the coast are the raised beaches, black intrusive trap dykes cutting through the older gneiss formation, and boulder barricades, that is to say large accumulations of glacial boulders lying between half and low tides.

The northern part of the coast is mountainous. Mountains rising to elevations of two and three thousand feet directly from the ocean, while inland some of the peaks are in the vicinity of 6,000 feet high.

The economic minerals found are pyrites, magnetic iron, labradorite, molybdenite, copper, and some limestone. There have been reports of gold findings, but to date no deposit of commercial value has been located.

Timber lands alone aggregate roughly twenty million acres, with an estimated coverage of 100,000,000 cords of pulpwood, sufficient to produce one million tons of paper per year for all time. The water power available for the entire country has been estimated by experts at about ten million horsepower.

The population of Labrador comprises the permanent settlers and livyeres, the Moravian and Grenfell missionaries, officers and employees of the Hudson's Bay Company individual fur traders, the Eskimos and Indians, and the floating population of fishermen and their families who come to the Labrador from Newfoundland each summer and return in the autumn.

The livyere, the lecturer indicated, is usually a person of a high moral code and strong family instinct. Having provided food and fuel for the winter months for his family, the livyere makes his way into the interior each fall, and does not return to his family until the following spring, being content to spend the winter alone trapping furs while his family remains in comparative comfort and within reasonable distance of hospital and mission schools.

Mr. Wightman had a good deal of praise for the Moravian and Grenfell missionaries who are content to spend their lives in that hard country in order to bring spiritual light to the Eskimo and Indian.

The Eskimos of Labrador are easy going and good natured, with quite a reputation for honesty. They mix freely with the white settlers and spend their time principally in fishing for cod, salmon and seals which they sell to the Hudson's Bay Company.

The Indians on the other hand do not readily mix with the white people and do not care to learn English. They are of two tribes, the Nascopie and the Montagnais. In the fall about September the Indians gather all their supplies together and leave 'en bloc' for their hunting grounds in the interior, taking their women and children and old as well as sick with them. They do not return to the coast until June when the ice breaks up.

The lecturer concluded his interesting talk with the information that Canadians as British subjects enjoyed equal rights in the Labrador with the natives of Newfoundland, timber rights and mineral licences being granted to Canadians in the same way and with no greater difficulty than to citizens of Newfoundland.

The meeting concluded with a hearty vote of thanks to the speaker, proposed by M. Dwyer, A.M.E.I.C., mayor of Sydney Mines, seconded by J. C. Nicholson, general superintendent of the Dominion Coal Company, Ltd.

Hamilton Branch

John R. Dunbar, A.M.E.I.C., Secretary-Treasurer.

Problems in Central Station Engineering

The annual joint meeting of the Hamilton Branch of The Engineering Institute of Canada and the Toronto section, American Institute of Electrical Engineers, took place in the auditorium of the Canadian Westinghouse Company on Friday, April 24th. W. F. MacLaren, M.E.I.C., chairman of the Hamilton Branch, welcomed the Toronto visitors. He turned the meeting over to D. A. MacKenzie, of Toronto, who introduced the speaker of the evening, R. E. Powers, of the Westinghouse Electric and Manufacturing Company, the subject of whose address was "Problems in Central Station Engineering."

Mr. Powers introduced his subject by stating that the problem in large metropolitan areas, such as New York, is to provide a system of distribution of energy that is flexible and suited to the varying demands made on it in different sections. Four systems of generating station connections were discussed. The first of these was the close linked system. This system, used largely in metropolitan areas, consists of linking all the low tension distributing lines together so that they are all interconnected. However, should a short circuit occur a considerable amount of damage would be done in all the areas connected in the system. Also when extensions in this system are undertaken a complete new set of circuit breakers would be needed and the old ones would become useless in the central station owing to their lower ratings.

The second method, the loose linked system, involves a number of separate distribution low tension lines. This system is for use in areas which are not so thickly populated but where communities are scattered. A short in one distribution line will not have any effect on other distribution lines.

Synchronizing at the load is another method of connecting the generator stations. This method involves less trouble if generators become out of phase, has increased reliability, a minimum fault current concentration and a maximum service voltage distribution.

Still another method, and perhaps the most modern method, is by double winding the generators. This reduces the effect of a short circuit to half the effect a single winding generator would have. The interrupting capacity of the circuit breakers is also only half that of a single winding generator. When a short circuit does occur, the generator affected is shut down. The busses are so arranged that when a generator is shut down the winding on that generator which was not short circuited is supplied with energy from the other generators. This method gives a minimum amount of service interruption and the fault may be remedied immediately.

The speaker said "In our large cities the task of supplying energy to large office buildings has become quite a problem. If all energy could be considered as concentrated in the base of a large building its supply would not be difficult. However, office buildings covering an acre of ground with 65 acres of floor space extending high up offer quite a problem, especially when considering distribution at 120 to 208 volts.

"Elevator motors, 100 to 150 h.p., mounted on the upper floors require considerable copper to prevent the flicker of lights during periods of motor starting. It becomes obvious that the same practice so popular in horizontal distribution can be employed to advantage in vertical distribution, that is, distribute at high voltage to the load centre and step down to service voltage directly at the point of utilization. Thus a large office building will be served from transformer vaults in the basement and on various floors where the load is concentrated, such as at the end of elevator shafts."

As an example, Mr. Powers took the Chrysler building, which has seventy-seven storeys and a tower and 1,160,000 square feet of floor space. There are transformer vaults on the first, thirtieth, sixtieth and seventy-fourth floors, which step down the network voltage to distribution voltage. Such a 4,000-volt vertical network system offers distinct economies in buildings of forty storeys or more.

Among its advantages are improved copper economy, reduced duty on oil circuit breakers, better regulation, small and standardized transformer units, capacity installed in small units, investment for load growth in small increments, reduced system losses, area of outage reduced, and no high tension breakers needed.

Mr. Powers stressed the need for construction units, which were becoming more and more important. Among these he mentioned transformers and reactors combined so as to obtain the correct reactance and reduce the scope of short circuits. Network switches, metering panels and movable disconnecting switches were more of these units.

The meeting was then thrown open to discussion, and the opportunity of joining in this was taken by a large number of visiting engineers. S. E. M. Henderson, M.E.I.C., moved a hearty vote of thanks to the speaker for his interesting address, coupling with it also the thanks of the meeting to the Canadian Westinghouse Company for their hospitality. There were 240 present.

Kingston Branch

L. F. Grant, M.E.I.C., Secretary-Treasurer.

The annual dinner of the Kingston Branch was held at the Badminton Club on Tuesday, April 7th. The Branch chairman, Professor A. Jackson, A.M.E.I.C., presided and there were about fourteen members present.

India

The speaker was Major G. R. Turner, A.M.E.I.C., and the subject of his address was India. Major Turner has recently returned from a two-years course at the Staff College, Quetta, and gave a very interesting and informative address.

The leading authority on the present state of India is Volume One of the famous Simon Report, which should be studied by those who wish to become familiar with the factors which affect the situation.

India has an area of about 1,800,000 square miles and a population of some 320,000,000 people. There are 222 vernaculars spoken, and about 2,500,000 people are literate in English.

The races of India are numerous as a result of some thirty major invasions of the country from the northwest. Among the more important of these invasions may be mentioned those of the Assyrians, Persians, Greeks, Arabs, Afghans, and Tartars.

About 71 per cent of the population is engaged in agriculture, 12 per cent in industry, 5 per cent in trade, 2 per cent in domestic service, and 3 per cent in professions, government service, and the Army, combined. The main products are jute, grain, rice, cotton, tea, sugar and tobacco.

The religions are almost as numerous as the racial origins of the people. The largest groups are the Hindus with 217,000,000; Mohamedans with 70,000,000; Buddhists 12,000,000; Christians 5,000,000 and Sikhs 3,000,000. One of the great difficulties of the situation arises from the fact that the two great religious bodies, Hindus and Mohamedans,—who are particularly antagonistic to each other—are not confined to any particular part of the country, but are widely scattered. In consequence the inter-religious strife is serious.

The depressed classes form about 30 per cent of the Hindu population. They are for the most part quite uneducated, and at the bottom of the economic scale. The origin of these classes is partly occupational and partly tribal. It is from these lower castes that Christianity makes most of its converts since it brings to them a hope of higher standards.

There are some 600 Indian states, varying in size from over 80,000 square miles to a few acres. The British government, by treaties and agreements, is responsible for the territorial integrity and external relations of all of these, but they manage their own internal affairs. There is practically no communal strife in these states.

The central government is charged with matters such as defence, external affairs, and relations with the native states. There are provincial governments in the nine major provinces. The legislative assembly in the central government and the legislative councils in the provinces consist mainly of elected members. About 10 per cent of the adult male population is entitled to vote, the franchise being based largely upon property qualifications.

The difficulties in connection with self-government arise from the Hindu-Mohamedan strife; the question of the native states; the wide diversity of peoples in many respects without common ground; the question of affording adequate protection to the rights of minorities, and the menace of attack from the northwest. The safeguards which have been pronounced essential at present by the British government deal with finance, defence, external affairs, and the protection of minorities.

At the conclusion of his remarks Major Turner showed some very interesting slides of India especially of industrial and engineering work.

London Branch

Frank C. Ball, A.M.E.I.C., Secretary-Treasurer.
John R. Rostron, A.M.E.I.C., Branch News Editor.

The regular monthly meeting of the Branch was held on the 22nd of April in the County Council chamber, the chair being occupied by the Branch chairman, W. R. Smith, A.M.E.I.C.

Engineering of the Ancients

The speaker of the evening was Colonel W. P. Wilgar, B.Sc., M.E.I.C., Professor of Civil Engineering, Queen's University, and his subject was "Engineering of the Ancients." He was introduced by H. B. Craig, M.E.I.C.

In his address, Colonel Wilgar pointed out that the profession of engineering is so old as to reach far beyond the age of accurate history. Man as an animal capable of thinking and fashioning tools and weapons has inhabited the earth for at least 350,000 years, but our accurate knowledge of his activities is, so far, restricted to about 8,000 years, and the caves and sepulchres, the temples and monuments which have perpetuated the skill and wisdom of our professional ancestors are the only trophies which have safeguarded through the ages traces of the culture and magnificence of ancient civilization that, otherwise, would have been completely lost.

The Bible is the oldest of our histories and in the last ten years the flood and the Tower of Babel have been definitely established by excavation of the city of Ur of the Chaldees, settled about 8,000 years ago by the Sumerians, who possessed a knowledge of engineering which enabled them to build the first city of the land on the fertile flats opposite the Tigris and the Euphrates. The Tower of Babel or Zigurat was supposedly built as a temple to the Moon God.

The Sumerians were dwellers of the hills and worshipped from high places. The bricks of the Tower were well burned and bound together by asphalt from the pools of Hit. Each brick was stamped with the name of the Emperor Ur-Nama. Bricks used in the city of Babylon had also been found bearing the name of "Nebuchadnezzar."

These Chaldees at Ur used gold, silver, copper and tin 6,000 years ago, and the art of the goldsmith, the armourer and the potter of that day is unsurpassed by any period of history.

The civic engineer of Ur designed and built brick arches 6,000 years ago. He understood canalization and irrigation and also the principles of hydraulics concerning stream flow and pressure. The great reservoirs built 3,000 years ago in the hills of Judah, designed as a water supply for the city of Jerusalem, are amongst the greatest of the technical achievements of the ancients. Drains and sewers existed 5,000 years ago and the gymnasium of Pergamon (2,000 years ago) had shower baths and flushing toilets.

The earliest arched bridge, a semi-circular brick arch, was built across the Tigris in Mesopotamia.

The people of India were mining, forging and fabricating metals more than 5,000 years ago. Near Delhi there is a shaft of wrought iron of 17 tons weight. It bears an inscription proving its age as 3,000 years and in all its length there is no mark of seam or weld and no spot of rust.

So far as we know the ancients had no knowledge of explosives for mining purposes although the Chinese used gunpowder for pyrotechnics. Herodotus, an historian of 2,000 years ago, said they broke the rocks by lighting fires on them and then throwing on vinegar. The miners of those days were all slaves and criminals.

Among the wonders of the world the Cheops pyramid occupies first place—not only as an engineering achievement but as a monument to the amazing knowledge its designers possessed in mathematics and astronomy and as a proof that instruments of precision must have been used in its erection. It is supposed to have been started as a tomb for Cheops, though no body was ever found in the sepulchres. It contains about 3,000,000 cubic yards of cut stone, many of the blocks weighing 70 tons. The stone was quarried on the banks of the Nile about a quarter of a mile away. So far as we know the only mechanical devices available at that time were the pulley, the lever, and the inclined plane.

It is a perfect square on plan with 775 feet to the side and was originally covered with a veneer of polished marble. The Egyptians used the plug and feather method of quarrying their limestone, but no one knows how they managed to secure such precision of finishing, that it is impossible to insert a knife blade between the courses of the stone.

These points are generally known, but the wonder of the pyramid is not in its size but in the theories that have been deduced by mathematicians and astronomers who have studied it.

The sides of the pyramid coincide precisely with the cardinal points of the compass. The exit to the lower sepulchre is so inclined that the pole star of that time shone at lower culmination directly on the sarcophagus of the dead Pharaoh. The star Sirius, worshipped by the Egyptians, and from which their time was calculated, culminated at an angle of 38 degrees and the faces of the pyramid have exactly an angle of 52 degrees, the complement of 38 degrees; and the ventilating shaft of the upper sepulchre is cut exactly at right angles to the southern face so that the star Sirius shines directly at culmination on the sleeping god of the upper sepulchre. Again as a result of the 52 degree angle of the faces, the pyramid casts no shadow at midday from the 1st of February until the middle of October, so that from Nature's awakening in the spring until her August decline "the Sun pours the full lustre of her rays on the resting place of Pharaoh." The indeterminate ratio π was calculated by a Dutchman in the Sixteenth century—or so it was believed until a few years ago, when Flammarion, the great French mathematician, discovered that the height of the pyramid bears to the perimeter of the base, the exact ratio π. This astounding fact can scarcely be an accident.

After referring to ancient road making and drainage, textile industries, architecture, building, town planning, water supplies and purification, etc., the speaker quoted from the writings of Vitruvius who was the first engineer who tried to leave a record of the technical sciences of his age and about 2,000 years ago wrote what might be called an encyclopædia of engineering. This author deals with most of the subjects mentioned above and also has a chapter on professional ethics which applies to the present as well as the ancient days. One paragraph under the heading of practice and theory is well worth repeating, "He who has aimed at acquiring manual skill without scholarship can "never reach a position of authority to correspond with his pains, and "he who relies on scholarship alone is hunting the shadow and not the "substance. He who has a thorough knowledge of both—like a man "armed at all points—soon attains his object and carries authority with him."

In closing, Colonel Wilgar remarked that the engineer of ancient days does not appear in history as a man of great wealth. Then, as now, he was an advisor to capital, and he was listened to with respect at the councils of his state in war and in peace. He built up for the profession, which he loved, a reputation for honesty and integrity which has lasted through the ages.

An interesting discussion followed the address. W. C. Miller, M.E.I.C., said that with regard to the excavation of rock without the facility of explosives he believed that some of this excavation was probably achieved by forming cavities or fissures in the rock and packing these with lime which was confined and afterwards slaked with water.

E. V. Buchanan, M.E.I.C., remarked that in the ancient days much was accomplished by a little at a time and the pay (if any, for slaves and criminals were employed) was so low that the economics of a job did not matter whereas in the present days the work was much more complicated and was often sacrificed to the question of cost.

A hearty vote of thanks proposed by T. Y. Harcourt, M.E.I.C., and seconded by W. C. Miller, M.E.I.C., was unanimously carried.

About thirty-eight members and guests were present.

Niagara Peninsula Branch

Paul E. Buss, A.M.E.I.C., Secretary-Treasurer.

Remuneration of Engineers

On March 26th the Branch held a dinner meeting at Welland to hear J. L. Busfield, M.E.I.C., explain the results of the recent questionnaire on remuneration. The meeting was poorly attended which might indicate that the engineers in this district feel that their remuneration is quite adequate, or again it might indicate that they consider their lot to be hopeless.

Mr. Busfield gave a clear and concise explanation of the various steps which had been taken and of the charts and diagrams which accompanied his talk. This report was published in the May issue of the Engineering Journal.

C. K. McLeod, A.M.E.I.C., had travelled with Mr. Busfield from Montreal and, in a few well chosen remarks, he metaphorically pulled the leg of the Branch by introducing an enlarged version of the Engineering Journal diametrically opposed to the principle for which our membership has expressed a preference.

The gesture was properly appreciated as indicating that at least a few of the Montreal members are alive to the necessity of making some modification to the present size.

About sixteen members from this Branch motored to Hamilton on March 2nd to participate in an inspection trip, dinner and evening meeting arranged by the Hamilton Branch.

The party split into three sections, going respectively to the plants of the Firestone Tire, the Westinghouse and the Steel Company of Canada. At 4.30 p.m. they all met at the Dominion Glass Works and from thence they went to the Hotel Connaught. After dinner some excellent motion pictures were shown through the courtesy of the Buffalo Section A.S.M.E. These pictures were taken at the almost incredible speed of 10,000 to 40,000 exposures per second. Professors Harrington, Hector and Taylor of the University of Buffalo explained something of the method used and the value of the pictures in the study of aero-dynamics.

Steam Storage

Mr. J. P. Wys then read an interesting paper on steam storage accompanied by lantern slides showing modern installations of accumulators and charts of the consequent flattening in the peak load curves. The Hamilton Branch may be congratulated upon providing a highly instructive programme with items of such varied interest.

Inspection Trip

A well attended meeting was held on April 30th at Niagara Falls to inspect the plants of the Canadian-Ohio Brass Company, the Ontario Power Company (H.E.P.), and the new filtration plant. The "Brass Company" is labouring under a misnomer because nothing but porcelain insulators are manufactured at this plant. The ball clay and kaolin are obtained from England in air-tight drums, mixed in exact proportions with the proper quantity of moisture—any variation in these proportions would affect the shrinkage and consequent dimensions of the finished product. This shrinkage is quite large, about 10 per cent in the initial drying stages and a further 8½ per cent in the final baking.

The soft clay is moulded to rough form on a modern electrically-driven potter's wheel and is then passed through the drying ovens to the finishers who bore any necessary holes and dip the insulators in a salt glaze solution. Packed in fire clay tubes the insulators are next stacked in one of the two immense kilns and fired at a temperature of 2,642 degrees F. The final step is to test every insulator with a flash-over voltage which will determine the actual resistance and which is severe enough to crack or fuse any but perfect specimens. A noticeable feature of the plant was the cleanliness and perfect order which prevailed.

The Niagara Falls filtration plant, which is situated near the village of Chippawa, is described by Mayor Swayze as being the most modern on the North American continent. The designing firm is H. G. Acres and Company, and Mr. S. W. Andrews of that firm described the plans and mechanical features. The visitors had a good opportunity of following the process from start to finish as the water had not yet been let in and they were therefore able to enter the intake well, coagulation basins and filter beds. A much appreciated buffet supper was served at the plant through the courtesy of the Board of Water Commissioners.

Harold Buck, M.E.I.C., proposed a vote of thanks, which was seconded by Alex. Milne, A.M.E.I.C.. Mr. Milne is responsible for a filtration plant at St. Catharines and stated that of the total filtered water he used but 3½ per cent for cleaning, whereas Mr. Andrews had suggested a possible 10 per cent as the requirements for the new plant.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Petroleum and Present-Day Civilization

At the noon luncheon held on the 23rd of April, A. W. Sime, technical engineer with the Imperial Oil Limited of Toronto, was the speaker, his subject being "Petroleum and its Relation to our Present-Day Civilization." Mr. Sime was introduced by G. J. Desbarats, C.M.G., M.E.I.C., chairman of the local Branch, and, in addition to the chairman and speaker, head table guests included the following: R. M. Stewart, M.E.I.C., E. Viens, M.E.I.C., W. S. Van Scoyoc, M.E.I.C., A. E. MacRae, A.M.E.I.C., C. W. Barber of the British American Oil Company; T. G. Madgwick, Petroleum Engineer of the Department of the Interior; G. M. Thomas of the Imperial Oil Company; H. Woods of the McColl-Frontenac Oil Company; F. H. Peters, M.E.I.C., G. O. Johnson, A.M.E.I.C., C. R. Coutlee, M.E.I.C.

Mr. Sime remarked that the story of petroleum in Canada had its birth about seventy years ago when J. H. Williams of Hamilton drilled the first wells on this continent for oil in Lambton county, antedating those of Colonel Drake in Pennsylvania.

Discovery of oil wells originally was by surface indications, seepages, etc. Today discovery follows upon the expert investigations of the trained petroleum geologist. To his aid he has recently summoned the aeroplane and from aerial photographs, together with maps compiled therefrom, he may study the general characteristics of the terrain—its outcrops, folds, etc. Also the geophysicist and the palaeontologist have assisted to reduce the number of profitless and dry holes. He stated that today we were better able to estimate available resources than we were ten years ago, and also a great advancement had been made in drilling methods and machinery.

In the matter of fuel transportation there are great engineering difficulties involved, and the construction of pipe lines for this purpose is the work of specialists.

At the refining end the engineer also plays a most important part and many interesting problems arise, also there is the manufacture and utilization of the so-called by-products which is a most fertile field for the chemical engineer. Again there is natural gas and its utilization and transportation.

Petroleum, stated the speaker in conclusion, is destined to play a more important part in our daily life than ever before. Its potentialities have barely been touched upon. Engines today are from 25 per cent to 30 per cent thermally efficient; and a greater efficiency will result from a development of increasingly better fuels, all to be brought about by further efforts of the engineer.

The Diesel Electric Drive Dredge "General Brock"

At the last noon luncheon of the Ottawa Branch for the 1930-31 season held at the Chateau Laurier on May 7th, the speaker was B. G. Flaherty, chief engineer of General Dredging Contractors, Limited. This firm has been engaged in dredging projects on the St. Lawrence and Saguenay rivers, one of which is the deepening of the ship channel to 35 feet for the Federal Department of Marine. Mr. Flaherty's address dealt with the new Diesel electric suction dredge "General Brock," the major features of which were designed by himself. This dredge is the last word in suction dredges and embodies a number of features which are entirely new.

G. J. Desbarats, C.M.G., M.E.I.C., chairman of the Ottawa Branch, presided at the luncheon, and at the head table in addition to the chairman and the speaker were the following: George E. Bell, M.E.I.C.; V. Meek, M.E.I.C.; S. Bray, M.E.I.C.; J. L. Rannie, M.E.I.C.; D. W. McLachlan, M.E.I.C.; K. M. Cameron, M.E.I.C.; A. T. Phillips, M.E.I.C.; Commodore W. Hose; E. Hawken; Col. A. E. Dubuc, M.E.I.C.; John McLeish, M.E.I.C.; Dr. R. M. Stewart, M.E.I.C.; and L. L. Bolton, M.E.I.C.

Mr. Flaherty, at the commencement of his address, stated that a controlling feature in the design of dredges is the velocity of water possible in the pipe line carrying away the dredged materials, as this has a bearing upon the kinds of material which may be moved. The power required for maintaining this velocity varies greatly, as a matter of fact, as the cube of the velocity. The suction dredge which he described may be considered as an ultimate development from the original sand or mud sucker type. It could handle almost any kind of material, excepting bed rock, and transport it through its pipe line for distances as far as three miles away from the scene of operations.

In working out the design of the dredge, the type of power to be used came in for early consideration, whether such power should be purchased from the shore and brought to the dredge by means of transmission lines, or whether it shold be produced on the dredge itself. The extra cost of building transmission lines, erecting transformers and inconveniences in connection with moving the dredge, together with the fact that purchased power uses almost altogether a constant speed motor which is very wasteful, early decided the question, so that this dredge had its power self-contained.

At this point the question arose as to whether the primary power should be from steam or from Diesel engines. The steam turbine was not as efficient in fuel economy for smaller sizes and there was really a dividing line at about 5,000 h.p. below which it could compete with the Diesel engine. In the "General Brock" the Diesel electric drive was chosen operating a 24-inch dredge. The usual amount of power required for the operation of this dredge was from 1,600 to 2,000 h.p., and the power plant accordingly consisted of four 700 h.p. Diesel engines running at 350 r.p.m., each connected to an individual generator.

The dredge had a vertical spud which could be let down so that the shoe at the bottom came in contact with the bed of the river, thus allowing the spud to act as an anchor around which the dredge would swing in carrying on its operations at any one particular point.

The dredge had been designed for work in fairly hard material. In fact, the cutting machinery was one of the main problems in the construction in that it was necessary to have it strong enough to withstand considerable shocks. It was estimated that the thrust at the edge of the cutter knives amounted to from 200,000 to 250,000 pounds. The dredge was well lighted with flood lights for use in carrying on the work at night.

After the speaker had given his address and before the close of the luncheon meeting, the chairman made a brief reference to the retirement from the government service and consequent removal from the city of Ottawa of one of the members who had been most active in the affairs of the local branch. The thanks of the branch, stated the chairman, were due to T. H. G. Clunn, A.M.E.I.C., who had been most assiduous in his work upon the Reception committee and in effecting arrangements for adequately carrying on the regular luncheon and other meetings of The Institute.

Peterborough Branch

F. G. A. Tarr, S.E.I.C., Secretary.
B. Ottewell, A.M.E.I.C., Branch News Editor.

Metal Enclosed Switchgear

At the April 9th meeting of the Peterborough Branch of The Engineering Institute of Canada, F. Kunst, S.E.I.C., of the Switchboard Engineering Department of the Canadian General Electric Company, read a paper entitled "Metal Enclosed Switchgear."

The subject pertains to those forms of switching equipments in which the current carrying parts, such as oil circuit breakers, disconnecting switches, buses, current and potential transformers etc., are enclosed by metal.

Among the subjects included under this heading are found the following: indoor metal clad switchgear, outdoor metal clad switchgear, truck panel type equipments, truck breaker type equipments, cubicle type equipments, outdoor switch house equipment.

Each type of equipment was considered from the viewpoints of fields of application and advantages peculiar to each type.

In order to cover a number of design and construction problems encountered during the course of development one type was selected and analysed.

Comparative costs of a typical installation were offered to assist the hearers in obtaining the proper perspective of these types of equipment.

A number of lantern slides materially assisted in supplementing the written material.

In order to provide material for further consideration of this subject which at present is a very vital one in the electrical industry, a bibliography was included as a supplement to the paper.

E. R. Shirley, M.E.I.C., occupied the chair. F. G. A. Tarr, S.E.I.C., Branch Secretary, assisted at the lantern.

The Manufacture of Refractories

This interesting paper was presented on April 23, 1931, by E. Rigby, superintendent of the Porcelain department, Canadian General Electric Company, Ltd., Peterborough.

A. B. Gates, A.M.E.I.C., presided, and introduced Mr. Rigby as a man with lengthy experience in refractories, both in Canada and in Great Britain.

The presentation of a purely technical subject was considerably aided with moving pictures, which were loaned for the occasion through the courtesy of the Harbison-Walker Company of Pittsburg, while J. R. Stirling, the company's Canadian representative, was also present and contributed to the very instructive and interesting programme.

The series of films showed the complete process of the manufacture of refractories, of fire resisting materials, from the mining of the raw materials to the shipping of the final product, refractories having become a highly specialized branch of the porcelain and electrical industries.

The tunnel kiln has now come to be largely adopted by manufacturers of refractories, who have an exceedingly large volume of business, but the more common type of kiln is the periodic kiln.

Refractories play an important part in modern industry, in providing furnace linings, where it is essential that such structures must be capable of withstanding high temperatures. Unusual care is taken to make every brick perfect, and many of the more intricate shapes are made entirely by hand, instead of being moulded in the hydraulic presses, which are in common use for the less complicated moulds.

The address was followed by an interesting discussion, and the meeting concluded with a hearty vote of thanks to Mr. Rigby for his address.

Saint John Branch

G. H. Thurber, A.M.E.I.C., Secretary-Treasurer.

Visit to New Power Plant of N.B. Electric Power Commission

A joint inspection trip by the Saint John Branch members of The Engineering Institute of Canada and the Engineering Society of the University of New Brunswick was made to the power plant now under construction for the New Brunswick Electric Power Commission at Newcastle Creek, Queens County, N.B., on April 16th, 1931.

Members of the Saint John Branch joined the students of the University at Fredericton and left by special train for Newcastle Creek.

The Grand Lake power station of the New Brunswick Electric Power Commission is located at Newcastle Creek, on the shore of a lake, within four miles of the centre of the Grand Lake coal fields. The plant had to be located on the shore of the lake in order to obtain sufficient condensing water for the present installation and future extensions.

The Commission have taken over or built about one and one-half miles of railway line to connect the plant with the Fredericton and Grand Lake coal and railway system, and the railway has put in effect a freight rate on coal which will be the same from all mines in the district. It is expected that about 20,000 tons of coal will be used initially.

The plant is one of the most up-to-date and complete units of its kind in Canada, all equipment being in duplicate. The most modern features are incorporated in the design, including mechanical equipment for handling coal and disposing of ashes.

The power station is to have an initial capacity of 5,000 kw. It is anticipated that this plant will produce power, for the purposes required, at a lower cost than could be obtained from any undeveloped water power site in the province.

The design and construction of the plant has been supervised by the United Engineers and Constructors (Canada) Ltd., and Dr. John Stephens, M.E.I.C., of the University of New Brunswick, has been consulting engineer to the Commission.

The Commission is under contract to supply power to the Maritime Electric Company at Fredericton, and to the Canadian Cottons Ltd., at Marysville, beginning September 1st next. They anticipate no difficulty in having the plant in operation before that date. Their transmission lines are now being built to Fredericton. A transmission line is also to be built to Moncton which will link up with the transmission line from Saint John and the Musquash Hydro-Electric Plant to provide a reserve capacity to take care of possible low water conditions at Musquash and to supply sufficient power for rapidly growing system demand.

The New Brunswick Electric Power Commission held a luncheon on completion of the trip of inspection. Speakers at this luncheon included Hon. C. D. Richards, Minister of Lands and Mines of the Province of New Brunswick; F. J. Robidoux of Shediac, member of the New Brunswick Electric Power Commission; S. R. Weston, M.E.I.C., Chief Engineer of the Commission; J. M. Woodman of Saint John, Superintendent of the New Brunswick District, Canadian Pacific Railway; C. C. Kirby, M.E.I.C., District Engineer of the Canadian Pacific Railway; Stewart Bull, President of the Engineering Society of the University of New Brunswick, and W. R. Johnston, A.M.E.I.C., Chairman of the Saint John Branch of The Institute.

Annual Dinner Meeting

The annual dinner meeting of the Saint John Branch was held at the Riverside Golf and Country Club on May 5th, 1931.

The meeting, which was largely attended by members and their guests. was presided over by the chairman, W. J. Johnston, A.M.E.I.C.

After the toast to the King, the toast to the City of Saint John was proposed by C. G. Clark, S.E.I.C., and responded to by His Worship Mayor W. W. White, M.L.A. His Worship recalled the early days of the city and in comparing them with the city of today declared that members of the engineering profession have been responsible for the great change which has taken place. He wished the Branch every success.

The toast to Our Guests was proposed by R. D. H. Wigmore, A.M.E.I.C., and responded to by Dr. W. J. Wright, Provincial Mineralogist and Professor of Mineralogy at the University of New Brunswick, and R. Hugh Bruce.

The toast to The Engineering Institute of Canada was proposed by Geoffrey Stead, M.E.I.C., and responded to by G. G. Murdoch, M.E.I.C. In replying to this toast, Mr. Murdoch told of the founding of the organization 40 years ago and something of its history.

During the business meeting held directly after the dinner, the reports of the various committees were received and adopted. The report of the Natural Resources and Engineering Industries committee, prepared by F. P. Vaughan, M.E.I.C., the chairman, and read by J. L. Feeney, A.M.E.I.C., in the absence of Mr. Vaughan, showed in part a closer accord between the Department of Lands and Mines and the provincial university and expressed the opinion that much could be accomplished in the application of these resources to industry if the services of the chemical and mining engineer be fully utilized. The tourist industry offers as good an opportunity as any to our people, and to this end our public services must not only be maintained but improved.

A. R. Crookshank, M.E.I.C., chairman of the Town Planning committee, said that he was glad to report that the town planning scheme for the city of Saint John was now in the last stages and only needed to be proclaimed by the Lieutenant-Governor-in-Council. He said that those interested looked forward to seeing it put in operation this year, as they had been assured that it would be dealt with by the provincial government at an early meeting.

Votes of thanks were extended to W. J. Johnston, A.M.E.I.C., the retiring chairman, A. A. Turnbull, A.M.E.I.C., the retiring secretary-treasurer, last year's executive, the Saint John Board of Trade and the Press.

The election of officers for the ensuing year resulted as follows:

Chairman	J. N. Flood, A.M.E.I.C.
Vice-Chairman	A. A. Turnbull, A.M.E.I.C.
Secretary-Treasurer	G. H. Thurber, A.M.E.I.C.
Executive	V. S. Chestnut, A.M.E.I.C.
	J. T. Turnbull, A.M.E.I.C.

Following the business meeting a social evening of cards and music was enjoyed.

Mr. Johnston, in his address as retiring chairman, thanked the Branch executive and chairmen of the committees, also Mr. Turnbull, the efficient Branch secretary, and noted with pleasure the interest in The Institute's affairs which had been maintained in the Branch.

Inauguration of the Saint John Branch

On March 7th, 1918, a paragraph appeared in the Saint John *Times* as follows: "Civil Engineers to have Society in City—A meeting of the local members of the Canadian Society of Civil Engineers was held today for the purpose of meeting Fraser S. Keith, M.E.I.C., Secretary of the Society, and of forming themselves into the Saint John Branch of the Society." Those present at this meeting were as follows: E. T. P. Shewen, M.E.I.C., A. Gray, M.E.I.C., C. C. Kirby, M.E.I.C., W. Colin Ewing, A.M.E.I.C., J. K. Seammell, M.E.I.C., H. H. Donnelly, A.M.E.I.C., G. N. Hatfield, A.M.E.I.C., R. H. Cushing, M.E.I.C., A. B. Blanchard, M.E.I.C., G. G. Murdoch, M.E.I.C., G. G. Hare, M.E.I.C., A. R. Crookshank, M.E.I.C.

Shortly after this, the name of the Society was changed to "The Engineering Institute of Canada" and on May 7th, 1918, the first officers of this Branch were elected as follows:

Chairman	A. Gray, M.E.I.C.
Secretary-Treasurer	A. R. Crookshank, M.E.I.C.
Executive Committee	J. A. Grant, A.M.E.I.C.
	C. C. Kirby, M.E.I.C.
	G. G. Murdoch, M.E.I.C.

At this time, the total membership of the Branch was 23.

Engineering Conditions in New Brunswick, 1931

Motor traffic originating beyond the boundaries of the province, namely tourist traffic, has created a business which surpasses even that of the development of most of its natural resources. Power facilities of the province are being greatly developed. One should note not only an increase in hydro-electric power development, but also the increase in the number of steam plants, the two most recently built steam plants being located within the city of Saint John and at Grand Lake to utilize Minto coal. This development is lessening the drudgery of farm life and other industries, and in this way the engineer is helping industry and his assistance is a distinct benefit to the province.

The harbour of Saint John is to a great extent being further improved by channel dredging and a large port development is in progress at Carleton.

In the municipal field one notes further mileage of paved streets year by year, improvements in water supply, extensions of sewerage systems and other municipal improvements in the cities and towns of the province of New Brunswick.

In the railway field, heavier rolling stock and greater speeds demand further improvements and betterments to the various railway systems.

Vancouver Branch

W. O. Scott, Jr.E.I.C., Secretary-Treasurer.

At the meeting of March 25th, 1931, J. P. Hodgson, M.E.I.C., gave a brief talk on "The Addition to the Jordan River Power Plant of the British Columbia Electric Railway Company, Limited, on Vancouver Island." This was accompanied by moving pictures which showed the detail of field operations in connection with the erection of pipe line No. 4.

This pipe line was fabricated locally and enumerated below are a few of the details:—

1. Head in feet, 1,150.
2. Length in feet, 9,482, composed of the following units:—
   a. 60 inch diameter—4,809 feet
      54 " " —1,990 "
      48 " " —2,683 "
   b. From the forebay 3,500 feet was lap-riveted and remainder down to power house, 5,982 feet, was butt-riveted.
   c. Plate varied in thickness from 3/8-inch at upper end to 1-1/16-inch at lower end.
3. There were 20 expansion joints, generally about midway between anchors.
4. The pipe is entirely above ground and supported on concrete piers, in general about 18 inches high and numbering approximately 360.
5. At vertical bends reinforced concrete anchors were placed numbering 21 in all.

Messrs. Hodgson, King and Marble of Vancouver, B.C., were the general contractors and the field erection of the pipe line was sub-let to the Vancouver Engineering Works.

An additional film was shown after the above of the installation of the Ladner, B.C., distribution system and the construction of a reinforced concrete reservoir.

Among those taking part in the discussion were Messrs. A. C. R. Yuill, M.E.I.C., C. Brakenridge, M.E.I.C., P. H. Buchan, A.M.E.I.C., J. Oliver, Jr.E.I.C. and W. O. Scott, Jr.E.I.C.

A joint luncheon meeting of the Vancouver Branch of The Engineering Institute of Canada and the Association of Professional Engineers of British Columbia was held in honour of the visit of tthe Institute President, S. G. Porter, M.E.I.C., on April 16th, 1931, at 12.15 p.m., in the Hudson's Bay dining room. There were sixty present.

H. B. Muckleston, M.E.I.C., occupied the chair and introduced the speaker.

THE ENGINEERING PROFESSION

S. G. Porter, M.E.I.C., expressed himself as pleasurably surprised to be able to speak to such a luncheon gathering during his short stay, as his trip was entirely unofficial.

Mr. Porter chose as his topic "The Engineering Profession," and a summary of his remarks follows:—

"The engineer's place in our social structure is particularly important because of the newness of our country and the vastness of its resources.

"The engineer is by nature a pioneer. He makes ready the way for civilization. He it is that combines the forces of nature, the discoveries of science and applies them to the needs of luxury-loving civilization.

"Present conditions afford a great opportunity and at the same time impose a great responsibility on the engineer. You occasionally hear the complaint voiced by engineers that they do not receive the recognition to which they are entitled from the public. This is no doubt true. The debt of civilization to the engineer is indeed beyond measure. He is human and vain enough to want some recognition and credit for that which he has done. After all is it not largely his own fault? Is he assuming his due share of the responsibility of shaping public policies and bearing the burdens of citizenship in his community? If his training fits him for the task of supplying to the public the utilities and the industrial facilities which it demands, does it not also qualify him for a voice in formulating the policies and directing the course of the activities of these bodies which govern and control us? The obligations of citizenship demand that we capitalize our engineering skill and the influence of our personality for the benefit of the community of which we are a member.

"Also, we owe a duty to our profession. The engineer who selfishly sticks to his own narrow job without regard to the welfare of his fellow-engineers is not meeting his full responsibility. He should be as keenly interested in the development of high ethical standards and of professional pride and loyalty as in his own personal success. A greater unity and solidarity in the profession are outstanding needs of the engineers of Canada today. How can we expect our voice to be heard and heeded unless it has behind it the force that can only come out of unity and solidarity. If all the engineers of Canada, working in harmony and professional loyalty, could provide a Dominion-wide medium for expressing the viewpoint of the engineering profession they would exert an influence otherwise unattainable both on public opinions and on legislature which affects, not merely the welfare of the engineers themselves, but the safety and welfare of the public where construction operation or control of engineering works and public service utilities are governed by legislative enactment. Such a condition would also result in greater public recognition and more favourable publicity which would create greater confidence in Canadian engineers and enable them to compete more successfully with outside engineers. All this would result in a reflex influence on the profession itself in creating a stronger professional consciousness and esprit de corps among engineers comparable to that existing in other professions."

At the conclusion of the speaker's remarks G. A. Walkem, M.E.I.C., M.L.A., very ably moved a vote of thanks, and was seconded by A. S. Gentles, M.E.I.C.

STUDENT SECTION

R. V. Anderson, S.E.I.C., Secretary.

The activities of the Student section of the Vancouver Branch for the second half of the University year are summarized as follows:—

Jan. 7.—Maj. W. G. Swan, M.E.I.C. "Engineering Aspects of Vancouver Harbour."

Jan. 14.—J. W. Kelly, Portland Cement Association. "Research Applied to Concrete."

Jan. 21.—Mr. Perry. "Motion pictures of the blasting into place of the Obelisk at Chute-à-Caron."

Jan. 21.—Annual Dinner.

Feb. 11.—Maj. J. C. MacDonald, M.E.I.C., President of the Professional Engineers of B.C., 1931. An illustrated lecture on "Water Power in B.C."

Feb. 18.—Dr. Perry Barr. "Forest Research."

Feb. 25.—H. B. Muckleston, M.E.I.C., Vice-President of The Engineering Institute, 1931. "Relativity, its Meaning and Consequences."

Feb. 25.—Student Night.

Mar. 4.—W. H. Powell, M.E.I.C. Illustrated lecture on "Vancouver's Water Supply."

The following field trips were taken since the beginning of the new year:—

Feb. 7.—Inspection of C.P. S.S. "Empress of Japan," holder of world's record for crossing the Pacific, Yokohama to Vancouver, in eight days, 3 hours, 18 minutes.

Mar. 14.—Trip to C.P.R. tunnel being built under the business section of Vancouver for steam railway traffic.

STATEMENT—1930-1931

	Debits	*Credits*
Dec. 20, 1930—Received from Vancouver Branch		$ 5.00
Jan. 21, 1931—Sale of tickets, 32 at $1.00......		32.00
Acct. Love's Cafe—32 dinners at $1.00....................	$32.00	
Gratuity, cigarettes, etc........	3.00	
Complimentary tickets.........	2.00	
Acct. Gehrke's — 50 banquet tickets.....................	2.40	
Feb. 25, 1931—Received from Vancouver Branch		6.00
Acct. R. Anderson — stamps, phones, transportation, slides for student night............	3.50	
	$43.00	$43.00

Coal

Raw Material for Chemical Manufacture

Science is just beginning to reveal coal as destined to become the foundation for vast industrial chemical operations. Its first use was as fuel. Of the 600,000,000 tons produced yearly in the United States, five-sixths is still used raw.

Far from being a simple substance, coal is a complex mixture of chemical compounds, largely hydrocarbons, together with such impurities as ash, moisture, and sulphur. Very little carbon as such exists in coal. This complex nature makes it easier to understand the transformations that occur when coal is distilled in coke ovens, such distillation being historically the second important step in the utilization of coal.

When distilled, coal yields coke, an essential raw material in blast furnace operations and in production of water-gas; coal gas or coke oven gas, valuable as a fuel and as a source of hydrogen for the synthesis of ammonia; ammonia, recovered as a water solution or combined with sulphuric acid to form sulphate of ammonia, the second most important nitrogenous fertilizer; benzol, raw material for various organic syntheses, also a motor fuel of valuable anti-knock properties; and coal tars, well known as raw material for synthetic organic chemical manufacture. About 15 per cent of the United States coal production is distilled, mostly in by-product coke ovens of efficient design.

There are under development uses for coal certain to be of vast importance to civilization, since they will assure indefinitely certain essential commodities, the chief being gasoline and lubricating oils, heretofore obtained solely from petroleum. Coal is destined to be the most important raw material ever available to chemical industry. Starting with coal, proceeding thence to water-gas (largely hydrogen and carbon monoxide), we have a material that is the immediate starting point in the synthesis of ammonia, of alcohols, and of motor fuels. Under suitable conditions of heat and pressure we can combine the hydrogen derived from water-gas with coal itself thus obtaining synthetic gasoline and other hydrocarbon oils comparable in utility with the present products from petroleum.

Use of coal as a raw material for chemical manufacture is the direct result of research, principally in Germany and to lesser extent in France, Great Britain, and the United States. The initial coal hydrogenation studies specifically should be credited to the Kaiser Wilhelm Institute for Coal Research in Mulheim-Ruhr, Germany. In these laboratories was conceived the idea of adding hydrogen molecules to the solid hydrocarbons of coal, thus obtaining liquid hydro-carbons similar to the fractions of petroleum. Hydrogen is combined with the powdered coal at elevated temperatures and at a pressure of several hundred atmospheres. The inherent mechanical problems are extremely difficult. The coal is introduced into the pressure or reaction chamber in the form of paste, made by incorporating the powdered coal with some of the heavy oil produced in the reaction. This paste is actually pumped into the system and in similar manner the ash and heavy oils resulting from the reaction are removed.

Separation of this crude oil into its constituents is accomplished in the same manner as in the treatment of petroleum. This process of hydrogenating coal has not yet been exploited generally because of the present surplus of petroleum in nearly all parts of the world. However, the Interessen Gemeinschaft Farbenindustrie (commonly known as the German Dye Trust) has expended millions of dollars on the process, which is now in production on a large factory scale.

Little imagination is required to forecast the economic and political significance of coal hydrogenation. Countries that do not possess adequate supplies of petroleum and gas, as for example, Germany, will be enabled to become self-sufficient in motor fuels and oils. Most important of all, however, future generations in all countries need not fear that the possible eventual decline of petroleum resources will cause difficulties and inconvenience. Relative to petroleum, coal appears to exist in virtually inexhaustible quantities widely distributed, and therefore is the logical economic basis of all fuel supplies whether solid, liquid, or gaseous. These new and large possibilities for the utilization of coal have come about with comparative suddenness and are attributable directly and entirely to the vision and genius of the research chemist.—Chaplin Tyler, B.Ch.E., B.B.A., M.S., in Research Narratives of The Engineering Foundation, New York, N.Y.

Civil Aircraft Accident Report on Miscellaneous Flying in the United States for the Last Six Months of 1930

A decrease in the number of passenger fatalities and an increase in the number of miles flown per passenger fatality in miscellaneous flying operations for the period July to December, 1930, is shown in the semi-annual report of the Aeronautics Branch on accidents to civil aircraft. The number of passenger fatalities was 104 and as the miles flown totaled 56,502,560, the miles flown per passenger fatality were 543,294.

While there was an improvement in the passenger fatality phase of miscellaneous flying, the number of accidents both fatal and non-fatal increased, bringing about a decrease in the number of miles flown per accident over the corresponding previous period. There were 1,116 accidents involving 2,021 persons, including pilots, members of crews, passengers and persons on the ground. Of this total 258 were fatally injured, 145 were severely injured, 277 received minor injuries and 1,341 were not injured in any way.

Miscellaneous flying for the purposes of this report, is divided into four classes: Miscellaneous commercial, pleasure, student instruction and experimental flying. Miscellaneous commercial includes such operations as charter flights, aerial photography, sightseeing, crop dusting and exhibition flying. Pleasure flying means operation of planes privately owned for pleasure only. Student instruction and experimental flying include operations implied by those terms.

The number of accidents in miscellaneous operations is more than twenty times greater than those reported for scheduled air transportation for the same period, but this is due primarily to the fact that there are more miscellaneous planes in operation; and they fly a greater total mileage and engage in a wider variety of operations.

Aircraft in miscellaneous operations are flying only about one-eighth as many miles per accident (including accidents of all kinds) as are those employed in scheduled air transportation. The total number of miles flown by aircraft in non-scheduled operations was nearly three times as great as the number of miles flown by air line craft in the last half of 1930, but there were 1,116 miscellaneous flying accidents as against 47 in scheduled operations. A comparison of the trend in scheduled flying, taken from the accident report on scheduled air transport operations in the Air Commerce Bulletin of April 1st, 1931, volume 2, No. 19, with that for miscellaneous operations follows:

	Miles Flown per Accident		
	July-December 1928	July-December 1929	July-December 1930
Scheduled Operations.......	121,350	209,739	426,436
Miscellaneous Operations...	74,883	72,165	50,630

NOTE:—Direct comparisons are made for corresponding periods because weather conditions during the last 6 months of the calendar year usually are more favourable for flying than during the first 6 months.

Of the total number of accidents occurring in miscellaneous operations during the 3-year period, it was found that the largest percentage—42.23—occurred in pleasure flying, and the next largest 38.45, in miscellaneous commercial flying. Student instruction was charged with 15.83 per cent of the accidents and experimental flying with 3.49 per cent.—*U.S. Air Commerce Bulletin.*

Neon Signs

The Neon sign is simply a gas-filled glass tube through which a high voltage current of electricity is passed, producing a luminous glow.

Neon gas was discovered by Messrs. Ramsay and Travers, English scientists, in 1898, but it was not put to practical use until several years later, when Professor Claude of France perfected a method of obtaining the gas in commercial quantities. It is of the same family as helium and argon, and is present in the atmosphere in the proportion of one part of Neon to 66,000 parts of air. It is colourless, odourless and tasteless, and is secured by means of the distillation of liquefied air. The supply of gas comes from France and Germany and is shipped in glass litre containers at atmospheric pressure costing in the neighbourhood of $24. per litre, which is sufficient for about 700 feet of 15 mm. tubing. The glass used in the tubing is a high grade, specially produced for this particular application. The popular sizes are 3, 12 and 15 mm. in diameter or approximately ⅛, ½, and ⅝ inches, the ½-inch tubing being used in the majority of signs in Ontario.

The glass tubing is formed into letters or designs with sections averaging perhaps 6 to 8 feet and invariably limited to 12 feet, on account of the difficulty of producing a suitable vacuum in greater lengths. The electrodes, usually copper and in one of several patented forms, are then attached and the section evacuated. When a proper vacuum is obtained the tube is "bombarded" by the application of high voltage (usually 6,600 volts) which heats up the glass and burns out any impurities, following which the gas is admitted through an ingenious arrangement of traps and filters, and the tube is tested and sealed.

The natural colour of the Neon tube is orange red, but practically any colour can be obtained by the introduction of other gases combined with coloured tubing. Blue is obtained from a combination of argon and Neon, known to the trade as B10 gas, with a small quantity of mercury added to give density. This gas, when used in yellow tubing, produces a green colour. The tube gives off practically no heat which accounts largely for its economy of operation. The gas does not burn up, and the tube has a life of from 15 to 20 thousand hours, although difficulties are encountered in the way of fading, due principally to leakage with a resultant reduction in the original vacuum. Experiments are being conducted in an effort to produce a white light, and if successful, it is claimed that interior lighting will be radically changed. The natural red Neon colour, having a long wave length, possesses high penetrating power which makes it especially attractive in daylight or fog, and it is being applied quite extensively to beacon lights for airports.

The tubes require an extremely high voltage, and the 110-volt supply is stepped up as high as 15,000 volts, the present day Ontario practice being confined to the use of three transformers with secondary voltages of five, twelve and fifteen thousand volts, and with respective volt-ampere ratings of 150, 350 and 450. With secondary operating current of only 25 milliamperes the signs cannot be considered as particularly dangerous, and the life and fire hazard is reduced to a minimum in Ontario due to our rigid standards.

The size and number of transformers to be used is determined from the length of the various sections of tubing in the sign, on the basis of the following approximate figures for ½-inch tubing operating at 25 cycles:

5,000-volt transformer, 9 to 11 feet.
12,000-volt transformer, 25 to 27 feet.
15,000-volt transformer, 35 to 40 feet.

For 60 cycles the lengths may be increased by approximately 20 per cent, and increased or decreased for the ⅝-inch or ⅛-inch tubing in the direct ratio of the diameters. The loading is approximately 8 watts per foot of tubing for the ½-inch size and 6 watts for ⅝-inch. A sign having a total of 160 feet of ½-inch tubing and operating at 25 cycles would require the equivalent of at least four 15,000-volt transformers, but the design of the sign, or the combination of the small 6-and 8-foot sections might necessitate one or more additional transformers. The sections of tubing are connected in series across each individual transformer, and the various transformers are paralleled on the low voltage supply. A 25-cycle transformer with a 15,000-volt rating weighs approximately 40 pounds, and costs the sign manufacturer about $19.

A Neon sign is decidedly heavier than an equivalent incandescent sign, and the capital cost is perhaps double. They are invariably sold at a price computed on the total length of tubing, ranging in the neighbourhood of $7 per foot, which covers the complete sign including transformers and erection. It is very difficult to get a definite basis of comparison as regards operation and maintenance, but it is a generally accepted fact that the cost of a Neon sign over a period of five years will be only about 25 per cent of the cost of an incandescent sign.

The transformers used for Neon signs have an inherently high reactance with a resultant low power factor. Tests recently conducted by an American power company on 611 straight Neon signs showed total volt amperes approximately 2¼ times total watts, giving a power factor of 44 per cent, with an average loading of 642 watts per sign. On another group of 330 Neon signs containing one or more incandescent lamps, the average power factor was 68 per cent. On the total of 941 signs the average power factor was 52 per cent. This naturally imposes a serious burden on the distribution system, and if billing is solely on the basis of kilowatt-hours, the consumer does not take his proper share of the cost. The regulations in Ontario call for a volt-ampere rating on the sign equivalent to the total rating of the individual transformers, so that as far as demand or installed capacity on a straight Neon sign is concerned, the power company is probably protected, and, even though the energy is measured in watt-hours, the apportioning on the basis of a volt-ampere demand seems reasonably fair.

The Neon sign may be classed as a commercial commodity with almost unlimited possibilities and the number is rapidly increasing from day to day.

—*The Bulletin of the Hydro-Electric Power Commission of Ontario*

"Advance Guards," recently issued by the Canadian Westinghouse Company, is a bulletin which is of great interest to every engineer connected with the transmission and distribution of electric power. It discusses fully the subject of lightning hazards on various types of systems and the many methods of eliminating them. The manufacturer will be pleased to send you a copy; ask for Circular 1737-F.

An interesting shipment of concrete reinforcing 1¼-inch square bars, 87 feet 6 inches long, was recently made from the Hamilton works of the Steel Company of Canada, Ltd., to the Stanley Construction Company of Hamilton, for use in connection with the erection of a new low level bridge at Hamilton.

Preliminary Notice

of Applications for Admission and for Transfer

May 20th, 1931.

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in July, 1931.

R. J. Durley, *Secretary.*

* The professional requirements are as follows—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

ABRAMSON—ISAAC ALBERT, of Seebe, Alta., Born at Winnipeg, Man., Feb. 12th, 1908; Educ., B.Sc. (E.E.), Univ. of Alta., 1929; 1929, mtce., Ghost River development; 1929-30, floorman, and 1930 to date, operator, Calgary Power Company, Seebe, Alta.

References: G. H. Thompson, H. J. McLean, C. A. Robb, R. S. L. Wilson, H. B. Sherman, W. R. Mount, H. J. MacLeod.

BLAKE—WILLIAM HENRY, Capt., R.C.E., of 81 Orange St., Saint John, N.B., Born at Pontefract, England, July 17th, 1890; Educ., 1920-22, complete course, School of Military Engineering, Chatham, England. All military qualifications by exam. up to the rank of Major of Engineers, including technical subjects; 1906 to date, with the Royal Canadian Engineers, as follows: 1906-09, at Halifax, N.S.; 1909-15, at Kingston, Ont.; 1915-19, overseas; 1922-27, works officers, M.D. No. 2, Toronto; 1927-31, district engineer officer, M.D. No. 12, Regina, Sask.; at present, district engineer officer, M.D. No. 7, Saint John, N.B.; (1918, Lieut., C.E., 1920, Lieut., R.C.E., 1927, Capt., R.C.E.)

References: W. B. Lindsay, A. C. Caldwell, H. T. Hughes, J. L. H. Bogart, A. C. Garner, J. W. D. Farrell, A. P. Linton, G. R. Turner.

BROWN—THOMAS, of 630 Byng Road, Walkerville, Ont., Born at Barrow-in-Furness, England, May 16th, 1885; 1910-12, shop clerk, American Bridge Co., Ambridge; 1912-18, Canadian Bridge Co. Ltd., Walkerville, Ont., Bundling, shipping, testing of acids, etc., later in charge of galvanizing shop. 1914, storekeeper and shipper, in charge of Govt. supplies for shell making and attendant reports; 1918-22, Ford Motor Company, Walkerville, Ont., mech'l. dftsman.; 1922-23, mech'l. dftsman., General Motors, Walkerville, Ont.; 1923-26, inspr. in tool room, Ford Motor Company, Highland Park, Detroit; 1926 to date, estimator and dftsman., T. J. Eansor and Sons Limited, (Structural Steel and Misc. Iron Work), Windsor, Ont.

FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

SMYTH—CHARLES McDOWALL, of Sydney, N.S., Born at Woking, Surrey, England, April 24th, 1890; Educ., 1906-09, The Polytechnic Institute, London, England. Senior Diploma Elect'l. Engrg. and silver medal; 1910-13, electrn., Dominion Iron & Steel Co., Sydney, N.S.; 1914, electrn., Dominion Coal Co., New Waterford, N.S.; 1915, night foreman, shell mfg. plant, Starr Mfg. Co., Dartmouth, N.S.; 1915-19, overseas., Can. Engrs., Lieut., M.M.; 1919, instructor, garage mechanics, D.S.C.R., Halifax; 1919-21, foreman in line dept. and asst. to light and power supt., N.S.Tramways & Power Co., Halifax, N.S.; 1921 to date, light and power supt., Cape Bretou Electric Co. Ltd., Sydney, N.S. (*Jr. 1920, A.M. 1921.*)

References: A. P. Theuerkauf, S. C. Mifflen, W. E. Clarke, P. A. Freeman, A. L. Hay, I. P. Macnab.

THOMSON—CLARENCE, of Montreal, Que., Born at Philadelphia, Pa., Jan. 1st, 1876; Educ., B.A.Sc., McGill Univ., 1897; 1895-97 (summers), with Fred Thomson Co., elect'l. engrs.; 1897-1902, examiner in charge of application for patents (elect'l) in the Patent Office, Ottawa; 1902 to date with Fred Thomson Co. Limited, elec'l. engrs., Montreal, from 1918 to date as manager (Design and manufacture of electric motors, generators, transformers and special elect'l. equipment, and planning and installn. of industrial power plants. Also engaged as consltg. elect'l. engrs. by a number of firms). (*A.M. 1899.*)

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Capital to Invest

BUILDING CONSTRUCTION EXECUTIVE located in New York city, Canadian born, graduate McGill University, wishes to locate in Canada, preferably Vancouver, B.C. Will invest $20,000 and services in established construction concern where capital is needed for expansion. Fifteen years' field and office experience. Past three years general manager of construction. Apply to Box No. 230-W.

ELECTRICAL ENGINEER. College graduate with about seven years designing experience with large manufacturer of electrical apparatus; would consider junior partnership with electrical contractor or electrical repair firm. Could invest several thousand dollars. Correspondence invited. Apply to Box No. 579-W.

Situations Wanted

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), 15 years experience, available on short notice. Experienced surveys, draughting, reinforced concrete design, municipal engineering, construction work, inspection, estimating. Apply to Box No. 107-W.

CIVIL ENGINEER, university graduate 1926, desires employment as junior engineer or instrumentman on construction work. Experience, resident engineer on railway construction, miscellaneous surveys. References. Available any time. Apply to Box No. 149-W.

ELECTRICAL ENGINEER, B.Sc., McGill 1926. Five years experience in the design of switchboards, layouts and wiring diagrams. Considerable experience in high and low tension switchgear design. Fifteen months experience in switchboard estimating. At present employed; available on short notice. Correspondence invited. Apply to Box No. 247-W.

REINFORCED CONCRETE ENGINEER, B.Sc., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

ELECTRICAL ENGINEER. Graduate '25, wide experience in hydro-electric power stations, desires position on power plant design or related work. Apply to Box No. 278-W.

CIVIL ENGINEER, A.M.E.I.C., Canadian, R.P.E., Nova Scotia, 21 years engineering experience, both field and office, in railway, highways, foundations, concrete structures, water power and conservation, electric transmission lines, etc., experience comprising both surveys and construction, desires employment. Single. Will go anywhere. Working knowledge of French and Spanish. Available immediately. Apply to Box No. 327-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing and hoists. Also some experience in ventilating and heating work and calculators. Accustomed to structural design and details. Good references. Present location Montreal. For interview apply to Box No. 329-W.

ENGINEERING REPRESENTATIVE. Experienced civil and mechanical engineer wishes to communicate with engineering or equipment manufacturing firm with a view to becoming Ontario or Quebec representative. Apply to Box No. 334-W.

CIVIL ENGINEER; age 48; married; A.M.E.I.C., R.P.E., Ontario and New Brunswick; 32 years experience in municipal engineering, on roadways, sewers, waterworks and buildings, desires position with either municipality or as engineer superintendent with contractor. Ten years with City of Toronto, construction engineer on roadway work; four years consulting engineer; three years engineer in charge of construction work; one year resident engineer, Dept. of Public Highways. Available immediately. Maritimes or Ontario preferred. Apply to Box No. 336-W.

CIVIL ENGINEER, S.E.I.C., graduate '29, desires engineering position with possibilities of advancement. Past experience consists chiefly of survey work and municipal construction. Location in western provinces preferred. Apply to Box No. 338-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., R.P.E. Ont., with twenty-four years experience embracing dams, wharves, grain elevators, foundations, pile driving, highways, municipal engineering, water power surveys, road locations, inspections and estimating is open for engagement as engineer or superintendent in construction, operation or maintenance. Location immaterial. Apply to Box No. 358-W.

CIVIL ENGINEER, graduate, age 32, A.M.E.I.C. Ten years experience; seven years on design, construction, erection work and maintenance of paper mill and mine buildings and machinery. Three years on hydro-electric work in charge of surveys and field investigations; associate hydro-electric engineer, U.S. Engineers, on office investigation, design and estimates; desires permanent position in Canada. Apply to Box No. 362-W.

STRUCTURAL AND CIVIL ENGINEER, Jr.E.I.C., age 31, married, Was instrumentman and structural engineer on erection of Royal York hotel, and asst. resident engineer on James Bay Extesnion, T. & N.O. Rly. Experience includes structural, civil and mechanical draughting and all kinds of instrument work and special work. Qualified as captain in military engineering, R.M.C., Kingston. Available anywhere in Canada, preferably Toronto, for any kind of work. Apply to Box No. 377-W.

SCOTS ENGINEER, 28 years old, desires situation as junior executive or some similar situation. Wide experience in mechanical, civil and hydraulic fields and four years as junior executive; A.M.E.I.C. exam., Jr.E.I.C. Will go anywhere. Apply to Box No. 381-W.

ENGINEER ADJUSTER, MANAGER, desires to connect with an industrial concern or department which is not showing a proper return with a view to suggesting more efficient methods and eliminating bad debts. Apply to box No. 411-W.

Situations Wanted

CIVIL ENGINEER, s.E.I.C., 1930 graduate of Nova Scotia Tech. with experience as plane table topographer, instrumentman and draughtsman and particularly interested in hydro-electric power development and reinforced concrete design, desires position. Willing to go to foreign fields. Available at a few weeks notice. Apply to Box No. 431-W.

CIVIL ENGINEER, s.E.I.C., 1930 graduate. Experience as instrumentman on city and railroad construction, desires to enter structural or hydraulic field. Available at once. Will go anywhere. Apply to Box No. 467-W.

CIVIL ENGINEER, experienced in road construction, mine surveying, transmission line survey and construction; paper mill construction; age 27. Available on short notice. Apply to Box No. 468-W.

CIVIL ENGINEER, A.M.E.I.C., age 39, with wide experience on design and construction of reinforced concrete structures, desires position. Apply to Box No. 475-W.

CIVIL ENGINEER, B.Sc., six years experience in paper mill and hydro-electric work, desires position with paper or power company. Paper mill experience covers design, layout, some estimating, and construction. Hydro experience covers preliminary and flowage surveys, transmission line location, design, and six months as resident engineer on construction. Available at once. Apply to Box No. 482-W.

STRUCTURAL ENGINEER, technical graduate, age 40, married, seeks position with architect or contractor. Fully experienced in design and supervision of all types of office and industrial buildings, structural steel or reinforced concrete. Available on short notice. Apply to Box No. 501-W.

ELECTRICAL ENGINEER, B.Sc., McGill University, Jr.E.I.C., age 32. Five years practical experience before graduating. Since graduation two years course with International Paper Co., including six months as electrical foreman, engineer in charge of installation of electrical equipment for two 28,000-h.p. units. Also electrical equipment for large coal-fired boiler house, designing some of the features. Apply to Box No. 506-W.

MECHANICAL ENGINEER, Jr.E.I.C., B.Sc., '26. Ten months experience in pulp and paper steam control. Four years experience in detail and design, in pulp and paper mill, industrial plant and hydro-electric development work. Age 27. Married. Location immaterial. Apply to Box No. 521-W.

CIVIL ENGINEER, B.A.Sc., '29, with experience in supervision of construction and general office engineering, desires permanent position with contractor or engineer. Available at once. Apply to Box No. 524-W.

CIVIL ENGINEER, A.M.E.I.C., with twelve years experience embracing survey and construction, railway, hydro-electric and highways foundations, pile driving, municipal engineering, water power surveys, road location, inspection and estimating, is open for engagement as resident engineer on construction or other responsible position. Experience comprises both office and outside work. Available immediately. Apply to Box No. 527-W.

MECHANICAL, CONSTRUCTION, AND DESIGNING ENGINEER, with special training in hydro-electric power development, underground steam distribution systems, and the operation of large electrical machinery. Active work desired. Apply to Box No. 528-W.

ELECTRICAL ENGINEER, s.E.I.C., B.Sc., E.E., 1931, desires to become associated with some branch of electrical engineering offering good opportunity for advancement. Sixteen months experience in draughting of electrical apparatus with large manufacturing concern; including layout work, and making of detail working drawings. Bulk of experience with industrial control apparatus. Location immaterial. Available on short notice. Apply to Box No. 532-W.

ELECTRICAL ENGINEER, married, graduate of McGill University, desires position in Ottawa, Montreal or Toronto. Experience includes four summers with a building concern as instrumentman and assistant engineer, two and one-half years with the Canadian Westinghouse Co., this time being distributed between tests, design and sales. At present employed but available on short notice. Apply to Box No. 533-W.

CIVIL ENGINEER, B.Sc., McGill University, Jr.E.I.C., age 32. Seven years general experience in hydro-electric power investigations and construction. Has been in charge of high power transmission lines location, also in charge extension surveys. Experience in office and field. Thorough knowledge of French. Best of references from former employers. Apply to Box No. 537-W.

STRUCTURAL ENGINEER, A.M.E.I.C., B.A.Sc. Wishes to join established firm of consulting engineers. Age 37. Married. Ten years experience design of reinforced concrete and steel on buildings. Two years practical contracting experience. Apply to Box No. 540-W.

CIVIL ENGINEER, McGill '20, A.M.E.I.C., P.E.G., age 31, single. Experience includes general engineering, especially reinforced concrete work, and eight years of pulp and paper mill construction and layout. Best of references. Available on short notice. Apply to Box No. 547-W.

UNDERGRADUATE ENGINEER, s.E.I.C., junior year standing (Sask.), desires work to complete course. Electrical or mechanical work preferred. Apply to Box No. 553-W.

ELECTRICAL ENGINEER, s.E.I.C., graduating 1931, desires employment in electrical engineering. Sixteen months draughting experience on electrical machines with a large manufacturing company. Work included making layouts and detail working drawings. Available immediately. Location immaterial. Apply to Box No. 555-W.

A.M.E.I.C., graduate of University of Toronto, 1915. Building engineer and superintendent, with considerable experience as installation, sales and promotion engineer. Present connection, four years in responsible position with large utility corporation. Open for immediate connection where he can use his past experience. Location immaterial. Apply to Box No. 560-W.

ELECTRICAL ENGINEER, A.M.E.I.C., university graduate 1924. Experience includes one year test course and five years on design of induction motors with large manufacturer of electrical apparatus. Four summers as instrumentman on highway construction. Several years experience in accounting previous to attending university. Available at reasonable notice. Apply to Box No. 564-W.

CIVIL ENGINEER, s.E.I.C., graduating this year. Experience in railway maintenance, and instrumentman on location and construction. Desires to enter any branch of civil engineering or industrial work affording technical experience and an opportunity for increasing responsibility. Will go anywhere. Apply to Box No. 567-W.

CIVIL ENGINEER, A.M.E.I.C., ten years experience as mining engineer of a colliery, six years railway construction, including location, construction, bridge construction, and maintenance. Also one year on hydro transmission lines; one year government land surveys. Would consider position in any branch of construction, as resident engineer or instrumentman. Apply to Box No. 569-W.

CIVIL ENGINEER, B.Sc. McGill Univ., Jr.E.I.C. Five years experience along the lines of general construction, including structural steel. Available at once. Apply to Box No. 570-W.

YOUNG ENGINEER, Jr.E.I.C., experienced in design, details and erection of steel and concrete structures. Also a good theoretical and practical knowledge of steam, hydraulic and I.C. engine power plant. Good practical mechanical and electrical engineer, able to operate and maintain any type of machinery or power plant. Location immaterial. Apply to Box No. 572-W.

MECHANICAL ENGINEER, s.E.I.C., B.A.Sc., (Univ. of B.C., '30), Undergraduate experience in pulp mill. One year's experience, Canadian General Electric Co., mech. dept. Single. Age 24. Desires position in technical design or sales. Location immaterial. Available on short notice. Apply to Box No. 577-W.

TEMPORARY EMPLOYMENT wanted by an engineer with wide experience in the design and operation of steam power plants and heating system. Apply to Box No. 584-W.

CIVIL ENGINEER, s.E.I.C., 1931 graduate, age 26. Experience in draughting, designing and estimating in structural engineering. Desires to enter structural, hydraulic (including hydrographic) or municipal field affording technical experience. Location immaterial. Available at once. Apply to Box No. 593-W.

ELECTRICAL ENGINEER, graduate Univ. of Alberta, '31, with excellent record, desires connection with electrical manufacturing firm, power or communication company. Good general experience includes one summer railway construction, two summers geological surveys in oil fields of Alberta, planetable topographer and asst. geologist. Available immediately. Apply to Box No. 596-W.

MECHANICAL ENGINEER, age 22, graduate '31, Univ. of Alberta, experience as draughtsman and instrumentman-inspector, is open for a position. Location immaterial. Apply to Box No. 598-W.

MECHANICAL ENGINEER, s.E.I.C., age 21, four years mechanical engineering, Queen's University, desires permanent employment. Experience in wood work, machine shop work, draughting and surveying. Location immaterial. Available at once. Apply to Box No. 600-W.

MECHANICAL ENGINEER, Canadian, technically trained; eighteen years experience as foreman, superintendent and engineer in manufacturing, repair work of all kinds, maintenance and special machinery building, desires change. Location immaterial. Available on one month's notice. Apply to Box No. 601-W.

ELECTRICAL OR MECHANICAL ENGINEER, B.Sc.'31, s.E.I.C., desires employment which will give experience and lead to advancement. Two summers in a large communication company, including draughting, switchboard and surveying. Available on short notice. Will go anywhere. Apply to Box No. 606-W.

CHEMICAL ENGINEER, s.E.I.C., University of Alberta '30, desires a position in any industry with chemical control. Experience includes three summer vacation periods of five months each as assistant chemist, and ten months as chief chemist with a cement company. Age 29. Single. Available at once. Apply to Box No. 609-W.

For Sale

TROUGHTON & SIMS 8" geodetic transit, with 8" vertical circle reading to 10 seconds. Three levelling screws and three verniers. New and in beautiful condition. Packed in two mahogany cases. Complete with framed mahogany tripod (half price), $400.00. Apply to Box No. 10-S.

GRAFLEX CAMERA, post card size, in good condition. May be seen at Institute headquarters. Price $75.00. Apply to Box No. 11-S.

Canadian Sheet Piling Co., Limited

An announcement of interest to the engineering profession in Canada is made by the recently formed Canadian Sheet Piling Co. Limited.

This Company will distribute in Canada the Larssen section of steel sheet piling. The new Company has its head office at Suite 1106 Castle Building, Montreal, with suitable sales and engineering representation throughout the Dominion.

The Board of Directors includes Mr. D. G. Macpherson, President of Watson Jack & Co. Limited, who is President of the new Company; Mr. H. T. Garvie, M.I.Mech.E., M.I.Struct.E., who is Managing Director of The British Steel Piling Co. Limited of London; Mr. M. J. McCarthy, A.M.Inst.C.E., M.I.Struct.E., A.M.I.Mech.E., who is also a Director of The British Steel Piling Co. Limited, and Mr. B. C. Talbot of Cargo Fleet Iron Co. Limited, who roll Larssen piling at Middlesbrough, England.

Both Mr. Garvie and Mr. McCarthy have had a long experience in the furnishing of Larssen section of steel piling in important engineering works all over the world. Mr. Macpherson is well known for his connection with the contracting and engineering trades throughout Canada, while Watson Jack & Co. Limited have been acting as sales representatives for The British Steel Piling Co. Limited for some time past. This combination, therefore, places the new company in a sound position in the Canadian market.

Steel sheet piling is a product that is not manufactured in Canada, and for many years the importation of this material has been exclusively from United States sources. Canadian contractors, engineers and architects will therefore welcome the possibility of now obtaining a British rolled steel piling.

Arrangements have been made for the carrying of representative stocks of piling at convenient localities in Canada to take care of urgent requirements and give the Canadian trade prompt and satisfactory service.

The Canadian government have recognized the desirability of showing preference for British products, and have placed a favorable preferential duty on steel piling rolled in Great Britain.

The users of this Larssen piling will be assured of having the assistance of structural engineers specializing in piling, and 27 years of proven design, in the planning of their various projects, as a competent staff of engineers will be maintained by the new company.

Some of the features of Larssen section of steel piling are the following:—

(a) Its patented interlock is truly rolled and water tight, and at the same time offers a minimum resistance to driving.

(b) The flanges of the Larssen section are subject to a minimum of live pressure due to the shape of the section approaching the rectangular.

(c) The Larssen section has maximum section modulus for a minimum of material, as it is rolled to furnish the greatest amount of metal at the point of greatest stress.

(d) The published section modulus of the Larssen section is the result of laboratory tests, and proven by twenty-seven years of field practice.

The use of Larssen section of steel piling is becoming more and more widely known as a method of construction, not only for temporary cofferdam work but also for the more permanent structures such as docks, seawalls etc., where its economical and sea-resisting properties make it ideal for this type of structure, and in the majority of cases a substantial saving over ordinary forms of construction can be demonstrated.

Amongst some of the important works carried out with Larssen piling in Canada are the following:—

Quebec Harbour Commission dock at Quebec.
Pier work at Kincardine, Ont.
Banc Brule Lighthouse foundations.
Ste. Anne Bridge Piers foundations.
Abitibi Canyon Power Development, Fraserdale, Ont.
Halifax Harbour Commission new docks.

Gliding

Interesting data regarding the various aspects of gliding are contained in a year book published by the Dorset Gliding Club, Weymouth, England, of which a copy has been received. The progress made in this sport during the past year in England has been extraordinary. While the achievements in Germany are, of course, outstanding, it must be remembered that gliding was taken up and developed in that country immediately after the War.

The booklet, besides full information as to the gliding clubs in Great Britain, has a series of articles on the theory of gliding flight; how gliding can be taught; the construction and design of gliders; materials used in glider construction, and the organization and possibilities of gliding clubs.

Historically, continuous progress is reported, commencing with the brief twenty-six minute gliding flight of the Wright brothers at Kitty Hawk in 1902, up to the engineless flight of Barstow in 1929, when he remained in the air for fifteen hours and thirteen minutes. In the same year Kronfeld in Germany succeeded in reaching a height of 8,514 feet, depending only on the motive power of the wind.

Copies of "Gliding" can be obtained from "Gliding," 10 Victoria Street, Weymouth, Dorset, England, at a cost of 2s. 6d. per copy.

Electrical Eyes

Television

Part I

One original invention is credited to Nipkow, a German; fifty years ago he explained scanning, line after line with a spot of light, the object of which an image was to be made visible at a distance. He lacked several essentials, particularly amplifiers and other devices made familiar since then through radio.

How far can a picture be "televised"? Experimenters of General Electric Company sent television waves from Schenectady, New York, to Australia and had them come back. After travelling 20,000 miles a rectangle still had four corners, although broken into pieces most of the time.

In 1927 a picture three inches square on the screen was achieved by Alexanderson; in the fall of 1929, a picture fourteen inches square, not simply black and white like a silhouette; all the gray shades were reproduced, registering every shadow and giving depth and detail. In May, 1930, television first appeared as part of a regular performance at a theatre. It was in Schenectady, and the image was six feet square.

Antenna radiation is modulated by a succession of impulses supplied by the beam of light scanning the object of which a picture is being transmitted. The subject stands before an incandescent lamp. Between subject and light is a metal disc the size of a bicycle wheel, drilled with forty-eight holes. The revolving disc covers the complete subject twenty times per second; that is, there are twenty complete pictures made up of light and shade. A frame contains four photoelectric tubes, sensitive to light. The tubes respond 40,000 times per second to impulses reflected back from the subject.

At the receiver the electrical impulses are passed on to a light valve, in the middle of an intricate lens system, in front of a high-intensity arc lamp similar to those used for projection of motion pictures. The light valve operates delicately and accurately to permit passage of light in correspondence to impulses received from the television transmitter. These light emissions are passed to a rotating disc supporting lenses in places corresponding to the holes of the disc at the originating point. Additional lenses pass the light forward to the screen, where these light impulses, at the rate of 40,000 per second, become the living, active image.

Part II

April 7, 1927, one-way systems for television over telephone circuits by radio were demonstrated in Bell Telephone Laboratories, New York, permitting an individual to see as well as to hear a person in Washington. On a large television screen the audience observed the person at Washington while hearing his words over the loud-speaker. This receiver was used also to demonstrate television by radio, at which time there was presented to an audience the first radio broadcast programme of sound and scene.

With photoelectric cells of greater sensitivity it became possible, in July, 1928, to illumine the subject broadly by daylight, and allow the photoelectric cell to "behold" only one small area of the picture at a time. This "direct scanning" lends itself particularly to action at a distance from the lens. Improvement of photoelectric cells sensitive at the red end of the spectrum, and glow-discharge tubes whose light is rich in blue and green rays, made possible in June, 1929, an image in colour, using beam-scanning and superposing three one-colour images.

Experimental two-way television service between American Telephone and Telegraph Company building at 195 Broadway and Bell Telephone Laboratories at 463 West street, nearly two miles apart, was demonstrated to representatives of the press on 9 April, 1930. Special telephone booths were equipped with television transmitters and receivers, designed by the Laboratories. A person seats himself in a booth before a frame in which he will see the face of the person with whom he is talking. His own face is rapidly scanned by a mild beam of blue light which reflects from his face to the photoelectric cells and gives rise to the current which transmits his image. There is no fierce glare to the scanning beam; one is not annoyed by its presence and may even gaze directly at it without inconvenience.

The first thing that strikes the observer when he steps into the booth, lighted with a dim orange light to which the photoelectric cells are insensitive, is the absence of the usual telephone. Special telephone transmitters and receivers are concealed in the booths. One talks face to face to the distant person and a hidden receiver speaks the words, which seem to issue from his mouth. An ordinary telephone is not used because it would hide part of the speaker's face. This novel arrangement adds naturalness to the conversation. The other party appears with sufficient detail for recognition of facial expression but the effect is like looking at an animated cabinet-size photograph, because the image is produced in monochrome. What one sees is like an instantaneous moving picture done in black on a pink background due to the colour of the neon tube, whose flashing light through the synchronized scanning disc forms the image.—*From Research Narratives of The Engineering Foundation.*

The Canadian General Electric Co. Ltd., announces a new pendant type push button for controlling small floor operated cranes. This is designed to supersede the present rope and chain types of control, with the advantages of greater safety to the operator, a saving in time (only one man being necessary to operate the crane) and less aisle space required on the factory floor.

Seven Sisters Hydro-Electric Development

F. H. Martin, M.E.I.C.,
Chief Engineer, Northwestern Power Company Limited,
Winnipeg, Man.

Presented before the Winnipeg Branch of The Engineering Institute of Canada, April 16th, 1931, and before the Montreal Branch of The Institute on April 30th, 1931.

SUMMARY.—The initial stage of the Seven Sisters development of the Northwestern Power Company is nearing completion, and will be delivering power this summer. This is the third hydro-electric development undertaken by the Winnipeg Electric Company, or a subsidiary, and is situated on the Winnipeg river, about 63 miles distant from Winnipeg. The initial development will produce 60,000 shaft horsepower, and the final installation will have a total installed capacity of 225,000 h.p. under a 66-foot head. Interesting features in this project include the dykes, which extend up river from the dam for several miles on both sides of the river; also the tailrace cut, which involves an excavation of about 1,000,000 cubic yards of granite rock, which will be used for railroad ballast.

The power house adjoins the main dam, which is of the solid gravity spillway type. Three high specific speed propeller turbine units of different manufacture are being installed, each of 37,500 h.p. rated capacity. The completed project calls for six such units. Special provision has been made for dewatering the power house substructure for the addition of future units. The generators are of welded structural steel design, each rated at 32,500 kv.a., 11,000 volts, 3-phase, 60 cycles, and 138½ r.p.m.

Power is transmitted by a double circuit 110 kv. line direct to Winnipeg, and a tie line also has been constructed to interconnect with the Great Falls development, further down the river.

General

The era of low price hydro-electric power for industrial use in Winnipeg dates from the time the 30,000 h.p. Pinawa plant of the Winnipeg Electric Company on the Lee channel of the Winnipeg river was placed in operation on June 11th, 1906. This was supplemented by a 12,000 h.p. steam turbo-electric plant in Winnipeg in 1912. Other developments on the Winnipeg river are the 105,000 h.p. Pointe du Bois plant of the city of Winnipeg, placed in service in 1911; and the 168,000 h.p. Great Falls plant of the Manitoba Power Company, Ltd., which started operating on January 3rd, 1923.

Two plants are now under construction, the Slave Falls plant of the city of Winnipeg, and the Seven Sisters plant of the Northwestern Power Company, Ltd. The ultimate installation of these plants will be 100,000 h.p. and 225,000 h.p., respectively.

The Manitoba Power Company Ltd., and the Northwestern Power Company Ltd., are subsidiaries of the Winnipeg Electric Company.

Geographical

The Winnipeg river possesses exceptional power and storage advantages, having a total drainage area of over 53,000 square miles; with regular and well distributed precipitation resulting in remarkably uniform natural run-off annually. In a normal year the maximum flow seldom exceeds four times the minimum.

The topography of the catchment basin has the typical characteristics of the Laurentian country, being rough, hilly, well forested, with numerous lakes and muskegs, which exercise a strong influence upon the natural flow of the river. In addition, several large lakes provide natural advantages for securing maximum uniformity in the flow by means of mechanical regulation. It is interesting to note that there are over 100 lakes varying from a few square miles up to 1,500 square miles in area, having a combined surface of 4,400 square miles or about 10 per cent of the drainage area above the power reach in Manitoba.

The Winnipeg river proper, having its source in the Lake of the Woods, flows northwesterly for a distance of 160 miles and empties into Lake Winnipeg, the total drop in that distance being 347 feet. The English river, 120 miles in length, having its source in Lac Seul, is the principal tributary and joins the Winnipeg some 50 miles below the outlet of the Lake of the Woods. The two main basins in the watershed regulated by storage dams are the Lake of the Woods with a surface area of 1,500 square miles, and a drainage area of 26,400 square miles, and Lac Seul which has a surface of about 420 and a drainage area of 11,700 square miles. The maximum and minimum regulated levels of the Lake of the Woods provide for a storage depth of 5 feet, equivalent to 7,500 square mile-feet of water, while at Lac Seul a depth of 5½ feet can be stored at present, with an ultimate depth of 16½ feet equivalent to 6,930 square mile-feet of water. Tributary to the Lake of the Woods are two other storage basins, Rainy lake and Lake Namakan with areas of 300 and 100 square miles respectively and together capable of storing 2,850 square mile-feet of water. The total storage at present available therefore amounts to more than 17,000 square mile-feet, equivalent to 470 billion cubic feet or a flow of 20,000 c.f.s. for 274 days. In other words storage facilities are available for 75 per cent of the dependable flow.

Hydrographic records available from 1907 to 1928 show a mean discharge of 25,800 c.f.s., the maximum flow being 86,600 c.f.s. in July, 1927, and the minimum of 9,440 c.f.s. as recorded in July, 1925. This excessive variation in a period of two years was due to manipulation before existing control methods were effective. Extensive studies by the engineers of the Dominion Water Power and Reclamation Service in 1915, indicate that a dependable flow of 20,000 c.f.s. can be maintained. More recent investigations which include the Lac Seul regulation lead to the conclusion that a regulated flow of 22,000 c.f.s. may be obtained with reasonable assurance except during very exceptional seasons.

Pinawa-Seven Sisters Reach

The Seven Sisters reach of the river, shown in Fig. 1, extends approximately 8 miles downstream from the point at which the Pinawa channel leaves the main river, and derives its name from the seven rapids encountered in this section, originally known as the Seven Portages. The total fall in the Pinawa and Seven Sisters reach is 72 feet, the effective head on the Pinawa channel is 60 feet, while on the main channel 66 feet can be utilized. The original plan submitted by the Dominion Water Power Department, contemplated four developments. The existing Pinawa plant and the Upper Pinawa plant, 3½ miles above, would both use the flow diverted down the Pinawa channel under heads of 42 and 18 feet respectively. The remaining flow would be utilized in the Seven Sisters reach in two stages; the lower Seven Sisters plant, situated at the foot of the reach developing the five lower falls, and the second plant situated 4½ miles upstream developing the two upper falls.

There were several reasons for this proposal. Firstly, the interests of the Winnipeg Electric Company, in respect to the diversion of water down the Pinawa channel, had to be fully considered in fixing the head water elevation. These interests involved the Pinawa power concession granted in perpetuity in 1902, based upon the diversion of 540,000 c.f.m., the unit in effect in those days, or 9,000 c.f.s. via the Pinawa channel to Lac du Bonnet. This diversion was effected by means of a rock fill diversion dam across the main river and two auxiliary dams across the secondary channels, thus reducing the dependable flow in the main river to 11,000 c.f.s. Secondly, the company had owned lands abutting on the river in the vicinity of the lower Seven Sisters falls since September 23rd, 1903, prior to the passing of the Dominion Water Powers act. The title to this land, which had been acquired by the company in order that it might construct the above mentioned diversion dam, carried with it certain rights to the power on this section of the river. Finally, the contours of the river banks were considered unfavourable to a development in one stage. Subsequent studies carried out by the company indicated that the full head could be utilized in one plant by placing the power house at some point in the Seven Sisters reach, between the two sites proposed by the government.

Experience in operating hydro-electric plants indicates that it is impossible to utilize water as effectively in four plants with divided flow, as it is in one plant, especially when such plants are operated independently. By abandoning the Pinawa plant, concentrating the head at one plant in the Seven Sisters reach, and utilizing the full flow in a single stage development, instead of in four separate plants, an increase of 50,000 commercial horsepower could be obtained with much less capital investment and less operating cost, as only one operating staff would be required. After due consideration of the above facts the government in 1928 granted the company a lease to develop this section of the river, thus removing the difficulties encountered by the government engineers.

After a single stage development had been decided on, four alternative arrangements (see Fig. 1) were studied. Due to their excessive cost the two long canal schemes were eliminated; but little difference in cost was found between the short canal and the tailrace cut scheme. However, the latter presented less hazard in construction and operation, and lent itself more readily to a partial initial development, so that this scheme was finally adopted. The full head of 66 feet will be obtained by constructing dykes to impound the water up to elevation 899, and excavating the tailrace to give a tailwater elevation of 833.

Seven Sisters Development

The capacity of the Seven Sisters plant when completed will be 225,000 h.p. Such a large block of power could not be absorbed immediately, consequently it was decided that the development should be carried on in progressive stages according to power demands. The initial stage, now practically completed, enables 60,000 h.p. to be developed from three units, operating under partial head. When further power is required the effective head on the plant will be raised, firstly by raising the dykes, and secondly by excavating the tailrace. Concurrently with

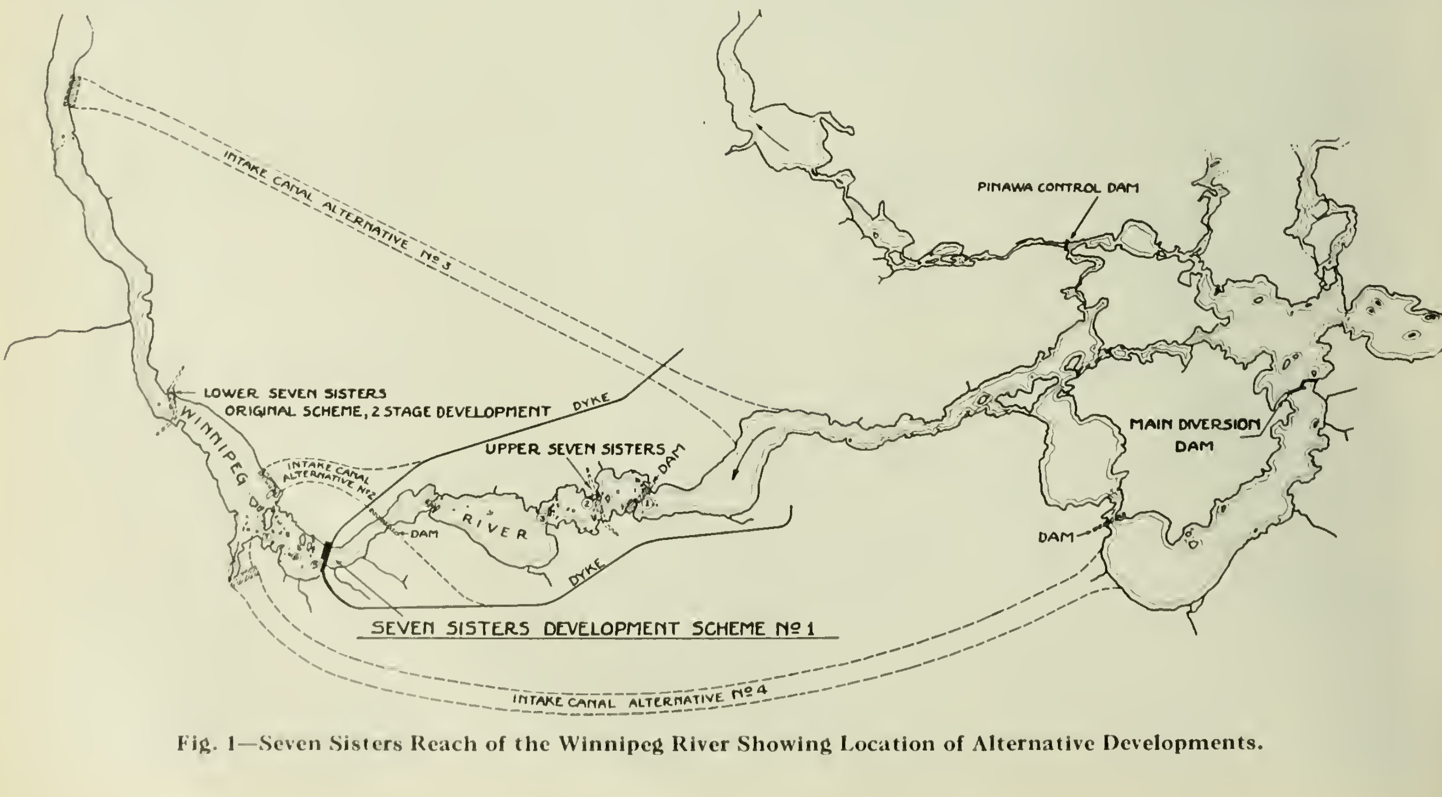

Fig. 1—Seven Sisters Reach of the Winnipeg River Showing Location of Alternative Developments.

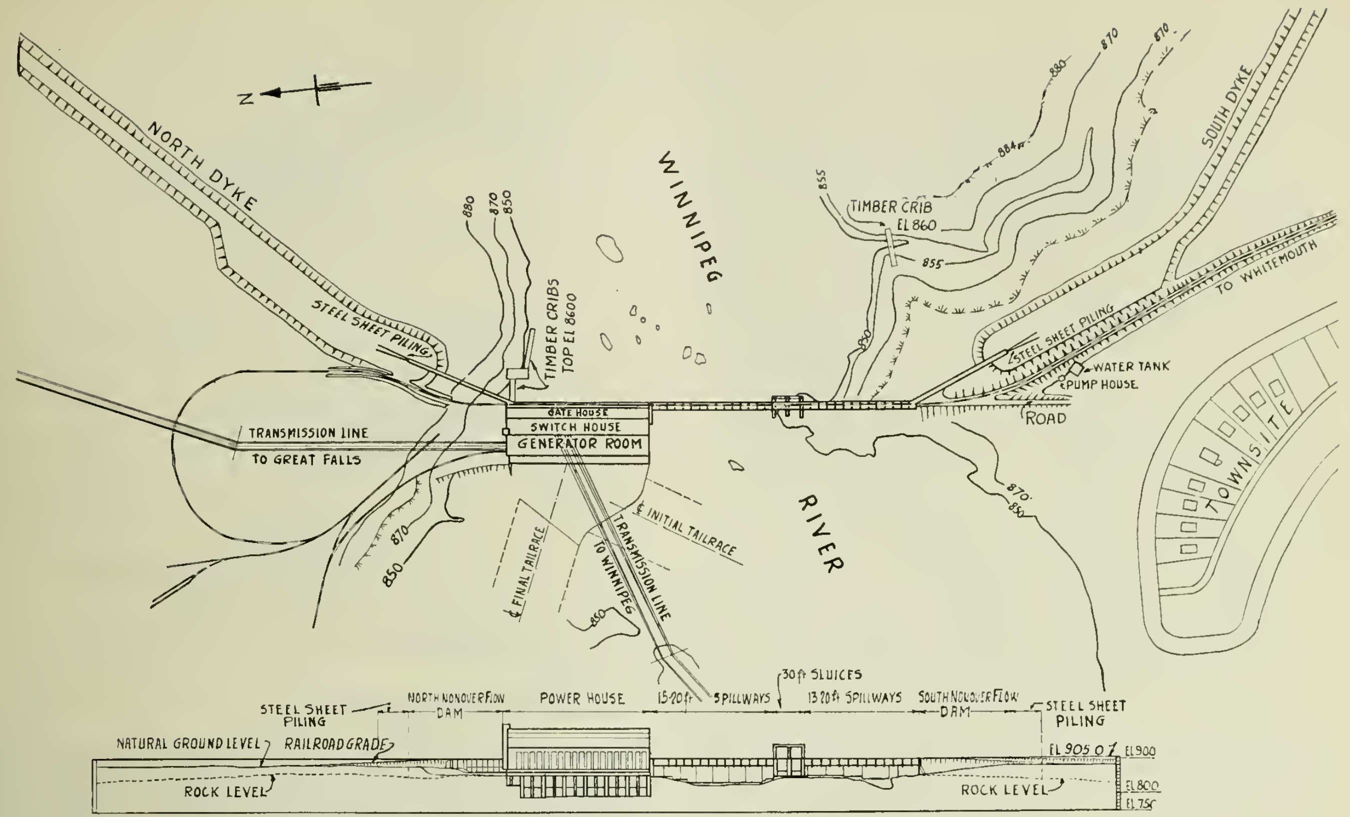

Fig. 2—General Plan Showing Power House and Dyke Location.

these procedures additional units will be installed until the full complement of six, operating under a head of 66 feet, will enable the whole of the effective power in this reach of the river to be developed.

The general arrangement of the development is shown on Fig. 2. Railroad connection is provided by a spur line 14 miles long which connects with the main line of the Canadian Pacific Railway at Whitemouth. The dam, of which the power house intake structure forms an integral part, is located at the fifth fall, where the river was relatively narrow and shallow and where advantage could be taken of an island in midstream. Due to the fact that the final forebay elevation would be above the natural ground level in this locality, dykes were constructed which extend upstream 3½ miles on the north and 4½ miles on the south shore, creating a lake 25 miles long, varying in width from one half to one and one half miles. The final tailrace excavation will extend downstream about seven-eighths of a mile.

A typical dyke section (Fig. 3) consists of a clay core 16 feet wide at the top with upstream slopes of 3½ to 1 and downstream slopes of 3 to 1. The core material is a colloidal clay and in order to protect the upstream slope from wave action, 4 inches of crushed rock is rolled into the surface and a 3-foot thick layer of 3-inch crusher run riprap is then deposited. The top is crowned and covered with crushed rock. The downstream slope is covered with stripping and seeded. In locations where the subsoil is porous but otherwise stable for a foundation, a core trench 10 feet wide is excavated and backfilled with compacted clay. Drainage ditches parallel the dykes and are provided with off-takes at suitable intervals.

Dam and Substructure

The dam is of gravity type spillway section, flanked to the south by a non-overflow concrete wingwall and to the north by the power house intake structure terminating in a non-overflow wingwall. Two sluiceways were provided in the middle of the spillway since it was considered desirable to have the discharge from the sluices remote from the tailrace, especially at the final stage of the development, when the tailwater will be about 12 feet below the water level in the natural channel. Each sluiceway has a clear width of 30 feet with sills at elevation 870, and a normal depth of 29 feet of water over the crest of the rollways. Provision has been made for placing stoplogs on both the upstream and downstream side of the sluicegates. The downstream logs can be placed by the stoplog winch, forming slack water between the two sets of stoplogs, thus equalizing the water pressure on the gates or upstream stoplogs, in case of emergency.

The spillway section has a total of 28 openings, each 20 feet wide, with sills at elevation 885, or a normal depth of 14 feet over the crest of the rollway, one of which is reserved for a log chute and a fish ladder. The spillway discharge is controlled by stoplogs handled by a winch operated from the spillway deck. For the initial development the crest elevation of the rollways was left at 874, to provide adequate flood discharge.

The spillways and sluiceways have a total discharge capacity of 126,000 c.f.s., with the normal forebay water level at elevation 899. The maximum discharge capacity under conditions of extreme high water is 185,000 c.f.s., including the Pinawa channel.

The design of the different structures is based on the following assumptions and data:

Water level....................Elevation 900.
Weight of concrete.............145 pounds per cubic foot.
Coefficient of friction...........0.65.
Uplift.........................75 per cent of static head at heel decreasing to zero at toe.
Ice pressure:
Against each spillway pier.....100,000 pounds at elevation 900.
Against each sluiceway pier....225,000 pounds at elevation 900.
Against each non-overflow section....................No ice pressure: these are protected by air bubbler system.

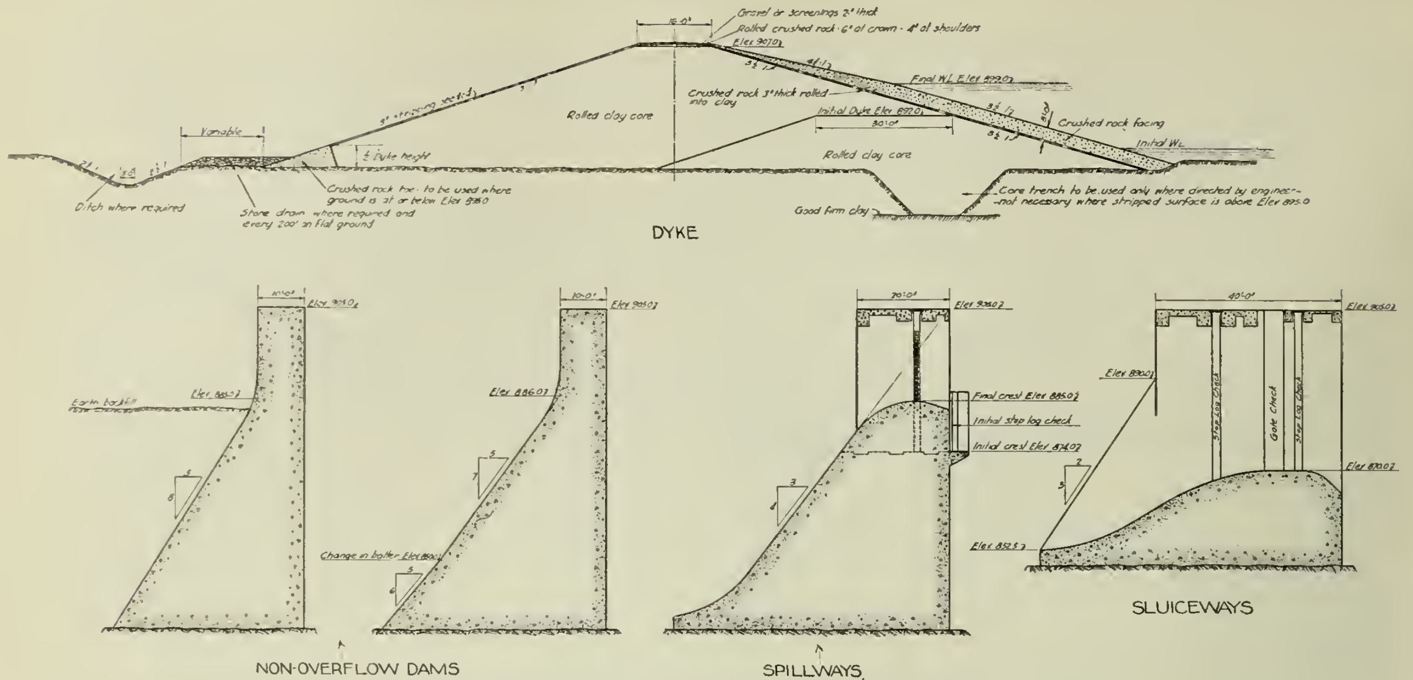

Fig. 3—Typical Sections of Dykes, Dams, Spillways and Sluiceways.

Ice apron, power house intake	25,000 pounds per linear foot at elevation 900.
Scroll case roof	Full static head plus 15 per cent for surge.
Live load on generator room floor	500 pounds per square foot.

The piers of the spillways and sluiceways are designed as reinforced concrete cantilevers carrying the ice thrust and reaction from the stoplogs and gates to the mass concrete below.

As the scroll cases and draft tubes for units 4, 5 and 6 were not built, the intake structure had to be designed to withstand full hydrostatic pressure and uplift without any assistance from these parts. The weight of the concrete not being sufficient to counteract the overturning moment, and the area of the intake piers not great enough to provide space for a sufficient number of dowel anchors into the rock, it was decided to make use of the weight of the water upstream from the emergency gates. The horizontal thrust which is exerted by the water on the head wall was transferred through the piers into the floor slab, the weight of water on the floor slab thus giving the necessary stability to the head wall. The latter was doubly reinforced (see Fig. 5), firstly by horizontal steel on the downstream side enabling the wall to take the load by beam action, and secondly by extending vertical steel from the roof of the intake flume up into the stream side of the wall, providing a cantilever action, and thus partly transferring the load into the roof.

All piers were considered fixed at the top and supported at the bottom with one adjacent water passage full and the other empty. A horizontal diaphragm was placed across the centre opening of each turbine intake at about half the height of the piers to give additional stiffness to the intermediate piers.

The bed rock being sound and remarkably free from fissures, it was not necessary to provide a cut-off wall or drainage for the intake structure foundation.

The hoop reinforcing of the scroll case was carried back to, and bonded with the reinforcing in the intake piers. In designing this reinforcing the volume of the concrete in the power house on the downstream side of the centre line of units and above the scroll case floor was assumed as a dam with a coefficient of sliding of 0.50. The walls of the scroll case and entrance were designed for water pressure only, the roof being considered as simply supported on the walls and producing no bending stresses in them. The construction joints were not assumed to be fully watertight, and dowels were provided to counteract the water pressure. In considering anchorage for the scroll case roof against water pressure, uplift was considered as full static head plus 15 per cent surge. Half the span between the stay vanes and vertical walls was considered as contributing to uplift on the stay vanes and the remainder assumed as anchored by the wall.

The reinforcement of the central part of the draft tube roof was arranged in beam-like strips which were assumed as taking part of the generator room floor load together with the weight of the generator, water wheel and hydraulic thrust. The pressure in the scroll case in excess of that due

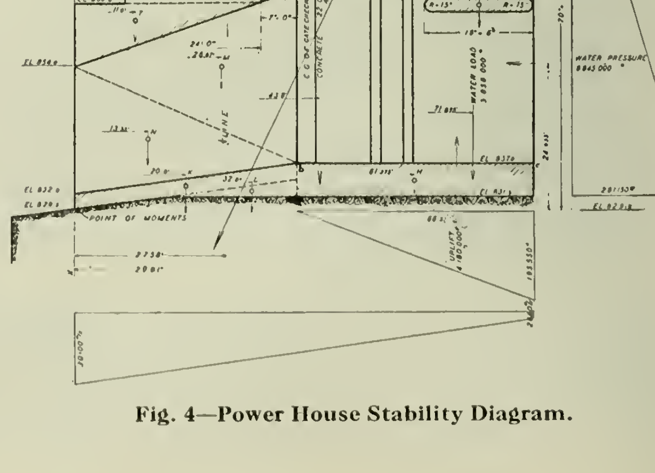

Fig. 4—Power House Stability Diagram.

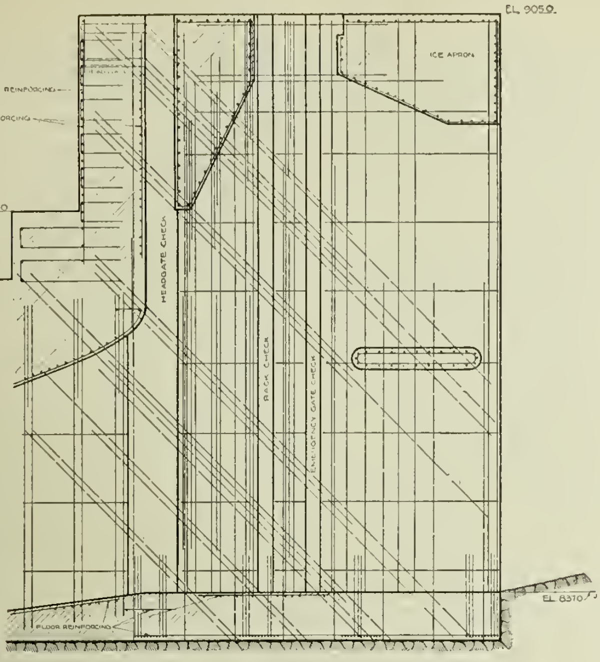

Fig. 5—Section Through Intake Showing Reinforcement.

to the weight of the water was not taken into account, since this pressure acts boths upward and downward and the speed ring stay vanes are capable of taking tension. The remainder of the draft tube roof carries the generator floor loads, the downstream wall column reactions and the water load due to tailwater on that portion of the roof outside the downstream wall. The uplift due to the tailwater head was neglected.

Superstructure

The superstructure (Figs. 7, 8 and 8a) consisting of three main sections, the generator room, transformer and switch room, and gate-house, has been completed to house the service and first three power units with a temporary end wall between units Nos. 3 and 4. It is built of concrete and structural steel throughout with walls separating the three main sections of the building. The transformers, oil switches, and high tension bus room have all been so separated by means of tile and concrete partitions, fire-doors, etc., that a fire or flashover originating in one part of the building will not be communicated to other parts. Metal sash is used throughout the building, and doors to switch pockets and transformer compartments are terne-clad or kalameine.

There are three main switch floors containing the step up transformers and 110,000-volt switching equipment, and a fourth floor is provided for the high tension bus. The control room between units Nos. 3 and 4 is situated on the level of the transformer floor and overlooks the generator room. Immediately above the control room are offices, and below a mezzanine floor for the local station service switches, control cables, transformer oil and water piping. At the north end of the generator room floor there is a machine shop, air compressors, and a room for housing the cooling water pumps. The compressors are required for the bubbler system and for pneumatic dewatering of the units. Erection pits are provided in the generator room floor for the generator shaft while erecting or handling the rotors. Railway connection is furnished by a track extending under the generator room crane. Tracks are installed on the transformer room floor for moving the transformers from their compartments to a loading platform which extends out into the generator room bay, from where they can be handled by the crane. Light tracks are also provided on other floors for moving circuit breaker tanks from the elevator to their respective locations.

Below the generator room level are located the local service turbine room, oil storage, and space for electric heating boilers. The floors of the transformer pockets slope sharply to the back and drain to the tailrace. Oil drainage is also provided for each circuit breaker compartment and each high tension breaker is enclosed in a compartment with openings at the top for the leads.

A 500-h.p. electric boiler is installed for providing steam heat during period of light load. For this purpose blower type heater units are mounted in the generator room and on the roof of the main air duct arranged to discharge heated air into the turbine pits when necessary to prevent the water, oil lubricating, and governor systems from freezing.

The generators are ventilated by air drawn from a ventilating duct below the generator room floor and continuous from end to end of the building. By means of adjustable louvres the air is supplied to this duct either from the generator room or from outside the building in any proportion. In the summer the generator room windows will be opened to get rid of the heated air, but in winter provision is made to circulate it through the switch-house and gate-house by means of exhausters installed in pockets at the level of gate-house floor. Openings are provided for free passage of the air which is drawn from the generator room at the roof trusses, through the switch-house and into the gate-house near the roof. It will be exhausted from the gate-house floor and forced back into the generator room through suitable ducts. Ventilators are installed on the switch-house roof, and in these fans will be used to clear the building of smoke in the event of a fire.

Intake Equipment

There are three headgates per unit, of the fixed roller type, 15 feet wide by 34 feet high. They were designed for a maximum head of water of 66 feet over the sill of the gate and have a normal lift of 69 feet, allowing them to be lifted completely out of the water when not in use, this feature being desirable on account of the corrosive action of the Winnipeg river water on mild steel. The headgates are designed for a maximum unit stress of 18,000 pounds per square inch. The gates are raised by individual hoists operated by a motor-driven line shaft, there being one motor reduction unit for every six gates. The gates are arranged for electrical remote control gravity lowering by means of push buttons on the gate-house floor for each individual gate, and on the switchboard for each unit, lowering the three gates for that unit simultaneously. Limit switches are provided for raising and lowering. On lowering, the tripping device applies the brake when the gate is a few inches above sill, thus preventing it from striking a heavy blow and unwinding the hoisting rope. In order to make the gates self-lowering under all conditions they are loaded with concrete weights.

The trash racks are located immediately in front of the headgates, and are made in removable panels arranged for

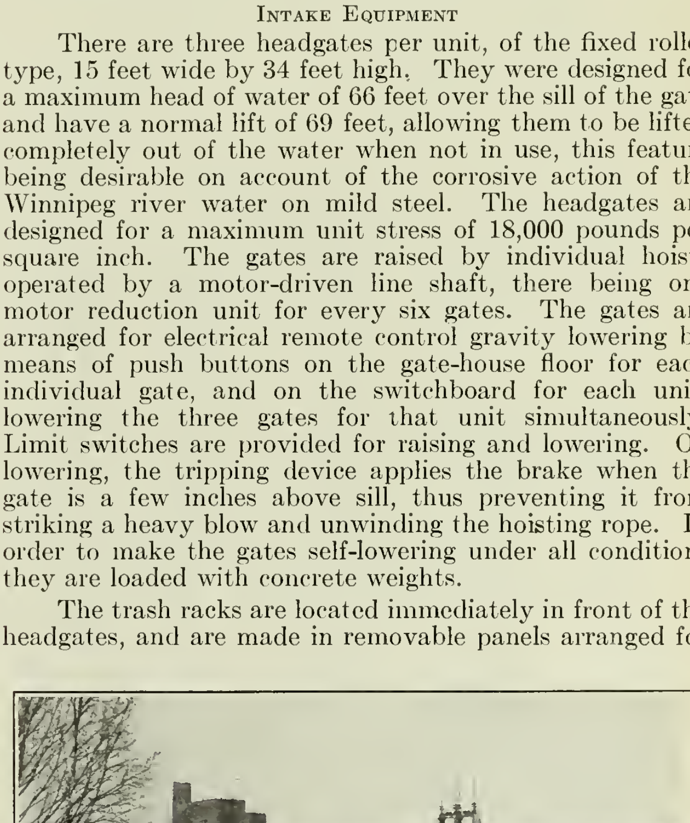

Fig. 6—General View of Power House and Spillways.

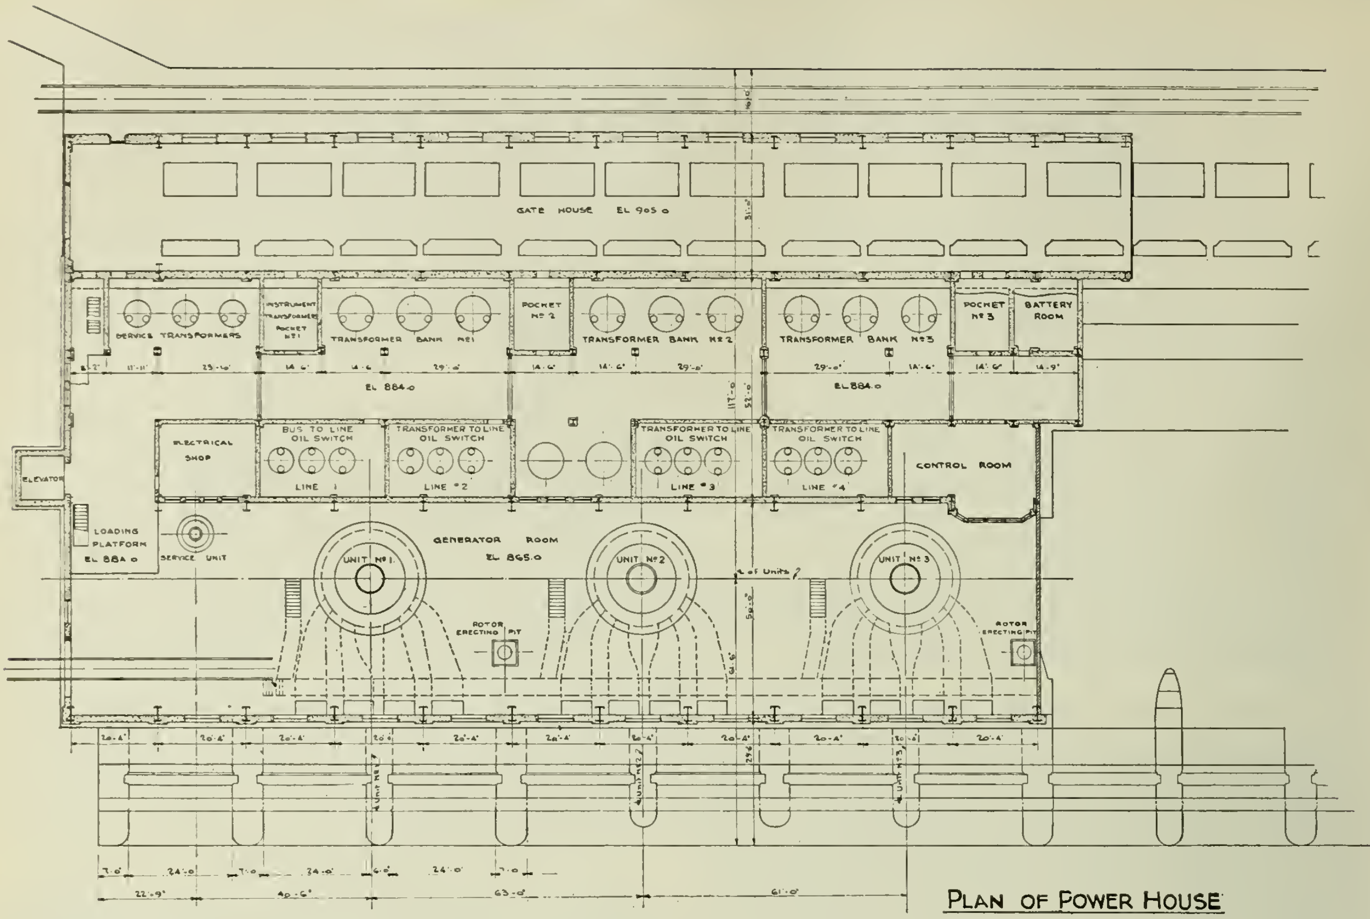

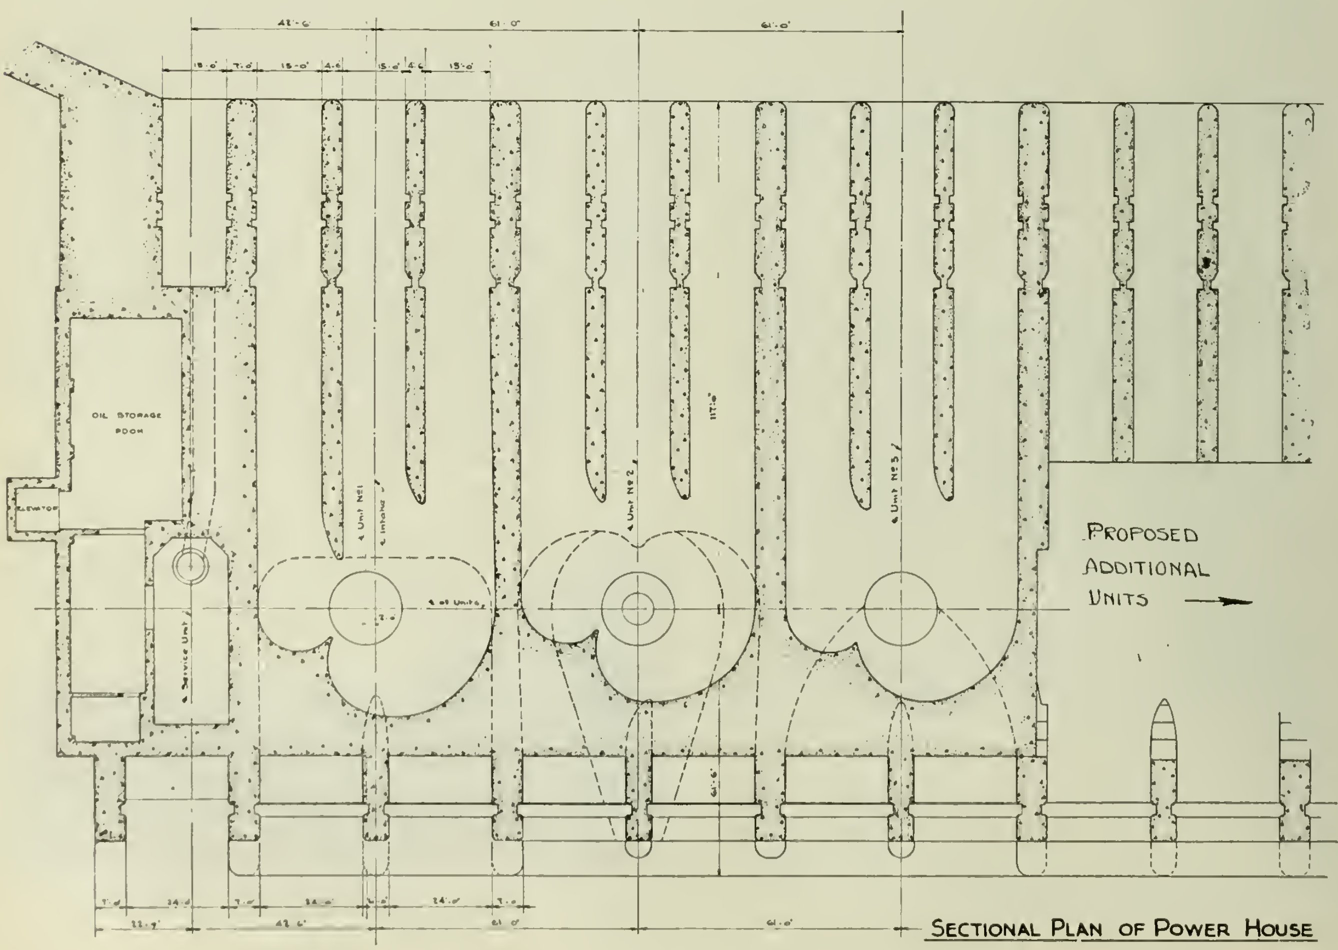

Fig. 7—General Arrangement of Power House.

hoisting by the gate-house crane. In removing the rack, the sections are lifted out one by one, by the crane, the remaining sections being supported in place by dogs engaging in bearing plates in the gate-house floor. Each section consists of a structural steel frame with the rack bars welded thereon. The racks are designed for a maximum stress of 22,000 pounds per square inch when completely blocked by debris under full head.

Four feet upstream from the racks, there is a series of steel gains for the emergency gates, of which there are three complete sets, sufficient for one unit. Sliding gates rather than those of the roller type were chosen for the reason that the flow can be shut off by either the headgates or the turbine gates, and the chances are slight of having to operate the emergency gates in swift flowing water.

The sluicegates have a height of 33 feet with a clear width of opening of 30 feet and are of the fixed roller type with individual hoists. The gates are provided with limit switches and gate position indicators and can be operated by push button control either from the hoist platform or from the deck of the dam. They are arranged for electric heating of the embedded parts and skin plate. For this purpose the backs of the gates were sheathed in, and a total of 30 kilowatts of heaters per gate are installed in the enclosed space. Bayonet heaters totalling 8 kilowatts per gain are installed in voids adjacent to the bedded parts. These gates are designed for a maximum stress of 18,000 pounds per square inch under the worst conditions.

The Winnipeg river is not subject to excessive freshets and for this reason the greater part of the flood water will be discharged by the spillway openings regulated by stoplogs. The stoplog hoist for handling and piling the stoplogs is electrically operated and travels by power drive on standard gauge track laid along the whole length of the dam. It has three speeds of operation in hoisting and lowering and is provided with a slipping clutch to guard against overloading. The frame of the hoist is adjustable in length so that it can handle the 20-foot spillway logs and also the 30-foot emergency logs for the sluiceways.

Turbines

Turbines of three different makes were purchased and this somewhat unusual policy was adopted in order to determine the most economical unit as regards first cost of machinery, concrete setting, efficiency, and operating characteristics, for installation in the final development. It was felt that a gain of a small percentage in efficiency would more than compensate for the additional cost. Piezometer tubes and facilities for applying the Gibson, Allen, and current meter efficiency tests have been installed in the intake passages.

Six units of the high speed propeller type were decided on for the complete development, and three of these have been installed in the initial development. The turbines are rated at 37,500 h.p. under a head of 66 feet and a speed of 138½ r.p.m. This gives a specific speed of 142, and a discharge at full load of about 5,500 c.f.s. for each machine, while the efficiencies at best gate opening are about 90 per cent. The WR^2 of the generators is 22,000,000 pounds feet squared, somewhat in excess of that required for good governing.

The turbines proper are somewhat of similar design but the draft tubes are quite different. The runners are cast steel and vary from 195 to 200 inches in diameter, both four- and six-blade types being used. Two of the units have ten stay vanes each, of cast iron and semi-steel respectively, while in the case of the third unit the complete speed ring is made of welded plate having twenty stay vanes. All units have steel plate throat rings and draft tube liners, the latter extending down about 16 feet below the centre of the speed ring. The scroll cases are all of the spiral formed concrete type, the draft tubes also being of formed concrete. No 1 draft tube is a modification of the hydraucone type employing a plane base; No. 2 of the Moody symmetrical spreading type with central cone; and No. 3 of the more usual elbow type. In the case of the No. 2 unit the upper 14 feet of the cone is plate covered. Each unit has 20 welded plate guide vanes, with the usual breaking links, or shearing pins. The main shaft is 27 inches diameter in all cases, and the lignum vitae water-lubricated guide bearings are all interchangeable. The runners have a low setting, the trailing tips varying from elevation 825 to 829 based on a minimum tailwater elevation of 833.

The governors are identical for the three units and are of the actuator type using oil under pressure, and with motor-driven flyballs. Each unit has its own oil pumps but these are of sufficient capacity for two units and are arranged for operation either singly or interconnected. The closing time for full stroke is from 2½ to 3 seconds, and the sensitivity ¼ to ½ per cent.

Mechanical Equipment

On account of the high tailwater of the initial development which will prevail for a considerable period, the tailwater will be above the roof of the scroll cases. It was felt that exceptionally good facilities should be available for dewatering the turbines for inspection and repairs. This can be accomplished separately in two ways; firstly by a system of air locks by which the water in the scroll cases can be depressed pneumatically; and secondly by pumping after placing gates over the draft tube outlets for which purpose a travelling gantry crane has been provided. The air lock (Fig. 9) will be used generally for inspection purposes but when any extensive work is necessary, such as the removal of a turbine head cover, the tailrace gates will have to be lowered and pumping resorted to. The draft tube dewatering pump of the bore hole type has a capacity of 3,500 gallons per minute at 70-foot head, and can be set up in each pump shaft as required. The motor and driving head are handled by a special hoisting drum on the gantry crane. However, provision has been made to handle the 60-foot length of 16-inch riser pipe, pump, and shafting by means of a jib crane attached to the downstream wall of the generator room.

An air bubbler system will be installed for preventing the formation of heavy ice in front of the dam, sluicegates, and stoplogs; and in front of the racks for the purpose of stirring up silt and debris as an aid in keeping them clear. For this purpose two 800 cubic feet per minute compressors with suitable air dryer are provided. They are also used for pneumatic dewatering of the scroll cases.

On account of high tailwater especially during the initial stages, it was necessary to provide ample sump pump capacity and for this purpose two 500 U.S. gallons per minute pumps were installed, and are arranged for automatic operation by means of float switches.

A 50-ton electric travelling crane is provided for the gate-house, and in order to cut down head room to a minimum a special spreader which can be substituted for the crane hook is used for handling the emergency gates, racks, and headgates.

The generator room is equipped with a 200-ton four-motor eletric travelling crane with a 25-ton auxiliary hoist, and in addition to serving the generators, turbines, and equipment on the generator room floor it is arranged for handling the main transformers, and switching equipment, all of which can be transferred by it from cars to a loading platform on the level of the transformer floor, from which point the switching equipment for the upper floors is handled by a freight elevator.

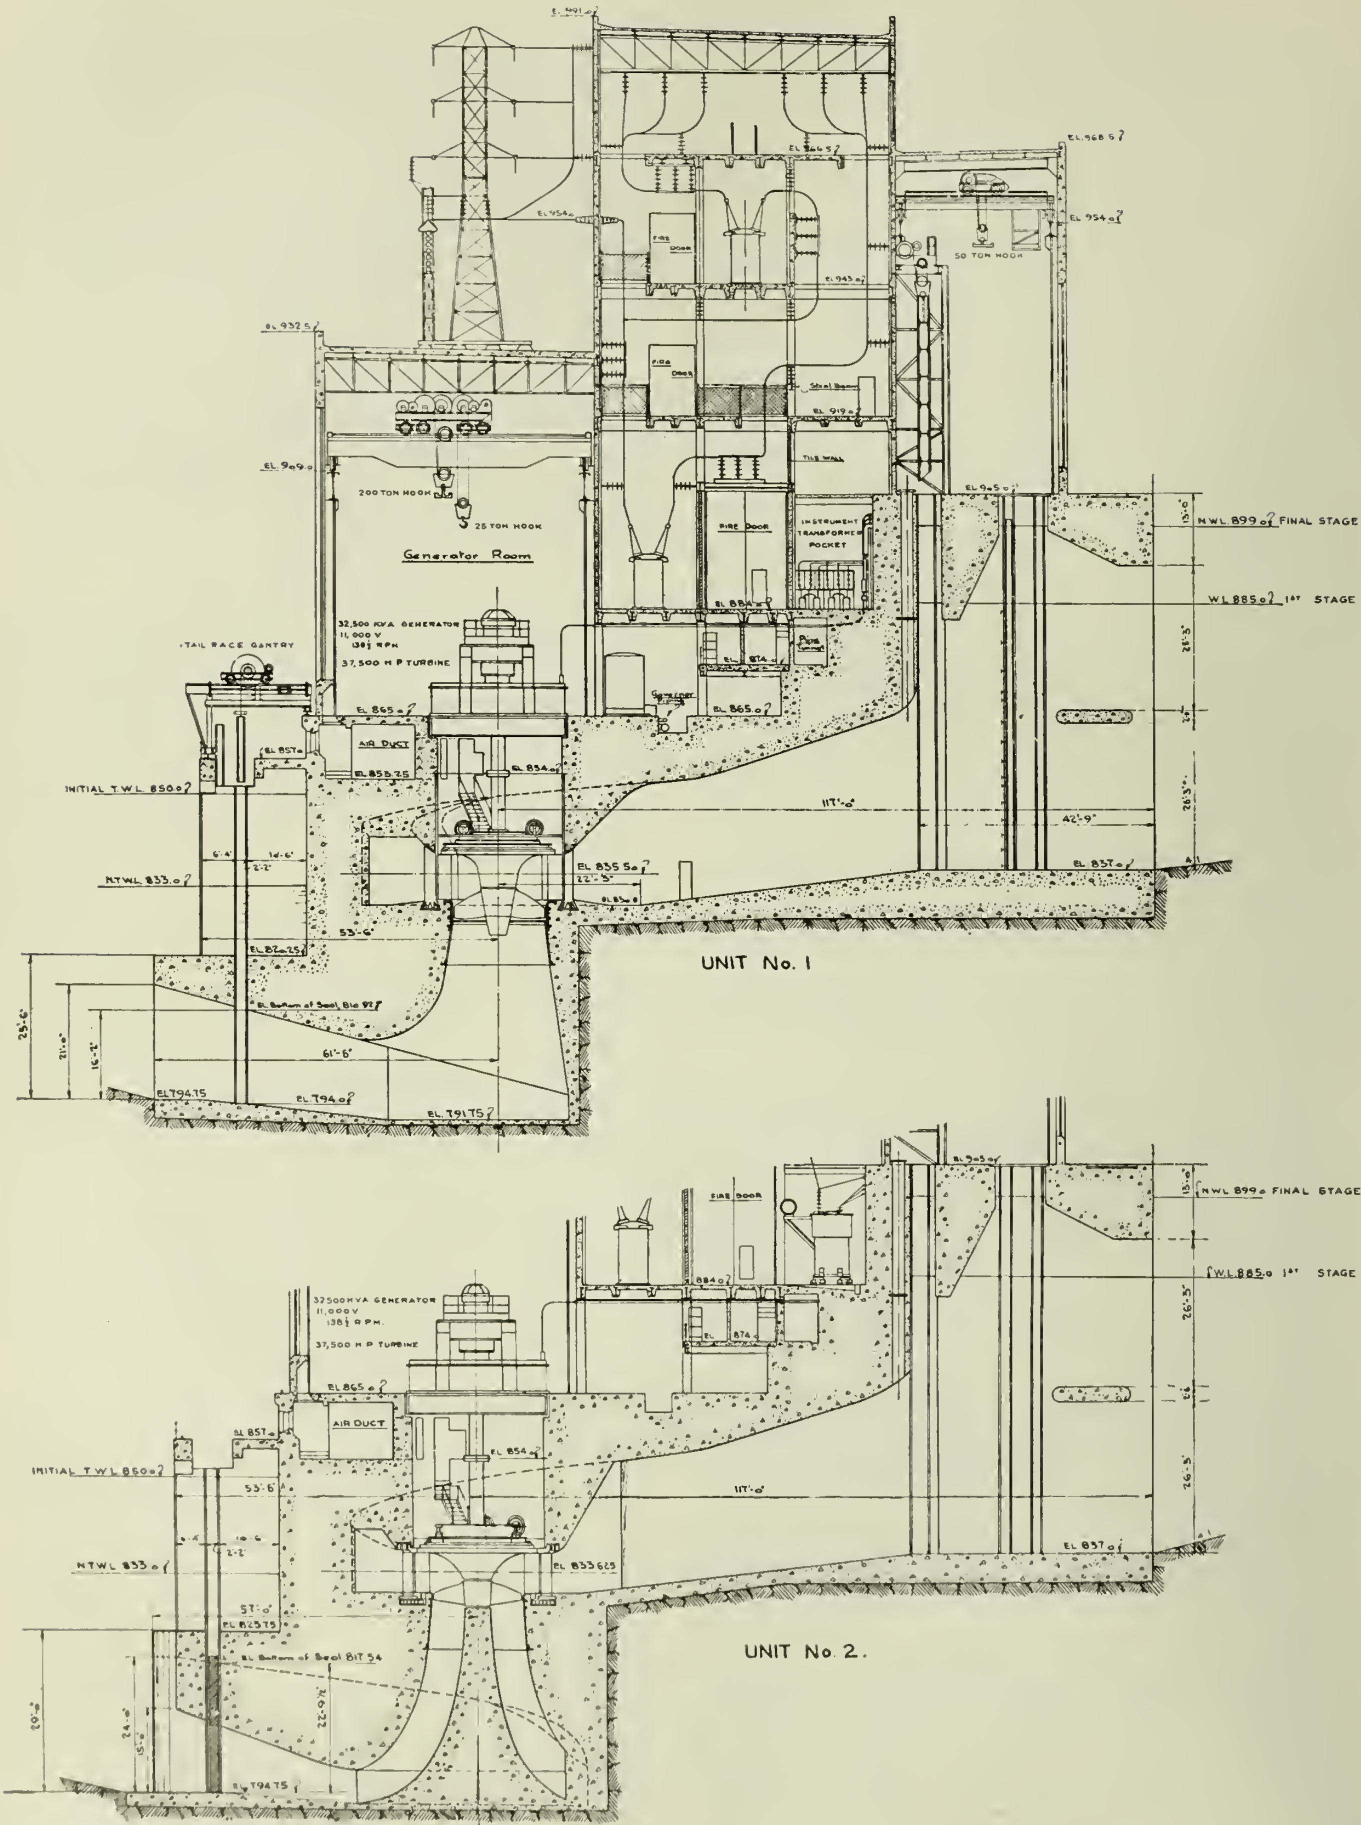

Fig. 8—Cross Section through Power House Showing Turbine Settings for Units Nos. 1 and 2.

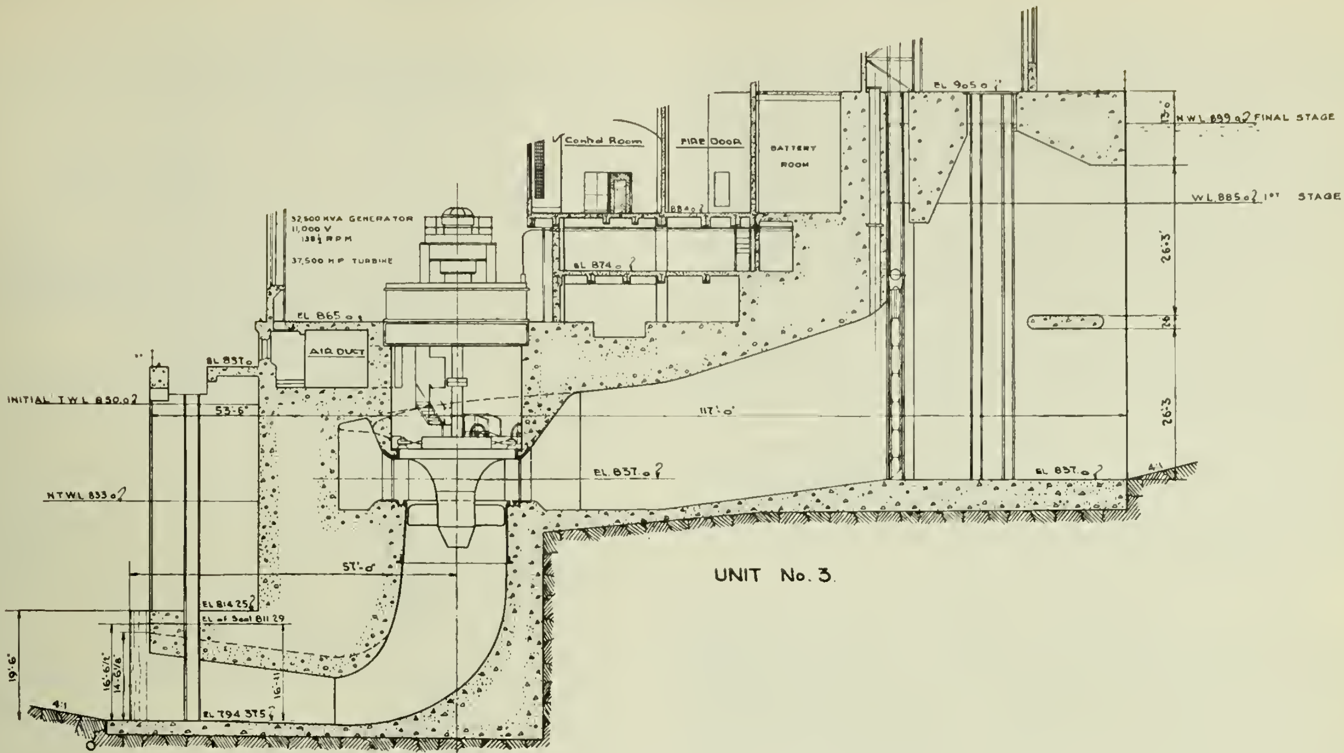

Fig. 8a—Cross Section through Power House Showing No. 3 Unit Turbine Setting.

A 5-ton freight elevator with push button control operating at 70 feet per minute serves all of the floors from the oil storage room at elevation 846 to the high tension bus room at elevation 966.5. The car is of sufficient size—9½ feet square by 13 feet high—to carry the high tension oil circuit breaker tanks. Rails are sunk in the floor of the car and line up with rails on the various floors on which oil circuit breakers are installed in order to facilitate the moving of this equipment.

Generators

As outlined above, the best size of water wheel appeared to be 37,500 h.p. and since there were no electrical features which rendered the use of such a unit undesirable, generators having a rating of 32,500 kv.a. at 85 per cent power factor were chosen. This rating is slightly in excess of that of the water wheels but additional kv.a. capacity was considered desirable. The generators are of the vertical type having a thrust bearing and two guide bearings. Each has a rating of 32,500 kv.a. at 85 per cent power factor, 11,000 volts, 3-phase, 60 cycles, at 138½ r.p.m. Full load temperature rise is 60 degrees C.; full load efficiency 97 per cent, and transient reactance 35 per cent. Temperature detector coils are supplied and each unit has a direct connected shunt wound interpole exciter rated at 165 kw. 250 volts.

The stator winding is a four parallel star. Two leads are brought out from each end of each phase winding so that split phase protection may be applied. Current transformers to give this protection on the neutral end of the winding are mounted in a sheet steel housing on top of the generator frame. The neutral lead and six main leads are brought out through the top of this housing in brass conduits. Non-automatic sprinklers are installed inside the generator frames by means of which the ends of the winding may be sprayed with water in case of fire. The individual oiling system is used, there being no connection between units and no central oil supply. A small filter and motor-driven oil pump is installed in the machine pit and a gear pump driven by the main shaft is located in the oil pan below the lower guide bearing. Under normal operation the shaft-driven pump will deliver oil to the thrust bearing and to each guide bearing independently. All three bearings drain to the filter. The motor-driven pump operates automatically in case of failure of the gear-driven pump and is also used for starting up. The generators are fabricated throughout of steel plates and structural shapes welded in place, only a few hundred pounds of cast metal being used out of a total weight of 713,000 pounds per unit. The rotor is built up on a small cast steel hub which is keyed to the shaft, the inner portion of it being a more or less open framework of heavy steel plate while the rim consists of laminated punchings which are keyed to the inner portion. A large number of fitted dowels and through bolts hold the laminations rigidly in place so that the rim takes care of all radial and tangential forces.

A centrifugal overspeed relay on the shaft will, by opening the governor safety solenoid circuit, close the turbine gates to no load position, and at the same time cut resistance into the exciter field by interconnection with the overvoltage relay. A two-pole electrically operated field circuit breaker and the field discharge resistor are mounted on the side of the top bracket thus shortening the exciter leads, and no auxiliary or emergency excitation circuit is provided.

The station service generator is rated 1,000 kv.a. at 75 per cent p.f. 2,200-volt 3-phase, 360 r.p.m. It is of the vertical type with a thrust bearing and two guide bearings, the upper one located in the same oil well as the thrust bearing. There is no forced oil circulation. The thrust bearing is water cooled. The winding is a single circuit star with both ends of each phase brought out for differential protection. The neutral is solidly grounded.

Transformers

The main transformers are oil insulated water cooled, single-phase, rated at 10,900 k.v.a., 45 degrees C. temperature rise; ratio 11,000/72,000 volts with full capacity taps for 63,500, 65,000 and 68,000 volts on the high tension winding. They will be operated delta Y connected at 110,000 to 125,000 volts with high tension neutral solidly grounded. Three banks of three transformers and one spare have been installed. They have a reactance of 10 per cent and a full load efficiency of 99.1 per cent. The cores are of the three legged type with windings on the centre leg only. The high tension bushings are of the condenser type equipped with bushing type current transformers. The low tension bushings are cemented porcelain. The transformers have conservators, no load tap changers, and all the usual accessories. The tanks are mounted on swivel bogies, which run on the previously mentioned tracks. The weight of a complete transformer is 98,000 pounds. It contains 2,400 Imp. gallons of oil; 25 gallons of cooling water per minute are required.

A bank of three 750 kv.a. transformers and a spare are provided for duplicate station service. They are oil insulated, water cooled, 50 degrees C. temperature rise, 63,500/2,200 ratio, Y delta connected with high tension taps and no load tap changers. They are equipped with conservator tanks, calcium carbide breathers, oil-filled high tension bushings and swivel rollers.

Electrical Layout

The relative advantages of indoor and outdoor switching equipment were carefully considered, and from estimates made it was felt that the installation of indoor apparatus was justified for several reasons. Considerable weight was given to the severity of the winter climate in this locality, making outdoor installation and maintenance more costly. To provide the same factor of safety as regards continuity of service, additional equipment would be required outdoors, also the cost of low tension connections and cooling system were relatively higher for the outdoor scheme. In addition to this with the building design decided upon there was considerable space available between the gate-house and the generator room; without involving great additional expense, it was found that this space could be enlarged sufficiently to house the switching apparatus.

The system of connections adopted is shown in Fig. 10 and while it has not quite the flexibility of a double high tension bus, it uses only three breakers per unit instead of four. It provides for unit operation of generator, transformer bank and line, and synchronizing at the receiver end can be conveniently carried out. A single high tension ring bus is provided so that any transformer bank may deliver power to any line and any circuit breaker may be overhauled without interrupting service. Relay connections also are simplified by this system. There is no low tension bus and no means of interconnecting units on the low tension side of the transformer banks.

The high tension breakers are rated at 138,000 volts, 1,500,000 kv.a. rupturing capacity, A.I.E.E.-2 O.C.O. duty cycle. They are operated by a D.C. motor mechanism of the fly ball type, with the mechanism auxiliary switch and control wiring completely enclosed in the mechanism housing. The circuit breakers are guaranteed to close in .9 seconds, and require approximately 90 amperes at 250 volts for operation.

All indoor high tension disconnecting switches are gang operated, remote manually controlled of the three insulator post type, the centre rotating insulator being mounted on double ball bearings. All switch handles may be locked in both open and closed positions. Insulator stacks consist of four units having a dry flashover of 330,000 volts. Line disconnecting switches are equipped with grounding blades gang operated by means of a separated handle and operating mechanism. The grounding blades and power blades are interlocked as described below.

The equipment will be interlocked throughout by Robinson interlocks, locking each circuit breaker compartment door, each oil circuit breaker, each bus section compartment, and each disconnecting switch handle.

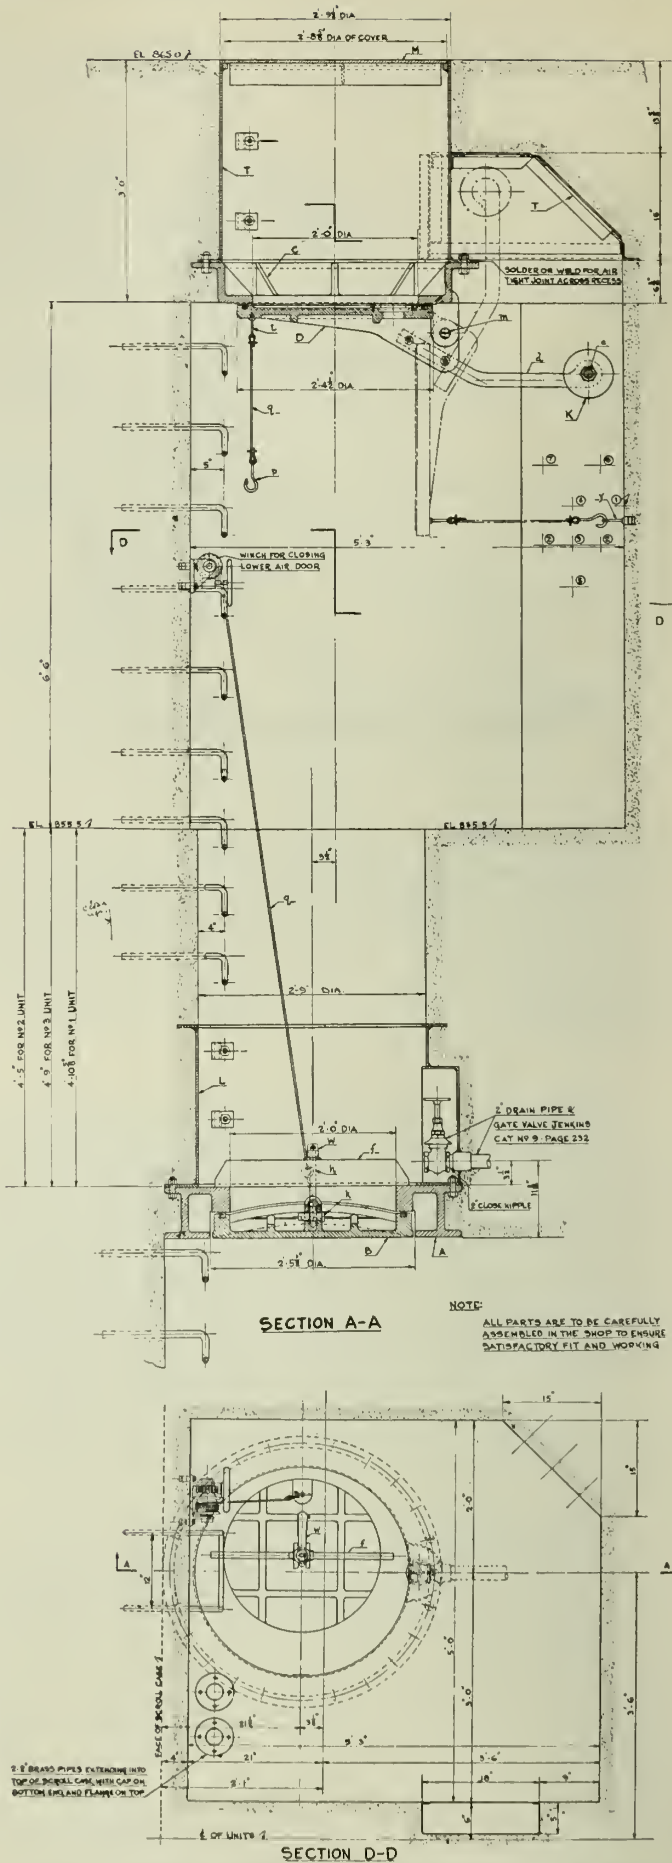

Fig. 9—General Arrangement of Air Locks for Dewatering Wheel Cases.

The circuit breaker interlock is electrical, and is essentially a key operated snap switch. With the key in the operating position, the circuit breaker can be opened and closed from the switchboard, but with the key removed from the lock the circuit breaker cannot be closed electrically. This interlock is mechanically connected to the circuit breaker operating mechanism and when the circuit breaker is closed the key is held in the lock and cannot be removed. The interlocks do not occasion the operator any additional work except the handling of the keys. They do, however, compel him to carry out all operations of clearing a piece of apparatus in a fixed sequence, which, when completed, absolutely assures him that none of the apparatus is alive. As long as he retains the clearance key none of the apparatus can be accidentally made alive, either from the control room or elsewhere. A master key will be available in the control room to give quicker access to a compartment in case of emergency.

A copper strap ground bus, bolted to the wall at a safe height, is carried the full length of each main floor. Connections are made to the building steel and to each insulator base, disconnecting switch, transformer, generator, and conduit run. Connection from apparatus to the ground bus will, in most cases, be buried in concrete, but the connections at both ends will always be open so that the condition of the ground can be checked up at any time. Three ground plates are buried in widely separated and permanently wet clay deposits, on both banks of the river.

The control switchboard is made of ebony asbestos lumber with an angle iron framework and channel iron base set on concrete pads with top four inches above the floor level. The control cables from the back of the board pass down through slots to cable trays in the room immediately below. The board is made in two sections mounted back to back. On the front section are mounted the indicating meters, control switches, test blocks and mimic bus; on the back section the relays, graphic meters, and integrating meters. Two voltmeters and two synchronoscopes are mounted on a swinging panel to the left of the front section.

The generators are protected by differential relays, split-phase balance relays, overvoltage, and overload relays. The latter, being required for protection of the high tension bus only, will be given a very high current and short time setting.

The transformers are protected by differential relays and the bus tie and line breakers by overload and ground relays. Where a relay is required to trip two or more circuit breakers simultaneously a multipole auxiliary relay is connected between the protective relay and the circuit breaker trip coils. The auxiliary relays are self-resetting except those operated by differential relays which are hand reset. If a breaker is tripped by differential relay it cannot be reclosed until the operator goes to the relay board and resets the auxiliary relay by hand, thus assuring that he will examine the apparatus involved before reclosing the breaker.

A signal equipment is provided on each generator panel and on pedestals near each governor, by means of which the floorman and the switchboard operator can exchange signals to start, stop, pick up load, drop load, and O.K. The switchboard operator controls an electric horn and a signal light adjacent to the machine which requires attention together with the standby signal on the signal pedestal. Arriving at the generator, the floorman will acknowledge the signal by turning out the standby light both at the pedestal and at the switchboard. The floorman can call the switchboard operator by means of a signal bell which may be operated from any signal pedestal. In addition to this, telephone connection is provided between the control room and signal pedestals.

By means of test blocks, any relay or meter may be calibrated in position. All work required in this connection can be done from the front of the switchboard and no connections whatever are disturbed. Circuit breaker trip circuits from relays are carried through the test blocks as well as current transformer leads, so that a cycle counter may be connected in circuit and relays accurately timed. When testing relays with test block covers removed, a tripping circuit from the control switch is maintained complete so that the circuit breaker may be tripped by the control switch if necessary.

Each generator has a voltage regulator of the exciter rheostatic type with hand-operated adjusting rheostat. Line drop compensation up to 24 per cent is provided, and cross current compensation can be used if necessary.

The station service switching is of the metal clad type, electrically operated and controlled from the main switchboard with protective relays and integrating meters mounted at the equipment. Under normal operation, essential circuits will be carried on the station service generator and non-essentials on the local service transformer bank. All services, however, can be carried on either source. By means of a transfer bus any circuit breaker may be taken out of service without causing an interruption. Power for the electric boiler, the townsite and outside construction work for future extensions will be distributed at 2,200-volt. All other circuits are carried to secondary transformer banks, 2,200/550 volt transformation ratio, and of ample capacity so that all essential service could be maintained with two transformers of any bank connected in open delta.

Racks with steel trays carrying control cables run the length of the building to the switchboard, and control conduits terminate in the tray tunnel. The control cables are multi-conductor 30 per cent rubber, and are lead-covered where subject to moisture but braid covered for the upper floors.

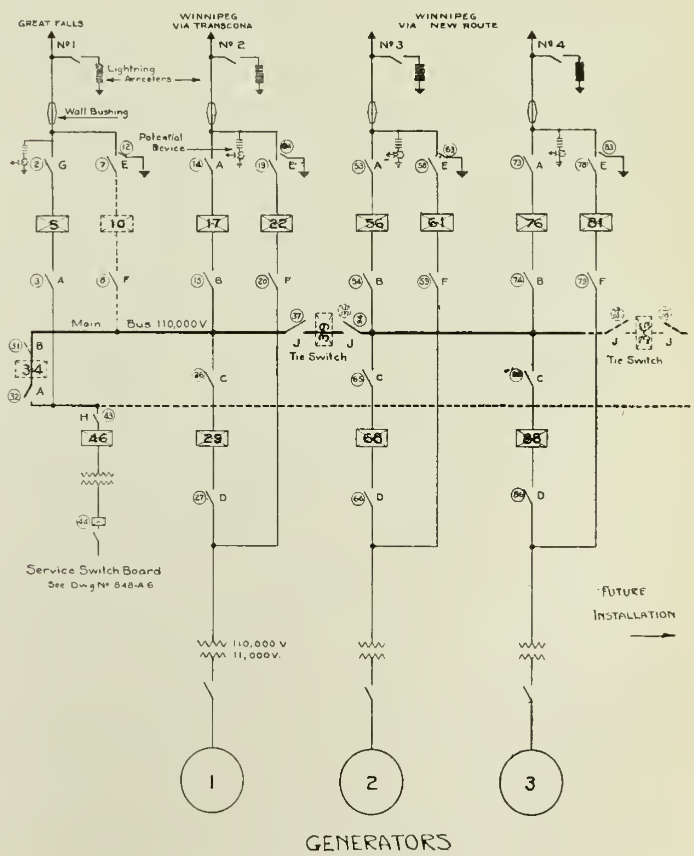

Fig. 10—Diagram of Connections.

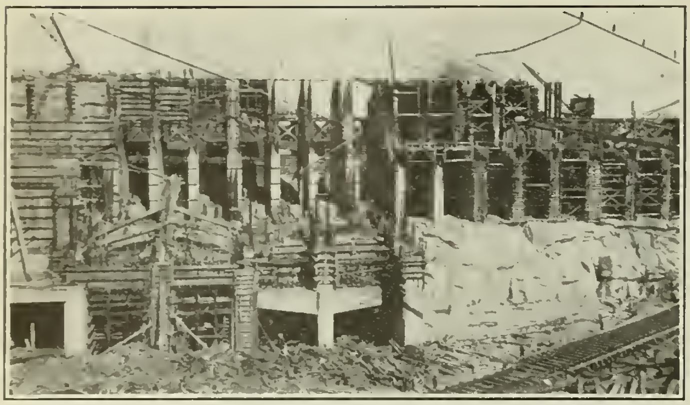

Fig. 11—South End of Power House From Downstream.

A fireproof instrument transformer pocket for current and potential transformers is provided for each main unit. There are six current transformers for split-phase protection and three others having five secondary windings each for transformer differential, generator differential, meters, relays, and voltage regulator compensation respectively. Potential transformers are isolated by concrete barriers. There are two potential transformers per unit for driving the governor speed head motor, two with double secondaries for meters and relays and one for the voltage regulator. Combination resistor type disconnecting switches and fuses are installed in the primary circuits of each.

High tension potential devices of the capacity coupled type will be used in place of the conventional potential transformers for measuring line voltage and for synchronizing. They consist essentially of a comparatively low ratio potential transformer connected to the line by means of condensers. A protective resistor is connected between the condensers and the line, voltage being measured from one phase to ground. The outgoing high tension lines are taken through the bus room wall by six wall entrance bushings of the condenser type and six of the oil-filled type. Both types are rated at 132 kv. with a wet flashover exceeding 275 kv.; they are installed with a universal wall mounting. Lightning arresters mounted on the new porous block and thyrite types will be installed. A very simple framework is required for these arresters, which occupy only a fraction of the space required for the older types.

Three 4,000-gallon tanks are provided for handling and storing transformer and switch oil. Direct connection is made to these tanks from the transformers which drain by gravity. The circuit breaker tanks are not permanently piped to the drain line. A pump delivers oil from the tank room to any transformer or circuit breaker pocket, where it will be passed through a portable filter into the transformer or breaker.

A storage battery of 120 lead-acid type cells with a rating of 240 ampere hours is provided for switch operation and emergency lighting. It has capacity to carry a lighting load of 5 kw. for three hours immediately followed by a discharge of 400 amperes while maintaining a potential of 1.75 volts per cell. It uses glass jars of the enclosed type, and will be floated on the control bus at 2.15 volts per cell.

The power house lighting is designed to eliminate shadows as far as possible and to give the following foot-candle intensities of illumination: generator room floor ten, gate-house floor five, stairway five, turbine pits ten, tunnels and passages three and control room fifteen. This latter room has a domed ceiling and totally indirect lighting is used. An emergency lighting circuit is arranged to throw over automatically on to the control battery in the event of the A.C. supply failing, and emergency lights are provided in the control room, stairways, and main passages, and at each governor.

The charging set has a rating of 7½ kw., and the control is semi-automatic, arranged to disconnect the generator on reverse power. If the A.C. supply fails the set will shut down, and start again when power is restored, in which case the generator will cut in as soon as its voltage builds up.

Transmission Line

A double-circuit 110,000-volt steel tower transmission line, 63 miles long, (see Fig. 12), was built from Seven Sisters to the Winnipeg district; this voltage having been adopted for interconnection with the existing 110,000 volt Great Falls system. The line was designed for a load of 32,500 kv.a. per circuit, with a receiver end voltage of 100,000 and a regulation of 15 per cent at 95 per cent power factor, without the use of synchronous condensers, future installation of which will increase the capacity of each circuit to 50,000 kv.a.

The conductors are 336,400 cm. A.C.S.R., spaced 10 feet vertically with the centre conductor offset 3 feet 6 inches; a 134,600 cm. A.C.S.R. ground wire is installed on the peaks of the towers and compression type joints and dead ends are used throughout. The normal spacing of towers is 1,000 feet, while the longest span is 1,620 feet, the minimum clearance of conductors to ground being 22 feet 6 inches. At railroad and important road crossings this clearance is increased to 35 feet and in the city to approximately 30 feet. Three main types of towers only are used, namely, standard suspension, dead-end, and angle type, in addition to which there are two special sectionalizing and a top-off structure. All are designed for a loading of 8 pounds per square foot wind, with half an inch of ice at 0 degrees C. and a maximum tension under this loading of 8,000 pounds per cable, which is approximately 68 per cent of the elastic limit of the conductors. They are galvanized throughout, set on steel grillages, and silicon steel is used in the heavier members to reduce weight. Fourteen towers rest on muskeg and all others on standard earth footings, there being no rock outcrops along the line. Strings of seven insulators are used on suspension towers and double strings of eight units at dead ends.

The line is completely transposed four times between Seven Sisters and Winnipeg, and in order to obtain information for use in future construction, two miles of it will be equipped with festooned cable vibration dampers.

In addition to the line to Winnipeg, a double-circuit 266,800 A.C.S.R. line will run to Lac du Bonnet where it will tie in to the Great Falls-Winnipeg system. Here spacing is 800 feet and the towers are considerably lighter than on the Winnipeg line.

Wood pole telephone lines paralleling the transmission circuits on the same right-of-way, will run to Lac du Bonnet and to Winnipeg, and will consist of a single metallic circuit of No. 8 copper except for the river spans where copper-clad steel is used. Twenty five-foot cedar poles with 6-inch top and a 150-foot span are standard.

Construction

Few power developments have been as happily situated as the Seven Sisters. Located within a convenient distance of the city, yet far enough away to avoid excessive labour turnover; served by main line train service with two trains daily each way; within two hours from Winnipeg on a gravelled highway open at least eight months of the year; and connected direct by telephone and telegraph service, there never has been a transportation or communication problem. Labour troubles have been non-existent and the number of fatal accidents less than half the ratio usually obtaining for work of this nature.

Throughout the duration of the job weather conditions exceptionally favourable to construction work have obtained, with a minimum of rainfall. River flow conditions have also been favourable; the normal flow of 10,000 c.f.s. in the main channel of the river having fallen to between 4,000 and 8,000 c.f.s. during the water-handling periods.

The permanent townsite, including staffhouse, twelve permanent cottages, hospital, general store, school, railway station, office building, and recreation hall, all connected with electric light, sewer and water service, as well as a dozen or more temporary foremen's cottages were built during the early stages of development, in addition to the usual camp buildings, and added materially to the comfort and efficiency of the employees during the construction period.

The main contract for constructing the dams, powerhouse substructure, superstructure and tailrace was awarded on a cost-plus-fixed-fee basis. The contract for earth dykes was given on a unit price basis. The contract for the transmission line erection was also awarded on a unit price basis. The Dominion Bridge Company of Winnipeg supplied and erected the structural steel. Power Corporation of Canada has co-operated with the Northwestern Power Company on design and supervision of construction.

Originally it was intended to have the plant in operation by December, 1930. By the fall of 1929, however, the impending business depression indicated that the additional power would not be required until the fall of 1931, and the schedule was consequently retarded as far as was then possible by setting back the equipment deliveries and closing down the concrete work for the winter.

Rock work was commenced in July, 1929. There were some 180,000 yards of rock to remove for power house and initial tailrace excavation. From this quarry approximately 130,000 yards of crushed stone were obtained for use as coarse aggregate and crushed stone facing for the initial dykes, the remainder being deposited in a waste pile for the sake of speed in excavating, to be reclaimed to the crusher at a later date for future dyke facing.

The spillways were built solid up to the initial crest level of 874 south of the sluiceways. The rollways of the sluices were left open between piers for carrying the flow of the river while the closure portion of the spillways were poured. When this was completed the sluices were stoplogged and the flow diverted through openings in the spillway section. These latter openings were successively closed by filling the rollways behind stoplogs, taking a 10-foot lift on from one to three openings at a time, and forcing the flow back over the completed sluice rollways.

Steel erection was commenced on the first of July, 1930, and completed on November 5th, 1930. The building was entirely closed in by November 20th, before the severe

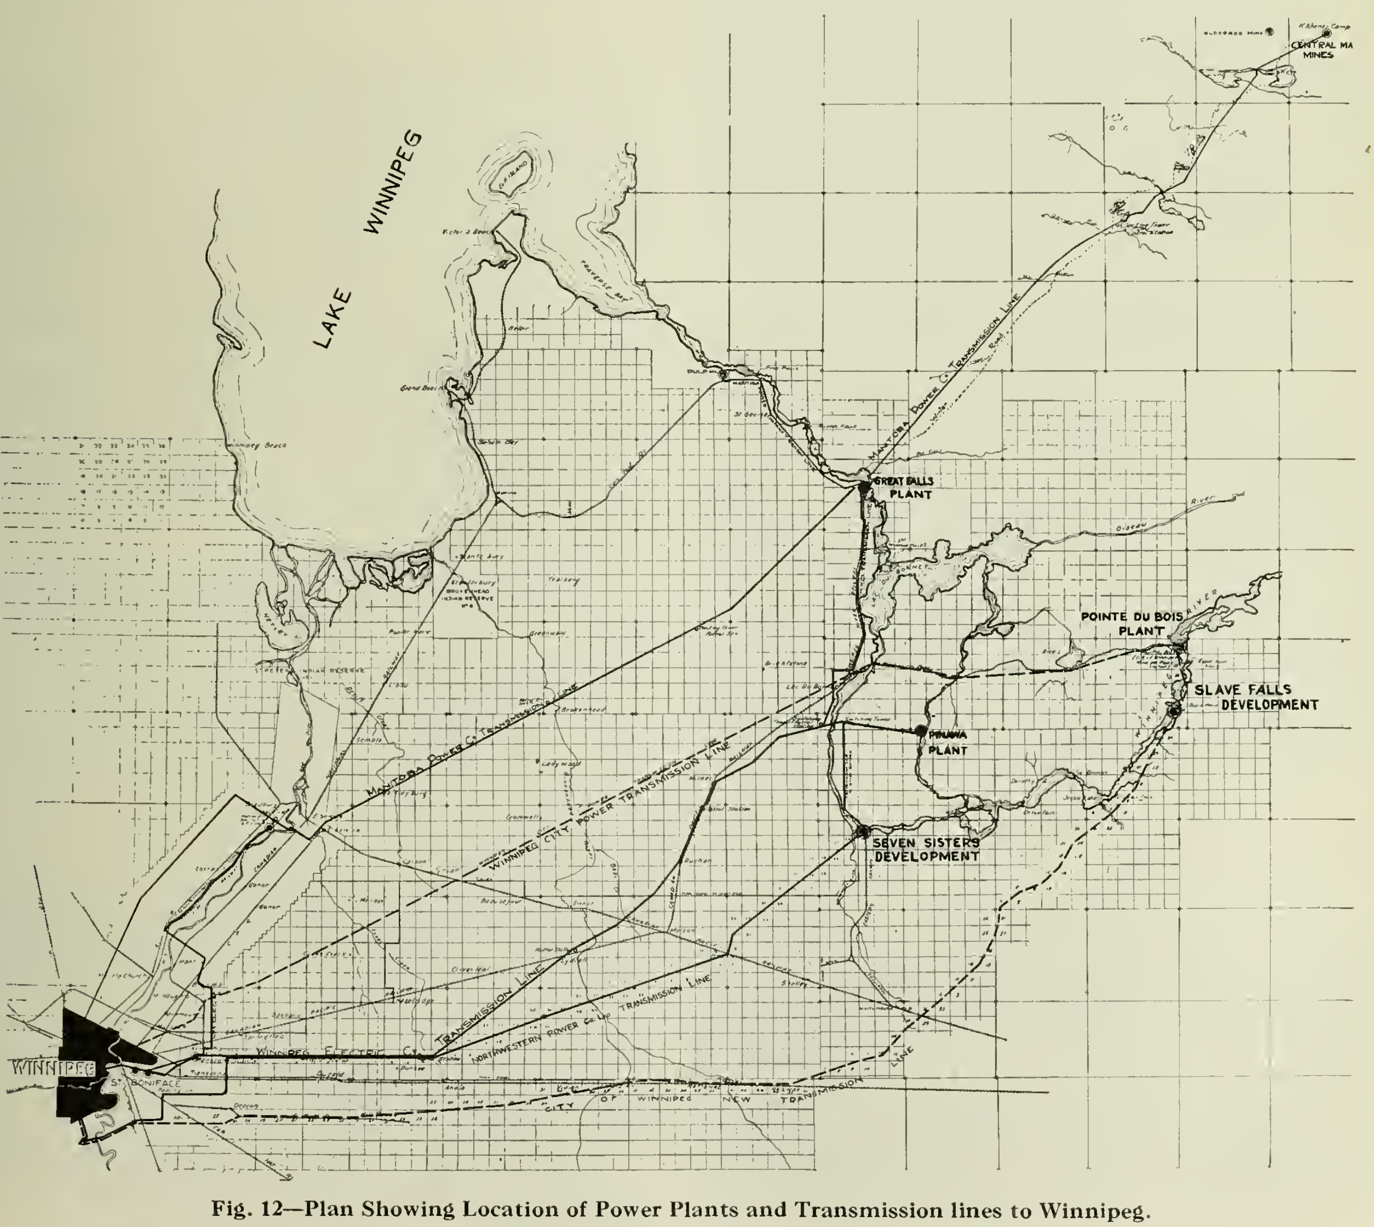

Fig. 12—Plan Showing Location of Power Plants and Transmission lines to Winnipeg.

winter weather set in, leaving the winter for pouring interior walls and floors, setting bedded parts of turbines, and completing substructure concrete around them. Generator installation was commenced in February, 1931, and the first unit is expected to be in operation by June 1st, and all three by September 1st, 1931.

The quantities involved in some of the principal features of the initial development are as follows:

Rock excavation	180,000 cu.yds. of solid rock.
Concrete	150,000 cu.yds.
Cement	650 carloads.
Reinforcing steel	3,000 tons.
Lumber	7,700,000 F.B.M.
Structural steel in power house superstructure	1,400 tons.
Machinery and equipment	300 carloads.
Earth dykes	350,000 cu.yds.
Stone facing	75,000 cu.yds.

Additional quantities for the final development include the following:

Earth Dykes	1,800,000 cu.yds.
Stone Facing	300,000 cu.yds.
Tailrace rock excavation	950,000 cu.yds.

For the initial development, it was necessary to build only the lower portion of the dykes for the first mile and three-quarters on either side of the river. Owing to the peculiar nature of the material available, great care and special equipment was required for compacting. The clay was excavated in side borrow pits with 1½-yard draglines, and hauled and deposited in 7-yard caterpillar wagons hauled by 60-h.p. caterpillar tractors. The clay was deposited in 6- to 8-inch layers, spread with a blade grader, and consolidated without sprinkling, by means of the travel of the tractors and wagons themselves, and by a heavy oil filled "Sheeps-foot" roller. The shrinkage in material averaged 10 per cent and frequent bearing tests indicated a consolidation considerably greater than the natural ground on which the dyke rested.

The first 4 inches of the crushed stone facing was spread and rolled into the surface of the clay core by means of a 30-ton roller, after which the balance of the 3-foot thick layer of crushed stone was deposited and spread with the same equipment as was used for placing the clay.

The construction plant was laid out on the north bank of the river. A No. 8 gyratory primary crusher and two No. 5 gyratory secondary crushers received the rock direct from the tailrace quarry, and the output was delivered by a belt conveyor to a stock pile, conveniently located so that a tunnel passing under the pile and containing a 30-inch conveyor belt carried the coarse aggregate direct to the mixer bins. A sand pit was opened and stripped near Whitemouth, and the sand was delivered in 2-yard dump cars to a track hopper, from which it was handled in to a storage pile by belt conveyor. Underneath the sand pile was another tunnel with a belt conveyor, loading the sand to the mixer bins. Cement was delivered in bulk and shovelled direct from the freight cars into a hopper bottom bin, from which it was drawn through weighing scales into concrete buggies which were dumped direct into mixer hoppers. The power house concrete was placed by chuting equipment from a tower 260 feet high.

A steel transmission line approximately 7½ miles long was built from the Pinawa line of the Winnipeg Electric Company to the site of the work to furnish power for construction, this line serving later as a tie line connecting the Seven Sisters plant with other plants of the Manitoba Power Company, and the Winnipeg Electric system.

Local substations containing transformer banks were located at points of load concentration and fenced in. They were connected for the most part by armoured cable and this arrangement has resulted in remarkably few power interruptions.

The total force employed reached a maximum of some 1,200 men during the peak of the construction period. Local labour has been employed almost exclusively, and with the exceptions of turbines, generators, and certain special apparatus, all material entering into the work has been purchased and fabricated in Winnipeg.

During the life of the development to date some 30,000 visitors have been shown over the job, which indicates the extent of public interest in the development.

Personnel

The work was carried out under the direction of the engineering staff of the Northwestern Power Company Ltd., of which Company Mr. Edward Anderson, K.C., is president, and F. H. Martin, M.E.I.C., chief engineer.

The preliminary studies of design and the selection of turbines, switching equipment, dykes, etc., was submitted for approval to an Engineering committee composed of Messrs. R. S. Lea, M.E.I.C., J. S. H. Wurtele, M.E.I.C., C. O. Lenz, W. G. Fargo, E. V. Caton, M.E.I.C., F. H. Martin, M.E.I.C.; and Dr. T. H. Hogg, M.E.I.C., representing the government of Manitoba.

The hydraulic, structural and electrical design, and office engineering were under the direction of M. V. Sauer, M.E.I.C., J. C. Krumm, J. P. Fraser, A.M.E.I.C., and H. C. Ligertwood, respectively.

The Power Corporation of Canada Ltd. co-operated throughout with the company's staff on the design, construction and inspection.

F. F. Griffin, A.M.E.I.C., was supervisory engineer, and H. G. Cochrane, A.M.E.I.C., was resident engineer on the work.

W. L. LeRoy, M.E.I.C., acted as construction superintendent for the contractors.

G. B. McColl, A.M.E.I.C., made the preliminary surveys, prepared all final plans for registration and planned the permanent townsite.

DISCUSSION

J. S. H. Wurtele, M.E.I.C.[1]

Mr. Wurtele stated that the author's paper was very interesting, particularly his description and the way he had outlined the unusual features of the development. He believed that the tendency in the future would be towards a more simple design of plant and one with automatic equipment, also he believed that new plants should be designed with this idea in view.

Some fifteen years ago outdoor power stations were first considered; there were several operating in recent years, but one in particular was now in operation in Montana under severe winter climatic conditions and he was looking forward to the time when these outdoor plants would be used in Canada. He found the draft-tube models which the author referred to of particular interest and would ask Mr. Christiansen to give a few figures on the reinforcing steel used in the development.

A. Christiansen[2]

Mr. Christiansen remarked that in the design of the generator room substructure there were some particularly interesting features, namely—

The three different types of units and their large size;

[1] Plant Manager, Power Corporation of Canada, Ltd., Montreal, Que.

[2] Chief Draughtsman, Power Corporation of Canada, Ltd., Montreal, Que.

The completion of the superstructure before the concreting of the scroll cases and, finally, the placing of contraction joints.

The draft tube being about 54 feet wide by 31 feet deep and all stay vanes omitted, placed the load of some 6,000,000 pounds on the nose of the draft tube centre pier, which called for careful and special reinforcing.

The completion of the superstructure before concreting the scroll cases called for building column loads to be carried on a concrete beam 9 feet wide by 10 feet deep, 54 feet free span with a loading in excess of 1,000,000 pounds at each one-third of the length of the beam. This problem was overcome by placing steel supporting columns integral with the beam formwork, and then concreting the beam. These columns were to be burned out after the scroll case roof was poured and the column load could be carried on the completed substructure.

He remarked the experience gained at the Hemmings falls and Back river power plants as to contraction of the substructure, and that this was applied to the Seven Sisters plant by placing contraction joints between every second unit, giving one at about every 120 feet.

He gave some figures on the weight of reinforcing steel per cubic yard of concrete for the different units at the Seven Sisters plant, and for comparative power plants of earlier dates.

E. S. Holloway, M.E.I.C.[3]

Mr. Holloway understood that the author had stated that a water-cement ratio as low as four gallons per sack was used in proportioning the concrete and had also intimated that some slight difficulty was encountered in placing this dry mix, it would, therefore, be interesting if he would give the proportions used in designing the mix and the water cement ratio employed for the different mixes as well as the actual strength of the concrete obtained. That is, of course, the strength water-cement curve for the job.

If the strength of the test cylinders reached a figure largely in excess of 3,000 pounds per square inch, as is to be expected with a water-cement ratio of four gallons per sack, what objection would the author have had to increasing the water to facilitate the handling and placing the concrete?

It is recognized that if the Winnipeg river water is alkaline it is necessary to keep the water-cement ratio down.

Mr. Holloway also understood Mr. Christiansen to say that, for design purposes, the strength of the concrete was assumed as 3,000 pounds per square inch. It would be of value to hear his opinion regarding the desirability of using a higher figure where considerations of durability of the concrete necessitated a strength of say 4,000 pounds and what would he estimate the saving to be in various parts of the structure as head-works, power house, etc.

F. H. Martin, M.E.I.C.[4]

The author replied that the mix varied according to the designed strength of the concrete. In the spillways 2,500-pound concrete was used, in the scroll cases 3,000-pound and in some places as low as 1,500-pound concrete was used. All testing of material was under the control of the National Testing Laboratories, Ltd. The mix also varied according to the materials, the quantities used and amount of water furnished.

A. Christiansen

Replying to Mr. Holloway, Mr. Christiansen stated that the strength of the concrete for the draught tube centre piers was specified to be 3,000 pounds per square inch after twenty-eight days, whereas that of the concrete for the balance of the substructure was specified to be only 2,500 pounds per square inch.

The substructure is practically bulk concrete, and the higher stresses could not be developed to advantage.

N. J. Kayser, M.E.I.C.[5]

Mr. Kayser asked whether there were any tests made on the models of the various types of units which were used in the plant before adopting the three different designs.

F. H. Martin, M.E.I.C.

The author remarked that he was not prepared to answer this question as the manufacturers would state that tests had been made, but unless all facts and conditions surrounding these tests were known, and they were not, he was unable to accept the figures given by the various manufacturers. It was difficult to make test models and obtain the same conditions as would be found in the field and that was why the models which had been used in this case were actually made on the site.

He stated that he was not prepared to guarantee the accuracy of the results, but he hoped to obtain what he wanted and that was to have a reasonable comparison between the three different types of units. This was all that was necessary and in the preparation and arrangement of the tests both Mr. Gibson and Dr. Allen had been consulted.

Regarding the development as a whole accurate information was available as to the quantities of concrete and steel used as had been mentioned by Mr. Christiansen.

The reason for obtaining this information was that the river included a long chain of power sites in its drop of 710 feet in 400 miles and it would therefore be possible to develop some 3½ million horse power, the heads ranging from 70 to 29 feet. Few people knew the length of the water shed around Lake Winnipeg and the possible storage reservoirs on this river.

D. S. Laidlaw, Jr.E.I.C.[6]

Mr. Laidlaw enquired the reason for the outlet of the service unit being at a higher level than the remaining three units.

F. H. Martin, M.E.I.C.

The author replied that he believed this was due to the variability of the head and the fact that the development had to be carried out in stages, there was a possibility that the tailrace might never be excavated to its full depth, also they wished to get ahead with the other units as soon as possible.

M. V. Sauer, M.E.I.C.[7]

Mr. Sauer in moving a vote of thanks expressed the opinion that the author was deserving of much credit in two particulars; first, in the decision to utilize the Seven Sisters falls in one development instead of two as originally contemplated, and second, to install high speed "Propeller" type runners for a head higher than ever before had been attempted.

The concentration of the development in one head would result in greater ultimate economy, and even in the initial installation the cost had been made low by virtue of the arrangement whereby the head can be increased in successive stages.

In regard to the high speed runners the profession will await with great interest the operating results of these units and he hoped that the author would supplement his excellent paper with data on their behaviour after they have been in service.

Quay Wall Design and Construction

Louis Beaudry, A.M.E.I.C.,
Designing Engineer, Harbour Commissioners of Quebec, Quebec, Que.

Presented before the Quebec Branch of The Engineering Institute of Canada, April 13th, 1931

SUMMARY.—This paper describes briefly various types of quay walls with special reference to the methods of construction suited to the severe climatic conditions in eastern Canada. Both cribwork quay walls and steel walls of the bulkhead type have proved satisfactory, the advantages of the former being cheapness, ease of construction and permanency under water, and of the latter, rapidity of construction and watertightness. The results of a number of tests of steel sheet-piling are given and the methods of protection against corrosion are briefly outlined.

General

It is essential that quay walls have a vertical face in order to permit vessels to lie close alongside, that they shall withstand the impact of ships against them, the pressure of current, waves, ice etc., resist overturning, sliding and deformation through the pressure of earth or other filling with its surcharge of merchandise.

Fig. 1—Crib No. 1.
Working on Course No. 25.

Solid filled quay walls are quite similar to an ordinary retaining or land wall. However, they involve features which make the necessary calculations therefor more complex and sometimes impossible. These features are the presence of water on both sides of the structure, the diminished weight of the wall due to its submergence in water, the variety of material usually found in the filling, and the variation in the weight of the filling due to the fact that part of it is submerged and part is not.

These uncertainties have at times lessened the faith in the theory that by careful calculations a quay wall may be made safe, and have convinced many that past experience is the best guide. However, this change of opinion may have been brought about through routine, misinterpretation in calculations, or discouragement through unsatisfactory results. Nevertheless, in view of the peculiar hazards involved, past experience alone is not sufficient to guarantee the stability of a quay wall.

The height of quay walls varies from that of land walls, particularly when important tide variations have to be provided for. In the port of Quebec the mean high tide is 18 feet above the lowest tide level, and the difference in elevation between the highest and the lowest tide is 22 feet, and even 24-foot tides have been experienced. To obtain 35 feet of water at mean low tide a quay wall having a minimum height of 65 feet is necessary, and over 70 feet to obtain a depth of 40 feet of water.

Classification of Quays

Quays may be divided into three types, namely:

1. Gravity;
2. Platform;
3. Bulkhead.

Gravity Type

The gravity walls are those depending on their intrinsic mass alone for their stability. They may be constructed of

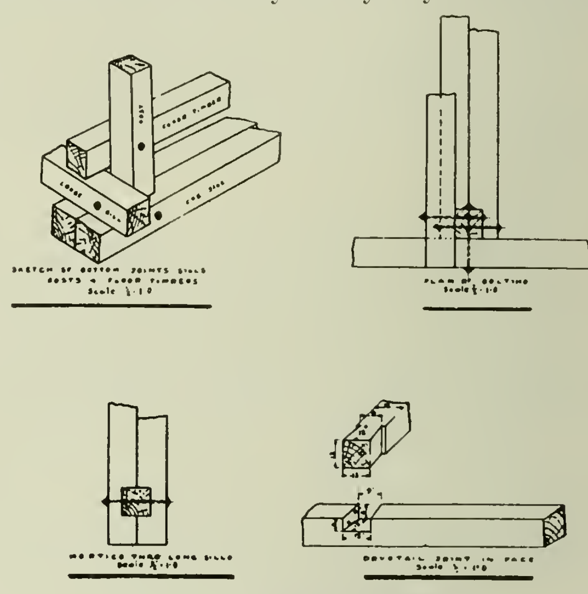

Fig. 2—Cribwork Connections.

rip-rap, cribwork, stone masonry, concrete blocks, mass concrete, caissons of concrete, steel, wood, or various combinations of these materials.

Platform Type

The platform or columnar types are those in which a platform on columns supports the live load. They are built over a sloping bank, either natural or artificial.

This type is adopted to allow freedom of movement of shore currents, for its economical advantages, and is mostly used for the construction of piers. When marine borers are not present, wooden piles are most suitable on account of their resiliency in resisting the impact of moving vessels.

However, this type of quay is not really a quay wall, so nothing further need be said on the subject.

Bulkhead Type

The bulkhead type of wall retains the fill behind by means of a row of sheet piles supported by the resistance of the ground into which they are driven, and also by tie-rods running back to anchors embedded in the ground in the rear.

Each of these types of wall have their respective advantages and often the different types are combined to the benefit of the completed wall; for example, when building a platform to support the surcharge and also a bulkhead underneath to retain the material of the ground or filling.

On account of winter conditions prevailing in eastern Canada, the wharves are nearly all of the solid filled gravity

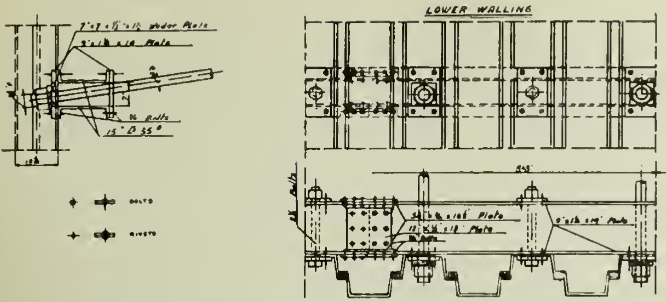

Fig. 3—Typical Section of Steel Wall.

type, built entirely of cribwork, or with a superstructure of concrete, with a few of concrete caissons. Cribwork is still extensively used as timber can be easily procured at reasonable prices.

Cribwork Quay Walls

For quay walls of the gravity type, cribwork has several advantages; its cheapness, ease of construction, and its permanency under water. As far as durability above water is concerned, there are cases where cribwork built over fifty years ago is still in good condition, although the timber exposed to the air, such as the facing, has been renewed every twenty years.

This wall was built for the port of Quebec in 1929-30. Although the superstructure, or portion of the wall extending from low water level to the top, is usually of concrete, this one is of cribwork so as to be similar to the rest of the wharf, of which it was an extension. Cross-ties are spaced eight feet on centres, and posts were used only in the substructure to connect all cross-ties to longitudinals. Fig. 2 shows the details of the connections. The timber used was all 12-inch by 12-inch B.C. fir, dressed on two sides.

This wall was calculated to resist overturning, for the maximum bearing capacity of the ground at any point of its base, to resist sliding, and was also designed to prevent deformation by back pressure. With a surcharge of 1,000 pounds per square foot, a safety coefficient of 2.5 against sliding was provided.

The unusual features in this design consisted in the provision for open pockets to permit the stone filling to penetrate into the ground, and the use of wooden piles to provide the required resistance against sliding.

Anchor Piles

The wooden piles were calculated as a cantilever, having the fixed end seven feet below the surface of the ground, or one-third of the total penetration. To obtain the required area for the fixed end, the length of pile was determined to be 35 feet, the diameter at the tip or small end to be 10 inches, and the penetration into the ground to be 20 feet. The use of 12-inch by 12-inch piles was permitted, but round piles of spruce were considered more convenient. The length was limited to 35 feet in order to reduce lateral deflection during driving, thus reducing the possibility of breaking, and also assuring more satisfactory driving. Since the use of a follower was not permitted the driving was done with a steam hammer working underneath the water. This method proved satisfactory and the driving proceeded under water to depths varying from 20 to 25 feet.

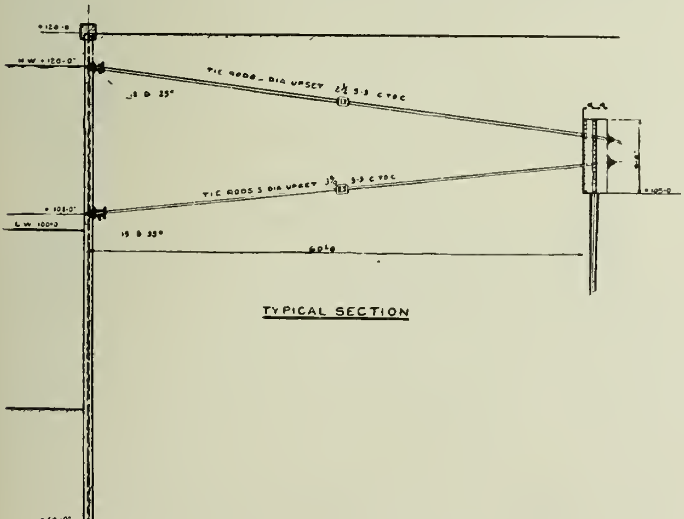

Fig. 4—Arrangement of the Anchor Rods and Walings.

Crib Seat

The operation upon which much of the success of a gravity wall depends, is the preparation of the ground to receive the wall. This is called the preparation of the crib seat for the cribwork walls.

To obtain a crib seat having a uniform elevation, and also to prevent disturbing the original compactness of the ground, a dredge of the bucket ladder type was the only one permitted to be used on this work. The ground consisted of fine sand mixed with a low percentage of clay and a few boulders.

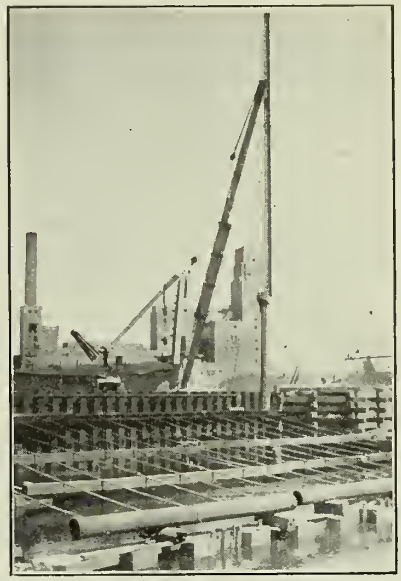

Fig. 5—Interlocking Last Sheet Pile.
Length of Pile 60 feet.

Steel Wall of the Bulkhead Type

Although the wharf walls in existence in the eastern part of Canada are mostly of the gravity type, in many cases the use of the bulkhead type would have been a more economical solution. As far as the writer is aware, this type has been used in only two cases. The first one is located at Sorel, Que., built of reinforced concrete and was completed in 1929. The other for the port of Quebec was built of steel and completed in 1930.

When the foundation permits its adoption the steel wall of the bulkhead type offers several advantages over wall of the gravity type, namely:

1. The stresses can be more definitely calculated;
2. Cheapness;
3. Rapidity of construction.

History

Although steel sheet piles have been fabricated in the United States for over twenty-five years, their use has been

Fig. 6—View showing Alignment of Steel Wall.

mostly limited to cofferdams, trenching, curtain walls of earth dams, and it is only rather recently that they have been used for quay walls of the bulkhead type.

In Europe steel walls of the bulkhead type were built as far back as 1885. As no appropriate shapes were rolled at that time sheet piles were fabricated with channels and angles. Some of these constructions are still in service, and although they may be classed as experiments they have afforded valuable opportunities for studying the exposure of these steel piles to corrosion, their durability, and their suitability for the construction of wharves.

Numerous shapes of steel piles have since been invented and rolled and at present some are rolled with a section modulus of nearly 80 cubic inches.

The steel wall of the bulkhead type was adopted by the port of Quebec as it eliminated the risk of a sliding movement, and also gave a wall of impervious construction. These two qualities were essential since it was necessary to build the wall as close as possible to a marine railway. A sliding movement might have blocked the railway, and any lack of imperviousness would have meant a loss of filling material, which would have been deposited on the railway tracks, and caused considerable damage.

The adoption of steel sheet piles was quite unusual considering the 48 feet of filling to be supported and the required level of 25 feet of water at low tide.

Fig. 7—General View showing Steel Wall, with Concrete Coping Completed.

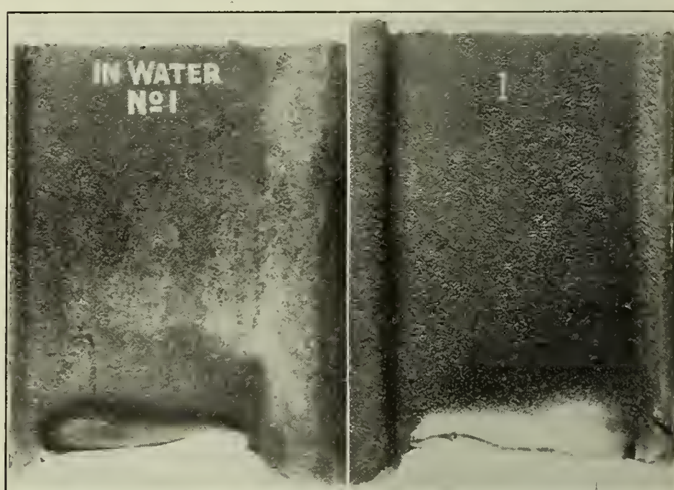
The fixed end was established five feet below the surface of the ground and the lower tie-rod was located two feet above mean low water. A span of 32 feet was the result.

Fig. 3 shows the typical section of the wall.

The sheet piles were calculated as a continuous beam, fixed at one end, and supported on two points at the walings. The required length of penetration was determined by the passive resistance of the ground. The Rankine theory was used to determine the ground pressure, the passive pressure, and to locate the anchor wall. In order to obtain sheet piles having the required section modulus without being excessive in weight, high tension carbon steel was specified, thus permitting calculations on the basis of 23,000 pounds. Structural steel grade was used for all the other steel members, and the resistance was calculated at 18,000 pounds.

Fig. 4 shows the arrangement of the anchor rods and walings. It is to be noted that they are placed at the back of the wall, to improve the appearance and also to eliminate obstructions to boats lying alongside.

The anchor wall is of reinforced concrete. It was built on wooden piles to prevent settlement. The penetration of these piles was determined by the engineering formula, on a capacity of ten tons, and with a minimum penetration of 12 feet.



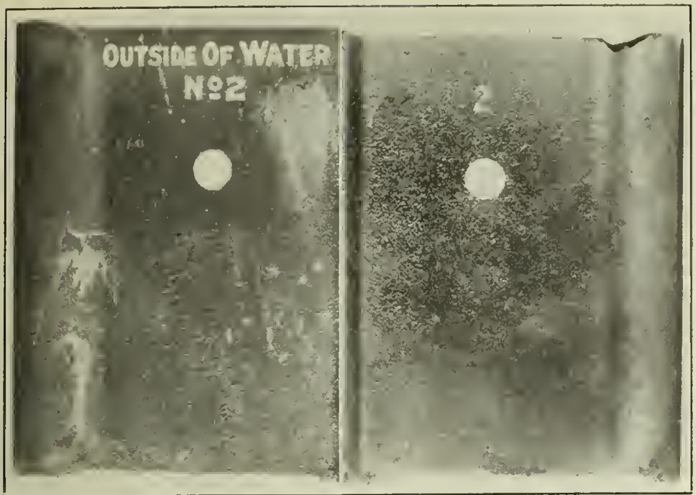
(*a*) (*b*)

Fig. 8—Pile submerged at Nearly All Times. (*a*) Before Cleaning. (*b*) After Cleaning.

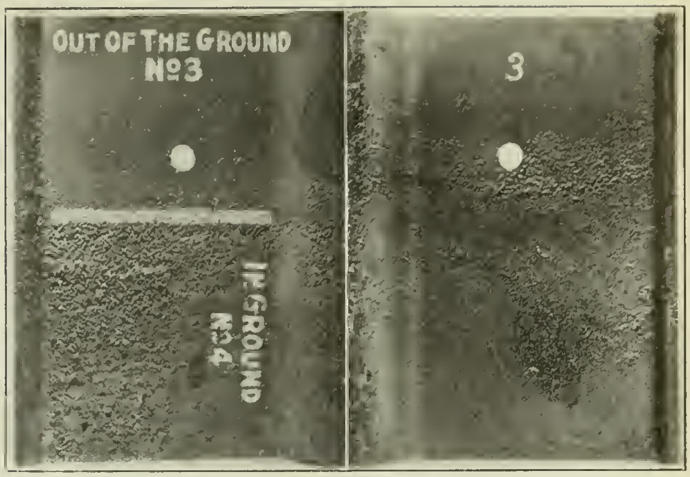
Although no heavy surcharge has yet been placed on top of the filling, the hypothesis on which the design was based, both as regards to earth pressure and location of the anchor wall, as well as the adaptability of the section modulus of two piles interlocked, has been confirmed as being correct. Since the filling was rapidly placed by the hydraulic method worse conditions were encountered than would be met should a heavy surcharge have to be supported by the wall.

Corrosion Tests

To find out the effect of corrosion on steel exposed to air, water, or soil, tests were made on steel sheet piles which were driven in on the property of the Harbour Commissioners of Quebec sixteen years previously. Three steel samples were taken. Sample No. 2 (see Fig. 9) is from the portion of pile above high water and exposed to the atmosphere at all times. Sample No. 1 (see Fig. 8) was cut at the level of the lowest tide, showing part submerged nearly all the time and part at ordinary low water mark. Sample No. 3 (see Fig. 10) shows steel buried in sand, sample being cut about two feet lower than the level of the ground surface. As for the piles located between tides, meaning in the zone between the low and high tides, they



(a) (b)
Fig. 9—Pile Continually Exposed to Air. (a) **Before Cleaning.** (b) **After Cleaning.**



(a) (b)
Fig. 10—Pile Partly Exposed to Air and Partly Buried in the Ground. (a) **Before Cleaning.** (b) **After Cleaning.**

were so perfectly preserved that a sample was not considered necessary. This perfect state of protection was attributed to the covering of the piles by a film of oil deposited by the tides.

Before the samples were cleaned of dirt and rust sample No. 3 gave the impression of being badly corroded. It was covered with a heavy crust of rust of a scaly appearance that could hardly be removed with a penknife. Sample No. 2 was clean, of a dark brown colour, and uniformly pitted. Sample No. 1 was dirty and the effect of corrosion was visible.

The samples were first given a wire brush treatment but it was only after they were subjected to a sand blast that a perfectly clean surface could be obtained. Sample No. 3 showed some pocking at the level of the ground surface, but a few inches below a good state of preservation was evident. In this sample the right half of (a) has received wire brush treatment. The even pitting that was visible can be attributed to the corrosion of the mill scale. The crust of rust and soil had undoubtedly the effect of affording protection against corrosion. The pocking at the ground surface was the result of the organic matter always present at the surface of the ground. Sample No. 1 showed some pocking. Without doubt the chemical composition of the mud that covered the ground in that vicinity had accelerated the process of corrosion. It must also be stated that the piles referred to were in the St. Charles river where at low tide the water is much polluted by the sewage of the city, which discharges in the vicinity.

To obtain a better idea of the extent of the corrosion a sample was machine cut, but this fresh cut showed no perceptible reduction in thickness.

Although no definite conclusions may be drawn from these isolated tests, the sixteen years of exposure justifies us in saying that the fears entertained as to premature deterioration of the steel wall through corrosion were not well founded. The results of the tests seem also to confirm the statements and findings of other engineers who have studied steel structures which have been exposed for even longer periods. Therefore, we may safely come to the following conclusion, "steel that is buried in sand or ground, or is submerged in water, is less exposed to damage through corrosion than when exposed to the air." This conclusion is doubly valuable since the portion of the steel wall which is most subject to corrosion is that portion which can be periodically inspected.

While the above results are no doubt encouraging, nevertheless all steel walls, as is the case with other steel structures, should be painted from time to time, at least where easily accessible, and the land side of the wall should be painted before placing the back fill.

Protection Against Corrosion

Additional protection against corrosion may be provided for steel quay walls of a permanent character, that is to say those designed for a longer than ordinary life, for example over forty years, by the following methods:

(a) Providing a cap of reinforced concrete on the top of the wall and filling the space between the upper and the lower walings so that water will not run directly on the piling.

(b) Covering all the surfaces of the steel to be buried with a heavy coating of paint, free from acid and oil, since the acid may cause corrosion and the oil may be saponified within a short period of time.

(c) Painting the piles before driving.

(d) Using heavier connections on walings and anchors because when two dissimilar metals are placed in contact with each other, riveted or bolted together, there is a tendency for one of the metals to be preserved from corrosion at the expense of the other, which will corrode much more readily in such a case.

(e) Using anticorrosive steel.

On account of its strength, elasticity and uniformity, steel is universally considered as the best building material. However, as there were doubts about its lasting qualities, the adoption of steel for several types of structures has been delayed. At present these reasons have not the same weight as formerly. Reports gathered together on steel structures which have been exposed over a long enough period of years have shown that corrosion does not cause deterioration as quickly as had been thought, where proper protection has been provided. The discovery of anticorrosive steels such as cupriferous, nickel and chromium steels has considerably changed our ideas as to the durability of steel.

Moreover, in these days of rapid change of design and methods, a considerable number of structures, in port works as well as in many other lines, tend to become obsolete in a comparatively short space of time, and thus it is sometimes not a good thing to build structures of too permanent a character since it may be necessary to demolish them before the expiration of their natural span of life in order to effect imperative improvements, involving greater wastage and sometimes considerable time and trouble in wrecking structures of too permanent a nature.

The Canadian Pacific Liner *Empress of Britain*

Features of Interest to Engineers

The following account is based largely on information furnished by Canadian Pacific Steamships Limited, and we are also indebted to descriptions in "Engineering" and in "Shipbuilding and Shipping Record"; Figs. 2 to 6 are reproduced from the latter paper with the Editor's kind permission.

The new Canadian Pacific liner *Empress of Britain,* which has just commenced her service between Southampton and Quebec, is remarkable as the largest, swiftest and most luxuriously appointed ocean-going vessel to ply between any two ports in the British Empire, and her propelling machinery is a notable example of high-pressure and high temperature steam practice.

The progressive policy of the Canadian Pacific in creating during the last six or seven years a large and up-to-date fleet of ocean steamships of all classes, for both passenger and cargo-carrying services, has involved new construction and the re-engining of existing vessels on an unprecedented scale; and not the least inducement to embark on this course, which has culminated in the building of the *Empress of Britain,* was provided by the marked economies in the cost of propulsion and operation which are now possible, and to which the work of Mr. John Johnson, the company's chief superintendent engineer, has so largely contributed.*

It may be recalled that the *Duchess* passenger steamships of the Canadian Pacific Line attained a fuel economy of 0.625 pound of oil per s.h.p. per hour for all purposes, and still more recently the same owners' *Empress of Japan* set up a world record of 0.603 pound for all purposes. Trial results indicate that this record will be surpassed by the latest and largest *Empress.*

The hull of the *Empress of Britain* has been constructed by Messrs. John Brown and Company Ltd., of Clydebank; and they have also built and installed the propelling machinery.

The principal particulars of the vessel are:

Length, overall	760 feet 6 inches
Length, between perpendiculars	730 feet
Breadth, moulded	97 feet 6 inches
Depth, moulded, to B deck	60 feet 9 inches
Depth, moulded, to top of superstructure (sun deck)	100 feet 6 inches
Load draught	32 feet
Gross tonnage	42,348 tons.
Net tonnage	22,545 tons.
Service power	60,000 s.h.p.
Speed in service	24 knots.
Passengers:	
First Class	465
Tourist Third Cabin Class	260
Third Class	470
Officers and crew	714
Total number of persons carried	1,909

*See "The Propulsion of Ships by Modern Steam Machinery" in The Engineering Journal for December, 1929, pp. 628-639.

Fig. 1—The *Empress of Britain* in the Clyde.

The ship has been constructed under survey by Lloyd's Register to meet their highest class, and complies with the latest requirements of the Board of Trade and the International Convention for the Safety of Life at Sea as regards subdivision and life-saving appliances.

The bunker capacity is sufficient to enable her to make the round voyage from Southampton to Quebec and back with adequate allowance for port use and a few days' supply of fuel in reserve.

On her official trials a maximum speed of 25.52 knots was attained, while the speed with only the two inboard turbines working was 22.6 knots. On her regular service a speed of 24 knots will enable her to make the open sea passage in three and a half days and the whole run in five days.

There are ten decks, namely, sun deck, sports deck, lounge deck, and decks *A* to *G*. *A* deck runs the full length of the vessel, the lounge deck above is 648 feet long, and the boat deck is 396 feet long at the sides.

The double bottom is subdivided into forty-four main compartments for oil, fuel, fresh water, and water ballast, and the scantlings of the vessel have been determined by treating the structure as a continuous girder to the sun deck, thus eliminating the use of expansion joints in the superstructure. Special high elastic limit steel has been used for some of the deck plating on the lounge deck and *A* deck, and for the side plating in that vicinity in order to save weight.

The lounge deck is chiefly occupied by the spacious first class public rooms, these being, starting at the bow, the ball room, the long double gallery, the American bar and writing room, the card room and the smoking room. Around these is the main first class promenade. Further promenade space is provided along the whole length of the boat deck, and also on the sun deck. The swimming bath extends from *D* deck to *G* deck, and is situated immediately abaft the after engine room. Two fully equipped gymnasiums adjoin this pool, and there is a tennis court on the after end of the sports deck, which is flood-lighted for night play. A regulation squash racquet court is also provided, and at the forward end of the sports deck a large clear space is available for deck games. The children's play room is also on the sports deck.

The main dining saloon is on *D* deck, and will accommodate 452 persons. The state room accommodation is liberally arranged as regards space. Over seventy per cent of the first class state rooms have private bath rooms, and all are outside rooms. The tourist third cabin and third class public rooms give accommodation much superior to that enjoyed by first class passengers thirty years ago.

In all living spaces on board the vessel a system of mechanical ventilation and heating on the thermotank principle has been used, separate systems of trunking being provided for each block of accommodation. The store rooms, galleys and pantries are also provided with fresh air by means of the punkah louvre system, and all lavatories, stores, kitchen spaces, hospitals, laundries, etc., are exhausted at adequate rates of air change. The first class and tourist third class public rooms and entrances are fitted with the latest revolving punkah louvres, which are suitably worked into the decorative scheme. There are over one hundred and thirty thermotank units, including the engine and boiler room fans, and about ten miles of trunking. Further provision is made where necessary for heating by means of low-pressure steam radiators, plugs being fitted in first class and tourist-third cabin state rooms to take an electric radiator when required.

A hot and cold fresh water supply is provided for all wash basins in the ship, as well as to the first-class baths and showers, while hot and cold salt water is also led to the first-class baths, and to the baths and showers in the remaining passenger spaces.

The navigating equipment includes a standard compass on the compass platform, with steering compasses in the navigating bridge wheel house and the after wheel house. The master gyro compass in the gyro room has repeaters in the wheel house, on the compass platform, and also in the captain's room and wireless office, with a course recorder in the chart room. Elaborate provision has been made for sounding, both by sounding machine and by electric echo sounding. A complete system of engine room, steering, and docking telegraphs is provided.

Ship's draught indicators, electric submarine signalling apparatus, an electric submerged log, searchlights, range finders, direction finders, semaphores, morse lamps, and clear-view screens are all available to aid in the navigation of the ship.

The anchor and warping capstans and cargo winches are all electrically driven. The steering gear is of the electric-hydraulic type with duplicate motors and pumps.

The lifeboats are handled by Welin-Maclachlan gravity davits, of which there are 22 sets, comprising: ten sets, handling 31-foot, 89-person single lifeboats; eight sets, handling nested lifeboats, each nest with a total capacity of 135 persons; two sets, handling 30-foot, 45-person motor lifeboats; and two sets handling 25-foot, 46-person emergency lifeboats. The motor lifeboats have Parsons four-cylinder engines with reverse gears. This equipment ensures that in an emergency, twenty-two lifeboats immediately become available, having a total capacity for about 1,800 persons.

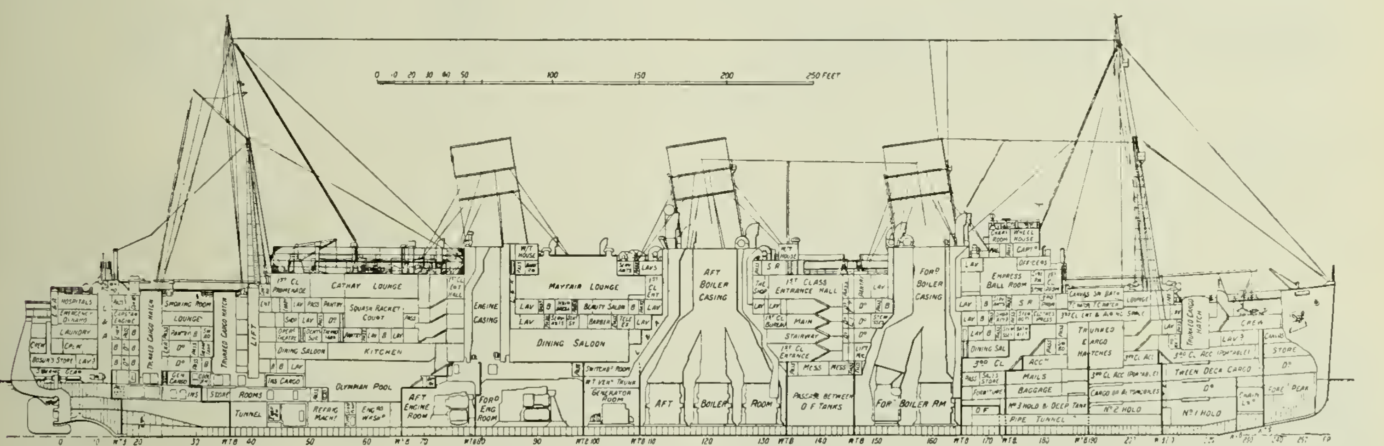


Fig. 2—Longitudinal Section.

The telephone equipment throughout the ship is most complete, loud speaking naval telephones being provided to communicate between the bridge, executive offices, engine rooms, wireless rooms, gyro room, steering engine room, boat deck, docking bridge, forecastle head, and crow's nests. The telephone system, besides including ninety lines for the service of the ship's personnel, includes two hundred lines of manual equipment for the use of passengers. Communication can be established with the shore services while the ship is in port, and the radio telephone service provides for ship to shore communication while the liner is at sea.

The wireless equipment, supplied by the Marconi International Marine Communication Company, includes a 2-kw. valve transmitter for long-wave telegraph transmission, together with a 2-kw. short-wave installation, and selective receivers ensure good reception over the complete band of wave-lengths. The short-wave installation will enable communication to be maintained over long distances with stations out of range of the long-wave transmitter.

The ordinary cabin telephones are connected to the wireless telephone through the ship's manual switchboard, so that passengers can communicate directly with any telephone in any country offering suitable terminal facilities.

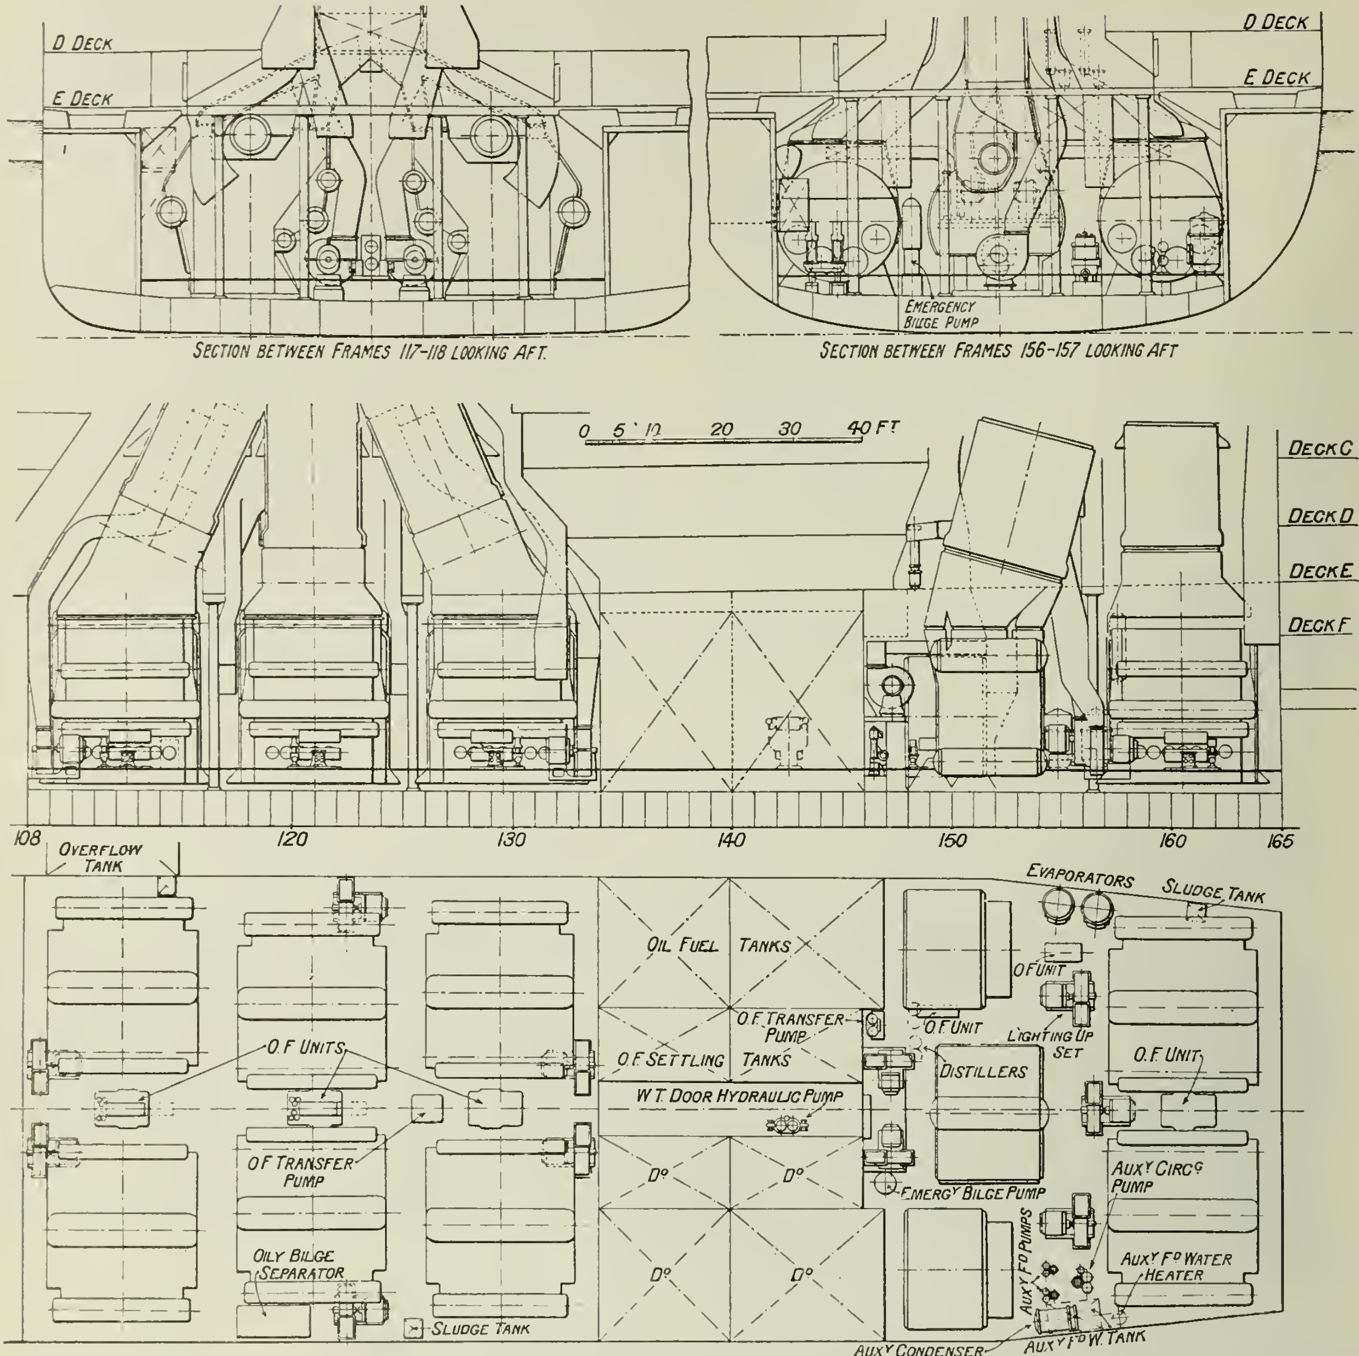

Fig. 3—Plan of Boiler Rooms.

Emergency and lifeboat Marconi equipment is also supplied, while a Marconi direction finder of the latest type, with the fixed-frame aerial system, has been installed.

Other electric equipment includes a system of electric clocks and burglar alarms, vacuum cleaning plant, talkie cinema apparatus, and an orchestra and gramophone repeater installation.

Four hospital wards are arranged on *C* deck, and a separate isolation hospital on the after end of *A* deck. There is an operating theatre, dispensary, and dental surgery.

Propelling Machinery

The vessel is propelled by four screws, each driven by an independent set of single-reduction geared turbines of the Parsons type. To suit the conditions under which the ship will run, viz., voyages between Great Britain and Canada during the summer and world cruises during the winter, the engines driving the two inboard screws are designed to develop two-thirds of the total power, while the engines driving the two outboard screws develop the remaining one-third. Under cruising conditions, if full power is not required, only the inboard engines will be used, and the vessel will then be virtually a twin-screw ship.

The machinery has been designed to develop normally a total output of 60,000 s.h.p. continuously at sea, in order to maintain a normal speed of 24 knots. If an increase of speed is necessary at any time, however, an overload power of 64,000 s.h.p. can be maintained for long periods.

Two engine-rooms are necessary for the main propelling machinery, the two inboard sets being arranged in a compartment forward of that in which the two outboard sets are installed; while much of the auxiliary machinery is in a separate auxiliary engine-room immediately forward of the two main engine-rooms.

The engineering staff on a vessel of this type is, of course, numerous, and the duties of the senior engineer officers are of a highly responsible nature. While the executive and navigating department includes nine officers and eighty-seven deck ratings, the engineering branch has forty-three officers and eighty-nine other ranks, a total of one hundred and thirty-two. The other services on the ship, including the office and medical staff, the stewards and service departments, employ nearly four hundred and fifty people.

Main Turbines

The main-turbine sets each comprise one high-pressure, one intermediate pressure and one low-pressure turbine, working in series; and each turbine drives a separate pinion, which engages with the main gearwheel. For astern running, a high-pressure unit is incorporated in the same casing with each of the two intermediate ahead turbines and a low-pressure unit in the exhaust end of each of the two low-pressure ahead turbines of the inner-shaft machinery only. No provision is made for astern working on the outer shafts, which are employed exclusively for ahead duty. The astern turbines are capable of developing 60 per cent of the aggregate ahead service power.

The high-pressure turbines are all constructed to withstand a maximum working pressure of 425 pounds per square inch and an initial steam temperature of 725 degrees F., but they have been designed to develop the service and overload powers when employing steam between the limits of 375 pounds per square inch (gauge) and 0.50 pounds per square inch (absolute), with an initial steam temperature of 700 degrees F.

The high-pressure ahead turbines are of the impulse-reaction type, comprising a two-row velocity wheel with blades of stainless steel, and a reaction portion fitted with end-tightened blades of Monel-metal. Nozzle-control valves are fitted to enable a gradual increase of power to be obtained, while at the same time maintaining as high a pressure as possible in the control chest for quick operation.

The intermediate-pressure ahead turbines are of the reaction type throughout, with end-tightened blades of phosphor-bronze.

The low-pressure ahead turbines are also of the reaction type, with phosphor-bronze blades.

The high-pressure astern turbines each have one three-row impulse wheel, while the low-pressure astern turbines each have two impulse wheels with two rows each, in which the blades are of stainless steel.

To eliminate vibration, all the rotors have been dynamically balanced. The low-pressure ahead turbines are of the double-flow balanced type, and each of the other turbines is fitted with a dummy to reduce the end thrust due to the difference in steam pressure. Michell thrust bearings of the spherical-seated type are fitted to each rotor to take up any remaining axial thrust.

Owing to the high steam temperature employed, the turbine casings are of cast steel, with the exception of the low-pressure casings, which are of cast iron.

To facilitate the lifting of the upper portions of the turbine casings, the receiver pipes have been connected to the lower halves of the turbines in every case. Emergency connections have been fitted, so that any of the turbines can be cut out if this should be found necessary at any time.

In each set the high-pressure turbine is fitted with an Aspinall patent governor combined with a fore-and-aft indicator and control, while the intermediate-pressure and low-pressure turbines are fitted with fore-and-aft indicators and controls only. With this arrangement, the steam would be shut off in the event of the turbine speed exceeding a certain limit. The fore-and-aft indicators show any axial movement of the turbine rotors; and should the wear on the thrust pads make this movement excessive, the control would then operate and shut off steam to the turbines.

Steam would also be shut off in the event of the oil pressure in the lubricating system dropping unduly or failing entirely.

Main Condensers

The main condensers, which are of the Weir two-flow regenerative type, with a large reservoir at the bottom for storing the water required for the successful operation of the closed-feed system, are slung underneath the low-pressure turbines. Each inboard condenser has a cooling surface of 20,700 square feet, the tubes being ¾-inch diameter and 14 feet 6 inches long; while each outboard condenser has a cooling surface of 9,600 square feet, with ¾-inch diameter tubes 11 feet 6 inches long. The tubes for all the condensers are made of cupro-nickel.

A particular feature of the condensers is the water doors, which have been designed to facilitate the quick examination of the tubes. Large hinged doors have been fitted in each end, and these are jointed with rubber rings recessed into the casing.

Gearing, Shafting and Propellers

The main gearing is of the usual double-helical, single-reduction type, and the main gearwheels of the inner and outer shafts have diameters of 14 feet 6 inches and 11 feet 3½ inches respectively. All the pinions are connected to their respective rotors by flexible claw-type couplings. The gearwheels and pinions are enclosed in strong cast-iron gear cases.

The thrust of the propellers is transmitted to the vessel through Michell thrust bearings of the single-collar type, fitted to the main lines of shafting immediately aft of the gearing; and the tunnel shafting is supported by bearings of the Michell pivoted-pad journal type.

The propellers, which are of solid bronze, have diameters of 19 feet 3 inches and 14 feet 0 inch for the inner and outer shafts respectively. When developing the

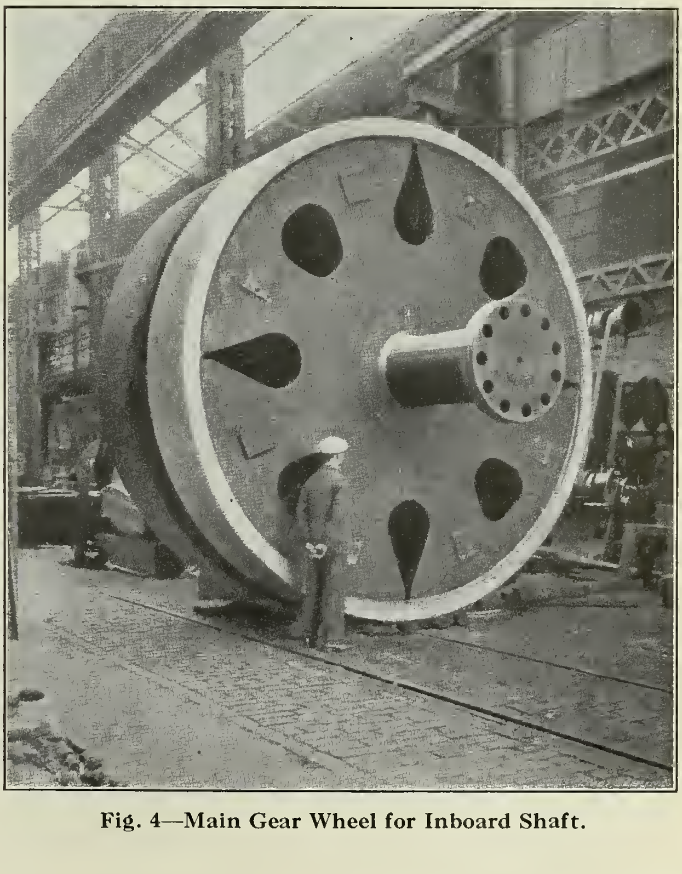

Fig. 4—Main Gear Wheel for Inboard Shaft.

normal service power of 60,000 s.h.p., the speeds of the propellers are 150 and 200 r.p.m. and the corresponding speeds of the turbines are 1,365 and 1,795 r.p.m. for the inner and outer shafts respectively. The reduction ratio, therefore, is about 9 to 1.

Steam-generating Installation

The main boiler installation consists of eight oil-fired water-tube boilers of the Yarrow type and one oil-fired water-tube boiler of the Johnson type.

Six of the boilers are placed in the after boiler-room, normally supplying the forward inboard engines; while three boilers are installed in the forward boiler-room, supplying the outboard engines in the after engine-room. The arrangements are such that any or all of the boilers can supply the ahead and astern turbines in the forward engine-room.

The Yarrow boilers are of the double-flow, side-fired type, having one steam drum, three water drums, and one superheater drum. The flow of the gases is through both sides of the boiler, after which they pass through a large tubular air-heater and thence to the funnel.

The boiler and superheater drums are hollow rolled forgings with ends formed integrally, and represent the latest practice for high-pressure boiler work.

The Johnson boiler consists of two large-diameter drums, placed vertically one above the other and connected to each other by curved tubes which are arranged longitudinally and across the ends in such a manner that the combustion space is almost entirely enclosed by water tubes. In addition, there is a wall of water tubes along the centre of the boiler, which divides the combustion space into two separate compartments. This arrangement of tubes provides for a considerably larger amount of tube surface exposed to radiant heat than in other types of marine water-tube boilers.

The boiler was constructed at Clydebank and a series of very complete trials showed that it is capable of generating double the amount of steam per square foot of heating surface, while registering the same efficiency as a Yarrow or other standard type of boiler worked at ordinary mercantile rating.

Each main boiler is fitted with two automatic feed regulators, one of the Weir and the other of the Mumford type, while Parry soot-blowers are also provided. In order to give the alarm when the water in the boilers falls below a pre-determined level, Mumford low-water alarm gear has been installed.

In the forward boiler-room there are also two cylindrical boilers of the return-tube type for auxiliary purposes. These boilers are arranged to burn oil fuel with the Howden system of forced draught, and work at 200 pounds per square inch.

The oil-fuel pumping and heating installation is of the Wallsend-Howden type.

Boiler Feed System

The satisfactory working of a boiler installation of this kind is dependent on a supply of pure de-aerated feed water, and for this purpose, in both forward and after engine rooms, a Weir closed feed system of the internal capacity type is installed. Fig. 6 shows a diagrammatic arrangement of the closed feed system for the forward engine room. The evaporation of the raw feed water takes place in the auxiliary boilers, the steam from these being led to an intermediate stage of the turbines.

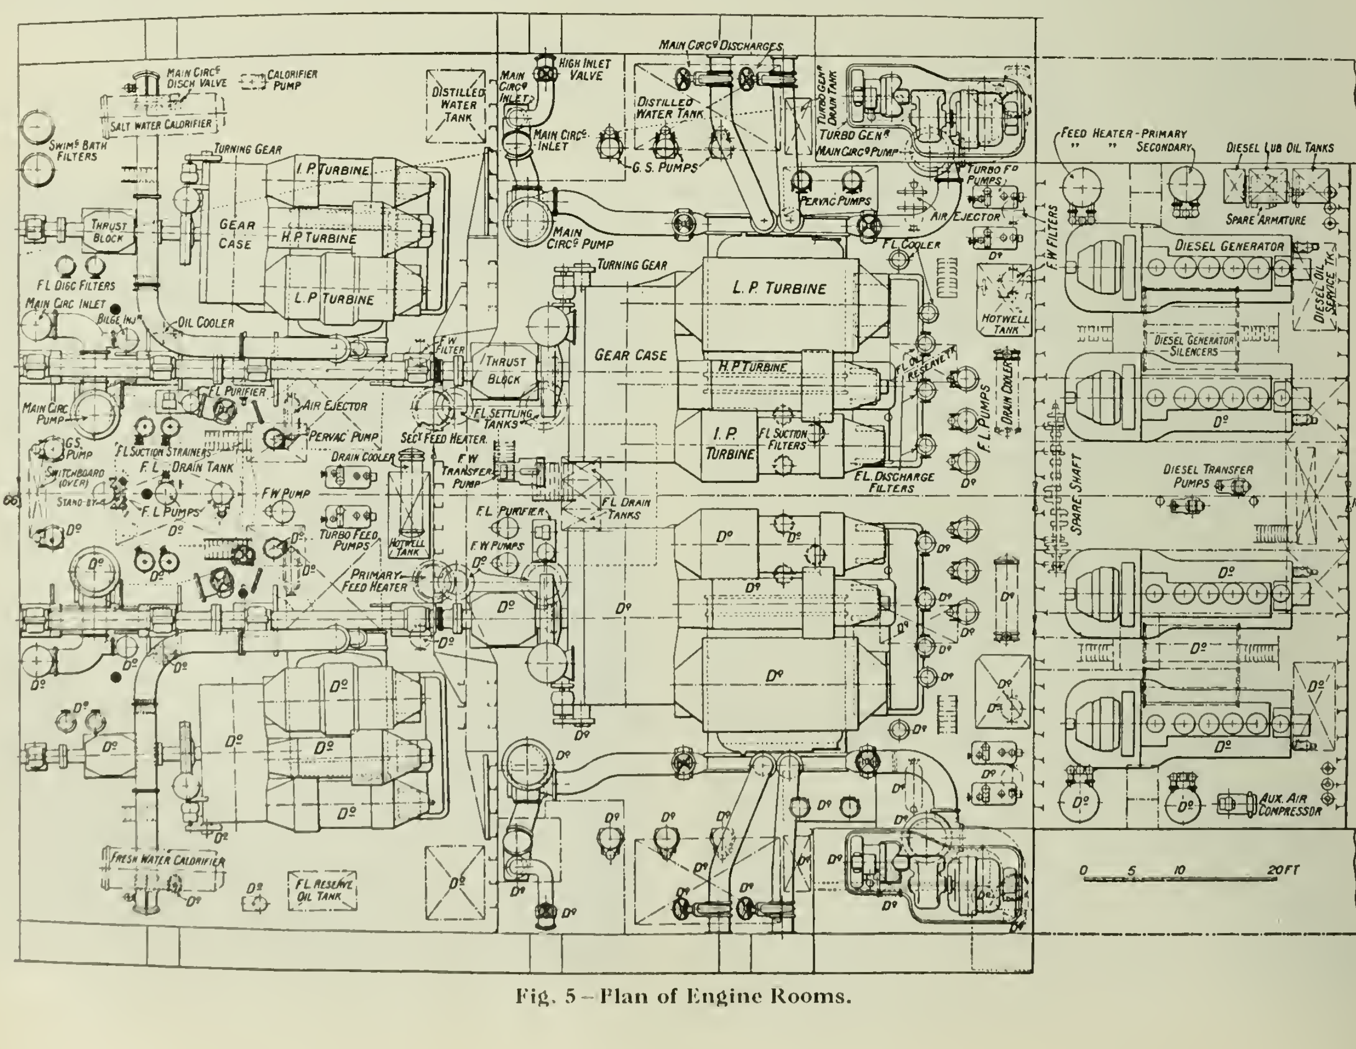

Fig. 5 — Plan of Engine Rooms.

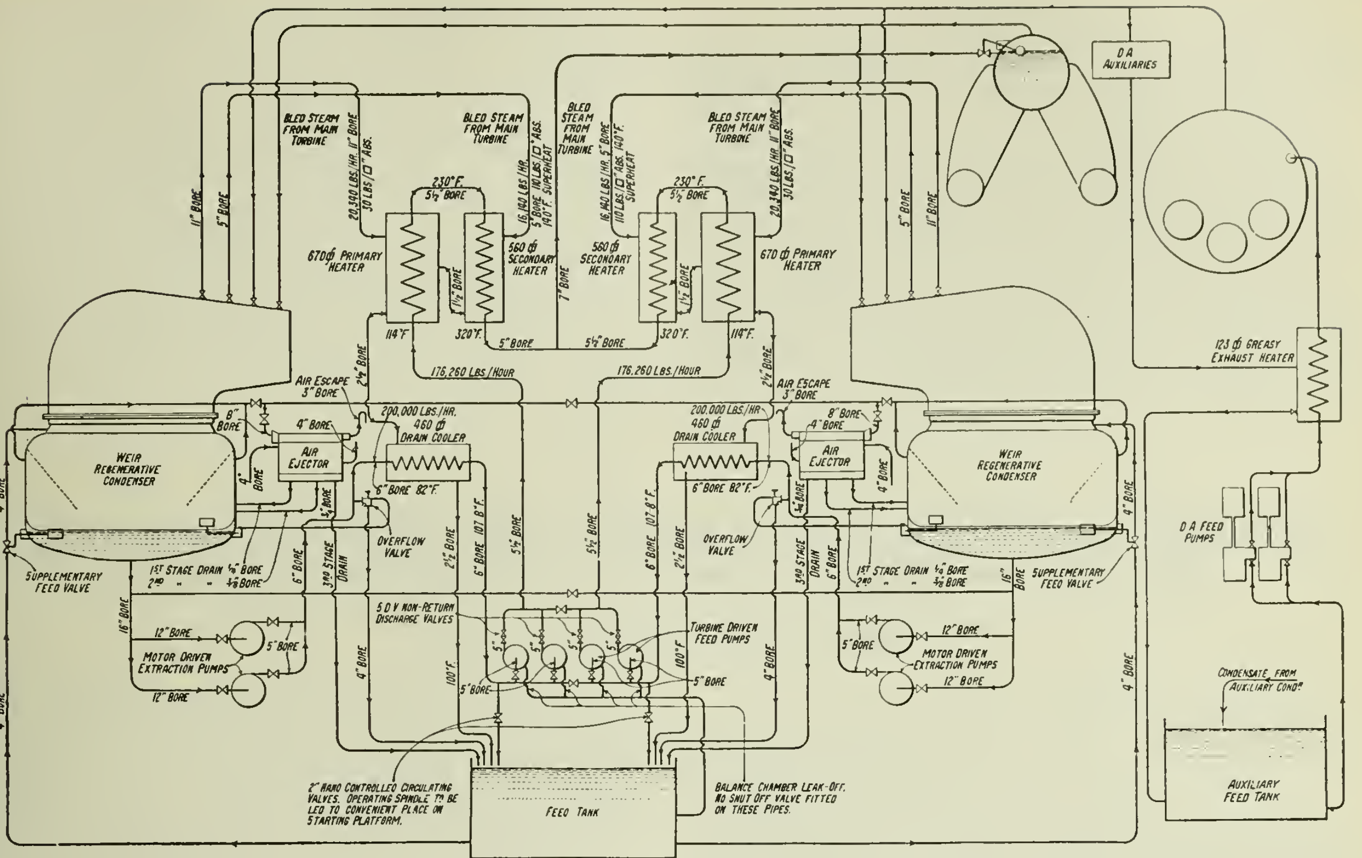

Fig. 6—Diagrammatic Layout of Closed Feed System for Forward Engine Room.

The regenerative condensers are fitted with condensate wells, the level of the water in which is maintained by float-operated supplementary feed valves admitting water from the feed tanks. The condensate is first passed through a drain cooler, where the heat of the drains from the primary heaters is absorbed before the feed enters the suctions of the feed pumps. The latter are turbine-driven and discharge through primary and secondary surface feed heaters, taking bled steam from the turbines at low and medium pressures, to the high pressure boilers through automatic feed-water regulators. As regards freedom from corrosion, the efficiency of a closed feed system of this type depends on the action of the condenser as a de-aerator, and the Weir regenerative condenser is ideal in this respect, delivering the condensate at practically the temperature corresponding to the vacuum, and with a very low oxygen content. Any feed water drawn in is thus completely de-aerated before entering the main circuit. In the event of the water level rising in the condenser, the excess feed is returned to the feed tank through overflow valves, also float operated.

Two motor-driven extraction pumps are fitted for each condenser, each capable of dealing with 120,000 pounds of condensate per hour; the air and non-condensable gases are withdrawn from the condensers by means of steam-jet air ejectors.

Four two-stage turbo-feed pumps are fitted in pairs, port and starboard, one working and one standby, each pump being capable of delivering 200,000 pounds of feed water per hour against a pressure of approximately 500 pounds per square inch. They are supplied with steam at 400 pounds per square inch, superheated to 725 degrees F., and exhaust to the main condensers, or against a pressure of 15 pounds per square inch to the primary heaters.

From the turbo-feed pumps the feed water passes through the primary surface feed heaters which are capable of raising the feed from 114 degrees F. to 230 degrees F., when supplied with steam bled from the turbines at a pressure of 30 pounds per square inch absolute, plus the drains from the secondary heaters. The secondary heaters are each capable of raising the feed from 230 degrees F. to 320 degrees F., when supplied with steam bled from the turbines at a pressure of 110 pounds per square inch absolute.

The closed feed system for the after engine room is on similar lines to that described above, but the capacity of each condenser is approximately half that of the forward set.

Electric-generating Plant

In the separate compartment between the forward main engine-room and the after boiler-room are situated four Diesel engine-driven generators.

Each of these has an output of 450 kw. and is driven by a Fiat-British single-acting, two-stroke, four-cylinder engine developing 660 b.h.p. at 260 r.p.m. Each engine drives its own double-acting scavenging pump, three-stage air compressor, circulating-water pump and lubricating-oil pump.

For emergency use and for supplying starting air, there is a Reavell electrically-driven compressor, and in the auxiliary engine-room there are also two fuel-oil transfer pumps.

In addition to the Diesel engine-driven generators, there are two British-Thomson-Houston turbo-driven generators of 800 kw. each. These are situated in the forward main engine-room and are supplied with high-pressure superheated steam from the main boilers, the exhaust being connected directly to the condensers. The turbo-driven generators are driven at 670 r.p.m. through gearing, the turbines running at 6,000 r.p.m. Two 75-kw. generating sets and a storage battery are provided for emergency use.

Other Auxiliaries

The remaining auxiliaries, which are mostly electrically driven, are arranged in three pairs, so that one pair will serve each of the larger main engines and the remaining pair the smaller outboard sets.

The main circulating pumps are of the vertical-spindle centrifugal type, driven by electric motors. Nine Drysdale Centrex pumps have been supplied for the forced-lubrication system, and Vickcen centrifugal separators are installed for the purification of the lubricating oil.

Centrex pumps are also provided for the bilge, ballast, sanitary, fire and wash-deck services, a battery of six pumps being situated in the forward engine-room and two in the after engine-room. Three smaller pumps of a similar type are also installed for dealing with fresh water.

A well-equipped workshop is situated in the shaft tunnel and the refrigerating machinery is also arranged in this tunnel.

The refrigerating equipment consists of two twin-compressor vertical enclosed CO_2 machines each of which is directly coupled to an electric motor of 64 h.p. The capacity of the insulated cargo chambers amounts to 27,000 cubic feet, part of which is fitted with brine grids while part is air-cooled. The capacity of the refrigerated provision chambers amounts to 29,500 cubic feet, and there are brine connections to thirty-four cold cupboards.

A complete Lux CO_2 fire-extinguishing system is provided in the boiler-rooms and in the auxiliary machinery room.

Discussion on "Steam Station for the Head Office Building of the Sun Life Assurance Company of Canada, Montreal, Que."

Paper by F. E. Combe, M.E.I.C.[1]

R. E. MacAfee, m.e.i.c.[2]

Mr. MacAfee observed that the steam generating equipment consisted of cross drum sectional header boilers and forced draft compartment type chain grate stokers.

The boiler tube bank of each boiler was composed of twenty sections in width, each section having eight plus two tubes in height, making a total of two hundred tubes 18 feet long. The arrangement, starting at the bottom or point nearest the furnace, consisted of two rows of tubes, a blank space the equivalent of two rows of tubes and then the main bank of eight rows of tubes. The two bottom rows of tubes acted to a certain extent as a slag screen. The blank space made it possible to baffle the boiler so that a large part of the two bottom rows of tubes were directly exposed to the furnace. The sectional header boiler could readily be arranged to make practically any provision required for a suitable slag screen, as well as making it possible to expose part or all of the bottom rows of tubes to the furnace. The actual arrangement of the tube bank would depend on the load to be carried, the volume of combustion space available and the coal to be burned.

The cross drum straight tube boiler would lend itself to installations where limited head room was essential, it being possible to provide reasonable combustion space in minimum headroom.

Each stoker was fitted with five air compartments between the upper and lower run of the chain. The air to each compartment was under control, making it possible to regulate the air supply to the fuel bed to meet any operating conditions desirable.

The speed of the grate could be varied and the thickness of the coal bed could be regulated. With the adjustment of the coal supply, the air supply, and the speed of the grate, all conditions of load between minimum and maximum could readily be taken care of.

When the load was below 15,000 pounds of steam per hour it was the intention to operate on natural draft. To do this it was simply necessary to shut down the forced draft fan and to open up the doors in the wind boxes at the sides of the stoker.

It was to be noted that this stoker, when properly set for a given load condition would operate practically smokelessly when burning Dominion coal. With slight modification when the original design was being made, the stoker could be adapted to burn such fuels as coke breeze, anthracite screenings or a mixture of anthracite screenings and bituminous slack as might be most economical.

Forced draft chain grate stokers were suitable for the application of preheated air. At this plant the air to the stoker compartment runs around 180 degrees F. and air temperatures up to 350 degrees F. could be used depending on the characteristics of the coal.

The fuel consumption per square foot of grate surface varied with the furnace volumes, load, and the coal to be burned. When using Dominion coal this rate varied from 25 to 35 pounds. For other coals with a higher ash fusion temperature the rate could be increased to 40 and in some cases as much as 60 pounds per square foot of grate.

From this it would be seen that the overall arrangement of the unit depended on a number of variables. For this reason it was essential that the design be prepared by engineers entirely familiar with the problems involved.

J. T. Farmer, m.e.i.c.[3]

Mr. Farmer stated that the author was to be congratulated on having conceived and carried to completion what was undoubtedly the most advanced example of a steam plant devoted to the services of a commercial building in Montreal, and probably in the whole of Canada.

Perhaps the most noticeable feature in the general scheme was that the owners had been wise enough to allow the mechanical design to control the design and disposition of the enclosing building. Consequently the design and layout of the equipment had not been hampered by architectural and other considerations which frequently in such cases introduced complications and often necessitated compromises and variations from the most desirable scheme.

In this instance, the design had apparently been worked out untrammelled by major considerations of meeting space limitations, and consequently it exhibited a harmonious combination of the mechanical units with the building structure, and an economic adaptation of the latter to the

(1) This paper was presented at the Annual General Meeting of The Institute, Montreal, February, 1931, and appeared in the February, 1931, issue of The Engineering Journal.

(2) Manager, Eastern Branch, Babcock-Wilcox and Goldie McCulloch, Ltd., Montreal.

(3) Mechanical Engineer, Montreal Engineering Company, Montreal.

coal-handling and other auxiliary equipment. It had also developed a symmetrical arrangement of the boiler units in individual settings spaced so as to afford ample accessibility for operation and upkeep which, in itself, constituted a valuable asset.

The concentration of population in a large modern office building led to heavy demands in steam and power for ventilation and air-conditioning, as well as for the numerous other services which modern ideas of convenience called for. In the instance under discussion, provision had been made for a total steam output of some 128,000 pounds of steam per hour. The paper was confined to a description of the means taken to meet this maximum requirement. No account was given of the preliminary calculations—which must have been quite extensive—in arriving at this estimate of maximum plant capacity. Such an estimate would be much simplified if, as in some manufacturing operations, a definite figure could be arrived at which would represent reasonably closely the demand to be met as long as operations continued. A heating load in a climate such as that of Montreal had very different characteristics. It had a fairly predictable seasonal variation, complicated by erratic peaks of short duration which might very greatly exceed not only the average, but the ordinary heavy load. It was interesting to note the steps taken to meet these varying conditions, particularly in providing for the extreme conditions, which must be taken care of, but at the same time arranging that the power demands necessary to carry the heavy loads were not made a continuous tax on the plant during the long periods when they were not needed. It would be interesting to know what proportion of the time it was estimated that the mechanical draft fans would be in operation.

Where such variable conditions were encountered, it must be recognized that it was physically impossible to meet every stage of the variations with the same efficiency. In general, the best that could be done was to design as nearly as practicable for the condition that represented the weighted average of the whole operation. For departures from this condition, there would be more or less loss of efficiency, but this was a minor consideration; the main one was to maintain continuity of operation through the most extreme variations met with.

There was one instance in which this principle appeared to have been departed from. In connection with the induced draft equipment, heat recovery apparatus was introduced in the shape of economizer surface of nearly fifty per cent of the boiler surface proper. The use of this apparatus was limited to the time when the induced draft was in use, which excluded the summer and the long mild periods in spring and autumn, leaving the three or four cold months of the winter, during most of which only a portion of the apparatus installed would probably be actually in service. In view of this relatively short period of activity, the question presented itself as to whether the demonstrable saving in fuel offset the considerable first cost of this heat recovery.

Another question which suggested itself was whether the situation would not have lent itself to the production of a block of base load power by the use of a high pressure turbine. By generating steam at 400 pounds pressure and 150 degrees superheat and exhausting at the pressure of 100 to 125 pounds into the heating system, an output of some 1,200 kw. could be secured in conjunction with the steam production of 50,000 pounds per hour, or one-half the maximum capacity, which, presumably, would be something of the order of the sustained demand during a large portion of the year. This, it would appear, would be a useful contribution to the power requirements of the building.

One would expect that the power requirements would relax somewhat during the summer—the period of light heating load—and that there would be excess power demands coincident with, and in part arising from the heavier heating loads. Thus, it would appear that the local generation of a varying block of power, when and as steam was available, would act to reduce to an approximately constant figure the amount of power required from outside sources, a very desirable condition from the standpoint of both the purchaser and the power supply agency.

The cost of power so generated in conjunction with the heating would consist in the main of the fixed charges and the operating and maintenance expense on the equipment involved, with very little expense for additional fuel. This should show up very favourably even as against the low cost of purchased power available in this city. A further advantage would be the availability of the secondary source of power in the event of a power interruption.

It was quite conceivable that, on closer investigation, under the actual conditions it would not prove possible to generate a sufficient block of power with sufficient continuity to materially improve the load factor or the overall cost of the purchased power; and that, consequently, the net saving effected would not warrant the additional investment involved.

It would be interesting to hear whether this possibility had been considered, and if so what were the reasons that decided against its adoption.

F. A. Combe, M.E.I.C.[4]

The author in reply to Mr. Farmer stated that he was sorry that the allotted length of paper did not permit of dealing with the reasons for the adoption of certain arrangements of design or the engineering problems involved. In view of the many features of interest in the engineering of the main building, it had been decided to confine the papers to a brief description of the equipment installed.

As regards the heating load on the plant, there were many variables which influenced the load curve relation with the outside temperature. The maximum load on a cold day would comprise approximately 25,000 pounds steam per hour for direct radiation, 60,000 pounds steam per hour for ventilation and 15,000 pounds steam per hour for miscellaneous services, bringing the total up to around 100,000 pounds per hour. This load would, however, be subject to variation due to the amount of air which may be recirculated for ventilation; the entrance heating, which will be at a maximum during entry and exit of employees; the natural heat from some 10,000 people during occupancy; kitchen, laundry and other services.

The question of installing a high pressure plant to generate power was carefully studied, but was considered undesirable, principally for the following reasons:—

> The load in the summer, which is made up to a large extent by ventilating fans, is practically the same as in winter.
>
> The possible saving would not justify the plant expenditure for power production throughout the year.
>
> The additional space required for plant.
>
> The higher class operating staff necessary for a high pressure power installation.
>
> The policy of the Sun Life Assurance Company to carry on only such service work themselves as other legitimate businesses cannot supply. Such policy also applies to printing, breadmaking and other services or supplies which no doubt might be furnished at some saving by plants of their own.

---

[4] Consulting Combustion and Steam Engineer, Montreal.

M. W. Booth, M.E.I.C.[5]

Mr. Booth observed that the paper described a steam generating plant, which although laid out on conventional lines, embodied an unusually complete equipment viewed from both the points of view of the steam requirements and of the economy in operating costs. The provision of three boilers, each of which could be operated economically over a wide range by the extra draft and economizer equipment provided, left very little to be desired in this respect.

The selection of the type of boiler was of course a matter these days largely of personal choice, and the stoker perhaps was in somewhat the same category, but it was interesting to note that the grate area and the details of the furnace setting were designed in particular for the use of Nova Scotia coal.

The analysis of this coal as given could be taken as fairly representative, but exception might be taken to the general statement that the iron content was high, which after all would only cover a certain section of the coals mined in Nova Scotia and shipped to the St. Lawrence district, and which were not in such proportion, as now generally selected for general stoker purposes, as to affect the burning and maintenance properties of this fuel.

It was difficult however in other respects to find other points for which the furnace design had not provided. The short arch was noted and was well off the grate, agreeing with the easily ignitable quality of the coal, with consequent low maintenance under any conditions of fuel and load requirements; and also, as specially mentioned in the paper, the large area of the boiler tube heating surface exposed to direct radiation from the grate, which would ensure both economical operation and low furnace maintenance.

However, returning to the general subject of the plant, Mr. Booth stated he could not but regret the absence of any tendency in the design to depart from the small station idea, and to embark upon something which would suggest the large central station.

Montreal was growing rapidly, steam was still accepted as being the cheapest and most convenient form of heating for domestic and general purposes, no matter whether the fuel was coal or oil; and in order to settle the problem from a smoke point of view, from a traffic convenience point of view, and from an economy standpoint, the trend must inevitably be towards the central station, whether for steam alone, or for steam and power.

An ideal opportunity appeared to be offered in this particular instance for departing from the usual procedure, and establishing a plant along modern and accepted lines for serving what was rapidly becoming a highly concentrated and important section of a rapidly growing city, and he would hope that this was by no means too late, and that such a plant if not already conceived and under way in some other location would be so in the very near future.

F. A. Combe, M.E.I.C.

In reply, the author stated that while the question of a central heating plant to serve a large district area was an interesting one, there would be no economy from such a plant to the Sun Life Assurance Company, and it could not afford to sell steam as cheaply as the company is making it. The previously mentioned policy of the Sun Life Assurance Company applied in this case,—that they do not wish to take on the functions of a general utility business.

J. H. Hunter, M.E.I.C.[6]

Mr. Hunter desired to ask the author if he could give any figures of the floor area and volume per horsepower developed, both for these steam generating units and also for the boiler plant as a whole, as it would appear that although very liberal working space had been allowed around the boilers and in the plant generally, the layout had provided a very high capacity for the dimensions of the building. This was of course reflected in the cost of the plant as a whole. Also, was the author at liberty to give out any costs?

In Mr. Hunter's opinion, the arrangement and setting of the main steam generating units was of particular interest. These illustrated the most advanced boiler practice of dividing the heating surface of the unit into separate water heating and evaporating sections, each with its independent circulation, so obtaining a greater difference of temperature between the gases and the water than was possible in a self-contained boiler with single circulation. It would be interesting to know what were the different temperatures throughout the unit under normal operating conditions.

This development in steam generating unit design showed how little was meant to-day by rating boilers on the old basis of ten square feet of heating surface per "boiler horse power." In the units installed in this plant the actual heating surface of the boiler proper was only 4,500 square feet, which would give a normal boiler capacity on this old basis of only 450 h.p. Actually the output of the boiler was approximately 1,150 boiler horse power, equivalent to 260 per cent of such rating, but with the particular arrangement of heating furnace the intensity of operation of the unit was probably not particularly high, due to the fact that the work done was more evenly distributed than would be the case in a boiler alone.

F. A. Combe, M.E.I.C.

In reply to Mr. Hunter, the author said that sufficient tests had not yet been carried out to give exact figures of temperatures through the steam generating units, but it might be said that under a load of approximately 30,000 pounds of steam per hour the gas temperature at boiler outlet was approximately 560 degrees F., and leaving the economizer approximately 340 degrees F. The feed water entered the economizer at 210 degrees F. and left it at around 310 degrees F. As the boilers are operated at 100 pounds pressure it would be seen that the feed water is heated up in the economizer to within 28 degrees F. of the actual steam temperature, making the water section of the unit very economical and efficient. These figures illustrated the advantage of splitting up a steam generating set into independent evaporating and water heating sections. The inefficient back end of a standard type boiler had been removed and replaced by a very efficient heat transfer section.

As regards figures of volume and area per unit capacity, the steam generating unit itself had a floor area of 480 square feet, giving about 2.3 h.p. developed per square foot of floor area. The volume of the unit worked out at approximately 9 cubic feet per developed horse power. The boiler plant as a whole had a capacity of approximately ½ h.p. per square foot of floor area and 100 cubic feet of building volume per horse power. For a plant of this type, these figures compared well with good practice while providing liberal working spaces. The cost of the plant would be in the neighbourhood of $70 per horse power, which was also very moderate.

F. S. B. Heward, A.M.E.I.C.[7]

Mr. Heward remarked that the author of the paper had referred to a number of quite ingenious arrangements that had been incorporated in his design of the plant, and one of them, in particular, in connection with the heat recovery apparatus, also appeared to be somewhat original.

[5] Steam Engineer, British Empire Steel Corp., Sydney, N.S.

[6] General Superintendent and Chief Engineer, Canada Starch Company, Montreal.

[7] F. S. B. Heward and Associates, Montreal.

In this regard the author had mentioned that when the boilers were operating under forced draft, the air for combustion was drawn down from above street level through an encasement around the chimney and steel flues leading thereto, with the result that the air, before reaching the grates, was preheated by heat extracted from the outgoing flue gases.

In his discussion of the paper Mr. MacAfee had mentioned that during certain tests recently conducted at this plant, the air temperatures were observed to run as high as 180 degrees F., and Mr. Heward had also understood Mr. MacAfee to say that the stokers in the plant could operate at air temperatures up to 350 degrees F., depending on the fuel being burned.

He would like to know whether the air heating device arranged by the author would permit of heat recovery to an extent of 350 degrees F., because, if so, it would be a most interesting device as it would then seem to render possible the combination of water economizer and air preheater which heretofore had been so difficult to justify from the economic standpoint, particularly in the case of the small steam plant. In any event, no doubt, the author would be able to confirm that the arrangement used in this plant to raise the air even to 180 degrees F., paid for itself very well.

F. A. Combe, M.E.I.C.

The author replied that it was not expected that the temperature of the air for combustion would be brought higher than 180 degrees F. in the main forced draft duct with the pre-heating arrangement adopted, but it might be noted that a small percentage of this air was circulated through the furnace lining and discharged under the arch at the front end of the stoker at a temperature of, probably, around 300 to 500 degrees F. Higher temperatures of air passing up through the grate were apt to cause trouble and high maintenance costs with Dominion coal.

M. B. Watson, A.M.E.I.C.[8]

Mr. Watson remarked that the author was to be congratulated upon having presented a most interesting description of the new steam plant; but he regretted that an opportunity had been missed of carrying out more fully one of the objects of The Institute, viz., the interchange of professional knowledge among the members, in that the reasons or considerations determining various features of the design had not been given.

Upon first glance at the illustrations, there would appear to be a great deal of waste space in the plant, but the author did not tell why the equipment was disposed as it was. For example, one wondered why the chimney was not placed in the same bay with boiler No. 4; why the chimney was not started at the level of the natural draft flue, thus saving the cost of that amount of chimney; why the economizer was not placed above the boiler smoke outlet, and the induced draft fans placed in the large empty space above the natural draft flue, which would leave the space where the economizers were now placed to be used for the incoming air duct to the forced draft fan and dispensing with about two-thirds of the ash basement volume.

There had been a number of unusual ideas worked into the layout which were worthy of emphasis. Among these were the following:—

(*a*) The use of economizers under heavy loads only. In this connection a statement of the expected terminal flue gas temperatures under each condition would have been real professional information. Also on what factors would depend the operation of one boiler at high rating with economizer, or the operation of two boilers at medium rating without economizers.

(*b*) The combination of ventilation of the upper part of the boiler room, with the furnace air supply, under forced draft operation was quite ingenious, especially the feature designed to prevent the dust from above the bunkers flowing into the boiler room. Mr. Watson doubted whether the velocity of air flow through the bunker space would be sufficient at more than a few points to carry the coal dust. The author did not state the degree of pre-heating expected, or whether this slight amount of pre-heat would increase the efficiency sufficiently to compensate for the reduction of draft and the expense of the complicated duct arrangement required. Once this duct arrangement was installed, it appeared to him that it should be made use of, under small load conditions, to ventilate, as far as possible, the overboiler space, because it was generally at small load periods that repair work in this space was carried out and when comfortable working conditions were of importance.

(*c*) The reasons for hydraulic soot disposal from the rear boiler pass, instead of using the ash cars, were not stated, but would be of interest. Was it not questionable whether the soot was sufficiently buoyant to remain in suspension in the ordinary slow flowing street sewer, or whether there might not be sufficient fly-ash in the soot to settle out and eventually block the sewers?

The facilities for removal of soot and fly-ash from the flues and economizers had not been described, but would appear to require special attention when such elaborate equipment was installed for rear boiler pass soot removal.

(*d*) It was stated that coal from the storage bin might be distributed in one-ton cars to the crusher or directly to the stoker hoppers. It was inferred that these cars were moved and dumped by hand. One would expect to find some arrangement whereby the motor trucks could dump directly to the suspended bunker or the conveyor above it, from the floor above, in order to save the extra manual and mechanical handling when it was unnecessary to crush the coal. It would be interesting to know whether this layout was dictated by architectural conditions or by the possibility that it was necessary to keep this coal, which was rather high in sulphur, moving and not in storage for any considerable time.

There was no mention made of ventilation in the coal handling floor.

(*e*) The availability of softened water for make-up was fortunate with regard to boiler cleaning. It was noted that a deaerating heater had been employed to preclude corrosion where the natural protection of scale would be missing.

Mr. Watson concluded by stating that he felt that valuable professional knowledge might have been given in further data on the furnaces: including the furnace volumes, expected maximum and normal rates of operation, b.t.u's per cubic foot per hour, also the types of refractory and insulation in the setting, with provision for expansion, if any.

F. A. Combe, M.E.I.C.

The author stated that many of the points raised by Mr. Watson had been dealt with in previous replies. It was hardly possible in such a paper to explain fully the reasons for adoption of particular details of plant layout

[8] Partner Angus and Watson, Toronto.

as these were governed by so many factors and condition requirements; for instance, the layout of the future building overhead, fronting on Mansfield street, and its communications with the main building, determined the location of the chimney and the method of coal handling.

In regard to the economizers it was very advisable, when the temperature of the water is raised to such a high degree, that the natural upward flow be maintained if possible.

It was hardly possible to give arbitrary times and loads for putting into commission certain sections of the boiler units and auxiliary equipment, as this must be left to the judgment of the operating engineer to suit conditions and the best results. The object was to design the boiler units to be elastic and to have a wide range of economic operation. It might be mentioned that on the completion of the building over the boiler plant, the increased height of stack would make unnecessary the operation of the induced draft fans to the same extent as at present.

In the matter of soot disposal, all familiar with the operation of boiler plants knew that while it was a comparatively easy matter to dispose of ashes, nobody wanted soot, and the method of disposal adopted at this plant had not given, and was not expected to give, trouble or cause difficulties. Soot from the economizers was disposed of in the same manner by flushing to the sump.

L. M. Arkley, M.E.I.C.[9]

Professor Arkley asked if the author had any information as to the efficiency of the boiler plant, and also why the special type of stoker he had put in was chosen, and why Nova Scotia coal was used.

F. A. Combe, M.E.I.C.

The author replied that during a test made the efficiency of the boiler and stoker worked out at around 75 per cent. With the economizers it was expected that an efficiency of around 80 per cent would be maintained.

The choice of stoker was determined largely by its suitability for Nova Scotia coal and by the necessity of having a smokeless chimney under all loads. The author was of opinion that the chain grate stoker with a properly designed furnace was best suited for smokeless operation under the conditions prevailing in a plant of this type. There had been an entire absence of smoke from this plant at any load so far carried.

The plant was designed to burn Nova Scotia coal as this is a Canadian product and is the lowest priced bituminous coal available in Montreal.

(9) Professor of Mechanical Engineering, Queen's University, Kingston, Ont.

J. Stadler, M.E.I.C.[10]

Mr. Stadler remarked that as he understood it, no provision had been made for the generation of power, consequently even the power required when the fans were in use would be supplied from outside. The peak of steam demand might possibly come at the same time as the maximum peak in the load in Montreal. Mr. Farmer had already mentioned the possibility of power that could be generated from steam by using a higher pressure; therefore, he would not cover that field. But he would ask whether it was possible to anticipate the load curve of the boiler plant in relation to the power demands of the city of Montreal? In other words, was it anticipated that their peak demands would not correspond with a maximum load demand of the city of Montreal. Further, had it been considered that it might be advisable to make provision for steam storage by operating the plant at a variable pressure.

F. A. Combe, M.E.I.C.

The author stated that the peak steam load on the station would not coincide with the peak electric power load in the city, in that being mainly a heating plant the maximum peak would come in the early part of the morning during the first hours of occupancy; later, by reason of its occupancy and since usually the outdoor temperature moderated, the steam demand would drop during the afternoon.

He did not think that steam storage could be used to advantage as the load curve was gradual and arrangements were made in the building for zoning of the heat in different sections to suit outdoor conditions by thermostatic or manual control.

In a central operating room in the main building the load dispatcher would be in a position to so regulate his load as to offset any sudden demand and also to iron out the peaks by diversity of steam usage. With such a system the author did not think that any large steam accumulator storage would be justified.

(10) Industrial Engineer, Montreal.

Communication on Civil Airways in Canada*

Lieut.-Colonel W. Arthur Steel, M.C., A.M.E.I.C.,
Royal Canadian Corps of Signals, Ottawa, Ont.

Paper presented on April 23rd, 1931, before the Aeronautical Section of the Montreal Branch of The Engineering Institute of Canada (Montreal Section, Royal Aeronautical Society).

SUMMARY.—In this brief survey of the various systems of communication applicable to aircraft and airways, radio aids to air navigation are first described. These include directive beacons and direction-finding equipment. As a means of two-way communication with aircraft in flight, radio telegraphy is considered more effective and reliable than radio telephony. In order to permit of continuous service, blind landing equipment is required, and the use of radio beams for this purpose is discussed. Reference is made to the present system of communicating meteorological reports by teletype, and the existing organization of civil airways in Canada is described.

Introduction

A great deal has been written in the technical press about communication for aircraft, but the whole subject of aviation is so new that some benefit may still be derived from a general survey of the various systems of communication applicable to aircraft and to the recognized airways over which these machines fly. In addition to this summary the writer hopes to show how these communication aids are being utilized in the development of civil aviation in Canada.

The systems of communication required on recognized air routes may be summarized under the following heads:—

1. A radio system to keep the plane on its course between airports.
2. Two-way radio communication between the plane in flight and the airports.
3. Blind landing facilities.
4. A system for the collection and dissemination of weather information along the airways.

A variety of systems have been developed and applied to these problems in different parts of the world and in the following paragraphs will be found a short description of the more important of these schemes that are at present in operation.

Radio Aids to Air Navigation

The Directive Beacon

The directive beacon, or equisignal beacon as it is sometimes called, provides a number of zones of equal signal strength, arranged normally at 90 degrees or 180 degrees to each other and which radiate in straight lines from the transmitting aerial. An example of this will be found in Fig. 8. These zones can be oriented in practically any desired direction. The pilot is informed when he is in one of these zones either by a characteristic signal received in the telephones in his head set, or by means of a visual indicator installed on his dashboard and operated by the receiver on the plane.

Either method will keep the pilot continuously informed whether or not he is on his correct course. It will also tell him whether he is drifting to the right or the left of the desired route. This indication, however, does not give the pilot his actual position but merely informs him when he is on the proper course. In certain instances attempts have been made to give the pilot his approximate location by means of marker beacons erected at periodic intervals along the course. These marker beacons consist of low power transmitters emitting a characteristic signal received by the pilot either in the telephones or on a visual indicator.

*This is the third of a series of papers on aeronautical subjects which have appeared as follows:
"Aerial Cameras and Photography" by Flight Lieutenant J. R. Cairns. May 1931 issue of The Engineering Journal.
"Some Problems Connected with Fluid Motion" by J. J. Green, A.R.C.Sc., Ph.D. June 1931 issue of The Engineering Journal.

The directive beacon system has been extensively employed on the airways in United States and satisfactory ranges up to 120 miles have been consistently obtained. The width of the equisignal zone is of the order of six degrees, that is, about seven miles wide at 100 miles from the transmitter.

By means of a vertical rod antenna on the aircraft it has been possible to reduce "night effect" to such an extent that the system is equally useful by day or by night.

A very satisfactory type of rod antenna has been developed in America. It is easy to install and yet does not detract from the performance of the aircraft. It is pointed out, however, that the use of such a small antenna necessitates a very sensitive receiver with high amplification, and, as a result, the engine ignition system must be completely screened. This problem, however, had already been partially solved in this country in connection with the work done on telephone reception in aircraft.

The directive beacon is most useful on established routes where the courses to be followed are straight for approximately 100 miles. Unless the route is comparatively straight for distances of this order, the cost becomes prohibitive due to the number of transmitters required.

Direction Finding Equipment

The methods used in marine direction finding can be applied to aircraft with practically no alteration in either equipment or method of operation. It is well known that in marine work the actual bearings may be taken either on the ground and transmitted to the ship, or may be taken on the ship itself. Both of these methods are equally applicable in aviation. The basic principle underlying the operation of all systems of directional reception is the receptive properties of the simple loop antenna. With such a receiving system the signals are at maximum when the plane of the loop is pointing towards the transmitting station, and at a minimum when the loop is turned at right angles to the line of transmission.

When the equipment is mounted on the ground, two large loops of wire are rigidly supported at right angles to one another and to the horizontal. Two of these stations are required in order to take a bearing on either a ship or an aeroplane. It is also essential that these two stations should be in communication with one another so that the two sets of readings can be taken, plotted, and the location of the resulting intersection transmitted to the ship or aircraft. When the receiving equipment is on the plane the bearings must be taken on two different transmitting stations on the ground. The big disadvantage in all direction finding stations lies in the time required to make these bearings. When the equipment is on the ground heavy and expensive transmitting equipment must be mounted on the aircraft. This system is also subject to excessive variations due to the so-called "night effects." It is also pointed out that while bearings are being taken the aircraft is bound to be out of touch with the ground for normal communication

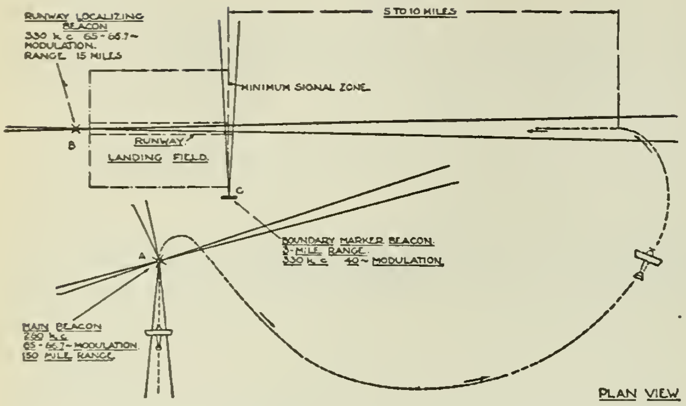

Fig. 1—General Arrangement for the Low Power Runway Localizing Beacon.

purposes. A further serious defect lies in the fact that any two ground stations can only serve one plane at a time. With dense traffic and poor visibility the subsequent delay becomes very serious indeed.

In order to reduce "night effect" a method known as the "Adcock System" has been evolved. Night error is due to the effect on the horizontal wires in the loops of vertically-polarized waves which have been reflected from the Heaviside layer. In the Adcock antenna system the horizontal members of the loops are eliminated by an ingenious method of construction. Unfortunately this system can only be erected on the ground. It does give very definite freedom from night variations but is subject to all the other defects of direction finding systems.

Another method, known as the "Robinson System" for aircraft, involves two loops, set at right angles to one another, and built into the wing structure of the plane. This system is, of course, only applicable for installation on aircraft. This device is essentially a method of homing the plane on a known transmitting station. It does not actually show the true position of the plane but only indicates when it is on the proper course. Strong cross winds, while causing the plane to drift badly, will not prevent it from reaching its final destination although the path, instead of being a straight line, will be a curve depending upon the strength and direction of the cross wind.

Two-Way Communication

This is required both by the operators on the ground and by the pilot in the air. The operator wishes to advise the pilot regarding changes in schedules, airport conditions, and other purely company business. On the other hand the pilot wants information about the weather ahead, about emergency fields and, in case of forced landings, to call for help and to advise his headquarters of his location. Having once made the decision to adopt two-way communication, the question then arises shall we use telephone or telegraph for this service? This whole question has been admirably treated by Mr. W. G. Logue of the Radio Marine Corporation of America in the June 21st copy of Aviation. Mr. Logue is strongly in favour of the use of radio-telegraphy for plane-to-ground communication, and his reasons may be summed up briefly as follows:—

(*a*) Radio telegraph apparatus in the planes is less complex than radio telephone apparatus, and is therefore less liable to failure.

(*b*) It is lighter in weight and less bulky.

(*c*) It is more economical. This applies to first cost as well as maintenance.

(*d*) It provides increased reliability of communications because telegraph signals are easier to "read" than telephone signals under bad atmospheric conditions, and certain types of telegraph signals are less subject to skipping and fading.

(*e*) Telegraph signals create less interference. Telephone communications occupy many times as much space in the ether as a telegraph signal. This is important in a service where channels are scarce.

Our air-to-ground work in Canada during the past ten years has led us to exactly the same conclusions as given by Mr. Logue. This is particularly true when reliability of communication is concerned. A two-way radio service for aircraft must be of such a type that it will provide 100 per cent communication or it will have failed in its purpose. It has been demonstrated through years of operation on other forms of transport that radio-telegraphy is the surest means of maintaining contact under the worst operating conditions. Communication with aircraft is fundamentally no different from communication in other mobile fields and, in the long run, the tried and proven methods will undoubtedly again prove to be the most satisfactory.

Blind Landing Equipment

It should be remembered that any system of blind landing aids must indicate to the pilot the position of the aircraft in three dimensions as it approaches and reaches the instant of landing. Up to the present this has been attempted by sub-dividing the problem into two parts: (*a*) field localization and (*b*) accurate height indication. Without going into detail the writer would point out that field localization has been attempted mainly by the use of buried "leader cables" providing a complete circuit around the landing field, or perhaps a straight cable down the field, with a visual indicating device on the plane instrument board. Height above ground has been measured in many ways but the only perfectly satisfactory device yet developed is the sensitive barometric altimeter so constructed that adjustments may be made in the air for any change in barometric pressure. This involves two-way communica-

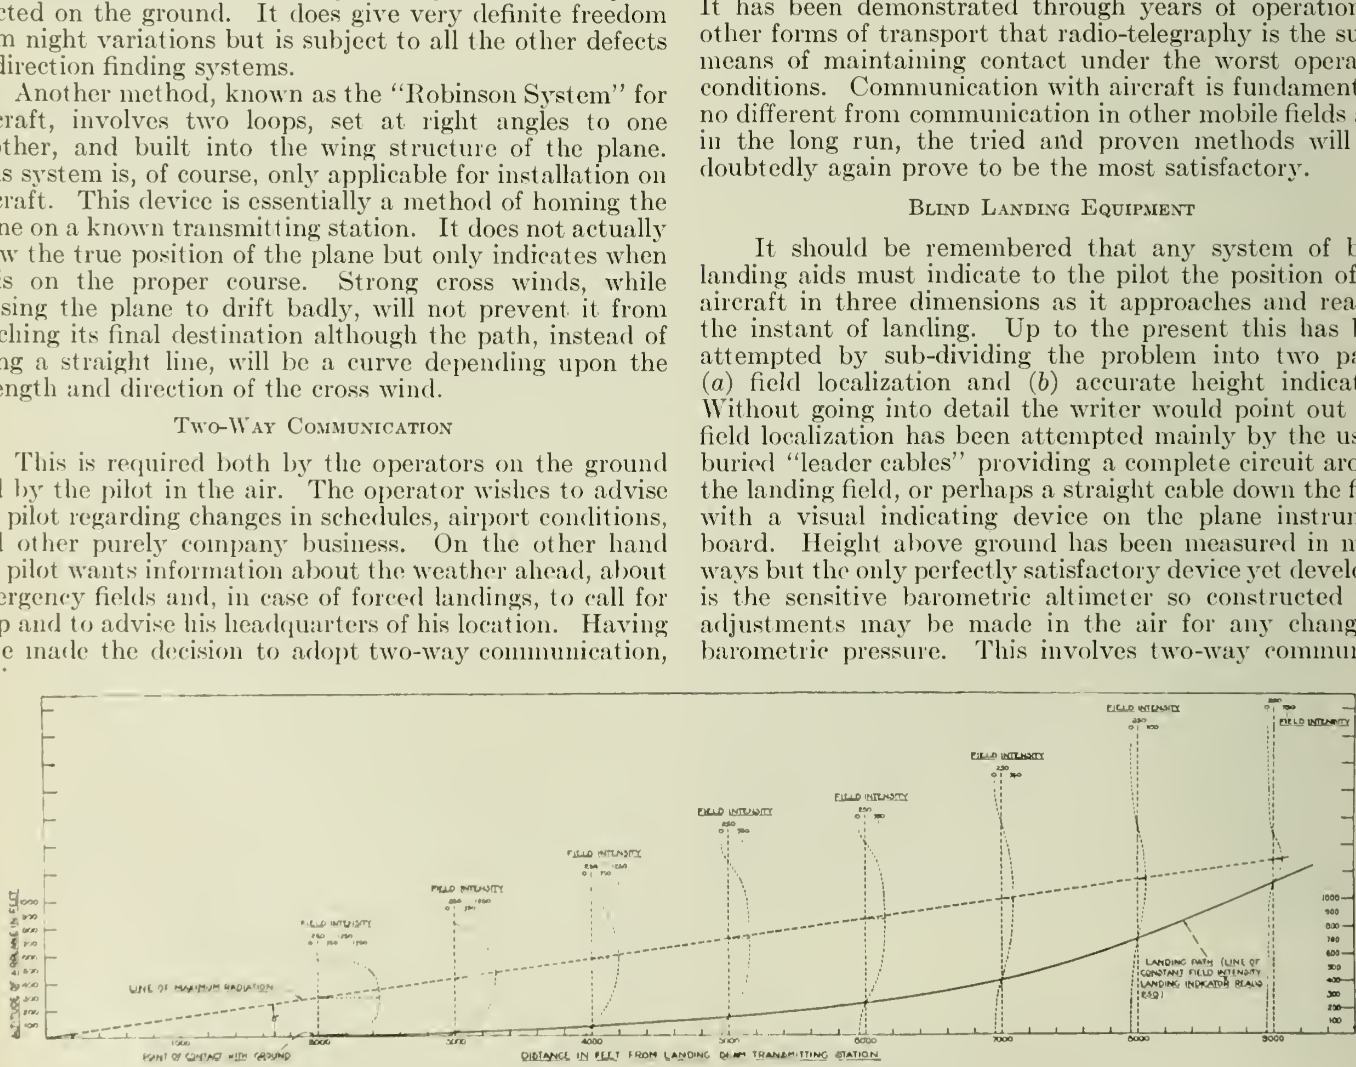

Fig. 2—Gliding Path Marked out by the Inclined High Frequency Beam.

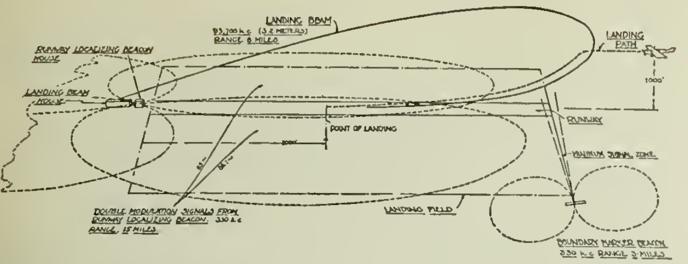

Fig. 3—A Three Dimensional View of the Blind Landing System

tion between pilot and airport to enable details regarding the change in pressure to be received in the air when required. Other schemes are being developed for height indication, the most promising ones being the sonic and the radio altimeters. Both of these depend upon the time taken for a wave to travel from the plane to the ground and back. However there are no instruments of either of these types at present available for practical use.

The Bureau of Standards at Washington have been working on the blind landing problem for several years in conjunction with their programme of radio aids to air navigation. The most successful, and at the same time the simplest system yet devised, is the one now installed at their experimental field near Washington.

The system is intended for use at airports where it may be necessary for aircraft to land under conditions of poor or perhaps no visibility. The system consists of three elements indicating to the pilot the path of the aircraft as it approaches the field and finally reaches the instant of landing. This system is a development of the directive beacon with visual indicators, as described earlier in this paper.

The three fundamental aids that must be available to the pilot are as follows:—

(*a*) The runway on which he is to land must be marked out by a clear, strong beam, along which he can readily guide his machine.

(*b*) He must be told, promptly, when he is exactly over the boundary of the airport.

(*c*) He must be provided with a definite path, marked out by means of a radio beam, which will coincide exactly with the gliding path of his plane.

In Fig. 1 will be found a diagram illustrating the first of these aids. A low power runway localizing beacon, using the same radio and audio frequencies as the main route beacons on the airway, is located just off the airport and is directed along the runway on which the plane is to land. The standard receiver and visual indicator on the plane are used to guide the plane along this path.

The boundary of the airport is marked out by a second low power transmitter, using the same radio frequency as the runway localizing beacon, but modulated at 1,000 cycles or similar audio frequency. The aerial used is so arranged that the radio field only extends for about 100 feet on either side of the airport boundary. This signal is heard by the pilot in the headphones normally used to receive the weather reports.

The landing path is obtained in a very ingenious manner. An ultra-high-frequency radio beam transmitter (a three-meter wave, actually) is set up near the runway localizing beacon and directed along the centre of the runway being used. This beam is inclined at eight degrees above the horizontal, as is shown in Fig. 2. The aeroplane is equipped with a high frequency receiver with a meter in the output circuit. If the plane were to fly along the line marked "line of maximum radiation," the reading of this meter would steadily increase as the plane approached the transmitter. If, however, the machine flies below this line, the signal will be less the further the plane is from this line of maximum radiation, i.e., from the centre line of the inclined radio beam. Therefore we have two forces acting—an increase in signal strength, due to the steady approach towards the source, and a decrease, due to the departure from the line of maximum radiation. These two operations can be made to balance, resulting in a steady reading in the meter as the plane approaches the transmitter. If the path, along which this signal is of uniform strength, is plotted out it will be found to coincide practically exactly with the gliding path of an aeroplane. Such a path is shown as a solid line in Fig. 2. The pilot watches the meter, if he is flying too high the meter will read "high," if he flies too low the meter immediately indicates this by reading "low." When he keeps the meter at its constant value, i.e., at midpoint on the scale, he is on the correct course.

Only one additional instrument is required, when the machine is already equipped for flying on airways provided with visual route indication. The normal reed or visual indicator, shows when the pilot is flying along the runway on which he is to land. The airport boundary indication is received audibly by means of the headphones used by the pilot to obtain his weather reports. The additional instrument consists of the high frequency receiving set with the meter in its output circuit. By keeping the deflection of this meter at a fixed value the pilot directs the plane along the curved path coinciding with the gliding path of the machine. Fig. 3 is a three-dimensional drawing, in which an attempt has been made to depict these three operations simultaneously. Fig. 4 is a drawing showing the arrangement of the various pieces of equipment in the plane itself.

The System of Civil Airways in Canada

Canada has not as yet a complete transcontinental air mail system but steady progress is taking place towards that end. It should be remembered that in this country a great deal of what might be called itinerant flying takes place. In this article no mention is made of such flying, although it is very important and constitutes a very large proportion of the total civil flying in this country. The writer has confined himself solely to recognized airways and to airmail routes carrying government mail contracts.

Our airmail system, as it exists at present, is shown in Fig. 5. It begins in Moncton, N.B., in the east and reaches Montreal via the state of Maine, crossing into the United States at McAdam, N.B., and returning to Canada at Megantic, Que. In the summer time there is a service connecting with the trans-atlantic passenger steamers at Father Point and reaching Montreal via Quebec and the St. Lawrence river route.

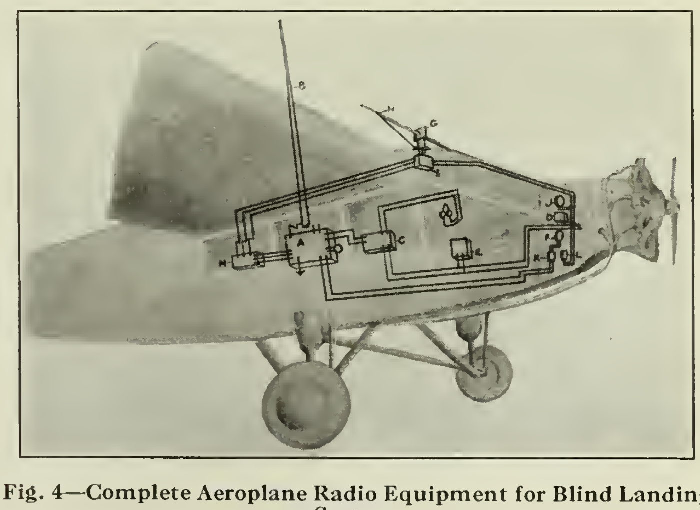

Fig. 4—Complete Aeroplane Radio Equipment for Blind Landing System.

Fig. 5—Map of the Canadian Airmail System.

From Montreal the mail goes to Detroit via Kingston, Toronto, Hamilton, London and Windsor. At Detroit trans-continental mail is transferred to the United States lines and taken as far west as Minneapolis. Here a United States branch line picks it up and takes it to Pembina on the international boundary just south of Winnipeg. At this point Canadian planes again pick up the mail and deliver it to Winnipeg in time to catch the night run across the prairies to Calgary.

From Winnipeg the mail route runs over Forrest (just north of Brandon), Broadview, Regina, Moose Jaw, Maple Creek, Medicine Hat, Lethbridge and Calgary, following in general the route of the Canadian Pacific Railway.

From Moose Jaw there is a northern mail route serving Saskatoon, North Battleford and Edmonton. It is probable, however, that this will be altered in the near future and that two feeder lines will be used, one from Moose Jaw to North Battleford, and the second from Lethbridge through Calgary and Red Deer to Edmonton.

The gap between Lethbridge and Vancouver has not yet been completed although aerial surveys have been made and a satisfactory route laid out through the Crow's Nest pass to Vancouver.

In addition to these routes across Canada, a northern service is being given by the Commercial Airways from Edmonton to Aklavik via the MacKenzie River valley. Mail is taken by train to Waterways (near Fort McMurray) from which point the planes fly northward via Fort Smith, Resolution, Simpson Norman and Good Hope to Aklavik in the delta at the mouth of the MacKenzie river.

These routes are all flown throughout the entire year and passengers as well as mail and express are carried on all flights.

In addition to those already mentioned there are several smaller routes scattered over the country. A winter service is given from Quebec to Seven Islands and Anticosti Island. It is hoped to expand this into an all-year route and to handle mail from Quebec to Belle Isle during the season of fast steamers from Quebec to England. This would save almost two days on the Montreal-Southampton mail run. A winter service is also given between Moncton and Magdalen Islands in the gulf of St. Lawrence.

Further inland there are three short mail routes. In Quebec, Oskelaneo on the Canadian National Railways connects with Chibougamau. In Ontario, Sioux Lookout, Red Lake and Woman Lake, all in the mining area, are interconnected, while in Manitoba, Cranberry Portage on the Hudson's Bay railroad is connected with Kississing by air. These three routes operate throughout the entire year.

In the east there is a second connection with the American airmail through the Canadian Colonial route between Newark, Albany and Montreal. This line carries passengers and express and is an all year round service.

The radio aids to air navigation now being installed on air mail routes in Canada by the Directorate of Civil Aviation, consist of directive radio beacons, two-way communication stations and a teletype service. Up to date no attempt has been made to provide blind landing equipment.

The western half of the system has been installed first, since the mail schedule in the west involved night flying. Beacon stations were placed at approximately 250 mile intervals, since the dependable range of the receivers and visual indicators is about 125 miles. The chain consists of 2 k.w. stations located at Forrest, Man., Regina and Maple Creek, Sask., Lethbridge and Red Deer, Alta. It will be observed from the map that at Broadview, Morse and Medicine Hat the direction of the mail route changes somewhat and the beams from the beacon stations intersect at these places. It is proposed to erect marker beacons at

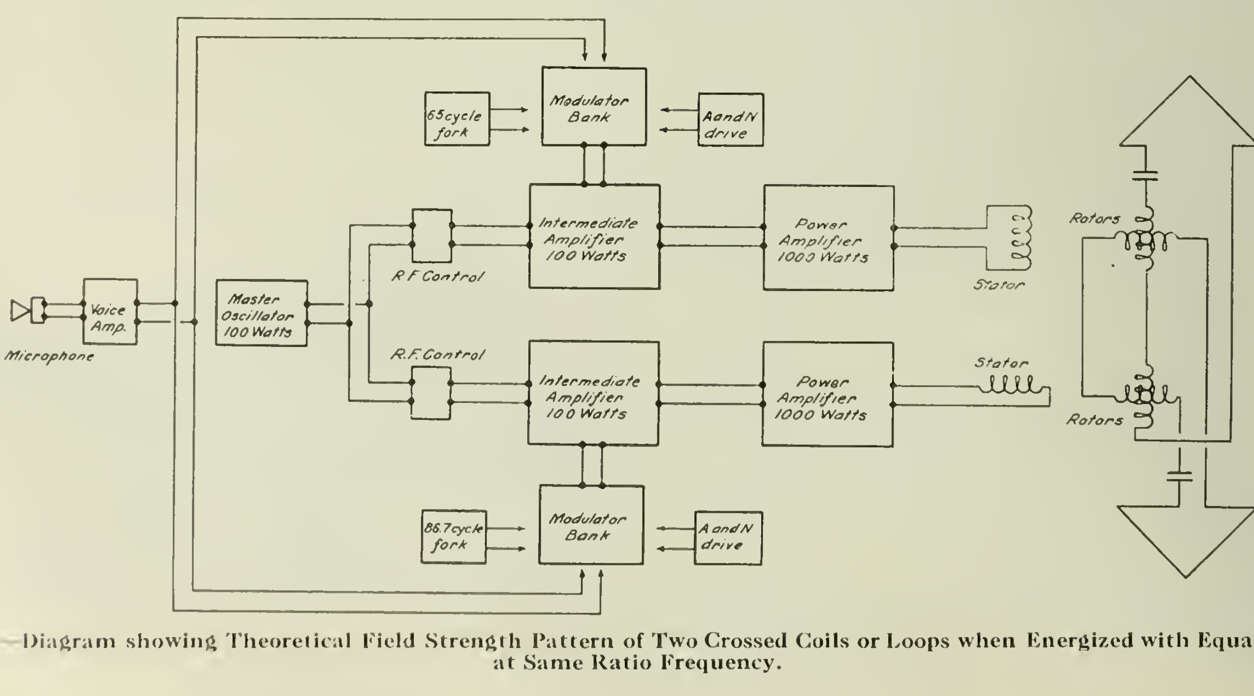

Fig. 6—Diagram showing Theoretical Field Strength Pattern of Two Crossed Coils or Loops when Energized with Equal Power at Same Ratio Frequency.

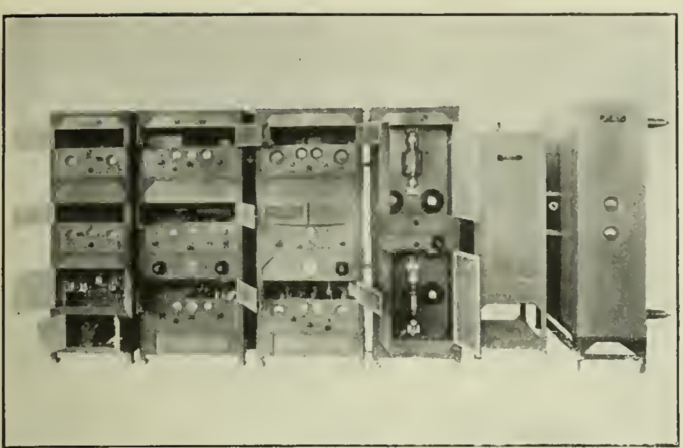

Fig. 7—The Marconi Beacon Transmitter.

these points and to use a third reed in the visual indicator. Until such time as these special stations can be erected, "on course" lights have been installed to indicate to the pilot that he must change direction.

The eastern radio system will have beacon stations at Moncton and McAdam in N.B., Megantic and St. Hubert in Quebec, Kingston, Toronto and London in Ontario. In addition there is a large station at St. Hubert equipped to transmit either by code or voice and it is used both for ground station traffic and for communication to planes in flight.

The section between Lethbridge and Vancouver, across the Rocky Mountains, will be served by means of two-way communication, since the route is far too tortuous for beacon stations to be used.

Under a recent agreement between United States and Canada the wavelengths between 850 and 1,350 meters are to be used for the radio beacon and weather broadcasting service. For the two-way communication between planes in flight and the ground stations, wavelengths in the band between 50 and 100 meters have been set aside. These wavelengths have been so chosen that machines flying between United States and Canada will be able to use the same apparatus in either country.

The Directional Transmission System as Applied to Canadian Civil Air Routes

Ground Equipment

No attempt will be made here to give the theory of the directive beacon but the accompanying diagrams and photographs will illustrate the equipment itself which has been designed and built in Canada by the Canadian Marconi Company in collaboration with the engineers of the Royal Canadian Signals. The equipment is similar in principle to the transmitters developed for use on American airways, but several unique features have been built into the Canadian apparatus. Fig. 6 is a schematic diagram of the arrangements of the parts of the beacon transmitter, while Fig. 7 is a photograph of the beacon transmitter with the doors of the various units open for inspection. The photographs of the antenna system and of the interior of the station were taken at Lethbridge, Alberta.

Beginning at the left of the diagram of Fig. 6 it will be noted that the transmitter consists of a master oscillator of 100 watts output feeding two intermediate amplifiers each of 100 watts. Between the master oscillator and the intermediate amplifiers are placed phase control devices so that either two or four courses may be produced by proper phase adjustment of the currents in the two loops. In Fig. 8 will be found the field pattern giving four courses from one beacon transmitter. Each of the intermediate amplifiers control a power amplifier of one kilowatt rating. The output from these last stages is fed through a four coil goniometer into the two loop antennae. Tuning is provided in each leg of each loop so that an exact balance of the aerial system may be secured. The modulation frequencies are introduced into the two intermediate amplifiers, and in this part of the circuit certain modifications have been introduced into the Canadian apparatus. It will be observed that the two audio frequencies of 65 and 86.7 cycles are obtained from two valve driven tuning forks, the temperatures of which are held constant by means of thermostats, at 90 degrees F. Two UX. 210 valves are used as an output amplifier for the tuning fork, the energy from this amplifier being fed into the intermediate amplifier through a bank of UX. 845 modulation valves. Means are provided to control the depth of modulation produced by the tuning fork signals. In order to provide for planes not equipped for visual indication, apparatus has been provided to convert the beacon to the aural, or A and N type. A small 500 cycle generator, together with a motor-driven set of interlocked cams, may be switched into the circuit in place of the forks and the output of the two loops, modulated with a 500-cycle signal, may be keyed as in the original American system. This modulation will provide for service to visiting American aircraft not equipped for the visual system, or for any of our own planes that may be flying beyond the range of operation of the visual indicator. No change is required on the aircraft receiver, as head telephones are already provided to receive the meteorological broadcast.

It is usual to supply the hourly weather report on the same wavelength as the beacon signals so that it will not be necessary for the pilot to make any change in his receiver. In the American system this is done by providing a second transmitter at the airport. There are two disadvantages to this scheme. First—the cost of the second transmitter with its power plant and associated equipment. Second—the time taken to change from one transmitter to another and back again several times each hour.

To overcome these difficulties a further modification has been added to the Canadian beacons. A microphone and speech input amplifier have been included in the transmitter, together with the necessary switching, so that

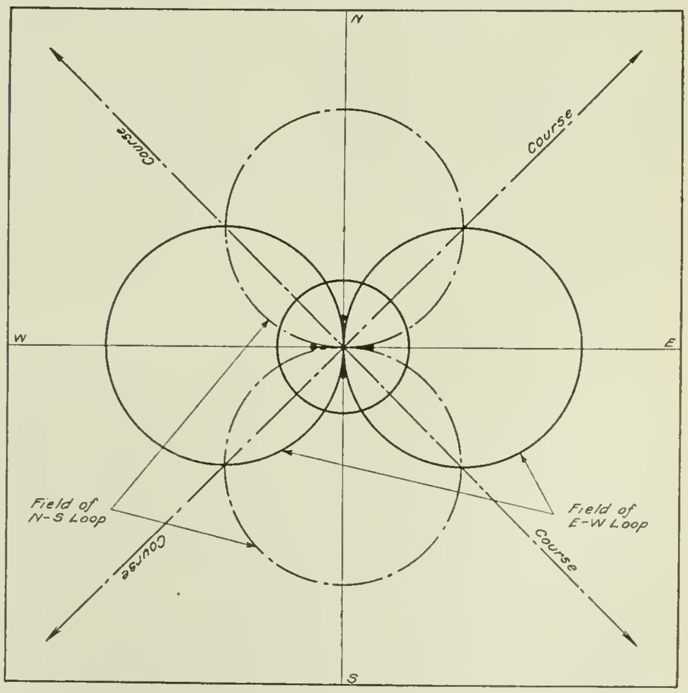

Fig. 8—Schematic Diagram of Arrangements of Parts of Canadian Radio Beacon.

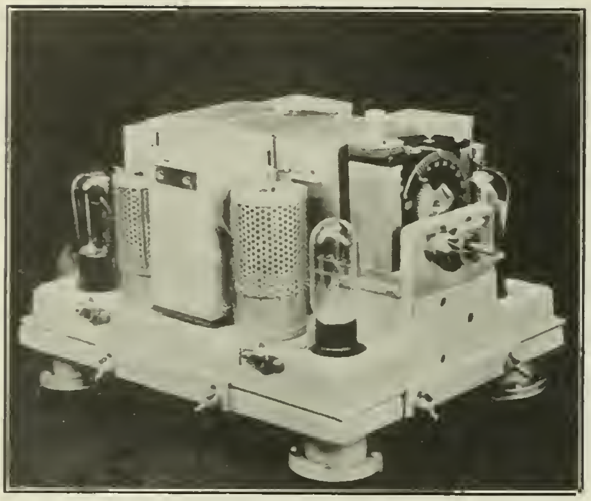

Fig. 9—The Western Electric Beacon Receiver of the Northern Electric Company.

voice modulation of the output of each loop can be secured. In order to transmit weather reports or other information to the pilot, it is only necessary for the operator at the station to throw the switch from either of the beacon positions to "voice" and to speak over the microphone provided. No change is required in the tuning of the aeroplane receiver and the pilot can adjust the strength of the speech by means of the volume control provided on the remote control device.

The goniometer, coupling the power amplifiers to the crossed coil antennae, is used to enable the courses mapped out by the beacon to be oriented in any direction required. The goniometer consists of four coils, two stator coils at 90 degrees to each other and two rotor coils also crossed at 90 degrees. The stator coils are connected to the plates of the power amplifiers, while the rotor coils are connected each in series with one loop antenna. The currents in the loop antennae, due to the driving voltage from each stator coil, create a resultant field in a direction such as would be produced by an imaginary antenna rotating with the goniometer rotor. Since there are two stator coils at 90 degrees, there are two such phantom antennae rotating as the two rotor coils turn together, thus allowing the equisignal zones or courses in space to be swung into any required direction.

There is a further advantage to be gained from this system. By suitable adjustments of the goniometer coils and the transmitter, two different effects may be secured. First—two of the right angle courses may be eliminated, leaving only one direction along which aircraft may fly. Second—the four courses may be retained but the angle between the two directions may be varied over quite wide limits. This is often necessary at airports where a number of radiating courses are in existence.

The Aircraft Beacon Receiver

The aircraft receiver is of the high gain type, employing three stages of screen grid radio frequency amplification ahead of a detector and two-valve audio amplifier. This amount of amplification is required to operate the visual indicator, since it has been found necessary to use a vertical rod type aerial on the plane to minimize "night errors," or variations in apparent direction due to reflections from the heavyside layer. This antenna consists of a streamlined metal rod, mounted on the fuselage of the machine and extending about seven feet above the upper surface of the plane body. The actual receiver is mounted in any convenient place in the tail of the aeroplane and the "on and off" switch, telephone jack and volume control are mounted in a small box on the instrument board. The visual indicator is also mounted on the instrument board in some spot where it can easily be seen. The effect of the electromagnets of the visual indicator on the compass has been completely eliminated by proper screening of the indicator box.

Fig. 9 illustrates the beacon receiver manufactured by the Canadian Marconi Company, while Fig. 10 shows the receiver handled by the Northern Electric Company.

In order to obtain the maximum benefit from these receivers, complete shielding of the ignition system should be employed. The high and low tension wires, the spark plugs and the magneto distributor blocks should all be shielded. Special shielded ignition harness has been developed by several United States firms, chief among whom is the Breeze Company of Newark, N.J.

In this harness the distributor blocks are covered by metallic shields and special metal shields are used around each spark plug. It is possible to use plugs, in which the shield is an integral part of the plug, but these do not give the same satisfaction as the metal shields. Shielding "cans" made by the R.F.L. Company of Boonton, New Jersey, were used at one time in this country, but these gave trouble in wet weather due to rain entering the ventilation slots and short circuiting the plug.

Power Supply for Beacon Stations

Where possible power is obtained from the system supplying the town or city near which the airport is located. In such cases the power is brought out by pole line at 2,400 volts, 3-phase, and from a distance of 1,000 feet from the station is carried underground by "Parkway" cable into the basement of the station. Transformers, lightning arresters and switch gear are provided in a transformer vault and power at 550 volts, 3-phase, is carried through the switch board to the motor-generator sets, also mounted in the basement of the station. Lightning arresters are mounted on the last pole erected, to protect the buried cable from damage during a storm.

Where power is not available locally, a 20 k.w. gasoline driven set is provided and operated in the same building as the beacon transmitter. Here the power is generated directly at 550 volts, 3-phase, 60 cycles and stepped down to 110 and 220 volts for the lighting and incidental services around the building.

A tungar rectifier and charging panel are provided on each station to take care of the batteries required for the operation of both the transmitter and receiver.

Fig. 10—The Beacon Station and Antenna System at Lethbridge, Alta.

The Teletype System for Meteorological Reports

The teletype service for the collection and dissemination of weather information has been devised with the idea of minimizing the amount of radio transmission required by civil aviation. It is well known that the number of channels available for this work is limited and that they must be conserved for the essential services between air and ground, since these services cannot be served in any other way.

The teletype system comprises leased telephone or telegraph circuits over which signals are transmitted by an automatic typewriter giving a typed record on all machines in the circuit. The transmission over this system is at a rate of approximately forty words per minute. All stations are equipped with transmitting and receiving equipment and consequently any two stations can intercommunicate, but the record of the conversation will be available in all other stations on the circuit.

It is not possible yet to use one single circuit from coast to coast. The area to be covered is, therefore, broken up into sections and when messages or weather reports have to be repeated between divisions, it is necessary for the terminal stations to retransmit this information into the next subdivision of the teletype system. However, this is an advantage in many respects as it speeds up traffic in each individual division.

Current weather information is collected on an hourly basis from the principal intermediate landing fields and from certain critical points along the route. This system of weather collection is co-ordinated with the radio beacon service. The beacon transmitter is stopped at a certain definite period each hour, the station identifies itself first and then gives the broadcast of current weather information.

In addition to the collection of weather information, the teletype circuit is used to transmit the information from the secondary net covering the off airways weather data. This report is given every three hours. In addition the available upper air data is transmitted from the weather bureau for the information of all transport operators and intermediate landing fields along the route.

As an example of the method of applying the general teletype system to a particular service, the following detailed description of the Canadian teletype service may be of interest. It may be followed by referring to the map of the Canadian air mail system, Fig. 5.

In order to permit the aerodromes to keep closely in touch with one another, a line has been installed with teletype instruments at St. Hubert, Kingston, Toronto, Hamilton, London and Windsor. The meteorological department in Toronto have arranged for special observers at each of these places and weather reports may be obtained from any station at any time during the day. In addition to these special reports, a number of routine weather reports are transmitted from each station to all other stations every day. These reports give full meteorological information so that every station on the teletype system has on hand at all times a complete file of weather reports covering all stations on the system. This information is available for pilots or others contemplating flights over any part of the route.

A second line has been installed from Winnipeg to Calgary with instruments at Forrest, Regina, Moose Jaw, Maple Creek, Medicine Hat, Lethbridge and Calgary. In addition there is a third line from Regina to Edmonton via Saskatoon to provide communication for the planes carrying the mail between these three towns. The Winnipeg-Calgary line will be night flying almost entirely, but for the time being at any rate, the Regina-Edmonton route will be given a daylight service only.

Observers have been provided by the Meteorological Department at each of the flying fields and the same routine followed as in the case of the eastern mail route. A weather report, collected over the teletype system from all other stations on the chain, is broadcast by voice once every hour from each of the beacon stations. This can be easily arranged since they are equipped to operate as broadcasting stations as well as radio beacons. The routine followed on each station is somewhat as follows: During the time when machines are in the air, the beacon signals are shut off exactly on the hour and the weather report transmitted for the information of the pilots. At this time special messages dealing with navigational matters, or orders for the pilots from owners of machines using the route, are broadcast. At present it is necessary to shut down the beacon while this broadcast is taking place but experiments are now under way to make it possible to operate both at the same time. It is hoped that this improvement will shortly be available for all ground stations and aircraft receivers.

In view of the fact that the teletype service in the east is not as yet very widely extended, steps have been taken to tie-in the various Marine Department radio stations along the St. Lawrence and on the eastern coast. Through the co-operation of the Radio Branch, Department of Marine, the stations at Saint John, N.B., Father Point, Quebec, Kingston and Toronto are co-operating with the airways station at St. Hubert in the collection and distribution of weather reports. This service has proved very valuable and will be maintained even when the teletype service is in more general use in the east.

THE
ENGINEERING JOURNAL
THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XIV JULY 1931 No. 7

Canadian Radio Broadcasting

Nearly two years have passed since the issue of the report of the Royal Commission on Radio Broadcasting. During this time the matter has received considerable attention in the press, and has been the subject of many newspaper items and editorials. No apology is needed for bringing it again* to the attention of the readers of The Engineering Journal, or for recalling the pioneer work performed in the early stages of Canadian radio engineering by two departments of the Dominion government. In 1927 the Department of Marine, in conjunction with the Bell Telephone Company, Canadian Pacific Telegraphs, Canadian National Telegraphs, and the Northern Electric Company, carried out the first Dominion-wide broadcast from coast to coast long before the existence of the special circuits and other technical facilities now available for such work; further, the staff of that department have developed what is probably the most complete and effective radio direction-finding system now available to assist navigators of ships at sea. Their radio service in aid of navigation extends from Coronation Gulf on the Arctic Ocean, through Hudson Bay and Strait, down to the Atlantic coast, up the St. Lawrence, and across the Great Lakes, and from Vancouver to Alaska, and is probably the largest system of its kind in existence to-day. In addition, the Department of National Defence has organized and equipped a remarkable network of radio communication with isolated stations in the northwest, and with aircraft flying on Canadian airways.

*See The Engineering Journal for October, 1929, p. 546.

Radio communication, and particularly general broadcasting, is of special importance in a country like ours, where the population to be served is scattered so widely, and where so many people in remote districts are dependent on radio for their contact with the outside world. It should also be noted that we are within the sphere of influence of one of the most extensive and powerful radio systems in the world, and for these reasons it is evident that the organization and management of radio broadcasting in Canada should receive the closest attention.

It will be remembered that the Royal Commission was appointed in 1928, following a somewhat heated discussion in the House of Commons arising from a decision of the Minister of Marine withdrawing the privileges of an association which was operating several broadcasting stations in Canada, and whose activities did not appear to be in the public interest. Under the chairmanship of Sir John Aird the Commission was asked "to examine into the broadcasting situation in the Dominion of Canada and make recommendations to the government as to the future administration, management, control and financing thereof."

Briefly, the Commission in its report proposed the organization of a national company operated on a basis of public service, the board of that company to be composed of representatives of the Federal and provincial governments. It was also recommended that provincial groups should have full authority over the programmes broadcast in their respective territories.

Since the issue of the report no definite steps have been taken to carry out its recommendations, and indeed before this can be done an important question as to the relative powers of the Federal and provincial governments under the British North America Act has to be settled by the courts. The business of radio broadcasting, however, in Canada has not been standing still, and has been developing rapidly along the lines which are followed in the United States, in which the funds for operation are provided entirely by revenue from the publicity given. On this basis it is inevitable that control will become centred in the hands of powerful commercial organizations, whose primary concern is their financial return, and not the benefit of the community at large.

It is doubtful whether the general public clearly understands the implications of the Aird report. Pamphlets, news items regarding the report, and other publicity matter have originated largely from quarters opposed to the Commission's suggestions, while, on the other hand, editorial comment throughout Canada has been generally favourable. The problem is of such importance, and the future development of our country is so dependent upon its proper solution, that every Canadian citizen should try to form his own considered opinion.

The essential points to be borne in mind are briefly these:

(1) Under the present system there is no way of controlling programmes so as to serve the best interests of the citizens of Canada, as distinguished from the financial or personal interests of the parties operating the broadcasting systems.

(2) Means of doing this are available without resorting to government ownership, as has been shown by European experience, particularly in England and Germany.

(3) If nothing is done Canadian broadcasting will follow the same course as in the United States, and will be operated on a profit-making basis.

(4) Is it desirable to permit such a development to continue, or is it worth while for the country to go to the trouble and expense of re-organizing the industry, so that radio can be used to the nation's best advantage?

In order to aid in forming a judgment on these points, the following paragraphs, based on notes kindly supplied by Dr. A. Frigon, M.E.I.C., are placed before The Journal's readers.

Business men are usually opposed to government ownership of any public utility. The Aird report does not propose that the Federal and provincial governments should own or operate radio broadcasting in Canada, but it does argue that broadcasting should be considered as an instrument of education in the broad sense and not as a money-making business. It seems evident that to attain such an ideal, broadcasting cannot be operated on a basis of go-getting publicity, and should not be a profit making enterprise. The Commission therefore suggests an organization which would be neither a private enterprise, nor a government department, whether Federal or provincial. The national company which is proposed would possess all the powers of a private enterprise, but would be controlled by a board of directors composed of representatives from every province and from the Federal government. This company would own and operate a group of stations throughout Canada, and the selection of programmes would be left in the hands of provincial commissions or provincial directors of broadcasting.

The question of financing such an enterprise is evidently an important one and is fully dealt with in the report. In this connection, consider for a moment the profound influence that broadcasting has in directing public opinion and in deciding the general lines along which youthful minds will develop. Think how important it is that this powerful instrument of contact with the public should be operated on a truly Canadian basis, while it is still possible to do so. It will then be realized that the expenditure of a million dollars more or less per year on such an enterprise is of little importance compared with the results to be obtained. If this were clearly understood there is no doubt that the public would willingly pay a three dollar annual license fee on radio receivers and would also approve of a substantial subsidy by the Federal government to the company in order to insure first-class Canadian broadcasting.

Comparisons have often been made between the British Broadcasting Company and the company recommended by the Aird Report. In the few articles published by the members of the Commission since the report was issued, it has been shown clearly that the system suggested for Canada is very different from that of the B.B.C. although both are based on the principle of control by the public. As a matter of fact, the Commission's proposal follows closely the method used in Germany, not that employed in Britain.

The Canadian government will soon have to decide whether radio broadcasting in Canada shall continue to follow the lines of broadcasting as it is done in the United States, or shall be directed along the lines adopted in most European countries and in Japan. Considering that the countries in Europe have organized their radio broadcasting systems with full knowledge of what has happened in the United States, it is interesting to note that nearly all of them have rejected the system of private ownership. Even in France, where broadcasting is still chaotic, successive Ministers of Communications have submitted *projets de loi* in favour of the public control of broadcasting.

If it is decided to adopt, wholly or with modifications, the report of the Royal Commission on Radio Broadcasting, there is one factor upon which success absolutely depends, namely, the spirit in which the Commission's suggestions are to be worked out and acted upon by the governmental authorities concerned. If a loyal group of men, not engaged in partisan politics, known for their integrity and their faithfulness to Canadian ideals, are appointed to take charge of the organization, the enterprise will succeed, and broadcasting in this country will take its proper place as a national institution, fulfilling national and not commercial ends. On the other hand, if nominations to the board of the radio broadcasting company, or the appointment of its general manager, are to be tinged ever so slightly with political colour, it would be far better to retain the system, or lack of system, which we now have.

We may well express the hope that this vital question will be settled with the least possible delay, and in a truly national spirit.

The Governor General Accepts Honorary Membership

The Institute has been honoured by the Governor General, His Excellency The Right Honourable the Earl of Bessborough, P.C., G.C.M.G., who has graciously consented to accept Honorary Membership in The Institute. Accordingly, the necessary formalities having been complied with, Council has given instructions for His Excellency's name to be added to the list of Honorary Members.

The Past-Presidents' Prize 1931-1932

The subject prescribed by Council for this competition for the prize year July 1st, 1931, to June 30th, 1932, is **"The Effect of the Development of the Electronic Valve upon Electrical Engineering and Industry."**

The rules governing the award of the prize are as follows:

The prize shall consist of a cash donation of the amount of one hundred dollars, or the winner may select books or instruments of no more than that value when suitably bound and printed, or engraved, as the case may be.

The prize shall be awarded for the best contribution submitted to the Council of The Institute by a member of The Institute of any grade on a subject to be selected and announced by the Council at the beginning of the prize year, which shall be July first to June thirtieth.

The papers entered for the competition shall be judged by a committee of five, to be called the Past-Presidents' Prize Committee, which shall be appointed by the Council as soon after the Annual Meeting of The Institute as practicable. Members and Honorary Members only shall be eligible to act on this committee.

It shall be within the discretion of the committee to refuse an award if they consider no paper of sufficient merit.

All papers eligible for the competition must be the bona fide work of the contributors and must not have been made public before submission to The Institute.

All papers to be entered for the competition must be received during the prize year by the General Secretary of The Institute, either direct from the author or through a local branch.

Recent Graduates in Engineering

Congratulations are in order to the following Students and Juniors of The Institute who have recently completed their course at the various universities.

McGill University

Honours, Medals and Prizes

Bennett, George Francis, Ottawa, Ont.—B.Sc., (El.); Montreal Light, Heat and Power Cons. Third Prize.

Charlewood, Charles Benj., Victoria, B.C.—B.Sc., (Me.); Crosby Steam Gauge and Valve Company's Prize for Summer Essay.

deChazal, Marc Philippe, Vacoas, Mauritius.—B.Sc., (Ci.); Honours in Civil Engineering.

Fogarty, James William Patrick, Moncton, N.B.—B.Sc., (El.); British Association Medal; Honours in Electrical Engineering; Montreal Light, Heat and Power Cons. First Prize.

Hawley, Eric Farwell, Ormstown, Que.—B.Sc., (El.); Undergraduates' Society's First Prize for Summer Essay.

Hulme, Gordon Donaldson, Westmount, Que.—B.Sc., (El.); Montreal Light, Heat and Power Cons. Second Prize.
Pimenoff, Clement John, Montreal, Que.—B.Sc., (Ci.); Honours in Civil Engineering; Jenkins Brothers Limited Scholarship.
Savage, Palmer Ernest, Montreal West, Que.—B.Sc., (Ci.); Departmental Prize for Summer Essay.

Degree of B.Sc.

Arcand, Louis Joseph, B.Sc., (Ci.), Montreal, Que.
Bennett, George Francis, B.Sc., (El.), Ottawa, Ont.
Blachford, Henry Edmund, B.Sc., (El.), Westmount, Que.
Charlewood, Charles Benj., B.Sc., (Me.), Victoria, B.C.
Clarke, George Frederick, B.Sc., (Me.), Jamaica, B.W.I.
Clarke, Owen Mawbey, B.Sc., (Me.), Jamaica, B.W.I.
Crain, Reginald Albert, B.Sc., (Ci.), Ottawa, Ont.
Crossland, Charles Wilfred, B.Sc., (Me.), Barrie, Ont.
Cunningham, Harold Emberson, B.Sc., (Ci.), Westmount, Que.
deChazal, Marc Philippe, B.Sc., (Ci.), Vacoas, Mauritius.
Ellis, David Edward, B.Sc., (El.), Ottawa, Ont.
Ferguson, Allan Andrew, B.Sc., (Me.), Pictou, N.S.
Fogarty, James William Patrick, B.Sc., (El.), Moncton, N.B.
Hawley, Eric Farwell, B.Sc., (El.), Ormstown, Que.
Hines, William Sylvias, B.Sc., (El.), East Noel, N.S.
Hulme, Gordon Donaldson, B.Sc., (El.), Westmount, Que.
Lea, Harry Windsor, B.Sc., (Ci.), Montreal, Que.
Massé, Gaston Wilfred, B.Sc., (El.), Sherbrooke, Que.
Morrison, Claude Wilson, B.Sc., (Me.), Town of Mount Royal, Que.
Pascal, Fred., B.Sc., (Mi.), Outremont, Que.
Pimenoff, Clement John, B.Sc., (Ci.), Montreal, Que.
Rogers, Howard Weaver, B.Sc., (El.), Montreal, Que.
Ross, Donald Ralph, B.Sc., (El.), Montreal, Que.
Sauer, George Douglas, B.Sc., (Ci.), Beauharnois, Que.
Savage, Palmer Ernest, B.Sc., (Ci.), Montreal West, Que.
Smith, Gordon Carington, B.Sc., (Chem.), Quebec, Que.
St. Jacques, Jean, B.Sc., (El.), Montreal, Que.
Thomson, Elihu, B.Sc., (Me.), Westmount, Que.
Warnock, Robert Nicholson, B.Sc., (Ci.), Westmount, Que.
Williams, Richard Louis, B.Sc., (Me.), Lachine, Que.

Queen's University

The L. M. Arkley Prize

Conn, Hugh Gordon, B.Sc., (Me.), New Lowell, Ont.

Degree of B.Sc. (with honours)

Campbell, James Stouffer, B.Sc., (Me.), Toronto, Ont.
Rice, Herbert Ralph, B.Sc., (Mi. and Met.), Niagara Falls, Ont.
Walker, William Deans, B.Sc., (Me.), Niagara Falls, Ont.

Degree of B.Sc.

Barton, Edward Allen, B.Sc., (Ci.), Lachine, Que.
Cairncross, Alexander Thomas, B.Sc., (Ci.), Long Branch, Ont.
Conn, Hugh Gordon, B.Sc., (Me.), New Lowell, Ont.
Fenwick, Stuart, B.Sc., (Ci.), St. Thomas, Ont.
Goodman, James Edward, B.Sc., (Ci.), Kingston, Ont.
Greenwood, Frederick Dwyer, B.Sc., (Me.), New Liskeard, Ont.
Hastings, Meredith Heath, B.Sc., (Me.), Kingston, Ont.
King, Peter Campbell, B.Sc., (El.), Toronto, Ont.
Mill, George Lawrence, B.Sc., (Met.), Quebec, Que.
Miller, Alexander Gordon, B.Sc., (Me.), Kingston, Ont.
Minns, Harold Clarke, B.Sc., (Me.), Iroquois, Ont.
Rombough, Joseph Harold Melville, B.Sc., (Ci.), Oshawa, Ont.
Seright, Robert, B.Sc., (Me.), Kingston, Ont.
Waite, Matthew J., B.Sc., (Me.), Kingston, Ont.

University of New Brunswick

The Ketchum Silver Medal

Parlee, Rutherford Justus, B.Sc., (Ci.), Lower Millstream, Kings County, N.B.

Degree of B.Sc.

Barbour, Clarence Allen, B.Sc., (El.), Saint John, N.B.
Hurley, Joseph Louis, B.Sc., (Ci.), Fredericton, N.B.
Macredie, John Robert Calderwood, B.Sc., (Ci.), Fredericton, N.B.
Parlee, Rutherford Justus, B.Sc., (Ci.), Lower Millstream, Kings County, N.B.
Patriquen, Frank Andrew, B.Sc., (Ci.), Fredericton, N.B.

University of Toronto

Prize

Phillips, Ernest Albert, Toronto, Ont.—B.A.Sc., (Ci.); The Canadian Engineer Prize.

Degree of B.A.Sc. (with honours)

Phillips, Ernest Albert, B.A.Sc., (Ci.), Toronto, Ont.

Degree of B.A.Sc.

Dutton, William Lawrason, B.A.Sc., (Ci.), Chatham, Ont.
Carter, John Russell, B.A.Sc., (Ci.), Toronto, Ont.
Hanly, John Bruce, B.A.Sc., (Ci.), Toronto, Ont.
MacLean, George Edward, B.A.Sc., (Chem.), Ottawa, Ont.

University of Manitoba

University Gold Medal and Joseph Doupe Gold Medal

Jones, Llewellyn Edward, B.Sc., (Ci.), Transcona, Man.

Degree of B.Sc.

Bell, George Moore, B.Sc., (El.), Weyburn, Sask.
Berry, Melville Douglas, B.Sc., (El.), Hamilton, Ont.
Courtney, Alexander Gordon, B.Sc., (El.), Winnipeg, Man.
Fraser, Ralph Percy, B.Sc., (El.), Norwood, Man.
Gingras, Francis Percival, B.Sc., (El.), Winnipeg, Man.
Gooderham, Walter James, B.Sc., (El.), Winnipeg, Man.
Hunt, Edward Victor, B.Sc., (El.), Peterborough, Ont.
Jones, Llewellyn Edward, B.Sc., (Ci.), Transcona, Man.
Leightner, Donald Benjamin, B.Sc., (El.), Winnipeg, Man.
Lyon, Grant MacKenzie, B.Sc., (Ci.), Winnipeg, Man.
Murray, Walter Muir, B.Sc., (Ci.), Winnipeg, Man.
Neufeld, James Cornelius, B.Sc., (Ci.), Winnipeg, Man.
Oddlafson, Axel Leonard, B.Sc., (El.), Winnipeg, Man.
Swartzman, Lewis, B.Sc., (Ci.), Winnipeg, Man.

University of Alberta

The Association of Professional Engineers of Alberta Prize in Electrical Engineering

Sillitoe, Sydney, B.Sc., (El.), Edmonton, Alta.

Degree of B.Sc.

Kent, William Leslie, B.Sc., (Ci.), Edmonton, Alta.
Nix, Charles Edward, B.Sc., (Ci.), Edmonton, Alta.
McIntyre, Douglas Vallance, B.Sc., (El.), Edmonton, Alta.
Patterson, Gordon Neil, B.Sc., (Eng. Physics), Edmonton, Alta.
Olsen, Arnold Mayne, B.Sc., (El.), Edmonton, Alta.
Peffers, William Oswald, B.Sc., (El.), Edmonton, Alta.
Sillitoe, Sydney, B.Sc., (El.), Edmonton, Alta.
Simons, Finlay William, B.Sc., (El.), Edmonton, Alta.

Nova Scotia Technical College

Alumni Medal

Ritchie, Kenneth Schaffner, B.Sc., (El.), Halifax, N.S.

Degree of B.Sc.

Black, Frank Leslie, B.Sc., (El.), Moncton, N.B.
Bowman, Albert Lorne Hay, B.Sc., (El.), Halifax, N.S.
Brown, William Broughton, B.Sc., (El.), Clarke's Harbour, N.S.
Chandler, Edward Sayre, B.Sc., (El.), Charlottetown, P.E.I.
Coffey, Laurence Edward, B.Sc., (El.), Moncton, N.B.
Egan, Edward Joseph, B.Sc., (Me.), Halifax, N.S.
Glotzer, Samuel, B.Sc., (El.), Odessa, Russia.
Hault, George Christie, B.Sc., (Ci.), Sydney, N.S.
Lang, John Taylor, B.Sc., (Me.), Halifax, N.S.
MacDonald, John Winston, B.Sc., (El.), Balmoral Mills, N.S.
Muir, Clarke Bower, B.Sc., (Me.), Shelburne, N.S.
Ritchie, Kenneth Schaffner, B.Sc., (El.), Halifax, N.S.
Tibbitts, Angus Gordon, B.Sc., (Me.), Truro, N.S.

University of Saskatchewan

Prize

Fourth Year Scholarship, Saskatchewan Branch, The Engineering Institute of Canada—awarded jointly to Clarence Rudeford Forsberg, B.Sc., (Ci.), Dunblane, Sask.; and to Donald Waldron Wood, B.Sc., (Me.), Morse, Sask.

Degree of B.Sc.

Anderson, Gordon Stuart, B.Sc., (Ci.), Theodore, Sask.
Clark, Ralph William, B.Sc., (Ci.), Saskatoon, Sask.
Douglas, Arnold Howard, B.Sc., (Ci.), Indian Head, Sask.
Forsberg, Clarence Rudeford, B.Sc., (Ci.); Dunblane, Sask.
Fowler, Jos. Sims, B.Sc., (Me.), Saskatoon, Sask.
Mollard, John Ellis, B.Sc., (Me.), Watrous, Sask.
Olson, Arthur Bishop, B.Sc., (Me.), Saskatoon, Sask.
Schnedar, Clarence Christopher, B.Sc., (Me.), Saskatoon, Sask.
Wood, Donald Waldron, B.Sc., (Me.), Morse, Sask.

OBITUARY

Francois Charles Laberge, M.E.I.C.

It is with deep regret that the death is recorded of Francois Charles Laberge, M.E.I.C., which occurred at Montreal on June 19th, 1931.

Mr. Laberge was born at Ste. Philomene, Que., on November 3rd, 1871, and received his education at the University of Ottawa and the Ecole Polytechnique, Montreal, graduating from the latter institution in 1892 with the degree of B.A.Sc.

FRANCOIS CHARLES LABERGE, M.E.I.C.

Following graduation, Mr. Laberge was for a time assistant on the Geological Survey and in 1893-1894 was in the engineer's department of the Keystone Bridge Works. In 1894 he was appointed professor of surveying geology, practical astronomy and meteorology at the Ecole Polytechnique. Entering private practice in 1895, Mr. Laberge acted as town engineer for four suburbs of Montreal and was consulting engineer on the Montfort Railway and for several municipalities and corporations. In 1905 he represented the Quebec government on the Interprovincial Boundary Commission which settled the boundary between Ontario and Quebec from Lake Temiskaming to James Bay. When the Quebec government established the Public Utilities Commission—now known as the Quebec Public Service Commission—Mr. Laberge was named one of its first members.

Mr. Laberge joined The Institute (then the Canadian Society of Civil Engineers) as an Associate Member on March 16th, 1899, and transferred to full Membership on October 24th, 1907. He took a keen interest in the affairs of The Institute and was chairman of the Montreal Branch during the year 1928.

PERSONALS

Sydney Sillitoe, S.E.I.C., who graduated from the University of Alberta in the spring of this year with the degree of B.Sc., is now employed by the Electric Light and Power Department of the city of Edmonton, Alta.

George G. Reid, S.E.I.C., who was formerly with the Canadian Consolidated Felt Company, Ltd., at Kitchener, Ont., is now a member of the staff of E. S. Stephenson and Company, Ltd., Saint John, N.B.

R. H. Moulton, Jr.E.I.C., formerly traffic superintendent of the west district, city of Montreal, for the Bell Telephone Company of Canada, Ltd., has been transferred to Sherbrooke, Que.

Major J. C. Craig, D.S.O., M.E.I.C., has returned to British Guiana for another term of duty as director of public works at Georgetown, which office he first assumed in 1927.

M. S. Madden, A.M.E.I.C., formerly of the Hydrometric Bureau, Dominion Water Power and Reclamation Service, Department of the Interior, North Bay, Ont., is now with the Hydrographic Bureau, Department of Marine, Ottawa, Ont.

D. N. McCormack, Jr.E.I.C., is on the staff of the Highways Division of the Department of Public Works of New Brunswick. Mr. McCormack was for a time with the Canadian Dexter P. Cooper Company at Welchpool, Campobello Island, N.B., and in 1930 was connected with the Donnacona Paper Company, Ltd., at Donnacona, Que.

M. F. Goudge, A.M.E.I.C., mining engineer, Department of Mines, Ottawa, is extending his investigations regarding the use of Canadian limestones for buildings. Work already carried out by Mr. Goudge has demonstrated that, within the Dominion, limestones can be produced which are superior in strength and durability to any that are imported.

O. J. McCulloch, A.M.E.I.C., is now connected with the tunnel division of the Rayner Construction Ltd., Toronto, Ont. Prior to accepting his present position, Mr. McCulloch was with the Sydney E. Junkins Company, of British Columbia, Ltd., at Vancouver, B.C. He was for a time with Porter Brothers and Robert Porter at Detroit, Mich., and in 1927 was engaged on the construction of the Welland Ship Canal at St. Catharines, Ont.

J. Murray Mitchell, Jr.E.I.C., has recently been appointed by the Bell Telephone Company of Canada to the position of district traffic superintendent of a newly-formed district embracing the territory lying largely north of the St. Lawrence river between the Quebec and Montreal suburban districts, and with headquarters at Three Rivers. Mr. Mitchell, a graduate of McGill, 1923, has had successive experience in the same position in the west and central districts of the city of Montreal.

Professor R. W. Angus, M.E.I.C., to Represent The Institute

Professor R. W. Angus, M.E.I.C., professor of mechanical engineering at the University of Toronto, Toronto, has consented to represent The Institute at the ceremonies connected with the seventy-fifth anniversary of the foundation of the Verein Deutscher Ingenieure, to be held

PROFESSOR R. W. ANGUS, M.E.I.C.

in Cologne, Germany, on June 28th, 1931. Professor Angus is head of the department of mechanical engineering at the University of Toronto, having held that appointment since 1906 when the department was established. His duties include the direction of all the heat-engine and hydraulic work in the university, and he is entirely responsible for the design and equipment of the mechanical and hydraulic laboratories of the university. Through extensive travel, Professor Angus has kept in touch with the most advanced engineering work in America and Europe.

M. H. Marshall, M.E.I.C., has retired from the Dominion Water Power and Reclamation Service, Department of the Interior, Calgary, Alta., and is now located at Glenmore dam, city of Calgary water works. Mr. Marshall had been connected with the Department of the Interior since 1914. In 1929 he was resident inspection engineer for the Department at the Island Falls power development, Island Falls, Sask., and is the author of a paper on that project which appeared in the June, 1931, issue of The Engineering Journal.

Major E. L. M. Burns, A.M.E.I.C., has been appointed general staff officer surveys at Headquarters, Department of National Defence, Ottawa. Major Burns, who was formerly district engineer officer for Military District No. 5, Quebec, is a graduate of the Royal Military College, Kingston, of the year 1915. He spent three years on active service during the late war. During the years 1928-1930 Major Burns was stationed at Quetta, India, where he attended the Staff College.

Ross L. Dobbin, M.E.I.C., General Manager of the Public Utilities Commission, Peterborough, Ont., was elected president of the American Water Works Association, at the fifty-first convention of that association recently held at Pittsburgh, Pa. Mr. Dobbin has been a member of the association for a number of years and has taken an active part in the committee work of the organization. He is also keenly interested in Institute affairs and has represented the Peterborough Branch on the Council for a number of years.

C. L. Blackmore, Jr.E.I.C., has joined the staff of the Montreal office of the James R. Kearney Corporation of Canada Ltd. as sales engineer. Following graduation in 1927 from McGill in electrical engineering, Mr. Blackmore was employed by the International Paper Company for over three years as engineer on maintenance and electrical construction. He also spent considerable time working as an electrician before graduation, and was employed by the Canadian Comstock Ltd. and the Northern Aluminum Company.

Morley G. Taylor, Jr.E.I.C., who has just secured the degree of M.Sc. at the Massachusetts Institute of Technology, has left for Venezuela, where he will take over the position of manager of the Barquisimeto branch of the Venezuela Power Company, Ltd., for the Montreal Engineering Company. Mr. Taylor graduated from the Nova Scotia Technical College in 1927 with the degree of B.Sc. in electrical engineering, and following graduation was for a short time with the Nova Scotia Tramways and Power Company at Halifax. In 1928 he was sent by the Montreal Engineering Company to Venezuela where he was located at Maracaibo with the Venezuela Power Company Ltd.

T. H. G. Clunn, A.M.E.I.C., who has been connected with the Department of the Interior, Ottawa, for the past twenty-eight years, first in the Topographical Survey and the International Boundary Survey and latterly with the supervisory mining engineer, has recently retired from the service. Mr. Clunn's work has taken him into all parts of

T. H. G. CLUNN, A.M.E.I.C.

Canada, including the Yukon, where he acted as Canadian attaché on the Alaska Boundary Survey. He is a member of the Professional Engineers of Ontario, is a Dominion Land Surveyor, and has been an Associate Member of The Institute since 1907. On the occasion of his retirement from the Government service, the members of the Ottawa Branch of The Institute, of which he was an active member, having acted as chairman of various committees, presented Mr. Clunn with a silver vase.

E. E. Eisenhauer, A.M.E.I.C., formerly field representative of the Alberta Wheat Pool, is now connected with the Colonization Department, Lethbridge Northern Irrigation District, Lethbridge, Alta. Mr. Eisenhauer graduated from the University of Saskatchewan in 1918, with the degree of B.Sc. in agriculture, and in 1922 secured the degree of B.Sc. in civil and irrigation engineering at the Colorado State Agricultural College and School of Mechanical Arts. During 1918, 1919 and 1920 he was assistant irrigation investigator on water work and ditch measurement in settlement of water disputes at Coaldale, and during the years 1923 to 1926 was in charge of irrigation instruction at Alberta schools of agriculture, being in charge of special instruction in irrigation at the University of Alberta in 1923-1924.

R. R. Duffy, A.M.E.I.C., of Price Brothers Sales Corporaton, has been transferred to the Toronto office of the corporation. Mr. Duffy graduated from Acadia University in 1910, with the degree of B.Sc. in arts, and from McGill University in 1913 with the degree of B.Sc. in applied science. On his return from overseas in 1919, Mr. Duffy became outside manager and vice-president of W. H. Duffy Sons, Ltd., at Hillsboro, N.B. In 1923-1924, he was with the logging division of the Bathurst Company at Bathurst, N.B., and from February to November, 1924, was with the Brompton Pulp and Paper Company at East Angus, Que. In November, 1924, Mr. Duffy became connected with Price Brothers and Company, Ltd., being in the engineering division at Kenogami, Que., assistant land surveyor and later assistant logging engineer at Chicoutimi, Que. In 1930 he was appointed district sales manager for Price Brothers Sales Corporation at Montreal, Que.

ELECTIONS AND TRANSFERS

At the meeting of Council held on June 16th, 1931, the following elections and transfers were effected:

Member

ALEXANDER, David Tasker, chief dftsman., Canadian Bridge Co. Ltd., Walkerville, Ont.

Associate Members

GUMLEY, Franc Stewart, (Heriot Watt Tech. Coll.), designer, Western Bridge Company, North Vancouver, B.C.

LUDGATE, James Vernon, B.Sc., (Queen's Univ.), Parry Sound, Ont.

RIDOUT, Geoffrey Swabey, B.A.Sc., (Univ. of Toronto), divn. plant engr., Montreal Divn., Bell Telephone Company of Canada, Montreal, Que.

RYBKA, Karel R., Mech. Engr., (Prague and Bruo), designing dftsman., engrg. dept., Ross & Macdonald, Montreal, Que.

SCRYMGEOUR, Charles, (Liverpool and Bootle Engrg. Colleges), refinery engr., Imperial Oil Refineries Limited, Dartmouth, N.S.

TJONNAAS, Ole Hansen, (Grad., Kristiania Tech. Inst.), dftsman., C.P.R. engrg. dept., Winnipeg, Man.

WIGHT, Cecil Douglas, B.Sc., (Queen's Univ.), partner in firm, MacRostie & Wight, consltg. engrs., Ottawa, Ont.

Juniors

BREAKEY, James, (Assoc. in Engrg., Sheffield Univ.), associate editor of technical publications, MacLean Publishing Company, Toronto, Ont.

FOSS, Wallace Leland, B.Sc., (Univ. of Sask.), field engr., City of Saskatoon, Sask.

LEACH, John William, B.Sc., (Univ. of Sask.), maintainer of Diesel electric cars, C.N.R., Montreal, Que.

MORTON, Philip S. A., B.A.Sc., (Univ. of Toronto), junior engr., Canadian General Electric Co. Ltd., Peterborough, Ont.

ROSS, Hugh Campbell, B.A.Sc., (Univ. of Toronto), asst. testing engr., H.E.P.C. of Ontario, Toronto, Ont.

Affiliate

GRAY, Donald Walker, B.Sc.F., (Univ. of Toronto), asst. forester, Ontario Forestry Branch, Parry Sound, Ont.

Transferred from the class of Associate Member to that of Member

Du CANE, Charles George, Lt.-Col., O.B.E., B.A. (Mech. Sci. Tripos), (Cambridge Univ.), partner in firm, Sir John Wolfe Barry & Partners, consltg. engrs., 2 Queen Anne's Gate, Westminster, S.W. 1.

Transferred from the class of Junior to that of Associate Member

DUNCAN, James Edgar, B.Sc., (Univ. of Man.), geophysicist, Canadian Western Natural Gas, Light, Heat & Power Co. Ltd., Calgary, Alta.

Transferred from the class of Student to that of Associate Member

ABBOTT, Arthur Caldwell, B.Sc., (McGill Univ.), distribution engr., commercial and distribution dept., Shawinigan Water & Power Company, Three Rivers, Que.

CLANCY, John, B.Sc., (N.S. Tech. Coll.), telephone systems engrg. dept., Northern Electric Co. Ltd., Montreal, Que.

KYLE, Willard Hugh, B.Sc., (McGill Univ.), asst. engr., Montreal district, C.N.R., Montreal, Que.

PIGOT, Charles Hugh, B.Sc., (McGill Univ.), asst. engr., rly. dept., Beauharnois Construction Company, Beauharnois, Que.

ROSS, William Thomas Dygnum, B.Sc., (McGill Univ.), chem. engr., explosives divn., Canadian Industries Limited, Montreal, Que.

Transferred from the class of Student to that of Junior

DURLEY, Thomas Richard, B.Sc., (McGill Univ.), asst. supt., Plant No. 1, Canada Cement Company, Montreal East, Que.

ROWE, Gordon William, B.Sc., (Univ. of Man.), field engr. on inspection of reinforced concrete grain elevators, C. D. Howe & Company, of Port Arthur, Ont., at Lethbridge, Alta.

Students admitted

LEIGHS, Clifford Henry, B.Sc., (Univ. of Alta.), Edson, Alta.

MILLER, Frank Robert, B.Sc., (Univ. of Alta.), P.O. Box 765, Kamloops, B.C.

CORRESPONDENCE

THE EDITOR, Montreal, May 14th, 1931.
THE ENGINEERING JOURNAL,

DEAR SIR:—

Following my previous letter, I would ask, how is the engineer to obtain the recognition due to his work, a recognition that will allow him to utilize his powers and qualities for the benefit of the community? He must advertise, not himself, but his work, but he must advertise in the right place; he must get into contact with that portion of the public who are in need of engineering services.

A merchant in contemplating the opening up of a retail business, may have a good line of goods, and an efficient staff; but unless his store is located in the right psychological place, the enterprise will be a failure. We have the ability, we have the men, and it is now our duty to see that the work we do is made known to those who are in a position to appreciate it; it is useless to advertise among the general public. You do not find Rolls Royce cars advertised in Le Canard, nor do you find in the Athenaeum advertisements which read "Learn to play the piano in five lessons"; so our advertising must be placed in periodicals regularly read by those likely to be interested.

All commercial and public enterprises are financed by means of borrowed money, which is obtained through the services of banks, loan companies and security brokers, and it is to the men in charge of these financial establishments that the engineer must display his wares.

The secret of successful advertising is to find out the particular point of self interest that will induce a man to part with his money. Of course, for the advertising to be continuously successful, it naturally follows that the advertiser must get continued value for his money, and the following are examples. The insurance company describes the destitution of a widow and children to stimulate the parental instinct; the house-furnishing firm draws a picture of a nicely furnished room to stimulate the sexual instinct in providing a home. The tooth paste manufacturer uses such words as gingivitis, pyorrhea, Riggs disease, etc., to raise the fear of toothache or lost teeth. The radio salesman tells Mrs. Smith that Mrs. Jones has just bought a 9 tube radio with dynamic speaker, so a feeling of pride induces Mrs. Smith to purchase a 9½ tube set with heterodynamic speaker. The stock salesman stimulates the instinct of acquisitiveness, to induce the prospective purchaser to buy bonds and stocks. The physician stimulates the instinct of fear, to encourage an interest in his business. So we engineers must stimulate the instinct of acquisitiveness, if not of fear, to attain the same ends.

The position of the financial magnate to-day in regard to engineering is exactly the same as was, at one time, that of the ordinary person to pyorrhea. Forty years ago the man on the street knew neither pyorrhea or gingivitis, was quite happy in his ignorance, and the tooth brush manufacturers were just ordinary citizens like himself. Ali Baba used the magic word "Sesame" to obtain untold wealth, and the manufacturer obtained a similar result by using the magic words pyorrhea and gingivitis, not once but millions of times. There does not seem to be any such simple way for engineers to use a magic word, but the same principles apply.

The bankers, loan companies and financial houses should be told of all the perils and dangers that lurk in poor construction; they have a hazy idea in principle that a poor workman produces poor work, but as to tangible results, they are absolutely ignorant. As everyone knows, major engineering works are designed and supervised by engineers, but the great mass of construction designed by architects and casual engineers is built according to rule of thumb methods, and is very wasteful, each individual piece of work being too small to allow of expert design and inspection. While the loss on each building is small, in the mass it is enormous.

I am not suggesting that architects and small consulting engineers are not competent; they are, but their hands are tied, because the man who handles the money cannot see the need of expert design, supervision and inspection.

All progress in material civilization has its inception in the brain of some man of vision: engineer, chemist or physicist (using these terms in their broad sense). These new ideas generally call for new kinds of material and new methods of working, which, if not faithfully carried out can only result in failure.

Every new process or innovation is opposed by the vast majority of mankind, and by innovation is not meant novelty, for there is a difference; a new song, a new shaped boot, high or low legs on the radio cabinet, are all novelties, they can be taken up without thinking; but to wear a sensible dress, eat sensible food, to operate a new kind of machine, are innovations, and as such, are strenuously opposed. Radio did not become generally popular until it was possible to produce music by a simple turn of a button; if any degree of skill were necessary, only a small number would be purchased, and radios would be no more plentiful than pipe organs.

If this mental inertia is so common among persons of ordinary intelligence, how much more is it among those who do the great mass of physical labour necessary to our existence? It is well nigh impossible to induce them to adopt new methods except under compulsion; if one wants a labourer to use a shovel or a hammer in a new way, only a threat of dismissal will bring him to a complacent state of mind; all thinking must be done for him, and he must learn the new way by numbers, as they do in the army.

To train men into new ideas and supervise new methods is the work of an inspector, and while all advance has been due primarily to the original thinker as explained above, the material success of the actual doing rests upon the inspector. In the mechanical world this is well understood, for without adequate inspection what is known as quantity production would be impossible, and all mechanical output would be limited to the extent of that produced by high grade workmen.

We engineers all know this, but the financial man does not. He realizes that his motor car is an assemblage of perfectly fitting parts, but he seldom knows how this perfection is attained, and if he could be got to understand that there is need of careful design and inspection in building, with commensurate lowering of costs, he would be willing to pay money for such engineering services.

This brings out the fact that the key to increased recognition is the inspector and his work. The inspector is the liaison officer who works between the owner and the contractor, who represents the owner on the job and who is in the best position to consider costs and profits. The inspector, his opportunities and restrictions, will be dealt with in another letter.

Yours very truly,

C. D. NORTON, A.M.E.I.C.

Montreal,
June 4th, 1931.

The Editor,
The Engineering Journal,

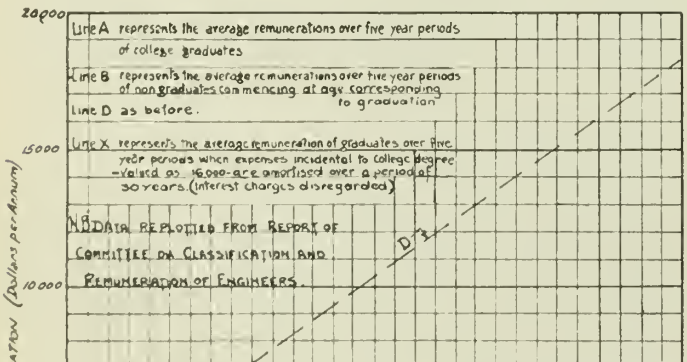
Re: Report of Committee on Classification and Remuneration of Engineers

Dear Sir:—

I wish to preface the following remarks on the above report by complimenting the committee on their valuable contribution to the engineering profession in drawing attention to tendencies in remuneration of engineers, based on the result of average accomplishment over a period of years. The conclusions cited by your committee have been read with considerable interest and the writer desires to bring forward a new graph which portrays the results from a slightly different viewpoint.

In replotting the figures, as shown in the graph attached, it has been assumed that the loss in income and costs incidental to education are equivalent to $16,000 and the line (X) represents the average remuneration allowing for the amortization of this expenditure over a thirty year period. (Interest on this amount has been neglected in plotting the results). It will be noted that the amortization is the most favourable to the comparison though least acceptable to practice, since it is held that thirty years is far too long a period over which to recompense the college trained man through increased earnings for his expenditures made on university studies.

According to statement, the results are based upon a 30 per cent answer to the committee's questionnaire. Since the filling in of the questionnaire form takes but a very few minutes, one may not be entirely wrong in assuming that at least two out of every three members of The Institute are either unthinking of the committee's efforts, or on the other hand, are so absorbed in technical details and other matters



that they cannot find time to consider material questions which have reference to the engineering profession generally, and the place which it occupies among the intelligentsia and informed throughout the various provinces of this Dominion.

Whatever be the reason, this is none the less an unhealthy condition, for it is essential to advancement and greater public usefulness that the profession take heed to itself and continually reconstruct the stones and mortar of its inner sanctum wherever they may show need for repair.

From the amended curves in graph (2), which roughly attempt to amortize, over a thirty year period, the costs and losses in earning incidental to a college education, it would seem that the small margin of remuneration between college and non-college trained indicates that the science course, as measured by success, is a waste of time. College training is held to be, at the present time, an essential requirement before entering the practice of engineering (there are, of course, exceptions to every rule), and while from the curves it appears that the college man has not raised the average earning standard relative to years of experience, the known tendency has been to continually substitute him throughout the entire profession for his not-so-trained colleague.

The question of remuneration has been given consideration by a number of members both in The Institute and other engineering bodies; however, in many cases the monetary reward of engineering skill still remains very small as compared with the proportion received by Capital and Labour.

I trust that it will not be deemed too radical to suggest that attention be given to the remuneration which it is within the power of older members to vouchsafe to the younger, and that the latter should be more liberally paid than is now the case. This would make it easier for them to contribute to the funds of The Institute, and in this way would aid the profession's manifold services to society.

Yours very truly,

STANLEY FARQUHARSON, A.M.E.I.C.

BOOK REVIEWS

The Airplane

By Frederick Bedell. Van Nostrand Company, New York, 1930, cloth, 6 x 9 in., 371 pp., illus., figs., tables, $3.75.

The author states that this book is intended to meet the needs of flyers and designers on the one hand, and of the general reader on the other. To some extent it is suitable for the general reader who desires to obtain some superficial knowledge concerning flight as applied to heavier-than-air craft.

The first portion comprises material which is said to have appeared in earlier editions, but which has been extended for this present issue. The material of the last five chapters now appears for the first time—and deals with engines, instruments, special problems and gives general information on particular types of heavier-than-air craft

In the first few chapters, lift and drag of aerofoils are discussed at some length, and their effect on performance indicated. A number of typical curves are included in the discussion of aircraft performance at ground level and at height. The airscrew, its general characteristics and relation to performance, forms the basis of two chapters. Climbing and gliding flight constitute the substance of another chapter. The functions of the various control surfaces, and the usual methods of actuating them are dealt with briefly. Stability, under the headings longitudinal, lateral and directional, is explained. The factors affecting each are individually discussed. The critical treatise on the aeroplane then ends.

A chapter has been included on the principles of internal combustion engines, both of the spark-ignition and the compression-ignition types, carburetters, fuel distribution, detonation, and such kindred subjects. Photographs of several modern engines have been reproduced in the chapter.

Two chapters are devoted to descriptions of typical modern aircraft, with illustrations.

Instruments, their various principles illustrated by sketches, and their uses, form the text of one chapter.

The final chapter presents a statement of what the author considers the present outstanding problems which confront aviation. It includes paragraphs on blind flying— actually a misnomer in that it is "instrument flying"—though commonly called "blind," the automatic pilot, altitude determination, collision, ice formation, fog penetration, and high altitude—high velocity transport.

The book ends with a glossary of American aeronautical terms reprinted from National Advisory Committee for Aeronautics report No. 240.

In conclusion, it must be stated that the subject of Dr. Bedell's book of necessity includes a number of highly theoretical problems—the treatment of which cannot be successfully effected without mathematical analyses if it is desired to cater to the designer or engineer. His analyses, for the most part, can only be considered to consist of somewhat superficial solutions, which may even be misleading to a reader who is unfamiliar with the subject. In attempting to cover an overwhelming range of topics and to bring the book up to date, the author has set himself a task which cannot be accomplished with complete success in a single small volume. For this reason, the book can hardly be said to be of more than general interest.

A. O. A.

The Rigid-Frame Bridge

By Arthur G. Hayden. Wiley & Sons, New York, 1931, cloth, 6 x 9 in., 236 pp., front., photos, figs., tables, $4.50.

Review by J. F. Brett, A.M.E.I.C.

The rapid development of highway communications which has taken place in the United States and Canada during the past few years has caused a great deal of attention and study to be given to the design and construction of the bridges required, not only to carry highways over valleys and streams, but also for grade separation of intersecting highways, city streets and railways.

Since the purely utilitarian pioneer view point of the past is rapidly passing away, to be replaced by a new consciousness of things beautiful and artistic, more attention is being paid to the appearance of public works in general.

The stereotype design of highway bridge consisting of simply supported beams and girders of constant depth offers only limited possibilities for artistic treatment. Continuous structures with varying moment of inertia, such as the type of frame described in Mr. Hayden's book, may be treated very effectively, as may be judged by the photographs of several fine bridges designed by the author and reproduced in the book.

Aside from its artistic merits, the author points out, the rigid frame bridge is particularly suitable for subways and underpasses. On account of the very small rise and the shallow depth of the deck slab, the height of the approach fill of the overhead traffic way is reduced to a minimum.

The following special types of frames are fully described in the book, complete design calculations being given:

Symmetrical single span free end concrete frame.
Symmetrical single span fixed end concrete frame.
Unsymmetrical single span concrete frame free end.
Unsymmetrical single span steel girder frame.

The theory and design of the symmetrical double span free-end concrete frame and the single span free-end concrete skew frame are also given.

The method of analysis employed is based on the method of work and the Maxwell-Mohr theorem of reciprocal deflections and dummy unit load, which is eminently suitable for the frames under consideration.

The author, who has had many years of actual experience with rigid frame bridges, has succeeded in presenting his method of analysis in a very practical and simple form, well adapted for use in engineering offices. Since the elastic equations used are based on geometrical relations, the calculus is not needed to apply the method and it is not used in the book.

Many practical points in connection with design and construction, such as the condition of stress at the corners, the influence of spread footings, the location and detailing of construction and expansion joints, placing of reinforcement, etc., are fully explained and illustrated.

A chapter by Professor Beggs deals with the mechanical analysis of rigid frames. It is pointed out that while the author's standardized method of analysis has been found easily and rapidly applicable to the frames discussed in the book, the Beggs deformeter gauge method may be used with advantage for multiple span frames which are highly indeterminate.

In the last chapter of the book, Gilmore D. Clark, of the American Society of Landscape Architects, treats of the architectural appearance of short span bridges. Live loads and unit stresses used by the Westchester County Park Commission in connection with the bridges described in the book are given in the appendix.

The volume is well illustrated; its usefulness would have been increased by the provision of an adequate index. Any engineer dealing with highway structures and grade separation will find the book a valuable addition to his library.

Handbook of Aeronautics

Published under the Authority of the Council of the Royal Aeronautical Society. Gale & Polden, London, 1931, cloth, 5½ x 8¾ in., 702 pp., diagrs., tables, 25/-.

This excellent compendium has been issued with the approval of the Council of The Royal Aeronautical Society, and is intended to present in easily accessible form such information as the aeronautical engineer requires in the course of his work. The contents have been selected judiciously, and the issue has been supervised by the joint technical editors, the present and past secretaries of The Royal Aeronautical Society. The list of contributors includes officers of prominent aircraft manufacturers, the Air Ministry, and the National Physical Laboratory, and the wise course has been taken of omitting the numerical tables of areas of circles, logarithms, and so on, which usually occupy so much space in engineering handbooks. In this way room has been found for a surprising amount of useful information grouped under the heads of materials, performance, aerodynamics, design and construction, airscrews, engines, air survey and photography, instruments and navigation, radio, and meteorology. Much of this material has been drawn from the reports of the Advisory Committee for Aeronautics which have been issued during the past twenty-two years, and which in themselves are too bulky for office use.

The editors gratefully acknowledge the co-operation of such bodies as the Air Ministry and the British Engineering Standards Association, and ask for constructive criticism, particularly with regard to any data which have been omitted, and which should be included in a future edition.

The handbook can be recommended as supplying a very definite need, and will be found of great value to aeronautical engineers.

High Speed Diesel Engines

By Arthur H. Goldingham. E. and F. N. Spon, London, 1931, cloth, 5½ x 8½ in., 148 pp., figs., charts, tables, 10/6 net.

Review by J. L. Busfield, M.E.I.C.

This book deals with automotive, aeronautical and marine high speed Diesel engines with full discussion of the various fuel injection mechanisms, together with sectional views of numerous existing designs with their working parts.

The first chapter deals with the history of the Diesel engine, the characteristics of its working cycle, heat losses, efficiency, and so forth.

The second chapter treats of details of fuel injection systems, and describes the fuel pump built by the Man Company, the Bosch fuel pump and also the Benes.

Chapters three, four and five describe and illustrate the following engines:—Packard (aviation); Junkers; Man; Hesselman; Cummins; Mercedes-Benz; McLaren-Benz; Deutz; Brotherhood-Ricardo; Treiber; Mumford; Lister; Saurer; Ruston; A.E.C.; Beardmore.

Brief descriptions are also given of the Gleniffer; De la Vergne; Gardner; and Aveling and Porter engines.

As the author states in the preface, the work is essentially a compilation of recent information and a record of the progress made during the last few years in this special field. The assistance of the several engine-builders is suitably acknowledged.

Textile Mechanics and Heat Engines

By Arthur Riley and Edward Dunkerley. Pitman & Sons, London, 1930; cloth, 8½ x 5½ in., 286 pp., figs., tables, 15/-.

This volume is one of a number of technical manuals issued by the same publishers and dealing with various phases of the textile industries in England, including the spinning and weaving of rayon, wool and cotton, the machinery involved in these various processes, and the testing of the finished products.

The volume under review is intended for students employed in textile work, and particularly in cotton spinning, and covers elementary mechanics and physics and their application to textile machinery and power plants for textile factories. It does not profess to give any advanced theory in these subjects, but gives a condensed course in applied mechanics and steam and internal combustion engine power as applied in the textile industry.

Most of the examples given are taken from spinning and weaving equipment and other mechanical applications likely to be familiar to textile students. The earlier chapters deal with such topics as the transmission of motion by belting and gearing, cams, ratchet gear, differential trains and so on, and these are followed by chapters on work, friction and simple machines. The elements of elasticity and strength of materials and hydraulics are then taken up, and chapters follow on heat and the properties of gases, steam boilers and accessories, the steam engine, and internal combustion engines.

Throughout the book the special interests of the readers are borne in mind. For example, in the chapter on heat, attention is given to problems connected with atmospheric humidity, and the mechanical questions discussed are almost all taken from examples occurring in the complex movements required in actual spinning and weaving machinery. The volume covers part of the course required by the City and Guilds of London Institute for their examinations in engineering applied to the cotton industry, and is more particularly intended for those taking the textile mechanics examinations of the Union of Lancashire and Cheshire Institute's cotton spinning courses. It is not intended as a textbook for advanced engineering students, but would seem to be eminently suited for the special audience to which it is addressed.

There is a useful index, the diagrams are clear, and each chapter is followed by a series of numerical examples and exercises.

Erratum

In the May issue of The Journal, when printing Mr. C. C. Paterson's address on "The National Electricity Supply Scheme of Great Britain," an error occurred which completely reversed the meaning of one of the author's remarks.

In line three of the right hand column, page 279, the words "are in doubt" should read "are in *no* doubt."

The S.S. Noronic of the Canadian Steamship Lines leaving lock No. 7 in the Welland Ship canal. The Noronic has a keel length of 362 feet, 52-foot beam and a gross tonnage of 6,905 tons. It will be noticed that the roof of the upper cabin is level with the top of the walls showing that the ship has a freeboard of about 51 feet.

In connection with the hydro-electric power development of the Northwestern Power Company at Seven Sisters on the Winnipeg river, The William Kennedy and Sons Ltd., Owen Sound, Ont., supplied a stoplog machine with a capacity of 24 tons, for pulling logs as well as ramming them down. This machine can handle logs from both the spillways and the sluiceways, the latter being 20 feet in height while the sluiceways are 30 feet long. In order to serve both openings, the machine is designed to telescope ten feet. The telescoping is done by means of a ratchet wrench, and locking devices are provided for holding the spuds at the desired centre distance. The machine is also equipped with a log piler and handles logs to and from the machine by means of trolleys which make the use of skids unnecessary. The depth from deck to sill of the spillways is 30 feet and the sluiceways are 35 feet from deck to sill. The gearing of each spud is provided with a clutch so that one spud may be disconnected and full power applied to the other in case a log sticks. Breaking pins are provided on the main frames supporting the rack pinions so that if foreign substances get into the teeth of the pinions or racks, the pins will break and prevent damage to the frames or teeth by letting the teeth drop out of mesh.

A crane type wound rotor motor was used for furnishing power and three speeds to hoistings are provided by means of sliding gears. The machine is also arranged for hand operation in case of emergency and has a power connection for traversing along the dam. The racks and rack pinion frames are steel castings and all the gears and pinions are steel castings with cut teeth.

BRANCH NEWS

Border Cities Branch

Harold J. A. Chambers, A.M.E.I.C., Secretary-Treasurer.
Harvey E. Bushlen, S.E.I.C., Branch News Editor.

New Developments at Copper Cliff and the Frood Mine

The regular monthly meeting of the Border Cities Branch was held on May 15th. The speaker of the evening was Mr. C. E. MacDonald, of the International Nickel Company of Canada, Ltd. In his address, he dealt with the Frood mine and indicated how this mine had revolutionized their old methods and processes. At the conclusion of his address, Mr. MacDonald showed slides of the mine and of some of the reduction processes.

Nickel is found in Manitoba, British Columbia and Quebec, as well as in northern Ontario. In the latter location the ores are associated with norites—a basic rock. The Creighton mine which is the older mine of the International Nickel Company has been in operation for over twenty-five years. The Frood mine, which is a later development, has been responsible for all the company's changes in plant and process.

Drilling for this latter mine revealed a high-grade ore below the 1,400-foot level. Above this high grade ore deposit existed ninety million tons of low grade ore. The company decided to commence operations at the 1,400-foot level and reserve the low grade deposit above this for future use. The cut and fill method was adopted. The drifts and stopes frequently caved and consequently it was necessary to timber them. Small stopes were essential for fire protection. The mining methods were dictated by the nature of the field.

The ore at the Frood mine was found to be mostly fines. On this account it could not be hand sorted, nor was it suitable for roasting, or for the blast furnace. This ore is three parts copper to one part nickel. Differential or select flotation is used to separate the copper. From this process the ore is taken to the mill and crusher plant, thence to the screens. Next it is placed in bins to which sulphuric acid is added. The ore is then put through the classifier. The oversize is sent back to the grinders and is ground to sixty-five mesh. After this grinding and screening, the ore is taken to flotation tanks, where the reagents are added. From this 40 per cent copper content product, more nickel and iron are removed until but 2 per cent nickel is left. The remaining product is then taken to the reverberatory furnace and thence to a converter where it is blown with air. The remainder of the nickel and iron is oxidized during this stage. The balance of the material is put through another flotation process and 99 per cent of the metal is recovered.

Prior to the working of the Frood mine all the copper had been refined in New Jersey. After development began in this mine they were unable to handle all the ore in New Jersey and it became necessary to build a copper refinery. This refinery was built at Copper Cliff, Ontario, at a cost of nine and one-half million dollars. At present the company is still shipping copper with nickel to the refinery at Port Colborne, Ontario. This plant, however, is to be removed to Copper Cliff, bringing with it five hundred men.

The Frood mine is at present one of the world's largest mines To date they have 22 miles of underground development. The shaft for this mine proved to be a big problem. A 14-foot by 6-foot cage, capable of 1,500 feet per minute, is operated along with an auxiliary, which operates at 3,000 feet per minute. It is necessary to handle one and one-half million feet of timber and between two and three thousand men per month in this shaft in addition to the ore.

This mine, as well as being rich in copper and nickel, is one of the largest platinum producing mines in the world. Their plant is capable of a yearly output of 300,000 ounces of this precious metal. Palladium is also found in this mine.

Hamilton Branch

J. R. Dunbar, A.M.E.I.C., Secretary-Treasurer.
J. A. M. Galilee, Aff.E.I.C., Branch News Editor.

Annual Meeting

The annual meeting of the Branch was held recently as a luncheon meeting in Murphy's restaurant. About twenty members of the Branch were present.

On the motion of E. M. Coles, A.M.E.I.C., seconded by W. A. T. Gilmour, Jr.E.I.C., the minutes of the last three meetings were taken as read.

The first item of business was the presentation of the Branch students' prizes. This is the first year in which a competition has been held for the Branch students' prizes and three papers were presented in the competition. A fourth student's paper is now in the course of preparation and the four papers will be submitted from this Branch for the John Galbraith prize.

The first prize was presented to D. E. Bridge, S.E.I.C., for his paper "Electrical Furnaces as Applied to Industrial Heating," the second prize going to P. R. Adams, S.E.I.C., for his paper "A Brief Résumé of the Air Brake and its Relation to Transportation."

The Secretary then read the report of the Executive committee for the year ending May 31st, 1931.

Report of Executive Committee for Year Ending May 31st, 1931

The Branch held the following meetings during the year:—

1930

Sept. 11.—"The Future of The Institute and How to Improve Finances and Increase Membership," by A. J. Grant, M.E.I.C., President of The Institute.
Several members of the Niagara Peninsula Branch were our guests at this meeting.
Dinner meeting. Attendance 40.

Oct. 10.—"Mechanical and Electrical Features of the Welland Ship Canal," by J. B. McAndrews, A.M.E.I.C., and L. P. Rundle.
The Hamilton Branch E.I.C. were the guests of the Ontario Section A.S.M.E. at this meeting.
Joint dinner meeting of Ontario Section A.S.M.E., Toronto Section A.I.E.E., and Toronto Branch E.I.C.
Attendance 113 at dinner, 175 at the meeting.

Oct. 21.—(1) "Illumination of the Endless Caverns of Virginia," by G. F. Foot.
(2) "Floodlighting and its Applications," by G. F. Mudgett.
Attendance 60, including ten ladies.

Nov. 4.—"Combustion of Pulverized Fuel," by E. G. Bailey.
The members of the Hamilton Branch E.I.C. were the guests of the Engineering Society of Babcock-Wilcox and Goldie-McCulloch Company at this meeting.
Attendance 175.

Nov. 12.—"Weather Reporting to the R 100," by J. Patterson.
Attendance 35.

Dec. 10.—"The Telephone Carrier System," by W. A. Dancey.
Attendance 55.

1931

Jan. 13.—"Railway Construction Through the Yellowhead Pass," by W. R. Smith.
Attendance 45.

Feb. 11.—"Construction and Operation of Oil Electric Rail Cars," by H. F. Finnemore.
Attendance 75.

Mar. 10.—Students' Meeting.
"A Brief Résumé of the Development of the Air Brake and its Relation to Transportation," by P. R. Adams, S.E.I.C.
"Electric Furnaces as Applied to Industrial Heating," by D. E. Bridge, S.E.I.C.
"The Power Supply of Southern Vancouver Island," by H. W. Blackett, Jr.E.I.C.
Attendance 25.

April 2.—"Steam Storage," by J. P. Wys.
This was a joint meeting with the Ontario and Buffalo Sections A.S.M.E. and Niagara Peninsula Branch E.I.C. In the afternoon visits were paid to works of the Canadian Westinghouse Company Ltd., Steel Company of Canada, Firestone Tire and Rubber Company, and Dominion Glass Company. After dinner Japanese research films were shown. Members of the Buffalo Section A.S.M.E. explained the films.
Attendance 100 at dinner, 120 at evening meeting.

April 24.—"Interesting Developments and Problems in Central Station Engineering," by R. E. Powers.
This was the annual joint meeting with the Toronto section A.I.E.E.
Attendance 240.

May 6.—Annual Branch meeting.
Attendance 20.

A total of ten Branch meetings were held during the year exclusive of meetings at which we were the guests of other organizations, with an average cost of approximately $32 per meeting.

A particularly interesting meeting was the Students' meeting on March 10th. Three papers of excellent quality were submitted.

By a vote, those present at the meeting decided that Mr. Blackett's oral presentation was the best, followed closely by Mr. Adams.

The Branch Prize Committee considered the papers and decided that Mr. Bridge's paper was so well prepared and contained such good material that he was entitled to the first prize. Mr. P. R. Adams was awarded the second prize. Mr. Blackett's paper, although it was not awarded a prize, showed evidence of careful preparation and his oral presentation deserves particular mention.

This year owing to unwillingness on the part of nominees for office to accept nomination, all Branch offices were filled by acclamation.

The proposal regarding the fees that was referred to in last year's report was drawn up this year as a formal amendment to the by-laws and submitted to headquarters. On the request of headquarters those who signed the proposed amendment again withdrew the proposal from consideration for this year.

Seven executive committee meetings were held during the year with an attendance of six or seven at each meeting.

The following is a statement of the membership.

MEMBERSHIP

Class	Resident	Non-Res.	Total	Last Year
Members	25	5	30	31
Associate Members	51	9	60	57
Juniors	13	4	17	14
Students	31	3	34	38
Affiliates	3	0	3	3
Branch Affiliates			20	21

The Executive Committee for the season 1931-32 were then introduced to the branch membership. The following are the members of the Executive Committee for the coming year:—

Chairman.....................E. P. Muntz, M.E.I.C.
Vice-Chairman.................H. P. Stuart, A.M.E.I.C.
Secretary-Treasurer............J. R. Dunbar, A.M.E.I.C.
Executive Committee..........E. M. Coles, A.M.E.I.C.
G. A. Colhoun, A.M.E.I.C.
W. A. T. Gilmour, Jr.E.I.C.
J. Stodart, M.E.I.C.
Ex-officio.....................E. H. Darling, M.E.I.C., Councillor
W. F. McLaren, M.E.I.C., Past Chairman.

An interesting discussion followed regarding the Branch activities for the coming year. It was suggested that a membership drive should be organized, which will be done as soon as the new Executive Committee is able to get functioning properly. Two or three of the members present suggested that noon luncheon meetings would be very desirable in addition to the regular evening meetings.

London Branch

F. C. Ball, A.M.E.I.C., Secretary-Treasurer.
J. R. Rostron, A.M.E.I.C., News Editor.

REFORESTATION

The regular May meeting of the Branch was held on the 19th in the auditorium of the city hall, the speaker being Arthur Herbert Richardson, forester in charge of reforestation, province of Ontario, and his subject "Reforestation."

An interesting feature of this meeting was the presence of a number of boys and girls from the county of Middlesex who had entered a competition, inaugurated by W. R. Smith, A.M.E.I.C., Branch chairman, for the best essay on "Reforestation." A number of these essays, which were read to the meeting, showed that the competitors had a thorough grasp of the subject and augured well for the preservation and cultivation of our wooded areas by the rising generation.

Mr. Smith, who presided, made some interesting comparisons between the progress of reforestation in the United States and in Canada, which went to show that the latter were not behind in this respect—in Ontario alone 2,000,000 trees were distributed by the government for planting purposes.

Mr. Richardson's address was illustrated by coloured slides showing the effect of land, otherwise waste, reclaimed by reforestation. Views were shown of various kinds of trees in all stages of growth from the planting up to thirty years old. Land, originally a barren waste, was transformed into a beautiful and profitable park. Roads which formerly drifted up with sand and were costly to maintain were shown now protected with growths of pine thus eliminating the cost of maintenance and beautifying the landscape. Views were shown of demonstration areas planted by the government in various parts of Ontario. The speaker pointed out that vast tracts of waste land as far as cultivation was concerned, such as hill sides, rocky places or swamps, could by this means be turned into profitable areas. He outlined the government's plan of raising trees from seedlings and distributing and planting them free if the land is provided and fenced by the municipality or county. Individual owners can also obtain this service either free or at a nominal cost according to the area of the land that is proposed to be planted. Such areas reforested will make their yield from twenty-five years up according to the kind of trees planted whether of quick or slow growth. It was estimated that say an acre planted with pine would yield about 1,200 trees or about 25,000 B.M. of lumber worth about $20 per thousand on the stump, thus a yield of from four hundred to five hundred dollars an acre could be expected. Carolina poplar was mentioned as a quick growing and profitable species. Not only this, but the areas so planted formed a windbreak and prevented aridness of the surrounding land, thus increasing its fertility and productiveness, while the trees themselves together with the undergrowth conserved the underground water supply.

It was urged that municipalities, counties, public or private persons, farmers, land owners, or any persons having control or interest in unprofitable areas of land, large or small, give this matter full consideration. Full information can be obtained by application to the Ontario Forestry Branch, Toronto. Any resident in Ontario may secure five hundred trees free each year for windbreaks, or 3,500 trees each year for planting on their property either for reforesting waste land or filling in the wood lot. Additional quantities may be purchased at the rate of $1 per thousand.

An interesting discussion followed the speaker's address and a hearty vote of thanks was ably proposed by W. C. Miller, M.E.I.C., city engineer of St. Thomas, who pointed out that his municipality had already accepted the government's offer and was planting trees in the vicinity of the waterworks, and J. R. Rostron, A.M.E.I.C., seconded the vote of thanks.

About fifty-five members and guests were present.

Following this meeting a motor trip was made on Saturday, May 30, to view the reforested area at St. Williams, which was much appreciated by about thirty interested people. There would have been a larger turn-out had it not been for the rainfall.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

The annual meeting was held on May 30th. L. H. Robinson, M.E.I.C., chairman of the Branch, presided. The annual report and financial statement was presented, and on motion adopted. The scrutineers reported on the result of the Branch elections, and it was announced that the following officers will act for the year 1931-32.

Chairman.....................G. E. Smith, A.M.E.I.C.
Vice-Chairman.................T. H. Dickson, A.M.E.I.C.
Secretary-Treasurer............V. C. Blackett, A.M.E.I.C.
Executive Committee..........E. T. Cain, A.M.E.I.C.
H. J. Crudge, A.M.E.I.C.
R. H. Emmerson, A.M.E.I.C.
A. S. Gunn, A.M.E.I.C.
H. W. McKiel, M.E.I.C.
A. F. Stewart, M.E.I.C.
Ex-officio.....................L. H. Robinson, M.E.I.C.
G. C. Torrens, A.M.E.I.C.

On motion of A. S. Gunn, A.M.E.I.C., seconded by G. E. Smith, A.M.E.I.C., a vote of thanks was extended the Branch members on the engineering staff of the University of Mount Allison for their work in interesting the students in The Institute. A vote of thanks moved by R. H. Emmerson, A.M.E.I.C., seconded by G. C. Torrens, A.M.E.I.C., was accorded the retiring Branch officers.

ELEVENTH ANNUAL REPORT

The tenth annual meeting of Moncton Branch was held on June 10th, 1930.

The Executive committee held five meetings during the year. There were seven meetings of the Branch, two of which were open to the public. At these meetings papers were read, addresses delivered and business transacted as follows:—

1930

Oct. 14.—A public meeting was held in the city hall. A very interesting illustrated address was given by G. A. Richardson, technical lecturer of the Bethlehem Steel Corporation, Bethlehem, Pa., on "The Manufacture of Structural Steel Shapes and Related Products."

Nov. 18.—A supper meeting was held in the Y.M.C.A. An instructive illustrated address was delivered by F. H. Peters, M.E.I.C., Surveyor General, Department of the Interior, Ottawa, on "Aerial Photographic Surveys."

1931

Jan. 13.—A public meeting was held in the council chamber, city hall. Major H. W. L. Doane, B.Sc., M.E.I.C., gave a very interesting address on "The Allenby Campaign in Palestine."

Feb. 18.—A supper meeting was held in the Y.M.C.A. An exceedingly instructive address on "Commercial Aviation" was delivered by Capt. A. F. Ingram, Manager of the Canadian Airways, Montreal.

Mar. 17.—A combined meeting of Moncton Branch and the Engineering Society of Mount Allison University was held at Sackville. A very interesting illustrated paper on "Municipal Engineering" was read by J. D. McBeath, B.A.I., Chief Engineer, City of Moncton.

Mar. 18.—A supper meeting was held in the Y.M.C.A. James Govan, M.R.A.I.C., Toronto, delivered an interesting and instructive address on "Recent Research Developments in Building Materials."

May 20.—A meeting was held for the purpose of nominating Branch officers for the year 1931-32.

The attendance at all our Branch meetings was good, and particularly so at the two meetings open to the public. At the first of these there were about two hundred present,—at the second, standing room was at a premium—an excellent indication of the service the Branch is rendering, not only to the profession but to the general public as well.

While many outstanding addresses have been delivered before the Branch in past years, it is quite safe to say that never before has such a high uniform standard of excellence been reached. Arrangements were made during the season to have two of our speakers address the other Maritime branches. L. H. Robinson, M.E.I.C., chairman of the Branch, also acted in the capacity of chairman of the Papers committee for the year just closed.

Our total membership shows an increase over last year of more than thirty per cent. There is one application pending and several more are in prospect. A very gratifying feature is the interest being taken in The Institute by the engineering students of Mount Allison University and the Branch should be sincerely grateful to our members on the staff of the university, who have so ably presented the advantages of membership to the students.

The following is a statement of our membership at the present time:—

MEMBERSHIP

	Resident	*Non-Resident*	*Total*
Members	10	2	12
Associate Members	21	5	26
Juniors	2	..	2
Students	26	3	29
Branch Affiliates	2	..	2
	61	10	71

The thanks of the Executive of Moncton Branch are due E. T. Cain, A.M.E.I.C., chairman of the Entertainment committee, for his efficient management of the details of our supper meetings, also the Moncton Tramways, Electricity and Gas Company Ltd. for the loan of a moving picture projector, and the gentlemen who so kindly furnished the musical entertainment for our meetings.

Niagara Peninsula Branch

Paul E. Buss, A.M.E.I.C., Secretary-Treasurer.

A meeting of the Branch was held at Niagara Falls on May 22nd. Reports of the scrutineers were received and the following slate of officers was declared duly elected for the year June 1st, 1931, to May 31st, 1932:—

Chairman.................. Walter Jackson, M.E.I.C.
Vice-Chairman.............. E. P. Murphy, A.M.E.I.C.
Secretary-Treasurer.......... P. E. Buss, A.M.E.I.C.
Executive.................. J. C. Moyer, A.M.E.I.C.
Alex. Milne, A.M.E.I.C.
C. G. Cline, A.M.E.I.C.
H. M. King, M.E.I.C.
W. R. Manock, A.M.E.I.C.
F. L. Haviland, M.E.I.C.
H. D. Davison, A.M.E.I.C.
C. N. Geale, A.M.E.I.C.
L. C. McMurtry, A.M.E.I.C.
Ex-officio.................. E. G. Cameron, A.M.E.I.C.
A. J. Grant, M.E.I.C.
C. H. Scheman, M.E.I.C.

At this meeting reports were received indicating that a stag dinner for the annual meeting would be preferred to a dinner-dance, which had proved so successful in previous years. Accordingly the programme was altered to conform with this desire. After luncheon the executive adjourned to the golf course at Niagara-on-the-Lake, where a feature of the contest was the excellent score card turned in by G. F. Vollmer, M.E.I.C., who, although somewhat of a novice, won easily on his handicap.

ANNUAL MEETING

The annual meeting was held at the General Brock hotel, Niagara Falls, on May 27th. Walter Jackson, M.E.I.C., was chairman and Mr. M. A. Sorsoleil, of Toronto, was the principal speaker of the evening. About eighty members and guests were in attendance.

MODERN TRENDS IN EDUCATION

Mr. Sorsoleil is assistant director of vocational education in the province of Ontario and spoke on the subject of "Modern Trends in Education" in a manner which convinced his audience that great changes were in progress and that careful thinking and planning was being done along these lines.

The word "education" said Mr. Sorsoleil has to-day an entirely different meaning from that in which it was formerly used. It has broadened out until no longer does it denote a mere bookish culture. There have been periods not so long ago when the sole ability to quote Greek or Latin classics was considered to be the mark of an educated man, and when artisans, even engineers, were not among the elite.

Fortunately this conception is a thing of the past and now an educated man might well be defined as "one who functions successfully in his environment." In other words, anyone who can do well the work for which he, or she, is particularly adapted may be termed educated—but only if that work is performed with skill and with the knowledge of how it should be performed.

A skilful cabinet maker, if his education be complete, can turn out a work of merit which will vie with any poem, painting or sonata as a conception of artistic skill and beauty.

Now, continued Mr. Sorsoleil, the vocational departments are recognizing this fact. No longer do they use the term sub-normal to define backward pupils—as a matter of fact very few pupils are mentally deficient in all things. The new way is to study the child and ascertain the particular work for which he is adapted and then educate him along those lines.

The vocational department is also looking ahead to the time, which is surely coming, when the percentage of leisure will be greatly increased. When the workers of the world will have six or eight hours a day for play or recreation and perhaps only five or six hours work. If the worker is not educated to employ this leisure properly he will deteriorate, but if he is taught how to play, to develope hobbies such as gardening, wood working, book study, etc., then will he retain mental equilibrium and remain the best type of citizen.

As an indication of how the world is even now moving in this respect, it may be noticed that the adolescent act of Ontario has raised the school age to sixteen years and many of the educators believe that it should have been eighteen years. However, concluded Mr. Sorsoleil, the most important thing in education is to train the young mind to think for itself.

Of interest to engineers was the fact that quite a few of their number had taken up the special course provided by the department and some eight or nine were already giving vocational guidance in the schools of Ontario. They are proving efficient teachers and this should in future be a splendid field for those of the profession who like that kind of work.

At the close of this talk W. R. Manock, A.M.E.I.C., and H. M. King, M.E.I.C., proposed and seconded the vote of thanks to Mr. Sorsoleil. Messrs. S. R. Frost, A.M.E.I.C., and G. G. Reid, Jr.E.I.C., then entertained the gathering with some very good songs.

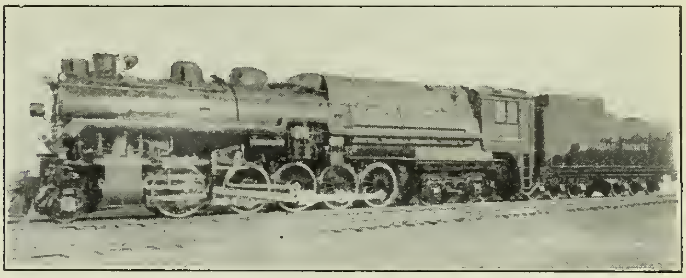
Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

FINAL EVENING MEETING OF SEASON

The last evening meeting of the season of the Ottawa Branch of The Engineering Institute was held in the Royal Canadian Air Force projection room, Jackson building, on May 14th. The speaker was W. A. Newman, chief mechanical engineer of the Canadian Pacific Railway Company, who described briefly the underlying principles in connection with the new C.P.R. locomotive No. 8000. His address was followed by moving pictures of locomotive No. 8000, including animated diagrams, prepared by the Associated Screen News of Montreal.

The new locomotive, stated Mr. Newman, utilizes a very novel and interesting system in the generation of steam which offers an improvement in economy. In improving the design of locomotives what is, of course, aimed at is the development of increased power with a decrease in costs. The history of increasing boiler pressures means that water tube boilers must be used, the principal reason being that small tubes can have an ample factor of safety with comparatively thin walls. A disadvantage in water tube boilers is that impurities are left behind as solids when ordinary water is used. These solids stick on the metal surfaces, forming a scale which interferes with the transmission of heat. In marine and stationary plants this is easily overcome by the use of condensers, but with a moving locomotive, weight and space limitations do not allow for the same methods as in stationary plants. The problem then becomes how to construct a water tube boiler without scaling difficulties.



T4a-Class—Multi-Pressure Locomotive.

Cylinders, h.p. (1), 15½" x 28"; Cylinders, l.p. (2), 24" x 30"; Diameter of Drivers, 63"; Tractive effort, 90,000 lbs.

Boiler Pressures: Closed Circuit 1,350 lbs.; High Pressure, 850 lbs.; Low Pressure, 250 lbs.

Weight on Drivers, 219,000 lbs.; Weight of engine, 485,000 lbs.; Weight of engine and tender, 785,000 lbs.

Total Length of engine and tender 99'3".

Water Capacity, 12,000 imp. gallons.

Oil Capacity, 4,100 imp. gallons.

The new locomotive is of the "multi-pressure" type. That is, there are three pressure systems with which three instead of two cylinders are used, and in this way it is radically different from ordinary locomotives.

The three pressure systems are, respectively, the "closed steam generating system," the "high pressure system" and the "low pressure system." The closed steam generating system is a box-like structure built up of a large number of tubes filled to a set level with distilled water and sealed. This system absorbs a large amount of heat to form steam, which when condensed gives out the same amount of heat. This is accomplished by collecting the steam in two longitudinal drums at the top of the firebox and then delivering it to a series of coils placed in the inside of a seamless steel drum and submerged in water. These are called heat transfer coils and the surrounding water condenses the steam and absorbs the heat given out. Condensation is then led from the bottom of the coils back to the lowest point in the closed system and re-evaporated.

In fact, the system has a continuous sponge-like action absorbing and giving out heat and on account of the use of distilled water no scale can accumulate. There is no set pressure although nominally the pressure is 1,350 pounds per square inch with an allowable maximum of 1,750 pounds per square inch.

The high pressure boiler develops pressure up to 850 pounds per square inch and the low pressure to 250 pounds per square inch.

The locomotive burns fuel oil, the capacity of the tender being 4,100 gallons and the capacity for water supply is 12,000 gallons. The Angus shops of the Canadian Pacific Railway were responsible for the construction. Canadian materials being used wherever possible. The total weight of the locomotive is 390 tons and the total length is 100 feet. The maximum tractive effort exerted is 90,000 pounds, but it is not intended for high speed as it was designed for use on some of the heavier grades in the Rocky mountains. The maximum speed is approximately 55 miles per hour.

At the meeting a short film was also shown dealing with the tipping of the obelisk at the Chute à Caron development on the Saguenay river on July 23rd of last year.

A most interesting feature which took place at this meeting was a presentation of a silver vase, by G. J. Desbarats, C.M.G., M.E.I.C., chairman of the local branch, to T. H. G. Clunn, A.M.E.I.C., one of the most popular members, who is retiring from the government service and, as a consequence, leaving the city.

Visit to Chats Falls

On the afternoon of June 6, 1931, the members of the Ottawa Branch of The Engineering Institute of Canada paid a visit to the Chats Falls hydro-electric development, now under construction by the Ontario Hydro-Electric Power Commission and Ottawa Valley Power Company, located on the Ottawa river, about 35 miles above the city of Ottawa. The members travelled by motor car, about one hundred and twenty-five making the trip, and were guests for the afternoon of the owners and of the general contractors, Morrow and Beatty, Ltd., of Peterborough, Ontario.

At the development the members were received by Colonel H. L. Trotter, M.E.I.C., resident engineer; A. E. Rowbotham; N. Malloch, A.M.E.I.C., and J. E. Dion, Jr.E.I.C., representing the owners; and J. Dick, A.M.E.I.C., chief engineer; J. Barrett, general superintendent; A. A. Richardson, A.M.E.I.C., superintendent in charge of work; and G. R.Evans, assistant engineer, representing the general contractors. They were taken direct to the power house by a work-train specially made up for their use and toured the extensive works for three hours after which the party was entertained at supper.

The interprovincial aspect of the development was a feature of particular interest, for the 627-foot long power house is half in Ontario and half in Quebec. The length of concrete and earth dam is approximately 3½ miles.

This is made up of 13,600 feet of concrete structure, including the power house, and 4,300 feet of earth dam, and accordingly is one of the longest dams in Canada. There are four sluice gate openings 40 feet wide by 25 feet high and four stop log dams having a total of 72 sluices 18 feet wide and an aggregate length of 1,752 feet. In connection with the development it has been necessary to divert a line of the Canadian National Railways for a distance of 2½ miles.

At the time of the visit there were some eight hundred men engaged on the work, although at times during the past year there had been upwards of twelve hundred men.

The present intended installation is eight units with an ultimate of ten units. The waterwheels are rated at 28,000 h.p. each and a speed of 125 r.p.m. under normal head of 53 feet.

Special 220,000-volt transmission lines will be erected to carry the power to western Ontario.

Peterborough Branch

F. G. A. Tarr, S.E.I.C., Secretary.
A. R. Jones, Jr.E.I.C., Branch News Editor.

Annual Meeting

The final meeting of the Peterborough Branch for the season was held on May 7, 1931, and took the form of a combined business meeting and social evening.

The various committees submitted very favourable reports of the season's activities, following which the scrutineers announced the result of the ballot for the election of officers as follows:

Chairman	A. B. Gates, A.M.E.I.C.
Secretary	F. G. A. Tarr, S.E.I.C.
Treasurer	B. Ottewell, A.M.E.I.C.
Executive Committee	B. L. Barns, A.M.E.I.C.
	A. E. Caddy, M.E.I.C.
	R. C. Flitton, A.M.E.I.C.
	A. L. Killaly, M.E.I.C.
	H. R. Sills, Jr.E.I.C.
	P. P. Westbye, M.E.I.C.
Ex Officio	R. L. Dobbin, M.E.I.C.
	W. E. Ross, A.M.E.I.C.

The following appointments and committees were also arranged:

Meetings and Papers Committee	H. R. Sills, Jr.E.I.C.
Branch News Editor	A. R. Jones, Jr.E.I.C.
Entertainment	R. L. Dobbin, M.E.I.C.
	W. E. Ross, A.M.E.I.C.
Attendance	D. J. Emery, S.E.I.C.
Membership	W. M. Cruthers, A.M.E.I.C.
	R. C. Flitton, A.M.E.I.C.
Auditor	E. R. Shirley, M.E.I.C.

The Students and Juniors section of the Branch again took an active part in the programme by staging a debate, "Resolved that Great Britain should give India Dominion Status." K. Anderson and E. McKeagan spoke for the affirmative and J. Cameron, S.E.I.C., and W. Brumby, Jr.E.I.C., for the negative.

On a standing vote of those present, the chairman announced that the "noes" had won by the close margin of one vote.

Light refreshments and a round of bridge concluded a very enjoyable evening.

Quebec Branch

M. Boyer, S.E.I.C., Secretary-Treasurer.

The annual meeting of the Quebec Branch of The Engineering Institute of Canada was held on Monday, June 15th, at 7.30 p.m., and presided over by S. L. de Carteret, M.E.I.C., chairman 1930-31.

Following the dinner, James Ruddick, M.E.I.C., and Louis Beaudry, A.M.E.I.C., were appointed scrutineers. While ballots were being counted, the minutes of the last annual meeting were read by Philippe Méthé, A.M.E.I.C., secretary, followed by the report of activities and finances for the year 1930-31.

An honorarium was voted to the secretary for his services during the year.

The following were unanimously elected to the legislating and nominating committees:—

Legislating	Alexandre Larivière, A.M.E.I.C.
	T. F. J. King, A.M.E.I.C.
	Louis Beaudry, A.M.E.I.C.
Nominating	Philippe Méthé, A.M.E.I.C.
	Alexandre Larivière, A.M.E.I.C.
	J. G. O'Donnell, A.M.E.I.C.

Ballot returns favoured the following officers for the year 1931-32:—

Chairman	J. N. Hector Cimon, M.E.I.C.
Vice-Chairman	Alexandre Larivière, A.M.E.I.C.
Secretary	Marc Boyer, S.E.I.C.
Executive Committee	Philippe Méthé, A.M.E.I.C.
	T. F. J. King, A.M.E.I.C.
	J. G. O'Donnell, A.M.E.I.C.
Ex-officio (Honorary President)	A. R. Decary, M.E.I.C.
(Executive Committee)	L. C. Dupuis, A.M.E.I.C.
	Louis Beaudry, A.M.E.I.C.
	A. B. Normandin, A.M.E.I.C.
	A. E. Doucet, M.E.I.C.
	W. G. Mitchell, M.E.I.C.
(Past President)	S. L. de Carteret, M.E.I.C.

It was voted that the ballots should be destroyed.

Short speeches were made by the new and retiring officers, and by several members present.

Topics of general interest to The Institute were discussed, among which was the necessity of a drive for membership.

The meeting adjourned at 10.30 p.m.

Vancouver Branch

W. O. Scott, Jr.E.I.C., Secretary-Treasurer.

Modern Trend in Aviation

On May 20th, 1931, Mr. R. Carter Guest, inspector of Civil Aviation for British Columbia, gave a very interesting informal talk on "Modern Trend in Aviation."

His discussion included such points as—

Inspection. Covering a brief outline of the duties of the staff, markings on planes to distinguish private and commercial crafts, airworthiness certificate and its meaning, number of inspections yearly and special inspections and their scope.

With the aid of a projection lantern pictures from air magazines and actual photographs were shown to illustrate the various types of planes. In this connection also the general design of the plane or planes was given, showing wing construction, bracing, types and positions of the power plant and so forth.

Further discussion brought out a few of the modern features and a number of views were shown of the Schneider Cup machine.

Progress in air mail service was explained by a few comparative figures for 1928 and 1929 for Canada, also for comparison those of United States for the same years.

Considerable interest was shown regarding the western section of the Canadian air mail service over the Rocky Mountains (Calgary to Vancouver).

Commercial uses of the plane today gave quite a large field for discussion and the speaker touched briefly on prospecting, timber cruising, inspection of mining ventures, transportation for game hunting, aerial photography and surveying.

P. H. Buchan, A.M.E.I.C., acted as chairman and thanked the speaker. At the same time he pointed out that such an interesting topic and discussion was worthy of a large turnout.

Victoria Branch

K. M. Chadwick, M.E.I.C., Secretary-Treasurer.

The annual dinner of the Victoria Branch of The Institute was held at West Point Barracks on April 11th, 1931, by kind permission of Colonel J. Sutherland Brown, C.M.G., D.S.O., Affil.E.I.C., and was attended by some forty members. A. L. Carruthers, M.E.I.C., was chairman and short speeches were made by R. A. Bainbridge, M.E.I.C., F. C. Green, M.E.I.C., P. Philip, M.E.I.C., and Colonel J. S. Dennis, M.E.I.C., who now resides in Victoria.

VISIT TO PLANT OF CANADIAN EXPLOSIVES

On June 5th, 1931, eighteen members of the Victoria Branch paid a visit to the Canadian Explosives plant at James island, about 12 miles from Victoria, and were welcomed by the management. The party was shown the various processes used in making modern explosives, also the acid plants, the glycerine mixing rooms, and the packing and shipping rooms, each section of the explosive side of the works being located in separate sheds set 100 yards or more away from each other, so that should an explosion take place it would be more or less restricted to a small portion of the plant.

Kill van Kull Bridge

The following information regarding the Kill van Kull bridge between Bayonne, New Jersey and Port Richmond, Staten Island, New York, is based on the second report of Mr. O. H. Ammann, chief engineer of the Port of New York Authority, published in March, 1931, and describes briefly the erection of one of the first arch spans ever attempted.

This arch involving the placing of almost 17,000 tons of steel necessitated unusual methods of construction, inasmuch as the falsework supports were not allowed to encroach upon the shipping channel which is near the south shore of the Kill van Kull bridge site. The major portion of this work has now been completed, and it is expected that the remainder will be speedily concluded, except for the street approach problem on the Staten Island side which has not been definitely solved.

The Kill van Kull is spanned by a two-hinged parabolic steel arch measuring 1,675 feet between bearing points on the abutments. The arch, which is more fully described in the first progress report, is composed of two arch trusses, spaced 74 feet on centres, with a rise of 274 feet from the centre of bearing to the crown of the lower chord. Each truss has a depth of 37 feet 6 inches at the crown and 67 feet 6 inches at the abutments.

The web members of the arch trusses are arranged in forty panels of equal length. The bottom web is of carbon-manganese steel of a cross sectional area of 980 square inches at the abutment and 580 square inches at the crown. It is designed to carry the greater portion of the dead load of the span, and thrusts against hinges formed by pins 16 inches in diameter which bear upon heavy steel forgings through which the loads are transmitted to the structural shoes. The top chord is of silicon steel varying in cross section from 272 square inches to 421.5 square inches. The web members of the trusses, the bracing between trusses, and the floor beams and stringers, which support the deck slabs, are partly of silicon steel and partly of carbon steel. The central part of the floor system is suspended from the arch trusses by means of wire rope hangers.

The arch was erected in two sections from the abutments. The method of erection was unusual, inasmuch as it involved cantilevering from both ends with the assistance of falsework bents placed successively as erection of the arch proceeded. The ideal procedure would have been to have the two sections meet at the crown of the arch. However, the falsework supports were not allowed to encroach upon the shipping channel, which at the bridge site is near the south shore of the Kill van Kull and therefore involved unsymmetrical arrangement.

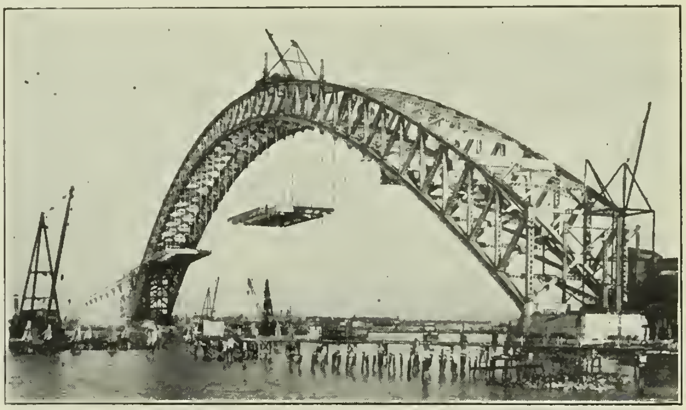
The south arm was completed before undertaking work on the north arm. A single erection traveller which operated on rails along the top chords of the trusses erected both arms. Some of the falsework bents used in erecting the south arm were again used for the north arm and, in general, the same procedure was followed in the early stages of erection of the two arms, except that the first panel of steel in the south arm was erected by a traveller which had been assembled on the abutment, while for the north arm the first panel was erected by floating equipment.

Closure of the arms at panel point 14 south was effected by lowering both sections of the arch simultaneously to bear upon a 16-inch diameter pin in the lower chord, a process which required particular care and close co-ordination. Guide castings were provided to insure horizontal alignment of the trusses upon closing. Possible errors in alignment of as much as six inches were anticipated. The precision in fabrication and erection had been such, however, as to result in an actual error in alignment of less than one inch.

The arch was then in a three-hinged condition. To convert the structure into a two-hinged arch the insertion of a top chord member in each truss was required. The arch had been designed upon the assumption that under the initial condition after closing, it would be three hinged with one hinge in the lower chord at the crown of the arch. A closing upper chord member at the crown would, under such condition, carry no stress. Under any condition of additional loading the arch would act as a two-hinged structure.

Following the completion of arch truss erection the remaining falsework bents and piers were removed, wire rope suspenders were placed and erection of the floor system was started. Main transverse floor beams occur at each panel point. At points where the floor system is suspended below the lower chord of the arch ring four $3\frac{1}{4}$-inch wire ropes attach to each end of a floor beam. These beams are connected by four roadway stringers in each panel. Transverse secondary floor beams are connected by four roadway stringers in each panel. Transverse secondary floor beams support bulb beams which will form part of the reinforcing for the roadway concrete slab. Wind chords, steel roadway curbs, lateral bracing and framing for a sidewalk on the west side of the bridge complete the floor structure. The design of the floor system is such as to provide for the later addition of two lines of rapid transit or for increasing the width of roadway from 40 feet to 65 feet.

The floor system was erected in two principal sections. The traveller on the top chord of the arch began erection one panel south of the crown of the arch and continued south to a point within two panels of the Port Richmond abutment. At the same time the Bayonne approach traveller started at the north abutment and proceeded with the erection of the floor steel of the main span. This traveller was on the floor level and was unable to operate for a short distance within and beyond the portal of the arch. Accordingly auxiliary tackle attached to the truss was used for hoisting the floor steel in this area. Later the traveller "A" frame was lowered and moved through the portal, reassembled at panel point 10 and thence proceeded to join the floor steel with the other section near the centre of the span. All main span floor steel except that required for two panels adjacent to the Port Richmond abutment is now in place.



Kill van Kull Bridge, January 1st, 1930.

The actual mass of concrete required at each abutment to transmit the thrust of the arch to bed rock is comparatively small. The top of the abutment block is only slightly over 20 feet above river level. For architectural reasons the abutments will be carried as solid appearing pillars to a height somewhat above the roadway level. They will actually be built of curtain walls faced with granite after the bridge is opened to traffic. The roadway deck at this location is carried on a skeleton steelwork.

Erection on the Bayonne approach steel was started January 28th, 1930, at West Third street and was completed at the abutment just prior to April 1st, 1930.

The Port Richmond approach construction is similar to that of the Bayonne approach. It consists in general of a series of plate girder spans of 126 feet maximum length on reinforced concrete piers. The transverse floor beams are spaced at approximately 20-foot intervals and carry stringers which will support the concrete slab. Special construction was necessary at Richmond terrace, which is crossed by a span of 183 feet 10 inches. At this location long girders continuous in three spans over four supports were provided. In all spans framing for a sidewalk 6 feet 6 inches wide is provided in temporary location on the west side of the approach only. As in the main span provisions are made for future changes in width of roadway or additions of rapid transit tracks and footwalks.

L. Mundet and Son, 461 Eighth Avenue, New York, N.Y., have published a new bulletin entitled "How to Deaden Machine Vibrations and Noise," which shows and tells how machinery should be isolated by means of natural cork so that noise and vibrations will be eliminated. It explains why natural cork mats are preferable for machinery isolation, gives a table of sizes and shapes of Mundet natural cork mats and also shows curves of compression tests on mats $1\frac{1}{2}$ inches and 3 inches thick. A copy of the bulletin may be obtained from L. Mundet and Son at the above mentioned address.

Preliminary Notice

of Applications for Admission and for Transfer

June 20th, 1931.

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in August, 1931.

R. J. Durley, *Secretary.*

* The professional requirements are as follows—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BATY—EDWARD, of 781 Maplewood Ave., Montreal, Que., Born at Tarraby, Carlisle, England, March 14th, 1893; Educ., 1909-13, Darlington Technical College, England. Stages I, II and III certs., Board of Education and London City and Guilds Institute, in mech'l. engrg. and associated subjects; 1909-14, privileged ap'ticeship, North Eastern Railway locomotive works, Darlington, England, shop and drawing office training in locomotive and machine tools; 1914, dftsman., Smith, Major & Stevens, Northampton, Eng.; 1915, on active service with Royal Artillery; 1916-18, acting chief works dftsman and electrician, North Eastern Railway Locomotive Works, Darlington, England; 1919, process and standards engr., machine tool and jig design and shop methods, Smith, Major & Stevens, Northampton; 1916-18, lecturer, evening classes, machine drawing and design and engrg. science, Darlington Technical College, England; 1920-21, engr. and works mgr., East Anglian Cement Co. Ltd., Cambridge and Walsall, England; 1922-23, gen. mech'l. and elect'l. installns. on own account; 1924, dftsman., boiler and plate work design, Canadian Vickers, Limited, Montreal; 1925-27, engrg. asst., and from 1928 to date, district plant engr., telephone plant design, estimation, installation and mtce., Bell Telephone Company of Canada, Montreal. Also instructor, evenings, in mech'l. drawing and design, Sir George Williams College, Montreal. (1919-21, 2nd Lieut., Corps of Royal Engrs., Retired with permanent rank).

CAMPBELL—HAROLD MONTGOMERY, of 23 Bellevue Terrace, St. Catharines, Ont., Born at St. Catharines, Ont., Dec. 17th, 1891; Educ., B.A.Sc., Univ. of Toronto, 1914; 1910-13, plant work during vacation periods; 1914 (Apr.-Sept.) and 1919-20, mech'l. dftsman., Welland Ship Canal; 1915-19, overseas, Major, M.C.; 1920-23, production mgr., in charge of production programme of plant engaged in small tool mfg. and special drop forgings, J. H. Williams, Limited; at present owner of Campbell's Hardware, Limited, St. Catharines, Ont.

References: A. J. Grant, C. H. Mitchell, T. R. Loudon, E. G. Cameron, W. P. Near.

HAGGAS—ERNEST, of 305 Cope St., Hamilton, Ont., Born at Lower Kipping, Thornton, Bradford, England; Educ., 1911-16, Technical College, Bradford, England. 1919-22, mech'l. elect'l. engrg. course with Bennett College, Sheffield. 1925-27, corres. study with University College, Cambridge, England, with view to obtaining B.Sc. (Mech.), (did not sit for exams.); 1929-31, 2nd year mech'l. drawing instructor at Wentworth Technical Institute, Hamilton, Ont., for two winter sessions; 1917-19, overseas. Air mechanic in R.A.F.; 1922-25, mech'l. dftsman., English Electric Co. Ltd., Phoenix Works, Bradford, England; 1925-28, senior mech. dftsman., layout and design A.C. and D.C. machines—some centrifugal pump practice, Harland Engineering Co. Ltd., Alloa, Scotland; 1928-29, senior mech'l. dftsman., Crompton Parkinson, Chelmsford, England; August 1929 to date, senior dftsman., A.C. vert. W.W. generators up to 50,000 kv.a., details, layout and design (mech'l), Canadian Westinghouse Co. Ltd., Hamilton, Ont.

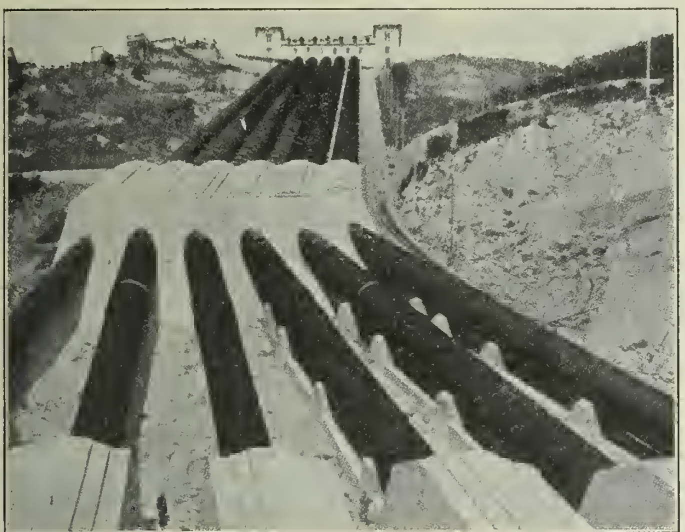
The Cardano Water Power Plant

The Societa Idroelettrica dell'Isarco, of Milan, has recently completed a large hydro-electric power station at Cardano, a village about three miles from Bolzano in northern Italy. The station works under a total head of about 541 feet and has at present an installed capacity of 270,000 h.p. (200,000 kw.), the annual output being equal to 550 million kw.h. The plant utilizes the water of the River Isarco, which rises in the Brenner Alps near the Italian-Austrian frontier. The water



is collected by means of a large dam and forebay, whence it passes through a tunnel to a surge tank, thence through the penstocks to the power house.

The forebay has a storage capacity of 63,828,000 gallons; it is located at a height of just over 1,500 feet above sea level and the tunnel is ten miles in length.

There are six penstocks. Five of the pipes, one for each turbine, are about 1,082 feet in length and they vary in inside diameter from 9 feet 2¼ inches down to 6 feet 2¾ inches, the static head being approximately 527 feet. The sixth pipe supplies the water for the turbo-generator set generating power for the operation of the electric trains on the Brenner railway. Five Francis vertical-shaft turbines each develop 45,000 h.p. at 242-250 r.p.m. Two 500-h.p. Pelton turbines were built to work at 500 r.p.m. for the supply of the power required for the station services, while three 14,700-h.p. 250-r.p.m. Pelton turbines are used to supply the railway.—*Electrical Review.*

The Electrical Testing Laboratories of New York have prepared a critical history of the development of rigid conduit, which has just been published by the Trade Extension Committee of the Rigid Conduit Section of the National Electrical Manufacturers Association. The book describes the various attempts made to eliminate hazards that developed in the early days when slightly protected wiring was buried behind plastered walls, in damp places and in positions subject to mechanical abuse. It points out the trial and failure of pasteboard and thin wall metal tubings of various types; the attempt to use a wood lined metal tubing and finally the successful employment of heavy wall mild steel conduit with suitable protective coatings which was approved by the first National Electric Code in 1897, and which has been employed to the present day with practically no changes in form or characteristics. Copies of the report may be secured by writing to George H. Sicard, Secretary, Rigid Conduit Section, National Electrical Manufacturers' Association, Utica, N.Y.

The Airship Service in Britain

The decision at which the government has arrived in regard to the Airship Service has commanded the almost unanimous approval of all parties in the House of Commons.

It may now be, perhaps, a fitting occasion to revert to an aspect of the building of these great airships to which, up till now, less attention appears to have been paid than is deserved. When they were built, the largest previous vessels were little more than half the size of what was proposed, and the methods of design, construction and operation employed in arriving at this great increase were, in many respects, radically new. The measures taken to supply the necessary fresh data were correspondingly far-reaching. All points on which information was wanted in regard to the mechanical construction, and some even in regard to metallurgical treatment, were settled by prolonged series of experiments, in the course of which the ships took some eighteen months more to build than had been anticipated. The mechanical result was according to the highest expectations. As everybody knows who has been on new ships, it is seldom that they are entirely free from what may be called structural stresses, and perhaps the best evidence of the perfection of the mechanical design and workmanship of this enormous structure, over 700 feet long and with a maximum diameter of over 130 feet, was the testimony of the highest authority in this country that the R.101 was the first airship ever built which showed no trace of creaking or vibration. This remarkable result, of the authenticity of which there can be no possible doubt, sums up over-all the care and the success with which the Ministry had tested its mechanical conclusions before putting them into practice, and when the ship took the air the same cautious and scientific spirit directed its earliest operations. In many respects, indeed, the ship had already proved itself, but, as we pointed out when it was first launched, the prospect of further progress in the development of this and other airships seemed to lie mainly in the continuance of the careful exploratory policy that had been pursued until then. It is easy after the event to see what changed this policy. The initial experiments on the vessel were made for the paramount purpose of discovering weaknesses if they were to be found, and thereafter of remedying them.

The catastrophe occurred when the vessel was used prematurely, not to discover weaknesses but to demonstrate achievement. It was known that there was something abnormal in the behaviour of the vessel, but it was decided to proceed without first clearing it up, presuming that it could not be a matter of serious consequence. It is idle now to speculate whether this presumption was adopted spontaneously by the brilliant and prudent staff who for five years had been leaving nothing to chance, or to some less scientific influence. The mistake that was made was in trusting to clearing up an obscurity in the vessel's action by the help of experience which had still to be acquired.

Having regard to the record of the Ministry's technical staff, the balance of probability seems to lie in favour of the hypothesis that they were at the least instigated to waive the more prudent practice of their earlier operations. If this be so, it adds great force to the demand for strengthening the scientific authority of the technical staff, as was in effect suggested by Sir John Simon. A clear distinction must be drawn between matters in regard to which practice is available to resolve questions of doubt and uncertainty, and those in which the practice has still to be acquired. When once the question has passed into the latter stage, it may well be that the supreme decisions should be made by the administrative staff. Until that point is reached, on the other hand, nothing should be done to weaken not only the authority, but the responsibility, of the scientific and technical staff.—*Engineering.*

The Garlock Packing Company, Palmyra, N.Y., have published a folder describing and illustrating Garlock 430 Chevron Packing, a new patented product of the company, which, it is stated, solves satisfactorily the problem of packing the rams and plungers of accumulators, presses, pumps and other heavy duty hydraulic equipment. Copies of the folder may be obtained from the company at the address shown above.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industria and other organizations employing technically trained men—without charge to either party

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Vacant

ROAD ENGINEER, with sales ability, speaking French and English fluently, for sales and inspection work in province of Quebec, by a Canadian company manufacturing and marketing road materials. Must be university graduate, not over 30 years of age. Permanent position with good prospects. Apply by letter giving qualifications, references, etc., to Box 729-V.

CHEMIST. Electrolytic chemist for laboratory work. Must have practical experience in this particular class of work. Location, Manitoba. Apply giving full information regarding experience to Box No. 731-V.

Capital to Invest

BUILDING CONSTRUCTION EXECUTIVE, located in New York city, Canadian born graduate McGill University, wishes to locate in Canada, preferably Vancouver, B.C. Will invest $20,000 and services in established construction concern where capital is needed for expansion. Fifteen years field and office experience. Past three years general manager of construction. Apply to Box No. 230-W.

ELECTRICAL ENGINEER. College graduate with about seven years designing experience with large manufacturer of electrical apparatus; would consider junior partnership with electrical contractor or electrical repair firm. Could invest several thousand dollars. Correspondence invited. Apply to Box No. 579-W.

Situations Wanted

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), 15 years experience, available on short notice. Experienced surveys, draughting, reinforced concrete design, municipal engineering, construction work, inspection, estimating. Apply to Box No. 107-W.

CIVIL ENGINEER, university graduate 1926, desires employment as junior engineer or instrumentman on construction work. Experience, resident engineer on railway construction, miscellaneous surveys. References. Available any time. Apply to Box No. 149-W.

CIVIL ENGINEER, B.Sc., age 34, is open for a position as construction engineer in charge of construction of hydro-electric plants or paper mills; designing engineer of hydro-electric developments or paper mills. Willing to make small investment. Apply to Box No. 157-W.

ELECTRICAL ENGINEER, B.Sc., McGill 1926. Five years experience in the design of switchboards, layouts and wiring diagrams. Considerable experience in high and low tension switchgear design. Fifteen months experience in switchboard estimating. At present employed; available on short notice. Correspondence invited. Apply to Box No. 247-W.

REINFORCED CONCRETE ENGINEER, B.Sc., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

ELECTRICAL ENGINEER. Graduate '25, wide experience in hydro-electric power stations, desires position on power plant design or related work. Apply to Box No. 278-W.

Situations Wanted

CIVIL ENGINEER, A.M.E.I.C., Canadian, R.P.E., Nova Scotia, 21 years engineering experience, both field and office, in railway, highways, foundations, concrete structures, water power and conservation, electric transmission lines, etc., experience comprising both surveys and construction, desires employment. Single. Will go anywhere. Working knowledge of French and Spanish. Available immediately. Apply to Box No. 327-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing and hoists. Also some experience in ventilating and heating work and calculators. Accustomed to structural design and details. Good references. Present location Montreal. For interview apply to Box No. 329-W.

CIVIL ENGINEER; age 48; married; A.M.E.I.C., R.P.E., Ontario and New Brunswick; 32 years experience in municipal engineering, on roadways, sewers, waterworks and buildings, desires position with either municipality or as engineer superintendent with contractor. Ten years with City of Toronto, construction engineer on roadway work; four years consulting engineer; three years engineer in charge of construction work; one year resident engineer, Dept. of Public Highways. Available immediately. Maritimes or Ontario preferred. Apply to Box No. 336-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., R.P.E. Ont., with twenty-four years experience embracing dams, wharves, grain elevators, foundations, pile driving, highways, municipal engineering, water power surveys, road locations, inspections and estimating, is open for engagement as engineer or superintendent in construction, operation or maintenance. Location immaterial. Apply to Box No. 358-W.

CIVIL ENGINEER, graduate, age 32, A.M.E.I.C. Ten years experience; seven years on design, construction, erection work and maintenance of paper mill and mine buildings and machinery. Three years on hydro-electric work in charge of surveys and field investigations; associate hydro-electric engineer, U.S. Engineers, on office investigation, design and estimates; desires permanent position in Canada. Apply to Box No. 362-W.

STRUCTURAL AND CIVIL ENGINEER, Jr.E.I.C., age 31, married. Was instrumentman and structural engineer on erection of Royal York hotel, and asst. resident engineer on James Bay Extension, T. & N.O. Rly. Experience includes structural, civil and mechanical draughting and all kinds of instrument work and special work. Qualified as captain in military engineering, R.M.C., Kingston. Available anywhere in Canada, preferably Toronto, for any kind of work. Apply to Box No. 377-W.

ENGINEER ADJUSTER, MANAGER, desires to connect with an industrial concern or department which is not showing a proper return with a view to suggesting more efficient methods and eliminating bad debts. Apply to Box No. 411-W.

CIVIL ENGINEER, S.E.I.C., 1930 graduate. Experience as instrumentman on city and railroad construction, desires to enter structural or hydraulic field. Available at once. Will go anywhere. Apply to Box No. 467-W.

Situations Wanted

CIVIL ENGINEER, A.M.E.I.C., age 39, with wide experience on design and construction of reinforced concrete structures, desires position. Apply to Box No. 475-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., with six years experience in paper mill and hydro-electric work, desires position in western Canada. Capable of handling reinforced concrete and steel design, paper mill equipment and piping layout, estimates, field surveys, or acting as resident engineer on construction. Now on west coast and available at once. Apply to Box No. 482-W.

MECHANICAL ENGINEER, Jr.E.I.C., B.Sc., '26. Ten months experience in pulp and paper steam control. Four years experience in detail and design, in pulp and paper mill, industrial plant and hydro-electric development work. Age 27. Married. Location immaterial. Apply to Box No. 521-W.

CIVIL ENGINEER, B.A.Sc., '29, with experience in supervision of construction and general office engineering, desires permanent position with contractor or engineer. Available at once. Apply to Box No. 524-W.

CIVIL ENGINEER, A.M.E.I.C., with twelve years experience embracing survey and construction, railway, hydro-electric and highways, foundations, pile driving, municipal engineering, water power surveys, road location, inspection and estimating, is open for engagement as resident engineer on construction or other responsible position. Experience comprises both office and outside work. Available immediately. Apply to Box No. 527-W.

MECHANICAL, CONSTRUCTION, AND DESIGNING ENGINEER, with special training in hydro-electric power development, underground steam distribution systems, and the operation of large electrical machinery. Active work desired. Apply to Box No. 528-W.

ELECTRICAL ENGINEER, S.E.I.C., B.Sc., E.E., 1931, desires to become associated with some branch of electrical engineering offering good opportunity for advancement. Sixteen months experience in draughting of electrical apparatus with large manufacturing concern; including layout work, and making of detail working drawings. Bulk of experience with industrial control apparatus. Location immaterial. Available on short notice. Apply to Box No. 532-W.

ELECTRICAL ENGINEER, married, graduate of McGill University, desires position in Ottawa, Montreal or Toronto. Experience includes four summers with a building concern as instrumentman and assistant engineer, two and one-half years with the Canadian Westinghouse Co., this time being distributed between tests, design and sales. At present employed but available on short notice. Apply to Box No. 533-W.

CIVIL ENGINEER, B.Sc., McGill University, Jr.E.I.C., age 32. Seven years general experience in hydro-electric power investigations and construction. Has been in charge of high power transmission lines location, also in charge extension surveys. Experience in office and field. Thorough knowledge of French. Best of references from former employers. Apply to Box No. 537-W.

STRUCTURAL ENGINEER, A.M.E.I.C., B.A.Sc. Wishes to join established firm of consulting engineers. Age 37. Married. Ten years experience design of reinforced concrete and steel on buildings. Two years practical contracting experience. Apply to Box No. 540-W.

CIVIL ENGINEER, McGill '20, A.M.E.I.C., P.E.Q., age 31, single. Experience includes general engineering, especially reinforced concrete work, and eight years of pulp and paper mill construction and layout. Best of references. Available on short notice. Apply to Box No. 547-W.

Situations Wanted

UNDERGRADUATE ENGINEER, S.E.I.C., junior year standing (Sask.), desires work to complete course. Electrical or mechanical work preferred. Apply to Box No. 553-W.

ELECTRICAL ENGINEER, S.E.I.C., graduating 1931, desires employment in electrical engineering. Sixteen months draughting experience on electrical machines with a large manufacturing company. Work included making layouts and detail working drawings. Available immediately. Location immaterial. Apply to Box No. 555-W.

A.M.E.I.C., graduate of University of Toronto, 1915. Building engineer and superintendent, with considerable experience as installation, sales and promotion engineer. Present connection, four years in responsible position with large utility corporation. Open for immediate connection where he can use his past experience. Location immaterial. Apply to Box No. 560-W.

ELECTRICAL ENGINEER, A.M.E.I.C., university graduate 1924. Experience includes one year test course and five years on design of induction motors with large manufacturer of electrical apparatus. Four summers as instrumentman on highway construction. Several years experience in accounting previous to attending university. Available at reasonable notice. Apply to Box No. 564-W.

CIVIL ENGINEER, S.E.I.C., graduating this year. Experience in railway maintenance, and instrumentman on location and construction. Desires to enter any branch of civil engineering or industrial work affording technical experience and an opportunity for increasing responsibility. Will go anywhere. Apply to Box No. 567-W.

CIVIL ENGINEER, A.M.E.I.C., ten years experience as mining engineer of a colliery, six years railway construction, including location, construction, bridge construction, and maintenance. Also one year on hydro transmission lines; one year government land surveys. Would consider position in any branch of construction, as resident engineer or instrumentman. Apply to Box No. 569-W.

CIVIL ENGINEER, B.Sc. McGill Univ., Jr.E.I.C. Five years experience along the lines of general construction, including structural steel. Available at once. Apply to Box No. 570-W.

MECHANICAL ENGINEER, A.M.E.I.C., experience in the design and maintenance of steel mills, zinc and sulphuric acid plants, cement plants; power house layouts; familiar with shop practices and costs, desires connection. Apply to Box No. 571-W.

YOUNG ENGINEER, Jr.E.I.C., experienced in design, details and erection of steel and concrete structures. Also a good theoretical and practical knowledge of steam, hydraulic and I.C. engine power plant. Good practical mechanical and electrical engineer, able to operate and maintain any type of machinery or power plant. Location immaterial. Apply to Box No. 572-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., (Univ. of B.C., '30), Undergraduate experience in pulp mill. One year's experience, Canadian General Electric Co., mech. dept. Single. Age 24. Desires position in technical design or sales. Location immaterial. Available on short notice. Apply to Box No. 577-W.

TEMPORARY EMPLOYMENT wanted by an engineer with wide experience in the design and operation of steam power plants and heating system. Apply to Box No. 584-W.

CIVIL ENGINEER, S.E.I.C., 1931 graduate, age 26. Experience in draughting, designing and estimating in structural engineering. Desires to enter structural, hydraulic (including hydrographic) or municipal field affording technical experience. Location immaterial. Available at once. Apply to Box No. 593-W.

ELECTRICAL ENGINEER, graduate Univ. of Alberta, '31, with excellent record, desires connection with electrical manufacturing firm, power or communication company. Good general experience includes one summer railway construction, two summers geological surveys in oil fields of Alberta, planetable topographer and asst. geologist. Available immediately. Apply to Box No. 596-W.

MECHANICAL ENGINEER, age 22, graduate '31, Univ. of Alberta, experience as draughtsman and instrumentman-inspector, is open for a position. Location immaterial. Apply to Box No. 598-W.

MECHANICAL ENGINEER, S.E.I.C., age 21, four years mechanical engineering, Queen's University, desires permanent employment. Experience in wood work, machine shop work, draughting and surveying. Location immaterial. Available at once. Apply to Box No. 600-W.

MECHANICAL ENGINEER, Canadian, technically trained; eighteen years experience as foreman, superintendent and engineer in manufacturing, repair work of all kinds, maintenance and special machinery building, desires change. Location immaterial. Available on one month's notice. Apply to Box No. 601-W.

ELECTRICAL OR MECHANICAL ENGINEER, B.Sc., '31, S.E.I.C., desires employment which will give experience and lead to advancement. Two summers in a large communication company, including draughting, switchboard and surveying. Available on short notice. Will go anywhere. Apply to Box No. 606-W.

CHEMICAL ENGINEER, S.E.I.C., University of Alberta '30, desires a position in any industry with chemical control. Experience includes three summer vacation periods of five months each as assistant chemist, and ten months as chief chemist with a cement company. Age 29. Single. Available at once. Apply to Box No. 609-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. (C.E.), Univ. of Man. '31, desires temporary or permanent employment on engineering work. Twenty months experience in summers as chainman, rodman and instrumentman on railway grade and bridge construction; also as inspector on reinforced concrete highway bridges. Salary and location immaterial. Available at once. Apply to Box No. 614-W.

DESIGNING ENGINEER, industrial building designer, Jr.E.I.C., age 31, married, capable of taking responsible charge of the structural design and architectural details of steel or concrete manufacturing plants or power houses, also has had considerable experience in the design of office buildings, etc., desires reasonably permanent position. Very highest references from present employers. Location immaterial. Apply to Box No. 615-W.

MECHANICAL ENGINEER, Jr.E.I.C., 5 years apprenticeship on general mechanical engineering; 10 years experience on heating and ventilating and mechanical equipment of buildings. Design, draughting and production. Desires change. Capable of taking charge of engineering department. Further particulars if required. Apply to Box No. 616-W.

POWER ENGINEER, M.E.I.C., age 42. Married. Thoroughly conversant with electrical, steam, mechanical and industrial engineering, desires executive position with large industrial, power or financial corporation. Best of references as to ability and positions held. Apply to Box No. 617-W.

CIVIL ENGINEER, Jr.E.I.C., B.A.Sc. '21, age 35, married. Five years designer and estimator with well-known firm of industrial builders; two years detailing, designing and estimating structural steel for bridges and buildings, also survey and municipal experience. Open for position immediately, will go anywhere. Apply to Box No. 618-W.

CIVIL ENGINEER, A.M.E.I.C., graduate '23, married, eight years municipal engineering experience. Sewerage and sewage disposal, water works, street pavement, etc. Also some experience highway construction. For the past three years engaged by firm of consulting municipal engineers. Desires permanent position. Location immaterial. Available immediately. References. Apply to Box No. 624-W.

ELECTRICAL ENGINEER, B.Sc., N.S. Tech. Coll. '31. Experience in design and construction of rural distribution lines, trouble shooting, inventories and general office work, desires position with public utility or industrial plant. Location immaterial. Available at once. Apply to Box No. 628-W.

The Dominion Hoist and Shovel Company, Ltd., which is jointly owned by the Dominion Bridge Company, Ltd., and Dominion Engineering Works, Ltd., recently completed the first "Dominion Gopher" gasolene shovel manufactured in Canada. The new machine has a bucket of one yard capacity and was built in accordance with the blue prints and specifications of American Hoist and Derrick Company of St. Paul, Minn., which is the American associate of Dominion Hoist and Shovel Company, Ltd. All casting, machine work and assembly was completed either in the Lachine or Longueuil shops of Dominion Engineering Works, Ltd., and in the opinion of experts, the quality and detail of the work are in every way equal, if not superior, to that turned out by the American associate company. It is stated that the manufacture of units of large capacity will be undertaken in the future. In addition, the company will make locomotive cranes, revolving cranes and contractors' hoists.

It is understood from officials of the parent companies that the "Canada First" policy of the Bennett government was an important factor in the decision to undertake the manufacture and sale of this equipment in Canada. In this connection the Dominion Bridge Company recently formed a new subsidiary, Canadian Pipe and Lining Company. This company will make concrete lined steel pipe in accordance with Hume specifications. Carrying the policy of diversification further, Dominion Engineering Works, Ltd., has recently concluded arrangements for the manufacture in Canada of Dominion Farrel-Sykes reduction gearing units.

Link-Belt Company, 910 S. Michigan Avenue, Chicago, Ill., are planning the preparation of a series of data sheets, one to be issued each month. The information and charts presented in this series of sheets will cover phases of material handling and power transmission technical data about which little has been published. Data Sheet No. 1, entitled "Material Handling and Power Transmission" and giving belt conveyor trajectory chart and data, and Sheet No. 2, containing data on belt conveyor horse power and stress, may be obtained from the Link-Belt Company, Chicago, Ill.

Vancouver Machinery Depot Ltd., 1155 Sixth avenue west, Vancouver, B.C., has recently published a booklet entitled "Atlas Excavators" which describes and illustrates this equipment. The company first constructed full revolving half-yard gasoline driven shovels in 1930, and have a number of machines of this size under construction at the present time. Copies of the booklet may be secured from the company at the above mentioned address.

The Upper Notch Automatic Hydro-Electric Power Plant

R. F. Legget, Jr.E.I.C., Resident Engineer,
P. J. Croft, Electrical Engineer,
J. R. Desloover, Co-ordinating Engineer,
Power Corporation of Canada, Ltd.

SUMMARY.—The Upper Notch plant is located on the Montreal river, 15 miles southeast of Cobalt, northern Ontario, in the centre of Canada's greatest mining district. The equipment consists of two 48-foot head, 6,500 h.p. 125 r.p.m. turbines; and two 6,500 kv.a., 11,000-volt, 25-cycle generators. The switchgear and control equipment are fully automatic and are designed for possible remote control from a distant supervisory point. The switchgear is of the metal clad type. The station output is transformed to 110,000 volts by three 4,500 kv.a. transformers and it is fed into an extensive transmission network by means of a line 32.7 miles long. The existing water storage developments and the possibilities for additional conservation projects on the Montreal river are worthy of note. The geological formation of the Montreal river is quite unusual. The difficulties of unwatering the river and concreting under very severe winter conditions constituted the major construction problems. The plant has been designed and constructed for the Northern Ontario Power Company, Ltd., by the engineering and construction divisions of the Power Corporation of Canada Ltd.

The Era of Automatic Plants

Automatic hydro-electric plants have definitely passed the experimental stage. A few small units were first equipped for automatic operation some ten years ago; since that time progress in the art has been rapid and today no unit is too large to be so controlled.

The Upper Notch plant, recently put into operation by the Northern Ontario Power Company, is one of the largest fully-automatic stations in Canada and represents the latest practice in this type of control. The extensive transmission network to which the plant is tied serves the important mining areas of Timmins, Gowganda, Kirkland Lake, Cobalt, Rouyn and other districts in northern Ontario and Quebec.

The outstanding features of a mining load are its high load factor, averaging around 90 per cent, and its most exacting requirements as to continuity of service. That the power supply must not fail is a cardinal rule in the mining country.

In designing the Upper Notch plant it was realized that a fully-automatic power station would not only offer the usual advantages of such control, but would also provide a standard of protection and reliability difficult to realize in a manually operated plant.

Hydraulic Features of the Montreal River

The area of the drainage basin tributary to the Upper Notch plant is 2,550 square miles. Most of the watershed is wooded and it is covered by a great number of lakes and swamps, a condition which has a considerable bearing on the regulation of the river.

The annual run-off at the plant averages fourteen inches (2,550 c.f.s.), which is rather low, when compared to values obtaining in most parts of the province of Quebec. In spite of the low run-off available, the Montreal river is, comparatively speaking, a well regulated stream. The present storage capacity is 13 billion cubic feet (297,000 acre feet), and it is expected that further conservation projects will increase the total available storage to 25 billion cubic feet (576,000 acre feet).

With this amount of storage used in the most efficient manner, the ultimate regulated flow is expected to reach 2,000 c.f.s. (0.78 c.f.s. per square mile), which is quite a high figure for a river of that size with an average yearly run-off of fourteen inches (1 c.f.s. per square mile).

The Upper Notch plant constitutes the first stage of a two-stage development on the lower portion of the Montreal river. The Lower Notch, or second stage, which will be developed at some future date, is capable of producing 40,000 h.p. at 67 per cent load factor. There already exist on the Montreal river four power plants having an ultimate aggregate capacity of 27,000 h.p. and the stream, when fully harnessed, will develop over 80,000 h.p. in six separate plants.

Geological Features of the Montreal River Valley

The developed head at the Upper Notch is 48 feet and the available undeveloped head at the Lower Notch, eleven miles downstream, is 148 feet. Studies were made to determine the advantages, if any, of developing the entire head of 206 feet in one stage at the Lower Notch, but this proposal was found unsuitable, partly on economical grounds and partly on account of the peculiar geological formation at the Lower Notch.

A geological fault runs up the valley of the Montreal river and close to the Lower Notch it joins the main Temiskaming fault running down the lake of that name. The Lower Notch itself is a gorge about 50 feet wide, caused by the fault, and diamond drilling operations have so far failed to reveal any considerable decrease in the width of the fault for some distance below the river bed.

Under such conditions the building of a dam, capable of creating a 200-foot head of water behind it, would involve problems difficult, though not impossible, to solve.

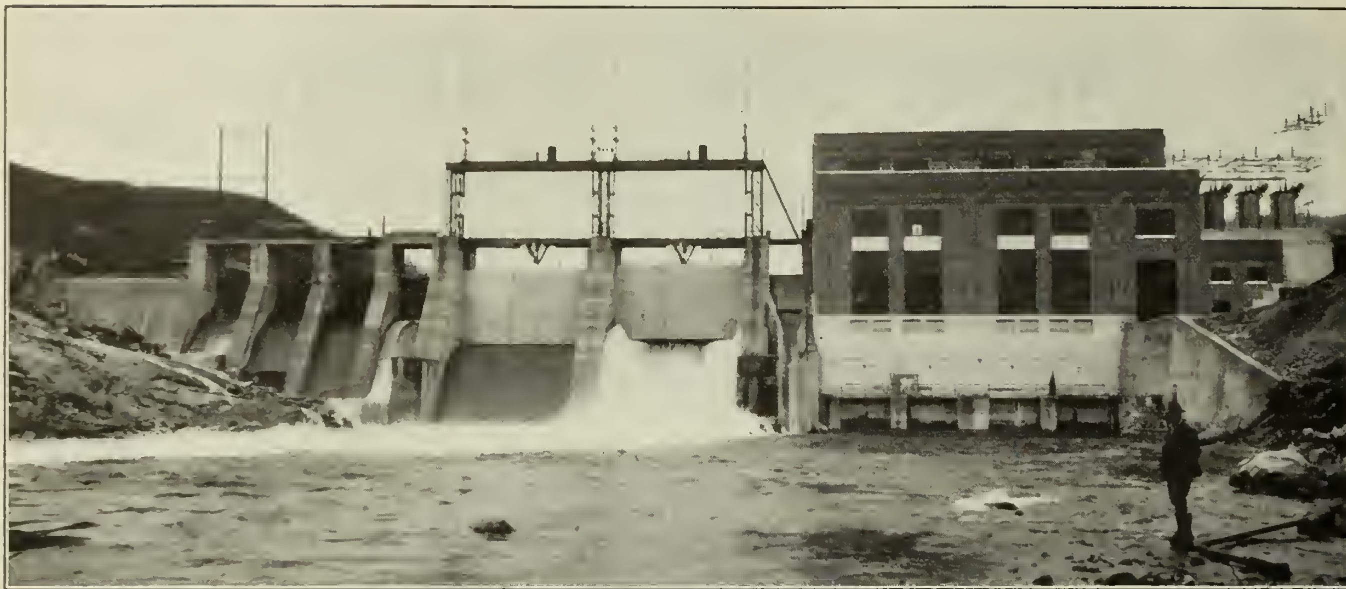

Fig. 1—General View of the Upper Notch Hydro-Electric Generating Station.

By adopting the multi-stage scheme, the difficulties which the lower site presents have been considerably reduced while the upper site presented no unusual foundation problems.

General Arrangement of Structures

The general layout of the development is quite simple, as shown by Fig. 1. The dam is a continuous, concrete, gravity structure, founded on bedrock and built at right angles to the river. It contains about 20,000 cubic yards of concrete and has a total length of 500 feet sub-divided as follows:—

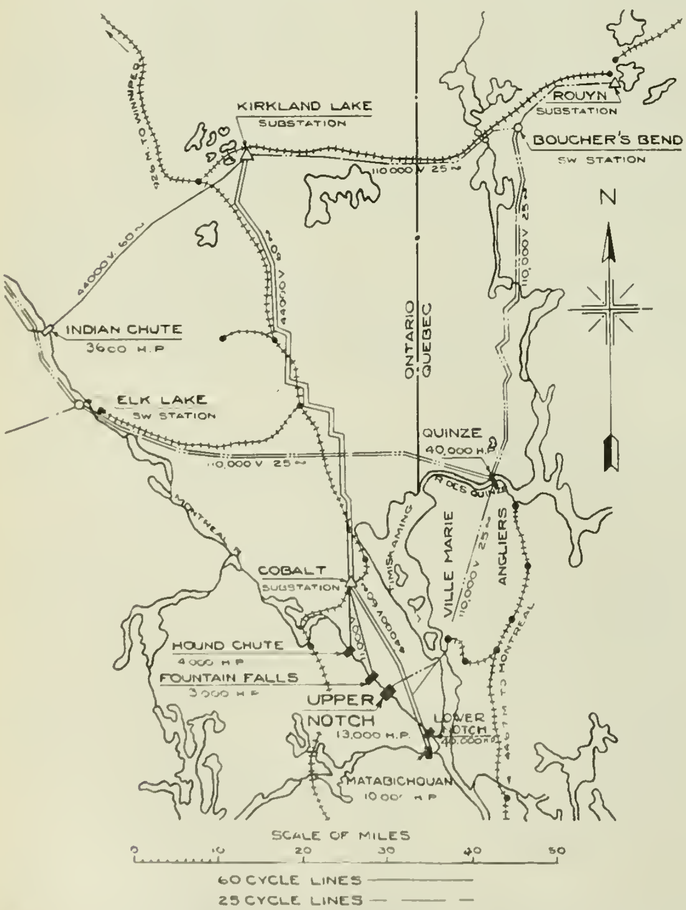

Fig. 2—Location Map of the Upper Notch Plant—Showing Part of the Mining District Served.

1. Beginning at the extreme east end of the dam, a cut-off corewall, 40 feet long.
2. A gravity section, 47 feet long, on which are located the transformer bank and runway to the gatehouse.
3. The power house section—100 feet long.
4. A 10-foot wide adjustable log chute.
5. A sluiceway section consisting of two 40-foot by 24-foot roller type sluicegates.
6. Four 15-foot wide stoplog openings over which are located a bridge and tracks for an electrically operated stoplog hoist.
7. An emergency spillway, 50 feet long, with crest at Elevation 784 (normal high water level).
8. A fishway pier and fishway, and, finally, at the extreme west end, a cut off wall, approximately 50 feet long.

The maximum discharge capacity of the sluicegates is 44,000 c.f.s. These are sheeted on the downstream side and electric heaters have been installed in the body of the gates and in the gains to facilitate winter operation.

The stoplogs are handled by means of an electrically driven hoist, which travels over the four stoplog openings.

The overflow structures have been designed for a maximum combined discharge capacity of 65,000 c.f.s. which corresponds to 25 c.f.s. per square mile of drainage, a figure which is conservative in view of the effect of the large storage reservoirs in reducing the flood flows.

General Arrangement of Power House

Referring to Fig. 3 and Fig. 4, it will be noted that the design is of the conventional type and that economy of space in the generator room is a feature.

The turbine intakes are divided into two openings, each equipped with a headgate and a set of trash racks and emergency gates. The headgates are hoisted electrically and may be operated from a set of control switches on the switchboard. The racks and emergency gates are handled by the 35-ton gatehouse crane.

The spiral scroll cases are of concrete and unlined and the draft tubes are of the elbow type and equipped with stoplog gains in order that they may be unwatered when required.

Turbines and Generators

The 6,500 h.p. turbines have Francis type cast iron runners. The guide bearings are lined with lignum vitae and are water lubricated.

The standard shifting ring and regulating cylinder method is used to operate the turbine gates.

The governors are located on the generator floor, but the pressure and sump tanks are mounted separately and the oil is pumped by motor-driven pumps installed near the tanks.

There is a complete pumping unit and tank for each machine and a spare motor-driven oil pump has also been installed. The three pumping units are interconnected and may be operated separately or in parallel.

The 6,500 kv.a. generators have direct-connected exciters. They have two guide bearings, and one thrust bearing, the latter supporting the weight of the generator, as well as the weight and thrust of the turbine.

The three bearings are lubricated by means of self-contained oil circulation systems operated from pumps geared to the generator shafts. Before entering the bearings the oil passes through oil coolers which are supplied with cooling water.

Each generator is equipped with a set of jacks which are normally used as automatic brakes to bring the unit to rest, but which may also be used to lift the entire unit sufficiently to permit the inspection or renewal of the thrust bearing parts. The jacks are oil-operated and form part of the automatic control.

In view of the fact that help may not be available immediately after a possible failure of the governors to keep the units under control, the generators have been designed to withstand operation at the runaway speed of the turbines (240 r.p.m.) for ten hours.

The principal dimensions and weights of the units are as follows:—

Maximum diameter of turbine runner....... 9.4 feet
Diameter of generator rotor................13.4 feet
Total weight of all revolving parts..........75 tons
Maximum overall diameter of generator.....19 feet

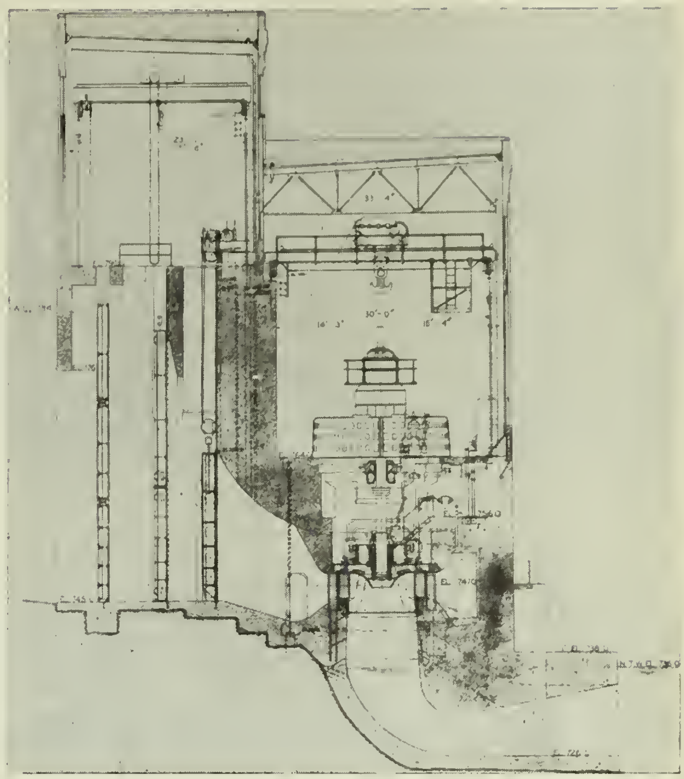

Fig. 3—Cross Section through Power House.

Switchboard and Switching Equipment

The switchboard is located at the east end of the generator room and consists of nine panels on which all the manual and automatic controls are mounted.

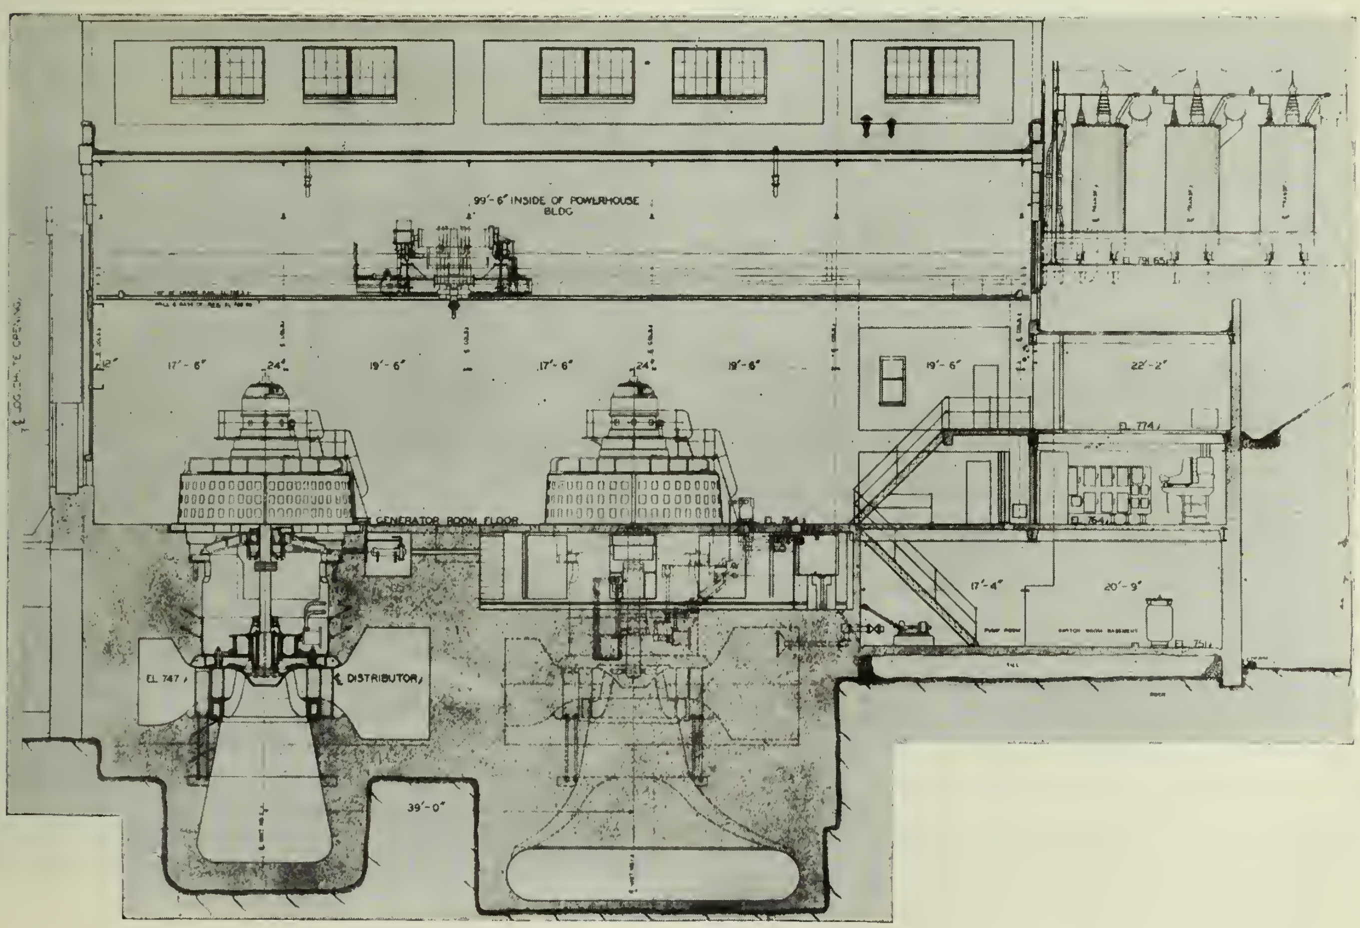

Fig. 4—Longitudinal Section through Generator Room and Switch Room.

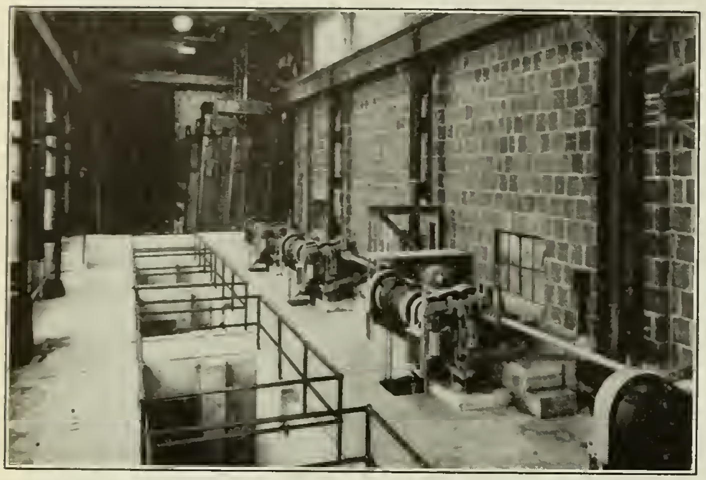

Fig. 5—View of the Gatehouse.

The equipment is described in more detail under "Automatic Operation."

The switchgear is installed in a separate room at the east end of the building. It is of the self-contained metal-clad type and apart from the station service transformer bus there is no bus work, either upon or in cells, anywhere in the plant. Four 250,000 kv.a. rupturing capacity oil circuit breakers are installed at present, one for each generator, one for the power transformers, and one for the station service transformer bank.

Transformers and Transmission Line

The transformers and the high tension switching structure are located outdoors. Three transformers are normally in service and a fourth is held as a spare. They are water-cooled and all oil and water piping enters the tanks through the bottom and is readily accessible from a tunnel located under the transformer platform.

The connections are 11,000-volt isolated delta to 110,000-volt grounded star.

The transformers may be disconnected from the outgoing line by means of an air-break switch, mounted on the switching structure.

The transmission line is 32.7 miles long and is strung with 286,800 c.m. A.C.S.R. on "H" frame wood pole structures. The average span is 450 feet. The telephone line is strung on the same structure and consists of two 20,870 c.m. special A.C.S.R. conductors.

Automatic Operation

The control apparatus in use at the Upper Notch is of the type known as "fully-automatic." Although as at present operated, the starting or stopping indication is given by an attendant, who throws up or down a small tumbler switch on the generator panel, the releasing of brakes, opening of turbine gates, bringing of the wheel to speed, matching of frequencies, and finally synchronizing and connecting to the line are fully-automatic and are beyond the control of the attendant until the full train of operations is completed.

Briefly, the train of operations for starting the plant is as follows:—The generator bus is kept alive at all times (even though both machines may be shut down), from the outer system, the transformer oil circuit breaker being kept closed. Station service is maintained from the generator bus, the breaker feeding the service bank being closed at all times. The main governor oil pump motors run only when required, and maintain pressure at approximately 175 pounds in the pressure tanks of both governors, under the control of a pressure relay and across-the-line starter.

The attendant, after checking all clearances, etc., as a precautionary measure, closes the small starting switch on the panel controlling the machine he proposes to start, completing a circuit through the coil of a master relay "3," provided that:—

(*a*) Generator windings are not overheated due to recent run at continued over-load.

(*b*) Annunciator lockout relays are not in the alarm position due to existence of some fault condition.

(*c*) Governor oil pressure is above the required minimum.

This circuit being completed, relay "3" closes a number of contacts, which control circuits to various parts of the automatic equipment. One of these circuits energizes the control solenoid of the generator brake valve, clearing the electrical interlock on the machine brakes. Another circuit energizes the control solenoid of the turbine governor, which in turn opens a number of oil ports, admitting oil pressure to:—first: the gate-latch cylinder, lifting the latch which locks the gates in the closed position during periods of shut down; second: to the generator brake valve, which, when the gate latch is fully lifted, closes and cuts off oil pressure from the brake cylinders releasing the brakes; and finally: to the pilot valve in the governor head itself, causing the governor slowly to open the turbine gates. A third circuit from relay "3" contacts closes a pilot relay on the pressure tank, short circuiting the pressure maintaining device previously referred to, and causing the pump to run continuously unloading automatically as required.

When the gates come to approximately the 1/10 position, the wheel begins to rotate, the gear-pump on the main shaft immediately taking hold of the lubrication requirements. After about two revolutions of the shaft, the oil stream appears in the gauge glass on the exciter platform, and after a further few seconds, appears also in the sight-flow indicators on the machine piping.

The unit continues to gain speed as the gates slowly open. At 65 per cent full speed, an element of the speed switch on the top of the exciter opens its contacts, clearing the lubricating oil and cooling water flow alarms, which, since they cause the unit to shut down, should the flow

Fig. 6—The Generator Room.

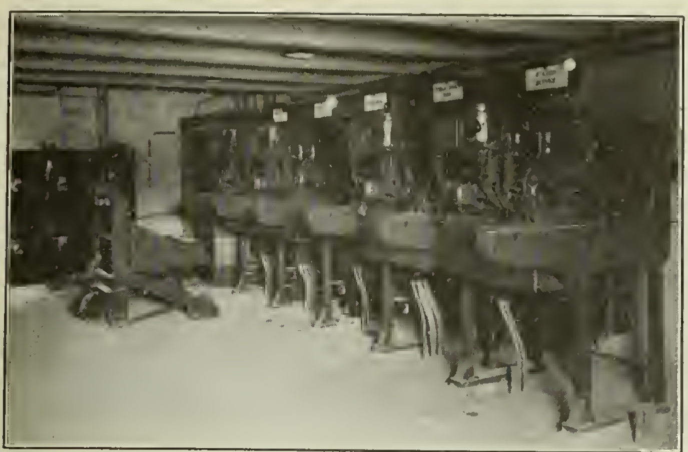

Fig. 7—Switchgear.

become inadequate, must of necessity be short-circuited during the start up, until the flow has been established in sufficient strength to hold their contacts closed.

As the machine gathers speed, voltage on the direct-connected exciter begins to build up, and at the exciter voltage of about 50 volts, a contact-making voltmeter relay (53) completes a circuit to the coils of two auxiliary contactors 40X and 41X on the field panel. These two contactors close their contacts, 41X closing the circuit to the field switch closing coil, and 40X closing the circuit to the lifting coil and field failure relay No. 40. The field switch now closes and the contactors drop out, 41X immediately and 40X after a delay long enough to allow the machine field current to build up and hold the field failure relay 40 in circuit.

The machine field is now excited and the main A.C. voltage builds up on the machine, the voltage coils of the various synchronizing devices becoming energized from the potential transformers connected to the machine leads. The motor driving the governor head begins to rotate, and the governor commences to regulate the speed of the unit. The voltage regulator commences to regulate the voltage of the generator, holding it steady when it reaches the normal value of 11,000 volts. The coils of the automatic synchronizing relays become energized, and the synchroscope begins to rotate at a speed corresponding to the difference between the frequency of the bus and that of the incoming machine.

By a patented system of relay connections, each time the synchroscope needle, travelling in a "Slow" direction, passes the zero-point of the dial, at a speed too great for synchronizing, a short impulse is given to the synchronizing motor of the governor to increase the gate opening. Conversely, each time the needle travelling in the "Fast" direction passes the zero-point too quickly for synchronizing, an impulse is sent to decrease the gate openings. The increase speed impulses are of longer duration than the decrease-speed impulses, so that the machine is rapidly brought to a speed just above synchronous speed, and slowed down by fine-step control. Finally, when the synchroscope needle, travelling in the "Fast" direction only, and at a suitably slow speed, approaches to within a short adjustable distance from the zero-point, a master contact is made to the auxiliary contactor, which closes the oil circuit breaker contacts on the point of synchronism. The auxiliary switches on the breaker disconnect the synchronizing relays as soon as the circuit is closed, and the machine is left running in synchronism, at full voltage and no load.

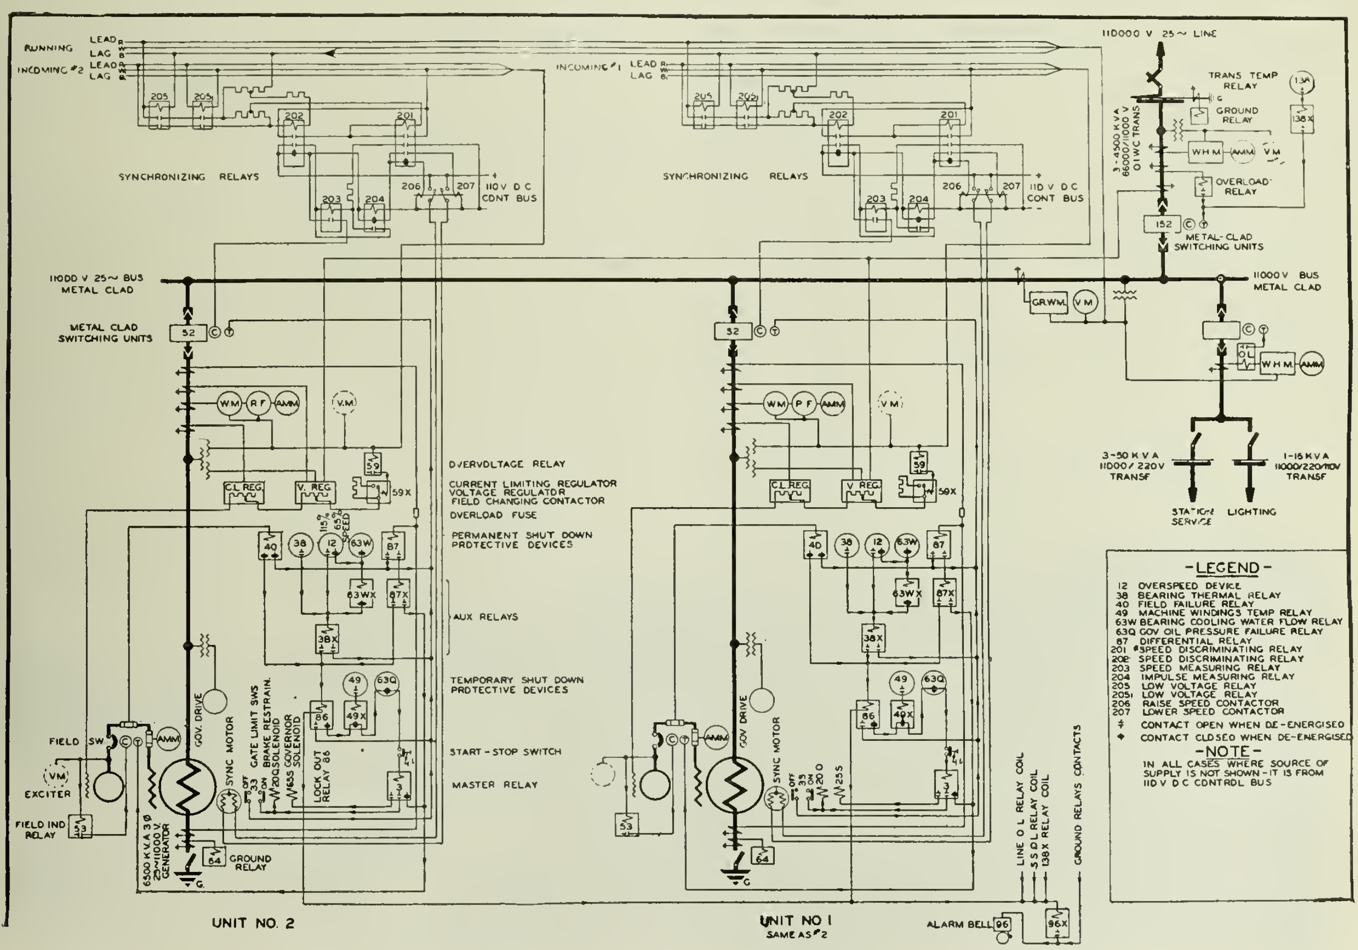

Fig. 8—Single Line Diagram of Automatic Features.

Fig. 9—General View of the Site on June 14th, 1929, showing First Camp Buildings.

At the same time, an auxiliary contact on the oil-circuit breaker sends a continuous impulse to the synchronizing motor to increase the gate opening. The machine takes up load until the governor comes up against its limit stop, which has been previously set for a fixed block of load. Shortly after reaching this point, the synchronizing motor is cut off by the limit switch on the speeder rod, adjusted to suit.

If, as at present, it is desired that the plant shall help in regulating the system, the automatic load-pick-up feature is disconnected, and the unit, after synchronizing, is left without load, until a suitable manual adjustment is made by the attendant. It is the intention that this feature will in the future be supervisorily controlled from a distant plant.

The unit, while running, is protected against a broad range of fault conditions, including winding-breakdown, grounds, overspeed, overvoltage, overcurrent, field failure, hot windings, hot bearings, oil flow failure, cooling water failure (thrust bearing) and loss of governor pressure. Overheated windings, due to a period at an overload not sufficient to operate the overcurrent relays, will cause the machine to shut down, as also will a loss of governor pressure from some cause; in either case the machine will re-start as soon as normal conditions are restored. A rise of voltage above 14,000 volts inserts a block of resistance temporarily into the field circuits, but does not shut down the machine. In all the other cases, the machine is tripped off the bus, shut down, and locked out, a warning signal summoning the attendant should he be away from the plant.

The normal shut-down is practically a reverse of the train described in detail for starting up. The attendant opens the tumbler starting switch, de-energizing the governor solenoid, and placing the pressure-system on the automatic pressure-maintaining cycle. The gates are brought promptly to the "Closed" position, and the gate latch descends into the "Locked" position. A limit switch on the gate rods trips the oil circuit breaker, and an auxiliary switch on the breaker trips the field switch. As soon as the gates are definitely closed, the latch locked and the oil circuit breaker open, the brake valve re-opens admitting oil pressure to the brakes, which bring the machine to rest after a coasting period of a few minutes.

The plant is equipped, in addition to the automatic features, with a full complement of manual gear of orthodox design, so that, if required, at any time, a unit may be started up by hand control or hand pump, and manually synchronized and connected to the line in the ordinary way.

Main Features of Construction

The site of the works was connected by a short spur line, built by the construction force, to the Silver Centre branch of the Temiskaming and Northern Ontario Railway on which runs a service of three trains per week. This was the only means of access to the job, the nearest road head being five miles distant.

Construction work started on July 1st, 1929, when the entire site was covered with untouched second growth bush. Within two weeks twenty acres had been cleared and the development of the construction camp was well advanced. Eventually the camp accommodated about 350 persons; it was operated by the Power Corporation of Canada and throughout the duration of the job it won the approval of the Provincial Sanitary Authority. A recreation hall was provided for the use of the men, and during the winter months a school was run in the evenings in which elementary subjects were taught to the men by a representative of the Frontier College.

Fig. 10—General View of the Site on July 4th, 1930, showing the Result of Twelve Months of Construction Activity.

Power for construction purposes was obtained from Fountain Falls, the nearest power station to the job, being delivered over a temporary 11,000-volt transmission line, the maximum load averaging about 400 h.p.

The dam is founded on close grained Nipissing diabase, a considerable area of that exposed showing marked signs of glaciation. The overburden was typical glacial drift, containing a high percentage of boulders which impeded excavation considerably. On the other hand, glacial action was also responsible for the extensive areas of comparatively level ground adjoining the dam site—approximately at the same elevation as the top of the dam—which served admirably as working areas. The diabase proved to be very hard drilling. At the west end of the dam, it proved to be somewhat fractured, as is so typical of the Cobalt region, but this did not affect the essential soundness of the foundation.

The construction schedule was governed by the fact that power had to be delivered before the end of 1930. As some winter concreting was thus inevitable, it was decided to equip the job for large scale winter work in order to place the main bulk of the concrete in the dam (i.e. that portion occupying the old river bed) in the early part of 1930, the reduced flow at this time being diverted through a special sluiceway left between dam and power house. In this way, the main sluiceways were ready to take care of the spring flood flow in the river with no liability of damage to cofferdams.

The following quantities of material dealt with will give some indication of the nature of the work to be done.

Cofferdams	4,880 cubic yards
Earth Excavation	27,850 cubic yards
Rock Excavation	12,170 cubic yards
Concrete (all classes)	19,890 cubic yards
Reinforcing Steel	482,050 pounds
Lumber used (about)	1,000,000 board feet
Equipment handled (about)	1,000 tons

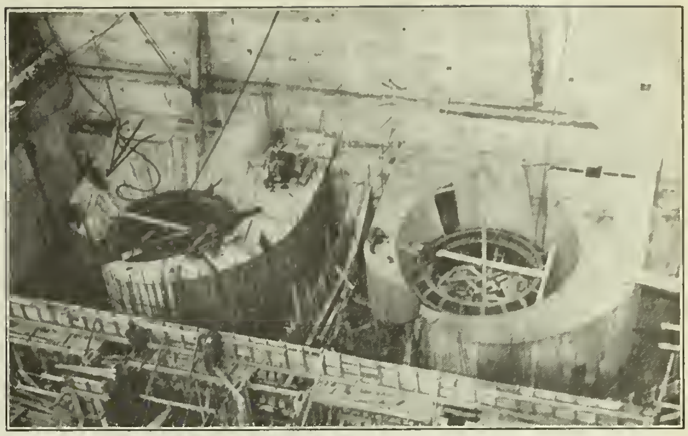

Fig. 11—Power House Substructure showing Forms for Concrete Spiral Scroll Case.

Earth excavation, on both sides of the river, was generally completed before the freeze-up of the 1929-1930 winter set in, sluicing being successfully employed for a great part of this work. Rock excavation in the headrace started as soon as practicable and thereafter proceeded steadily, through power house foundations and tailrace, all the rock excavated being passed through jaw crushers, and conveyed by bucket and belt to a store pile for use as concrete aggregate.

Concreting started on October 25th, the gravity dam east of the power house being first constructed, the gatehouse piers and sluice piers 1 and 3 (lower portions) following. Work on the main cofferdam, spanning between sluice piers 1 and 3, started in December and proceeded concurrently with the concreting of the gatehouse which was completed up to its top level in order to withstand the pressure against it due to the raising of the water upstream by the main cofferdam.

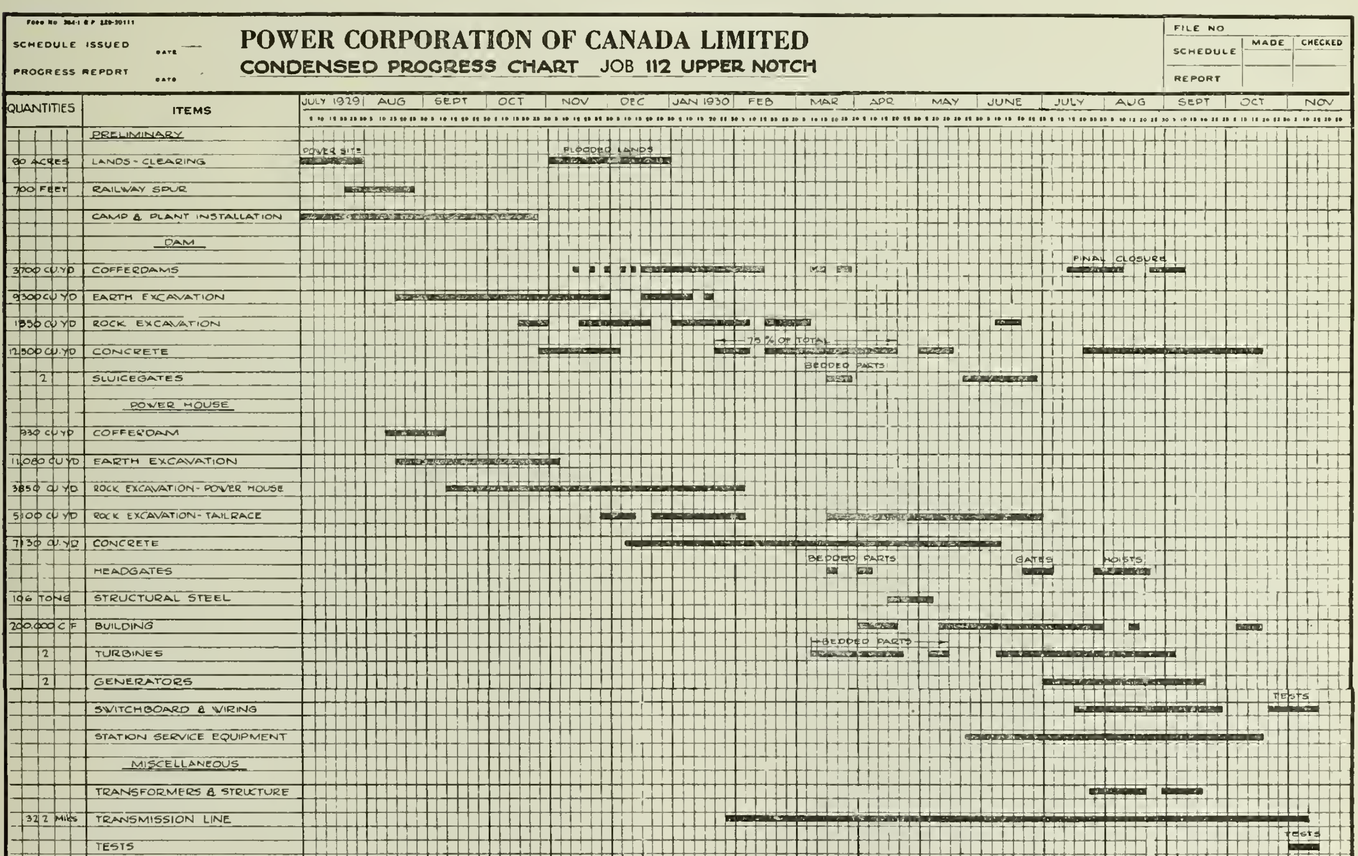

Fig. 12—Condensed Progress Chart Upper Notch Job.

The area enclosed by this cofferdam was pumped dry on February 18th; the pumps were withdrawn on March 11th, five weeks before the spring flood started, 5,615 cubic yards of concrete having been placed between these dates. Concreting of the power house substructure was by this time in full swing, being completed on June 7th, after which the installation of mechanical and electrical equipment proceeded without interruption, the last of the main concreting being done meanwhile at the western end of the dam. The first unit was started up on August 27th, and power was delivered over the transmission line for the first time on November 12th. The works, complete in every respect, were handed over to the Northern Ontario Power Company on December 24th, 1930.

Construction methods were not, in general, unusual, the placing of concrete during winter months, for example, following methods which can now be regarded as almost standardized in Canada. Great care was exercised in the adoption of these methods, as a result of which no concrete froze; no anti-freezing compounds were used; and concrete was deposited with the air temperature as low as minus 40 degrees F.

Careful records were kept of the extra cost involved due to this winter concreting; the increase amounted to one per cent of the total construction cost. This was more than offset, however, by the saving which the general schedule effected in the cost of cofferdams. This saving was due to the fact that the cofferdams had not to be designed for spring flood conditions (although the main cribs had to withstand ice pressure), and that further, the tops of the main cribs were below the sills of the main sluiceways, and there was, therefore, no necessity for them to be removed. All the cofferdams were built as timber cribs, rock filled, and sheeted with either 2″ or 3″ T & G sheeting, the greater part of the 3″ sheeting being salvaged.

All concrete was mixed in a central mixing plant, equipped with a one cubic yard mixer, which discharged directly into what was called a "Dump Hopper." This had a capacity of three cubic yards, and was fitted with a radial gate in the bottom so arranged as to discharge into the two cubic yard dump cars used for transporting the concrete to the dam and power house. This arrangement rendered necessary the use of one concrete "train" of two dump cars only to deliver regularly the output of the mixer, in which all batches were mixed for at least 1¼ minutes; and as proof of its efficacy, it may be recorded that in fifteen working hours, 449 cubic yards of concrete were placed in the dam, at a point over 500 feet from the mixing plant, the time given including that required for starting up and cleaning up the entire concreting system.

Rock excavation methods call for no special mention.

The power house superstructure was constructed of hollow tile built around a steel framework, experience on several previous jobs in the same district having proved that tile withstands the severe climatic conditions of northern Ontario very well. The placing of the tiles was done from platforms suspended by means of patent scaffolds cantilevered out from the steel roof beams, this arrangement proving to be most satisfactory, the entire building being completed in two working weeks. The saving effected by the use of these scaffolds more than offset the freight costs from Toronto.

During the construction of the plant (in June, 1930), an exceptional flood was experienced, caused by a week of heavy rainfall culminating in a fall of five inches in twenty-seven hours. The only damage to the works was the washing away of the tailrace cofferdam, but as demolition of this was just about to commence, the "damage" saved the job a considerable amount of money.

Construction of the 32.7 mile transmission line was carried out during 1930, hauling being done during the previous winter; it followed standard methods, the only special section being the crossing of Lake Temiskaming by a 1,400-foot span between two 150-foot steel towers.

Mr. D. Hutchison was construction superintendent in charge of the construction of all the work herein described, with R. F. Legget, Jr.E.I.C., as resident engineer.

The total cost of the completed plant and transmission line was approximately $1,500,000.

The Corrosion of Metals

Alfred Stansfield, D.Sc., M.E.I.C.,
Professor of Metallurgy, McGill University, Montreal.

An address delivered at a meeting of the Ottawa Branch of The Engineering Institute of Canada, April 9th, 1931.

In prehistoric times, when our ancestors used weapons of bone and flint, such weapons were not affected by atmospheric conditions, although, of course, the wooden handles would decay if exposed to moisture. Coins and ornaments of gold and silver, the so-called "noble metals," are scarcely corroded at all even after centuries of exposure to the atmosphere. In the bronze age, articles of copper or bronze were corroded gradually when exposed to water containing carbonic acid and would become covered with a beautiful carbonate patina, but many such articles of bronze have survived thousands of years and can be seen in our museums today.

The metal iron, although much stronger than the other metals, is corroded far more rapidly when exposed to moisture and, as a consequence, we have very few relics today of the early iron age. In our present steel age the rapid corrosion of tools and structures, accelerated by sulphuric acid fumes in the air resulting from our use of coal, takes a heavy toll of our metallic possessions.

The corrosion of a metal means, in effect, its chemical combination with oxygen or other non-metallic element to form a chemical compound. The affinity of a metal for oxygen may vary from that of gold, which has no affinity, and the other "noble metals," silver, mercury and platinum, which have very little affinity, to metals like magnesium and calcium which have a great affinity for it. The degree of affinity of a metal for oxygen can be measured roughly by the amount of heat given out while the combination is taking place. The tendency of a metal to combine with oxygen and other non-metallic elements and to pass into solution in water as a chemical compound can be measured electrically. The metals can be arranged in order in accordance with these properties. The two lists are quite similar and show the *tendency* of each metal to become corroded, but not its actual corrodibility; thus the metal aluminum has a greater tendency than iron to form chemical compounds, but it does not corrode so readily on account of the strong protecting film of oxide with which it is covered.

The exact nature of rust is extremely difficult to explain. In the corrosion of metals by liquid reagents direct re-action does not usually take place. Thus, if a piece

Fig. 1

of pure zinc be placed in dilute sulphuric acid it will not dissolve, but if a piece of copper is placed alongside, an electrolytic action will take place and the zinc will dissolve. This electrolytic action is the basis of most of the cases of ordinary rusting. Thus, one condition for avoiding corrosion is that the metal should be pure. Zinc may be produced electrolytically with a purity of 99.994 per cent. This zinc when exposed to dilute sulphuric acid or hydrochloric acid will suffer scarcely any corrosion. Also aluminum refined by the Hoopes process may be 99.983 per cent pure, and this metal if sprayed with a 20 per cent salt solution for two weeks, will not lose its bright surface.

It has been deduced from microscopic examination of cast iron that the heterogeneous arrangement of the graphite and pure iron particles tends to produce electrolysis and corrosion. Similar actions take place in the case of other metals. For instance, steel consisting of pure iron with ribs of chemical compounds, carbides, etc., shows the same tendency to rust.

Steel containing about 0.85 per cent of carbon, which has cooled slowly from a red heat, shows when highly magnified a structure termed "pearlite" consisting of alternating bands of "ferrite" or pure iron and "cementite" or carbide of iron as shown in Fig. 1. Steel with a smaller proportion of carbon shows in addition large areas of ferrite or pure iron as shown in Fig. 2.

It is very difficult to get the various constituents in steel sufficiently homogeneously arranged so that electrolytic action will not take place.

The nearest that is possible toward this homogeneity is obtained in electrolytic iron where the atoms throughout each crystalline grain are oriented in a particular direction.

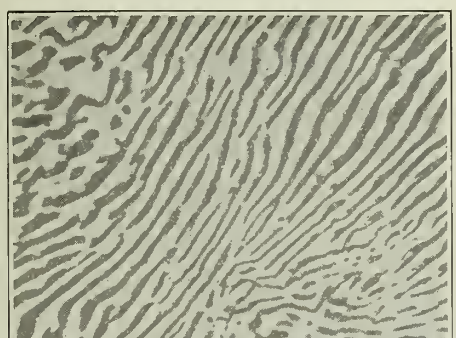

Fig. 2

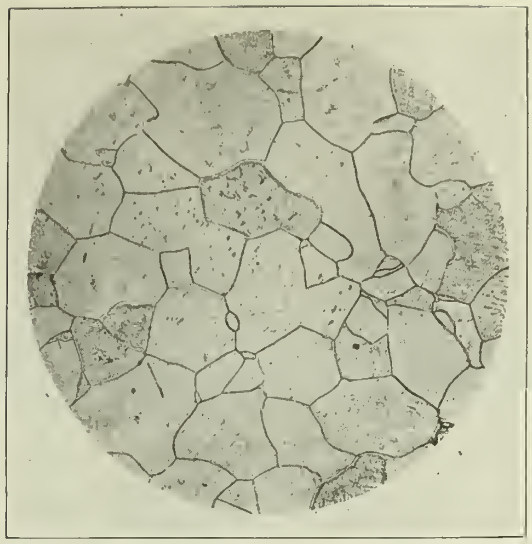

Fig. 3

Fig. 3 is a highly magnified view of pure electrolytic iron. All the grains are equally pure, but owing to differences in orientation some of them appear different after etching with an acid. The joints between the grains are clearly marked.

This form of iron is not so rapidly attacked, although even in this case some electrolysis takes place on account of the fact that the orientation of the atoms in the different grains will be in different directions.

This orientation can be deduced from observation of the diffraction pictures obtained by the use of X-rays. From such pictures the arrangement of the atoms in a metallic crystalline grain can be worked out, the atoms being distributed in regular lattice patterns throughout the crystal.

It is a remarkable thing that the metal is actually stronger at the joints between the various crystalline grains than in the grains themselves, but in spite of the greater strength, which depends on the heterogeneous arrangement of the atoms in these joints, there is a greater tendency for corrosion, possibly on account of electrolysis between the adjacent grains, and the joints are dissolved and made visible when a polished piece of metal is treated with etching reagents as in Fig. 3. Another interesting feature is that in preparing a specimen for microscopic examination the surface is highly polished and in this act of polishing an amorphous layer of uncrystallized metal is smeared over the surface. This layer is more resistant to corrosion on

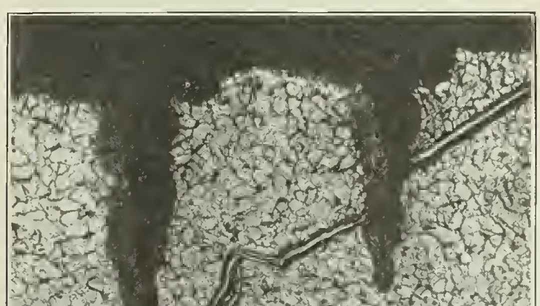

Fig. 4

account of its homogeneous make-up. This it may be stated that polished metals have better rust-resisting properties than unpolishing metals.

If a piece of iron and a piece of copper are placed together in water or in a weak acid solution, an electrolytic action is obtained and the iron is corroded. However, if one-quarter of one per cent of copper is united with iron to produce a copper-steel, there is less liability to corrosion than with iron itself. The copper contained in the steel is not separate from the iron, but exists as "a solid solution," that is, the atoms of copper are spread uniformly throughout the mass of iron and the copper in this combination does not cause electrolysis but to some extent confers its non-corroding properties upon the surrounding metal.

In Monel metal, which consists of 70 per cent nickel and 30 per cent copper, the two constituents form a solid solution, being uniformly mixed in the mass and there is no difference between one crystalline grain and another. The same may be said with regard to stainless steel when it has been given a suitable heat-treatment. Thus, as a summing up, freedom from corrosion may be approximated by having the metals pure or by having the constituents of the metals homogeneous.

Even if the metal itself is homogeneous, electrolysis will be produced if the liquid to which it is exposed has a different composition at different parts, and even a difference in the amount of dissolved oxygen will set up electrolysis and cause corrosion of the metal. In a beaker of water there is usually more oxygen near the surface than lower down, and if a strip of pure iron is placed vertically in the water, electrolysis will be set up, the upper part of the strip acting as a cathode while the lower part acts as an anode. It follows that the upper part, where there is plenty of oxygen, is protected and that rusting takes place at the bottom of the strip where there is less oxygen. This explains the well-known fact that corrosion takes place beneath loose patches of rust and within any small cavities in the metal.

It may be wondered why iron rusts more readily than, for instance, aluminum, when the latter has a much stronger affinity for oxygen than the former. The fact is that aluminum, on account of this strong affinity, becomes immediately covered with an oxide film which prevents further corrosion. The film of oxide which develops over iron, on the other hand, is not as a rule strong enough to prevent corrosion. The film of oxide on the surface of aluminum and even the thinner film on the surface of iron has been isolated by chemical means and examined under a microscope.

As an example of a somewhat unexpected result of corrosion, the piece of boiler plate shown in Fig. 4 may be taken. In this plate cracks had developed, and investigations showed that the apparent cracks were really corrosion lines in the steel. It appeared that scale had formed over the steel and that the warping of the plate had repeatedly cracked the scale, thus enabling corrosion to penetrate deeply at certain points. Such action may be termed "corrosion fatigue." It is supposed that electrolytic action takes place between metal in distress and metal not in distress; this causes corrosion cracks across the direction of mechanical bending.

The irregular line crossing Fig. 4 is a scratch produced by drawing a needle across the polished surface in order to find whether the corrosion cracks were empty or had a solid filling. This test showed that the cracks contained a very hard material resulting from the corrosion of the steel.

The Lighthouse Service of Canada

J. G. Macphail, B.A., B.Sc., M.E.I.C.,

Commissioner of Lights, Department of Marine, Ottawa.

Based on an Address presented before the Montreal Branch of The Engineering Institute of Canada, January 22nd, 1931.

The coastline of Canada extends over 52,800 miles. The Lighthouse Service of Canada is distributed over a large part of that coastline; also over the south and east coasts of Newfoundland and Newfoundland-Labrador. The Service comprises 1,855 lighthouses, 374 fog signals, 11 lightships, 584 gas and signal buoys, and approximately 9,000 unlighted aids to navigation of various kinds, a total of 11,824 aids to navigation of all kinds. In addition to those signals which are picked up directly by the natural senses, the government maintains 12 radio direction finding stations and 18 radio beacons.

Altogether over two thousand persons are employed in the Lighthouse Service of Canada, extending as it does from Cape Race in the extreme east to Queen Charlotte islands in the Pacific ocean.

When one thinks of the Lighthouse Service, he is apt to associate it with some particular light or buoy with which he is familiar: for example, persons living in Montreal and making an occasional steamer voyage, either above or below, will naturally think of those flashing lights, red and white, on the buoys which are passed on either hand. Viewing lighthouse establishments from the deck of a steamer, the individual establishments may appear small and trivial, but those flashing gas buoy lights are quite complex in their arrangement. The buoy itself weighs from 5 to 8 tons; the lantern is equipped with polished cut glass lens and flashing apparatus, the whole costing about $3,000. Gas buoys employed on the open sea coast vary in size up to 19 tons, with an over-all length of 60 feet, and having a draught of 30 feet. They are moored in depths

Fig. 1—Placing Gas Buoy.

of water up to 52 fathoms, the weight of chain mooring being approximately 5 tons.

Fig. 1 shows one of these buoys being placed in position.

The means of illumination is acetylene, the gas being either dissolved in acetone and stored under pressure in steel containers placed in pockets in the buoy, or generated from calcium carbide in the buoy itself. In buoys of this type (as shown in Fig. 2) seawater entering through the bottom valve acts upon the carbide and the gas thus produced expels the water either wholly or in part. As the

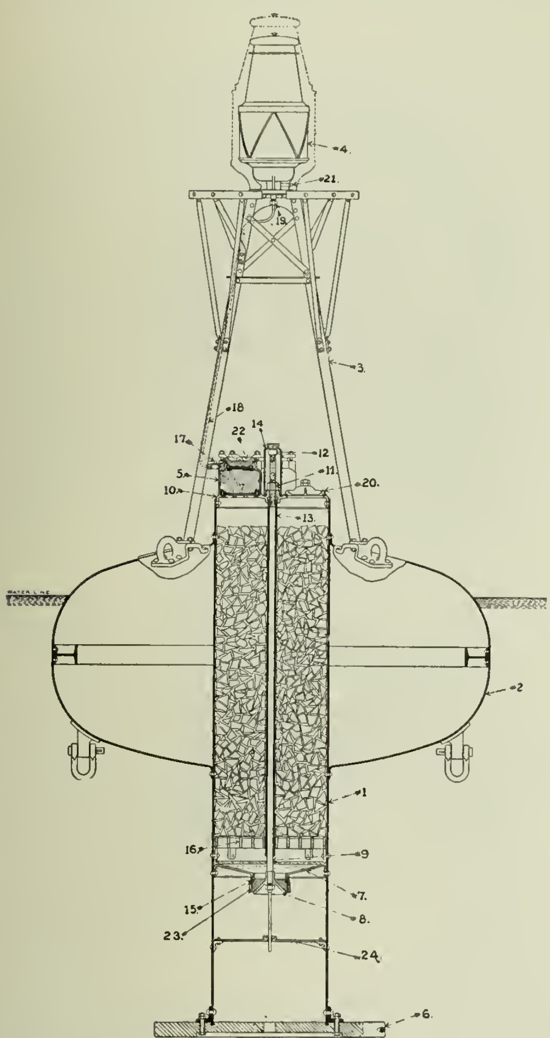

Fig. 2—Diagram of Gas Buoy.

imprisoned gas is consumed in the lantern the seawater gradually rises in the carbide chamber and the operation is repeated over and over again. The carbide charge, depending on the size of the buoys, is from ¾ to 1¾ tons.

The lightships, of which there are twelve in the service, are self-propelling and are equipped with electric lights, fog signals, and some with radio beacons and submarine bells. They are for the most part of the trawler type, while those in the more exposed positions on the Atlantic coast are more powerfully constructed. A lightship carries a crew numbering from eight to fifteen men, depending on the location and type of vessel.

As an example of a principal coast station, possibly Cape Race, being one of the largest and best known in the world, will serve best. It has an electric incandescent light of 1,100,000 candle power which takes 1,500 watts, gives a flash every 7½ seconds and has been seen from a distance of 76 miles. The apparatus and enclosing lantern required

Fig. 3—General View of Cape Race Lightstation.

to produce this result weigh 42 tons and cost $40,000. The tower cost $10,000. The fog signal has been heard 45 miles. Four hundred tons of coal a year are required to develop the necessary power. Four lightkeepers maintain continuous watch. Fig. 3 shows a general view of this station.

There are, of course, important lighthouses on the great lakes. Two of these are shown in Figs. 4 and 5. The light station at Point Abino at the eastern end of Lake Erie is not only a guide for the many vessels making for Port Colborne or Buffalo, but is of interest as it stands in front of an important summer resort. The architectural features of the structure have regard to the aesthetic sensibilities of the neighbouring residents.

A structure of very different type is the Southeast Shoal light, which is built in 21 feet of water on a sand shoal six miles south of the extremity of Pelee Point.

Lighthouse optical apparatus is divided generally into two classes, lens apparatus and reflectors, and each group is divided into several sizes depending upon the requirements of the particular lightstation where it is used. The lens apparatus is built up of lens elements and refracting prisms, and is so designed as to present two or more illuminating faces, which, by revolution around the light source, produces to the ship at sea the effect of groups of one, two, three or four flashes.

The optical apparatus is carried on an annular cast iron float supported in a corresponding annular bath of

Fig. 4—General View of Point Abino Lightstation.

Fig. 5—Southeast Shoal Lightstation, Lake Erie.

mercury, which, in turn, is supported on the pedestal proper. and is revolved by a clockwork driven by a weight. In the case of the largest size, like that at Cape Race, the floating part of the apparatus weighs seven and a half tons, but, by reason of the design of the mercury bath and float, only 950 pounds of mercury are required to float the apparatus. Ball bearings at the bottom and roller bearings at the top prevent undue lateral movement when the tower is swaying under wind pressure.

Fig. 8 shows a horizontal section of a Second Order Triple Flashing Light and the lens arrangement to produce groups of three flashes. The general arrangement of the lantern is shown in Fig. 10; the base "A" consisting of heavy cast iron sections; the glazing "B" of plate glass bent to the curve of the lantern and secured in gun-metal framing; the roof "C" of steel framework, copper covered; and ventilator "D" of the same construction. The whole surrounded by gallery railing "E," and furnished with ventilating pipe "F" to carry off the heat and moisture. These lanterns vary in diameter from ten to eighteen feet.

Illumination is derived generally from kerosene burned as oil vapour under an incandescent mantle. In recent years, electricity is being introduced both from commercial power lines, where available, and by the installation of small plants in the lighthouses.

Inasmuch as the parabolic reflector is familiar to everyone, no description need be given of it, but a very interesting and useful adaptation of the parabolic principle was made some years ago by L. E. Côté, M.E.I.C., now chief engineer of the Marine Department. The parabolic reflector, in its familiar form, is designed with a relatively short focal distance, as shown by curve "A" in Fig. 9. Mr. Côté determined by mathematical calculations that a parabolic reflector of relatively long focal distance, as shown in curve "B" in the illustration, yielded equal reflecting power, and, at the same time, a narrower beam of light, approximating in this respect to dioptric apparatus. But the great advantage of the discovery is that a system of such reflectors can be revolved around a single central source of light and give the effect of groups of flashes, as in the case, also, of dioptric apparatus. The diagram "C" shows such an arrangement for a single flashing light, while

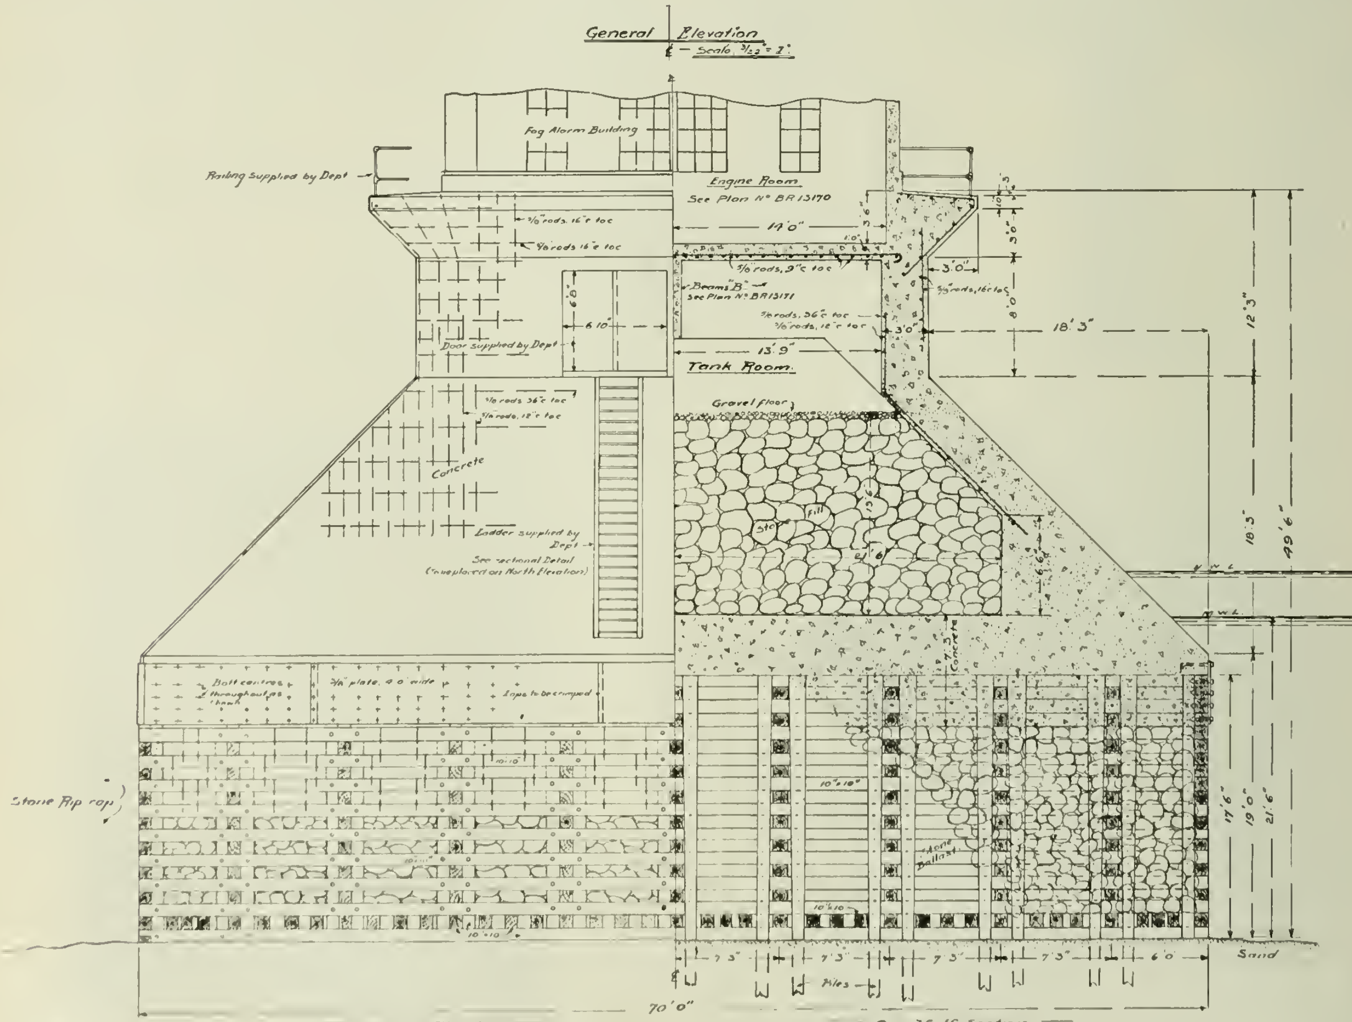

Fig. 6—Elevation and Section, Southeast Shoal Lightstation.

diagram "D" indicates a rearrangement of the same three reflectors to produce a triple flash. In like manner double flash and quadruplicate flash groups may be arranged. In the case of the short focus, or deep reflector, each reflector requires a separate source of light.

The fog signal in general use in the service is known as the Diaphone (see Fig. 11). This consists essentially of a piston reciprocating in a cylinder, in both of which are cut circumferential slots or ports. The piston is fitted with an operating head to which compressed air is admitted first on one side and then on the other, thus producing the reciprocating motion. As the ports in the piston pass and

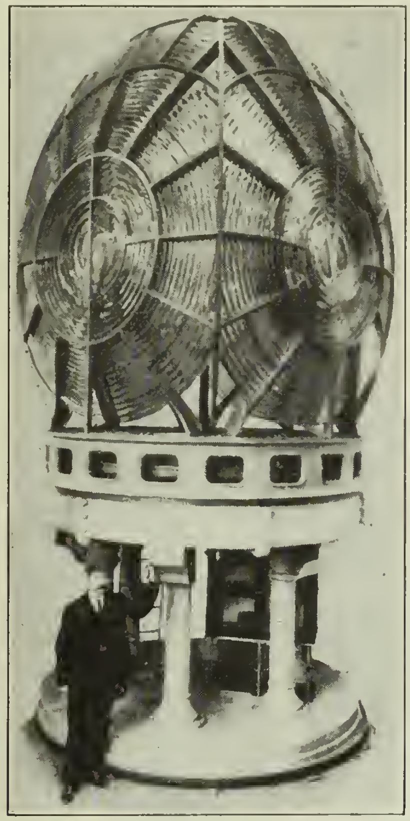

Fig. 7—Optical Apparatus of Lighthouse, Outside View.

repass the ports in the cylinder air at 30 pounds per square inch is admitted, giving 180 vibrations per second. The sound from this instrument has been heard over a distance of 45 miles.

While the lighthouse service is in operation every day in the year, strictly and literally speaking that applies only to the Atlantic and Pacific coasts. But, while the interior services are laid up in December and again placed in operation in April, the actual management of the service is continuous. Before these services are finally laid up in the fall, arrangements must be under way to place them in operation on the opening of navigation. Operations attending the closing and opening of navigation place a heavy strain on the lighthouse service. From the Gulf of St. Lawrence to the head of Lake Superior 2,819 floating aids to navigation must be removed including 8 lightships, 311 gas and signal buoys, and 2,500 unlighted buoys. This work must be accomplished at and after the actual close of commercial navigation. All aids to navigation are maintained in operation until actually threatened by ice, and, after commercial navigation has ceased, the steamers and men of the lighthouse service must do the best they can to recover these floating aids to navigation and place them in

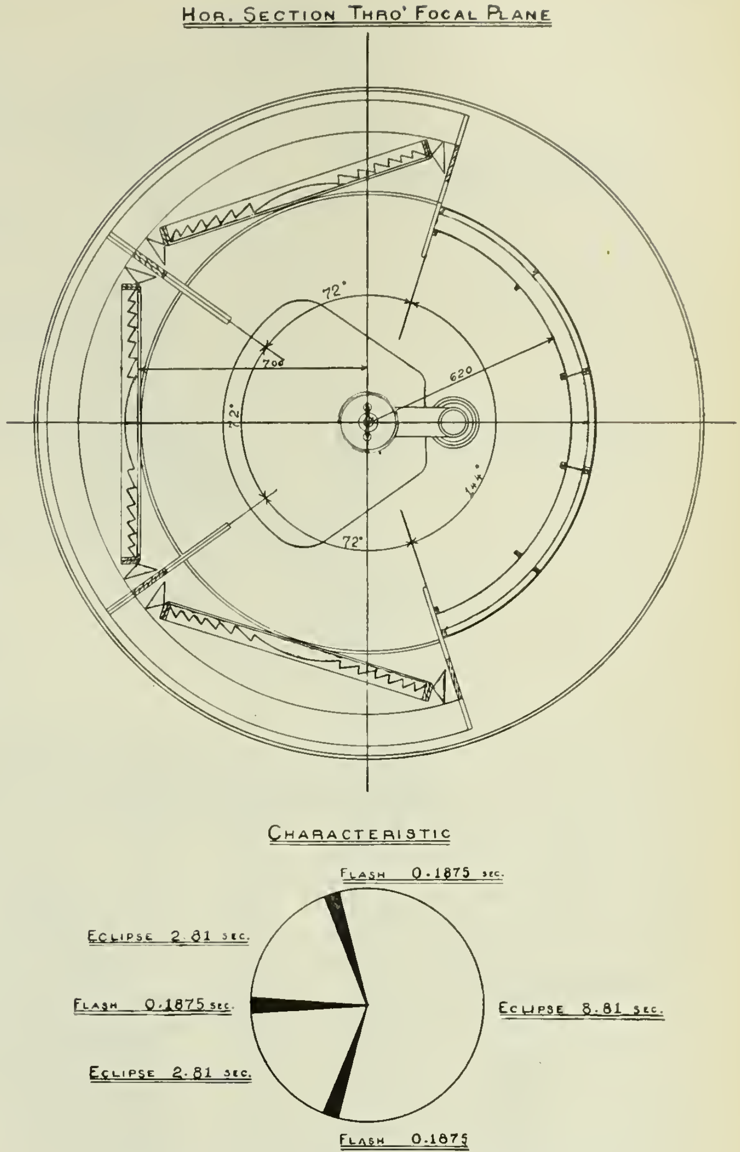

Fig. 8—Section of Second Order Flashing Light.

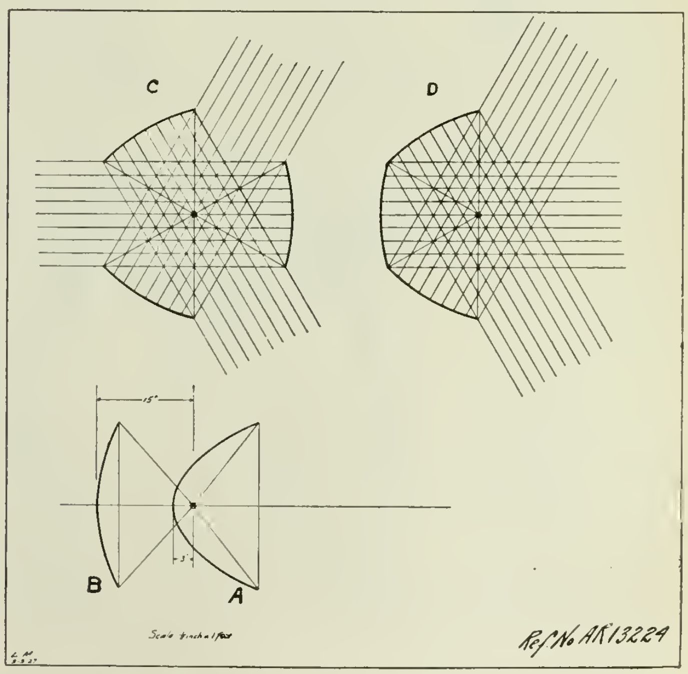

Fig. 9—Diagram of Parabolic Reflector Systems.

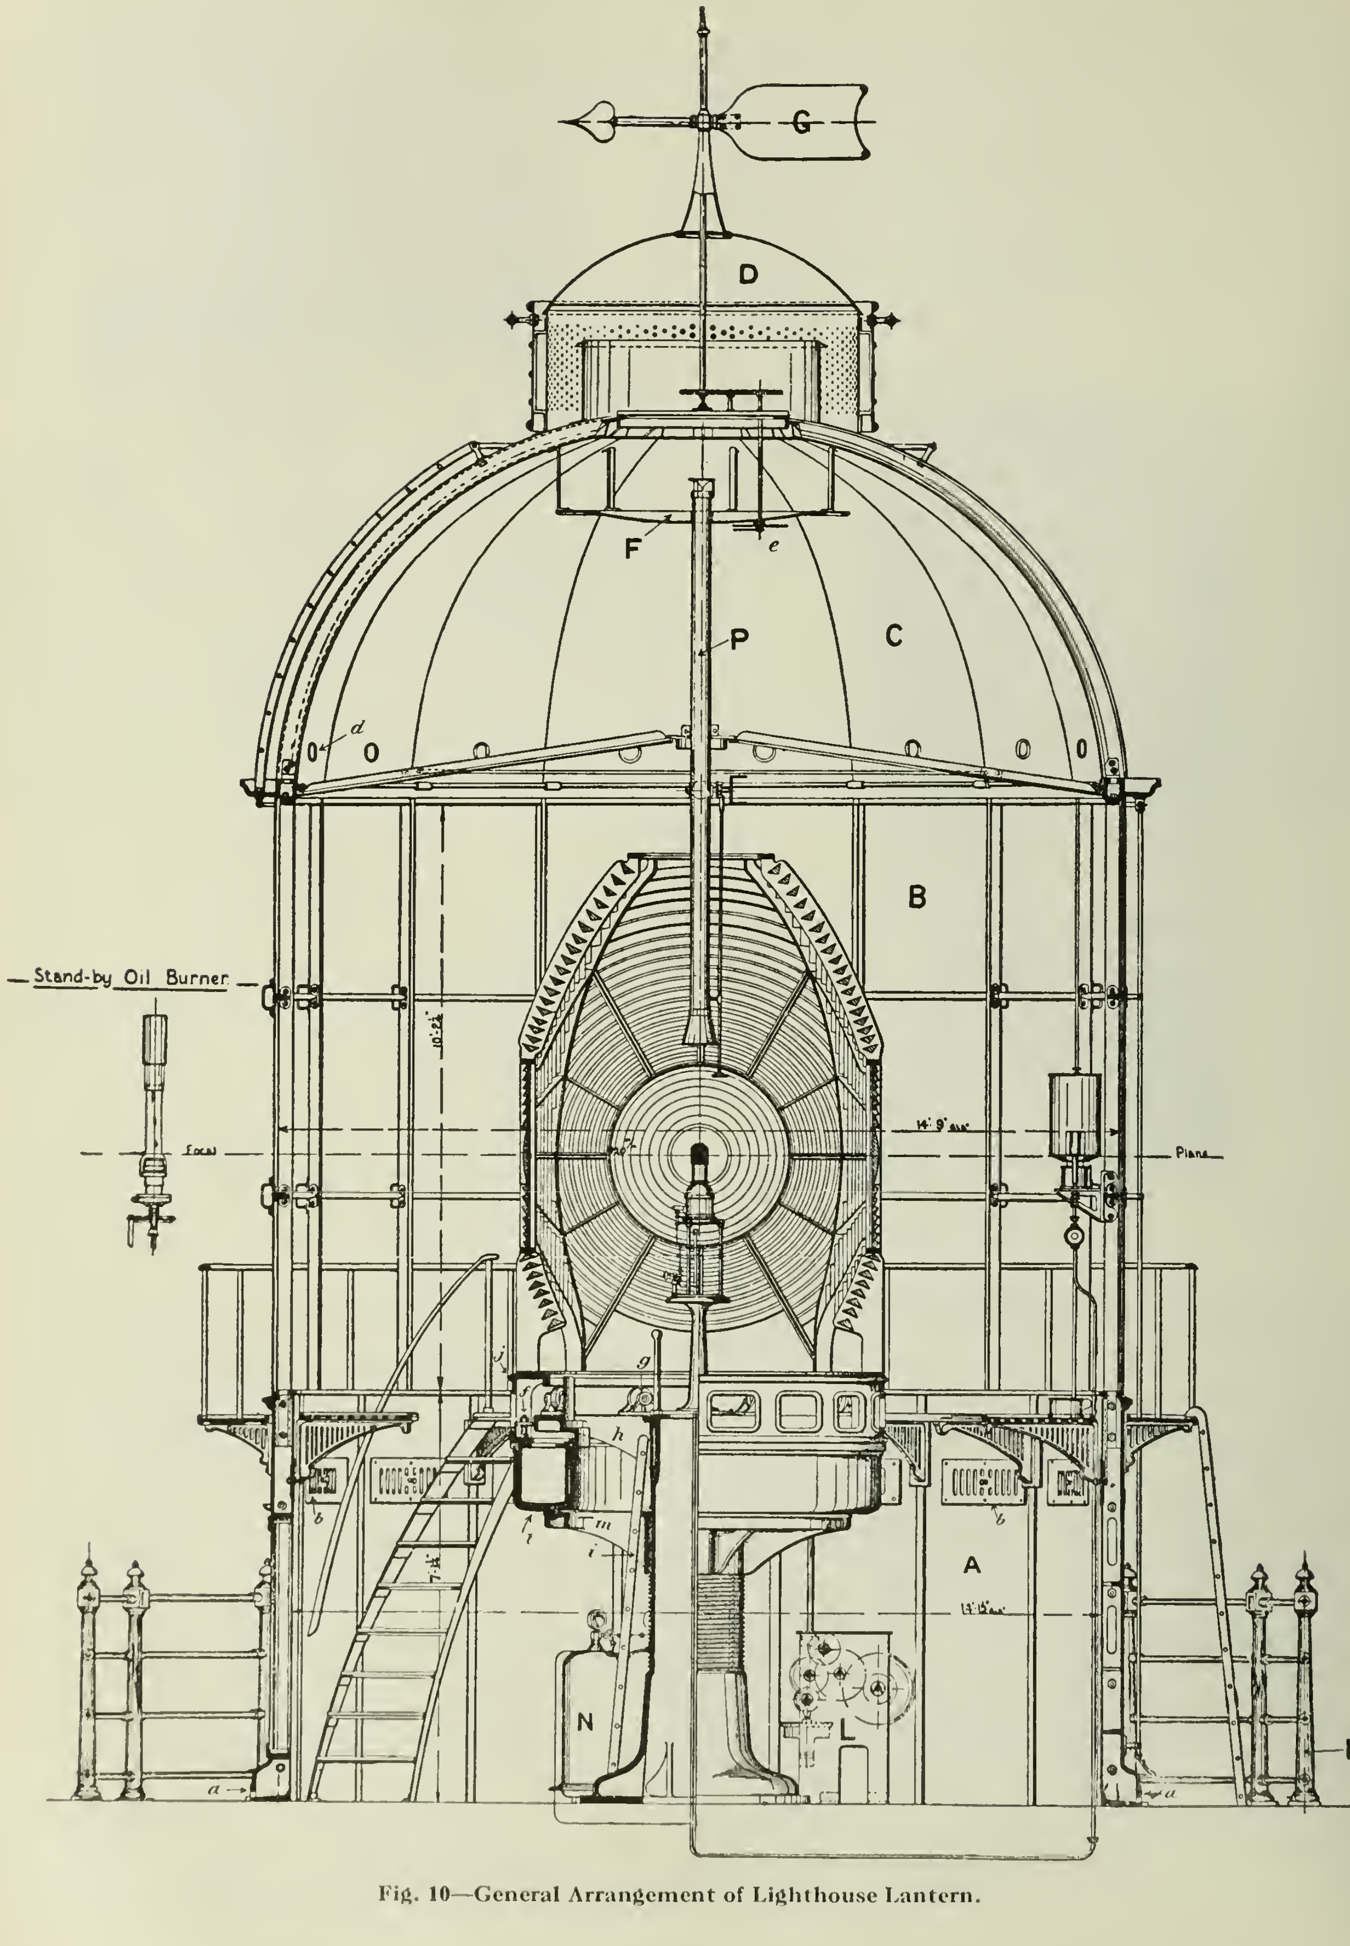

Fig. 10—General Arrangement of Lighthouse Lantern.

winter quarters to be got ready for service on the opening in the spring. Thus, long after commercial vessels are safe in winter quarters, the vessels and men of the lighthouse service are contending against extreme weather and ice conditions in the performance of their allotted tasks.

A discussion of the lighthouse service would perhaps not be complete without some reference to Sable Island, "The Graveyard of the Atlantic." The phrase "Graveyard of the Atlantic" is used because it is a familiar one and doubtless up to forty or fifty years ago was applicable. But, with the passing of sailing vessels, the advent of steam power, the improvement of aids to navigation and the art of navigation, the graveyard aspect of Sable Island is a thing of the past. But occasionally, possibly once in three or four years, a vessel does go ashore there and means are provided for the safety of those aboard. Sable Island is about 18 miles in length, somewhat crescent shaped, consisting wholly of sand, in places 100 feet high and for the most part covered with a rank growth of vegetation. Sand bars extend several miles from each end of the island. In addition to two first class lightstations, one at each end of the island, several watch towers and life saving stations are maintained at strategic points. In clear weather the entire coastline of the island is under observation from the lighthouses and watch towers. When fog or thick weather occurs, mounted men patrol every mile of the coast. All stations are connected by telephone. When a watch tower or patrol man sights a vessel in danger, he communicates by telephone with the superintendent of the establishment. The superintendent lays out his plan of operation, and by telephone calls the life saving crew and equipment of two, three, four, or five stations to proceed to the scene. Thus immediately a vessel is reported in danger or even approaching the possibility of danger several life saving equipments are under way converging to the scene of danger. The equipment consists of Lyle guns, a useful device to fire a projectile to which a cord is attached. The gun is directed over the stranded vessel. The cord is seized and hauled aboard by the crew. The life saving men ashore bend on a line, and, as that line is hauled aboard, they bend on a hawser which in turn is made fast to the mast of the vessel. It is then made fast ashore by the life saving crew and a breeches buoy is rigged whereby the crew and passengers of the vessel may be taken ashore. Self-baling lifeboats also are kept in readiness at all times mounted upon wagons to be drawn by a team of five horses. The Lyle gun and breeches buoy are used only when it is not possible on account of heavy sea to launch a lifeboat, and the rule is that efforts to launch the boat may not be abandoned until three trials have been made, and a trial is regarded as unsuccessful only when the lifeboat has been either swamped or capsized by the sea. A sufficient stock of clothing, blankets, and food is maintained to meet any possible emergency.

To complete the discussion of the lighthouse service, something should be said of the personnel, which includes over two thousand persons, about half of whom are full time employees and to whom the following observations primarily apply.

It must be remembered that the principal light stations are situated in far isolated places. By the very nature of the service, the coast stations must occupy the headlands and the promotories and the islands of the sea, and thus one finds at such a station, many, many miles from other habitation, the keeper and his wife, his assistant and in some cases his wife, and the children of the one or two families. Here, within the compass of an acre of ground, or less, there is full play of every emotion arising out of joy-sorrow, love-hate, sickness-health, life-death, and occasional echoes of these emotions penetrate even to Ottawa. For example, the wife of a keeper, finding herself suddenly widowed, in destitute circumstances, and with infant children, asks to be retained in her husband's place until she can find some other means of sustenance and shelter "for the sake of my little children" she says; the keeper whose children are coming of school age asks transfer to some station where means of education are available; the sick woman or child to whose relief the service does not hesitate to send a steamer smashing through a hundred miles of storm and ice. These are cases where sympathetic considerations are permitted to operate—but, apart from cases of that kind, the lighthouse service is a hard one. It is inexorable. It is in operation three hundred and sixty-five days in the year. It is in operation twenty-four hours every day. Of all public or private services it is perhaps the most insistent. A railroad train may be late, power lines may fail, the telephone may be interrupted, and nothing serious happen. But a thousand ships are traversing our 50,000 miles of coast and river, and, if one light or fog alarm fail for an hour, or, if one of those thousands of buoys be out of place, shipwreck is imminent with a possibility of vast loss of life and property.

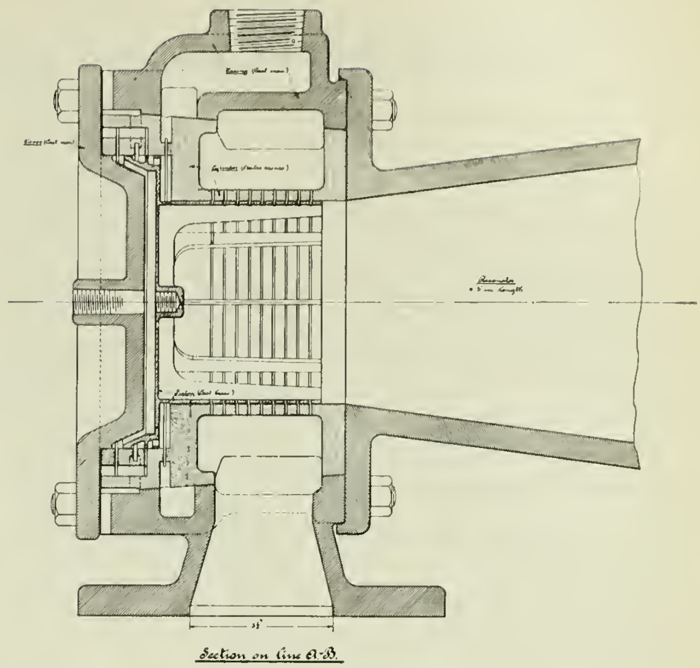

Fig. 11—Diaphone.

Accordingly, no excuse is accepted for neglect of duty—failure is visited by instant dismissal—the principle is well understood. And yet in all that far scattered service few failures are recorded in the year, and none among the principal stations.

One who knows the Lighthouse Service well cannot but marvel at the faithfulness of the men and women of it, those men and women who at this very hour and every hour are standing watch across Newfoundland and Canada, from Cape Race far east in the Atlantic to Langara, far west in the Pacific.

Lieutenant-Colonel John By — A Biography

By Hamnett P. Hill, K.C., Ottawa.

Lieutenant-Colonel John By, of the Royal Engineers, should be remembered in Canada as the officer sent out by the British government in charge of the construction of the Rideau canal in 1826, and as the founder of the little village of Bytown, now the city of Ottawa.

Lieutenant-Colonel By came of a family which had been, for many years, associated with the Custom House in London. His grandfather, John By, resided in Archbishop's walk in the parish of St. Mary Lambeth and held a situation, as Chief Searcher, in the Custom House in London. He had four sons, John, George, Charles and William, all of whom resided in Archbishop's walk, and all of whom held situations in the Custom House in London and all of whom are buried in the Churchyard of St. Mary Lambeth. His second son, George, married Miss Mary Bryan and had three sons and several daughters, Lieutenant-Colonel John By, the subject of this sketch, being his second son. The eldest son, George, obtained a position in the Custom House in London and his younger son, Henry By, was a broker in London.

Lieutenant-Colonel John By was born in the year 1779 and was baptized in the parish church of St. Mary Lambeth. After passing through the Royal Military College at Woolwich, he obtained his commission as Second Lieutenant in the Royal Artillery on 1st August, 1799, but changed his allegiance to the Royal Engineers in December of the same year. His further commissions were dated: First Lieutenant, 18th April, 1801; Second Captain, 2nd March, 1805; First Captain, 24th June, 1809; Brevet Major, 23rd June, 1814; and Lieutenant-Colonel, 2nd December, 1824. After serving at Woolwich and Plymouth, he came in August, 1802, to Canada, where he was stationed for nine years at Quebec. While there, he had much to do with building and extending the fortifications and also was the officer in charge of the construction of a canal that was built at the Cedars on the St. Lawrence river. In January, 1811, he was sent to Portugal and served in the Peninsular war, taking part in the sieges of Badajos in May and June of that year. He was later recalled from the Peninsula and placed in charge of the works at the Royal Gun Powder mills at Faversham, Purfleet and Waltham Abbey, a position he occupied with great credit from January, 1812, until August, 1821, when, owing to reductions made in the establishments of the army, he was placed on the unemployed list. While employed in the powder mills, he designed a bridge on the truss principle for a span of 1,000 feet, and constructed a model of it, which is in the possession of the Royal Engineers at Chatham. A description of the bridge appeared in the "Morning Chronicle" of 14th February, 1816.

Lieutenant-Colonel John By.

During the war of 1812-15, the difficulty and expense of protecting the settlements in the western part of the province of Ontario were very great, and in addition there was the constant apprehension that an army from the United States might be thrown across the St. Lawrence river at any point and effectually prevent troops and supplies going up the river into Lake Ontario to take part in hostilities in the western part of the province. The War Office in London decided, in order to render the necessary protection, that a back water route away from the United States boundary should be obtained, and accordingly it was decided to improve the navigation of the Ottawa river to the foot of the Chaudiere falls, and to utilize the Rideau river and the Cataraqui river to obtain access from there by water to Lake Ontario.

By was selected as the officer in charge of the work on the latter two rivers and in the summer of 1826 came to Canada for this purpose. His instructions were to design and carry out a military water communication from the outlet of the Rideau river into the Ottawa river to the outlet of the Cataraqui river at Kingston.

The country was then in a state of wilderness and unexplored, the only mode of progress being by canoe. On his arrival in Canada he surveyed the route and proceeded with the work. The survey plans and estimates, sent to the Home Government in the spring of 1827, were approved, and By was directed to push forward the work by contract as rapidly as possible without waiting for the usual annual appropriations of money.

The Earl of Dalhousie had, in 1823, purchased from Colonel Hugh Fraser of Three Rivers a block of land fronting on the heights overlooking the Ottawa river and extending from the Chaudiere falls to the Rideau river. Lieutenant-Colonel By was instructed to subdivide this area into lots and to form a village. This he did, and the village became known as Bytown. He made his headquarters there and built himself a house in what is now known as Major's Hill Park. Two companies of sappers and miners were sent from England, and barracks were built on the present site of the parliament buildings.

The canal was opened for navigation in the spring of 1832, when the steamer, Bumper, was able to pass from Bytown to Kingston.

By's instructions were to complete a water communication having a uniform depth of five feet. This was obtained by the erection of dams at various places across the Rideau river, which, in some cases, backed up the water and drowned out small rapids for miles above them. Locks were built to enable boats to pass through the various dams. The same procedure was followed on the Cataraqui river. This required the construction of forty-seven locks, with a total lockage of 446½ feet. The intention of the War Office originally was to build the canal solely for military purposes, but on By's insistence it was altered to permit navigation for mercantile purposes and the locks were increased from the original small size of a width of 20 feet to a width of 33 feet and to a length of 134 feet instead of 100 feet.

The War Office had undertaken the project on a report which had been prepared by Mr. Samuel Clowes, an engineer who had been appointed by the Upper Canada government to make reports on various waterways. Clowes had estimated that the cost of the improvements would be one hundred and forty-five thousand, eight hundred and two pounds. By, shortly after his arrival, reported that it would be impossible to do the work for this figure and that it would cost at least four hundred thousand pounds. His first report to the War Office set out a detailed estimate of cost amounting to four hundred and seventy-five thousand pounds. Owing to changes and unexpected difficulties and the necessity of various additions, the ultimate expenditure was in the neighbourhood of eight hundred thousand pounds. During the progress of the work, the attention of the British government was called to the expenditure and two investigations were held. Both investigations resulted in laudatory references to Lieutenant-Colonel By's efforts and approval of the spirit of economy practised by him, but criticism was directed by the Parliamentary committee to the manner in which the War Office had instituted the work. In the spring of 1832, on the receipt of By's annual report of expenditure and estimate of the amount needed to complete the work, the Lords of the Treasury directed that Lieutenant-Colonel By should be ordered to return to England, that he might be called upon to afford such explanations, in regard to the greatly increased cost, as the Lords of the Treasury might consider necessary. On his return to England, By appeared before a third committee of the House of Commons. The committee, while admitting that the work had been carried out with care and economy and had been well performed, concluded their report with a strong expression of regret at the excess expenditure over the estimate and the Parliamentary Votes.

By, who had expected high commendation, including knighthood, on the completion of this magnificent work in so short a time and under so many difficulties and at a cost by no means extravagant, felt himself extremely ill-used and never recovered from the disappointment. It must be conceded that By was a victim of circumstances and politicians. Every commission and committee of the House of Commons had approved of the work, in some cases highly praising him, and in other cases expressly excepting him from any criticism. Every engineer who had gone over the work had approved of it. During the whole progress of the work not one word of disapproval had emanated from the Ordnance Board under whom By was carrying on the undertaking. A scapegoat, however, had to be found to satisfy the politicians and By was allowed, by the military authorities, to bear this stigma. No one can read the letters and reports in the government Archives at Ottawa without sympathizing with By in the disappointment he suffered and the indignation he felt.

Sir Richard Bonnycastle, in "The Canadas in 1840," says, "If ever man deserved to be immortalized in this utilitarian age, it was Lieutenant-Colonel By. In an unexplored part of the country, where the only mode of progress was the frail Indian canoe, with a department to be organized, workmen to be instructed and many difficulties to be overcome, he constructed a truly remarkable work."

Lieutenant-Colonel By was married twice. His first wife was Elizabeth J. Baines who died shortly after the marriage. He subsequently married, on the fourteenth day of March, 1818, Esther, the daughter of John March of Harley Street, London, by whom he left two daughters, Esther, who married in 1838 the Hon. Percy Ashburnham, the second son of the third Earl of Ashburnham, and Harriet Martha, who died unmarried.

After his return to England, owing to failing health, he was placed on the unemployed list and retired to his estate near Frant, in the County of Sussex, and there died on February the first 1836.

On his tombstone is engraved the following pathetic obituary:

> "Sacred to the Memory of Lieutenant-Colonel John By, Royal Engineers, of Shernfold Park in this Parish, zealous and distinguished in his profession, tender and affectionate as a husband and a father, charitable and pious as a Christian, beloved by his family and lamented by the poor. He resigned his soul to his Maker in full reliance on the merits of his Blessed Redeemer on the first of February, 1836, aged 53 years, after a long and painful illness brought on by his indefatigable zeal and devotion in the service of his King and Country in Upper Canada. This stone is erected by his afflicted widow in remembrance of every virtue that could endear a husband, a father and a friend."

An entry in the Baptismal Register of the parish of St. Mary Lambeth states that John By the son of George By was baptized on August the tenth, 1779, and an entry in the Burial Register of the parish of Frant is to the effect that he was buried there on February the twelfth, 1836, and that his age was fifty-three. It would therefore appear that this entry and the age mentioned on his tombstone are both wrong, as it is obvious that he must have been fifty-six years old at his death.

(*See photograph of Rideau Canal on page 459*)

General Principles of Air Transportation

A. F. Ingram,
Operating Manager, Air Mail Division, Canadian Airways, Ltd., Montreal.

Paper presented before Branches of The Engineering Institute of Canada as follows: London Branch, January 15th, 1931; Border Cities Branch, January 16th, 1931; Saint John and Moncton Branches, February 18th, 1931, and Montreal Branch, March 12th, 1931.

SUMMARY.—Success in the operation of air transport depends primarily on effective ground organization. Without this, the intensive use of aircraft on which financial success depends cannot be attained. Conditions for economical operation are discussed, together with the effect of traffic conditions upon economy. Attention is drawn to the very different traffic problems which exist in Europe and in the Dominions, and the author discusses briefly the main items in the balance sheet of an operating company which make up the standing charges and running costs.

General Principles

The problems connected with the operation of air transport services are innumerable and, generally, it will be found in the study of any particular scheme that conflicting issues arise, which it is necessary to weigh carefully in order to arrive at a just balance.

Regularity, reliability, and safety, may be taken as the watchwords to be applied to commercial aviation. These three factors are to a very great extent dependent on the efficiency with which the ground organization of an air route is provided, therefore, the first essential for the successful operation of air transport lies not in the air, but on the ground. The various items which in combination make up ground organization have not yet reached perfection, nevertheless much has been achieved since the first commercial services started, and steady and rapid progress is being made. The main items which are included in the general term "ground organization" are aerodromes, landing grounds, wireless and meteorological services, lighthouses and light beacons, aerodrome and obstruction lights, fog signals, hangars, workshops, stores, offices and quarters (where these are necessary), and customs and immigration facilities.

In studying the possibility of the operation of services on any particular route consideration must be paid to the following points:—

1. Time which can be saved over existing means of transport.
2. Traffic already existing on the route.
3. Proportion of such existing traffic which may be attracted to the air.
4. New traffic which may be created.
5. Nature of the terrain to be operated over.
6. Meteorological conditions to be met with.
7. Length of non-stop stages to be flown.
8. Frequency of service.
9. Cost of labour, imported or native.
10. Cost and supplying of fuel.
11. Customs duties and local taxation.
12. Difficulties involved in salvage.
13. Best position for the establishment of the operating base.
14. How the service will connect with existing forms of transport.
15. Local legislation.
16. Subsidies which may be available.

Other points may arise for consideration in particular instances, but generally speaking, as a result of a close study of the conditions included in the above headings, it will be possible to indicate with regard to a particular service:

1. Whether it shows a reasonable prospect of being or becoming a sound financial proposition.
2. The type and number of machines to be employed.
3. The method of operating the route, for example, the number of services per day, per week, or per month, the position of the operating base, intermediate stations, etc.
4. Whether day or night services or a combination of both should be instituted.

Aviation, supplying as it does a rapid means of transport, the speed of which is so far in excess of anything which exists in any other means of transit, is ideally suited for operation over long distances, especially where either no facilities for transport exist, or where the needs of civilization and commerce are badly served, for here obviously the greatest advantage will accrue.

It may then reasonably be asked, why the operation of air transport has advanced mainly in Europe, which is well served with fast rail communication? That progress has been so amazingly swift is largely to be accounted for by the very fact that the primary work has been carried out in Europe. There the weather conditions are as bad or worse than are normally to be met with in any other part of the globe, there highly organized transport already exists, and there the travelling public has to be inveigled away from the form of travel with which it has grown up, and which in consequence it regards as a normal part of its daily life.

Crossing the Rocky Mountains.

Air transport has consequently had to establish itself in a hard school. It has had to struggle to bring its equipment to the highest pitch of perfection possible in the short time available. It has been necessary to evolve instruments, devices and methods of navigation, in order to render it capable in large measure of defying the elements. It has had to provide comfort of travel and prove that it is safe and reliable, and to overcome the natural prejudice of the average person to leave *terra firma* and embark on an unknown undertaking. While it is true that it has not achieved perfection in all these things, very great progress towards it has been made.

The great strides in the development of air transport which have been made as a result of the operation of European services are also due to the fact that they have been carried out where the designers of the aircraft, engines and equipment have been able to keep in the closest touch with their products. It has consequently been possible for them to discuss with pilots and personnel on the spot weaknesses, failures, shortcomings and defects which have come to light as the result of constant daily use.

Basic Principles of Operation

The first and prime factor in air transport, which must be regarded as the basic principle of operation, is the intensive use of the aircraft. In this respect, at any rate, the problem as to how to employ the vehicle, whatever it may be, whether ship, train, motor lorry or aeroplane, so as to obtain from it the maximum number of hours work in any given period, puts air transport on the same footing as every other form of transport.

One very obvious fact which appears frequently to be overlooked is that a fleet of aircraft represents capital. Capital lying idle cannot earn dividends and, consequently, it is clear that the fleet which represents so much capital must be worked to its fullest capacity. It is equally obvious that since the expansion of a business normally requires the provision of new capital, it is essential if the application of air transport is to be extended, that it must be put on a paying basis within the shortest space of time possible, as new money will not flow into an industry unless, under normal trading circumstances, a return in the form of interest on the capital invested can be assured.

To work aircraft intensively, certain conditions must exist. Firstly, the route to be operated must either be of sufficient length to keep the aircraft working it fully employed, or if of short length, to produce sufficient traffic for the aircraft to operate backwards and forwards more or less continuously. Secondly, the organization of a transport company must be such that machines, while being thoroughly and efficiently inspected and, when need be, overhauled, can be dealt with expeditiously.

On the shorter routes only by frequency of service can machines be used to their fullest capacity, but in order to warrant a frequent service it is necessary that a sufficient volume of passengers, goods and mails is forthcoming; and, in addition, that the traffic is distributed throughout the day. This stage has not yet been reached on the London-Continental airways, where the majority of the passengers desire to travel about midday, and only a limited number of mail dispatches take place.

Here let it be remarked that mere unqualified statistics are sometimes misleading. For instance, returns of travelling public which only show numbers may indicate a steady increase, but if this increase is all centred round about a popular hour of travel, no economic advantage is gained, since the number of machines to cope with the traffic must be increased, instead of it being possible to increase the number of flying hours per machine by a more equal distribution of the travellers throughout the day. Where an increase in traffic occurs in one direction it may happen in the reverse direction at about the same hour, thus calling for a large number of machines, all of which are in operation for a short period with only a small chance of obtaining paying return loads.

Only by the slow process of gradual education of the public to the advantages which accompany the use of air transport will these difficult problems be solved. As the travelling public makes more and more use of the air services and as these become, in increasing measure, a regular feature of daily life, then only will a more even distribution of passengers be obtained. Looking at this question of even distribution of services and intensive use of aircraft from another aspect, it will be realized that since the overhead standing charges involved in the operation of air transport may amount to as much as 75 per cent, or even more, of the total operating costs in cases where only a limited number of services are running, the remaining 25 per cent being due to pure running costs, the surest way of bringing about a more even distribution of the two classes of cost which make up the total is to increase the services, and consequently the running costs, to the highest point which it is possible to do without an increase in the standing overhead charges. For all practical purposes this means running the machines to their maximum capacity. Let us here consider a purely imaginary case and see what is the effect of intensive versus non-intensive operation. Assuming that on a certain route over which a service is operated once daily in each direction, and on which each machine flies on an average six hours per diem, the running costs amount to 25 per cent of the total operating costs, which for sake of example may be put at $100 per diem, then the standing overhead charge will amount to $75 and the running costs to $25. Now assume that the same route is operated on the intensive system to the extent that each machine averages eighteen hours flying per diem, the standing overheads will still amount to $75, while the running charges will have risen to $75, making a total of $150 per diem. For this $150 three return services per diem will be flown, or each return service will cost $50 per diem as against $100 per return service when operated under the non-intensive system. It is obvious that, in actual practice, the results would not come out quite as simply as here stated, but the example gives a sufficient indication of the general effect which will be produced when real intensive operation becomes the normal method of working air transport. Now let us go a step further. An increase in the number of machines in a fleet does not increase the standing charges in direct proportion, and the bigger the aircraft operating organization becomes, the smaller will be the proportionate increase due solely to additions to the fleet. Consequently, it follows that when traffic is forthcoming in sufficient volume, while equally distributed over the twenty-four hours of the day so as to permit the employment of machines in increasing numbers which can be intensively used, the costs of operation will fall, when the charges made for transport will be automatically reduced.

This line of argument naturally leads to consideration of the development of Empire routes and Dominion development. If the remedy for the high cost of air transport is intensive operation, it may be argued, how will it ever be possible to bring about a reduction of costs in territory which, comparatively speaking, is only thinly populated? On the trunk Dominion routes, intensive operation will be provided by the length of line, and increase in fleets will be brought about as the advantages to be gained by making use of rapid means of transport become fully appreciated. On these routes a vast volume of traffic already exists, a very small percentage of which, when diverted to air transport, will provide the means by which it can be put on a self-supporting basis; moreover, since the advantage to be gained in the saving of time over these long routes is so great, the traffic can stand comparatively heavy charges. This is not the case over the shorter routes in Europe, which are already supplied with good and comparatively rapid means of communication, where the charges must bear some relation to fares levied by the older systems of travel either by sea or land, with which air transport is rapidly becoming, if not a serious competitor, at least a factor which must be considered.

Air services in the Dominions and in more or less undeveloped territory, in some cases, even to-day, supply the only practical means of communication. Here the conditions are entirely different from those which exist in thickly populated countries already well supplied with communications, or in the trunk routes which are only waiting to be developed. Where there is no form of regular transport other than, for example, canoe, dog teams or porters, and where a journey which takes, say three or four weeks, or even months, may be carried out by air in as many hours, it is manifest that air transport is in a position to charge fares which would be unreasonable in other parts of the world, and yet effect a saving in expense on a journey. Under these conditions services must be limited and the corresponding cost of transport must be high. In such territories other work could generally be combined with transport, such as air survey, taxi work, etc., which assist in reducing costs, but are unlikely to assist materially in balancing expenditure. This case, however is equivalent to the opening up of new territory by railroads, on which no return is expected during the years which pass while the country is in the process of development.

Here, air transport can, and will, undoubtedly fulfil a most important role, by keeping those far-away districts in touch with the world, supplying the scattered inhabitants with the necessities and some of the comforts of civilization, bringing them medical aid when needed and, in general, by supplying a link with the outside world.

Economic Factors in Operation

It is well to consider in some detail the main items which figure in the balance sheet of an operation company.

These fall under two headings, namely, "Standing Charges," in which category are placed all charges and costs which are independent of the actual hours flown and must be borne whether a large or small amount of flying takes place; and "Running Costs," which comprise those charges which are directly dependent on the amount of flying done. Perhaps the clearest way of indicating the main charges which are relevant to air transport under their respective headings will be to set out a statement of the items as follows:

Standing Charges.

Insurance of aircraft and engines complete.
" " spare engines.
" " equipment.
" " buildings, plant, etc.
" " motor transport.
" " personnel.
Depreciation of equipment.
" " buildings, plant, etc.
" " motor transport.
Obsolescence of aircraft and engines.
Rents, rates and taxes.
Housing fees.
Office expenses, postage, telegram and telephone charges.
Lighting and power.
Cartage, travelling and salvage charges.
Advertisement.
Directors' fees and legal expenses.
Salaries and wages.
Sundry trading expenses.
Interest on capital.

Running Charges.

Gas and oil.
Maintenance of aircraft and engines.
" and running of motor transport.
Pilots' and mechanics' flying pay.
Wireless charges.
Landing fees.

When a company is operating regular services it is customary to pay a yearly rate to cover landing and housing fees, in which case the former charge will be included under the heading of "Standing Charges," and can consequently be omitted from "Running Charges."

Under the heading "Standing Charges," the heavy items of expenditure are:—

Insurance of aircraft and engines.
Obsolescence of aircraft and engines.
Salaries and wages.

With regard to insurance of aircraft, the percentage rate varies according to the type of machine used, the nature of the country operated over, the meteorological conditions existing, the system of maintenance and inspection employed, and the ability of pilots. In addition to this there is at the present day another factor which has an important bearing on insurance rates as a whole, which is the limited field, comparatively speaking, over which risks can be spread. As the number of aircraft in regular operation increases so the field for insurance will increase, with a consequent natural fall in rates.

Given a thoroughly sound operating organization, the factor which plays the most important part in insurance rates is the type of machine used. For example, a single engined machine of sound and reliable construction may call for a rate varying from 12½ to 25 per cent per annum, or even more, whereas an efficient three-engined machine, operated by a reputable company, may cost only 7½ per cent per annum. These rates may be obtained at the present day, and may be expected to be materially reduced as the market for aviation insurance widens.

Another factor which bears considerably on insurance rates is whether aircraft are operated as land machines or sea-going craft. This is obvious, since with the marine type of aircraft, the whole of their routes, lying as they normally do over water, are provided with a natural emergency landing ground from end to end, always assuming that the aircraft concerned is a seaworthy machine. Then again, an important consideration which weighs with aircraft insurance underwriters, is the ease with which aircraft can be repaired in the event of damage. Obviously a machine which, from its form of construction, is costly and difficult to repair, calls for a higher insurance rate than one of which the reverse is true. The influence on rates due to the nature of the country on any particular route, the prevalent meteorological conditions, the system of maintenance and ability of the pilots employed, are too obvious to need any explanation.

As regards obsolescence, no prudent concern equipped with present day aircraft could base obsolescence charges on a longer life than five years, in other words, the value of aircraft must be written down annually at a rate of 20 per cent. At the end of five years, an aircraft of sound construction which in the meantime has been efficiently maintained, would still possess a certain value, but it is doubtful if it would be possible to realize it practically. This charge of obsolescence raises one of the most difficult problems for consideration in connection with the present day operation of air transport. So long as extensive developments in the design of aircraft are likely to occur, these charges must be faced, and constitute an additional reason for the system of intensive operation on which so much stress has already been laid.

The item of expenditure due to salaries and wages requires little comment. There is, however, one aspect which deserves consideration. It has been explained that there are two alternatives, by either of which extensive operation can be achieved, namely, by flying over long routes or by running frequent services backwards and forwards over short routes. The former necessarily calls for the establishment of a number either of main or subsidiary stations, which involves the employment of personnel at each of them, and incidentally of aerodrome equipment additional to that which would be required when operating intensively over a short route.

Dealing now with "Running Charges," the main items of expenditure are centred in fuel consumption and maintenance of aircraft and engines.

Fuel consumption depends mainly on the horse-power of the engines employed, and varies only slightly per unit of power output with the design or type of engine used. This is true with the several types of engines now in use, but will not necessarily continue.

Maintenance constitutes one of the heaviest items of expenditure in the operation of air transport. Even the very best and highest pitch of efficiency which can be obtained is not good enough. The nearest approach possible to absolute perfection is essential, and this obviously costs money. Economy under this heading cannot therefore be obtained by any reduction in efficiency, and must be sought for and effected by faultless organization based on a thorough and sound system.

It cannot be too forcibly stressed that, apart from ground organization, reliability in the operation of air transport is almost entirely dependent on efficient maintenance, and consequently, anything short of perfection in this respect is false economy. It must be remembered that a lack of reliability has a repercussive effect on insurance rates; interferes with the regularity of services, thereby affecting receipts; upsets routine methods of working; and destroys confidence.

A brief study of this question of cost of operation makes it abundantly clear that many factors are in opposition to each other, and that a careful balance must be struck between the various advantages and disadvantages. For example, insurance and obsolescence, both serious items of expenditure, are directly dependent on the capital cost of the aircraft and engines used; cheapness of aircraft may, therefore, appear at first sight to be a primary consideration; against this, however, it may well be that the costs of maintenance may be so much greater for a cheap aircraft than for a more expensive one, that the advantages obtained over lower insurance and obsolescence charges may be outweighed by higher maintenance costs. These and many other problems of a similar nature are continually arising in the study of transport, and require very mature consideration in order that a sound conclusion may be arrived at.

Recent Air Mail Development in South America

R. A. Logan, A.M.E.I.C., A.F.R.Ae.S.,
Pan American Airways Inc., Halifax, N.S.

Progress in commercial aviation in South America during the past two or three years has been so rapid and extensive that it is difficult for one who left that country four months ago to state correctly the conditions at this date, therefore, unless otherwise stated, the following remarks deal with the state of development of commercial air mail routes as of January 1st, 1931.

In many ways the most energetic and progressive people of South America are those living in the southern half of the continent: in Argentina, Chile, southern Brazil, Uruguay and Peru, and in these countries the development of air mail routes has been most extensive. Some of the other republics of South America have had regular air mail and passenger lines in operation for years, especially Colombia, but the most extensive operations are in the hands of French, German or North American interests.

The most important commercial centres are: Buenos Aires in Argentina, and Rio de Janeiro and Sao Paulo in Brazil. Buenos Aires—generally known to English speaking people in South America as "B. A."—is one of the finest cities in the world and is by far the largest city south of the equator. It has a population of nearly two and a half million people, and naturally a city of that size needs means of rapid communication with the cities of Europe and North America.

Mail by fast steamers takes seventeen to nineteen days between London and Buenos Aires, or between New York and Buenos Aires, but by air mail the time between the former points has been reduced to eight days and between the latter points to seven days.

It is noteworthy that the air mail from Montreal or New York to Buenos Aires does not travel via the eastern coast of South America but is flown down the Pacific coast to Santiago de Chile and then over the Andes and almost due east across the continent to its destination—over a route about 600 miles longer than the eastern coast route; and the air mail from and to Europe is not flown across the Atlantic but is carried across the water between Africa and Brazil by fast steamers.

At the beginning of 1931 Buenos Aires received and dispatched European air mail once a week and North American air mail twice a week. At that date the large cities of Brazil were six days distant from New York and six and one-half days from London by air mail, while the fastest time possible by mail steamer would be twelve days. Sao Paulo was the southern terminus of the eastern coast route of the North American air mail, but it was expected that this route would be continued to connect with Buenos Aires some time in 1931.

The European air mail service is operated by the French "Compagnie Générale Aéropostale" and its subsidiaries or associated companies in the various South American countries.

The operations of the company are conducted under its own name between Buenos Aires and Natal and in Venezuela, while the S.A. Aeropostal Argentina is the operating subsidiary in Argentina. Passengers, mail and express are transported by these companies over the following routes, totaling 6,914 miles:

Under the Compagnie Générale Aéropostale: (weekly) Natal — Pernambuco — Maceio — Bahia — Victoria — Caravellas — Rio de Janeiro — Santos — Paranagua — Sao Francisco—Florianopolis—Porto Alegre—Pelotas—Montevideo —Buenos Aires, 2,895 miles.

Maracaibo — Maracay — Ciudad Bolivar — Maturin (Venezuela), 689 miles.

Under the S.A. Aeropostal Argentina: Buenos Aires—Mar del Plata, 240 miles.

Buenos Aires—Bahia Blanca—San Antonio del Oeste, Comodoro Rivadavia — Puerto Desecado — San Julian — Santa Cruz—Rio Gallegos (bi-weekly), 1,650 miles.

Buenos Aires—Mendoza—Santiago de Chile (weekly), 750 miles.

Buenos Aires — Monte Caseros — Posadas — Asuncion (Paraguay) (bi-weekly), 690 miles.

The air mail from and to North America is carried over the system of the Pan American Airways, which includes the operations of the Pan American Grace Airways Inc. operating between the Canal Zone and Montevideo, via the Pacific coast, the Pan American Airways Inc., which operates from Miami, Florida, to Para at the mouth of the Amazon river, and Panair do Brazil, the operating company for Brazil.

The Pan American system, which is owned by the Aviation Corporation of the Americas, Inc., during 1929 and up to October 1st, 1930, increased its lines from 216 miles to over 19,000 miles. This was done by the absorption of pioneer companies' lines and their subsequent reconstruction, and by the extension of new lines in practically every American country or island-group south of the United States.

This system is the holder of United States Post Office Department foreign air mail contracts which cover the transportation of air mail from the United States to Latin American countries.

On September 1st (1930) the company's records showed that 5,344,447 miles had been flown; 30,727 passengers, 1,022,730 pounds of baggage and over 580 tons of air mail had been transported on the international routes with northernmost terminals in Brownsville, Texas, and Miami, Florida, and southern extremities at Montevideo and Buenos Aires, and that the volume of traffic of all kinds was increasing rapidly.

The German interests include the Scadta Company (Sociedad Colombo-Alemana de Transportes Aereos), in Colombia, the Sindicato Condor Ltda., of Brazil, and the Lloyd Aero Boliviano, in Bolivia.

The Scadta maintains an air mail service between Colombia, Panama, Ecuador and Peru, supplemented by steamship service to the United States and various other countries. The Condor Syndicate transports mail between Bolivia and the long coastal region of Brazil south of Natal, and connects with German steamers at the Island of Fernando do Noronha. The Lloyd Aero Boliviano maintains an air mail service between the interior cities of Bolivia and connects with lines of other companies carrying mail to the north, south, east and west.

All the aircraft and ground stations of the Pan American Airways, Inc., and of Panair do Brazil, are equipped with two-way radio facilities and the aircraft are in constant touch with at least two ground stations, while in flight. Short-wave radio telegraphy is used and expert operators are always carried. Each plane has a pilot and a relief-pilot, and, where passengers are carried they are attended by a trained steward, speaking English and Spanish or Portuguese, whose sole duty is to look after their comfort. From four to twenty passengers are carried on each plane. The nature of the country determines the general type of aircraft to be used—whether land plane, sea-plane or amphibian. The machines in general use are: Ford tri-motor land planes, Fokker F-10, Sikorsky amphibians, Commodore flying boats and Fairchild land and sea planes.

While the majority of the planes of the Pan American system are multi-motored, those of the French system are single-motored. Much of the flying over the French routes is done at night but without any special lighting of the routes. Planes of both systems cross the Andes through the same pass—between Santiago and Mendoza. The usual altitude for crossing the pass is about 18,000 feet, with higher mountain peaks on each side, one of which goes up to about 23,000 feet above sea-level.

Information given out by the three companies shows the following:—

The passenger and mail routes being operated by the Scadta company, totalling 2,440 miles, in October, 1930, were as follows:

1. *Magdalena Line.*—Barranquilla—Girardot—Bogota (daily), 650 miles.

2. *Inter-Oceanic Line.*—Barranquilla—Quibdo—Buenaventura—Tumaco (Colombia)—Guayaquil (Ecuador) (weekly), 1,200 miles.

3. *Atlantic Line.*—Santa Marta—Barranquilla—Cristobal (Canal Zone), 500 miles.

4. *Trans-Andean Line.*—Bogota—Girardot—Ibague (bi-weekly), 90 miles.

The company states that in 1929, a total of 781,000 miles were flown by its scheduled planes and a total of 5,500 passengers and of 134,400 pounds of mail were transported.

The Condor Syndicate, Ltd. reported that during 1929, 2,146 passengers, 44,447 pounds of baggage, 14,289 pounds of freight and 10,923 pounds of air mail were transported over its lines. The following lines making a total of 2,992 miles were in operation:

Southern Division: Rio Grande do Sul—Pelotas—Porto Alegre—Santos—Rio de Janeiro (weekly), 935 miles.

Northern Division: Rio de Janeiro—Bahia—Natal—Fernando do Noronha Island (weekly), 1,511 miles.

Bolivian Division: Rio de Janeiro—Corumba (Brazil) (weekly), 546 miles.

The Compania Lloyd Aero Boliviano operates a network of seven lines wholly within Bolivia. The routes totalling 2,264 miles are as follows:—

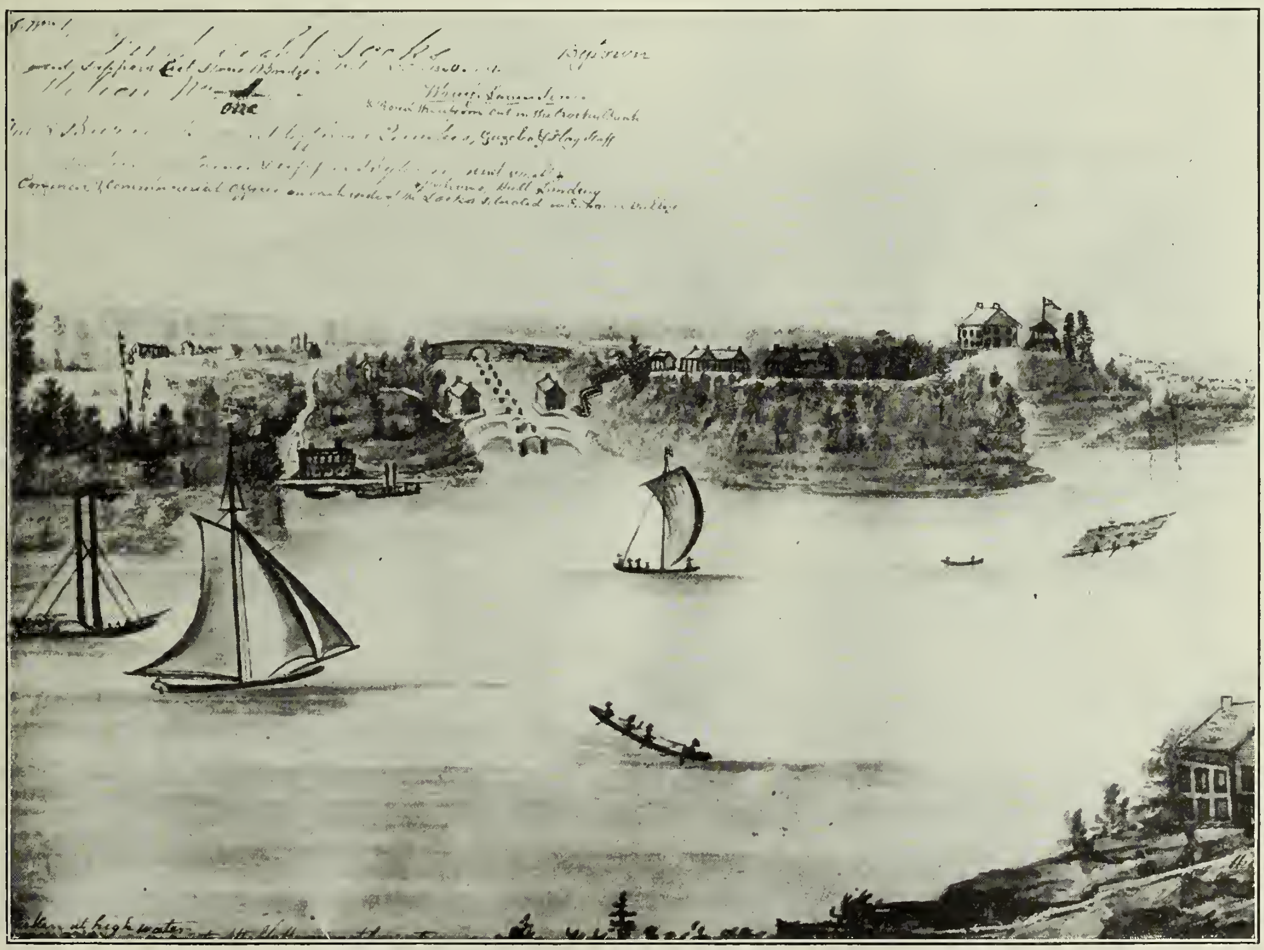
Cochabamba-Vallegrande-Santa Cruz	274 miles
Santa Cruz-Puerto Suarez	469 "
Cochabamba-Sucre	150 "
Santa Cruz-Yacuiba	375 "
Cochabamba-Todos Santos	135 "
Todos Santos-Riberalta	625 "
Cochabamba-Oruro—La Paz	236 "

In addition to these three large systems or groups of interests there are several smaller organizations operating regular air lines. These include the national air lines of Chile—half of which are operated by the Army Air Service and half by the Naval Air Service, and the Faucett Aviation Company of Peru.

Air mail is by far the most important subject of air transportation, due to its benefits to commerce and to the income it furnishes. Canada is now connected by air mail services to the following countries and colonies of Latin America:

Argentina
Bahamas (Nassau)
Brazil
British Guiana
British Honduras
Canal Zone
Chile
Colombia
Costa Rica
Cuba
Curacao
Dominican Republic
Dutch Guiana
Ecuador
Guatemala
Haiti
Honduras
Leeward Islands
Mexico
Nicaragua
Panama
Peru
Porto Rico
Salvador
Trinidad
Uruguay
Venezuela
Virgin Islands
Windward Islands

A letter from Montreal to Rio de Janeiro carried over the international air lines would be flown over 8,000 miles in seven days; across more than twenty-four international frontiers and over people speaking six different European languages.



Entrance to Rideau Canal at Bytown

THE
ENGINEERING JOURNAL
THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XIV AUGUST 1931 No. 8

Annual Meeting of The Institute

It is announced that the next Annual Meeting of The Institute will be held at the Royal York Hotel, Toronto, Ont., on February 3rd, 4th and 5th, 1932, under the auspices of the Toronto Branch of The Institute.

Report of the R.101 Enquiry

The report, dated the 27th of March, 1931, of the court appointed to investigate the accident of the airship R.101 is based upon an agreement on all points by the three members of the court, namely:—

Sir John A. Simon,
Lt.-Col. J. T. C. Moore Brabazon,
Professor C. E. Inglis.

The first part of the report deals with the early history of airships, and the circumstances which led up to the 1924 programme of construction of airships. It is pointed out that in undertaking the construction of the two airships R.100 and R.101, the Air Ministry ordered much more complete investigations of all the conditions to be met in the design of these airships than had ever been previously attempted.

These two airships were to be nearly twice the capacity of any previous airships built in England, and more than a third larger than the largest existing Zeppelin. The gross lift was supposed to be 150 tons, of which structure weight must not exceed 90 tons and the useful lift was to be 60 tons. Further the power plant was to operate on fuel that could be carried safely in tropical climates.

The Airship R.101 was designed by the Royal Airship Works at Cardington, although the actual construction of the parts of the ship was carried out by an outside contractor. This work was so well done that erection was made at Cardington without any difficulty.

The R.101 contained a number of experimental features, covering such things as the design and method of construction of the hull framing, the construction of the gas valves, and the design of the gas bag wiring which maintains the gas cells in position and transmits the lifting forces from the gas cells to the frame of the airship. In addition the method of construction and application of fabric covering included a number of changes over previous practice, and finally the use of engines employing a fuel oil instead of gasoline represented a big departure from what had been done before.

By the end of September, 1929, the construction of the R.101 was complete, but by this time it was known that the useful lift of the airship was considerably below the 60 tons originally estimated. Her fixed weights amounted to as much as 113.6 tons, leaving only about 25 tons for useful lift. The increase in the weight was partially due to the engines being overweight, but also due to the weight of the structure being greater than the estimated figure.

Two preliminary trials of 5½ hours and 9½ hours duration were carried out on October 14th and 18th, 1929, respectively. Four more trials took place between November 1st and November 14th. These were all of short duration from 3 to 14 hours, during which very complete data were collected, indicating the care with which these preliminary trials were carried out.

During this time on November 11th the airship rode out a severe gale while at the mast, without damage, but during which it was discovered that there was some chafing of the gas bags due to roll of the ship.

On the 17th and 18th of November an endurance flight was undertaken lasting 30 hours 41 minutes, although it had been intended that the flight should be of 36 hours with a possible extension to 48 hours; turning trials were carried out during this test, but a bridle connecting the gas bag wiring broke just prior to landing. The airship was then put into her shed where she remained until June of the following year, having done a total of 70 hours flying since launching, mainly in good weather and not including any trial at full speed. During these trials she had behaved well.

The question now arose as to how to increase the useful lift to make the voyage to India possible. These discussions resulted in a proposal to lighten the ship as much as possible by removing the servo gear, which supplemented hand steering, and a number of other fixed loads, and to enlarge the gas bag wiring so as to enable the gas bags to occupy more space. In addition it was decided to increase the length of the ship by inserting an additional middle section or bay, which it was estimated would increase the useful lift by nine tons.

When these changes were completed, with the exception of the insertion of the additional bay, the airship was brought out of the shed again on June 23rd, 1930, and was moored at the tower, when a split developed in the outer cover extending to a length of about 140 feet. Weather conditions did not permit putting the ship into the shed, and the tear was repaired in place at the mast. The next day another tear occurred, and it was similarly repaired.

The eighth, ninth and tenth flights took place on June the 26th, 27th and 28th, these being of 4½, 12½ and 12½ hours duration respectively.

Squadron Leader Booth's impression of the flight on June 27th indicated that the ship flying at reduced speed appeared to be bumping rather a lot, and during the day was getting heavier than seemed to be consistent with the temperature and height at which they were flying.

On July 3rd, 1930, the inspector in charge at Cardington reported considerable chafing of the gas bags against projecting parts of the structure, and on July 22nd the insertion of the new bay was authorized. The parts for this had already been received from the contractor.

In all the trial flights up to this time four engines had been used only for driving ahead and a fifth engine had been used for driving astern, due to the fact that the reversible propellers originally proposed had not been delivered. While the airship was being modified it was decided to install two reversing engines, and this and other delays resulted in keeping the airship in the shed until October 1st.

In previous documents Lord Thomson, the Secretary of State for Air, had approved the alterations to the airship, provided that she was ready to go to India by the last week in September. In the first design of this airship considerably more attention than usual had been paid to investigations upon strength and airworthiness of the structure, but although the insertion of a new bay necessitated a complete recheck of these design features, the time available did not permit of this being done, with the result that the consultants employed on this work had not finished their report at the time of the accident and had released the ship on October 1st, mainly upon general considerations rather than specific calculations.

The time fixed for the journey to India had now been passed and conferences took place with the Secretary of State, in order to fix the date of departure. It was decided that as the air business of the Imperial Conference might be put off until about October 20th the airship should start, if possible, on October 4th, giving the Secretary of State time to get back to England in time for the Imperial Conference.

In the early morning of October 1st the R.101 again left her shed and was taken to the mast. Up to this time the airship had not done the 48-hour trial, which was necessary for airworthiness purposes, and it was realized that to carry out a trial of this length would leave insufficient time for preparations before the India flight on October 4th. Therefore, permission was asked from the Air Ministry to reduce the trial flight to 24 hours, if Major Scott was satisfied with the ship's behaviour. If any report was made of this trial it was destroyed with the ship, but from such records as are available it is indicated that it was impossible to carry out the full speed test owing to the failure of an oil cooler in one of the engines. Also flying conditions were very perfect, and under these conditions the ship behaved well.

It is significant that at this point Squadron Leader Booth states that the ship's officers would have preferred a series of further flights had the time permitted. Flight-Lieutenant Irwin, commander of the ship, had particularly stated that he hoped they would fly 36 or 48 hours in bad weather.

Following this trial flight a conference was held at the Air Ministry at which it was decided that the ship would leave on the evening of Saturday, the 4th of October. At this conference it was pointed out that as the ship had not done a full power trial she would do full power tests near home after leaving Cardington for India. Subsequent events proved that this trial was not carried out.

The R.101 started on her flight for India on Saturday evening, October 4th, 1930, leaving Cardington at 6.36 (G.M.T.) in the dark with the wind blowing in gusts increasing in intensity and with the barometer falling.

There were fifty-four people on board, six of whom were passengers, six were officials from the Cardington Airship Works and the remaining forty-two were the officers and crew. Messages were received by wireless from the airship from 8.21 p.m. until 1.28 a.m., indicating that everything appeared to be normal on board the ship, also the watch was changed at 2 a.m., which is assumed to be an indication that all was well, otherwise this change of watch would not have taken place.

About this time the ship was passing to the east of Beauvais, and was seen by a number of citizens from the ground.

The evidence of the survivors shows that a few minutes after 2 o'clock the vessel got into a rather long and steep dive, then was brought out with approximately even keel, then went immediately into a second dive of shorter duration which brought her nose first to the ground, when she burst into flames.

Orders were given before the crash to reduce the speed of the engines. The contact with the ground was not severe, and the ship moved forward about 60 feet before finally coming to rest. It seems to be clearly indicated that no one was injured in the actual crash and that the loss of life was entirely occasioned by the subsequent fire, which is attributed to an electric spark.

The court find that the accident was not due to structural weakness, or to a failure of the control gear, also that the officers and crew were competent in the carrying out of their duties. They find, however, that the disaster was probably caused by a substantial loss of gas in very bumpy weather, this loss of gas being attributed to the failure of one or more gas bags in the forward part of the ship, which in turn might have been caused by some misfortune, such as the ripping of the forward part of the envelope.

Subsequent calculations made by the National Physical Laboratory appear to confirm that the path of the airship under these assumed conditions would be consistent with the evidence obtained.

Publications of Other Engineering Societies

From time to time announcements have appeared in The Engineering Journal and the E-I-C News regarding the exchange arrangements which exist between The Engineering Institute of Canada and the founder engineering societies of the United States, whereby members of The Institute may secure the publications of the American societies at the same rate as charged to members of those societies. A list of these publications, with the amounts charged, is given below, and subscriptions may either be sent direct to New York or through Headquarters of The Institute.

	Rate to Members	*Rate to Non-Members*
American Institute of Electrical Engineers		
Electrical Engineering, single copies	$ 0.50	$ 1.00
Per year	5.50	10.50
Transactions, per year:		
Paper	5.00	10.00
Cloth	5.00	10.00

PERSONALS

D. R. Ross, S.E.I.C., has joined the staff of the Consolidated Mining and Smelting Company at Trail, B.C. Mr. Ross graduated from McGill University this spring with the degree of B.Sc.

W. L. Kent, S.E.I.C., who graduated from the University of Alberta with the degree of B.Sc. in the spring of this year, is now connected with the Provincial Department of Public Works, Edmonton, Alta.

K. S. Ritchie, S.E.I.C., is on the staff of the Research Products Engineering Department of the Northern Electric Company, at Toronto, Ont. Mr. Ritchie graduated from the Nova Scotia Technical College in 1931 with the degree of B.Sc.

W. B. Hutcheson, A.M.E.I.C., has been appointed assistant engineer, Department of Northern Development of the province of Ontario, at Kapuskasing, Ont. Mr. Hutcheson was formerly with the Dominion Water Power and Hydrometric Bureau, at Ottawa, Ont.

K. B. THORNTON, M.E.I.C.

K. B. Thornton, M.E.I.C., Honoured

K. B. Thornton, M.E.I.C., general manager of the Montreal Tramways Company, was elected president of the Canadian Electric Railway Association at a recent meeting of that society. When the present owners of the Montreal Tramways took control in 1925, it was found necessary to carry out many major improvements to that property and Mr. Thornton was then appointed assistant general manager, and had charge of the modernization of all departments. The improvements included the renewal of tracks, purchase of new cars, and an almost complete revision of the power supply. The rail services have been supplemented by numerous bus lines, so that to-day the Montreal Tramways is one of the largest operators of buses in Canada. Mr. Thornton has been connected with the Canadian Electric Railway Association for a number of years, having served on the board of directors, and his election to the office of president is the highest honour that can be conferred on an electric railway operator in Canada.

F. C. Tempest, A.M.E.I.C., is now located at Barranca Bermeja, Colombia, South America, as a member of the staff of the Tropical Oil Company. In 1930 Mr. Tempest was construction engineer and plant foreman with the Royalite Oil Company at Okotoks, Alta., and prior to that was with the Imperial Oil Refineries at Calgary, Alta.

K. E. Buchmann, A.M.E.I.C., is now on the engineering staff of Lake Shore Mines, Ltd., Kirkland Lake, Ont. Prior to accepting his present position Mr. Buchmann was with the International Nickel Company at Copper Cliff, Ont., and was at one time assistant to the chief engineer of the Deloro Smelting and Refining Company at Deloro, Ont. He is a graduate of the University of Toronto of the year 1925.

M. S. Blaiklock, M.E.I.C., assistant chief engineer of the Canadian National Railways, has retired after more than fifty years' service. He was for a number of years engineer of maintenance of way, and in 1930 received the appointment from which he now retires. Mr. Blaiklock, who has been active in connection with the co-operative management plan with maintenance of way employees on the national system, has consented to continue as chairman of the General Co-operative Committee of Maintenance of Way employees. Mr. Blaiklock joined The Institute as a Member on June 12th, 1909.

Lieut.-Colonel Charles G. DuCane, O.B.E., M.E.I.C., has been appointed by Council to represent The Institute at the Faraday Centenary Celebrations which are to be held this year. Colonel DuCane, who is well known in Canada, particularly in British Columbia, where he was head of a successful consulting organization, is now associated with the firm of Sir John Wolfe Barry and Partners, London, England. The Faraday Centenary Celebrations which are to take place in London on September 21st, 22nd and 23rd, 1931, commemorate the discovery on August 29th, 1831, by Michael Faraday, which made the dynamo possible, and formed the starting point of the utilization of electric power for the purposes of man.

A. Lariviere, A.M.E.I.C., has been appointed engineer of the Public Service Commission in Montreal in succession to the late F. C. Laberge, M.E.I.C. Mr. Lariviere is a graduate of the Ecole Polytechnique, Montreal, from which he received his degree of B.Sc. and C.E. in 1913, and E.E. in 1916. Immediately following graduation, Mr. Lariviere was engaged on highway engineering for the roads department of the province of Quebec, and for a short period on highway contracting. On the completion of his post-graduate course in electrical engineering in 1916, he joined the staff of the Quebec Public Utilities Commission, with which he has remained until the present time, first as electrical and road engineer, and since 1923 as chief engineer.

H. E. M. Kensit, M.E.I.C., after fifteen years in the Dominion of Canada Civil Service, has retired to enter

H. E. M. KENSIT, M.E.I.C.

private practice. After a number of years on investigation work in Canada and the United States, and on construction work in Canada for Messrs. Smith, Kerry and Chace, Mr. Kensit was appointed to the Water Power Branch of the Department of the Interior, and since that time has been engaged on the analysis of the financial and engineering aspects of power undertakings and the study of power markets in various localities. In 1918-1919 he represented the Department on the Government Water Power Committee and on the water power committee of the Conjoint Board of Scientific Studies, in London, England. On returning to Canada he investigated the power situation in Winnipeg and in Calgary, and took an active part in the preparation of the Dominion Water Power Regulations. Latterly he has been engaged on studies of the power demand and duration of water power resources in the St. Lawrence and Great Lakes basin and other large areas.

S. J. Fisher, B.Sc., M.E.I.C., has recently been appointed to the position of general superintendent in charge of the Riverbend mills of Price Brothers and Company, Ltd., and is now located at Riverbend, Que. Mr. Fisher was for six years sales and service engineer for Babcock and Wilcox, Ltd., and from 1916 for three years was engaged in mechanical engineering work at Ottawa for the Canadian and British governments. At the close of 1921 he entered the newsprint field with the E. B. Eddy Company, Ltd., at Hull, Que., where he was woods manager for four years, and also supervised the engineering, installation and start of operation of the new Eddy newsprint mill. In 1926 he joined the staff of John Stadler, M.E.I.C., in charge of the drawing office of the Lake St. John Power and Paper Company, Ltd. After supervising the installation of the machinery in the new newsprint mill at Dolbeau, Mr. Fisher was appointed mill manager, and started up and operated the mill for over three years.

BOOK REVIEW

Transactions of the Second World Power Conference, Berlin, 1930

Volume I: Uses of Electricity

Published by VDI-Verlag, GmbH, Berlin, 1930, cloth, 6 x 9½ in., 640 pp., figs., charts, tables. Agents: Percy Lund, Humphries & Co. Ltd., £2.0.0.

This is Volume I of the series of twenty volumes forming the set of publications of the Second World Power Conference. Eighteen of these volumes are each devoted to one of the Conference sections and give in convenient form for reference the papers presented and discussed at the Second World Power Conference held in Berlin in June, 1930. The papers are printed in either English, French or German, as the case may be, these being the three official languages of the conference.

The first volume of transactions contains twenty-eight of the three hundred and seventy-six papers presented at the conference, being those devoted to the uses of electricity. An introduction gives a general account of the Second World Power Conference and its proceedings, this being followed by a list of the distribution of the papers according to sections, and then the papers themselves, divided into two sections, Electricity in the Household and in Agriculture, and, Electricity in Crafts and Industry. At the conference, the whole field covered was divided among thirty-four such sections.

The discussions which arose are not given in detail but to each section of the volume is appended a brief summary in German of the discussion which took place on the papers it contains, together with a general report of the proceedings in each section.

Section 1 includes contributions on electrical supply in the house and on the farm, in Canada, Great Britain, Germany, France, Italy, Norway, Sweden, Greece, Japan, and the United States, while Section 2 contains papers on the applications of electrical power to electro-chemistry, electro-metallurgy, electrical heating, lighting, and gas purification, in most of the principal industrial countries of the world.

The volume is admirably printed and produced, and indicates that the whole series of eighteen volumes will be a most valuable addition to the shelves of public or institutional libraries, while individual engineers will find the volumes dealing with their special interests well worthy of perusal.

RECENT ADDITIONS TO THE LIBRARY

Proceedings, Transactions, etc.

American Welding Society: Year Book, August, 1930.
International Federation for Housing and Town Planning: International Housing and Town Planning Congress, Berlin, 1931: Part 1: Papers.

Canadian Limestones for Buildings

Canadian builders and architects are turning to the deposits of native stone for the material with which to build the finest structures within the Dominion. The Canadian limestones are ousting imported stones from the domestic market. Evidence of this may be seen in most of the principal cities from coast to coast wherever important buildings are being erected. The new store of the T. Eaton Company in Toronto is being faced with Tyndall limestone from Manitoba. This building covers eight acres of ground and will contain one million cubic feet of stone. The imposing new customs house in Toronto is faced with Queenston limestone. The head office buildings of the Royal Bank of Canada and of the Bell Telephone Company of Canada in Montreal, are faced with limestones brought from Queenston, Ontario, and St. Marc, Quebec. A similar combination of these two Canadian limestones is used in the fine new building of Price Brothers in Quebec city. Hamilton, Ontario, contains several fine structures in which both Queenston and Tyndall limestones have been used.

The cities of western Canada, especially Winnipeg, contain many structures of Tyndall limestone. The beautiful parliament buildings of Manitoba and Saskatchewan exemplify the architectural possibilities of this stone in the monumental type of building. Both the new post office in Calgary and the recently completed administration building of the government of Alberta in Edmonton are faced with Tyndall limestone. The same stone was used in the construction of the Hall building, Vancouver, and for the trim of the new wing of the Empress hotel in Victoria.

During 1930, the value of dimension-stone produced from Canadian limestone quarries was the highest ever recorded—$1,726,413—an increase of 42 per cent over 1929. This record production was concurrent with a decrease of nearly 30 per cent in value of building permits and a decrease of 20 per cent in imports of foreign limestone. A further increase in production is anticipated for 1931.

The principal quarries from which limestone for building purposes is obtained are located in three widely separated localities: St. Marc, 50 miles east of Quebec city; near Queenston in the Niagara peninsula of Ontario; and at Garson, 30 miles northeast of Winnipeg. The Queenston stone is a beautiful silver-grey. The St. Marc limestone is also grey. The Garson quarries produce the mottled Tyndall limestone, of which there are two varieties—one having a grey base, mottled with grey-brown, the other a buff base with buff-brown mottlings. All the Canadian stones are used for interiors as well as exteriors of buildings—particularly the Tyndall stone which, on account of its unique and handsome mottling, is commonly used as a decorative interior stone; a prominent example of its use for this purpose being the interior of the Houses of Parliament at Ottawa.

A very necessary quality in a building stone for exterior work is ability to resist the action of the weather and other agencies which cause decay. Researches by the Mines Branch, Department of Mines, Ottawa, and examination of structures erected many years ago, demonstrate that from the limestone deposits within the Dominion, building stones can be produced which are superior in strength and durability to any limestone imported into the country.

BRANCH NEWS

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Self Preservation in the Wilds

On Friday, 26th of June, at 8.15 p.m., in the lecture room of the Royal Canadian Air Force Photographic section, the Aeronautic section of the Ottawa Branch listened to a very interesting paper by Inspector A. H. Joy, of the Royal Canadian Mounted Police, on the subject of "Self Preservation in the Wilds."

Inspector Joy has had many years of experience in the Northwest Territories and in the eastern Arctic archipelago. Some of the personal experiences which he related in order to illustrate special points in his address proved that he was a master of his subject.

The matters upon which he spoke are vital to aviators who fly over the unoccupied territories of the north of Canada. After the lecture the Royal Canadian Air Force Photo Section showed a film illustrating the building of an Eskimo igloo and of an Eskimo dog sleigh.

Professor J. H. Parkin, M.E.I.C., of the National Research Council of Canada, was in the chair.

Sault Ste. Marie Branch

A. A. Rose, A.M.E.I.C., Secretary-Treasurer.

The regular meeting of the Branch was held in the Windsor hotel following a dinner. The speaker of the evening was Mr. Russel Wiber of the contracting firm of McLartys, Harten and Wiber, Ltd., who had taken as his subject "Construction Features of the New Windsor Hotel, Sault Ste Marie, Ont."

The New Windsor Hotel, Sault Ste Marie

The structure of this hotel is "reinforced concrete on the so-called pan system," that is, the columns, beams, joists, floors, etc., are of reinforced concrete, the joists being separated by pans over which the concrete is poured. Joists are placed two feet on centre and are continuous from front to back. The beams and lintels (outside beams) run across the building from east to west.

For the concrete a compression test was specified. As a very wet mix was necessary in order to work the concrete down around and into close contact with the reinforcing, some difficulty was anticipated in getting a mix that would fulfil requirements, but using screened gravel, sand and cement it was readily obtained.

The reinforcing steel was produced and bent by the local mill. That for the columns was assembled on the ground and then hoisted and dropped into place inside the forms. That for the beams and joists was fabricated in place. The floors were reinforced by round rods and expanded metal. A floor was poured in one day and construction was restricted to two storeys per week to give the concrete time to develop necessary strength.

The excavation is 14 feet below the sidewalk level, 10 feet of this being in solid rock. Piers are anchored in pockets. The rock was all hand quarried as it makes good building stone.

The outside walls are 8-inch tile, faced with brick, the tile being built in between the lintels and the whole wall carried by the framework from floor to floor, the brick work being tied into the lintels and tile. The partition walls are gypsum blocks except for bathrooms where they are terracotta.

The metal lath was put down before the concrete and is secured mainly by the grip of the concrete. There are suspended ceilings in the bathrooms, rotunda and dining-room. The hangers were left in the concrete between pans; to these channel irons were attached and lath applied to the channels.

A number of wells about two feet by four feet extending from bottom to top of the building take care of all plumbing, heating, etc. The wiring is all above the metal lath in the ceiling and below the concrete floor.

The stairs are of the service type, built of reinforced concrete. The window frames are yellow pine and the door frames are metal. The terrazzo floors were the only part of the building constructed by other than local artisans. The electric elevators are all manually controlled.

The roof is concrete slab, the same as the floors, with insulation and roofing. Another feature is the steel smoke stack, the lower 30 feet of which is lined with fire brick.

The rotunda finish is imitation travertine being first an ordinary three-coat plaster job on metal lath and after thorough drying a thick coat of "Gyptex" (powdered gypsum and plaster of paris) applied with heavy brushes and on partial hardening struck down with a steel trowel. The tinted effect is obtained by colour, integral with the Gyptex while in mortar state.

A hearty vote of thanks was tendered Mr. Wiber for his interesting paper. To add to the pleasure of the evening, Messrs. W. and E. Fulcher, of the Chateau Films, showed the Canadian National moving picture "Fishing Across Canada," which was greatly enjoyed by all.

Methods of Treating Roads

The regular June meeting of the Branch was held in the Windsor hotel on June 26th following the regular dinner.

The speaker of the evening, Mr. H. F. Coon, of the rotar department of the Alexander Murray Company of Toronto, being unable to be present, forwarded his paper, which was read by J. Hayes Jenkinson, A.M.E.I.C.

This paper described various methods of treating roads with tar products to make a durable dustless surface low in first cost and economical in upkeep. This was of special interest to those present, as the city plan to do some work of this type during the present season, and considerable discussion followed the reading of the paper.

Their Royal Highnesses the Prince of Wales and Prince George in Brazil

During their recent visit to Brazil, Their Royal Highnesses the Prince of Wales and Prince George visited the Sao Paulo-Parana Railway which is under construction by Macdonald, Gibbs and Company (Engineers) Ltd., and the lands of Parana Plantations Ltd., London.

The Institute is indebted to C. B. R. Macdonald, A.M.E.I.C., for the accompanying photographs, the first of which shows the triumphal arch erected in honour of Their Royal Highnesses by Macdonald, Gibbs and Company, and the second, the Prince of Wales returning to base camp after a 16 kilometer "stroll" over the partly finished railway line. Accompanying the Prince are: Lieut.-Colonel H. C. Macdonald, D.S.O., M.Inst.C.E., M.E.I.C., Lord Eldon, The Master of Lovat, C. B. R. Macdonald, A.M.E.I.C., Mr. Storrier, Scotland Yard. In the foreground are Captain T. D. Hamilton, M.C., M.Inst.C.E., Superintendent of the Sao Paulo Parana Railway, A. H. M. Thomas, Managing Director, Cia Tinas Notre de Parana.

Arch Erected in Honour of the Prince of Wales and Prince George.

Prince of Wales returning to Base Camp after a 16 kilometer Walk.

Committee on Trail Smelter Smoke Investigation of the National Research Council

Co-operating Organizations: British Columbia Department of Agriculture, Dominion Department of Agriculture and Dominion Forest Service

An international problem of some importance has arisen through the proximity to the Washington state line of the smelting and refining plants of the Consolidated Mining and Smelting Company of Canada, situated at Trail, B.C., in the Columbia river valley. It has been alleged by residents of the valley immediately south of the international boundary that smoke from the smelter is blown down into that territory, and that it has caused serious damage to forests, farm crops, livestock, exposed metal, and even to the soils of that area. The question was brought to the attention of the respective federal governments which asked the International Joint Commission to investigate and recommend a basis upon which settlement should be effected. The Dominion government instructed the National Research Council to make a scientific investigation of the effect of smelter smoke in that area, and field studies were accordingly begun in the spring of 1929. Obviously, no detailed report of that investigation can be issued until a settlement has been made, but something may, nevertheless, be said as to the method followed in the scientific studies.

The works of the Consolidated Mining and Smelting Company at Trail constitute one of the most important metallurgical plants in the world, one which, from the point of view of tonnage of metal produced, actually occupies the leading position. The company has some thousands of employees, both at Trail and at the principal mine and concentrator at Kimberley, B.C., and many more thousands are indirectly dependent upon the operations of this company for a livelihood. Its continued operation is therefore a matter of great importance, not only locally but also to the industrial life of the Dominion. During the last six years the operations of this company have been greatly expanded and improvements in metallurgical practice have been effected which not only have resulted in marked economies in operation but also have reduced, in some cases practically to the point of complete elimination, those constituents of the smelter gases which might have an adverse effect upon animal or plant life. In this respect also, the company has kept well in advance of the usual metallurgical practice. This has been fully borne out by an independent report made by G. L. Oldright, metallurgist of the United States Bureau of Mines.

Unfortunately, sulphur dioxide, which is one of the constituents of smelter smoke, is not readily eliminated from it, and has passed into the atmosphere in quantity up to 600 tons per day. This gas, in sufficient concentration, is harmful to vegetation and its action has therefore been the subject of the most careful study. Pursuing its established policy of advanced practice, the company has taken steps to convert a large part of this gas into sulphuric acid, which it proposes to use in the manufacture of super-phosphate and other fertilizers. This development will require an expenditure in excess of $10,000,000 for the first unit, which it is expected will be brought to completion in 1931, and the operation of which will, it is hoped, greatly reduce any present effect of the smelter smoke upon vegetation in the vicinity.

Field crop studies in the Northport district have been carried out for the National Research Council by Dr. G. H. Duff of the University of Toronto. Careful observations have been made both within and without the area in which it is claimed that damage has been caused by smelter smoke. A study has been made of farming practice, including the need for and use of fertilizers, irrigation, the prevalence of plant diseases and other related questions. A similar study of orchards in the district has been made by M. S. Middleton, horticulturist of the British Columbia Department of Agriculture. Soil conditions have been investigated by Dr. F. A. Wyatt, of the University of Alberta, who has determined the amount of plant food available, the activity of those micro-organisms necessary to plant life, the acidity of the soil and its content of soluble sulphate, a possible source of which might be the sulphur dioxide of the Trail plant.

Dr. S. Hadwen, recently of the University of Saskatchewan, and now in charge of veterinary research for the Ontario Research Foundation, has made a careful study of livestock in the district. Many animals found to be diseased or in poor condition were slaughtered and examined to determine the cause. Stock was inspected at points outside the area and where kept in immediate proximity to the smelter, and the condition of stock, fed on hay grown in the area where sulphur dioxide was frequently observed, was noted.

An extensive study of forests in the Northport district was made by A. W. MacCallum, forest pathologist, and R. Hopping, entomologist, both of the Dominion Department of Agriculture. In addition to the careful examination of the forests over a large area for evidences of sulphur dioxide markings, plots were selected both within and without the district, and a census was made to determine not only the condition of every living tree, but also, where dead trees were found, the cause of death. In this way a reliable comparison was secured between conditions prevailing in the zone of damage and those where sulphur dioxide is never found. In addition, some 3,600 trees were bored and the cores obtained were measured for annual growth by the Dominion Forest Service. The detailed study and interpretation of these measurements was undertaken by F. E. Lathe of the National Research Council. This study was somewhat complicated by the fact that for years there was operated in the town of Northport itself, a smelter which was the source of a considerable quantity of sulphur dioxide. A second factor of importance was that in the Northport area the precipitation is so low that under ordinary conditions it is the controlling factor in forest growth. In spite of these difficulties it nevertheless proved possible to determine the area within which retardation of growth has occurred, due to the operation of the two smelters, and to form an approximate estimate of the amount of retardation.

As a further check on the effect of sulphur dioxide in the district, the percentage of this gas present in the atmosphere was accurately determined, both by the extensive use of a portable apparatus with which a large territory could be readily covered, and by the installation of automatic recorders at two points where determinations were made every twenty minutes over a period of many months. Observations were made of the prevailing conditions of humidity, temperature, sunlight, wind direction and other known factors affecting sulphur dioxide presence and damage. In addition, the sulphur content of the vegetation was determined by analysis of samples obtained over a wide area, in order to detect any abnormal conditions. This chemical investigation was carried out by Dr. G. S. Whitby, Director of the Division of Chemistry in the National Research Laboratories, and by Dr. Morris Katz of his staff.

The results of these investigations to date have been presented to the Dominion government in the form of a report prepared by the president of the National Research Council, and also in testimony given by the scientific staff before the International Joint Commission in session in Washington, D.C., in January and February, 1930. It is proposed to continue the field investigations until a settlement of the case has been effected.

—*Thirteenth Annual Report of the National Research Council.*

International Business Machines Corporation announce that they have exclusive world rights to the Filene-Finlay Translator, a method of multiple, simultaneous translation, which provides for equipment to be installed in convention halls or other assembling places either in temporary or permanent form. When necessary, amplifiers throughout the hall insure that the whole audience may easily hear the speech delivered from the platform or the questions from the floor, microphones being provided at both points. In addition, however, a telephone line from these microphones carries the speech to a translators centre which may be a separate room, a series of soundproof stalls or merely a row of desks in some part of the auditorium. At the translators' centre are a number of highly trained translators, one, of course, for each language which is to be presented to the audience. Each translator wears a telephone headset, through which he hears the speech being delivered. In addition, each translator has a microphone before him, and all of these microphones are connected by a system of telephone cables to every seat in the auditorium. In cases where a speech is made in a language which all of the translators do not understand, one of them becomes a master translator. He receives the speech and translates to the other translators in a language which all understand.

The system is largely made up of standard telephone and radio units. Radio amplifying units are used to increase and control the volume of sound from the loud speakers as well as that delivered to the translators and from them to the audience. A special type of microphone has been developed for the use of the translator, so that no sounds other than his own voice can enter the instrument and the sound of his speaking is not heard by those working next to him. By this means, it will be possible for translators to work in the open hall instead of sound-proof booths for each man being required.

The Ohio Brass Company, Mansfield, Ohio, has recently succeeded in developing a new line of light weight malleable iron suspension clamps which will accommodate all sizes of conductors from 2-0 to 795,000 c.m. These clamps, it is stated, are well suited to A.C.S.R. conductor with armour rods and will equally well accommodate other types of conductors of comparable size requirements. Made of O-B Flecto malleable iron, the new clamps, while conforming to the same general design principles of former O-B clamps, have a number of new and valuable features. A smooth conductor seat of proper curvature to best serve the cable; much lighter weight at no sacrifice to strength; "J" or "U" bolts, depending upon the grip required; high resistance to corrosion, and general compactness are a few of the outstanding features.

Link-Belt Company, 910 S. Michigan Avenue, Chicago, Ill., announces the publication of Material Handling and Power Transmission Data Sheet No. 3, entitled "Selecting the Positive Drive," and containing suggestions which may aid in determining which type of positive drive will give most satisfaction. Copies of the sheet may be obtained from the company at the above mentioned address.

Preliminary Notice

of Applications for Admission and for Transfer

July 17th, 1931

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in September, 1931.

R. J. Durley, *Secretary.*

* The professional requirements are as follows—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

HOGG—SIDNEY, of 32 Sydney Street, Saint John, N.B., Born at Dundee, Scotland, January 1901; Educ., 1917-22, Dundee Technical College (Naval Architect); Member, Assn. Prof. Engrs., N.B.; 1918-21, dftsman., arrangement, steel and piping, 1921-22, designing, shiplines, stability, trim, etc., 1922-23, squad leader, Dundee Shipbldg. Co. Ltd.; 1923-24, struct'l. steel detailer, 1926-28, asst. struct'l. steel designer, Canadian Vickers, Ltd.; 1924-25, struct'l. steel detailer, 1925-26, checker, struct'l. D.O., Canadian Bridge Co. Ltd.; 1928-31, designing engr., Saint John Dry Dock & Shipbldg. Co. Ltd., at present in charge of struct'l. design dept., bridges, bldgs., tank and plate work. (Also responsible for design of highway bridges for Prov. Govt. of N.B. during past three years—Prof. R. E. Jamieson, McGill, and design of steelwork for pulp mill, F. O. White).

References: R. E. Jamieson, J. N. Flood, H. Thorne, J. Portas, V. S. Chesnut, A. A. Turnbull, H. J. A. Chambers.

KERRY—ARMINE JOHN, of Quebec, Que., Born at Montreal, Que., Aug. 6th, 1905; Educ., Diploma (Honours), R.M.C., 1927. B.Sc.(Civil) McGill Univ., 1929; 1924-25 (summers), asst. to plant engr., Canadian Paperboard Co., Frankford, Ont.; 1926 (summer), asst. to camp engr., Petewawa Camp; 1927-28, regimental employment, R.C.E., Halifax, N.S.; 1929-31, regimental duties in conjunction with various courses at the School of Military Engineering, Chatham, etc.; at present, Works Officer, M.D. No. 5, Quebec, Que. (Capt., R.C.E.)

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Vacant

Assistant Commissioner of Works

ASSISTANT COMMISSIONER OF WORKS for the City of Ottawa, Ontario. Should be a graduate of the Faculty of Engineering in a recognized university, have complete and comprehensive knowledge of theory and modern practice of engineering, at least five years engineering practice, preferably municipal engineering experience, have held positions of professional responsibility and been in charge of work as principal or assistant engineer. Salary $4,000.00, increasing to a maximum of $4,500.00 per annum. Application forms may be obtained from the Headquarters of The Engineering Institute of Canada, 2050 Mansfield Street, Montreal, Que., and should be forwarded to the Board of Control, Transportation Building, Corporation of the City of Ottawa, Ontario. Applications will be received up until twelve o'clock noon (D.S.T.) August 18th, 1931.

CHEMIST. Electrolytic chemist for laboratory work. Must have practical experience in this particular class of work. Location, Manitoba. Apply giving full information regarding experience to Box No. 731-V.

PRODUCTION ENGINEER, for industrial plant in Quebec province, age about thirty-five, must speak French and English fluently, at least ten years experience in mechanical engineering, automatic machinery and general production work. Must have had actual experience in plant operation in a supervisory capacity, and able to introduce planning and production methods and maintain them. Apply to Box No. 738-V.

Capital to Invest

BUILDING CONSTRUCTION EXECUTIVE, located in New York city, Canadian born, graduate McGill University, wishes to locate in Canada, preferably Vancouver, B.C. Will invest $20,000 and services in established construction concern where capital is needed for expansion. Fifteen years field and office experience. Past three years general manager of construction. Apply to Box No. 230-W.

ELECTRICAL ENGINEER. College graduate with about seven years designing experience with large manufacturer of electrical apparatus; would consider junior partnership with electrical contractor or electrical repair firm. Could invest several thousand dollars. Correspondence invited. Apply to Box No. 579-W.

Situations Wanted

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), 15 years experience, available on short notice. Experienced surveys, draughting, reinforced concrete design, municipal engineering, construction work, inspection, estimating. Apply to Box No. 107-W.

CIVIL ENGINEER, university graduate 1926, desires employment as junior engineer or instrumentman on construction work. Experience, resident engineer on railway construction, miscellaneous surveys. References. Available any time. Apply to Box No. 149-W.

CIVIL ENGINEER, B.Sc., age 34, is open for a position as construction engineer in charge of construction of hydro-electric plants or paper mills; designing engineer of hydro-electric developments or paper mills. Willing to make small investment. Apply to Box No. 157-W.

ELECTRICAL ENGINEER, B.Sc., McGill 1926. Five years experience in the design of switchboards, layouts and wiring diagrams. Considerable experience in high and low tension switchgear design. Fifteen months experience in switchboard estimating. At present employed; available on short notice. Correspondence invited. Apply to Box No. 247-W.

REINFORCED CONCRETE ENGINEER, B.Sc., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

ELECTRICAL ENGINEER. Graduate '25, wide experience in hydro-electric power stations, desires position on power plant design or related work. Apply to Box No. 278-W.

CIVIL ENGINEER, A.M.E.I.C., Canadian, R.P.E., Nova Scotia, 21 years engineering experience, both field and office, in railway, highways, foundations, concrete structures, water power and conservation, electric transmission lines, etc., experience comprising both surveys and construction, desires employment. Single. Will go anywhere. Working knowledge of French and Spanish. Available immediately. Apply to Box No. 327-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing and hoists. Also some experience in ventilating and heating work and calculators. Accustomed to structural design and details. Good references. Present location Montreal. For interview apply to Box No. 329-W.

CIVIL ENGINEER; age 48; married; A.M.E.I.C., R.P.E., Ontario and New Brunswick; 32 years experience in municipal engineering, on roadways, sewers, waterworks and buildings, desires position with either municipality or as engineer superintendent with contractor. Ten years with City of Toronto, construction engineer on roadway work; four years consulting engineer; three years engineer in charge of construction work; one year resident engineer, Dept. of Public Highways. Available immediately. Maritimes or Ontario preferred. Apply to Box No. 336-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., R.P.E. Ont., with twenty-four years experience embracing dams, wharves, grain elevators, foundations, pile driving, highways, municipal engineering, water power surveys, road locations, inspections and estimating, is open for engagement as engineer or superintendent in construction, operation or maintenance. Location immaterial. Apply to Box No. 358-W.

CIVIL ENGINEER, graduate, age 32, A.M.E.I.C. Ten years experience; seven years on design, construction, erection work and maintenance of paper mill and mine buildings and machinery. Three years on hydro-electric work in charge of surveys and field investigations; associate hydro-electric engineer, U.S. Engineers, on office investigation, design and estimates; desires permanent position in Canada. Apply to Box No. 362-W.

STRUCTURAL AND CIVIL ENGINEER, Jr.E.I.C., age 31, married. Was instrumentman and structural engineer on erection of Royal York hotel, and asst. resident engineer on James Bay Extension, T. & N.O. Rly. Experience includes structural, civil and mechanical draughting and all kinds of instrument work and special work. Qualified as captain in military engineering, R.M.C., Kingston. Available anywhere in Canada, preferably Toronto, for any kind of work. Apply to Box No. 377-W.

ENGINEER ADJUSTER, MANAGER, desires to connect with an industrial concern or department which is not showing a proper return with a view to suggesting more efficient methods and eliminating bad debts. Apply to Box No. 411-W.

CIVIL ENGINEER, S.E.I.C., 1930 graduate. Experience as instrumentman on city and railroad construction, desires to enter structural or hydraulic field. Available at once. Will go anywhere. Apply to Box No. 467-W.

CIVIL ENGINEER, A.M.E.I.C., age 39, with wide experience on design and construction of reinforced concrete structures, desires position. Apply to Box No. 475-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., with six years experience in paper mill and hydro-electric work, desires position in western Canada. Capable of handling reinforced concrete and steel design, paper mill equipment

Situations Wanted

and piping layout, estimates, field surveys, or acting as resident engineer on construction. Now on west coast and available at once. Apply to Box No. 482-W.

MECHANICAL ENGINEER, Jr.E.I.C., B.Sc., '26. Ten months experience in pulp and paper steam control. Four years experience in detail and design, in pulp and paper mill, industrial plant and hydro-electric development work. Age 27. Married. Location immaterial. Apply to Box No. 521-W.

CIVIL ENGINEER, B.A.Sc., '29, with experience in supervision of construction and general office engineering, desires permanent position with contractor or engineer. Available at once. Apply to Box No. 524-W.

CIVIL ENGINEER, A.M.E.I.C., with twelve years experience embracing survey and construction, railway, hydro-electric and highways, foundations, pile driving, municipal engineering, water power surveys, road location, inspection and estimating, is open for engagement as resident engineer on construction or other responsible position. Experience comprises both office and outside work. Available immediately. Apply to Box No. 527-W.

MECHANICAL, CONSTRUCTION, AND DESIGNING ENGINEER, with special training in hydro-electric power development, underground steam distribution systems, and the operation of large electrical machinery. Active work desired. Apply to Box No. 528-W.

ELECTRICAL ENGINEER, S.E.I.C., B.Sc. E.E., 1931, desires to become associated with some branch of electrical engineering offering good opportunity for advancement. Sixteen months experience in draughting of electrical apparatus with large manufacturing concern; including layout work, and making of detail working drawings. Bulk of experience with industrial control apparatus. Location immaterial. Available on short notice. Apply to Box No. 532-W.

ELECTRICAL ENGINEER, married, graduate of McGill University, desires position in Ottawa, Montreal or Toronto. Experience includes four summers with a building concern as instrumentman and assistant engineer, two and one-half years with the Canadian Westinghouse Co., this time being distributed between tests, design and sales. At present employed but available on short notice. Apply to Box No. 533-W.

CIVIL ENGINEER, B.Sc., McGill University, Jr.E.I.C., age 32. Seven years general experience in hydro-electric power investigations and construction. Has been in charge of high power transmission lines location, also in charge extension surveys. Experience in office and field. Thorough knowledge of French. Best of references from former employers. Apply to Box No. 537-W.

STRUCTURAL ENGINEER, A.M.E.I.C., B.A.Sc. Wishes to join established firm of consulting engineers. Age 37. Married. Ten years experience design of reinforced concrete and steel on buildings. Two years practical contracting experience. Apply to Box No. 540-W.

CIVIL ENGINEER, McGill '20, A.M.E.I.C., P.E.G., age 31, single. Experience includes general engineering, especially reinforced concrete work, and eight years of pulp and paper mill construction and layout. Best of references. Available on short notice. Apply to Box No. 547-W.

UNDERGRADUATE ENGINEER, S.E.I.C., junior year standing (Sask.), desires work to complete course. Electrical or mechanical work preferred. Apply to Box No. 553-W.

Situations Wanted

ELECTRICAL ENGINEER, S.E.I.C., graduating 1931, desires employment in electrical engineering. Sixteen months draughting experience on electrical machines with a large manufacturing company. Work included making layouts and detail working drawings. Available immediately. Location immaterial. Apply to Box No. 555-W.

A.M.E.I.C., graduate of University of Toronto, 1915. Building engineer and superintendent, with considerable experience as installation, sales and promotion engineer. Present connection, four years in responsible position with large utility corporation. Open for immediate connection where he can use his past experience. Location immaterial. Apply to Box No. 560-W.

ELECTRICAL ENGINEER, A.M.E.I.C., university graduate 1924. Experience includes one year test course and five years on design of induction motors with large manufacturer of electrical apparatus. Four summers as instrumentman on highway construction. Several years experience in accounting previous to attending university. Available at reasonable notice. Apply to Box No. 561-W.

CIVIL ENGINEER, S.E.I.C., graduating this year. Experience in railway maintenance, and instrumentman on location and construction. Desires to enter any branch of civil engineering or industrial work affording technical experience and an opportunity for increasing responsibility. Will go anywhere. Apply to Box No. 567-W.

CIVIL ENGINEER, A.M.E.I.C., ten years experience as mining engineer of a colliery, six years railway construction, including location, construction, bridge construction, and maintenance. Also one year on hydro transmission lines; one year government land surveys. Would consider position in any branch of construction, as resident engineer or instrumentman. Apply to Box No. 569-W.

CIVIL ENGINEER, B.Sc. McGill Univ., Jr.E.I.C. Five years experience along the lines of general construction, including structural steel. Available at once. Apply to Box No. 570-W.

MECHANICAL ENGINEER, A.M.E.I.C., experience in the design and maintenance of steel mills, zinc and sulphuric acid plants, cement plants; power house layouts; familiar with shop practices and costs, desires connection. Apply to Box No. 571-W.

YOUNG ENGINEER, Jr.E.I.C., experienced in design, details and erection of steel and concrete structures. Also a good theoretical and practical knowledge of steam, hydraulic and I.C. engine power plant. Good practical mechanical and electrical engineer, able to operate and maintain any type of machinery or power plant. Location immaterial. Apply to Box No. 572-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., (Univ. of B.C., '30), Undergraduate experience in pulp mill. One year's experience, Canadian General Electric Co., mech. dept. Single. Age 24. Desires position in technical design or sales. Location immaterial. Available on short notice. Apply to Box No. 577-W.

TEMPORARY EMPLOYMENT wanted by an engineer with wide experience in the design and operation of steam power plants and heating system. Apply to Box No. 584-W.

CIVIL ENGINEER, S.E.I.C., 1931 graduate, age 26. Experience in draughting, designing and estimating in structural engineering. Desires to enter structural, hydraulic (including hydrographic) or municipal field affording technical experience. Location immaterial. Available at once. Apply to Box No. 593-W.

Situations Wanted

ELECTRICAL ENGINEER, graduate Univ. of Alberta, '31, with excellent record, desires connection with electrical manufacturing firm, power or communication company. Good general experience includes one summer railway construction, two summers geological surveys in oil fields of Alberta, planetable topographer and asst. geologist. Available immediately. Apply to Box No. 596-W.

MECHANICAL ENGINEER, age 22, graduate '31, Univ. of Alberta, experience as draughtsman and instrumentman-inspector, is open for a position. Location immaterial. Apply to Box No. 598-W.

MECHANICAL ENGINEER, S.E.I.C., age 21, four years mechanical engineering, Queen's University, desires permanent employment. Experience in wood work, machine shop work, draughting and surveying. Location immaterial. Available at once. Apply to Box No. 600-W.

MECHANICAL ENGINEER, Canadian, technically trained; eighteen years experience as foreman, superintendent and engineer in manufacturing, repair work of all kinds, maintenance and special machinery building, desires change. Location immaterial. Available on one month's notice. Apply to Box No. 601-W.

ELECTRICAL OR MECHANICAL ENGINEER, B.Sc., '31, S.E.I.C., desires employment which will give experience and lead to advancement. Two summers in a large communication company, including draughting, switchboard and surveying. Available on short notice. Will go anywhere. Apply to Box No. 606-W.

CHEMICAL ENGINEER, S.E.I.C., University of Alberta '30, desires a position in any industry with chemical control. Experience includes three summer vacation periods of five months each as assistant chemist, and ten months as chief chemist with a cement company. Age 29. Single. Available at once. Apply to Box No. 609-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. (C.E.), Univ. of Man. '31, desires temporary or permanent employment on engineering work. Twenty months experience in summers as chainman, rodman and instrumentman on railway grade and bridge construction; also as inspector on reinforced concrete highway bridges. Salary and location immaterial. Available at once Apply to Box No. 614-W.

DESIGNING ENGINEER, industrial building designer, Jr.E.I.C., age 31, married, capable of taking responsible charge of the structural design and architectural details of steel or concrete manufacturing plants or power houses, also has had considerable experience in the design of office buildings, etc., desires reasonably permanent position. Very highest references from present employers. Location immaterial. Apply to Box No. 615-W.

MECHANICAL ENGINEER, Jr.E.I.C., 5 years apprenticeship on general mechanical engineering; 10 years experience on heating and ventilating and mechanical equipment of buildings. Design, draughting and production. Desires change. Capable of taking charge of engineering department. Further particulars if required. Apply to Box No. 616-W.

POWER ENGINEER, M.E.I.C., age 42. Married. Thoroughly conversant with electrical, steam, mechanical and industrial engineering,

Situations Wanted

desires executive position with large industrial, power or financial corporation. Best of references as to ability and positions held. Apply to Box No. 617-W.

CIVIL ENGINEER, Jr.E.I.C., B.A.Sc. '24, age 35, married. Five years designer and estimator with well-known firm of industrial builders; two years detailing, designing and estimating structural steel for bridges and buildings, also survey and municipal experience. Open for position immediately, will go anywhere. Apply to Box No. 618-W.

CIVIL ENGINEER, A.M.E.I.C., graduate '23, married, eight years municipal engineering experience. Sewerage and sewage disposal, water works, street pavement, etc. Also some experience highway construction. For the past three years engaged by firm of consulting municipal engineers. Desires permanent position. Location immaterial. Available immediately. References. Apply to Box No. 624-W.

ELECTRICAL ENGINEER, B.Sc., N.S. Tech. Coll. '31. Experience in design and construction of rural distribution lines, trouble shooting, inventories and general office work, desires position with public utility or industrial plant. Location immaterial. Available at once. Apply to Box No. 628-W.

Konel*

A Substitute for Platinum

A man set out to find a cheap substitute for platinum. He was so successful that for almost a year his results were not taken seriously. Oxide-coated filament for radio tubes was known as early as 1904; platinum as a core appeared to be the best material for life, strength, and emission of electrons. In 1925, five years after radio broadcasting had aroused public imagination, tubes were being made, in ever-increasing quantities, with platinum or platinum-iridium core filament. Platinum people were overjoyed; but not makers of tubes. Material for filaments was costing $186 an ounce.

Dr. E. F. Lowry, Research Physicist of Westinghouse Research Laboratory, undertook a search for a cheaper substitute. He was not a metallurgist, but as a physicist he knew something about behaviour of electrons and characteristics of a cathode in radio tubes. Others had tried. Iron, nickel, nichrome, tungsten, various ferrous alloys were already pronounced worthless. All had a poisonous effect on emission or had proved mechanically weak. But nickel looked good to Lowry, and he tried it in spite of preponderant opinion that on account of mechanical frailty nickel was impossible.

The first filament of pure nickel gave surprising results. Emission appeared as good as with platinum cores; nickel gave no more trouble from mechanical failures. It was too successful. Scientists, tube manufacturers, even colleagues hesitated to believe that the first attempt had succeeded when hitherto undisputed authority had pronounced nickel no better than other metals. Against claims that nickel filaments should have a life of only eighty hours, Lowry produced tubes on life tests for 1,500 hours and still burning. But none of his nickel filaments were manufactured commercially.

Convinced that he was working in the right direction and failing to convince others by the very simplicity of his methods, he decided to employ the wisdom of the serpent to drive home a simple idea: a nickel alloy with a new name might be more psychologically successful.

He tried 20% cobalt; the crystalline structure was unsatisfactory and it could not be drawn. The case looked hopeless, when he thought of the qualities of cobalt-ferrotitanium (a compound of iron and titanium) wire used in experiments several years previously. The first filament of nickel, cobalt and ferrotitanium, in proportion of 80, 20, and 10, gave results better than ever before. It seemed incredible that the first proportions tried could be the best possible. Even the discoverer began to hesitate, but scores of experiments failed to produce a better filament. Hundreds of experiments have since been made, but the alloy used today is essentially the same as that produced by Lowry's first attempt.

He named the new metal Konel, and in December, 1926, persuaded the Westinghouse Lamp Company to make fifty commercial tubes with it as filament core. About the same time the manufacturers discovered that Lowry was right also about nickel and started to use that for filaments. Within a year every manufacturer ceased the use of platinum in radio tubes! And none has used it since. Platinum-iridium cost $1,600 a pound; Konel costs a few dollars; a penny now buys what a dollar used to.

But for the discovery of a satisfactory substitute for platinum, development of radio tubes would be far behind its present status. Use of Konel not only appreciably increased tube life (operating 175 degrees colder than platinum filament), but also showed definitely that the filament core had a marked influence on emission. A new theory of electron emission from oxide filaments has been formulated; on this work the discoverer is now engaged.

Konel is harder to forge than high-speed steel, is very tough at high temperatures, when most metals lose their strength. Its ultimate strength is more than 60,000 pounds per square inch at 600 degrees C., compared with 40,000 pounds for stainless iron, 28,000 pounds for nickel and 35,000 pounds for chrome-nickel steel. It is extremely resistant to most acids, does not sputter, does not scale like iron under heat, and has a high electrical resistance. These unusual characteristics give promise of many uses outside radio tubes: valves for gas or Diesel engines, turbine blades, or other structural pieces which must withstand temperatures equal to red heat.

It is an electric-furnace product of extreme purity. For filaments it is produced in 20-pound ingots, forged, cold-rolled, drawn into wire, and then rolled to a ribbon of requisite dimensions. The smallest filament, rolled from a wire .001 inch in diameter, is .002 by .0005 inch, and must not vary by more than .0001 inch. Of this fairy-like ribbon, 57 miles would weigh only one pound.

The Diesel Electric Suction Dredge "General Brock"

B. G. Flaherty,
Chief Engineer, General Dredging Contractors Ltd., Montreal, Que.

An address delivered before the Montreal Branch on January 15th, 1931, and before the Ottawa Branch on May 7th, 1931.

SUMMARY.—This paper describes the successful employment of suction dredges in excavating difficult boulder-strewn material in the St. Lawrence ship channel between Montreal and Quebec, and deals with the arrangement and construction of the latest Diesel-electric dredge "General Brock," which has proved very efficient at this type of work. The author discusses the advantages of installing a self-contained power plant for such duty as compared with the purchase of electric power. The mechanical and electrical equipment is described including the main pump, the cutter and cutter drive and the machinery for handling and manoeuvring the dredge.

The past quarter of a century has been a period of improvement, refinement and the finding of new applications for materials and machines rather than of production of new or original ideas or methods. This is as true of dredging as of most other lines. Practically every kind of machine that we have to-day, or at least their prototypes, existed a quarter to a half a century ago. The first suction dredge was suggested and the idea patented by a German as long ago as 1857, and some were actually built and used in the harbour waters of Holland in the '60's. Later, this class of dredge was adopted more fully in America on the Mississippi river bars, and the California harbours and rivers.

The cumbersomeness (i.e. the excessive size and weight per horse power) of the primary power units of those early days, however, as well as the lack of development along other lines, made it so that, while these dredges could handle large quantities of water or mixtures of soil and water at low velocities through a pipe line, they could only handle comparatively fine material like silt or fine sand with any success. From that time the hydraulic suction dredge became (and remains to this day) fixed in the lay mind which has not seen the later developments, as a "sandsucker" or a "mudsucker." Nevertheless, improvements in this line have kept pace with those in most other lines until, to-day, this is one of the most practical, economic and efficient tools available, where large quantities of almost any kind of material except solid bedrock are to be moved and placed. This, in spite of the apparent paradox that the suction dredge must move from five to fifty volumes of water as a carrying medium for every volume of solid material moved into place through the same distance. Suction dredges now dig and pump solid shale, coral beds and marl, or pump heavy sand and gravel to distances of three miles from the borrow ground, and in some cases elevate the material as high as a hundred feet above the level of the water from which the material is dug.

Suction dredging along the St. Lawrence river under the old or "sandsucker" idea, practically had its beginning and ending with the "J. Israel Tarte" which did a great deal toward opening up the 30-foot depth channel through Lake St. Peter, and established some records for its time. Considerable work of this class has been done, of course, on the Great Lakes, the Welland canal, and the harbours of the Maritime provinces, but the St. Lawrence valley has always been considered a difficult, if not impossible, field for this type of dredge, on account of the prevalence of numerous boulders left by the icebergs when they melted in this glacial age inland sea.

The first real attempt at tackling this boulder strewn and embedded river bottom was when the 24-inch electric hydraulic suction dredge "General Wolfe" started in July, 1926, at Wolfe's cove, Quebec, to excavate in the proposed new harbour, and to fill in valuable areas along the shore line with the excavated material. This machine has just closed its fifth successful season at this work, and will soon finish the work laid out for it there. The success of the "Wolfe" led to the design and construction of the all-steel 24-inch electric hydraulic dredge "General Montcalm" which, in June, 1929, began a very difficult filling job for the Harbour Commissioners of Montreal, at Sections 56 and 57, completing a fill behind the wall in ten weeks, on which loading began immediately afterward, a valuable feature of the hydraulic fill. This dredge has finished its second season, with a good record for performance, under very difficult conditions.

When the contract for deepening of certain portions of the St. Lawrence river channel to 35 feet was let last March, it was felt that enough experience of conditions in this river district had been gained to provide for the design of an hydraulic suction dredge to do a major share of this work. Consequently, the design was authorized to go ahead; the steel was laid for the hull in Sorel in April, 1930, and the dredge "General Brock" went to work on Longueuil shoal, September 28th, 1930.

Following this brief résumé of dredging history on the St. Lawrence, we will proceed to analyze some of the problems that arose in the design of the latter plant in the order in which they occurred. Without wishing to bring up at this time a detailed discussion of the cost of power from various sources for a certain specific work, we do wish to state the proposition in general, thus: the laws of economics determine that, over a period of years, the cost of power

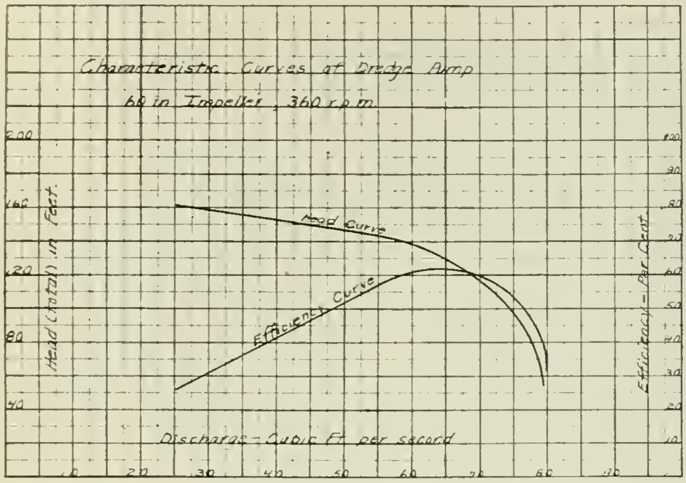

Fig. 1—Characteristic Curves of Dredge Pump.

per unit to be used in a certain definite place or way will be practically the same, whatever the means or manner of producing that power may be. Rather fine distinctions need to be drawn to-day to determine the difference between the cost of power obtained from hydro-electric systems, from external combustion (steam, etc.) plants, or from internal combustion engines, it being granted that the best modern practice is considered in each case. The argument might be endlessly prolonged to show that either one or the other method is most efficient or economical.

This being granted as a general statement, it becomes evident that the particular application determines in each case the best power to use. Purchased power shows to the advantage of the dredging or earth moving contractor only where large quantities (millions of cubic yards) are to be moved in a single locality, for the following reasons:—

1. The cost of the set up or connection is absorbed by the large yardage without appreciable effect on the unit cost.
2. Lower operation and maintenance costs, as less skilled help is required and greater part of plant cost is already absorbed in power price.
3. Less plant involved results in less fixed and standby charges.
4. Reliability is as good or better than in self-owned power plant. Thus for certain specific jobs, the purchase of power is desirable for suction dredges.

For the general dredging contractor, operating over a large territory, however, a self-contained power plant on the dredge is very necessary. First, the cost of moving from one set up to another and connecting up to the work is much less and there is no power connection charge; second, it is not dependent on variations of local power supply as to cycles, phase, voltage or capacity; third, utilization of the power can be made more efficient so as to get more work done with the same quantity of power used.

This latter feature is the most important single item to be considered in the application of power to dredging, and we must here enter into a short discussion of the centrifugal dredge pump and its drive in order to make clear just why this is so. The suction dredge pump is merely a rather crudely designed centrifugal pump, such as all are familiar with; necessarily crude because it must have large, unobstructed passages and clearances, and so built that wearing surfaces on the interior can be easily, quickly and cheaply replaced. Wear on these parts when handling certain classes of materials is very rapid, and they must be repaired often if any efficiency at all is to be maintained. The head and efficiency curves of such a pump are shown in Fig. 1, from actual operating data. This is the same type of pump, designed especially for dredging service, as those used on the last three dredges mentioned above.

For each kind of material that is to be handled by such a machine by suspension in water, there is a certain velocity of the mixture which will carry it most economically through the system. If the power applied to, and the speed of, the pump is too low to produce this velocity, the material will tend to settle out of suspension, and will then drag slowly along the pipe line, greatly reducing the output of useful spoil. If more power and speed is applied than needed, the power lost in friction in all the passages increases as the third power of the velocity, while the output (assuming a fixed percentage of load) increases only as the first power, resulting in a greatly increased unuseful power demand, without any appreciable increase in output.

In all dredging of this kind, the length of the discharge line and the static head to which pumping is done is continually changing with the natural shifting of operations. It is evident that to maintain the best efficiency, the speed and power applied should change with the changes in delivery conditions.

Alternating current motors operated from purchased power systems, such as are used by practically all electric dredges, are essentially constant speed machines (except as resistance is used to some extent in reducing the speed of wound rotor induction motors, a very inefficient and uneconomical practice for constant load service.) It is at once seen that with such a machine and a given diameter of impeller, there is only one condition of the delivery line which is truly efficient, there being an unusual loss either of output or of power for any change in discharge status. Of course, it is possible to convert the purchased A.C. to direct current and thus achieve complete speed regulation, but the initial cost then becomes practically equal to that of the self-powered dredge, without added advantages of mobility and flexibility of the whole plant, and also with a sacrifice of approximately 20 per cent of the power bought. The self-contained power plant generating direct current is perfectly adapted to this type of drive, for the distances of transmission are very short, and direct variation of speed of the main pump is obtainable without the necessity of varying the speed of the prime mover.

Having reached this point in our problem, we are faced with the necessity of making a choice of the kind of power to use in the self-contained plant. Practically the choice for electric generating purposes rests between the steam turbine and the Diesel engine. The capacity of the plant is the determining factor in making this decision. Where the total amount of power to be developed is less than 5,000 h.p. the Diesel engine has a decided advantage over

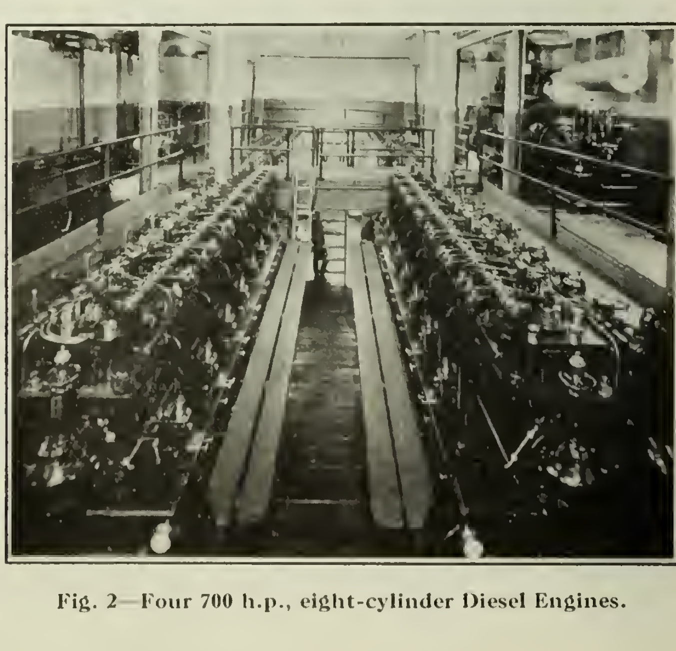

Fig. 2—Four 700 h.p., eight-cylinder Diesel Engines.

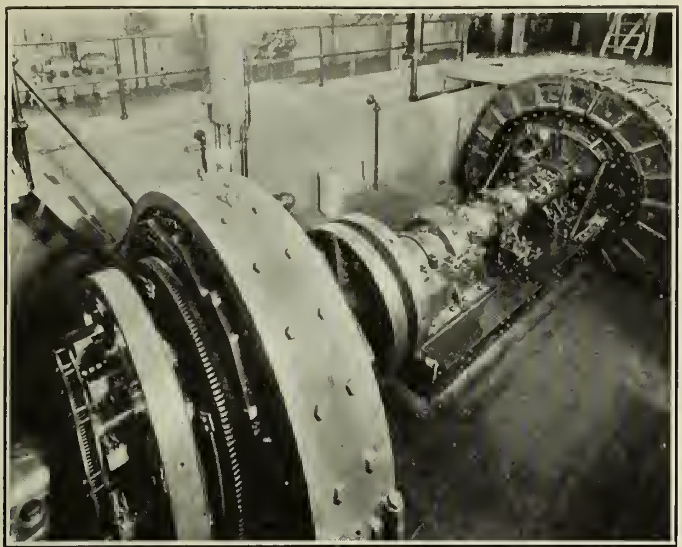

Fig. 3—Main Pump and Drive Motor.

the steam turbine in fuel economy, operating, fuel handling, attendance and standby cost. As the plant is increased beyond this point the steam turbine gains rapidly in all these points and becomes the logical choice for large power. Only a few years ago the steam plant held a more favourable position because of less first cost for a given output in units of any appreciable size, but to-day this advantage has disappeared due to the improvements in design and materials, and increased production, until now Diesel engined generating plants can be installed for approximately the same cost per horse power as steam plants, and have the added advantage of much better fuel economy.

Direct drive of dredge pumps by Diesel engine is not suitable because of the possibility of many complications arising in the combination, from critical speeds which may shift their position considerably with changing conditions in the dredge pump itself and the undesirability of running the engine at varying speeds for the same reason. A multiplicity of critical speed conditions may arise in such a combination that can hardly be predicted, or be protected against.

The main power plant and scheme of operation of the dredge "General Brock" was laid out with all these points, and some other minor consideration in mind. It consists of four (4) M.A.N. (Maschinenfabrik-Augsburg-Nürnberg)

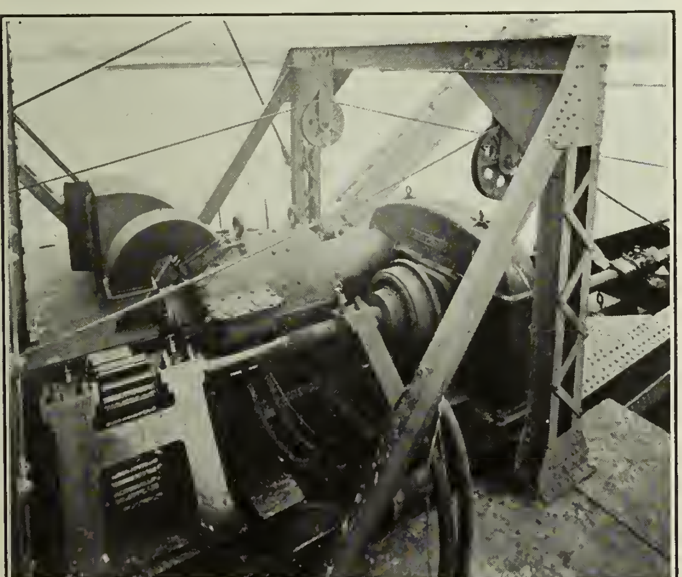

Fig. 4—Cutter Shaft Drive.

G Vu50 airless-injection, four-cycle, 8-cylinder full Diesel engines (see Fig. 2) rated 700 h.p. at 315 r.p.m. direct connected to 400-k.w., 250-v., D.C. generators of Canadian General Electric Company make. Great care and careful checking was used by both parties to the manufacture of these units to avoid proximity to critical speed points at the rated revolutions of engine and generator combination. The generators have a single outboard self-aligning bearing, and the engine end of the rotor shaft (flanged) is carefully fitted to a counter bore in the engine flywheel hub, and securely fastened thereto with fitted bolts. They are fitted with both shunt and series windings and may be operated either shunt or compound wound as explained later in describing the dredge operation and control. An auxiliary generator set consisting of a 3-cylinder M.A.N. Diesel engine of a similar type to the above, rated 95 h.p. at 450 r.p.m. direct connected to a Siemens-Schuckert 250-v., D.C. 60-k.w. generator is provided for standby power when the main plant is shut down. This set has its own independent circulating water and lubricating oil pumps so that it can operate without the necessity of running the general service pumps which furnish cooling water for the main units.

Four cylindrical fuel storage tanks with a combined capacity of about 600 barrels are placed below decks in the

Fig. 5—Pilot House.

outside holds of the dredge. These are all interconnected and the fuel handling pumps (electrically driven and furnished in duplicate) deliver oil from any or all of them to the daily service tanks, which latter are carefully graduated so that a careful check on the fuel consumption can be obtained. Filling connections to the interconnecting piping system are provided on either side of the dredge, air vents from each tank to above the house roof, and oil level indicators for each tank are furnished.

Lubricating oil tanks (duplicates) with a combined capacity of about 20 barrels, are located on the upper deck, above the level of the engines, furnishing gravity feed to each engine lubricating system. A lubricating oil centrifuge with electric heaters and electric driven pumps to draw the oil from the engine sump tanks and return it to the system is placed in the lower outside compartment next to the engine room.

Cooling water for the main engines is supplied from the general service water system, which is furnished by 1,500 gallons per minute Cameron centrifugal pumps (in duplicate) at 40 pounds pressure direct driven by 40-h.p. 1,750 r.p.m. 250-v. compound wound motors. This cooling water is drawn from a sea well with well screened intake in the outer hold, and may be discharged overboard, or turned

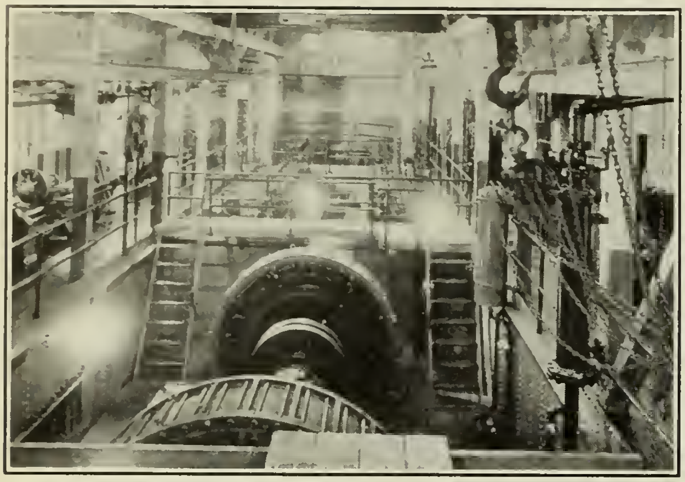

Fig. 6—General View of Interior of Dredge.

through the outer casing of the engine silencers to provide hot water on board if desired.

The bulk of power used by an hydraulic dredge is of course consumed in the drive of the main dredge pump and with varying conditions this may at times be as much as three-quarters of the total. Switching arrangements on this dredge are such that any number of the main units may be operated as separately excited shunt generators in parallel to drive the main pump motor. Any other one unit is of sufficient capacity to operate all the other machinery on board, usually termed the auxiliaries. The unit selected for this service operates as a flat compound wound generator, furnishing constant voltage and the excitation for all the other machines, including the main motor.

This arrangement practically provides a simple electrical coupling between the engines chosen (variable at the operator's discretion) for the main pump drive and the pump itself. It also provides a simple easy method of paralleling as many of the generators as desired and avoids some of the minor difficulties of paralleling compound wound generators driven by Diesel engines. The main control bus from which the excitation is taken is provided with a potentiometer type of rheostat which acts on the fields of all the generators which are paralleled so that their voltage may be reduced practically to zero for starting the main motor and raised or lowered as the operator desires to control the speed of the latter.

The main motor is rated 1,200 h.p. at 300 r.p.m., 1,500 h.p. at 360 r.p.m. and may be operated up to 400 r.p.m. by reducing the strength of its shunt field. It is direct connected through a link and pin type flexible coupling and a Kingsbury thrust bearing to the main shaft of the pump. (See Fig. 3.) No control apparatus is required in the main motor circuit other than a single pole solenoid operated circuit-breaker of 6,000 amp. capacity which opens and closes the positive side, the negatives of all generators being solidly connected together through the D.P.D.T. 2,000 amp. lever switches which select the service for which each of the latter is to be used.

Fig. 7—Diesel Electric Suction Dredge "General Brock."

Each generator has a 2,000 amp. solenoid-operated circuit-breaker in its positive circuit on its own individual panel at the engine room floor level, and a k.w.h. meter for measuring its total output. Indicating ammeters for each are provided on its panel in the main control switchboard on the main deck, where the rheostat control wheels for each are also located. Beside the control panels for the generators is the main motor control panel with a tachometer indicating its speed at all times and the rheostat wheels for varying the latter. Pull switches on the main control board operate all solenoid circuit-breakers. Two panels beside the control board provide distribution of the auxiliary power through fused lever switches, and switching for the auxiliary standby generator set.

Fig. 8—Ladder and Cutter.

After the main pump, the most important user of power is the cutter drive. In some dredges the motor for this is placed in the forward hold and drives through a chain of spur and bevel gears along the centre line of hinge of the ladder to the cutter shaft, but in the "General Brock" the motor is mounted on the ladder itself. This results in the use of a completely enclosed, ventilated motor capable of operating at an angle of 45 degrees or more to the vertical equipped with ball and roller bearing and thrust bearing. This is a 250-h.p., 250-v. compound wound motor 375/750 r.p.m. with speed variation by shunt field control from master control in the pilot house. It drives through a C.H. No. 28 magnetic clutch to the drive pinion of a completely enclosed, single reduction forced oil lubricated Citroen helical gear. This gear is also equipped with ball and roller bearings allowing it to operate at an angle of 45 degrees to the vertical. The slow speed shaft of this gear reduction drives through a Wellman Bibby flexible coupling to an intermediate shaft and pinion, which latter drives the main gear on the upper end of the cutter shaft. This gives full flexibility and isolation of both gear box and motor from shocks due to the cutter striking heavy obstructions on the bottom and torsional movements of the ladder frame itself. The speed relation between the motor and cutter shaft is 12 r.p.m. of the latter at 375 r.p.m. of the former. (See Fig. 4.)

The operation of the cutter is controlled in the pilot house by a master controller which, through a contactor panel in the lower hold and a shunt field resistance, gives starting resistance speed regulation on three points, and field regulation above 375 r.p.m. on 18 points. The horse power rating is constant at 250 h.p. continuous above 375 r.p.m. Ventilation is provided by a blower motor inside the hull, which is connected across the motor terminals so as to start automatically with the latter.

The hoisting machinery for handling and manoeuvering the dredge is divided into two parts, driven by identical motors, of mill type, 60 h.p. continuous rating, 90 h.p. intermittent, compound wound, with 50 per cent shunt, 50 per cent series fields, the shunt field being suited for continuous full voltage. The forward portion, known as the swinging machinery, consists of gearing and shafting driven through Hill type clutches, three hoist drums, one for the ladder hoist, and a port and starboard swinging rope drum. Behind this is the spud hoisting machinery with drum, clutch and brake for each spud anchor. These motors are operated by manual drum controller and resistance regulation from the pilot house. The spud motor control includes dynamic braking in the off position for lowering the spuds gently in soft material.

The pilot-house arrangement, the dredge interior, showing the main pump room with power plant and switchboard, and a general view of the dredge in operation are given in Figs. 5, 6, and 7. The latter was taken at Three Rivers in November, 1930, at the end of a swing to port while pumping a heavy percentage of sand and silt.

The following list gives some of the general features and dimensions of the dredge:

1. *Hull*—Length—150 feet 0 inches (moulded).
   Width—40 feet 0 inches.
   Depth—12 feet 0 inches.
   Height main deck house—10 feet 0 inches.
   Ladder well—11 feet 0 inches by 16 feet 0 inches.
2. *Ladder*—Built up of 30-inch, 240-pound I beams, with C.S. strong backs and head length from hinge 76 feet, cutter shaft diam. 9 inches under keyways.
3. *Suction Pipe*—26½-inch inside dia. ¾-inch wall machine welded steel, with C.S. fittings and swivel elbow at hinge centre of ladder, furnished with clear water packing under pressure from general service pumps.
4. *Discharge Pipe*—24-inch dia. machine welded steel, with C.S. fittings and C.S. swivel elbow at stern of dredge. Swivel elbow gland supplied with clear water under pressure from general service line.
5. *Spuds*—34½-inch dia. in 36-inch casings, 85 feet long, built up of 16, 6-inch Tee bars with flange moulded to outside cylindrical plate, and tied together on inside edge of web with 1 inch by 4 inch rings at 4 foot 0 inch intervals.
6. *Main Pump*—9 feet 6 inches dia. casing (cylindrical) with 60 inch dia. runner, main shaft 10 inch dia.
7. *General Service Water Pumps in Duplicate*—Cameron centrifugal 40 lb., disch. pressure 1,500 g.p.m., driven by 40 h.p., 1,750 r.p.m. motors.
8. *Machine Shop*—Lathe, drill, press, bolt threader, emery wheels, air compressor and tools. Oxy-acetylene and electric welding sets.
9. *Vacuum Tank.*
10. *Vacuum Pump*—Nash Hytor driven by 10 h.p. motor.
11. *Lighting*—3 k.w. balancer set to furnish 125 v. for lighting distribution, four flood-lights, one searchlight. Vapour proof fixtures in oil storage compartments.
12. *Bilge Pump.*
13. *Booster Pump*—400 g.p.m., 15 h.p., 1,750 r.p.m. to boost general service pressure to 80 lbs. when required, or to paralled general service pumps.

On the Determination of Stringing Tensions for Transmission Lines and Cables

J. W. Campbell,
Professor of Mathematics, University of Alberta, Edmonton, Alta.

SUMMARY.—This paper gives a method, illustrated, for finding temperature-tension relations for suspended cables. Three types of problem are considered, viz.: single spans with points of support at the same level, single spans with points of support at different levels, composite spans which have intermediate supporting structures. Hyperbolic methods are used throughout, and in the concluding paragraph the validity of the method for sags of any magnitude is shown.

In his *Numerical Tables of Hyperbolic and Other Functions,** the author has given a handbook of formulae for solving catenary problems of various types, and in particular for finding variations produced by changes in weather conditions. The purpose of this article is to give a method which greatly facilitates the obtaining of a set of tabular values from which a temperature-tension stringing chart can be constructed. The calculations are considerably simplified by the availability of the continuous process of computation for certain parts of the work.

The problem divides itself naturally into two main cases.

Case I. *Points of Support at the Same Horizontal Level*

From the formulae given in *Numerical Tables* we have

$$\frac{s}{x} = \frac{\sinh u}{u},$$

$$\frac{2\,q}{x} = \frac{\cosh u - 1}{u},$$

$$\frac{2\,T}{wx} = \frac{\cosh u}{u},$$

where s = length of cable, x = span, q = sag, T = tension at supports, w = weight of cable per unit length, and u = a parameter (span divided by twice the depth of the directrix below the vertex).

Then if we denote by t the temperature, by α the coefficient of linear expansion of the cable, and by λ its modulus of stiffness (ratio of tension to strain) we have

$$\Delta t = \frac{1}{\alpha}\left(\frac{\Delta s}{s} - \frac{\Delta T}{\lambda}\right).$$

Hence starting from a certain condition, e.g. a maximum allowable sag, or a maximum allowable tension, we may construct a table of values of the following quantities in the order given; $2\,T/wx$, u, $(\sinh u)/u$, $\Delta(\sinh u)/u$, $(\Delta s)/s$, $(\Delta s)/s - (\Delta T)/\lambda$, Δt, $(\cosh u - 1)/u$; T, t, q.

We may illustrate by an example:

A No. 3/0 B & S gauge solid copper wire weighs 0.508 lb./ft., has a diameter of 0.410 in. and a coefficient of linear expansion of 9.6×10^{-6} per degree F. An 800 foot horizontal span is to be erected so that the tension shall not exceed 3,000 lb._w when the temperature falls to $-50°$. Required a temperature tension chart for stringing, assuming the modulus of elasticity to be $18 \times 10^6\ \text{lb.}_w/\text{in.}^2$

Here we start with a tension of 3,000 lb._w and so the initial value of $2\,T/wx$ is 14.77. Then using decrements of 0.50 in $2\,T/wx$ we have

$$\Delta T = -101.6\,n,\ \Delta T/\lambda = -0.0000428\,n,$$

where n is the number of the entry, counting the initial entry as zero. Hence we may form the following table:

*Published by Houghton Mifflin Co., 1929.

TABLE I

$$\Delta\frac{2\,T}{wx} = -\,0.50\,n, \quad \Delta T = -\,101.6\,n, \quad \frac{\Delta T}{\lambda} = -\,0.0000428\,n, \quad \alpha = 9.6 \times 10^{-6}.$$

n	$\frac{2\,T}{wx}$	u	$\frac{\sinh u}{u}$	$\Delta\frac{\sinh u}{u}$	$\frac{\Delta s}{s}$	$\frac{\Delta s}{s} - \frac{\Delta T}{\lambda}$	Δt	$\frac{\cosh u - 1}{u}$	T	t	q
0	14.77	.0679	1.00077	0	0	0	0	.0339	3000	− 50°	13.55
1	14.27	.0703	83	.00006	.00006	.00010	10.4	.0352	2898	− 40	14.08
2	13.77	.0728	88	11	11	20	20.8	.0364	2797	− 29	14.56
3	13.27	.0756	95	18	18	31	32.3	.0378	2695	− 18	15.12
4	12.77	.0786	1.00103	26	26	43	44.9	.0393	2594	− 5	15.72
5	12.27	.0818	111	34	34	56	58.3	.0409	2492	+ 8	16.37
6	11.77	.0853	121	44	44	70	72.9	.0427	2391	23	17.09
7	11.27	.0891	132	55	55	85	88.5	.0446	2289	39	17.83
8	10.77	.0933	145	68	68	102	106.1	.0467	2188	56	18.68
9	10.27	.0978	159	82	82	121	126.0	.0489	2086	76	19.57
10	9.77	.1029	177	100	100	143	148.8	.0515	1985	99	20.60
11	9.27	.1085	197	120	120	167	173.9	.0543	1883	124	21.70
12	8.77	.1148	220	143	143	195	203.0	.0575	1782	153	23.00

The required chart is obtained by plotting T against t as given by this table.

Remarks:—

1. The values of $2\,T/wx$ and of T are best found by repeated subtraction (the continuous process), and the deductions $\Delta T/\lambda$ which are to be made from $\Delta s/s$ can best be set down by repeated addition. The other columns are obtained by using the *Numerical Tables*, and most of the necessary multiplications can be done on a slide rule.

2. A maximum tension at a specified temperature is the simplest critical condition from which to start in the construction of a Table I, but if the limitations are not of this form they can easily be reduced to it by means of the formulae given in *Numerical Tables*. Thus, suppose the tension is not to exceed 3,000 lb._w when there is a half-inch coating of ice at 0° F. and a wind pressure of 10 $\text{lb.}_w/\text{ft.}^2$

The weight of the ice per lineal foot is

$$3.14\left(\frac{.705^2}{144} - \frac{.205^2}{144}\right)\frac{62.5}{1.1} = .564\ \text{lb.}_w$$

The weight of ice and wire per lineal foot is

$$.564 + .508 = 1.072\ \text{lb.}_w$$

The force of the wind per lineal foot is

$$\frac{1.41}{12} \times 10 = 1.175\ \text{lb.}_w$$

Then the effective w is

$$(1.072^2 + 1.175^2)^{\frac{1}{2}} = 1.591.$$

$$\text{Then}\quad \frac{\cosh u}{u} = \frac{2\,T}{wx} = \frac{2 \times 3000}{1.591 \times 800} = 4.713,$$

$$\text{whence}\quad u = .2172,\ \frac{s}{x} = \frac{\sinh u}{u} = 1.00788.$$

The equation for a change in the value of w with a fall in temperature of t is (*Numerical Tables*, p. 69)

$$\frac{\sinh u_1}{u_1} - \frac{w_1 s}{2\,\lambda}\,\frac{\cosh u_1}{u_1} = \frac{s}{x}\,(1 - \alpha t - T/\lambda),$$

where the letters denote conditions before or after the change according as they are without or with the subscript 1.

Hence to get the conditions at 0° F. without wind and ice, take $w_1 = .508$ and $t = 0$.

$$\text{Then}\ \frac{w_1 s}{2\,\lambda} = \frac{.508 \times 1.00788 \times 800}{2 \times 23.7 \times 10^6} = .0000864,$$

$$\frac{s}{x}\,(1 - \alpha t - T/\lambda) = 1.00788\,(1 - .001265) = 1.00661$$

Therefore

$$f(u_1) = \frac{\sinh u_1}{u_1} - .0000864\,\frac{\cosh u_1}{u_1} - 1.00661 = 0.$$

To solve, form a table:

u_1	$\frac{\sinh u_1}{u_1}$	$\frac{\cosh u_1}{u_1}$	$.0000864\,\frac{\cosh u_1}{u_1}$	$f(u_1)$
.200	1.00668	5.100	− .00044	− .00037
.205	1.00702	4.981	− .00043	− .00002
.206	1.00709	4.958	− .00043	+ .00007

Therefore $\quad u_1 = .2053.$

$$\text{Then}\quad T_1 = \frac{w_1 x}{2}\,\frac{\cosh u_1}{u_1} = \frac{.508 \times 800}{2} \times 4.974 = 1011.$$

The procedure now is as before, with 1,011 lb._w as the limiting tension at 0° F. without ice or wind.

CASE II. *Points of Support at Different Levels*

This is the case which usually occurs in practice, but though at different levels the line joining the points of support does not usually make a large angle with the horizontal.* In such cases the tensions will be given to a close approximation by calculating them as for Case I, with the direct line joining the supports taken as the span. The limit of the inclination at which the approximation is satisfactory seems to be about 10°.

On the other hand, there is a method analogous to that used in Case I which will apply regardless of the inclination, and which will give the sag and other characteristics of the span at various temperatures.

By the formulae given in *Numerical Tables*, p. 70, we have:

$$y = c\{\cosh(x/c + k) - \cosh k\},$$
$$s = c\{\sinh(x/c + k) - \sinh k\},$$
$$\sqrt{s^2 - y^2} = 2\,c\sinh x/2\,c,$$
$$y/s = \tanh(x/2\,c + k),$$
$$T = wc\cosh(x/c + k)\ ,$$

where one end of the span is at (0,0) and the other is at (x, y);† s is the length, c is the depth of the directrix below the vertex, T is the tension at (x, y) and $\sinh k$ is the slope of the curve at (0,0).

In this case it is simpler to proceed from a series of values of s as independent variable and calculate the corresponding values of the other elements. The third of the above equations may be written

$$(\sinh x/2\,c)/(x/2\,c) = \sqrt{s^2 - y^2}/x,$$

$$\text{and}\quad \Delta\frac{\sqrt{s^2 - y^2}}{x} = \frac{s^2}{x\sqrt{s^2 - y^2}} - \frac{\Delta s}{s}$$

if we neglect terms of higher than the first order in Δs.

*This angle may conveniently be referred to as the inclination of the span.

†Actually (x, y) can be regarded as an arbitrary point on the catenary, but we are usually interested in the terminal conditions.

We may therefore form a table of values of the following quantities: s, $(\sinh x/2\,c)/(x/2\,c)$, $x/2\,c$, $x/c + k$, k, c, $\cosh\,(x/c + k)$, T/w, T, Δs.

The initial value to be taken for s is determined by some extreme allowable condition, and may be calculated by the method given in *Numerical Tables*, or it may be taken by finding the length for supports at the same level and separated by a distance equal to the direct distance between the given supports. As it is not essential that the initial value taken be exact, the latter method is usually good enough and it is more convenient.

The values of $x/c + k$ and of k are obtained by combining $x/2\,c + k$ with $x/2\,c$. But since the total change in s will not usually affect the fourth decimal place in y/s, the initial value of $x/2\,c + k$ may be used throughout the formation of the table.

We may illustrate again by an example:

Suppose that with the wire used in the example worked above, the horizontal distance between the supports is 800 feet, and that one end is 200 feet above the other. Required a temperature-tension relation so that the tension at the upper support shall not exceed 3,000 $lb._w$ at a temperature of $-50°$.

We have $x = 800$, $y = 200$, and if we denote the direct distance between the supports by $\bar{x}$ ft., then

$$\bar{x} = \sqrt{800^2 + 200^2} = 824.621.^*$$

Then for $T = 3000$, $w = .508$, $\bar{x} = 824.6$ we have

$$\frac{\cosh u}{u} = \frac{2\,T}{w\bar{x}} = 14.32,$$

whence $u = 0.0700,$

and $s = 824.621 \times 1.00082 = 825.397.$

This will serve for an initial value of s.

Then

$$\tanh\left(\frac{x}{2\,c} + k\right) = \frac{y}{s} = \frac{200}{825.4} = 0.2423,$$

and therefore $x/2\,c + k = 0.2472.$

Also

$$\sqrt{s^2 - y^2} = 800.800,$$

$$\frac{\sqrt{s^2 - y^2}}{x} = 1.00100,$$

$$\frac{s^2}{x\sqrt{s^2 - y^2}} = 1.064.$$

*The reason and justification for retaining six significant figures is given in the discussion following Table III.

Then if we take

$$\Delta s/s = 0.0001\,n,$$

we have

$$\Delta s = 0.0825\,n,\ \ \Delta(\sinh x/2\,c)/(x/2\,c) = 0.0001064\,n.$$

Hence we may form Table II.

In forming this table, it is well to leave two or three blank lines at the beginning to allow for additional entries. In this case, for example, the initial s adopted gives a T lower than the required initial T, but a couple of back entries remove this defect, and if now T be plotted against Δs, by the data of the last two columns, a series of values of Δs, starting from zero at an initial tension of 3,000 $lb._w$ and equal decrements of 100 $lb._w$, may be read off. The use of standard size graph paper of about 1 mm. fine mesh makes this possible with ease. Thence we may calculate the corresponding temperatures by constructing the following table:

TABLE III

$s = 825.277$, $\alpha = 9.6 \times 10^{-6}$, $\lambda = 2.37 \times 10^6$,
$\Delta T = -100\,n$, $\Delta T/\lambda = -0.0000422\,n$.

n	T	Δs	$\frac{\Delta s}{s}$	$\frac{\Delta s}{s} - \frac{\Delta T}{\lambda}$	Δt	t
0	3000	.000				− 50°
1	2900	.050	.000061	.000103	10.7	− 39
2	2800	.103	125	209	21.8	− 28
3	2700	.160	194	320	33.3	− 17
4	2600	.223	270	439	45.7	− 4
5	2500	.298	361	572	59.6	+ 10
6	2400	.380	460	713	74.2	24
7	2300	.475	575	870	90.6	41
8	2200	.585	708	1046	108.9	59
9	2100	.710	860	1240	129.0	79
10	2000	.860	1040	1462	152.2	102
11	1900	1.035	1253	1717	178.6	129
12	1800	1.225	1483	1990	207.0	157

There are several points of interest that may be mentioned regarding this solution:

1. In the matter of significant figures, although the horizontal and vertical distances between the supports are known only to the nearest foot say, one is justified in calculating the direct distance to six significant figures, as has been done, when differential changes are sought. The case is analogous to the finding of $\Delta(x^2)$ for $x = 417.3$ and $\Delta x = 0.0127$. The increment we know will contain three significant figures if we use differentials and apply ordinary

TABLE II

$\frac{\Delta s}{s} = 0.0001\,n$, $\Delta s = 0.0825\,n$, $\Delta\frac{\sinh x/2\,c}{x/2\,c} = 0.0001064\,n$, $\frac{x}{2\,c} + k = 0.2472$.

n	s	$\frac{\sinh x/2\,c}{x/2\,c}$	$\frac{x}{2\,c}$	$\frac{x}{c} + k$	k	c	$\cosh\left(\frac{x}{c}+k\right)$	$\frac{T}{w}$	T	Δs

rules. But the same increment may be obtained by taking the difference $417.3127^2 - 417.3000^2$.* In the case of the increments in this solution, differentials cannot be used and one is obliged to use extended figures and subtraction. The practice, however, is in no way a violation of the fundamental principles of significant figures.

2. When a value for $\Delta s/s$ is adopted, the increment of $(\sinh x/2c)/(x/2c)$ should be calculated. The tabular values of the latter function are then obtained by the method of repeated addition.

The adoption of a simple increment for $\Delta s/s$, such as $0.0001\,n$ which has been used here, has advantages over the adoption of a simple increment for Δs, especially when dealing with spans of different lengths.

3. The values of $x/2c$ are given from column 2 by interpolation from the *Numerical Tables.* They can be obtained to three significant figures. It is true that when $x/2c$ is less than 0.1, the value of the third figure so obtained is slightly in doubt, but in practice not more than to the extent of 1 or 2. This slight uncertainty can, however, be overcome if desired by noting that at this range $(\sinh u)/u$ is given by $1 + u^2/6$ to the sixth decimal place. Hence if the decimals in the column $(\sinh x/2c)/(x/2c)$ are multiplied by 6 and their square roots taken, the results will be $x/2c$. The square roots are readily read from the table of squares, *Numerical Tables*, pp. 54, 55, or the operation may be performed on a slide rule. As a matter of fact, interpolation from the *Tables* gives accuracy which is as close as is warranted by the data in problems such as these, and the tabulation of an extra decimal place in the *Tables* would not have been worth while.

4. When k is negative, the obtaining of the values of q, the sag below (0, 0), may be useful as a check on stringing conditions. The values may be obtained by a slide-rule since the table already contains both c and k, and since $q = c(\cosh k - 1)$.

The foregoing two cases illustrate the fundamental principles involved in problems of this nature. There is, however, a type of problem which involves the application of these fundamental principles to more complex cases.

Case III. *Composite Spans*

In the erection of transmission lines when several consecutive spans are strung at the same time, we might call the several spans so strung together a composite span. When the wire is run through single fixed sheaves at the intermediate supports the tensions on the two sides of each sheave will be equal until the wire is clamped. Hence when the individual spans are of the same length, and when the inclinations of the separate spans are not too large, the temperature tension relation which would apply to an individual span will also apply for the composite span. But when the individual spans are unequal, or when their inclinations are unequal and not small, then the temperature tension relations for the individual spans are unequal and that for the composite span needs to be worked out.

We shall consider an example.

A copper wire such as that used in the two previous problems is to be strung over a composite span of three sections. With the origin at one end, the co-ordinates of the other three supporting structures are (800, − 60) feet, (1,300, − 68) feet and (2,000, 12) feet. Required a temperature tension stringing relation so that the tension shall not exceed 3,000 lb.$_w$ at − 50°, and so that there shall be no uplift on any of the structures.

*The same result would also be obtained by taking the difference $417.3273^2 - 417.3146^2$, or by using any other set of three figures to extend the number 417.3, before adding 0.0127, provided the rounded off value of the extended number remains 417.3. That is, there is no assumption that 417.3 is exact. But of course, the simplest set of digits to use is three zeros.

A general method of procedure which will work with all problems of this type is as follows:*

1. From a sketch of the composite span it is obvious that the point at which uplift will first occur is at the structure between the second and third spans. Therefore construct a Table II, as in Case II, for each of the second and third spans, designed to give a maximum value of 3000 for T_3.

Now, since $dy/dx = \sinh(x/c + k)$, there will be uplift between spans 2 and 3 if the $x/c + k$ of 2 is less than the k of 3 for corresponding values of T_3 and T_2. In the initial parts of the tables, this will be found to be true. Also the values of T_2 are less by 40 (= 80 × .508) than the corresponding values of T_3.

Hence plot T_3 against the value of k for span 3, and on the same sheet plot T_3 against the value of $x/c + k$ for span 2. The value of T_3 at which the two curves intersect is the maximum allowable value of T_3. This value will be found by this means to be 2390.

2. Form a Table II for span 1, contemplating a maximum tension of 2,390 lb.$_w$ Data for greater tensions are now known to be irrevelant.

3. From the Tables II for the three spans plot T_1 against Δs_1, T_2 against Δs_2, and T_3 against Δs_3. Then from these graphs, remembering that for values of T_3 the corresponding values of T_1 and T_2 are less by 40, form the following table:

Table IV

$\Delta T = -100\,n$, $\Delta T/\lambda = -0.0000422\,n$, $\alpha = 9.6 \times 10^{-6}$,
$s_1 = 803.240$, $s_2 = 500.309$, $s_3 = 705.095$, $s = 2008.844$.

n	$T(=T_3)$	Δs_1	Δs_2	Δs_3	Δs	$\frac{\Delta s}{s}$	$\frac{\Delta s}{s} - \frac{\Delta T}{\lambda}$	Δt	t
0	2390	0	0	0	0			0	− 50°
1	2290	.085	.020	.060	.165	.000082	.000124	12.9	− 37
2	2190	.190	.045	.125	.360	174	258	26.8	− 23
3	2090	.310	.070	.205	.585	291	418	43.6	− 6
4	1990	.450	.105	.290	.845	421	590	61.4	+ 11
5	1890	.620	.140	.410	1.170	583	794	82.7	33
6	1790	.810	.185	.535	1.530	762	1015	105.6	56
7	1690	1.035	.240	.690	1.965	979	1274	132.6	83
8	1590	1.315	.300	.855	2.470	1230	1568	163.2	113

The first and last columns of this table give the desired relation between tension and temperature for the composite span. When the wire is strung at any one temperature and then clamped to string type insulators at the intermediate structures, adjustment of equilibrium for subsequent changes of temperature, which before clamping would have been by a slight slipping of the wire through the pulleys, will now be by a slight motion of the hanging insulators in the plane of suspension. The maximum of such motion will however be slight.

The method here given is perfectly general and will work in all cases, but there is an alternative method which will work with sufficient accuracy when the slopes of the individual spans are not too great. Using the direct distances between the supports as the spans, one may form for each span a table, such as Table I, but for the following five quantities only: $2T/wx$, u, $(\sinh u)/u$, $(\sinh u)/u$, Δs. Then without plotting the T's against the Δs's, a Table IV may be constructed for the composite span directly. There are, however, the following points of disadvantage with this method:

1. The maximum allowable tension to avoid uplift, 2,390 lb.$_w$ in this case, would have to be determined before forming the tables, and this involves considerable work.

*To save space, only the steps which are not illustrated fully by Cases I and II are given in detail.

2. Although the tables formed are somewhat shorter and the drawing of graphs is avoided, the Tables II, on the other hand, give full information of all the characteristics of each span at each tension. Also, the graphs of T against Δs afford useful checks on the accuracy of the numerical work.

It is therefore questionable whether there is any real gain in this method over the former one which is perfectly general.

The foregoing discussion shows how temperature-tension relations, and other mechanical characteristics, can be obtained for spans of any nature. It is believed to be fairly common practice, when the span is not too great and when the inclination is small, to use the parabolic approximation for calculating conditions. However, with the *Numerical Tables* available which have been tabulated, the parabolic solution for the cases in which it gives sufficiently accurate results is no simpler than the hyperbolic solution for the same cases. The advantages are therefore all with the hyperbolic method, which solves the simple cases with at least equal ease and which without essential modification solves cases where the parabolic method will not apply.

There is, in conclusion, a further point worth noting. In developing the fundamental equations of the catenary the cable is assumed to be of uniform density, but if the sag is large, the tension will depart considerably from uniformity and so there will be unequal effects on the density. But for wire cables the variation in tension will not be sufficient to produce an appreciable variation in density, and when there is a large change in tension due to change in weather conditions, the changes at all points will be very nearly equal. Therefore Hooke's law will apply in giving change in length just as if the tension were uniform throughout, provided we consistently deal with the increments of tension at some one chosen point, the error introduced in so applying it being negligible. That is, the methods which have been given will yield sufficiently accurate results for wire cables for sags of any amount, and not for small sags only. Any attempt therefore at refinement by making allowance for variation in tension by calculating an average tension only adds complexity to the calculations and secures no increase of accuracy. There are some, it is true, who appear to prefer to find the unstretched length of a suspended cable as a preliminary step, and then use this length as a basis for subsequent calculations. The theoretically correct value for such a length is of course best obtained from the average tension, but equally serviceable for the use to which it is to be put, would be what might be called a pseudo-unstretched length, viz., the unstretched length based on the tension at the chosen point already referred to. Actually there is no need for using the unstretched length at all, but for those who prefer to do so, this pseudo-unstretched length is equally serviceable. There is therefore no need to introduce average tensions and the methods here given are good for wire cables and sags of any magnitude.

The Development and Operation of Oil-Electric Rail-Cars on the Canadian National Railways

H. F. Finnemore, B.Sc., A.M.E.I.C.,

Assistant Electrical Engineer, Canadian National Railways, Montreal, Que.

Paper presented before the Hamilton Branch of The Engineering Institute of Canada, February 11th, 1931

SUMMARY.—After briefly discussing the various types of rail-car, attention is drawn to the development of the Diesel-electric drive for such cars by the Canadian National Railways. The four, six and eight cylinder cars are described and data given as to the results of experience in their operation. The paper concludes with a description of the Diesel-electric switcher locomotive now in service in Montreal, and its method of operation.

The unit rail-car is not, as many people suppose, a new development in the railroad field. Cars of this type were built and operated twenty-five years ago, but it is only within the last ten years that their use has become general on practically every large railway on this continent and on many railroads in Europe.

A unit rail-car may be described as a car which operates in ordinary railway service by power furnished from a source within the car itself. This source may consist of storage batteries or some form of power plant. In the case of storage batteries, power is delivered to the car wheels through electric motors. When a power plant is used, it consists of a prime mover transmitting power to the wheels through either a mechanical or electrical transmission.

Where the power from the engine is transmitted to the driving wheels through a mechanical transmission, the car is called a gasoline-mechanical. This was the first type of rail-car to be developed, and the McKeen car, many of which were built and operated chiefly in the middle western states, was a pioneer so well designed that it has survived in service to the present time, and has a wonderful record of performance. One car shows a total of 1½ million miles. The mechanically driven rail-car is particularly suitable for light service. It requires very little attention and has a high mileage per gallon of fuel. Although the heavier types of rail-car with a combination mechanical-electrical power plant are gaining in popularity, there is still a wide field for the light weight mechanically driven car.

Since the mechanically driven car of large size and weight has poor starting characteristics and involves a somewhat complicated gear shift, it is natural that the next development in rail-cars should combine a gasoline engine with electrical apparatus—in other words, an electrical transmission. This type of car is called gas-electric. This combination gives good starting and an extremely flexible speed control system. The power plant takes the form of a gasoline engine directly connected to an electric generator which in turn supplies power through suitable control apparatus to electric traction motors geared directly to the car axles. An ample number of speed ratios are available, which are simply and easily controlled by the operator, either by varying the engine speed; by changing the connections to the traction motors; by varying the generator voltage, or by combinations of these methods. Smooth acceleration is assured since the transitions in electrical connections can be made even by an inexperienced man without any effect being perceptible to the passengers. The driver is relieved of all except the simplest operations and can devote all his attention to the track ahead. On account of these advantages, the car of the internal combustion engine-electric type undoubtedly leads the rail-car field today.

During the War, none of the railroads were in a position to pay very much attention to the self-propelled car. After the conclusion of hostilities, however, they found themselves faced with serious competition from the automobile. The internal combustion engine, together with the whole automotive industry, had developed greatly, and trucks, buses and other public carriers began to make serious inroads into railroad revenues. In order to meet this

Fig. 1—400 h.p. Eight-Cylinder Articulated Car.

Fig. 2—200 h.p. Four-Cylinder Car.

competition, it was necessary to find some means of transportation which would provide a rapid and suitable service and at the same time do it economically. The Canadian National Railways, along with others, found that such a service was very desirable, in fact, necessary, if the railroad's position in the transportation field was to be retained.

Among the first efforts to meet this competition was the storage battery car. This consisted of a comparatively small passenger car equipped with electric traction motors which received power from storage batteries carried beneath the car floor. No power plant of any kind was carried on the car itself, but the storage batteries were charged at the ends of the run. This car proved satisfactory for short, frequent runs with a sufficient interval in between for battery charging. For longer runs, the schedule had to be arranged to allow charging time at each end. This in itself was a serious drawback, since the schedule was necessarily governed in many cases by the limitations imposed by battery charging, rather than by the actual requirements of the service. Charging facilities involved heavy costs for the installation of two charging plants, one at each terminal, since a direct current supply was very rarely available. A charging plant meant a skilled attendant, and so a car often had two maintainers. Flexibility of operation was lost since a car could not be changed to another run in emergency or for heavy traffic needs, without moving or providing additional battery charging facilities.

Other limitations also made themselves felt. A storage battery is necessarily limited as to capacity, and while a car might prove entirely satisfactory during the summer months, the first fall of snow would call for an output of power entirely beyond its resources and a failure would result miles from the terminal.

It was obvious that the storage battery car could not fulfil long distance requirements. When the first battery renewals became necessary, two cars were converted to gas-electric by the removal of the storage batteries and the installation of a gasoline engine generator set. These converted cars proved satisfactory and showed conclusively that the rail-car with the self-contained power plant was the solution for light traffic on branch lines.

As the converted cars were small, the seating capacity was found insufficient for many runs. There was no baggage space, since the power plant had been mounted in the space originally provided for that purpose. These cars were therefore suitable only for shorter runs where little, if any, baggage requirements were necessary.

Attention was turned toward cars of a larger type, designed with a special view to average conditions and incorporating suitable baggage, seating and other facilities. Studies of gas-electric car operation, as carried on in the United States, showed that with considerably higher gasoline costs in Canada, expected economies might not be so apparent. About this time, many reports were heard of the radical improvements to the Diesel engine which had been effected in Europe. Further information was obtained and proved so encouraging that several members of the mechanical department of the Canadian National Railways went to England and the continent to investigate thoroughly the progress which had been made.

As is generally known, the Diesel engine operates under quite high pressures and until a few years ago was of massive construction in order to withstand the stresses set up. With such a heavy engine, it would be impossible to design a rail-car within practicable limits. However, with the impetus to research provided by the War, alloys were developed which reduced the weight per horse power to such a point that Diesel engines were available which were no heavier nor larger than gasoline engines of equivalent power. Among the firms which had made notable strides in this direction was Wm. Beardmore and Company Ltd., Glasgow. In co-operation with the British Air Ministry they had developed an engine, using special aluminum alloys and high tensile steels, which weighed about 14 pounds per horse power as compared with 50 or 60 pounds per horse power, using older materials and methods. Here was a Diesel engine eminently suitable for rail-car application.

After investigation and tests, the Canadian National Railways decided to build some unit rail-cars using this engine. These were the first oil-electric cars built for regular railroad operation on this continent. Two sizes of engines were chosen—a four-cylinder and an eight-cylinder. Seven cars were built using the smaller unit, the power plant comprising a Beardmore engine of 200 h.p., direct connected to a 105 kw. 600-volt D.C. generator. Two cars using an eight-cylinder Beardmore engine of 400 h.p. were also constructed. The engine is connected to a 200 kw. 600-volt D.C. generator. These two cars are of the articulated type, that is, they consist of two separate car bodies connected together at one end and supported by a common truck at the joint. This truck contains no traction motors, the motors, four in number, being mounted two on the front truck and two on the rear. The car is shown in Fig. 1 and is 102 feet in length over all, it weighs approximately

Car Data

Builder	*Canadian National Railways*
Length Over End Sills	*73 ft. 9 in.*
Width Over Side Sills	*10 ft. 0 in.*
Overall Length	*13 ft. 11 5/16 in.*
Length of Main Compartment	*22 ft. 8 in.*
Length of Smoker Compartment	*11 ft. 4 in.*
Length of Baggage Room	*15 ft. 11 in.*
Length of Engine Room	*16 ft. 10 in.*
Main Compartment Seating Capacity	*37*
Smoker Compartment Seating Capacity	*20*
Truck Wheel Base (front)	*8 ft. 0 in.*
Truck Centre Distance	*53 ft. 3 in.*
Wheel Diameter	*36 in.*
Car Weight, Complete	*141,000 lb.*

185,000 pounds, and as constructed, seated one hundred and twenty-six passengers and provided a large baggage space, as well as a smoking compartment. Since then, the baggage space has been increased and the seating accommodation consequently reduced.

The four-cylinder cars shown in Fig. 2 are somewhat smaller and consist of the regular type of car body 60 feet over all, seating fifty-seven passengers and with a good sized baggage compartment. These cars have not been changed materially and are in service today practically as built.

With the exception of the steel car frames, which were built by one of the Canadian car companies, all car work, including the finishing, equipping and installing, of every piece of equipment, on both four and eight-cylinder cars, was done at the Railway's Montreal shops. Construction was carried out during 1925 and all cars went into service before the end of the year.

As an initial effort in an entirely new field, these cars have proved very satisfactory, the four-cylinder type particularly. They are capable of hauling light trailers, and are doing so on practically all runs, attaining speeds of from 50 to 60 miles per hour where conditions are favourable. All are equipped for double end operation, this feature being thought necessary, as it was planned to operate the cars on branch lines where turning facilities might not always be available. Actually, however, on nearly every run, some means was found of turning the car at its terminal. It was also found that the drivers much preferred to operate with the engine end leading, as in this way they were always beside the power plant and in constant touch with it.

Auxiliary equipment of both cars comprises a fuel oil tank, a water supply for engine cooling, and a tank for lubricating oil. Storage batteries are provided for car lighting, field excitation and engine starting, using the generator as a motor. Suitable controls and switching apparatus perform all electrical functions. Radiators mounted on the roof provide for cooling the engine circulating water and lubricating oil. In these cars, the engine room is provided with a hatch in the roof for lowering the power plant into place.

The electrical equipment on the four-cylinder cars consists of a single-bearing generator directly connected to the engine and having an exciter mounted on an extension of the armature shaft. Both engine and generator are mounted on a common bed. The exciter operates at 60 to 80 volts and provides field excitation for the main generator and charging for the storage batteries. Current is taken from the main generator through a K-type controller, which provides series, parallel and shunt-parallel connections to the traction motors, both of which are mounted on the front truck. The engine throttle control is mechanical through flexible cables.

An undesirable feature on these cars is that current for the operation of the air compressor is taken from the main generator, which means that the supply of air will only be kept up while the voltage is near 600, that is, when the car is running. On long down grades, the engine must be operated at almost full speed and practically no load so that full air pressure will be available at all times for braking. This feature is probably the greatest drawback to the type of control used on these cars. However, it does not prevent these units giving excellent results in service.

The articulated cars have a main generator only, with two sleeve-type bearings connected to the engine through a flexible coupling. Field excitation is obtained from the storage battery, which, in turn is charged from the generator when its voltage is above a given value. Two air compressors are provided, one of which operates from the storage battery when the engine is at rest and the other from the main generator during car operation. In this way, full air

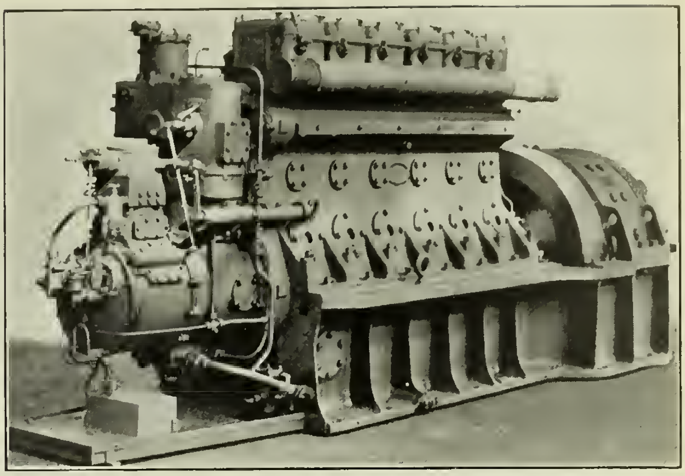

Fig. 4—Beardmore Six-Cylinder Engine.

pressure is always assured. Car speed is controlled by varying the generator field through a master controller. The engine throttle is also controlled electrically through this same controller.

On account of its construction, somewhat more electrical equipment is necessary than would be the case with a single unit car. Also it is more or less difficult and always undesirable to carry conductors for heavy electric current across a gap, such as the articulation makes necessary. The size of the car renders it unsuitable for any but especially selected runs and it is not likely that any more of this type will be built. This car is equipped throughout with S.K.F. roller bearings on the truck axles.

After a year's operation, with the cars under constant observation while records of performance, suitability, etc., were kept, information was obtained which indicated the desirability of some modifications in future oil-electric cars. The four-cylinder engine units were found to be somewhat lacking in power and the eight-cylinder articulated cars too special in their design and scope of service, so that a design in between these two was selected as the next step. Accordingly five six-cylinder cars were built at the Canadian National Railways shops, Montreal, and placed in service in 1927. They are shown in Fig. 3, are 73 feet 9 inches long, and weigh approximately 140,000 pounds. The engine shown in Fig. 4 is a Beardmore, developing 300 h.p. at 750 r.p.m., and, like the first two types of engines used, has an 8¼-inch bore by 12-inch stroke. The generator is 198 kw. 600-volt D.C., with a single sleeve type bearing and is mounted on the same bed plate with, and rigidly connected to, the engine. On the same shaft with the generator is mounted a 5.6 kw. 64-volt exciter. It is usually spoken of as the auxiliary generator, for the reason that it not only provides field excitation, but at full engine speed, battery charging and air compressor operation. Two traction motors permanently connected in parallel are mounted on the front trucks. It may be noted that on all single unit cars, the motors have been mounted on the front truck which carries the weight of the power plant and all auxiliaries, thus obtaining maximum adhesion.

All electrical connections, including engine starting, are established through electro-pneumatic and electromagnetic contactors from a master controller, which is combined with a mechanically connected engine throttle. Based on experience with previous rail-cars, single end control only is provided, all controls being mounted in the engine room.

Engine starting is accomplished by motoring the generator from a 64-volt storage battery. This battery also provides 32-volt lighting through a three wire system. The air compressor is driven by a 64-volt motor which may receive its energy from three sources,—the storage

Fig. 5—300 h.p. Six-Cylinder Car and Trailer.

battery when the power plant is at rest, the auxiliary generator at full engine speed, or the main generator at idling engine speed. It will be noted that the faults in air compressor operation as they existed on the four-cylinder cars are entirely eliminated, as all contingencies met with in normal service are provided for. The storage batteries are charged from the auxiliary generator during car operation and from the main generator during idling periods which means that they are charging practically all the time.

The radiators are mounted vertically at the front of the car, five sections on the roof for water cooling and one section below the front window of the engine room opposite the driver for lubricating oil cooling. Both the water and lubricating oil radiators are fitted with shutters in front which may be opened or closed depending upon weather conditions. On the last cars built, the water radiators are completely enclosed with a metal housing and have shutters both front and rear. This has been found desirable as the cooling effect in very cold weather at high car speeds has been found a great deal more than is necessary to keep the engine at its most efficient operating temperature.

So successful have these cars been and so near to meeting average operating requirements that this type has been practically standardized for further development. (See Fig. 5.)

After three years' operation with the six-cylinder cars, seven more were placed in service in 1930. These cars are practically duplicates of the first five, except that Westinghouse-Beardmore engines are used.

The Westinghouse Company, after spending nearly three years investigating the performance of the oil-electric cars on the Canadian National Railways, secured the American rights for the manufacture of Beardmore engines.

In appearance, the Westinghouse engine is very much the same as the Beardmore and in operating principle, of course, is identical. The chief difference in the two engines is in the governor speed control and in the construction of the fuel pumps which deliver fuel oil to each cylinder. Where Beardmore uses a mechanical type of governor, Westinghouse uses a hydraulic. A shorter engine, consequently a shorter overall length of power plant is attained, which is of particular advantage in rail-car construction where every inch saved in the engine-room means more space for revenue use. (See Fig. 6.)

The mechanical governor used by Beardmore is rather complicated and is made up of many moving parts, requiring very careful fitting. Experience has shown, however, that this governor is readily adjusted and, once in working order, remains that way and requires no further attention.

The Westinghouse hydraulic governor is simpler and consists of a minimum of parts. As with the Beardmore governor, its actuating medium is the engine lubricating oil. Since there is a change in viscosity of this oil, from cold to engine operating temperature, some variation in the speed of the engine occurs when it is first started, but this disappears very quickly as the engine warms up.

The Beardmore fuel pump, for a six-cylinder engine, consists of three main plungers, each plunger delivering fuel oil to either of two cylinders, the cylinder being selected by a switch valve. The amount of fuel oil delivered, depending upon the load conditions of the engine, is regulated by a control valve. For each of the three main plungers, there is, therefore, a control valve and a switch valve, making a total of nine parts. Very high grade materials are required in these fuel pumps and great care is necessary in fitting the parts. The plungers are finally lapped in place using rouge as the abrasive. A fuel pump in good condition will give pressures up to 8,000 pounds per square inch, which will give some idea of the high quality of workmanship required.

The Westinghouse fuel pump, again considering a six-cylinder engine, provides a main plunger and control valve combined in one, for each cylinder, making a total of six plungers. With this arrangement a switch valve is unnecessary, since each cylinder has its own pump unit. This design was adopted since it eliminates three moving parts. It offers certain other advantages also. In the Beardmore engine, failure of one main plunger puts two cylinders out of commission, since both receive fuel from the same pump alternately. Using an individual plunger for each cylinder means that one cylinder only fails in case of a pump failure. The use of separate fuel pumps also provides adjustment for each cylinder individually and the eccentricities of one cylinder are not necessarily reflected in another.

Excepting for some slight modifications and refinements, the electrical circuits and controls on the Westinghouse cars are the same as on the earlier Beardmore cars. The radiator arrangements for both engine cooling water and lubricating oil are identical, except that on the later cars, thermostatic control combined with manual operation is used. The lubricating oil is carried in a separate tank in the newer cars, where in the first units it was carried in the engine sump. With a view to easier maintenance, a general re-arrangement of the engine-room layout has been made to make the electrical contactor panels and connections more accessible. The traction motors on both the first six-cylinder cars and the last, are the same. Although the Westinghouse engine is of higher rating, this additional power is used only during acceleration and the capacity of the motors is ample for this load since it exists for relatively short periods only.

The main generator has been re-designed to use a single ball bearing which shortens it considerably. The capacity is 300 kw. and as before, it is directly connected to the engine shaft.

All the six-cylinder cars have trucks equipped with roller bearings for easy starting and to cut down maintenance.

A feature of the electrical equipments on all the six-cylinder cars is the generator torque control. This device, in the form first developed for oil-car application, consists of a small motor, the armature of which tends to revolve against the tension of a spring and whose shaft carries a contact-making arm. The field of this motor is proportional to that of the main generator and the armature is in series—through a shunt—with the main generator armature. Thus the torque of the small motor is directly proportional to that of the main generator. When the torque exceeds a pre-determined value, a contact is made which inserts resistance into the generator field, reducing the voltage and thereby the generator output. When the load is relieved, the original condition is restored. A manual adjustment is provided on the torque governor to take care of a condition where the engine is incapable of producing its full power and the electrical load thus limited at a lower point than normally.

The torque governor has accomplished good results, but since it is entirely dependent on the generator, that is, the electrical load, for its functioning, it will readily be seen that if the engine is incapable of producing the output for which the torque governor is set, an overload condition will result. In other words, if the torque governor is set for the full electrical load of a six-cylinder engine-generator set and only five cylinders are firing, the engine will be overloaded to the extent of one cylinder's output. To protect against such a contingency, the torque governor is usually set considerably below the normal torque of the engine throughout its speed range. Of course, if the operator realizes engine overloading is taking place, he can immediately reduce the torque governor setting, but a falling off in engine power is not always readily detected.

On future equipments, a more recent development, known as "engine torque control," will be used. This device prevents overloading of the engine by limiting the fuel to each cylinder to the amount corresponding to full load fuel at any one of several working speeds between idling and full speed positions. The engine throttle is mechanically connected to the control for the fuel admission and positively limits the amount of fuel for any given throttle position.

The auxiliary generator is also provided with a special field winding so that its voltage is very closely proportional to the engine speed. In addition, by means of electrical connections, varying resistances are set up for the different throttle positions and the voltage is limited by a control relay. With these conditions, an overload will cause a drop in engine speed as the fuel admitted to each cylinder is positively limited by the throttle.

This drop in engine speed causes a drop in voltage which in turn actuates the control relay, introducing resistance into the generator field circuit, thus reducing the generator load to a point below normal for that speed.

The engine torque control gives an electrical output curve more nearly in agreement with the engine output than has previously been obtained and actually prevents overload.

Large baggage space is provided in all six-cylinder cars and the seating capacity considerably cut down, since it is customary to use a trailer for passenger accommodation. In connection with passenger seating accommodation, it may be noted that there is a tendency to eliminate passenger facilities in the motor car itself, these being transferred to a trailer. Space in the motor-car is then utilized for baggage, express and mail. Although railway post office compartments are seldom seen on Canadian rail-cars, they are widely used in the United States. In a rail-car train with a motor-car of this design, passengers are completely separated from the power plant, there is no noise or vibration, and gas fumes, if there are any, never reach the trailer. The transfer of passenger accommodation from the motor-car to trailers is particularly evident on many railroads where very large, or in many cases, double power plants, are in use.

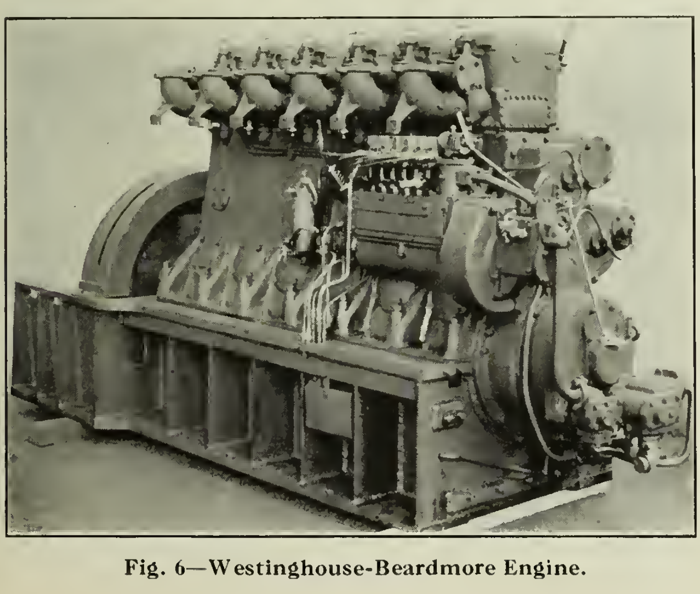

Fig. 6—Westinghouse-Beardmore Engine.

Six more cars will go into service on the Canadian National Railways during this year and two have been designed along these lines, with baggage and express accommodation only. The service in which these two cars will operate is on the main line, for local traffic where a large quantity of express is handled.

A great deal of interest has been evident on the part of many railroads in the oil-electric car development, but there has been considerable timidity in its adoption. There are various reasons for this and the high first cost is undoubtedly one of them. Admittedly, the oil-electric car does cost more than the same type of car using a gasoline engine, but with expanding use, mass production will play its part and costs will sooner or later reach a common level. Even now, the Diesel engine does not cost a great deal more than the gasoline engine and there is nothing inherent in its construction which will prevent the adoption of quantity production methods when the demand justifies.

Another reason which has often been voiced is an idea that the Diesel engine is complicated. That there is no foundation for this is borne out by the experience on the Canadian National Railways where the first nine cars built were widely seattered over the entire system, some of them in remote locations, with no special provision made for them. Remembering that these were the first cars of their kind to be built, all maintenance work must necessarily have been carried out by men who had never seen such equipments before. Yet they operated successfully. It should be borne in mind also that since the oil-electric car is a new development and consequently a novelty, all eyes are focused upon it and so every mishap and failure is apt to become exaggerated and magnified.

Considering these facts and allowing for errors in design, and in the use and application of various mechanical parts, certain to be present in a first attempt, these cars made an excellent record. As an example of what was accomplished with no special arrangements for maintenance, a four-cylinder, 200 h.p. oil-electric car operated for 200,000 miles with a serviceability of 86 per cent. This car operates throughout the year under all sorts of weather conditions and is in a remote location. After making this mileage, the car went in for general overhaul. Only such wear as might be considered normal was found.

Another four-cylinder, 200 h.p. car operated 19 months with 100 per cent serviceability and covered 59,000 miles. (It was one of these four-cylinder units which made the run from Montreal to Vancouver in sixty-seven hours.) A six-cylinder, 300 h.p. car operated 109,000 miles with 92 per cent serviceability.

In service, it has usually been found necessary to have one man specially detailed to look after the maintenance of each car. The reason for this is that in nearly all cases the cars are widely separated. Where several cars operate out of a common terminal, it has been found entirely practicable for a maintainer to care satisfactorily for more than one unit. Each maintainer reports to a supervisor who usually has control of a number of cars operating in a fairly wide territory. His duties are to see that each car under his supervision is properly cared for, to advise and assist the maintainers, and to instruct the men operating the equipment.

General overhaul of the cars has been carried out at Moncton, Toronto and Winnipeg and also, to some extent, at Montreal, at all of which points railroad shops are located. No particular effort has been made to gather

Fig. 7—450 h.p. Six-Cylinder Switching Locomotive.

together a personnel made up of mechanics with former experience on Diesel engines. The best men, however, have been drafted from the regular shop staff to perform such work.

No attempt has been made, as yet, to set up an organization purely for oil-electric car work. With a comparatively small number of units in operation, twenty-four in all to date, and realizing that these are widely scattered, it will be appreciated that special equipment could not economically be provided at a number of points. Neither would it be feasible to concentrate a special staff on oil-electric car work only, as it is evident that there would not be enough work to keep them occupied full time. The most elaborate attempt to take care of this new equipment has been made at the Toronto shops, where a special machine for testing fuel pumps has been set up and various machine tools installed. The work is in charge of one man who, when not engaged in the overhauling of cars, supervises the making of various engine replacement parts.

All work in connection with gas-electric and gas-mechanical cars is handled at this point also, as the machine tools used in oil-electric car work are equally suited to gasoline engines.

As the use of unit rail-cars increases, as it undoubtedly will, and more cars are placed in service, the time will come when facilities devoted entirely to engine re-conditioning and general overhauling will be essential. Several American railroads which have gone in for rail-cars on a large scale have already taken this step. The advantages of such facilities are immediately apparent. Special tools and machines can be provided with building space set aside for them, to care for nothing except internal combustion engine work. A staff of specially trained men who will always be fully occupied with rail-car maintenance can be retained permanently. Under these conditions, repair work will gain in efficiency, since it will be possible to properly organize it and experience gained can be utilized to better advantage.

As mentioned before, the oil engine used by the Canadian National Railways is very similar to the gasoline engine in general appearance. In construction, the oil engine is built to withstand much heavier stresses and special alloys and materials are used to attain this end, without undue increase in size and weight. The engine cylinder block is of cast steel. The cylinders are formed of steel liners pressed into the cylinder block and sealed around all water passages with rubber gaskets of special composition. Pistons are aluminum alloy with compression rings at the top and one or two oil scraper rings at the bottom. Connecting rods are forgings with a floating bearing, steel in bronze and aluminum at the piston end and bronze babbitt-lined on the crank pin. The crank shafts are nickel-chrome steel forgings supported by a main bearing between each cylinder, bronze babbitt-lined, and with an additional bearing at the generator end to provide for thrust. With the exception of the connecting rod bearing in the piston which is dependent on splash lubrication, every bearing in the engine receives lubricating oil under pressure. On all engines the cylinder heads are aluminum alloy with cast iron valve seats imbedded in the aluminum. Two valves are provided on both inlet and exhaust ports. These are of the overhead type. All valves are actuated by one camshaft through push rods and rocker arms.

The fuel pump, lubricating oil pump, water circulating pump, camshaft, etc., are driven through a train of gears from a main gear on the crank shaft at the front of the engine.

In the four-cycle Diesel engine of the solid injection type, such as is used on the Canadian National Railways rail-cars, the sequence of operations is practically the same as in a four-cycle gasoline engine, but with these exceptions. On the induction stroke, air only is drawn into the cylinder. At the end of the compression stroke, fuel is sprayed into the cylinder by an atomizer in the cylinder head. The compression in the Diesel engine is extremely high so that the temperature of the air when compressed is sufficient to ignite the spray of fuel oil without any auxiliary device, such as a spark plug. The remaining two strokes in the cycle, the explosion and exhaust, are the same as that of the gasoline engine.

The temperatures reached in the cylinder of a Diesel engine are so high that incomplete combustion is practically impossible. Analysis of exhaust gases shows a negligible quantity of carbon monoxide. Compare this with the gasoline engine, where carbon monoxide is always present in large quantities, and you will appreciate that the Diesel has very efficient combustion.

Tests made by the American Railway Association last year on unit rail-cars, using gasoline, distillate and fuel oil (Diesel), showed an over-all efficiency of the power plants that is, from the fuel tank to the generator terminals, as follows:

Gasoline and distillate, approximately 12 to 15 per cent.
Fuel Oil or Diesel, 23 to 26 per cent.

These tests were made on different railroads and the cars were tested exactly as found, without adjustment or change to any part of the equipment. The operators were told to carry on as usual and endeavour to forget that any tests were in progress. Expressing these results in another way, the kilowatt hour output per gallon for gasoline and distillate averaged about 5, while for Diesel fuel oil it averaged over 10, just double.

Besides the application of the oil engine to rail-cars, there is another field in railroad service where the Diesel has already proved its economy and aptitude. This is in switching service.

In theory, the greatest fuel saving possible in any service is by eliminating stand-by losses. As switching service represents a form of operation with wide fluctuations of load and much idle time, it would seem to offer an excellent field for the internal combustion engine. A number of tests made in representative switching service were analyzed and certain fundamentals established. In the first place, it was shown that the maximum power actually developed by the locomotive did not average more than 40 per cent of its rating and this for not more than a one minute period. Further, for only fifteen minutes of a sixteen hour test was power developed beyond 36 per cent of the locomotive's rated horse power. For the entire sixteen hours, the average horse power developed was slightly under seven per cent of normal rating.

A study of these operations indicated that an engine of 450 h.p. could handle the service successfully. While there would be certain periods during which time would be lost, due to inability to meet peak loads, there would be many other times where this could easily be made up by a greater utilization of the oil engine in movements not requiring its maximum power. The tests mentioned covered only certain classes of switching service and it must not be assumed that a 450 h.p. locomotive will satisfactorily meet all conditions of railroad switching work. There are certain services, such as heavy transfer work, where a more powerful locomotive will be required.

A switcher locomotive, equipped with a 450 h.p. engine, maximum rating, was built and placed in coach yard service at Montreal, making up passenger trains, at the end of May, 1930. It is shown in Fig. 7, and its operation to date indicates that the assumptions based on steam switcher operation, as previously outlined, have been well justified. The locomotive operates three shifts a day—twenty-four hours—every day in the week except for one eight-hour shift every fifth day when it has to be brought in for fuel, lubricating oil, water, sand, etc. An inspection of all parts of the engine, electrical equipment, brakes, etc., is made at the same time. The first cost of the oil-electric locomotive is, of course, higher than for an equivalent steam locomotive. It can hardly be otherwise where only one unit is considered. For one thing, development costs can not be distributed, as would be the case where a number are built at one time.

Considering all features which we are able to develop, the 450 h.p. oil-electric switcher now in operation saves in twenty-four hours approximately $40, an amount ample to meet any extra costs over and above the cost of a standard steam locomotive of the same capabilities. As compared with a steam unit, there is no time lost in cleaning fires or taking coal and water and idle time is dependent only upon what lost motion there is in the actual switching operations.

The Westinghouse Beardmore six-cylinder engine used in the switcher locomotive is the same as used in the rail-cars. It normally develops 350 h.p. at 800 r.p.m. Since the power output of the engine is proportional to the speed, it will be seen that if the speed is stepped up, the horse power output will step up also. An auxiliary foot throttle is provided which increases the engine r.p.m. to one thousand and this speed gives approximately the 450 h.p. rating. Considering the power requirements of average switching services as indicated by the tests made on steam switchers, the increased rating of the engine is seldom called upon.

The power plant in the switcher is very much the same as that of the rail-cars, but naturally the service requirements call for higher ratings and more ruggedness in design, particularly in the electrical equipment. Various changes in design are also necessary for some of the auxiliary devices.

Comparing the operation of a switching locomotive with that of a rail-car, several differences are immediately obvious. The rail-car, except for short periods during acceleration, operates at high speed and always in one direction. Since the locomotive may be called upon to operate in either direction and at slow speeds, mounting the radiators on the roof at one end and depending on the natural current of air for cooling is out of the question. These are therefore mounted in the roof itself and ventilated by motor-driven fans.

The average power developed in a rail-car throughout a run is usually not over 175 or 200 h.p., a figure established by actual tests on a number of cars. The switcher, on the other hand, may make many movements which, while possibly of short duration, may call for a heavy power output for practically the whole of the movement. It has, therefore, been necessary to make the traction motors much heavier. These are four in number, one on each axle, and of such capacity that forced ventilation is unnecessary. Advantage is taken of the fact also that most switching movements are short, with usually an interval between during which a great deal of heat can be radiated.

Since switching service calls for the continuous use of the air brakes, large air storage and compressor capacity is necessary. Two air compressors are installed with a total of 150 cubic feet of air per minute. Large air capacity is also an essential in some passenger car switching movements where the number of cars makes necessary the connection of the train line. The air requirements to bring the brake pressure in a string of passenger coaches up to the point for proper operation, without undue delay, are considerable.

Both air compressors operate from the main generator during idling and from the auxiliary generator during running. This is similar to the air compressor operation on the six-cylinder rail-cars.

Operation of the switcher is from one end only. The control is practically the same as for the six-cylinder cars, except that the traction motors operate through the first positions two and two in series, after which they are connected in parallel. No shunt field connection is provided. The throttle consists of a single lever which actuates the engine throttle mechanically and makes connections to the electrical equipment through a contact drum. The number of controls which the engineman has to operate is exactly the same as for a steam locomotive and consists of the throttle, reverser and air brake.

If the oil engine is to play an extensive part in railway service, it will have to be further simplified, and those parts which require frequent examination must be made more readily accessible than has been yet accomplished. Not only can improvements be made in simplifying the oil engine itself, but also the number of auxiliaries and accessories used in the electrical and mechanical apparatus can be greatly reduced, and possibly many eliminated entirely. Simplicity of all parts should be the key-note in rail-car construction. It must be remembered that the organization which now takes care of all railroad rolling stock is the result of years of operation, and any new development in the railroad field, to be successful, must meet with their approval and co-operation.

Type Testing of Aircraft

Flying Officer A. L. James, R.C.A.F., A.F.R.Ae.S.
Department of National Defence, Ottawa.

SUMMARY.—Type testing of aircraft is carried out to determine the airworthiness and flying qualities of a machine before approval for general service, and these tests also determine the capabilities of the type and aid in the selection of proper machines for special work. The paper describes the qualitative and quantitative tests regularly carried out for this purpose, explains briefly the theory of stability and discusses the methods of determining the performance of the aircraft as regards rate of climb, power consumption, service ceiling and maximum range at different heights. The method of reduction of performance trials to a uniform standard of comparison is also described.

"Type Testing" is the term commonly used to describe the trials or tests which an aircraft undergoes to establish its characteristics and normal performance for the purpose of comparison with contemporary aircraft of similar type.

The necessity of establishing the general flying qualities of an aircraft before it is put into general service, where it is flown by less experienced pilots, will be readily appreciated. On the other hand, knowledge of the capabilities of an aircraft is very essential when it comes to the selection of aircraft for operational work. Then again, of course, the choice between two types of aircraft hinges principally on performance, while a secondary, and also very important, consideration is general suitability from the point of view of constructional robustness, maintenance, and disposition of crew and equipment.

Thus, Type Testing may be divided into two classes, viz.:

1. Qualitative Tests,

and 2. Quantitative Tests.

Qualitative Tests

The qualitative tests are done first and are for the purpose of determining the balance, manoeuvrability, controllability and stability of the craft both on land, or water, and in the air. The ground tests consist of taxying the aircraft across smooth surface, rough ground, soft and hard surfaces (or glassy water, rough water, and in water currents, as the case may be) under all the various wind conditions, such as, no wind, medium, severe wind, and gustiness. The aircraft is then taxied, in the case of a landplane, along on its wheels with tail up, or in the case of a water craft, along on its step, at a speed just under flying speed, in order to establish lateral and longitudinal stability and controllability under such conditions. The aircraft is next taken off and landed again in what is termed "straight hops," that is to say, the aircraft is simply taken into the air to a height of a few feet, and then landed again. This is done three or four times in order to ascertain any peculiarities of the type in taking off, and landing before any further tests are attempted.

In all such tests, besides the obvious behaviour of the aircraft, a great deal of the aircraft's characteristics are determined by "feel." That is why a test pilot must have a good deal of experience on various types of aircraft. It is usual to have the tests carried out by two or more pilots, especially if any unusual behaviour is reported.

The aircraft is now taken into the air for its general flying tests to establish balance, manoeuvrability, controllability and stability. All trials commence with gentle manoeuvres and progress by easy stages up to the limit of the evolutions as established for the particular type.

Balance, manoeuvrability and controllability are closely related to stability and co-ordinated with it. An aircraft is said to be properly balanced when it maintains level flight with no persistent tendency to dive or to stall. Manoeuvrability, as the name suggests, is the power of executing manoeuvres, or of rotating about any axis with a high angular velocity and acceleration. All aircraft do not have the same degree of manoeuvrability, which as one would expect, varies considerably from small high speed single engined aircraft to the slow, large freight-carrying multi-engined type. One need only think of the analogy of small motor-cars versus commercial trucks to appreciate this.

Controllability implies easy movement of controls with the application of only moderate forces and prompt and positive response of the aircraft to the control movement. In addition it is essential that the forces required to operate the three systems of control, viz.: aileron, elevator, and rudder, give equivalent relative reactions on the pilot's hands and feet. To quote from a recent article on controls, "the three controls should be in harmony with each other. The angles and forces required from each for general manoeuvring should be of the same order." For instance, an aircraft which is described as "heavy on rudder" is one in which the force required to operate the rudder is excessive as compared with that necessary to operate aileron or elevator control. It may happen also that the control reactions alter considerably, relative to each other, on acceleration from slow speed to high speed or in certain manoeuvres.

As may be seen in all flying tests for controllability and manoeuvrability, the characteristics are determined entirely by "feel" and indicate the necessity for an experienced pilot.

Researches are being carried out in various countries, at the present time, with the object of producing instruments and methods for establishing manoeuvrability and controllability in terms of control forces required, rates of turn, and speeds. However, no system has been put forward, as yet, and the general flying characteristics are still based on opinions, although admittedly expert opinions.

The study of stability is a complex one and it would be impossible to attempt a full discussion of it here. It is intended merely to explain the various types of stability and show how flight tests indicate the degree of stability exhibited by an aircraft.

Since the motions to be analyzed are so complex, a rather elaborate system of symbols for the forces, moments, velocities and accelerations existing is required, and the first step in the creation of such a system is the choice of a reference frame of three mutually perpendicular axes. Fig. 1 shows these, together with the symbols employed for the various quantities involved in considering stability.

The theory of stability deals with the study of the motions of an aircraft about a steady state of flight, when left to its own devices.

A stable aircraft is one which, from any position in the air into which it may have got, either as the result of gusts or the pilot's use of the controls, will recover its correct

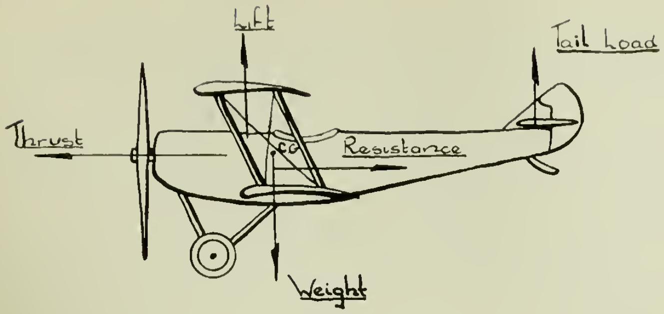

Fig. 2

flying position and speed, when the pilot leaves the machine to choose its own course.

The study of stability comes under two headings, viz.:

(*a*) Longitudinal.

(*b*) Lateral.

Longitudinal Stability

An aircraft is said to be longitudinally stable when it returns to its original attitude and speed of flight after a disturbance in pitch, i.e., rotation about the lateral axis.

Longitudinal stability must not be confused with balance, i. e., the tendency to dive or to stall. Let us consider a perfectly balanced aircraft in horizontal flight, the forces acting on which are as shown in Fig. 2.

The resultant pitching moment about the centre of gravity (the point about which all rotation takes place) is zero. Let it be supposed that the aircraft is disturbed in flight and changes its attitude, the speed of flight remaining the same or changing, depending on the magnitude or continuance of the disturbance. The moments due to the main planes and tail plane alter considerably with change of incidence, attitude, and speed of airflow. The effect of change of inclination of thrust and drag, relatively speaking, is not of much importance unless the balance between main plane and tail plane moments is very fine.

For a stable aircraft, the resultant pitching moment, in disturbed flight, should be such as to cause the machine to return to its original attitude. That is to say, if from normal flight the nose of the aircraft is suddenly pushed upwards, the resultant pitching moment must be a nose-diving moment and vice versa. For example take a general diagrammatic representation of pitching moments of an aircraft, as shown in Fig. 3.

The relative value of moments, due to the main planes, tail plane, and other causes, is readily appreciated. It will be seen also that the resulting moment satisfies the condition of proper correcting moment for disturbed flight.

Obviously the position of the centre of gravity is the controlling factor in longitudinal stability. The cure for longitudinal instability is to move the C.G. forward. The increase of control surface is, but rarely, the solution for instability, because the increased weight gives a moment which aids the unstable condition, and the greater surface means greater control loads and poorer manoeuvrability. This will be discussed again later.

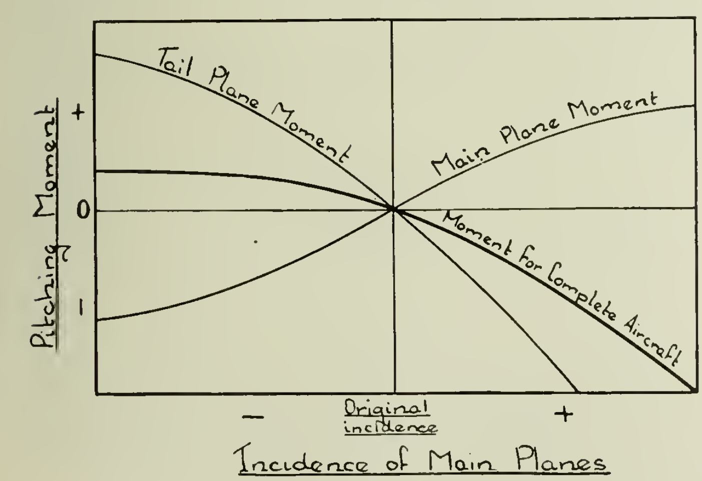

Fig. 3

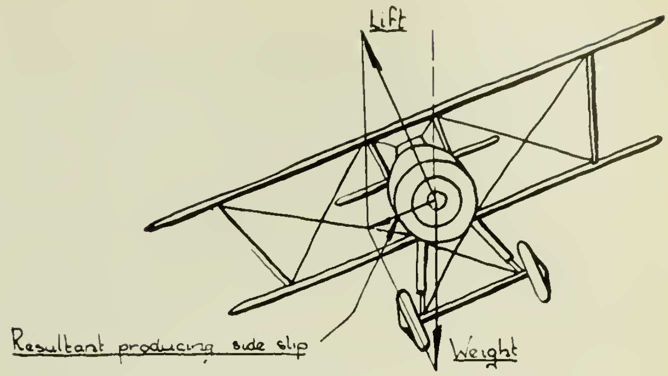

Fig. 4

In general the tail plane of an aircraft is in the slip-stream of the airscrew wherein the velocity of the air is greater than that on the wings. Stability in gliding flight, where the velocity of the airflow is approximately the same over both main planes and tail plane, may be quite different and consequently gliding flight also requires investigation. This is particularly important on aircraft with a fixed tail plane where balance in gliding flight is obtained by constant use of the elevators.

Lateral Stability

Let us now consider a normal and well balanced aircraft in straight flight suddenly banked by the pilot's action or by a gust of wind.

The condition produced is shown by Fig. 4. The weight acts in the direction of gravity, the lift is always at right angles to the span and hence the resultant force produces side slipping.

In Fig. 5 are shown the forces and moments caused by the side-slipping which affect lateral stability.

The velocity of side-slip "v" added geometrically to the forward velocity "u" produces the angle of yaw ψ. The aircraft is side-slipping to the right, consequently the air acting on the vertical fin and rudder causes a yawing moment N_v tending to turn the aircraft into the relative wind with the angular velocity "r". This tendency to lead the aircraft into the relative wind is known as "*Directional Stability*."

As the aircraft yaws to the right under the action of the moment N_v generated by the fin and rudder, the left wing moves forward and the right wing backward. The motion combined with forward velocity "u" results in the left wing moving faster than the right wing. This results in increased lift on the left wing and a reduction of lift on the right wing, and the difference in lift generates the rolling moment L_r, tending to roll the aircraft in the direction of

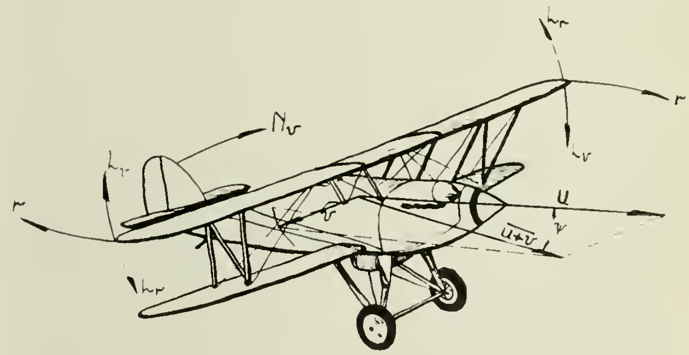

Fig. 5

the original bank. The presence of the vertical fin makes the machine stable in yaw by generating the moment N_r but it has a secondary effect, generating the moment L_r, which is detrimental to lateral stability. It tends to roll the aircraft in the wrong direction and to increase the bank.

The side-slip, however, acts directly on the wings as well as on fin and rudder. Dihedral angle on the wings sets up a moment L_v which is a stabilizing moment. This moment tends to raise the wing on the side of the side-slip and hence reduce bank. Thus if the stabilizing moment L_v is greater than the destabilizing moment L_r, the machine will oscillate in roll slightly and then resume straight flight, i.e., it is *laterally stable*.

If, on the other hand, the moment L_v is smaller than the moment L_r due to yaw, the latter will roll the machine to the right, increasing the bank. Increased bank will cause increased side-slip, which will in turn increase the rate of yaw and the destabilizing moment L_r.

Thus we have a small initial side-slip generating yaw and yaw aggravating side-slip. The aircraft deviates from the straight path and travels along a spiral path gradually tightening the turns. This form of lateral stability is known as "*Spiral Instability*."

If, now, the stabilizing moment L_v is very much greater than L_r the aircraft would level out too quickly. The forces due to angular as well as translational velocity of roll and of side-slip would carry the machine past the normal attitude. The machine would bank to the opposite side, side-slip, and the cycle would be repeated on that side. Instead of straight flight, here we would have a series of oscillations alternating from one side to the other, known as "*Unstable Oscillations*."

The nature of this flight varies from a slight persistent roll up to severe oscillations (as the fin area is decreased or the dihedral increased). In the latter instance, the aircraft is unstable in yaw and the severe rolling oscillations are accompanied by large degrees of yaw. Finally the tendency is for the machine to swing severely dropping a wing. This wing immediately stalls due to the sudden loss of speed caused by the severe yaw; the upper wing follows suit as the aircraft loses forward speed. The nose of the aircraft drops and autorotation about the longitudinal axis is set up. This is known as "*Spin Instability*" and is caused by improper ratio of fin area to dihedral, i.e., either too little fin area or too much dihedral on the wings.

In the above discussion, only one forward velocity of the aircraft was considered. It will be appreciated that the forces and moments will not all alter directly as the forward speed, nor all to the same ratio. Consequently stability may alter with change of speed.

During type trials, the behaviour of the aircraft is observed for all possible disturbances in straight flight at three different speeds with engine on, and with engine off. The pilot trims the aircraft for level flight, causes a disturbance by depressing the nose, dipping the wing, etc., releases all controls and notes the behaviour of the aircraft. The aircraft is also put into various degrees of turning, both in power flight and in a glide, the controls are then released completely and behaviour noted. For instance, the pilot depresses the nose of the aircraft and then leaves the machine to its own devices. In a stable aircraft, the nose of the aircraft rises to a point above the normal attitude, then depresses again below the normal, and after a few such oscillations, resumes the original attitude of level flight. If slightly unstable, the oscillations continue for a considerable period and small oscillations may even persist. The latter is usually termed "hunting." If very unstable, the oscillations become increasingly greater until the aircraft either stalls or goes into a nose dive. Similarly, the behaviour of the aircraft is studied and recorded for disturbances about the other axes.

It may possibly appear as though a perfectly stable aircraft is the ideal, but this is not so. A very stable machine requires large forces or control movements to break its will, and responds to every gust and can be kept steady only with difficulty in bumpy weather. In addition, it probably has a large change of trim engine on and off. Thus it is seen how closely balance, stability, controllability and manoeuvrability are related, and how important it is to carry out experimentation in order to discover which of the various qualities may be sacrificed and to what extent.

After having completed the qualitative tests and having been proved to have the normal and requisite characteristics of a good flying machine, the aircraft is ready for the quantitative tests to establish its measurable performance. Should the craft have been discovered to be unstable in a spin or to have any vicious characteristic, it is immediately qualified as "not airworthy."

Quantitative Tests

These tests consist of the determination of the performance of the aircraft at all altitudes from ground level to the maximum height at which it can fly.

In order that direct comparison may be made of any two things, no matter what, it is essential that the results be compared on the same basis. In aircraft work, we are dealing with the performance of machines operating in a gas which is neither uniform in density, pressure or temperature throughout, nor do such changes take place in a regular nor constant manner. This has led to the adoption of a "standard atmosphere" which specifies the normal or average conditions from the ground up to very great heights. As is well known, the "standard atmosphere" is never found, that is to say, at no time or place do "standard" or average conditions of all meteorological elements at all altitudes occur simultaneously. Nevertheless, it is necessary to adopt so-called "standard" values, and it is desirable to have these represent as closely as possible the true mean values in order that corrections due to departures from these means may be comparatively small in most cases. The adoption of an "isothermal atmosphere," although a desirable simplification in some respects, is inadvisable because of the large corrections that would have to be applied at practically all altitudes. What is required, in defining the "standard atmosphere," is a series of values of pressure, temperature, and density, at different altitudes, these values to represent as closely as possible actual average conditions. It has been shown from observations over a long period that up to 11,000 metres, the mean variation of the temperature with altitude at latitude 45 degrees or so is expressed very closely by Toussaint's formula:

$$\theta = 15 - 0.0065\ Z$$

where θ is the temperature in degrees Centigrade and Z the altitude in metres.

An International Standard Atmosphere was formulated from this, and has been universally adopted.

The International Standard Atmosphere is defined as follows:

1. It will be assumed that the air is dry and that its chemical composition is the same at all altitudes; the composition in volume is approximately as follows: 78.03 per cent. nitrogen, 20.99 per cent. oxygen, 0.94 per cent. argon and 0.04 per cent. carbon dioxide. The value of "g" will be taken uniformly as 980.62 in c.g.s. units.
2. It will be assumed that at mean sea level the temperature is 15 degrees C. and the barometric height, reduced to 0 degree C., 760 m/m of mercury.
3. Under these conditions the atmospheric pressure is 10,332 kg. per square metre (1013.2 millibars) and the weight of a cubic metre of air is 1.226 kg.*

*More exactly 1.2257 kg.

4. It will be assumed that, for any altitude Z, measured above mean sea level and between 0 and 11,000 metres, the variation of the temperature θ of the air is as follows:

$$\theta = 15 - 0.0065\, Z.$$

5. It will also be assumed that, for all altitudes above 11,000 metres, the temperature of the air is constant and equal to − 56.5 degrees C.

6. It follows that, for any altitude Z measured above mean sea level and between 0 and 11,000 metres, the barometric pressure p_z, the specific weight a_z, and the specific mass ρ_z of the air will vary according to the following equations:

$$\frac{p_z}{p_o} = \left(\frac{288 - 0.0065\, Z}{288}\right)^{5.256}$$

and

$$\frac{\rho_z}{\rho_o} = \frac{a_z}{a_o} = \left(\frac{288 - 0.0065\, Z}{288}\right)^{4.256}$$

7. Similarly, for all altitudes above 11,000 metres, the foregoing equations will be replaced by the following:

$$\log_{10}\frac{\rho_{11000}}{\rho_z} = \log_{10}\frac{p_{11000}}{p_z} = \log_{10}\frac{a_{11000}}{a_z} = \frac{Z - 11000}{14600}$$

8. The following table shows the values of temperature, pressure and density at heights from 0 to 11,000 metres. These values are derived from the equations given in paragraph 6 above.

Temperature, Pressure and Density at Heights Up to 11,000 Metres

Height in kilometres	Temperature			Pressure in Millibars	Density in grammes per cubic metre
	Degrees Absolute	Degrees Centigrade	Degrees Fahrenheit		
0	288	15	59	1,013.2	1,226
1	281.5	8.5	47.3	898.6	1,112
2	275.0	2.0	35.6	794.8	1,007
3	268.5	− 4.5	23.9	700.9	909
4	262.0	− 11.0	12.2	616.2	819
5	255.5	− 17.5	0.5	540.0	736
6	249.0	− 24.0	− 11.2	471.6	660
7	242.5	− 30.5	− 22.9	410.4	590
8	236.0	− 37.0	− 34.6	355.8	525
9	229.5	− 43.5	− 46.3	307.2	466
10	223.0	− 50.0	− 58.0	264.1	413
11	216.5	− 56.5	− 69.7	226.1	364

Performance Trials

The actual flying tests consist of a series of short or partial climb trials covering a range of speeds from 5 m.p.h. above stalling speed to 10 m.p.h. above maximum level speed at the given height (the last, of course, is a descent). These "partial climbs" are done at four heights chosen as 4/5, 3/5, 2/5 and 1/5 of the estimated or specified service ceiling of the aircraft. The height range covered at each speed is adjusted so that not more than 3 minutes is occupied in covering it, and must be at least 500 feet. Full throttle is used unless maximum r.p.m. are reached, when the throttle is adjusted to give these r.p.m. From these figures, rate of climb at each point is plotted against indicated airspeed, and the maximum rate of climb, best climbing speed, and maximum level speed at each height may then be determined with reasonable accuracy.

Two straight climbs are also performed. Besides establishing the rate of climb at all heights up to absolute ceiling, these climbs prove the adequacy, or otherwise, of cooling systems, lubrication, etc. Maximum level speeds at heights are determined on descent from one of the climbs.

Information on the power required to fly level at speeds intermediate between the best climbing speed and the maximum level speed at the service ceiling is also required for such purposes as determining the maximum range of the aircraft at different heights. This is obtained by finding the r.p.m. to fly level at all speeds throughout the range, and the test is combined with that for finding the position error of the Pitot head. The aircraft is flown over a surveyed speed course at four or five speeds between stalling speed and maximum horizontal speed.

To avoid waste of flying time, the tests are performed in the following sequence:

(1) Partial climbs at 3/5 and 1/5 of service ceiling. These give the correct climbing speeds to be used for subsequent climbs.

(2) Climb to service ceiling, partials at 4/5 service ceiling.

(3) Climb to service ceiling and level speeds at intervals of two thousand feet on the descent.

(4) Position error and r.p.m. to fly level, partials at 2/5 service ceiling.

The flying time required to complete all the tests is approximately seven hours. This does not include, of course, repetition of tests which may often occur due to bad atmospheric conditions.

Method of Reduction

Until a few years ago, the reduction of performance trials was based on the assumption that the brake horsepower was a function of density only, i. e.,

$$F(H) = \text{a power factor} = f(\sigma) = f\left(\frac{p}{\theta}\right)$$

As a result of considerable experimentation, it was then shown that the power developed by normally-aspirated engines should be considered a function of pressure only, rather than of density only, i. e.,

$$F(H) = f(p)$$

A complete review of all experimentation was made quite recently, the results of which show that, whereas,

(*a*) The simple pressure law is undoubtedly better than the simple density law.

(*b*) The law defined as $F(H) = f(p^{\frac{3}{4}}\sigma^{\frac{1}{4}})$ is a more accurate representation of the power law.

For the supercharged engine, the position is not entirely satisfactory, but from limited evidence available it appears that above full throttle height, the brake horsepower should be regarded as a function of density rather than of pressure. Thus the density method is used for such reductions.

The power factor can be expressed as $(p^{1-\alpha}\sigma^{\alpha})^m$. Hence the reduction to standard conditions of the performance of an aircraft carried out on a day when the density associated with a particular pressure is not standard, will depend on the relative importance of p and σ in the expression. That is, the reduction depends on the index α but is independent of the index m.

The principle underlying the method of reduction is as follows. Suppose that for any aircraft the power curve is of the form $HP \propto F(H)N^r$, where "r" is a constant, and "$F(H)$" is the power factor of the particular engine and constant at any given height. Let $V_c\sqrt{\sigma}$, $V\sqrt{\sigma}$ $(= V_i)$ and $N\sqrt{\sigma}$ be called the "indicated" values of the rate of climb, airspeed, and r.p.m. respectively. Then if these "indicated" quantities are obtained from the test observations and plotted against $F(H)\sigma^{\frac{1-r}{2}}$, the results should lie on the same curve irrespective of the atmospheric conditions under which the tests were made. To give the proof of this:

The power curve for an aircraft engine may be represented to a good order of accuracy at ground level by $HP = An^r$ where "n" = r.p.s. and "A" and "r" are constants. Then if Q_o and Q_h represent the torque at the ground and the height "h" respectively,

$$Q_o = An^{r-1}$$

and

$$Q_h = Q_o F(H) = An^{r-1}F(H)$$

$$= \text{airscrew torque} = k_Q \rho n^2 D^5$$

i.e.,

$$AF(H) = k_Q \rho n^{3-r} D^5$$

Now, if we write $J = \dfrac{V}{nD}$,

then

$$n^{3-r} = \frac{V^{3-r}}{J^{3-r} D^{3-r}}$$

so that

$$AF(H) = k_Q \rho \frac{V^{3-r} D^{2+r}}{J^{3-r}}$$

and

$$AF(H)\, J^{3-r} = k_Q D^{2+r} \rho_o \sigma V^{3-r}$$

Now $V_i = V\sqrt{\sigma}$ so that $\sigma V^{3-r} = \dfrac{V_i^{3-r}}{\sigma^{\frac{1-r}{2}}}$

therefore

$$AF(H)\, J^{3-r} \sigma^{\frac{1-r}{2}} = f(J) \rho_o D^{2+r} V_i^{3-r}$$

(assuming $k_Q = f(J)$ and neglecting secondary effects of compressibility and centrifugal twist).

For a given aircraft

$$F(H)\, \sigma^{\frac{1-r}{2}} f(J) = B V_i^{3-r},$$

where B is a constant.

Therefore at a given value of $F(H)\, \sigma^{\frac{1-r}{2}}$,

$$J = f(V_i) \qquad \ldots\ldots\ldots\ldots\ldots (1)$$

From the above

$$\frac{V}{N} = f(V_i)$$

so that

$$\frac{V_i}{N\sqrt{\sigma}} = f(V_i)$$

Therefore

$$N\sqrt{\sigma} = f(V_i) \qquad \ldots\ldots\ldots\ldots\ldots (2)$$

The thrust equation gives

$$k_T \rho n^2 D^4 = k_D \rho\, S V^2 + \left(a + b\frac{R}{R_o}\right) \rho V^2 + W \frac{V_c}{V}$$

Dividing by ρV^2,

$$k_T \frac{D^2}{J^2} = k_D S + a + b\frac{R}{R_o} + W \frac{V_c}{\rho V^3}$$

Now k_T and $\dfrac{R}{R_o}$ are functions of J, neglecting secondary effects, and $\rho V^2 = \rho_o V_i^2$ (since $V = \dfrac{V_i}{\sqrt{\sigma}}$ and $\rho = \rho_o \sigma$) therefore for a given aircraft,

$$Cf(J) = k_D S + a + E + W\frac{V_c\sqrt{\sigma}}{V_i^3}$$

where "C" and "E" are constants.

Now k_D is a function of V_i, therefore at a given value of $F(H)\, \sigma^{\frac{1-r}{2}}$ when $J = f(V^i)$

$$V_c\sqrt{\sigma} = f(V_i) \qquad \ldots\ldots\ldots\ldots\ldots (3)$$

Hence for a given aircraft at a given value of $F(H)\sigma^{\frac{1-r}{2}}$, at full throttle, $\dfrac{V}{N}$, $V_c\sqrt{\sigma}$ and $N\sqrt{\sigma}$ are functions of V_i.

Consequently for level speeds, where $V_c\sqrt{\sigma} = 0$, $\dfrac{V}{N}$, $N\sqrt{\sigma}$ and V_i may be plotted directly against $F(H)\sigma^{\frac{1-r}{2}}$.

In the case of climbs, a definite relationship between V_i and $F(H)\, \sigma^{\frac{1-r}{2}}$ should be maintained, and $V_c\sqrt{\sigma}$, $N\sqrt{\sigma}$ and $\dfrac{V}{N}$ are then also functions of $F(H)\, \sigma^{\frac{1-r}{2}}$ and may be plotted as above. As climbing speeds are specified to the pilot in terms of altimeter height (i.e., pressure), this condition is satisfied when $F(H)\, \sigma^{\frac{1-r}{2}}$ is of the form p^m, i.e., on the pressure basis of reduction. On any other basis when $F(H)\, \sigma^{\frac{1-r}{2}}$ contains a power of σ, the climbing speeds specified to a pilot should be modified in terms of actual temperatures prevailing. As, however, the climbing speed is normally an optimum value, a small change would make no appreciable difference in rate of climb.

There is a definite relationship between the values of $F(H)\, \sigma^{\frac{1-r}{2}}$ for any aircraft and the standard height and, therefore, standard height may be specified in terms of this function. Hence the indicated quantities for an aircraft may be plotted against standard height and the results are still independent of the atmospheric conditions at the time

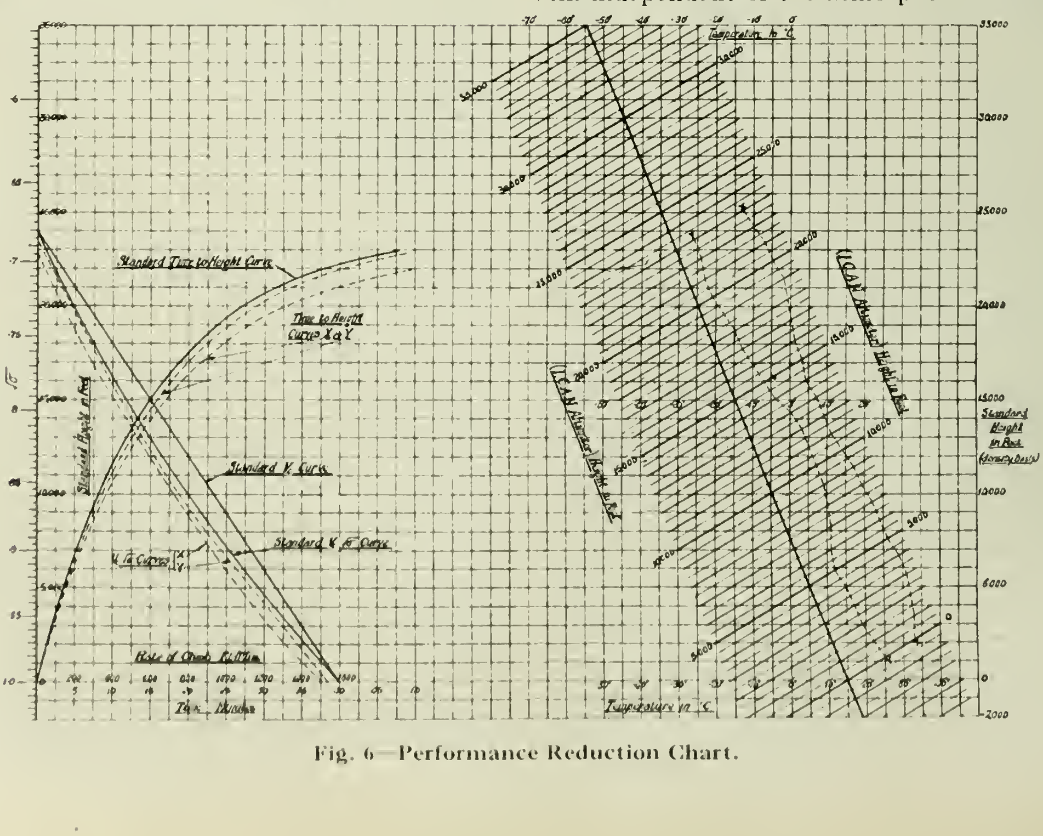

Fig. 6—Performance Reduction Chart.

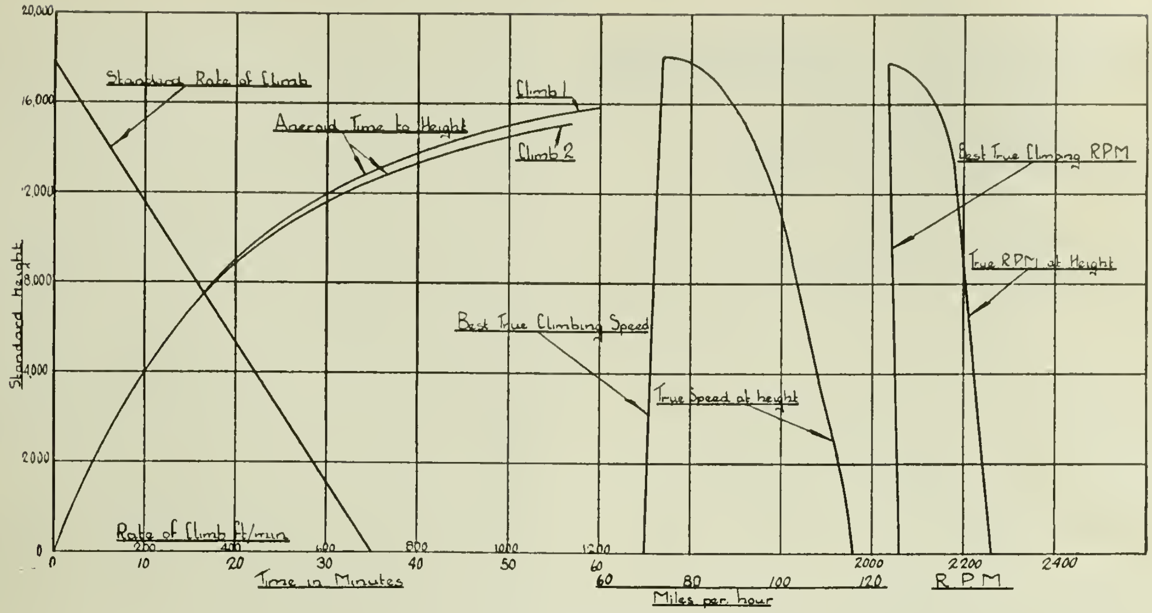

Fig. 7—Typical Performance Curves.

of the tests. The quantities which must be obtained from the test observations are therefore $V_c\sqrt{\sigma}$, V_i, $N\sqrt{\sigma}$ and the corresponding standard heights.

As explained previously, the best agreement between the results of observations taken under different atmospheric conditions is obtained when the observations are reduced on neither the pressure nor the density basis, but on some intermediate basis $(p^{1-\alpha}\sigma^{\alpha})^m$. Thus the procedure is to reduce two sets of observations by both methods, and from the ratio of the displacements of the two curves on the pressure and density reductions, the evaluation of the index α may be made. In a recent report (R. & M. 1316) Messrs. H. L. Stevens and A. E. Woodward Nutt publish a set of charts which they divised to simplify the reductions and eliminate a lot of tedious arithmetic. It is not intended to explain the use of the charts in the reduction, since it is covered most completely in their report. However, the chart shown in Fig. 6 is taken from their report for the purpose of indicating the evaluation of the index α.

The two $V_c\sqrt{\sigma}$ curves X and Y shown, were reduced on the pressure basis. The observed temperatures taken during the climbs, are plotted on the right hand side of the chart. The mean relative movement between the two $V_c\sqrt{\sigma}$ curves corresponding to the observed temperature difference for a change from the pressure to the density basis may be seen, and from the $V_c\sqrt{\sigma}$ curves themselves may be seen the mean relative vertical movement which will give the best agreement between them. The ratio of the second of these two relative movements to the first will give the best basis for reduction, i.e., the value of α in the expression $F(H) = (p^{1-\alpha}\sigma^{\alpha})^m$. The proportionate correction from the chart may then be applied and the mean standard $V_c\sqrt{\sigma}$ curve found. The standard rate of climb curve is found by dividing a series of points on the curve by the appropriate values of $\sqrt{\sigma}$ on the chart and, if required, the time to height curve may then be found by integration.

Level speed at heights, climbing speeds, r.p.m. at heights and r.p.m. climbing, are reduced to true speeds and true r.p.m. by both methods and the best basis obtained in a similar manner to that previously described for true rates of climb.

The results are then plotted in the form of the curves shown in Fig. 7, which give a complete representation of the performance of the aircraft.

Symbols Used in Reduction Theory

ρ	Density
σ	Relative density
p	Pressure
θ	Temperature
N	Engine Speed
V_c	Rate of Climb
V	Airspeed, true
V_i	Airspeed, indicated
n	Airscrew speed
Q	Airscrew torque, with coefficient $k_Q = \dfrac{Q}{\rho n^2 D^5}$
T	Airscrew thrust, with coefficient $k_T = \dfrac{T}{\rho n^2 D^4}$
D	Airscrew Diameter
J	$\dfrac{V}{nD}$
W	Weight of Aircraft
L	Lift, with coefficient $k_L = \dfrac{L}{\rho S V^2}$
D	Drag, with coefficient $k_D = \dfrac{D}{\rho S V^2}$
S	Area
$\dfrac{R}{R_o}$	Slipstream effect on resistance or drag

VOLUME XIV SEPTEMBER 1931 No. 9

The Fifth Plenary Meeting of Council

Plenary Meetings of Council have been held annually since 1927, and have had an important influence on The Institute's work and policy. In an organization like The Institute, whose branches are scattered over a vast extent of country between Cape Breton and Vancouver Island, co-ordination of the activities of these units can only be insured if there are periodical opportunities of this kind for the personal exchange of views between branch representatives. Such meetings, which all councillors have the opportunity of attending, enable council to shape its policies so as to express the aims of the membership as a whole. They also afford occasions on which councillors can form and renew personal acquaintanceships, and can obtain first hand knowledge of the way in which the business of The Institute is conducted. This year the Plenary Meeting will be held on Monday, Tuesday and Wednesday, September 21st, 22nd, and 23rd. A full attendance is likely, and the agenda include many subjects of importance as regards The Institute's policy and development.

Highway Traffic and Its Problems

In Canada the development of our highway system was comparatively slow until the end of the nineties, when the growth of motor traffic created a demand for improved means of road communication. Naturally in the older provinces it has been necessary to improve existing roads and make them suitable for the new conditions, while in the west, the mountain and prairie trails have had to be replaced by roads fitted for modern traffic. The magnitude of the task which has been accomplished will be realized from the statement that in 1904 only 535 motor vehicles were registered in Ontario, while there are now licensed in Canada nearly a million and a quarter automobiles. Some 400,000 miles of road now exist in Canada, so that with our present population there are only about twenty-five persons per mile of road. Our people are scattered over an enormous area and this makes our road transportation problem particularly difficult of solution. It is further complicated by the trend of population towards urban centres, so that while large stretches of country are still inadequately provided with road transportation and there is, as yet, no trans-Canada highway, we have in and near our larger centres of population, areas where traffic congestion already presents problems of administration and control comparable with those which are so pressing in the United States.

Our provincial and municipal authorities are also confronted with the question of finance. The annual expenditure on Canadian highways is now some $90,000,000, of which maintenance alone requires about $50,000,000. A substantial proportion of the whole is covered by registration fees and taxes, including that on gasoline, leaving a considerable balance to be taken care of from other Federal or provincial funds. The apportionment of the funds between maintenance and new construction; the decision as to the best way of expending the amount available for new roads, whether main highways or local feeders; the type of construction to be adopted, must not be based on guesswork but on the best judgment available.

In addition to our local and purely Canadian traffic, we have to provide for an ever-increasing number of visitors, and it is estimated that in 1930 about two and a half million cars crossed the border for a longer or shorter tour in the Dominion of Canada. The total number of cars entering Canada from the United States was of course much greater than this.

At first sight the effective control of traffic on our main highways would appear to be an administrative rather than a technical matter. On closer examination, however, many engineering questions arise which call for immediate decision. Many of the highway problems confronting us in Canada have already presented themselves in the United States, where there are twenty times as many cars and highway construction has taken place on a much more extended scale, but where the funds available have been correspondingly more abundant. Experience there and in Europe, as well as in Canada, has shown that in employing public funds for highway construction adequate results can only be obtained when the expenditure is based on close study, the results of experimental investigation and the advice of qualified engineers. Unwise design or methods of construction lead not only to the waste of public money but also to a needless increase in the hazards which face the road user. In a recent article, the Engineering News-Record pointed out that the highway engineer

> "is involved in design and construction, so that the highway roadbed may be inherently safe; in the provision of those accessories which are essential to safe operation, as signals, information signs, lane marks and shoulders; in the treatment of special problems that arise at branches, intersections and other danger points; and finally in safe maintenance of the road."

His engineering activity is, of course, not limited to the roadway itself. Modern traffic conditions call for many items of operating equipment undreamt of in the easy-going days of the past, and in particular much remains to be done before a reasonable degree of efficiency is reached as regards safety measures. There is, indeed, at the present time no agreement on such vital points as speed limit legislation; methods of signalling from motor vehicles; the question of red light turns; the effect of safety islands on congested traffic; and the proper adjustment and use of the automobile head-lamp. All of these affect the engineer's work.

When it is realized that an important highway may cost from $40,000 to $70,000 per mile and may carry an average traffic of more than 3,000 cars per day, it will be understood that on our main roads the closest consideration must be given to such questions as safety at grade crossings and intersections; the delay due to traffic congestion at these points; the visibility required for travelling at high speeds; the surface in relation to its durability, freedom from skidding and correct width and banking at curves; the formation of adequate shoulders and the proper provision of warning signals for approaching traffic. The best highway practice to-day looks upon maintenance as of equal importance with construction in its bearing on transportation efficiency and aims at steady improvement to take care of the inevitable increase in volume and speed of traffic.

While the highway engineer's work has led to a striking development of the art of road-building, the mechanical and electrical engineer has accomplished an equally remarkable task in the development of the automobile itself. Automobile engineers have now placed at the disposal of the motoring public comparatively cheap cars capable of comfortable driving at sustained high speeds which a few years ago could only be reached by cars in the luxury class, and a corresponding change has taken place in the performance of commercial vehicles. The result has been that the average highway speed is steadily increasing and highways are being improved and reconstructed to provide for this. Automobile design has already done so: brakes, steering gear, tires, motors and the chassis itself, on any good make of modern car, are adequate and reliable if the machine is intelligently maintained and used. The increased risk of present day driving is not so much due to the roadbed or the motor car as to the ignorance and lack of judgment of a few motorists, whose irresponsible actions cannot be controlled by any legal restrictions and who can only be eliminated by education or death.

All these points and many others have long been the subject of discussion by public bodies and technical associations in Canada and the United States, and it is a pleasure to draw attention to the excellent work which has been done in this country by the provincial governments, the automobile clubs and the various good roads associations. Their efforts have not only aided in determining the methods of construction and operation most suited to our arduous Canadian conditions, but have also done much towards educating the motorist. The Canadian Good Roads Association and the Inter-provincial Conferences of Highway and Transportation Officials have also been active in promoting that uniformity in practice which is necessary in order that in passing from one province or locality to another the road-user may not be confronted with unfamiliar signals, road-conditions calling for speeds to which he is not accustomed, or local regulations with which he finds it difficult to comply.

Much still remains to be done, but the publicity which is now being given to highway and automobile questions cannot fail to have its due effect in educating the motor-vehicle operator. It is hoped to make him realize that accidents result not so much from unsuitable road conditions as from unfitness of vehicle or driver or from his negligence, lack of experience or inattention.

There is no question as to the effective work done by those who design and construct our roads and automobiles; but there is a real difficulty in providing for their proper use by people who have no technical knowledge, little experience and not enough imagination to picture the possible results of carelessness or ill-judged action.

Engineers as a body realize far more clearly than does the general public the great diversity of factors on which the safe use of our highways depends and are thus specially qualified to help in educating the motoring public to a proper sense of its responsibilities. As individuals, and collectively, should we not take a more prominent part in this work?

Students' and Juniors' Prizes

Papers presented to any branch by Students or Juniors of The Institute during the prize year July 1st, 1931 to June 30th, 1932, are eligible for one of the five Institute prizes (each of the value of $25.00), which will be awarded in 1932. These prizes are assigned as follows:

The H. N. Ruttan Prize in the four Western Provinces.

The John Galbraith Prize in the Province of Ontario.

The Phelps Johnson Prize for an English Student or Junior in the Province of Quebec.

The Ernest Marceau Prize for a French Student or Junior in the Province of Quebec.

The Martin Murphy Prize in the Maritime Provinces.

Papers in competition for these prizes must be received by branch secretaries before June 30th, 1932. Further information as to the requirements and rules may be obtained from the General Secretary.

OBITUARIES

George Cleghorn Mackenzie, M.E.I.C.

Members of The Institute will learn with regret of the sudden death of George Cleghorn Mackenzie, M.E.I.C., which occurred at Bark Lake, Que., on August 22nd, 1931.

Mr. Mackenzie was born at Kincardine, Ont., on July 26th, 1877, and received his early education at public and high school in Brantford, Ont., and graduated in Arts from Trinity College, Toronto. In 1903 he graduated from Queen's University with the degree of B.Sc.

Following graduation he was, until 1905, assistant blast furnace superintendent with the Londonderry Iron and Mining Company at Londonderry, N.S., and from 1908 to 1910 Mr. Mackenzie was engaged on special mining reports and claim inspection for the Ontario Bureau of Mines, Toronto. In 1910 he was appointed chief of the ore-dressing and metallurgical division of the Mines Branch, Department of Mines, Ottawa, and in 1915 he also became secretary and commissioner, Canadian Munitions Resources Commission, holding both appointments until 1918, at which time he joined the Electric Steel and Engineering Company, Welland, Ont., as general manager. In 1921 Mr. Mackenzie became general secretary of the Canadian Institute of Mining and Metallurgy, at Montreal, and for ten years he filled that position with outstanding efficiency and success. Within the same period he acted as secretary to the Canadian meetings of the Empire Mining and Metallurgical Congress, in 1927, and was active in promoting the success of those meetings.

Mr. Mackenzie joined The Institute as a Member on March 27th, 1923.

George William Volckman, M.E.I.C.

Regret is expressed in recording the death in London, England, on July 15th of George William Volckman, M.E.I.C.

Mr. Volckman was born at London, England, on March 27th, 1873, and was educated at Dulwich College and King's College, London, graduating from the engineering department of the latter institution in 1890. From 1890 to 1899 he acted as assistant to Mr. G. W. Manton, Mr. W. J. S. Binnis and Sir J. Wolfe Barry and Partners. Under the first he was connected with excavation and training works on the Mersey locks giving access to the Bridgewater and Runcorn docks and docks at the Royal Dockyard, Portsmouth. Subsequently he was engaged on the staff of Messrs. Price and Reeves on the Notting Hill Gate-Marble Arch section of the Central London Railway, and next was in charge of the construction of a four and a half mile main line section of the South Eastern Railway. Later he was connected with the widening of the London and North Western and Great Western joint line from Chester to Birkenhead.

In 1902 Mr. Volckmann was in charge of the sinking of caissons at the site of the then proposed Avonmouth docks, and later of the sinking of the Sloane street station shaft of the Piccadilly Tube railway. Between 1902 and 1907 he acted as engineer and manager in charge of the Bermuda Dockyard extension for the Admiralty, and in the latter year he visited Canada to report on lake ports. In 1908 he took up the position of engineer for the Montreal Ottawa and Georgian Bay Canal Company, and in 1910 was engineer to the Dominion Dry Dock Company for which he designed docks at Quebec and Saint John, N.B. From 1910 to 1912 Mr. Volckmann was chief engineer for MacArthur, Perks & Company, Ottawa, and in this capacity was responsible for the design and construction of concrete piers at Havana, and also for section dredging and reclamation for Messrs. Barclay Parsons and Klapp of New York. He was later engaged on railway work on the Pacific coast for the same firm. In 1928 he accepted the appointment of chief engineer and representative in India and the East for Sir Alexander Gibb and Partners.

Mr. Volckmann was a member of the Institution of Civil Engineers and of the American Society of Civil Engineers. He became a Member of The Engineering Institute of Canada (then the Canadian Society of Civil Engineers) on October 9th, 1909.

PERSONALS

George M. Bell, S.E.I.C., is now engaged on the two year course for student engineers of the Canadian Westinghouse Company at Hamilton, Ont.

J. C. Neufelt, S.E.I.C., a graduate of the University of Manitoba of the current year, is now on the staff of the Department of Mines and Natural Resources of the province of Manitoba, and is a draughtsman on the survey of the Dauphin river water power scheme.

D. B. Leightner, S.E.I.C., who graduated from the University of Manitoba in the spring of the current year, is at present with the Canadian Westinghouse Company at Hamilton, Ont., being engaged on the student apprenticeship course.

Frank C. Askwith, A.M.E.I.C., formerly deputy city engineer of Ottawa, has been appointed by that city as Commissioner of Works, to succeed A. F. Macallum, M.E.I.C., who retired early in 1931. Mr. Askwith entered the service of the municipality in 1907, and has since that time been chief draughtsman, sidewalk engineer, roadway engineer and deputy city engineer.

PROFESSOR ERNEST BROWN, M.E.I.C.

Professor Ernest Brown, M.E.I.C., Becomes Dean of the Faculty of Engineering at McGill University

Professor Ernest Brown, M.Sc., M.Eng., M.E.I.C., formerly professor of mechanics and hydraulics at McGill University, has been appointed Dean of the Faculty of Engineering of that institution.

Professor Brown graduated from University College, Liverpool, in 1897, with the degree of M.Eng., having already secured the degree of M.Sc. from Victoria.

In 1898-1900 he conducted a research at the Central Technical College, London, on "Temperature Rise in Field Coils of Dynamos," and from 1900 to 1903 was a lecturer in engineering at the same university, while continuing his research work with Professor Hele-Shaw. In 1903-1905 he was lecturer in applied mechanics at the University of Liverpool. Coming to Canada in 1905, Professor Brown was, until 1911, assistant and then associate professor in applied mechanics at McGill University, at which time he became professor of applied mechanics and hydraulics. Professor Brown has engaged on special laboratory investigations in reinforced concrete, and has contributed important papers on this subject to the Transactions of The Institute. He has also carried on investigations and made reports and designs in connection with special problems for the Quebec Bridge Commission, the St. Lawrence Bridge Company, the Laurentide Company, the Atlas Construction Company, etc. Professor Brown has been for some time connected with the Shawinigan Water and Power Company on hydraulic work. He is greatly interested in the affairs of The Institute, and represented the Montreal Branch on the Council during the years 1918-1919 and 1920.

H. P. Lingley, S.E.I.C., formerly with the engineering department of the Canadian National Railways, Moncton, N.B., is now connected with the Saint John Harbour Commission, Saint John, N.B. Mr. Lingley graduated from the University of New Brunswick in 1930, with the degree of B.Sc.

John Stephenson, A.M.E.I.C., is at present on the staff of the engineering department of the Saint John Harbour Reconstruction, at Saint John, N.B. Mr. Stephenson, who was formerly with the Canadian Steel Corporation at Ojibway, Ont., was for a time with the Riverside Iron Works at Calgary, Alta., and also with the Inland Steel Company of Indiana Harbour, Indiana, U.S.A.

Professor C. V. Christie, M.A., B.Sc., M.E.I.C., Macdonald professor of electrical engineering and head of the department of electrical engineering of McGill University, has been appointed a member of the main committee of the Canadian Engineering Standards Association.

Fred. A. Robertson, A.M.E.I.C., secretary to the chief engineer and engineer in charge of the library, Hydro-Electric Power Commission of Ontario, Toronto, was appointed a director of the Special Libraries Association at the annual convention of the society recently held in Cleveland, Ohio. The appointment is for a term of three years. This is the first time a Canadian has been invited to sit on the board of the Special Libraries Association, which is the business branch of the American Libraries Association.

F. S. Small, M.E.I.C., has been appointed assistant chief engineer on the Saint John Harbour Reconstruction, West Saint John, N.B. Mr. Small was assistant engineer with the Federal Department of Public Works on the Saint John River, N.B., in 1914, and in 1916 he was appointed acting district engineer, which position he held until 1917. In April, 1917, he became connected with the Fraser-Brace Engineering Company, and has been with that company with the exception of one year until the present time, holding the following positions: office engineer on the extension of the power plant at Cedars, Que., designing engineer, field engineer, manager of the Hydrolithic Waterproofing Company, one of the company's subsidiaries, superintendent of construction, and resident engineer on hydro-electric plant construction on the Gatineau and Churchill rivers.

Fred Newell, M.E.I.C., has recently been appointed by the Dominion Bridge Company, Ltd., Montreal, to the position of assistant chief engineer. Mr. Newell was educated at the London and Woolwich Polytechnic School, London, England. After several years engineering experience in England, he came to Canada in 1907, and shortly afterwards joined the engineering staff of the Dominion Bridge Company. In 1921 he was appointed mechanical engineer, and has since been intimately associated with the construction throughout Canada of a wide variety of important structures, including hydraulic regulating gates, cranes, car unloaders and moveable bridges of various types. Mr. Newell is recognized as an outstanding authority on the design of hydraulic equipment and has been closely associated with practically all construction of this nature in this country during recent years.

FRED NEWELL, M.E.I.C.

R. A. Bainbridge, M.E.I.C., has retired from the service of the Canadian Pacific Railway Company after forty-five years' service. Entering the company's service in 1886, he was engaged as rodman and leveller on construction of a line from Montreal to Saint John, N.B., until 1888, and from 1888 to 1890 he fulfilled the same duties on surveys for diversions of line or elimination of various trestle crossings of lakes between Fort William and Winnipeg, and on surveys from Regina to Prince Albert. During the year 1890-1891, Mr. Bainbridge was on the construction of the first railway built in the Kootenay district of British Columbia, from Robson to Nelson, and on improvements being made on the portion of the Canadian Pacific Railway between Yale and Savona, B.C. From 1901 to 1905 he was resident engineer at Nelson, B.C., and from 1905 to 1908 was assistant engineer, Pacific district, at Vancouver, B.C. From 1908 to the present time, Mr. Bainbridge has been engineer of the Esquimalt and Nanaimo Railway, located at Victoria, B.C. Mr. Bainbridge joined The Engineering Institute of Canada (then the Canadian Society of Civil Engineers) on April 23rd, 1903.

Correction

We regret that through an error in the August, 1931, issue of The Journal it was stated that A. Lariviere, A.M.E.I.C., had been appointed engineer of the Quebec Public Service Commission. Mr. Lariviere has, in fact, held that important position since 1922 and now relinquishes it on appointment as a member of the Commission. Mr. Laberge, the late Commissioner, was justly esteemed and it is a matter for great satisfaction to the profession that the government has named as his successor an engineer of such high standing and professional qualifications as Mr. Lariviere.

CORRESPONDENCE

Montreal, Que., July 8th, 1931.

The Secretary,
The Engineering Institute of Canada,
Montreal.

Sir:—

At a recent meeting of the Montreal Branch, Mr. Tennant of the Dominion Bridge Company expressed the opinion that the qualifications for admission should be relaxed in favour of individuals who had specialized along certain narrow lines.

In addition to those particular men with whom Mr. Tennant is acquainted, there are many others who are employed on engineering work, specialists in their line, yet because they have a very narrow range of experience and a limited education, they cannot be termed engineers. If I remember aright, the feeling of the meeting was against Mr. Tennant, but it has occurred to me that these men should be admitted as Affiliates.

Numbers may not mean strength in the discussion of "The Quantum Theory" or on "Stresses in Rigid Frames," but they most certainly do in the matter of finances, and if a thousand Affiliates could be added to The Institute, its prestige and usefulness would be much increased.

C.I.E.M.A.

Acknowledgment

With reference to the article on the *Empress of Britain* appearing in the July number of The Journal, it should have been stated that Fig. 4 was reproduced from *Engineering*.

We have received from the Structural Clay Tile Association of Canada a folder entitled: "Structural Clay Tile Data," containing information on construction details, technical data and research work relating to the uses of this material. Additional data sheets for the folder will be printed and distributed from time to time and will contain further reports on the uses of structural clay tile. Inquiries of a technical nature regarding this product should be addressed to the Structural Clay Tile Association of Canada, at Montreal, Toronto and Vancouver.

BOOK REVIEWS

Underground Systems Reference Book

Published by the National Electric Light Association, New York, 1931, cloth, 8½ x 11½ in., 377 pp., illus., figs., tables. Members, $4.00; Non-members, $6.00.

L. A. Kenyon, a.m.e.i.c.*

The publication of this Reference Book fills a gap in the list of books usually found on the desk of men connected with the transmission and distribution of electrical energy. It is alike interesting to office and field men, and, being well and profusely illustrated, it should be appreciated by cablemen who ordinarily read but little. It has been compiled and edited by practical men directly connected with the industry through the medium of the various committees of the N.E.L.A. Underground System Section.

The compilation has covered a period of years and has been carried out by men who are acknowledged specialists in their line, and under circumstances tending to free the book from pedagogic inaccuracies and the oft-times biased assertions of individual authors.

The practice of conduit construction, cable manufacture, installing, splicing, training and fireproofing varies considerably with the training received by the workmen and the local facilities available. Methods and practices which are commercial for one system may not be so for another where experience has evolved somewhat different arrangements to obtain the same general result, i.e., safe and satisfactory installation along with economic operation.

The above precludes laying down hard and fast rules and practices, but, where the same end is obtainable by several methods, these are discussed and illustrated so that a choice can be made best suited to local conditions.

The book has a good index, as well as two appendices—one giving general information and the other a bibliography. The body of the work is divided into eight chapters, the first of which is introductory, giving an historical sketch of the underground transmission of electricity and the use of cables as a solution of this problem.

The remaining seven chapters deal with cables, conduits, cable installation, cable splices, maintenance and operation, equipment and safety practices. The book is well bound and the illustrations clear and legible.

The Engineers' Technical Dictionary

English-French

By Mark Lvoff. E. and F. N. Spon, London, [1931], cloth, 4 x 6½ in., 296 pp., 6/- net.

Most existing technical dictionaries besides being out of date contain a great deal of unnecessary matter which increases their size and price without increasing their efficiency. The present dictionary obviates these faults and at the same time is of handy size.

It is chiefly intended for the use of mechanical and electrical engineers and contains a large number of new words used in general

*Assistant Engineer, Electrical Department, Montreal Light, Heat & Power Cons.

engineering, in wireless and the motor and aeroplane industries, technical expressions from other branches of industry which cannot be found in any other dictionary, and current commercial and legal expressions of use to engineers. Care has been taken to include not only new technical expressions, but also new meanings attached to ordinary words in special branches of engineering. In accomplishing this object and in the selection of words and expressions, and the elimination of others, the author has drawn upon his long experience extending over a quarter of a century in translating technical literature, including engineering, legal and commercial matter.

Transactions of the Second World Power Conference Berlin, 1930

Volume 20: Index-Volume

Published by VDI-Verlag, GmbH, Berlin, 1930, cloth, 6 x 9½ in., 315 pp. Agents: Percy Lund, Humphries & Co. Ltd., London, E.C. 4. £2.10.0.

The publication of the Index Volume completes the Transactions of the Second World Power Conference, held in Berlin in June, 1930. The Transactions are a complete record of the work of the conference, which owes its success to the collaboration of forty-nine National committees and over one thousand engineering experts from all over the world.

Over three hundred and fifty papers were presented by the National committees for discussion. These reports were grouped under the heads of 34 Sections (technical meetings). A number of the sections were devoted to special branches of engineering, whilst others gave a general review of the present status of engineering in different countries. Others, again, discussed particular questions relating to power-economy in which a number of related fields of engineering are concerned.

This method of organizing the proceedings has also made it possible to publish the Transactions of the Second World Power Conference—departing from previous practice in this respect—in twenty volumes, instead of the two to four volumes that have been usual hitherto. As a result, the individual volumes, which can be purchased singly, are cheaper and of a handier size. The work of the conference is thus made accessible to much wider circles than would be the case if only the comparatively expensive complete publication were available.

The study of the papers published in the Transactions is greatly facilitated by the alphabetical index of subjects and of authors which is contained in the Index Volume just published. The list of authors contains the names of the contributors of the individual papers and of the general addresses, together with the titles of the papers in the particular conference language (English, German, French) in which they were written. Furthermore, the authors and the titles of the general reports are given in the three official languages of the conference, and all those who spoke at the various discussions are mentioned by name.

The alphabetical index of the subject matter is drawn up in the three languages of the conference, each language being separated and rendered readily distinguishable from the others by coloured insert leaves. The individual reports, general reports, contributions to the discussions, and the general addresses are arranged here according to the matters treated. In order to facilitate the use of the trilingual index, each of its three sections is preceded by a terminological index of subjects in the three languages, arranged in alphabetical order.

Even those who possess none, or only a few, of the volumes of the Transactions will find the Index Volume a valuable source of information.

The American Bureau of Standards has been studying the penetration of water into brickwork. The results show that when the interior walls of brick buildings become wet during a rain it is likely that water has entered through open spaces between brick and mortar rather than directly through these solid materials. Such openings may be produced either by poor workmanship or by shrinkage of mortar. If there are no openings of this sort, the probability of penetration by water through solid 8-inch brick walls is exceedingly remote under normal climatic conditions and if proper precautions in design have been taken. One necessary precaution is to avoid plastering directly on the brick in an 8-inch wall, and that may be accomplished either by furring the wall or by the use of metal ties in place of header bricks. The time required for water to travel through a brick, thence through a mortar joint, thence through another brick is far greater than the time taken for water to penetrate the two bricks and the mortar joint when those materials are tested separately and out of contact with one another. Probably one reason for this is the fact that the pores in one material do not communicate directly with those in the other. It is also known that a brick must become highly saturated before it transmits water to another material. This degree of saturation is not attained when the brick is merely wetted through.—*The Engineer.*

BRANCH NEWS

Hamilton Branch

J. R. Dunbar, A.M.E.I.C., Secretary-Treasurer.
J. A. M. Galilee, Affil.E.I.C., Branch News Editor.

First Meeting of the New Executive Committee

The first meeting of the newly elected Executive committee of the Hamilton Branch was held recently at a joint luncheon meeting with the outgoing Executive committee, with a total attendance of eight.

W. F. McLaren, M.E.I.C., outgoing chairman, called the meeting to order.

Minutes of the previous Executive committee meeting were read and approved and the revised financial statement was presented. Messrs. D. W. Callander, A.M.E.I.C., and W. L. Miller, A.M.E.I.C., were appointed auditors.

Mr. McLaren then called upon E. P. Muntz, M.E.I.C., to take charge of the meeting.

Mr. Muntz expressed his appreciation of the honour the branch had done him by electing him chairman, and asking the Executive committee for their full co-operation to make the coming year one of the most successful the branch has had.

It was decided that the standing committees for 1931-32 would be as follows, with the duties as given below:

Meetings and Papers Committee.

Duties: 1. To arrange for speakers for at least one meeting per month.
2. To ascertain from the speaker if a lantern, blackboard, etc., would be needed, and to arrange to have them available.
3. To arrange for a suitable hall for each meeting.

Membership Committee.

Duties: 1. To obtain applications for admission from qualified engineers.
2. To pursuade present members to apply for transfer to a higher grade, when eligible.
3. To investigate and to report on applications for admission or transfer, when the applicant is not personally known to a member of the Executive committee.
4. To handle cases of members in arrears, members resigning or over age, etc.

Entertainment Committee.

Duties: 1. To arrange for entertainment and refreshments at all Branch meetings, as required.
2. To arrange for Branch luncheons and dinners.
3. To arrange for transportation when required.
4. To arrange for visits to industrial plants.

Publicity Committee.

Duties: 1. To prepare a report of all meetings for Branch News.
2. To insert advertising in the local papers when instructed to do so.
3. To co-operate with the representatives of the press in giving general publicity to Branch activities.

Reception Committee.

Duties: 1. To assist the chairman to look after the speaker while he is in Hamilton, except during the meeting.
2. To arrange informal dinners before the Branch meeting, to enable the speaker to meet members of the executive, and others.
3. To welcome new members and visitors at the Branch meetings.

The following members were appointed to the various committees for the coming year:

Meetings and Papers Committee.

Chairman........................E. M. Coles, A.M.E.I.C.
Members........................J. Stodart, M.E.I.C.
T. S. Glover, A.M.E.I.C.
G. Moes, A.M.E.I.C.
J. R. Hutton, S.E.I.C.

Membership Committee.

Chairman........................H. B. Stuart, A.M.E.I.C.
Members........................J. Stodart, M.E.I.C.
W. A. T. Gilmour, Jr.E.I.C.
H. W. Blackett, Jr.E.I.C.

Entertainment Committee.

Chairman........................G. A. Colhoun, A.M.E.I.C.
Members........................W. A. T. Gilmour, Jr.E.I.C.
C. Anderson, A.M.E.I.C.
A. R. Hannaford, A.M.E.I.C.

Publicity Committee.

Chairman........................J. A. M. Galilee, Affil.E.I.C.
Members........................V. S. Thompson, A.M.E.I.C.
P. R. Adams, S.E.I.C.

Reception Committee.

Chairman........................W. F. McLaren, M.E.I.C.
Members........................H. A. Lumsden, M.E.I.C.
W. L. McFaul, M.E.I.C.
L. W. Gill, M.E.I.C.
J. J. MacKay, M.E.I.C.
J. W. Tyrrell, M.E.I.C.
F. W. Paulin, M.E.I.C.
E. H. Darling, M.E.I.C.
H. U. Hart, M.E.I.C.
R. K. Palmer, M.E.I.C.

Some discussion took place regarding revision of the branch by-laws, and Messrs. Darling and Dunbar were appointed a committee to consider the revision to the by-laws and bring their recommendations before the Executive committee.

After some further discussion regarding address stencils and members in arrears of fees the meeting adjourned.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Notes on the Mineral Industry of South Africa

The following notes are based on an address delivered at a meeting of the Ottawa Branch of The Institute on January 15th, 1931, by Dr. Charles Camsell, M.E.I.C., Deputy Minister of Mines, who was one of the Canadian representatives at the Empire Mining and Metallurgical Congress in South Africa last spring.

Dr. Camsell remarked that some two hundred and forty delegates gathered in Capetown at the congress from all parts of the world, of whom twenty-four were Canadians.

After the congress meetings at Capetown, which were presided over by the Governor-General of South Africa, the Earl of Athlone, the members were enabled to travel by special train all over the Union of South Africa and Rhodesia, and had the opportunity of seeing a good deal of the important mineral industries of the country.

Four principal points were of particular interest to Canadians, these being, the mineral resources of South Africa and how they compete with or supplement those of Canada; the relationship of the government to the mineral industry; the fuel problem of the Union and Rhodesia and how it is handled, and the system of concessions for prospecting.

The Union's mineral industry is similar to that of Canada in many ways, but a point of dissimilarity is that ninety five per cent of this value is attributable to three minerals—gold, diamonds, and coal. The small remainder is, however, derived from a great variety of minerals, including asbestos, tin, platinum, copper and manganese. Dr. Camsell gave it as his opinion that these other minerals which occur in such variety are not being developed to the fullest extent.

In the matter of asbestos, Canada is beginning to feel the competition from the Transvaal and Southern Rhodesia. Canadian asbestos production, which a few years ago amounted to eighty per cent of the world production, is now beginning to fall off on account of South African and Russian competition. There are great asbestos resources in southern Africa, particularly of the long fibre type, and undoubtedly South Africa will in future contribute a greater and greater percentage of the world's supply.

As regards copper production, although there is no large output at the present time, the mines of northern Rhodesia are likely to become an important factor in the world's market. Figures were quoted by the speaker comparing the amount of resources known in the United States, Chile, Cuba and Mexico, together with the recoverable copper contained as compared with northern Rhodesia. An interesting point in this connection was that in the prospecting of concessions and the making of geological surveys the work in northern Rhodesia was being done by Dr. Bancroft of McGill University with his staff of Canadian and Canadian-trained geologists.

With regard to gold production, although on account of its fixed price South African gold does not affect Canada, it has a very important bearing on the world's supply. About fifty-three per cent of the total recovery of this metal in the world comes from South Africa and at the present time the future outlook is not very optimistic. It is estimated by engineers that production is now at its peak and that in a period of three or four more years it will suffer a sharp decline owing to the fact that lower grade ores will have to be utilized for the recovery of this metal. Thus, the future supply of gold is a little uncertain and is a cause of concern to economists.

At Village Deep mine on the Rand a vertical depth of 7,640 feet has now been reached, with an increase of 300 feet per year. It is expected that mining can be carried on to a total depth of 9,000 feet. In this operation difficult problems have to be faced, in a rising temperature that becomes almost unbearable to the white man and an atmosphere that is saturated with moisture in order to keep down dust. Dr. Camsell related it as his personal experience that a descent to the lowest depth—wherein the first 4,000 feet drop was made in a matter of two minutes—was very trying.

In touching upon the water supply situation, Dr. Camsell stated that while at dinner with General Smuts the latter made the statement that Canada's greatest national asset was her winter's snow. By this the General meant that, as the snow was one of the greatest sources of supply for the waters of our rivers and lakes, it was a most important consideration. The water supply of South Africa is a serious problem. There are no natural lakes in the Union and, of course, there is no snow. There are also no extensive forests to retard the run-off. The precipitation varies from ten to forty inches per year but there are great difficulties connected with the matter of conservation in that the rate of evaporation is very high due to the almost continuous sunshine. In Johannesburg this rate is about 60 inches per year and in Buluwayo about 100 inches per year.

South Africa is, for the most part, a high plateau with a steep gradient along its edges toward the sea, and as a result the streams are not navigable for more than a few miles up from the coast. When the rains come the water runs off rapidly in the streams so that for the various periods of the year there is a great variation in the rate of flow. During the dry season many of the streams become absolutely dry. These conditions are so serious as to affect the growth of the population. Facilities, however, are provided by the government in the matter of drilling wells for water.

Another difficult matter is the racial problem. So far as the relationship between the English and the Dutch is concerned, any difficulties resulting as an aftermath of the Boer War are gradually being straightened out and in this regard conditions are constantly improving. The really serious question, however, is that of the coloured races. In southern Africa there is a total population of about 9,000,000, the proportion of whites and blacks varying from 1:4 in the Union to 1:150 in northern Rhodesia. Further, the growth of the black population is more rapid than that of the white. This results from the curtailment by the government of their one-time warlike activities and the introduction of hygienic services together with the very small amount of immigration of the whites. The government is fully cognizant of these conditions and the changes that are taking place in the coloured races.

Largely on account of the preponderance of natives, opportunities in South Africa for the white man are not as great as one might be inclined to believe. In spite of the fact that they have one of the finest climates of the world, development and settlement are not going on rapidly enough to furnish full opportunities for white immigrants. The labourers are coloured and this race is also encroaching upon the skilled trades. There are four universities in the Union with a student attendance of between six and seven thousand, of which, under government auspices, a sufficient number of technical and professional men are turned out to meet their own requirements.

Dr. Camsell stated in concluding his talk that the congress afforded a remarkable opportunity to meet representatives from all parts of the British Empire.

New National Safety Code for Elevators

The elimination of all speed limits for passenger elevators is one of the features of the new national safety code for elevators announced recently by the American Standards Association. Approval of the code by the association followed nearly four years of research on elevator safety devices at the United States Bureau of Standards and extensive investigation by a technical committee composed of thirty-eight representatives of architectural, engineering, governmental, and other organizations.

For the first time, the national elevator code permits the operation of more than one elevator in a single shaft, thus removing one of the obstacles to the erection of skyscrapers—the excessive space required for elevators. The code provides rigid safeguards to eliminate any possibility of collision between two elevators in the same shaft. The code also provides for two-storey cars which consist of two separate cages, one above the other, to serve two floors simultaneously from the same shaft. These will not be "one man cars," however, an operator for each of the two cages being required by the code. Safety devices will prevent the two-storey car from moving until the safety gates of both cages are closed.

Further provision is made for a new type of express-local system in which the master express elevator will stop at only three or four express or plaza floors, ten, fifteen, or even more stops apart, at which points passengers will transfer to local elevators starting from the plaza floors rather than all from the first floor, the present practice in skyscrapers.

The code insists upon fireproof elevator shaft enclosures and fireproof housing for the elevator machinery so that elevator evacuation of a fire-swept skyscraper will be possible.

Although the framers of the code found that present safety devices would permit safe elevator operation at any speed it is believed that the limit of speed will not go much beyond 1,200 feet per minute because of the discomfort to passengers resulting from rapid change in air pressures in ascent or descent.

Any speed above 700 feet per minute requires automatic operation with automatic floor leveling devices because of the difficulty of stopping more rapidly moving cars at floor levels. It was also found that at speeds of over 800 feet per minute an operator could not read floor numbers four feet high.

The code also includes provisions for the safe operation of freight and other types of elevators, the passenger-operated lifts, escalators, and dumb-waiters.

Pneumatic Tires

As pneumatic tires for both cars and commercial vehicles give such great reliability to-day, with life mileages which even a year or two ago would have seemed incredible, their trustworthiness and durability are now taken as a matter of course. It is true that the big advance made in road surfaces throughout this country and the general improvement of the highways are distinct contributory factors to the longer wear of tires. Speeds, together with more rapid acceleration and deceleration, have, however, also progressed, and, therefore, it may be said that tire design and manufacture together with improved systems of testing, have been largely responsible for the beneficial results accruing to motor vehicle users. An account of the process adopted by the Dunlop Rubber Company in the manufacture of pneumatic tires will illustrate how scientific this branch of the motor industry has become and what care is taken to maintain a high standard.

Rubber Preparation

Raw rubber is prepared on the plantations in the form of thin sheets of crepe or smoked sheet. After compression for packing purposes, these sheets form practically a solid block of rubber. On receipt at the works the packing is removed, and each block of rubber is immediately divided into eight parts by one cut of a heavy star-shaped knife against which the rubber is forced by hydraulic pressure. An important purpose of this cutting operation is to permit the rubber from many different cases to be mixed together in a methodical manner. This blending is one of the many precautions taken to ensure uniformity in the finished tire.

The raw rubber is next submitted to a process of working or mastication between large steel rollers, reducing it to a comparatively soft and plastic condition and in this state it is possible to mingle with it all the ingredients required to give the various mixed or compound rubbers the physical properties required in the various parts of the complete tire. The ingredients are of many kinds—for example reinforcing and toughening agents, dispersing agents, activators of vulcanization, vulcanizing agents, softeners, and colouring matter if required. The compounding of rubber for tire purposes is a science in itself, not only in the selection of the ingredients and the prescription for the compound but in the scientific control which has been found necessary in this important basic process. A large and up-to-date closed type mill, capable of dealing with a batch of rubber weighing 800 pounds, will produce over 150,000 pounds of compounded rubber in twenty-four hours. The total mixing capacity at Fort Dunlop exceeds 2,000,000 pounds weekly. Batches of mixed rubber are fully tested before issue to the manufacturing departments. Samples from each batch are sent by vacuum tube to the central control-room, where the tests occupy an hour. Pass-out warrants are then issued if the batch has proved satisfactory, and the compounded rubber is released for use in the different processes required. The standards of physical qualities and uniformity are high, and every precaution is taken to avoid anything which would produce variations in the capacity for service of the finished tires. The compounded rubber, having been distributed to the various departments of the factory, has now to be formed in such a way that it can be used in the particular portion of the tire for which it is intended. The hard-wearing rubber composing the visible tread and side walls of the tire is run out in the form of strips specially shaped for the purpose, thick in the centre, tapering to the edges. This is done by a profiling calender consisting of four steel rollers, one being provided with grooves of the requisite shape, through which the rubber compound is passed. The strips as they emerge from the calender are carefully gauged for accuracy, cooled by running through a water tank, and eventually cut to the lengths required for the particular sizes of tire. In this unvulcanized state the rubber is comparatively soft and has little elasticity.

Making Cotton Cord

Preparation of the cotton cord made to exacting specifications involves special processes. The finished fabric is not woven into warp and weft, but, as it ultimately consists of only warp threads, it is known as weftless cord. The threads are laid side by side in parallel lines almost touching each other, and while in this state they are fed through a four-roll calender, which is kept supplied with suitably compounded rubber. As a result they are completely embedded in a sheet of soft elastic material, which not only insulates every separate cord from its neighbour but forms a substantial layer of rubber which will, in due course, insulate and cushion each ply of material when built into the finished tire. Each cord, from a series unwinding from bobbins or cheeses, is led through its individual hole in a specially pierced plate and eventually guided out into the form of a flat sheet which is moving forward into the calender. Special control devices are used to provide uniformity of tension and to ensure the attainment of exact dimensions.

A machine is used to measure the strength and elasticity of cotton cords. It records automatically the character of the cords tested and is another of the precautions taken to ensure the maintenance of a high standard of suitability and uniformity. The actual operation on the prepared and rubbered cord fabric is to cut it into strips at an angle across the sheet or on the bias. These strips will ultimately form the plies of fabric which are built up into a tire casing. The width depends on the type and size of the finished tire; both it and the bias angle must be very accurately determined, and thereafter carefully produced in the cut strip. Once set to the dimensions required, the automatic machine will cut strips of the correct angle and width without variation. The long diagonal knife clamp is automatically fed forward to the requisite amount for cutting and the cut-off strip is rolled in a liner. The rubber surface of the strip is tacky and the liner prevents the fabric sticking to itself. The rolls of strip are passed forward for the tire-building process. Strips received from the cutting machine are assembled or buit up one on the other to form the casing of the tire. They can be built on a cylindrical former, the periphery of which is practically flat, or upon a former, or core, shaped almost exactly like the interior of a finished tire. Each ply on the core is so arranged that the cords run the opposite way across—that is, the bias of one strip opposes the bias of the other. As each pair of plies is laid down, the former is revolved and an ingenious mechanism of rotating discs gradually rolls the fabric down into shape, smoothly and without pucker. The wires forming the inextensible cover edges are added and the building up of the raw outer cover is practically completed. As the core is arranged so that it can be collapsed, the outer cover can easily be lifted from it.

The built-up cover is next moulded. First, a thick type of inner tube, known as an air-bag, is inserted in the cover. The cover and its air-bag are placed in the bottom half of the mould. A connection from a compressed air supply is made to the air bag, and the mould is then shut and fastened by special clamping arrangements. The mould consists of a hollow chamber through which steam is continually circulated. The mere act of closing the mould sets in movement a series of automatic controls. First the air is admitted to the air-bag to a predetermined pressure and continuously kept at that pressure. Electrical contacts operate the mechanism in the control room. This mechanism signals by lighting a red lamp above the mould when the allotted time of vulcanization has expired. The operator then immediately opens the mould, but it should be noted that this cannot be done until the pressure in the air-bag has been exhausted. The tire, after removal from the mould, has the air-bag extracted and is passed forward for the finishing processes.

As an example of the detailed care necessary in modern tire production the operation of balancing covers in certain sizes may be mentioned. The covers are mounted upon special wheels which are balanced with micrometer accuracy, and this enables any slight "out of balance" in the tire to be detected. The portion of the cover which is lighter in weight is marked with an indicating label, and when mounted on the wheel of a car, the valve of the inner tube is fitted at this portion so that the most accurate running balance is obtained.

Inner Tubes

In the manufacture of inner tubes compounded rubber which will give a soft and elastic vulcanized product is used. The tube compound is of a special type adapted for its purpose and formulated with reference to its resistance to oxidation and the effects of ageing. The thickness of the tube wall being relatively small, it is very important that there should be no particles of grit or foreign matter embedded in it. The rubber is therefore subjected to a process of refining. There are several ways of doing this, but one of the most effective is by screening or forcing the rubber through a fine metal mesh. This is done by means of a very powerful forcing machine.

Dunlop inner tubes are manufactured in circular form, not only as to section, but in circumference. This enables them to fit properly into the outer cover without puckering, renders the operation of fitting the complete tire to the rim comparatively easy, and removes the danger of trapping the inner tube. For this purpose the soft, unvulcanized tube, which has been cut off into a length from the forcing machine is blown on to a circular mandrel by means of compressed air and skilled manipulation. The tube is vulcanized on this mandrel and eventually removed; at the same time it is turned inside out so that both the interior and the exterior surfaces come under the closest scrutiny. The joining up of the inner tube to make a complete air-tight chamber is a special feature of the operations. The joint is not merely overlapped, solutioned and stuck down, but the tube ends are carefully bevelled by patented methods matched up together with a suitable vulcanizing compound between them, and then placed in an appropriate collar apparatus where the joint is steam-vulcanized throughout, so that in substance it practically does not differ from the remainder of the tube.

After the operations of fitting the valve patch, valve, printing the size, trade mark, etc., the tube may be regarded as a finished article, subject, however, to an exacting test for air-tightness in every part. The test involves the use of very efficient and ingenious machinery which is the subject of Dunlop patents. There is a circular water tank in which revolves a series of arms like the spokes of a wheel. These arms each carry two large bobbins over which the inflated tube is placed. As the arms revolve they carry the tubes through the water tank. The air pressure which can be carried by an inner tube when unsupported by an outer cover is comparatively small, so that to give the effect of the actual pressure used in the tires, the bobbins move apart and thus considerably stretch the tube in the process. Observers are stationed alongside the tank. Their special duty is to watch for any bubbles arising, which would indicate a slight leak.—*The Times Trade and Engineering Supplement* (abridged).

Preliminary Notice

of Applications for Admission and for Transfer

August 22nd, 1931

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in October, 1931.

R. J. Durley, *Secretary.*

* The professional requirements are as follows—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BOWEN—JOHN ALFRED CLARKE, of Long Branch, Ont., Born at Haverfordwest, South Wales, Apr. 5th, 1905; Educ., Cambridge Local, 1918. O.L.S. Prelim., 1925. Honour and Pass Matric., Long Branch High School, 1931. 2 years, evening classes, Toronto Technical School; 1923-25, chaining and some instrument work, W. J. Baird, O.L.S.; 1925-26, on survey of Lake Nipigon for late W. R. B. Rubidge, Surveyor; 1927 (Apr.-Nov.), transitman, and 1928 (Jan.-June), chief of party, flooded areas, etc., Kerry & Chace; 1928 (Aug. Oct.), chief of party, topog'l. work, mining claims, E. M. MacQuarrie, A.M.E.I.C.; 1927 (Jan.-Mar.), and from Oct. 1928 to May 1930, with Messrs. Lang & Ross, as transitman on flooded areas, chief of party, power line location, junior engr., placing footings for steel towers, chief of party, damsite cross sections and power line location, instr'man. on machy. footings, chief of party, locating towers, and foreman on switch tower footings; 1930 (July-Dec.), senior layout man, concrete dam, rock shaft, tunnel, etc., Algoma District Power Co.

MITCHESON—SEPTIMUS, of 2056 Belgrave Ave., Montreal, Que., Born at Tynemouth, North'd., England, Jan. 14th, 1891; Educ., 1908-11, Marine School of Engineering, South Shields, England; 1907-11, apprentice, Wallsend Slipway and Engrg. Co., Wallsend-on-Tyne, England; 1911-12, junior dftsman., with above company; 1912-13, dftsman., C. A. Parsons & Co., Heaton Works, England, on turbine driven generators and condensing plants; 1913-14, dftsman., R. and W. Hawthorne Leslie & Co., England, on turbine details and pipe arrangements for naval vessels, and 1917-19, with same company on geared turbines; 1914-17, corporal in Royal Engrs ; 1919-27, senior dftsman., Wallsend Slipway & Engrg. Co., on pipe arrangements, oil fuel installns., oil engine arrangements and details, etc.; 1927-28, designing dftsman., on special elevators and conveyors, transmission mach'y., The Dodge Mfg. Co., Toronto; 1928, designing dftsman., on power plant layout for paper mill, Kerry & Chace, Toronto; 1928-30, group-leader with Babcock-Wilcox & Goldie-McCulloch Ltd., Galt, Ont., in charge of group detailing Stirling boilers, air heaters, superheaters, and pulverized coal plants; 1930 (Feb.-Nov.), group-leader with Ontario Refining Co. Ltd., Copper Cliff, Ont., in charge of group designing, and supervising erection of steam piping and other pipe lines, also gen. plant layout work; March to May 1931, designing dftsman., United Engineers and Constructors, Montreal, on mech'l. side of foundry extension.

McQUEEN—HOWARD RENTON, of 4876 Cote des Neiges Rd., Montreal, Que., Born at New Glasgow, N.S., June 11th, 1885; Educ., Grad. with Honours, R.M.C., Kingston, 1907; Three years service in office of chief acct., N.S. Steel & Coal Co.; 1907-08, topog'r., rly. survey; 1908, survey, prov. of Quebec, for Dept. Militia and Defence; 1908-09, mining engr., Keokee Coal & Coke Co., Keokee, Va.; 1909, transit traverse, Militia and Defence; 1909-15, mining engr., U.S. Steel Corpn. and Oliver Iron Mining Co., Chisholm and Hibbing, Minn.; 1915-19, overseas, Capt., 1st Can. Rly. Troops; 1919-27, gen. contractor, roads and bridges; 1927 to date, President and gen. mgr., Iron Fireman Ltd., Montreal. Equipped approx. 200 small and medium sized boiler plants with Iron Fireman Automatic coal stokers, including Hotel Dieu, Montreal, Notre Dame Hospital, Seminary of Quebec, Seminary of Three Rivers, etc.

FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

MACDONALD—CHARLES BEVERLEY ROBINSON, of Sao Paulo, Brazil, Born at Halifax, N.S., Dec. 8th, 1893; Educ., Grad. with Honours, R.M.C., Kingston, 1914; 1910-11 (summers), chainman and rodman, C.P.R. irrigation dept. surveys; 1914 (July-Nov.), asst. hydrographer, Hudson Bay Hydrographic Survey; 1914-19, overseas. Capt., Royal Engrs.; 1919-20, visiting various engrg. works in Canada, and gaining practical experience on Welland and H.E.P.C. canals; 1920 (May-Sept.), instr'man. and asst. engr., Capreol divn., C.N.R.; 1920-22, asst. chief engr., constrn. of two locks for Belgium Govt. by the firm of Constructions Civiles et Travaux; 1922-23, asst. office engr., Macdonald, Gibbs & Co., London, England; 1923-25, sectional engr., Argentine Transandine Railway Co.; 1925 to date, as employee and later director of the firm of Macdonald, Gibbs & Co. (Engrs.), Ltd., engrs. and contractors, London, England, as follows: 1925-26, engr. i/c surveys and constrn., Lobetas Development Rly., Northern Peru; 1926 (July-Dec.), engr. i/c surveys, Pellonis-Salinas Project, Southern Peru, for the Borax Consolidated Ltd.; 1927 (Jan.-Sept.), chief asst. engr. and later i/c survey parties, for the Sao Paulo Rly. Co., Brazil; 1927-28, engr. i/c surveys, Orinoco Rly. Project, Venezuela; Sept. 1928 to date, engr. i/c surveys and constrn., Sao Paulo-Parana Railway Co., Parana, Brazil. (*S. 1914, A.M. 1919.*)

FOR TRANSFER FROM THE CLASS OF JUNIOR TO A HIGHER CLASS

BARNETT—HAROLD EVANS, of Fraserdale, Ont., Born at Moncton, N.B., May 24th, 1897; Educ., B.Sc. (Civil), Univ. of N.B., 1918; 1915 (summer), surveys, Can. Govt. Rlys.; 1917 (summer), Can. Govt. Geol. survey; 1918-19, overseas. C.E.F.; 1919-20, rodman on survey and constrn. work, 1920-22, instr'man. on mtce and location surveys, Can. Govt. Rlys.; 1922-23, dftsman., right of way dept., C.N.R.; 1923-26, chief dftsman., N.B. Electric Power Commission, on rehabilitation of Musquash Div. and prelim. work on Grand Falls Div. in N.B.; 1926-30, designing engr., H. G. Acres & Co., Niagara Falls, Ont., on power developments, filtration plants, industrial bldgs., reports, estimates, etc.; 1930 to date, designing engr., Dominion Construction Corporation, on Abitibi Canyon power development, Ontario. (*Jr. 1921.*)

References: H. G. Acres, R. L. Hearn, G. Mitchell, S. R. Weston, P. C. Kirkpatrick.

BARRETT—ANDREW GRANT, of Asbestos, Que., Born at Summerstown, Ont., Oct. 26th, 1896; Educ., B.Sc., Queen's Univ., 1921; Summers 1917, 1920, 1921, instr'man., topog'l. divn., Geol. Survey of Canada; 1921-22, instr'man. on municipal engrg., 1922-23, instr'man., Dept. Public Highways, Ontario; 1924 (Jan.-June), instr'man., Quebec Development Co.; 1924 (June-Nov.), municipal engrg.; 1924 to date, with the Canadian Johns-Manville Co., as follows: 1924-26, instr'man. and office work; 1926-29, asst. chief engr., and 1929 to date, chief engr. (*S. 1921, Jr. 1925.*)

References: H. R. Lynn, S. R. Newton, W. L. R. Stewart, R. C. Smith, D. D. MacCrimmon.

RICKARDS—CHARLES SELBY, of Toronto, Ont., Born at Banff, Alta., Nov. 20th, 1896; Educ., Senior Matric., also advanced maths. (one year) at Hamilton Technical School. 1921-22, 2 years maths. under private tutor; 1912-13 (summers), mech'l. ap'tice (student), Ogden Shops, C.P.R., Calgary; 1915 (8 mos.), hydrographic survey, Dom. Govt.; 1916-19, electr'l. ap'tice, Canadian Westinghouse Company, Hamilton, Ont.; Also with same Company as follows: 1919-20, trouble engr., 1920-21, asst. dist. engr., Calgary district; 1921 (6 mos), engr.'s asst. on constrn.; 1921-22, meter engr., Abitibi Power & Paper Co. Instructor of electr'l. classes in technical school at Iroquois Falls. (Industrial Technical and Art School Cert. No.365); 1923-26, elect'l. mtce. dept., Toronto Hydro-Electric System, work particularly in connection with automatic stations and supervisory control; 1926 to date, erecting engr., Can. Gen. Elec. Co. Ltd., Toronto, Ont., specializing in industrial and automatic control equipment, supervisory control and telemetering, having full responsibility of the installn. of equipment for various projects throughout Canada. (*Jr. 1922.*)

References: C. H. L. Jones, W. E. Ross, A. B. Gates, G. N Thomas, J. H. Coruish, W. A. Bucke.

FOR TRANSFER FROM THE CLASS OF STUDENT TO A HIGHER CLASS

BALLENY—JAMES LISTER, of Montreal, Que., Born at Colinsburgh, Fife, Scotland, May 19th, 1904; Educ., B.Sc. (E.E.), McGill Univ., 1925; 1919-24 (3 years in all), gen. elect'l. work in paper mill; 1925-26 (15 mos). test course with Can. Gen. Elec. Co.; 1926-27 (4 mos), indust. control work, and 1927-29, industrial heating engr., on design, manufacture and installn. of electric heating equipment for Can. Gen. Elec. Co., Davenport Works; Feb. 1929 to date, asst. elect'l. engr., Dominion Bridge Company, Montreal. (*S. 1922.*)

References: W. E. Ross, C. E. Sisson, F. Newell, R. H. Findlay, D. C. Tennant, K. O. Whyte, G. Kearney.

BULLER—FRANCIS H., of 1095 Brierwood Blvd., Schenectady, N.Y., Born at Montreal, Que., Nov. 23rd, 1900; Educ., B.Sc., McGill Univ., 1923. M.S. in E.E., Union College, Schenectady, 1931; 1923 to date, with General Electric Company as follows; 1923-24, test course; 1924-25, transformer engrg. dept.; 1925-26, A.C. engrg. dept.; 1926 to date, asst. engr., cable section, central station engrg. dept. (*S. 1920.*)

References: C. V. Christie, E. G. Burr, G. A. Wallace, C. M. McKergow, R. M. Wilson.

DES BRISAY—ARETAS WILLIAM YOUNG, of Camp Borden, Ont., Born at Petit Rocher, N.B., June 21st, 1904; Educ., Grad., R.M.C. 1925. B.Sc. (E.E.), McGill Univ., 1927; Summers: 1925, operation, hydro-electric plant of Bathurst Co. Ltd. at Grand Falls, N.B., also mtce gang in pulp mill for same co.; 1926, instr'man. on hydro-electric investigation survey on Nepisiguit River for same co.; 1927-28, instr'man., prelim. rly. survey, and dftsman. in pulp mill, summer 1928, for same company; 1928-31, engrg. staff, transmission engrg. dept., Northern Electric Company, Ltd., Montreal; at present, Lieut., Royal Canadian Signals, Camp Borden, Ont. (*S. 1926.*)

References: H. J. Vennes, W. B. Cartmel, A. G. L. McNaughton, E. Forde, W. A. Steel, P. Earnshaw.

ENNIS—LEO E., of 5154 Mountain Sight Ave., Montreal, Que., Born at Perth Road, Ont., Dec. 1st, 1902; Educ., B.Sc. (Civil), Queen's Univ., 1923; 1923-24, asst. field engr., Ford Motor Co. of Canada, Ford City, Ont.; 1924 to date, with the Bell Telephone Company of Canada, as follows: 1924-26, student engr. on inventory, central office, installn. and constrn. studies; 1926-27, divn. constrn. engr., eastern divn., on special organization and constrn. problems; 1928-29, divn. constrn. supervisor, eastern divn., technical adviser to the constrn. supt. and in charge of organization programming of all major outside plant constrn.; 1929 (June-Sept.), special studies engr., in charge of special problems and budget work connected with the plant engr. dept.; Oct. 1929 to date, toll pole and wire engr., Quebec Divn. (*S. 1922.*)

References: J. E. Porter, W. P. Wilgar, V. C. Jones, F. M. Corneil, A. M. Mackenzie, W. H. Slinu.

FAIRBAIRN—JOHN MACFARLANE, of Montreal, Que., Born at Ottawa, Ont., Apr. 17th, 1903; Educ., B.Sc., McGill Univ., 1924; 1922, office work, Grand Trunk Arbitration; 1923, lightkeeper, Can. Govt. Geod. Survey; 1924-25, ap'tice, Steel Company of Canada; 1926-27, inspr. of malleable castings and steel forgings in mfg. plants, The P. & M. Co., Chicago, (Railway Supplies), and 1927-28, selling rail anchors, rail oilers, ballasters, etc. to American rld. engrs. and inspecting performance in service, with same company; 1928, sales engr., Maintenance Equipment Company, Chicago; 1928-29, with Chas. Warnock & Co., Toronto, district mgr. i/c of soliciting, arranging plans and specifications, and handling of all inspection work in that district; 1929 to date, with Chas. Warnock & Co., Montreal, gen. mgr. i/c of all functions of company. (*S. 1921.*)

References: J. A. McCrory, C. Warnock, P. B. Motley, R. L. Latham, F. J. Blair, J. H. Larmonth.

LOVETT—PERCY ARTHUR, of 107 Morris St., Halifax, N.S., Born at Liverpool, N.S., Apr. 17th, 1903; Educ., B.Sc. (E.E.), N.S. Tech. Coll., 1928; Summers, 1927, C.G.E. factory at Peterborough, Ont.; 1928, asst. with Nova Scotia Fuel Board; 1928-30, student ap'tice course, Canadian Westinghouse Co., Hamilton, Ont.; Nov. 1920 to date, asst. equipment engr., Maritime Telephone and Telegraph Co., Halifax, N.S. (*S. 1928.*)

The Constitution of Portland Cement and the Deterioration of Concrete in Alkali Soils

Co-operating Organization: University of Saskatchewan

Silicates and aluminates of widely varying composition constitute a large part of the material used in the ceramic, glass building and insulating industries. Due to the wide variation in the chemical and physical properties of the compounds, as evidenced by the appearance of the rocks and their slow deterioration, the behaviour of the substances when exposed to external agencies is not always so well known as to ensure the best use of the substance. This is particularly true of newly developed materials or materials used in new surroundings. In this respect, the resistance of silicates and aluminates in concrete against the attack of sulphates is a very pressing problem for western Canada where the losses due to the deterioration of concrete are serious.

It is now generally accepted that tricalcium aluminate is one of the important components of Portland cement; the action of sulphate on the hydrates of this substance is considered to be the main cause of the failure of concrete in solutions of sodium and calcium sulphate, that is, in alkali water containing these two salts in solution. One crystalline hydrate of tricalcium aluminate has been known previously; it forms hexagonal plates, needles and spherulites. By treating pure tricalcium aluminate with steam under a pressure of approximately 70 pounds per square inch and drying the product over quicklime, a new form of hydrated tricalcium aluminate was prepared, belonging to the isometric system and crystallizing as cubes and trapezohedrons. It is stable at 100 degrees C. but at 275 to 300 degrees C. it gives up three-quarters of its water and forms a stable hydrate of composition $3CaO\ Al_2O_3\ 6H_2O$. This is decomposed, on heating at 500 to 600 degrees C., to $5CaO\ 3Al_2O_3$ and free lime. When the resulting mixture is placed in saturated steam at 150 degrees C. recombination takes place, and the hexahydrate of tricalcium aluminate is again formed. It was found that it could also be obtained directly by exposing a mixture of lime and alumina of appropriate composition to steam at 150 degrees C. The crystals produced are cubes and more rarely dodecahedrons. When pure tricalcium aluminate is exposed to steam at 150 degrees C. the crystals of the hexahydrate appear as trapezohedrons. In each case the refractive index is the same. A hydrate composed entirely of hexagonal plates is obtained when the temperature at which the tricalcium aluminate takes up water is kept low. At about 25 degrees C. and at atmospheric pressure, the hexagonal form goes over into the cubic form, the change apparently taking place the faster the larger the initial percentage of water in the material.

Parallel experiments were made on a number of commercial Portland cements obtained from four different mills. Previous work had shown that prolonged curing in saturated steam at 175 degrees C. renders the mortar almost completely resistant to the action of solutions of sodium sulphate and increases very materially the resistance of the mortar to the action of solutions of magnesium sulphate. A microscopic study of the changes taking place was made and it was found that free lime gradually disappears and that crystals of calcium hydroxide take their place. These disappear in turn when steaming is continued, while a new crystalline substance is formed which is very stable in solutions of sodium and calcium sulphate, but is decomposed slowly by solutions of magnesium sulphate. The crystals are orthorhombic. They are decomposed by very dilute acids, but are stable in solutions of sodium hydroxide and are not affected by temperatures as high as 400 degrees C. The great increase in the resistance of Portland cement mortar to alkali action produced by steam curing for twenty-four hours or more is evidently connected with the production of this crystalline material. Curing in water vapour at temperatures below 100 degrees C. was found to lessen the strength of the material and at a temperature of 50 degrees C. the resistance to the action of sulphates decreased.

Another way of producing high resistance to sulphate action was found to be the addition of siliceous substances; this has been practised for a long time for the purpose of obtaining a mass of greater workability and greater impermeability to water. The capacity of such substances for binding free lime suggested that they might be effective in preventing sulphate action. This was found to be the case when a pure silica gel was added to ordinary Portland cement. Further studies with silica gel and with many natural and artificial products rich in silica are in progress.

As a preparation for a study of the heats of formation of the constituents of Portland cement, new determinations on the heats of solution of calcium oxide and calcium hydroxide in hydrochloric acid were made. The heat of solution of the calcium hydroxide at room temperature was found to be three calories higher than that obtained with material hydrated in steam at 150 degrees C., but after subtracting the heat of wetting the average values were 550.7 and 550 degrees C. The heat of hydration of calcium oxide did not agree with calculated results; a microscopic examination indicated that physical changes in the hydrated material continue for a long time after the temperature of the calorimeter comes to apparent constancy. The heat of solution of calcium oxide was 46.50 calories per mole, and was not materially affected by the temperature of ignition between 800 and 1,200 degrees C.

—*Thirteenth Annual Report of the National Research Council.*

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Vacant

CHEMICAL ENGINEER, for industrial plant in the province of Quebec. Age 25 to 30. At least two or three years practical experience necessary, preferably in supervisory or control capacity in a manufacturing plant. Apply at once to Box No. 739-V.

Situations Wanted

TECHNICALLY TRAINED INDUSTRIAL EXECUTIVE, open for employment. Canadian, age 40, with extensive Canadian and American industrial experience, particularly in metal manufacturing industries, including grey iron and steel foundries, machine and steel fabricating shops—arrangement and equipment of plant and mechanical handling systems to improve manufacturing methods, cut costs, step up production and quality of product—wants connection with progressive company in Canada preparing for business expansion. Apply to Box No. 35-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), 15 years experience, available on short notice. Experienced surveys, draughting, reinforced concrete design, municipal engineering, construction work, inspection, estimating. Apply to Box No. 107-W.

CIVIL ENGINEER, university graduate 1926, desires employment as junior engineer or instrumentman on construction work. Experience, resident engineer on railway construction, miscellaneous surveys. References. Available any time. Apply to Box No. 149-W.

CIVIL ENGINEER, B.Sc., age 34, is open for a position as construction engineer in charge of construction of hydro-electric plants or paper mills; designing engineer of hydro-electric developments or paper mills. Willing to make small investment. Apply to Box No. 157-W.

ELECTRICAL ENGINEER, B.Sc., McGill 1926. Five years experience in the design of switchboards, layouts and wiring diagrams. Considerable experience in high and low tension switchgear design. Fifteen months experience in switchboard estimating. Available at once. Apply to Box No. 247-W.

ELECTRICAL ENGINEER. Graduate '25, wide experience in hydro-electric power stations, desires position on power plant design or related work. Apply to Box No. 278-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing and hoists. Also some experience in ventilating and heating work and calculators. Accustomed to structural design and details. Good references. Present location Montreal. For interview apply to Box No. 329-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., R.P.E. Ont., with twenty-four years experience embracing dams, wharves, grain elevators, foundations, pile driving, highways, municipal engineering, water power surveys, road locations, inspections and estimating, is open for engagement as engineer or superintendent in construction, operation or maintenance. Location immaterial. Apply to Box No. 358-W.

STRUCTURAL AND CIVIL ENGINEER, Jr.E.I.C., age 31, married. Was instrumentman and structural engineer on erection of Royal York hotel, and asst. resident engineer on James Bay Extension, T. & N.O. Rly. Experience includes structural, civil and mechanical draughting and all kinds of instrument work and special work. Qualified as captain in military engineering, R.M.C., Kingston. Available anywhere in Canada, preferably Toronto, for any kind of work. Apply to Box No. 377-W.

STRUCTURAL AND CIVIL ENGINEER, B.Sc., age 35, married. Thoroughly experienced in design, shop work and erection of steel bridges, buildings and movable structures. Seeks position as designing engineer or engineer on construction. Available on short notice. Will go anywhere. Apply to Box No. 399-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., with six years experience in paper mill and hydro-electric work, desires position in western Canada. Capable of handling reinforced concrete and steel design, paper mill equipment and piping layout, estimates, field surveys, or acting as resident engineer on construction. Now on west coast and available at once. Apply to Box No. 482-W.

DESIGNING ENGINEER, A.M.E.I.C., P.E.Q., with extensive experience in design and construction of power plants, industrial buildings and hydraulic structures, desires position as designing engineer or resident engineer on construction. Apply to Box No. 492-W.

MECHANICAL ENGINEER, Jr.E.I.C., B.Sc., '26. Ten months experience in pulp and paper steam control. Four years experience in detail and design, in pulp and paper mill, industrial plant and hydro-electric development work. Age 27. Married. Location immaterial. Apply to Box No. 521-W.

CIVIL ENGINEER, B.A.Sc., '29, with experience in supervision of construction and general office engineering, desires permanent position with contractor or engineer. Available at once. Apply to Box No. 524-W.

CIVIL ENGINEER, A.M.E.I.C., with twelve years experience embracing survey and construction, railway, hydro-electric and highways, foundations, pile driving, municipal engineering, water power surveys, road location, inspection and estimating, is open for engagement as resident engineer on construction or other responsible position. Experience comprises both office and outside work. Available immediately. Apply to Box No. 527-W.

MECHANICAL, CONSTRUCTION, AND DESIGNING ENGINEER, with special training in hydro-electric power development, underground steam distribution systems, and the operation of large electrical machinery. Active work desired. Apply to Box No. 528-W.

ELECTRICAL ENGINEER, married, graduate of McGill University, desires position in Ottawa, Montreal or Toronto. Experience includes four summers with a building concern as instrumentman and assistant engineer, two and one-half years with the Canadian Westinghouse Co., this time being distributed between tests, design and sales. At present employed but available on short notice. Apply to Box No. 533-W.

UNDERGRADUATE ENGINEER, S.E.I.C., junior year standing (Sask.), desires work to complete course. Electrical or mechanical work preferred. Apply to Box No. 553-W.

ELECTRICAL ENGINEER, A.M.E.I.C., university graduate 1924. Experience includes one year test course and five years on design of induction motors with large manufacturer of electrical apparatus. Four summers as instrumentman on highway construction. Several years experience in accounting previous to attending university. Available at reasonable notice. Apply to Box No. 564-W.

CIVIL ENGINEER, S.E.I.C., 1931 graduate, experienced instrument man and surveyor. Wishes to join reliable engineering firm on survey party, or draughting, steel and concrete design, estimating, building, construction, etc. Good references. Residing in Montreal. Available immediately. Apply to Box No. 567-W.

CIVIL ENGINEER, B.Sc. McGill Univ., Jr.E.I.C. Five years experience along the lines of general construction, including structural steel. Available at once. Apply to Box No. 570-W.

MECHANICAL ENGINEER, A.M.E.I.C., experience in the design and maintenance of steel mills, zinc and sulphuric acid plants, cement plants; power house layouts; familiar with shop practices and costs, desires connection. Apply to Box No. 571-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., (Univ. of B.C., '30), Undergraduate experience in pulp mill. One year's experience, Canadian General Electric Co., mech. dept. Single. Age 24. Desires position in technical design or sales. Location immaterial. Available on short notice. Apply to Box No. 577-W.

TEMPORARY EMPLOYMENT wanted by an engineer with wide experience in the design and operation of steam power plants and heating system. Apply to Box No. 584-W.

ELECTRICAL ENGINEER, graduate Univ. of Alberta, '31, with excellent record, desires connection with electrical manufacturing firm, power or communication company. Good general experience includes one summer railway construction, two summers geological surveys in oil fields of Alberta, planetable topographer and asst. geologist. Available immediately. Apply to Box No. 596-W.

MECHANICAL ENGINEER, age 22, graduate '31, Univ. of Alberta, experience as draughtsman and instrumentman-inspector, is open for a position. Location immaterial. Apply to Box No. 598-W.

MECHANICAL ENGINEER, S.E.I.C., age 21, four years mechanical engineering, Queen's University, desires permanent employment. Experience in wood work, machine shop work, draughting and surveying. Location immaterial. Available at once. Apply to Box No. 600-W.

Situations Wanted

MECHANICAL ENGINEER, Canadian, technically trained; eighteen years experience as foreman, superintendent and engineer in manufacturing, repair work of all kinds, maintenance and special machinery building, desires change. Location immaterial. Available on one month's notice. Apply to Box No. 601-W.

ELECTRICAL OR MECHANICAL ENGINEER, B.Sc., '31, S.E.I.C., desires employment which will give experience and lead to advancement. Two summers in a large communication company, including draughting, switchboard and surveying. Available on short notice. Will go anywhere. Apply to Box No. 606-W.

CHEMICAL ENGINEER, S.E.I.C., University of Alberta '30, desires a position in any industry with chemical control. Experience includes three summer vacation periods of five months each as assistant chemist, and ten months as chief chemist with a cement company. Age 29. Single. Available at short notice. Apply to Box No. 609-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. (C.E.), Univ. of Man. '31, desires temporary or permanent employment on engineering work. Twenty months experience in summers as chainman, rodman and instrumentman on railway grade and bridge construction; also as inspector on reinforced concrete highway bridges. Salary and location immaterial. Available at once. Apply to Box No. 614-W.

DESIGNING ENGINEER, industrial building designer, Jr.E.I.C., age 31, married, capable of taking responsible charge of the structural design and architectural details of steel or concrete manufacturing plants or power houses, also has had considerable experience in the design of office buildings, etc., desires reasonably permanent position. Very highest references from present employers. Location immaterial. Apply to Box No. 615-W.

MECHANICAL ENGINEER, Jr.E.I.C., 5 years apprenticeship on general mechanical engineering; 10 years experience on heating and ventilating and mechanical equipment of buildings. Design, draughting and production. Desires change. Capable of taking charge of engineering department. Further particulars if required. Apply to Box No. 616-W.

POWER ENGINEER, M.E.I.C., age 42. Married. Thoroughly conversant with electrical, steam, mechanical and industrial engineering, desires executive position with large industrial, power or financial corporation. Best of references as to ability and positions held. Apply to Box No. 617-W.

CIVIL ENGINEER, Jr.E.I.C., B.A.Sc. '24, age 35, married. Five years designer and estimator with well-known firm of industrial builders; two years detailing, designing and estimating structural steel for bridges and buildings, also survey and municipal experience. Open for position immediately, will go anywhere. Apply to Box No. 618-W.

CIVIL ENGINEER, A.M.E.I.C., graduate '23, married, eight years municipal engineering experience. Sewerage and sewage disposal, water works, street pavement, etc. Also some experience highway construction. For the past three years engaged by firm of consulting municipal engineers. Desires permanent position. Location immaterial. Available immediately. References. Apply to Box No. 624-W.

ELECTRICAL ENGINEER, B.Sc., N.S. Tech. Coll. '31. Experience in design and construction of rural distribution lines, trouble shooting, inventories and general office work, desires position with public utility or industrial plant. Location immaterial. Available at once. Apply to Box No. 628-W.

ELECTRICAL ENGINEER, B.Sc., N.S. Tech. Coll., '31. Experience includes geological survey work in Rouyn mining area and hydro-electric power plant construction both civil and electrical work. Available at once. Apply to Box No. 639-W.

SALES ENGINEER, A.M.E.I.C., McGill '23. Past four years sales representative electrical power apparatus in Northern Ontario mining district, western Canada and with some sales experience in Montreal, Toronto, Ottawa, and eastern Ontario. Two years electrical estimating and engineering on steel mill applications, mine hoists, elevators, pulp and paper drives, crushing and cement and other special applications. Two years design, engineering, test and some erection on steam turbines. Available short notice; location immaterial. Apply to Box No. 641-W.

ELECTRICAL GRADUATE, McGill '30, S.E.I.C., with thirteen months experience on General Electric test course, twelve months draughting and five months as instrumentman on power plant construction. Available September first. Location immaterial. Apply to Box No. 644-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.). Extensive experience as executive and in charge of construction of complete water power developments, including transmission lines, harbour developments, including hydraulic dredging and land reclamation, industrial plants and municipal works. Apply to Box No. 647-W.

OPERATING ENGINEER. Position wanted as operating superintendent or assistant. Age 43. Married. No children. Nineteen years experience operating hydro-electric plants, sub-stations, transmission lines. Available immediately at any reasonable salary and for any location. Apply to Box No. 654-W.

ELECTRICAL ENGINEER, Jr.E.I.C., 1926 grad. of English Tech. Coll. Past two years inspector of communication apparatus; three years varied power and sub-station experience, including automatic sub-stations, on comprehensive training scheme. Age 24, single. Location immaterial. Available at once. References. Apply to Box No. 658-W.

ELECTRICAL ENGINEER, B.Sc.E.E., 1931, N.S. Tech. Coll. Experienced in armature winding and apparatus repairs, in conduit and cable work. Students' course in elevator manufacture, ship's electrician on tropical run. Good cultural education. Available at once, for Canada or tropics. Apply to Box No. 659-W.

ELECTRICAL ENGINEER, university graduate '28. Experience includes one year with operating department of a large public utility and two years with manufacturer of electrical equipment, work including design, test and correspondence. Available on short notice. Apply to Box No. 660-W.

ELECTRICAL ENGINEER, B.Sc., S.E.I.C. Experience: Installation staff Can. Gen. Elect.; students test course with the same company, concrete inspection, transmission line surveying and inspection, also some railway construction experience. References. Desires position with electrical concern. Location immaterial. Available at once. Apply to Box No. 665-W.

RADIO ENGINEER, with thorough general experience covering short wave, marine, broadcast, wire communication, and sound picture work. Capable of taking responsibility in engineering, operating, manufacturing, or executive fields. University graduate; single; age 27. Apply to Box No. 667-W.

For Sale

FOR SALE "en bloc" to wind up an estate: 1 Transit (Buff & Buff), 1 Dumpy Level (Harrison & Co.), 1 Water Meter (Price), 1 Hand Level (Gurley), 1 Hand Level (Harrison & Co.), 3 Levelling Rods, 3 Pickets, 1 Extra Tripod. For further information apply to The Royal Trust Company, 105 St. James Street, Montreal. Telephone HA. 4221, Local 10.

The Pterodactyl Aeroplane

Departures from the conventional form in aircraft-design are so uncommon that considerable interest will be felt in the Westland Hill Pterodactyl Mark IV aeroplane. The machine is a tailless monoplane provided with a three-seater cabin, and the power plant consists of a De Havilland Gipsy III engine, driving a pusher airscrew. The object of the design is to obtain a higher degree of safety, comfort and performance than is possible with aircraft of the normal form, and the features relied upon to secure the first desideratum are the shape of the wings, the arrangement of the control surfaces and the clear view forward, rendered possible by the employment of a pusher airscrew.

With regard to the shape of the wings it may be pointed out that they are swept back in plan, somewhat in the form of a broad arrow, are washed out in incidence towards the tips, and are set at a small negative dihedral angle. It should be mentioned, however, that the extent to which the wings are swept back can be adjusted on the ground or in flight, for the purpose of trimming the machine for different loads and speeds. Both fore and aft and lateral control is obtained by surfaces mounted on the wings tips, and capable of being moved to large negative angles, while steering is effected by means of single-acting vertical wing-tip rudders used separately; both rudders can, however, be used simultaneously in landing, to act as an air brake. It is claimed that stalling and spinning are avoided by the high degree of lateral stability at low speeds inherent in the shape of the wings, together with effective controls in all three directions, and that the possibility of collision is rendered negligible by providing the pilot with a clear view over a wide angle. Another advantage claimed for the pusher airscrew is that the noise in the cabin is reduced. The engine, it may be mentioned, is completely cowled in, the necessary cooling air being drawn in through a duct by the airscrew working close to the outlet end.

The undercarriage is of the tandem-wheel type, the two wheels being mounted on a rocking frame to give easy running over rough ground, but a check is fitted to limit the rocking motion, and thus prevent the machine from overturning in the event of the wheels sinking into soft ground. Steering on the ground is effected by turning the front wheel after the manner of a bicycle, and a brake is fitted on the rear wheel only, also to obviate any danger of overturning. The whole undercarriage is faired with a streamline casing, and should therefore have a low air resistance. It is claimed that the arrangement is but little inferior to a retractable undercarriage from the point of view of performance, while avoiding the mechanical complications of the latter.—*Engineering.*

Wind Tunnel Design

A great deal of interest, by no means restricted to visitors to the National Physical Laboratory, centres just now round the compressed air tunnel. Whilst not yet in commission, the tunnel is complete as regards all major items and only the aerodynamic balances remain to be installed.

The tunnel shell, 50 feet long overall, is in the form of a circular cylinder 17 feet internal diameter, with hemispherical ends. Apart from cusp-shaped fairings at the ends, it constitutes the outer boundary of the annular return flow duct. The working section of the tunnel is an open jet 6 feet in diameter, and 7 feet 8 inches long, co-axial with the shell. Circulation of the air is produced by a two-bladed Duralumin fan of airscrew type mounted on a shaft which passes through labyrinth packing at one of the hemispherical ends of the shell. The screw is driven by a 400-h.p. (overload 500-h.p. for one hour) direct current motor mounted on a pedestal just outside the tunnel. The maximum power is expected to give an airspeed of 90 feet per second at full pressure. Access to the working section for the manipulation of models, is provided by a hinged circular door at the end of the shell remote from the fan.

The air-compressor equipment, which is designed to raise the pressure in the tunnel to 25 atmospheres in 80 minutes, is housed in an adjacent room. It comprises three identical three-stage units with inter-stage cooling. Each set is driven at 300 r.p.m. by a 400-h.p. autosynchronous motor operating on 3,000 volts. The electrical arrangements are such that the nine cranks of the complete plant can be synchronized 40 degrees out of phase so as to minimize, during the operation of the compressors, vibrations, which disturb delicate apparatus in other parts of the laboratory. The auxiliary electrical plant includes a motor generator to provide direct current for the tunnel fan, a storage battery to supply steady current to the solenoids of the aerodynamic balances, and a small step-down transformer for lighting and various general purposes.

A somewhat notable feature of the wind tunnel is the exclusion from the interior of all combustible material. The importance of this precaution becomes at once apparent when the concentration of oxygen, due to the compressed air in the tunnel, is realized. In this aspect of the design advantage has been taken of unfortunate experiences with the American variable density tunnel, at the Langley Memorial Aeronautical Laboratory, which in its original form was damaged by fire.

The aerodynamic design of the compressed air tunnel has been based, to a great extent, on the results obtained with a small-scale wooden model operating at atmospheric pressure. Experimental modifications of shape, intended to improve the characteristics of the working section, can, in this way, be tried out with a rapidity and economy impossible with the metal prototype. The same procedure is now being followed in the case of the first of two 8-foot open-jet atmospheric pressure tunnels which are projected to replace the present 7-foot No. 1 enclosed tunnel. Sanction has now been obtained for the first of these 8-foot jets which is at present in the drawing office stage, experiments with the small-scale model having been brought to a successful conclusion. From the indications of the latter, it appears that the maximum speed obtainable with the consumption of 300 h.p. will be about 190 feet per second. A novel feature of the design, so far as British practice goes, is a double return flow, with one duct above and one below the open jet—a type of construction admirably suited to the accommodation available in the existing 7-foot No. 1 tunnel room. For the second 8-foot open jet, which will be housed in the same building, a less powerful fan to absorb 100 h.p., and a maximum wind speed of 125 feet per second, are contemplated.—*Engineering.*

Hollow-Forged Steel Drums

Hollow forging might be taken to cover the production of small articles such as cartridge cases by deep drawing; tube drawing; tire rolling; and deep dishing, such as is employed in the manufacture of boiler ends. In this article, however, it is proposed only to deal with hollow forgings produced hot, either under hydraulic presses of the vertical type or in hollow rolling mills.

Some remarks may not be out of place concerning the origin and development of hollow forging. So far as I have been able to ascertain, the demand was felt some forty years ago for hollow shafting for naval vessels, and as it was not possible at that time to produce these by boring from the solid, attempts were made to hollow forge them, with considerable success. The diameters were very small, which added to the difficulty, and special precautions had always to be taken against overheating and jamming of the mandrels. Hollow forged gun barrels have also been in demand for many years, and the skill of the forgeman has been greatly developed by the manufacture of these.

Three branches of engineering are responsible for the present-day demand for large hollow vessels.

(1) *Boiler Making.*—The introduction of the Diesel engine caused turbine manufacturers to make an effort to produce a turbine power unit of an increased overall efficiency, such as would compare favourably with the Diesel engine. Speeds were already developed to a very high degree, and, as a result, the only direction in which improvement could be hoped for was an increase in pressure. The boiler maker was accordingly called upon to supply high-pressure boilers operating at pressures which, twenty years ago, were undreamed of. These pressures have now risen to, at any rate, 1,700 pounds per square inch, that is, excluding Benson boilers, and it was quite obvious that riveted construction could never prove satisfactory for such pressures. Accordingly, the demand arose, first, for seamless drums, open-ended, and arranged for riveting—in single piece dished ends—these being used for moderate pressures up to about 400 pounds per square inch—and later for single-piece seamless forged high-pressure drums.

(2) *Oil Cracking.*—The phenomenal increase in motor transport has multiplied the demand for volatile petroleum spirits to an extraordinary degree. Researches have resulted in the introduction of two methods of oil cracking, the first being known as the Dubb's process, which employs a low or moderate pressure, the second being the Cross process, which employs high pressures up to about 1,000 pounds per square inch and high temperatures up to about 900 degrees F. Information on this subject is very sparse, but it may be stated that forgings of very large size are required for the Cross process.

(3) *The Chemical Industry.*—The preparation of synthetic ammonia and dyestuffs and other chemical processes call for the manipulation of gases and liquids at high pressures and high temperatures, and this industry has made very special demands on the metallurgist and the forgeman in the production of hollow forgings in difficult alloys and often of very intricate shape.

Researches are also being conducted in various quarters on the synthesis of oils from coal. It seems probable that this process will follow the lines of the oil-cracking process, the method being to admit coal dust, or a mixture of crude oil and coal, into a chamber containing hydrogen at a very high temperature and pressure. As forgemen we must look forward to a rapid development in this class of work, as it seems that, once established, a great and increasing demand would exist for high-pressure vessels for the process—Mr. E. V. T. Ellis in *Engineering.*

Busfield, McLeod, Limited, Montreal and Toronto, are exhibiting Diesel engines, both marine and stationary types, Lux system of fire extinguishing, Permutit water treating plant, diving equipment and excavating equipment at the Canadian National Exhibition this year. Engineers should make a point of visiting the Engineering and Electrical building at the Exhibition, where they will have the opportunity of seeing the very latest developments in the way of engineering equipment.

DEPARTMENT OF RAILWAYS AND CANALS

WELLAND SHIP CANAL

PILE DOCK AND TURNING BASIN AT WESTCHESTER AVENUE, ST. CATHARINES, ONT.

Notice to Contractors

SEALED TENDERS, addressed to the undersigned and marked "Tender for Pile Dock and Turning Basin at St. Catharines, Ont.," will be received at this office until 12 o'clock noon (standard time) on Tuesday, September 15, 1931.

Plan, specifications and form of contract to be entered into can be seen at the office of the Chief Engineer, Department of Railways and Canals, Ottawa, and at the office of the Engineer-in-Charge, Welland Ship Canal, St. Catharines, Ont.

Copies of plan and specifications may be obtained from the Department at Ottawa, or from the Engineer-in-Charge, Welland Ship Canal, St. Catharines, Ont., on payment of the sum of Twenty-five ($25.00) Dollars. To bona fide tenderers, this amount will be refunded upon the return of the above in good condition.

An accepted bank cheque, on a chartered bank of Canada, for a sum not less than ten per cent (10%) of the contractor's tender, and made payable to the order of the Department of Railways and Canals must accompany each tender. Bonds of the Dominion of Canada, or Canadian National Railways Bonds, guaranteed by the Dominion of Canada, may be used in lieu of or in conjunction with such accepted cheque. In any case, the sum so deposited will be forfeited, if the party tendering declines to enter into contract for the work at rates stated in the offer submitted.

Cheques and bonds thus sent in will be returned to the respective contractors whose tenders are not accepted.

The cheque and/or bonds of the successful tenderer will be held as security or part security for the fulfilment of the contract into which he enters.

The lowest or any tender not necessarily accepted.

By order,

J. W. PUGSLEY,
Secretary.

Department of Railways and Canals,
Ottawa, August 27, 1931.

New Fire Alarm Headquarters of the City of Montreal

C. J. Desbaillets, M.E.I.C.,

Chief Engineer, Montreal Water Board, Montreal, Que.

Presented before the Montreal Branch of The Engineering Institute of Canada, April 23rd, 1931.

SUMMARY.—The fire alarm system of the city of Montreal has developed with the growth of the city, and its present form, equipment and operation are discussed in this paper. The system now installed is of the most modern type, in which the alarm from one box is effective even though an alarm from another box is being sounded simultaneously, and includes complete arrangements for recording and repeating to the fire engine houses all signals received from the street boxes, for locating trouble, and for duplicate service in emergency.

This paper describes the new fire alarm headquarters which the city of Montreal is now building on Fletchers' Field.

The present fire alarm headquarters are located on Ontario street in the upper storey of the fire alarm station. It contains apparatus of an older design and can only accommodate a maximum of sixty circuits.

This was quite sufficient for Montreal when the city had a population of from three to four hundred thousand people, but due to the rapid growth of the city and in order to make provision for future extension and requirements, the present station was found to be absolutely inadequate. Therefore, in November, 1929, it was decided to build a new fire alarm headquarters along modern lines, both building and equipment to be of the latest design.

It will be realized that with such an important service as the fire protection of city property it is necessary that the new construction as well as the change over in operation will have to be carried out without an interruption in service.

Extensive studies have been made in order to use as much of the existing conduit and cable system as possible. With this in view, the most economical location for the new central station was found to be on Bleury-Park avenue between Craig street and Mount-Royal avenue, as all the present cables enter or cross this north-south line at some point between Craig and Mount-Royal. Some of the cables now feeding the northern half of the city will only need to come to Fletchers' Field and the existing runs of cables from Fletchers' Field to the present old central station will be used to extend some of the existing cables now feeding the southern half of the city. This re-grouping and re-connection work naturally involved the re-designing of certain parts of the underground conduit system as well as additions to the same system, but this distribution circuit will not be gone in detail into as the object of this paper is mainly to describe what a fire alarm system consists of and how the alarms are conveyed from the box to the operators and in turn transmitted to the various fire stations, some forty-six in number.

As these circuits have to be maintained in good condition throughout the year under any climatic conditions, and as trouble in any point of the distribution system has to be determined and remedied in the shortest possible time, it will be seen from the following description of the equipment that a good deal of thought has been given to methods of quickly detecting trouble, and that these have influenced and actually become part of the equipment.

The paper is in two parts:—

(*a*) A description of the fire alarm equipment.

(*b*) A brief description of the building in which it is installed.

Description of Fire Alarm Equipment

General

A fire alarm system consists of a number of street boxes arranged in a series closed circuit, fed by a source of direct current, into which are connected bells and lamps, located at the central station, these for the purpose of receiving, audibly and visually, signals transmitted from the boxes. In a completely manual system, equipment is provided at the central station for repeating manually on the circuits through the fire engine houses, all fire alarm signals received from the street boxes. Equipment for the recording and dating of signals, received or transmitted, and for the protection of the apparatus, is also provided.

Storage Battery Switchboard

On entering the operating room on the ground floor of the new fire alarm headquarters, a row of switchboards is seen facing the walls. These are for controlling the charge and discharge of the storage batteries necessary for the operation of the system. There are twenty-four of these boards, each with a capacity of ten duplicate sets of batteries, and each provides means for the charging of one set of batteries in series, or in series-multiple combinations,

In a demonstration of the equipment used for the reception and transmission of alarms, the author was assisted by Mr. Charest, Superintendent of the Department of Signals and Alarms, and Mr. Chaussee, Assistant Engineer in the same department.

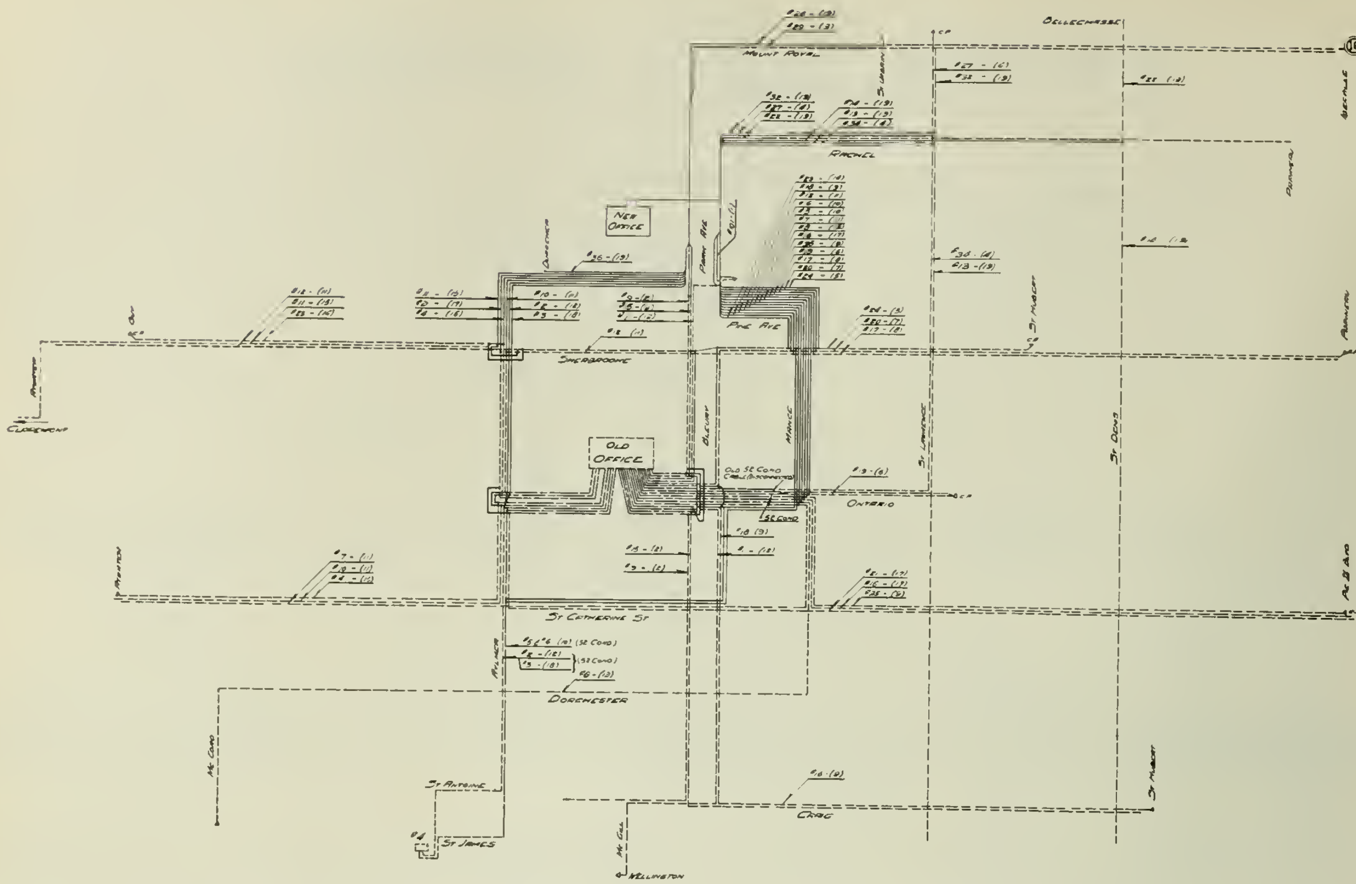

Fig. 1—Cable Layout—Connections from Old Stations to New Central Station.

while the other set is discharging on the line. Each circuit is provided with its own separate battery called "A," and with a duplicate set called "B," so as to provide for maximum safety in operation. Should a circuit develop trouble due to grounds, or short-circuited cells, only this circuit is affected, thus causing not more than twenty boxes to be temporarily out of commission. In the case of short-circuited or broken cells in a battery, the switching over of the circuit on to the duplicate set would allow for the immediate resumption of the service while the first set was being put back into shape. On each of these switchboards meters are provided to take readings on each battery, its condition of charge and discharge. Facilities are also provided to adjust at their normal values the electrical characteristics of either the charge or the discharge of each battery. The total capacity of these boards, that is two hundred and forty circuits, provides for one hundred and thirty box circuits, twenty primary alarm circuits, twenty secondary alarm circuits, forty locals and thirty spare circuits. Behind these boards and inside the metal cabinets enclosing them are seven small panels at which all the leads from the storage battery switchboards and from the storage battery racks terminate to provide for cross-connections. This is advantageous in that when new batteries for a circuit are to be set up or when replacing old ones, the transfer of the circuit connections is done at these panels instead of on the main boards.

Main Line Relay Boards

At the back of these boards, six feet away from them and facing the centre of the room on the south side, are the main line relay boards, each of five circuits capacity, and are for the box circuits, the primary alarm circuits, and the secondary alarm circuits. Each of these circuits consists principally of a main line relay, a tap bell, and a lamp mounted behind a bull's-eye, wired into a closed circuit with the street boxes. When a fire alarm box is pulled for "fire," the circuit is opened a number of times, this corresponding to the number of the box. Every time the circuit is opened, the armature of the main line relay is released thus closing a pair of contacts which control the lamp and cause it to flash, and also a second pair of contacts which control the registers. At the same time, the armature of the tap bell is released thus causing the hammer to strike a gong. For each opening of the circuit there is a flash on the lamp and a blow on the gong, thus providing visual and audible means of receiving signals. Both means are provided in case two or more alarms on different circuits are received at the central office at the same time. When such occasions arise the bells are usually cut out of circuit by means of a suitable switch to prevent confusion in counting the blows, and the flashes on the lamp are counted by the attendants. A check on the signals received is made on the registers which will be described in one of the following paragraphs. In addition to the apparatus described, each circuit is provided with a high-low current relay and a pilot lamp. This relay is so adjusted that when the normal line current of 100 milliamperes falls below 80 or rises above 120 milliamperes, the relay causes the closure of a pair of contacts which close a local circuit through the pilot lamp and through a trouble bell common to all circuits, as an indication of trouble. A suitable cut-off key allows for the cutting off of the trouble bell, but the pilot lamp remains lighted until the trouble is cleared. Other keys furnish means for cutting out of circuit any auxiliary apparatus, such as the common register, the main register, etc. These keys are suitably marked to designate their functions. A jack is provided for each circuit to enable the operators to plug into the circuit either a register, a meter or a telephone set when tests are being carried out on the line. The primary alarm boards

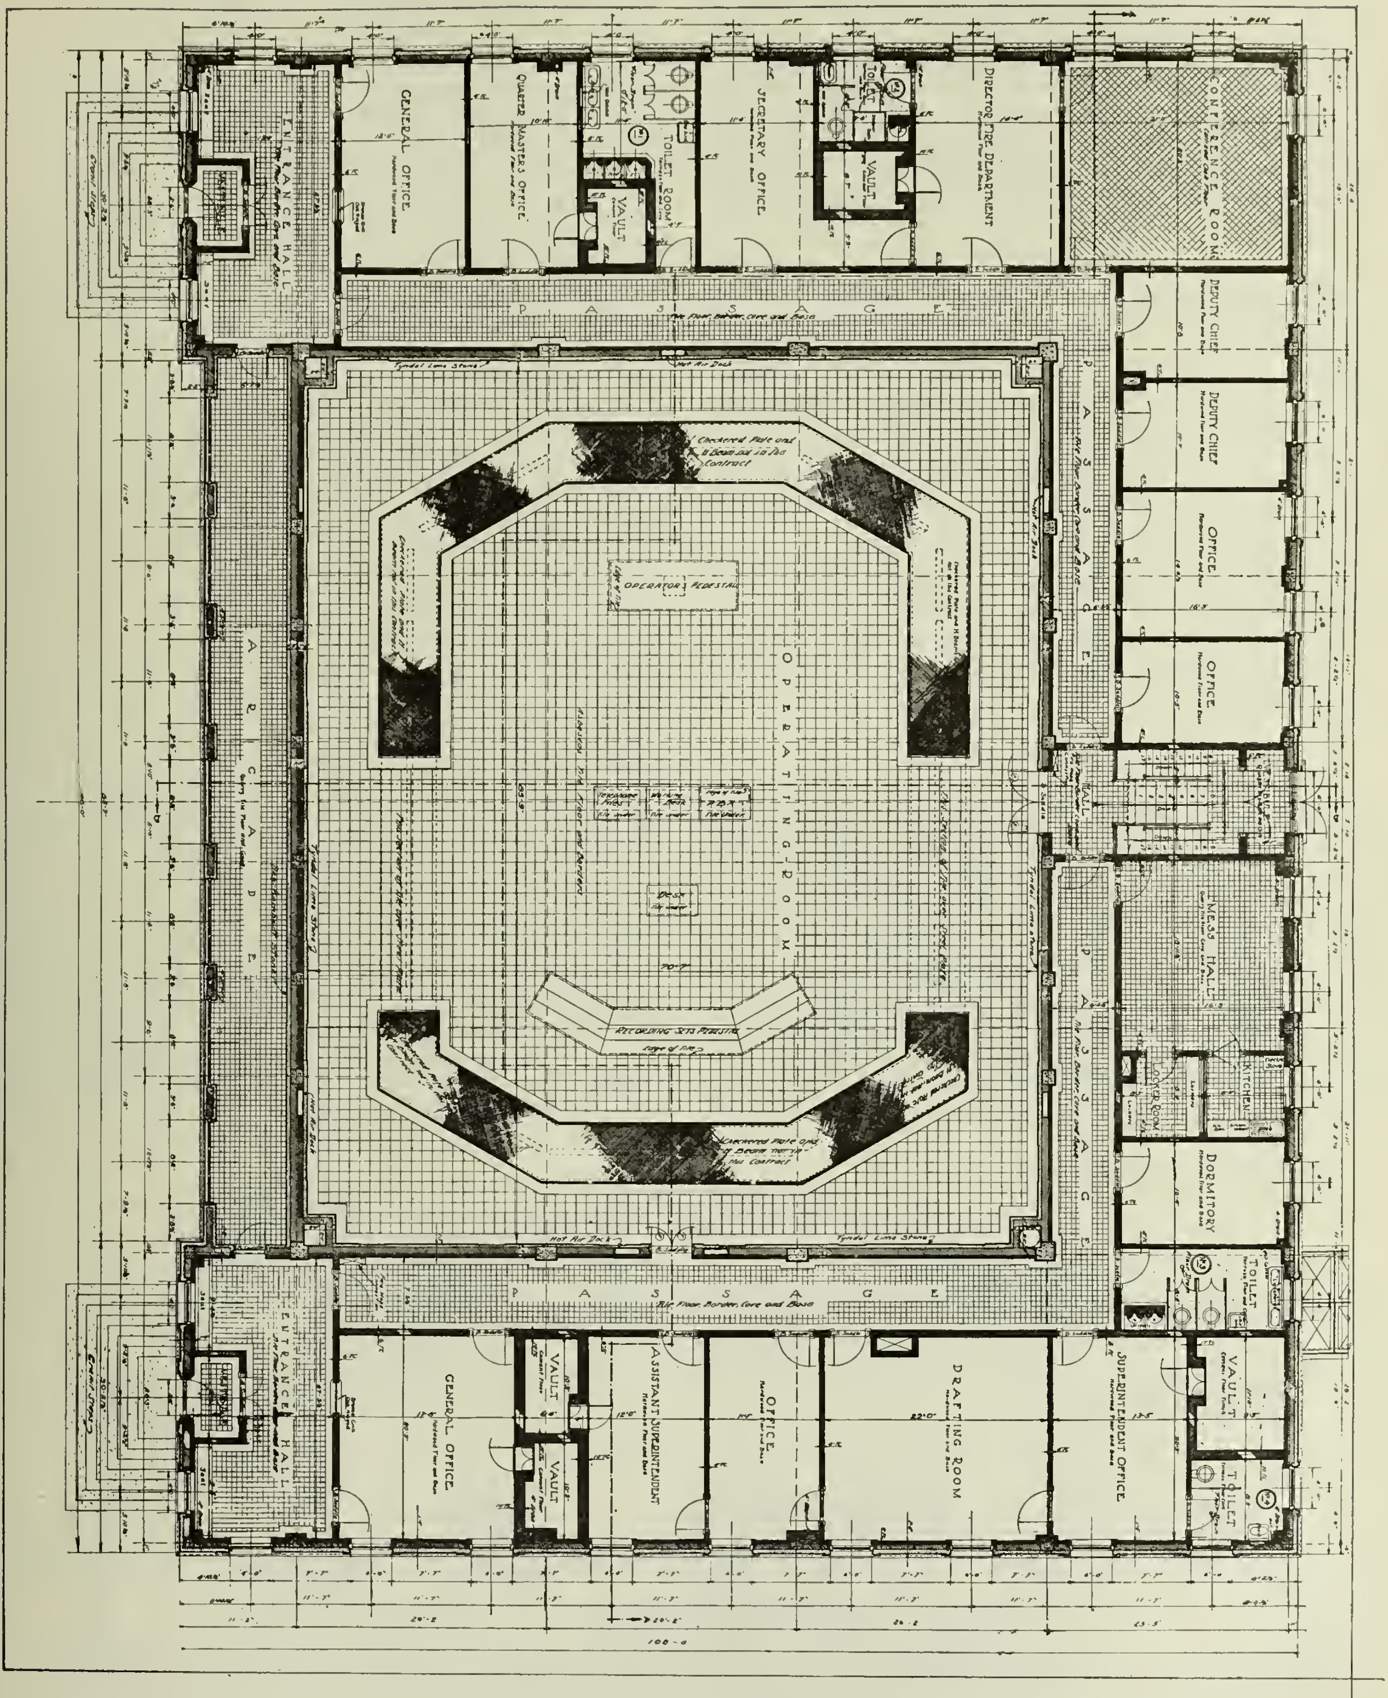

Fig. 2—Ground Floor Plan.

provide facilities for circuits through the fire engine houses for the transmission of signals at one-half second interval between blows, and the secondary alarm boards provide facilities for circuit through the fire engine houses for the transmission of signals also at three-quarter second interval between blows. These boards differ from the box boards only in the colour of the bull's-eye, which is red for the box line circuits, green for the primary alarm circuits, and amber for the secondary alarm circuits. On each is painted the number of the circuit. Power for the lamp in the bull's-eye is provided from the lighting service through a transformer.

Protector Board

The protector board is located at the north end of the operating room and facing the relay boards. On it is mounted for each side of each line circuit the necessary apparatus for the protection of the central station equipment, that is, a first fuse of a capacity of ½ ampere for protection against sneak currents, a second fuse of a capacity of 3 amperes at 2,000 volts for protection against heavy currents due to crosses between the fire alarm wires and high tension wires, and a lightning arrester for protection against lightning.

The central panel of this board is equipped with a voltmeter and with the necessary switches to provide means for taking voltmeter readings between the two sides of a circuit, or between either side of a circuit and ground.

In front of these various switchboards are two pedestals, one for the registers and the other called the operator's pedestal.

Recording Set Pedestal

The recording set pedestal has mounted thereon thirty-five registers, each of five circuits capacity, and thirty-five paper take-up reels. Every time a fire signal is transmitted from a street box, the main line relay is actuated as described above, thus closing the second pair of contacts on its armature a number of times corresponding to the box number. Every time these contacts come together, a local circuit through a register is closed, thus causing a puncturing blade in the register to puncture a triangular hole in a moving strip of paper. Thus, if box number 3912 be pulled for fire, the blade would puncture in the paper three holes, about one-half inch apart followed by a blank strip of paper, then nine holes about one-half inch apart followed by a blank strip, a single hole followed by a blank strip of paper and then two holes about one-half inch apart followed by a blank strip of paper longer than the first three, and then the same series of holes and blanks three times over. In other words, each box repeats its number four times and a corresponding number of series of holes with blank intervals is punctured in the paper. The holes are punctured in such a way as to prevent reverse readings. One blade is provided for each individual line circuit and the register is so designed that the blades operate independently. It would be possible to receive fire signals from five different circuits at the same time on the same register and the series of holes would appear in five neat rows, one above the other, on the same strip of paper. The paper take-up reel is set in motion as soon as the register starts operating and merely winds the paper tape on a drum.

Operator's Pedestal

The operator's pedestal is one of the main features of the central station equipment, as it provides means for manually transmitting through the engine houses all fire signals received from street boxes. On this pedestal are mounted two common recording sets, each consisting of a register, a take-up reel, and a time and date stamp. All signals received at the central office are recorded on one of the individual registers as described in the preceding paragraph, and also in the same manner on one of the common registers. At the end of a series of signals, the magnets of the time and date stamp are energized, thus causing to be printed on the paper tape the hour and the minute, and the day, the month and the year, that the signal was received. This device takes care of long and short months, also of leap years. The time magnets are controlled by a master clock mounted in the superintendent's office, which closes a local circuit once every minute, thus advancing the minute wheel one notch. This wheel controls the hour wheel, which in turn controls the day wheel, this one in turn the month, and the month wheel controls the year wheel. This arrangement enables the operator to check on the tape any fire signal received. On each side is a transmitter so arranged that the operator by means of dials can set up the number of the street box transmitting a fire signal. When the number is set up, the mechanism is set in motion by means of a lever and this causes the coded signal to be transmitted to the fire engine houses. Each signal is repeated two, three or four times as desired by the

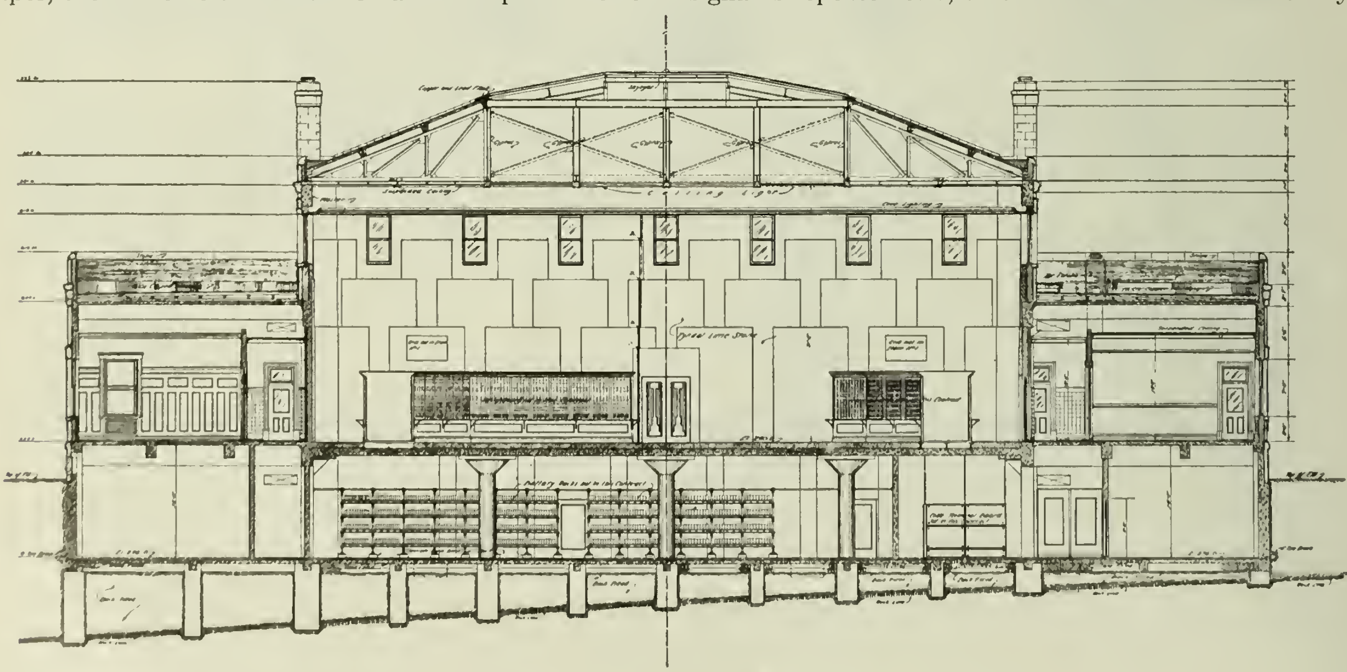

Fig. 3—Longitudinal Section.

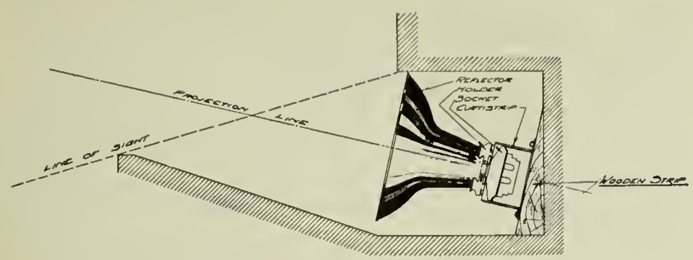

Fig. 4—Cove Light.

operator, and is received at the fire engine houses on a small bell and on a register. As soon as this first transmitter comes to rest the second one, on which the same coded signal has been set, is started by means of a lever, and the signal is caused to be repeated on a big gong in the fire engine houses, on a gong in the police stations and other public places such as newspaper offices. On this pedestal are also mounted two multiple telegraph keys to stop the transmission of signals by the transmitters in case of error in setting up the coded signal, and a set of cut-off switches to cut out of the transmitter circuit any alarm circuit which is out of commission, or which should not receive certain signals.

Batteries and Racks

The above completes the description of the equipment in the operating room. The equipment in the basement will now be described. First of all the battery room houses all the storage batteries required to provide the necessary direct current power for the operation of the fire alarm system. These are arranged in duplicate sets on metal racks especially designed for the purpose, with four tiers of double shelves on each rack. The "A" batteries are installed on one side of the racks and their mates or duplicate "B" sets are installed on the other side. The batteries have a capacity of 12 ampere-hours. Should trouble develop in the operation of the low current equipment associated with the batteries, a daily check of them would bring it to light before any serious damage was done. Yet each battery has enough capacity to supply safely the necessary power to its circuit for a period of ninety-six hours should trouble develop in its duplicate set of a nature such as to require the setting up of new cells.

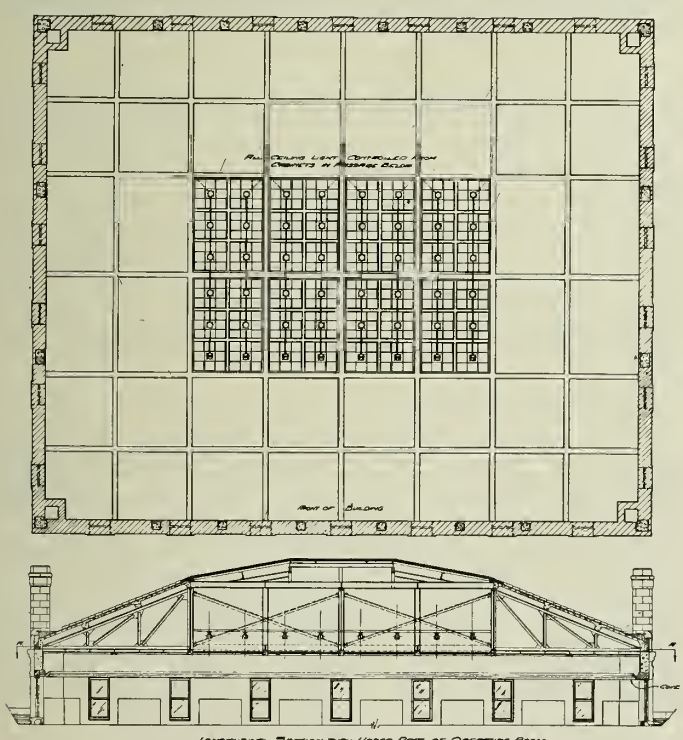

Fig. 5—Cove and Skylight Lighting System Operating Room.

Charging Equipment

In the power room is located the charging equipment for these batteries. It consists of a motor-generator set made up of an alternating current motor coupled to a shunt wound direct current generator, of a suitable size. A duplicate machine has been provided to prevent interruption of service in case of break down of the first machine. A motor control panel shall be installed on which shall be mounted the necessary control switches for the motors and the generators, fuses, generator field rheostats, and also a voltmeter and an ammeter to provide facilities for taking meter readings.

Historical Side of the Fire Alarm Department*

There is no department of municipal service which has been the subject of more thoughtful and patient experiment than that of fire alarm and this is reflected in the high state of perfection to which it has been brought in recent years.

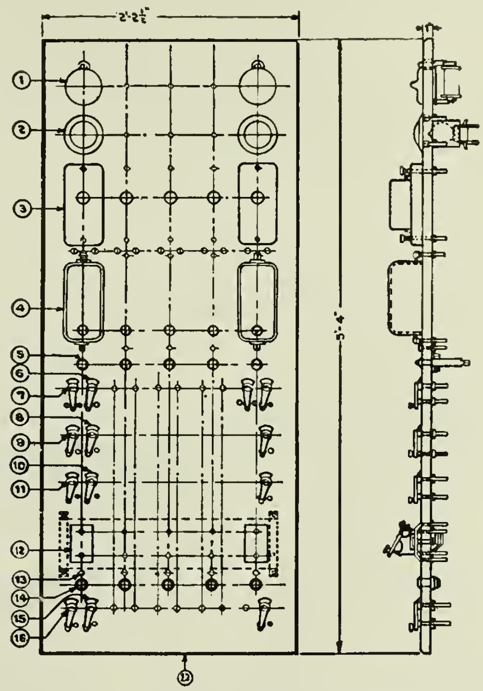

Fig. 6—Layout of Relay Board, Main Line, Primary Alarm and Secondary Alarm.

Description of Material

1, Tap Bell; 2, Red Bull's Eye Annunciator; 3, Supervisory Relay; 4, Main Line Relay; 5, Supervisory Pilot Lamp; 6, Common Register Switch; 7, Line Register Switch; 8, Annunciator Switch; 9, Main Line Relay Switch; 10, Telegraph Key Switch; 11, Tap Bell Switch; 12, Telegraph Key; 13, Number Plate; 14, Instrument Jack; 15, Trouble Bell Switch; 16, Supervisory Relay Switch; 17, White Marble Panel, 2′-2½′ × 5′-4′ × 1′.

Fifty or sixty years ago, no adequate means of locating a fire existed. On the breaking out of a fire, it took hours to bring the firemen, who were usually volunteers, to the scene of their labours. Buglers were despatched through the town to arouse the citizens and naturally it took time to collect the entire brigade. Another tremendous handicap to the effectiveness of the fire corps lay in the fact that no means existed of guiding the men to the proper locality, unless an unusually large blaze could be distinguished. The companies were thus frequently misled and precious time wasted.

*By Mr. Ls. A. Charest.

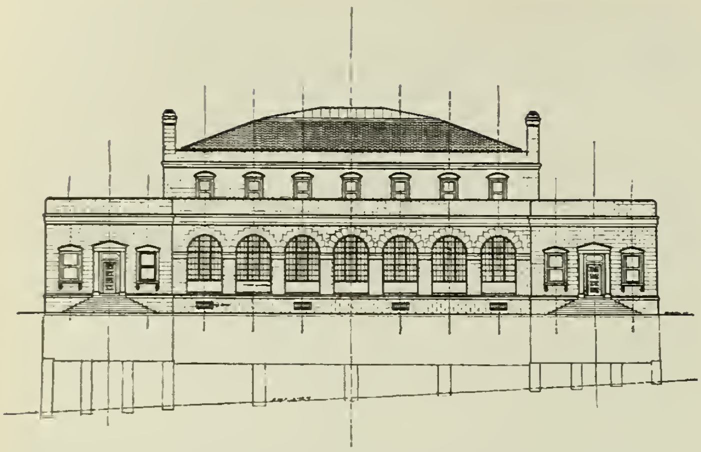

Fig. 7—Front Elevation, New Fire Alarm Central Station.

The origin of the fire alarm telegraph is due to the late Dr. W. F. Channing of Boston, who died in 1901 at the age of eighty-one, having lived to see the idea which he had given to the world brought into successful operation, he having conceived the idea of the fire alarm in 1845.

The trend of modern inventions is towards simplicity and accuracy in apparatus as opposed to the complicated fittings of former years.

No city can afford to neglect an opportunity of improving its fire alarm service, as this investment is one which never fails to pay.

The original installation of the Montreal fire alarm service was inaugurated in the year 1863 with Mr. F. Badger as its first superintendent, he having come from the city of Boston where a system was then in operation.

In March, 1909, the present system was put in operation and at that time it was planned that the system would be sufficient for the next forty years, but increased population together with annexation of bordering municipalities made conditions such that for the past few years the Department could not extend sufficiently to meet even present requirements let alone to take care of the future.

In the year 1905 the city was divided into numerical districts in order to overcome the conditions of box location, for at that time, for example, box 95 was located in the extreme eastern part of the city while 96 was located in the extreme western part. However, under the new district system, boxes 95 and 96 are located in district 9 and this relation is maintained throughout.

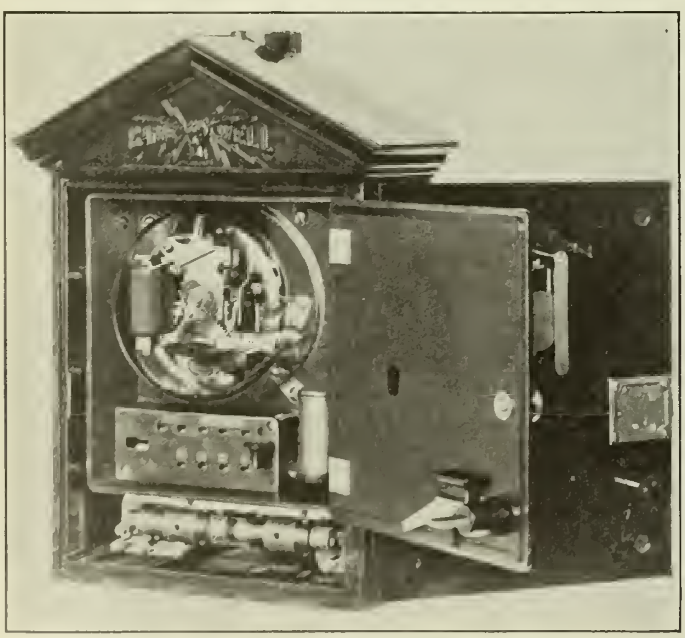

Fig. 8—Positive Non-Interfering Successive Alarm.

At present the city has three types of fire alarm boxes, the old sector type, the non-interfering type and the positive non-interfering successive type; the sector and non-interfering boxes have for various reasons been condemned, as not being capable of giving adequate security to the citizens of the city.

A Comparison of the Three Types of Boxes

"Sector."

This type of box was constructed in such a simple way that when two or more of them were pulled at the same time, on the same circuit, it caused such a confusion of signals that only a conglomeration of blows were received at the central office, resulting in no definite number being given, consequently, no direct location of the fire could be transmitted to the fire department.

"Non-Interfering."

Many years elapsed before the next modern improvement took place, in what became known as the "Non-Interfering-Type." This improvement made possible the receiving of a first alarm as well as succeeding ones, providing there was no open circuit and the outside door of the box was closed before attempting to give the alarm, as these two points were absolutely essential to the successful operation of the alarm. If the outside door of one of these boxes was open or ajar when a person attempted to give the alarm, especially if another box on the same circuit had been pulled a few seconds previously, no alarm could be given due to the non-interfering feature of this particular box having been interrupted when the operation of the first box took place with the outside door contact removed from its normal position. However, this type of box was later improved as it did not give the citizens the entire security and reliability necessary for the protection of life and property.

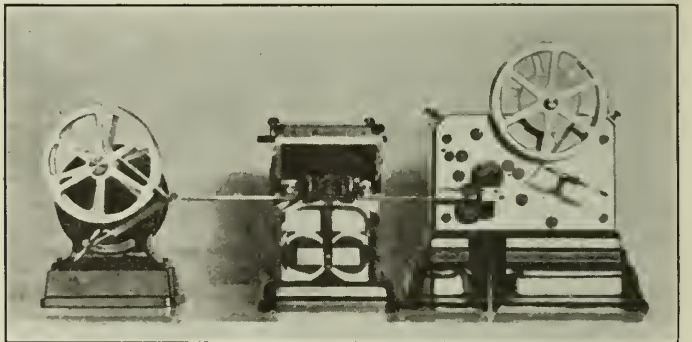

Fig. 9—Date Stamp—Operator's Pedestal.

"Positive Non-Interfering."

The latest and most modern improved fire alarm box is the "Positive Non-Interfering Successive" type. This is so constructed as to be not only non-interfering in its make-up, but it can also be used by citizens in giving additional alarms from other boxes on the same circuit even though a previous box has the right of way in sending in its alarm and this without any further manipulation of either box on their part. Each succeeding box pulled, after a first is set in motion will follow automatically due to the successive feature of its equipment.

The three different types of boxes may be briefly explained as follows:

Sector Box: An alarm from this type of box *may* be received from it providing no other box is set in motion on the same circuit.

Non-Interfering Box: An alarm *will* be received from it even though another box is pulled on the same circuit.

Positive Non-Interfering Successive: An alarm from this box *will not only be received but also any others pulled on the same circuit even though a previous box is then sounding its alarm; that is to say, each one will come in automatically when the previous right-of-way box has concluded its own signal.*

There is an additional feature to this latter type in that should an accident to the box take place, it would not prevent signals from other boxes on the same circuit being received.

Demonstration

The following is an illustration of what happens between the time the lever of fire alarm box number 3912 is pulled and the time at which the fire engines reach the street corner where the box is located.

As soon as the starting lever of the fire alarm box is pulled the mechanism is released, thus allowing a wheel in the box about one inch in diameter to rotate around its axis. On the rim of this wheel are a number of protruding teeth, first of all three close together, then a space, then nine more teeth, another space, then one tooth, another space, then two more teeth, and finally a long space. This gives the number of the box thus, 3-9-1-2. There is a definite relation between the space from the top of one tooth to that of the adjoining one, the space between digits, and the long space at the end. No matter what the number of the box may be, the governor of the mechanism is so set that the time taken to travel between the top of two consecutive teeth is always the same, viz., three-quarters of a second. Just over these teeth a pair of springs are located so that the teeth of the wheel will travel under them and will cause one of the springs to fall in the hollow of a tooth, thus opening the circuit. As soon as this happens, the relay in the circuit of this box on the main line relay boards in the central station will be de-energized, thus causing its armature to fall away and close a number of local circuits, and immediately the lamp of the bull's-eye in the central station is lighted and a blow is struck on the bell of the circuit. These operations are repeated for each and every tooth on the wheel. The number 3912 is flashed on the lamp and at the same time struck on the bell, registered on the paper tape of its register on the recording set pedestal, and also on one of the common registers of the operator's pedestal. This operation is repeated four times. When the first blow is struck on the bell, the operator in charge rushes to the operator's pedestal while counting the blows on the bell or the flashes of the lamp. When the round is completed he checks the number on the tape of the common register and sets the same number of the transmitter to the left of the pedestal and then calls it out to his assistant who is now standing at the recording set pedestal. This man checks the number given to him with the number punctured in the tape of the individual register and if found correct, shouts "O.K." The first operator after counting the blows or the flashes of the second round to be sure that the correct number has been received, presses down the starting lever of the transmitter. This releases the mechanism and causes the number 3912 to be transmitted over the primary alarm circuit boards to the fire engine houses, where it is struck on a small bell usually located in the office of the floor man. While this is going on the operator in the central station sets the same number on the second transmitter and as soon as the two rounds of the first transmitter are completed, starts the second one. This causes the alarm to be transmitted over the secondary alarm circuit boards through the fire engine houses, the police stations, etc., where it is struck on a large gong. All these alarms transmitted from the central station are recorded on the tape of the alarm registers and on one of the common registers.

The floor man of an engine house in the district in which the fire alarm box is located immediately causes the local gongs in the engine house to strike and, while the men are getting the apparatus ready, checks the number as counted off the bell with the number punctured in the tape. As soon as the second round is received and he is then positive of the number of the box, he calls the number out to the officer in charge as well as its location. The engines then pull out of the station and proceed to the box.

Elimination of Taste in Water Passing Through Creosoted Wood Stave Pipe

J. F. Harkom, A.M.E.I.C.,
Chief, Division of Wood Preservation, Forest Products Laboratories of Canada, Ottawa,
and
C. Greaves,
Chemist, Division of Wood Preservation, Forest Products Laboratories of Canada, Ottawa.

SUMMARY.—This paper presents the results of an investigation as to the probable results in passing potable water through a very long pipe line of creosoted wood stave construction, having regard to the possibility of objectionable taste arising from the creosote.

Creosoted wood stave pipe provides a very economical means for supplying drinking water to towns and cities. Many such pipe lines have been constructed, and from such reports as have been obtained, the following conclusions are drawn:

(1) The pipes should be flushed out for a considerable time before use—from one and a half to two months.

(2) If no chlorine is used, no complaints as to bad tastes are received.

(3) If the water is chlorinated, in many cases bad tastes are produced, these tastes gradually becoming less pronounced until finally—after in some cases nearly a year—there is no noticeably bad taste.

The Forest Products Laboratories, Forest Service, Department of the Interior, were requested to investigate the possibility of using creosoted wood stave pipe for conveying water up to a distance of about 100 miles. For this length of pipe line it is calculated that the approximate time the water would take to travel the length of the pipe would be slightly more than one week. No information is available for pipe lines of such great length which offer such exceptional opportunities for contamination with creosote. In such long pipe lines it is quite possible that conditions would be so severe that bad tastes would continue for considerably longer periods than has been the case in shorter lines which have been built.

Bad tastes, in water that has been chlorinated, have been experienced by many water-distributing concerns, and considerable experimental work has been carried out to determine the cause. It is believed that the presence of one or more of many substances may cause the bad, so-called "iodoform," taste of water. It has been clearly shown by several workers—see Howard and Thompson*—that phenol and phenolic bodies cause very bad tastes. Now the identity of all the substances present in a sample of normal Grade I creosote has never been established, but it is known that a considerable portion of the creosote consists of what are known as "tar acids," which are of a phenol-like nature. It is very probable that the tar acids are the main cause of the bad taste in creosoted wood pipe lines. However, it is likely that the other constituents of creosote also contribute in a smaller degree. Hence it seemed advisable to make experiments with a special creosote which contained only a small quantity of tar acids, as well as with ordinary creosote conforming to the specifications of the American Railway Engineering Association for Grade I creosote oil.

It has also been shown by Howard and Thompson that the bad, chlorophenol taste in chlorinated water can be removed by a superchlorination treatment. In this treatment the water, after filtration, is given an excessively large dose of chlorine—at least 1 to 2 p.p.m.—the taste-producing substances being destroyed by the chemical action of the chlorine. After the chlorine has been in contact with the water for the necessary period, determined by laboratory experiments, the excess chlorine which would give a disagreeable taste to the water, is removed by the addition of sulphur dioxide.

Tests were carried out on water containing small quantities of creosote in solution, and also on water which had been stored in creosoted wooden pails.

Experimental Work

The analyses of the two grades of creosote used are given in Table I. The Grade I creosote is such as is ordinarily used in treating plants in Canada, and the special creosote was the same as the Grade I creosote with the low-boiling fractions removed. The removal of the low-boiling fractions reduces considerably the percentage of tar acids present.

In the experiments carried out with water containing small quantities of creosote in solution, it was found that:

(1) Water containing 3 parts per million of Grade I creosote oil and 5 p.p.m. of the special creosote could be rendered palatable by a process of superchlorination followed by dechlorination with sulphur dioxide.

(2) Confirming the findings of previous workers, the higher the concentrations of chlorine used for superchlorination, the shorter the contact period required. From the tests, the best contact period appeared to be 24 hours when using 2 to 3 p.p.m. of chlorine on water containing 0.50 p.p.m. creosote.

(3) The length of the contact period of the sulphur dioxide was of no importance.

*Jour. New Eng. Water Works Assoc., Vol. 40, 276-296, 1926.

Table I

Analysis of Grade I creosote

Using the specifications for creosote analysis issued by the American Wood Preservers' Association, the following results were obtained:

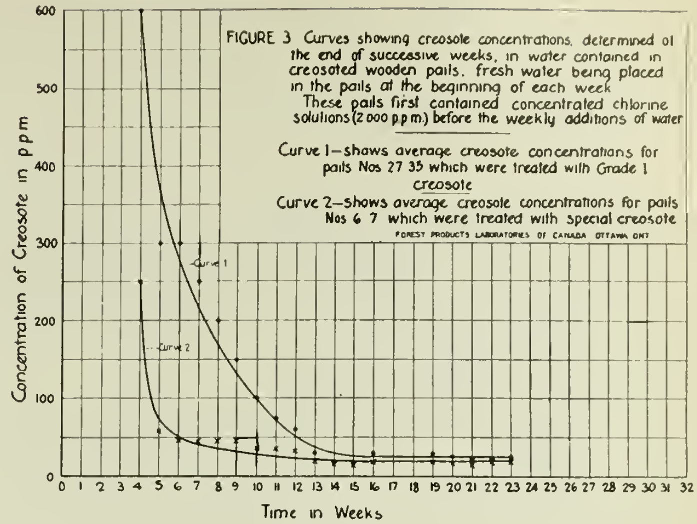

Fig. 3.

of wooden pails were creosoted, some with the Grade I creosote, and some with the special creosote. The pails were impregnated under pressure, using the Rueping process. Details of the creosote treatments are given in Table II.

The procedure adopted was to allow the pails to stand filled with water for one week, and then determine the percentage of creosote in the water in parts per million. The pails were then filled with fresh water and allowed to stand for another week. Fig. 1 shows the percentage of creosote found in pails containing Ottawa tap water up to and including thirty-one weeks. Fig. 2 shows the same information for water which was chlorinated with 6 p.p.m. of chlorine before being placed in the pails. These tests were carried out for twenty-three weeks. Fig. 3 gives the results of tests on pails which had been filled with concentrated chlorine solutions (2,000 p.p.m.) before the weekly additions of the water. It will be noted that in all cases, the special creosote caused less contamination than ordinary creosote.

Chlorinating the water with 6 p.p.m. of chlorine before it was placed in the pails greatly increases the contamina-

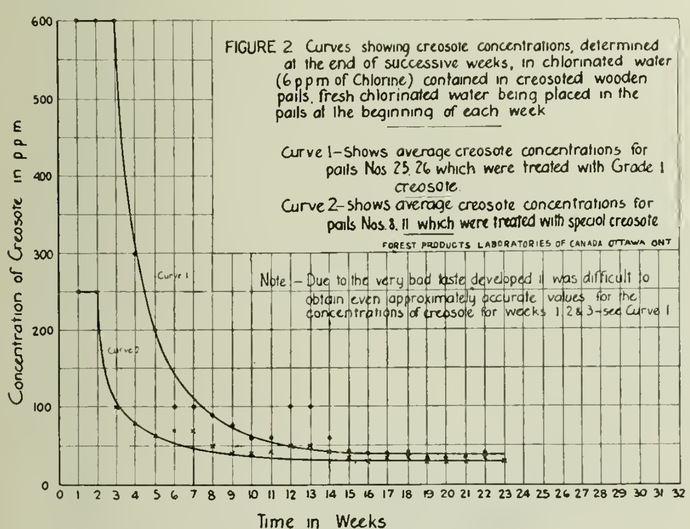

Fig. 2.

tion for the first twelve weeks, as shown in Fig. 2, and from that point on, the contamination is slightly greater than when untreated water is used. There would be no advantage in flushing pipes with highly concentrated chlorine solutions, judging from the results given in Fig. 3.

It should be emphasized that the concentrations of creosote shown in Figs. 1, 2 and 3 are only approximate. The method used to determine the percentage of creosote in the water was as follows:

It had been found that for Grade I creosote, the highest concentration that was rendered drinkable by superchlorination was 3 p.p.m., and for the special creosote, 5 p.p.m. In order to determine the concentration of creosote in any particular sample of pail water, a mixture was made up of Ottawa tap water and 1, 5, 10, etc. percent of the pail water. By assuming that the highest percentage of the mixture that can be rendered drinkable by superchlorination and dechlorination contains 3 p.p.m. of Grade I creosote or 5 p.p.m. of special creosote, the concentration of creosote in the pail water can be calculated. This assumption is not strictly tenable, as the creosote dissolved in the pail water is not necessarily of the same composition as the original creosote used for the pail, and creosotes of different compositions probably produce different tastes in water containing the same concentration.

As shown by Figs. 1, 2 and 3, the concentrations of creosote in water stored in the pails were far greater than could be removed by superchlorination and dechlorination. Experiments were therefore carried out on filtering water from the pails through activated carbon. The water obtained from the pails during even the first week of the tests could be rendered palatable in spite of the high concentration of creosote, by filtering through activated carbon. The same carbon was used each week with satisfactory results as long as the tests continued, and at the end showed no signs of deterioration. The water could be chlorinated with 0.25 p.p.m. of chlorine after filtering, without producing an objectionable taste. A total of 600 litres of contaminated water was passed through 250 grammes of activated carbon without destroying the effectiveness of the filter, but this, of course, does not give an indication of the cost of using activated carbon on a commercial scale.

Conclusions

It is considered that filtration tests should be continued to determine the cost of using activated carbon, since there does not appear to be any prospect of obtaining satisfactory taste removal by superchlorination followed by dechlorination.

The Canadian Torpedo-Boat Destroyers *Saguenay* and *Skeena*

We are indebted to "Engineering" for material for the following article and for permission to reproduce Figs. 2 to 8. Additional information and the photograph in Fig. 1 were kindly supplied by the Department of National Defence, Ottawa.

The list of vessels of the Royal Canadian Navy has recently been increased by the arrival in Canada of two new destroyers, H.M.C.SS. *Saguenay* and *Skeena*. These ships were ordered by the Canadian government, in February, 1929, from Messrs. John I. Thornycroft and Company, Ltd., Woolston Works, Southampton, after a number of competitive tenders had been examined.

The *Saguenay* was launched in July, 1930, and the *Skeena* in the following October. Satisfactory steam trials of both ships were run on the Clyde early in 1931. The former vessel was completed and delivered on May 21st, 1931, and the latter on the 9th June. Both ships left Portsmouth in company on the 25th June for Halifax, being the first vessels of the destroyer class to cross the Atlantic direct by the northern route. It is noteworthy that on arrival in Halifax the ships had used less than half of their oil fuel supply. All the officers, and with a few exceptions, the ratings manning these ships, are Canadians. The Assistant Canadian Overseer for building, Engineer Commander G. L. Stephens, R.C.N., M.E.I.C., is now Engineer Officer of H.M.C.S. *Skeena*.

Consideration of the conditions of service obtaining in Canada led to some modifications in the design when contrasted with standard British construction. The climatic conditions under which the vessels will operate are extreme, viz.: from the sub-zero of northern regions to the tropical temperatures of the West Indies.

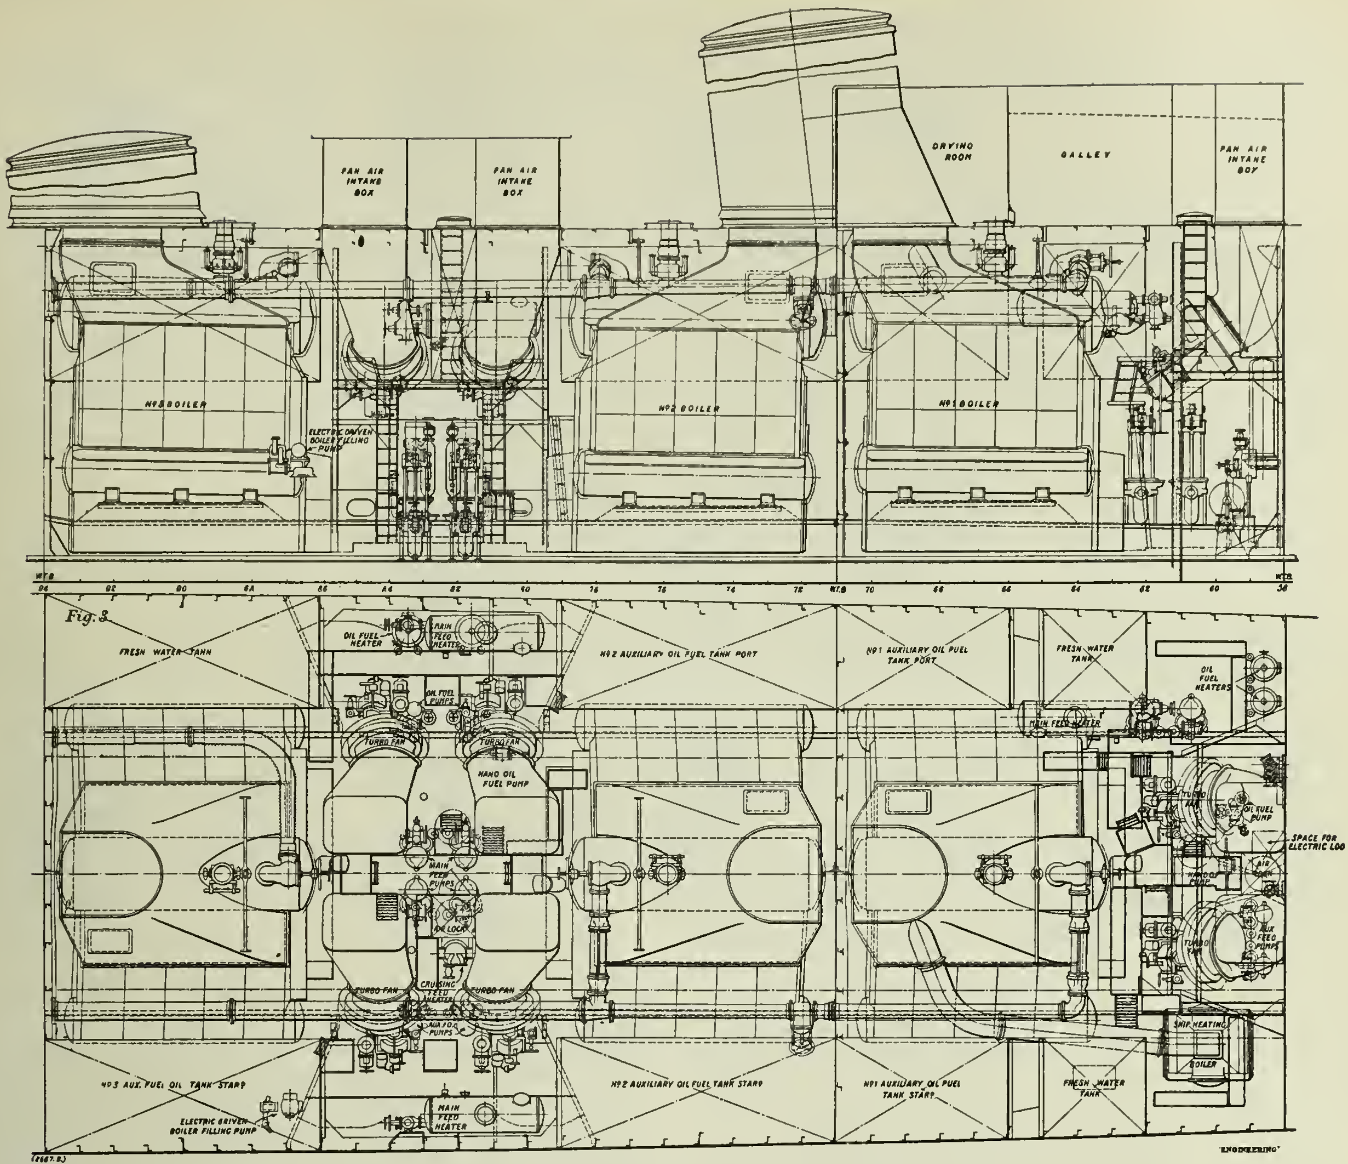
Winter service in northern waters implies accumulation of ice, not only in the water in which the vessel is floating, but also on her upper decks, bridges, rigging, etc., and this, in turn, involves both heavier scantlings and an increased degree of stability. The extreme cold also, bearing in mind the arrangement of the accommodation of a destroyer, has necessitated the provision of a somewhat elaborate heating system. On the other hand, periods of service in a hot climate have made imperative an equally complete ventilating system, ice-cupboards, shower baths, etc. Such provisions, though they have had some effect on the structure and machinery lay-out, have had yet more on the living accommodation. This, moreover, is extraordinarily spacious and well-found, the officers' cabins, for example, being not far behind those of a modern liner, while the crew is excellently berthed in distinct rooms, according to rating, and, in addition, a recreation room is provided.

The departures from recent Admiralty design on the part of the technical officers of the Canadian Naval Service to meet their particular requirements have necessitated modifications of standard practice which Messrs. Thornycroft have skillfully developed, and the results show an advanced type of ship which is not only capable of service as an independent vessel, but is also suitable for operating with destroyers of the Royal Navy.

The type of destroyer selected as the basis for the *Saguenay* and *Skeena* was the *Acasta* class, and the British Admiralty assisted in ensuring that there was practical correspondence between the two types by the examination of all designs, and the supervision, in conjunction with the Canadian officials, of the material and building of the ships. The vessels, then, are very similar in dimensions, speed and armament to the corresponding British destroyers, as the following figures will show:

	H.M.C.SS. *Saguenay* and *Skeena*	Standard British vessels *Acasta* class
Length between perpendiculars.....	309 ft.	312 ft.
Length Over all.......	321 ft.	323 ft.
Breadth..............	32 ft. 6 ins.	32 ft. 3 ins.
Displacement.........	1,320 tons	1,330 tons
Designed Speed.......	35 knots	35 knots

Fig. 1—Skeena at Portsmouth, June 1931.



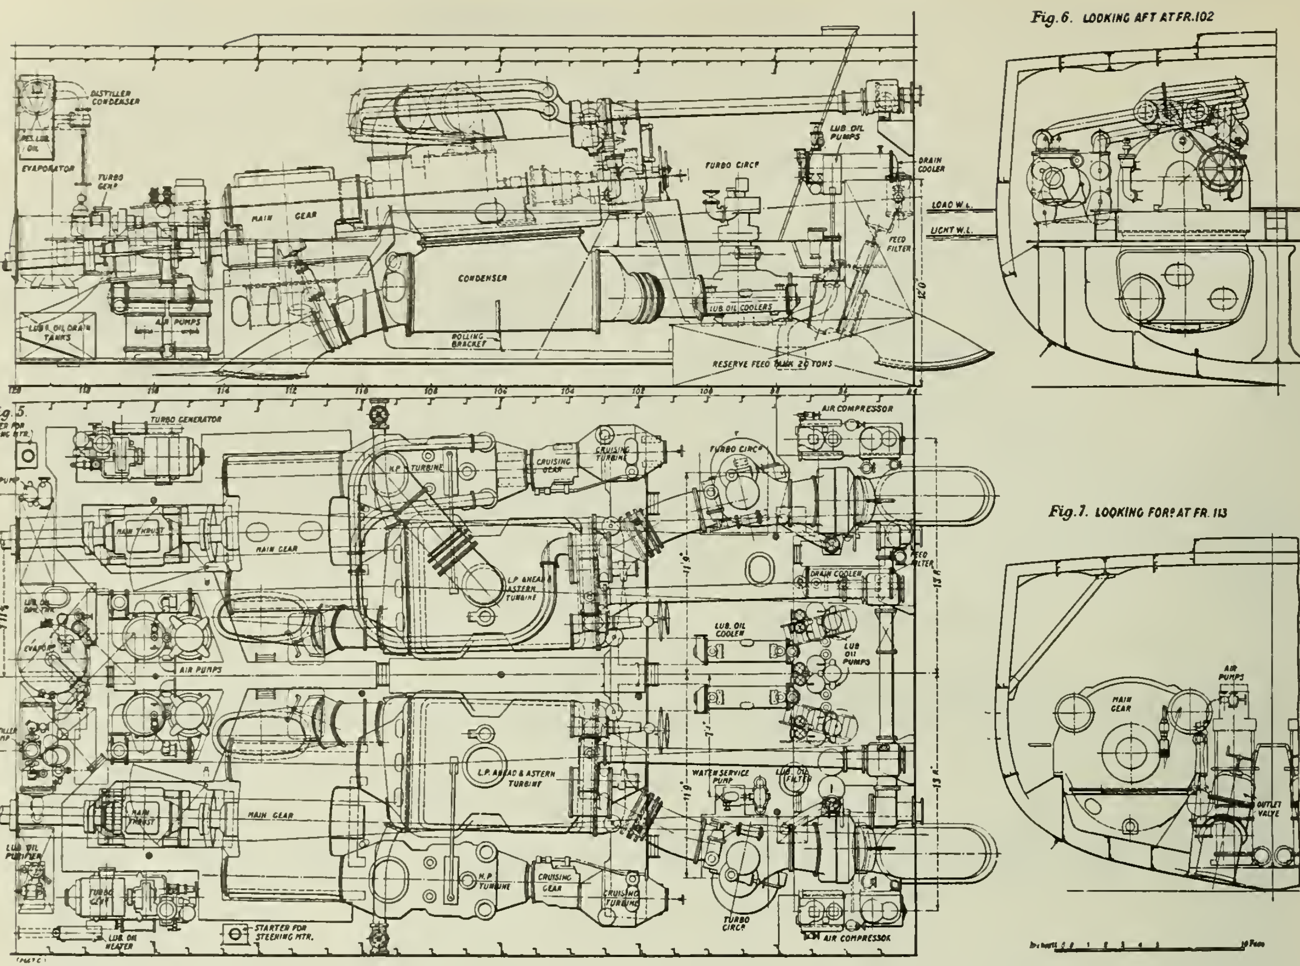
Figs. 2 and 3—Arrangement of Machinery in Boiler Rooms.

The main armament in both cases, includes four 4.7-inch guns, and eight 21-inch torpedo tubes.

The general appearance of the *Skeena* is shown in Fig. 1, taken at Portsmouth in June last. The bridge is accessible both by means of the usual external ladders from the decks and also by internal ladders communicating with the accommodation. There are two funnels and two masts, the main mast being unusually tall. This is to comply with the new International rules which lay down that a second steaming light has to be carried at a height of 15 feet above the forward light. The masts are of the steel-pole type which have proved very successful on the six Chilian destroyers recently built by Messrs. Thornycrofts. Steel masts are, as a matter of fact, becoming almost imperative as the weight of wireless gear, signalling lamps and yards increases.

The propelling machinery consists of two independent turbines arranged in a common engine room. Steam is supplied by three water-tube boilers of the Thornycroft type arranged in two boiler rooms as shown in Figs. 2 and 3. The engine-room lay-out is shown in Figs. 4 and 5 with cross sections in Figs. 6 and 7. Commencing with the boiler rooms, reference to the cross section given in Fig. 8 will show that the boilers are of the three-drum pattern. They are fitted with ten oil burners in two tiers, the burners being of the latest Admiralty pattern. The total heating surface of the three boilers is 25,600 square feet, and the working pressure is 300 pounds per square inch. There are no superheaters, it having been decided that saturated steam together with cruising turbines was the most satisfactory arrangement for the conditions of service. The forward boiler is situated in a boiler room extending aft from frame 58 to frame 71, the uptake being carried above the main deck to clear the bulkhead between the two rooms, the after one of which, extending from frame 71 to frame 94, houses two boilers. Boilers Nos. 1 and 2 share the forward funnel.

It will be clear from the several figures that the closed-stokehold system of forced draught is used, there being six turbo-fans set at an angle as shown in Fig. 8, and driven by geared turbines. Other auxiliaries situated in the boiler rooms include six main feed pumps, four auxiliary feed pumps, and three oil-fuel pumps. There are three main feed heaters which are capable of dealing with the whole of the auxiliary exhaust at all powers, and a drain cooler for taking the drain from the heaters or for use as an auxiliary condenser when the ship is in harbour. A small steam-driven centrifugal pump supplies circulating water to the drain cooler. An auxiliary boiler is provided for heating the vessel in port when the climatic conditions are severe, and is fitted in the starboard wing of the forward boiler room as shown in Fig. 3. Whilst under way, heating steam is supplied from the main boilers. The heating



Figs. 4, 5, 6 and 7—Arrangement of Machinery in Engine Room.

boiler is fired with oil by special burners, and has also a vacuum and circulating pump to ensure a good circulation. Automatic devices are fitted for regulating the temperature and oil and water supplies.

The main turbines consist of two independent units. The total horse-power developed on the official trials of the *Skeena* was about 34,500, but at this power the vessel was exceeding the guaranteed speed; thus on the measured mile a little over 36 knots was reached with 35½ knots as the average of a six hours' trial. As the machinery was not forced in any way, and it is stated that these results can be readily repeated on service, it may be taken that 34,500 h.p. is the full power output. At this load, the air pressure in the boiler rooms was 3 inches of water and the fuel-oil consumption worked out to 0.85 pound per shaft horse power hour. This result, considering the high rate of working and the fact that no superheat is employed, may be considered good.

Each turbine consists of a high-pressure cruising turbine geared to the shaft of the main high-pressure turbine, which is arranged parallel to the low-pressure turbine, both these turbines driving pinions on opposite sides of the shaft gear wheel. The gear is single reduction with double-helical teeth. At full power the high-pressure turbine runs at 3,100 r.p.m. and the low-pressure turbine at 2,100 r.p.m., the propeller shaft running at 375 r.p.m. The cruising turbines, which have two impulse wheels, can be disconnected when not required, and are designed to produce up to about 4,000 shaft horse power each.

They may, however, if inadvertently left in gear when the main turbines are running, be safely run at the full power speed. The high-pressure turbines consist of two impulse wheels followed by three reaction stages. The low pressure ahead turbine is of the Parsons double-flow reaction type. The astern turbine is incorporated in the low pressure casing and is of the impulse-reaction type.

The condensers, as will be seen in Figs. 4 and 6, are underslung from the low-pressure turbine casing; the tubes, which are of cupro-nickel, can be withdrawn in the space under the starting platform. The total cooling surface of

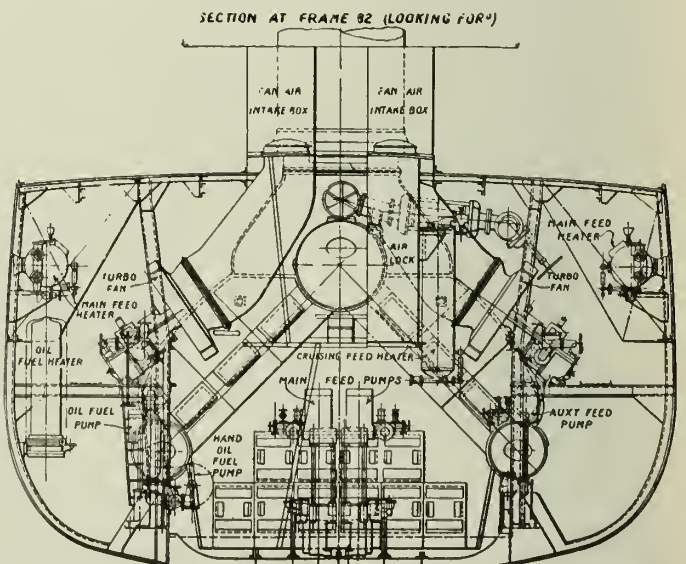


Fig. 8—Starting Platform in Engine Room.

both condensers is 12,000 square feet. The inlet and outlet connections with the hull are, as will be clear from Fig. 4, to some extent streamlined, and the outlets are situated near the centre line of the vessel, while the inlets are more in the wings, as shown in Fig. 5. This arrangement has rather a remarkable effect on the water circulation, since the full vacuum can be maintained by means of the natural flow of water as the vessel moves, without using the circulating pumps at all. This effect can be obtained with all powers up to 20,000 shaft horse power, i.e. for nearly sixty per cent of the full power. The vacuum at full power is 28½ inches and is easily maintained.

Electric current for harbour use is supplied from two 20-kw. petrol-driven generating sets. Other auxiliaries, including a 40-ton evaporator, can be identified in the several figures of the engine and boiler rooms. The steering gear is of the electro-hydraulic type. It may be said that the engine-room is not only well arranged, so that the whole of the machinery is very accessible, but is also well lighted naturally by side-lights. The first of these two points also applies to the boiler rooms, the whole of the propelling machinery forming an excellent example of modern warship layout. In the *Saguenay* and the *Skeena* the Canadian government has been supplied with two outstanding craft, and both it and the builders are to be congratulated on the results attained.

The design and construction of these ships was carried out on behalf of the Canadian government under the direction of Engineer-Commander R. C. Phillips, R.C.N., M.E.I.C., the principal technical officer of the Naval Service of Canada.

Care and Use of Explosives

E. Godfrey,

Explosives Division, Canadian Industries Limited Montreal.

Presented before the Cape Breton Branch of The Engineering Institute of Canada, October 17th, 1930.

SUMMARY.—The author treats briefly the precautions necessary in the use of explosives for various industrial purposes and the requirements for their safe storage. He also touches on the methods of drilling and spacing holes and the type of explosives required for quarrying, mining and construction work.

The use of explosives is a very live question, for if the source of practically all our industrial processes is investigated it will be found that their development was made possible through the use of explosives. It has been said that explosives are almost as indispensable as capital and labour. Every year millions of pounds of explosives are used for a great variety of purposes, and in view of the manner in which they are used or misused it is noticeable that there are surprisingly few accidents.

As sold today, commercial explosives will not explode of their own accord; they are carefully made from tested ingredients mixed in the proper proportions and thoroughly incorporated, so that the resultant mixture, when exploded, will give off certain predetermined gases, of such volume and speed that their concentrated power will be exerted on objects which it is intended to disrupt or shatter. Therefore, if it is necessary for the explosive manufacturer to exercise great care when making explosives, it is evident that care should also be taken by the consumer to see that the explosive is handled and stored in such a manner that the explosive ingredients are in no way changed, as any change will alter the characteristic of the explosive.

Storage

The addition of moisture will affect all explosives, especially the ammonia brands (practically all coal mining explosives are of this class), and cause them to become insensitive; old age has a similar effect; therefore, all explosives should be stored in well ventilated, dry, magazines and old stock always used first. Where possible, regulate the stock so that explosives over six months old will not be used. Cases of explosives should be stored right side up and piled so that a man can easily lift off the top case. Cases should not be opened in the storage magazine. When opening cases use only a wooden wedge and mallet—never iron or steel instruments. Explosives should be checked into the magazine, and on going out, and a record kept showing the quantities in stock at all times, also the persons to whom explosives are issued. The magazines should be kept clean and free from grit of all kinds, and no metallic substances should be permitted there.

Generally speaking, all results, both good and bad, from the use of explosives are directly due to either human direction or misdirection. A careful man who understands what he is handling is far safer while using explosives than he is crossing some of the busy streets of our large cities; but a careless man who knows nothing of the character of the explosives or their use is a source of danger both to himself and others. Blasting accidents are generally not due to explosive deficiency but to human deficiency. On rare occasions accidents have been traced to stray ground currents, storms, hot sparks, and lightning, but all these causes can be guarded against by a foresighted blaster. The most frequent cause of blasting accidents is carelessness and next comes ignorance as to the proper and safe use of explosives. Accidents from explosives will be rare if they are used in a sensible manner.

To prevent blasting accidents the consumer must know how they have been caused or may be caused. We find the chief causes of accidents can be grouped under the following heads:—

1. Proper cover not taken.
2. Playing with blasting caps.
3. Premature blasts.
4. Boring into unexploded charges.
5. Hang-fires.
6. Striking explosives in blasted material.
7. Preparing charges.

1. Proper cover not taken. Accidents under these heads could have been prevented if reasonable precautions had been taken. It hardly seems credible that many accidents should occur due to persons being hit by flying material from a blast, yet we find practically half the accidents laid at the door of explosives come from this source, and they can only be laid to carelessness or ignorance. When no natural cover exists, cover should be provided, and in all cases plain and timely warning should be given before a blast is made.

2. Playing with blasting caps. Children particularly do not know the danger of these caps and every year a number of them are maimed for life. Blasting caps should be issued only to reliable persons and they should be held responsible for their safe keeping. Parents who know what blasting caps are should instruct their children regarding them.

3. Premature blasts. Accidents under this head are more or less conjectured—usually the cause is removed by the blast. The majority of such accidents are due to careless handling such as ramming explosives into a hole of insufficient size, and especially ramming the primer cartridge. Using too short a length of fuse and being caught by a blast is often called a premature blast.

4. Hang-fires. As a rule the blaster attributes hang-fires to a slow fuse. It is far more likely that the number of fuses ignited have been miscounted and the blaster returns too soon to the face. If in doubt as to whether all the shots have gone, take plenty of time—do not guess—consult a watch.

5. Boring into unexploded charges. With reasonable care this type of accident can be eliminated. In block-holing boulders in quarries or mines a careful examination of the rocks should be made before commencing to drill. It frequently happens that a blockhole is loaded and not fired and a nearby blast turns the boulder over and unless an examination is made disaster may result. Drilling into old bottoms or "bootlegs" is forbidden by law, which states that "No drilling shall be done in any hole that has been charged or blasted."

6. Striking explosives in blasted material. Cut-off holes are the most frequent cause of powder being found in blasted material. These can probably never be eliminated entirely but an examination of the working face after the blast will generally indicate whether or not there are cut-off holes, and if any are found muckers should be warned and instructed to use care in shovelling or picking into the material.

Another cause of powder being found in this material is due to stemming not being used in the holes, particularly in uppers or holes having an upward slant. This sometimes results in the shock or air disturbance of the blast throwing the cartridges out of a nearby hole. This could not occur if stemming was used.

7. Preparing explosive charges. When making up primers care should be taken and a wooden or copper punch used for making holes. The fuse should not be forced into blasting caps, also it should never be screwed or twisted when in contact with the detonating compound. When making up charges of explosives all lights should be placed at a safe distance and no smoking allowed. If a steam shovel or locomotive is in the neighbourhood care should be taken that no sparks can fall around the explosives. In fact always treat explosives with respect. It is often the old hands who should know better who are the cause of accidents. It is difficult to correct the methods of old blasters but efforts must be made. When damp or oily stains appear on the cartridge wrapper or when the explosive is wet and soggy it should not be used before obtaining the advice of the manufacturer's representative. He will know whether it should be used and, if not, the manner in which it should be destroyed. High explosives will stand a lot of abuse when in a normal condition, but this cannot be made an excuse for rough handling, which should be avoided. The Dominion, the provinces and the municipalities all have acts which include some regulations regarding the handling, use and storage of explosives as does also the Mines Act, and where applicable these should be carried out.

Explosives are used for a great variety of purposes in developing our industries. The more important uses of explosives are in coal mines, metal mines, quarries, railway construction, hydro-electric development work, farming and demolition.

Coal Mines

The rules and regulations governing the use of explosives in coal mines are, of necessity, very strict and should be enforced to protect both the employee and employer. Practically all high explosives used in coal mines are of the ammonium nitrate class and in most of our coal mines before they can be used they must have passed a specified test. When they have passed this test they are placed on the permitted list. This list states the maximum charge which shall be used in any one shothole and also the strength of blasting caps which must be used to detonate the explosive. After an explosive has been named and defined as a "Permitted Explosive" under the Mines Act, it is not used in a permitted manner if one or more of the following conditions prevail:—

1. If a greater weight than the charge specified is used in any one hole.

Therefore, the charge limit should not be exceeded as the heavier charge might prove dangerous.

2. If stored under improper conditions until it undergoes a change in character.

Improper storage will cause deterioration of the explosive and may lead to misfires or partial misfires with their attendant dangers.

3. If used in a frozen or partially frozen condition.

Frozen explosives are less sensitive and less efficient.

4. If more than one class, grade, or quality of explosive is used in one hole.

Different kinds of permitted explosives placed in one hole may lead to a combination which would not act in the same manner as either one of them separately and the result may be erratic, dangerous, and likely to give off bad fumes.

5. If fired without stemming.

Stemming should always be used to prevent the flame from the shot being projected into the atmosphere, and also to ensure the maximum results with a minimum of danger.

6. If fired with combustible stemming.

Combustible stemming may be ignited and thrown from the hole by a blast.

7. If fired in the presence of a dangerous percentage of combustible gas.

Before a shot is fired, the place must be examined for gas, which, if found, must be removed.

8. If fired in a place which is dry and dusty without first thoroughly watering, rock dusting, or treating in an equivalent manner all contiguous accessible places within a radius of 60 feet therefrom including the floor, roof, and sides.

When blasts are made in a dusty atmosphere there is danger of a dust explosion. Therefore, the hole should be cleared of fine coal dust, all fine coal from the undercutting machine removed, and after the shot has been fired sufficient time should be allowed to elapse to permit the dust to settle before another shot is fired.

9. If the shot is a depending shot or the hole is bored into the solid or has a burden so heavy that the shot is liable to blow out.

Blown-out shots are generally accompanied with a projection of flame from the hole, therefore, the firer must see that the shot holes are properly placed and not drilled beyond the undercut.

10. If more than one shot is fired at any one time in any one place except only in tunnels, shafts, and slopes driven in rock.

When more than one shot is fired in one place at one time it increases the danger. This is not good practice, as better judgment of charge can be made after an examination of the results of each shot.

11. If an electric blasting cap of less strength than that specified for use with the particular explosive is used.

Weak blasting caps may cause incomplete detonation or a burning charge, resulting in bad fumes and other attendant dangers. The fact that an explosive is on the permitted list is not a guarantee that under all circumstances it will not cause an ignition of firedamp or coal dust, and it cannot be too strongly emphasized that there must be no relaxation in any way of the rules and regulations governing the use of explosives in coal mines on the ground that "Permitted Explosives" are being used.

To blast coal safely and to produce a good marketable product it is necessary that care be taken in preparing the coal before blasting. The coal should be properly undercut, shot holes drilled in the proper place and to the proper depth, and no hole should be fired which is drilled into the solid or has too much burden for the permitted charge to break. It pays to experiment before laying down hard and fast rules. One pound of explosive may break from four to seven tons of coal depending on the nature, thickness, etc., of the coal seam.

New men starting in a mine are often a source of danger. They may be old miners, or men with short experience gained at other mines, and do not know the proper manner to go about their work under the new conditions. The mine officials may think that someone will take care of such cases but this does not always follow, and the new men may be the cause of injury to themselves and others through ignorance of proper methods. Therefore, someone should be definitely detailed to instruct every new man thoroughly in regard to the best method of mining and use of explosives.

Overcharging of shots is expensive for the miner and operator as it means less marketable coal. Usually the miner does not concern himself about the condition of the coal and would rather shoot every hole too hard than do the pick work necessary should an occasional shot hang up. It would pay to have a foreman instruct each miner how to produce the grade of coal which sells best and, at the same time, save money by decreasing the quantity of explosives used. Explosives are used in coal mines to bring down the coal in as large blocks as can be conveniently handled because fine coal is of less market value than lump coal, and, as quick, dense, and strong explosives tend to shatter material, it follows that they are not suitable for coal blasting, but a low density, low bulk strength explosive will usually produce coal of the required size.

Metalliferous Mining

This branch of mining is usually carried on in hard rock and shafts have to be sunk, drifts and cross-cuts driven and raises put through from level to level. This is termed 'developing the mine' and the explosive best suited for this is quick and dense. Gelatin explosives have these characteristics and are recommended for general use in metal mines. When the mine has been developed and the extent and quality of the ore has been ascertained, stopes are usually opened up in the ore. In places where the veins are narrow and tight a gelatin explosive should be used, but where the stopes are of good width a less dense explosive can be utilized with a saving over gelatins. Ammonia dynamites are being used satisfactorily in this class of work. The object of blasting in metal mines is to reduce the ore to a size which will conveniently flow through the various chutes and feed into the existing crusher without undue secondary blasting.

Blasting of shafts, drifts, cross-cuts, raises, etc., is arranged by drilling a number of holes to a predetermined depth in a certain direction. This is called a round of holes and usually consists of two or more holes to take out a cut. These are blasted first and open up the centre of the work leaving a free face to which other holes may break. No one arrangement of holes has yet been found suitable for blasting all kinds of rock and the different arrangements are too numerous to be described in a paper of this nature.

When drilling cut holes they should be directed so as to bottom together then they will all explode at once and have a greater tendency to pull the cut clean than if each hole is fired separately. The cut should be blasted first and should the holes not pull to the bottom, they should be blasted a second time with the square-up holes because the square-up holes will not pull beyond the depth of the cut. For this reason it is generally wise to blast the cut holes first, then charge and fire the square-up holes.

Care should be taken in cutting fuse lengths for rotation firing because if one hole fires before it should, it is likely to spoil the whole round. For rotation firing when using safety fuse a difference of three inches in the length of the fuse should be allowed. The same sequence of rotation of firing can be obtained with the use of delay electric blasting caps. The amount of explosives used per cubic yard of rock broken in drifts, shafts, and other tight work varies from 5 to 7 pounds, in stoping work from .8 to 1.5 pounds.

Quarry Work

By this is meant work in open pits producing materials such as stone, gravel, sand, shale, and other non-metallic minerals, also open pit, metallic ore operations. In this type of work practically all the holes are drilled vertically and if an even or predetermined quarry floor is to be maintained it is necessary to drill from two to six feet below the desired bottom depending on the nature of the material to be broken. In quarry work the tendency is to fire a large number of holes at one time for the purpose of getting better fragmentation of the material, reducing stoppages for blasting and often to maintain a sufficient quantity of broken material in front of the power shovel.

Well drills, making holes from four to six inches in diameter, are very popular for this class of work where faces 25 feet and over in depth are to be broken. The advantage of such large holes is that explosive charges large enough to break a large quantity of rock can be placed without enlarging the holes by the old and dangerous method of springing smaller holes. In spacing well drill holes in quarry work it is rarely wise to drill them more than 15 feet apart in the row and 18 feet back from the face of the quarry. From 3 to 6 tons of rock should be broken per pound of explosive with explosives ranging in strengths from 35 to 60 percent. However this depends upon the nature of the rock, what the rock is to be used for, and the equipment for handling the rock.

When charging a large number of holes as few men as possible should be employed. All loose material should be taken away from around the holes and every care should be taken to prevent any foreign substance falling into them. Explosives of a diameter suitable for the holes should be used; there will then be no necessity for slitting the cartridges and forceful tamping of the explosives.

Railroad Construction and Hydro-Electric Development Work

In this class of work the main object is to break the rock so that it can be economically handled with the equipment on hand. Approximately one pound of explosive, 40 to 60 per cent strength, is used to break one cubic yard of rock. Occasionally large blasts are made with the object of wasting the rock. To do this the shot is over-charged, sometimes to the extent of 6 pounds to the cubic yard, depending on the location of the work with respect to probable property damage. Practically all blasts of this nature are carried out by driving small tunnels under the material to be wasted and the explosive charges are placed in the tunnels.

Farming

The farmer is now saving time and money by the use of explosives for blasting out stumps, blasting ditches, and breaking boulders. Much land has been reclaimed from swamps and turned into profitable farm land by blasting out drainage ditches. Stumps, that in the old days were burned out, resulting in months or years to clear an acre or so, are now blasted out in a few hours. A low grade dynamite is used for blasting stumps, and a higher grade for boulder breaking and ditching.

Demolition

Taking out concrete engine beds, breaking concrete walls, blasting down chimney stacks, wrecking sunken ships, etc., is now done in a much shorter time with the correct explosives properly used than by any method previously used.

Aeronautics as a Branch of the Engineering Profession

Squadron-Leader Alan Ferrier, R.C.A.F., A.M.E.I.C.,

Aeronautical Engineering Division, Department of National Defence, Ottawa, Ont.

Paper presented on October 16th, 1930, before the Aeronautical Section of the Montreal Branch of The Engineering Institute of Canada (Montreal Section, Royal Aeronautical Society).

SUMMARY.—In this address the author discusses the relations between the principal divisions of aeronautical engineering and the corresponding branches of structural, mechanical and electrical engineering, and draws attention to the extent to which aeronautics is indebted to workers in other fields for its development. He shows that aeronautical engineering problems, while solved by the application of accepted engineering principles, present characteristic difficulties and require the co-operation of the physicist, mathematician and skilled investigator.

Introduction

Although the author was invited to give this address before the Aeronautics section of the Montreal Branch of The Engineering Institute of Canada, he was given to understand that the greater part of the audience would consist of engineers engaged in the older branches of the profession, and consequently it was thought that it might be of interest to show how aeronautics is not a thing apart, requiring a highly specialized early training, but on the contrary has its roots in the very soil of the profession, and that the aeronautical engineer is but an ordinary member of the brotherhood whose art is to bend the forces of nature to their will and make them pay dividends on the dollars expended on their taming.

The Scope of Aeronautical Engineering

Though aeronautics, like all other engineering activities, demands the services and co-operation of the metallurgist, chemist, physicist and a host of other scientists, it may be said that aeronautical engineering is compounded of structural, mechanical, and aerodynamic engineering. The first and last of these are in eternal opposition, forever placing limitations on each other, and the highest art of the aeronautical engineer lies in forcing them to be friendly. An excessive sacrifice of aerodynamic requirements will result in an aircraft which will not fly well, while a neglect of structural needs produces one which will not hold together, and in either case one may expect a crash. For this reason, although there is already room for specialists in the subdivisions of the profession, it is better that the specialist should be a person recruited from the general ranks, who, having had his attention turned by natural inclination or by force of circumstances towards a particular division, is none the less entitled to be styled an aeronautical engineer.

As an illustration of this specialization in subdivisions take the man who designs airscrews. Time was when every aeroplane designer produced his own drawings and specifications for this component. This is no longer the invariable rule and the services of the airscrew specialist are being sought more and more. This man's work, based upon a bed-rock of aerodynamics and buttressed by a knowledge of mechanics and strength of materials, is an art in itself. Again, the present rule is for aeroplane manufacturers to design and construct their own wings and control surfaces, but the time can be foreseen when this construction will be concentrated in a few big plants to whose engineering staffs the individual designer will bring his specification of plan form, aerofoil section and loading, leaving the detail internal structure to their expert care. As a matter of fact such a development has already commenced in England.

In addition to the subjects already mentioned the aeronautical engineer should have a knowledge of meteorology and navigation. The extent of this knowledge necessary for the individual depends of course upon the direction in which he is applying his engineering. In the remainder of this paper, however, it is only proposed to discuss the main divisions, namely structural, mechanical and aerodynamic engineering. As the aerodynamic aspect is the first to be considered in any aircraft it will be dealt with first.

Aerodynamics

Aerodynamics is the science of the motion of bodies through the air, or of the air flowing past bodies, and of the resulting reactions created by virtue of this motion. It is the only one of the three main sections within the scope of the aeronautical engineer, the study of which can at present be said to be peculiar to aeronautics. There is no doubt that at some time in the future a course of aerodynamics could, with benefit, be included in the curriculum of general engineering training. Dealing with the motion of a fluid, aerodynamics is very closely allied to hydraulics, and any one conversant with the latter subject can read the text books on the former with a strong sensation of familiarity. Aerostatics, which is so essential to the "lighter than air" engineer, that is the balloon and dirigible man, has close analogies to hydrostatics. The future course mentioned above would deal in a comprehensive way with the laws which govern the actions of the compressible fluids or gases, and the incompressible fluids or liquids. In practice, the compressibility of air enters into the aeronautical engineer's sphere in only two important ways as yet. First, and most important, there is, of course, the variation in density, as well as pressure, with altitude. Secondly, compressibility has to be taken into consideration when dealing with airscrews whose tips travel at a speed of a very high order. At the speed of sound, viz., 760 odd miles an hour, it has been found that compressibility alters the ordinary "square law" relationship between force and speed. When the highest speed that aircraft have yet attained has been doubled, then we shall be dealing with projectiles and we shall have to resort to a study of ballistics for the furtherance of our aims.

The man in the street probably has the impression that aeronautics as a science is of comparatively recent birth. He knows that there exist records of crude and unscientific attempts at flight, some of which records are legendary and date back many hundreds of years, but does he know that aerodynamics as a truly scientific and mathematical study has written records from 1686, more than two hundred and forty years ago. Galileo and Mariotte in the 17th century, Newton, Bernouilli, Euler, Borda, Coulomb and a number of others in the 18th century, prosecuted researches on the resistance of the air. The earlier work was most likely prompted by a very pure enthusiasm for fundamental research, then later on, investigations were made which had a direct application to the needs of the day. Thus Smeaton, builder of lighthouses, who experimented in 1759, was evidently interested in determining the possible wind loads upon his structures. The windmills in Holland and Denmark were the subject of some research. The Englishman, George Cayley, who described his experiments in his "Aerial Navigation" of 1809, appears to have been the first to apply the study of aerodynamics solely towards the development of aeronautics. This man was a genius and far ahead of his time. The germs of the present day aeroplane are easily recognizable in his designs, and there is little doubt that had he had a reasonably light power plant at his disposal, the 19th century would have seen the successful commencement of power driven flight in heavier than air machines. It is possibly the lack of such a power plant that diverted many good men from entertaining dreams of "heavier than air" flight in the early 19th century. During the first half of that century, the needs of the naval architect, the structural and general engineer, and of the artilleryman, continued to be responsible for the greater part of the experiments which were undertaken on the resistance of the air. In the second half of the century, the application of aerodynamic research to aeronautics came strongly to the fore, and a number of names in the honour roll of aviation appear: names such as Lilienthal, Horatio Phillips, Ader, Langley, Eiffel and Hiram Maxim.

The earliest experiments, such as those of Newton, were performed by dropping spheres vertically through still air, then a little later on the common medium for investigation was the "whirling arm" which is, in its simplest terms, a long arm or beam rotating about a vertical axis. The model is mounted on one end of the arm and moves in a circular path, the forces on the model being measured by means of balance weights. The disadvantages of the methods employing a rotary motion are the introduction of the complication of centrifugal effect and the generation of a rotary motion in the air containing the apparatus. Nearly all the experimenters of the 18th century employed the method of a moving body in still air, though Rouse in 1759 appears to have been the first to reverse the process and experiment with fixed bodies in moving air. He measured the forces on bodies exposed to the direct action of the wind. His method has the obvious disadvantage that the relative velocity was entirely out of his control. It depended on the weather. It was not until 1864 that the modern method of experimentation made its first crude appearance. Wenham in 1864 put his models into the draft of a ventilator. Twenty-one years later Horatio Phillips built and used the first recognized wind tunnel. The flow of air in this tunnel was created by means of a steam jet and a steady velocity of nearly 60 feet per second could be maintained. The methods of the whirling arm and of the free drop survived until the early nineteen hundreds, but today all pure and applied aerodynamic research, except full scale work in real flight, is carried out in the wind tunnel.

One of the phenomena associated with aerodynamic research is that of "Scale Effect." The same effect appears in connection with the flow of liquids through pipes and channels. It has been found that the value of coefficients of resistance depend upon a factor called the "Reynolds Number." This factor is the product of velocity and a linear dimension, divided by the kinematic viscosity of the experimental medium. The linear dimension chosen for aeronautic work is generally the span of the model. Measurements made at equal Reynolds numbers will result in coefficients of equal value. There is a great disparity between the Reynolds number of a full scale aeroplane or airship and the corresponding number for a model in an ordinary wind tunnel, consequently, though qualitative results may be dependable, there enters some element of doubt as to the exact relation of the quantitative results as between model and full scale. There is no simple formula connecting results at different Reynolds numbers. In the United States, ahead of the rest of the world in the matter of physical equipment, the problem has been dealt with in a royal manner. There are two possible lines of attack, the most direct one being to build a wind tunnel large enough to take full sized models. This they have done, and the Propeller Research Tunnel of the National Advisory Committee for Aeronautics has a throat diameter of 24 feet, and is capable of wind speeds of 100 miles an hour, which require upwards of two thousand horse power for their creation. The other method is to change one of the variables in the Reynolds number function. An increase in velocity above full scale speeds is obviously too wasteful of power, an increase in linear dimension is clearly absurd, so nothing remains but to alter the kinematic viscosity, which can be done by altering the density of the air by compressing it. This method has also been followed in the United States and they have a completely enclosed tunnel in which the air is operated at many atmospheres above normal pressure. The construction of such a tunnel has now been undertaken in England. It will be obvious that such equipment is a thing for governments and not for private enterprise.

It may be asked of what benefit will a knowledge of the flow of air be to the average engineer and why should its study be included in a general engineering course? Possibly the improvement to be derived from this knowledge will be minute compared with the sacrifices involved in the inevitable compromise between ideal theory and practical economics. But the compromise which is permissible today, tomorrow becomes a crudity, and there are fields in which a proper application of aerodynamic knowledge would be of benefit. It is highly probable that this application has already been considered in most of the fields to be mentioned, but if practice in the use of air in general engineering falls as far short of the ideal as admittedly it does in aeronautics, then there is still room for considerable improvement.

Combustion and ventilating engineers are among the largest users of air today. For instance, every ton of coal burnt in a furnace requires 15 tons of air which often pass through the flues at a speed approaching 2,000 feet a minute. This is a low velocity in aeronautics, but it is high enough to create appreciable reactions on any obstructions in the stream. It is not necessary to use streamline lumps of coal, but unavoidable obstructions should be designed to create as little turbulence as possible, and where changes of direction are required, the use of guide vanes for combing out turbulent flow might well be considered. We are only at the beginning of the application of guide vanes in aeronautics. The air-cooled radial aero engine has a terrible shape aerodynamically, but recent developments of guide vane devices placed in proper relation to the engine have resulted in tremendous reductions in resistance to forward motion. The N.A.C.A. cowling produced in the United States and the Townend ring developed in England are merely annular guide vanes cunningly disposed. The conservation of energy in wind tunnel plants has been the subject of much work, the records of which should be of direct interest to the combustion and ventilating engineers.

The transportation engineer, whether automotive or railroad, might conceivably profit. At the lower speeds air resistance probably merits little consideration, but at high speeds it becomes appreciable. On the basis of one square foot of projected area the resistance at 60 miles per hour of a flat plate is of the order of eleven pounds, while that of the corresponding streamline form is less than one-fifth of a pound, that is one-fiftieth times as much. Minimum air resistance may come very low down on the list of the transportation engineers' requirements, but where it can be obtained at little cost, the closer attainment of the aerodynamic ideal should not be neglected. The accepted form of closed automobile of today has a better streamline form going backwards than it has going forwards. Every winter illustrates the aerodynamic imperfections of the under side of an ordinary railroad passenger coach. After passing through a sleet storm almost every obstruction under the coach will be clothed in a frozen streamline form manufactured by nature itself. A general cleaning up of the vehicles if it did nothing else would reduce the dustiness of railway travel.

It is generally understood that the rules used by structural engineers for computing the wind loads upon buildings, bridges, cranes and other structures are of a most empirical nature. Are these loads not calculated on a basis of projected area without taking cognizance of shape? It is known that a flat plate offers far more resistance to the wind than a rectangular prism whose cross section has the same shape as the plate, and also that where intersections are rectangular in the plane transverse to the direction of motion, the resistance at the joint is less than where the intersections are acute. A more exact application of the knowledge already available would result in a refinement of design tending towards greater safety or greater economy while wind tunnel tests could easily be undertaken for tackling special problems.

The naval architect is interested in the wind pressure exerted on the side of his ships and he might well employ the wind tunnel in addition to the water channel to improve the upper form as much as he has perfected the form below the water line.

The hydraulic engineer should benefit indirectly by the extension of knowledge of fluid motion and its applications which are due to the recent intensive study of the subject stimulated by the needs of aeronautics.

Structural Engineering in Aeronautics

The difficult part of the problem of the structural strength of aircraft in flight is the determination of the external loads. This information is supplied by aerodynamics and from then on the computations of the loads in the members are clear cut and fairly precise and should be easy for any engineer familiar with the theory of structures, once he has accustomed himself to dealing with structures that are never rectangular, are usually full of redundancies and are subject to different combinations of loading under different attitudes and speeds of flight.

When it comes to the design of the various members, however, one must revolutionize the scale of relative values commonly accepted in heavy engineering and modify considerably one's trend of thought.

Considering first the relation of the designed strength to the loads imposed, it must be realized at the very outset that there is no such thing as a "Factor of Safety" in the structural part of aeronautics. "Load Factors" are used, which in turn are increased by a further factor which provides a margin of safety of somewhat indeterminate value. The loads upon an aeroplane in flight at a uniform velocity can be computed with a fair degree of accuracy, but when a change of attitude is imposed, a change in magnitude and point of application of the resultant force takes place, producing linear and angular accelerations which cause considerable increases or decreases and a redistribution of the loading. The meeting of a sudden gust of wind is equivalent to an acceleration imposed upon the aircraft. The magnitude of the accelerations which occur during the various manoeuvres of an aircraft have been determined and some very dangerous work has been done to fix the maximum acceleration possible. Records of values exceeding nine times the acceleration due to gravity have been obtained. Such violent movements are beyond the ordinary capacity of the human frame, and, if repeated often in a machine strong enough to withstand them, would result in permanent injury to the pilot. Roughly speaking, a value of three times g is near the limit of ordinary human comfort and is of the same order of magnitude as the acceleration which bumps one's head against the roof of an automobile. The values of the accelerations determined, whether they be maximum possible values, or ordinary values appropriate to certain manoeuvres, are used as a basis for laying down the "load factor" required in a particular condition of flight and the additional factor required to provide a margin of safety is purely arbitrary, though it may be judged a little on the probabilities of exceeding the basic load factor, a little on consideration of inaccurate manufacture, deterioration caused by age or use and other similar indeterminate influences, and finally a little by the very human desire to stick to nice easy round numbers and simple fractions. Some people have advocated yet another variable factor to look after uncertainties in the properties of certain materials largely used in the construction of aircraft. Such a factor might well be christened a "factor of ignorance." A much better way is to take cognizance of this uncertainty when specifying the maximum working stresses permissible in a certain material. In this way the design load is not changed, but remains the same whether the member to resist that load is made of metal or wood. The specification of design load factors is the most critical and the weakest link in the whole chain of the design, but in this matter aeronautical engineers have by no means reached finality. A concrete example will show the sort of way in which the total design load factor can be arrived at. An aeroplane is flying at its maximum horizontal speed. By pulling roughly back on the elevator control it is found that a normal acceleration of three times g is imposed, while at the new attitude the centre of pressure moves forward towards the leading edge of the wing. The probabilities of exceeding the three times g in moments of excitement are fairly high, so an arbitrary margin or "safety factor" of two is imposed, thus the design load factor for the centre of pressure forward condition becomes six. That is to say, the loads calculated for flight at a uniform velocity corresponding to the forward position of the centre of pressure are multiplied by six. Another way of looking at it is that the design loads correspond to a speed $\sqrt{6}$ times the normal speed. The inertia of the aeroplane supplies the power required to maintain this speed for a fraction of a second.

The federal government is in most countries the authority which lays down the design load factors to be used for different classes of aircraft.

The aeronautical structural engineer holds an attitude towards weight which is essentially different from that adopted by his confrere in the heavier line.

Except for very large structures where the dead load constitutes the major proportion of the total load, the steel and concrete man's greatest incentive for refinement in design and economy in material is reduction in cost. The finished price per ton varies slowly with total tonnage and extra weight costs money in raw material, in fabrication, in transportation and in erection. The aeronautical engineer's job, however, is to reduce weight to the utmost possible degree without incurring too great an increase in cost, under penalty of producing an entirely unsuccessful aircraft. Every pound added to the structure is a pound taken away from the profit paying load of the vehicle, but extra lightness costs money in design, in fabrication and in the price of special materials, and it is necessary to strike a very nice balance. The situation is complicated in aeronautics by the fact that a certain sacrifice of lightness is justifiable in order to attain a decrease in resistance having a greater economic value. For example, the ideal section for a long thin pin-jointed column is a circular tube, but where such a member is exposed to the wind the aeronautical engineer prefers to use a tube of streamline section or he clothes his circular column with a thin metallic or wooden streamline covering which has no structural value whatever. The desire for reduction in weight imposes the necessity for making every bit of material included in the structure carry a stress as near to the limiting design stress as possible, and this, coupled with a trend towards the use of metal to the exclusion of wood, has led aeronautical engineers to great lengths in the design of thin walled sections made of special steels and aluminum alloys. The walls of these sections are ingeniously crinkled in a variety of ways to guard against failure by local instability.

Other influences on the structural design of aircraft are inertia and rigidity. Large inertia of the structure as a whole is unfavourable to controllability, manoeuvrability and stability, while a large inertia of some component part coupled with a lack of rigidity may result in dangerous undamped oscillations in the region of that component.

It has been said that once the external loads have been determined the stress analysis of an aircraft should be easy for a structural engineer. This is not strictly true of rigid airship structures, where new methods of analysis entirely outside the range of ordinary structures have had to be devised to cope with the intricacies of this type of elastic and highly redundant frame.

Mechanical Engineering in Aeronautics

The chief mechanical problem in aircraft is most evidently that of the power plant. This problem is so vast and has so many subdivisions of its own that it has become a separate branch of the aeronautical engineering profession, and it is that part of aeronautics which has the most common ground and the closest relationship with non-aeronautical activities. It might be said that aeronautics has fathered a good big healthy child whose mother is automotive engineering. Aeronautics is the father, for though admittedly the invention of the internal combustion engine preceded flight and made it possible, it is notable that the Wright brothers were constrained to build a special aero engine for themselves because no existing motor would meet their needs. Later on automotive engineers entered the new field in force, with the result that today the four-cycle electrically ignited gasoline aero-engine has reached what the economists call the "marginal stage." Any further improvement in thermal efficiency can only be gained very slowly indeed and at great sacrifice of labour. Much larger rewards from research are to be looked for in the development of motors working on a different cycle and at much higher compression ratios than are possible with a poppet valve design. For an interesting outline of present and possible future research reference should be made to a recent number of the English publication "Aircraft Engineering," to which Ricardo has contributed an article forecasting the line of progress. It is needless to emphasize that the refinements necessitated by the stringent demands of aeronautics have reacted to the benefit of the parent automotive industry.

The distinctions between the power plant of aircraft and the power plant on the ground are all incidental and with one exception involve no factor which is not absolutely common to all forms of internal combustion engineering. The excepted factor is the variation of atmospheric pressure and density with altitude. For example, at a height of 20,000 feet the atmospheric pressure is roughly one half the pressure on the ground. This variation is responsible for the development of special carburettors which are designed to maintain a proper mixture strength under widely different conditions and also for the peculiar use of the device known as the supercharger. This device when fitted to automobile or boat engines performs the functions which its name implies and boosts the mean effective pressure and the power output of a given plant by increasing the weight of the charge. The name, however, is an ill chosen one to describe the most common application of this device to an aero engine, which is made not to boost the power of the engine on the ground but to maintain ground level power or rated power at an altitude. Admittedly there are engines with gear-driven superchargers which can be operated at full throttle on the ground and are therefore known as ground boosted engines, but the ordinary kind of gear-driven supercharged engine actually has to be throttled down on the ground so as not to exceed the rated mean effective pressure, and full throttle opening and full power are not attained until a certain altitude has been reached.

In a manner analogous to that already mentioned in the structural section of this paper, the aeronautical mechanical engineer has a different scale of values to that held by his counterpart on the ground. Their guiding principles are identical and the sum of their final objects may be the same, but their motives are different. Safety, economy of weight and compactness are the factors of overwhelming influence and the other desiderata have to give place.

Consider for a moment the motive behind the search for fuel economy. The main motive is emphatically not the reduction of operating costs but the reduction of overall power-plant weight including fuel. The aircraft designer does not merely consider the weight of a motor on a pounds per horse power scale but in pounds per horse power hour on a six hour, seven hour, or longer basis.

Take again the matter of cost. The aero-engine maker cannot juggle with quality, and there is no such thing as producing a "line" to suit the capacity of every pocket. Engines of a similar power have a similar cost and if your pocket is small you can only afford to buy a small engine; you cannot buy a cheap big one.

Leaving the power plant aside, the aeroplane as a vehicle offers some scope for the mechanical engineer in the design of alighting gears, control gears, and so on. The automatic gyroscopic control of aircraft is now being satisfactorily perfected. An enormous amount of ingenuity has been displayed in the design of fixed and retractable undercarriages, combination ski-wheel and ski-float gears and many other accessories. Most of the problems involved are the application of well known mechanical devices in the simplest and lightest possible way and the aeronautical engineer borrows freely from the products of his brethren. It is difficult to see how there can be much beneficial return to the profession in general from these borrowings.

The scattered paths of engineering are today many and varied and each reveals such lengthy vistas that the ordinary pilgrim cannot afford to wander far on any but his chosen way. Few of the paths are straight, and every little while one crosses another and perhaps for a space merges with it to make a broad highway. It is hoped that some who read this paper may perhaps be led to journey further along the highways of aeronautics.

THE
ENGINEERING JOURNAL
THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XIV OCTOBER 1931 No. 10

The Engineering Institute of Canada and the Provincial Associations of Professional Engineers

All members of the engineering profession in Canada are naturally concerned with the inter-relation of the activities of our various professional and technical organizations. The present situation is sufficiently complicated. Among distinctively technical societies we have, to begin with, The Engineering Institute of Canada, a Dominion-wide, Canadian organization, whose objects need not be described here, and which includes engineers of all branches of the profession. Another Dominion-wide organization, The Canadian Institute of Mining and Metallurgy, ably represents the mining industry as well as the professional mining engineer. Further, there are in Canada a number of active branches or sections of American engineering societies, who deal with specific subdivisions of engineering work, and who naturally look to the United States rather than to Canadian sources for professional guidance.

With aims distinct from those of the voluntary bodies just named, eight Provincial Associations of Professional Engineers have been created to deal with questions regarding the licensing of professional engineers and the protection of the public against incompetent practitioners. Membership in them, in most cases, is compulsory, their activities are definitely regulated by provincial enactments, and they are now in existence in all of the provinces of the Dominion except Prince Edward Island.

The difficulties arising from this complex structure have, for some years, received consideration from the Council of The Engineering Institute, particularly with respect to The Institute's relations with the Provincial Associations, and there has developed a general desire for some real progress towards an ideal condition in which the activities and requirements of all these bodies will be mutually co-ordinated. Some have even expressed the hope that eventually engineers will not be faced with the necessity of belonging (and contributing) to a multiplicity of entirely independent organizations.

The question of the relations between The Institute and the Provincial Associations is thus one of the important topics on the agenda for the Fifth Plenary Meeting of Council, and at this time it seems desirable to place in the hands of members of The Institute a brief account of the activities of The Institute in regard to this matter up to the present time.

In 1918, shortly after the transformation of the Canadian Society of Civil Engineers into The Engineering Institute of Canada, it appeared desirable that further and more consistent development should take place in regard to the legal registration and licensing of professional engineers. This movement had been initiated by the Society in regard to Manitoba (1896), and Quebec (1899), and it was then realized that provincial (not federal) legislation had to be secured, the protection of the public being essentially a provincial and not a federal responsibility.

A committee appointed by the Council of The Institute drew up a Model Act (see Engineering Journal, May, 1919, page 411), which it was thought would be suitable for submission to the various provincial legislatures, and this act served as a basis for the legislation which was obtained shortly thereafter, establishing Associations of Professional Engineers in nearly all of the provinces of the Dominion. In British Columbia, the passing of the act in 1920 was largely due to the activities of a body formed for that specific purpose, and called the British Columbia Technical Association. The resulting acts, however, were by no means alike in their provisions, the legal powers of the various associations differed in degree, and from time to time amendments to several of the acts have rather tended to emphasize this lack of uniformity.

In February, 1926, in order to consider this situation and other points affecting the common interests of the then seven provincial associations, delegates from these bodies met at the Headquarters of The Institute and discussed points of mutual interest for three days, the resulting recommendations being submitted in due course to the Councils of the several professional associations. The Institute was not represented at this conference.

In October, 1927, the first Plenary Meeting of the Council of The Engineering Institute of Canada took place, and at this time the hope was definitely expressed that The Institute might aid in the co-ordination of the work of the various provincial associations, a committee being appointed under the chairmanship of George R. MacLeod, M.E.I.C., to report regarding this. The committee, consisting of Institute members from all of the provinces, was unable to commence work for some time, the chairman ultimately being compelled to resign through pressure of other work, and being succeeded by S. G. Porter, M.E.I.C., of Calgary. (See Engineering Journal, November 1927, page 497.)

In the same year The Institute's Board of Examiners, on instructions from Council, exchanged views with the Boards of Examiners of a number of the professional associations to see what could be done towards obtaining uniformity in examination requirements, and in 1928 a revised examination syllabus of The Institute was prepared and communicated to the associations. No further progress in this respect seemed possible at that time without meetings for discussion.

At the second Plenary Meeting of the Council of The Institute in 1928, The Institute's Committee on the Relations of The Institute with the Professional Associations was continued, the committee not yet being ready to present a report.

At the third Plenary Meeting in 1929, the committee presented a report indicating that there was a general sentiment in favour of closer relationship between The Institute and the associations, and making definite recommendations as to the course which should be taken by The Engineering Institute. This report was adopted by Council, and it was agreed that it should be submitted for the consideration of The Institute membership at the next Annual General Meeting. This was accordingly done, and at the Annual Meeting of 1930 the report led to prolonged discussion, being finally received and adopted, attention being drawn to the fact that effect could not be given to all of its recommendations immediately. (See Engineering Journal, March, 1930, pp. 191-194.) The recommendations with which the report terminated, and which were thus endorsed by the Annual Meeting of The Institute, are as follows:

1. That this committee or a similar one be continued.
2. That at least one member of Council in each province be added to the committee to act during his term of office in all cases where Council is not already represented.
3. That this committee be authorized to appoint a small sub-committee whose duty it shall be to approach the provincial associations and in conjunction with them devise a detailed proposal to bring about a co-ordination of the interests and activities of the various professional associations and The Engineering Institute of Canada; and further it is recommended that a sum of $1,800 be appropriated towards a fund to provide for the expense of this work.
4. That The Engineering Institute of Canada, through The Journal and otherwise, continue to encourage and support the activities of the professional associations and contribute in every reasonable way to their success.
5. That immediate steps be taken to arrive at an agreement among the professional associations and The Institute for the adoption of standard uniform requirements for admission to membership and that these requirements be rigidly adhered to.
6. That upon the acceptance of such standard requirements The Institute should adopt the policy of accepting membership in a professional association as sufficient evidence of qualifications for admission to The Engineering Institute of Canada.
7. That steps be taken to secure the necessary amendments to the By-laws so that membership or registration in a professional association be one of the requirements for admission to corporate membership in The Engineering Institute of Canada for all applicants residing in a province where an engineering professions act is in effect.

The committee was accordingly continued, and at the meeting of Council held on April 11th, 1930, Past-President H. H. Vaughan, M.E.I.C., was appointed chairman in succession to Mr. Porter, and a sub-committee was appointed in accordance with recommendation No. 3 to approach the provincial associations.

At the fourth Plenary Meeting of Council in September, 1930, Mr. Vaughan presented a report from his committee, including the views of the sub-committee, which recommended that a study of the possibilities in the matter should be made by a committee nominated by all of the provincial associations and The Engineering Institute, to be known as the National Committee. This proposal was to be communicated to the provincial associations, who would be asked to nominate members, after which an analysis and comparison of the various provincial acts and requirements for admission would be made, which it was hoped would lead to the working out of a draft set of by-laws and requirements for membership that could apply to all the provincial associations and to The Engineering Institute of Canada. This work of analysis and drafting was to be done by a sub-committee of three (afterwards changed to four) members of the National Committee representing the Maritime Provinces, Quebec and Ontario, the Prairie Provinces, and British Columbia respectively. It was thought that when such a draft had been prepared and had been criticized by all members of the National Committee it might then be submitted to the Councils of the associations and of The Engineering Institute of Canada for their consideration.

At The Institute's Annual Meeting in February, 1931, the Committee on Relations of The Institute with the Provincial Associations of Professional Engineers presented a further report (see Engineering Journal, February, 1931, page 102,) which stated the situation, and announced that the proposals for a National Committee were under consideration by the governing bodies of the professional associations, and that some of these had already approved of the suggestion and had appointed their members on that Committee. Ultimately members of the National Committee were appointed by the Councils of seven of the eight professional associations, who thus concurred with the course proposed.

The Council of one of the provincial associations, however, maintained that co-ordination of all activities of engineering associations throughout Canada might be obtained more readily by developing a plan which would at first apply only to the provincial associations. Definite objection was made to any plan which would at once include The Engineering Institute of Canada. Further, the Council in question was unable to approve of the proposed Committee of Four unless its members were accredited by the associations alone, The Institute taking no further active part for the time being.

The President of The Institute and the Chairman of its committee allowed this objection and a committee of four representatives of the provincial associations was convened in Montreal August 24th. The first report of this committee was made to the Councils of the provincial associations in September.

The German Engineers' Society's Meeting, 1931.

By Robert W. Angus, M.E.I.C.,
Professor of Mechanical Engineering, University of Toronto, Toronto.

The well-known Verein deutscher Ingenieure (German Engineers' Society) celebrated this year at Cologne, from June 26 to June 29, their 70th General Meeting and also the 75th Anniversary of their establishment, since the Society was organized in 1856. With a membership of nearly 30,000, it far exceeds in size any other similar society, but, of course, it includes many classes of engineers; its technical publications are of very high order.

That the meeting was a success every one attending it would testify, for about 1,000 were at the main meetings and considerably over 1,200 sat down to the dinner in the evening. The regular sessions of the meeting were devoted entirely to technical papers, differing in this respect from the practice of some other engineering societies, and the papers were of decidedly high order on the whole. In one session that I attended there were some excellent papers on the subject of cavitation in turbines, etc., but the papers were not printed beforehand, although some of them will appear later in the Society's "Zeitschrift."

The two anniversary meetings were held on June 28th, the first being the formal meeting and the second one the dinner. The afternoon meeting was held in the Fest Saal of the Gurzenich, a building well known to all who visit Cologne, for it was erected in 1452 and was designed with this hall for the special entertainment of distinguished visitors to the city, so that the elaborate interior decorations may be readily imagined. The setting was, I thought, very fine.

An opening address by the Chairman, Dr. Köttgen of Berlin, outlined the history of the Society from its inception. He was followed by Dr. Konen, Rektor of the University of Bonn, who gave a learned address on "Stream Flow Problems."

The rest of the afternoon session was taken up with reading the greetings of universities and of engineering societies from various parts of the world. The German delegates were, of course, most numerous, but addresses were presented by various British, American and other societies, all of the foreigners being well received. Some honours were also bestowed and as the addresses were usually long, the session was not a short one. I almost omitted to say that the first message was from President Hindenburg and was received by the audience standing, and was accorded a hearty "Hoch" at its conclusion.

The dinner at night was a notable and unusually interesting affair, being attended by over 1,200 men and women, who met in the new and very tastefully decorated "Grosse Halle," in the Rhein park on the Deutz side of the Rhine. The dinner proper lasted from eight till eleven o'clock, and was preceded by a fine selection on the large organ. But three courses were served and the speakers came between them, but as there was no head table each speaker came, unannounced, to a rostrum at the end of the room and delivered his speech, so that there were no tiresome "Chairman's Remarks." Smoking did not begin till about eleven, and the diners moved about the room and chatted together and drank their wine in a friendly way. During the latter interval, there was a most instructive movie entertainment. It was a memorable and delightful affair and I am glad I was able to attend it.

Visits to various plants and to Aachen and Koblenz, and a final "get together" in the evening concluded the interesting meetings. I attended the meetings both by special personal invitation of the society and also as the representative of The Engineering Institute of Canada.

OBITUARIES

Donald Cameron, M.E.I.C.

In the passing of Donald Cameron, M.E.I.C., at North Vancouver, B.C., on July 26th, 1931, the engineering profession has lost a valued member.

Mr. Cameron was born at Appin, Argyll, on November 5th, 1851, and received his education at school in Appin and Glasgow and at Glasgow University. In 1867-72 he was a pupil with David Smith and Ritchie at Glasgow. After being engaged for several years on sewage disposal work, he was in 1878 appointed deputy city surveyor and in 1883 city surveyor and engineer of Exeter. It was while he was at Exeter that Mr. Cameron patented a system of sewage disposal by passing sewage through a closed tank, to which he gave the name "septic tank." He also devised automatic gears for alternating the flow of effluent to the filters, and was thus one of the chief pioneers of modern sewage treatment. While his ideas were widely adopted and his methods proved successful in practice, there were many attempts to produce something equally effective, and much litigation followed. The failure of certain installations, alleged to be based on the principles he advocated, led to undeserved disparagement of his claims and thus he never received adequate recognition of his great services to sanitary engineering.

In 1902 Mr. Cameron entered private practice. Coming to Canada in 1907, he became engineer to the municipality of North Vancouver and in 1909 entered into partnership with E. A. Cleveland, M.E.I.C.

Mr. Cameron joined The Institute as a Member on February 10th, 1914, and was made a Life Member on December 22nd, 1925.

Charles Lyon Fellowes, M.E.I.C.

Much regret is expressed in recording the death at Toronto, on September 18th, of Charles Lyon Fellowes, M.E.I.C.

Mr. Fellowes was born at Ottawa, Ontario, on September 17th, 1846, and was educated at a private boarding school and at Ottawa College, Ottawa.

During the years 1870-1872, Mr. Fellowes was engaged on a trigonometrical survey for the Welland canal, and in 1872-1881 he was first assistant engineer on the construction of the northern division of the same canal. In 1881 he was a contractor on the Credit Valley Railway, in 1882 he was section engineer on the Chicago and Atlantic Railway, and from 1882 to 1886 he was in private practice. During the year 1887 Mr. Fellowes acted as assistant engineer at the head office on the Temiscouata Railway and in the same year returned to private practice, in which he remained until 1890. From that year until 1896, he was engaged on special work for the city of Toronto sewers, and was also water-works engineer. In 1896 Mr. Fellowes was appointed deputy city engineer and water-works engineer of Toronto, which positions he held for over thirty years.

Mr. Fellowes joined The Institute as a Member on February 11th, 1907, and became active in Institute affairs, being a member of Council during the years 1911, 1912, 1913 and 1914.

Graham Ferguson Paterson, A.M.E.I.C.

Members of The Institute will learn with regret of the death of Graham Ferguson Paterson, A.M.E.I.C., which occurred at Montreal on May 6th, 1931.

Mr. Paterson was born at Paisley, Scotland, on March 4th, 1890. He received his early education at the Glasgow High School and Ayr Academy, graduating from the Glasgow Royal Technical College in 1909. From 1906 to 1911 he was pupil with Messrs. Warren and Stewart, civil engineers, Glasgow. In 1911, Mr. Paterson became connected with W. P. Weir, civil engineer, on the preparation of plans, specifications, etc., for the Irvine ship-building yard and slip-dock. From 1912-1913 he was assistant on the staff of engineers to the joint railways committee of the Caledonian and Glasgow and Southwestern Railways, being in charge of permanent way maintenance, Glasgow and Kilmarnock section. Coming to Canada in 1913, Mr. Paterson was employed in the Sewer Section, Works Department of the city of Toronto. From 1914 to 1919 he served overseas, first as a lieutenant and later as a captain in the Royal Engineers (Imperial Forces). After the war he accepted a position with the Maxwell Motor Corporation, Detroit, in charge of inspecting and supervising work in the erection of a new plant, and in 1920 was appointed assistant on the staff of the chief engineer, department of sewer construction for the city of Detroit. In 1921 Mr. Paterson became designer, sewer section, city of Toronto, and in 1922 resigned that post to join the Technical Service of the city of Montreal.

Mr. Paterson became an Associate Member of The Institute on June 27th, 1922.

George Fillmore Swain, M.E.I.C.

It is with deep regret that the death is recorded of George Fillmore Swain, S.B., LL.D., M.E.I.C., which occurred on July 1st, 1931, at Holderness, N.H.

Professor Swain was born at San Francisco, Calif., on March 2nd, 1857, and graduated from the Massachusetts Institute of Technology in 1877 with the degree of S.B., and from the Berlin Banakademie in 1880.

In 1887 Professor Swain became consulting engineer for the Massachusetts Railway Commission and in 1894 was appointed as engineer member of the Boston Transit Commission. The latter Commission has built all subways in Boston and a number of bridges. In 1880-1883 Professor Swain was expert on the Tenth Census on water power. In 1909 he was in charge of the Department of Civil Engineering at the Massachusetts Institute of Technology and in the same year was appointed McKay Professor of Civil Engineering at Harvard, which appointment he held up to the time of his death.

While his active nature carried him into many fields, including transportation, structures and hydraulics, yet throughout his entire life Professor Swain remained true to his primary calling—he was one of the great engineering teachers.

Professor Swain joined The Institute as a Member on January 11th, 1913.

PERSONALS

James C. Neufeld, S.E.I.C., has been appointed instructor in the Faculty of Engineering at the University of Manitoba, Winnipeg, Man. Mr. Neufeld graduated from that university with the degree of B.Sc. this spring.

O. S. Platou, A.M.E.I.C., is at present engaged on the Saint John Harbour Reconstruction, at Saint John West, N.B. Mr. Platou was formerly designing draughtsman with the Power Corporation of Canada, Ltd., at Montreal.

M. F. Dixon, S.E.I.C., formerly with Jenkins Bros. Ltd., is now associated with Crane Limited, Montreal, as sales engineer. Mr. Dixon is a graduate of McGill University of the year 1930.

C. D. Evans, Jr.E.I.C., has joined the staff of the Canadian Gypsum Company, Ltd., Montreal. Prior to accepting his present position, Mr. Evans was estimator and engineer with Gypsum Lime and Alabastine, Canada, Ltd., at Toronto, Ont.

Earl M. Brydon, A.M.E.I.C., formerly assistant engineer, Public Service Corporation of Northern Illinois, Chicago, Ill., has returned to Canada, and is now connected with Canadian Line Materials Limited, Scarboro Junction, Ont. Mr. Brydon graduated from the University of Manitoba in 1924 with the degree of B.Sc.

E. L. Miles, M.E.I.C., has been transferred by the Standard Paving Limited from Toronto where he was promotion engineer, to Halifax, N.S., where he is connected with Standard Paving (Nova Scotia,) Limited. Before joining his present company, Mr. Miles was for some years county engineer and superintendent of roads, county of Victoria, Ontario.

C. L. Kenney, S.E.I.C., is now located in Saskatoon, Sask., where he is employed on the construction of the new Canadian National Railways hotel. Mr. Kenney, who graduated from the Nova Scotia Technical College in 1929 with the degree of B.Sc., was formerly with the Otis-Fensom Elevator Company Ltd., Montreal.

A. G. Tibbits, S.E.I.C., has joined the staff of the Acadia Sugar Refining Company Limited, as assistant engineer, and is located at Woodside, Dartmouth, N.S. Mr. Tibbits graduated from the Nova Scotia Technical College this year with the degree of B.Sc.

NOEL J. OGILVIE, M.E.I.C.

Noel J. Ogilvie, M.E.I.C., Director, Geodetic Survey of Canada, Ottawa, has been appointed international boundary commissioner by the British Government, to act with a representative of the United States government in arranging all matters pertaining to the boundary between Canada and the United States. Mr. Ogilvie is chairman of the National Committee of Canada of the International Geodetic and Geophysical Union, and is also chairman of the Association of Geodesy of that Committee.

T. H. Nicholson, A.M.E.I.C., announces that his company, T. H. Nicholson Limited, Montreal, which was recently formed for the distribution through Canada, Newfoundland and the British West Indies of domestic electrical devices, has been appointed exclusive representative for Dennisteel products in the province of Quebec. Mr. Nicholson's company intends to specialize on that general line of equipment.

Major W. M. Miller, A.M.E.I.C., Royal Signals, has been appointed chief signal officer, Burma. This is a special appointment due to the Burma rebellion. Major Miller is responsible for all the telegraph, telephone and radio arrangements for the troops engaged in quelling the rebellion. He was formerly stationed at Trimulgherry, Deccan, India.

H. W. R. Shepherd, A.M.E.I.C., lately with United Engineers and Constructors, Canada, Ltd., at Newcastle Creek, N.B., is now with the Saint John Harbour Reconstruction, Saint John West, N.B. In 1928 Mr. Shepherd was resident engineer at the Seven Sisters Falls development, Whitemouth, Man., for the Northwestern Power Company, and prior to that was resident engineer with the Foundation Company on the construction of the Ghost river dam for the Calgary Power Company. Mr. Shepherd, who was at one time resident engineer for the highway department of the province of Alberta, was overseas with the Alberta Dragoons and the Second Battalion of Canadian Engineers from 1914 to 1919.

R. N. Blackburn, M.E.I.C., Retires

R. N. Blackburn, M.E.I.C., Chief Mechanical Superintendent, Department of Public Works, government of Saskatchewan, Regina, Sask., retired from the service of the government on September 1st. Prior to taking over the duties of the office which he now relinquishes, he was Chief Inspector of Steam Boilers for the province.

Mr. Blackburn was born in England, and was educated in that country at the Liverpool of Science, obtaining first

R. N. BLACKBURN, M.E.I.C.

class honours in mechanical engineering at the City and Guilds of London in 1888. Before coming to this country, Mr. Blackburn was in private practice as a consulting engineer at Liverpool. During his official career at Regina, his technical advice has been sought on many important engineering questions affecting the welfare of the province, more particularly as regards the utilization of local fuel resources, the generation and distribution of electric power, and the problem of water supply.

Joining The Institute as a Member in 1920, Mr. Blackburn has always taken a keen interest in its affairs. He served on Council from 1923 to 1925, and is a past-chairman of the Saskatchewan Branch.

Lieut.-Colonel W. A. Steel, M.C., A.M.E.I.C., Appointed to Staff of National Research Laboratories

Lieut.-Colonel W. A. Steel, M.C., A.M.E.I.C., who as an officer of the Royal Canadian Corps of Signals has directed the radio development of the Department of National Defence, has been appointed to the staff of the National Research Council, to have charge of its radio research programme.

In co-operation with other officers of the Department of National Defence, Colonel Steel has invented a direct reading radio compass which is now in general use both on this continent and in Europe. As a result of his investigations important transmitting and receiving equipment and directive beacon apparatus have been evolved. At several international radio conferences he has been the Canadian representative, and he accompanied the Prime Minister to the last Imperial Conference.

Lieutenant-Colonel Steel commenced his military career in the ranks of the 2nd Field Company, Canadian Engineers, Toronto, and served in that unit from 10th October, 1911, to September 30th, 1914, when he transferred to the Toronto University Contingent of the Canadian Officers Training Corps, in which unit he was appointed to a commission as Lieutenant on the 21st February, 1916. He served in the Canadian Expeditionary Force as an officer of the Canadian Signal Service, was twice mentioned in despatches and was awarded the Military Cross.

During the last year and a half of the World War he had charge of all the radio work of the Canadian Corps in France.

He was engaged on radio research work at the University of Toronto under the direction of Professor T. R. Rosebrugh, from the time of demobilization in 1919 until June 1, 1920, when he was appointed to the Permanent Force with the rank of Major in the Royal Canadian Corps of Signals. He received promotion to the rank of Lieutenant-Colonel on August 7, 1930, in recognition of the outstanding technical work in signals and communication which he had performed for the Department of National Defence.

The Economic Status of the Engineer in the United States*

Abridged (by permission) from the report published in Mechanical Engineering for September 1931

1930 Earnings of Mechanical Engineers

The following conclusions are based on replies from over 50 per cent of the membership of the American Society of Mechanical Engineers in the United States on questionnaires where identification was impossible. Some 9,199 engineers replied. The results are believed by the committee to be the most reliable that have been obtained as to engineering earnings.

In studying the figures, it is important to keep in mind that (*a*) They are based on 1930 earnings, and the effect of the present depression had not been felt; (*b*) figures refer to professional incomes only and consequently can only be compared with other figures which refer exclusively to professional incomes; (*c*) the figures do not refer to average, but to "median" earnings;† (*d*) throughout the report, earnings are figured for groups based on years after graduation and on comparable ages. By using this method instead of individual years, more reliable figures were obtainable due to the larger numbers in the group for which the median is taken.

Fig. 1 indicates the 1930 professional earnings of mechanical engineers in the United States as a whole. Comparison of these curves indicates the years in which the increase is greatest, and it will be noted that engineering earnings do not decline seriously with age.

An examination of the median earnings which are roughly typical of all comparative earnings of mechanical engineers in the main geographical areas of the United States indicate that these are affected to some extent by location. The New York Metropolitan district gives the highest median earnings at all ages below 63. These are not substantially above the earnings in the mid-Atlantic states, except for men over 40, or the middle West, except for men over 50.

Numerical distribution of members of the Society in the separate geographical areas, together with the maximum median earnings in each area, can best be observed in Table 1.

Table 1
Distribution of Membership

Geographical Area	No. of Members‡	Per Cent of U.S. Membership	Maximum Median Salary
Metropolitan	4,928	27	$10,000
Middle Atlantic	3,857	22	8,000
Middle West	4,506	25	7,300
New England	2,038	11	7,200
Southern	1,097	6	6,000
Pacific	1,015	6	6,000
Prairie and Mountain	469	3	6,000
	17,910	100	

‡*This figure is the total membership of the Society in each area, and does not indicate the number who replied to the questionnaire.*

Fig. 2 indicates the effect of education upon earnings. "Engineering B.S." comprises only men who had received a degree of B.S. in engineering from an engineering school of recognized college rank. "Engineering B.S. plus" comprises those men who added to their B.S. degree a year or more of technical graduate work at a recognized engineering college. "Non-graduates" are those men who had completed at least three years of work at a recognized engineering school, but who did not get their degree. "Sub-collegiate" includes all men whose education comprised a course of study of at least three years in a night school or school of less than college grade. "Non-technical" includes all men whose training is less than "non-graduate" or "sub-collegiate."

*Prepared by the above committee of the American Society of Merchanical Engineers under the chairmanship of Conrad N. Lauer. The survey and the preparation of the report were directed by Professor Elliott Dunlap Smith of Yale University. The statistiscal computation was directed by Professor Hudson B. Hastings of Yale University.

†To get the "median" earnings in any classification, the salaries of all the engineers in the classification are arranged in a column in order of size. The total number of entries in the classification is then counted, and the salary of the man who comes in the middle of all the men in the classification is then taken as the "median" of the classification.

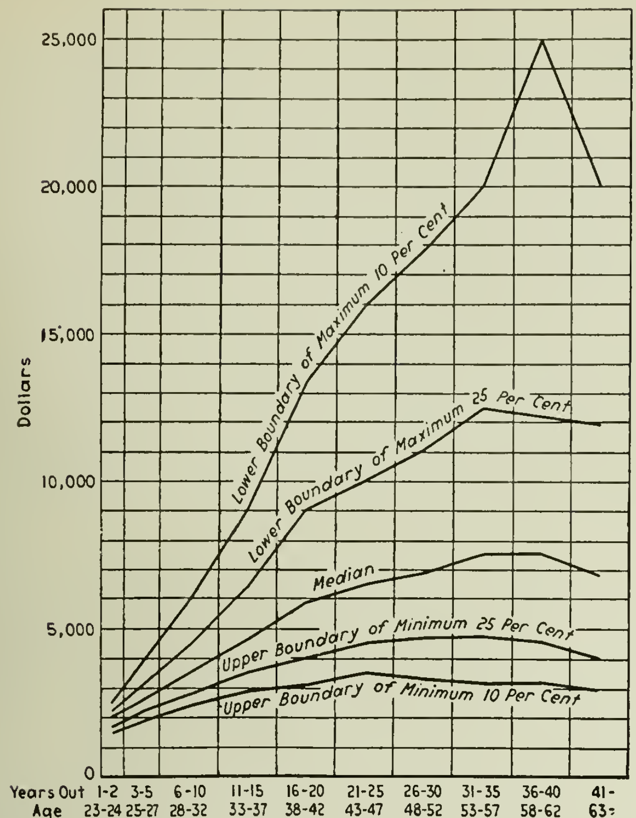

Fig. 1—1930 Earnings of Mechanical Engineers—United States as a Whole.

The fact that men with training of sub-collegiate rank at almost all ages earn less than men without technical training, may be partly due to the fact that men without technical training are not likely to take out membership in the Society unless they have made a moderate success in engineering, while men with night-school or similar training are more likely to register as engineers regardless of success.

The distribution of members who replied to the questionnaire among the various industrial classifications is shown in Table 2.

"Machinery manufacturing" and "chemical" follow closely the United States median. "Consulting," "construction" and "non-metal manufacturing" industries show slightly higher pay for ages up to 50, at which age they come down close to United States median earnings. Although the number of returns from railroads is small, the results at

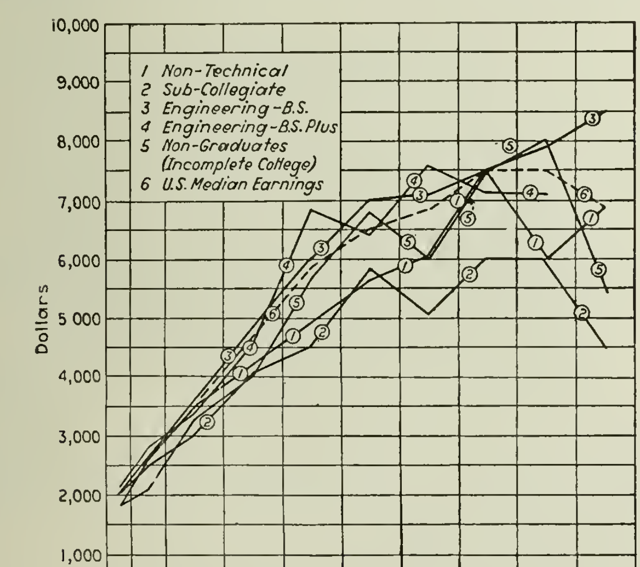

Fig. 2—1930 Median Earnings by Type of Education.

TABLE 2

DISTRIBUTION OF ENGINEERS BY INDUSTRIES

	Number of Replies	Per cent of total
Machinery manufacturing	3,051	38
Power Machinery manufacturing	934	12
Public Utilities	776	9
Consulting	755	9
Non-metal industries	648	8
Academic Institutions	593	8
Chemical	585	7
Construction	251	3
Railroads	127	2
Financial	91	1
Commercial	74	1

all wage boundaries are so consistent as apparently to justify the inference that railroads pay below the median wage almost from the start.

Median academic wages begin to fall below the median of the country as a whole at 28, and by 55 are approximately $2,000 below.

Fig. 3 gives comparative median earnings in the various sorts of work in which engineers engage. "Designing" includes all industrial research. "Technical operation" includes all maintenance, inspection, production control and similar technical work relating to operation. "Consulting" as a type of job includes only actual consultants and does

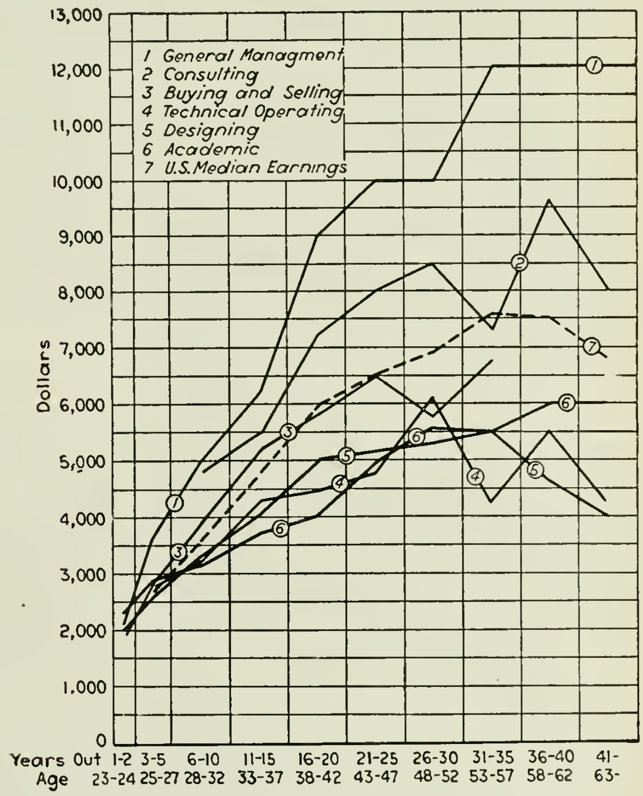

Fig. 3—1930 Median Earnings by Type of Occupation.

not include consultants' employees as consulting as an industry does. "General management" includes all men in general executive work from assistant foreman up.

The relations between the median earnings of the different types of jobs also hold at other salary ranges, the differences becoming more emphatic, however, as higher wage levels are reached. This is illustrated by the salary boundaries of men in the "designing" and in the "general management" classifications at typical ages, and by the percentage by which managerial earnings exceed designers' earnings.

Not only is there this striking difference between general management and consulting on the one hand, and design research and technical operation on the other, but there is a significant difference in earnings, especially among designers and research men, between those engineers doing technical work who have managerial duties and those who do not.

SUMMARY

The outstanding points about earnings in 1930, brought out by the survey are:

1. That the maximum professional income of the typical mechanical engineer is $7,600. One quarter age over $12,500; one tenth age over $25,000.

2. That the age of maximum earning power of the typical mechanical engineer is 55, earning power ordinarily not declining seriously with age even in the 60's.

3. That the differences in earning power between high-paid men and men in the middle salary ranges are strikingly great, the lower boundary of *the highest 10 per cent* at its maximum being 233 per cent higher than the maximum of median earnings.

4. That salaries are distinctly lowest in the far West, and that the New York Metropolitan district has much the largest percentage of high-paid men above the age of 50.

5. That a good education is worth while.

6. That apart from railroads and academic institutions, the differences between industries as regards salary opportunities are not great at most ages.

7. That the differences in earning power between men whose work is exclusively technical and those who combine with their technical ability the capacity to handle independent businesses or to manage men or affairs, are great—so great as to indicate the importance of most engineers seeking to develop themselves in this respect, and of engineering schools bending their curricula somewhat toward this end.

BRANCH NEWS

Hamilton Branch

John R. Dunbar, A.M.E.I.C., Secretary Treasurer.

The first meeting of the Hamilton Branch this season was held in the Royal Connaught hotel on September 17th, and took the form of a dinner meeting. E. P. Muntz, M.E.I.C., was in the chair. The speaker, Lieut. Col. W. P. Wilzar, M.E.I.C., of Queen's University, was introduced by L. W. Gill, M.E.I.C.

Engineering of the Ancients

The speaker commenced by stating that while it can be proved that man existed 350,000 years ago, all we have historical record of is 10,000 years. Into that comparatively brief time have been crowded all the discoveries of engineering principles as they have been handed down to us.

The earliest records we have are the dwellers of Ur, the Chaldeans. Between the Tigris and the Euphrates, a canal was built. The Tower of Babel was built of brick, on each brick was stamped the name of the ruler. A high degree of civilization was reached by these people. They instituted customs for revenue and wrote receipts.

One of the earliest forms of engineering was that of mining and metallurgy which the ancients brought to a high level in the working of gold, silver, tin and copper.

Many of our records showing engineering achievements of the past have been made interesting by Herodotus, who wrote entertainingly although perhaps not accurately of these.

In earliest times miners were nearly always criminals and the mines were state owned. It is said that Rameses II drew an annual income of sixty-five million dollars from this source.

In the olden times the engineer made weapons for war, after that he became a civil engineer. Caves, sepulchres and monuments bear testimony to their enduring work. The earliest text book on engineering was written two thousand years ago. Brick arches were constructed six thousand years ago. The Romans were perhaps the greatest engineers of the past. The Aqua Julia and Aqua Claudia, which were respectively fourteen and ninety-seven miles long, still show the features of construction. It is said that the Romans built altogether 47,000 miles of road; they understood the various principles of road building, such as piles, mortised caps, dirt roads, macadam, drainage.

The Egyptians have left many monuments, chiefly pyramids, the most famous of which is that of Cheops. In the building of these pyramids, stones weighing as much as seventy tons were drawn to a height of 700 feet and in the construction of Cheops the Egyptians used only a pulley and the inclined plane, yet the accuracy of measurement has always been a matter of wonder to subsequent engineers. In the placing of this pyramid in such a position that the Pole Star shone on the face of the dead Pharoah the Egyptians showed no small knowledge of astronomy. The speaker read extracts from Petrovius, a Roman engineer who drew up a code of ethics, many of the items being startlingly apt to-day.

F. W. Paulin, M.E.I.C., moved a hearty vote of thanks to the speaker for his instructive address which R. K. Palmer, M.E.I.C., seconded.

The chairman then gave an address on the prospects of the Branch for the coming year and exhorted the members to give something to the Branch rather than look only for the good that they might get out of it. E. H. Darling, M.E.I.C., councillor, outlined some of the points that were to be discussed at the plenary meeting to be held in Montreal the to be discussed at the plenary meeting to be held in Montreal on September 21st. There were thirty-two members present.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Thomas Telford, Father of Modern Civil Engineering

The fall programme of the Ottawa Branch was inaugurated with a luncheon at the Chateau Laurier on Thursday, September 17. The speaker was Sir Alexander Gibb who was in Canada making a survey of the national ports on behalf of the Federal government. Among those at the head table, in addition to the speaker and to G. J. Desbarats, C.M.G., M.E.I.C., the chairman, were the Honourable Alfred Duranleau, Minister of Marine; Alex Johnston, Deputy Minister; E. Hawken, Assistant Deputy Minister; Dr. Charles Camsell, M.E.I.C., Deputy Minister of Mines; Commander C. P. Edwards, A.M.E.I.C., F. H. Peters, M.E.I.C., Surveyor General; John Murphy, M.E.I.C.; J. McLeish, M.E.I.C.; J. L. Rannie, M.E.I.C.; and the following members of Sir Alexander's party, E. Palmer, T. Paton and H. Beaver.

Sir Alexander spoke upon the career, character and achievements of "Thomas Telford, Father of Modern Civil Engineering," a subject which was felt to be most appropriate when Sir Alexander explained that his own great grandfather, John Gibb, was a personal friend of Telford's and was, in fact, one of the great engineer's superintendents.

In tracing the life history of Thomas Telford, Sir Alexander characterized him as the father of professional engineering as we now know it and the honoured founder as well as the first president of the Institution of Civil Engineers of Great Britain, the "doyen" of civil engineering institutions throughout the world. The sum and total of his works during the course of a busy lifetime would be staggering if, indeed, it would be possible to completely enumerate them today. They related to the construction of canals, roads, bridges, docks and harbours, involving expenditures ranging into the tens of millions of dollars at a time when such sums signified a great deal more than they do now.

Telford was born in 1757 at Westerkirk in Eskdale, Dumfriesshire, Scotland, his father being a poor shepherd who died three months after the birth of his son, leaving his widow practically destitute. However, adversity did not affect Telford's disposition and he early in life earned the sobriquet of "Laughing Tam." While a boy he was employed as a herder, occasionally attending the parish school of Westerkirk where his quickness and diligence helped to make up for his lack of opportunity. At an early age he was apprenticed to a journeyman mason and in this capacity was engaged on works in various parts of the country.

Filled at all times with a restless ambition, he found time to gain a sufficient acquaintance with Latin, French and German to enable him to improve his knowledge in all branches of science.

His first great step forward was his appointment in 1793 as engineer of the Ellesmere canal, for which he built the Chirk and Pont-y-Cysyllte aqueducts. This work, the most important of its kind in the country at the time, led on to other work, so that he quickly became recognized as the principal canal expert in the world. Another canal upon which he was engaged and upon which he set high hopes, visualizing it as a means of making Scotland "the emporium of commerce," was the Caledonian canal. It, however, failed of its purpose and was not properly completed until thirteen years after his death.

The range of Telford's activities, in addition to his canal work, covered nearly a thousand miles of road and twelve hundred bridges, and it was stated also that there was scarcely a harbour with which he was not connected. Among the latter were the St. Katharine's docks of London, constructed in 1828. These were nearer to the heart of London than any others previously built; for their time they were a marvellous construction and under Telford's direction in order to meet the desires of the authorities were an exceedingly short time in building. Telford himself, however, protested against this haste in building such important structures, claiming that the practice involved dangerous risks to life and reputation.

In his work of bridge building, the masonry constructions ranked as high as any others built and the ingenuity and skill exercised in the design of his cast-iron bridges were truly remarkable. As an evidence of the durability of Telford's structures, Sir Alexander stated that in connection with his own work for the Ministry of Transport he investigated the state of the famous Menai straits suspension bridge over a hundred years after its construction and found it to be in sound condition, having due regard to the change of type of transport over that period of time.

Telford was never married. His tastes were simple and pecuniary reward had no great interest for him. He had an intense love for his motherland and a deep pride in the country's efforts. Combined with his own personal modesty was a readiness to give praise to others wherever it was due. He died in 1834 at the age of 77.

The De Laval Steam Turbine Company, Trenton, N.J., have recently published a leaflet describing and illustrating single-stage, double-suction centrifugal pumps of the horizontally split casing design. This type of pump was introduced by the De Laval Company in 1901, and is characterized by relatively high speeds, high efficiencies and the ability to work against high heads per stage. The catalogue, B-2, "De Laval Single Stage Double Suction Pumps," may be obtained from the company's office at Trenton, N.J.

The Garlock Packing Company, Palmyra, N.Y., have issued a new folder describing and illustrating the Garlock 701 brake lining, which is constructed of high quality asbestos cloth, impregnated with a special rubber compound, folded, moulded and vulcanized under 2,000 pounds pressure. The booklet, which may be obtained from the company at the address given above, also includes a price list of the brake lining.

Canadian National Exhibition, Toronto, 1931

Electrical and Engineering Building

During the past few years there has been a considerable increase in the number and importance of the engineering exhibits at the Canadian National Exhibition. These are doing much to indicate the progress of Canada in this field, and as a result, this section of the exhibition is becoming a recognized feature of the engineering world.

Readers of The Engineering Journal will be interested in a brief resume of some of the leading exhibits. Space does not permit the inclusion of all displays of an engineering nature, and it is unfortunate that so many items of importance were placed away from the main exhibits in the Electrical and Engineering building.

Busfield McLeod Limited

The chief exhibit of Busfield McLeod Ltd. consisted of a Gardiner 3-cylinder 54-h.p. 400 r.p.m. full Diesel marine engine in operation; the cylinder bore was 8 inches and the stroke 9¾ inches. This was manufactured by Norris Henty Gardiners Limited of Manchester, England, and is a modern direct reversing engine compression ignition cold start. It is of the type which has recently been supplied to a number of Canadian installations. While this is primarily a marine engine, the same type is used for stationary purposes such as for direct connection to generators in power plants. In Fig. 1 a 4-cylinder engine of similar type may be seen.

A interesting exhibit was a complete working model of a 3,000 i.h.p. North-Eastern marine Diesel engine, built by the North Eastern Marine Engineering Company Ltd., of Wallsend-on-Tyne, England, and installed on the 8,000-ton motorship "Raby Castle." This model shows the operation of the direct reversing system applicable to large engines of this type.

The Lux system of fire protection such as used for protection of generators and other electrical equipment, and for combating oil and inflammable liquid fires, was also on display. The exhibit consisted of a number of the portable Lux units which operate in principle exactly the same way as large built-in installations.

The latest model of a standard domestic type Permutit water softener was shown.

In the material handling field, there was also to be seen a standard heavy weight type clamshell bucket, suitable for either the handling of heavy materials or for digging work, manufactured by Priestman Brothers, Ltd., of Hull, England.

An additional exhibit was a complete standard diving outfit by Siebe, Gorman and Company, Ltd., and of the type used as standard equipment in the Royal Navy.

The Canada Machinery Corporation

The Canada Machinery Corporation exhibited a number of machine and woodworking tools manufactured in their factory at Galt, Ont.

Fig. 2 illustrates a 32-inch by 36-inch heavy duty crank shaper of a type suitable for shipyards, railway and machine shops. The ram has a maximum stroke of 32½ inches and the table a maximum cross travel of 36 inches; the rise capacity is 16 inches between the jaws. The column is a single-cored casting and all bearings are cast integral with the column including the bull gear bearing which is of large diameter providing ample wearing surface. The base is a heavy single piece casting, and is made with an extension with a planed surface for holding table support and is provided with flanged sides to collect oil and chips.

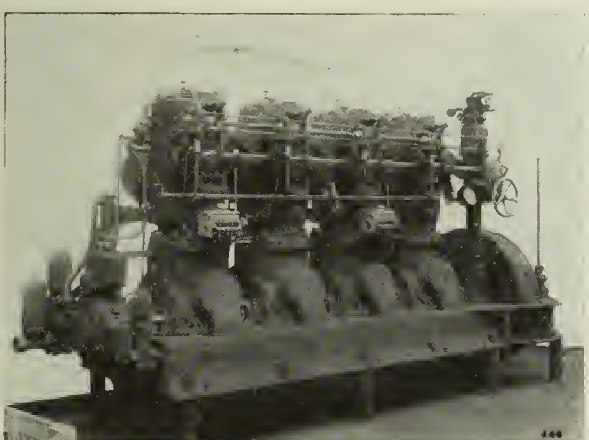

Fig. 1—Gardiner Diesel Engine.

The tool head is of improved design, having both automatic and hand feed which can be set to feed either up or down at any angle. Swivel is graduated so that the head may be set at any angle up to 90 degrees to right or left. The raising and lowering screw is provided with micrometer index collars, graduated in thousandths. The wear on the tool head slide is taken up by means of a taper gib which is also used for clamping the head when cross feeding.

The down feed mechanism is provided with nine changes of feed and can by a convenient crank handle be instantly stopped or reversed. It is provided with an automatic throw-out which disconnects the feed in case of over travel of ram and is also equipped with friction washers which slip in case of obstruction or overrun of tool slide.

The drive is direct from the line shaft or constant speed 15-h.p., 1,200-r.p.m. motor through single pulley and twin disc clutch to gear box built right into the machine containing heat treated nickel steel gears. The driving pulley is mounted on the opposite side to the operator but the main feature is that all speed changing, start, stop and brake operating levers are on the operating side of the machine, the latter being extended along the side of the shaper to operator's working position, to give him perfect control of the ram when tool setting. The rocker arm and bull gear are placed directly in the line of the cut and the rocker is attached to the ram by a double link which ensures an even motion and further eliminates the tendency of the rocker to lift the ram at the beginning of the stroke, and also neutralizes the upward thrust of the tool. The eight speeds provided give a range from six to one hundred strokes per minute to the ram.

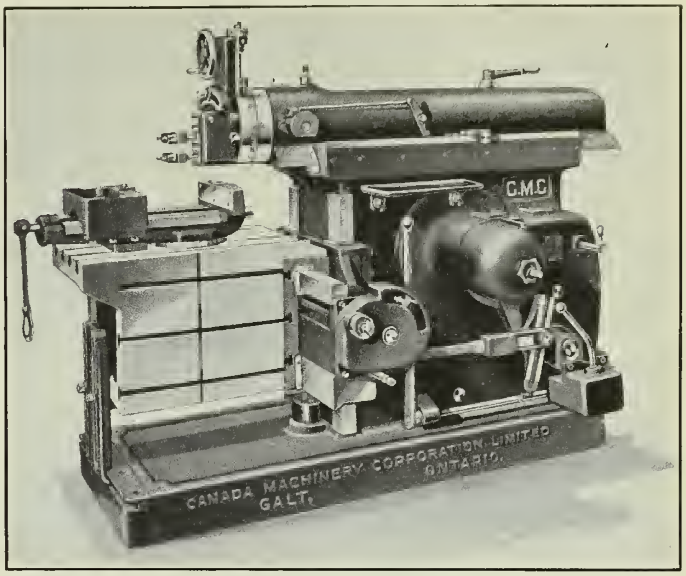

Fig. 2—Heavy Duty Crank Shaper.

A 35-ton power press was on view. This is intended for heavy duty; weighs 4,400 pounds and is operated by a 3-h.p. motor, either a belt or motor drive can be supplied.

In woodworking machinery a 43-inch revolving bed sander fully motorized was of interest. This was equipped with individual motors on each drum, the first two drums revolving at 1,200 r.p.m. and having 12-h.p. motors, the third revolving at 1,800 r.p.m. and having a 7½-h.p. motor. The shafts of these drums rotate in ball bearings of the self-aligning spiral type. The bed is 43 inches in width having a full rubber surface. The feed is by an independent 3-h.p. motor and the first reduction is by a V-belt drive through a gear box giving three rates of feed. The control is by push button.

The Sandilands Valve Manufacturing Company of Galt, a subsidiary of the Canada Machinery Corporation, were also exhibiting on this stand and displayed a 1½-inch, 150-pound pressure regrinding bronze gate-valve, which they claim effectively overcomes the high cost of maintenance while retaining every commendable feature of the gate valve, in that it can easily be reground without removing it from the line in precisely the same manner as a globe valve, and without the use of any special tools. This is made possible by a solid wedge type disc similar to the frustrum of a cone.

Canadian Atlas Steels Limited

Canadian Atlas Steels Ltd., of Welland, Ont., exhibited a large range of the finer types of steels from fine machinery steels to rapid cutting alloys. Also "No-Kor-O" stainless steel which is a low carbon ferrous metal containing 8 to 10 per cent nickel and 18 to 20 per cent chromium and having a specific gravity of 7.6. In addition there were various sizes of hollow mining drill and hollow stay bolt steel.

Canadian Blower and Forge Company Ltd.

Unit heaters, ventilating fans, blowers and air filters made up the largest portion of the exhibit of the Canadian Blower and Forge Company, Ltd., of Kitchener, Ont.

Among the more outstanding was a No. 300 Highboy unit heater, with electrically controlled damper. This is operated by a one-h.p. motor and with five pounds of steam pressure, and the entering air at 60 degrees F., gives 300,000 B.t.u. per hour and is designed particularly for the heating of industrial plants.

A 5½ E electric blower for industrial oil or gas furnaces and combustion systems was on exhibit. This is driven by a one-h.p. motor and has a maximum capacity of 1,000 cubic feet of air against 3-inch static press.

Also "Compact" and "Krimpak" air filters for use with various types of commercial equipment where filtered air is required. The manufacturers claim a rating of 800 cubic feet per minute each for standard "Krimpak" units 20 inches by 20 inches, with the initial resistance of 10 inches water gauge—this for average conditions.

Canadian Carborundum Company Ltd.

Carborundum brand silicon carbide and alonite brand aluminum oxide grinding wheels and discs of various grades and grits and shapes were on exhibit by the Canadian Carborundum Company Ltd., of Niagara Falls, Ont., from which some idea may be obtained of the large number of uses for which grinding materials may be employed.

Canadian S K F Company Limited

The Canadian S K F Company exhibited various sizes and types of ball and roller anti-friction bearings. Models of C.N.R. locomotive 6100 with tender and C.P.R. locomotive 2335 with tender and two cars, gave an opportunity to show the application of spherical type roller bearings to railway rolling stock and indicators pointed to places on these models where S K F bearings were used on the actual equipment.

Combustion Engineering Corporation Ltd.

The C.E. fire-tender stoker of which we reproduce a photograph, Fig. 3, was an exhibit of considerable interest by the Combustion Engineering Corporation, Ltd. It is a simple, rugged mechanical stoker, manufactured in Canada to their design, which automatically feeds coal to a boiler furnace by the underfeed method. It is an electrically operated, self-contained unit which consists primarily of a coal hopper, a conveyor screw, an electric motor and a variable speed gear case, a forced draft fan, air tuyeres and dead plates.

The operation is simple, the coal being fed from the hopper to the retort by means of a screw which operates in a barrel within the air duct. Air supplied by the fan is controlled by a butterfly damper and enters the air chamber supplying the air for combustion uniformly into the four sides of the fuel bed through the tuyeres. The dead plates accumulate the ash which is worked over on to them by the underfeed agitation of the fuel bed. The motor is direct connected to the fan and operates the conveyor screw through a six-speed gear case. Any of the six rates of coal feed may be obtained through adjustment.

A standard automatic control supplied with each stoker maintains uniform operation of the boiler at any desired steam pressure or water temperature. The unit on exhibit develops 150 h.p., consuming 600 pounds of coal per hour, and a 3-h.p. Lincoln motor, 550-volts, 1,500-r.p.m. drives a Sheldon forced draft fan and the screw conveyor through a silent chain drive.

The stoker body can be shipped completely assembled ready for placing under a boiler. The entire stoker is self-contained and all parts of the stoker under the furnace are supported by the air chamber casing. The dead plates rest on heavy ribbed transverse bars, also supported by the air chamber casing.

This stoker has been designed for firing small boilers ranging in size from 15 to 100 B.h.p. such as are found in apartment houses, schools, factories, etc., and can burn cheap grades of fuel efficiently.

Delamere and Williams Limited

Delamere and Williams Limited of Toronto, automatic machinery designers and manufacturers, displayed bottle fillers and washers, and in operation, a mixer. a "Vacu" draft blower and a conveyor table with conveyor belt in centre. This type of conveyor table with a conveyor belt running down the centre operated by a small electric motor, is exceedingly useful in general assembly plants and packing houses for facilitating the handling of equipment. This firm also manufactures a large range of testers, cutters and weighing and packaging machines for all kinds of materials.

Dominion Bridge Company Ltd. and Associated Companies

The Dominion Bridge Company exhibited an interesting example of the Kane System of Composite Construction which it is claimed combines the advantages of steel frame structures with the economy of reinforced concrete construction in buildings where welded steel construction is used. It consists of a structural frame of either built-up or rolled columns and welded trusses designed to carry the construction loads but which, when fireproofed with concrete, acts as a reinforcing and results in a composite structure in which both the steel and concrete act together in supporting the superimposed loads. This struction can be used with any type of floor system and owing to the use of built-up members, all material is obtainable from Canadian mills. Fig. 4 gives an example of this type of construction. It lends itself to economical and flexible construction in the field and facilitates the placing of piping through the use of the open web type of steel joists and floor girders.

Another display was a gear and pinion of a type now standard and manufactured by this company; that is, a pinion with a tooth having a long addendum meshing with a gear having a tooth with a short addendum. This tooth form is a correction of the 20-degree involute equal addendum type making it suitable for cranes, and other machinery handling heavy loads. The gear centres are standard with the equal addendum type.

Among the advantages claimed for this type of gearing is that there is no undercutting of the teeth and a thicker and stronger section is obtained at the base. Pinions with twelve teeth are as strong as those with twenty-three teeth of the equal addendum type and when operating the teeth roll on each other with a minimum of slip.

Also to be seen was a 10-ton electric travelling crane, the hoist operated by a 7½-h.p. motor and the drive by 2-h.p.

The display of the Dominion Engineering Works, Ltd., consisted of samples of a few of the many lines manufactured by them, a Farrell Sykes reduction gear, type S-15, ratio 8.3 to 1 with continuous herring-bone teeth, a five-inch Larner Johnson hydraulic valve manufactured to the patents of I. P. Morris de la Vergne, and a Dominion gearflex coupling , designed for 500 h.p. at 100 r.p.m. Also test models of a Francis turbine runner, an adjustable blade propeller type turbine runner, and a propeller type.

Canadian Pipe and Lining Company, Ltd., exhibited a section of 42-inch pipe manufactured in Canada at Montreal according to the Hume process, W. R. Hume, an Australian, being the inventor. This is welded steel pipe with the interior lined with concrete applied by centrifugal action and the exterior treated to resist corrosion. This is used for carrying water supplies under high pressure and has the advantage of not being subject to interior and exterior corrosion in

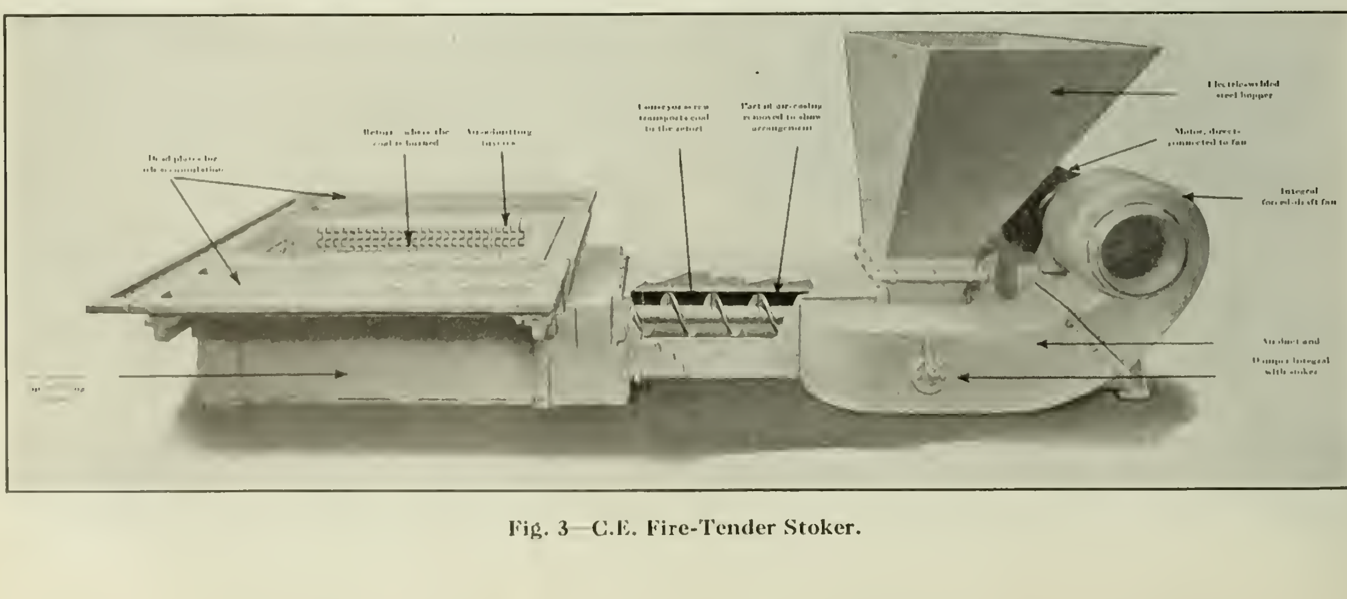

Fig. 3—C.E. Fire-Tender Stoker.

the same manner as steel pipe. An important feature of this pipe is the expanded reinforced faucet, an example of which is shown in Fig. 5 and which is believed to be more efficient than the usual type of joint.

The Dominion Hoist and Shovel Company Ltd. had on view a 1-yard gopher shovel crane as a sample of the excavating and materials handling equipment which they manufacture at Montreal. This is adaptable for shovel, crane, hook, clamshell or dragline work and can be operated by gasoline, electric or Diesel motors, approximately 85 h.p. being necessary. The weight is about 65,500 pounds, the continuous chain treads are of cast chrome steel and of the multiple hinge type, fully enclosed bevel gears drive across shaft which drives the tread sprockets by means of roller chains. The control is from an all-steel cab and all machinery rollers, shafts, etc., are of exceptional quality.

Manitoba Bridge and Iron Works Limited, of Winnipeg, were showing a Canadian Fire-King automatic stoker which they are now manufacturing. This is designed to burn Canadian slack coal and screenings and is built in eleven sizes from 10 B.h.p. for the home to a heavy duty unit for 500 B.h.p. boilers. They are built with the intention of competing against oil burners gas furnaces and central steam heat and large savings in fuel costs are claimed.

It is the underfeed type of stoker, the coal being fed to the retort by a spiral feed worm. The electric motor which drives the worm also operates a forced draught fan which delivers the proper proportion of air to the fuel bed. A variable speed drive is used, automatic controls provide a constant pressure or temperature under all conditions.

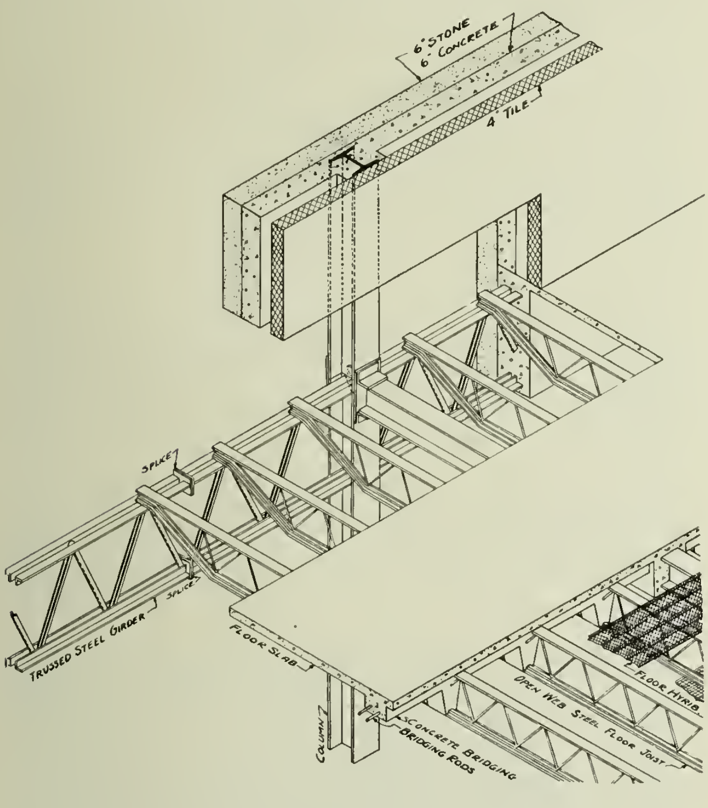

Fig. 4—Kane System of Composite Construction.

McGregor-McIntyre Iron Works Ltd., of Toronto, had on view samples of steel railings, stairs and safety gratings manufactured by them. These are for use in various types of buildings and industrial plants.

Robb Engineering Works, Ltd., of Amherst, N.S., exhibited two "Victor" boilers manufactured by them and of a type designed either for steam pressure up to 15 pounds per square inch or hot water heating, and constructed of steel with electrically welded seams. The two types can each be equipped for either hand, stoker, oil or gas firing. These are built in sizes from 74 square feet to 2,658 square feet of boiler heating surface and may be used for domestic or industrial use.

Elliott and Whitehall Machine and Tool Co.

Drills, dies, jigs and fixtures, small tools and parts, mining machine parts, gauges and air valves, were displayed by the Elliott and Whitehall Machine and Tool Company of Galt, Ont., who manufacture a fine range of equipment in these lines.

Ferranti Electric Limited

The display by Ferranti Electric Limited consisted of samples of their large range of standard watthour meters and instrument transformers, also a neon sign transformer, the core and coils of a 300-kv.a. transformer and cross section of the core and coils of a pole type transformer manufactured in Toronto, Ont. The new hand hole cover which is now standard equipment on distribution transformers was being shown for the first time, and prevents the necessity of removing the top cover of a transformer when changing taps.

A compact instrument which appeared in this booth was the Clip-on-Ammeter, see Fig. 6, which affords a quick and convenient method of measuring the current in any A.C. leads of bus bars without disconnecting them for the insertion of the usual current transformer or ammeter leads. This consists of a split-core current transformer, the primary of which is formed by the conductor whose current is to be measured. The secondary is connected to a high grade damped Ferranti 2½-inch dial milliammeter with a 2½-inch, 110-degree scale calibrated for direct reading in amperes.

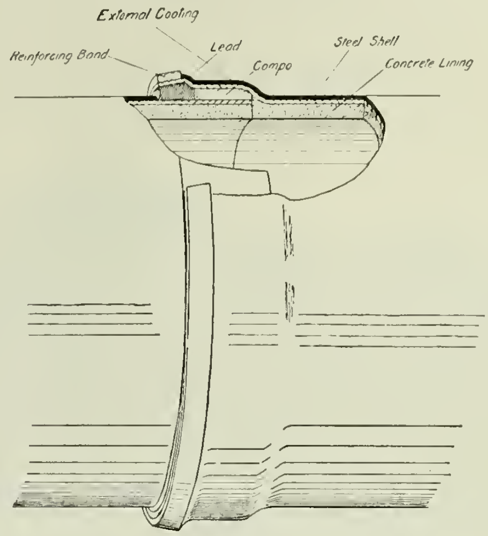

Fig. 5—Section Through Hume Pipe Joint.

The operating handle is well insulated from the core legs of the current transformer and is tested to withstand 15,000 volts from the handles to a bare copper bar placed within the core and adjacent to the coils, but the instrument is not intended for use on circuits above 600 volts without the use of rubber gloves. A conveniently placed trigger for opening and closing the core enables the instrument to be used with one hand. The core is self-aligning and is insulated to minimize the danger from accidental contact with live conductors. The maximum overall dimension of cable which can be accommodated is two inches.

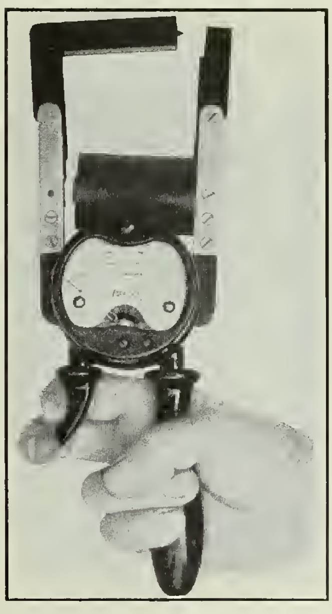

Fig. 6—Ferranti Clip-On-Ammeter.

A switch on the meter changes the reading from the 0-100 ampere scale to the 0-500 ampere scale or vice versa.

There was further shown summation metering equipment of the type being used on the English Grid system, eight sources of power being recorded separately and totalized.

WILLIAM AND J. G. GREEY LIMITED

A large number of machines for the paint and ink industry, bakeries and also grain working machinery was to be seen on the stand of William and J. G. Greey Ltd., of Toronto, Ont. Among those included were a number of ball mills, the largest being 60 by 60 inches, pony and laboratory mixers and stone paint mills, all for paint manufacture. Grain cleaners, crushers and grinders were included in the display of grain working machinery. This equipment all being manufactured by the above company.

HAMILTON GEAR AND MACHINE COMPANY LTD.

An interesting exhibit of gearing was on display at the stand of the Hamilton Gear and Machine Company, Ltd., of Toronto, Ont., and this included cut gears and pinions of various types. A high speed herringbone gear drive, speed reducers of the worm, herringbone and spur type, rawhide and Celeron silent pinions and flexible couplings for many uses. There was also an example of the Hamilton-Ramsey silent chain drive.

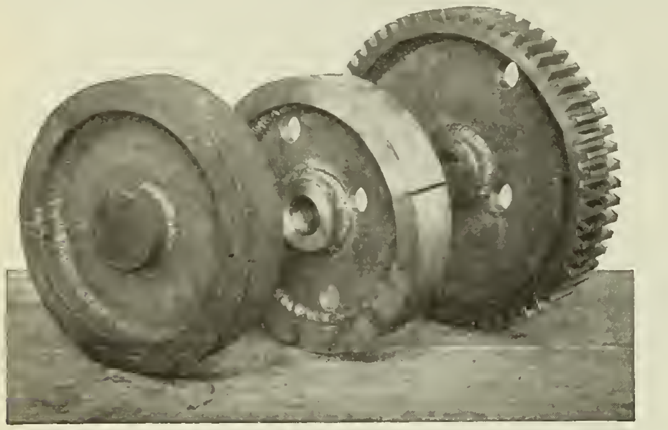

Fig. 7—Three stages in the manufacture of a Roldweld Speed Gear.

A new feature on the stand was the Roldweld spur gear, the rim of which is formed in a hydraulic press from a rolled bar of .45 per cent carbon steel. This material is rolled from selected and chipped billets of forging quality steel. The welding together of the rim, plate web and two hubs is by the metallic electrode process after which the assembled gear blank is heat treated to develop the best combination of strength, toughness and wear resistance. The result is a practically unbreakable gear.

Three stages in the manufacture are illustrated in Fig. 7. These gears are now being made in sizes up to 6 diametral pitch, a maximum face width of 2½ inches with a maximum of one hundred and thirty teeth.

JOHN T. HEPBURN LIMITED

An interesting piece of equipment exhibited by John T. Hepburn Limited of Toronto, Ont., was their 3-ton "Low Head Room" electric hoist for industrial plant use. This is designed and manufactured by them to give the maximum lift for the space available and for this size the standard hook lift is 24 feet, the hoisting speed 25 feet per minute, the motor required is 5 h.p. and the number of ropes, four. It can be made for either hand or electric travel.

The gears used are all machine cut from solid steel forgings and heat treated, the shafts are of steel and the fall block has ball bearing swivel for the hook, the sheaves are at each end of the centre piece and a cast rope guide is placed over the sheaves on each side. The hoisting drum is of rigid construction and has right and left hand grooves to take the cable without overlapping.

The automatic holding brake works on a pulley mounted on the hoist motor shaft. By means of levers and a cam between the shoes it is released when the operator pulls the control lever and is applied when the control lever is released. The automatic mechanical brake is of the helix disc type and controls the lowering. The upper limit control is positive, being connected with the operating lever of the controller. On the controller, a return spring holds the operating lever in the off position, as soon as the operator releases the pull, the controller springs back to the off position. Timken bearings are used throughout.

Further exhibits were a power press of the inclined table type, belt driven with an adjustable table that can be inclined at various angles to accommodate different kinds of work. The portable sandslinger manufactured by J. T. Hepburn Ltd., as licensee for Canada of the Beardsley and Piper Company of Chicago, appeared to be a complete and flexible piece of equipment. This occupies a floor space of 15 feet by 4 feet, has an overall height of 12 feet, and weighs 9,500 pounds. It can be picked up by a crane and moved about a shop.

A number of pumps on exhibit included a vertical ram feed pump for marine or land service and a horizontal ram feed pump with mechanically actuated valves suitable for feeding boilers carrying high steam pressures. This latter pump had a steam cylinder of 8-inch diameter, a water ram of 5-inch diameter and a stroke of 12 inches. The capacity was 1,374 Imperial gallons per hour, it occupies a floor space of 24 inches by 84 inches, and will feed 457 boiler horse power. It is rated at 30 single strokes per minute, and weighs 1,150 pounds. The pipe sizes are steam 1 inch, exhaust 1¼ inches, suction 3 inches, and delivery 2½ inches. The steam cylinders have cast iron pistons fitted with self-adjusting rings and steel rods. The ram is also of cast iron, working in a brass sleeve. Valve seats are brass and pressed into a taper seating and secured by brass stops. These may be lifted out with the valves for examination and repairs without disturbing any pipe connection. A drop lubricator or force feed oil pump can be furnished.

JOHN INGLIS AND COMPANY LIMITED

John Inglis and Company Ltd., of Toronto, Ont. showed a Farasey asphalt mixer and sand dryer manufactured by them to the design of J. D. Farasey Company, Inc., of Cleveland, Ohio.

The mixer exhibited was of one ton capacity, with steam or air used for opening or closing the dump gate. The sand dryer weighed 15 tons and had a capacity of 70 tons per hour, with drying done by an oil burner. This is 66 inches in diameter and 24 feet long, and is principally used for drying and heating sand and stone for hot mix asphalt pavement. It is a self contained unit, that is, it is built on a sub-frame to which all driving mechanism is attached. A 100-h.p. motor is sufficient to drive the mixer, dryer and elevator.

A Bay City shovel of ⅜ yard capacity, manufactured in Canada, was also on display.

An exhibit of three sizes of "Supreme" domestic hot water boilers and one "Supreme" heating boiler provided examples of the large range of boilers of this type manufactured at the John Inglis plant in Toronto. As an example of a medium sized boiler of the domestic hot water type, this has a heating surface of 65 square feet and a grate surface of 5.7 square feet, a shipping weight of 2,250 pounds and under normal load has a capacity of 255 U.S. gallons of water per hour raised 100 degrees F. All are of flange steel construction and electrically welded, with single-tube pass, and the firebox and combustion chamber can be adapted for fuel oil burning.

A. B. JARDINE AND COMPANY LTD.

A. B. Jardine and Company Ltd. showed pipe threading tools and dies manufactured by them at Hespeler, Ont.

A new feature was a new one-die pipe threading tool adjustable from one inch to two inches, also a portable speedomatic one-half inch to two-inch pipe threading machine with receding die head, cut off head and reamer, and with attachable universal joint for cutting pipe to six-inch diameter. This is driven by a two-speed, one-third-h.p. universal motor but can be equipped with a one-h.p. gasoline engine.

H. W. PETRIE LIMITED

The stand of H. W. Petrie Limited contained a fine display of machine tools including a number of foreign make.

The new Capstan Lathe 5-B manufactured by Alfred Herbert Ltd., of Coventry, England, made an exceptionally fine display. The swing over slide covers 15 inches, the over cross side 8 inches and the feed bar capacity is 1⅝ inches diameter. The lathe as illustrated in Fig. 8 has several new features such as the patented covered slides. These

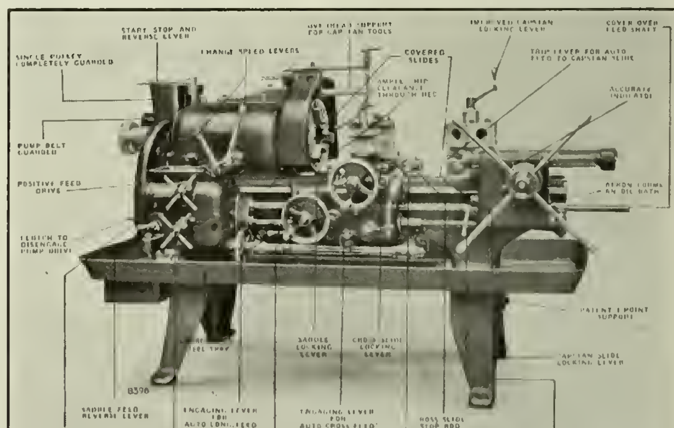

Fig. 8—Herbert Capstan Lathe.

are completely covered by the company's patented system by which the working surfaces of the slides are protected in all positions from chips, dirt, cooling fluid and from injury by dropping work or tools. The slide overs are in actual working contact with the surfaces, so that continuous lubrication of the sliding surfaces is secured. The spindle is provided with a flange to which the chuck can be bolted direct and the same spindle can be used whether the head is "plain," fitted with draw-in chuck, or with an air operated chuck. The single pulley head provides eight spindle speeds in either direction, obtained by sliding gears and friction clutches. The head forms an oil bath for the gears and bearings and all gears are of steel, hardened where necessary.

An improved feed box gives four changes of feed in geometrical progression to the longitudinal and transverse motions of the saddle and to the turret side.

The upper pilot wheel controls the capstan slide feeds, the lower one the saddle and cross slide feeds. The lever on the left-hand side of the lower pilot wheel reverses the saddle and cross slide feeds.

The shafts of the pilot wheels carry large, easily read dials showing the rates of feed in cuts per inch, the figure appearing at the top being the feed in use.

Each feed shaft has a safety clutch preventing injury to the mechanism should an excessive load be put upon it.

The traversing saddle has a loose apron of box form containing the mechanism for the automatic longitudinal and transverse feeds. The transverse feed screw is fitted with ball thrust bearings.

Balanced handwheels are provided to the longitudinal and transverse hand motions. Cross slide is of steel. Hand wheel has an adjustable index disc. Front tool post is of the swivelling, open side type. The back tool post is specially adapted for holding form tools.

The automatic rotation of the capstan can be disengaged when not required. Tool holes are relieved to facilitate easy insertion and removal of tools and to prevent wear in holes.

The capstan slide carries a hexagon stop bar geared to rotate with the capstan; the stops trip the feed and act as dead stops. The slide has a graduated scale with an adjustable pointer; the pilot wheel has an accurate indicator for obtaining lengths within fine limits.

Using a constant speed motor with direct or alternating current, the various spindle speeds, eight in number, are obtained mechanically in the headstock and this gives a range of spindle speeds for general work of from thirty to five hundred and eleven.

The range of spindle speeds can be increased and a very fine gradation obtained by using a direct current variable speed motor.

The control gear for direct current motors is of the enclosed, contactor type, with no-volt and overload releases, fuse and isolating switch. The control gear for alternating current motors is of the enclosed contactor type, with no-volt and three overload releases and isolating switch. With either type of control gear a push button switch arranged for "start" and "stop" is mounted on a bracket in a convenient position for the operator.

Also on exhibit were a Cadem Gap lathe manufactured in Belgium; a portable gasoline engine air compressor with capacity of 180 cubic feet per minute at 800 r.p.m. manufactured by Schram and Company, Westchester, Pa.; a five-foot radial drill manufactured by Sculfort-Fockedey, Vautier and Cie of France and motor driven, was equipped with five automatic feeds and eighteen spindle speeds. There was also a new Hako Rekord power hack saw. Others were a H. W. Petrie 30-inch pedestal band saw, equipped with ball bearings, a 16-18 inch geared crank shaper, manufactured by the Peerless Machine Tool Company of Guelph, Ont., also a combination saw and jointer, with 8-inch circular saw, a boring and routing attachment, and one moulder cutter outfit driven by a half-h.p. motor and manufactured by the Delta Specialty Company of Milwaukee.

Link-Belt Limited

Materials for elevating, conveying and power transmission machinery were on view on the stand of Link Belt Limited, and these consisted of various types and sizes of pulleys, chains, pillow blocks, hangers, a car puller, a bucket conveyor and a No. 1 Reeves variable speed transmission.

Powerlite Devices Limited

Powerlite Devices Limited of Toronto and Montreal featured an instrument panel containing miniature control units for A.C. and D.C. apparatus, using a new size of small rectangular instrument which has been developed to meet the trend of modern switchboard practice towards smaller control boards. These are manufactured by the Weston Electrical Instrument Corporation of Newark, N.J., and the units consist of vertical steel strips mounted with the necessary control instruments, a switch panel and a connecting panel. The strips are five inches wide, and of any desired length, spot welded to angle iron sides by means of which the several units are rigidly bolted together.

The unit assemblies are mounted complete with instruments, switch and connecting panels and completely wired ready to bolt together into a complete switchboard and connect to the external circuits. The instruments, switch and connecting panels are interchangeable in size and mounting. The units are also interchangeable in the complete board assembly.

Instruments of the flush type with flange fronts, four inches wide by four and a half inches high, and a body three and a half inches square projecting through the rack. The scales are three and a half inches long, wide open and legible. Inside the case two miniature 32-volt lamps with reflectors give full scale illumination with freedom from shadows.

The instruments known as Model 610 are made as D.C. ammeters and voltmeters, A.C. ammeters, voltmeters, single-phase wattmeters, polyphase wattmeters and reactive kv.a. meters. The movements are of the same size as are used in the large Weston rectangulars with the exception of the D.C. instruments, which are slightly smaller. The instrument insulation will withstand test voltages as specified by recognized standards.

Switch panels have either one or two switches, each equipped with three control lights, amber, red and green, for use in signalling the operator the condition of his controls. On the generator panels one switch may control the circuit breaker and the other the motor operated field rheostat. On feeder panels one switch may control the circuit breaker and one switch the electrically operated disconnector.

The connecting panel is the same size as the switch panel and instrument fronts and is usually located at the bottom of the rack or strip. The cover is removable from the front, exposing the terminal clips.

They also exhibited a motor-operated controller valve adapted for floating control designed especially for use on temperature control applications where steam is the heating medium, and manufactured by the Bristol Company of Waterbury, Conn., U.S.A.

A new recording seven-day triplex ammeter having three overlapping charts rotated by one telechron motor, which provides visual indication of balance of polyphase circuits, also their new portable duplex recording voltmeter, having two pens each recording on separate arcs the line voltage on polyphase circuits. Also on display was a new duplex controller for controlling the temperature of milk during the pasteurization process. This operates with the Bristol floating motor-operated valve, supplying the heating medium.

Redler Patents

Redler Patents, Sharpness, Gloucester (England), were showing samples of various types and sizes of conveying chains as used with Redler conveying systems, and a section of a 30-inch circuit chain designed to convey 210 tons of coal an hour at a speed of 25 ft./min. or 600 tons of wheat in the same time at a speed of 60 ft./min. These systems are designed to convey coal, wheat, flour, or any bulk materials.

In operation at the stand was a 5-inch Redler Circuit Elevator with H-link type chain conveying wheat. This type operating with a chain speed of 30 ft./min. can convey 5¼ tons of wheat in an hour. The circuit in this case consisted of a horizontal, a vertical and an included conveyor, the one continuous chain being used throughout.

An explanation of this system, which was first exhibited in 1924 at Wembley, should be of interest. First, however, it may be noted that the design consists of a light endless chain operated in a closed or open trough. The type of conveyor and chain varies with the material to be conveyed and may be divided into four classes: (*a*) where the

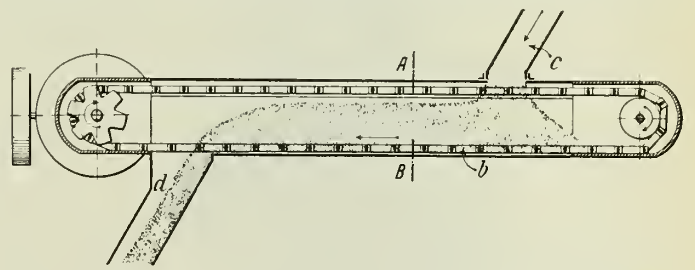

Fig. 9—Diagrammatic Section of Standard Redler Conveyor.

conveying member sweeps one side of the conveyor casing (for conveying horizontally); (*b*) where the conveying member sweeps two inner sides (for conveying horizontally); (*c*) where the conveying member sweeps three inner sides (for conveying up an incline); (*d*) where the conveying member sweeps four inner sides (for conveying vertically).

An example of (*a*) the Standard Redler is illustrated in Fig. 9. In this system the material is not carried bodily as with belt or bucket conveyors, but is induced to flow more or less of its own accord, a condition rendered possible by the friction between the particles of the material. A closed trough *A* forms the body of the conveyor and within this trough is a specially formed endless chain *B*. Material enters at *C* and falls upon the moving chain, the links of which become filled and generate virtually a ribbon of moving material. The remainder of the material rests upon this moving ribbon and is carried along by it. At the point where it is desired to release the material, it is only necessary to cut an aperture in the base of the trough and it will fall away freely through the links of the chain as at *D*. A slow speed of chain travel is adopted, and the material rides along in a body without agitation.

This type of chain, regarded as standard, is suitable for conveyors which are approximately horizontal. When the inclination exceeds the angle of repose of the material a different form of chain is adopted, for instance, to convey vertically the H-type of chain sweeping four sides of the enclosed conveyor is used.

The troughs or casings are constructed in wood and/or metal. The terminals are of simple construction and consist of special driving sprockets mounted on shafts running in dust-tight ball bearings. Reduction gear is either spur or bevel in a gear box and suitable oil bath. The position can be changed to suit any drive required or double reduction employed for direct driving by electric motor.

These conveyors are made in sizes of 3 inches upward to 17 inches and in the smallest size have a capacity of 10 tons per hour with a material weighing 100 pounds per cubic foot. The maximum chain speed is 60 ft. min. A conveying system of this nature has an advantage over many others where first a belt conveyor is used for horizontal movement and then a bucket conveyor to hoist the material vertically in that it obviates the necessity of switching from one type to the other, one continuous chain handling the material throughout the system.

Riley Engineering and Supply Company Limited

This exhibit well illustrates the lines of material handling equipment for factory and industrial use now manufactured by the Riley Engineering and Supply Company, Ltd., at Toronto, Ont., a firm well-known for their power plant equipment.

On display was a Barrett portable elevator. These hoists are manufactured in Canada, to the design of Barrett Cravens Company, U.S.A. They are made in the hand or electric operated types in the telescopic or hinged design, with either gearless or gear enclosed lift mechanism. Capacities range from 500 to 5,000 pounds, with lifts up to 20 feet. All are governor controlled, providing for a controlled descent of the platform. This in conjunction with a clutch on the electrically-controlled type enables the current to be cut off on the descent. Two lifting speeds are provided for loaded or empty platform.

The bearings in the gear shaft are integral with this housing, which makes certain that the bearings are at all times in alignment. The steel platform is removable.

The lifting speed varies according to the size and capacity of the motor and for a motor of ½ h.p. operates at 13 ft./min., for ¾ h.p. 20 ft./min., and 1 h.p. 27 ft./min.

These are exceptionally useful for industrial plants, warehouses, and storage rooms.

Also on display were a ½ and 1 ton "Reco" rapid hoist. These are of the chain block type and are manufactured in capacities up to 20 tons. The gears are of cut steel and the load sheave, driving pinion and gears are supported by S.K.F. bearings, eight in all, and there is also a Timken bearing to ensure easy swivelling. Alemite lubrication is provided.

In conjunction with this a light type of built-up monorail of improved design and new type switching system was to be seen.

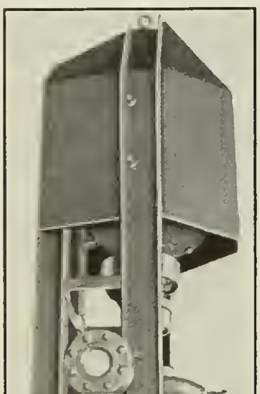

Fig. 10—Vertical Application of Centrifugal Pump.

N. Slater and Company Ltd.

N. Slater and Company Ltd., of Hamilton, Ont., exhibited a large number of specimens of stampings and forgings, also pole line hardware manufactured at their plant in Hamilton.

Smart Turner Machine Company Ltd.

The most interesting piece of equipment displayed on the stand of the Smart Turner Company Limited was a three-inch, multi-stage, double-suction, horizontally split shell, centrifugal pump, used vertically as in Fig. 10.

This pump is built into a steel framework supplied with a lifting eyebolt and the unit is designed so that it may be hung from a cable and operated in any position, vertical or horizontal, and is suitable for mine sinking, well-boring, pumping out excavations, etc. Special precautions have been taken to protect the motor from moisture or water splashing from the walls of a shaft.

Also in operation was a new type domestic water supply pump of capacity of 300 Imperial gallons per hour at 40 pounds pressure, driven by a Westinghouse ¼-h.p., 1,425 r.p.m., motor.

Further exhibits consisting of centrifugal pumps, an automatic cellar drainer, and a six-by six-inch double-cylinder air compressor were to be seen, also a steam-driven direct acting eight-by six-by twelve-inch vertical single-cylinder boiler feed pump, all equipment being manufactured by the Smart Turner Machine Company at Hamilton.

Toronto Technical Schools

The Toronto Technical Schools occupied eight booths and very ably succeeded in demonstrating the work done by the various departments of these schools.

Each booth was devoted to one department, such as art, aircraft, machine shop, metal work, modelling, printing, science and woodworking, and in each were displayed samples of the work done by students. A number of these departments had equipment operating.

A. R. Williams Machinery Corp. Ltd.

One of the largest exhibits of machinery was that of A. R. Williams Machinery Corporation, Ltd., with head office in Toronto, Ont.

The Association of British Machine Tool Makers Ltd. were well represented on this stand, with an exhibit of shapers and drills. Of interest was a crank shaper with an 18-inch stroke manufactured by the Butler Machine Tool Company Ltd., of Halifax, England. A vertical drilling machine manufactured by James Archdale and Company, Ltd., Birmingham, was displayed. This was designed for high production manufacturing duty. The head is a self-contained unit enabling the machine to be effectively arranged in gang form. The frame consists of a massive head casting bolted to a rigid well-ribbed box section column which in turn is mounted upon a pan type baseplate.

The drive to the spindle is by means of belt through fast and loose pulleys and a change speed gear box of the slip-on gear type. All the main transmission shafts run in ball bearings and hardened spiral bevel gears are used for the pulley bracket and for the spindle drive. The machine can be arranged for self-contained motor drive.

The spindle is of high carbon steel, and has six accurately ground driving splines machined from the solid. The drive to the spindle is through heavy duty hardened spiral bevel gears running in ball bearings. The spindle is carried in a hard steel sleeve provided with ball journal bearings and ball thrust washers at each end. The feed rack is cut integral with the sleeve, not bolted to it as in the case of some machines. The spindle speeds are changed by means of hardened steel slip gears.

Four rates of self-acting feed motion are available through the feed box on the head of the machine. For repetition drilling of holes to a pre-determined depth, automatic trip motion is provided, the graduated disc having widely spaced divisions. In addition to automatic feed, quick hand traverse and fine hand feed are also provided.

Under test conditions the machine will drill a 1¼-inch diameter hole in mild steel at a penetration rate of 7 inches per minute, or a 3-inch diameter hole at a penetration rate of 1¼ inches per minute.

The "El Champion" spot and projection welding machine, manufactured by The Taylor-Winfield Corporation, Warren, Ohio, appeared on this stand and is capable of welding two pieces of ¼-inch stock on slow speed with the large size transformer. On projection welding it is capable of welding five projections in an area of seven square inches of 1/16-inch stock at slow speed or lighter stock at correspondingly higher speeds. The transformer capacity of this machine is 20 to 60 kv.a. on 50- or 60-cycle current. Fifteen to thirty kv.a. on 25- to 30-cycle current.

This machine is furnished with a 1-h.p. constant speed motor; however, if desired, a four-speed constant torque multi-speed motor may be furnished.

The four-speed control for this motor, together with the stop position, is incorporated in the base of the machine and operated by a hand-wheel.

The speed at which the machine operates has a direct bearing on the thickness of stock which can be welded.

The operating head is actuated by cam through toggle action which gives a very smooth quiet movement. The slides are 12 inches long with take-up gibs for alignment and wear. There is also a visible water flow connection in full view of the operator at all times. The lower arm has an adjustment up and down of 5½ inches, permitting adjustment up and down by the adjusting nut plainly in view at the bottom of the pedestal on front of the machine. It is equipped with an eight-step selector switch and the clutch and transmission are totally enclosed in the housing of the machine and running in oil continuously.

The contactors are mounted in the base of the machine out of the way of all danger as a safety feature, but are readily accessible by removal of the perforated metal guard for adjustment or inspection.

Another exhibit in operation on this stand was an 10-B.h.p., 1,200-r.p.m. type 1 HK 60 Junkers vertical single cylinder opposed piston Diesel engine, manufactured by Junkers Motorenbau of Dessau, Germany.

A single type is illustrated in Fig. 11 with outer casing partially removed.

A similar type of engine is suitable for various kinds of industrial, agricultural and marine work and belongs to the solid or airless injection type of Diesels. Spray atomization of the fuel by injection with an open nozzle, opposed pistons, and the absence of valves as well as cylinder heads form the characteristic features of the Junkers engine which thus differs fundamentally from all other designs of Diesels.

The two pistons of a pair always work in opposite directions. The space between their faces and the cylinder liner forms the combustion chamber. The upper piston controls the admission of air for combustion by opening the upper scavenging ports, whilst the lower one, which opens the exhaust ports, controls the escape of the waste gases after combustion.

In the outer dead-centre position, the exhaust and scavenging ports are open. The pistons enclose fresh air. As they approach each other, they compress the air and raise it to the temperature needed to ignite the charge.

In the inner dead-centre position, the fuel pump injects fuel into the hot air charge through an open nozzle as a well-atomized spray. The fuel ignites at once and spontaneously. Forced apart by the gases of combustion, the pistons impart motion to the crank shaft

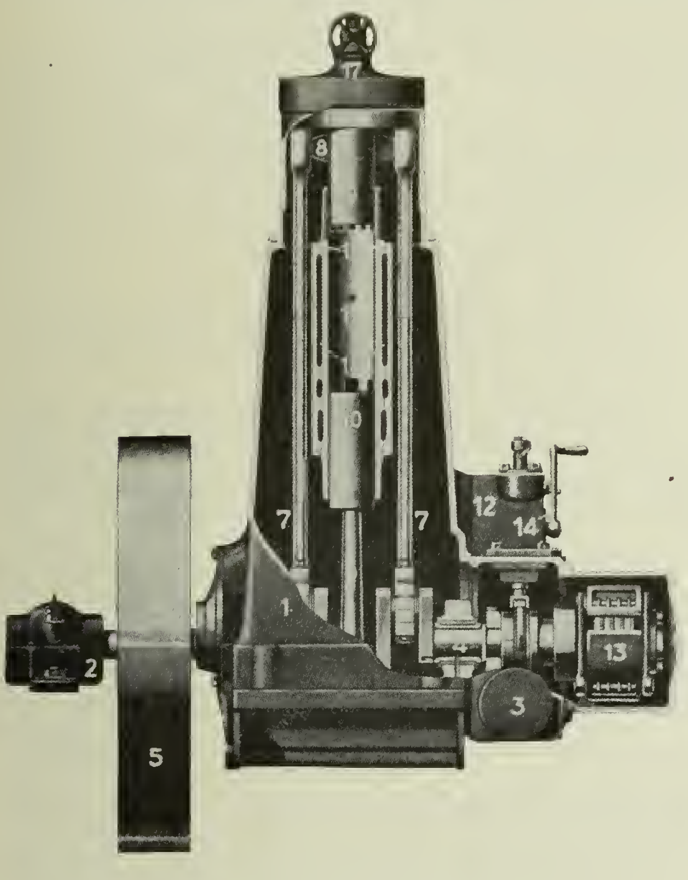

Fig. 11—Junkers Diesel Engine.

1, Frame; 2, Outer bearing; 3, Oil pump; 4, Crank shaft; 5, Fly-wheel; 6, Connecting rods under compression; 7, Connecting rods under tension; 8, Cross-head; 9, Upper piston; 10, Lower piston; 11; Cylinder; 12, Fuel pump; 13, Shaft regulator; 14, Starting lever; 15, Injection nozzle; 16, Scavenging pump; 17, Starting air-pump; 18, Water jacket.

through the pressure and tension connecting rods. Just before the working stroke ends, the lower piston opens the exhaust ports, allowing the waste gases to escape. This is followed by an upper piston opening the scavenging ports. The air previously compressed by the scavenging pump piston rushes into the cylinder, expels the remainder of the burnt gases and then fills the cylinder on the lower piston having shut off the exhaust ports.

As given by the makers the fuel consumption for test runs at full loads amounts to about .350 pounds of oil per B.h.p. hour.

The engine is enclosed in a cast iron housing, automatic lubrication of the entire engine is provided by oil pump (3). Pistons are provided with patent oscillating oil cooling. Cams on the crank shaft drive the fuel pump (12) which at the same time controls the whole process of injection.

The fuel-pump cams are controlled by the shaft governor. The latter instantly adjusts the delivery of fuel according to the momentary requirements and thus keeps the speed of the engine constant. The speed drop from idling to full load is no more than about 3 to 5 per cent.

The shaft-governor can be supplemented with a hand lever which permits of altering the speed of the engine by hand while running. With the aid of the hand-operated speed control gear the number of r.p.m. may be cut down to about 30 per cent of the normal amount.

The fuel-pump is combined with the control gear for starting, stopping and feeding fuel to the nozzle prior to starting. All these operations are performed with a single, positively-acting starting lever.

The starting air-pump is fitted above one of the scavenging-pump cylinders only. Its object is to replenish the compressed-air contents of the starting flasks after the engine has begun to work. As soon as this is finished, the starting air-pump should be changed over to idling when it consumes no further useful work. Engines of small output are started by hand, using a starting crank for the purpose.

Cooling is effected with water supplied either by a geared pump included on the engine itself, or by a plunger pump driven off the engine shaft; as a third alternative the water may be taken from an elevated tank. The cooling water traverses the engine from the bottom to the top, circles round the cylinder and the fuel injecting organs, and finally leaves the engine again at the top of the cylinder after passing through a control device.

Also included were a Universal No. 2, portable pipe cutting machine, manufactured by the Peerless Machine Company of Racine, Wis., various types of woodworking machinery including band saws and drum sanders manufactured by Heath Machine Company of Philadelphia, and four sizes of tool-room lathes manufactured by the South Bend Lathe Works of South Bend, Ind. The smallest of these had a 3-foot bed and a 9-inch swing, and the largest a 6-foot bed and a 16-inch swing. All were equipped with four speeds and a quick change gear, a new feature being that all were motor driven with the motor in the base of the machine.

A quadruple combination punch, plate shear, bar angle, tee cutter and notcher was in operation and appeared most efficient and capable of handling a large variety of work. This was manufactured by David H. Smith and Sons, Inc., of Brooklyn, N.Y., who also displayed a motor driven bending machine for rolling angles, tees, beaver channels, and a variety of other shapes, cold.

Completing the exhibit was a straight line edger manufactured by the White Woodworking Machinery Company of Paisley, England. A combination tool which included an 8-inch circular saw, 14-inch band saw, a lathe bed of 4 feet and 10-inch swing, a boring and mortizing attachment and shaper also a 6-inch joiner operated by a ½-h.p. motor and manufactured by the Woodworking Machine Company of Philadelphia. A full line of small drills, hack saws and a pedestal grinder manufactured at Preston, Ont., by the Williams Tool Corporation.

Williams and Wilson Limited

A number of machine tools were in actual operation on the stand of Williams and Wilson, Ltd., Montreal and Toronto, such as a 6-inch "Rapiduction" pipe threader, a new feature of this being the automatic opening die head, also a 2-inch Willie Williams Pipe Threader, both manufactured by the Williams Tool and Machine Company of Brantford, Ont. In addition, a 21-inch Corona drill was in operation, equipped with two spindles and pickoff feed and speed gear changes, each spindle driven by a 2-h.p. motor, manufactured by F. K. Pollard and Company of Leicester, England.

A Firth "Hardometer" was on display. This is a new hardness

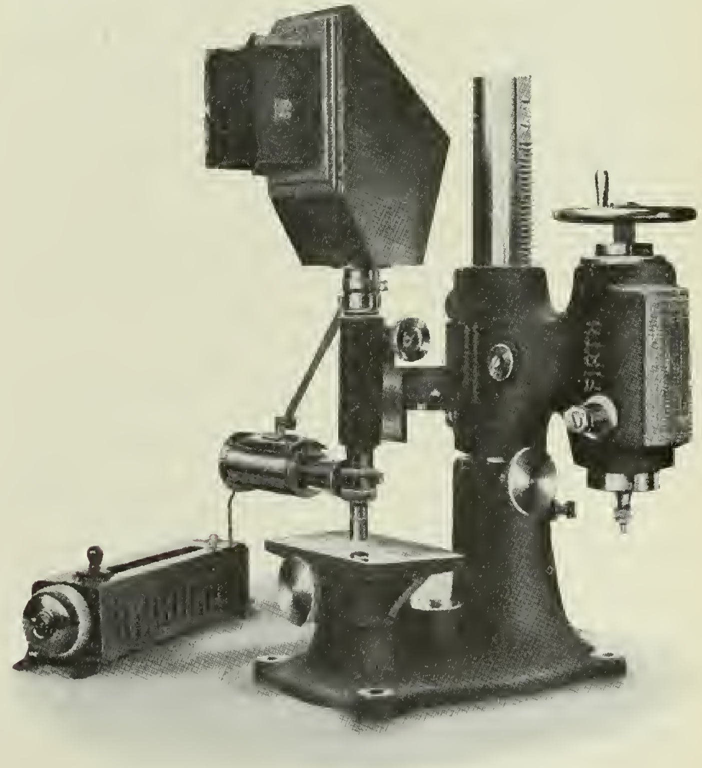

Fig. 12—The Firth Hardometer.

tester manufactured by Thos. Firth and John Brown Ltd., of Sheffield, for testing departments and covers a wide range of hardness testing requirements. This is illustrated in Fig. 12, and the principle embodied in it for determining the hardness of metals is similar to that of the Brinell machine in which a hard steel ball is pressed, by means of a known load, into the specimen to be tested, the hardness being determined by measurement of the impression. Owing to the limitations of the hardened steel ball when testing the harder materials, a pyramidal diamond indenter is recommended and can be supplied with the machine in addition to the hardened steel ball.

The hardness numbers are obtained by dividing the load in kilogrammes by the area of the impression in square millimetres, and this rule applies both in regard to the steel ball and the diamond indenter. In the latter case the hardness numbers obtained should be referred to as the diamond hardness numbers.

The microscopic method of measurement has been adopted rather than the direct dial reading for the following reasons:

(*a*) The direct dial indicator is governed by the depth of impression, which is only from one-eighth to one-sixteenth of the diameter or diagonal of the impression.

(*b*) As the checked microscope reading remains fixed, it is more reliable than a mechanical measuring device which is called upon to function on each reading made, the sensitiveness of which must be from eight to sixteen times as great as the microscope to achieve only the same result.

(*c*) Compression of grease and dirt below the piece being tested has no effect on the reading.

The applied load is spring-controlled and this method was adopted in order to overcome the effect of inertia which is so common a trouble in machines employing the dead-weight or lever principles.

The low stress and the limitations of the stress of the spring are such that no discrepancy is to be feared over a long working period.

The maximum space between the face of the anvil and the head is 8 inches unless otherwise specified. This distance determines the maximum thickness of material which can be tested. The distance between centre of indenter and face of pillar is 3⅞ inches.

On repetition work, readings can be taken at the rate of over 100 per hour on the type "D2" machine. The scale of impression diameters and Brinell hardness numbers corresponds exactly to that of the 3,000 kg. 10 m/m ball Brinell machine.

The type "D2" machine with 30 kg. load cylinder is 19 inches in height, weighs 67 pounds and occupies a bench space of 12 inches by 12 inches, and is complete with microscope, which is equipped with a micro-projection head—this head causes a magnified image to be projected on a screen and allows the operator to use both eyes.

Also on exhibit a 32-inch "Insto" Firth segmented cold saw of new design with inserted tooth segments.

A feature was the operation of a 16-inch 16-speed Monarch lathe with a 5-foot bed manufactured by the Monarch Machine and Tool Company of Sidney, Ohio, and fully equipped with Timken bearings and helical gears.

All Timken bearings are guaranteed to tolerance limits of .0002 inch, and are tested for accuracy by the Monarch Machine Tool Company before being mounted in headstocks. Bearings lapped to tolerance limits of .0001-inch are used in precision tool room lathes.

The Timkenized spindle never has more than .0001 inch end movement. The radial error is never more than .001-inch at a distance of 20 inches from spindle nose.

Noiseless operation, accuracy and absence of wear are claimed by the makers through these features. The drive is a 5 h.p. motor and belt with motor mounted in the leg of the lathe.

BOOK REVIEWS

Engineering Materials

Vol. 3: Theory and Testing of Materials

By Arthur W. Judge. Pitman & Sons, London, 1930, cloth, 5¾ x 8½ in., 498 pp., illus., figs., tables, $6.00.

G. J. Dodd, A.M.E.I.C.*

This volume is a thoroughly revised and extended account of the section of the author's Aircraft and Automobile Materials, Vol. 1, Ferrous; dealing with the theory and testing of materials.

The author devotes two chapters to stress, strain and elasticity and the properties of materials under test. He gives but does not derive all the formulae necessary, assuming that the reader is familiar with their derivation. He discusses their application to testing generally and in many cases in particular.

The third chapter is devoted to the testing of cast iron and contains a description of the Brico piston-ring testing apparatus and a comparison of test results made according to British and American Standards. Chapter IV deals fully with the effect of temperature upon the strength of metals.

Chapters V to X deal with failure of materials under test, modern theories of materials, the fatigue strength of metals, stress

*Assistant Professor in Civil Engineering and Mathematics, McGill University, Montreal.

formulae for design work with an interesting discussion on factors of safety, impact tests and the hardness of metals and the methods of its determination.

Chapter XI describes modern testing machines and methods, and Chapter XII takes up testing machine accessories, such as shackles and grips, extensometers, etc. It omits a description of the Martens extensometer.

Chapter XIII describes the machines for testing hardness and abrasion, and Chapter XIV describes special testing machines, such as the Izod machines, the Cambridge impact machines, etc.

Chapter XV will be found the most interesting to the structural engineer as it describes methods of stress determination, such as by scale model tests for bridge stresses, by optical means using polarized light, by the use of Coker's lateral extensometer. It gives some typical cases of practical application, using the Polariscope method.

The book is well printed and very fully illustrated. The diagrams are pleasing and a great deal of valuable and interesting data is given concisely in a tabular or graphical form. More important are the references from which the information is gathered which would enable the reader to go to the original sources if he so desired. It should prove to be a valuable book of reference for engineers, and especially to those engaged in testing materials in laboratories. It brings the subject up to date and makes available in one volume a great deal of new information which has been found in the many and recent researches which have been undertaken in the last thirty years.

Modern Aviation Engines

Vols. 1 and 2

By Major Victor W. Pagé. Henley Publishing Co., New York, 1929, cloth, 6 x 9 in., vol. 1, 997 pp.; vol. 2, 927 pp.; illus., figs., tables. $5.00 volume, or $9.00 set of 2 vols.

R. J. G.

In this book, which consists of two volumes of approximately 1,000 pages each, the author has collected a mass of information regarding aero engines both past and present. The preface states that it "has been prepared primarily for instruction purposes, and is adapted for students who wish to become aviators or aviation mechanicians, and for mechanics in other lines who wish to enter the aviation industry as experienced aviation engine maintenance and repair men." To complete this intention, each chapter concludes with a short questionnaire, which gives the student the opportunity for gauging whether he has thoroughly digested the contents of the chapter. The author has augmented his own experience by drawing freely from various sources of information, including the reports of leading engineers engaged in internal combustion engine research, national bureaux, and aero engine manufacturers, with due acknowledgment in each instance.

As the book explains the elementary principles and forms of internal combustion engines, and gives considerable space to early types, the word Modern might have been omitted from the title with advantage. There also appears to be too much extraneous matter and one gets the impression that a single well edited volume would have been better than the two volumes which form this work. Alternatively the size of each volume could have been reduced. Apart from these general criticisms, which are not intended to detract from its usefulness, the work contains a wealth of reliable information. The thorough manner in which the subject is discussed, and the various angles of attack, combine to make it one of real value to the student. The same factors and the full acknowledgment of all sources from which information has been extracted, also makes it valuable as a book of general reference for the more advanced enquirer who can supplement it by reference to the original authorities.

In addition to the description of general principles, and detailed design of practically all well known types and many lesser known types of aero engines, are excellent chapters on fuel and lubricating oil.

These chapters and the references they contain are recommended for study by many who pose as experts on aircraft engine operation.

Public-Spirited Engineers

The Cleveland Engineering Society has recently had an opportunity to show what a valuable service can be given the community by an organization of engineers. Cleveland holds its engineers and their society in high regard, an attitude that has been both demonstrated and intensified by recent events. In planning a long viaduct over the Cuyahoga river valley, the authorities were divided on the location of the eastern approach. The commissioners of Cuyahoga county, under whose auspices the bridge is to be built, requested the Regional Planning Division of the society to examine the merits of the two proposed plans and to make a recommendation as to the one to be chosen. In less than two weeks the committee appointed had interviewed the principal engineers and laymen especially interested in the improvement, had had its recommendation approved by the trustees of the society and had submitted its report to the authorities. A subsequent request by the county for a bill for the service was declined. Since much of the work of civil engineers is of direct social import it is not surprising that they should display in a marked degree a desire to be of public service. It is most gratifying that the officials in direct control of the public business of Cuyahoga county show that they appreciate the significance of that public spirit and the value of the service the engineers can render.—*Engineering News-Record.*

Power for Flight

An interesting memento of the early attempts at flying is contained in the following letters, one from the late Edward Dean Adams of New York, giving an account of his experiences when permitted to ride in the Maxim steam-driven flying machine in 1892; and the second from Hiram S. Maxim to Mr. Adams, describing the results obtained with that machine on the occasion when he became convinced that his engine could actually develop sufficient power to lift the machine it propelled.

New York, September 29, 1930

Mr. Alfred D. Flinn, Director,
Engineering Foundation

For your information I enclose a letter from Mr. Hiram S. Maxim. I visited Mr. Maxim at Baldwyn's Park, where he had his laboratory and his trial course for the flying-machine that he sought to build using steam created by the machine itself for the engine he had invented. The machinery was placed upon a platform of two stages, the lower one accommodating passengers. It was about ten feet wide and slightly longer, the wheels similar to railroad car wheels with a pronounced flange. There were two sets of rails, a lower and an upper, the upper one held with its face below, so that the wheels could also when lifted sufficiently run on the upper rail.

There was no brake to control the speed except at the end of the mile, where there were two capstans on each side of the rail, around which a stout rope was wound; both capstans revolved when pressure was brought upon the rope by the curved extensions on the front of the car for the purpose of catching the rope and restraining movement. Experiments had suggested for greater safety of the passengers the use of two additional capstans placed 15 feet beyond the first pair, and an additional rope was provided of considerable length that was expected to fully overcome the movement of the machine.

In order to determine to what extent, if any, the propellers had lifted the machine the rails were painted on the side of each rail that faced the other.

I rode in this machine standing and holding on to the cable guides attached to the second floor. Almost immediately after starting, my eyes began to water as I attempted to look ahead; we were very soon at the end of the line; the jaws of the machine caught each rope successfully and the speed was suddenly arrested. Not far from the terminal there was a grove of trees; you can well imagine as we approached this terminal that I was quite apprehensive that, if the ropes gave out the machine might plunge into or over the foliage before me.

Sincerely yours,
Edward Dean Adams.

Stonyhurst, Crayford, Kent, April 11, 1892

My dear Mr. Adams:

The experiments at Baldwyn's Park must have convinced those who witnessed them that it is really possible to get a grip on the air. One of the principal reasons which has been advanced why Flying Machines could not succeed was that it was not believed that the air was of a sufficiently resisting nature to get a hold on it. The last run at Baldwyn's was most convincing to myself. In this case, three-fourths of the whole weight of the machine was on the hind wheels. The wheels themselves were of solid cast-iron and of great weight. There was 600 pounds of water also 100 pounds of petroleum on the rear end of the machine to say nothing of from 15 to 20 passengers.

Nevertheless the machine actually ran away at railway speed dragging the hind wheels on the track, both wheels being locked to the axle tree. It was found that twenty men could not push the machine back into the shed until the track had been greased.

The two hind wheels had about a pound each of iron taken out of them in this run and will have to be re-turned.

The propellers were 17 feet 10 inches in diameter and 16-foot pitch. The pair which you saw in the house are of the same diameter with a mean increasing pitch of 24 feet. These will give a much higher speed.

You might have observed that the engines were only supported by light tubes and wires; still they were so well balanced, not only in weight, but the force of one cylinder is balanced against the other, that they ran very smoothy notwithstanding their high speed and the enormous quantity of power developed.

The steam pressure was 275 pounds to the square inch. The bursting pressure of the tubes of which the boiler is formed is about 2,000 pounds per square inch while cold, and by actual experiment were burst by generating steam in them, at a pressure of 1,750 pounds per square inch. Therefore you will see that the factor of safety is very high. So far the highest amount of power developed has been at the rate of one horse-power to every 7.14 pounds of motor complete, that is, including engines, pumps, casing about the boiler, propellers, smoke-stack, etc., etc. I think this is six or seven times as high as has ever been accomplished before.

I think I shall succeed unless there is some new factor which we do not understand, as Prof. Langley expresses it. Another question is the cost. If every step in these experiments takes as long as the development of the power did, it may be that my friends and myself may not be able to furnish the necessary cash to follow up the experiments to finality.

Yours very truly,
Hiram S. Maxim.

These letters are contained in a Research Narrative just issued by the Engineering Foundation, New York.

Preliminary Notice

of Applications for Admission and for Transfer

September 18th, 1931

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in November 1931.

R. J. Durley, *Secretary.*

* The professional requirements are as follows—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

COWIE—NORMAN CLAUDE, of Sault Ste Marie, Ont., Born at Espanola, Ont., Oct. 2nd, 1907; Educ., B.A.Sc., Univ. of Toronto, 1931; 1929 (summer), Algoma Steel Corpn., Sault Ste Marie, Ont.; 1930 (summer), elect'l. dfting, Algoma District Power Company, Sault Ste Marie; May 1931 to date, elect'l. engrg., design, dfting, estimating, constrn., etc., Algoma District Power Company and the Great Lakes Power Company, Sault Ste Marie, Ont.

In a booklet received from the Ohio Brass Co., entitled, "Insulation of Some of the Higher Voltage Lines," the advantages of increased insulation and methods for obtaining transmission line reliability are discussed, and the author covers, among other things, conductor heights, the effect of polarity and height upon direct lightning strokes, increasing flashover by the efficient use of tower clearances, the use of high ground wires, span lengths, station insulation, radio interference and high ultimate porcelain insulators.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men—without charge to either party

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Capital to Invest

A.M.E.I.C., with ten years industrial, engineering, manufacturing and executive experience in Canada, England and the United States, is interested in investing both time and capital in a suitable venture. Located in Montreal. Apply to Box No. 675-W.

Situations Wanted

ELECTRICAL AND RADIO ENGINEER, B.Sc. '28. Experience in the design and testing of broadcast radio receivers, including latest superheterodyne practice, and capable of constructing apparatus for testing same. Also familiar with telephone and telephone repeater engineering. Thorough experience in design, construction and inspection of municipal conduits. Apply to Box No. 12-W.

TECHNICALLY TRAINED INDUSTRIAL EXECUTIVE, open for employment. Canadian, age 40, with extensive Canadian and American industrial experience, particularly in metal manufacturing industries, including grey iron and steel foundries, machine and steel fabricating shops—arrangement and equipment of plant and mechanical handling systems to improve manufacturing methods, cut costs, step up production and quality of product—wants connection with progressive company in Canada preparing for business expansion. Apply to Box No. 35-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), 15 years experience, available on short notice. Experienced surveys, draughting, reinforced concrete design, municipal engineering, construction work, inspection, estimating. Apply to Box No. 107-W.

CIVIL ENGINEER, university graduate 1926, desires employment as junior engineer or instrumentman on construction work. Experience, resident engineer on railway construction, miscellaneous surveys. References. Available any time. Apply to Box No. 149-W.

CIVIL ENGINEER, B.Sc., age 34, is open for a position as construction engineer in charge of construction of hydro-electric plants or paper mills; designing engineer of hydro-electric developments or paper mills. Willing to make small investment. Apply to Box No. 157-W.

ELECTRICAL ENGINEER, B.Sc., McGill 1926. Five years experience in the design of switchboards, layouts and wiring diagrams. Considerable experience in high and low tension switchgear design. Fifteen months experience in switchboard estimating. Available at once. Apply to Box No. 247-W.

REINFORCED CONCRETE ENGINEER, B.Sc., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

MECHANICAL ENGINEER, B.Sc. McGill 1919, A.M.E.I.C., married. Eleven years experience, including structural, reinforced concrete, piping and high pressure boiler and furnace design, heating and ventilating, hydraulic and boiler plant operating problems. Apply to Box No. 265-W.

Situations Wanted

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing and hoists. Also some experience in ventilating and heating work and calculators. Accustomed to structural design and details. Good references. Present location Montreal. For interview apply to Box No. 329-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., R.P.E., Ont., with twenty-four years experience, embracing dams, wharves, grain elevators, foundations, pile driving, highways, municipal engineering, water power surveys, road locations, inspections and estimating, is open for engagement as engineer or superintendent in construction, operation or maintenance. Location immaterial. Apply to Box No. 358-W.

STRUCTURAL AND CIVIL ENGINEER, Jr.E.I.C., age 31, married. Was instrumentman and structural engineer on erection of Royal York hotel, and asst. resident engineer on James Bay Extension, T. & N.O. Rly. Experience includes structural, civil and mechanical draughting and all kinds of instrument work and special work. Qualified as captain in military engineering, R.M.C., Kingston. Available anywhere in Canada, preferably Toronto, for any kind of work. Apply to Box No. 377-W.

STRUCTURAL AND CIVIL ENGINEER, B.Sc., age 35, married. Thoroughly experienced in design, shop work and erection of steel bridges, buildings and movable structures. Seeks position as designing engineer or engineer on construction. Available on short notice. Will go anywhere. Apply to Box No. 399-W.

CIVIL ENGINEER, B.A.Sc., C.E., A.M.E.I.C., age 29, married. Experience over nine years includes railway location and construction as resident engineer. Hydro-electric report on estimates and investigation, also design, construction and teaching on hydraulic structures, bridge foundations and caissons. Location immaterial. Apply to Box No. 447-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., with six years experience in paper mill and hydro-electric work, desires position in western Canada. Capable of handling reinforced concrete and steel design, paper mill equipment and piping layout, estimates, field surveys, or acting as resident engineer on construction. Now on west coast and available at once. Apply to Box No. 482-W.

DESIGNING ENGINEER, A.M.E.I.C., P.E.Q., with extensive experience in design and construction of power plants, industrial buildings and hydraulic structures, desires position as designing engineer or resident engineer on construction. Apply to Box No. 492-W.

MECHANICAL ENGINEER, Jr.E.I.C., B.Sc., '26. Ten months experience in pulp and paper steam control. Four years experience in detail and design, in pulp and paper mill, industrial plant and hydro-electric development work. Age 27. Married. Location immaterial. Apply to Box No. 521-W.

Situations Wanted

CIVIL ENGINEER, B.A.Sc., '29, with experience in supervision of construction and general office engineering, desires permanent position with contractor or engineer. Available at once. Apply to Box No. 524-W.

MECHANICAL GRADUATE, 1927, age 26. One year with specialized piping contractor on design and cost estimates. Three years on hydro-electric power plant design, proportioned 25 per cent electrical, 25 per cent civil and 50 per cent mechanical. Five months field engineering on hydro-electric power house construction. Pre-graduate experience on power plant operation and general construction. Canadian, married. Available at once. Apply to Box 528-W.

ELECTRICAL ENGINEER, married, graduate of McGill University, desires position in Ottawa, Montreal or Toronto. Experience includes four summers with a building concern as instrumentman and assistant engineer, two and one-half years with the Canadian Westinghouse Co., this time being distributed between tests, design and sales. At present employed but available on short notice. Apply to Box No. 533-W.

UNDERGRADUATE ENGINEER, S.E.I.C., junior year standing (Sask.), desires work to complete course. Electrical or mechanical work preferred. Apply to Box No. 553-W.

ELECTRICAL ENGINEER, A.M.E.I.C., university graduate 1924. Experience includes one year test course and five years on design of induction motors with large manufacturer of electrical apparatus. Four summers as instrumentman on highway construction. Several years experience in accounting previous to attending university. Available at reasonable notice. Apply to Box No. 564-W.

CIVIL ENGINEER, B.Sc. McGill Univ., Jr.E.I.C. Five years experience along the lines of general construction, including structural steel. Available at once. Apply to Box No. 570-W.

MECHANICAL ENGINEER, A.M.E.I.C., experience in the design and maintenance of steel mills, zinc and sulphuric acid plants, cement plants; power house layouts; familiar with shop practices and costs, desires connection. Apply to Box No. 571-W.

YOUNG ENGINEER, Jr.E.I.C., experienced in design, details and erection of steel and concrete structures. Also a good theoretical and practical knowledge of steam, hydraulic and I.C. engine power plant. Good practical mechanical and electrical engineer, able to operate and maintain any type of machinery or power plant. Location immaterial. Apply to Box No. 572-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., (Univ. of B.C., '30), Undergraduate experience in pulp mill. One year's experience, Canadian General Electric Co., mech. dept. Single. Age 24. Desires position in technical design or sales. Location immaterial. Available on short notice. Apply to Box No. 577-W.

PARTNER. Full time engineering partner to establish welding firm. Must have business and structural steel experience, and be able to invest substantial amount in firm. Apply to Box No. 589-W.

ELECTRICAL ENGINEER, graduate Univ. of Alberta, '31, with excellent record, desires connection with electrical manufacturing firm, power or communication company. Good general experience includes one summer railway construction, two summers geological surveys in oil fields of Alberta, planetable topographer and asst. geologist. Available immediately. Apply to Box No. 596-W.

Situations Wanted

MECHANICAL ENGINEER, S.E.I.C., age 21, four years mechanical engineering, Queen's University, desires permanent employment. Experience in wood work, machine shop work, draughting and surveying. Location immaterial. Available at once. Apply to Box No. 600-W.

MECHANICAL ENGINEER, Canadian, technically trained; eighteen years experience as foreman, superintendent and engineer in manufacturing, repair work of all kinds, maintenance and special machinery building, desires change. Location immaterial. Available on one month's notice. Apply to Box No. 601-W.

ELECTRICAL OR MECHANICAL ENGINEER, B.Sc. '31, S.E.I.C., desires employment which will give experience and lead to advancement. Two summers in a large communication company, including draughting, switchboard and surveying. Available on short notice. Will go anywhere. Apply to Box No. 606-W.

CHEMICAL ENGINEER, S.E.I.C., University of Alberta '30, desires a position in any industry with chemical control. Experience includes three summer vacation periods of five months each as assistant chemist, and ten months as chief chemist with a cement company. Age 29. Single. Available at short notice. Apply to Box No. 609-W.

MECHANICAL ENGINEER, Jr.E.I.C., 5 years apprenticeship on general mechanical engineering; 10 years experience on heating and ventilating and mechanical equipment of buildings. Design, draughting and production. Desires change. Capable of taking charge of engineering department. Further particulars if required. Apply to Box No. 616-W.

POWER ENGINEER, M.E.I.C., age 42. Married. Thoroughly conversant with electrical, steam, mechanical and industrial engineering, desires executive position with large industrial, power or financial corporation. Best of references as to ability and positions held. Apply to Box No. 617-W.

CIVIL ENGINEER, Jr.E.I.C., B.A.Sc. '24, age 35, married. Five years designer and estimator with well-known firm of industrial builders; two years detailing, designing and estimating structural steel for bridges and buildings, also survey and municipal experience. Open for position immediately, will go anywhere. Apply to Box No. 618-W.

CIVIL ENGINEER, A.M.E.I.C., graduate '23, married, eight years municipal engineering experience. Sewerage and sewage disposal, water works, street pavement, etc. Also some experience highway construction. For the past three years engaged by firm of consulting municipal engineers. Desires permanent position. Location immaterial. Available immediately. References. Apply to Box No. 624-W.

ELECTRICAL ENGINEER, B.Sc., N.S. Tech. Coll. '31. Experience in design and construction of rural distribution lines, trouble shooting, inventories and general office work, desires position with public utility or industrial plant. Location immaterial. Available at once. Apply to Box No. 628-W.

Situations Wanted

CIVIL AND MECHANICAL ENGINEER, experienced in design, layout, installation and selling. Sixteen years association with largest Canadian industries manufacturing equipment particularly relating to pulp, paper and lumber and five years design and construction of sulphite mill, including electrolytic bleachmaking from salt. Apply to Box No. 633-W.

ELECTRICAL ENGINEER, B.Sc., N. S. Tech. Coll., '31. Experience includes geological survey work in Rouyn mining area and hydroelectric power plant construction both civil and electrical work. Available at once. Apply to Box No. 639-W.

SALES ENGINEER, A.M.E.I.C., McGill '23. Past four years sales representative electrical power apparatus in Northern Ontario mining district, western Canada and with some sales experience in Montreal, Toronto, Ottawa and eastern Ontario. Two years electrical estimating and engineering on steel mill applications, mine hoists, elevators, pulp and paper drives, crushing and cement and other special applications. Two years design, engineering, test and some erection on steam turbines. Available short notice; location immaterial. Apply to Box No. 641-W.

ELECTRICAL GRADUATE, McGill '30, S.E.I.C., with thirteen months experience on General Electric test course, twelve months draughting and five months as instrumentman on power plant construction. Available September first. Location immaterial. Apply to Box No. 644-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), Extensive experience as executive and in charge of construction of complete water power developments, including transmission lines, harbour developments, including hydraulic, dredging and land reclamation, industrial plants and municipal works. Apply to Box No. 647-W.

OPERATING ENGINEER. Position wanted as operating superintendent or assistant. Age 43. Married. No children. Nineteen years experience operating hydro-electric plants, sub-stations, transmission lines. Available immediately at any reasonable salary and for any location. Apply to Box No. 654-W.

ELECTRICAL ENGINEER, Jr.E.I.C., 1926 grad. of English Tech. Coll. Past two years inspector of communication apparatus; three years varied power and sub-station experience, including automatic sub-stations, on comprehensive training scheme. Age 24, single. Location immaterial. Available at once. References. Apply to Box No. 658-W.

ELECTRICAL ENGINEER, B.Sc.E.E., 1931. N.S. Tech. Coll. Experienced in armature winding and apparatus repairs, in conduit and cable work. Students' course in elevator manufacture, ship's electrician on tropical run. Good cultural education. Available at once, for Canada or tropics. Apply to Box No. 659-W.

Situations Wanted

ELECTRICAL ENGINEER, university graduate '28. Experience includes one year with operating department of a large public utility and two years with manufacturer of electrical equipment, work including design, test and correspondence. Available on short notice. Apply to Box No. 660-W.

ELECTRICAL ENGINEER, B.Sc., S.E.I.C. Experience: Installation staff Can. Gen. Elect.; students test course with the same company, concrete inspection, transmission line surveying and inspection, also some railway construction experience. References. Desires position with electrical concern. Location immaterial. Available at once. Apply to Box No. 665-W.

MECHANICAL ENGINEER desires position with manufacturing or other company offering opportunity in design and draughting. Thorough technical training and four years experience since graduation. Prefer western Canada, but location and salary of secondary importance. Age 29, unmarried, thoroughly reliable and capable of handling junior position of responsibility or taking charge of technical work for small concern. Apply to Box No. 669-W.

ELECTRICAL ENGINEER, B.Sc., McGill Univ. '23, Jr.E.I.C. Eight years experience as sales engineer in all classes of electrical machinery, also switching, mine hoists, steam and hydraulic turbine generator sets, street railway and railroad equipment. Good commercial experience. Highest references. Age 30. Single. Available immediately. Apply to Box No. 670-W.

CIVIL ENGINEER, graduate University of New Brunswick '31, in C.E. Experience consists of three seasons on a survey party. Available October 1st. Desires permanent position. Willing to go anywhere. Apply to Box No. 672-W.

MECHANICAL ENGINEER, A.M.E.I.C., Canadian, technically trained; six years drawing office. Office experience, including general design and plant layout. Also two years general shop work, including machine, pattern and foundry experience, desires position with industrial firm in capacity of production engineer or estimator. Available on short notice. Apply to Box No. 676-W.

CIVIL ENGINEER, age 25, single. Experience includes mill construction, design and supervision. Also design of hydraulic features, bridge foundation, rigid frames and caissons. Will go anywhere. Apply to Box No. 677-W.

MECHANICAL ENGINEER. Spare time work wanted by mechanical engineer, A.M.E.I.C., with broad experience in the design of automatic machinery. Telephone EL. 5936, Montreal, or apply to Box No. 678-W.

RADIO ENGINEER. Graduate McGill Applied Science '30. Experience includes the design, development and production of broadcast receivers, as well as general radio laboratory practice. Apply to Box No. 680-W.

TREASURER
W. C. ADAMS, Montreal, Que.

SECRETARY
R. J. DURLEY, Montreal, Que.

OFFICERS OF BRANCHES

HALIFAX
Chairman, J. L. ALLAN
Sec-Treas., R. R. MURRAY, 87 Cambridge St., Halifax, N.S.
Executive, L. M. ALLISON, G. S. STAIRS, W. H. NOONAN, S. L. FULTZ, J. J. SEARS, J. H. CLARK, W. J. DeWOLFE, A. F. DYER, J. D. FRASER
(Ex-Officio) F. R. FAULKNER, W. P. COPP

CAPE BRETON
Chairman, A. P. THEUERKAUF
Vice-Chair., Y. C. BARRINGTON
Sec.-Treas., SYDNEY C. MIFFLEN, Dom. Coal Co. Ltd., Glace Bay, N.S.
Executive, J. A. FRASER, J. R. MORRISON, W. L. STUEWE
(Ex-Officio) A. L. HAY

SAINT JOHN
Chairman, J. N. FLOOD
Vice-Chair., A. A. TURNBULL
Sec.-Treas., G. H. THURBER, P.O. Box 1417, Saint John, N.B.
Executive V. S. CHESNUT, J. T. TURNBULL, G. A. VANDERVOORT
(Ex-Officio) A. R. CROOKSHANK, W. J. JOHNSTON

MONCTON
Chairman, G. E. SMITH
Vice-Chair., T. H. DICKSON
Sec.-Treas., V. C. BLACKETT, Eng. Dept., C.N.R., Moncton, N.B.
Executive, E. T. CAIN, H. J. CRUDGE, R. H. EMMERSON, A. S. GUNN, H. W. McKIEL, A. F. STEWART
(Ex-Officio) L. H. ROBINSON, G. C. TORRENS

SAGUENAY
Chairman, N. D. PAINE
Vice-Chair., J. F. GRENON
Sec.-Treas., W. P. LEBOUTILLIER, Price Bros. & Co. Ltd., Kenogami, Que.
Executive, G. F. LAYNE, J. W. WARD, G. E. LAMOTHE, G. O. VOGAN
(Ex-Officio) R. E. PARKS, H. R. WAKE

QUEBEC

Canadian Pacific Railway Company's Wolfe's Cove Branch and Tunnel at Quebec

Colonel D. Hillman, D.S.O., M.E.I.C.,

Engineer of Construction, Canadian Pacific Railway Company, Montreal.

Paper presented before the Montreal Branch of The Engineering Institute of Canada, October 1st, 1931.

SUMMARY.—The tunnel which forms the subject of this paper was rendered necessary to give access to the first unit of the new Quebec harbour development above Cape Diamond. The paper describes the equipment and method used for driving the tunnel, and also gives the requirements as regards lining, drainage and ventilation during construction.

The Wolfe's Cove branch of the Canadian Pacific Railway Company was built during the past year to provide the company with a means of access to the new Wolfe's Cove terminal at the Quebec harbour.

The older part of Quebec harbour at the confluence of the St. Charles and the St. Lawrence rivers could accommodate, in the Princess Louise basin, boats drawing 25 feet and because of the ever increasing size of vessels, deeper water for berths became necessary if Quebec wished to retain her position as an ocean port. Quebec has always occupied an important place in the shipping trade of Canada. In the days of sailing ships, Quebec turned out some of the finest vessels in the world and at Quebec was built the "Royal William," first vessel to cross the Atlantic entirely by steam.

Extensive studies carried out over a period of years led the Harbour Commissioners of Quebec to decide that the future improvements and extensions of the harbour facilities should be carried out along the shore of the St. Lawrence upstream from the citadel and a scheme has been worked out for a harbour development extending from a point about two miles above Cape Diamond to Sillery. At the location selected there will be better shelter than at the old docks and only a small amount of dredging is necessary to give deep water alongside the quay walls.

The first unit of the harbour development called the "Wolfe's Cove Terminal" was completed in June this year and consists of a quay wall 4,300 feet long with 40 feet of water alongside at low tide, a two-storey steel and brick shed 1,380 feet long by 100 feet wide with railway tracks and roadway to permit of the proper handling of traffic to and from steamers.

The first vessel to use the New Wolfe's Cove terminal was the new Canadian Pacific steamship "Empress of Britain" which docked there June 1st, this year.

The Wolfe's Cove branch was constructed on the location finally selected after extensive studies of various routes covering the territory from Cape Diamond to the Rouge river and extends from a point on the main line of the Canadian Pacific Railway about 2½ miles west of the

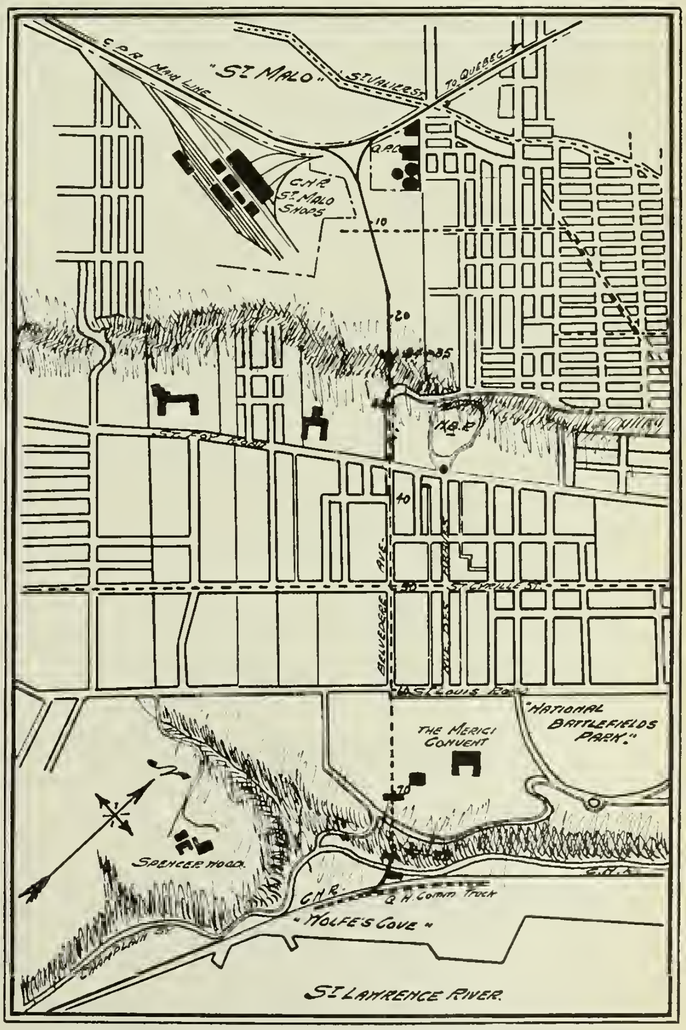

Fig. 1—Location of Tunnel under Quebec City.

Fig. 2—South Portal of Tunnel.

Palais station at Quebec, to the Wolfe's Cove terminal of the Harbour Commissioners. The new line is 1½ miles long, one mile being in tunnel through the ridge which lies between the valley of the St. Charles river and the St. Lawrence. This ridge rises to a height of 250 feet to 350 feet above the St. Lawrence. The railway where the branch takes off is 60 feet above the St. Lawrence. The Harbour Commissioners' railway is about 20 feet above river level. The tunnel passes through the ridge slightly west of the Plains of Abraham and comes out on the St. Lawrence a little to the east of the historic site of Wolfe's Landing, the centre line being directly under Belvedere avenue. Grade on the branch is carried out about level from the existing main line to the north portal of the tunnel and drops through the tunnel on an 0.8 per cent grade.

There are no grade crossings of streets on this branch line. Champlain street alongside the St. Lawrence was the only street which would be crossed at grade level and grade separation for this street was provided by constructing a diversion and carrying it over the tunnel lining extended past the face of the cliff a sufficient distance to accommodate the roadway.

The selection of this location was influenced by the topographical features, the expected geological formation and the desire to avoid interference with the existing appearance and conditions of the terrain at the historic site of Wolfe's Landing. Published data of the geological formation were studied and a further examination of the geological structure was carried out by means of trenching from the surface to the rock at a number of locations. The overburden on the plateau is generally from five to twelve feet deep. From the information obtained it was expected that most of the tunnel would run through Quebec City limestone and that possibly one hundred yards or so would be in shale formation at the north end of the tunnel. Considerably more of the shale formation than expected was encountered. Both these rocks are quite soft and weather on exposure. The limestone is self-supporting for tunnel such as was built but had to be protected to prevent weathering. The shale had to be supported immediately with timbers to hold it in position until concrete lining could be placed.

In establishing the centre line care was taken to insure accurate chainage and levels. A 500-foot steel band tape was used and measurements were taken with the tape held at a uniform tension, approximately parallel to the surface and between fixed points. The angle between the tape and a horizontal line was read and the horizontal and vertical

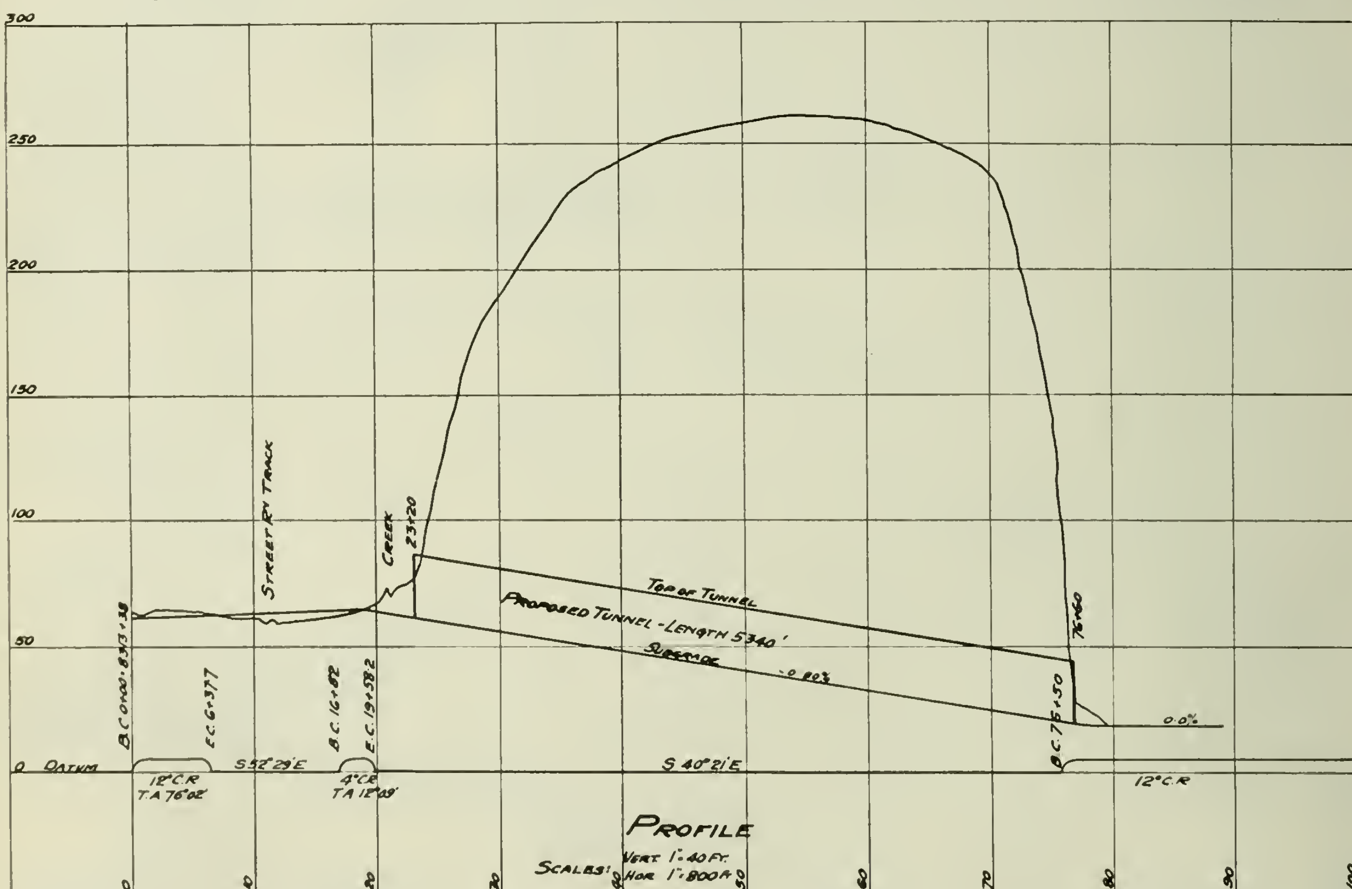

Fig. 3—Profile of Tunnel.

Fig. 4—Timber Lining, North Portal.

distance between such points calculated. The horizontal distance was also calculated by using the measured distance on the slope and the difference in elevation between points as established by level. These operations were carried out several times until similar results were obtained and the accuracy of the work established, after which a number of fixed points were made permanent by constructing concrete monuments, each carrying a metal plate on which the point was fixed. The foundations for these monuments were carried below frost level. Where ground level would be disturbed along the centre line during construction, points were referenced out and the reference points were established in permanent form. Location of the line outside the tunnel portion was fixed and handled in the same manner as the tunnel portion. At the north end there is about 2,300 feet of such line between the main line and the north portal, and at the south end about 300 feet between the portal and the junction with the Harbour Commissioners' railway.

The location plan, profile and book of reference were approved by the Board of Railway Commissioners July 2nd, 1930, and the contractor was advised at once to proceed with the work. Prior to this date, competitive bids had been received from several of the leading contracting firms and the Dominion Construction Company having the low tender, was selected to do the work. The spread in price between three low bids on this job was less than 10 per cent. The time for completion of the work was specified as June 1st, 1931, that is, eleven months only were allowed for the construction of this 1½ mile branch line with one mile of it in tunnel. Within three days after approval of the plan the contractor had men on the work, having moved a small force in boarding cars so as to get an early start.

The tunnel is constructed for single track. The clear width inside is 16 feet and the clear height above base of rail at the centre line is 22 feet 6 inches, the side walls being vertical and the top being formed by a semi-circular arch with a radius of 8 feet.

Grading of the approaches or sections of the line outside the tunnel entailed the moving of about 9,000 cubic yards of material. This grading was completed and the tunnel excavation started early in August. The north end went under August 5th and the south end August 9th. In the meantime, the contractor had supplied and assembled the plant and equipment required for tunnel work. The plant was arranged in two complete units, one at each end of the tunnel, each unit consisting of a battery of two air compressors with a capacity of 1,650 cubic feet, a 200-h.p. generating set, one compressor air blower 5,000 cubic feet capacity at 2½ pounds pressure with direct connected 50-h.p. motor, one blacksmith shop with drill sharpening machine, drill steel furnace and complete blacksmith outfit. At each end there was also a complete set of drills, drifting machines, piping, cars, locomotive, etc. At the north end only, there was a saw-mill completely equipped for the sawing and framing of the timber required for lining the tunnel, or for breakdown timbers. Most of the employees were housed in boarding cars but separate buildings were supplied for use as wash rooms and drying rooms where the men changed when going on and off duty. Electric power for all the plant and equipment on this job, as well as for lighting, was supplied by the Quebec Power Company.

For excavating the tunnel the bottom heading method was adopted because it was thought that by this method it would be possible to keep closer to the true section than by any other method, and with the class of rock expected here, it was thought that excessive overbreak might occur if the top heading or the full section method were used.

The heading driven from each end was taken out about 12 feet high by 14 feet wide. The drilling for this heading consisted of about twenty-four holes eight to ten feet deep. The work was carried on in two shifts over the twenty-four hours and each shift generally drilled and shot one round. The shot was arranged in seven delayed actions, the central holes being fired first. About three pounds of powder per cubic yard was used. The advance in each heading averaged 16.1 feet per day. Work was carried on for one hundred and sixty-six days in the north end and one hundred and sixty-two days in the south end and the heading was holed through February 16th at 7.45 o'clock a.m. The bores met almost exactly. In firing the last shot, the wires from the caps in the charges in the Wolfe's Cove end were passed through a drill hole to the St. Malo face and all wires were

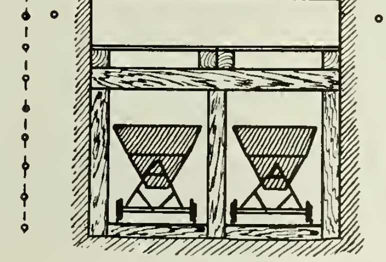

Fig. 5—Layout of Drill Holes in Heading.

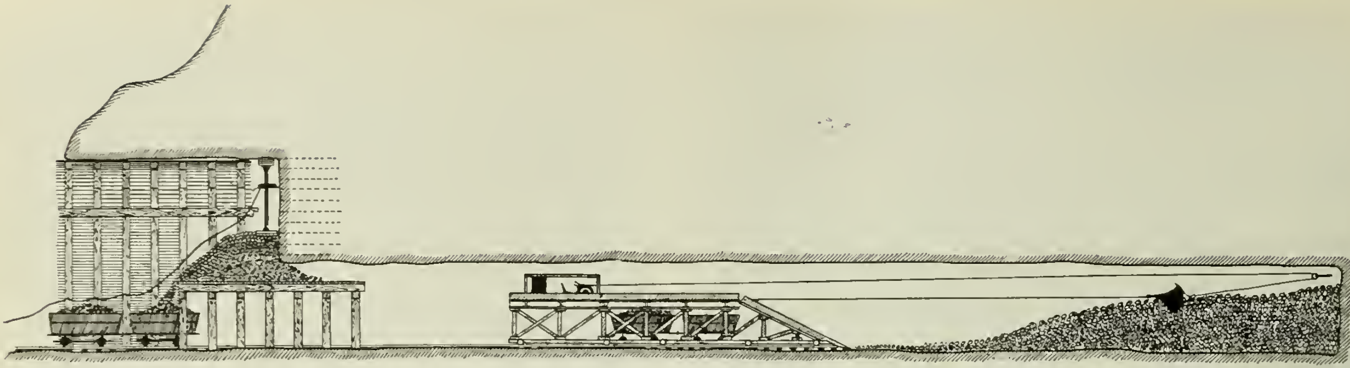

Fig. 6—Mucking Machine.

attached to the one firing switch. There were eighty holes, forty in each end, fired in the last shot. The muck from this shot filled the headings except for two small holes about three feet high at each of the upper corners. On the breakdown the drilling was arranged according to quality of rock and other conditions and blasting required about one and a half pounds of dynamite per cubic yard.

The muck from the heading was first handled back from the face to clear a space for the drillers to work and then loaded on 2½-yard cars run on a 36-inch gauge track. A five-ton electric mine locomotive handled the muck trains, consisting of five or six cars, out of the tunnel. For the handling and loading of the muck in the heading, a mucking machine was used. This mucking machine consisting of a steel platform with a steel plate ramp on the front end was carried on steel bents, mounted on wheels running on rails. The platform and bents were so constructed that the muck cars could be placed under traps in the platform for loading. On the platform was mounted a 50-h.p. double drum hoist with motor and from this hoist a drag was operated which pulled back the muck from the face or pulled it up the ramp and through the traps into the cars, as desired. The drag was shaped like a Gillette razor with on one side a plate and on the other side teeth like steam shovel dipper teeth. When returning empty to the front, the drag slid along on its rounded back. This drag was attached to and operated on an endless cable fixed to the hoist and passing through a pulley on the front end, the pulley being attached to eyebolts or to a timber attached to eyebolts set in the rock.

The whole machine was very efficient and it ran very low in maintenance cost as well as having a low first cost. It handled up to twenty 2½-yard cars per hour for several consecutive hours.

Behind the mucking machine distant probably 300 or 400 feet from the face, breakdown timbers were erected in the heading at a height of about seven feet. On these timbers the drilling and blasting for the breakdown to the full section of the tunnel were carried out. The muck from this operation landed on the breakdown timbers and was then shovelled into muck cars either over the end or through traps. The muck from both the breakdown and the heading was disposed of at the north end by loading into standard gauge cars for delivery and use on the main line of the Canadian Pacific. At the south end muck was used for filling in alongside the waterfront in accordance with instructions from the Harbour Commissioners.

It was necessary to use the blower for clearing the gases from the tunnel after the heading had advanced about 1,500 feet. Until then the drillers were able to get back to the face in about twenty minutes after a shot was fired without suffering any ill effects from gas or dust. A spray was turned on the muck heaps after each shot and this tended to expel the gases and permit of earlier reoccupation of the heading. The man using the spray would go up for this purpose and stay only 20 to 25 minutes, after which he was free for other duties not in the heading.

At the south end where the tunnel is in Quebec City limestone, the only timber required for supporting the rock

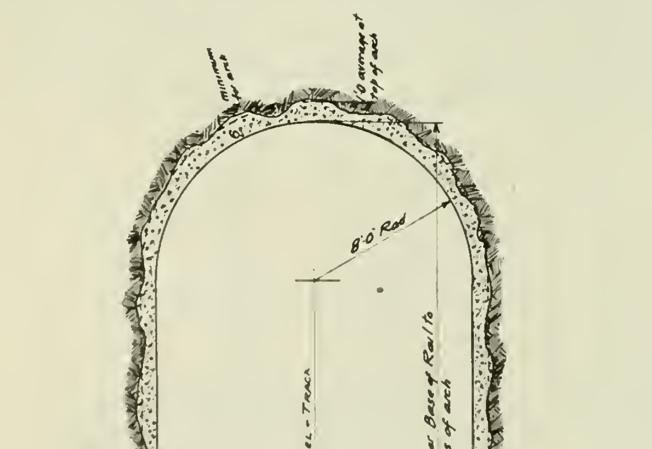

Fig. 7A—Typical Section of Interior Where Rock is Self-Supporting.

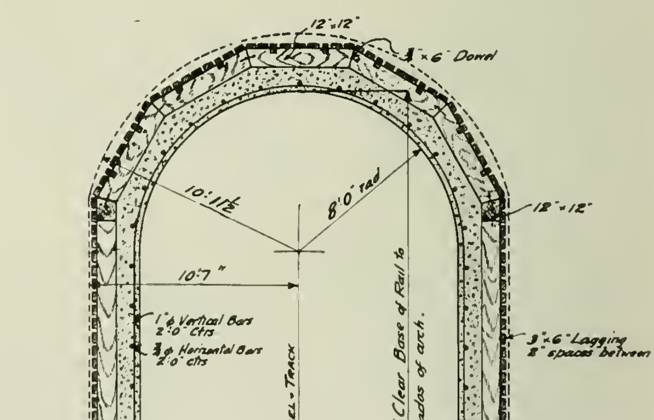

Fig. 7B—Typical Section in Loose Shale Where Timbering is Required.

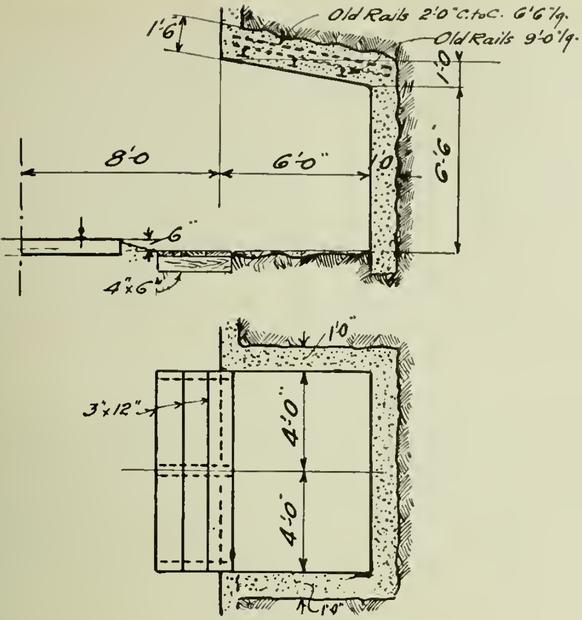

Fig. 8—Refuge Bays.

was three square sets at the portal. In the north end where the tunnel passed through shale it was necessary to place complete timber lining to prevent further falls of rock outside the section required. The timber lining consists of a five-segment arch and plumb posts of 12-inch by 12-inch timber at 4-foot centres with 3 inches by 6 inches lagging. The wall plate and foot plate are also of 12-inch by 12-inch timber. The lagging was placed with 3-inch opening between planks so that if swelling of shale occurred, pressure could be relieved by picking out material from behind the lagging. Such spacing also permitted the free flow of concrete to fill the interstices in the dry packing and make solid the space between the lagging and the undisturbed rock. The swelling of shale is sometimes a very serious matter but did not cause serious trouble here.

In placing the timber, the wall plates and arch timbers were placed first, the lagging was next placed on this portion of the lining and the whole dry-packed with timber to give solid bearing between the timbers and the undisturbed rock. The plumb posts were placed in position later and lagging as required placed behind same. Two gangs were employed on timber lining in the north end, each making an average advance of about ten feet per day. Full timbering extends from the north portal for a distance of 2,500 feet. It was started September 12th, 1930, and completed April 3rd, 1931, and about 1,000,000 f.b.m. of timber was used.

The rock in the tunnel drilled easily and shot small. Many falls of rock occurred, fortunately without serious results. The falls occurred in the shale only and generally where boulders of foreign rock were embedded in the shale. No warning, such as small pieces of rock dropping off, occurred prior to such falls, and it was due to careful inspection and prompt placing of timbers that serious accidents were avoided. Wherever there was any indication of foreign boulders in the shale, breakdown timbers were placed at once. Breakdown was started September 12th, 1930, and completed March 25th, 1931. Total tunnel excavation amounted to 100,000 cu. yds.

The tunnel is lined with concrete throughout and the type and quantity of concrete used varies according to the class of material through which the bore passes.

The lining used where an open cut was excavated and backfilled, is 2 feet 6 inches of reinforced concrete. Where timber supports had to be used in soft rock, the lining is 2 feet 3 inches of reinforced concrete. Where the rock is self-supporting and where concrete is placed simply to prevent weathering of the rock, plain concrete 12 inches thick is used. Where the rock is self-supporting but where slight stresses might result from frost action or from any other cause, reinforced concrete lining 1 foot 3 inches thick is used. At three places located at equal distances in the tunnel, refuge bays are constructed to provide a place for the section gang to get clear of trains. Two refuge bays are located in the west wall of the tunnel and one in the east wall. In the east wall are also located three 3-inch wood fibre conduits for carrying signal and telegraph cables.

At the south end of the tunnel where the lining was carried out beyond the face of the rock cliff a sufficient distance to permit the rerouting of a street over the tunnel to preclude a crossing of the tunnel track at grade, the lining was made 2 feet 6 inches thick and was heavily reinforced. All of the concrete used in the lining was 1-2-4 mix, with the water content carefully controlled.

Construction of the lining progressed from both ends of the tunnel at the same time and was put under way even before the breakdown work was completed. In placing the concrete lining, bench walls about four feet high were placed by hand. The forming for such walls was of timber. Materials were handled to location in muck cars and deposited in the ordinary way. Above these bench walls the concrete was placed and flowed into position by air. Steel forms were used. Two sections of such forms 40 feet long being used, one at each end. These were mounted on wheels and carried on rails adjacent to the bench walls. They were so designed that they could be drawn away from the concrete when it was desired to move them ahead. For the placing of concrete, the plant at each end consisted of a one-yard mixer with pneumatic placer and necessary pipe. The concrete was mixed in the ordinary way and deposited in a hopper, and thence in the pneumatic placer, after which a plate was set over it, and when the air was turned on, it was caused to flow through a 6-inch pipe, and delivered behind the form at the top of the tunnel lining, the pipe extending along the floor of the tunnel and then being carried up to the top of the form bulkhead in each case. Bends in the pipe line consisted of 24-inch sections of pipe

Fig. 9—Concrete Plant in Tunnel.

with 22½ degrees of curvature, these sections being made up with an upper and a lower half bolted together through flanges. The lower half of each section was constructed of manganese steel to increase its resistance to wear, but even this material wore down and had to be built up electrically with Stelite. Placing of concrete was carried out from the north end and from the south end or from two of the three intermediate stations which were established. Two of the points within the tunnel were about 1,200 feet and 2,500 feet from the north portal respectively, and the third point was about 1,400 feet from the south portal. From these locations the concrete was delivered by the pneumatic placers. At the three stations inside the tunnel, 8-inch well drill holes were drilled from the surface and concrete materials were delivered to the mixer from these holes. The set-up of the plants at the three inside mixing points was both effective and interesting. At each of these points, the equipment was mounted on a tower of heavy timber construction with two main platforms, the lowest of which was of sufficient height above the tunnel floor to permit the free movement of muck trains beneath it. The lower platform carried the concrete mixer, while the upper platform was used for the storage of cement and supported an aggregate hopper which discharged through a chute directly into the mixer beneath. The concrete placer was located on the floor of the tunnel to one side and received the concrete shots, of predetermined size, directly from the mixer.

Cement was delivered to the inside mixing stations in cars, but the sand and rock which were premixed in the proper proportions, were shot directly into the aggregate hoppers, in batch quantities, through well drill holes with 6-inch metal liners, put down from 185 feet to 215 feet through the rock ledge, from a roadway above. This method of delivering the aggregate to the mixers not only facilitated its handling, but also reduced to a minimum interference with the muck trains by the concreting operations. Daily progress of concrete lining was about twenty feet per day at each end.

Ground water caused some trouble, particularly in the placing of concrete. The major difficulty encountered was with the seepage of water through the rock, which, throughout a considerable length of the tunnel, was sufficiently severe to cause apprehension concerning the ability of the green concrete to set up without becoming over-watered and porous. At these points, sheet tin was applied in the arch back of the timbering, and in some cases back of the plumb posts, to shed the water and to give the concrete a chance to set up. Approximately 10,000 square feet of tin was used for this purpose. All of the seepage water in the finished tunnel is brought from behind the lining through weep holes at the bases of the side walls, and is readily carried to the south end of the tunnel in the sloping side ditches.

At a few points where leakage occurred through the lining in spite of the precautions taken, Sika waterproofing was applied to the inside face of the lining and proved effective in stopping the flow of water. Concreting was started October 10th, 1930, and completed April 29th, 1931 Total concrete in portals and tunnel lining is 27,000 cubic yards.

No ventilating equipment has been installed although housing for such equipment is provided for in the south portal. The tunnel clears within ten minutes after the passage of a train and no inconvenience or ill effects are felt by persons on a train passing through the tunnel.

Traffic on the branch line is controlled by signal indication only, the signals being controlled from a centralized traffic control machine in a signal tower located on the main line at St. Valier. In addition this machine also controls the signal protection at two street railway level crossings, one steam railway level crossing, the junctions between the branch line and the Canadian Pacific main line, the junction between the Canadian Pacific and Canadian National main lines, and the junction between the branch line and the Harbour Commissioners Railway, all the switches being electrically operated.

Riveted Tension Members

T. R. Loudon, M.E.I.C.,

*Professor of Applied Mechanics, University of Toronto, Toronto, Ont.**

SUMMARY.—This paper describes a research carried out by the photo-elastic method to determine if possible a reasonable reduction formula for use with riveted tension members. Stress lines were ascertained both for tension plates with rivet holes in them and for tension plates actually riveted together; both types of specimen being tested to destruction. The results were further studied by tests on steel plates, and as a result a deduction formula is proposed taking account of the stagger and gauge distance.

Considerable attention has been given from time to time to the problem of arriving at a rational deduction formula for use with riveted tension members. Some of the attempts that have been made to derive a formula from a strictly analytical basis had an apparent amount of success; but the writer showed in the results of a research published in the Canadian Engineer of August 26, 1924, that certain assumptions that had been made in these investigations were not correct. These results were obtained by using the photo elastic method; and while they served to disprove the assumptions in question, there was no clear indication from them as to an easy method of determining the actual stress distribution in riveted tension members.

The research was continued, using the photo elastic method, with a view to determining whether or not there were certain simple factors governing the stress distribution from which a reasonable deduction formula could be put together.

There are two avenues of approach to the problem. The first, and apparently the more popular of the two, is to use tension plates with rivet holes in them and to observe their behaviour when tested to destruction. The second method is to observe what happens when tension plates which are actually riveted together are treated in a similar manner. Both kinds of models were investigated; as it was felt at first that there might be some fundamental difference in stress distribution between these two types which would affect the general workability of a formula drawn up from observations on only one type of plate.

Some idea of the general difference in stress distribution in the two types of plates may be had from Figs. 1 and 2. Fig. 1 shows one set of principal stress lines for a plate with merely a rivet hole in it; Fig. 2 shows the corresponding set of principal stress lines for a plate into which the load is transferred by means of a rivet. The type of variation of stress intensity on a right section through these holes in both Figs. 1 and 2 is illustrated in Fig. 3. There is a region of high stress concentration close to the rivet or rivet hole depending upon which plate is used; and the highest unit stress in either case may be three or four times the average unit stress on the uncut right section of the plate. This means, of course, that the ordinary elastic limit may be

*Assisted by Messrs. K. B. Jackson, G. W. Smart, W. Turner and H. St. P. Butler.

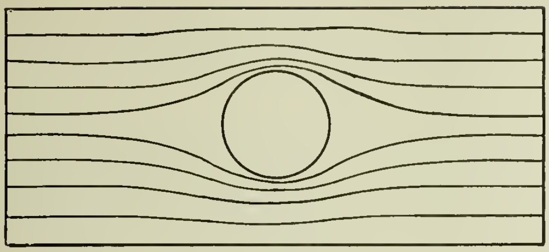

Fig. 1

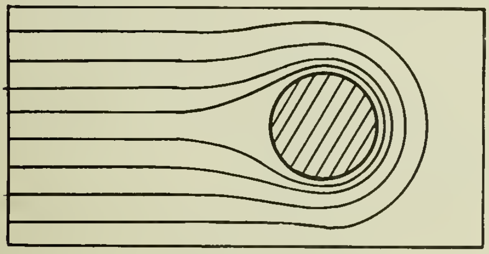

Fig. 2

Fig. 3

exceeded in these areas around the holes even when the average stress on the gross sections is well below this limit.

It was intended originally to explore the stress distribution for both types of models; but it was seen, as will be shown, that a certain factor common to both types was the governing effect, so that merely plates with holes in them were used finally.

The photo elastic method gives on a screen properly placed, a colour variation scheme from which the values of the algebraic differences between the two principal stresses in the main plane of the specimen may be obtained. As the load is placed on a specimen, there appear in succession the colours yellow, red and blue followed by the repeated sequence of the same colours as the stress becomes greater and greater. The outlines shown on Figs. 4 and 5 may be called isochromes as they give roughly the central lines of the various colours for a given load. These colour bands may be taken as representing the lines along which the principal stress differences have certain values. The principal stress differences shown on these isochromes are in pounds per square inch, and if one of the principal stresses is small, as is the case in this problem, it is not very far from the truth to say that the isochromes show the regions along which the other principal stress has a given value. The celluloid tension models used in making Figs. 4 and 5 were 1½ inches wide and approximately 3/16-inch thick with ¼-inch rivet holes. The edge distances were ⅜-inch and the gauge lines ¾-inch apart. The rivet stagger is ¾-inch in Fig. 4, and 2 inches for Fig. 5.

The average unit stress on the uncut right section in Figs. 4 and 5 is below the elastic limit of the material; but in the areas around the edges of the rivet holes the elastic limit is exceeded. This was done in order to give a more striking stress picture; although it is realized that the elastic limit having been exceeded, the specimens could not have been used for accurate stress determination. These diagrams are merely used here to illustrate a point that is not so convincingly seen from isochromes in which low stress values are used; although it must be clearly understood that almost the same configuration of results obtains for loads which keep the stresses below the elastic limit.

Many sections such as those illustrated in Figs. 4 and 5 were examined. Various stagger ratios were used and it was found that the salient features in all of these, conformed to the same type of stress distribution as shown in these figures.

It was while investigating the stress along various sections of these models that a certain persistent fact was noticed; namely: that there is a region of very high stress around the rivet holes which is so much higher than anywhere else that one would naturally expect first failure always to take place in or about that locality. *This is not new evidence; but it is doubtful whether its full significance has ever been taken into account as far as the present problem is concerned.*

When this was noticed, an attempt was made by the photo elastic method to deduce the effect of varying the stagger and gauge on these maximum stresses at the edges of the rivet holes; but it can be seen from Figs. 4 and 5 that there is not a very great decrease in stress value at the rivet holes for an increase of stagger from ¾-inch to 2 inches. Fig. 6 shows the stress variations on the edge distances of right cross sections through rivets for three specimens of the same dimensions given for Figs. 4 and 5, the staggers being varied as shown and only one half the load applied as in Figs. 4 and 5. It is evident that the failures of the specimens would most likely be in the order of No. 1 to No. 3; but the actual variation of maximum stress at the edge of the rivet hole is not very great as we go from No. 1 to No. 3. The reason why No. 1 would fail first follows, of course, from the fact that there is a greater average stress on the section. But the difference between any two of these cases is not such as to give rise to the conviction that it would require considerable variation of material on the right section to look after it. Indeed, one would almost form the conclusion that having allowed for the worst case, the remaining cases require very little variation of material. *The condition at the edge of the rivet holes is startling enough in all cases.*

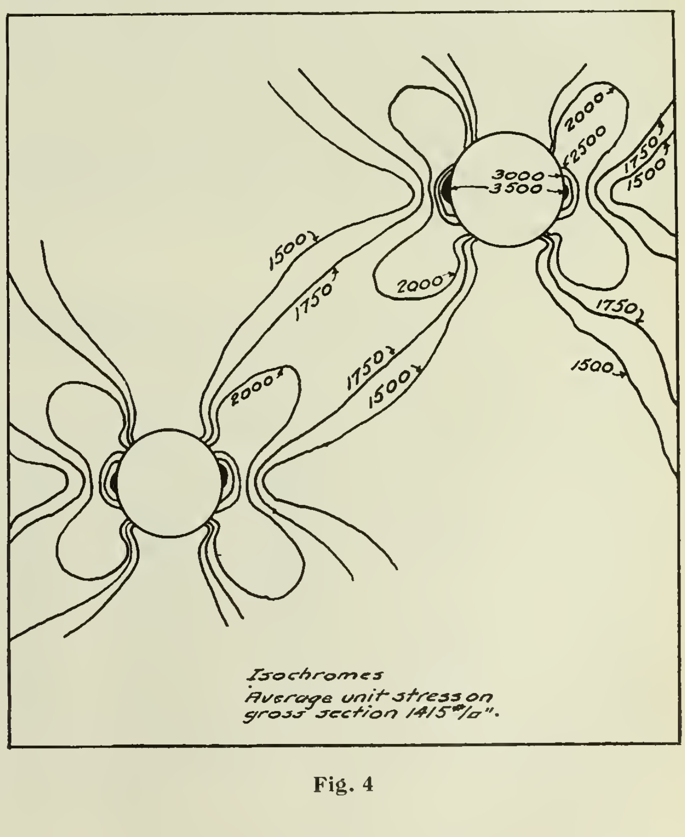

Fig. 4

Table I

Specimens 24″ × 4″ × ¼″ ; ½″ holes; gauge lines 2″ apart

Specimen	Stagger	First Failure
A	0	47300
B	¼ in.	46800
C	½ in.	47850
D	¾ in.	47500
E	1 in.	48600

The variation of stress on a right cross section on the other side of the rivet hole is of the same nature in all cases as shown in Fig. 3. The average stress in this case is very much lower than for the edge distance side; and, therefore, one would not expect first failure to begin on that side.

The supposition that the dangerous area was located at the edge of the rivet hole *on the edge distance side* was borne out in a few preliminary tests of steel plates. *In every case, failure commenced at that locality;* that is, with practical edge distances and rivet spacing values.

It was decided then to find out by means of a series of such tests on perforated steel plates whether or not any more pronounced law could be determined than was evident from the photo elastic method. The results of two of a series of ten tests is given in Table I. The plates used were 24 inches by 4 inches by ¼ inch with ½-inch holes in them on gauge lines 2 inches apart. These results are typical of the series. Certainly there is nothing convincing in these figures. They are the variations one might expect as being due either to the slight variations of the internal steel structure itself or to the errors in placing the specimens in the testing machine even with the greatest of care being taken.

Another series of tests is given in Table II. These are the results from using steel plates 15 inches by 3 inches by ⅛-inch. The edge distances in all cases were the same on each side for a given test, two holes ⅜-inch diameter being used for all specimens.

The variation of figures in both Table I and Table II may be taken as typical of the results obtained in all the tests. Altogether, a total of two hundred and ninety-two plates were tested, with more or less the same type of results.

There is one very curious fact that seems to be persistent although it has not any great bearing on the present problem. It will be noticed that the plates seem to be weakest not when the two rivet holes are on the same right section, but when the holes are slightly staggered. This

Loads in Table are First Failure loads.

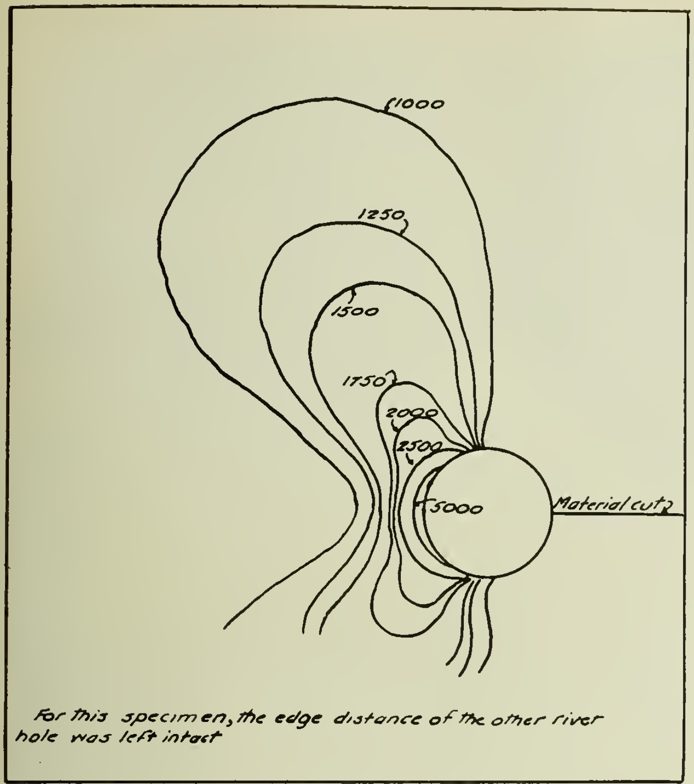

Fig. 6

same fact was suspected during the photo elastic investigations.

It is obvious that if the basis of considering first failure as the governing factor in the problem is admitted, that there is no necessity for a very complicated deduction formula. And what other basis of argument is required? It is this first failure which must be prevented. What happens after first failure is of no practical importance. It might be thought, of course, that the method of failure of the material after this first failure takes place would give some clue to the conditions before first failure. But the writer cannot hold with this idea. The stress distribution after first failure is so different that it is not possible to correlate the after effects with those before first failure. Fig. 7 shows the isochrome lines around one hole for a specimen of the same dimensions as that used in Fig. 5 with only one half of the load placed upon it and the edge distance cut through to the boundary of the plate. It is obvious that the failure on the edge distance side has increased the stress at the rivet hole beyond all proportion and the stress distribution in the remaining material bears no similarity to that in Fig. 5.

Before the tests in Table II were made, several plates of the same material with no holes in them were tested to determine their strengths. The average of these tests gave the ultimate strength as 57,000 pounds per square inch. If two ⅜-inch rivet holes be deducted from a given right cross section and the ultimate strength calculated in the customary manner assuming an average strength of 57,000 pounds per square inch, a figure of 16,100 pounds is obtained which is sufficiently close to the results of Table II for zero stagger to pass without comment. On the other hand, if merely one rivet is deducted, an ultimate strength of 18,700 pounds is given which is considerably higher than

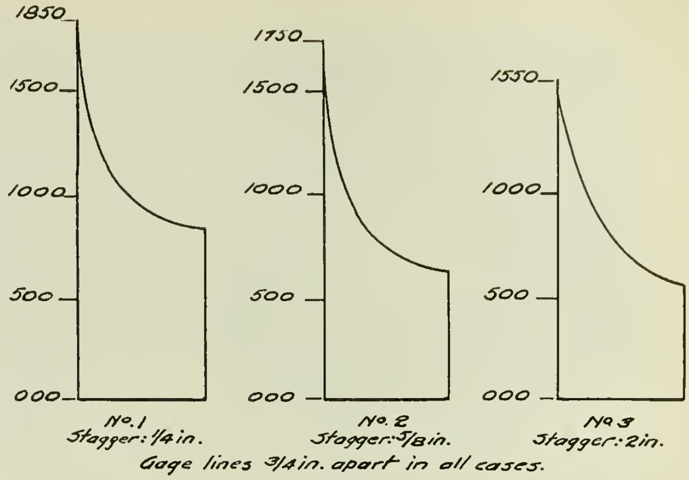

Fig. 7

any of the tests show for first failure. This can be explained by the high stress concentration at the rivet holes which is not very much affected by increased stagger as has been shown by the photo elastic results; and also by the fact that the ultimate failure of the riveted tension plates would be a higher value than first failure, in the neighbourhood of the holes.

One might almost feel safer after looking at these results in always deducting two rivets in order to allow for the effect of damage done to rivet holes in the shop. Certainly the practice of adding ⅛-inch to the rivet diameter in figuring deductions is a factor of safety in the right direction when the high stress in the neighbourhood of the rivet is remembered. Edge distances certainly should not be made too small.

Examining the results in Table II and other results of a similar character, the writer makes the following arbitrary observations:

(*a*) As the stagger ratio, $\frac{s}{g}$, increases in value from zero to about $\frac{6}{10}$ there is very little increase in strength of the tension member. The first failure values in Table II above the double lines lie between these limits of stagger ratio.

(*b*) There seems to be very little increase in strength of the tension member for increase of stagger ratio beyond a value of 1.6.

Based upon these opinions, the writer at first thought of proposing the following deduction formula:

$$x = 1.6 - \frac{s}{g}$$

where x is the deduction to be added to one rivet deduction, x in no case to exceed a value of unity.

s = the stagger in inches

g = the gauge distance in inches.

This formula, of course, gives a deduction for two rivet holes up to a considerable stagger ratio which will appear excessive to many structural designers. The fact that ⅛-inch is usually added to the rivet diameter in calculating net areas lends weight to the objection; and in view of this practice, the writer feels that a concession should be made and proposes the following formula:

$$x = 1.5 - \frac{s}{g}$$

The Practical Application of the Microscope in Railway Service

Frederick H. Williams, M.Sc.,
Canadian National Railways, Montreal.

Paper presented before the Montreal Branch of The Engineering Institute of Canada, October 29th, 1931.

SUMMARY.—Microscopic examination of the material involved in the fracture of machine and structural parts has been found of very great value, and this paper gives illustrations of a number of typical failures, principally in locomotive work, and discusses their probable causes, with special reference to the occurrence of failure from fatigue cracks.

To the engineer, if he happens to be working on a railway, his line of work appears to be the most important; to the civil engineer, the material that is used in the making of tracks, bridges, or buildings, seems to be of supreme importance; to the chemist, the use of the microscope in determining the quality of paints, oils, chemicals and various other materials used by him will seem of very great value. So on through the many branches of engineering and railway work.

However, this paper only attempts to cover the practical application of the microscope to that particular branch of the service in which the writer is most interested, namely, the locomotive.

The locomotive of the present day that hauls passengers and freight between distant points tends to give a feeling of security and a knowledge that both human lives and possessions are well protected in transportation.

The microscope has a great deal to do with that safety. It is also most useful in the interesting study of the parts of the locomotive.

The part that the microscope plays is to inform the observer whether or not the laws of nature are being followed and whether the best results are being obtained from the materials used, such as iron and steel. It shows the structure that results from any treatment which has been given the part under observation.

The illustrations reproduced in this paper are made from photographs of fractures and microscopic structures and have been selected from over five hundred reports and three thousand photographs.

The use of iron in its pure form is not generally practicable. Iron with alloying elements, which make it into steel, is the material used in making the greater part of a locomotive, and the following will, therefore, refer to steel with particular reference to the application of the microscope to failures.

It would save some expense if the average engineer could learn more of the nature of a failure from its fracture. This knowledge would be the result of a study of the failed materials by tests, chemical analyses and microscopic examination.

Everything is not known regarding microscopic examination, but that is the most interesting part of the work. New features appear and new values are attained which help to reduce the number of failures and in the case of railroads to make travelling safe.

What does the observer expect to see in a microscopic examination of a piece of steel? Very often, what experience teaches him to look for. The structure can be observed, whether coarse or fine grained, the impurities, etc. Also the structure of the steel can be compared with standard structures to find if it conforms to what is desired.

It is well, before cutting specimens for examination under the microscope, to examine the defective or broken part to see what can be learned from it. A typical case where such an examination is of assistance, is the following case of a broken steel axle on a self-propelled passenger car that failed in service.

The axle is fractured at the end of the keyway. The ends of the fractured axle show that the failure is, without doubt, a fatigue failure, starting at both sides of the keyway. A view of the key and keyway, as seen in Fig. 1, show at once that the fault and cause of this failure are mechanical. The square-ended key in a round-ended keyway is not good practice. Fig. 1 also shows the ends of the fractured axle. The square end of the key to the left of the notches in the end of the key-way should be noted, also that the crack creeps across the section. The two original cracks join and meet one another when nearly across. The final break can be detected from the coarse grain. Further examination shows that the key is made of steel that has been carburized

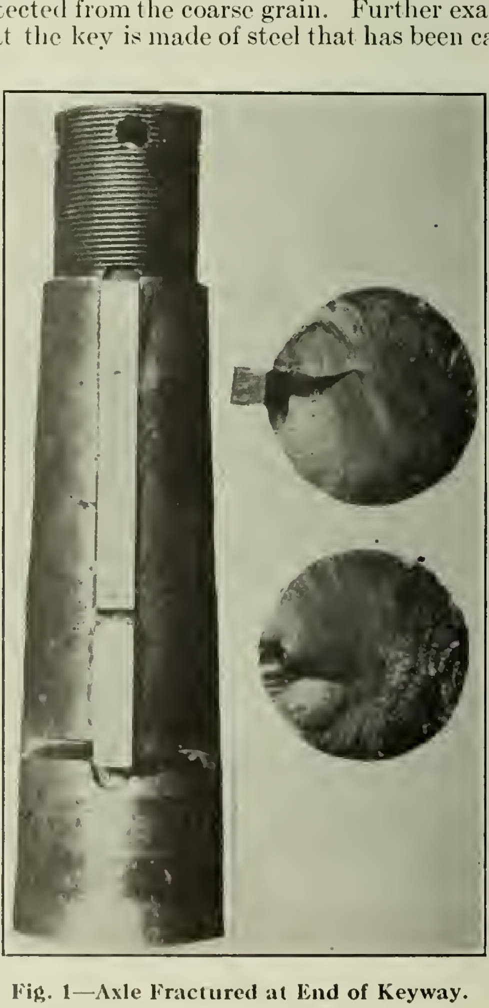

Fig. 1—Axle Fractured at End of Keyway.

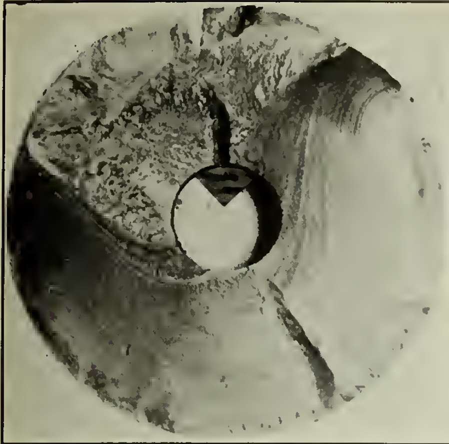

Fig. 2—Section Carbon Steel Axle that Failed in Service.

Fig. 3—Fractured end of Nickel Steel Driving Axle.

Fig. 4—Fracture due to Tool Marks and Poor Material.

and hardened. The result is that a hardened key is driven into a comparatively soft steel keyway, and the nicks made on each side develop into a crack and ends in failure of the axle. This is one of the first main causes of failure of steel parts of a locomotive, or, in fact, any machine, and this fault cannot be too clearly impressed upon anyone who desires to reduce the preventable failures to a minimum.

Scratches, tool-marks, sharp corners and any similar unfinished surface, no matter how small, if located where there are stresses at work, will result in fatigue cracks and failure. This statement is, perhaps, too critical, but one cannot be too careful where life is concerned.

Had it been necessary to substantiate any of the facts observed by this examination, a microscopic study of the structure would have shown that the steel axle was of the best, that the key had been case-hardened and the failure could be from one cause only, namely, the improper shape and structure of the key.

A carbon steel main driving axle that failed in service is seen in Fig. 2. This is something entirely different from the previously described failures. Here it should be noted that the fatigue cracks start at about ⅜-inch from the surface and that they commence at several points. This is peculiar and until an examination of the structure of that steel has been made at several places, the cause of this break can only be guessed at. The microscope, however, shows that overheating of the axle was the cause of the start of this crack.

This axle has been so hot that the structure of the material has been changed from a coarse structure of passable size, into a very fine structure. The change goes in to a depth of ⅜-inch. In failures of this type the copper in the bronze of the bearing actually penetrates into the steel and thus embrittles the steel and causes the crack to penetrate from the surface to the depth above mentioned. Fatigue cracks start at the root of these primary cracks. A failure is the result.

Fig. 3 illustrates a larger section of steel that failed in service. A nickel steel driving axle on one of the large locomotives. This failure is serious mainly in that it is expensive and results in delay of the train. Generally such a failure takes place as the locomotive starts up after stopping at a water tank or at some station. The locomotive when running does not exert stress sufficient to more than increase the crack, but with a sudden strain at the start, the crack completes the failure of the section and the locomotive has to go out of service for repairs.

This failure started in the keyway at both sides, and joined after passing the bottom of the keyway. As will be observed, the creeping crack extends across two thirds of the cross section; it is a question how much of the fracture is due to the fatigue or creeping crack and how much was final fracture. The fact that nearly three-quarters of the section was fatigue crack indicates good material. Possibly a poorly sharpened or damaged cutter tore the steel along the bottom of the keyway and cracks started from several of these tears, ending in failure through fatigue.

The grain of the steel in the final break is fine and uniform. The microscope would come in well in this case if one were wanting a satisfactory structure for further comparisons, otherwise it need scarcely be resorted to.

A clear case of poor material is shown in Fig. 4, and this can readily be seen from the fracture, also the fact that the fatigue crack extends but a short distance into the steel. The complete failure followed not long after the fatigue crack started. The microscope turned upon this steel showed a very coarse, dirty steel. The failure started in the poor material, through fatigue, and possibly began through some tool mark or tear in the axle and rapidly continued until the section gave away under the stress, when four-fifths or nearly the whole section was still holding.

The case shown in Fig. 5 is undoubtedly a freak failure, or rather fracture, of a steel axle. The cause of the strange fracture became plain when the microscope was brought into the case. It will be noted that there are three pockets where balls of steel rested when the axle was taken off the locomotive. There are also faint outlines of the

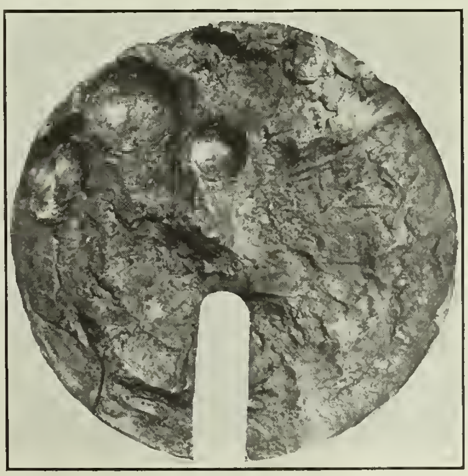

Fig. 5—Fracture in Steel Axle Caused by Overheating.

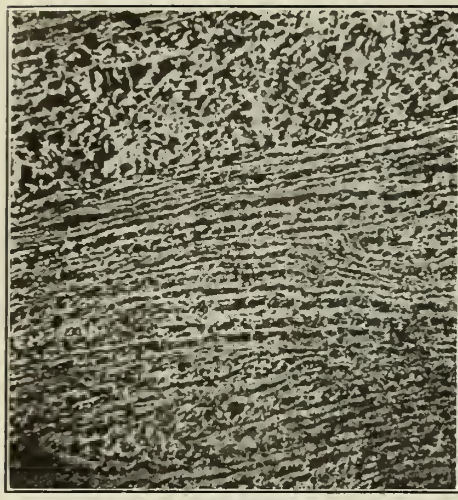

Fig 5A—Structure of the Steel of a Ball Near the Surface.

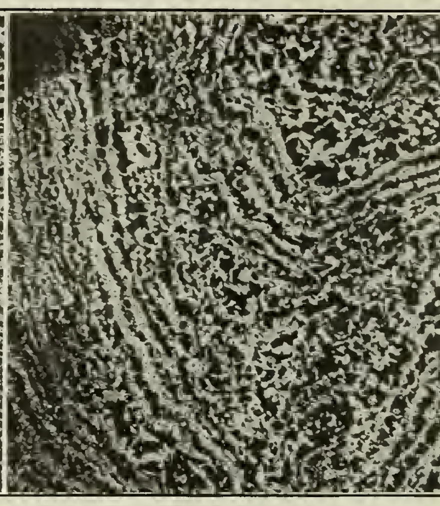

Fig. 5B—Structure of the Steel Near the Centre of the Ball.

Fig. 5C—Fine Grain Metal that has not received Rolling Stresses indicating Structure of the Metal at the Time of Fracture.

paths where the balls rolled before finally settling in the deep impressions or pockets. The steel of the included balls proved to be of the same material as the rest of the axle, and the structure as shown in accompanying pictures, shows that the steel of the balls was torn from the axle in service and rolled into the balls. The axle failed through overheating and twisted off at the last. Heat cracks extend in from the surface to considerable depth. The metal fractured at several places and chunks of hot metal rolled into the balls, also making pockets in the ends of the axle to mislead one in forming conclusions as to the cause of failure. The microscope clearly shows the details, as illustrated in Figs. 5A, 5B and 5C.

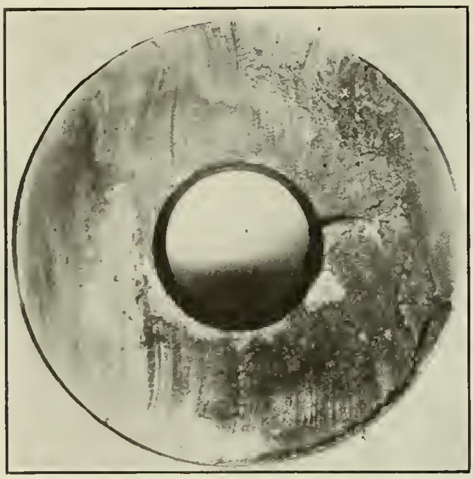

Fig. 6—Service Failure of Nickel Steel Crank Pin.

The chemical analysis of the balls found in this axle and the axle itself, give the following information: drillings were taken from the cross section of axle:—

Location	Car	Phos.	Sul.	Mang.	Si.
	per cent	per cent	per cent	per cent	per cent
Halfway from centre to surface	.436	.036	.025	.57	.060
Centre	.423	.036	.023	.57	.....
Wall of Spherical Cavity	.44	.....	.....	.58	.....
Spherical ball found in cavity	.42	.028	.....	.58	.....

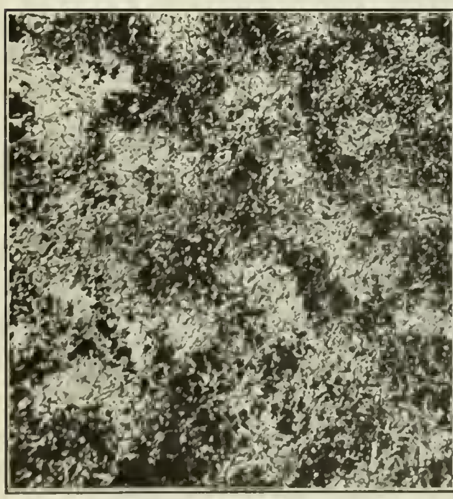

Fig. 6A—Structure of Cross Section of Crank Pin, Grain Fine.

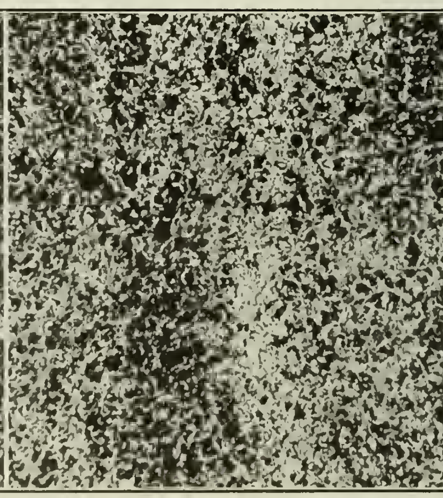

Fig. 6B—Structure of Steel in Longitudinal Section Near Surface of Pin.

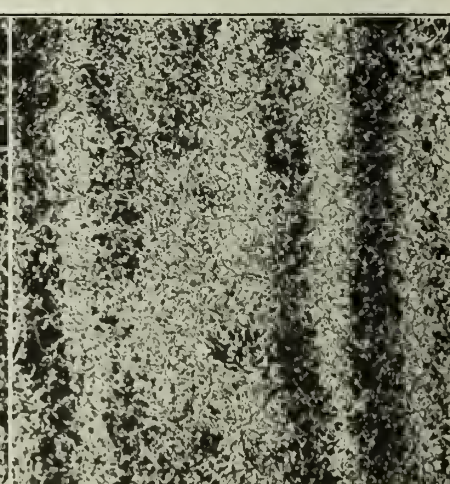

Fig. 6C—Structure of Steel in Longitudinal Section Near Centre of Pin.

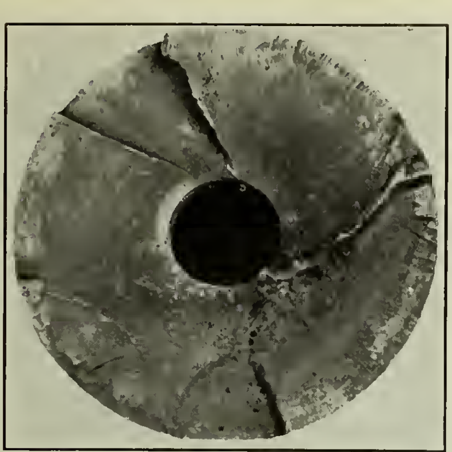

Fig. 7—Failure in Carbon Steel Axle.

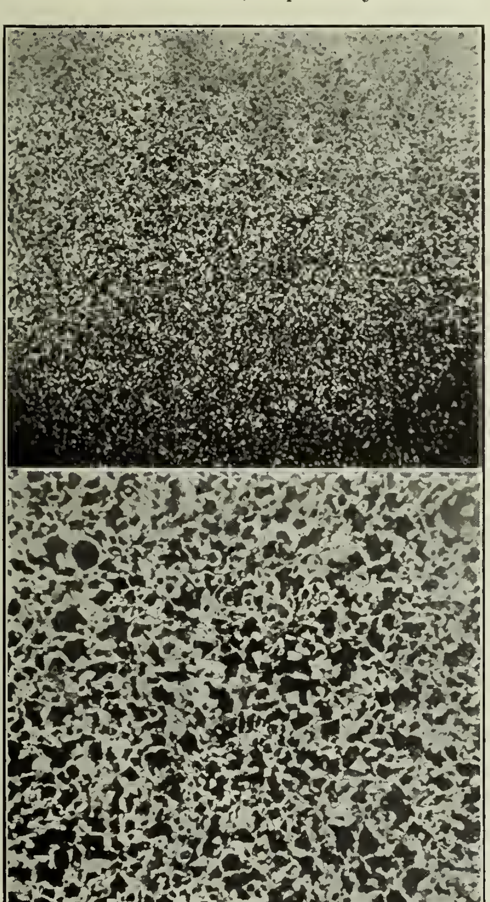
This table does not show any difference between included balls and the axle. The microscope, however, gives a clue and results in clearing the mystery.

A crank pin failure as illustrated in Fig. 6 will next be considered. The steel is nickel and of good quality, as judged from the fracture. It will be noted that the fatigue crack covers nearly the whole section, showing that there was resistance to the final break until the last. This is typical of nickel steel. Carbon steel, unless of the very best, fails before half the section is covered with the fatigue crack.

The crack started in the fillet near the wheelfit and, judging from the microscopic structure of the steel, the crack started in either a banded structure or a scratch in the steel as there were very fine tool marks that gave rise to the crack. A mark of less than one-sixty-fourth of an inch will be sufficient to cause failure, especially in fillets. Fillets should be made free from the least tool mark or cut, and should be finished of ample dimensions and polished. The grain of the steel is very fine with banded areas. Fig. 6A illustrates a somewhat non-uniform distribution of pearlite and ferrite.

A

B



Figs. 7A and 7B

Another case of an overheated carbon steel main driving axle that failed in service is shown in Fig. 7. This axle has been overheated and developed primary cracks, and from fatigue the axle failed completely, when only a small portion of the section held. This is an example of the resisting qualities of good steel. The structure at the surface of the journal was refined to a depth of ⅜-inch, readily noted under the microscope.

Fig. 7A illustrates the structure of the steel near the surface of the axle. It is very fine and uniform to a depth of ⅜-inch. This is due to the axle becoming very hot with a temperature in the neighbourhood of 1,400 degrees F., which is sufficiently hot to refine the grain.

Fig. 7B shows the structure of the steel about one inch in from the surface. The difference between this structure and that in Fig. 7A on the surface should be noted.

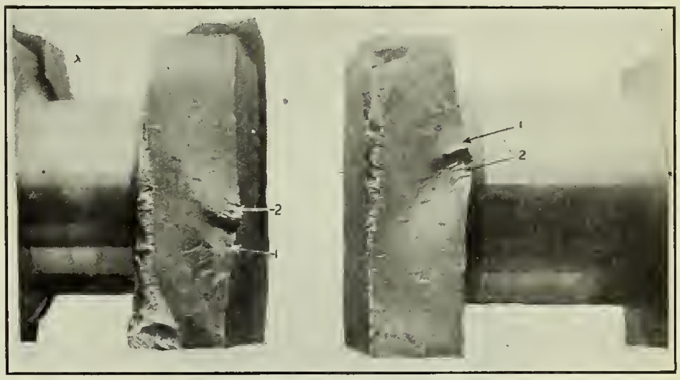


Fig. 8—Fractured Ends of Crank Shaft.

Fig. 8 illustrates a crank shaft for a 6-cylinder engine that failed in early life due to improper manufacture. The shaft was forged into a slab and cut out to form, twisted to give the right angles between arms and turned up to sizes. The section to the left shows the fractured end of the crank

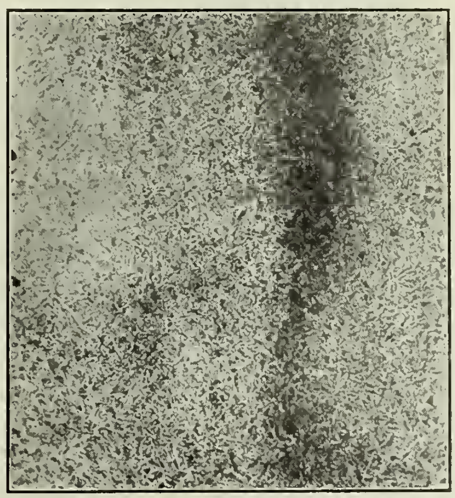

Fig. 8A—Structure of Steel in Section of Crank Shaft near Fillet—Note Dark Horizontal Band with Non-Metallic Inclusion.

shaft; the bearings turned on this, allowing the grain of the steel to be cut at the fillets. The shaft failed from fatigue starting at several places in the fillet, as indicated by the arrows. The defects were minute ends of non-metallic inclusions. It will be noted that the combined fatigue cracks continued over nearly seven-eighths of the section. Excellent steel but poor forging practice. The section to the right shows the opposite fractured end. Here the finish on the fillet was free from tool marks and scratches.

There is another type of failure, or rather a start of failure. A weld on a steel forging sometimes is the cause, and great care should be used in the welding operations on parts that are subjected to heavy stresses. Fig. 9 shows a view of a locomotive crosshead-end (right section cut off

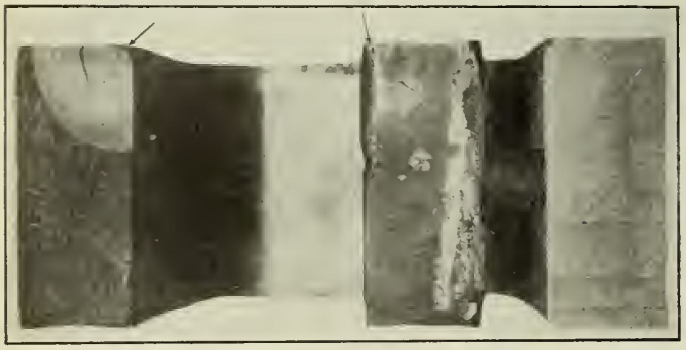

Fig. 9—Failure Caused by Weld.

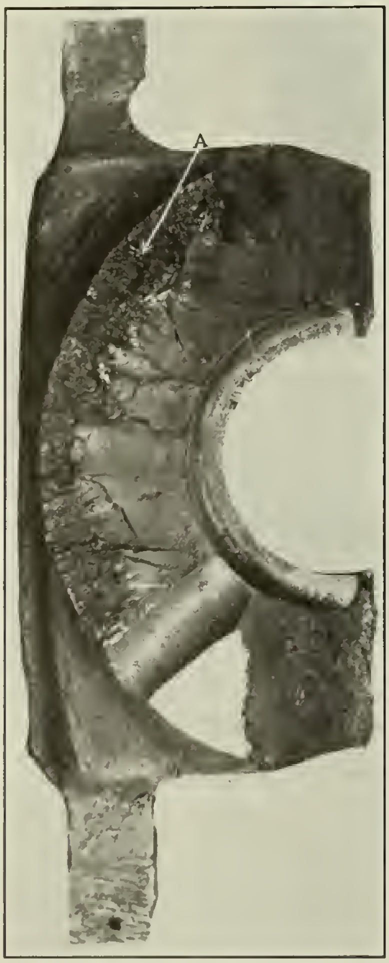

Fig. 10—Failure due to Flaws in Casting.

and moved towards the centre) which failed from a fatigue crack that severed one section and started another fatigue crack on the opposite section. The start of the failure is readily seen, the cracks in the right-hand section being the older of the two, both were progressive, starting from deposited metal.

Fig. 10 illustrates a failure of a casting, a steel crosshead. This shows that the metal in that portion of the casting

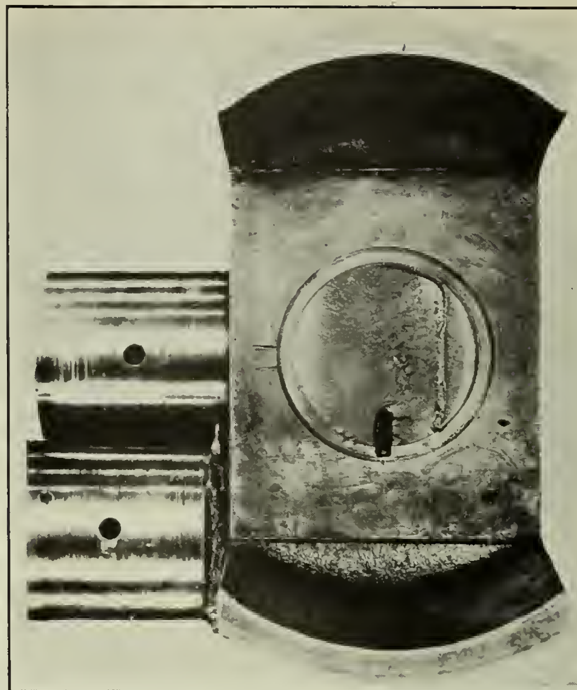

Fig. 11—Score Marks Causing Failure in Stationary Engine Crosshead.

near the riser or gate was poor and cracked due to flaws. The microscope reveals the fact that the impurities weaken the material, so that on cooling, the casting either cracks or is so weakened by stresses that it fails when subjected to heavy strains in service, as occurred in this case. Note flaw to the left of the fracture at A.

Fig. 11 explains a most interesting failure in the crosshead of a stationary engine. This failed in service and is a

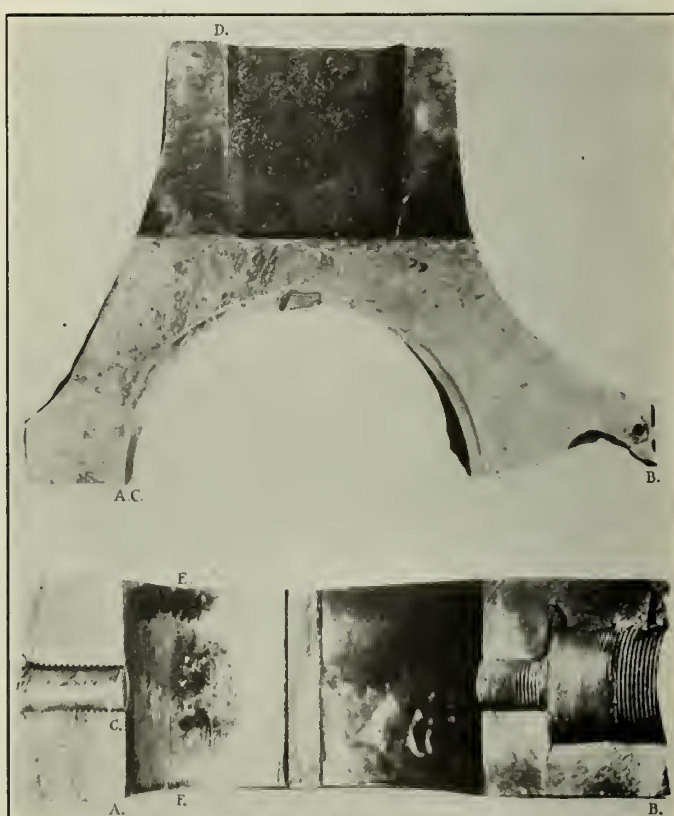

Fig. 12—Side and End View of Broken Leading Locomotive Side Rod.

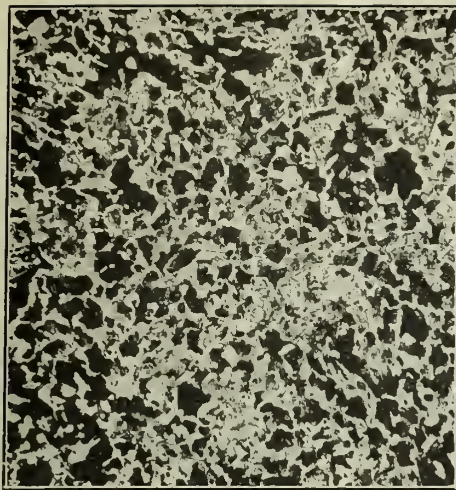

Fig. 12A

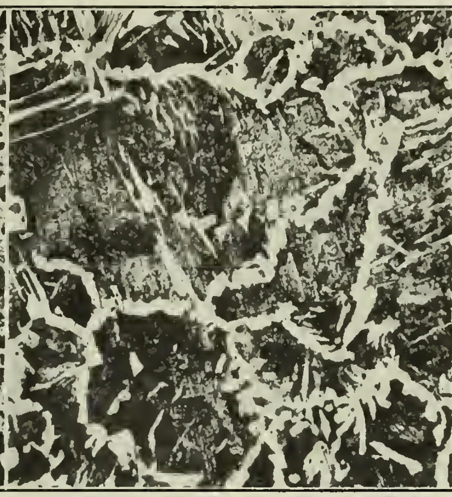

Fig. 12B

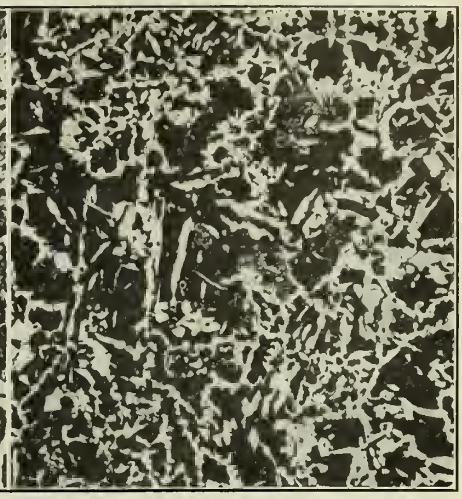

Fig. 12C

typical example of fatigue cracks starting from score marks due to wear. These were not removed when under repair and failure was the result. The usual fatigue crack with its ending in failure is as sure as if the material was broken up deliberately. In this case the fillets on both pins were slightly cut in service and the fatigue cracks started from these small marks.

Fig. 12 shows a side and end view of a broken leading left side rod from a locomotive. At *A* is the location of the specimen for the microscope, the structure of which is illustrated in Fig. 12B. The grain is very coarse, giving indication of the high temperature to which the rod has been subject in service. The fracture started in material with this structure. At *B* is the location of another specimen for the microscope whose structure appears in Fig. 12A. The grain here is fine and uniform, giving indication of heat which changed the structure from the original. For that at *C* see Fig. 12C, indicating the fine structure throughout the rod when put in service. The grain is fine and uniform over the greater portion; some areas have a coarse grain with traces of forging structure. *C* is the location of the start of the crack and the dark bands at *E* and *F* are where the fit of the bushing is at least 1/32-inch slack, tapering towards the centre, leaving for bearing a strip scarcely two inches wide of fit, the rest being slack.

Examination of fractured steel forgings throws considerable light on the subject of failures of steel parts, and the importance of lubrication in service.

When a steel forging, in contact with bronze, heats up, some of the copper, or content of that bronze, enters the steel resulting in hot short, causing a number of cracks which start fatigue failures, if not the failure itself.

Fig. 13 illustrates the outer surface of a piece of boiler plate. The depression shown has the appearance of a crack; however it is a corrosion crack and often causes failure. It is due to the combination of corrosive action, a question of electrolysis, and strain in the metal.

The structure of steel in boiler plate is shown in Fig. 14 where the rolling lines are quite pronounced. This is taken near the centre of a piece of plate, and the microscope here shows that the plate has been finished at a proper temperature and that the metal is clean with carbon evenly distributed.

A decarbonized surface of a section of a spring leaf is illustrated in Fig. 15. Spring leaf failures are a study in themselves and though failures are known to occur from this structure just what the limits are is now under observation by a number of companies using and manufacturing carbon steel.

This subject is one of great interest to all engineers whether from an operation, maintenance or safety point of view. The microscope is a very valuable instrument in caring for the safety of the travelling public, more valuable, perhaps, than anyone realizes. It tells by vision the paths that should be followed if safety is to be fully achieved.

Aviation in Canada and the National Research Laboratories

J. H. Parkin, F.R.Ae.S., M.E.I.C.,

Assistant Director, in charge Aeronautical Research, Division of Physics, National Research Laboratories, Ottawa, Ont.

Paper presented on October 15th, 1931, before the Aeronautical Section of the Montreal Branch of The Engineering Institute of Canada (Montreal Section, Royal Aeronautical Society).

SUMMARY.—After a brief account of the progress in aviation in Canada during the past ten years, the author points out the necessity for research facilities in Canada to provide for the development of aircraft types specially suited for Canadian use. He then describes the wind-tunnel, the tank for testing seaplane floats and the equipment for making endurance and economy tests on aircraft engines, which have been established in the National Research Laboratories at Ottawa, Ont.

The development of a country is dependent upon transportation and communication and can only proceed as fast as these facilities permit. This fact is particularly true of Canada, and is of great significance at the present stage in the development of the Dominion.

In Canada, like most other countries, transportation was at first confined to the natural waterways of the country. The early explorers and traders penetrated the country along the chains of rivers and lakes. As settlement proceeded roads and railways were constructed and settlement and development followed these arteries. With increase in population and traffic, improvements in these systems of transportation were demanded—single track railroads were double tracked, locomotive power was increased and trains were operated on faster and faster schedules. Waterways were improved and provided with better safeguards, canals were enlarged and the capacity of harbour facilities was increased. Highway systems were extended and road construction was bettered.

Examination of a map will disclose the fact that at the present time some three-quarters of the area of the Dominion are still unserved by roads or railways. Most of this area has been but little explored owing to its relative inaccessibility by surface transportation. Aircraft, however, requiring no prepared surface track between point of departure and destination, and, when of the boat or float type requiring only the natural landing facilities provided in the numerous lakes and rivers, are well able to give access and transportation to such regions. Once this fact was properly appreciated the exploration and a certain amount of development of these territories began by means of aircraft and has been proceeding rapidly during recent years. As a result, it is learned that much of this country is rich in natural resources.

The mobility and range of vision provided by aircraft enable the topography of country to be readily and rapidly determined and air transportation of personnel and supplies of ground parties greatly facilitates detailed geological, water power and other investigations in promising locations, as disclosed by aerial reconnaissance. Aircraft have thus, in the past few years, been the means of greatly extending our knowledge of the natural resources of the northern regions. But knowledge of the vast potential wealth locked in these regions will be of little use unless the key, in the form of transportation, is provided.

Provision of rail transportation in the near future to much of this territory is impracticable and water transport, even when feasible, is limited to a short period of the year. Air transportation, on the other hand, is practicable with adequate frequency and regularity throughout the year with the exception of relatively short periods during the fall freeze-up and spring break-up. While air transportation is not likely in the near future to be able to handle bulk freight, such as grain, it has already been demonstrated to be quite feasible, even with existing types of aircraft, for the transportation of construction supplies, mining equipment and machinery into this country and products, such as furs and gold, out of it.

It is, therefore, considered that, until the development in any particular locality is sufficient to justify the building of a railroad, aircraft must be largely depended upon to provide the necessary transportation. It is not improbable that in certain regions the requirements and conditions may be such that aircraft can continue to provide all the facilities needed. It thus appears that the key to the development of these regions for many years to come exists in aircraft. This being the case, the production of suitable freight aircraft for such services in the Dominion is an urgent necessity. That aircraft of adequate capacity can be produced is evidenced by the freight carriers already built and in operation, notably the Junker and Vickers freight aircraft.

While in perhaps no other country are aircraft being used in a greater variety of ways or to a greater extent in relation to the population, the most effective uses to which aircraft have been put in Canada have been those in connection with the investigation, development and protection of the natural resources of the country. Aerial surveying and the preparation of maps from aerial surveys have been brought to a very high state of perfection in the Dominion. Each year, large areas are photographed and mapped. Aircraft are performing valuable services in the protection and development of our timber resources through the detection and suppression of fires, combating insect pests and in the preparation of plans for the most economical utilization of the timber. Fishery patrol by aircraft has been demonstrated to be the most effective and economical method yet employed. The possibility of combating the wheat stem rust by dusting from aircraft has been indicated from preliminary trials. The surveyor, geologist and engineer are finding aircraft invaluable aids in the location of railroads, highways, and transmission lines and in connection with river improvements, harbour, terminal and water power developments.

While Canada is undoubtedly well adapted to exploit air travel, the sparse population and excellence of existing railroad facilities in the more settled sections has militated against the successful operation of air routes for the transportation of passengers, mail and express, except in the more remote regions. In spite of these and other handicaps, the air mail traffic in the Dominion has, since its inception, shown a continual increase in volume. The air lines operating in the north country and those serving isolated communities fill a very definite need and have been generally successful. Some of the first self-supporting air lines in the Empire were those serving mining centres in the north.

It is believed that air lines for mail and express in the older sections of the country can be made to pay well if divorced from passenger carrying, if suitably designed aircraft are operated and if public patronage is solicited by a well directed policy of education. Regular passenger air lines, covering territory served by railroads, are, for a number of reasons, unlikely to be self-supporting for some years.

The accompanying diagrams (Figs. 1 to 3), prepared from information published in the Reports on Civil Aviation, indicate the present situation in Canadian aviation

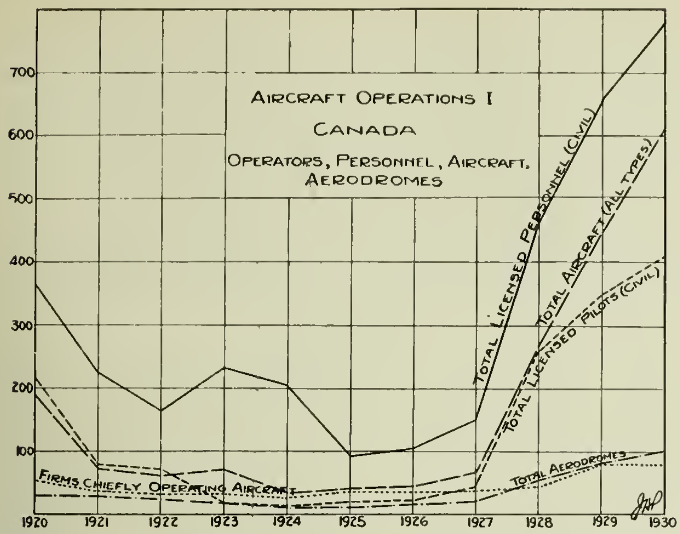

Fig. 1—Number of Aircraft, Personnel and Aerodromes in Canada, 1920-1930.

and the development during the past ten years. The rate of expansion of civil aviation in Canada in recent years has been exceeded in only one other country. They show a remarkable extension during the years 1927-1929, and while progress has naturally been less rapid during 1930-1931, there is no doubt that the upward trend will be resumed when more favourable economic conditions obtain.

Just as the extensive sea-borne commerce of the great maritime nations gives rise to and supports the thriving ship-building industries of those nations and their prosperous maritime commerce at the same time depends upon an up-to-date and efficient industry, so is successful aviation dependent upon a healthy industry. The sound development of national aviation depends upon the building up of an industry capable of constructing and servicing the aircraft required and a flourishing industry depends upon successful aviation. The two are mutually interdependent.

If Canadian aviation is to be enabled to assist, as it is capable of doing, in the development of the country and to be independent of foreign builders and aircraft, every effort must be made to build up a strong aircraft industry in the Dominion. Otherwise, as in the case of most countries which are backward industrially, Canada must purchase from other countries, and, in so doing, pay these countries for their expenditures and efforts in developing their aircraft. Not only will the cost then be greater than if a strong Canadian industry had been developed but the Dominion will be rendered dependent upon foreign builders for her aircraft, which, however unsatisfactory it may be in ordinary times, may be disastrous in times of emergency.

Up to the present, aircraft builders in Canada have been seriously handicapped in their efforts to develop improved aircraft suited to Canadian requirements through lack of adequate research and testing facilities. They are also placed at a distinct disadvantage in competing with builders in foreign countries having at their disposal extensive government research laboratories.

Research facilities are most needed and can do most useful work during the early stages of the establishment of the industry and yet it is precisely during this period that the industry is itself least able to provide such facilities. Well-equipped aeronautical laboratories such as have been provided by the governments of most other countries, would make possible the securing of information essential in the production of improved aircraft and motors suited to the needs of the country, place at the service of the aircraft builders of Canada means for the solution of their technical problems and enable the Dominion to do her share in adding to the scientific and technical knowledge so necessary in the successful development of commercial air routes within the British Empire.

The accompanying diagram (Fig. 4) prepared from information published in the Reports on Civil Aviation and supplied by the Census of Industry Division, Dominion Bureau of Statistics and Customs Division, Department of National Revenue, indicates the relation between the aircraft industry in Canada, foreign imports and Canadian production.

Scientific knowledge and research are playing today a more important part in industrial progress than ever before and, while most industries are indebted to these, none are more so than aviation. The rapid development in all branches of aviation during the past twenty years has been very largely the result of valuable painstaking research in the science of aeronautics. Further progress in air transportation and the aviation industry is dependent

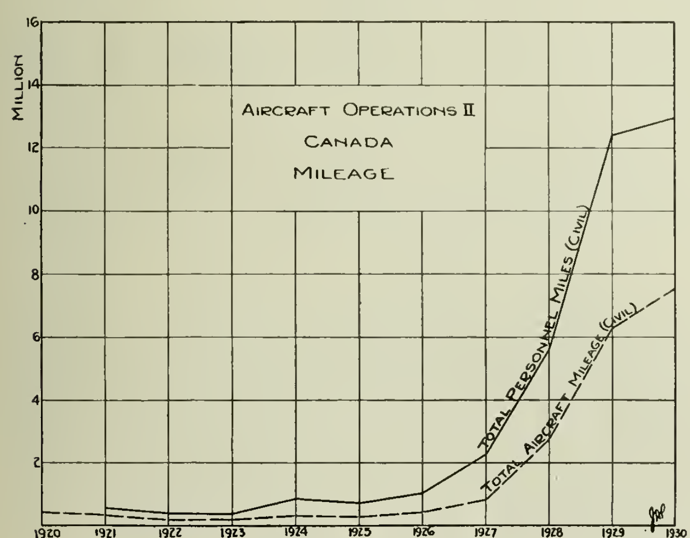

Fig. 2—Aircraft Mileage in Canada, 1920-1930.

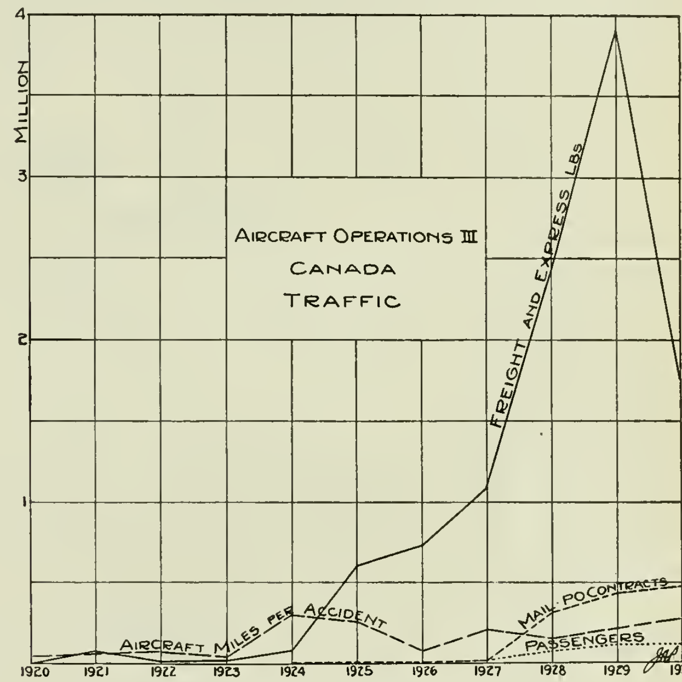

Fig. 3—Traffic Statistics in 1920-1930.

on continued research effort. Advances greater than any yet made may well result from future research in aeronautics.

Research work may, in a general way, be divided into three types, which are adapted to three different classes of organization. So-called "fundamental" research, contributing to basic theory or pure science, is generally carried on in educational institutions and private research laboratories and occasionally in laboratories of far sighted industries. "Practical" research on the other hand, directed to the invention of a particular method or device, or the solution of a special problem of manufacture, is the work of the industrial laboratory. The principal function of a government laboratory is the conducting of researches of general and immediate application and primarily national in character. Studies for the solution of problems or improvement of methods or products of a whole industry for the general good of the industry and the country are properly the work of a government laboratory.

Thus, the great mass of general information accumulated from work in government aeronautical laboratories is largely the basis for the design and construction of aircraft and engines, for government regulations for the construction and operation of aircraft and engines and for improvements in the efficiency, safety and comfort of aircraft.

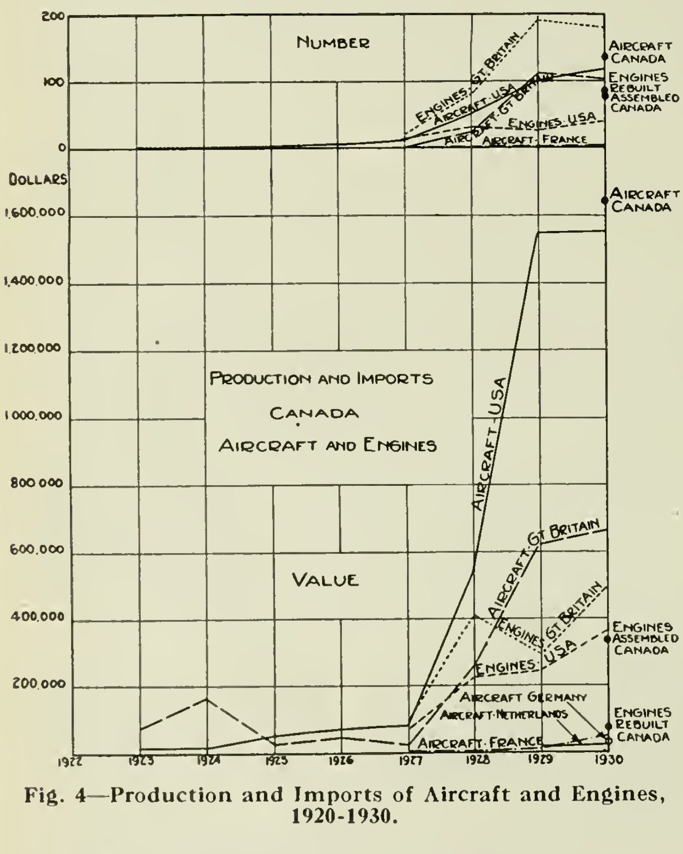

Fig. 4—Production and Imports of Aircraft and Engines, 1920-1930.

If the most effective use is to be made of aircraft in Canada in the future, adequate research facilities must be provided to assist designers and the industry to develop improved aircraft, suited to the conditions and requirements of the country and to solve the problems arising in Canadian aviation. The National Research Council has, therefore, with the approval of the Sub-Committee of the Privy Council for Scientific and Industrial Research, undertaken to provide, in the National Research Laboratories now being established at Ottawa, facilities for aeronautical research.

While aeronautics embraces most branches of engineering, the special equipment being installed for aeronautical research at Ottawa includes a wind tunnel for aerodynamic investigations, a test tank for hydrodynamic studies and tests and an engine dynamometer for aircraft engine work. Aeronautical investigations in other branches of engineering, such as in strength of materials, metallurgy, radio, sound, illumination and photography, will be made in the laboratories of the Physical, Chemical, Engineering and other divisions of the National Research Laboratories.

As design, construction and installation of the equipment for aeronautical research is still proceeding, it is not possible at this time to do more than describe the equipment in a general way, without giving specific information as to its operation.

Wind Tunnel

The wind tunnel is now recognized as the most important element of an aeronautical laboratory. As its general use, construction, theory and requirements are well known, it is not proposed to deal with them in detail in this paper.

Tunnels now in use, with the exception of variable density tunnels, are of the atmospheric type, in which the pressure in the air stream is substantially atmospheric. Such tunnels may be classified as follows:

(*a*) Open return, closed air stream (N.P.L. and R.A.E. types).
(*b*) Open return open air stream (Eiffel type).
(*c*) Closed return, closed air stream (modified Göttingen type).
(*d*) Closed return, open air stream (Göttingen type).

An important requirement in a wind tunnel is a steady uniform current of air and, from this standpoint, open and closed return tunnels are equally satisfactory. The closed return tunnel, however, possesses certain important advantages compared with the open return, namely:

1. Compactness, requiring a smaller building to house the tunnel and consequently lower initial cost.
2. Low power consumption, due to conservation of the energy in the return air stream.
3. Greater accessibility and convenience of operation.

The first advantage is strikingly demonstrated by the fact that it is possible to build two closed return tunnels in the space occupied by one open return tunnel.

The measure of the efficiency or power economy of wind tunnels is the ratio of the brake horse power of the driving motor to the kinetic energy per second of the air passing the working section. This ratio, termed the power factor, may be expressed

$$\frac{550P}{\frac{1}{2}\rho A V^3}$$

Some typical values of the power factor for atmospheric wind tunnels are as follows:

Open return tunnels—N.P.L. type	1.60
Open return tunnels—R.A.E. type	0.89
Closed return—open jet—single return Göttingen tunnel	0.68
New 5-ft. tunnel—Farnborough	0.38
10-ft. tunnel—California Institute of Technology—open jet	0.28
closed jet	0.192
20-ft. tunnel—Langley Field—double return	0.62

The very low power factors reported for the California tunnel are attributable principally to, first, the extremely short length of the open air jet, namely 0.8 diameters* as compared with 1.5 and 1.83 diameters for the Göttingen and Farnborough tunnels, respectively, and, second, to the fact that the cross section is circular throughout the circuit.

There appears to be some slight sacrifice in economy if, in closed return tunnels, a double return duct is used

*Measured from nozzle exit to collector throat.

(as in Ottawa), instead of the single duct. Based on model tests, a figure of 0.48 has been estimated for the double return as compared with the figure above, 0.38, for the single return. Preliminary tests of the Ottawa tunnel have yielded results indicating a power factor of 0.38 without honeycomb or propeller screen, the length of jet being 2.1 diameters. The maximum air speed so far attained is about 150 miles per hour.

The greater freedom and accessibility permitted by the closed return arrangement with open air stream is not the least advantage of this type of tunnel. Free access to the model not only makes the setting up and adjustment much simpler and more convenient, but makes it possible to assemble the model complete with balances outside the air stream. In addition, while the corrections to be applied to allow for the influence of the stream boundaries in the open and closed stream tunnels differ but little on tests of aerofoil and streamline models, in the case of propeller tests, the corrections are much smaller for the open air stream.

There were two features in which the original Göttingen tunnel differed from other tunnels and which contributed largely to its low power consumption. These were the rapidly converging nozzle at the entrance to the experimental section of the air stream, and the cascades of guide vanes at the corners of the air passages. In the nozzle, the contraction in area, usually about 4:1, results in a corresponding increase in velocity of the air stream thereby reducing the effect of velocity fluctuations existing at the entrance to the nozzle. At the same time, it permits the honeycomb to be placed in a region of low velocity with consequent reduction in the power loss due to the honeycomb.

The guide vanes direct the air around the corners of the air passages in such a way as to maintain a uniform distribution of velocity across the air stream and with a minimum of turbulence.

Because of these advantages, the closed return, open air stream type was adopted for the Ottawa tunnel. The actual arrangement of the tunnel was governed by certain local conditions.

The building in which the tunnel was to be housed was already in existence and was of such form that a double return tunnel, with the plane of the circuits horizontal, could be housed to better advantage than a single return. Previous to making this decision comparatively few double return tunnels of this type had been built. It has been since learned that the construction of two such tunnels is under consideration in England and one in Germany.

The dimensions of the building were sufficient to permit the construction of a tunnel having an air stream not larger than 9 feet in diameter.

A small hydraulic power plant was available on the property, having a minimum continuous generating capacity of 600-h.p. at low water. It was originally proposed to employ the whole output of the plant for the wind tunnel.

Accordingly the decision was made to construct a 9-foot diameter, 600 h.p. open jet, double return wind tunnel. Design was started in September, 1929, and construction in November, 1929. The tunnel was first operated at full power early in June, 1931.

The general arrangement of the tunnel will be apparent from Fig. 5. The principal dimensions are tabulated below:

Building (inside) length		140′ 4½″
width		50′ 6″
height—side		17′ 6″
centre		25′ 0″
Tunnel—overall inside dimensions—length		107′ 6″
width		50′ 6″
Nozzle—17 ft. square at entrance, 9 ft. diameter at exit.		25′ 0″ long overall
Free air stream	9′ 0″ diameter	13′ 0″ long
Collecting bell	14′ 0″ diameter at entrance. 10′ 0″ diameter at exit.	6′ 0″ long
Expanding cone	13′ 0″ diameter at exit	25′ 0″ long
Transition section	13′ 0″ diameter at entrance. 13′ 0″ square at exit.	14′ 0″ long
Return passages (two)	6′ 6″ × 13′ 0″ high at entrance, 125′ 0″ long (approx.) on centre line. 8′ 6″ × 17′ 0″ high at exit.	

The tunnel, with the exception of part of the nozzle, collecting bell and expanding cone, is constructed of reinforced concrete, resting directly on bed rock. The tunnel is self-supporting and is quite independent of the building.

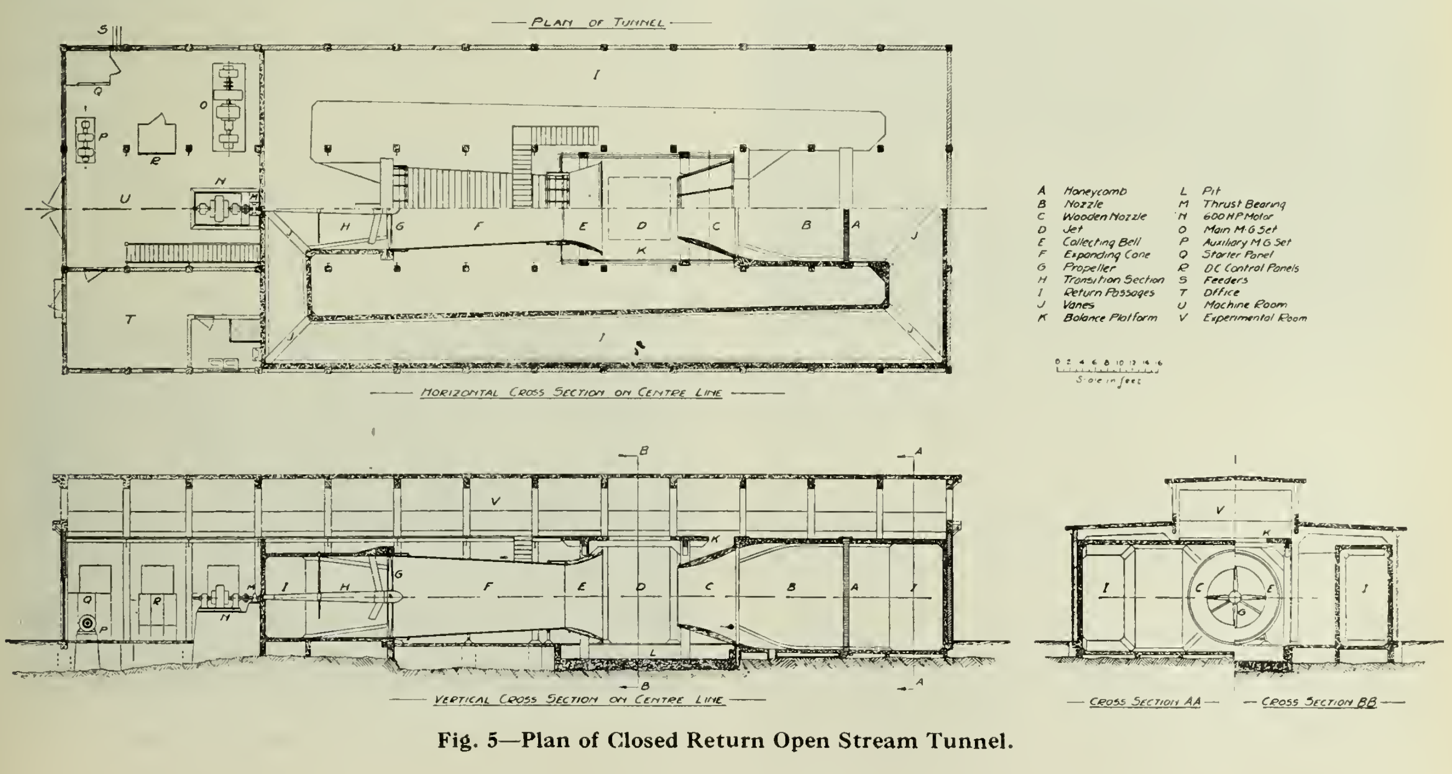

Fig. 5—Plan of Closed Return Open Stream Tunnel.

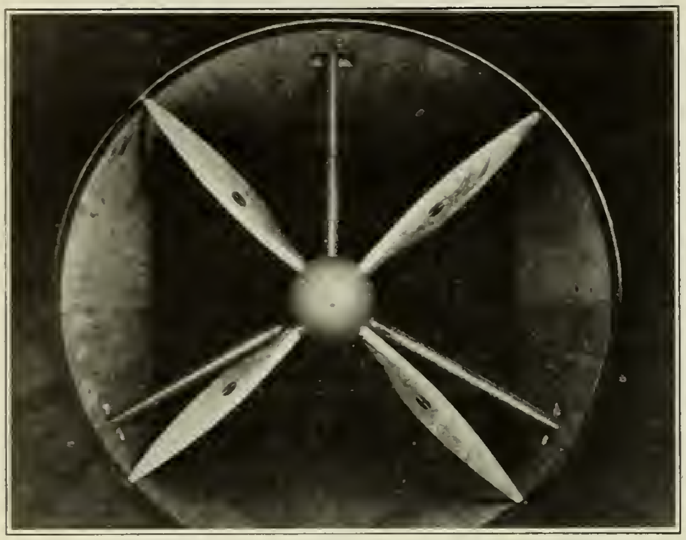

Fig. 6—Propeller.

All foundations of machines rest directly on bed rock.

The nozzle is constructed partly of reinforced concrete and partly of wood.

The contraction in area in the nozzle is over 4½ to 1, and the bursting pressure on the walls of the square section is about 55 pounds per square foot at maximum air speeds. In the concrete portion of the nozzle the section changes from 17 feet square to 14 feet 9 inches diameter circular.

The remainder of the nozzle is constructed of staves of B.C. cedar with steel hoops and is held by means of eight tie rods to a heavy steel ring anchored on the face of the concrete portion of the nozzle. The attachment is so arranged that adjustment of the nozzle is possible in order to align the jet.

The honey comb is composed of straight and crimped strips, spot welded together in units which are suspended from above and compressed from the two sides. To permit this, the honeycomb is located within a structural steel frame set in the concrete of the tunnel. The material of the honeycomb is 26 gauge (.018 inches thick) non-corrosive alloy. The cells are trapezoidal in cross section, averaging 2 inches to a side and are 9 inches long.

The collecting bell and expanding cone are constructed of B.C. cedar staves, those of the bell being shaped to the required curvature. The cone is of usual wood stave pipe construction. The bell and cone are supported on structural steel cradles. The large end of the cone fits in a recess turned in a cast iron ring embedded in the concrete of the transition section and is held thereto by means of a series of bolts.

Provision has been made for the insertion of a cylindrical section between nozzle and collecting bell, should it be desired to enclose the jet for high speed work.

The propeller is of the usual aircraft type, with four adjustable dural blades held in an alloy steel hub. The diameter is 13 feet. Its maximum speed when absorbing 600 h.p. is 1,000 r.p.m., at which speed the tip velocity is about 680 f.p.s.

The propeller (shown in Fig. 6) is carried on a steel shaft, some 25 feet long, which is coupled directly to the shaft of the driving motor. The propeller shaft is carried on roller bearings at motor and propeller ends with a roller steady bearing midway between.

The propeller bearing is supported on three radial cast iron arms of streamline cross section, bolted to the cast iron ring previously mentioned. The propeller turns inside this ring which is bored out to permit a small clearance (about ¼ inch) between blade tip and ring. Three radial arms are employed to avoid synchronization with the propeller blades and the arms, from the shaft outward, are inclined downstream in order to support the shaft close to the propeller hub, while keeping the arms as far as possible from the tips of the propeller blades.

The shaft extends in front of the propeller to carry a wooden spinner and is enclosed back of the propeller in a tapering sheet metal casing. The shaft passes through a sealing plate in the tunnel wall to the motor coupling.

In the original Göttingen tunnels and in later tunnels of the same type built elsewhere, the vanes are roughly of aerofoil section, relatively thick and of large chord. As little published information was available concerning the proper shape and arrangement of the vanes, before designing those for the Ottawa tunnel, an experimental investigation of the subject was undertaken.

The study was made using a wind tunnel 18 inches by 36 inches in cross section, arranged with a right angled bend in which the vanes were placed for testing. Vanes of a number of different cross sections were tested and the effect of profile, chord, spacing, incidence, and other factors studied. Based on the information derived from this research* the vanes employed in the Ottawa tunnel are made of sheet steel, rolled to a 90-degree circular arc. The gap between vanes measured at right angles to the air-stream approaching the vanes is ⅓ chord or roughly ½ chord measured along the diagonal of the corner. The vanes are supported at the ends only, any spacers or stiffeners between vanes having been found to have a detrimental effect on the velocity distribution behind the vanes. The incidence of the vanes will not be finally fixed until tests have been made of the tunnel, although a variation of incidence from 0 to 6 degrees was found to have a relatively small influence on the pressure drop across the vanes in the model tests.

As there is a probability, particularly if the tunnel is run with the air stream enclosed, of the air temperature rising excessively, provision is being made for cooling the air by arranging two of the cascades at the propeller end of the tunnel for water cooling. These vanes are hollow and constructed of welded steel plate.

Power for the wind tunnel is supplied from a hydraulic turbine-driven, 1,000-kv.a., 2,200-volt, 3-phase alternator in a power plant on the property. The plant contains two alternators, either of which can be isolated to supply the wind tunnel only, thus avoiding any mutual interferences between the wind tunnel and other laboratory loads being supplied from the plant.

An electrical machine room is provided at the propeller end of the wind tunnel building.

The 2,200-volt current entering the building passes to a 2,200-volt panel and thence to the main m.g. set. This

*The Design of Corners in Fluid Channels. Klein, Tupper and Green. Canadian Journal of Research, Vol. 3, September 1930.

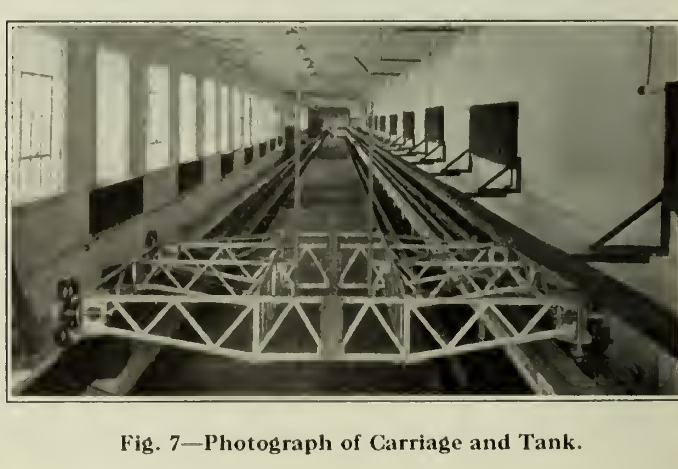

Fig. 7—Photograph of Carriage and Tank.

set comprises a 760-h.p., 2,200-volt, 3-phase, 60-cycle, synchronous motor and a 2,000-amp., 250-volt variable voltage d.c. generator together with necessary exciters. The set is started by semi-automatic starter and may be stopped by push button from any one of a number of stations. Between generator and propeller motor the current passes through the d.c. control panel. The propeller motor is of the shunt type with commutating poles, a continuous rating of 600 h.p. at 1,000 r.p.m. with 40 degrees C. rise of temperature and a two-hour 25 per cent overload at about 1,075 r.p.m. A speed range from under 100 r.p.m. to the overload maximum is provided.

Speed control of the propeller motor initially will be manual from any one of three control stations, one on either side of the air stream below and one on the balance platform above. An automatic control, actuated directly by the air, is under construction.

Complete protective devices and meter equipment are provided.

In addition a 50-h.p. induction motor, variable voltage, d.c. generator set, complete with control equipment is provided for supplying current for testing model propellers in the tunnel.

Balances of the wire suspension type are now being designed and constructed. They are to be mounted on a heavy steel and concrete platform above the experimental section of the air stream. The platform is quite independent of tunnel and building. A large mass of concrete is placed in the floor of the platform to reduce the period of vibration.

Above the tunnel, extending the whole length of the building, is a well lighted room to be employed as an observation room, computation room and shop in which minor adjustments of models and instruments may be made.

In addition to purely aeronautical work, much other work may be conveniently done in the wind tunnel, including the determination of wind pressures on buildings, towers and other structures, design of windmills and ventilators, wind effects on transmission cables, air resistance of motor cars and locomotives and the calibration of instruments.

Test Tank

Flying boats and aircraft fitted with floats are extensively used in Canada, particularly in the north country where the numerous lakes and rivers provide landing places for such craft in country lacking other landing facilities. Improvement of floats and hulls and of the performance of aircraft fitted with them is therefore of considerable importance in the Dominion. For this work a testing tank is essential.

Test tanks are fewer in number than wind tunnels and the greater number of existing tanks are designed and used for ship work. Until quite recently, there was only one tank, that of Messrs. Short Bros., of Rochester, Kent, England, designed for aircraft work. While ship tanks have been used for many years for testing aircraft models, the conditions in aeronautical and in marine work differ materially and ship tanks are not altogether satisfactory for aircraft work. In spite of handicaps, however, much valuable information pertaining to aircraft floats and hulls has been accumulated from work in ship tanks.

High speed is the principal requirement in a tank for aeronautical work. No existing ship tank is able to test a model of usual scale up to flying speed. Although the model speed is the square root of the scale times full scale speed and hence the smaller the model the lower the speed, it is not possible to reduce the scale indefinitely without sacrifice of accuracy in construction of model and in observations.

To attain high speeds, without excessive accelerations and deceleration, a long tank is required. In northern climates a long tank necessitates large capital expenditure for a building to house and heat the tank. The cross section of the tank, however, may be smaller than for marine work, since beam and depth of tank are dependent on model size and aircraft models may be smaller than ship models without sacrifice of accuracy.

There are now under construction in England, Germany and the United States, test tanks designed for aeronautical work only. These are in every case longer and smaller in cross section than existing ship tanks and provision is being made for much higher carriage speeds.

A German ship tank is being provided with a new high speed carriage for aeronautical work.

In fixing on the dimensions of the Ottawa tank, in addition to the foregoing general considerations local factors had to be considered. As in the case of the tunnel, a building was available some 410 feet by 18 feet by 16 feet high. In this building a tank 394 feet 2 inches long by 9 feet 0 inches wide by 6 feet 0 inches deep has been built.

The general arrangement of tank and building are shown in Fig. 8.

The tank is constructed of reinforced concrete and rests on solid rock for about 100 feet of its length at one end, the remainder resting on well tamped rock fill, varying in depth from zero to 6 feet. The bottom of the tank is about 4 feet below the floor of the building.

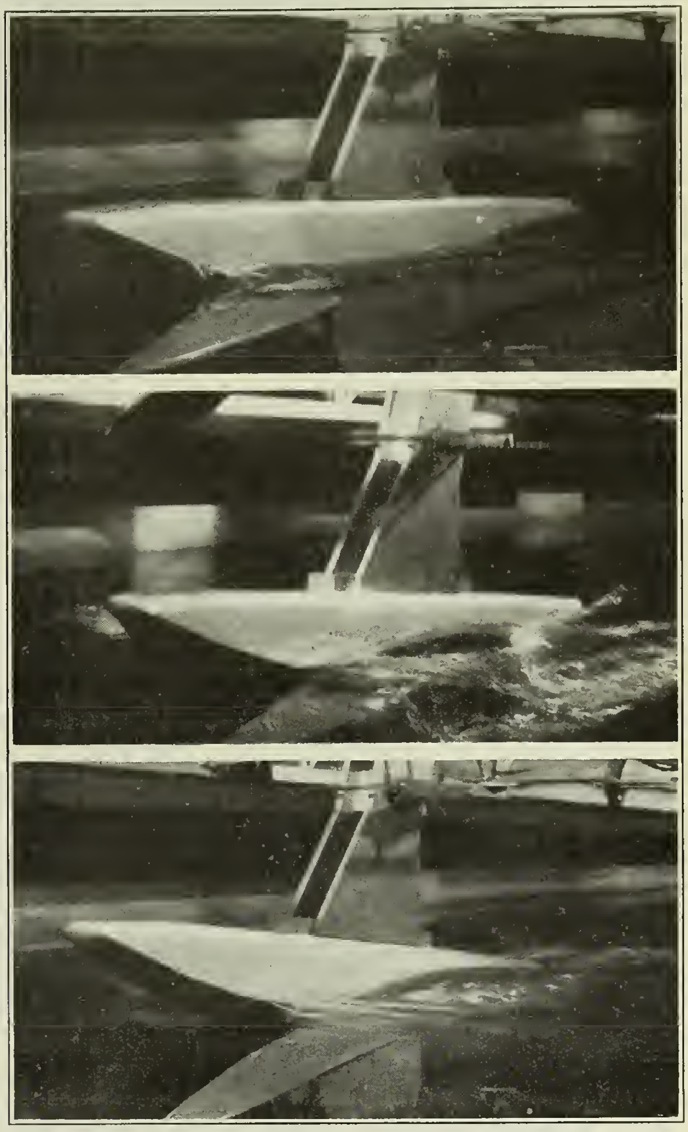

Fig. 8A—Test of Seaplane Float—Speed Three Feet per Second.
Fig. 8B—Speed Seven Feet per Second.
Fig. 8C—Speed Ten Feet per Second.

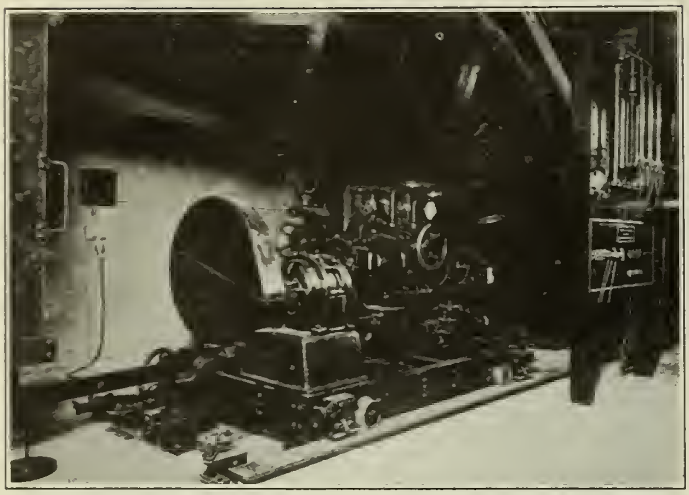

Fig. 9—Dynamometer and Air Duct as Arranged for Test of Tractor Type Air-Cooled Engine.

The rails (80-pound railroad rails) on which the carriage runs are carried on H-beams which in turn rest on the cast iron caps on concrete piers extending above the tank sides. The ends of the rails are planed square and are joined by carefully fitted fish plates. The rails are accurately aligned and levelled.

The carriage (see Fig. 7), is constructed of light structural steel and runs on four light steel disc wheels with narrow flat steel treads (without flanges). The wheels turn on roller bearings on fixed axles. At each end of the carriage on one side is a pair of guide rollers running in contact with the sides of the rail head. The rollers on the inside of the rail are fixed. Those on the outside are maintained in contact with the rail head by spring pressure.

As the speeds being provided for in the design are too high to permit of securing the necessary acceleration by traction between steel wheels and steel rails (probably wet) the carriage is to be drawn along the tank by steel cables. The arrangement will in general be similar to that in a traction elevator, using an endless steel cable passing around a driving sheave at one end and an idler sheave at the opposite end of the tank. Wooden troughs at one side of the tank support the cable and eliminate catenary sag between the sheaves.

The driving sheave is driven through a speed reducer and variable speed gear from an induction motor. An automatic control has been designed for the driving system which will control the car during acceleration, constant speed run and deceleration. As the balance is also to be automatic, it will not be necessary to carry an observer on the carriage.

Owing to the very short time available for measurement and observation during the constant speed portion of the run, the towing balance must necessarily record automatically. The actual design of the balance embodies a number of new features as compared with existing towing balances. It is being constructed throughout of metal.

The tank may also be used for work on surface vessels, calibration of current meters and certain hydraulic work in addition to the purely aeronautical work.

The tank is now being prepared for regular work and Figs. 8A, 8B and 8C show the wave formation at various speeds, exhibited during a preliminary run with a model of a seaplane float.

Power Plant Equipment

There are now three firms in Canada assembling aircraft engines and Canadian assembled engines have been exported. The Dominion government, under Air Regulations 1920, is required to test aircraft engines for export to establish their airworthiness. Up to the present the government has not possessed facilities for making such tests. As the testing of engines for this purpose is very properly a function of the National Research Council, an engine testing laboratory is being equipped in the National Research Laboratories.

The equipment, the installation of which is now practically completed, includes an hydraulic type dynamometer of British manufacture capable of accommodating aircraft engines of any type, air or water cooled, tractor or pusher, right or left hand rotation, and of absorbing power up to 1,000 h.p. at speeds up to 2,500 r.p.m.

For cooling air-cooled motors under test, a large motor driven centrifugal fan is arranged to discharge a blast of air through a cylindrical duct and adjustable nozzle past the engine cylinders. Air speeds up to 130 m.p.h. are obtainable.

The equipment is unique in that provision is made for the application of thrusts to the engine crankshafts corresponding to propeller thrusts up to 6,000 pounds.

Fig. 9 shows the dynamometer and air duct as arranged for testing an air-cooled tractor type engine. The lever and apparatus for the application of end thrust is seen at the left.

All necessary accessories and instruments such as flow meters, tachometers, thermometers and oil temperature control are included.

As the equipment is being installed in the city of Ottawa, the question of noise suppression is a serious one. The dynamometer is being placed below grade level in a room excavated out of the rock. The exhaust and cooling air pass from the room into a large exhaust silencing chamber, also below grade, from which they escape to the open air through small openings in a wall facing across a river.

Again, while installed primarily for aircraft engine work the equipment because of its flexibility and range will enable much general research and testing of internal combustion engines to be done and, being the only equipment of its kind in the country, permits investigations not otherwise possible to be made.

Shops

Well-equipped machine and wood working shops have been fitted up on the property to serve all divisions of the National Research Laboratories. In these shops much of the equipment of the aeronautical laboratories has been and is now being made, including the tank carriage, wind tunnel and towing balances. The models for wind tunnel and test tank will be made in these shops.

In addition to the central shops, small shops equipped with bench lathe, drill and grinder and the necessary hand tools are located in the different laboratories. In these small jobs incidental to the arranging of experimental apparatus may be done by the researchers, more satisfactorily and economically than in the main shops.

While the aeronautical laboratories are being equipped primarily for aeronautical investigations and testing, they will be found useful for a great variety of work of a non-aeronautical character. The equipment, because of its type and capacity, enables investigations, not otherwise possible, to be made in the Dominion. From an aeronautical standpoint, the laboratories provide the government with urgently needed testing facilities and relieve the Canadian aircraft industry of serious handicaps under which it has previously laboured.

FORTY-SIXTH ANNUAL GENERAL MEETING IN TORONTO

ON

FEBRUARY 3rd, 4th and 5th, 1932

The forty-sixth Annual General Meeting of The Engineering Institute of Canada is scheduled to convene at Headquarters, 2050 Mansfield street, Montreal, during the third week in January, 1932, for the reading of the minutes of the last Annual General Meeting and the appointment of scrutineers and auditors, after which the meeting will be adjourned and reconvened at Toronto, Ont., on Wednesday, Thursday and Friday, February 3rd, 4th and 5th, 1932.

The reconvened meeting and other functions will be held at the Royal York Hotel, Toronto, Ont., and arrangements have been made to accommodate a large number of guests.

The programme of the functions is now being arranged, and a most interesting and enjoyable three days are in prospect.

The Annual General Meeting was last held in Toronto in 1926 at which time the members of that Branch amply demonstrated their capacity for organization, and their enviable record is sure to be equalled, if not bettered, in February, 1932.

VOLUME XIV NOVEMBER 1931 No. 11

Our Branches and Their Activities

One of the most active discussions which took place at the Plenary Meeting of Council centred around the report of the Papers committee. It will be remembered that this committee was reorganized last year, and its membership considerably extended, for it was felt that heretofore this important standing committee of The Institute had not been able to function as originally intended. Committee reports are, as a rule, somewhat dry reading, but in this case the report contained information gathered by the committee as to the doings of practically all of The Institute branches, large and small, which afforded a notable cross-section of their activities. The data collected on this subject were accompanied by interesting comments and suggestions from the chairman, R. B. Young, M.E.I.C., and the information presented was so striking that the Council has directed its transmission for the information of all branches.

It cannot be too strongly urged that the accomplishment of The Institute's task of facilitating "the acquirement and interchange of professional knowledge among its members," and enhancing "the usefulness of the profession to the public," depends primarily upon the work of the branches. Our general professional meetings and our publications are sponsored by The Institute as a body, but the educational work of The Institute, the stimulation of the interest of its members in professional and technical questions, and the dissemination of professional information, should be, and are, very largely the objects of our branch meetings. These meetings afford the needed opportunities for our members to express themselves regarding engineering affairs, and, particularly in the larger branches, give scope for making and maintaining those personal contacts between members of different divisions of the profession, which are often so valuable.

There is another aspect to which attention was drawn during the discussion on the report, namely, the fact that, particularly in our smaller branches, local resources are apt to be limited, and it was shown that there certainly exists a need for some effective agency which will assist such branches to obtain their due share of papers, technical communications, and lectures.

Mr. Young's committee rightly laid stress on the social side of The Institute's work, and showed how successful some branches have been—and these not necessarily the largest—in securing public recognition of the place held in their community by The Institute and its members. This has been accomplished in many cases in spite of many obstacles, and there are a number of instances where functions sponsored by our branches really hold a leading place among local social events. In the committee's opinion, branch activities should not be exclusively directed towards professional ends. Entertainment and hospitality should have their place along with engineering, and branch programmes should be selected to suit local needs in these respects.

The Papers committee, as reorganized, if it fulfils the aims outlined in the report, will be performing a task of considerably greater importance and wider scope than that defined in the by-law which now governs its activities. The additional duties which it is now proposed that the committee should undertake form a legitimate extension of its activities, and cannot fail to be of great assistance to our branch executive committees and branch secretaries.

During the discussion the hope was expressed that members of Council, on their return from the Plenary Meeting, will take an early opportunity of laying before their constituents some of the salient points brought out in the report of the Papers committee, and in the discussion which followed its presentation.

List of Nominees for Officers

EXTRACT FROM BY-LAWS

Section 68—Not later than the seventh day of November, the Secretary shall mail to each corporate member of The Institute the list of nominees for officers, as prepared by the Nominating committee and the Council.

Additional nominations for the list of nominees for officers signed by ten or more corporate members and accompanied by written acceptances of those nominated, if received by the Secretary on or before the first day of December, shall be accepted by the Council and shall be placed on the officers' ballot. The words "Special Nomination" shall be printed conspicuously near such names, and the names of the members making such nominations shall be printed on some part of the officers' ballot.

Section 74—Notices shall be deemed to have been mailed to members as prescribed by the By-laws if such notices are printed in The Journal of The Institute and mailed by the dates prescribed in the By-laws.

NOMINATIONS

The report of the Nominating Committee was presented to and approved by Council at the meeting held on October 16th, 1931. The following is a list of the nominees for officers as prepared by the Nominating Committee and now published for the information of all corporate members as provided by Sections 68 and 74 of the By-laws.

List of Nominees for Officers for 1932 as Proposed by Nominating Committee

PRESIDENT:	Charles Camsell, M.E.I.C.	Ottawa.
VICE-PRESIDENTS:		
**Zone "B"*	A. H. Harkness, M.E.I.C. R. S. McCormick, M.E.I.C.	Toronto. Sault Ste. Marie.
**Zone "C"*	A. B. Normandin, A.M.E.I.C.	Quebec.
**Zone "D"*	Sydney C. Mifflen, M.E.I.C.	Glace Bay.
COUNCILLORS:		
‡*Cape Breton Branch*	J. R. Morrison, A.M.E.I.C.	Sydney.
‡*Moncton Branch*	J. G. Mackinnon, A.M.E.I.C. L. H. Robinson, M.E.I.C.	Moncton. Moncton.
‡*Quebec Branch*	Hector Cimon, M.E.I.C.	Quebec.
††*Montreal Branch*	A. Duperron, M.E.I.C. D. Hillman, M.E.I.C. F. Newell, M.E.I.C. P. L. Pratley, M.E.I.C.	Montreal. Montreal. Montreal. Montreal.
‡*Ottawa Branch*	G. J. Desbarats, M.E.I.C. John McLeish, M.E.I.C.	Ottawa. Ottawa.
‡*Peterborough Branch*	R. L. Dobbin, M.E.I.C.	Peterborough.
‡‡*Toronto Branch*	J. J. Traill, M.E.I.C.	Toronto.
‡*Hamilton Branch*	F. W. Paulin, M.E.I.C.	Hamilton.
‡*Niagara Peninsula Branch*	E. G. Cameron, A.M.E.I.C.	St. Catharines.
‡*Sault Ste. Marie Branch*	A. E. Pickering, M.E.I.C.	Sault Ste. Marie.
‡*Winnipeg Branch*	J. N. Finlayson, M.E.I.C. J. W. Porter, M.E.I.C.	Winnipeg. Winnipeg.
‡*Lethbridge Branch*	J. B. deHart, M.E.I.C.	Lethbridge.
‡*Calgary Branch*	B. Russell, M.E.I.C.	Calgary.
‡*Victoria Branch*	F. C. Green, M.E.I.C.	Victoria.

In accordance with the directions of Council and in order to provide for the representation of the Saskatchewan Branch for one year to complete the term for which the late Mr. R. W. E. Loucks had been elected, the following nomination has been made by Council on the recommendation of the Branch Executive Committee:

†*Saskatchewan Branch* C. J. Mackenzie, M.E.I.C. Saskatoon.

It will be noted that councillors are being elected this year by only fifteen branches. This is in accordance with the recent change in the By-laws, making the term of office for councillor two years instead of one year, thus insuring a measure of continuity for Council membership.

*One Vice-President to be elected for two years.
†One Councillor to be elected for one year.
††Two Councillors, to be elected for three years each.
‡One Councillor to be elected for two years.
‡‡One Councillor to be elected for three years.

The Fifth Plenary Meeting of Council

The Fifth Plenary Meeting of the Council of The Institute was held on Monday, Tuesday and Wednesday, September 21st, 22nd and 23rd, 1931, the following members being present:

President S. G. Porter, M.E.I.C., in the chair; Past-Presidents R. A. Ross, D.Sc., M.E.I.C., and H. H. Vaughan, M.E.I.C.; Vice-Presidents O. O. Lefebvre, D.Sc., M.E.I.C., (Province of Quebec), T. R. Loudon, M.E.I.C., (Province of Ontario), W. G. Mitchell, M.E.I.C., (Province of Quebec), and H. B. Muckleston, M.E.I.C., (Western Provinces); Councillors P. H. Buchan, A.M.E.I.C., (Vancouver), G. H. Burbidge, M.E.I.C., (Lakehead), J. L. Busfield, M.E.I.C., (Montreal), K. M. Chadwick, M.E.I.C., (Victoria), C. V. Christie, M.E.I.C., (Montreal), H. Cimon, M.E.I.C., (Quebec), F. A. Combe, M.E.I.C., (Montreal), W. P. Copp, M.E.I.C., (Halifax), A. R. Crookshank, M.E.I.C., (Saint John), E. H. Darling, M.E.I.C., (Hamilton), R. L. Dobbin, M.E.I.C., (Peterborough), B. Grandmont, A.M.E.I.C., (St. Maurice Valley), N. M. Hall, M.E.I.C., (Winnipeg), G. N. Houston, M.E.I.C., (Lethbridge), G. E. LaMothe, A.M.E.I.C., (Saguenay), J. A. McCrory, M.E.I.C., (Montreal), P. B. Motley, M.E.I.C., (Montreal), W. P. Near, M.E.I.C., (London), F. H. Peters, M.E.I.C., (Ottawa), R. W. Ross, A.M.E.I.C., (Edmonton), T. Taylor, M.E.I.C., (Toronto), D. C. Tennant, M.E.I.C., (Montreal), G. C. Torrens, A.M.E.I.C., (Moncton), R. S. Trowsdale, A.M.E.I.C., (Calgary), A. E. West, M.E.I.C., (Border Cities), L. W. Wynne-Roberts, A.M.E.I.C., (Toronto), R. B. Young, M.E.I.C., (Toronto), and Treasurer W. C. Adams, M.E.I.C., (Montreal).

Expressions of regret at being unable to attend the meeting were received from Past-Presidents M. J. Butler, M.E.I.C., C. H. Mitchell, C.B., C.M.G., D.Eng., M.E.I.C., and George A. Walkem, M.E.I.C.; Vice-President F. R. Faulkner, M.E.I.C., (Maritime Provinces) and Councillor E. G. Cameron, A.M.E.I.C., (Niagara Peninsula).

MONDAY, SEPTEMBER 21ST

Following the President's introductory remarks of welcome the first item of business taken up was the confirmation of the proceedings of the meeting held on September 8th, 1931, together with other routine business.

The report of the Finance Committee was next presented, including the financial statement for the first eight months of the year, which, considering the present adverse economic conditions, was considered satisfactory.

The Finance Committee having presented a list of members of all classes in arrears for three years or more, discussion followed as to the manner in which these should be dealt with, and in this connection the chairman of the Finance Committee submitted a recommendation which had already been communicated to Council proposing a change in The Institute's By-laws regarding arrears of annual fees. If approved by the membership, this would involve the adoption of procedure similar to that of the American Society of Civil Engineers, whereby a member in arrears for twelve months would automatically forfeit his connection with The Institute and would be so notified by the Secretary. Reinstatement would, of course, be possible on payment of arrears and at the discretion of Council. Prolonged discussion followed, during which the present method of dealing with members in arrears was considered in detail, and ultimately the matter was referred to the Legislation Committee for the drafting of a suitable amendment to Section 37 of the By-laws and other sections affected, for submission to the membership at the Annual General Meeting, and for ballot thereafter, this amendment to follow the lines recommended by the Finance Committee.

The List of Nominees for Officers, prepared by the Nominating Committee, was received, but as acceptances had not yet been sent in from all nominees its consideration was postponed until the October meeting of Council.

After adjournment for lunch, applications for admission and for transfer were considered, together with a number of special cases, and the following elections and transfers were effected.

Elections		*Transfers*	
Assoc. Members	11	Assoc. Member to Member	2
Juniors	7	Junior to Assoc. Member	9
Affiliates	4	Student to Assoc. Member	6
Students admitted	4	Student to Junior	7
		Student to Affiliate	1

The tentative programme for the Annual Meeting at Toronto in February 1932 was approved, and discussion followed as to the necessary action to be taken by The Institute in connection with the meeting which is to be held in Canada at the Bigwin Inn, Ontario, by the American Society of Mechanical Engineers in June 1932. On the invitation of that Society it was decided that The Institute should take part in this meeting, and that the cordial co-operation of The Institute should be offered to the Board of Direction of the society.

Discussion followed on the general question of the extent to which The Institute can helpfully participate in meetings of this kind, and consideration was next given to the proposed visit to Canada in September 1932 of the Institution of Mechanical Engineers (Great Britain). The Secretary reported that he had been in correspondence with the Institution and with Canadian members of the Institution in this connection, and that he had been able to furnish to them information as to the projected Canadian tour, which had been found helpful. His action was approved, and he was directed to give any assistance possible, and, at a later date, when the itinerary is known, to request our branches to do what is possible in receiving and entertaining the Institution party.

The report of the Committee on Membership was next presented, and from this it was noted that while the figures for admissions to The Institute show an increase for the first half of 1931 as compared with 1930, the efforts of the Committee on Membership to promote effective action by the branches regarding this matter have not been so successful as had been hoped. The committee, however, considered that in view of the existing economic situation the results should be regarded as satisfactory, and in their report recommended that the effort to increase membership through the medium of the branches be continued and encouraged, detailed suggestions being proposed with this end in view.

During the discussion several speakers commented on the difficulty arising from the fact that membership in the Professional Associations was compulsory in most provinces, and that particularly in times of financial stringency members were unwilling to pay fees to more than one engineering organization. Further discussion was held over until the following day.

Tuesday, September 22nd

Continuing the discussion on the report of the Committee on Membership it was pointed out that this subject was intimately connected with the service given by The Institute to its members, and with the requirements of the Professional Associations. In the opinion of some Councillors The Institute had not devoted enough study to one of its principal objects, the acquirement and interchange of professional knowledge among its members, and the time had come for a change in The Institute's policy, which would be reflected in a more effective appeal to prospective members. It was felt that special efforts should be made to interest and bring in the younger men, which can most effectively be done by the branches themselves.

The President pointed out that this discussion was covering some of the items which would come up later in connection with the report of the Papers Committee, after which it was resolved that the report be received and that the chairman be asked to present a further report at the Annual Meeting.

The next item of business was the report of the Committee on the Relations of The Institute with the Provincial Associations of Professional Engineers. H. H. Vaughan, M.E.I.C., the chairman of this committee, stated that while his committee had succeeded in securing from nearly all of the Provincial Associations co-operation in nominating members on the proposed National Committee, this proposal had not become effective owing to certain difficulties, the Council of one of the Provincial Associations having maintained that co-ordination of all activities of engineering associations throughout Canada might be obtained more readily by developing a plan which would at first apply only to the Provincial Associations. The Council of that Association in fact declined to approve of the formation of a Dominion-wide committee unless its members were accredited by the Associations alone, the Engineering Institute of Canada taking no further active part for the time being. Under the circumstances his committee had acquiesced, and as a result a committee of four had been convened, the members of which were accredited by the Professional Associations as follows:

C. C. Kirby, M.E.I.C., New Brunswick and Nova Scotia Associations.

J. M. Robertson, M.E.I.C., Quebec and Ontario Associations.

C. J. Mackenzie, M.E.I.C., Manitoba, Alberta and Saskatchewan Associations.

A. S. Gentles, M.E.I.C., British Columbia Association.

The Engineering Institute of Canada had no representation on this committee, whose purpose was, to advise as to the best means for obtaining co-ordination of the activities of the various Provincial Associations.

At the date of the first meeting of the Committee of Four Dean Mackenzie was unfortunately unable to attend, and his place was therefore taken by Dean R. S. L. Wilson, M.E.I.C., of the University of Alberta. Mr. Vaughan announced that a copy of the report of the above committee of four had been sent to him for the information of the Council of The Institute, and he now submitted it for that purpose. As an introduction to the discussion which ensued the members of Council from British Columbia gave a detailed explanation of the policy of the Professional Association of British Columbia in regard to this matter, and pointed out that they had been invited to the Council meetings of that Association in order that they might be able to interpret to The Institute Council the feelings of that body. They believed that the policy adopted would work out eventually to the benefit of The Institute.

After further discussion it was suggested that the matter might perhaps be discussed more freely if Council sat as a committee of the whole, and it was unanimously resolved to do this. While in committee, letters were presented from several absent members of Council regarding the problem of co-ordination, and the general opinion was expressed that The Institute was under great obligation to Mr. Vaughan and his committee for the work which they had accomplished, which had resulted at last on definite action on the part of the Councils of the Provincial Associations. It was felt that further development must necessarily be slow, and that while The Institute was now taking no part in the negotiations it would be desirable to maintain The Institute's committee so as to keep in touch with the Committee of the Associations, and render any assistance which might be requested.

The President felt that definite progress had now been made, and while he still thought it would have been wiser to have had The Engineering Institute recognized as a party to the work of co-ordinating the requirements of the Provincial Associations, he had not insisted on this personal view. He felt also that The Institute should, for the present, withdraw from active participation in the movement, and should continue its own committee as a means of contact and for the consideration of any matters which might arise affecting the interests of The Institute. He thought that as far as the Associations were concerned the provisions of the British North America Act did not form such a barrier to Dominion-wide legislation as some had supposed, and he believed that it would ultimately be possible for the Association Councils to enter into joint agreements with each other and possibly with The Institute.

After adjournment for lunch the discussion was continued, and further suggestions were made, several members being of the opinion that membership in the Associations should be recognized as a qualification for admission to The Institute, and that as the co-ordination of their work was now to be considered by the Associations alone, the way was left clear for The Institute to develop its own policy along constructive lines to take care of the changed conditions of to-day.

Some members felt that the time had come for a really active committee on the policy and development of The Institute, which should report at the next Plenary Meeting of Council, and believed that such changes in the constitution of The Institute should be made as would increase its usefulness to all members of the profession, and prepare for a future change in its relations with the Provincial Associations. After further discussion a small committee was appointed to draft a resolution for the consideration of Council, and on receiving their report the committee rose and reported to Council.

The Council having reconvened with the President in the chair, it was unanimously resolved that The Institute's Committee on the Relations of The Institute with the Provincial Associations of Professional Engineers, including Mr. Vaughan's sub-committee, be discharged; that the thanks and appreciation of Council be extended to Mr. Vaughan for the work his sub-committee has done during the past year, and that a new committee be appointed to keep in touch with and assist the committee of the Associations.

It was also resolved that the Council of The Engineering Institute of Canada wishes to record its appreciation of the efforts of the Committee of Four appointed by the Provincial Associations to consider ways and means of co-operation between them, and to express the hope that these efforts will be continued to a successful conclusion. The Council of The Institute will continue to co-operate with the Associations to the fullest possible extent, and gladly offers to the committee all the facilities at its disposal. A copy of this resolution to be sent to the Council of each Provincial Association.

Council then passed on to the report of the Committee on the Relations of The Institute with other Technical Societies, presented by the chairman, J. A. McCrory, M.E.I.C. This report stated that the arrangement entered into last year with the Council of The Royal Aeronautical Society, London, was working satisfactorily and that negotiations are proceeding for a somewhat similar arrangement with the Institution of Electrical Engineers (Wireless Section), but that in view of the experimental nature of these arrangements, it would be desirable to wait until their operation had been proved before entering into similar agreements with other bodies. In the committee's view action as regards such affiliation should be limited for the time being to the interchange of publications on some equitable basis. Discussion followed, and the report of the committee was accepted, after some criticism as to the indefinite nature of its recommendations. Eventually the latter portion of the report was referred back to the committee with the suggestion that after further study more definite recommendations should be made if possible.

R. B. Young, M.E.I.C., chairman of the Papers Committee, next presented a detailed report on its work, and pointed out that on undertaking the chairmanship of this committee he had felt that its usefulness could be greatly extended if its constitution were changed. This had been done, with the permission of Council, and during the past year he had gathered a good deal of information as to the existing nature of branch activities, particularly as regards the preparation and presentation of papers, and the effective organization of branch meetings. He pointed out that his committee now consisted of a chairman and five members, one from each vice-presidential zone, except Zone A, from which two representatives had been appointed. Each zone member of this committee is, in turn, chairman of a zone committee, whose members are appointed by the branches in that zone, and this arrangement is intended to provide close touch with the problems of the individual branches. In Mr. Young's opinion the most useful function which the Papers Committee could perform was the promotion of branch activity as regards papers and meetings. He presented a tabulated statement as to the number of members in each branch; the frequency and character of the meetings held, and comments and suggestions received from the branches as to how a Papers Committee could best render service. Mr. Young pointed out that the great variation in the size of branches, from 34 to 1,193 members, and their scattered geographical situation, led to great diversity in the problems faced by different branches in providing the desired instruction and entertainment for their members. In general, meetings that are both instructive and social seem to be best adapted to the smaller branches, while in the larger branches regular evening technical meetings seem to be the most popular. He felt that the Papers Committee could perform the following functions with great advantage to the progress of The Institute. First, it can act as a clearing house of information as to the methods adopted by the branches, so that each branch may benefit by the experience of the others. Next, the committee can offer suggestions for the improvement of their meetings for the consideration of branches. Thirdly, joint activities can be organized, and, finally, the committee could collect and distribute information as to subjects and speakers that might be available to the branches. He would ask Council to consider this problem in detail, as the branch activities were really the life of The Institute.

Members present expressed general appreciation of the committee's report, and were particularly impressed by the work which had been accomplished, and the definite nature of the suggestions made. Prolonged discussion followed, during which other valuable suggestions were brought forward, and on the conclusion of the discussion it was unanimously resolved that the report of the Papers Committee be accepted; that the thanks of the Council be extended to it for its report; that the committee be asked to continue its efforts in regard to collecting information from the branches, and that the completed information, together with a summary of the discussion, be printed and distributed to the branches.

In order to provide, as far as possible, for continuity in the functioning of this important committee, it was suggested that while the committee, as a standing committee of The Institute, has to be appointed in February of each year at the Annual Meeting, it would be desirable, each year, for the chairman to continue his activities by retaining office as vice-chairman of the committee after the new committee is appointed, and also that every effort should be made to secure as much continuity as possible in the membership of the committee.

The report on the Committee on Biographies was presented by Mr. F. H. Peters, M.E.I.C., the chairman, and outlined a system of procedure which would result in providing for The Journal biographical sketches of deceased engineers born in Canada or who have worked in Canada. Mr. Peters stated that the Committee on Biographies had been in existence for some considerable time but for various reasons had not been able to undertake a systematic programme, although a number of biographies had been prepared and some of them published. The procedure recommended included the systematic collection of information by questionnaire and otherwise so as to insure that material for the biographies of prominent engineers would always be available when required. After brief discussion the Council adjourned at six thirty p.m., to reconvene at nine thirty a.m. on Wednesday.

Wednesday, September 23rd

After further discussion on the report of the Committee on Biographies it was unanimously adopted, and appreciation was expressed of the service rendered by the committee.

The President stated that Past-President H. H. Vaughan had kindly consented to accept the chairmanship of the new committee whose duty would be to keep in touch with and assist the committee of the Professional Associations which is dealing with the co-ordination of the activities of those bodies. This intimation was warmly welcomed.

The Council next proceeded to the consideration of the proposal of R. L. Dobbin, M.E.I.C., as to the desirability of revising the constitution and By-laws of The Institute, and it was pointed out that this matter would be greatly influenced by any action taken by the Committee of Four representing the Professional Associations. Several members felt that it would be unwise to take any definite action until some progress had been made by that committee. Other members were of the opinion that it would be of great advantage to appoint a Committee on Development to which could be referred not only questions regarding desirable changes in the constitution of The Institute, but also questions of internal policy regarding the relations between Headquarters and the branches, or the method for obtaining increased activity in the educational work of The Institute. The desirability of changing the present classes of membership and methods of admission of new members might also be taken up. The view was taken that it would be some time before the activities of the Professional Associations would be co-ordinated, and in the meantime The Institute should get its own affairs in order, and should not stand still. On the President's suggestion it was agreed to postpone further action on this matter and pass on to the next item on the agenda, this being a suggestion from Professor Copp that means should be adopted for obtaining closer contact between Headquarters and the branches. It was the feeling of the Council that the most important agency in this matter would be the councillors themselves, and that they should pass on, at their discretion, for the benefit of the branch executive committees and members, such information as to the activities of Council as they consider proper and desirable.

Another proposal affecting The Institute's policy came from Professor F. R. Faulkner, M.E.I.C., who advocated the appointment of paid regional secretaries. While it was felt that such an arrangement would probably work out to great advantage, the Treasurer pointed out that the proposal was not a new one; that the principle had indeed been approved by Council, but that for financial reasons it had so far been impossible to entertain it. It would also be very advantageous if Council could make a grant towards the onerous work of the branch secretaries, on whose activities so much depends.

Mr. Trowsdale drew attention to the provisions of Section 56 of the By-laws according to which the percentage of rebates paid to a branch depends on the number of corporate members of the branch He pointed out that in Calgary a change in the number of corporate members from slightly less to slightly more than one hundred had actually caused a material reduction in the branch revenues, and he suggested that an amendment to Section 56 of the By-laws would be proper, so that when the membership of a branch increases to a point where the rebate scale changes, the minimum amount payable under the new scale shall not be less than the maximum received under the old

After further discussion it was unanimously resolved that a payment should be made to the Calgary Branch which will bring their revenue from rebates this year up to an amount at least equal to the maximum paid to them before the increase in membership, and that the whole question of rebates be referred to the Legislation Committee for study

Vice-President Loudon drew attention to the desirability of The Institute undertaking some work which would indicate its interest in the economic side of engineering. He felt that in The Institute one of the greatest difficulties was to get engineers to take interest in their fellow men. In the hope of stimulating this interest, and in view of the present economic situation, Professor Loudon thought that The Institute should now undertake the investigation of one phase of the causes of unemployment, and make the resulting information available to the membership as a whole. He would move that a committee be appointed, possibly with one member from each branch, to (*a*) collect the published information on technological unemployment, and (*b*) to investigate the limits of the commodity requirements of Canada. It was explained that by "technological" unemployment was meant the unemployment resulting from the displacement of labour by machines.

An active discussion followed, from which it appeared to be the consensus of opinion that such an investigation was not within the province or power of The Institute and that such investigations seemed more properly the function of the government, or possibly the National Research Council, bodies which would have at their command funds, resources and information not available to a committee of The Institute. It was eventually decided that a committee be appointed to study the problem and report to Council as to whether The Institute can undertake the investigation suggested, and, if not, what steps should be taken to bring this valuable suggestion before the proper authorities.

Mr. Trowsdale drew the attention of Council to the cost of the E-I-C News, which, according to the financial statement, was approximately $1,600.00 per annum net, and questioned the value of this publication to the membership. He felt that this expenditure on the part of The Institute was not justified, particularly if, as he believed, the outlying branches found it of little value. He asked for discussion on this matter. The opinions of members of Council present were expressed and seemed about equally divided, but it was pointed out that during the inquiry of the Special Committee on Publications in 1929 and 1930, opinions received from the branches showed that a great majority appreciated the E-I-C News, and further that this publication had proved extremely useful in connection with the service of the Employment Bureau. After further discussion it was unanimously resolved that a small committee be appointed to investigate the question of continuing the E-I-C News and present a report on this matter to Council at an early date.

The President reminded the Council that a decision had not yet been reached as to the desirability of appointing a Committee on Development, as suggested by Mr. Busfield, and after some discussion, from which it appeared that the consensus of opinion was that it would be desirable to appoint such a committee, it was decided that this meeting should go on record as being in favour of the appointment of such a committee, and the matter was referred to the next meeting of Council for action.

The Plenary Meeting then adjourned.

OBITUARIES

Donald Allan Andrus, M.E.I.C.

Deep regret is expressed in recording the death of Donald Allan Andrus, M.E.I.C., which occurred recently in Roumania.

Mr. Andrus was born at Southfleet, Kent, England, on October 6th, 1870, and was educated at the Crystal Palace School of Practical Engineering, London, graduating in 1889.

In 1890-1894, Mr. Andrus was with the Ottoman Railway Company (Smyrna-Aidin) as instrumentman, draughtsman and on general railroad maintenance work; in 1894-1895, he was resident engineer on the construction of the Sokia branch, and during the years 1895-1890, he was in charge of surveys and location work in the field for the extension of the Ottoman Railway through Central Asia Minor to Konia on the line of the proposed Baghdad Railway. From 1901 to 1903, Mr. Andrus was engineer in charge for J. W. Williamson and Co., contractors, Cairo, Egypt, on their contract for widening the Suez canal between Ismailia and Suez, and from 1903 to 1911 he was continuously on contracts secured in his own name from the Egyptian government for the construction and maintenance of irrigation works in upper and lower Egypt. Mr. Andrus came to Canada in 1913 as chief engineer for Messrs. Baldry Yerburgh and Hutchinson Ltd., of London, England, on their contract with the Dominion government for the construction of Section No. 2, Welland Ship canal, until the work closed down in 1916. In 1918-1920 he was general manager and chief engineer of the St. Lawrence Dock and Shipbuilding Company at Levis, Que. In 1922 Mr. Andrus became superintendent for Sir Wm. Arrol and Co. Ltd., in the construction of Lock No. 7 of the Welland Ship canal, and the pit for Lock No. 4 at Thorold, Ont. Upon the completion of this section of the work his firm obtained the contract for the Hollinger dam at Island Falls, after which he returned to London, as agent in Europe for Quinlan, Robertson and Janin Ltd., and later became connected with the European Amiesite Ltd., also in London.

Members of the Niagara Peninsula Branch will remember Mr. Andrus describing to them a few years ago contracting and engineering conditions in Egypt about the time of the Assouan dam construction, the number of years spent by him in Asia Minor enabling him to speak with authority upon native life and characteristics in the Orient.

Mr. Andrus joined The Institute as a Member on April 29th, 1924.

William Jackson Fuller, A.M.E.I.C.

Members will learn with regret of the death at Fort William, Ont., on October 7th, 1931, of William Jackson Fuller, A.M.E.I.C.

Mr. Fuller was born at Leamington, Ont., on July 14th, 1877, and attended the School of Practical Science, University of Toronto, in 1897, 1898 and 1899.

In 1900 Mr. Fuller entered the employ of J. G. Sing, D.L.S., O.L.S., and was for two years in charge of a survey of the Georgian Bay Islands. This was an intricate triangulation survey for the Department of Indian Affairs, Ottawa. In 1902 Mr. Fuller entered the service of the Department of Public Works, with which he remained until the time of his death. He was for some sixteen years district engineer for the Department at Sault Ste. Marie, Ont., and last year was transferred to Fort William, where he occupied the same office.

Mr. Fuller joined The Institute (then the Canadian Society of Civil Engineers) on February 11th, 1908, as an Associate Member.

PERSONALS

John E. Macdonald, S.E.I.C., is with the West Kootenay Power Company at South Slocan, B.C.

C. E. Hogarth, A.M.E.I.C., is resident engineer at Klock, Ont., on the Trans-Canada Highway.

T. S. Armstrong, M.E.I.C., has been appointed assistant district engineer at Port Arthur, Ont., for the Department of Northern Development, Ontario. Mr. Armstrong was at one time with the Toronto Transportation Commission.

J. S. Kyle, Jr.E.I.C., is now located at Cartagena, Colombia, S.A., where he has taken over the duties of electrical engineer with the Tropical Oil Company. In 1930, Mr. Kyle was electrical inspector with the Canadian National Railways, at Toronto.

T. A. McGee, A.M.E.I.C., formerly advisory engineer with the Bishop Sales Corporation, Montreal, is now manager of the concealed heating division of the Gurney Foundry Company Ltd., Montreal. Mr. McGee was at one time vice-president and chief engineer of F. W. Pennock and Company, Montreal.

Dr. Arthur Surveyer, M.E.I.C., consulting engineer, Montreal has been appointed chairman of the Chignecto Canal Commission. Dr. Surveyer is a graduate of the Ecole Polytechnique and of the University of Montreal, and a Past-President of The Engineering Institute of Canada.

Martin F. O'Day, S.E.I.C., is now with the Northern Construction Company, at West Saint John, N.B. Following his graduation from the University of Manitoba in 1926, with the degree of B.Sc., Mr. O'Day joined the staff of Fraser-Brace Engineering Company, and was for several years located at Santiago, Colombia, S.A., later being sent to Island Falls, Sask. In 1930 he became connected with the Ontario Refining Company, Ltd., at Copper Cliff, Ont.

F. B. Goedike, A.M.E.I.C., who has for a number of years been Commissioner of Works, Township of York, Ont., has been appointed city engineer of Oshawa, Ont. Mr. Goedike is a graduate of Queen's University of the class of 1910, and since graduating has had a wide engineering experience in municipal work and other fields. Following graduation he was for a time with the Irrigation Department of the Canadian Pacific Railway, and in 1912 he took charge of a hydrographic survey of Toronto Bay for the Toronto Harbour Commission. In the latter part of the same year Mr. Goedike was appointed resident engineer with the sewer department of the city of Toronto, with which department he was engaged until the middle of 1915, when he was appointed locating and estimating engineer for a commission investigating radial railway entrances for the city of Toronto. In 1916 he became assistant engineer of the Toronto Harbour Commission, and in 1918 was associated with the firm of Barber and Wynne-Roberts, consulting engineers, Toronto. Towards the end of 1918, and for the following three and a half years, he was engaged on designing and estimating work of bridges, sub and superstructures, for the Hydro-Electric Power Commission of Ontario. For a short period in 1922 Mr. Goedike was engaged on the water works extensions for Toronto, and in the same year was appointed resident engineer on the tunnel sewer construction for the city of Hamilton.

ELECTIONS AND TRANSFERS

At the meeting of Council held on September 21st, 1931, the following elections and transfers were effected:

Associate Members

BATY, Edward, (Darlington Tech. Coll.), district plant engr., Bell Telephone Company of Canada, Montreal, Que.

BEMAN, Edwin Arthur, B.E. (Mech.), (Univ. of Sask.), res. engr., Dept. of Highways, Regina, Sask.

BLAKE, William Henry, Capt., R.C.E., (Sch. of Mil. Engrg., Chatham), District Engineer Officer, Mil. Dist. No. 7, Saint John, N.B.

CAMPBELL, Harold Montgomery, B.A.Sc., (Univ. of Toronto), 23 Bellevue Terrace, St. Catharines, Ont.

CARPENTER, Edward Stanley Cameron, B.E., (Univ. of Sask.), res. engr., Dept. of Highways, Regina, Sask.

FENNIS, Albert M., E.E., (Engrg. School, Zwickau, Saxony), 4510 Girouard Avenue, Montreal, Que.

HAGGAS, Ernest, (Tech. Coll., Bradford), senior dftsman., Canadian Westinghouse Company, Limited, Hamilton, Ont.

HAY, Charles Cecil, B.Sc., (Univ. of Sask.), mgr., Gibbs Bros. & Hay Ltd., Lumsden, Sask.

HOGG, Sidney, (Dundee Tech. Coll.), struct'l. engr., Saint John Dry Dock & Shipbuilding Co. Ltd., Saint John, N.B.

NOBLE, George, B.Sc. (Civil), (Univ. of Birmingham), dftsman., Imperial Oil Refineries, Ltd., Sarnia, Ont.

WILHJELM, Frits Erik, B.Sc. (Civil), (Royal Tech. Coll., Copenhagen), asst. engr., mtce., C.N.R., Moncton, N.B.

Juniors

ABRAMSON, Isaac Albert, B.Sc. (E.E.), (Univ. of Alta.), operator, Calgary Power Company, Seebe, Alta.

AVELING, Frederick Edward, (Royal Tech. Coll., Glasgow), 1929 Tupper St., Montreal, Que.

CAREY, Cyril Joseph, (Memorial Univ. Coll.), 142 Military Road, St. John's, Nfld.

KERRY, Armine John, Capt., R.C.E., (Grad., R.M.C.), B.Sc., (McGill Univ.), Works Officer, Mil. District No. 5, St. Louis Barracks, Quebec, Que.

MARLATT, Victor Egerton, B.Sc., (Univ. of Man.), instr'man., Dept. Railway and Canals, Fort Churchill, Man.

PICHE, Arthur, C.E., (Ecole Polytechnique), combustion engr., Anthracite Coal Service, 509 Dominion Square Bldg., Montreal, Que.

WHITE, Walter Edmund, B.A.Sc., (Univ. of Toronto), technical engr., Northern Electric Company, Ltd., Montreal, Que.

Affiliates

FOWLER, James, M.A., B.Sc., (Edinburgh Univ.), Vice-Principal, Institute of Technology and Art, Calgary, Alta.

INGRAM, Arthur Ferguson, operating manager, Canadian Airways Limited, 920 University Tower, Montreal, Que.

SAMUEL, Myron, (Diploma, Engrg., College of Dantzig), Canadian representative, J. I. Bernitz (Machy. Importers), of New York and Toronto, 118 Spadina Road, Toronto, Ont.

TODD, William L., (Purdue Univ.), Manager and President, Layne Canadian Water Supply Co. Ltd., 903 Kent Bldg., Toronto, Ont.

Transferred from the class of Associate Member to that of Member

SMYTH, Charles McDowall, (Polytech. Inst., London, Eng.), light and power supt., Cape Breton Electric Co. Ltd., Sydney, N.S.

THOMSON, Clarence, B.Sc., (McGill Univ.), manager, Fred Thomson Co. Ltd., 915 St. Genevieve Street, Montreal, Que.

Transferred from the class of Junior to that of Associate Member

BECKER, Fred Artland, B.A.Sc., (Univ. of Toronto), sales engr., Canadian General Electric Co. Ltd., Winnipeg, Man.

CLARK, George S., B.Sc., (McGill Univ.), mech'l. supt., Molson's Brewery, Limited, Montreal, Que.

GORDON, Charles Howard, (Grad., R.M.C.), B.Sc., (McGill Univ.), contracting engr., Atlas Construction Co. Ltd., 679 Belmont Street, Montreal, Que.

KELSEY, Ernest Starkey, B.Sc., (Univ. of Man.), asst. to director of technical service, Northern Electric Co. Ltd., Montreal, Que.

McDONALD, James A., B.Sc., (Univ. of Alta.), Bradley, Ont.

McLENNAN, Gordon Roderick, B.Sc., (McGill Univ.), elect'l. engr., C. D. Howe & Company, Port Arthur, Ont.

OS, Hartvik, C.E, (Univ. of Trondjhem), engr. and dftsman., C. D. Howe & Company, Port Arthur, Ont.

ROSS, Donald Grant, B.Sc., (Dalhousie Univ.), asst. engr., Saint John Harbour Commissioners, Saint John, N.B.

THOMPSON, Trevor Creighton, B.Sc., (McGill Univ.), divn. trans. engr., Quebec Divn., Bell Telephone Company of Canada, Montreal, Que.

Transferred from the class of Student to that of Associate Member

ANGUS, Frederic William, B.Sc., (McGill Univ.), dial engr., equipment engrg. dept., Bell Telephone Company of Canada, Montreal, Que.

ARCHAMBAULT, Joseph U., B.A.Sc., and C.E., (Ecole Polytechnique), engr., Quebec Public Service Commission, Quebec, Que.

HARDCASTLE, Sydney, B.A.Sc., (Univ. of Toronto), designer, Dominion Bridge Company, Ltd., Montreal, Que.

HOVEY, Lindsay Mansur, B.Sc., (McGill Univ.), asst. elect'l. engr., Winnipeg Electric Company, Winnipeg, Man.

MILLER, John James Hutchison, B.Sc., (McGill Univ.), plant engr., Northern Electric Company, Ltd., Montreal, Que.

O'DAY, Martin Frederich, B.Sc., (Univ. of Man.), Northern Construction Company, West Saint John, N.B.

Transferred from the class of Student to that of Junior

ABBOTT-SMITH, Henry Bancroft, B.Sc., (McGill Univ.), asst. meter engr., Shawinigan Water & Power Company, Montreal, Que.

EDWARDS, Hubert John, B.Sc., (Queen's Univ.), municipal dept., H.E.P.C. of Ontario, Toronto, Ont.

GATHERCOLE, John William, B.Sc., (Queen's Univ.), steam control and meter engr., Canada Sugar Refining Co. Ltd., Montreal, Que.

GREGORY, Hurd Anthony Forbes, B.Sc., (McGill Univ.), engr., Aluminum Company of Canada, Shawinigan Falls, Que.

HARGROVE, Paul, B.Sc., (Univ. of Alta.), transitman, Lethbridge Dvn., C.P.R., Lethbridge, Alta.

HUNT, Albert Brewer, B.A.Sc., (Univ. of Toronto), asst. operating supt., Northern Electric Company, Ltd., Montreal, Que.

SIMON, Robert Carleton, B.Sc., (McGill Univ.), designing, etc., Imperial Oil Refineries, Ltd., Montreal East, Que.

Transferred from the class of Student to that of Affiliate

COWAN, Lucien, engrg. sales dept., Crane Limited, 1170 Beaver Hall Square, Montreal, Que.

Students admitted

HANINGTON, Frederick Augustus, B.Sc. (E.E.), (Univ. of N.B.), meter supt., meter dept., New Brunswick Power Company, Saint John, N.B.

HULBERT, Edward, B.Sc. (E.E.), (Univ. of Man.), Lieut., R.C.C.S., Camp Borden, Ont.

PEREGO, Henry Anthony, (Undergrad., McGill Univ.), 3837 Old Orchard Avenue, Montreal, Que.

SMITH, Norman Janson Winder, (Grad., R.M.C.), Lieut., R.C.E., M.D. No. 4, 1254 Bishop St., Montreal, Que.

At the meeting of Council held on October 16th, 1931, the following elections and transfers were effected:

Associate Member

McQUEEN, Howard Renton, (Grad., R.M.C.), President and General Manager, Iron Fireman Limited, Montreal, Que.

Transferred from the class of Associate Member to that of Member

MACDONALD, Charles Beverley Robinson, Capt., R.E., (Grad., R.M.C.), chief engineer and agent, Macdonald, Gibbs & Co. (Engineers), Limited, Sao Paula, Brazil.

WELDON, Richard Laurence, B.Sc., M.Sc., (McGill Univ.), manager, International Power & Paper Co. of Nfld. Ltd., and chief engineer, International Paper Company, New York, N.Y.

Transferred from the class of Junior to that of Associate Member

BARRETT, Andrew Grant, B.Sc., (Queen's Univ.), chief engineer, Canadian Johns-Manville Co. Ltd., Asbestos, Que.

Transferred from the class of Student to that of Associate Member

BALLENY, James Lister, B.Sc., (McGill Univ.), asst. elect'l. engr., Dominion Bridge Company, Ltd., Montreal, Que.

ENNIS, Leo E., B.Sc., (Queen's Univ.), toll pole and wire engr., Quebec Division, Bell Telephone Company, of Canada, Montreal, Que.

FAIRBAIRN, John M., B.Sc., (McGill Univ.), general manager, Charles Warnock & Company, Montreal, Que.

Transferred from the class of Student to that of Junior

LOVETT, Percy Arthur, B.Sc., (N.S. Tech. Coll.), asst. equipment engr., Maritime Telephone & Telegraph Company, Halifax, N.S.

DesBRISAY, Aretas William Young, Lieut., R.C.C.S. (Grad., R.M.C.), B.Sc., (McGill Univ.), Officers' Mess, Camp Borden, Ont.

The Preparation of a Topographical Map from Aerial Surveys

The following account is abridged from material kindly furnished by Canadian Airways Limited, and is of interest as showing the manner in which aerial survey methods can be utilized for the rapid production of contoured maps.

A survey of the mouth of the Montreal river on Lake Superior, some 60 miles north of Sault Ste. Marie, was recently undertaken with a view to the preparation of a map suitable for the study of this area for the location and building of a hydro-electric plant and later to be used as the basis of a contour survey to be made by stereoscopic methods from the photographs. The scale of the map was to be 1/9600 or 800 feet to the inch, showing contours at 50-foot intervals over most of the area, and at 25-foot intervals along the river where possible engineering works were to be considered and where flood lines would be required.

The contract for the survey was made September 19th, 1930, and on September 22nd a seaplane arrived at the Soo to make the necessary photographs. Fortunately the weather was favourable, and in a two and a half hour flight on the morning of September 23rd, some two hundred vertical exposures were made and a number of stereo-obliques obtained. The films were developed and found satisfactory, and the machine was recalled on September 30th, no further flights being necessary.

On October 7th the preliminary layout of the mosaic of vertical prints was ready for preliminary inspection, and a rough model of the area had been made, which was sufficiently accurate to give the engineers a general idea of the formation and relief of the country.

Fortunately, some ground surveys had already been made in the district, the plans of which were available, and these were used for the necessary ground control. A comparatively small amount of ground survey work had to be done so as to complete a closed traverse, and some further information was obtained by altimeter readings of certain points adjacent to bench marks or other points of known elevation.

The finished mosaic, without contours, but on the proper scale, was ready on January 7th, 1931, and work on the contours was then proceeded with. The contours were located on the original overlapping photographs by the use of a Barr and Stroud topographical stereoscope and the actual contouring took about six weeks. The contours were then transferred by point to point inspection on to the original mosaic, which was copied in six sections, contact prints of which were mounted together to form a continuous map about 4 by 8 feet. The six negatives, each 22 by 24 inches, form the permanent record of the job. The finished mosaic was delivered on March 6th, 1931, and the whole map covered an area of about 60 square miles.

In order to derive full advantage from an aerial survey, it is advisable to have the area photographed immediately at the commencement of such work. A rapid study of the area in relief then indicates what ground work is required. It also gives camp locations, transportation routes, and provides a complete set of scalable prints for the use of the field party in recording data, checking angles and distances and planning work. Later these same pictures may be used, provided further investigation is warranted, in making reconnaissance or accurate maps and contoured plans.

For such an area as described, it would seem that a comprehensive reconnaissance report could normally be made available three to four weeks from the taking of the photographs.

A portion of the contoured map is reproduced above to show the result of this survey. So far the only check on the accuracy of the contours has been the comparison of the 1,000 feet contour along the river with a flood-line survey since made on the ground by engineers, on which very good agreement was obtained.

A map of the nature and extent of that described above could be furnished at a cost in the neighbourhood of $100 per square mile. On smaller areas the cost per square mile increases as the size of the area diminishes.

Scale—1 inch = 3,290 feet.

CORRESPONDENCE

The Editor,
The Engineering Journal.
Sir:

In a previous letter it has been shown how necessary it is for the engineer to advertise his work, that this advertising must be placed where it will receive attention, and that "Inspection" is the key note to adequate response.

The three parties essential to a construction project are, the owner, the designer and the constructor. The owner is of prime importance, the designer projects the owner's ideas on to paper, and the constructor materializes these ideas after receiving the results of the designers work

At the beginning, the only two parties are, the owner and the designer, but after the contract is signed, the constructor enters in, and these three are represented in the field, by the inspector, the plans and specifications, and the superintendent; the first is the representative of the owner, the second is the work of the designer and the third is the representative of the contractor, and the same relative importance still holds; the interests of the owner are paramount.

In factory operation, quantity production has lowered the cost of the innumerable labour saving devices that contribute to our well being, and quantity production depends upon inspection, absolutely; save money reducing inspection costs and the result is total failure; whereas, on construction in the field, while the individual parts have undergone inspection at the place of origin; the assembling of these individual parts—steel, wood, concrete, etc. etc., seldom has adequate inspection.

In the building industry, where the vast majority of work is done under a lump sum contract, the tenderer frequently does not understand new processes or ideas, and makes a stab at the cost; hoping one of two things, either that he will get the contract in spite of the high price inserted for the unknown, or, that if he gets the contract, he will not be obliged to live up to specifications. Anyway he necessarily leaves all details to the foreman, whose main interest is the making of profits for the boss, and who has neither time nor inclination to do anything out of the ordinary, which is the very reason why, during their preparation, all plans and specifications should be gone over by the inspector in collaboration with the designer.

When the stonemason cut his stone on the job, and the carpenter framed the lumber, the architect had ample time to do the inspection himself, but with modern high speed construction, one storey a week and the roof on before the basement is finished, neither the owner, architect nor professional engineer can hope to supervise all the work, which should be inspected hour by hour, and sometimes minute by minute, during the whole time of construction.

In theory, all will agree with the foregoing, but many subordinates in the contracting business object, especially those with an engineering training. They imagine that the presence of an inspector is a criticism of their ability; these individuals, unfortunately, look at only one side of the picture, viz., their duty as employees to work at a profit.

The contractor who stays in business is an honest man, who sincerely desires to live up to the spirit of his contract—but no matter how high minded and impartial he is, he cannot expect the same of all his employees, some at least of whom are men of more or less limited intelligence.

The employee—whether foreman or superintendent—holds his position on account of his ability to work at a profit, or to do fast work at a low cost; this is the opportunity for the inspector, who while recognizing the legitimate aim of the contractor to make profits, sees that specifications are followed.

The work of the inspector and the contractor is complementary, the latter to make profits, and the former to see that the work is good; no good work can be accomplished except under the stimulus of adequate compensation, and no material progress can be made, unless the work done is increasingly better and more efficient. To attain these ends and to enable them to work harmoniously together, the representatives of the contractor and of the owner should have equal standing: in other words, on the same piece of work, they should receive equal remuneration.

The ordinary person always thinks in terms of money, a man's worth is reflected in his pay cheque, and it is not long, on any job, before the foreman finds out how much the inspector is getting, and his respect varies directly as the amount. There are of course, men of high morale, who can command respect while labouring under the handicap of poor pay, but they are not common.

To obtain greater efficiency and economy in construction work, two things are highly desirable. Firstly, that plans and specifications be gone over by the inspector with the designer (the architect or professional engineer) before the contract is let. Secondly, that the inspector should receive the same remuneration as the superintendent or foreman with whom he is working. Doubtless the designer will object, saying that he knows quite well what he wants, and is prepared to pay a fair price for it. Undoubtedly he knows what he wants, but is it commercially practical? Does he know what it will cost? Can he look at it from the same angle as the contractor? Does he know the psychological effect such ideas will have on the workmen? Is he prepared to risk his reputation on a problematical attitude on the part of the contractor?

With regard to greater remuneration for inspectors; once the need of inspection is recognized, greater remuneration will naturally follow, and instead of inexperienced men holding such positions, they will be filled by men of high ability.

It is not the object of the writer to exalt the position of inspector above designer but to demonstrate that the inspector is the liaison officer who can obtain for engineers the adequate recognition of their work. A designer can draw a few lines and show them to a banker and say—behold a pulp mill—a bridge—a skyscraper, but he does not thereby convey any idea of the innumerable operations and inspections which must take place between the getting the raw material out of the ground to the time that the operating man takes charge of the finished structure.

To demonstrate the value of inspection, examples must be given which will make prospective owners aware of the dangerous possibilities that occur in all engineering work, many of which, if allowed, can never be remedied; and the ideal way of doing this is, to get printed in the financial and municipal papers and magazines, a series of articles—short and to the point—similar to those which advertise the medical profession in the Montreal Star, under the heading, "That Athletic Body of Yours." These will keep continually before the financial public the work done by the engineer.

Summary

Practically all our material welfare is due to the activity of the engineer, what he has done in the past is only a fraction of what he could do in the future, if given the opportunity.

To obtain the opportunity his work must be known. To make his work known he must advertise—but he must place his announcements before the right people, the people who finance all engineering work—the bankers, trust companies and bond houses, etc. He must reach the vital point, and show them how the contents of their pocket books are dependent upon the excellence of the work done for them, that this excellency depends upon thorough inspection at all times and in all places, that such inspection will cost money, but that it will be money well spent.

This publicity will eventually arouse recognition; increased recognition will bring increased remuneration, and increased remuneration, opportunity for increased service as outlined in the beginning.

Yours truly,

C. D. NORTON, A.M.E.I.C.

BOOK REVIEW

Analytical Mechanics

By H. M. Dadourian. Van Nostrand, New York, 1931, cloth, 6 x 9 in., 427 pp., figs., tables, $4.00. 3rd ed., revised.

Lieut.-Col. E. J. Schmidlin, M.E.I.C.*

It is difficult, in a work on such a fundamental subject as Mechanics, to introduce much material which is of an entirely novel character. The author of such a work must therefore rely, for success in his effort to gain recognition, on his skill in arranging his subject matter, on his methods of presentation, and on the use of illustrative examples to clothe the bare bones of the basic theories which he is expounding. Professor Dadourian's book indicates that the author, himself a teacher of wide experience in the field of Mechanics, has been fully cognizant of these requirements—as, in fact, he states in the preface. The measure of success attained is sufficiently attested by the fact that the book has reached a third edition.

The contents may be considered as divided into three sections, although no such division is shown, chapter headings only being used. The first section deals with statics, in four chapters which progress in perfectly logical order from the basic definitions, through the necessary conditions for equilibrium of a particle to the consideration of the equilibrium of rigid bodies, concluding with two chapters in which the foregoing principles are applied to the study of structural frames and flexible cords.

The treatment is unusual in that forces are considered throughout as physical entities, i.e., as applied to solid particles or bodies. This is, of course, strictly correct, but leads to the absence of the familiar paragraphs on resolutes, resultants, equilibrium, etc., of disembodied system of forces, and may seem strange at first sight to one who studied his mechanics in an earlier day. The method has much to recommend it when the subject is being introduced to junior students.

A feature of this section of the work which is worthy of note is the extensive discussion of static friction and its application to various problems of equilibrium.

Following the section on Statics comes a single chapter on Kinematics—the geometry of motion—which is the natural and necessary

*Senior Professor of Engineering, Royal Military College, Kingston, Ont.

precursor of the third and largest section of the book. This third section deals, of course, with particles and bodies in motion, and, like the first section, it has some decidedly original characteristics, of which perhaps the most noteworthy is the stressing of the analogy between translatory and rotational motion of bodies.

It is usual to find the discussion of these two classes of motion definitely separated—sometimes even in separate volumes—but Professor Dadourian brings out clearly their essential similarity by treating them side by side, and generally in absolutely parallel manner. The result is highly interesting and instructive, and the idea is undoubtedly excellent. It is not quite so certain, however, that the exclusive use of the calculus throughout this section is so desirable. In many problems, of course, this is the best, and perhaps the only method, but a purely mathematical treatment in all cases may lead the student to forget what was so carefully emphasized in the Statics section—namely, that the actions under consideration are physical.

The use of the Newtonian notation ($\dot{V} = \frac{dv}{dt}$, etc.) for derivatives with respect to time is also open to criticism. This notation is not particularly legible, and the close attention to the text which it demands makes some of the longer derivations more fatiguing to read than they should be.

Engineers reading this section of the work may not agree with Professor Dadourian's action in making his fundamental definitions in accordance with the Einstein hypotheses, but they cannot fail to find the result interesting, particularly as several numerical examples of the effect of relativity are given. After all, whether we consider "inertia" as a property of matter, or as the "kinetic reaction" of the universe, the results obtained in the sort of problems which have to be solved in practice are precisely the same. The engineer may consider himself fortunate that he need not, for the present at any rate, concern himself either with the ultimate nature of matter or with velocities of solid bodies approaching that of light.

It is gratifying to note that a full discussion is given of the relations between the "absolute" and "Engineering" units of force, work and energy, and that the latter are used. This is a matter which still, unfortunately, proves a stumbling block to many a student who has learned his mechanics entirely on the "absolute" system.

In conclusion, attention may be drawn to one unusual inclusion, and one regrettable omission in the final section of the work. The first is a chapter on orbital motions, which is seldom found in a text of this character, although it is a most appropriate place. The second is the lack of any mention of gyroscopic action, which might well be included in the next edition.

Professor Dadourian's book is worthy of a place in the library of every engineer who wishes to keep his fundamental theory—and his calculus—up to date, and who desires a mechanics text which is thoroughly readable, plentifully supplied with excellent illustrative examples and problems, and contains many unusual and interesting features.

BRANCH NEWS

Cape Breton Branch

S. C. Miflen, M.E.I.C., Secretary-Treasurer.
Louis Frost, Branch Affiliate, Branch News Editor.

The Cape Breton Branch, through the courtesy of the Canada Cement Company, Ltd., was able to avail itself of an exceptionally fine series of lectures on concrete mixtures. The course, covering a series of nine lectures, was presented at Sydney by Messrs. J. M. Portugais, B.Sc., A.M.E.I.C., technical engineer, and S. Boyd, B.Sc., chemical engineer, of the Canada Cement Company. More than one hundred engineers from municipal centres in Cape Breton attended these lectures which commenced on Tuesday, September 15th, and were concluded on September 22nd. The branch chairman, A. P. Theuerkauf, M.E.I.C., presided at the opening and concluding lectures, with Y. C. Barrington, A.M.E.I.C., and J. A. Fraser, A.M.E.I.C., presiding at the second and third lectures respectively.

During the course, desirability of establishing proper balance in strength was stressed, also the durability and economy, by apportioning the design of the concrete mixture to the relationship of cement to water in the ratio which as established by extensive research will give the greatest compressive, flexural and tensile strengths, impermeability, and resistance to weathering.

The selection of aggregates, testing, and control of the concrete mixes in the field was fully described and a series of practical demonstrations on the sampling and testing of aggregates and concrete mixtures were given.

The following lectures were delivered:

Fundamentals of Concrete.	Design of Mixtures.
Manufacture of Portland Cement.	Tests of Cements and Concretes.
Aggregates.	Quality Control in the Field.
Manufacture of Concrete.	Pavements.
Curing of Concrete.	

The complete set of lectures in book form as well as a good deal of interesting literature on the design and control of concrete mixtures was presented to those attending the course.

At the conclusion of the final lecture a vote of thanks was tendered the lecturers and the Canada Cement Company, Ltd., for their courtesy in allowing the lecturers to come to Sydney.

Halifax Branch

R. R. Murray, A.M.E.I.C., Secretary-Treasurer.
W. J. DeWolfe, A.M.E.I.C., Branch News Editor.

The Halifax Branch of The Institute held a special meeting on the evening of September 25th to extend a welcome to the President of The Institute, S. G. Porter, M.E.I.C. The meeting was preceded by a supper at the Nova Scotian hotel, there being some forty members present. J. Lorn Allan, M.E.I.C., chairman of the branch, presided.

Mr. Allan, before introducing Mr. Porter, asked D. W. Robb, M.E.I.C., for a few remarks re the Chignecto ship canal scheme, a proposal to connect the Bay of Fundy with Northumberland strait, thereby converting Nova Scotia into a virtual island. Mr. Robb, who has recently appointed to the Commission to investigate the practicability of the scheme, acceded to the request, and gave a short outline of the usefulness and value of the canal from the standpoint of trade development, inasmuch as the canal, if constructed, will shorten the water distance between the St. Lawrence river and eastern United States points and the south.

A letter of regret from Professor F. R. Faulkner, M.E.I.C., vice-president of The Institute, was read, he being unable to attend on account of illness.

Mr. Allan then indicated the pleasure the branch members felt in greeting the President.

Mr. Porter referred to the number of ways in which the branches can further the work of The Institute, and commented on the size of the Dominion and the difficulties encountered in getting members together. In his opinion, the Plenary and Annual Meetings seemed to be two ways of overcoming this separation of branches and through these meetings, improve the contact with headquarters.

He suggested that live branches mean a live Institute and, that when papers are to be read a well-developed discussion should be organized in advance with the younger members induced to take part. Moving pictures have their value and even "talkies" on some large projects might be secured. Visits to construction works, increasing the number of affiliates, attendance committees to call members to meetings; social meetings, such as ladies' night, golf tournaments, large dances, etc., etc., were among the further suggestions offered as a means of boosting interest in the branch. Mr. Porter also made a plea for new members and explained that it is the branches which must be depended upon to obtain them.

He next referred to the efforts being made to effect a co-ordination of the work of The Institute and the various Provincial Associations of Professional Engineers. It was his opinion that, while the British

North America Act might prevent engineers from obtaining a Dominion charter, yet the matter could be done by individual branches and associations working together for a central body which would permit, without interfering with local autonomy, all members to function in any province. Mr. Porter said these were only suggestions, offered in good faith, as ways and means of advancing the Engineering Profession.

He then spoke on the status of the engineer in the present economic depression and of the great services the engineer can and should be able to render to the world.

On the conclusion of his address, a standing vote of thanks was extended to Mr. Porter.

A motion expressing the deep regret of the branch in the death of the late Lieutenant-Governor, Mr. Frank Stanfield, and offering sympathy to the bereaved family, was passed unanimously.

Moncton Branch

V. C. Blackett, A.M.E.I.C., Secretary-Treasurer.

A large and representative gathering of Branch members met in the Y.M.C.A. on September 26th, to welcome S. G. Porter, M.E.I.C., President of The Engineering Institute of Canada, and to hear him speak on matters of importance to engineers. G. E. Smith, A.M.E.I.C., chairman of the branch, presided.

Mr. Porter expressed his pleasure at this, his first visit to the provinces by the sea. He was agreeably surprised to find in Moncton such a live and agressive branch of The Institute. In the case of a nation-wide organization, strength in the widely separated individual branches was highly essential.

The speaker stressed the improved status of engineers. The practical self-educated engineer has had his day and that day is nearly over and the profession now requires thorough technically trained men. The progress of negotiations for the co-ordination of the work of the various provincial associations with The Institute was dealt with at some length. Under the British North America Act each province must control the practice of engineering within its own borders, and it is probable that in the proposed union, the provincial units will continue to administer their respective laws and protect the public against so-called and incompetent engineers, while the national body will provide technical, social and economic service.

Mr. Porter's address was followed by a lively discussion. A. S. Gunn, A.M.E.I.C., enquired if there was a possibility of a merger of provincial associations into one federal union. Mr. Porter replied that under the British North America Act, this could not happen. J. G. MacKinnon, A.M.E.I.C., pointed out that the act referred to was a stumbling block not only to engineers but to other professions as well. The medical men had their provincial associations and their Dominion association, and a practitioner licensed in one province had his own troubles in obtaining the right to practice in other parts of the Dominion. C. S. G. Rogers, A.M.E.I.C., expressed the opinion that The Institute should maintain its academic standing and not become a semi-protective organization. Professor H. W. McKiel, M.E.I.C., enquired as to just what opposition there was to the proposed co-ordination of work. The majority of the members of the New Brunswick Association, he said, possibly 85 per cent, were also members of The Institute, and whole-heartedly in favour of the union.

A vote of thanks was tendered Mr. Porter, on motion of C. S. G. Rogers, A.M.E.I.C., seconded by G. C. Torrens, A.M.E.I.C. Refreshments were then served, after which the meeting adjourned.

Niagara Peninsula Branch

Paul E. Buss, A.M.E.I.C., Secretary-Treasurer.

Construction of the "Akron"

The Niagara Peninsula Branch held a very well attended meeting at the Fox Head inn, Niagara Falls, on October 6th, to hear Mr. W. C. Young relate some of the problems connected with the recent construction of the dirigible "Akron."

Mr. Young is manager of the Aeronautics Department of the Goodyear Tire and Rubber Company and sales manager of the Goodyear-Zeppelin Corporation.

He made the trip to Germany in connection with the preliminary arrangements regarding the bringing of the German Zeppelin patents and Dr. Karl Arnstein, noted airship designer, to the Goodyear-Zeppelin Corporation. He assisted in the plans for closing the contract with the United States navy in 1928 for the construction of two huge airships.

The two United States navy ships now under construction will each be nearly twice the size of the Graf-Zeppelin and about three times the size of the Los Angeles, and will have greater speed and load carrying capacities than any airship ever built. The great airship dock in which the "Akron" was constructed is 1,200 feet long, 325 feet wide and 210 feet high, without interior supports.

Mr. Young stated that there should be no quarrel between the lighter-than-air and the heavier-than-air advocates. Both types are developing into very distinct spheres of action; the first for long distance overseas transport and the latter for land transport. The economical non-stop flight for planes is less than 500 miles, whereas the modern dirigible can carry sufficient fuel to go half-way around the world and the cost of mooring comprises a large percentage of the flight cost on short hops.

The crusing speed of the Pittsburg-New York planes is 120 m.p.h., which can be speeded up to 160 m.p.h. when necessary, and Mr. Young quite expects to see cruising speeds as high as 250 m.p.h. in the near future.

The research and engineering problems, which are engaging the attention of aircraft officials at the present time, resolve themselves into three groups: first, better streamline shapes; second, lighter and stronger metals; third, more efficient motive power.

Duralumin, with an elastic limit of about 50,000 pounds per square inch, is the favoured metal at present, particularly in the design of airships, but the metal beryllium is receiving very close attention. It has the advantage of possessing an elastic limit about twice that of duralumin while the weight is approximately 25 per cent less and it can be welded and otherwise worked without losing strength under heat.

Although it has not yet been proven, the belief is prevalent that the "Akron" will be capable of doing the same work as six scouting cruisers. She will cost about $5,000,000, as against $10,500,000 for each cruiser, will have three times the speed and will present a more difficult target for enemy artillery. The saving in personnel is also a great consideration. Dirigibles would not be so seriously considered in the United States were it not for the advantages enjoyed in the production of helium. This gas, which originally cost $1,500 per cubic foot to produce, now costs $7.60 per 1,000 cubic feet and is cheaper than hydrogen, which costs $10. The lifting power is about 62 pounds per 1,000 cubic feet, as against 68 pounds with hydrogen, and, of course, the great advantage is that it is non-inflammable.

One of the most interesting points in the design of the "Akron" is the construction of the twelve large gas bags. These are made on somewhat the same principle as the puncture proof tire. A very fine cotton fabric is covered with several thin coats of latex, followed by several coats of gelatin and then several more coats of rubber. The gelatin is tacky and acts as a filler, flowing into any holes or pores which may exist, or which may form, in the rubber and thus reducing gas loss to practically zero. At one time gold-beater skin was used instead of the gelatin, but this was costly.

"The "Akron" has a designed speed of 82 m.p.h. and a cruising radius of 11,000 miles. She is 785 feet long and 133 feet diameter. The eight motors of 560 h.p. each were developed by the German-Zeppelin Corporation and use Blau fuel gas or gasoline. No dirigible motors has as yet been constructed on this side of the Atlantic. The engines are mounted within the hull, four on each side, and drive the 17-foot propellers through bevel gear shafts which are mounted on outriggers. The propellers and their fixed portion of the shafts may be moved up or down in a vertical arc, thus giving assistance to the dirigible in rising or descending. A variation is made in the pitch of each following propeller in order to avoid turbulance from the back-wash of the preceding propeller. The total weight of material in the "Akron" amounts to 85 tons, which, following an observed characteristic of all aircraft design, is slightly greater than the calculated weight. She carries a crew of 15 officers and 50 men, and if converted to a commercial trade could carry a load of about one hundred passengers.

Five aeroplanes are carried within the hull, all of which may be launched through trap doors and picked up again while in flight. The question of fastening these planes below and outside the hull received consideration, but was finally abandoned. The arguments in favour of the outside position consisted of a theoretical assistance in uplift from the wings of the planes and an emergency source of extra power from the engines.

As a matter of comparison, Mr. Young gave the "Akron's" gas capacity as 6,500,000 cubic feet; the "R100" as 5,000,000 cubic feet and the "Graf Zeppelin" as 3,700,000 cubic feet.

Walter Jackson, M.E.I.C., presided at the meeting, and Alex. Milne, M.E.I.C., proposed the vote of thanks to Mr. Young and to the Goodyear Company for the excellent films which illustrated the construction features. E. G. Cameron, A.M.E.I.C., welcomed the visitors from Hamilton, Buffalo and Niagara Falls, and Mr. Graham, Chairman of the A.I.E.E., Frontier section, introduced the speaker.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

Luncheon to President

The Ottawa branch were favoured with a visit from the President of The Institute, S. G. Porter, M.E.I.C., of Calgary, Alberta, at their noon luncheon held at the Chateau Laurier on October 2. The occasion was in the nature of a "get-together" meeting affording the members an opportunity of becoming acquainted with the President and of listening to him.

G. J. Desbarats, C.M.G., M.E.I.C., chairman of the Branch, in introducing Mr. Porter referred briefly to his career since coming to Canada, first in the Civil Service and later with the Canadian Pacific Railway.

Mr. Porter stated that he had been spending his holidays visiting the various branches in the Maritimes and in Quebec and hoped on his way back to the west to be able to visit other branches as well. The Engineering Institute, owing to the wide range of country covered by its activities, suffers to some extent by its very bigness. Members from widely scattered points are largely prevented from coming into intimate contact with each other and it is in this regard that the branches fill an important function, namely, that of allowing the members in the various localities to get together among themselves, thereby carrying on more effectively the work of the organization. It was true of The Institute, just as of any other organization, that "what you get out of it is measured by what you put into it."

The President at this point dwelt upon the matter of increasing the membership of The Institute and stated that this was a concern largely for the branches themselves working through the individual members.

A considerable portion of the President's address was taken up with the question of bringing about a closer relationship between the various provincial engineering associations and The Engineering Institute of Canada. In eight out of the nine provinces of Canada there are now registered Provincial Engineering Associations, each organization being based upon the Provincial Act for that province. Uniform legislation in this regard is most difficult of achievement and it is hoped that The Engineering Institute of Canada might be able to assist in obtaining, if not a uniform act, legislation of as near uniformity as possible.

The President also spoke of the place of the engineer in public affairs and stated that he should find opportunities to contribute more thoroughly than he has done to the solution of society's problems. The engineer's place in our social structure is particularly important in a country like Canada on account of its newness and the vast amount of work that requires to be done in connection with the country's development.

Engineers are beginning to occupy in increasing numbers administrative positions of importance, and this is as it should be, for in these positions he might well take his place along with the sociologist and the educationalist in solving the present vitally pressing problems relating to a proper distribution of labour. How pressing these problems are may at once be recognized when it is stated that the work of ten men only a decade ago may be produced equally well by seven men today.

Professional Engineers of Ontario

At the noon luncheon on October 8th the local branch listened to addresses by A. H. Harkness, M.E.I.C., President of the Ontario Association of Professional Engineers, and H. Hellmuth of Toronto, also of the same Association.

Mr. Harkness outlined briefly the history of the Ontario Association of Professional Engineers and stated that since its inception in 1919 it has attained a membership of nearly 1,200. Its main object was the obtaining of proper legal recognition of the profession of engineering in Ontario and, in this connection it was backed by an act of the legislature of Ontario. Unfortunately, however, two clauses dealing with penalties for those who represented themselves as engineers without authority which were intended to be included in the Act, had been struck out at the time it was passed. This, stated Mr. Harkness, really destroyed the value of the Act so far as its main purposes were concerned, and it was in an endeavour to get over this difficulty that further action was contemplated.

Mr. Harkness mentioned that there seemed to be a tendency among the members of The Engineering Institute not to take an active part in the affairs of the Association. This was unfortunate as there was no intention to have the activities of the Association infringe in any way upon those of The Institute. Each has its own field and these do not conflict. The Ontario Association of Professional Engineers is not a technical organization, as that term is generally understood, but is a body created purely for the purpose of protecting its members against unscrupulous practitioners, and the public in their endeavours to obtain professional engineering services.

Mr. Hellmuth, who spoke next, elaborated upon some of the points mentioned by Mr. Harkness. He compared the profession of engineering with that of law, medicine and other professions in Ontario and stated that all had a standing which engineering itself lacked.

Prince Edward Island is the only province in Canada where there is no engineering legislation. All other provinces require registration excepting Ontario. If the Ontario Professional Engineers Act was made similar to the acts of other provinces it would be possible to seek and to ask for reciprocal action in the matter of registration and right to practise. At this point, Mr. Hellmuth mentioned that graduates in the professions find adequate protection in Ontario in everything except the profession of engineering (outside of land surveying), thus influencing them to seek other provinces or other places where such protection could be secured. The lack of this is a result of the lack of interest on the part of the public and the deplorable laxness on the part of the engineers themselves.

The present Ontario Act, as had been intimated by Mr. Harkness, was considered inadequate and a new bill was being drafted for presentation at the next session of the legislature. It was intended to send a copy of this bill beforehand to every member of The Engineering Institute of Canada for suggestions and comments.

Visit to Fuel Research Plant

A tour of inspection of the Fuel Research and Ore Dressing laboratories of the Department of Mines on Booth street was made on Tuesday evening, October 13, by the members of the Ottawa Branch and their friends. The tour was arranged through the courtesy of John McLeish, M.E.I.C., director of the Mines Branch, and invitations were also extended to the ladies. About a hundred of the members and their friends were present.

The apparatus used in the laboratories in conducting tests upon coals with particular reference to their coking qualities, and upon oils, oil-shales, gasolines, bituminous shales, etc., was examined. The conduct of this examination was facilitated by descriptive placards attached to each piece of apparatus. A special feature of the evening was the "pushing" of the coke oven, wherein the experimental oven maintained as a part of the equipment of the laboratories was emptied of a charge of coal which had been converted into coke.

The determination of the coking qualities of various Canadian coals is a valuable work of these laboratories, having an important bearing upon the utilization of these coals, particularly for industrial purposes.

Quebec Branch

Marc Boyer, S.E.I.C., Secretary-Treasurer.

On September 27th and 28th, the Quebec Branch was honoured by the visit of the President of The Institute.

On the afternoon of his arrival in Quebec, Mr. Porter was the guest of Hector Cimon, M.E.I.C., chairman of the Branch, at his home, where the officers of the Quebec Branch had gathered.

On September 28th, over thirty members of the Quebec Branch availed themselves of the opportunity of meeting the President, at a luncheon held at the Chateau Frontenac, and presided over by Mr. Cimon.

Upon introducing the President, Mr. Cimon made it clear that although this was Mr. Porter's first visit to Quebec, he was indeed not a stranger to the Quebec Branch, "because his many activities in connection with The Institute were well known, and more recently, his able work as chairman of the Committee on Relations of The Engineering Institute of Canada with the Provincial Professional Associations had been highly appreciated by every engineer," and particularly by the engineers of Quebec. As early as 1910 and 1912, Mr. Cimon pointed out, the Quebec Branch made the first steps towards the organization of provincial engineering associations throughout Canada. Mr. Cimon added a few words of hearty welcome to Mr. Louis St. Laurent, K.C., President of the Canadian Bar Association, who had kindly accepted the invitation of the Branch to attend the meeting.

Mr. Porter's most interesting address embodied the ideals of The Engineering Institute as well as that of every professional engineering association. The President made a strong appeal for the co-operation of every member and branch of The Institute, and ultimately for the co-operation of all professional engineering institutions, in progressing towards one representative, nation-wide organization.

Mr. Louis St. Laurent congratulated the Branch on the address of the President, Mr. Porter, and compared the Canadian Bar Association to The Engineering Institute of Canada, the object of both being to promote a better understanding and to facilitate interchange of knowledge among its members for the benefit of the public and of the country as a whole.

A. R. Decary, M.E.I.C., and W. G. Mitchell, M.E.I.C., added a few words of thanks in the name of the Quebec Branch, and the meeting adjourned.

Following the luncheon, Mr. S. G. Porter, accompanied by a small group of members, visited the new C.P.O.S. terminal and wharf at l'Anse au Foulon and the government dry-docks at Lauzon, two very interesting pieces of modern engineering.

Saint John Branch

G. H. Thurber, A.M.E.I.C., Secretary-Treasurer.
C. G. Clark, A.M.E.I.C., Branch News Editor.

A meeting of the Saint John Branch of The Engineering Institute of Canada was held on September 24th, the speaker being S. G. Porter, M.E.I.C., President of The Institute. Prior to the meeting members attended an informal dinner held at the Admiral Beatty hotel. John N. Flood, A.M.E.I.C., chairman of the Branch, presided.

Mr. Porter stated that branch activities constitute the real life of The Institute due to the fact that such a small percentage of the members can attend the annual meetings. It is thus essential that interest of all members be maintained in branch affairs. He made a number of practical suggestions for increasing and holding the interest of members, such as prepared discussions on papers before presentation, meetings devoted to non-technical subjects of local interest, which would encourage the attendance of men outside the profession, engaged in allied occupations, who could join The Institute as affiliates. A number of moving picture films are available and could be used advantageously. Social activities were also to be encouraged. Zone committees could assist branches by the exchange of speakers and papers.

Mr. Porter also touched on the work of the committee at present engaged in drafting a plan to obtain closer co-operation between the various Provincial Associations of Engineers and The Institute. This, he said, should result in greater uniformity of legislation affecting engineers.

Observations on the Engineering Profession

Mr. Porter said the chief object of The Institute was the exchange of ideas for mutual benefit by members of the profession. He stated that the standards for admitting men to the profession should be as high as possible, especially with reference to fundamental education.

The obligations of engineers to the profession were stressed, as only by national solidarity could public confidence and the influence of the profession be increased. As to the obligation to the public, Mr. Porter stated that the chief reason for lack of public recognition was the backwardness of engineers to take an active part in public governing bodies. He stated that an engineer's training made him well adapted to the solution of social problems.

It was also pointed out by Mr. Porter that whereas only a few decades ago engineers' activities were confined to designing and building, now they have extended their working sphere in many directions, notably towards the management side, many leading executives being technical men.

As to the cause of present economic conditions, it was stated as being largely due to the fact that engineering development had gone beyond the power of civilization to absorb its products. Mr. Porter suggested that the engineer could very materially aid the economist and sociologist in the solution of the present problems.

In the discussion which followed A. A. Turnbull, a.m.e.i.c., suggested that a branch meeting be held to receive the reports of branch representatives acting on national committees. Dr. John Stephens, m.e.i.c., President of the Association of Professional Engineers of New Brunswick, stated the Association would favour any attempt at co-operation between provincial associations which would not jeopardize the standings of these associations.

A hearty vote of thanks to Mr. Porter, moved by C. C. Kirby, m.e.i.c., and seconded by G. G. Murdoch, m.e.i.c., was unanimously passed.

While many of our permanent members, due to seasonal activities, were absent from the city and could not be present at the meeting, the attendance was gratifyingly large owing to the presence of a number of the engineers who have recently been added to our Branch membership through their coming here to engage in work, chiefly in connection with the Saint John Harbour reconstruction.

It is a great pleasure to have these men as members of our Branch and their attendance at our regular meetings during the coming season will be of great value in making the season a successful one.

Sault Ste. Marie Branch

A. A. Rose, A.M.E.I.C., Secretary-Treasurer

Dredging, with Particular Application to the St. Marys River

The first regular meeting of the Sault Ste. Marie Branch after the summer vacation was held on Friday, Sept. 25, 1931, at the New Windsor hotel, dinner being at 7 p.m. and the meeting at 8 o'clock.

The speaker of the evening was Mr. O. M. Frederick, engineer, Sault Ste. Marie, Michigan. Mr. Frederick spoke on the subject, "Dredging, with Particular Application to the St. Marys River."

In his opening remarks Mr. Frederick surveyed the operations of his department in the sixty-mile-long St. Marys river, forty of which have been dredged beginning in 1855. In the river there are many stretches where the water is less than twelve feet deep and previous to 1928 the channel had been deepened to twenty-one feet and widened to three hundred feet in the one-way section and between five and six hundred feet in the two-way channel. This has resulted in a great decrease in the cost of transportation. Under the present plans the whole system is being widened to five hundred feet and deepening of the whole system is being considered.

The speaker then gave in detail the methods of taking soundings and probings from which complete plans and accurate quantity and cost estimates are made. The specifications are as complete and brief as possible, the whole engineering work being so accurately done that contractors can depend on its results. He described the various dredging jobs completed since 1928 and those now in progress, giving details of their extent, materials encountered, methods of dredging, and costs.

The whole paper was most interesting and informative and following a lively discussion those present expressed their appreciation of Mr. Frederick's kindness in giving the branch this paper, by a hearty vote of thanks.

Vancouver Branch

W. O. Scott, Jr.E.I.C., Secretary.

Economic Effect of Russian Five-Year Plan on Canada and the United States

The meeting of October 14th, 1931, was held in the Auditorium of the Medical-Dental Building at 8 p.m.

Speaker—J. Friend Day, Associate Professor, Department of Economics, University of British Columbia.

Subject—The Economic effect of the success of the Russian Five-Year Plan on Canada and the United States.

This subject was most ably presented and the speaker without doubt had a very clear insight of Russia and her problems.

Professor Day began with a brief résumé of Russian history and traced the various changes of government and government policy from sometime previous to 1913 to the present date.

A brief outline of the Five-Year Plan was then given and a few control figures suggested to give a fair idea of the progress made in the plan. Difficulties had been pointed out but these had been overcome and he stated that this was only the beginning of Russia's industrial expansion, that the Five-Year Plan was not by any means the end.

He further touched on Russia's vast storehouse of raw materials, timber, mining, oil, water power, etc. and pointed out the development in the past few years.

He mentioned how Canada and the United States were linked in this great problem, through the various commodities that Russia required in the raw state or through the competitive nature of manufactured articles on the world market.

A hearty vote of thanks was moved and seconded by Messrs. E. E. Brydone-Jack, m.e.i.c., and A. S. Wootton, m.e.i.c., to the speaker for the splendid presentation.

Future meetings will be held in the same auditorium and on the second Monday of each month, unless otherwise notified.

Winnipeg Branch

Eric W. M. James, A.M.E.I.C., Secretary-Treasurer.

The regular semi-monthly meeting of the Winnipeg Branch of The Engineering Institute of Canada was held in the Engineering building, University of Manitoba, on October 15th, 1931, at 8.15 p.m. Charles T. Barnes, a.m.e.i.c., occupied the chair, there being 24 members and visitors present, according to the register. Moved by J. W. Sanger, a.m.e.i.c., seconded by Professor Norman Hall, m.e.i.c., that the appreciation of the Branch be extended to our Secretary for his complete report of our last meeting. Carried. Professor Hall read a letter received from S. G. Porter, m.e.i.c., President of The Engineering Institute of Canada, stating that he would visit Winnipeg on October 26th, 1931, and would like to meet the members of the Winnipeg Branch in the evening. Moved by Professor J. N. Finlayson, m.e.i.c., seconded by Professor R. W. Moffatt, a.m.e.i.c., that a special meeting be held on that evening to meet Mr. Porter, it being left to the Executive Committee to decide whether this would be a dinner meeting or not. Carried. Moved by Mr. Sanger, seconded by R. H. Andrews, a.m.e.i.c., that we proceed with the paper in spite of the small attendance. Carried.

Impact Values of Rail and other Steels at Low Temperatures

J. F. Cunningham, affil.e.i.c., Superintendent, Testing Laboratories, University of Manitoba, then read a paper prepared by James Gilchrist, chief inspector of materials, Canadian National Railways, and himself, entitled "Impact Values of Rail and other Steels at Low Temperatures." In the pearlitic rail steels tested, a reduction in impact resistance was found to occur gradually down to temperatures of 18 degrees below zero, F., to 20 degrees below zero, F. From that temperature down, the resistance to shock has reversals at fairly definite temperatures. Tests were also made on 0.92 per cent Carbon, 0.42 per cent Carbon, 0.10 per cent Carbon steels and Armco Iron. With the exception of the 0.10 per cent rivet steel, all the materials show this definite change in impact values at similar temperatures. The 0.10 per cent rivet steel does not show similar reversals, but gradually loses resistance to shock after a temperature of 40 degrees below zero, F., is passed, The conclusions were advanced that the different components in these steels (cementite or iron carbide, ferrite, etc.) may have different coefficients of contraction due to temperature change, and cause minute strains in the structure which are fully developed at or near 18 degrees to 20 degrees below zero, F., and also that these coefficients may be constant down to a temperature of −18 degrees F. to −20 degrees F., but not below that temperature.

The acting secretary read a letter from Professor A. N. Campbell, Department of Chemistry, University of Manitoba, in connection with allotropic properties of steel. Mr. Gilchrist described the discussion at the convention of the American Steel Treaters' Association in Boston, Mass., last September. The paper was one of 37 chosen for publication out of a total of 160 papers submitted, and was well received by the large number of members present, there being considerable discussion.

Professor Hall asked if tensile tests at low temperatures could be tied up with impact tests, but Professor Moffatt thought this could not be done.

Mr. Sanger wanted to know the practical value of finding this critical temperature of about 20 degrees below zero, F., and Mr. Cunningham replied that if the low impact resistance point (−18 degrees F. to −20 degrees F.) could be moved down to say −58 degrees F., by changing the composition of the steel, the methods of forging, rolling, etc., or the heat treatment of the steel, we would have less failures of steel rails, for instance, at low temperatures until 50 degrees below zero, F., was reached.

Mr. Gilchrist stated that engine-drivers could run faster at 30 or 40 degrees below zero than at 20 degrees below zero, with safety, and that all steel rails should be normalized after rolling, to take care of the stresses due to the unequal sections of the rail, i.e. head, web, and foot. He also stated that Bessemer steel is not as good as the acid open hearth steel for rails, but that rails do not get as many passes through the rolls as was the case thirty years ago, which is a great disadvantage.

Professor Hall moved, Mr. Sanger seconded, a vote of thanks to Messrs. Gilchrist and Cunningham for their interesting paper.

The meeting adjourned at 10.50 p.m. for refreshments.

Unemployment

There were 44 members and visitors present according to the register.

After the reading and confirmation of the minutes of the previous Branch meeting, the Secretary read a letter of resignation as member of the Executive Committee from W. E. Hobbs, A.M.E.I.C., who has been ordered by his physician to refrain from all possible activities. The Chairman invited the Branch to nominate a successor to Mr. Hobbs; but upon the motion of J. W. Sanger, A.M.E.I.C., seconded by E. V. Caton, M.E.I.C., it was resolved that the appointment should rest with the Executive Committee.

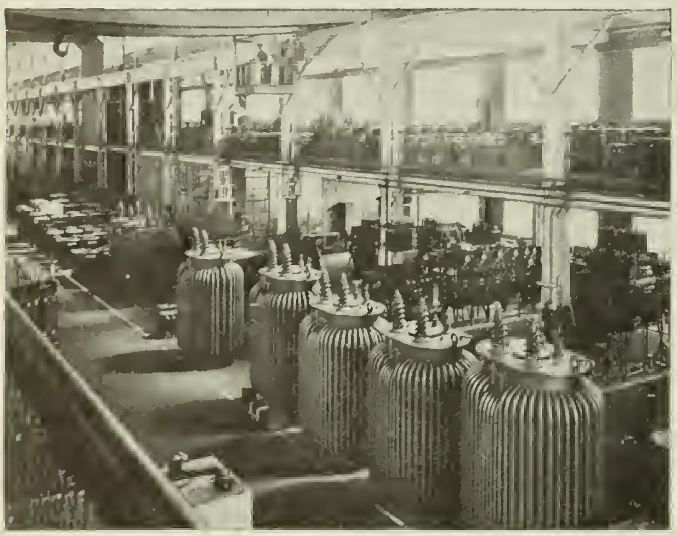
The Chairman then introduced the speaker of the evening, F. H. Martin, M.E.I.C., consulting engineer, Northwestern Power Co., who delivered a most timely and interesting address under the title of "Unemployment."

Mr. Martin designated a new principle contained in his paper as "Employment Insurance" as opposed to unemployment insurance, or the dole system, and stated that in brief the paper might be entitled "Surplus Work for Surplus Labour."

It was pointed out by the speaker that a large number of public works could be undertaken by the Federal government for the relief of unemployment, and that such work could be financed by the underwriting of a twenty-year endowment policy which could be subscribed by people whose surplus funds are at present on deposit in savings banks. Such activities as would be undertaken by the government for the relief of unemployment could be done without in any way interfering with private enterprise; and so when industrial conditions should improve to the extent that private activities could be resumed, surplus labour would be released from government pay rolls to fill the needs of private enterprise.

Mr. Martin's paper was well received, and the subsequent discussion was carried on in a very spirited manner until a late hour in the evening, when it was moved by J. W. Porter, M.E.I.C., that the discussion should be continued at a later date, and that mimeographed copies of Mr. Martin's paper should be distributed to the Branch members in advance of the date fixed for discussion, so that the details of Mr. Martin's well worked out principle could be intelligently discussed.

Among the visitors who took part in the preliminary discussion were Mr. Jules Proudhomme, city solicitor for Winnipeg, and Mr. H. E. McLuhan.



The above illustration shows part of the test department in the new Ferranti transformer factory with a number of 264,000-volt transformers for the Hydro-Electric Power Commission of Ontario ready for test. The dimensions of the factory which is situated on 16 acres of land between Mount Dennis airport and the Canadian Kodak factory, are 110 feet by 400 feet, plus two extensions containing: (*a*) a heating plant, transformer-oil storage, oil treating equipment and (*b*) varnish impregnating tanks and heating ovens. Average night illumination is 14-foot candles and vita glass has been used throughout the building.

Smart Turner Machine Company Ltd., Hamilton, Ont., has recently added to its other lines the manufacture of a stainless steel pump for various industrial plants. These are of the regular centrifugal type with only slight alterations made in the design to simplify the machining of the stainless steel or to conform to the requirements of the special service for which they are being used. The metal used in their construction, KA2, is a low carbon ferrous metal containing 8 to 10 per cent nickel and 18 to 20 per cent chromium, with a specific gravity of 7.6. It is non-magnetic and in its heat treated condition it is highly resistant to chemical attack of many acids and to high temperatures.

Power Supply in Yugoslavia

Great efforts have been made in Yugoslavia since the war to improve the production and the distribution of electric power. Several large power stations have been built by municipalities as well as under government control. A number of private companies with mainly foreign interests are owners of a number of plants supplying electric current to large towns and to the Yugoslavian chemical industry.

Among the latter the Kralyevac water power station should be mentioned. This power station belongs to a French company, which uses the largest part of the output in its chemical works on the Adriatic shore. To a small extent the power is absorbed by the city of Split. The power house, which is situated on the Cetina river, 65 kilometres distant from Split, includes two 16,000 kv.a. and two 26,000 kv.a. generating sets, giving a total output of 84,000 kv.a. The power is transmitted from the power house to the substations through an 80-kv. overhead line.

Another important water power plant has been built by a Swiss company on the Drava river in the vicinity of Maribor. The output of this power station is 34,700 kv.a. Here again the power is distributed through an 80-kv. overhead transmission line. The power station is connected to a steam power plant at Trbovlje, this allowing a very satisfactory distribution of the load between the two stations. The capital of Croatia, Zagreb, possesses a large fuel power plant, which is connected to a small water station at Karlovac. The present output of the Zagreb power plant is 19,500 kw., the largest turbo-generating unit having an output of 10,000 kw.

The most important fuel power plant in Yugoslavia is that which supplies Belgrade, the capital of the country. The power station of Belgrade is now increased by the installation of three new 6,000 kv.a. turbo generating units. This power plant is built by a Swiss company, which will also be responsible for the power distribution among the different parts of the area which surround Belgrade.

A Swedish company owns a number of power plants installed at Subotica, Senta, N. Becej, Velk Beckerek, Zemun, Pancevo, Pozarevac, Svilanajac, Lesovac and Scoplje, all situated in the north-eastern part of the country. The output of these power plants is small, as only units having an output of 200-300 kv.a. are in use. The construction of one large power plant which would supply the electrical current to all the towns mentioned above is under consideration.

An American firm recently acquired the concession for the power plant at Novi-Sad with an output of about 5,000 kv.a. It is quite possible that the company will be extending its interests in the near future as a need for a larger power supply is available in this part of Yugoslavia.

At present some fifty-seven water power plants have been registered in Yugoslavia. The number of fuel power plants including engine-driven generators supplying electrical current for electric light and power was recently one hundred and fifteen. From the 302,000,000 kw.hrs. produced during 1929, 200,000,000 kw.hrs. have been supplied to electro-chemical works, leaving only 100,000,000 kw.hrs. for general purposes and giving a yearly consumption which corresponds to about 9 kw. per inhabitant.—*Nikolay Von Kotschubey in The Electrical Times.*

National Research Council and Radio Research

Radio research has been assigned a definite place in the plans of the National Research Laboratories. An associate committee on radio research has been appointed and is expected to do work similar to that of the radio research boards of the other Dominions. There will be close co-operation with the radio work of other government departments. Arrangements are being made whereby the radio standardization laboratories of the Department of Marine will be placed in the new National Research Laboratories building.

Numerous radio problems have already been brought to the attention of the Research Council. One of the most important is that of assuring that Canada shall have at all times a highly accurate primary standard of radio frequency. Administration of radio in Canada, including allotment of frequencies to stations and seeing that they are adhered to, is the responsibility of the Department of Marine. This department is being equipped with a frequency standard apparatus of a high degree of precision but has joined in a recommendation that the National Research Council undertake a study of the frequency standard problem, that Canada may not be at a disadvantage in this important respect. Other problems which it has been suggested that the Research Council should attack are: Refraction over fresh water, impediments to long distance transmission in certain regions, height of the Heaviside layer, effect of the aurora on wave propagation, superimposed waves or discrepancy in frequency when received as compared with frequency when transmitted, and dependence of wave propagation on meteorological conditions.

Cork Insulation Company, Inc., 154 Nassau street, New York, have issued a 39-page booklet entitled "Corinco Cork Products," describing their product and outlining its uses. In Canada this company is known as Cork Insulation Company (Canada) Ltd., with offices at Montreal, Que., and Vancouver, B.C.

Preliminary Notice

of Applications for Admission and for Transfer

October 20th, 1931

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in December 1931.

R. J. DURLEY, *Secretary.*

* The professional requirements are as follows—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

FOULIS—ALLAN DODGE, of Saint John, N.B., Born at Yarmouth, N.S., June 25th, 1906; Educ., B.Sc. (M.E.), N.S. Tech. Coll., 1929; Since graduation with The Canadian Fairbanks-Morse Co. Ltd., first six months in engrg. dept. of scale factory at St. Johnsbury, Vt., obtaining knowledge of various types of scales and later on design of larger types of rly. track, hopper and special scales. On returning to Saint John placed in charge of scale dept., covering Maritime Provinces and Nfld. Also does considerable sales engrg. work on Diesel engines, pumps, motors and various lines manufactured by company.

The Frick Company, Inc., Waynesboro, Penna., has issued bulletin No. 208-A, describing and illustrating the company's system of split-stage low temperature refrigeration. In this system, it is stated, operation of the first stage machine under a vacuum is avoided by substituting carbon dioxide equipment in place of ammonia machinery for the low pressure, low temperature part of the cycle. Carbon dioxide affords temperatures down to − 60 degrees F. and even lower, while still maintaining a positive pressure in the suction piping. This suction pressure will vary in practice between about 60 and 200 pounds gauge—which for carbon dioxide compressors is very moderate. Copies of this booklet may be secured from the company's offices at Waynesboro, Penna., U.S.A.

The Combustion Engineering Corporation, 200 Madison avenue, New York, have recently published a pamphlet entitled "X-Ray Examination of Welded Pressure Vessel Seams," in which the X-ray method of testing, which is prescribed in the A.S.M.E. Code, is discussed, and an installation of X-ray equipment which is representative of the latest development is illustrated and described. Copies of the booklet may be secured from the company at the above mentioned address.

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men — without charge to either party.
All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada
2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Wanted

ELECTRICAL ENGINEER, graduate 1924, experienced home and foreign in electrical design and construction, surveys, reports, etc., capable of taking charge of same, desires any opening in engineering work. Age 32, married. Location immaterial, including foreign countries. Apply to Box No. 7-W.

ELECTRICAL AND RADIO ENGINEER, B.Sc. '28. Experience in the design and testing of broadcast radio receivers, including latest superheterodyne practice, and capable of constructing apparatus for testing same. Also familiar with telephone and telephone repeater engineering. Thorough experience in design, construction and inspection of municipal conduits. Apply to Box No. 12-W.

TECHNICALLY TRAINED INDUSTRIAL EXECUTIVE, open for employment. Canadian, age 40, with extensive Canadian and American industrial experience, particularly in metal manufacturing industries, including grey iron and steel foundries, machine and steel fabricating shops—arrangement and equipment of plant and mechanical handling systems to improve manufacturing methods, cut costs, step up production and quality of product wants connection with progressive company in Canada preparing for business expansion. Apply to Box No. 35-W.

ELECTRICAL ENGINEER, graduate '25. G.E. test: switchgear eng. dept., relay engineer, public utility. First-class record. R.P.E., B.C. Apply to Box No. 68-W.

REINFORCED CONCRETE ENGINEER, B.Sc., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

MECHANICAL ENGINEER, B.Sc. McGill 1919, A.M.E.I.C., married. Eleven years experience, including structural, reinforced concrete, piping and high pressure boiler and furnace design, heating and ventilating, hydraulic and boiler plant operating problems. Apply to Box No. 265-W.

CIVIL ENGINEER, B.A.Sc., C.E., A.M.E.I.C., age 29, married. Experience over nine years includes railway location and construction as resident engineer. Hydro-electric report on estimates and investigation, also design, construction and teaching on hydraulic structures, bridge foundations and caissons. Location immaterial. Apply to Box No. 447-W.

CIVIL ENGINEER, B.Sc., A.M.E.I.C., with six years experience in paper mill and hydro-electric work, desires position in western Canada. Capable of handling reinforced concrete and steel design, paper mill equipment and piping layout, estimates, field surveys, or acting as resident engineer on construction. Now on west coast and available at once. Apply to Box No. 482-W.

DESIGNING ENGINEER, A.M.E.I.C., P.E.Q., with extensive experience in design and construction of power plants, industrial buildings and hydraulic structures, desires position as designing engineer or resident engineer on construction. Apply to Box No. 492-W.

MECHANICAL ENGINEER, Jr.E.I.C., B.Sc., '26. Ten months experience in pulp and paper steam control. Four years experience in detail and design, in pulp and paper mill, industrial plant and hydro-electric development work. Age 27. Married. Location immaterial. Apply to Box No. 521-W.

MECHANICAL GRADUATE, 1927, age 26. One year with specialized piping contractor on design and cost estimates. Three years on hydro-electric power plant design, proportioned 25 per cent electrical, 25 per cent civil and 50 per cent mechanical. Five months field engineering on hydro-electric power house construction. Pre-graduate experience on power plant operation and general construction. Canadian, married. Available at once. Apply to Box 528-W.

ELECTRICAL ENGINEER, married, graduate of McGill University, desires position in Ottawa, Montreal or Toronto. Experience includes four summers with a building concern as instrumentman and assistant engineer, two and one-half years with the Canadian Westinghouse Co., this time being distributed between tests, design and sales. At present employed but available on short notice. Apply to Box No. 533-W.

ELECTRICAL ENGINEER, A.M.E.I.C., university graduate 1924. Experience includes one year test course and five years on design of induction motors with large manufacturer of electrical apparatus. Four summers as instrumentman on highway construction. Several years experience in accounting previous to attending university. Available at reasonable notice. Apply to Box No. 564-W.

CIVIL ENGINEER, B.Sc. McGill Univ., Jr.E.I.C. Five years experience along the lines of general construction, including structural steel. Available at once. Apply to Box No. 570-W.

MECHANICAL ENGINEER, A.M.E.I.C., experience in the design and maintenance of steel mills, zinc and sulphuric acid plants, cement plants; power house layouts; familiar with shop practices and costs, desires connection. Apply to Box No. 571-W.

YOUNG ENGINEER, Jr.E.I.C., experienced in design, details and erection of steel and concrete structures. Also a good theoretical and practical knowledge of steam, hydraulic and I.C. engine power plant. Good practical mechanical and electrical engineer, able to operate and maintain any type of machinery or power plant. Location immaterial. Apply to Box No. 572-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., (Univ. of B.C., '30), Undergraduate experience in pulp mill. One year's experience, Canadian General Electric Co., mech. dept. Single. Age 24. Desires position in technical design or sales. Location immaterial. Available on short notice. Apply to Box No. 577-W.

PARTNER. Full time engineering partner to establish welding firm. Must have business and structural steel experience, and be able to invest substantial amount in firm. Apply to Box No. 589-W.

MECHANICAL ENGINEER, S.E.I.C., age 21, four years mechanical engineering, Queen's University, desires permanent employment. Experience in wood work, machine shop work, draughting and surveying. Location immaterial. Available at once. Apply to Box No. 600-W.

MECHANICAL ENGINEER, Canadian, technically trained; eighteen years experience as foreman, superintendent and engineer in manufacturing, repair work of all kinds, maintenance and special machinery building, desires change. Location immaterial. Available on one month's notice. Apply to Box No. 601-W.

CHEMICAL ENGINEER, S.E.I.C., University of Alberta, '30, desires a position in any industry with chemical control. Experience includes three summer vacation periods of five months each as assistant chemist, and ten months as chief chemist with a cement company. Age 29. Single. Available at short notice. Apply to Box No. 609-W.

MECHANICAL ENGINEER, Jr.E.I.C., five years apprenticeship on general mechanical engineering; 10 years experience on heating and ventilating and mechanical equipment of buildings. Design, draughting and production. Desires change. Capable of taking charge of engineering department. Further particulars if required. Apply to Box No. 616-W.

POWER ENGINEER, M.E.I.C., age 42. Married. Thoroughly conversant with electrical, steam, mechanical and industrial engineering, desires executive position with large industrial, power or financial corporation. Best of references as to ability and positions held. Apply to Box No. 617-W.

CIVIL ENGINEER, Jr.E.I.C., B.A.Sc. '24, age 35, married. Five years designer and estimator with well-known firm of industrial builders; two years detailing, designing and estimating structural steel for bridges and buildings, also survey and municipal experience. Open for position immediately, will go anywhere. Apply to Box No. 618-W.

CIVIL AND MECHANICAL ENGINEER, experienced in design, layout, installation and selling. Sixteen years association with largest Canadian industries manufacturing equipment particularly relating to pulp, paper and lumber and five years design and construction of sulphite mill, including electrolytic bleachmaking from salt. Apply to Box No. 633-W.

ELECTRICAL ENGINEER, B.Sc. '26, Jr.E.I.C. Age 31. Experience includes one year operation and maintenance work in hydro-electric power plant. Three years on power plant construction work, consisting mostly of relay, meter, and remote control wiring. One year out-door sub-station construction, as assistant engineer. Also geological survey and highway construction experience. Desires position of any kind. Available at once. Apply to Box No. 636-W.

ELECTRICAL ENGINEER, B.Sc., N.S. Tech. Coll., '31. Experience includes geological survey work in Rouyn mining area and hydro-electric power plant construction, both civil and electrical work. Available at once. Apply to Box No. 639-W.

Situations Wanted

SALES ENGINEER, A.M.E.I.C., McGill '23. Past four years sales representative electrical power apparatus in Northern Ontario mining district, western Canada and with some sales experience in Montreal, Toronto, Ottawa and eastern Ontario. Two years electrical estimating and engineering on steel mill applications, mine hoists, elevators, pulp and paper drives, crushing and cement and other special applications. Two years design, engineering, test and some erection on steam turbines. Available short notice; location immaterial. Apply to Box No. 641-W.

ELECTRICAL GRADUATE, McGill '30, S.E.I.C., with thirteen months experience on General Electric test course, twelve months draughting and five months as instrumentman on power plant construction. Available September first. Location immaterial. Apply to Box No. 644-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), extensive experience as executive and in charge of construction of complete water power developments, including transmission lines, harbour developments, including hydraulic, dredging and land reclamation, industrial plants and municipal works. Apply to Box No. 647-W.

OPERATING ENGINEER. Position wanted as operating superintendent or assistant. Age 43. Married. No children. Nineteen years experience operating hydro-electric plants, sub-stations, transmission lines. Available immediately at any reasonable salary and for any location. Apply to Box No. 654-W.

ELECTRICAL ENGINEER, Jr.E.I.C., 1926 grad. of English Tech. Coll. Past two years inspector of communication apparatus; three years varied power and sub-station experience, including automatic sub-stations, on comprehensive training scheme. Age 24, single. Location immaterial. Available at once. References. Apply to Box No. 658-W.

ELECTRICAL ENGINEER, B.Sc.E.E., 1931. N.S. Tech. Coll. Experienced in armature winding and apparatus repairs, in conduit and cable work. Students' course in elevator manufacture, ship's electrician on tropical run. Good cultural education. Available at once, for Canada or tropics. Apply to Box No. 659-W.

ELECTRICAL ENGINEER, university graduate '28. Experience includes one year with operating department of a large public utility and two years with manufacturer of electrical equipment, work including design, test and correspondence. Available on short notice. Apply to Box No. 660-W.

MECHANICAL ENGINEER. Age 26, university graduate. Experience in machine shop and foundry productions and cost control, and considerable experience with arc welding. Interested in sales engineering. First-class references. Available at once for any location. Apply to Box No. 664-W.

ELECTRICAL ENGINEER, B.Sc., S.E.I.C. Experience: Installation staff Can. Gen. Elect.; students test course with the same company, concrete inspection, transmission line surveying and inspection, also some railway construction experience. References. Desires position with electrical concern. Location immaterial. Available at once. Apply to Box No. 665-W.

RADIO ENGINEER, with thorough general experience covering short wave, marine, broadcast, wire communication, and sound picture work. Capable of taking responsibility in engineering, operating, manufacturing or executive fields. University graduate; single; age 27. Apply to Box No. 667-W.

MECHANICAL ENGINEER, desires position with manufacturing or other company offering opportunity in design and draughting. Thorough technical training and four years experience since graduation. Prefer western Canada, but location and salary of secondary importance. Age 29, unmarried, thoroughly reliable and capable of handling junior position of responsibility or taking charge of technical work for small concern. Apply to Box No. 669-W.

ELECTRICAL ENGINEER, B.Sc., McGill Univ. '23, Jr.E.I.C. Eight years experience as sales engineer in all classes of electrical machinery, also switching, mine hoists, steam and hydraulic turbine generator sets, street railway and railroad equipment. Good commercial experience. Highest references. Age 30. Single. Available immediately. Apply to Box No. 670-W.

CIVIL ENGINEER, graduate University of New Brunswick '31, in C.E. Experience consists of three seasons on a survey party. Available October 1st. Desires permanent position. Willing to go anywhere. Apply to Box No. 672-W.

MECHANICAL ENGINEER, A.M.E.I.C., Canadian, technically trained; six years drawing office. Office experience, including general design and plant layout. Also two years general shop work, including machine, pattern and foundry experience, desires position with industrial firm in capacity of production engineer or estimator. Available on short notice. Apply to Box No. 676-W.

CIVIL ENGINEER, graduate, Jr.E.I.C., age 25, single. Experience includes mill construction, design and supervision. Also design of hydraulic features, bridge foundation, rigid frames and caissons. Will go anywhere. Apply to Box No. 677-W.

RADIO ENGINEER. Graduate McGill Applied Science '30. Experience includes the design, development and production of broadcast receivers, as well as general radio laboratory practice. Apply to Box No. 680-W.

ELECTRICAL ENGINEER, graduated 1914, desires position with engineering firm or electric utility. Experience in design and layout of power houses and sub-stations, including automatic and supervisory control equipment; design of switchboards and switching equipment; manufacturing, testing, erection and operating of electrical apparatus of all kinds. Anywhere in Canada. Permanent position preferred. Apply to Box No. 681-W.

OPERATING ENGINEER, A.M.E.I.C. Operating superintendent or assistant. Age 44, married. Twenty years experience in industrial manufacturing, steel mills, power plants and quarrying operations, both large and small. Very successful with labour problems, cost accounting, etc. Will take any position with view to betterment. Available immediately in any location. Apply to Box No. 682-W.

ELECTRICAL ENGINEER, B.Sc.E.E., Univer. of Man. 1921, A.M.E.I.C., married. Two years Westinghouse test course, three years sales engineer, five years draughting and electrical design on hydro plants, transmission lines, etc. Apply Box No. 687-W.

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available on short notice. Apply to Box No. 692-W.

Electrification of Canadian Copper Refiners Plant, Montreal East, Que.

A. D. Ross, A.M.E.I.C.,

Manager, Canadian Comstock Company, Ltd., Montreal.

Paper presented before the Montreal Branch of The Engineering Institute of Canada, October 22nd, 1931.

SUMMARY.—This paper deals with some of the important problems in electrical design which arose in connection with the installation of an electrolytic copper refinery having a capacity of 75,000 tons per year. It includes a general account of the buildings, equipment and the process carried out, and discusses in some detail the design and construction of the electrical equipment, particularly with reference to the bus bar system which is unusually heavy and extensive. Its construction required the solution of a number of special problems. Precautions had to be taken to ensure absolute continuity of supply and adequate protection for the power system.

The completion of the Canadian Copper Refiners plant at Montreal East definitely places Canada in the position of an exporter of electrolytically refined copper, as well as the world's third largest producer.

The plant has a capacity of 75,000 tons per year, and is of particular interest to the electrical engineering profession, since it is completely electrified and the product is largely consumed in the electrical industry. It is situated on the Canadian National Railway, near the St. Lawrence river, and is favourably located in regard to power, labour and shipping facilities. A considerable portion of the product is taken by the Canada Wire and Cable Company, who have built a rod mill and cable plant adjacent to the refinery.

The refinery is designed to receive blister copper from the smelter and ship refined copper as wire bars or ingots. Provision is also made for reclaiming precious metals contained in the blister copper.

Before proceeding with a description of the plant, it may be of interest to give a few particulars in regard to the fundamental principles of electrically refining copper. The process is very simple. If two plates of copper are placed near each other in a solution of copper sulphate and sulphuric acid, and direct current made to flow from one plate called the *anode* to the other called the *cathode*, it will be found that the anode is eaten away while pure copper is plated on the cathode. In the refinery, the anode consists of blister copper, and a thin sheet of pure copper forms the cathode. Under the action of the current, the copper sulphate may be considered to break up into Cu ions and SO_4 ions. The Cu ions are attracted to the cathode and deposited, while the SO_4 ion migrates to the anode where copper becomes ionized in equivalent amount. The less active metals and impurities are not ionized in the presence of the more active copper, and fall to the bottom, as sludge.

At the plant under discussion, the cycle of operations consists of weighing and sampling the blister copper, casting the blister into anodes, refining the anodes into pure cathodes, casting the cathodes into wire bars, purification of the electrolyte, and treatment of the slimes to obtain the precious metals. This process is carried on in a building 1,000 feet long, of one-storey construction, with a basement under the tank house.

Many interesting problems were solved in the design and construction of the electrical plant, caused principally by the following:

1. Necessity for continuous operation throughout the year.
2. High cost of shutdowns through failure of any part of the plant.
3. The presence of acid fumes in certain parts of the refinery.
4. Massive size and length of bus bars.

An economic study was made in the design of each constituent part, so that the cost would be a minimum consistent with all factors involved.

Tank House

The tank house where actual refining is carried on, is 660 feet long and 120 feet wide, contains forty-eight commercial tanks for electrolytic refining and four stripper tanks for making starting sheets. Each tank is divided into nine cells, making a total of four hundred and thirty-two commercial cells and thirty-six stripper cells. Each commercial cell is 16 feet 7 inches by 3 feet 7½ inches and 4 feet 1½ inches deep, and is lined with sheet lead.

The tanks are built of monolithic concrete with 5-inch walls, each mounted on twenty concrete columns. The tanks are separated from the floor on all sides by an air space and insulated from ground by column cappings consisting of a glass plate 1½ inches thick, and a rubber sheet. Wooden launders, lined with sheet lead, are provided in the basement beneath the tanks to convey the slimes to tanks in the basement floor.

The electrolyte is conveyed to and from the tanks by lead pipes. The feed and return pipes are connected to the cells by rubber tubes to prevent loss of current through

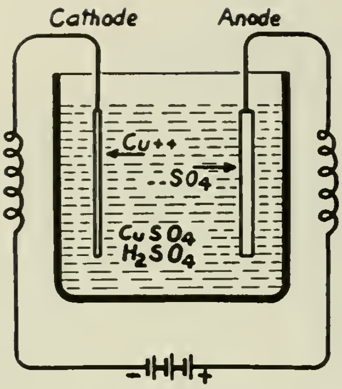

Fig. 1—Simple Electrolytic Cell.

the solution lines, which would also cause copper to deposit in the pipes. This electrolyte consists of a solution of copper sulphate and sulphuric acid, maintained at a temperature of 140 degrees F. and circulated continuously.

Each cell is charged with forty-two anodes of blister copper weighing 700 pounds each, and forty-three starting sheets. A current density of about 17 amperes per square foot of anode surface is maintained, and when the cathodes reach a weight of about 200 pounds, they are removed and new starting sheets put in. The anodes last approximately thirty-five days and about three cathodes are made from each anode. After being washed in an automatic washing machine, to remove the electrolyte, the cathodes are sent to the cathode furnace to be cast into wire bars or ingots.

The starting sheets are made in the thirty-six stripper cells by depositing copper on specially treated starting blanks. The deposit reaches a thickness of about 1/30 inch in twenty-four hours, after which it is stripped from the blank cathode, trimmed and attached to a conducting bar for use in the commercial section.

The fifty-two tanks are connected in series, but the nine cells of each tank form a series-parallel connection. The bus current of 15,000 amperes flows into each cell through the forty-two anodes and out at the other side through the forty-three cathodes. The cathodes of one cell make contact with the anodes of the next, so that while the cells are in series with each other there are forty-two paths through the nine cells of each tank.

A small test switchboard with a mimic bus representing the tank circuit is installed near the foreman's office. A wire from each side of each tank is so connected to contacts on this switchboard that the voltage across any tank can be read by means of a voltmeter.

A pump bay extending along one side of the tank-house contains solution pumps, storage tanks and miscellaneous equipment required for the handling and control of the electrolyte.

Casting Building

The blister copper received at the plant is melted in a reverberatory oil-fired furnace for casting into anodes. The molten copper from this furnace is run into copper moulds set on the periphery of a casting wheel 39 feet in diameter.

The cathodes of pure copper are melted in a similar furnace and cast into ingots or wire bars in copper moulds set on a wheel with a diameter of 44 feet. The wire bar or ingot when solidified is automatically dumped from the mould into a Bosch conveyor tank containing water, and conveyed to the inspection platform before going to the shipping bay.

The casting wheels are motor-driven and each is equipped with a motor tilted ladle. During the casting operation, liquid copper runs continuously from the furnace to the ladle which is tilted intermittently to fill the moulds as they pass in succession. The controls for the various operations are located in a control station where the operator and electrical equipment are protected from the intense heat.

Both furnaces are provided with waste heat boilers and the steam generated is used for heating the electrolyte in the tank house and for heating the buildings.

A Morgan charging machine operated by seven slip-ring motors and running on a special track is used for charging the furnaces with copper.

Power Requirements

The total power required is not large, but the continuity of supply is most exacting. The electrolytic process runs continuously twenty-four hours a day, each day of the year. Certain parts of the system would be seriously injured by a power interruption of over a few minutes and, for several reasons, serious loss would follow a protracted interruption. The largest load consists of the motor generators, which supply direct current to the electrolytic process. Power is also used for cranes, hoists, pumps, air compressors, furnace charging machines, casting wheels, machine shop, locomotive battery charging, lighting, etc. The total connected load is 5,830 h.p. in one hundred and seventy-two motors, ranging in size from ¼ to 980 h.p.

It may be of interest to note that, in a single electrolytic cell, 380 ampere-hours will deposit one pound of copper. An average figure for the energy consumed in the refining process is 290 kw.-hr. per ton of copper.

Power is supplied by the Montreal Light, Heat and Power Consolidated at 12,000 volts, 3-phase, 60 cycles, from two different substations, over two separate lines. One line is always used as a reserve, and can be instantly switched into service, in case of trouble on the other circuit.

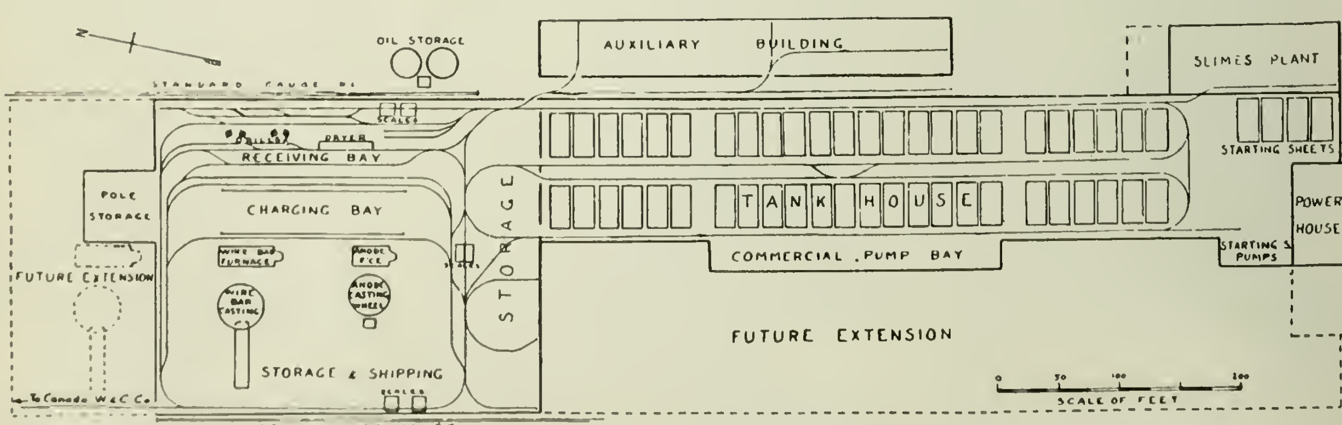

Fig. 2 General Arrangement of Plant.

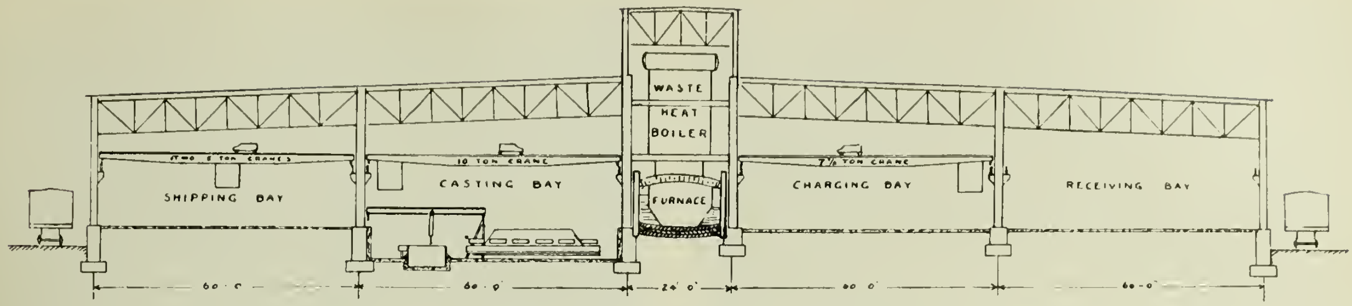

Fig. 3—Cross Section of Refinery.

Bus Bars

At each end of every tank is a massive copper bus bar, which is thought to be the largest ever used. These bus bars are of four different sizes and shapes, the largest being 17 inches wide, 3 inches thick and 19 feet long, and, when received from the rolling mill, weighed 3,500 pounds. These bars were cast at Laurel Hill, N.Y., rolled in Detroit, machined at Lachine, and hand finished at the site. (See fig. 8.)

The design and installation of the copper bus bars presented the most interesting problem connected with the electrification of the plant. Application of Kelvin's law involving power cost, copper resistance-loss and capital cost of copper, showed that a cross-section of 40 square inches was the most economical bus section to carry the normal current of 15,000 amperes. After this, the problem of jointing, heat dissipation, bending and installation required solution. The problem hinged around the fact that, at one hundred and four places in a bus 3,500 feet long, the section must consist of only one bar. While charts are readily available, showing the carrying capacity of smaller bus bars, the sizes of bars necessary for this installation were located on the charts far beyond the curves which dipped sharply toward that area representing high temperature and low capacity. A search for information indicated that little was known regarding the use of large bus bars or the best method of jointing in the larger sizes. It was therefore necessary to sift from available information all that would serve as a guide and complete the design from basic principles. Zest was added to the problem by the large amount of copper involved and the fact that the plant would be tied up by a failure of any part of the bus system. (See fig. 9.)

The bus was finally designed to consist of eight 10-inch by ½-inch copper bars, spaced ½ inch apart, in parallel on the main runs, two 10-inch by 2-inch U-connector bars, and one 10-inch by 3-inch connection between tank bars.

Lap joints were adopted in all cases, and the lap was made as short as possible, resulting in the saving of copper and, owing to the method of installation, in producing an extremely efficient joint.

Bars ½-inch thick came from the rolling mill with a good finish and required only draw filing with emery cloth to remove oxide before installation. The 2-inch and 3-inch bars were planed and scraped, since commercial rolling did not produce the even surface required. All joints were bolted under a pressure of approximately 2,000 pounds per square inch. High tensile steel bolts were used to reduce the size of section required for bolt holes, and the bolt pressure was evenly distributed by thick, flat washers. All joints were assembled with the surfaces covered with vaseline. The bolts were stressed so that changes of temperature would not cause loadings beyond the elastic limit. This design has proved relatively cheap in first cost and the maintenance has been nil. After eight months service, each joint has proved to have less resistance than an equal length of solid bus.

The current is transmitted from bus to anode and from cathode to bus, through knife-edge contacts. These contacts consist of triangular sections arc-welded to the 3-inch bus bars. About 4,000 lineal feet of arc-welding was required. A neat and very satisfactory joint was obtained. So far as the writer can determine, this was the first time copper had been arc-welded for carrying currents of any magnitude.

No expansion joints were used, although straight runs of bus as great as 500 feet were installed. Each end of each bus was connected to the tank bar through a 90-degree horizontal angle, as well as a 90-degree vertical angle. The horizontal runs were suspended by strain insulators and swivels, so that the bus was given perfect freedom of motion in the horizontal plane. This freedom of motion, together with the bends at each end, relieved all expansion strains. (See fig. 4.)

The bus weighs 160 pounds per lineal foot, and was suspended at 10-foot intervals from I-beams cast in the concrete floor beams. A very simple and efficient bus hanger was designed, consisting of slotted pitch-pine blocks

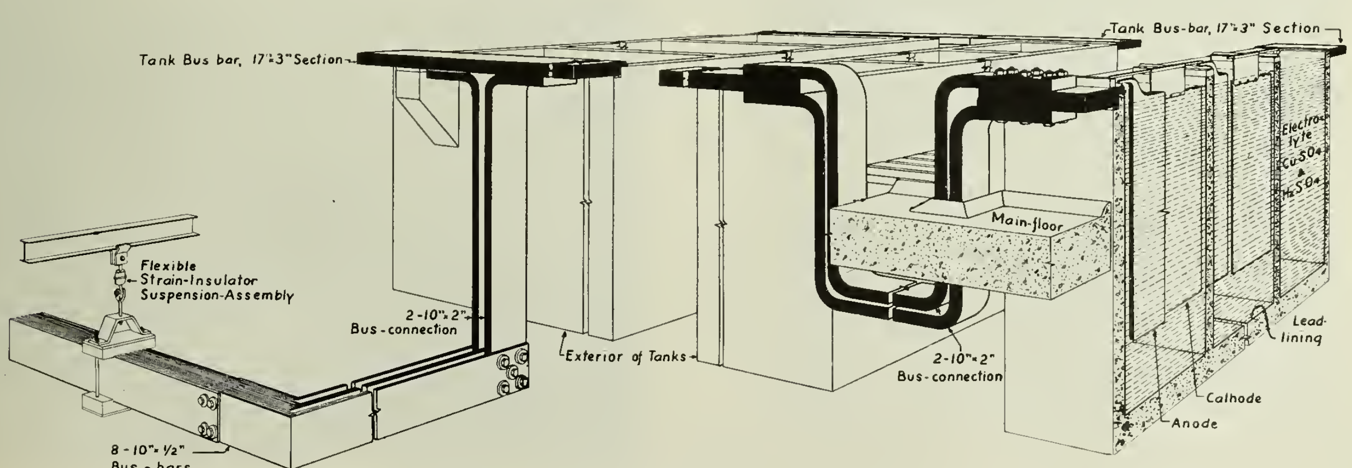

Fig. 4—Section Through Electrolytic Tanks.

placed above and below the bus and clamped by flat steel members and through-bolts. These blocks served as spacers to separate the laminations, as well as to prevent electrolysis between the copper and steel, should acid be present. Supported in this manner, the bus formed a continuous beam which offered considerable resistance to bending. Since lengths up to 500 feet were necessary, it was recognized that a dangerous situation would arise if local settling of the building columns should occur. However, the strength of the strain insulators gave a factor of safety of 12 in respect to the weight of the bus, and it was decided this safety factor, together with an occasional inspection during the first few months to see that all hangers were under strain, would solve the situation. (See fig. 9.)

An interesting problem in the design of the bus was to calculate the loading capacity of the 500-foot section when considered as a column, to determine the possibility of buckling when the expansion force would be opposed by the stiffness of the two right angle end connections. The bus must be regarded as a composite column of eight laminations bolted together every 20 feet and the end connections are also laminated and bolted near the angles.

The 10-inch by ½-inch sections were received in 20-foot lengths weighing 400 pounds each, and were drilled in sets of eight clamped together, by two radial drills set

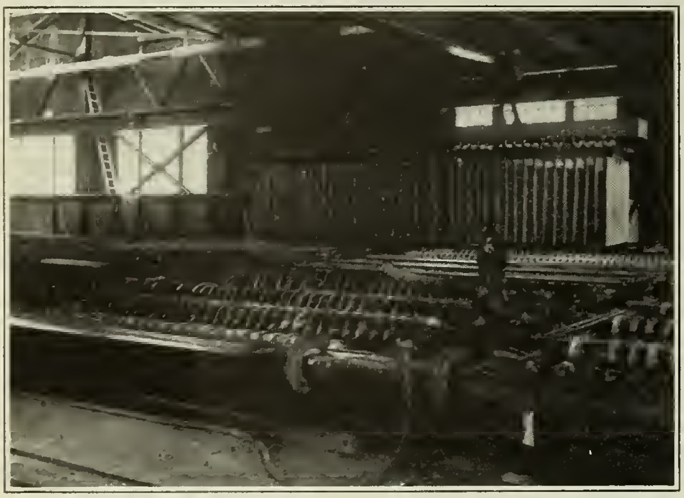

Fig. 5—Method of Removing Cathode with Tanks Short Circuited.

twenty feet apart. Methodical identification and routing of bars facilitated assembly.

The large bars installed on the tanks were insulated by means of ⅜-inch sheet-fibre set in asphalt and pitch. This proved very effective, since the voltage in each tank was of the magnitude of 2.5 volts only.

About 300 tons of copper was required for the bus bar system, and this was ordered cut to length in the various cross sections required, before the building was erected. It is interesting to note that only 500 pounds remained as scrap, exclusive of drillings and planings, after the bus was assembled.

Outdoor Substation

A study of the relative advantages of indoor and outdoor transformer stations showed that the outdoor system should be adopted. This system proved much lower in cost and permitted flexibility for future expansion, at the same time making possible a very convenient arrangement of the power house.

A single line diagram of the switching and circuit arrangement is shown in fig. 6.

The two incoming 12,000-volt transmission lines, consisting of No. 4/0 stranded cable, are dead ended at the outdoor substation on an A-frame structure. This structure

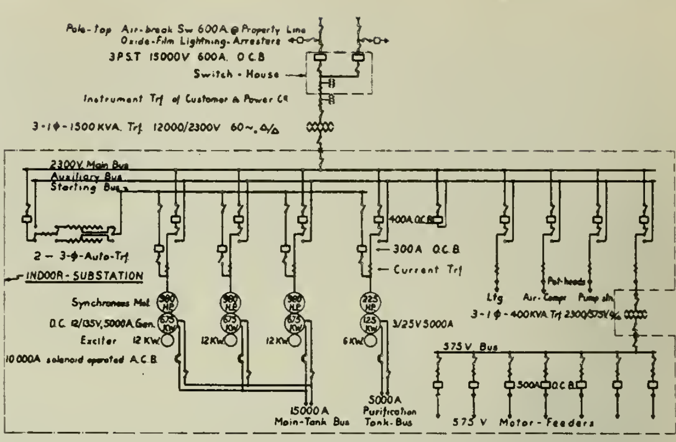

Fig. 6—Diagram of Switching and Circuit Arrangement.

also carries two 600-ampere, 3-pole, gang operated disconnecting switches, as well as two sets of oxide film lightning arresters with single pole disconnecting switches. Two 15,000-volt, 600-ampere oil circuit breakers, with a rupturing capacity of 6,600 amperes, at 12,000 volts, serve for main line switching and transformer protection. These circuit breakers, mounted in an outdoor switch house, are electrically interlocked and controlled from the power house switchboard. Provision is made to prevent operation of the line disconnecting switches, while the circuit breakers are closed, by means of a simple interlock system.

The primary transformer bank consists of three 1,500-kv.-a., single-phase, 12,000/2,300-volt, o.i.s.c. power transformers, fitted with externally operated ratio adjusters and conservator tanks. A bank of three 400 kv.-a., 2,300/575-volt, o.i.s.c. transformers is used for the 550 volt supply. Both transformer banks are connected delta-delta, and disconnecting switches are installed on both primary and secondary sides of all transformers. This permits a quick change to open delta operation, in case of failure of any transformer. Power is carried overhead from the substation to the main 2,300-volt and 550-volt bus in the power house, by 1,300,000 cir. mil cable.

The A-frame and bus structures are built of angle iron framing arc-welded together on the site. All insulators have porcelain designed for 33,000 volts to prevent flashovers owing to gas, smoke and other air impurities present in the district.

Power House

The power house, located adjacent to the tank house, contains control switchboard, switching equipment, motor generator set, storage battery and auxiliary equipment.

Fig. 7—Wire Bar Casting Wheel.

Fig. 8—General View of Tank House Showing Method of Splicing Bus Bar.

The building is of solid brick construction, with dimensions of 80 feet by 45 feet, is 33 feet high, with basement, and provides ample space for the convenient arrangement of equipment. Ventilation is provided by adjustable louvres admitting cool air to the main floor and basement, while the heated air is discharged through roof ventilators.

Three synchronous motor generator sets, consisting of 675-kw., 135-12 volts, 5,000-ampere, direct-current generators driven by 980-h.p., 760-kv.a. unity power factor, 3-phase, 60-cycle, 2,300-volt motors and each having 12 kw., 125-volt direct connected exciters, operating in parallel, supply 15,000 amperes to the main electrolytic circuit. Another set consisting of 125 kw., 25-3-volt, 5,000-ampere direct-current generator driven by a 225-h.p., 180-kv.-a. unity power factor 2,300-volt synchronous motor and having a 6-kw., 125-volt direct connected exciter, is used for the purification circuit. These sets are mounted at main floor level but on foundations separate from the building. The synchronous motors are sufficient to bring the plant power factor well beyond the limits set by the penalty clause of the power contract.

The switching equipment consists of a 2,300-volt switch structure for controlling the synchronous motors and 2,300-volt feeders, and a 550-volt switch structure for the 550-volt feeders. The 2,300-volt oil circuit breakers have a rupturing capacity of 27,000 amperes at 2,500 volts, while the 550-volt circuit breakers have a rupturing capacity of 25,000 amperes at 750 volts. The 2,300-volt switch structure containing the electrically controlled circuit breakers and the necessary disconnecting switches is mounted on the main floor. The 550-volt structure with manually operated circuit breakers is installed in the basement, directly beneath the switchboard on which are mounted the operating handles. Each generator circuit is provided with a 10,000-ampere air circuit breaker mounted in the basement and conveniently arranged for connection in the bus system. (See fig. 11.)

The control switchboard is made of ebony asbestos lumber with iron pipe frame work and space is saved by mounting all main line voltmeters, ammeters, power factor meter, as well as a common exciter voltmeter, on a swinging bracket. The 12,000-volt incoming power and power factor is measured by a polyphase watthour meter, a polyphase watthour meter connected to read reactive energy, and a graphic wattmeter with peak load alarm.

A concrete wiring trough is constructed in the floor, immediately behind the board for the arrangement of control cables.

Overload protection consists of induction type inverse time relays on 2,300-volt circuit breakers, dash-pot type inverse time relays on 550-volt circuit breakers, and instantaneous relays on the 10,000-ampere direct-current air circuit breakers. The latter are also equipped with reverse current relays.

Auto transformers are installed for starting the synchronous motors. A considerable saving in the cost of the starting equipment has been effected by using low rupturing capacity circuit breakers, which function only as oil immersed disconnecting switches, and do not open or close under load. They are electrically interlocked, so as to be fully protected by the circuit breaker which energizes the auto transformer.

Since the 2,300-volt circuit breakers are in continuous service, an auxiliary bus and disconnecting switches were installed, so that any 2,300-volt circuit can be connected directly to this bus. This bus is fed through an auxiliary circuit breaker. The purpose of this auxiliary bus and circuit breaker is to provide rapid and complete substitution for any main circuit breaker taken out of service for inspection, or in case of failure. This auxiliary circuit breaker is not furnished with any form of control or protection directly. When it is desired to substitute this breaker for any other, it is simply necessary to operate a Yale lock switch on the panel controlling the faulty breaker, after which the control and protective system of the faulty circuit breaker will apply to the auxiliary circuit breaker.

A 60-cell storage battery with a rating of 35 amperes for eight hours is installed in the basement. It provides energy for closing and tripping circuit breakers for pilot lights and for the emergency lighting system.

Duplicate motor generator sets rated 7½ kw. each are used for charging the battery. The charging equipment is automatic in operation, except that charging must be manually started.

Motors and Control

The motors are standard induction type, with acid-proof windings and ball or roller bearings. Motors rated

Fig. 9—View of Main Bus Bar Showing eight 10 by ½ inch Bars in Parallel.

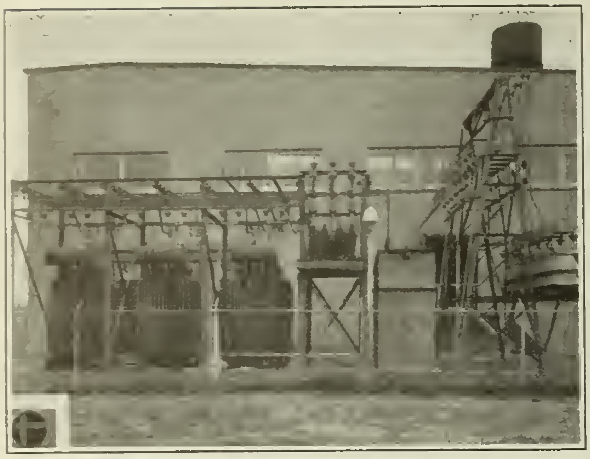

Fig. 10—Outdoor Sub-Station.

50-h.p. and under operate at 550-volt, 3-phase, while larger motors operate at 2,200 volts. Squirrel cage motors of 50 h.p. and smaller are started by application of full voltage.

All 550-volt motors are controlled and protected by magnetic type starters with thermal overload relays. Standard fused safety type switches protect all motor circuits. Both motor starters and safety switches are placed on power distribution racks and the motor starter push button near the motor. This arrangement eliminated the necessity for an extra safety switch per motor. The secondary control of slip ring motors consists of standard resistors and drum controllers. The 2,200-volt motors are protected and controlled by starting compensators and disconnecting switches.

Motor starters and safety switches were selected with the maximum clearance between parts of opposite polarity to prevent short circuits that are liable to occur when dust, acid fumes and moisture are present. Since fuses in the motor circuits are used only for short circuit protection, a make of fuse giving a long time delay was selected to prevent blowing fuses when starting motors.

Fig. 11—Method of Connecting 10,000-ampere Air Circuit Breaker in the Circuit.

All cranes are equipped with face plate controllers, placed on the crane bridge above the cab and operated by vertical levers. This arrangement gives the operator the clear field of vision so important for the work required.

Power Distribution

Electric power was carried from the power house to distribution centres throughout the plant by means of paper insulated, lead covered cable, in rigid iron conduit. The use of this type of cable proved lower in first cost than braided cable, while the lead sheath insured against deterioration from acid fumes.

Braided cable of 30 per cent para rubber was generally used for motor feeders, since the Canadian Code requirements, combined with the high cost of lead covered cables when used on short runs with numerous bends, made lead covered cable more costly than several replacements of braided cable.

At certain locations in the casting building, cables are subjected to high temperatures, wide ranges of temperature, and high moisture content. In these locations, rubber insulated, lead sheathed cables were used, to meet these trying conditions.

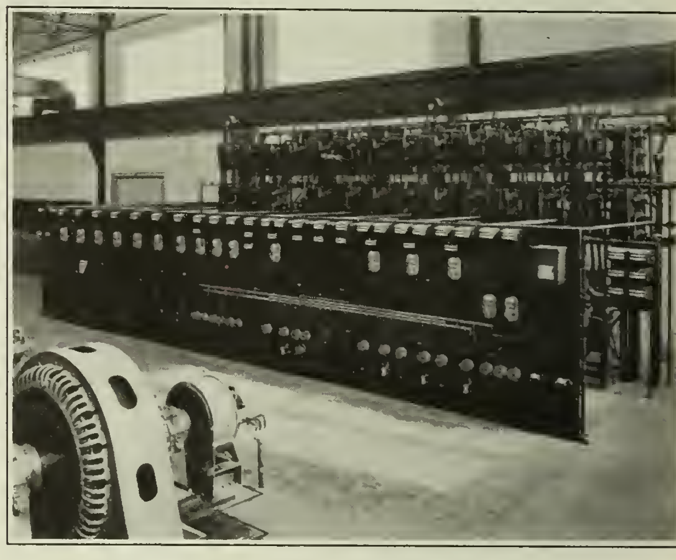

Fig. 12—Main Control Board.

The 550-volt distribution centres consist of sheet steel boxes in which the feeder cables are carried by insulators to form a three-phase bus. Taps from this bus extend to the safety switches and starters which are mounted beneath the box on iron pipe frame work with flat iron cross members. This arrangement of distribution centres proved low in installation cost and economical of floor space, since each rack carries protective and starting equipment for one motor per foot of length of rack.

All cables are carried in rigid metal conduit painted with acid-proof paint and cast iron condulets were used for all fittings. Condulets were fitted with special acid-resisting gaskets and all cable joints were painted with acid-resisting varnish to prevent electrolytic action between the solder and the copper.

Plant Lighting

The lights operate at 110 volts from 110/220-volt, 3-wire panels. In general, all branch circuits are switched at the panels. Special acid-proof lighting cabinets were installed in the tank house. Power for lighting is distributed through the plant by a 2,300-volt, 3-phase, cable, which feeds five lighting transformers. Each transformer is located near its load centre and the secondary current is distributed to the lighting cabinets through safety switches located near each transformer.

It was realized that lighting fixtures would be subjected to the action of acid fumes, but acid-proof fixtures were very expensive and the action of the acid in etching the glass would decrease the efficiency. It was therefore decided to use standard R.L.M. reflectors, which could be cheaply replaced when necessary. Simple one-piece reflectors were selected, and chipping of enamel was replaced by acid-proof paint after installation. This solution has proved satisfactory, and it appears that the reflectors will last for many years.

An emergency lighting system fed by the power house storage battery is arranged to automatically go into service in the event of failure of the a.c. supply. The emergency lights are located as needed throughout the plant and can be turned off as conditions permit, by means of local switches. The emergency lighting cabinet is located in the power house and the operator can control the rate of battery discharge by opening the branch switches, should any department not reduce its emergency load within a scheduled time.

Purification of Electrolyte

In electrolytic refining, most impurities present in the blister copper anode find their way to the bottom of the cells as anode slime. Some of these impurities dissolve in the electrolyte and must be removed to assist in making a pure cathode. To purify the electrolyte, a certain portion is diverted to a set of tanks provided with insoluble anodes of lead, where the impurities are plated out and the acid returned to the circuit. A cascade system of cells is used for this purpose, and direct current is supplied from a 3-25-volt, 5,000-ampere, direct-current generator, through a bus of six 3/8-inch by 6-inch copper bars.

Slimes Plant

Since the copper being refined at the plant is of high gold and silver content, the treatment of the slimes is of great commercial importance. The sludge which is collected in the sump tanks in the tank house is pumped to the slimes plant. Here it passes in order through a thickener, filter and roaster. The roasted material is then leached, filtered, dried and finally fluxed in a dore furnace. The resulting alloy of gold and silver is cast into anodes and parted into gold and silver in electrolytic cells. This electrolytic process consists of five earthenware cells with cathodes of silver and the silver drops to the bottom of the tank in crystaline form. The anodes are enclosed in sacks to retain the gold. Power is supplied from a direct-current generator rated 7.5 kw.-7.5 volts, 1,000 amperes, with direct-connected exciter rated 1¼ kw.-125 volts, both of which are driven by a 10-h.p. induction motor.

The flue dust from the furnaces and roasters contains high gold and silver values. This dust is recovered by settling chambers, scrubbing towers and a Cottrell precipitator.

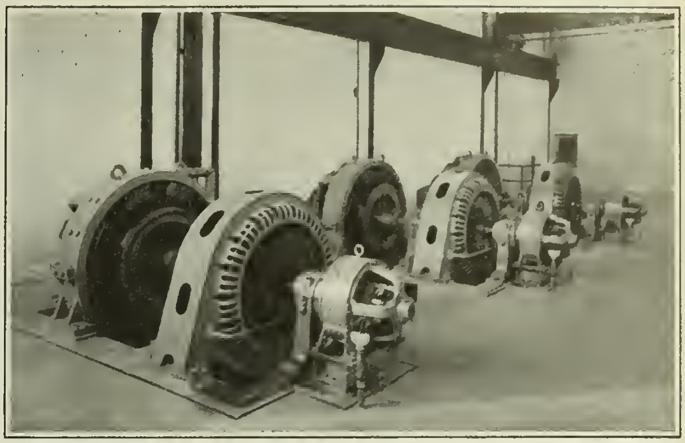

Fig. 13—Motor Generator Sets Supplying Current to Refining Circuit.

Miscellaneous

A well-equipped laboratory is located in the main office building near the refinery. Part of the work carried on there consists of assaying the blister copper received at the plant, to determine the copper and precious metal content. Forming part of the laboratory equipment is a miniature electrolytic refining plant, complete with motor generator and switchboard. This miniature plant is used exclusively for testing purposes.

Two storage battery type locomotives running on narrow gauge tracks are used to handle material in the plant. Each locomotive has a rated drawbar effort of 4,000 pounds and is provided with dynamic braking and series-parallel control. As the locomotives are in constant use during the day, two automatic battery charging sets are provided for night charging. This arrangement of charging equipment ensures against uncharged batteries, if one charging set should give trouble.

An air compressor plant containing four reciprocating compressors driven by two 150-h.p. and two 125-h.p. motors provides compressed air for hoists and furnaces.

A pumping plant installed at the St. Lawrence river, about one-half mile from the refinery, provides an adequate water supply. Two centrifugal pumps driven by one 250-h.p. motor and one 125-h.p. motor are used. This pumping plant is supplied with 2,300-volt power from the power house, by means of a wood pole transmission line.

A twenty-five-station automatic telephone system provides communication throughout the plant, and extends to the river pumping station.

A well-equipped machine shop, with individual motor-driven tools, is provided for plant maintenance and repairs.

The refinery was designed and erected by the Nichols Copper Company, Laurel Hill, N.Y., who operate it for the owners.

The complete electrical system was installed by the Canadian Comstock Company, Ltd.

The writer is deeply indebted to the late Mr. Frank R. Corwin, of the Nichols Copper Company, and to the works manager and staff of the Canadian Copper Refiners, for their advice and suggestions.

Arc Welding of High Conductivity Joints in Copper

T. C. Stuart,
Dominion Engineering Welding Company Ltd., Montreal.

Steel, on account of its low cost, its natural higher physical properties and its scope of application, has long since displaced copper and its alloys as the medium in which man fashions the products of his mechanical mind. This, no doubt, accounts for the fact that the development of the joining of pure copper by welding has lagged behind that of steel.

At the present time, there are many ways of making connections between copper parts. Difficulties arise, however, when the sections are heavy, or where the equipment is subject to the attack of corrosive elements which cause either the formation of an insulating film of salts between the joined parts or the disintegration of the bonding material by chemical or electrolytic action. There seems little doubt, however, that research leading to a satisfactory method of joining copper parts by means of a positive, pure copper joint would, in many cases, be rewarded by an increase in the efficiency of apparatus and equipment in the electrical field in which this material plays such an important part.

An interesting example illustrating the necessity for a joint such as is described above is found in the manufacture of the bus bars which flank the batteries of tanks in a copper refinery and make electrical connection with the anode plates at one side and the cathode plates on the other. In normal production, the busses carry a comparatively high amperage current (15,000 amperes) at low voltage (about 100 volts), with a current density of 375 amperes per square inch, so that any fault in the circuit tending to increase electrical resistance figures largely in the cost of production.

In an endeavour to cut these losses to a minimum and to reduce maintenance costs on the joints in the bus bars to be used in their new Canadian plant, the Canadian Copper Refiners Limited decided to adopt a welded joint, as described below and illustrated in Fig. 1, providing it could be shown that such a joint could be made to comply with conductivity requirements.

Considerable research on welded connections was carried out by the Dominion Welding Engineering Company Limited in collaboration with the Canadian Comstock Company, which company held the contract for the installation of the electrical equipment. This research showed that such a joint was obtainable and consequently welding was decided upon.

The bus bars as designed for this plant consist of two parts,—the heavy current carrying bus with a cross section of approximately 13½ inches by 3 inches, and 18 to 19 feet long and an equilateral triangular strip of a little over one half square inch in cross sectional area, extending almost the full length of the bar and welded to it on the sharp edge on which rest the lugs of the plates suspended in the electrolyte, each bus weighing about 2,800 pounds. The problem was therefore one of welding continuously a light strip of copper to an exceptionally heavy one and since the bars run very close to the edge of the tanks, it was of vital importance that the joint be made of material which would not be affected by the corrosive action of the copper sulphate solution.

In order to decide on the welding procedure qualified to produce the most satisfactory results, it was necessary to run a series of preliminary tests. Triangular copper bars were machined from solid material similar to that which was ultimately to be used and welded in a number of different ways to a heavy section of copper corresponding to the bus bar. Two inch long sections of the welded bars were next parted off ready for testing. On account of the increased current density towards the apex of the triangular strip, it was thought advisable to measure the voltage drop across the joint between two points not further apart than would give a readable value on the instruments available, when comparing a similar section of pure copper. This minimum distance was found to be half an inch and points half an inch apart and straddling the joint line were marked for tapping.

Two distinct types of joint were investigated; the first was made by sweating the bars together using a spelter or silver solder; the second by depositing beads on each side of the triangular strip to form a current carrying fillet between the strip and the bar. It was found that while the first method produced a joint of neat appearance and comparatively high electrical conductivity, it had three distinct disadvantages:—

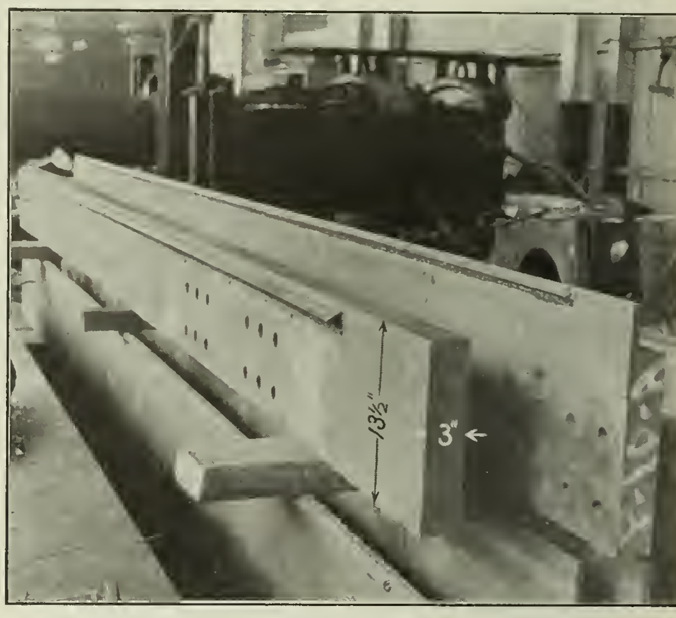

Fig. 1—Two Bus Bars on which Triangular Strips have been Welded.

(*a*) The cost of raising the temperature of the heavy section to the melting point of silver solder would be high.
(*b*) It was probable that the lower melting point spelters with their zinc content would be affected electrolytically by the refining solution.
(*c*) It was impossible to guarantee perfect "tinning" over the whole area of contact, and this type of joint precludes inspection.

Chiefly on account of easy inspection the second method was adopted and tests were next run on pure copper as a filler material and a phosphor copper welding rod produced by the Westinghouse Electric Manufacturing Company. Excellent results were obtained with the pure copper, showing that a joint of 95 per cent to 100 per cent conductivity efficiency could be made with this material. However, owing to a time limit for delivery, it was considered advisable to use the latter material as a filler because of its faster flowing qualities at somewhat lower temperatures giving a weld of adequate conductivity and neat appearance.

During the investigation outlined above, both the electric arc and the oxy-acetylene methods were tried. It had not been anticipated that the former method of welding would be applicable to such heavy sections and as far as is known to the writer, no data pertaining to the arc welding of such masses of copper existed at the time this work was carried out. Results, however, proved the contrary, and not only was this method found feasible but it was adopted, due consideration being given to the speed of arc welding and the lessening of the physical discomfort of operators working close to highly preheated material.

To assemble the bars for welding, special clamps, heavy enough to stand up to the high temperatures encountered, were made. It was also found necessary to protect the apex of the triangular strip from arc splashes and to this end a cold rolled steel bar was slotted to fit over it for its full length. The clamps spaced about twelve inches apart operated on the steel bar and held the whole assembly rigid.

The preheating was carried out in a furnace specially designed for the job and was arranged so that two bars could be heated simultaneously. Because of the liquid qualities of the weld metal, it was found necessary to make provision for rotating the bars about their longitudinal axes through an angle of thirty degrees from the horizontal position in both directions so as to form troughs between the sides of the triangular strip and the bus bar in order to retain the molten weld metal immediately after deposition from the filler rod.

This was accomplished by setting the bars on steel frames pivoted on the main structure of the furnace, which frames also served to support the bars should they tend to sag at the elevated temperatures. In a period of about three weeks, one hundred and four bus bars weighing over one hundred and twenty tons were handled.

After removal from the furnace and after cooling, the bus bars were rigidly inspected for thorough fusion, only the first four bars being rejected. After cleaning, all the bars were straightened, weighed and shipped.

Montreal Incinerators

H. A. Gibeau, A.M.E.I.C.,

Assistant to Director of Public Works of the city of Montreal.

Paper presented before the Montreal Branch of The Engineering Institute of Canada, April 16th, 1931.

SUMMARY.—After a brief discussion of the general problem of refuse disposal, and the system adopted in the city of Montreal, the paper describes the buildings and equipment of the incinerator recently constructed to serve the Northern Zone of the city, in which the rubbish is dried and burnt in cells provided with forced draught and preheated air supply. Details of the operation of the plant are given, together with the results of the acceptance tests during which the guaranteed performance was considerably exceeded.

Municipal engineers are called upon to solve problems in diversified branches of engineering and one of these, the problem of refuse collection and disposal in an efficient and sanitary manner, is not always easy of satisfactory solution, particularly when the public of a rapidly developing city has to be considered.

The growth of the city of Montreal has been phenomenal. Its population numbering 270,000 inhabitants in 1900 has more than tripled in thirty years and has been estimated at 900,000 in 1930. The realty value, in 1900 amounting to $185,228,477, in 1930 increased to $1,245,-734,559 or more than six times that of 1900.

The area of the city of Montreal is 50.24 square miles, and the area of the island of Montreal is 194 square miles.

The past growth of Montreal foretells what municipal engineers must foresee when solving their problems and in planning for the future. Therefore in the case of refuse disposal in the city of Montreal it was evident that methods other than that of dumping had to be resorted to.

This problem of refuse disposal may be divided into four parts:

1. The house treatment of refuse.
2. Collection.
3. Transportation.
4. Final disposal.

House treatment includes the preparation of the refuse in general and the separation of ashes and incombustibles from the garbage, rubbish and combustibles and also comprises the types of receptacles and the location from which refuse is to be collected.

The by-law actually in force in the city of Montreal provides for the separation above described, but does not specify the type of the receptacle although it limits its capacity to 100 pounds and stipulates that there shall be a free space of at least six inches between the contents and the top of the receptacle.

The householder is called upon to facilitate the collection by providing a proper receptacle and in separating combustible from incombustible material.

Receptacles are placed in the lanes, and where there are no lanes they are deposited at the edge of the sidewalk or at the yard entrance in residential districts.

A new by-law is now under advisement by the Public Works Commission, providing for the separation of combustible from incombustible material, for the wrapping of garbage, for proper receptacles, etc.

The city of Montreal, through its Department of Public Works, owns and operates all equipment used for the collection, which is effected by horse-drawn vehicles and motor trucks.

This equipment comprises:—

250 horses.
58 team drawn summer vehicles.
63 " " winter "
188 one-horse drawn summer vehicles.
204 " " " winter "
10 trucks.

On an average five hundred men are employed daily in the collection and transportation of refuse.

It is estimated that 406,670 tons of refuse were disposed of during 1930, at cost of $877,124.06, or $2.16 per ton, this being paid out of the revenue derived from municipal taxes.

Refuse is collected twice a week during the day from all sections of the city with the exception of the district included between Delorimier and McGill streets, from the St. Lawrence river to Craig street, where the collection is made during the night.

Refuse is transported to dumps, to transfer stations or to the incinerators.

There are at present two transfer or loading stations, one located on Western avenue, in Notre Dame de Grace ward, and the other near the intersection of Clarke and Lagauchetiere streets.

The buildings of these transfer stations are so designed that odours and dust cannot become objectionable.

Horse drawn vehicles deliver the refuse to the transfer stations from which motor trucks transport it to dumps or

Fig. 1—Incinerator on Des Carrieres Street, Montreal.

to the incinerators. All ashes and some refuse are deposited in dumps which are kept sanitary and sightly by covering with chloride of lime and by periodic grading. Valuable land has been reclaimed by dumping: Laurier and Prefontaine parks are examples of old quarries, 40 or more feet in depth, filled with city refuse.

The available dumps within the city limits have been decreasing and the resultant long haul has augmented the cost of final disposal.

The problem of final refuse disposal was then studied from all viewpoints and eventually incinerators were decided upon.

Local conditions were the deciding factors against the reduction process and in favour of incineration. The reduction process was discarded because of its cost, the variation in the price of the products of reduction making the financial returns uncertain, the absence of grease from our garbage during the winter due to our climatic conditions, the non-wasting characteristics of a large part of the population, the development of odours from reduction making the isolation of the plant necessary and resulting in a lengthy haul, and the probability of the city competing with industries in grease, fertilizer, etc., and the taxation of these industries to pay the losses of the municipal business.

Salvaging in connection with incineration was not considered, for it could not be recommended from a general health standpoint.

Another reason militating against salvaging was the proportionately small quantities of rubbish present in the refuse collected during the summer months, all such rubbish being necessary during that period for complete combustion of garbage otherwise the addition of fuel such as coal, oil or gas would be necessary.

With regard to the development of power by these incinerators, a project of the city for erecting and operating, for municipal services, a hydro-electric power plant by making use of its existing aqueduct canal, did not warrant an investment in steam boilers and power producing equipment in connection with these refuse disposal plants.

Furthermore, incineration permits disposing of the refuse near its source of production in a manner that is proven to be sanitary and inexpensive. It was therefore imperative to locate the incinerators as near as possible to the centre of the refuse production area, each plant to take care of the refuse collected in a specified zone.

The population density map of the city of Montreal, as prepared by the Bell Telephone Company, has been a great help in determining the centre of the production area. To limit the maximum economical haul of the horse-drawn vehicles to about two miles, the city has been divided into three zones, known as the Northern, Western and Eastern zones. The incinerator for the Northern zone has been erected at the cost of $350,000 last year on Des Carrieres street near Papineau avenue, on land adjoining the Canadian Pacific Railway, and that of the Western zone is now being constructed at the cost of $400,000 near the intersection of Atwater and Greene streets, on the site of the Thackeray incinerator erected in 1894 and destroyed by fire in 1920. The latter site is located next to the Canadian National Railway line. The construction of the third incinerator, that of the Eastern zone, is not yet authorized and the site not located.

Each zone has at present, including contributing areas through the transfer or loading stations of the central business district and of Notre Dame de Grace ward, a population of approximately 300,000.

It has been estimated that the location of the Northern zone incinerator would result, from a decreased haul, in a saving sufficient to partly compensate for the cost of the operation of the plant. The vehicles, before operating the Northern zone incinerator, transported on an average three loads per day to the dumps. At present, they are transporting an average of five loads to the incinerating plant.

The average production of garbage and rubbish is estimated at 800 pounds per thousand population per day. A population of 300,000 would therefore produce 240,000 pounds or 120 tons per day.

Allowing for district, seasonal, and daily variations 150 per cent of the average of 120 tons per day and allowing for increase in population and shut down periods, the rated capacity of each plant was fixed at 300 tons per day.

Description of Equipment

The incinerators are of the brick furnace Sterling type incorporating the use of forced draft and preheated air, using heat recovered from the flue gases. They are constructed with separate mutually assistant cells having common furnace chambers over the cells with brick drying hearths continuous throughout the furnace chambers and combustion chambers, regenerators and flues connecting to the chimney and properly dampered to provide independent control of each unit.

Each of the three furnaces is a completely independent unit throughout, permitting separate or simultaneous operation. Each furnace has a furnace chamber with four cells or grates, a drying hearth at the rear of the grates and one feed hole for each cell in the arch over the furnace chamber. Each cell has an individual ash pit provided with separate draft control and is separated above the grates from the adjoining cell for a distance high enough to permit separate and individual stoking and fire cleaning of each cell. Each furnace chamber is lined with nine inches of fire brick The outside walls are constructed 12 inches in thickness, leaving an air space of one inch between the fire brick lining and the outer wall. Each furnace is steel cased with No. 10 gauge plate. The roof arch of the furnace chamber has a secondary arch of common brick built over the fire brick arch. There is a 2-inch air space between the fire brick arch and the secondary arch. The whole furnace chamber lining is supported independent of the structural parts of the furnace and is so constructed that it can be erected without disturbing the outer walls or structural parts. The roof of the chamber is so constructed with cast iron relief beams and struts that repairs to the lining around the charging holes may be made without necessitating the rebuilding of the entire arch. All stoking door openings and clinker door openings are protected with air-cooled cast iron jamb blocks and arch bars.

Each cell is provided with stationary cast iron grates carried on cast iron supports and built in two sections, front and rear Each grate is separated from the adjoining grate by means of a heavy air-cooled casting to permit of separate stoking and fire cleaning. At the rear of the grate between the grate surface and the drying hearth and the sides of the two end grates between the grate surface and the fire brickwork, there is protection provided for the brickwork by means of a heavy casting of similar pattern to the castings which separate the adjoining grates.

The drying hearth upon which the refuse falls after passing through the charging hole is built at the rear of the grates for the entire length of each furnace chamber. Its width is 45 inches. It is constructed of fire brick laid on edge.

In the space below each grate is an individual ash pit separated in each case from the adjoining one and provided with a draft control device, so that the forced draft pressure may be individually controlled in each ash pit. The draft control is accomplished by means of a butterfly valve built into a cast iron air nozzle entering the rear wall of each ash pit. The operating mechanism for the butterfly valve is carried to the front of the furnace and the control is by means of a lever operating between buckstays near the floor line at the front of the furnace.

The stoking doors are of cast iron fire brick lined of the guillotine type. A stoking opening is provided in each stoking door, so that the fire can be stoked without raising the entire door.

The dead plate is of cast iron one inch in thickness.

Steel charging chutes connect the feeding floor with the feed holes in the tops of the furnace. Each chute, built in two sections, is provided with hopper doors at the lower end to prevent excessive back lash of hot gases and to prevent the refuse in the containers coming in contact with the heated surface of the charging hole cover. The bottom hopper doors are arranged to operate simultaneously with the feed hole cover and is under control of the stoker and mechanically operated by compressed air. The containers are hung from the building structure and are entirely free and independent from the furnace structure.

Each furnace of four cells is provided with a combustion chamber, having a volume of 1,600 cubic feet, which is proportioned and designed to give a rolling action to the gases to insure complete combustion and to cause the fine dust to be trapped. The lining and outer walls and roof of the combustion chamber have the same construction as

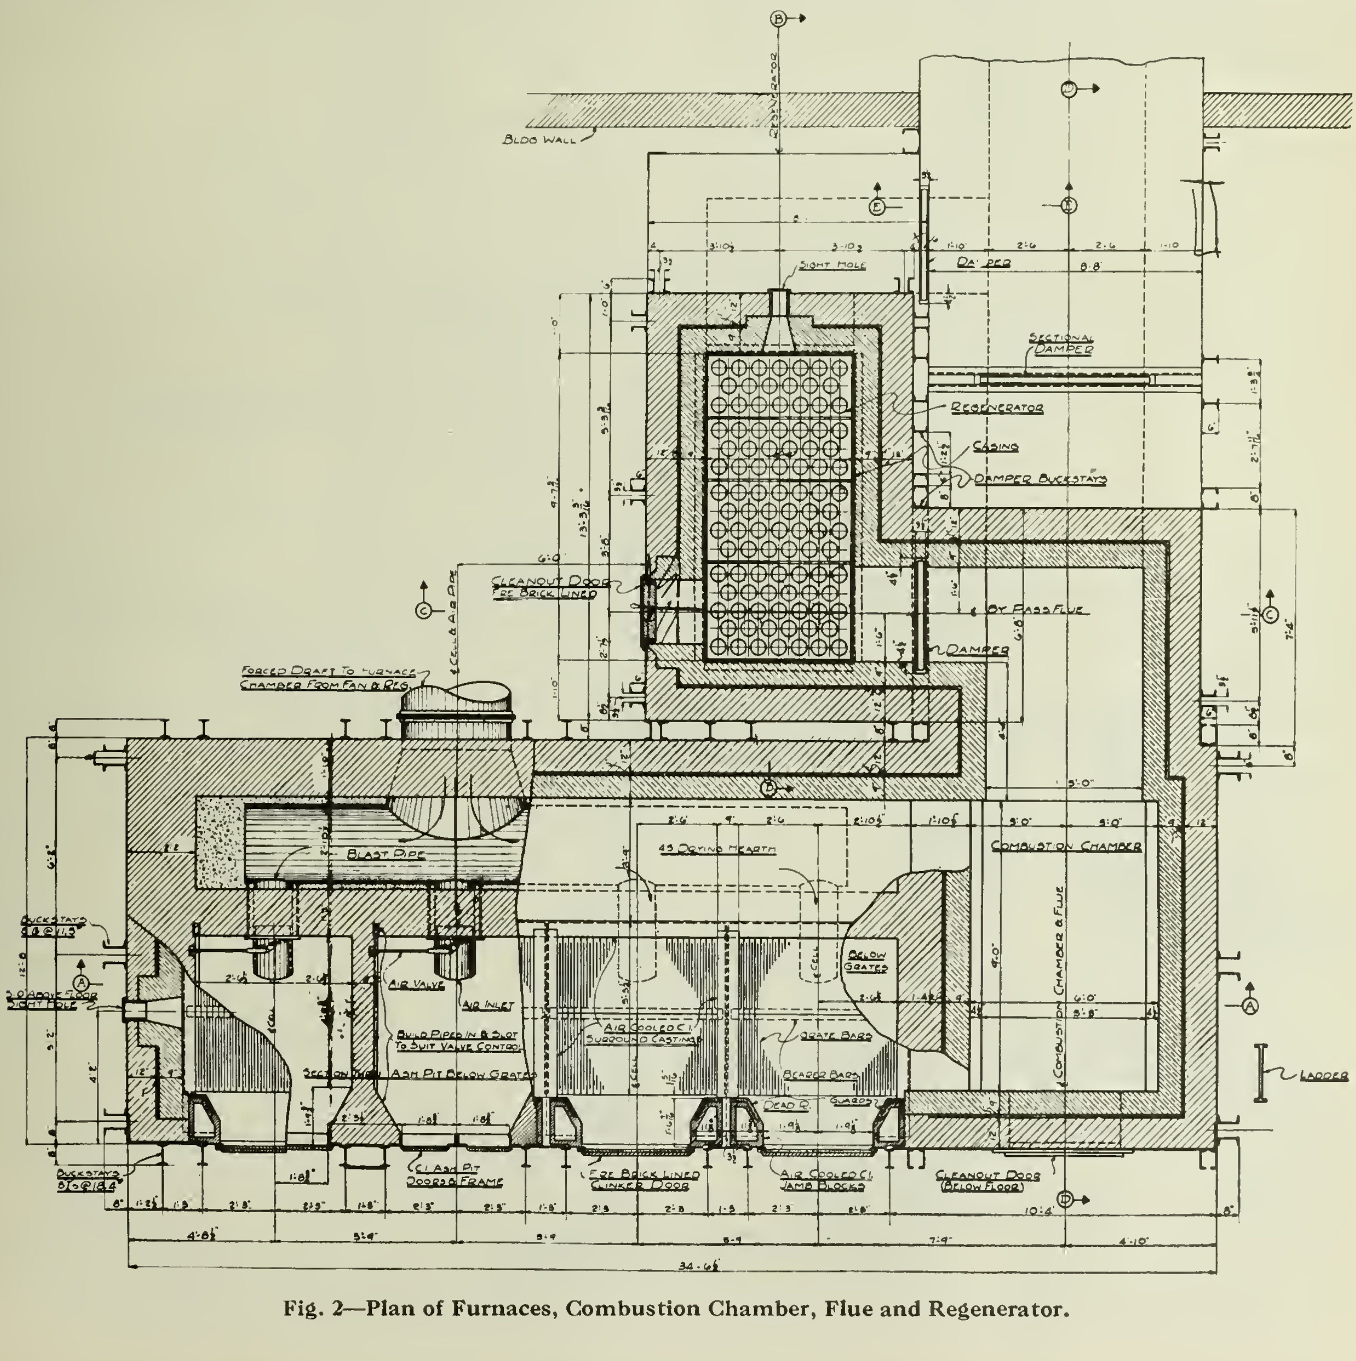

Fig. 2—Plan of Furnaces, Combustion Chamber, Flue and Regenerator.

those of the furnace chamber. The floor of the combustion chamber is paved with 4½ inches of fire brick.

From the main flue of each furnace, gases can be by-passed through a regenerator to heat air supplied for combustion. Dampers are provided so that a sufficient quantity of flue gas can be by-passed through the regenerator to produce a temperature of not less than 300 degrees F. in the forced draft. The regenerator is constructed of cast iron plates and tubes built up in sections so that renewals can be easily effected. There are ninety-nine tubes per regenerator, consisting of 5-inch wrought iron pipes, 6 feet long.

The regenerator is provided with baffle plates and the entire structure of plates and tubes is encased in a steel housing ¼-inch in thickness, the whole set in brickwork.

The tubes and surfaces of plates can readily be cleaned and the tubes can be withdrawn in the setting.

The regenerator is constructed with four sections of tube plates at the top and four at the bottom. These plates are made of cast iron and machined on their edges so that there is an air tight fit between the adjoining plates or baffles or regenerator housing, as the case may be. These plates are built with ribs and provided with bosses for packing the tubes air tight.

The upper flue gas chamber regenerator is covered with a flat fire brick roof held in castings. This roof is built in sections easily removed for renewals of tubes and plates.

When the refuse contains large quantities of moisture, the regenerator cannot be dispensed with, as it makes combustion possible. Besides improving the starting of fires, it serves to drive off the moisture previous to ignition, and owing to the increased eagerness with which the oxygen will combine with the carbon, it is possible to decrease the excess of air, so that the gases are not so diluted, which means that for the same fuel a much higher temperature is obtained.

The advantages of the preheater are therefore as follows:—

The addition of a considerable amount of heat units to the furnace side of the heat balance sheet:

A reduction of the excess air supplied and the consequent diminution of the dilution of the combustion gases;

Increase in the rapidity of igniting a fresh charge of refuse;

Increase in the temperature obtained in the combustion chamber;

Increase in the evaporation due to the above advantages.

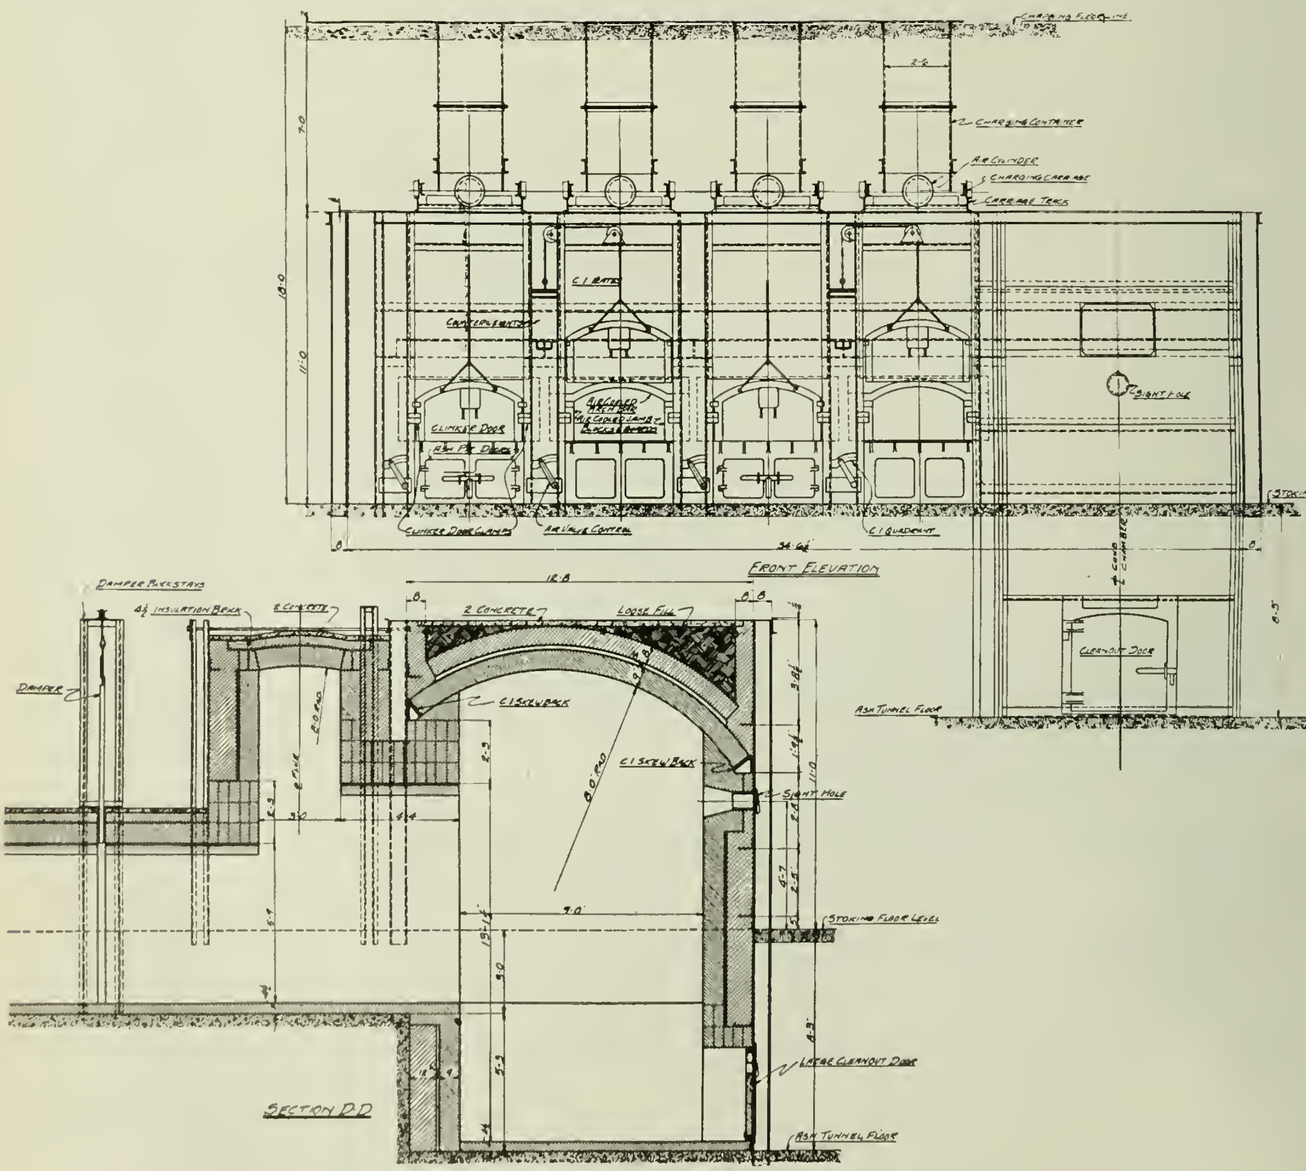

Fig. 3—Front Elevation of Furnace and Combustion Chamber. Section Through Combustion Chamber.

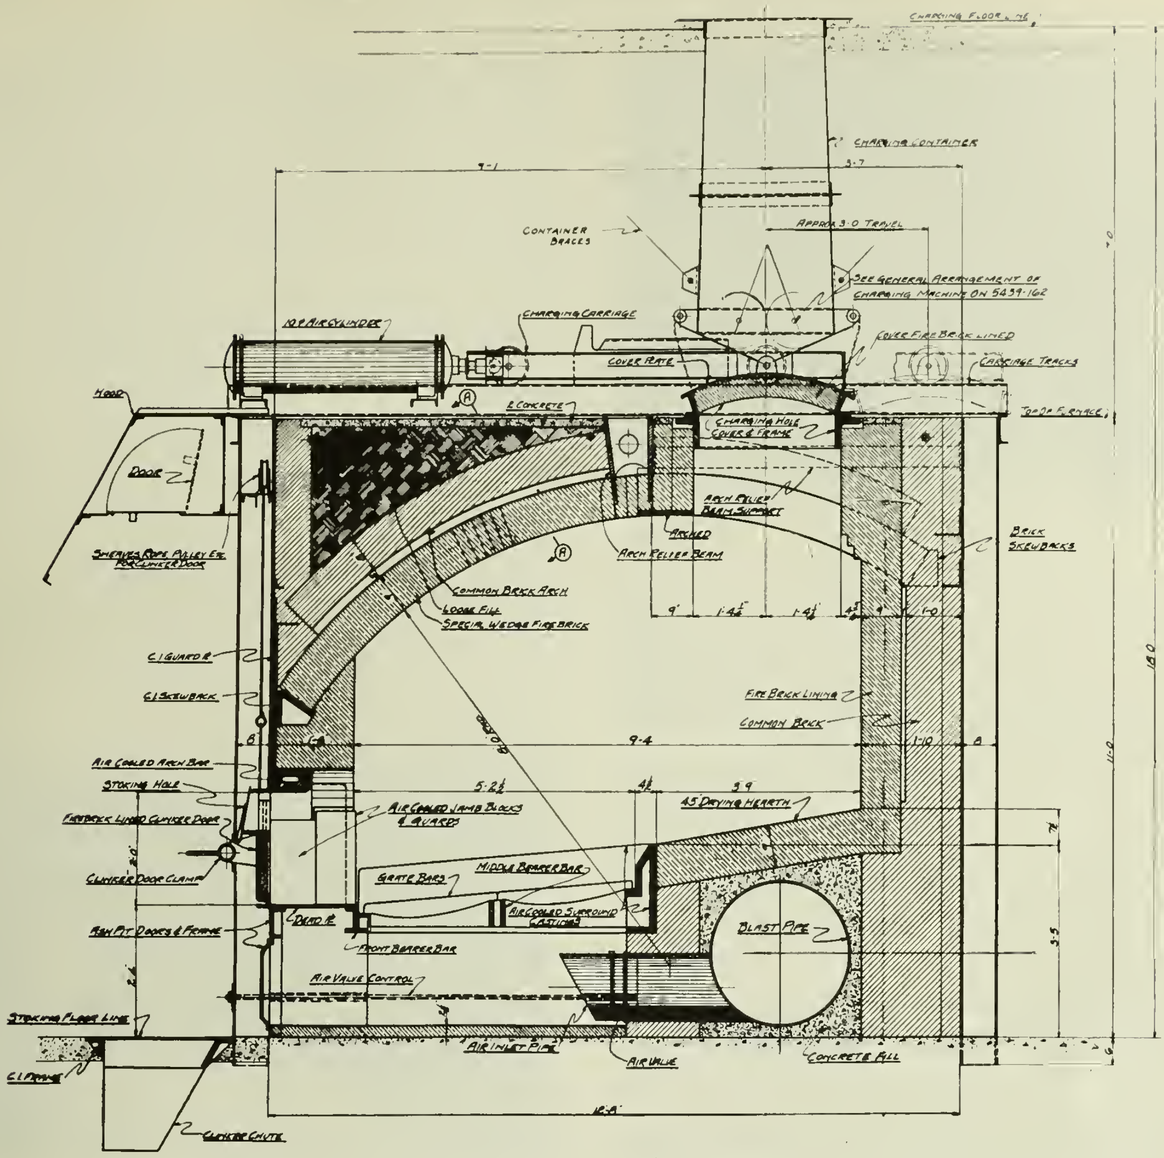

Fig. 4—Section Through Furnace.

The area of all flues and gas passages is sufficient to prevent back lashing of the furnace. The flues are constructed with a 9-inch fire brick wall lining and a 9-inch fire brick arch, and with a 9-inch common brick outside wall and secondary arch, with an air space between the fire brick and the common brick. Outside walls are encased with 10-gauge steel plate. The floors of all flues are paved with a 4½-inch fire brick.

The radial brick chimney is 150 feet high and 9 feet inside diameter. It has an independently supported fire brick lining throughout the entire length guaranteed for 2,250 degrees F. regular operating temperature.

The interior lining is constructed using steel bands with vertical sections between the bands, which is commonly termed "corset" construction, to minimize the effects of expansion and to prevent cracks. This lining is used up to a height of 50 feet in order to assure stability. A target wall 4½ inches in thickness is constructed on the interior of this lining for a height of 30 feet. This target wall is entirely independent of the fire brick column or lining of the chimney and is installed to take the brunt of the hot gases coming from the furnaces as they enter the chimney and to protect the self-supporting lining.

The brickwork of all furnace chambers, combustion chambers, flues and regenerators are securely bound together using heavy vertical buckstays, structural steel belt channels and angles, and tie rods provided with lock nuts. The furnaces and flues are securely tied so that they act as one unit and take up the stresses without dislocation or rupture. The main fire brick arch over the furnace chamber is carried on cast iron skewbacks in front and on fire brick skewbacks in the rear backed up with structural steel angles and channels, so that all horizontal stresses are carried directly to the buckstays and the entire fire

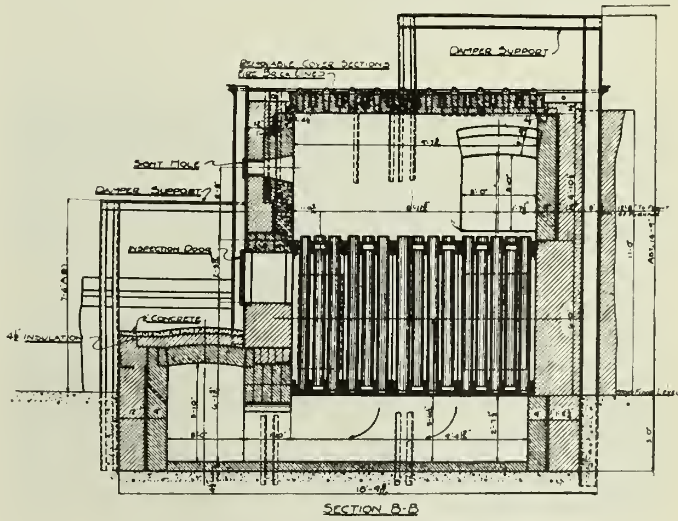

Fig. 5—Section Through Regenerator.

Fig. 6—Feeding Floor.

brick lining in the walls below the arch can be renewed without disturbing the arch in any way.

The main fire brick arch over the combustion chamber is carried both front and rear on cast iron skewbacks, so that the entire arch is supported directly between the buckstays and the fire brick wall lining can be renewed entirely without disturbing the main arch.

The main buckstays front and rear of the cells are made of 8-inch by 18.4-pound I-beams. These buckstays are each built with two I-beams tied in pairs with main tie rods of 1¼-inch diameter. The buckstays at front and rear of the combustion chamber are built of channels tied in pairs, each channel being 8-inch by 11.5-pounds.

The furnaces, combustion chambers, flues and regenerators are all metal cased with No. 10 gauge steel plate bolted to the buckstays.

The fire brick used throughout the furnaces, combustion chamber, regenerators and flues have a pyrometric cone equivalent of 32 to 33.

There are two direct connected electric motor driven air compressors of the duplex single acting vertical type. The compressors have a piston displacement of 95 cubic feet per minute at a discharge pressure of 100. The compressors supply air to the rams which open the charging doors.

The necessary draft for combustion is supplied by means of a direct connected electric motor driven centrifugal fan (one motor and one fan for each furnace), each fan having a capacity of 10,000 cubic feet of air per minute, at 70 degrees F., when operating at a speed of 1,160 r.p.m. against 4½ inches static pressure.

Operation

The refuse is delivered to the receiving pit in horse-drawn wagons and motor trucks and transferred to the charging hoppers by means of the grab bucket cranes The refuse in the hoppers falls by gravity into the charging containers located on top of the furnaces as previously described. The bottom of the charging container is closed to prevent the material coming in contact with the hot surface of the furnace. The charging door is moved backward mechanically by controls operated by the stoker from the stoking floor. As the door travels back to full opening it engages with lugs on the side of the charging containers and automatically opens the doors on the bottom of the charging container, dropping the full charge into the furnace.

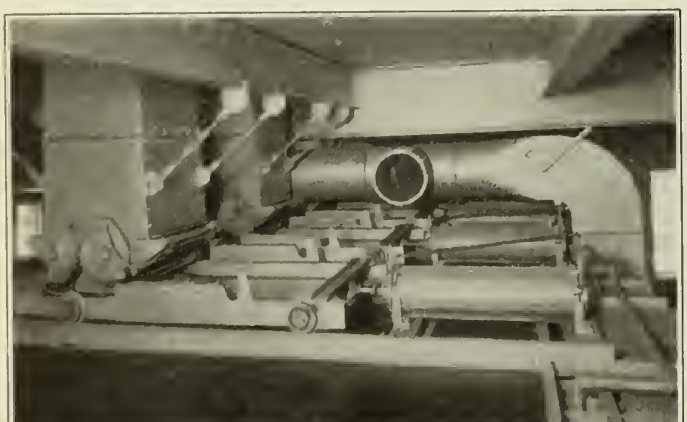

Fig. 7—Chutes Connecting Feeding Floor to Furnaces, Hopper Doors and Rams.

The containers are specially designed to prevent refuse sticking and to permit free and rapid discharge when doors are opened.

The charge is dropped on a drying hearth at the rear of the furnace, where the hot gases assist in drying the refuse before it is drawn forward on the grate by the stoker.

The refuse when drawn on the grate is consumed and the operation is continued by dropping successive charges as needed.

The furnace chamber being continuous above the four grates, permits the dropping of charges on alternate grates, so that the hot fire from the adjoining grates will assist in the combustion of the fresh charges of refuse.

As the gases from the furnace chamber pass into the combustion chamber at one end of the row of cells, they

Fig. 8—Ash Tunnel.

strike the farther wall of the combustion chamber and produce a rolling action and a thorough mixture of the gases, so that final and complete combustion takes place developing a temperature higher than 1,200 degrees F. While passing through the combustion chamber most of the dust is deposited.

Part of the gases from the combustion chamber are carried by flues direct to the chimney and part are passed through the regenerator for heating the forced draft air used in the furnaces, thereby utilizing a large part of the waste heat and returning the same to the furnace. The regenerator being installed in a separate chamber permits its being closed off entirely by means of a damper and the regulation of the quantity of hot gases to pass through the regenerator.

In operating the furnaces, the forced draft and the passage of gases through the regenerator as well as the charging of the furnaces, can be regulated to meet the varying conditions, each furnace being equipped with recording pyrometer and each regenerator with a recording thermometer.

Fires are cleaned separately from each cell of a furnace, by raking the ashes and clinkers from the grate and dropping them into cars in the ash tunnel. The bodies of the cars are emptied into truck bodies placed in the ash pit of the building. From there the furnace residue is transported to dumps.

Tests

The city, before accepting the plant on DesCarrieres street, appointed a Board of Engineers and Aldermen to inspect and test the incinerator. The results of the test were as follows:—

Date	Tuesday, October 14th, 1930.
Weather	Fair.
Temperature	Max. 74.0 degrees F.
	Min. 56.2 "
	Mean 64.4 "
Barometer	Max. 30.01 ins.
	Min. 29.93 "
	Mean 29.97 "
Humidity	71 per cent.
Start of test	9.50 a.m.
Finish of test	8.55 p.m.
Duration of test	11 hours, 5 minutes = 11.08 hours.
Weight consumed	206.7 tons.
Weight of residue	50.45 tons with water content for quenching ash.

Percentage of moisture in refuse	39.83 per cent
Pounds of moisture per ton of refuse	796.6 pounds
Percentage of organic matter in refuse	44.92 per cent
Pounds of organic matter per ton of refuse	898.4 pounds
Percentage of inorganic ash, tin, glass, etc.	15.25 per cent
Pounds of inorganic ash, tin, glass, etc. per ton of refuse	305.0 pounds

Area of grate surface, three furnaces at 100 square feet =	300 square feet
Rate of burning per square foot grate per hour obtained by test	124.4 pounds
Rate of burning per square foot grate per hour guaranteed by contractor	104.1 "

Rate of burning tons per furnace hour	6.22 tons
Guaranteed rate of burning tons per furnace hour	5.2 "

Capacity of plant per 24 hours	448 tons
" " " " " specified	300 "
" " " " " guaranteed	375 "
Actual increase in capacity, percentage over specified capacity	49⅓ per cent

Furnace No. 1

Maximum temperature of combustion chamber	2,025 degrees F.
Minimum " " " "	1,500 "
Average " " " "	1,730 "

Furnace No. 2

Maximum temperature of combustion chamber	2,250 degrees F.
Minimum " " " "	1,350 "
Average " " " "	1,975 "

Furnace No. 3

Maximum temperature of combustion chamber	In excess of 1,800 degrees F.
Minimum " " " "	1,370 degrees F.
Average " " " "	1,720 degrees F. approx.

Combustion chamber temperature guaranteed not less than 1,250 degrees F., for more than 3 minutes, average temperature at least 1,400 degrees F.

Furnace No. 1

Maximum temperature of regenerator air	480 degrees F.
Minimum " " " "	300 "
Average " " " "	370 "

Furnace No. 2

Maximum temperature of regenerator air	450 degrees F.
Minimum " " " "	280 "
Average " " " "	360 "

Furnace No. 3

Maximum temperature of regenerator air	400 degrees F.
Minimum " " " "	300 "
Average " " " "	350 "

Analysis of residue—	Moisture	14.37 per cent
	Unburnt garbage brought out from drying hearth with the clinker by careless stoker	2.80 "
	Glass, metal, etc	47.41 "
	Carbon dioxide	4.74 "
	Ash residue	30.07 "
	Combustible organic matter excluding carbon	0.61 "

Residue content of organic guaranteed not more than 1 per cent of organic matter exclusive of carbon.

Total man hours of labour, actual burning including cranemen, chargers, stokers and ash-run men	135 man hours
Man hours of labour per ton	0.653 man hour
Guaranteed man hours of labour per ton	0.9 " "

Electric power consumed during test for operating forced draft equipment, air compressor, cranes and other equipment of building	560 kilowatt hours
Kw.h. per ton of refuse obtained	2.7 "
" " " " guaranteed	3.6 "

Density of smoke—Chart No. 1 of Ringelmann's Smoke Scale.
Density of smoke guaranteed—not greater than Chart No. 1 of Ringelmann's Smoke Scale.

Nuisance through escape of noxious odours, gases, sparks or dust. None.

Since the above paper has been written, the second plant on Atwater avenue has been tested, giving the following results:—

Date	Thursday, September 10th, 1931.
Weather	Mostly fair and warm—Showers.
Temperature	9 a.m. 72 degrees F.
	1 p.m. 84 "
	5 p.m. 86 "
Barometer	29.85 ins.
	29.82 "
	29.79 "
Humidity	78 per cent.
Wind	South-west.
Start of test	9.45 a.m.
Finish of test	8.58 p.m.
Duration of test	11 hours, 13 minutes = 11.22 hours.
Weight consumed	212.81 tons.
Weight of residue	52.75 tons with water content for quenching ash.

Percentage of moisture in refuse	53.23 per cent
Pounds of moisture per ton of refuse	1,064.6 pounds
Percentage of organic matter in refuse	24.95 per cent
Pounds of organic matter per ton of refuse	499 pounds
Percentage of inorganic ash, tin, glass, etc.	21.82 per cent
Pounds of inorganic ash, tin, glass, etc. per ton of refuse	436.4 pounds

Area of grate surface, three furnaces at 100 square feet	300 square feet
Rate of burning per square foot grate per hour obtained by test	126.4 pounds
Rate of burning per square foot grate per hour guaranteed by contractor	104.1 "

Rate of burning tons per furnace hour	6.32 tons

Nuisance through escape of noxious odours, gases, sparks or dust. . None.

Both plants are now operated by the city of Montreal.

Discussion on "The Practical Application of the Microscope in Railway Service"

Paper by F. H. Williams, M.Sc.[1]

C. F. Pascoe[2]

Mr. Pascoe observed that the paper had been very interesting but it seemed to him that the importance of coarse crystalline structure had been over-emphasized. He had found that this was not so important a factor as inspecting engineers often seemed to think.

F. H. Williams[3]

The author in reply stated that he believed the answer could be found in the slides which had just been shown. A great proportion of these had shown the whole fracture and not the microstructure. Besides coarse grain as a cause of failure, the results of overheating in service, scratches in fillets, etc., had been shown, while he maintained that coarse grain was often a cause contributing to the growth of a fatigue crack or a sudden failure; he realized that there were numerous other factors.

Harold J. Roast[4]

Mr. Roast remarked that the author had mentioned in several instances the effect of "overheating" and showed micrographs showing a fine grain, which he had attributed to overheating. He was accustomed to think that overheating caused a coarse grain and he wondered if the author would explain this point.

F. H. Williams

The author replied that in many cases of overheating the fine grain was caused by the chilling action of the interior of the heavy axle.

G. St. G. Sproule, A.M.E.I.C.[5]

Professor Sproule stated that before proposing a formal vote of thanks, he wished to make a few remarks regarding the very interesting talk which had been given. The subject was really of fundamental interest to all engineers, involving as it did, the design, material, workmanship and service treatment of mechanical parts, and he thought that the author had treated the subject in a well-balanced manner.

With regard to the question by Mr. Roast, this was a matter of ambiguity of terms. From the metallographic point of view, overheating meant raising the temperature of the metal to a *very high point*, which produced a coarse grain. From the mechanical point of view, a journal might be considered overheated when it reached the temperature of boiling water or 200 degrees C. or 300 degrees C., which would destroy the lubrication. In the cases of overheating which the author had illustrated, the temperature at the surface evidently reached a degree somewhat above the critical temperature that is sufficient to alter the grain but not to make it coarse.

The author had illustrated cases of failure due to various causes. His experience had usually been that a failure was due to a combination of causes. Even in Case 1, which had been described as being due to "one cause only—design," the coarse grain of the metal was also mentioned.

The case in which loose balls of metal from the fracture were found was very interesting indeed, if not unique. A point which engineers might well notice was the great area of the fatigue cracks before final failure. This might be taken as indicating good design, but it depended on the point of view. It would appear that if design, material and workmanship were more perfect, a much smaller amount of metal would have served the purpose. In some cases, structures appeared to be killing themselves with their own weight. The importance of preventing the start of a fatigue crack was very great, as once it was started, it would surely continue to grow with increasing rapidity. This was prevented by good design, ample fillets, good finish and sound, tough, elastic material, with good impact strength. It was up to engineers in general to insist on their steels being made by the best possible practice, fully deoxidized and cast in big-end-up moulds. This was not a criticism of the practice of Mr. Pascoe, because he was not making ingots for rolling and forging.

He remarked that there was one diagnosis of the author's which he wished to dispute, as he considered it open to question. This was the case of a main rod end in which a coarse microstructure was showed as being due to overheating in service, although, as mentioned previously, if through overheating in service the temperature rose above the critical point at all, usually gave a fine grain. He believed that main rods and crank pins actually did sometimes heat to a red heat, but it was doubtful if they ever became hot enough to grow a coarse grain such as was illustrated. He believed that the variable grain in this rod end was produced in the forging. Except for this point, he thought all would agree that the author's micrographs and photographs really showed what they claimed to show, which could not always be said for micrographs accompanying published articles.

Another very interesting case was the corrosion crack. This was a comparatively little-known thing, and attention should be drawn to the fact that it was referred to and illustrated in an article by Dr. A. Stansfield, M.E.I.C., presented before the Ottawa Branch of The Institute on April 9th, 1931, and published in the August, 1931, issue of The Engineering Journal.

In conclusion, Professor Sproule proposed a hearty vote of thanks to the author.

The Design and Construction of Metal Hulls for Boat Seaplanes

R. J. Moffett, A.F.R.Ae.S.,
Chief Engineer and Designer, Aircraft Department, Canadian Vickers Limited, Montreal.

Paper presented on October 2nd, 1931, before the Aeronautical Section of the Ottawa Branch of The Engineering Institute of Canada (Ottawa Section, Royal Aeronautical Society).

SUMMARY—The general design of seaplane hulls and floats is carried out by methods familiar to naval architects, but modified to take account of the special conditions arising in aircraft work. The methods of construction and the materials employed in hulls and floats are discussed and the necessary investigations for strength are described. The shop procedure for metal hulls requires special precautions when aluminum alloys are employed and precautions must be taken to prevent damage from corrosion in service. The paper concludes with an appendix discussing some of the fundamental calculations involved in hull and float design.

The following paper is presented as a short survey of the procedure adopted when designing and building a boat seaplane, and most of the material has been published already at various times.

General Design

A good hull is one which combines satisfactorily the very different qualities—seaworthiness and airworthiness.

The requirements for seaworthiness can be divided into two distinct classes, namely:—

Seaworthiness while on the water (*a*) without engine running; (*b*) with engine running.

(*a*) requires excess buoyancy and good static stability in all directions; while (*b*) requires low water resistance and good dynamic stability both during taxying and planing.

In normal modern boat design the fully submerged buoyancy of the hull is always very much in excess of that required. Low water resistance is included as a requirement of seaworthiness as it is assumed that the quicker the take off time, the less is the need for true seaworthiness. That a quality which reduces the necessity for true seaworthiness should be deemed advantageous, may sound paradoxical, but it must be confessed that at the present stage of flying boat development, these aircraft are much more airworthy in rough air than they are seaworthy in rough sea. Seaworthiness exists only to a negligible extent in flying boats if the standard of comparison is the normal sea going vessel. Fig. 1 shows a twin engine boat seaplane taking off.

A seaplane hull must also be capable of leaving the water in a reasonable time and of returning safely to the surface after flight. For quick take off, a flat bottom is preferable, but is liable to considerable damage from pounding when alighting. The evolution of planing bottom shapes has been from flat to straight vee and now to curved vee. These are shown in Fig. 2. In each case it has been necessary to add steps (see Fig. 3) so that when taking off the surface tension of the water is overcome by breaking down the flow.

The questions of static and dynamic stability are considered in detail later.

Airworthiness requirements are, low air resistance with the centre of resistance as high as possible and convenient accommodation for the crew, load, and for the manipulation of any special equipment.

Design work commences with weight estimates of the various components and of the position of the centre of gravity of the fully loaded boat. When these estimates are sufficiently satisfactory to fix the all-up weight the lines of some predetermined hull shape are drawn out and the load water line added in side view (see Fig. 3). This line is first estimated from previous experience and is usually inclined at from 3 degrees to 5 degrees to the fore body keel line at the main step. A perpendicular to the water line and passing through the all-up centre of gravity should be slightly forward of the main step. The buoyancy of the under water body is then checked and modified until close agreement with the all-up weight is obtained.

The usual method of determining the under water volume is the same as that used by the naval architect, i.e., the half areas under water of the various sections have Simpson's Rule applied or are plotted as a curve (Fig. 4). The area of this curve multiplied by two and by the weight of water gives the required buoyancy in pounds.

The next step is to determine the centre of buoyancy by taking moments of volumes about some point of reference. A quick method of finding the longitudinal position is to cut out the curve shown in Fig. 4 and find its centre of gravity by the suspension method.

When the centre of buoyancy has been found and indicated on the side view of the boat the line joining the all-up centre of gravity and the centre of buoyancy should be perpendicular to the estimated water line. If this is not so, corrections must be made, for instance, assuming that the relative positions of centre of gravity and main step are correct, either the water line or the hull shape must be modified.

A model of the hull is now made to some convenient scale for tank testing in order to obtain data regarding its behaviour on the water.

Fig. 1—Seaplane Taking Off.

The method adopted follows closely that in use for many years by naval architects and which was used first by Froude. The model is towed in a long tank by means of an electrically driven carriage at various speeds, the support being such that the resultant loads on the model are accurately recorded. Tests on flying boats are necessarily more complex than for ships, because of the variation in support received by the hull and the wings at different speeds and attitudes. The flying boat model is pivoted at the all-up centre of gravity and the towing force applied at the centre of thrust. The attitude for any given speed is estimated and the corresponding lift from the wings calculated so that this lift can be reproduced on the model by means of counter weights. A preliminary run at the corresponding speed is then made to check the estimated attitude and any further corrections to wing lift made if this is found to vary.

When these corrections are found over the range of speeds required final runs are made and the total resistance recorded plotted against speed (see Fig. 5). Observations are made at the same time, usually by cameras, of the waves, spray, etc. Other runs are then made with varying pitching moments applied, to obtain qualitative data on the water stability of the design. Of all the data obtained from these tests, only a part of the total resistance follows Froude's Law of Corresponding Speeds. Stability data are

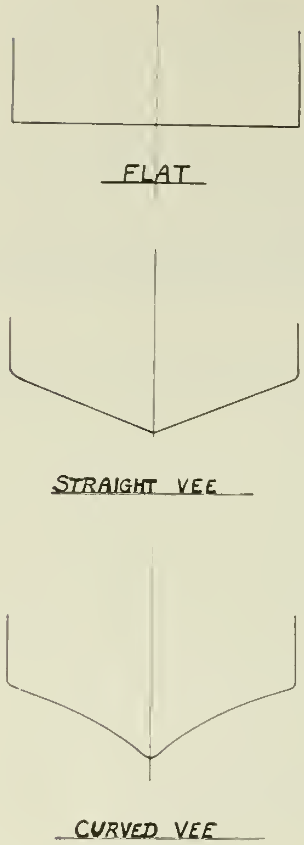

Fig. 2.

qualitative only and it is usually found that a stable model predicts stability in full scale.

The total tow rope resistance of a body moving on the surface of a fluid is made up of two main parts:—

(1) Skin friction and eddy making;

(2) Residuary resistances made up of (*a*) wave making resistance, (*b*) air resistance;

and only the residuary resistance follows Froude's Law. The following is the method for obtaining the division of these resistances from model tests. The skin resistance is a function of actual speed and size only and can be expressed in the form of

$$R = k\rho s v^2 \left(\frac{lv}{\nu}\right)^a$$

When

k = constant depending on the shape of the body.
ρ = mass density of the fluid.
s = wetted area of the body.
v = relative speed of the body.
l = linear dimension of the body.
ν = kinematic viscosity of the fluid.
a = constant depending on the shape of the body.

In R. and M. No. 1199 by Professor B. Jones, it is shown that for perfect streamlined bodies the flow is turbulent and the value of '*a*' is approximately .015.

From the model tests the total resistance is plotted against forward speed, see curve (1), Fig. 6.

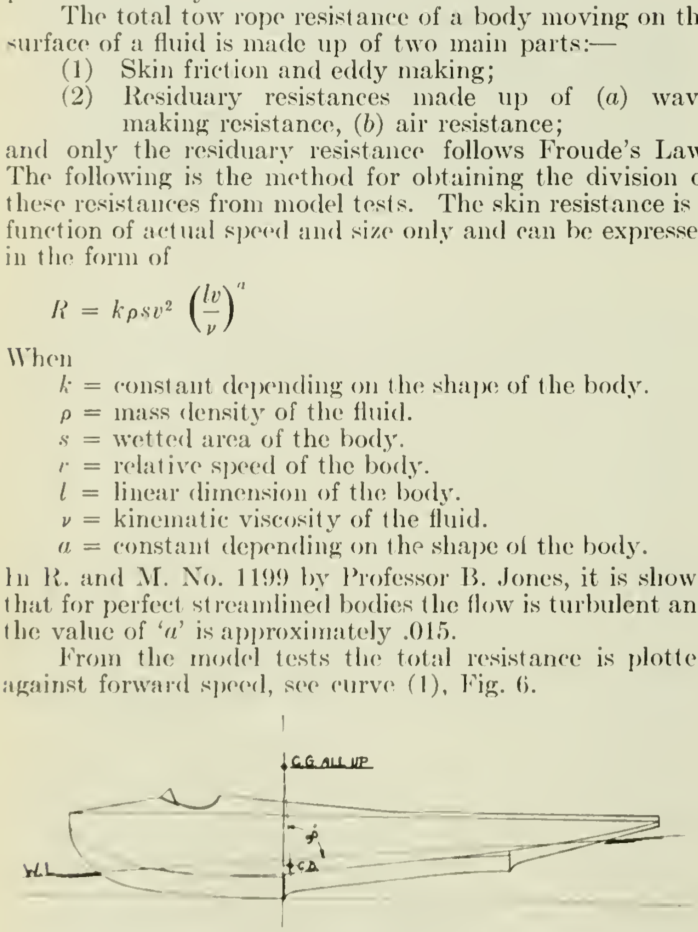

Fig. 3.

Then from the model conditions the skin friction is calculated by the above expression and plotted as curve (2). The intercepts between these curves then give the wave making resistance which can be corrected and plotted for full scale. The full scale skin resistance is calculated and added to the corrected wave making resistance giving the full scale total resistance. These figures can then be compared with those of a known successful design and used for estimating the water performance of the complete boat.

Stability

Flying boats are stabilized laterally either by stubs or by outboard floats, as the hull and superstructure alone are transversely unstable due to the fact that the metacentric height is negative. In order to estimate the required buoyancy of these stabilizers, it is necessary, therefore, to decide the position of the metacentre and the value of the metacentric height of the complete aircraft and the method is identical with that used by the naval architect (Fig. 7). The height of the metacentre above the centre of buoyancy is found from the simple expression

$$B.M. = \frac{I}{V}.$$

Where I = second moment of area of the water plane
V = volume of the underwater body.

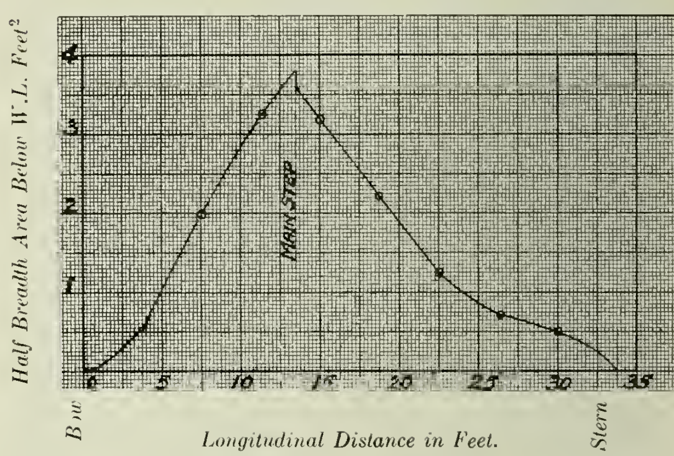

Fig. 4—Buoyancy to L.W.L.

I is obtained from the cubes of the ordinates of the water plane shape and the application of Simpson's Parabolic Rule.

In Fig. 8 $C.B.$ is the centre of buoyancy, $M.$ the metacentre and $C.G.$ the centre of gravity. Obviously the buoyancy acts upwards at $C.B.$ and the weight downwards at $C.G.$, and it will be seen that when the boat is slightly tilted to one side, these two forces do not act in the same line so that there is a resultant couple tending to increase the tilt. It is this upsetting couple which must be counteracted by the outboard floats or stubs.

The value of the upsetting couple is

$$W.\ (G.M)\ \sin\theta$$

Where W = all-up weight of boat
$G.M$ = metacentric height
θ = angle of tilt

and the righting couple (see Fig. 8) is represented by

$$BL \cos\theta$$

Where B = effective buoyancy of the outboard float
L = horizontal distance from $C.L.$ of the boat to the centre of buoyancy of the outboard float.

The totally submerged buoyancy of outboard floats should be at least 20 per cent in excess of that shown by

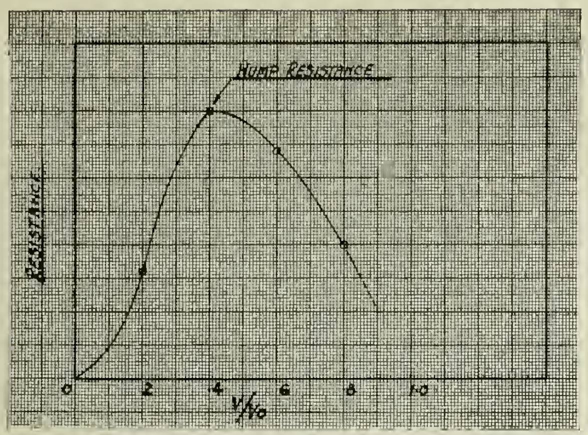

Fig. 5.

the above method in order to satisfactorily counteract the effects of side winds.

From considerations of static stability only it will be seen that it is advantageous to have the buoyancy of the outboard floats become operative immediately the boat begins to roll, so that the upsetting moment is small. However, another condition affects the positioning of these floats, namely, taxying. Usually at approximately 20 knots the water forces on a hull are sufficient to preserve lateral stability and as, while taxying, the total resistance, and therefore the total wetted surface, should be reduced as much as possible, it is advisable to keep the floats high up. Also the forces on floats which are driven at high speed through waves are considerable and tend to unduly stress the wing structure so that the actual position of the stabilizing floats must be a compromise between the two requirements. Normal values of the natural angle of roll at rest on smooth water and with no wind vary from three to four degrees.

The usual British practice is to fit "wing tip" floats, that is, floats positioned as far as possible from the centre line of the boat. This arrangement offers two important advantages:—

(1) A reduction in weight due to the smaller buoyancy required with a large arm.
(2) A smaller resistance both on the water and in the air, again due to the reduced size of float.

It is possible that the hull fitted with stub stabilizers is the most seaworthy, but the weight of the stubs and loss of efficiency on the water due to the extra resistance is too costly at present, although with very large boats this may be considerably improved.

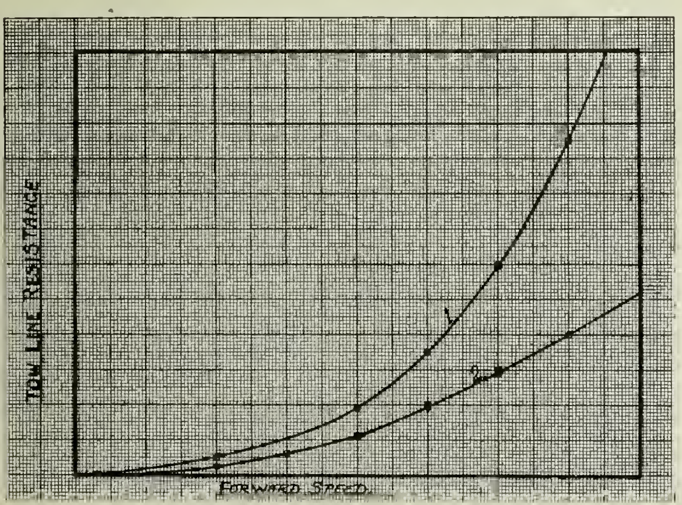

Fig. 6.

Inboard floats also must be proportionally larger and therefore heavier than wing tip floats, and for a given angle of roll, when fully submerged, must be closer to the normal water line, giving increased resistance during taxying.

The relative merits of outboard and inboard floats and stub stabilizers offers a subject for tank tests which urgently requires investigation as no truly comparable data are available at present.

The requirements for longitudinal stability have not been reduced yet to any form giving a simple solution and still offer difficulty in a new design which departs radically from shapes of known characteristics and proved performance. Longitudinal instability occurs in its worst form as "porpoising" during planing. Porpoising is a fore and aft oscillation obviously due to lack of damping moments and the elimination of this characteristic in any particular case is not obtainable by increasing the damping but rather by modifications to the primary causes, namely, the shape of the hull and the disposition of the various masses. Generally porpoising will occur if the centre of gravity of the complete boat is very far forward of the main step or if the distance between the steps is comparatively small. Very approximately it may be said that while planing the boat is supported at the two steps and a comparison of the two reactions is suggested as a subject for investigation. The full conditions, which must include airscrew thrust together with air and water resistances, are complex but it is believed that light would be thrown on a subject which is still somewhat obscure.

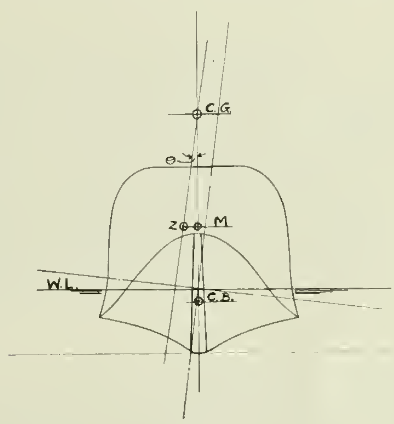

Fig. 7.

Construction and Materials

In the early types of successful boats, notably the F class, the hull construction was of the braced structure type, similar to the fuselage frames of present day land machines and divided into watertight compartments by means of bulkheads. After the war and due principally to the work of Linton Hope and Commander Porte, transverse construction was developed following closely the true monocoque. This method is still in use for wooden hulls and Fig. 9 shows a good example of this construction. Light frames closely spaced form the transverse sections and these are connected by light fore and aft members or stringers, the assembly forming a complete open framework of considerable strength but of light weight. The skin is then attached to this framework, the result being a very strong hull with a reasonable degree of flexibility.

The great disadvantage of wooden hulls is water soakage which in the course of a few days may exceed 14 per cent of the hull weight. Investigations of the possibilities of constructing metal hulls were made with the result that the first metal hull was commenced in 1924

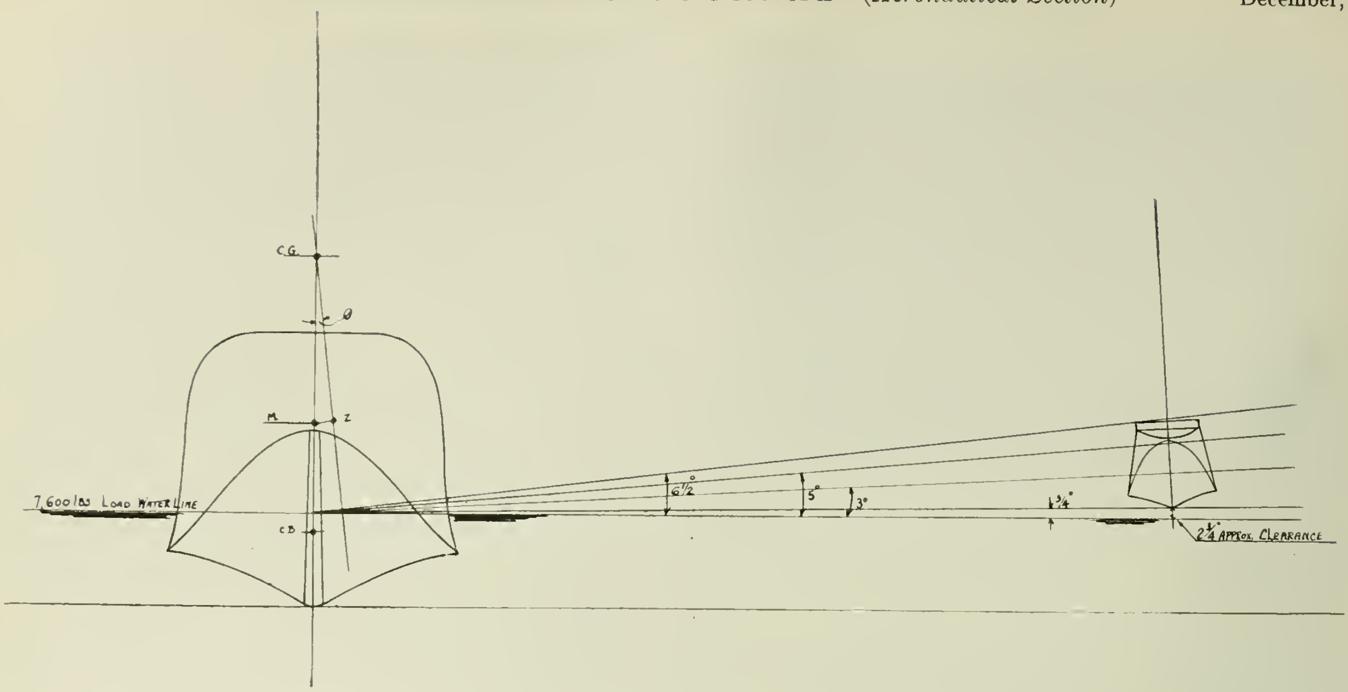

Fig. 8.*

by Short Bros. of England, the material being duralumin. This hull was adapted for the standard F5 superstructure and since then there has been rapid development as the construction has been found to present no serious difficulties. Not only has the weight been reduced by the elimination of soakage but the weight of a metal hull of modern design is less than its wooden prototype. Fig. 10 is a curve showing the variation of hull weight with all-up weight and indicates that larger boat seaplanes should show marked improvements. The usual type of construction adopted is longitudinal which differs from the transverse type in that the frames and stringers are deeper and spaced comparatively far apart. Typical spacings are 18 inches for frames and 6 inches for stringers. Frames are either built up or hooped, the built up type being more adapted to flat sided design. Examples of these two types are shown in Figs. 11 and 12. Stringers usually are continuous but sometimes are intercostal between the frames and bulkheads. Fig. 13 shows some of the sections commonly used. A very cheap construction is one based on hooped frames of approximately X section carrying continuous stringers supporting the skin, which is connected only to the frames at bulkheads and special points where concentrated loads exist. This method is indicated in Fig. 12. It will readily be seen that with any shell type of construction concentrated loads should not exist. As these occur principally at the wing spar joints, it follows that a multi-spar wing construction is desirable, i.e. the ideal is a shell type hull with shell type wings. With the present conventional wing construction these concentrated loads are distributed as quickly as possible through finger plates which, consistent with weight, should have a maximum number of connections to the main structure.

*Machine displacement in lbs. = 7,600.
Transverse *B.M.* = 29.875 inches.
Transverse *G.M.* = −46 inches.
C.B. above Datum = 20.8 inches.
Area of Load Water Plane = 19,040 sq. inches = 132 sq. feet.
Transverse M. of I. of Load Water Plane = 6,310,000 inches^4.
Volume of Wing Tip Float at 6½ degrees heel (Fully Submerged) = 14 cubic feet = 871 lbs. Δ
Volume of Δ of Float at 5 degrees heel = 11.4 cubic feet = 709 lbs. Δ
Volume of Δ of Float at 3 degrees heel = 4.65 cubic feet = 289 lbs. Δ
Volume of Δ of Float at 4 degrees heel = 8.36 cubic feet = 520 lbs. Δ
M.Z. = *G.M.* sin θ = at 6 degrees − 37′ = 46 × .11523 = 5.301 inches.
= at 4 degrees − 55′ = 46 × .08571 = 3.943 inches.
= at 2 degrees − 56′ = 46 × .05117 = 2.354 inches.
= at 4 degrees − 00′ = 46 × .06976 = 3.209 inches.
Pounds per inch immersion at Load Water Plane = 685 pounds.
Note:—Δ = Displacement.
Weight of Water Taken at 62.2 pounds per cubic foot.

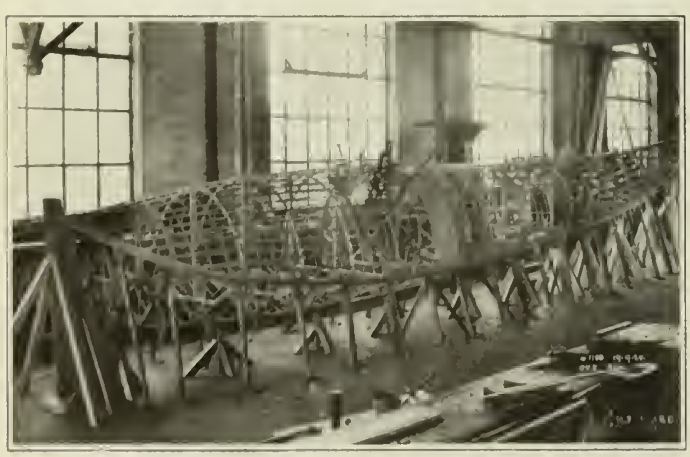

Fig. 9.

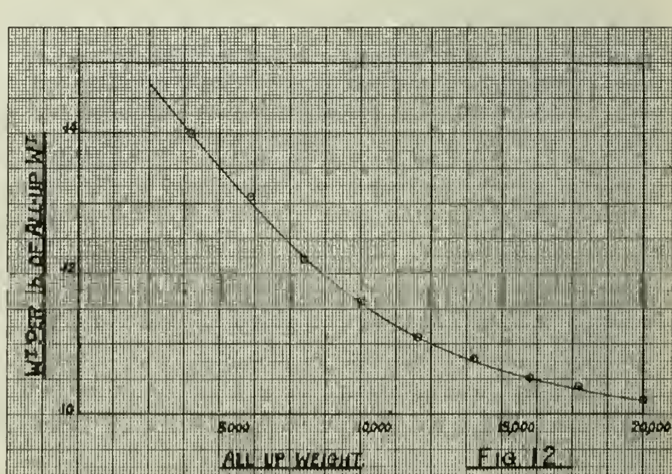

Fig. 10 Hull Weights.

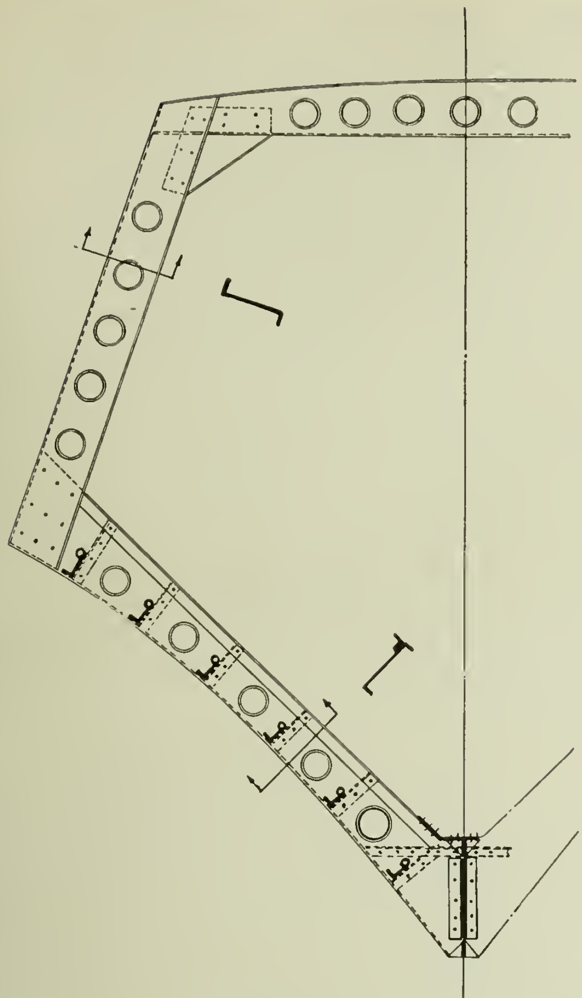

Fig. 11.

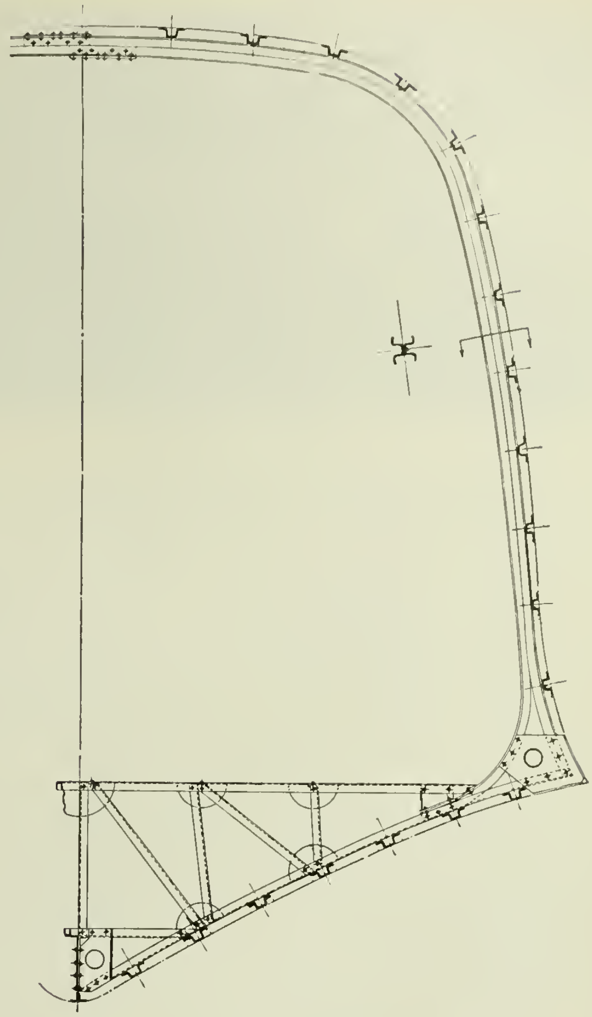

Fig. 12.

The complete hull structure is investigated for strength under several conditions of loading, which briefly are as follows:—

(*a*) At the maximum cross sectional area, the section is checked for strength under an applied bending moment calculated from an empirical expression which includes the length, breadth and depth of the under water volume.

(*b*) *Nose down landing.* The boat is assumed to land nose down at an angle of $\tan^{-1}\frac{1}{3}$ to the line joining bow and bottom of main step at the keel.

(*c*) *Step landing.* In this case it is assumed that the factored all-up weight is distributed evenly over that part of the planing bottom bounded by the wing spar frames and the chines. From full scale tests, carried out in America, the maximum pressure on one type of boat bottom has been found to be 15 pounds per square inch.

(*d*) *Two wave landing.* The boat is assumed to land on two wave crests, one at the rear step and the other at a point forward, determined by the standard (trochoidal) wave length for the particular hull, i.e. the "pitch" is equal to the length of still water line and the depth 1/15th of this.

(*e*) The fore body planing bottom is investigated for loading varying from zero at the bow to 7 pounds per square inch at the main step.

It will be seen that these various cases are all arbitrary but they are justified because they give satisfactory results, —indeed, satisfactory results are expected as the cases are based on known weaknesses in early boats and on the known strength of successful hulls. Stringers are checked as beams each supporting an area of plating given by (length of stringer between frames) times (stringer pitch) and the area is assumed to carry a loading equal to the appropriate pressure. Investigations are still proceeding into the strength of flat plates and various empirical formula are already in use. Reference to these are to be found particularly in "The Strength of Materials" by Case. At present, however, the thickness of planing bottoms, decking, etc. is usually fixed from experience and from practical considerations, although in very large hulls,

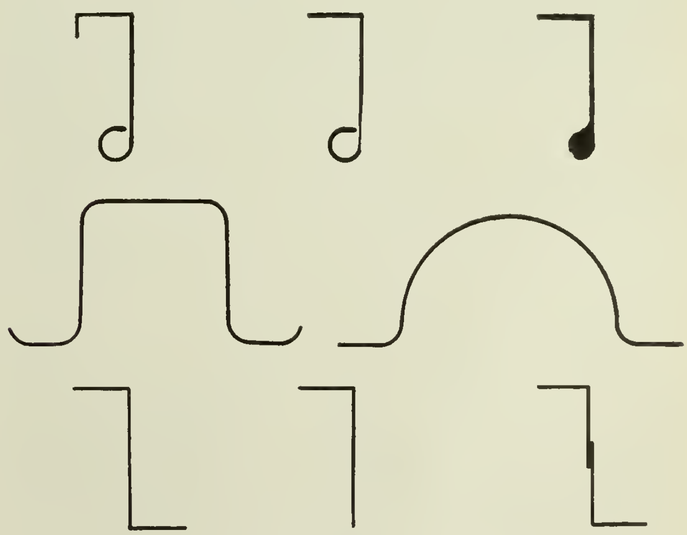

Fig. 13.

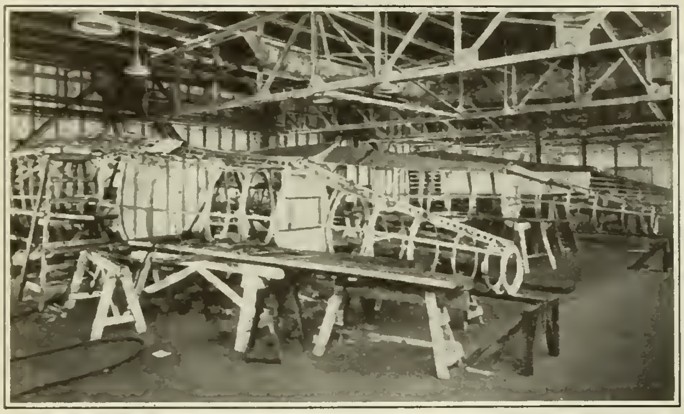

Fig. 14.

detailed investigations will probably result in appreciable saving in weight.

The most commonly used materials for metal hull construction are the aluminum alloys such as duralumin, but as these alloys are all subject, to some extent, to electrolytic action and corrosion when in contact with salt water, the use of stainless steel is growing steadily. Aluminum alloys are protected, with varying degrees of success, against corrosion, the best results being obtained from the use of gum base paints and anodic treatment. Anodic treatment is an electrolytic deposition of a thin film of an hydroxide of aluminum, which in turn requires protection against abrasion. Any hull which has been treated in this way requires constant attention, as should this film be broken, local and very concentrated corrosion will occur. The most recent form of aluminum alloy is Alclad, in which the alloy during manufacture is coated with very thin and pure aluminum which is not subject to corrosion. Not only does this film of pure metal protect the alloy, but in effect "attracts" the electrolytic action from any exposed alloy. The best anti-corrosion surface has been found from experiments in America to be Alclad, anodically treated and painted.

Shop Procedure

Shop work commences with the laying out full size of each frame and the keel and the manufacture of jigs for these parts.

The use of aluminum alloys such as duralumin and alclad present complications but no serious difficulty is experienced once a routine becomes familiar. Normally, these alloys crack and split when subjected to heavy cold working, but can be softened by heat treatment. Fully annealed alloy, i.e. soaked at 350 degrees C.-380 degrees C. and quenched in water, is amenable to complicated working without damage, but the material "ages" at room temperature, regaining nearly full strength and approaching semi hardness in about four days. By normalizing and ageing the material can be brought to its maximum hardness and strength although the full strength is not attained immediately after treatment. After twenty-four hours, almost full strength and hardness are reached but the material does not reach its final stage until after four days, when the condition is permanent until retreated.

For most working on hulls it is sufficient to normalize only, work the material for one hour, and if necessary, retreat. Every piece of material including rivets is subjected to this treatment, so that essential parts of the shop equipment are a large furnace to take full size sheets, and a small salt pot for treating rivets. As rivets are subjected to the most severe working, the time between salt pot and job should be as short as possible, and in one plant is as low as 15 minutes. Recent developments indicate that by refrigeration after treatment it will be possible to treat a week's supply of rivets at one time.

A complete set of frames and keel are made up to jigs, the workers being kept constantly supplied with freshly treated material and rivets, and when the finished parts have been inspected and accepted, assembly commences. For boats up to about 15,000 pounds all-up weight it is convenient to build the hulls upside down so that the riveting of the planing bottom can be given close attention without difficulty. The usual type of assembly jig consists of a heavy steel channel backbone firmly fixed to the floor, and carrying at the correct frame spacing steel ribs to which the frames are attached. (See Fig. 14.) When the frames have been squared and checked for alignment, the keel is positioned, checked, bolted up and then riveted so that the frames are held rigidly by the keel and by the jig. The stringers are laid on next and riveted and then plating begins. The planing bottom is finished first and as much side plating as can be conveniently finished, and the hull is then turned over, lined up on trestles, and the top plating finished. All interior flooring, etc., are mounted and fixed, and fittings for wings, tail, etc. assembled with jigs when the hull is ready for the erection shop.

All the photographic illustrations to this paper are of work designed and built in Canada and my acknowledgements are due to Canadian Vickers Limited for permission to use the original photographs.

Appendix I

Froude's Law of Corresponding Speeds

It is assumed that the total resistance to motion of a body towed along the surface of a fluid is dependent on

(1) The density of the fluid
(2) Relative velocity of motion
(3) Linear dimensions of the body
(4) Gravity.

The first three items obviously affect the resistance to motion and the fourth, i.e. gravity, is intimately related to the wave making resistance of the body.

Let R = total resistance made up of skin friction, wave making resistance, eddy resistance and wind resistance.
ρ = mass density of the fluid.
v = relative velocity of motion.
l = length of the body.
g = gravity acceleration.

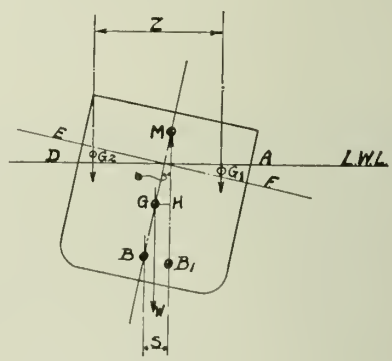

Fig. 1.

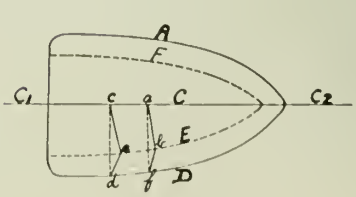

Fig. 2.

Assume,

$$R = f(\rho, v, l, g)$$
$$= \Sigma \rho^a v^b l^c g^d$$

Dimensionally,

$$MLT^{-2} = [ML^{-3}]^a [LT^{-1}]^b [L]^c [LT^{-2}]^d$$

Equating indices of like dimensions

$[M]$ $1 = a$ . . . . (1)

$[L]$ $1 = -3a - b + c + d$ . . . . (2)

$[T]$ $2 = -b - 2d$ . . . . (3)

Expressing b and c in terms of d

from (3) $b = 2 - 2d$

" (2) $c = 4 - (2 - 2d) - d$

$= 2 + d$

$$\therefore \quad R = \Sigma \rho v^{(2-2d)} l^{(2+d)} g^d$$
$$= \rho v^2 l^2 \Sigma \left(\frac{lg}{v^2}\right)^d$$
$$= \rho v^2 l^2 f\left(\frac{gl}{v^2}\right)$$

i.e. the total resistance is the product of the mass density of the fluid, relative velocity squared, length of body squared, and some non-dimensional constant which is a function of gravity acceleration times length of body over relative velocity squared.

This constant can be described as the variable co-efficient of resistance of a particular body to motion on the surface of a fluid whose mass density is ρ, the value of the co-efficient changing for different relative velocities.

The object of model tests of ships and flying hulls is to determine the values of this co-efficient of resistance at various speeds, and it will be seen that in order to obtain the full scale co-efficient from the model the value of $\left(\frac{gl}{v^2}\right)$ of the model tests must equal that for the predicted full scale results.

Neglecting the slight variation in the value of g, this requirement can be expressed as

$$v \propto \sqrt{l}$$

or
$$\frac{vm}{v} = \sqrt{\frac{lm}{l}}$$

or
$$vm = v\sqrt{\frac{lm}{l}} = v\sqrt{\frac{\text{scale}}{\text{ratio}}}$$

where suffix m signifies the model test conditions.

If this condition is satisfied, i.e. if $\frac{v^2}{l}$ is the same for both model and full scale, then the ratio of resistances is given by

$$\frac{Rm}{R} = \frac{\rho m\, l^2 m\, v^2 m}{\rho\, l^2 v^2} = \frac{\rho m}{\rho}\left(\frac{lm}{l}\right)^3$$

Appendix II

To Calculate the Metacentric Height

Assume the angle of displacement to be small and equal to θ (see Fig. 1). Since the weight of the vessel is constant the volumetric displacement must be constant and the volume of the wedge CDE must be equal to that of CAF. Also in Fig. 2, the volume C_1C_2DE must equal the volume C_1C_2AF.

Let G_1 and G_2 be the centres of gravity of the volumes C_1C_2AF and C_1C_2DE respectively. The rolling of the vessel moves the mass of water C_1C_2DE to the position C_1C_2AF, i.e. from G_2 to G_1, and the movement causes the centre of gravity of the total fluid displaced to move from B to B_1.

Let Z = horizontal distance from G_1 to G_2 when AD is horizontal

S = the perpendicular distance from B to B_1M

V = total volume displacement

v = volume of wedge

w = weight of unit volume of the fluid.

Then,

$$w.v.Z = w.V.S. = w.V.\,(B.M)\sin\theta$$
$$= w.V.\,(B.M)\,\theta \text{ for very small value of } \theta \ldots (1)$$

The restoring couple is

$$w.V.\,(H.G)$$
$$= w.V.\,(G.M)\sin\theta$$
$$= w.V.\,(G.M)\,\theta \text{ for very small value of } \theta$$
$$= w.V.\,[(B.M) - (B.G)]\,\theta$$
$$= w.v.Z. - w.V.\,(B.G)\,\theta \ldots\ldots (2)$$

$w.v.Z.$ is twice the sum of the moments about their axis C_1C_2 of all the elements such as $abcd$ which make up the wedge C_1C_2DE.

Let $af = x$

$bf = x\theta$ for very small value of θ

$ac = \delta l$

Then volume of element $acbd = \frac{1}{2}\theta x^2 \delta l$.

The $C.G.$ of this element is at $\frac{2}{3}x$ from C_1C_2, so that

$$Z = 2x\tfrac{2}{3}l$$

$$\therefore \quad w.v.Z. = 2w\theta\int_0^l \tfrac{1}{2}x^2\delta l \, x \, \tfrac{2}{3}x$$
$$= 2w\theta\int_0^l \frac{x^3 d\,l}{3} \ldots\ldots (3)$$

$\frac{x^3dl}{3}$ is the second moment of area of the area $acdf$ about C_1C_2.

Hence $2\int_0^l \frac{x^3dl}{3}$ is the second moment of area of the whole fluid plane about C_1C_2

and $w.v.Z. = w.I.\theta.$

From (2) the restoring couple

$$= w.I.\theta - wV\,(B.G)\,\theta$$

and if this expression is positive the equilibrium is stable, if negative, the equilibrium is unstable.

From (1)

$$w.I.\theta. = w.V.(B.M.)\,\theta$$

Therefore $B.M. = I/V$

Forty-Sixth Annual General Meeting

TO BE HELD IN

TORONTO, Ont.

FEBRUARY, 3rd, 4th and 5th, 1932

AERIAL VIEW OF A PORTION OF TORONTO

By courtesy of Toronto Industrial Commission.

A Record Attendance is Expected

Plan to Attend

Outline of Programme

(Subject to Minor Change)

Wednesday, February 3rd.

Morning	Registration and Business Session.
Noon	Formal Luncheon.
Afternoon	Business Session. Induction of Incoming President and Council.
	Reception and Tea for Ladies.
Evening	Smoking Concert.
	Entertainment for Ladies.

Thursday, February 4th.

Morning	Technical Sessions.
Noon	Luncheon.
Afternoon	Technical Sessions.
Evening	Annual Dinner of The Institute followed by a Dance.

Friday, February 5th.

Morning	General Session and Debate on the Railway-Highway Problem.
Noon	Luncheon.
Afternoon	Visits to Engineering Works of Interest.
Evening	Free.

A special ladies committee has been appointed to arrange for the entertainment of visiting ladies.

At the technical sessions on Thursday, the 4th, papers will be presented for discussion dealing with topics of a wide range of interest, among which may be mentioned the following:

Hydro-Electric Developments on the Lievre River.
Ice Pressure on Engineering Structures.
Filtration Plant at Niagara Falls, Ont.
Meteorology in its Relation to Engineering Works.
The Utilization of Low Grade Fuels.
Central Heating at the Toronto Terminal and at Winnipeg.
Recent Developments in Carrier-Current Telegraphy.
Power Supply for Radio Transmitters in Aircraft.
The Train-Ferry Steamer "Charlottetown."

The morning of Friday the 5th will be devoted to a discussion on an engineering-economic problem which is just now very pressing in Canada: the co-ordination of our Railway and Highway Transportation systems and the justification for the expenditure which they involve. The subject will be introduced by Mr. S. W. Fairweather of the Canadian National Railways, who will be followed by Mr. R. M. Smith of the Ontario Department of Highways, and other prominent speakers.

THE
ENGINEERING JOURNAL
THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XIV DECEMBER 1931 No. 12

Annual General Meeting for 1932

Notice is hereby given that the Forty-sixth Annual General Meeting of The Institute will begin at Headquarters, 2050 Mansfield Street, Montreal, on Thursday, January 14th, 1932, at 8 o'clock p.m. After the reading of the minutes of the last Annual General Meeting, the appointment of scrutineers to count the Officers' Ballot, and the appointment of auditors for the ensuing year, the meeting will be adjourned to reconvene at the Royal York Hotel, Toronto, Ontario, on February 3rd, 4th and 5th, 1932.

R. J. DURLEY,
Secretary.

The Institute and Engineering Education

Among the avowed objects of The Engineering Institute of Canada, the promotion of engineering education takes a prominent place. Those responsible for the framing of our by-laws announced as one of the purposes of The Institute "to collaborate with universities and other educational institutions in the advancement of engineering education," for they believed that in this way The Institute could render the most valuable assistance in the training of young engineers. The Council's interest in engineering education has been shown by the many references to the subject at Council meetings, and by the appointment of what is practically a standing committee on Engineering Education. The annual reports of this committee have given rise to active discussions at our annual meetings, and the topic has been selected on two occasions as the subject for essays in competition for the Past-Presidents' Prize.

The Institute, like the Professional Associations, is concerned with the efficiency of our educational system as a means of raising the professional status of the engineer, and it is for this reason that all of these organizations include definite educational tests in their requirements for admission. The maintenance of such standards for admission is now insured in practically all our professional bodies by insistence on qualifications equivalent to those of a degree from a recognized engineering school, or in default of this, the requirement that the candidate for admission must pass the examinations of The Institute or the Association as the case may be. The mere maintenance of such standards however, is not all. While they must be adequate and reasonably uniform throughout the Dominion, they should be capable of modification from time to time, to keep pace with changing conditions and with the development of the professional courses of our engineering schools. It is for this purpose that the services of our Committee on Engineering Education are available in an advisory capacity.

At the Annual Meeting of 1931, that Committee presented a report suggesting more intimate contact between The Institute and engineering schools throughout the country so that The Institute may become in large measure an active connecting medium between the universities and industry. The Committee also urged the consideration by the universities of a higher matriculation standard for engineering students, or a six-year engineering course, and the desirability of devoting more time to public speaking and literature.

As a result, arrangements have been made to hold a conference on Engineering Education at the forthcoming Annual Meeting in Toronto in February next, at which representatives of the engineering departments of Canadian universities will meet other members of The Institute's Committee with a view to giving practical shape to its proposals. The fact that such a conference is to be held will go far towards fulfilling some of the recommendations quoted.

Those in charge of the engineering courses at our universities have a very difficult course to steer. Critics are numerous, and their criticisms are occasionally more destructive than constructive. The opinion most frequently heard, as recently expressed by the President of Yale University, is "that our engineering schools are not training men who are, as such, fundamentally sound scientists. Young graduates may be alert young fellows, they may have fairly good elementary training in this direction or that, but in general it is alleged that they are not satisfactorily trained in fundamental science, including mathematics. If the engineering school admits any justice in this criticism, it is apt to pass back responsibility for the condition to the poor training given by the preparatory school."

Another point of view which is put forward is that the young engineering graduate lacks general culture and is apt to place undue emphasis on the purely technical side of his college training, forgetting that his technical knowledge, however profound, will be of little service to him unless he is able to think clearly, to express his ideas correctly and to use his own language effectively, and unless he has that familiarity with literature and questions of the day which any well-educated man should possess.

Our engineering schools have to reconcile these ideals with the limitations imposed by lack of time and money, increasing enrollment and by the attitude of the student himself, who too often enters a professional course with the notion that his education merely involves the accumulation of a sufficient number of useful facts and their storage in notebooks for reference as required. Such students fail to realize that an engineer worthy of the name must be something more than a walking pocket-book full of technical data, and in many cases they resist with considerable success all efforts designed to train them in orderly thinking, in the expression of their thoughts, or in non-technical subjects of fundamental importance.

It is unfortunate that frequently the post-graduate professional activities of the young engineer do so little to correct this attitude of mind. As a rule, unlike the young lawyer or medical man, the young engineer in his daily work does not get much of the polish which results from a continual contact with his fellow men, and it is in regard to this aspect of the question that participation in the meetings and activities of a professional body like The Engineering Institute can be of invaluable service to him.

Our Canadian engineering schools are to be congratulated on the progress made in recent years towards better training in fundamental subjects and less specialization, and this in spite of insistent demands for instruction in an ever-increasing number of highly specialized subdivisions of engineering science.

In the past we have had a great deal of discussion and criticism of engineering education and too few actual conferences between those engaged in the business of teaching and laymen who are employers of, or workers with, the young engineer. It is to be hoped that the conference to be held at the Annual General Meeting of 1932 will do much to remove this disadvantage as far as The Institute is concerned and that teachers and outsiders will gain a better mutual comprehension of the way in which they can co-operate.

Proposed Amendment to By-laws

In accordance with Sections 74 and 75 of the By-laws, Council presents for the consideration of corporate members the following proposal for the amendment of Section 37, dealing with arrears of fees. This proposal will in due course be submitted for discussion at the Annual General Meeting on February 3rd, 1932, in Toronto, and will subsequently go out to ballot.

At the recent Plenary Meeting of Council, attention was drawn to the large number of members in arrears of fees for two, three or more years, on whose cases Council was asked to pass judgment. It was noted that in other societies with aims similar to our own, such a condition is not permitted to arise, members in arrears for one year or more being *ipso facto* removed from the list unless relieved from this penalty by resolution of Council.

After discussion it was decided to propose such an amendment to Section 37 of our By-laws as would bring our practice into line with the above policy, so that, in the event of the amendment carrying, the amount of fees outstanding will be reduced and the expense of collecting them greatly lessened.

The section in question as now proposed by Council is given below, new wording being underlined.

Arrears—Exemptions—Life Membership List.

Section 37.—The Secretary shall notify any member whose fees become in arrears. No member shall be considered in arrears for any year until after the thirtieth day of June of that year. <u>A</u> member who is in arrears shall <u>not</u> have the right to vote, <u>he shall not receive the publications of The Institute,</u> nor shall he be eligible for office in The Institute or any of its Branches.

<u>Should his fees still be in arrears on the first day of October, he shall again be notified in form prescribed by the Council, and if still in arrears on the first day of January of the year following, he shall forfeit his connection with The Institute and shall be so notified by the Secretary.</u>

<u>The Council, however, may for cause deemed by it sufficient, extend the time for payment and for the application of these penalties.</u>

<u>Further</u> the Council may for sufficient cause temporarily excuse from payment of annual fees any member who from ill health, advanced age, or other good reason assigned, is unable to pay such fees, and the Council may remit the whole or part of fees in arrears.

The Council, at its discretion, may <u>as a privilege</u> exempt from further payment of annual fees any corporate member who has reached the age of sixty-five, or who has been a corporate member for thirty years, or who has rendered signal service to The Institute. The names of such members shall be placed on a Life Membership List."

Meeting of Council

A meeting of Council was held on Tuesday, November 17th, 1931, at eight o'clock p.m., with Vice-President O. O. Lefebvre, M.E.I.C., in the chair, and five other members of Council present.

The minutes of the Plenary Meeting of Council held on September 21st, 22nd and 23rd, 1931, and of the meeting held on October 16th, 1931, were confirmed.

The membership of the Committee on Development was approved as follows:

Past-President	G. H. Duggan, M.E.I.C.
	J. M. R. Fairbairn, M.E.I.C.
	A. J. Grant, M.E.I.C.
	C. H. Mitchell, M.E.I.C.
	R. A. Ross, M.E.I.C.
	J. C. Smith, M.E.I.C.
	A. Surveyer, M.E.I.C.
	H. H. Vaughan, M.E.I.C.
	George A. Walkem, M.E.I.C.
Vice-President	O. O. Lefebvre, M.E.I.C.
Treasurer	W. C. Adams, M.E.I.C.
Chairman	J. L. Busfield, M.E.I.C.

The chairman pointed out that the committee would have the advantage of the counsel and advice of no less than nine past-presidents, which would be available in dealing with the vital problems to be considered by this committee.

A report from the Legislation Committee was approved, giving the text of the amendment to be proposed to Section 37 of the By-laws dealing with the question of arrears, as decided upon at the Plenary Meeting of Council. It was decided that no action should be taken at the present time with regard to any change in the present arrangements for rebates.

The report of The Institute's examinations held on November 3rd, 1931, was presented and approved, and it was noted that Mr. George Stephenson of Ottawa had passed the examinations under Schedule "C" for admission as an Associate Member, and that S. G. Lochhead, S.E.I.C., had passed those under Schedule "B" making him eligible for transfer to the class of Junior.

A letter was presented from the chairman of The Institute's Membership Committee suggesting that action should now be taken to carry out some of the suggestions in the report of that committee which was presented at the Plenary Meeting of Council. The Secretary was directed to communicate with the Executive committees of all branches drawing attention to the situation, and asking them to co-operate with General Mitchell's committee.

A letter was presented from the secretary of the Institution of Electrical Engineers (Great Britain), approving the draft agreement with that body in regard to the formation of Radio sections of branches of The Engineering Institute of Canada, this being generally along similar lines to the agreement already entered into with the Royal Aeronautical Society, and providing for an interchange of publications and affiliation of local Radio sections with the Institution of Electrical Engineers. This agreement was approved.

A request was received from the City Improvement League for The Institute's support in connection with a petition to the provincial government of Quebec asking for a comprehensive Provincial Town Planning and Zoning Enabling Act. As this is a provincial matter the Council, while generally in favour of the proposal, directed that the question should be referred to each of the branches in the Province of Quebec for their consideration and action.

Five resignations were accepted, four reinstatements were effected, and three special cases were dealt with.

A number of applications for admission and for transfer were considered, and the following elections and transfers were effected:

Elections		*Transfers*	
Associate Member	1	Junior to Assoc. Member	2
Junior	1	Student to Assoc. Member	3
Students admitted	16	Student to Junior	3

The Council rose at eleven fifteen p.m.

Publications of Other Engineering Societies

From time to time announcements have appeared in The Engineering Journal and the E-I-C News regarding the exchange arrangements which exist between The Engineering Institute of Canada and the founder engineering societies of the United States, whereby members of The Institute may secure the publications of the American societies at special rates which in most instances are the same as charged to their own members. A list of these publications with the amounts charged is given below, and subscriptions may either be sent direct to New York or through Headquarters of The Institute.

	Rate to E.I.C. Members	*Rate to Non-Members*
American Society of Civil Engineers		
Proceedings, single copies	$ 0.50	$ 1.00
Per year	4.00	8.00*
Civil Engineering, single copies	.50	.50
Per year	4.00	5.00
(Plus $.75 to cover Canadian postage.)		
Transactions. per year	6.00	12.00†
Year Book	1.00	2.00
(Other publications 50 per cent reduction on catalogue price to E.I.C. members).		

* *If subscription is received before January 1st, otherwise $10.00.*

† *If subscription is received before February 1st, otherwise $16.00.*

	Rate to E.I.C. Members	*Rate to Non-Members*
American Institute of Electrical Engineers		
Electrical Engineering, single copies	$ 0.50	$ 1.00
Per year	5.50	10.50
Transactions, per year (cloth binding), (issued quarterly)	5.00	10.00
Pamphlets	.25	.50
American Society of Mechanical Engineers		
Mechanical Engineering, single copies	$ 0.50	$ 0.60
Per year	4.00	5.00
Transactions, new, bound, fourteen sections, complete (over 300 papers)	12.50	25.00
(Other publications, same rate to E.I.C. members as to A.S.M.E. members.)		
American Institute of Mining and Metallurgical Engineers		
Mining and Metallurgy, single copies	....	$ 0.50
Per year	....	3.00
(Plus $1.00 for foreign postage.)		
Transactions, per volume	....	5.00
(Plus $.40 for foreign postage.)		
Technical publications: Supplied at $.01 per page, with a minimum charge of $.25 for single copies, or at a subscription rate per year of..	....	7 00
(Plus $1.00 for foreign postage.)		

No special rates for members of The Engineering Institute of Canada.

OBITUARIES

Edward Fleming Bateman, A.M.E.I.C.

The death of Edward Fleming Bateman, A.M.E.I.C., occurred at Saskatoon, Sask., on October 21st, 1931.

Mr. Bateman was born at Mirfield, Yorkshire, England, on August 1st, 1854, and received his education at Victoria College, Jersey, the training ship "Worcester" at Erith, Kent, and the Engineering School of Kings' College, London.

Mr. Bateman was a pupil with the late J. F. Latrobe Bateman, past-president of the Institution of Civil Engineers, and was later engaged for three and a half years with Messrs. Jas. Watt and Company, Birmingham. For two years Mr. Bateman was with the Lambeth Engineering Company, London, as draughtsman and manager, and in 1883 entered private practice. Following this, he was for nearly ten years chief mechanical draughtsman to the Commissioners of Irish Lights, during which time he had varied experience on important lighthouse works around the coast. Coming to Canada in 1910, Mr. Bateman settled in Saskatoon, Sask., where he carried out many works of importance, including the erection of the structural steel and bunkers at the new power house, the reconstruction of the pumping station, the laying of sidewalks, etc., for the city. At the time of his death, Mr. Bateman was practising as a civil and mechanical engineer.

Mr. Bateman joined The Institute as an Associate Member on October 22nd, 1918.

Orville Frank Bryant, M.E.I.C.

Members will learn with regret of the death of Orville Frank Bryant, M.E.I.C., which occurred suddenly at Montreal on October 27th, 1931.

Mr. Bryant was born at Meredith, N.H., on August 27th, 1887, and graduated from the University of New Hampshire in 1910 with the degree of B.S. in chemical engineering.

From 1911 to 1914, Mr. Bryant was chemical engineer with the Nekoosa-Edwards Paper Company at Port Edwards, Wis., and then became chief of the Forest Products Laboratories of Canada, in Montreal, which position he held until 1918. Being desirous of extending his technical knowledge of the paper-making industry, Mr. Bryant became technical advisor to Bennett Ltd., Chambly Canton, and later chemical engineer to the Laurentide Company at Grand'Mere, where he remained from 1920 to 1927. From there, Mr. Bryant went to Saint John, N.B., as manager of the Nashwaak Pulp and Paper Company, where he remained until 1930. He served with the representatives of the government and the universities on the administrative committee which brought about the establishment of the Pulp and Paper Research Institute, and was largely instrumental in its development, and in 1930 he was appointed as technical adviser to the association, which office he held at the time of his death.

Mr. Bryant joined The Institute as a Member on May 7th, 1929.

Harold Elmer McLellan, A.M.E.I.C.

Regret is expressed in recording the death of Harold Elmer McLellan, A.M.E.I.C., on September 24th, 1931.

Mr. McLellan was born at Souris, P.E.I., on June 24th, 1893, and received his education at Charlottetown, P.E.I., and McGill University, graduating from the latter institution in 1919 with the degree of B.Sc.

From 1920 to 1923, Mr. McLellan was with the Canadian National Railways as inspector and transitman under the harbour engineer, the work mainly consisting of repairs to piers and breakwaters and dredging at Car Ferry Terminals at Port Borden, P.E.I., and Cape Tormentine, N.B. In 1923-1925, Mr. McLellan was engineer in charge of the laboratory of the Dominion Fire Prevention Association, and following that period was for one year demonstrator at McGill University. During the period 1926-1930, he was assistant engineer with the Laurentide Construction Company, in charge of structural design and estimating. Later Mr. McLellan was concrete designer with the Lucerne-in-Quebec Community Association, and in 1930-1931 was structural designer with United Engineers and Constructors of Canada, Ltd., Montreal.

Mr. McLellan joined The Institute as an Associate Member on March 25th, 1925.

Eugene Washington Stern, M.E.I.C.

It is with deep regret that we record the death of Eugene Washington Stern, M.E.I.C., on November 9th, 1931.

Mr. Stern was born at Toronto, on August 20th, 1865, and in 1884 graduated in civil engineering from the School of Practical Science, University of Toronto. Following graduation, until 1891 he was engaged on railroad surveys and construction, and on structural work including the Washington bridge over the Harlem river. During this period he was for one year Fellow in engineering at the School of Practical Science. In 1892 he became chief engineer in charge of the design and supervision of construction of buildings and bridges with the Koken Iron Works, St. Louis, Mo. In 1902 he entered private practice as a consulting engineer, making a specialty of buildings and foundations. Mr. Stern designed and was in charge of the constructive features of many important buildings such as the D. L. and W. Railway terminal, Hoboken, N.J., the 20-storey addition to R. H. Macy and Company, the New York Evening Post building, the Guaranty Trust Company building, the nurses home of Mount Sinai hospital and the Temple Emanu-El. In 1915-1917 he was chief engineer of highways for Manhattan. During the Great War, Mr. Stern served as a major of engineers in the American Expeditionary Force. He was with the 8th French Army from November, 1917, to December, 1918. Later he became chief road officer, Base Section No. 2, and was recommended for promotion to the rank of lieutenant colonel. In 1919 he returned to private practice.

Mr. Stern was a member of the American Society of Civil Engineers, the American Institute of Construction Engineers, the American Construction Institute, the Society of American Military Engineers, the American Legion, and the Military Order of the World War.

Mr. Stern joined The Engineering Institute of Canada (then the Canadian Society of Civil Engineers) as a Member on April 17th, 1909.

Henri Etienne Vautelet, M.E.I.C.

By the death of Henri Etienne Vautelet, M.E.I.C., at Montreal, on November 13th, 1931, The Institute loses one of its senior members who was a distinguished representative of the engineering profession in Canada.

Mr. Vautelet was born at Sedan, France, on February 25th, 1856, and was educated at the Sorbonne and the Ecole des Mines, Paris, graduating from the former school in 1873 and from the latter in 1877.

Coming to Canada in 1884, he engaged in mining work in the Cobalt district, and subsequently became connected with the Colonization Department of the Dominion government. In 1886 Mr. Vautelet entered the service of the Canadian Pacific Railway Company, a connection which was to continue for nearly twenty years. He was soon promoted, becoming principal assistant engineer in 1893, and assistant chief engineer in 1902. Mr. Vautelet's high professional reputation was largely based on his wide experience in bridge design and construction, principally gained in connection with the many bridges necessary to carry the Canadian Pacific Railway across the rivers and canyons along its route. He was responsible for many of these and later for a number of other important structures, among which may be mentioned the moveable dam at St. Andrews, near Winnipeg, and some of the earliest grain elevators to be constructed in this country.

Severing his connection with the Canadian Pacific Railway in 1903, he entered partnership with the late Percival W. St. George, founding the firm of St. George and Vautelet, consulting engineers. In 1908 he was ap-

HENRI ETIENNE VAUTELET, M.E.I.C.

pointed chairman of the Commission appointed to deal with the reconstruction of the Quebec bridge following its first collapse, and was engaged on this project until 1911, when he retired from active professional life.

Mr. Vautelet's eminence as an engineer may be traced to the thoroughness of his scientific and mathematical training, his wide professional experience and an originality of idea and treatment which has led to the wide adoption of many of his methods and details of construction.

Personally popular, his outlook was consistently optimistic and he will be greatly missed by those who were privileged to be his associates.

Mr. Vautelet joined The Institute (then the Canadian Society of Civil Engineers) as a Member on January 9th, 1888, and was the first recipient of the Gzowski Medal on its establishment in 1890.

Mr. Vautelet is survived by his widow, one daughter, a son, a brother in Brazil and a sister.

PERSONALS

Chas. W. Deans, S.E.I.C., is graduate assistant in civil engineering at Iowa State College, Ames, Iowa. Mr. Deans graduated from the University of British Columbia with the degree of B.A.Sc. in 1930.

G. W. E. Nicholson, A.M.E.I.C., is now connected with the Southern Kraft Corporation, at Mobile, Ala. Mr. Nicholson, who is a graduate of the Chalmers Technical Institute, was for a time with the Bogalusa Pulp and Paper Company, Inc., at Bogalusa, La., and more recently lived in Montreal.

J. C. Higbee, Jr.E.I.C., is now resident engineer at Vermilion Bay, Ont., for the Department of Northern Development, Kenora District. Mr. Higbee was formerly located at Newcastle, Ont.

Charles W. Crossland, S.E.I.C., who graduated from McGill University this year, is now located in Cambridge, Mass., where he is taking a post-graduate course in aeronautical engineering at the Massachusetts Institute of Technology.

H. R. Bissell, A.M.E.I.C., of the Grout Engineering Company, Ltd., has been transferred from Fergus, Ont., to Toronto. Before joining the Grout Engineering Company, Mr. Bissell was manager of the Sterling Mine, at Sterling, N.S., and in 1927 he was mine superintendent at the Tetreault mine of the British Metal Corporation (Canada) Ltd., Montauban, Que. Mr. Bissel graduated from McGill University with the degrees of B.Sc. and M.Sc. in mining in 1922 and 1923 respectively.

Geo. R. Pratt, A.M.E.I.C., has re-established himself in Winnipeg, Man., in private practice as consulting steam power and combustion engineer. He has recently completed a two year engagement with the United Engineers and Constructors, Montreal, as assistant designing engineer on the Glace Bay, N.S., plant of the Dominion Coal and Steel Company, and a similar power plant erected at Minto, N.B., for the New Brunswick Power Commission. For a number of years, Mr. Pratt was in charge of the Alberta government campaign for marketing the coals of the province.

A. S. Williams, A.M.E.I.C., formerly electrical designer with the Northwestern Power Company, Ltd., is now chief operator of the company's plant at Seven Sisters Falls. Mr. Williams graduated from the University of Manitoba in 1921 with the degree of B.Sc., and following graduation was demonstrator in physics at that university. In 1922-1923 he was with the Canadian General Electric Company at Peterborough, Ont., and in 1923-1924 was draughtsman on electrical layouts with the Hydro-Electric Power Commission of Ontario. From 1924 to 1929 Mr. Williams was with the Manitoba Power Company, Ltd., as chief operator at the Great Falls generating station of that company.

Some Observations on the Engineering Profession

S. G. Porter, M.E.I.C.,
President of The Engineering Institute of Canada.

Following the Plenary Meeting of Council held in September, S. G. Porter, M.E.I.C., President of The Institute, visited and addressed the following branches in the Maritime Provinces, Quebec and Ontario: Halifax, Moncton, Saint John, Chicoutimi, Quebec, St. Maurice Valley, Montreal, Ottawa and Toronto. More recently he has addressed the Lethbridge and Saskatchewan branches of The Institute, his subject being: "Some Observations on The Engineering Profession."

The following is a summary of his remarks:—

It is worthwhile occasionally to stop and consider what are the duties and obligations which rest upon us as members of the engineering profession, and whether or not we are meeting them in a worthy manner.

We have first an obligation to ourselves. We are in the profession because we like the work and we have chosen it as a means of making our livelihood. It is our duty then to avail ourselves of whatever advantages are offered for our personal advancement.

One means of advancing our own interests is to join with others who are similarly interested in order to benefit from an interchange of professional knowledge and experience. Prompted primarily by selfish motives, we soon find that this interchange cannot persist as a "one-way traffic," and that an obligation rests on us to contribute our share to the common good. And thus we come to a recognition of our duty to our profession.

It was with these aims of mutual benefit in mind that our Institute was formed for the purpose of advancing engineering and scientific education; developing high standards of practice; and for advancing the professional, social and economic welfare of the members of the profession.

These are objects which we cannot successfully accomplish working as independent individuals. They require the organized efforts of the profession as a whole, and it is only through the success of the organized efforts of the profession to better its own position that the benefits are reflected in the improved welfare of the individual members. For whatever benefits the profession benefits the members of the profession.

In stating that one of the objects of The Institute is the advancement of engineering and scientific education, I think we should go one step further and say that we stand for higher educational and technical qualifications to entitle one to use the title and practise the profession of engineering. Our educational facilities, especially for engineering education, are far superior to what they were a generation or so ago. Likewise, the thoroughness of the scientific and engineering investigations which are necessary in order to meet the exacting requirements of modern construction and industry, makes it essential that the engineer have a high degree of educational and technical training as well as practical experience before he is entrusted with such professional responsibility.

I believe that the day is past when the instrumentman or the construction foreman, having acquired a smattering of knowledge of engineering practice without knowing the why or the wherefore of it, is entitled to pass into the ranks of professional men and call himself an engineer. I would not disparage the so-called self-educated engineer. He is to be highly commended. Nor would I specify that every engineer must have a college degree. But I would require that he have the equivalent of an engineering course before he be accepted as a professional engineer. Now that registration is becoming compulsory throughout the country before one can practise engineering, entrance into the profession will soon be entirely through the channel of registration. And since this must precede the practice of the profession, the result will be that the young engineer will prepare himself for meeting the educational and technical requirements and will not expect to be admitted into the profession without having them. This will not work a hardship on the young engineer, for he will know what the requirements are and can prepare himself accordingly, just as he would have to do to enter any other profession. While we are passing through the transition period, due consideration needs to be given to the older engineers who did not have the benefit of a technical education, but they are rapidly passing off the stage, and the profession is being more and more confined to the scientifically educated engineer, and entrance into the profession more and more restricted to such. This in itself gives engineers a higher professional status, and should tend to the solidarity of the profession.

The next object is to develop high standards of practice. The engineering profession enjoys a high reputation for the observance of professional ethics, for honesty and good faith in the performance of duty. There is occasion, however, for careful consideration of the methods and ethics of some semi-engineering activities—some industries or sales organizations in which engineers are engaged or which they partially or fully control. There is no objection to the engineer being a manufacturer, or a salesman, or a promoter. But instead of permitting himself to accept some of the doubtful practices he occasionally encounters, he might render a service both to his profession and to the business interests he represents, by using his influence for the abolishing of objectionable practices. It is his duty to call upon his fellow engineers to support him in any such effort, and the duty of his fellow engineers to give him their support. There is where our organized effort would be effective.

A further object of our Institute is to advance the professional, social and economic welfare of the members of the profession.

We owe a duty to our profession. The engineer who selfishly sticks to his own narrow job, without regard to the welfare of his fellow engineers, is not meeting his full responsibility. He should be as keenly interested in the development of high ethical standards and of professional pride and loyalty as in his personal success. A greater unity and solidarity in the profession are outstanding needs of the engineers of Canada today. How can we expect our voice to be heard and heeded unless it has behind it the force that can only come out of unity and solidarity? If all the engineers of Canada, working in harmony and professional loyalty, could provide a Dominion-wide medium for expressing the viewpoint of the engineering profession, they would exert an influence otherwise unattainable, both on public opinion and on legislation which affects, not merely the welfare of engineers themselves, but the safety and welfare of the public where the construction, operation or control of engineering works and public service utilities are governed by legislative enactment. Such a condition would also result in greater public recognition and more favourable publicity, and would create greater confidence in Canadian engineers and enable them to compete more successfully with outside engineers. All this would result in a reflex influence on the profession itself in creating a stronger professional consciousness and *esprit de corps* among engineers, comparable to that existing in the other professions.

Those are the things that an engineering organization should aim to achieve for the professional, social and economic welfare of its members.

There remains another important duty, and that is our obligation to the public.

There is an obligation resting on each member of our profession, as well as on the profession as a whole, to contribute to the solution of society's problems. The engineer should remember that he is a member of society and not merely a technician. From the nature of his training, co-ordination and co-operation should be instinctive in him, and he should be ready to apply them in his relations to society as well as to his machines. And yet one of his failings is likely to be that he is so engrossed with the immediate task of his own work that he fails to give thought to the problem of how his task meshes with that of his brother engineer, and how the tasks of the two of them mesh with those of still others, and so with all organized society.

The engineer's place in our social structure is particularly important because of the newness of our country and the vastness of its resources. The engineer is by nature a pioneer. He makes ready the way for civilization. He it is that combines the forces of nature and the discoveries of science, and applies them to the needs of luxury-loving civilization. Although many of the principles of mathematics, physics and mechanics were known thousands of years ago, greater advances in their application to industry and the needs of a highly organized social structure have been made within the lifetime of the men of this audience than in all preceding time combined.

This very condition presents a great opportunity, and at the same time imposes a great responsibility on the engineer. You occasionally hear the complaint voiced by engineers that they do not receive the recognition they are entitled to from the public. This is no doubt true. Civilization's debt to the engineer is indeed beyond measure. And he is human and vain enough to want some recognition and credit for what he has done. But after all, is it not largely his own fault? Is he assuming his due share of the responsibility of shaping public policies and bearing the burdens of citizenship in his community? If his training fits him pre-eminently for the task of supplying to the public the utilities and the industrial facilities which it demands, does it not also qualify him for a voice in formulating the policies and directing the course of the activities of those bodies which govern and control us? The obligations of citizenship demand that we capitalize our engineering skill and the influence of our personality for the benefit of the community of which we are members.

One particular field of opportunity lies in the influence which we may exert in the development of our natural resources. Our training as engineers should enable us to appreciate more keenly than others the necessity of a wise public policy in the development and utilization of our natural resources. That fact imposes on us the duty of giving leadership to our governments and to public opinion in formulating wise policies and guiding them in their execution. We have a higher obligation than merely doing well the professional job we are hired to do in exploiting the resources of a new and rich country. The people of the next generation and the next will praise or condemn our generation according to whether we wisely conserve or selfishly exploit the wealth that has been given us by a generous Providence. We are its trustees. If we fail in our trusteeship, the engineering profession must bear a large share of the blame.

The same reasoning applies to many of the complex problems that are troubling industry and governments today. The solution of a problem consists in determining the value and influence of the several factors of which it is made up. Where could you find a better mode of approach to the complex problems that are troubling industry, commerce, economics and politics today than those used by the engineer in studying the problems involved in his own special field. I do not wish to imply that the engineer has some mystic or superior power which will enable him to set right the times that are so badly out of joint, but if he will apply the sound principles of engineering analysis to them he will enhance the value of his citizenship and perform a patriotic service to his country of a much higher order than the haphazard policy of the average politician.

Engineering is the link between science and industry. Its function is the "application of scientific methods to the utilization of the resources of nature." There are no sharp lines of division separating its activities from those of science on the one side, and from industry on the other. The tendency during the past few decades has been to extend the activities of the engineer further and further in both directions. The engineer and the scientist work hand in hand in the research laboratories. The nature of their work is often very nearly identical. It is impossible to say whether the scientist is an engineer, or the engineer is a scientist. In fact, either statement is true, and there need be no jealousy on either side, for their professions are equally worthy.

So on the other hand, in the direction of industry, engineers have been brought into more and more intimate contact with manufacturing and industrial processes. Whereas a few decades ago the engineer only designed and built the machines and factories, he now plays a prominent part in operating and managing them. An outstanding example of the recognition of the value of technical training for executive and administrative positions is seen in the fact that practically all the major executives in the electrical manufacturing industries, and of electric utilities, are technically trained engineers. The same tendency is seen, though not to so marked a degree, in other industries, in railway administration, in public utilities and particularly in city management.

The industrial engineer has been so successful in the application of his technical abilities to methods of production that production has run ahead of the means of distribution, and the ability of the community to absorb his products. Improved methods of production and efficiency of management have brought about an increase of more than forty per cent in the past decade in the per capita production in the United States and Canada. That is, seven men now produce as much as ten did only one decade ago. That ratio applies to industry. In agriculture the increase in per capita production has been still more pronounced. This has brought about our present problem of maladjustment. Is it not possible for the engineer to assist the economist in applying similar methods to this new problem, and bring about a new relationship that will result in a more equitable control of all the elements which enter into the production, distribution and utilization of all manufactured articles? This must include the human element as well as materials. It must likewise include the equitable distribution of the burdens and benefits of labour. He must, furthermore, join with the sociologist and the educationalist in creating a proper distribution of the time element—its division between labour and leisure.

There is an abundance of wealth, an abundance of goods, in the world. There should also be an abundance of work. An inventory of labour is needed. How much have we available? How much is required to do the world's work? How much should be allotted to each worker?

These are difficult problems. Their difficulty arises out of the fact that the human element is involved. If they involved machines only, we could solve them. But since they are human, are we to give them up?

I am not proposing a remedy for unemployment and the other problems that attend it. I do suggest, however, that there is a fertile field for scientific and engineering investigation into the problem of the proper distribution of labour so that all will share more equitably both in its burden and its reward. In saying this, I am not advocating the principles of communism. Far from it. On the contrary, if we are not able, by the application of scientific and engineering methods, to bring about a material improvement in the haphazard system of the distribution of labour that now prevails, the forces of communism will continue to grow at an alarming rate, and will threaten the very foundations of our national existence. I repeat that I am not competent to offer a solution, but if I can arouse the engineers of Canada to become more alive to their responsibilities of citizenship, and become more aggressive and constructive in their efforts to render assistance in the solution of Canada's problems, I shall have performed a duty to my profession and to my country.

BOOK REVIEWS

American Civil Engineers' Handbook, 5th Edition

Thaddeus Merriman, editor-in-chief. Wiley & Sons, New York, 1930, 4½ x 7¼ in., 2,263 pp., figs., charts, tables.
In one volume (atholeather) $8.00. In two volumes (real leather) $10.00.

The practising engineer uses a handbook or pocket book if he can obtain from it facts, formulae or methods more readily than from original papers or text-books. He often desires also some compendium which will give him a concise account of recent progress in subjects allied to his own special field. For example, a civil engineer engaged on bridge work, while not himself an authority on highway construction or electrical illumination or tunnelling, should have available some work from which he can ascertain the effect on his own work of standard practice or recent development in these or other subsidiary divisions of his work.

The new edition of Merriman well fulfills these purposes as regards civil engineering practice on this side of the Atlantic. Its twenty-two sections have all been prepared by well-known authorities working under Thaddeus Merriman as editor-in-chief, and they strike the happy medium as regards the selection of practical information and mathematical formulae.

The book is well illustrated and the diagrams are clear, although some are necessarily small in scale and others attempt to include too much detail. The index occupies 198 pages and accompanies each volume in the two-volume edition. In future issues it might be well to indicate the beginning of each section by thumbtabs, so as to facilitate ready reference. The book is so favourably known from its previous editions as to need little or no recommendation from a reviewer. It is an authoritative book of American practice in the wide field it covers.

The Automobile Engineer's Pocket Book of Rules, Tables and Data

By H. Kerr Thomas. E. and F. N. Spon, Ltd., London, 1931, cloth, 3¾ x 6¼ in., 126 pp., figs., tables, 6/-.

Essentially a book for the drawing office, this is intended for the designer, not the operator, and collects for his reference a series of formulae systematically arranged to be employed in chassis and engine calculations. Where descriptions or discussions are given they are necessarily of the briefest.

Due attention has been given to methods for determining frame stresses and to the subject of suspension and spring design. The information on tooth gearing takes account of modern methods. In addition to its utility to the designer, the book will be found of value to anyone who desires to study the many detailed calculations needed in proportioning modern automobiles.

To those accustomed to stating weights or forces in pounds, it seems strange that such units as tons and cwt. are still employed in a book of this kind. On page 78 we even find a pressure stated in cwt. per square inch.

Molesworth's Pocket Book of Engineering Formulae, 30th edition

By Sir Guilford L. Molesworth. E. & F. N. Spon, Ltd., London, 1931, cloth, 3 x 5 in., 935 pp., figs., tables, 6/-.

First issued in 1862, "Molesworth" still goes on from edition to edition and keeps up with the times. For a man who must carry in his pocket his technical library of reference for all branches of engineering, there is no handbook so concise and comprehensive, although in the limited compass of nearly nine hundred small pages of text it is of course impossible to give the detailed information available in larger pocket books. The new 30th edition includes much new matter on topics of recent interest and the book has been thoroughly revised.

Spons' Electrical Pocket Book, 4th edition

By W. H. Molesworth. E. and F. N. Spon, Ltd., London, 1931, cloth, 3¾ x 6¼ in., 401 pp., figs., tables, 6/-.

In size and form this is really a pocket book. Like "Molesworth" it is much condensed and gives little theory but many tables and much explanatory matter. The additional material included in the edition now issued deals briefly with such subjects as electric welding, radiation, wireless transmission, and television. The methods and standards referred to naturally follow British rather than trans-Atlantic practice. The book can be recommended for use where more elaborate handbooks are not available.

Mechanical Engineers' Handbook, 3rd edition

Lionel S. Marks, editor-in-chief. McGraw-Hill, New York, 1930, cloth, 4½ x 7 in., 2,264 pp., figs., charts, tables, $7.00.

A glance over the pages of a book like this gives a striking impression of the extent of the field which must be covered by a man who is competent even in one of the many divisions of the art of mechanical engineering. Recent development has been rapid in many branches and it is necessary to take account of researches and theories which even ten years ago were conveniently ignored, but which now urgently require the engineer's attention, since pressures, speeds, temperatures and rates of operation are constantly being pushed to higher limits.

The third edition of this well-known handbook fully maintains the reputation of previous issues and the various special fields of rising importance are well covered. For example, reference is made to the work of Ricardo on detonation in internal engines; that of Timoshenko on vibration problems, and so on. It would not be possible for any one individual to deal with a mass of technical material, which even when presented in the excellently condensed form of this handbook occupies 2,180 closely printed pages. In preparing this new edition, Professor Marks enlisted the aid of groups or individual engineers for the revision of existing sections or the contribution of new material, and the result justifies this policy.

The book is of convenient size and typography; the diagrams are legible; it opens easily and, best of all, it is adequately indexed. It can be recommended as an indispensable book of reference for the mechanical engineer.

Erratum

In the paper on "Riveted Tension Members" by Professor T. R. Loudon, M.E.I.C., in the November, 1931, issue of The Engineering Journal, page 557, first column, line 15, *for* Fig. 7 *read* Fig. 6.

ELECTIONS AND TRANSFERS

At the meeting of Council held on November 17th, 1931, the following elections and transfers were effected:

Associate Members

SCHWING, Hans J., (Swiss Federal Coll., Zurich,) engr., Beauharnois Power Corporation, Montreal, Que.

*STEPHENSON, George, E. B. Eddy Co. Ltd., Hull, Que.

Junior

COWIE, Norman Claude, B.A.Sc., (Univ. of Toronto), elect'l. engr., Algoma District Power Company and the Great Lakes Power Company, Sault Ste Marie, Ont.

Transferred from the class of Junior to that of Associate Member

BARNETT, Harold E., B.Sc., (Univ. of N.B.), designing engineer, Dominion Construction Corporation, Fraserdale, Ont.

JOY, Clyde Barber, B.A.Sc., (Univ. of Toronto), 124 High Park Ave., Toronto, Ont.

Transferred from the class of Student to that of Associate Member

BULLER, Francis H., B.Sc., (McGill Univ.), M.S. in E.E., (Union Coll., Schenectady), asst. engr., cable section, central station dept., General Electric Company, Schenectady, N.Y.

FOY, Albert Joseph Bernard, B.Sc., (McGill Univ.), inspr., sprinkler risk dept., Canadian Fire Underwriters Association, Montreal, Que.

HALPENNY, Merle B., B.Sc., (McGill Univ.), estimator, Dominion Bridge Company, Limited, Montreal, Que.

Transferred from the class of Student to that of Junior

*LOCHHEAD, Stuart George, (McGill Univ.), junior engr., City of Westmount, 309 Brock Avenue North, Montreal West, Que.

MORGAN, James Clarence, B.A.Sc., (Univ. of Toronto), graduate student and demonstrator in electrochemistry, University of Toronto, Toronto, Ont.

NORMAN, Douglas, B.Sc., (Univ. of Man.), engr., transformer engrg. dept., Canadian General Electric Co. Ltd., Toronto, Ont.

RACEY, Herbert John, B.Sc., (Queen's Univ.), concrete inspr., Shawinigan Engineering Company, Ltd.; Montreal, Que.

Students admitted

BELYEA, Harry A., (Univ. of Tor.), 64 Pacific Ave., Toronto, Ont.

BUTLER, John Arthur Tweed, (McGill Univ.), 5037 Grosvenor Ave., Montreal, Que.

COLE, Alfred Herman Purkis, (McGill Univ.), 314 Broadway, Lachine, Que.

CUMMING, John Elliott, (McGill Univ.), 3483 Peel St., Montreal, Que.

DONOHOE, Gordon Miller, B.Sc. (E.E.), (Univ. of N.B.), 199 Market Place, Saint John West, N.B.

DWYER, John Norman, (McGill Univ.), 371 St. Joseph Blvd. West, Montreal, Que.

GIRDWOOD, Arthur J., (Univ. of Tor.), 328 Huron St., Toronto 5, Ont.

HOWARD, Albert Warren, (Univ. of Tor.), 89 Charles St. West, Toronto 5, Ont.

LAWRASON, William Murray, (Hamilton Tech. School), asst'g. engr., Hamilton Hydro Electric System, Hamilton, Ont.

LAZORKA, Demetrius, (Univ. of Sask.), P.O. Box 1260, Saskatoon, Sask.

LICHTY, Lyall J., (Univ. of Tor.), 8 Ellen St. East, Kitchener, Ont.

LOVE, Edwin Reginald, (Univ. of Man.), 184 Good St., Winnipeg, Man.

OUIMET, Joseph Alphonse, (McGill Univ.), 448 Outremont Ave., Outremont, Que.

PHILLIPS, Robert Weston, (McGill Univ.), P.O. Box 31, Chambly Canton, Que.

RANSOM, Rosmore, (McGill Univ.), 57 Somerville Ave., Westmount, Que.

SANDILANDS, Adam, Jr., (Univ. of Man.), 609 Goulding St., Winnipeg, Man.

**Has passed the examinations of The Institute.*

The British Grid Crosses the Thames

The height of the "Grid" towers which cross the Clyde at Renfrew is 275 and 283 feet. The crossing of the Forth calls for higher towers than these; they reach a height of 340 feet and the conductors have a span length of 3,050 feet—over half a mile.

Special towers are to be erected at Crossness where the Board's Barking-Swanscombe 132-kv. transmission line crosses the River Thames. The towers will carry six line conductors and an earth conductor. These conductors are of aluminum bronze with a cadmium copper core. Each conductor will consist of nineteen 0.102 inch cadmium copper wires and forty-two 0.102 inch aluminum bronze wires, giving an overall diameter of 0.918 inch. The span length will be approximately 3,060 feet, giving a clearance of 250 feet at the centre.

The earth conductor will be electrically connected to the towers and the towers will be earthed by means of cast iron earth pipes with bonded connections to each leg.

The base width of the towers will be approximately 120 feet. The towers will be constructed of rolled steel sections, and the cross-arms and tower tops down to approximately 20 feet below the bottom cross-arm will be galvanized and bolted, whilst below this point the steelwork will be ungalvanized, riveted and painted.

Each cross-arm, of which there will be three in all, having lengths of 30, 32 and 44 feet, will be provided with a rail from end to end outside the tower framework, designed to carry a travelling chair suspended from a set of grooved wheels, to be used for maintenance facilities. and platforms will be provided approximately 8 feet below each cross-arm. Railed steel ladders will run from ground level to the inside of the tower peak, broken by railed platforms approximately 50 feet apart.

Provision is made for the future accommodation of a lift running up the centre of the tower to the level of the bottom cross-arm should it be found advisable to provide lift access.—*The Electrical Times.*

Address given before the Hamilton Branch of The Institute, September 17th, 1931, by E. P. Muntz, M.E.I.C., Branch Chairman*

I trust you will bear with me for about fifteen minutes while I read some thoughts which I have jotted down since I dare not trust myself to speak extemporaneously. I hope most sincerely this will be of more than passing interest to all members since it is an attempt to help protect our future welfare as a professional institution.

Everywhere we go we hear such remarks as these: "What has The Institute done for me?" or "What can I tell a prospective member The Institute can do for him?" "Why should I join The Institute?" "The whole show is run from Montreal. You'll never get anywhere with anything no matter how sound if they don't want it."

My general answer to all of these and like questions is that the individual only benefits according to his own interest and endeavour, and that by the act of trying to do something to the best of one's ability, the individual is always more than repaid.

I am also sure we can all find plenty of instances in our own experience which bear out my detailed answers to the above questions. Anyone who attends Institute meetings with an open mind, and constructively tries to co-operate, is bound to benefit very materially.

I have questioned a number of the older members, and I find that some of the outstanding points of their lives have hinged on some point developed, or paper read, or person met at Institute meetings, or through The Institute.

I know this is true in my own case, not once but many times,—the most recent instance being in connection with one of the most important economic subjects of the present time. This I have tried to study somewhat this summer. I became interested because of a suggestion made at our first executive meeting in June. We were discussing material for papers. Your Vice-Chairman, H. B. Stuart, A.M.E.I.C., suggested a meeting devoted to Hamilton transportation problems. "Why had radials died? Why could Hamilton no longer be advertised as the hub of a fine radial system? Why did we have to go to Toronto to go to Owen Sound by rail? Why did it take from three to four days to ship by rail to Toronto, etc." It caught my interest, and I have since been drawn in a minor way into the greatest problem facing the railways of this continent today, namely, how to carry on in face of truck, bus, motor car, and other competition. The subject is very large, but like all subjects, the solution can and will be found. The discussions it has been my privilege to have with a number of railroad executives and others have been remarkably interesting, and very valuable to me personally. Some tangible results will come before long. The subject is closely allied to many phases of engineering, and it is worthy of note that this subject is directly of interest to about one-sixth of the total population of the United States and Canada, since their bread and butter are somewhat at stake.

My personal thanks are due to Mr. Stuart for his "thoughts out loud" as he expressed them today and I hope the meeting he suggested will be as successful as the subject warrants, and I have to thank The Institute again for enabling me to meet a number of very influential people and possible clients on their own ground.

What can Rotary, Kiwanis, or any other organization or club tell or do for their prospective members? They get them. We can tell them the same things which they can tell, and in addition we have a well established professional organization, a good channel of professional communication in The Journal, a reasonably common bond in training and avocations, and undoubtedly we have prestige to bestow professionally and no one who has attended an annual meeting in recent years had to go away empty.

As far as Montreal is concerned, Montreal will continue to rule, and more power to them, just as long as the rest of us are willing to do little or nothing about it. Our representatives on Council now make a personal sacrifice which should in our own interest be reduced. This sacrifice is both of time and money for so far they have paid their own way except to the Plenary Meeting once a year. There is now a committee reporting on more adequate Branch representation and after the Plenary Meeting of Council, certainly at the Annual Meeting, we expect to have an answer. Let us adopt the attitude in the meantime no matter what our present private opinions may be that Montreal has accomplished much. We hope they will now freely let us co-operate with them to accomplish more.

I hope these answers may appeal to a number of those who have not been favouring the Branch with their active support, and that also in them a sufficiently virile germ may be found which all members, and particularly the membership committee, may be able to nourish into arguments sufficiently strong and forceful to win over "doubting Thomases" both within the membership and outside. Our membership is barely 50 per cent of the potential in this district. I firmly believe The Engineering Institute can and will do more than any of us expect, if we are each and everyone willing to take a constructive part.

*President, E. P. Muntz, Limited, Toronto, Ont.

Now let us consider for a few minutes what is wrong or what is giving rise to these questions.

As we all know, the railroads are in a bad way,—looking longingly for a solution. The railroads in the past have been considered fine, upstanding, solid examples of progress and this until quite recently. Transportation, however, has changed radically, and continues to change, and the railroads have not done more on land than move goods from point to point by rail as they did when they first started. And by this rather caustic comment, I have no intention of detracting in any way from the marvels of engineering both mechanical, electrical and civil developed by these same roads.

Our Engineering Institute is exactly like the railroads, a fine, solid, old institution, as we look on the age of anything these days. As a matter of fact, it has grown up with the railroads, but like the railroad's special trouble—the motor vehicle—along now have come the professional associations, supplying a cheaper vehicle to professional respectability. The Institute is temporarily embarrassed, and like the railroad industry will be glad to see some definite working arrangement consummated. A committee is working now on The Institute's problems, just as there are a hundred committees or more working on the railroad's problems. If I might presume to offer a suggestion to all these committees (The Institute's included) it would be to forget the past, and not try to mould the present into the past, but let us have some radically new, workable and worth while functions to fill performed by new organizations, if necessary.

The railroad man must forget that the prime things in life are to move railroad trains from here to there on time. If he is merely a railroad man, and nothing more, that may be all he can do, but his place is now being taken by the forwarder who moves goods from the farm, the woods, the seacoast, the minehead, the city house, or warehouse, with or without railroad sidings, in the cheapest way and in the shortest time,—no matter if he uses truck, bus, rail, water, or air, or any combination of them. In this chain the railroad is only a part. Incidentally it should be an important part, but it will not be if the roads do not give what every shipper wants, that is, complete pickup and delivery service, one responsibility supplying all types of transportation to serve the best interests of the shipper.

The Institute, on the other hand, we all know, has got to develop some interlocking working arrangement with the professional societies. That we hope is now being worked out. The Institute has also got to realize that there are a very great number of people with engineering training employed in industry and all kinds of commercial activity. These people on the whole are anxious to keep up their engineering affiliations. Many of them would like to be associated with The Institute. They realize, possibly more than some of us, the extent to which engineers have filtered into the whole industrial and commercial fabric.

You may not know that this whole question is also being studied by a committee and again we expect some definite recommendation for the annual meeting. There are also the men with very special training and qualifications along some one line—but who could not qualify for membership under present standards. They must be cared for in some way. Our professional group or association is not yet by any means complete.

The question of fees is another important one. Due to the good work of preceding executives the Branch has a substantial surplus. Headquarters on the other hand are inadequately financed.

The affairs of The Engineering Institute, as I see it, can not be kept anything like as separate as those of a medical institute from the body politic. We, therefore, have to offer something much broader and bigger than purely technical discussions and qualifications. Like the railroads, The Institute is only fulfilling a part of a chain of functions which it should fulfill.

Preceding executives of this Branch are more than deserving of the thanks of all of us for not only the surplus but for the excellent spade work which they have done in working out sound answers to both classification and fee problems. These I hope to see written up shortly and placed in your hands. I believe two recommendations of your former executives provide *ipso facto* the answers to most of our troubles. Your present executives will more than welcome criticism and advice from those who have already gone a long way on the road to the solution of our problems.

Now each Branch, like all the individual railroads, has its own problems. We right now are confronted with doing our best to meet conditions as we see them. We, in Hamilton, have a lot to do no matter whether the millenium for the major difficulties comes this year or later. Therefore finally let us consider why we are banded together and why we are here now as members of The Engineering Institute. Let us also consider some comments indicating lines on which we might proceed.

The "avowed" purposes of The Institute (whether we entirely agree or not) are (A) "to facilitate the acquirement and interchange of professional knowledge among its members," (B) "to promote their professional interests," (C) "to encourage original research," (D) "to develop and maintain high standards in the Engineering Profession," and (E) "to enhance the usefulness of the Profession to the Public."

These purposes are very wide, and we, as a Branch, of course, subscribe to them.

The objects of the Branch according to Section 1 of the Branch by-laws are:

(*a*) To promote the interests and objects of The Institute;
(*b*) To raise the prestige of The Institute and the profession in the community;
(*c*) To unite the members for their mutual improvement.

It is presumed we facilitate (A) "the acquirement and interchange or professional knowledge among our members" by getting good papers by men of high standing and by arrangements to attend meetings elsewhere, etc. This is covered by Branch by-laws, Section 1A.

(B) "to promote their professional interests" seems to me to require the lively support of the Ontario Association of Professional Engineers, so that more definite legislation may be obtained among other desirable ends. At the same time a very much more distinct connection should exist between this Institute and the Ontario Association, than the indefinite relation now existing. This really amounts to nothing more than the fact that a large number of one belong to the other. I understand there is a committee working on this now and feel we should develop a policy on this subject as quickly as possible. The relations are not at all satisfactory at present, and there appears to be a great danger of one usurping the functions of the other; whereas one should assist the other.

(C) "to encourage original research." This is probably the most interesting branch of The Institute's "avowed" purposes. In some form or another original research is possible and open to every member of the profession and for that matter to the majority of human beings. It might have been written "to encourage original thinking." The meaning of "original research" which I understand is the original work done to obtain a new result, or an old one by a new process, with the assistance of the sciences or the correlation of information and deduction therefrom. Whether the research has to do with new methods of obtaining a result which we are now obtaining in our usual occupations or some new discovery or invention, I believe does not matter. It is important to stimulate original thinking to the point where everyone of us is every now and then producing the tangible and preferably beneficial results or thoughts of original endeavour on the part of the author. While we are probably primarily interested in engineering research, original research or thinking of any kind is worthy of attention.

The next item in the "avowed" purposes is to develop and maintain high standards in the engineering profession. Can not this best be done through the Professional Engineering Association and by seeing to it that we each maintain a high standard of ethical conduct and behaviour.

The last "purpose" and one of the utmost importance is "to enhance the usefulness of the profession to the public." I do not see quite why we should consider the altruistic side only. Unquestionably by the interchange of knowledge and original research and all the rest we are enhancing our usefulness to the public. I do not know who really benefits but the public by the average engineering research and the general improvement in engineering knowledge, methods, legislation protecting the owner against unqualified practitioners, *et al.* My conception of this clause is that it is a redundancy unless conceived as requiring that we "sell" the public on the usefulness of the profession.

We can not put paid advertisements in the newspapers. If we are going to sell anybody anything we must, however, have some means of definite contact on which or through which to work. There is little use in making ourselves invaluable to the public (as we no doubt are) if the public does not know wherein that value lies, so they can make full use of it.

Employers usually know where they can get engineering brains. If those brains are in the possession of a member of a really live organization which is a potent factor in the community, if the organization stands high in the opinion of employer and public alike, aren't those brains liable to be worth quite a lot more? Unless I know where I can purchase service or commodities it is little use to me if such service and commodities, as I may be able to use profitably from time to time, exist but are unknown to me. If the purveyors of these services or commodities did not "register" with me in some way I would not know of their use nor be in a position to secure them when opportunities arose. I believe the public is in the same relation to our Engineering Institute. If we do not make it possible for the public to recognize us we can not expect to be recognized. I do not think "recognize" is too strong a word in this connection.

Unquestionably The Institute already has prestige of a vague, indefinite kind in the minds of the public and of a very definite kind in certain particular channels like railroad executives and some government departments.

There is no reason why The Institute can not be before the country and the people of this district continually and sell themselves to the people and various public bodies by the soundness of their professional advice on a variety of questions arising in any community growing the way Hamilton and Canada will for some years, or for that matter in the country which undoubtedly has the brightest future in the world.

I am not proposing to become involved in politics in any way, but I believe we can endorse this project or object to that one, even though we may tread on the toes of some. When we have a speaker or subject of interest to the public let us make sure the public comes. If all this results in some paid assistance to the Secretary, as it surely will, let us get it. We will certainly find that action and reaction are equal and opposite and that if properly managed such propaganda with some amplification is bound to result in our opinion, collectively and individually, having a much higher value in the community.

I believe it possible and essential to send a notice of motion and possibly a copy of the actual proposed resolution covering such questions to members before a meeting. This only has to be done three or four times a year on sufficiently live subjects to obtain a large part of the contact which I feel should be fostered.

The Ontario fruit situation is now receiving considerable attention from some of our members. A paper on fruit marketing to which a great many people might be invited and to which they would be glad to come, followed by suitable if more or less prearranged discussion and resolutions and subsequent publicity in the press, might result in Hamilton getting that cold storage fruit warehouse which appears held up temporarily at least in Toronto. If not that, maybe another.

We are a centre for iron and steel, electrical manufacturing and a host of mechanical and other lines. I am sure in our membership there is a direct contact possible in many lines which will be of benefit to all of us and to the community, if it were made known by the means I have indicated.

We will find from time to time that there may be some feeling against this or that, particularly when it comes to patting someone on the back. There may be objections, but I believe a gracious act on our part would be a resolution appreciating the high quality of the recent advertising being done by the Pigott Construction Company.

I mentioned that there would be criticism, but my point is that if we are not ready to pat the other fellow on the back when he does something a little better and on a little higher plane, we will not find the other fellow ready to co-operate and help along some idea we are very anxious to foster.

With dignity but at the same time fearlessly we should make ourselves known to all men. First by co-operation and assistance and then by leadership, and not by insularism nor professional "high hattedness," can this be brought about.

I am sure the large manufacturing concerns we have as well as the railroads, the hospitals, parks and other boards all have the occasional problem which, if laid before us, would benefit by our endorsation or the discussion which would disclose reasons for withholding endorsation. I am sure we would benefit greatly by such work. I would curb promiscuous and idle subjects by making it a rule that we as a body could only act upon a request for endorsation accompanied by full, written particulars from some other properly constituted body or upon a paper prepared by one of our own members with resolutions made and seconded in writing. In either case, our Executive committee would pass upon it and circularize the members with their comments and stating the question would be discussed and the resolution voted upon at the next or some definite subsequent meeting.

The first two objects of the Branch as defined in the Branch by-laws are clearly covered by The Institute's "avowed" purposes. The third object "to unite the members for their mutual improvement" is sufficiently broad to embrace almost any activity and I certainly feel that this object can cover within reason all parts of what I believe is still called a liberal education.

We can without overburdening ourselves or building up too much machinery go a long way to obtain the objective which a number of our members, I am sure, think desirable.

Without doubt it is in your power to obtain just as much benefit from The Institute as your own ambition desires. Action and reaction as usual and as previously referred to are still equal and opposite and you must be prepared to give if you are to partake. Do not expect to partake too quickly,—but be ready to give *co-operation, considered constructive criticism, regular attendance* and *above all a certain amount of tolerance.* If you are willing to thus spread your bread on the waters, and I am sure you will, I am also sure you will be more than repaid.

In these remarks, I hope there is sufficient meat to bring out many constructive suggestions. Let me say most emphatically it is also in your power to make this professional organization outstanding in this community,—one to which anyone will be proud to belong, before which anyone will be proud to speak.

Natcoflor, a new product of the National Fire Proofing Company of Canada, Ltd., was subjected to exhaustive tests at the company's plant at Aldershot, Ont., on October 30th last. The main test, carried out under the supervision of the Canadian Inspection and Testing Company Ltd., was designed to show the load-bearing properties of Natcoflor. The panel was tested until the total live load was 468 square feet without failure. Natcoflor is a new type of structural clay tile used in combination with concrete joists to form a one-way system of composite floor construction. A number of members of The Institute were present at the test, among the more prominent being: Brig. General C. H. Mitchell, C.B., C.M.G., D.S.O., D.Eng., M.E.I.C., a past-president of The Institute, and Dean of the Faculty of Applied Science of the University of Toronto; J. P. Hynes, A.M.E.I.C., of Toronto; A. E. Beck, A.M.E.I.C., of the Petrol Oil and Gas Company, Toronto; A. H. Harkness, M.E.I.C., of the firm of Harkness and Hertzberg, Toronto, and C. S. L. Hertzberg, M.E.I.C., of the same firm, and J. Morrow Oxley, M.E.I.C., a member of the firm of Chapman and Oxley, of Toronto.

BRANCH NEWS

Calgary Branch

A. W. P. Lowrie, A.M.E.I.C., Secretary-Treasurer.
W. H. Broughton, A.M.E.I.C., Branch News Editor.

On the afternoon of Saturday, September 26th, a very enjoyable and instructive visit of inspection was paid to the Glenmore water storage reservoir and dam now almost completed on the Elbow river south-west of Calgary.

The party of about forty members and friends was divided into small groups with an official guide in charge of each, this by courtesy of N. G. McDonald, A.M.E.I.C., resident representative of Messrs. Gore, Storrie and Naismith, engineers of the project, and the contractors, Messrs. Bennett and White of Calgary.

The dam will impound about 3,600,000,000 gallons of water in a natural basin west of the city, or sufficient to supply a population of about 200,000 people for three months. As the present population is less than one-half this number the project will cover the city's demands for many years to come.

The whole project, which consists of the reservoir and its dam, hydro-electric pumping plant, mains to supply adequate pressure to all parts of the city, and a sedimentation, filtering and chlorination plant will cost about $3,770,000 and will eliminate the very strenuous and just complaints which have recurred about June every year, of the quality of the water supply. During its construction it has provided work for many otherwise unemployed; part of the work being done exclusively by rotating gangs of unemployed under the supervision of the engineers and a few permanent employes as experts in the various trades.

The visitors were first conducted around both sides of the dam and the cushion basin designed to allow any large overflow to swing into the natural channel of the Elbow river without shock or erosion of the banks. While the dam rests on a solid sandstone and shale foundation, pipes were provided every 8 or 10 feet for grouting after the superstructure is finished by means of air pressure at 100 pounds per square inch. It was found that not a great deal of grouting was necessary and in some cases the grout was forced up through adjacent pipes.

The dam is of concrete construction throughout. An overhead mixer was installed on one side of the river and the concrete distributed by means of a cable way with a tower on each side of the river and dumped by drop bottom skips.

The party was then conducted over and into the purification plant designed for a capacity of 27,000,000 Imperial gallons per day and which consists essentially of three portions providing for coagulation, sedimentation and filtration. Each of the three settling tanks has four coagulating tanks and eight filter beds through which the water flows in series at a very low velocity, taking about three hours for the complete circuit.

The pipes are all of concrete construction, manufactured locally, with a patented lead joint, reinforced with a steel cylinder and wire mesh which is bonded at the joints and then grouted in. Manholes are provided at convenient intervals for internal inspection. The delivery main forms a ring around the city which is tied in to the existing distributing system at convenient places.

Regular tests are being conducted on samples of each of the three grades of concrete used, the contractors being bound to very close limits of aggregate, water content, and physical strength in each case.

The project is believed to be the largest of its kind in the west and those present spent a very enjoyable afternoon.

The thanks of the members are due to the engineers and the contractors for the arrangements made for the visit.

Golf Tournament

By courtesy of the Earl Grey Golf Club, to which many of our local members belong, the Calgary Branch of The Engineering Institute held its annual golf tournament on the afternoon of Saturday, August 28th, in ideal golfing weather. The ladies of the party served tea in the club house.

The prize-list was as follows:

Best net score (18 holes):
First: R. C. Harris, M.E.I.C. (chairman).
Second: R. S. Stockton, M.E.I.C.
G. H. Patrick, A.M.E.I.C. (tie).

Best gross score (18 holes):
First: G. P. F. Boese, A.M.E.I.C.
Second: H. J. McEwen, A.M.E.I.C.

Best net score (1st nine):
W. Anderson, A.M.E.I.C.

Best net score (2nd nine):
G. H. Morton, A.M.E.I.C.

Hidden Hole (Handicap):
R. McKay, A.M.E.I.C.

Putting:
Men: E. N. Ridley, M.E.I.C.
Ladies: Mrs. F. G. Bird.

Hamilton Branch

J. R. Dunbar, A.M.E.I.C., Secretary-Treasurer.
J. A. M. Galilee, Affil.E.I.C., Branch News Editor.

Joint Meeting with Ontario Section A.S.M.E.

A joint meeting of the branch with the Ontario section A.S.M.E. was held in Hamilton on Friday, October 30th. E. P. Muntz, M.E.I.C., occupied the chair and opened the meeting by welcoming the Toronto visitors. He called on Mr. S. L. Fear, chairman of the Ontario Section A.S.M.E., to introduce the speaker. In his remarks Mr. Fear referred to the desirability of having joint meetings of the different engineering organizations.

The speaker for the evening was Professor J. W. Bain, of the University of Toronto, who spoke on "Mechanical Industries and the Chemical Engineer."

Mechanical Industries and the Chemical Engineer

(Reported by V. S. Thompson, A.M.E.I.C.)

The speaker in his opening remarks gave a definition of a mechanical engineer as one primarily interested in mechanisms and drew the distinction between the mechanical engineer and the chemical engineer, the latter being interested in matter or material. Thus the two are complementary and he proceeded to relate a number of examples, as for instance how a young Scotch mechanical engineer named McArthur had revolutionized the gold mining industry by his improvement of existing filter presses.

The filter press at that time used by chemical engineers was only for liquids containing a small amount of solid material which was pumped in and allowed to drain out leaving the solid inside. McArthur reversed this process by making a frame covered with filter cloth which was slipped into the solution and suction applied from the inside. This was cleaned by applying air pressure instead of suction, the cake dropping off the outside of the filter cloth.

Up until 1912 the total ammonia production (about four million tons) was obtained from coal. The German, Haber, conceived the idea of making Nitrogen and Hydrogen unite under pressure using a catalyst. He passed SO_2 and O_2 through a tube at 120 degrees without result until platinum was tried as a catalyst, when sulphur trioxide was obtained, ($2SO_2 + O_2 = 2SO_3$). The amount of SO_3 obtained is increased with increase in pressure and this requires extremely carefully designed mechanical equipment.

Incidentally this process was a very important incentive for the development of special alloy steels. Many alloys will sustain fairly high tensile stresses but keep on stretching under load at high temperatures. At 800 degrees C. ordinary carbon steel will sustain 1,000 pounds per square inch for 107 hours before failure.

The British practice maintains that a specimen must not expand more than 1/100,000th inch per day while American practice requires not more than 1 per cent extension in 10,000 hours.

A good example of modern alloy is made in England to-day (18 per cent chromium, 8 per cent nickel) which will sustain 2½ tons per square inch indefinitely at 800 degrees C., or five times as strong as ordinary carbon steel.

These steels made synthetic ammonia possible and now tubes are made 40 feet long, 30 inches diameter with a wall thickness of 5 inches to 7 inches to carry loads up to 300 atmospheres at 500 or 600 degrees C.

Similarly the speaker cited the development of synthetic methyl or wood alcohol used in the manufacture of dyes. Hydrogen and carbon monoxide are combined synthetically using zinc oxide as a catalyst. This process has completely killed the old wood distillation method within the last eight years.

Professor Bain then described special electric furnaces with electrodes 2 feet square for the manufacture of carbide and showed a chart giving a long list of products obtained from it, Acetic Acid, Ethyl Acetate, Ethyl Lactate and Carbon Black among others.

It was discovered that ordinary cotton dipped into Nitric Acid and washed undergoes a profound chemical change by becoming soluble in alcohol and ether, and dries leaving an elastic film; duPont thickened this film by concentrating the liquid and applied it by means of a spray giving a hard lustrous finish, which he called "Duco" (Nitro Cellulose Lacquer).

A Frenchman called Chardounet dissolved cellulose and squirted through minute holes so that the solvent evaporated leaving a fine thread. Two Englishmen, Cross and Bevan, elaborated this process and founded the modern Rayon or Artificial silk industry.

Synthetic resins have been common since about 1910 and many of these are used in the manufacture of varnishes, but it was left for a Belgian inventor to perfect a substance which is used in hundreds of different forms to-day. This is Bakelite, a resinous product made from carbolic acid and formaldehyde, which when heated thickens up and sets.

In closing, Professor Bain paid tribute to the success of the mechanical engineer and metallurgist in keeping up with the demands of modern chemistry and without whose aid very few of these developments could have progressed to the commercial stage.

Lethbridge Branch

Wm. Meldrum, A.M.E.I.C., Secretary-Treasurer.
G. W. Rowe, Jr.E.I.C., Branch News Editor.

The Lethbridge Branch of The Engineering Institute of Canada held its first meeting of a series of bi-monthly dinner meetings.

Among the guests of the Branch on this occasion were several representatives of the teaching profession.

A splendid dinner was served during which the orchestra conducted by George Brown rendered an excellent musical programme. A short period of community singing followed with vocal solos by Bob Lawrence, A.M.E.I.C., and Miss J. McIlvena.

"The Mid-North"

Dr. W. G. Carpenter, B.A., LL.D., principal of the Institute of Technology and Art, Calgary, was the speaker and took for his subject "The Mid-North."

W. Meldrum, A.M.E.I.C., presided and introduced the speaker in the unavoidable absence of the branch chairman, N. Marshal, M.E.I.C.

The vast resources of this mid-north country, aside from its agricultural possibilities as illustrated by what has been done in the Peace River country, are almost unbelievable, according to the speaker, who told of the tar sand deposits, salt and the indications of radium bearing ore found at Great Bear lake.

Numerous facts and figures were presented to illustrate the country and its possibilities and of these perhaps the most striking was the statement that the average summer and winter temperatures were comparable to those in the southern part of Saskatchewan.

Mention was also made of other natural resources of the province such as coal, gas and oil, for which, while perhaps at the present time the outlook was none too favourable, nevertheless would in their time play a big part in the development of the province.

It is impossible to predict just what the development of these natural resources will lead to, concluded the speaker. They are a challenge to the youth of today, a gleam of optimism at a time when so much pessimism is prevalent.

Following the motion pictures, N. H. Bradley, A.M.E.I.C., moved a hearty vote of thanks to the speaker.

On October 31st, 1931, the Lethbridge branch of The Engineering Institute of Canada held the second of their regular bi-monthly dinner meetings in the club dining-room of the Marquis hotel.

Grain Handling

The speaker was C. D. Howe, M.E.I.C., consulting engineer of Port Arthur, Ontario, who addressed the branch on the subject of "Grain Handling," illustrating his remarks by a series of slides.

Mr. Howe is internationally regarded as a leading authority on this subject, having designed and supervised the construction of grain elevators in all parts of this country from Prescott and Buffalo in the east to Vancouver and Victoria in the west, the most recent undertakings being the interior terminal elevator at Lethbridge and the first elevator at Churchill on Hudson's Bay.

Mr. Howe recently returned from a trip to the Argentine and in his address gave a brief account of the grain handling methods of that country.

In opening his subject, Mr. Howe told of the enormous increase in the production of wheat in Canada during the last twenty years. While the crop in 1909 was only some 100,000,000 bushels this steadily increased until it reached the peak in 1928. During that year 550,000,000 bushels were grown in this country.

Discussing the economic factors which have so depressed the wheat market during the last two years, the speaker commented on the enormous wheat crop of the Argentine in 1928 and the return of Russia as a wheat exporting country for the first time since the world war.

However, the events of the past two weeks, continued the speaker, are such as to entertain every hope that the grain business in the not too distant future will return to normal.

Continuing, Mr. Howe explained the function of the 5,000 country elevators scattered throughout the west and the part they play in rushing the grain to the outlet ports. He also discussed briefly the construction and equipment of this type of elevator.

Turning from the country elevator to the interior terminal such as the one located at Lethbridge, Mr. Howe spoke of the various problems involving the design and construction of these large reinforced concrete structures.

Mr. Howe devoted the concluding part of his address to the Churchill elevator. This elevator has a capacity of 2,500,000 bushels of grain. Future possibilities however have been carefully kept in mind and it can be extended to hold 10,000,000 bushels later on if necessary.

The speaker mentioned the recent arrival at Royal Victoria dock of the "Farnsworth" with its cargo of 227,000 bushels of grain.

Particular attention was drawn to the fact that while insurance rates on this shipment were twenty-two times greater than via Montreal it had still been able to show a profit to the western farmer of 1½ cents over the lake and rail route, the bay being readily navigable from the 1st of July until the middle of November.

Following the address, J. B. deHart, M.E.I.C., moved a hearty vote of thanks to the speaker for his highly interesting and enlightening address.

W. Meldrum, A.M.E.I.C., occupied the chair, and the speaker was introduced by Mr. W. N. Chater, resident engineer for C. D. Howe and Company on the Lethbridge elevator.

During the afternoon, through the courtesy of Mr. J. Pickering, acting superintendent, and Mr. J. Taylor, acting foreman, government elevator officials, the members inspected the new Lethbridge interior terminal elevator. The grain inspection department proved particularly interesting to many, and thanks are due to Mr. Herb. Goddard, chief grain inspector, for his explanation of this part of the work.

During the dinner the orchestra under the direction of George Brown rendered an excellent programme of high class music. This was followed by a period of community singing interspersed with two solos by Mr. Fred Teague, which were greatly appreciated.

Ottawa Branch

F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.

The Coming Total Solar Eclipse

At the luncheon meeting of the Ottawa Branch of The Engineering Institute of Canada, on Thursday, October 22, the guest speaker was Mr. R. Meldrum Stewart, Director of the Dominion Observatory, who spoke on the subject "The Coming Total Solar Eclipse." In addition to the speaker and G. J. Desbarats, C.M.G., M.E.I.C., the chairman of the local branch, the other guests at the head table included Hon. T. G. Murphy, Minister of the Interior; H. H. Rowatt, Deputy Minister of the Interior; Dr. Charles Camsell, M.E.I.C., Deputy Minister of Mines; John Murphy, M.E.I.C.; F. H. Peters, M.E.I.C., Surveyor General; Louis H. Berger, W. M. Tobey, M.E.I.C., Commander C. P. Edwards, A.M.E.I.C., H. Ewart and Noulan Cauchon, A.M.E.I.C.

Mr. Stewart stated that eclipses may be predicted very closely, but sometimes slight discrepancies in their times occur. As these discrepancies are due to some cause, they are, therefore, of the greatest interest to astronomers, for from them these causes may possibly be deduced. There will be a total eclipse on August 31, 1932, visible in a portion of Quebec, and it was in this connection Mr. Stewart mentioned some of the problems involved in making observations of it for scientific purposes.

There are a number of problems which accurate observations of eclipses can help solve. An eclipse party measures the time of the eclipse as accurately as possible and also endeavours to measure the limits of the shadow cast on the earth. For data concerning the path of the eclipse, the public can very materially assist by advising the officials of the Observatory of their observations. If sufficient observers would do this, the limits of the shadow could be plotted fairly accurately.

The theory of relativity can be checked at the time of a total eclipse by photographing the stars around the sun and comparing the photograph with one taken during normal conditions.

Another study at the time of the eclipse is that of the sun's corona. When it is realized that only one or two minutes per year is all the time that is available for the study of the corona, it is easily realized that there is a good deal yet to be learned about it.

The sun's atmosphere also may be studied at the time of the eclipse, as a careful record is kept of the spectra observed as the sun passes into the shadow.

Terrestrial magnetism is also believed to be affected by the sun and interesting observations may be made of the effect of cutting off the sun's light. A study of the sun's effect on wireless reception may also be studied at such a time.

This path of totality of the coming eclipse will travel from the Arctic coast to a point on the international boundary in southern Quebec. The width of the shadow zone in southern Quebec is approximately 100 miles: the western edge passes through Montreal and the eastern about 25 miles east of Three Rivers. The maximum period of totality at any one site will be in the neighbourhood of one hundred seconds. The party will therefore be occupying the site of the observation several weeks before the date of the eclipse, erecting instruments and rehearsing the procedure to be followed.

In studying the meteorological records for the possible location of the site, the speaker stated that a station in southern Quebec would have about a fifty-fifty chance of having favourable weather for the observation. In locating the site, various local conditions would have to be taken into account, such as keeping away from towns or cities to avoid smoke, avoiding high hills on account of the possibility of clouds collecting over them, accessibility, etc.

The previous total eclipse visible in Canada occurred in 1925, the next will be in 1954, so every precaution for next year's observation will be taken.

Visit to Dominion Observatory

At the above luncheon meeting, the invitation was extended to the members of the Branch to visit the Dominion Observatory on the following Saturday evening, October 24. A large attendance was present to avail themselves of this opportunity, despite the adverse weather conditions.

Everything had been done to make the visit of an interesting nature, and every instrument and apparatus in use at the Observatory was on display for their examination. At the conclusion of their visit members of The Institute expressed their thanks to Mr. Stewart.

The Ottawa branch, at their noon luncheon on November 12th, had as their guest speakers Walter Lambert, M.E.I.C., M.I.N.A., senior partner of the firm of Lambert and German, consulting naval architects, Montreal, and J. W. Hughes, electrical engineer for the Eastern Lines of the Canadian Pacific Railway. G. J. Desbarats, C.M.G., M.E.I.C., chairman of the branch, presided at the meeting, other guests at the head table being C. P. Edwards, A.M.E.I.C., E. Hawken, J. G. Parmalee, R. F. Howard, M.E.I.C., and C. S. Morse.

Mr. Lambert's firm was responsible for the design and constructional supervision of the "Prescotont-Ogdensburg" unit, operating to ferry the railway traffic of the New York Central Railroad and the Canadian Pacific Railway across the St. Lawrence river between Prescott, Ontario, and Ogdensburg, New York. This unit consists of the tug "Prescotont" and the car float "Ogdensburg," in which are embodied certain radical features which constitute possibly the first commercial development of the conception of what might be termed "more remote control." Mr. Hughes co-operated with the naval architects in supervising the manufacturers' tests, and the installation of the electrical equipment of the tug "Prescotont."

The addresses, which were most interesting, were supplemented by lantern slides, which served more readily to illustrate the novel features of the design.

Peterborough Branch

W. F. Auld, Jr.E.I.C., Secretary.

Arthur R. Jones, Jr.E.I.C., Branch News Editor

The annual dinner of the Peterborough Branch of The Institute, which was held at the Empress hotel on November 17th, was a most successful function, being attended by over one hundred members and guests. The meeting was presided over by A. B. Gates, A.M.E.I.C., chairman of the Branch, and among the prominent guests present were: Brig. General C. H. Mitchell, C.B., C.M.G., D.S.O., D.Eng., M.E.I.C., past-president of The Institute, and the principal speaker, J. L. Busfield, M.E.I.C., chairman of the Finance committee of The Institute; C. S. L. Hertzberg, M.E.I.C., chairman of the Toronto Branch of The Institute; J. Roy Cockburn, M.E.I.C., vice-chairman of the Toronto Branch; E. A. Peck, M.P., and J. F. Strickland, M.P.P.; city solicitor J. R. Corkery, representing the legal profession; A. S. Zavitz (of the Collegiate staff), representing the teaching profession; Dr. N. H. Sutton, district officer of health, representing the medical profession, and the Rev. A. H. Going, secretary of the Peterborough Ministerial Association.

W. E. Ross, A.M.E.I.C., a past-chairman of the Branch, who is leaving Peterborough for Toronto, was the recipient of a small gift.

Following the toast to "The King" and after Mayor Denne had voiced an official welcome to the visiting engineers, a toast to "The Engineering Institute of Canada" was proposed by Ross L. Dobbin, M.E.I.C. Mr. Dobbin pointed out that The Institute now has twenty-five branches reaching from coast to coast and with an approximate total membership of five thousand. Not the least of these branches, said Mr. Dobbin, was the Peterborough Branch, with a membership of one hundred and twenty-five. The toast was responded to by Mr. Busfield and J. F. Plow, A.M.E.I.C., who both had interesting observations to make regarding the work of The Institute among the engineers of Canada.

Brig. General Mitchell, who also spoke in reply to the toast, said in part:

The members of the engineering profession possessed a curious ability to size up the affairs of a country. They held the same relationship to the country as a whole as did a staff officer in the war as against an officer of the line. The staff officer was able to view a much wider horizon than the officer of the line whose knowledge was confined to a particular sector of his front.

"We have been going through a difficult period. Far be it from me to speak in gloomy terms. I would ask you, are these times so difficult as we have been led to think. There has been a good deal of talk. What's the matter with the country? But I would ask. 'What's the matter with ourselves?'"

The trouble, he was convinced, consisted a great deal in wrong thinking along pessimistic channels. And a great deal of that trouble was, he said, "due to our playing about with extravagances and not practising economy—economy in our personal life, in business life, and in civic life."

"Do we suit our demands to what we need or to what we want," the speaker challenged. "We have extravagances and they have been increasing. Can we not practise some limit to our wants and luxuries."

Uttering a word of warning, General Mitchell said, "we should not fool ourselves with dreams of the future or of profits on paper."

Striking off to another thought which conveyed a wealth of optimism and hope, General Mitchell invited his deeply absorbed audience "to look across the seas to Great Britain and the Great Empire.

"Empire trade is at this very hour being discussed and plans are being formulated for trade arrangements for the Empire alone. That is an influence that has come about by reason of our hanging together as an Empire people."

There was another influence—that of the United States—which he also referred to. "We living close to the United States have a natural tendency and inducement to spend on things we don't need in 'keeping up with the Jones,' and quite naturally we are induced to buy from them."

He noted a very pleasing feature in this connection, however, which he thought was an indication that Canada was waking up. "During the month of October," he said "our trade balance with the States turned from an unfavourable to a favourable balance."

Viewing for a moment the things which Canada has not only in her shop window but the goods which she has packed away in the basement not yet opened, the speaker dealt with the country's agricultural potentialities.

It was true that the west had been and still was facing a period of depression, but he said, "we must also remember that only four years ago the west produced a wheat crop of five hundred million bushels, three million bushels of which were shipped overseas. And a good price was obtained for it."

The speaker mentioned also Canada's pulp and mineral resources. The fact that this country ranks first in the production of nickel, second in gold, fourth in copper, and third in silver.

Canada's water power resources also provided for turbine capacity of six million horse power—over six-tenths horse power per inhabitant in the country.

"Let me also point this out to you that as we have and are developing this country in various directions which I have indicated, Canada's direction geographically is turning northwards. A few years ago Canada was a narrow strip of territory running for three thousand miles east and west. Can't you imagine what is going to happen when the breadth of that strip is doubled?"

But it was not in possession of huge natural resources that Canada's future prosperity and success lay, General Mitchell said in closing. It was not in her great rivers and lakes, her vast mineral regions and wheatlands. Such things alone did not make a country. That could only come about by the right people going out to develop those resources and co-operating in harmony. Out of that combination a great and prosperous nation could not help but evolve.

"It is not walls or ships devoid of crews, but men who make a city," he said quoting from the saying of a Greek historian.

"Our men with all their initiative, fortitude and courage are going to make this country and help develop her unbounded natural resources."

"The Branches" was the toast proposed by A. L. Killaly, A.M.E.I.C., and was responded to by Messrs. C. S. Hertzberg,, M.E.I.C., N. E. D. Sheppard, A.M.E.I.C., and J. R. Cockburn, M.E.I.C.

The final toast on the list, that to "Sister Professions and Other Guests," was proposed by W. M. Cruthers, A.M.E.I.C., and replies were made by the various representatives of the sister professions.

Quebec Branch

M. Boyer, S.E.I.C., Secretary-Treasurer.

Dinner to Alexandre Lariviere, A.M.E.I.C.

On the evening of October 26th the Quebec Branch feted its vice-chairman, Alexandre Larivière, A.M.E.I.C., on the occasion of his recent appointment as a member of the Quebec Public Service Commission.

The celebration took place in the Riverview dining-room of the Chateau Frontenac, with an attendance of over seventy guests, among whom were several members of the engineering profession from Montreal, Three Rivers, Chicoutimi and Rimouski.

Following the dinner, Hector Cimon, M.E.I.C., chairman of the Quebec Branch, expressed his keen satisfaction in presiding over such an enthusiastic gathering, and said that the Quebec Branch of our nation-wide professional association, The Engineering Institute of Canada, which had been working in the interests of engineers for the past forty-five years and knew how to appreciate the success of its members, had naturally taken the lead in promoting this manifestation in honour of its devoted vice-chairman, Mr. Alexandre Larivière.

Many letters and telegrams had been received from prominent citizens and engineers who expressed their regret at being unable to attend, among whom he might mention the Honourable L. A. Taschereau, Prime Minister; the Honourable J. N. Francoeur, Minister of Public Works; Ivan E. Vallée, A.M.E.I.C., Deputy Minister of Public Works and Labour; Mr. Noel Belleau, K.C., Bâtonnier of the Quebec Bar Association; Chief Magistrate Ferdinand Roy, a substitute member of the Public Service Commission, and Messrs. Aurelien Boyer, A.M.E.I.C., Principal of the Ecole Polytechnique de Montréal; Prof. A. Mailhiot, B.A.Sc., E. A. Evans, M.E.I.C., Henri Kieffer, B.A.Sc., F.E., J. A. Duchastel de Montrouge, M.E.I.C., and J. E. Gibault, B.A.Sc.

On behalf of all, Mr. Cimon sincerely congratulated Mr. Larivière upon his recent appointment as Commissioner, and expressed feelings of gratitude to the Provincial government and the officers of the Quebec Public Service Commission for their judicious choice of Mr. Larivière as an able successor to the late and esteemed François-Charles Laberge, M.E.I.C., who had been a member of this Commission since its creation.

L. C. Dupuis, A.M.E.I.C., division engineer for the Canadian National Railways, proposed the toast to the hero of the evening, which was seconded by James Ruddick, M.E.I.C., consulting engineer, and by Mr. Edouard Hamel, chief engineer of the city of Quebec, and the former partner of Mr. Larivière at the time they were both engaged in private practice as consulting engineers.

The toast was followed by the singing of "Il a gagné ses épaulettes" and, after prolonged applause, Mr. Larivière addressed the meeting as follows:

Monsieur le Président,

Mes chers amis,

Je suis profondément touché de la démonstration à la fois sympathique et enthousiaste que vous me faites, ce soir, à l'occasion de ma récente nomination comme membre de la Commission des Services Publics de Québec.

A en juger par les paroles de ceux qui m'ont précédé, j'ai bien des mérites et des qualités que je ne me connaissais pas. Je suis porté à croire qu'elles ont été inspirées à ceux qui les ont prononcées plutôt par les bons sentiments dont ils sont animés à mon égard que par mes mérites réels.

Quoiqu'il en soit, je dois maintenant faire appel à votre indulgence car je me sens tout à fait incompétent pour répondre convenablement aux flots d'éloquence et d'éloges qui viennent de déborder à mon sujet, d'autant plus qu'en ce moment, l'émotion qui m'étreint l'emporte sur tous mes autres sentiments.

J'aurai donc recours, pour exprimer toute ma reconnaissance, à un seul mot que l'on retrouve sur les lèvres de quiconque reçoit une faveur, sur celles du pauvre ou du riche, du plus humble ou du plus puissant, de l'illettré ou de l'érudit, c'est le mot: merci.

Pour combler la vacance créée par le décès du regretté M. Laberge, le Premier Ministre et ses collègues ont bien voulu considérer les années de service de votre humble serviteur et choisir un employé du service civil; permettez que je leur exprime d'abord, ainsi qu'à ceux qui m'ont recommandé, ma vive gratitude pour le grand honneur qu'ils m'ont fait et la confiance qu'ils m'ont témoignée. Je puis les assurer que dans l'exercice de mes nouvelles fonctions, tout mon dévouement, mon énergie et mes connaissances seront mises au service de la justice.

C'est avec plaisir que je constate la présence ici ce soir de mes collègues, messieurs Beaudry et Macalister et de mon ancien Commissaire, Sir Georges Garneau. Cette courtoisie de leur part ne me surprend pas et je les en remercie sincèrement. Les membres de la Commission ont été pour moi non seulement des supérieurs doués d'une extrême bonté, des conseillers précieux et même des amis, mais, mon association à leur œuvre m'a procuré les plus beaux exemples d'honnêteté, de droiture, d'esprit de travail, du sens de la justice et du devoir.

Depuis que j'ai été nommé commissaire, j'ai souvent ressenti, en montant sur le banc, une profonde émotion en songeant aux nombreuses qualités du cœur et de l'esprit dont était doué celui que j'ai été appelé à remplacer, en songeant à sa haute compétence en matière technique, à sa conception profonde de la justice et à son jugement sain et profond.

Sur la tombe à peine fermée de M. Laberge, je dépose l'hommage de mon admiration, de mon respect et de mon meilleur souvenir.

En cette circonstance où on a fait allusion à ma formation technique, il n'est que juste de signaler que je la dois à l'Ecole Polytechnique et à ses professeurs. Ces derniers n'ont peut-être pas réussi à faire de moi tout ce qu'ils auraient voulu, mais ma dette de reconnaissance envers eux et envers l'Ecole est bien grande, car mes succès sont, en grande partie, attribuables à leur enseignement, à leur dévouement et à l'intérêt qu'ils m'ont porté même après ma sortie de l'Ecole.

Je m'en voudrais de ne pas mentionner les quelques années que j'ai passées avec mon ancien associé, Edouard Hamel, maintenant ingénieur en chef de la Cité de Québec et président de la Section de Québec de l'Association des Anciens de Polytechnique. Il était mon aîné et, à son contact, j'ai acquis, dans le domaine des travaux municipaux, une expérience qui me fut fort précieuse dans l'exercice de mes fonctions d'ingénieur de la Commission.

Enfin, je vous remercie, mes chers amis de l'Engineering Institute of Canada, de la Corporation des Ingénieurs Professionnels, de l'Association des Anciens Elèves de l'Ecole Polytechnique, pour vos bons souhaits et pour le témoignage d'estime que vous avez bien voulu me donner en ce jour, soit en participant à l'organisation de cette fête, soit en y prenant part.

It is not my intention to repeat in English all that I said in French, as most of you understand both languages, but I wish to convey my deep appreciation of your presence at this gathering and my most sincere thanks for your good wishes as expressed so eloquently by your "spokesman," Mr. James Ruddick.

The courtesy that you have shown in participating in this banquet and the friendship that it signifies are very pleasing to me and I wish to assure you that I shall always keep the happiest remembrance of tonight's celebration.

Sir Georges Garneau, B.A.Sc., President of the National Battlefields Commission and a former member of the Public Service Commission, paid an eloquent tribute to the new Commissioner, whose character and services as engineer of the Public Service Commission he had truly appreciated when acting as a Commissioner.

The next speaker, Mr. Adrien Beaudry, K.C., President of the Quebec Public Service Commission, offered flattering comments on the career of Mr. Larivière, and Dr. A. R. Decary, M.E.I.C., President of the Corporation of Professional Engineers of Quebec, added a brief but eloquent contribution of best wishes and congratulations to the new Commissioner.

Dr. Augustin Frigon, M.E.I.C., Director of the Ecole Polytechnique de Montréal, took pride in recalling the days when, as his pupil, the guest of honour had followed a post graduate course in electrical engineering.

Olivier Lefebvre, D.Sc., M.E.I.C., one of the vice-presidents of The Institute, and chief engineer of the Quebec Streams Commission, spoke on behalf of the Council of The Engineering Institute, and delivered messages of friendship and congratulation from the out-of-town engineers.

Alderman Wilfrid Lacroix, B.A.A., architect, a graduate of the Ecole Polytechnique de Montréal, referred to the many occasions on which the Quebec city council had sought Mr. Larivière's technical opinion and advice, which had been greatly valued, and the last speech was from Mr. Ludger Gagnon, assistant engineer for the city of Quebec, who, as spokesman for the younger engineers, offered to the new Commissioner most sincere wishes for a long career.

The meeting was brought to a close to the cheering tune of "For he's a Jolly Good Fellow."

We wish that the promotion of our friends always brought about such merry and unforgotten moments of rejoicing!

Saint John Branch

G. H. Thurber, A.M.E.I.C., Secretary-Treasurer.
C. Gordon Clark, S.E.I.C., Branch News Editor.

The Saint John Branch of The Engineering Institute of Canada held a meeting on November 5th, 1931, in the Georgian ballroom of the Admiral Beatty hotel. This took the form of a cabaret dinner, dance and bridge and was the first social event sponsored by the Branch in some years. It was well attended by members and friends. John N. Flood, A.M.E.I.C., chairman of the Branch, presided.

Dinner music and the dance programme of the evening were provided by Bruce Holder and his orchestra.

This marked the opening of Branch activities for the 1931-32 season. One of the chief objects of this social gathering was to give the numerous outside engineers employed on the reconstruction of the Saint John harbour an opportunity of meeting local engineers.

The arrangements for the meeting were in charge of J. N. Flood, A.M.E.I.C., and G. G. Murdoch, M.E.I.C., chairman of the Entertainment committee. They were assisted by a committee composed of Messrs. A. A. Turnbull, A.M.E.I.C., G. H. Thurber, A.M.E.I.C., V. S. Chestnut, A.M.E.I.C., C. G. Clark, S.E.I.C., J. P. Mooney, A.M.E.I.C., F. M. Barnes, A.M.E.I.C., and W. J. Johnson, A.M.E.I.C.

Saskatchewan Branch

Stewart Young, A.M.E.I.C., Acting Secretary.

The first regular meeting of the Saskatchewan Branch of The Engineering Institute of Canada for the season, was held in the Kitchener hotel on Tuesday evening, October 27th, 1931, being preceded by a dinner at which there were thirty-six guests.

Immediately after dinner E. E. Poole, Affil.E.I.C., presented a moving picture of scenes taken on a recent trip to Churchill. The reel shown included views of the Flin Flon and Sherritt-Gordon mines, views of the harbour at Churchill, the old Hudson's Bay fort and the new storage elevators.

Before proceeding with the regular business of the evening, E. R. Jenkins of the engineering staff of the Department of Telephones favoured the meeting with two songs.

The speaker of the evening, S. G. Porter, M.E.I.C., President of The Engineering Institute of Canada, was then introduced by the Chairman, D. A. R. McCannell, M.E.I.C.

Mr. Porter, before proceeding with his address on "Some Observations on the Engineering Profession," reviewed briefly certain Institute activities, calling attention in particular to the fact that the ultimate value of The Institute to its membership depended largely on the proper functioning of the Branches and that these, in turn, depended upon the efforts of the individual membership. He stated that in its final analysis the value of The Institute to each member depended on his personal interest in Institute affairs. He receives benefit only to the extent to which he renders assistance to The Institute.

As a means towards better attendance at meetings Mr. Porter suggested:

(1) Organized discussion;
(2) Obtaining the interest and support of the younger members;
(3) The use of films on subjects of general interest, these being available from government departments, corporations and industrial organizations;
(4) Occasional addresses on subjects of general or popular interest, rather than purely technical or engineering subjects;
(5) Mixed gatherings, including a Ladies Night;
(6) An Attendance Committee.

In concluding his remarks in this connection Mr. Porter stressed particularly the necessity for the Branch keeping up its contact with the individual membership.

Sault Ste. Marie Branch

A. A. Rose, A.M.E.I.C., Secretary-Treasurer.

The regular monthly meeting of the Sault Ste. Marie Branch was held in the Windsor hotel following the regular dinner.

The speaker of the evening, Mr. C. F. Layne, was introduced by the Chairman, A. H. Russell, A.M.E.I.C.

Deep Well Pumps and Well Drilling

Mr. Layne had taken as his subject, "Deep Well Pumps and Well Drilling."

In his introductory remarks, Mr. Layne said that while wells were known from very early times as shown by Biblical history, many improvements in drilling have recently been made.

He described his own method of drilling as follows: First, test holes are sunk to determine the nature of the formation before selecting a location. Second, a large casing is sunk to the water bearing formation. Third, a second casing with a screen on the end is set inside the first casing so that the screen is in the water bearing formation and it is there surrounded with gravel to above the level of that formation.

Next by pumping out the inner casing the sand is gradually taken out and the gravel sinks down in its place. The gravel may extend back from the screen as far as fifteen feet, forming a good filter for the water.

The pump is a vertical centrifugal type, the shaft being enclosed in tubing with bronze bearings every five feet. It discharges underground to the main to prevent freezing. The pumphouse contains the electric equipment and the vertical hollow shaft motor. The capacity varies from 20 to 5,000 gallons per minute. With the exception of the motor, the entire pump is made in Sault Ste. Marie by the Northern Foundry and Machine Company.

The discussion which followed brought out many interesting points on the subject.

On motion of Messrs. J. H. Jenkinson, A.M.E.I.C., and H. F. Bennett, A.M.E.I.C., a very hearty vote of thanks was tendered Mr. Layne for his interesting talk.

W. S. Wilson, A.M.E.I.C., showed a number of slides obtained from the Department of Interior, National Development Bureau, illustrating "The New Commercial Canada." Mr. Wilson reported that the November meeting would be addressed by Mr. L. Hollingsworth, on the subject, "Lumbering in Canada."

Toronto Branch

W. S. Wilson, A.M.E.I.C., Secretary-Treasurer.

Astronomical Telescopes

Some eighty odd members of the Toronto Branch of The Institute listened with much interest to Professor C. A. Chant, M.A., PhD., who described the general construction and use of astronomical telescopes, and Professor R. K. Young, B.A., Ph.D., who described the construction of a new telescope for the University of Toronto.

"The general use of a telescope is to enlarge the image of distant objects so that they may be carefully studied and photographed," stated Dr. Chant, who described further the types of telescopes in the world today. Two general types are used, first, the type which employs large lenses to obtain suitable images, and second, the type that uses large curved mirrors to reflect the light to the desired images.

It is necessary to build telescopes of large diameter to allow sufficient light to be collected to form the image; yet, they are limited in size because, if too large, strains in the lenses or mirrors may cause errors in images. In Mount Wilson observatory there exists a telescope with a mirror 100 inches in diameter, the largest in the world. One at Victoria, B.C., is 72 inches in diameter and has produced excellent results. The new telescope now being built for Toronto will be 74 inches in diameter and of the mirror type. It is being constructed by Sir Howard Grubb, Parsons and Company, at Newcastle-on-Tyne, England, and is about half completed. It will be finished in 1933. It is being provided by Mrs. David A. Dunlop as a memorial to her late husband, and will be presented to the University of Toronto. It will be the second largest in the world.

Professor Chant then explained some slides taken from photos of celestial bodies. One remarkable photograph of a nebula clearly indicated the wonderful results obtained by astronomers with some modern large instruments. "This nebula," stated Professor Chant, "is probably 900,000 light years away." When the speed of light is estimated to be about 186,000 miles per second, or 11,160,000 miles per minute, the distance is difficult for most of us to comprehend. It is roughly estimated that this nebula rotates about once in 160,000 years. It is probably an aggregation of stars much like our Milky Way.

Another interesting slide was that of a globular star cluster. Of such, some 86 star clusters have been discovered and there are as many as 50,000 stars in some of the clusters.

The chairman then called on Dr. Young to tell the meeting about the new telescope. Dr. Young has used the Lick refractor and the Victoria reflector which are two of the world's finest telescopes and he went to England to assist in designing the new one.

"There are two main difficulties in designing and building a telescope," stated Dr. Young, "one being the minute accuracy of the parts involved and the other the enormous weight which has to be moved so slowly, once in twenty-four hours." He explained the equatorial mounting of the telescope which allows the instrument to be pointed in any direction and to follow the motion of the stars—due to the earth's rotation.

The clock drive is made with extraordinary precision and tolerances rarely exceed 1/20,000 inch; even with this accuracy errors are compensated for in fitting parts. When the slowness of rotation is considered and the weight involved, in this case about fifty tons, it can readily be seen that there must be no drag or loss, because clockwork would have to overcome inertia. Some telescopes were floated on mercury to obtain a smooth bearing but the accuracy of ball bearings now make it possible to dispense with this.

The speaker then showed several interesting slides showing and explaining the process of manufacture of the 74-inch telescope. He stated that even the fixture holding the mirrors for grinding must be especially constructed in order that the process of grinding and testing can be done together.

In the discussion which followed, one question caused considerable interest. Dr. Young had explained that the large steel dome which housed the telescope was so constructed that it could be moved to allow the aperture to be always over the telescope. The question was asked: Would not vibration be caused by this movement? The speaker explained that the walls of the observatory are on a separate foundation to the telescope and that vibration is not transmitted.

A. H. Harkness, M.E.I.C., moved a fitting vote of thanks, which was conveyed by the chairman to the speaker and heartily endorsed by all present.

C. S. L. Hertzberg, M.E.I.C., occupied the chair and thanked the members for their increasing attendance at the meetings. "Your executive have chosen subjects of general important interest to all technical divisions and it is a source of gratification to find an increasing interest."

Vancouver Branch

W. O. Scott, Jr.E.I.C., Secretary-Treasurer.

Students' Section

E. J. Merrett, S.E.I.C., Secretary.

October 7th, 1931

The first meeting of the year was held on October 7th., A. S. Gentles, M.E.I.C., vice-president, and E. A. Wheatley, A.M.E.I.C., registrar of the Association of Professional Engineers of British Columbia, respectively addressed the members and many Applied Science men. A very clear description was given of the work of the Association of Professional Engineers in British Columbia. The speakers were most emphatic in urging co-operation between the Association and The Engineering Institute.

October 14th, 1931—History of Town Planning in Vancouver

Mr. J. Alexander Walker, of the Town Planning Commission, gave a talk on the "History of Town Planning in Vancouver." He traced the history of the City from the date it was founded in 1792 to when it was incorporated on May 26th, 1886.

Mr. Walker outlined the city's growth and estimated a population of 500,000 in 1940 and 1,000,000 in 1950. To cope with increasing population existing streets will have to be widened and new thoroughfares made. There are 225 miles of major streets in Vancouver of which 101 miles will require widening and 19 miles of new connections are projected.

The commission has plans for filling in of False Creek, leaving a 600-foot water-way and turning basin, and reclaiming many acres of what will be valuable property as the city continues to grow.

October 21st, 1931—The Science of Geology

Outlining the science of geology in various divisions, and the part it plays in modern engineering, Dr. J. A. Walker, of the Geological Survey of Canada, delivered an address before the Applied Science E.I.C. members on Wednesday, October 21st, 1931.

Reviewing briefly the various theories that had existed regarding the origin of the earth and the planets, the speaker said that the one which is accepted by the majority of modern scientists is the solar theory. He explained that according to this theory the planets were originally part of the sun and had been separated from the latter by the impact of another heavenly body.

He went on to deal with the crust and interior of the earth. "The geologist's work covers only the thin outer shell of the earth," he pointed out. He continued that the interior of the earth had physical properties like those of a fluid, but that its exact properties are unknown. He revealed that if an earthquake shock is recorded more than 1,000 kilometers from its origin, two shocks are recorded, one travelling directly through the earth, the other over the surface.

He then spoke of the history of the earth's formation, showing how the gradual cooling of the earth caused its crust to buckle and thus form mountains.

Proceeding to a discussion of geology as a science, the speaker referred to its two main divisions, Palaeontology, concerned with the study of fossils, and general Geology, which includes the study of the structure of rocks. "By studying the structure of the surface rocks, a geologist can determine the exact nature of their formation in a given area."

In conclusion, he expressed the belief that in the future the young geologist would be used more than ever. "The old time prospector has done all he can in some districts," he said, "but I believe that the vicinities of the old mining camps are still rich in hidden ore and with the aid of the geologist this buried wealth can be uncovered."

Preliminary Notice

of Applications for Admission and for Transfer

November 20th, 1931

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.*

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

Communications relating to applicants are considered by the Council as strictly confidential.

The Council will consider the applications herein described in January, 1932.

R. J. Durley, *Secretary.*

* The professional requirements are as follows—

A Member shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years in the case of a candidate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

An Associate Member shall be at least twenty-seven years of age, and shall have been engaged in some branch of engineering for at least six years, which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch of engineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more years.

A Junior shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

A Student shall be at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

An Affiliate shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BOYD—HAROLD CECIL TRAYNER, of 3126 Maplewood Ave., Montreal, Que., Born at Penang, Straits Settlements, July 6th, 1901; B.A., 1925, M.A., 1928, (Mechanical Sciences), Cambridge University; 1925 to 1927, pupil to W. T. Halcrow, M.Inst.C.E., of Messrs. C. S. Meik & Halcrow, London, England; 1927-29, asst. to the res. engr. on constrn. of Lochaber Water Power, Fort William, Scotland (approx. value of work $15,000,000); 1929-31, on designing staff of Power Corporation of Canada Ltd., Montreal, Que. (Stud.Inst.C.E., 1927. Assoc. Member Inst.C.E., 1931.)

ERIKSEN—GUDMUND, of Port Arthur, Ont., Born at Haugesund, Norway, Mar. 10th, 1899; Educ., Diploma, Oslo (Kristiana) Technical College. Day course, 1922-25; 1925-26, inspr. in charge of bldg. constrn., J. T. Munch, engr., Oslo, Norway; 1926-30, with C. D. Howe & Co., Port Arthur, Ont.; at present, city engr.'s dept., Port Arthur, Ont. Work since 1926 has included design without assistance, except general instruction, Grand Trunk Pacific Welfare Bldg., Fort William, (reinforced concrete steel and wood); Canadian Govt. Elevator Office Bldg., Port Arthur, (reinforced concrete steel and brick); structural designing and supervising, Port Arthur Technical School, (reinforced concrete and brick); layout design and supervision, addition to St. Joseph's Hospital, Port Arthur, (reinforced concrete and brick); elevator work-design steel and concrete, and check mfrs. drawing; new city plan of Port Arthur; small addition to waterworks pumping station.

Caustic Embrittlement of Steel

Some Waters Weaken Boiler Plate

Greater size, higher pressure, more elevated temperatures for steam boilers demand greater precaution and more knowledge of materials and of operating conditions.

Within recent years a phenomenon of somewhat frequent occurrence has been distinguished from other kinds of cracking of steel plates in boilers. It was termed "embrittlement" because the fracture resembled that of brittle metal, although it is now known that the steel does not truly become brittle. The cracks are formed between the crystals of the steel and not across the crystals as are always cracks due to stresses of various kinds and to "fatigue" so-called.

An investigation begun in 1895 by the University of Illinois defined an area nearby within which the water from tube wells used in many boilers was of unusual mineral composition. Almost no sulphates were present. The water underwent unexpected chemical changes in the process of steam making, producing caustic soda. Carbon dioxide was separated and removed with the steam. As the explanation of this was not disclosed the investigation ceased with filing of the notebooks in 1900.

In 1912, boiler distresses at the University began to develop in a serious manner and revived the question whether the method of construction, the material, or chemical action was at fault. The fact was brought to the surface again that the particular water used would become caustic in the boiler, and, since similar distresses were known to develop where strong caustic solutions were handled in chemical industries, there was sufficient evidence to call for investigation along chemical lines.

Coincident with these studies, boilers installed in 1911 began to show signs of weakness and by 1915 were so badly cracked as to require replacement. Neighbouring regions in Illinois were being discovered where this kind of water was used. Within these zones, up to 1912, there had occurred four boiler explosions and thirteen replacements of drums, due to cracking. There was presumptive evidence, at least, that the cause lay in the caustic condition attained by the water under steaming conditions.

On this theory, to protect new boilers at the University, there was added to the water, before admission to the boiler, sufficient magnesium sulphate to neutralize three-fourths of the causticity. This treatment was shortly altered to the addition of crude sulphuric acid in amount sufficient to neutralize all but twenty-five per cent of the sodium alkalinity.

In connection with new studies begun in 1925, a method was developed for producing this cracking phenomenon at will, making it possible to investigate all conditions, such as kind and concentration of solutions, inhibitive agents, effect of stresses on test pieces, and kind of steel that might be used in boilers. Approximately five hundred tests were made. It was shown that the original treatment was a fortunate guess. The boilers where that regime was adopted were, after twelve years, in perfect condition. In all the field studies no boiler distress was met where this ratio of sulphate to carbonate was maintained. Conversely, all cracking has been accompanied by an excessive ratio of caustic to sulphate.

Guided by the data thus assembled, the Boiler Code committee of The American Society of Mechanical Engineers adopted the requirement that this ratio of three parts of sulphate to one of alkalinity, be maintained in practice.

Fortunately, the signs of caustic embrittlement are in evidence before a dangerous weakness develops, so that actual explosion from this cause is the exception.

The cracks develop as a result of two factors, strain and concentration of the caustic solution, not under either condition alone.

The quantity of caustic required for cracking, equivalent to not less than 100 grams per litre of water, is easily accounted for by the natural concentration that occurs in capillary spaces between plates, connected at some point with the main volume of water in the boiler. The strains in the metal are readily accounted for by processes of construction and operation. The cracks occur in the riveted areas under lap joints and butt straps or similar parts where strain and capillary spaces occur.—*From Research Narratives of the Engineering Foundation.*

Fifty Years of Canada's Development

Canada is but a new country, and its engineering progress is measured only by decades. It cannot be said that its engineering dates back for a hundred years; rather, is it more nearly fifty or seventy-five. Canada's first people, coming originally from France three hundred years ago, and Great Britain a hundred and fifty years later, occupied only the regions around the Atlantic coast and Great Lakes. It was but seventy-five years ago that the expansion began, and it is not more than fifty or sixty years since the definite movement of population commenced to the prairie regions westward of the Great Lakes, and to the Pacific coast. The present widely-scattered districts of population and development are confined to a belt across the continent from the Atlantic to the Pacific, which may be said to be 3,500 miles long, varying in width roughly from 300 to 400 miles. Economically, however, the Dominion forms a much larger figure. Its developable area, now being disclosed as containing the most valuable of natural resources and largely capable of sustaining population, may be viewed as nearly three times this size. In other words, the belt can, and undoubtedly will in time, be expanded to a region from 800 miles to a 1,000 miles wide.

Canadian development activities were accelerated thirty years to fifty years ago, when they rapidly moved westward, and it was within that period that the marked growing time was most pronounced. In the decade before the war, the westward growth was continuing, but rather in the nature of consolidation than in wider expansion.

To-day, Canada's development is, by contrast, definitely moving northward. The new north of Canada is now beginning to be realized, for, within the past few years, especially since the war, there has been a distinct northward movement of population and development as the more adventurous and enterprising of the Canadians have reached out to these new regions further afield.

It is easily understood that such a young country as Canada should have had a very active life during this growing period of the past fifty years. The history of its material development where engineering was required, does not date much further back than seventy-five years. That early period was the age of road building and of rail and water communication, when steam application was in its infancy, and when most of the manufactured articles of use were imported from the United States or Great Britain. The country then was necessarily agricultural, with such industry as was required to supply domestic wants, and with export trade only in lumber.—Brig.-General C. H. Mitchell, CB., C.M.G., D.S.O., D.Eng., M.E.I.C., in *Engineering.*

EMPLOYMENT SERVICE BUREAU

This Service is operated for the benefit of members of the Engineering Profession and Industrial and other organizations employing technically trained men — without charge to either party.

All correspondence should be addressed to

The Employment Service Bureau, The Engineering Institute of Canada

2050 Mansfield Street, Montreal

All notices intended for publication must be received not later than the Tuesday of the week preceding the date of the issue in which they are to be inserted.

Situations Wanted

ELECTRICAL ENGINEER, graduate 1924, experienced home and foreign in electrical design and construction, surveys, reports, etc., capable of taking charge of same, desires any opening in engineering work. Age 32, married. Location immaterial, including foreign countries. Apply to Box No. 7-W.

ELECTRICAL AND RADIO ENGINEER, B.Sc. '28. Experience in the design and testing of broadcast radio receivers, including latest superheterodyne practice, and capable of constructing apparatus for testing same. Also familiar with telephone and telephone repeater engineering. Thorough experience in design, construction and inspection of municipal conduits. Apply to Box No. 12-W.

ELECTRICAL ENGINEER, graduate '25. G.E. test; switchgear engrg. dept., relay engineer, public utility. First-class record. R.P.E., B.C. Apply to Box No. 68-W.

REINFORCED CONCRETE ENGINEER, B.Sc., P.E.Q., eight years experience in construction design of industrial buildings, office buildings, apartment houses, etc. Age 30. Married. Apply to Box No. 257-W.

MECHANICAL ENGINEER, B.Sc. McGill 1919, A.M.E.I.C., married. Eleven years experience, including structural, reinforced concrete, piping and high pressure boiler and furnace design, heating and ventilating, hydraulic and boiler plant operating problems. Apply to Box No. 265-W.

CIVIL ENGINEER, B.Sc. and C.E., age 26. Thirty months engineering experience, including testing laboratory work, instrument and inspection work on hydro power plant construction, location and field engineering on transmission line job, plane table contour work, triangulation and ground control for aerial photography. Applicant now open for employment, preferably on construction work with a reliable company in North America. Apply to Box No. 431-W.

CIVIL ENGINEER, B.A.Sc., C.E., A.M.E.I.C., age 29, married. Experience over nine years includes railway location and construction as resident engineer. Hydro-electric report on estimates and investigation, also design, construction and teaching on hydraulic structures, bridge foundations and caissons. Location immaterial. Apply to Box No. 447-W.

DESIGNING ENGINEER, A.M.E.I.C., P.E.Q., with extensive experience in design and construction of power plants, industrial buildings and hydraulic structures, desires position as designing engineer or resident engineer on construction. Apply to Box No. 492-W.

MECHANICAL ENGINEER, B.Sc., Jr.E.I.C., '26. Ten months experience in pulp and paper steam control. Four years experience in detail and design, in pulp and paper mill, industrial plant and hydro-electric development work. Age 27. Married. Location immaterial. Apply to Box No. 521-W.

Situations Wanted

ELECTRICAL ENGINEER, married, graduate of McGill University, desires position in Ottawa, Montreal or Toronto. Experience includes four summers with a building concern as instrumentman and assistant engineer, two and one-half years with the Canadian Westinghouse Co., this time being distributed between tests, design and sales. At present employed but available on short notice. Apply to Box No. 533-W.

ELECTRICAL ENGINEER, A.M.E.I.C., university graduate 1924. Experience includes one year test course and five years on design of induction motors with large manufacturer of electrical apparatus. Four summers as instrumentman on highway construction. Several years experience in accounting previous to attending university. Available at reasonable notice. Apply to Box No. 564-W.

CIVIL ENGINEER, B.Sc., McGill University, Jr.E.I.C. Five years experience along the lines of general construction, including structural steel. Available at once. Apply to Box No. 570-W.

MECHANICAL ENGINEER, A.M.E.I.C., with twenty years experience in mechanical and structural design, familiar with shop practices and costs, desires connection. Apply to Box No. 571-W.

YOUNG ENGINEER, Jr.E.I.C., experienced in design, details and erection of steel and concrete structures. Also a good theoretical and practical knowledge of steam, hydraulic and I.C. engine power plant. Good practical mechanical and electrical engineer, able to operate and maintain any type of machinery or power plant. Location immaterial. Apply to Box No. 572-W.

CIVIL ENGINEER, B.A.Sc. Toronto '28. Experience, hydro-electric, building design, bridges and culverts, inspection and testing of materials. Married. Present location Montreal. Apply to Box No. 576-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc. (Univ. of B.C., '30), Undergraduate experience in pulp mill. One year's experience, Canadian General Electric Co., mech. dept. Single. Age 24. Desires position in technical design or sales. Location immaterial. Available on short notice. Apply to Box No. 577-W.

MECHANICAL ENGINEER, S.E.I.C., age 21, four years mechanical engineering, Queen's University, desires permanent employment. Experience in wood work, machine shop work, draughting and surveying. Location immaterial. Available at once. Apply to Box No. 600-W.

MECHANICAL ENGINEER, Canadian, technically trained; eighteen years experience as foreman, superintendent and engineer in manufacturing, repair work of all kinds, maintenance and special machinery building, desires change. Location immaterial. Available on one month's notice. Apply to Box No. 601-W.

Situations Wanted

MECHANICAL ENGINEER, Jr.E.I.C., five years apprenticeship on general mechanical engineering; 10 years experience on heating and ventilating and mechanical equipment of buildings. Design, draughting and production. Desires change. Capable of taking charge of engineering department. Further particulars if required. Apply to Box No. 616-W.

POWER ENGINEER, M.E.I.C., age 42. Married. Thoroughly conversant with electrical, steam, mechanical and industrial engineering, desires executive position with large industrial, power or financial corporation. Best of references as to ability and positions held. Apply to Box No. 617-W.

CIVIL ENGINEER, Jr.E.I.C., B.A.Sc., '24, age 35, married. Five years designer and estimator with well-known firm of industrial builders; two years detailing, designing and estimating structural steel for bridges and buildings, also survey and municipal experience. Open for position immediately, will go anywhere. Apply to Box No. 618-W.

CIVIL ENGINEER, A.M.E.I.C., graduate '23, married, eight years municipal engineering experience. Sewerage and sewage disposal, water works, street pavement, etc. Also some experience highway construction. For the past three years engaged by firm of consulting municipal engineers. Desires permanent position. Location immaterial. Available immediately. References. Apply to Box No. 624-W.

CIVIL AND MECHANICAL ENGINEER, experienced in design, layout, installation and selling. Sixteen years association with largest Canadian industries manufacturing equipment particularly relating to pulp, paper and lumber and five years design and construction of sulphite mill, including electrolytic bleachmaking from salt. Apply to Box No. 633-W.

ELECTRICAL ENGINEER, B.Sc. '26, Jr.E.I.C. Age 31. Experience includes on year operation and maintenance work in hydro-electric power plant. Three years on power plant construction work, consisting mostly of relay, meter, and remote control wiring. One year out-door sub-station construction, as assistant engineer. Also geologival survey and highway construction experience. Desires position of any kind. Available at once. Apply to Box No. 636-W.

ELECTRICAL ENGINEER, B.Sc., N.S. Tech. Coll., '31. Experience includes geological survey work in Rouyn mining area and hydro-electric power plant construction, both civil and electrical work. Available at once. Apply to Box No. 639-W.

ELECTRICAL GRADUATE, McGill '30, S.E.I.C., with thirteen months experience on General Electric test course, twelve months draughting and five months as instrumentman on power plant construction. Location immaterial. Apply to Box No. 644-W.

CIVIL ENGINEER, A.M.E.I.C., R.P.E. (Ont.), extensive experience as executive and in charge of construction of complete water power developments, including transmission lines, harbour developments, including hydraulic, dredging and land reclamation, industrial plants and municipal works. Apply to Box No. 647-W.

OPERATING ENGINEER. Position wanted as operating superintendent or assistant. Age 43. Married. No children. Nineteen years experience operating hydro-electric plants, sub-stations, transmission lines. Available immediately at any reasonable salary and for any location. Apply to Box No. 654-W.

Situations Wanted

ELECTRICAL ENGINEER, Jr.E.I.C., 1926 grad. of English Tech. Coll. Past two years inspector of communication apparatus; three years varied power and sub-station experience, including automatic sub-stations, on comprehensive training scheme. Age 24, single. Location immaterial. Available at once. References. Apply to Box No. 658-W.

ELECTRICAL ENGINEER, B.Sc.E.E., 1931. N.S. Tech. Coll. Experience in armature winding and apparatus repairs, in conduit and cable work. Students' course in elevator manufacture, ship's electrician on tropical run. Good cultural education. Available at once, for Canada or tropics. Apply to Box No. 659-W.

ELECTRICAL ENGINEER, university graduate '28. Experience includes one year with operating department of a large public utility and two years with manufacturer of electrical equipment, work including design, test and correspondence. Available on short notice. Apply to Box No. 660-W.

MECHANICAL ENGINEER, age 26, university graduate. Experience in machine shop and foundry productions and cost control, and considerable experience with arc welding. Interested in sales engineering. First-class references. Available at once for any location. Apply to Box No. 664-W.

ELECTRICAL ENGINEER, B.Sc., S.E.I.C. Experience: Installation staff Can. Gen. Elect.; students test course with the same company, concrete inspection, transmission line surveying and inspection; also some railway construction experience. References. Desires position with electrical concern. Location immaterial. Available at once. Apply to Box No. 665-W.

RADIO ENGINEER, with thorough general experience covering short wave, marine, broadcast, wire communication, and sound picture work. Capable of taking responsibility in engineering, operating, manufacturing or executive fields. University graduate; single; age 27. Apply to Box No. 667-W.

MECHANICAL ENGINEER, desires position with manufacturing or other company offering opportunity in design and draughting. Thorough technical training and four years experience since graduation. Prefer western Canada, but location and salary of secondary importance. Age 29, unmarried, thoroughly reliable and capable of handling junior position of responsibility or taking charge of technical work for small concern. Apply to Box No. 669-W.

ELECTRICAL ENGINEER, B.Sc., McGill Univ. '23, Jr.E.I.C. Eight years experience as sales engineer in all classes of electrical machinery, also switching, mine hoists, steam and hydraulic turbine generator sets, street railway and railroad equipment. Good commercial experience. Highest references. Age 30. Single. Available immediately. Apply to Box No. 670-W.

CIVIL ENGINEER, graduate University of New Brunswick '31, in C.E. Experience consists of three seasons on a survey party. Available October 1st. Desires permanent position. Willing to go anywhere. Apply to Box No. 672-W.

MECHANICAL ENGINEER, A.M.E.I.C., Canadian, technically trained; six years drawing office experience, including general design and plant layout. Also two years general shop work, including machine, pattern and foundry experience, desires position with industrial firm in capacity of production engineer or estimator. Available on short notice. Apply to Box No. 676-W.

CIVIL ENGINEER, graduate, Jr.E.I.C., age 25, single. Experience includes mill construction, design and supervision. Also design of hydraulic structures, bridge foundation, rigid frames and caissons. Will go anywhere. Apply to to Box No. 677-W.

RADIO ENGINEER. Graduate McGill Applied Science '30. Experience includes the design, development and production of broadcast receivers, as well as general radio laboratory practice. Apply to Box No. 680-W.

ELECTRICAL ENGINEER, graduated 1914, desires position with engineering firm or electric utility. Experience in design and layout of power houses and sub-stations, including automatic and supervisory control equipment; design of switchboards and switching equipment; manufacturing, testing, erection and operating of electrical apparatus of all kinds. Anywhere in Canada. Permanent position preferred. Apply to Box No. 681-W.

OPERATING ENGINEER, A.M.E.I.C. Operating superintendent or assistant. Age 44, married. Twenty years experience in industrial manufacturing, steel mills, power plants and quarrying operations, both large and small. Very successful with labour problems, cost accounting, etc. Will take any position with view to betterment. Available immediately in any location. Apply to Box No. 682-W.

ELECTRICAL ENGINEER, B.Sc.E.E., University of Man. 1921, A.M.E.I.C., married. Two years Westinghouse test course, three years sales engineer, five years draughting and electrical design on hydro plants, transmission lines, etc. Apply to Box No. 687-W.

MECHANICAL AND STRUCTURAL ENGINEER. Six years experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available on short notice. Apply to Box No. 692-W.

ELECTRICAL ENGINEER, S.E.I.C., B.A.Sc. '31. Age 21. Three months undergraduate experience in electric railway substation. Five and a half months Canadian General Electric test course on induction motors and industrial control apparatus. Available on short notice. Location immaterial. Apply to Box No. 700-W.

AERONAUTICAL ENGINEER, M.Sc. Mass. Inst. of Tech., B.Sc. Mech. Eng. Queen's Univ. '30. Capable of aircraft design work and stress analysis. Experience also in machine design, etc. Canadian, single, available immediately for position anywhere. Apply to Box No. 702-W.

MECHANICAL ENGINEER, B.Sc., '27, Jr.E.I.C. Four years maintenance of high speed Diesel engines units, 200 to 1,300 h.p. Also maintenance of D.C. and A.C. electrical systems and machinery. Draughting experience. Westinghouse apprenticeship course. Practical mechanical and electrical engineer with a special study of high speed Diesel engine design, application and operation. Location in Western or Eastern Canada immaterial. At present in Montreal. Apply to Box No. 703-W.

MECHANICAL ENGINEER, Jr.E.I.C. Graduate Inst. Mech. Engrs. Age 25. Nine years practical experience, design and construction, air compressors, Diesel engines, elevating, transporting, stone and woodworking machinery. Three years at pulp and paper mill, design and construction of paper and board machinery, reinforced concrete construction. Available at once. Apply to Box No. 704-W.

ELECTRICAL ENGINEER, B.A.Sc., graduate '28. Test experience D.C. motor and generator design, and industrial electric heating design experience. Single. Location immaterial. Apply to Box No. 709-W.

Stoker Manufacturers Association, Detroit, Mich., have recently published a new forty-page catalogue, illustrating and describing forty-eight different types of mechanical stokers manufactured by the fourteen member companies of the Association. The various stokers are grouped into the following classifications: multiple retort underfeed stokers, single retort underfeed stokers, chain grate stokers and overfeed stokers. The text is limited to engineering descriptions of the various types of machines, and a supplementary section on engineering data relating to modern stoker practice is included. Copies will be sent upon request to W. V. McAllister, Secretary of the Association, Foot of Walker street, Detroit, Mich.

Kingsbury Machine Works, Inc., Philadelphia, Pa., have published Bulletin HV, combining in one 39-page booklet descriptions and illustrations of vertical and horizontal thrust bearings, whose parts are to a large extent interchangeable. Only standard self-aligning, equalizing thrust bearings are covered. Capacities, weights, and principal dimensions are given for the usual forms of these bearings. This bulletin supercedes the company's previous Bulletins D, F and parts of G. Copies may be secured from the company at 4324 Tackawanna street, Frankford, Philadelphia, Pa.

Combustion Engineering Corporation, New York, has recently placed on the market the C-E Electric Stoker Drive. This drive is now available as standard equipment for both the Type E and Type K stokers and is applicable wherever the steam pressure is insufficient for the standard steam drive or where other conditions favour the use of an electric drive.
