The present mining development in northern Quebec, tributary to the Harricana river, may be taken as an illustration. Rising north of the height of land and flowing north to James Bay the resources of timber or of the agricultural areas on its watershed were not economically exploitable. The construction of the National Transcontinental Railway, crossing the rivers of the northerly slope of that area, provided a means of transport to market of the lumber, and of the produce of farms. The supplies of machinery for saw mills, and for lumber camps had to be handled by the river. In 1919 a small dredge was assembled at Amos, where the river and railroad meet, for use in improving the main and branch channels of the river, which until then was not usable for craft of over 3½ ft. draft, and only for a distance of about 4 miles above Amos. About the same time the development of the gold resources of the region began, the original development work on the Siscoe mine commencing in 1920. There are now eleven plants in operation handling from 100 to 600 tons of ore per day. Thus the waterway improvements have had to be continued, the channels maintained and improvements carried farther afield as more properties were opened up.

As development demanded, the provincial government has since constructed highways; railways were also added, the Nipissing Central being built in 1928, and the Canadian National having now under construction a branch line from Senneterre through Val d'Or to Rouyn. The growth of the district and of the water-borne traffic may be indicated as follows:—

1920—Approximately 12,000,000 ft.b.m. spruce and jack pine in round logs towed down the river by steamers, and about 200 tons of mining and lumbermen's supplies.

1936—Approximately 350,000 ft.b.m. of timber and 180,000 tons of machinery and supplies (including gasoline) moved by water.

The future of the region seems assured for many years to come, and the wisdom of the expenditure to aid the pioneers and their successors is amply demonstrated.

In the Maritime provinces, the accessibility of the sea coast has rendered services of this nature largely unnecessary, but the St. John river and its large tributaries, and the Miramichi river, both in New Brunswick, are used as waterways.

The Yamaska, the St. Francis, the Lievre and the larger tributaries of Lake St. John in Quebec, the Trent, the Grand and the Thames rivers in old Ontario, and in later years the Red, the Hole and the Echimamish rivers in Manitoba, the Saskatchewan, the Montreal, the Cumberland, the Beaver and the Meadow rivers in Saskatchewan, the Lesser Slave and the Peace in Alberta, and the Columbia, the Fraser, the Stikine, the Finlay, in British Columbia, together with the Yukon river, among many, form other examples of the varied uses of the waterways in facilitating the pioneering efforts of Canadians, and of the diversity of public works required, such as dams, training works, lining cables, removal of boulders and snags, and dredging.

### Bridges

Mention has been made in the earlier part of this paper of the activities of the provinces of Canada in the construction of roads, and as a result of these works and the canal construction, the present policy of the Dominion in respect to the construction of highway bridges has developed.

The Ottawa city bridges, maintained by the Department, include the Laurier bridge over the Rideau canal and C.N.R. tracks (rebuilt 1901), and the Connaught Plaza, built in 1912 to replace the old Dufferin and Sappers bridges crossing the canal at Sparks and Wellington streets.

Incidentally, Colonel By, R.E., who built the Rideau canal, also bridged the turbulent Chaudiere channel between Upper and Lower Canada in 1837, with an arch bridge, successively replaced by a suspension bridge in 1843, a pin-connected truss bridge in 1899, and a riveted truss bridge in 1919; a good example of the changes required to meet increasing traffic demands across the Ottawa during the past century.

Fig. 8—Bow River Bridge, Banff, Alta.

When reconstruction of the Union bridge below the Chaudiere falls was necessary in 1919, the cost was borne share and share alike by the Dominion and the two provinces of Quebec and Ontario, subsequent upkeep being assumed by the Dominion. The bridges at Bryson (1886); Portage du Fort (1901 and 1904); Chapeau (1876 and 1912); DesJoachims (1886); and North Timiskaming (1919), on the Ottawa river were constructed at Dominion expense, as a liability connected with the Ottawa river slides and booms and storage works, and as a contribution towards the development of the district.

The original Intercolonial Railway bridge over the Restigouche river, the boundary between Quebec and New Brunswick, having become too light for heavy rail traffic, the Dominion assumed the bridge, and has maintained it for highway traffic.

A bridge over the Assiniboine river near the boundary between Manitoba and Saskatchewan, near Shellmouth, Man., was built and is maintained by the Department. Several bridges were also built in the North West Territories, at Battleford; at Calgary (1897); MacLeod (1897); Edmonton (1899), and the Banff, Alta. bridge was rebuilt (1920) (Fig. 8).

The bridge over the Ottawa river between Hawkesbury, Ont. and Grenville, Que. was built in 1930 under the policy which has been adopted of constructing bridges, where warranted, over interprovincial waterways, when the adjoining provinces will absorb equal shares of the cost with the Dominion; subsequent maintenance, not including replacement, being borne chiefly by the Dominion. This does not apply to bridges wholly within a province, the cost in such cases being considered as the affair of the province.

Bridges over streams forming part of the International Boundary are in a different category, and the policy is to construct such bridges as are considered warranted, for highway traffic, in conjunction with the appropriate authority in the United States, each bearing one half of the first cost and subsequent maintenance. The bridges at Edmundston, Clairs, and St. Leonards, over the St. John river, and that at Vanceboro over the St. Croix river, boundary streams between New Brunswick and Maine, are in this class.

The LaSalle causeway and bridges, over the outlet of the Cataraqui river at Kingston, Ontario, arise out of the main provincial highway constructed by the province of Canada prior to Confederation, and in this case over a reach of the Rideau canal, a continuing liability of the Dominion.

**Fig. 9—Lift Bridge, Selkirk, Man.**

The construction programme of the Dominion undertaken for the relief of unemployment, during the recent depression, provided funds for the construction of highway bridges over the Red river at Selkirk, Man. (Fig. 9); over the South Saskatchewan river at Outlook, and over the North Saskatchewan at Borden,[9] in Saskatchewan. These, being within their boundaries, will be turned over to the province on completion.

### Aviation

The development of aviation in Canada has been under the supervision of the Department of National Defence in both its military and civil aspects. That Department, however, enlisted the aid of the engineering services of the Public Works Department in the development of the landing field, at St. Hubert, P.Q., and in the provision of mooring facilities there for H.M. dirigible R-100.[10]

### The Dry Docks Subsidies Act

Running through the reports from year to year of the Public Works Department are descriptions of governmental activities to safeguard ships against possible accident.

Since it is inevitable that damage to ships will occur, repair facilities must be provided. For the smaller classes of vessels, up to about 3,000 tons, marine railways are built, but above about that limit recourse must be had to dry docks.

To supplement the lighthouses, buoys, and other aids to navigation, and channel improvements, and as a means of keeping down insurance rates, the government built the Lorne dry dock, at Levis, Que., in 1888, and the dry dock at Esquimalt, B.C., in 1887. These were adequate to receive the largest ships of that time, up to about 25 ft. in draft and 500 ft. in length.

On the Atlantic coast of Canada there was no corresponding facility, and to meet the situation the Halifax Graving Dock Company Limited was subsidized by the Dominion Parliament. The British Government assisted by subsidy in the construction in order to have a repair base for the North Atlantic Squadron, and financial assistance was given by the city of Halifax. The Halifax dock was built in 1886-1889.

As the first decade of this century brought increasing trade through the St. Lawrence route with correspondingly larger ships, and in view of possible expansion of the ship building industry in Canada the Government, to aid both the shipping and the shipbuilding industries enacted the Dry Docks Subsidies Act. Under its terms private companies could secure, on a favourable report by the Minister of Public Works as to the need of the facility, a guarantee of reimbursement of the cost of construction of graving or of floating dry docks with ship repair facilities, the Act setting out the minimum dimensions and capacities the subsidized structures are required to have.

Under the provisions of the Act dry docks were subsidized, as follows:

| Year completed | Place | Type | Dimensions |
|---|---|---|---|
| 1904 | Collingwood, Ont. | Graving | 526.15 ft. by 59.8 ft. by 14.8 ft. |
| 1910 | Collingwood, Ont. | Graving | 413.2 ft. by 95 ft. by 19.2 ft. |
| 1910 | Port Arthur, Ont. | Graving | 723.4 ft. by 77.6 ft. by 16.2 ft. |
| 1912 | Montreal, P.Q. | Floating Class II | 601 ft. by 100 ft. by 32.6 ft. |
| 1915 | Prince Rupert, B.C. | Floating Class II | 600 ft. by 103 ft. by 32 ft. |
| 1923 | Saint John, N.B.[11] | Graving Class I | 1,164.6 ft. by 131 ft. by 40.3 ft. |
| 1925 | Vancouver, B.C. | Floating Class II | 556.6 ft. by 104 ft. by 28 ft. |

**Fig. 10—"Duke of Connaught" Floating Drydock, Montreal.**

To meet the need of adequate drydocking facilities for the larger ships on the St. Lawrence, the Government constructed the Champlain dry dock, at Levis, Que., work

[9]The design and construction of this bridge are described in another paper by Messrs. C. J. Mackenzie, M.E.I.C., Dean of Engineering, University of Saskatchewan, and B. A. Evans, Senior Assistant Engineer for the Department of Public Works of Canada.

[10]The St. Hubert Airship mooring tower has been described by R. deB. Corriveau, M.E.I.C., assistant chief engineer. See The Engineering Journal for April, 1930, pp. 277-281.

being commenced in 1911 and the dock taken over from the contractors in 1921.[12] The need of larger facilities than those already existing on the Pacific coast was met by the construction of the New Esquimalt dry dock, at Esquimalt, B.C., in 1920-1926, by the Department.[13] It is 1,150 ft. long, 125 ft. clear width at entrance, and carries 40 ft. over the entrance sill at high water. (See Fig. 12.)

THE NAVIGABLE WATERS PROTECTION ACT

From earliest times man has made use of the facility provided by waterways in his business affairs, and the reservation of this right of common user to the public descends to us in the Common Law of England.

Parliament did not enact legislation to protect the public against damage or obstruction to the navigable waterways until 1886, when it passed the Navigable Waters Protection Act. This arose from the need of checking the harmful practice of dumping the refuse from saw mills into streams and lakes. As industry developed the need of wharves or piers, of bridges, or telegraph or telephone or power lines or other works which might affect the use of the waterway by commerce, the scope of the Act was extended in 1927. As now enacted, any work is unlawful if constructed in, over, under or through a navigable body of water in Canada if the approval of the Governor-General-in-Council is not obtained prior to construction, and if a work, not so approved, is considered by the Governor-General-in-Council to be an obstruction to navigation he may order its removal at the expense of the owner. The Act applies to works of any private individual or corporation, or municipality or provincial government. It does not apply to bridges over the St. Lawrence river, for which structures special Dominion legislation is individually required.

Part I of the Act, which relates to works in navigable waters, is administered by the Department of Public Works, while Part II, relating to the depositing of materials in navigable waters is administered by the Department of Transport.

PRECISE LEVELLING

In the course of the development, in its several stages, of the deep water channel of the St. Lawrence river to Montreal, from the original natural depth of 12 ft. to the present depth of 35 ft. at low water, it became increasingly important that accurate knowledge be available of the true level of the sloping surface of the river in relation to mean sea level.

To secure this basic information precise or geodetic levelling was inaugurated in Canada in 1883, the first work being done on that section of the Richelieu between St. Johns and Rouse's Point on Lake Champlain, N.Y.; the datum assumed was at a height of 100 ft. above the zero of the U.S. Engineer Corps at Fort Montgomery, N.Y.

The first few seasons' work embraced the whole Richelieu river from Lake Champlain to the St. Lawrence at Sorel.

Work on a line between Montreal and Quebec along the south shore of the river was started in 1885 and completed in 1888. It was decided by the Department that work be pushed along from Quebec towards the Atlantic coast, and westwardly to the Great Lakes. Below Quebec the work would be of great service almost immediately, in connection with the proposed determination of the low water plane to which soundings could be reduced in the Beaujeu channel, previous to engaging in expensive sounding operations, and also the connect determination of mean sea level at some point in the gulf.

Seasons were spent in establishing flood levels between Lachine and Quebec. Tide stations were maintained between Levis and Champlain and one far down in the gulf, at Rivière aux Renards (Fox river).

Levelling continued along the beach of the south shore of the gulf to some 25 miles beyond Father Point, where the right-of-way of the Intercolonial Railway was used for the first time. By 1903, after twenty years, the total length of line levelled, including cross sections, was 637 statute miles, and the number of metallic and other permanent bench marks established, 261.

**Fig. 12—New Drydock at Esquimalt, B.C.**

In 1904 work began in connection with the extensive surveys undertaken by the Department on the projected ship canal from the Georgian Bay in Lake Huron through the valleys of the French and Ottawa rivers down to Montreal. This was completed in 1906, and the mileage was 889.

In 1907 the levelling reached Halifax, where connection was made with the bench mark used by the Tidal Division of the Hydrographic Service in establishing mean

The Champlain Dry Dock for Quebec Harbour, by U. Valiquet, M.E.I.C., Trans. Can. Soc. C.E., 1918.
[13]The New Esquimalt Dry Dock, by J. P. Forde, M.E.I.C., The Engineering Journal, December, 1925.

sea level. Mean sea level at Halifax is now the datum to which all records are reduced. The main base line between Halifax and Father Point, across almost three provinces, and nearly 500 miles long, turned out to be of great accuracy.

With the completion of the main line, work was systematically extended. The lower provinces offered a great field for checking accuracy at the various harbours and ports in establishing low water datum for charts and design of harbour works, and dredging. In Nova Scotia and New Brunswick about 1,000 miles of levelling was done.

In Quebec a large loop line some 450 miles long was run, starting at Matapedia and following the shore of Baie de Chaleur, across Gaspé harbour, thence over the route (now the new highway) to Fox river and along the north west shore of the gulf to Father Point. Including cross sections and spur lines some 2,100 miles were covered.

In Ontario the main line followed the upper St. Lawrence to Lake Ontario, then from Toronto to the Welland canal and across Niagara to Lake Erie, thence along the shore line to Windsor, finally to Sarnia and Point Edward, covering over 1,900 miles including the Georgian Bay work.

In Manitoba the work requested started at Stephen, Minn., and reached the boundary at Emerson, continuing to Lake Winnipeg.

Between 1883 and 1930 the total distance amounted to 5,500 miles.

Having accomplished the object of relating to mean sea level the elevations of permanent bench marks from which to establish the true height of the surface of the majority of Canada's navigable waterways and harbours, these activities of the Department were discontinued, and the records were transferred to and incorporated with those of the Geodetic Survey of Canada.

### Testing Laboratory

The present testing laboratory of the department was inaugurated in 1892, as a cement testing laboratory, and continued until 1911 testing Portland cement exclusively, when the activities were extended to testing gravels, crushed stone, reinforcing steel, and brick. Towards the close of the Great War, and coincident with the reconstruction of the Parliament building at Ottawa, the field of usefulness was greatly extended, so that it now covers all classes of materials used in building construction and of goods purchased for government use, as well as processes.

The experience gained in the testing and examination of these goods and materials has been incorporated in specifications under which these are purchased for departmental use. A further development of great promise has been to correlate field and laboratory tests and studies of foundation materials and conditions.

With the development which ushered in the present century, the engineering activities and staff of the Department of Public Works expanded to the extent that some 36 districts had been established, with the staffs in proportion. The realignment of effort consequent on the Great War necessarily imposed on the department, as on other governmental activities, a curtailment of effort, and this resulted in a reorganization under which the districts were consolidated to sixteen in number, and with a reduction in staffs to correspond.

In view of the manifold and diversified activities of the Public Works Department throughout the Dominion, including not only the nine provinces but the North West Territories and the Yukon, a basic scheme of decentralized administration has been found the most suitable and effective, as it permits a close contact being kept not only with the works but with the trend of business, and permits of that degree of flexibility necessary to meet changing conditions.

### Chief Engineers of the Department

Samuel Keefer was the first Engineer of Public Works of Canada. Born at Thorold, Ontario, January 22nd, 1811, he was Secretary and Assistant Engineer of Public Works of Canada, 1833-1841, becoming Chief Engineer on August 17th, 1841, which office he held until 1852. He was the second president of the Canadian Society of Civil Engineers.

John Page, senior, succeeded as Engineer of Public Works on November 5th, 1853, and continued in the capacity of Engineer of Public Works after Confederation. He stayed with the Canals, becoming the first Engineer of Canals when the separate Department of Railways and Canals was formed in 1879.

Henry F. Perley, who had served his apprenticeship on the engineering staff of the Government of New Brunswick which he joined in February, 1848, with that of the Nova Scotia Government from 1863 to 1865, then as Superintending Engineer of New Brunswick Railways from 1870 to 1872, as Superintending Engineer of Public Works for the Maritime Provinces from May, 1872, succeeded John Page in 1880, and held office until 1890. He was the first "Chief Engineer" of Public Works, that title being created and conferred on him by Order-in-Council of November 25th, 1880. In 1887-1889 he was vice-president of the Canadian Society of Civil Engineers.

Louis Coste, M.Can.Soc.C.E., who had been an engineer on Public Works from 1884, succeeded Henry F. Perley, and was in turn succeeded by Eugene D. Lafleur, in 1899.

Mr. Lafleur, who died in harness in 1922, after continuous service since September 27th, 1881, had seen major developments under the Department initiated and carried out, including the construction of the Champlain dry dock at Levis, the deep water wharf on the River St. Charles at Quebec, the ocean terminals and the dry dock at St. John, N.B., the Georgian Bay Canal Survey, the development of Port Arthur and Fort William, and of Vancouver and Victoria, in British Columbia.

His successor, Arthur St. Laurent, past president of the Engineering Institute of Canada, had joined the public service with the Department in 1885. A man of sound judgment and wise counsel, he had gained the respect, esteem and affection of all, and his untimely death in 1923 was a great loss to the public service.

**Fig. 13—New Customs Building, Montreal.**

The author, then occupying the position of Assistant Chief Engineer, succeeded Mr. St. Laurent.

### Government Telegraphs

The Government telegraph and cable lines, which have been under the control of the Public Works Department since 1879, have played an important part in Canada's development since that time.

Following the construction of a telegraph line which was to connect Halifax with the trans-Atlantic cable terminal at Canso, telegraph and cable lines soon began to function as aids to fishing and navigation along the coast of the Gulf of St. Lawrence and the Bay of Fundy. In addition, submarine cables were laid to such important fishing centres as the Magdalen islands, Anticosti, and Grand Manan islands.

Well in advance of the construction of the Canadian Pacific Railway, the Government telegraph lines passed beyond Winnipeg and extended out over the Saskatchewan and Alberta prairies and, upon the incorporation of British Columbia into the Dominion, the Public Works Department took over the privately owned land and cable lines then in operation in that new province.

From this small beginning, there has developed in the past fifty years the present Government Telegraph Service, with some ten thousand miles of land line, serving many of the important agricultural, timber, fishing and mining areas in eight provinces and the Yukon Territory.

A factor which contributed to the early development of the telegraph service along the Gaspé coast was the necessity of establishing a system of news broadcasting for the fishermen there. Daily bulletins were sent over the wire by each office between Matane, on the St. Lawrence side of the Peninsula, and New Carlisle, on the Bay of Chaleur, reporting:

1. The result of the local fishing on the previous day.
2. The bait supply of the preceding night.
3. The prospect for cod fishing; the state of the weather and the wind of the day up to the moment the bulletin was sent over the wire.
4. The Meteorological Bureau's probabilities and storm warnings.

Each office made manifold copies of these reports, which were prominently displayed and passed out to the fishermen.

Another factor which stimulated the policy of telegraph line construction along the St. Lawrence river and gulf coast was the growth of steamer traffic on the Strait of Belle Isle route. This resulted in the building of a line slightly over a thousand miles in length between Quebec and Belle Isle.

The Department undertook the construction of this line along the north shore of the St. Lawrence river and gulf from Murray Bay to Chateau bay, Labrador.

The work was arduous. It was carried on each season during the period of navigation, for in the absence of roads of any kind, the employment of schooners was necessary for the transportation of poles, wire, provisions, and workmen. It was not until 1901 that the last pole was planted at Chateau bay, and a submarine cable laid out to the important lighthouse located on Belle Isle.

In British Columbia up to 1885, quite an extensive telegraph system had been put into operation. After the original purchase, from the Western Union, of the lines and cables in British Columbia, which represented 430 miles of land lines and 16 nautical miles of cable, the service was extended by new construction and by adding to the lines already in operation. In 1885, the lines in this new western province had a length of 676 miles.

The main line of the C.P.R. having been completed, the activity in the west was largely confined to the centres touching or in close proximity to the railway. Possibly for this reason, telegraph construction up to and between 1885-1898 was limited to the construction of some 200 miles of line on the south coast of Vancouver island and on the mainland.

In the east, some attention was given to cable laying, with the result that the following islands were furnished with a means of communication by submarine cable:

**Fig. 14—New Public Building, Winnipeg.**

Ontario—The important agricultural area on Pelee island was connected by cable and land line to Leamington.

Quebec and Maritime Provinces—Brier island and Digby Neck were given cable service.

A cable was laid between the coast of Cape Breton and St. Paul's island, which is located in the main shipping channel 19 miles from the northern part of Cape Breton island.

A cable was laid between Mingan, on the northern shore of the St. Lawrence, to Anticosti island to permit direct communication between these two areas.

Communication was established between Shippigan island and Miscou island, N.B., by the construction of 23 miles of land line.

Ile aux Coudres, in the St. Lawrence channel, was connected with Baie St. Paul.

In 1898, the announcement that much gold had been discovered in the Yukon started thousands of miners up the trails from Skagway and Dyea, Alaska, and thence by boat and scow downstream from Lake Bennett to Dawson. This called for quick action in providing communication with these new gold fields.

Upon the arrival of telegraph material at Lake Bennett, construction was immediately begun, and within a year 565 miles of line brought Dawson into touch with the outside. Between Lake Bennett and Skagway the wires of the White Pass Railway were used. From Skagway south, communication was by steamer. The Government line under the Public Works Department was next extended southward to Atlin, and two years later the line had reached Quesnel, 885 miles southward, by way of Telegraph creek and Hazelton, to tie-in with the line which was then in operation between Quesnel and Ashcroft, B.C. This line was, in 1902, extended 90 miles north of Dawson to the Alaska boundary to connect with the U.S. Army system operating in Alaska.

Between the years 1900 and 1910, increased activity was displayed in providing telegraph lines in various parts of Canada, particularly in British Columbia.

During the early years of the War, notwithstanding the activities overseas, the Government Telegraph Service extended its communication lines to serve many rapidly developing outlying points, largely in British Columbia and Northern Alberta.

Fig. 15—New Public Building, Moncton.

The extent to which the Government Telegraph Service had developed up to and including the year 1916 is reflected in the fact that in the above-mentioned year the mileage of the government lines held second place amongst the telegraph services in Canada. The figures are as follows:

| | Land line | Submarine cables |
|---|---|---|
| Great North Western Telegraph Company..... | 10,064 | 13 |
| Canadian Pacific Telegraph Company.......... | 14,617 | 95 |
| Government Telegraph Service................ | 11,516 | 336 |
| Grand Trunk Pacific Telegraphs.............. | 5,277 | 1 |

In the years immediately following the War, the mileage of the Government Telegraph Service reached its highest figures.

During the period, however, from 1925 to 1931, owing to the construction of additional railways in the West and the adoption of a policy of expansion on the part of the British Columbia Telephone Company, certain lines, both telegraph and telephone, having served their purpose as pioneer undertakings, were abandoned or sold.

At the time of the construction of the trans-Canada telephone system in 1928-29, the British Columbia Telephone Company, wishing to extend their lines eastward to the Alberta border and develop the telephone field on the south-easterly portion of British Columbia, negotiated with the department for the sale of its lines in that teritory. This purchase was on a rather large scale and brought about the transfer of 1,666 miles of pole line and 3,000 miles of wire to the Telephone Company

Pursuing the same policy of expansion several years later, the British Columbia Telephone Company purchased telephone lines on Vancouver island from the department to the extent of 223 miles of poles and 455 miles of wire.

During this period other lines in Saskatchewan and Alberta, having served the purpose for which they were constructed, were also abandoned to avoid duplication of telegraph services, the railroads having entered the fields formerly served exclusively by the department.

While the department was disposing of non-essential lines in certain sections, new fields requiring telegraph and telephone facilities were not neglected. The policy of the department was to furnish communication and service to localities urgently requiring same and which could not be be served by other agencies. Thus in 1929 an important telegraph line was constructed between the town of Peace River and the thriving frontier settlement of Fort Vermilion, 253 miles to the north.

In British Columbia there is no provincial telephone system as is the case in Alberta, Saskatchewan and Manitoba. For this reason the Government Telegraph Service is called upon to provide local telephone service for quite a few of the towns in that province which have not grown to such a size as to attract the attention of commercial telephone organizations. Some of these communities have grown up around the original government telephone office and are now given local telephone service through switchboards established therein. Some of the larger places enjoying such service are: Ashcroft, Clinton, Lillooet, Lytton, Williams Lake, Burns Lake, Smithers, Vanderhoof, Hazelton and Alert Bay. More than 1,100 subscribers take this service.

The recent recurring drought years in Southern Alberta and Saskatchewan brought about quite an extensive migration of settlers to the well-watered land in the Peace River Block. In this area the department was called upon to construct some hundreds of miles of rural telephone lines. The growing towns of Pouce Coupé and Dawson Creek, the latter at the terminus of the Northern Alberta Railway, have been given local and long distance telephone service through the telephone exchange located in each of these centres. This is in addition to a fast telegraph service to all important points between Hudson Hope, in the extreme westerly part of the Block, and Edmonton. This line is operated as one circuit and has a length of 720 miles.

In the east, the major construction work undertaken in recent years was the rebuilding of the western portion of the forty-year old line which follows the north shore of the St. Lawrence. This was made necessary to provide for the requirements of the pulp and paper industry along the coast. Within the last fifteen years, some of the larger paper interests have established pulp operations at many places along the coast as far east as Seven islands. A new cedar line, carrying two wires, has been completed as far as that point, a distance of 350 miles.

Fig. 16—Administration Building, Central Experimental Farm, Ottawa.

The laying, in 1930, of the fourth submarine cable across Northumberland strait to Prince Edward island was an important addition to the communication service to that island province. This new installation is the latest type of telephone cable and in addition to long distance telephone lines, carries the Island's radio broadcasting service.

Except in a few instances in the last ten years, when the department has built lines into outlying areas, it has been occupied more or less with the increasing of facilities in territories already served in a general way. The service as a whole has been and is a very important factor in Canada's upbuilding.

CANADA'S GOVERNMENT BUILDINGS

One of the main responsibilities of the Department of Public Works is that of providing and maintaining Dominion government buildings in various parts of the country. The extent to which this problem has grown may be judged from a few figures in connection with the Post Office and National Revenue Departments, which are perhaps those most familiar to the public. In 1886 there were 7,295 post offices in Canada. Fifty years later this number had increased to 12,156. As regards the Department of National Revenue, the number of persons employed in 1887 was 1,393, and in 1936 the number had risen to 4,620.

Recent figures indicate that nearly 53,000 persons are employed by the Dominion Government in all parts of Canada.

The increase in the number of public buildings under the Department of Public Works is indicated in the number of buildings owned and in use from time to time. In 1892 there were 159 buildings; in 1902, 285; in 1912, 328; in 1925, 428; in 1930, 593, and in 1936, 612 buildings.

The majority of Government buildings are erected and maintained by the Department of Public Works under the Chief Architect's branch. The great variety of buildings designed and the wide range of services therein accommodated may be realized when one mentions not only such departmental buildings as the Confederation, Justice and Connaught buildings, the East and West Blocks, the National Museum, the National Gallery, the Public Archives, the Royal Mint, the Central Experimental Farm, and the Dominion Observatory, all in Ottawa; but also such large Dominion buildings as those of Halifax, N.S., Moncton, N.B., large postal terminals and customs buildings at Montreal, buildings for the Royal Military College at Kingston, Ont., the Museum building at Louisburg, N.S., and the smaller post offices as at Notre Dame de Grace, Que., and Westport, Ont., not to mention armouries, barracks and military hospitals, quarantine, immigration and detention hospitals, fuel testing and ore dressing laboratories, research laboratories for the Agricultural Department, and many other types of buildings throughout Canada. Several of these classes are illustrated in Figs. 13 to 17.

In addition to the foregoing work carried out by the Chief Architect's branch of the Department of Public Works, it has been and still is the policy of the Government from time to time, when there is a particularly heavy building programme which would overtax the capacity of the Chief Architect's branch, to employ outside architects in private practice to design and supervise erection of buildings under the supervision of the Chief Architect. There are many excellent instances of these throughout the land. At Ottawa one finds examples of these in such works as the Parliament Building (with its Peace Tower, Memorial Chamber, Hall of Fame, and the two great Legislative Chambers of the Commons and the Senate), the new Postal Terminal, the National Research Building, and the Administrative Block of the Central Experimental Farm, whilst further afield the Dominion Government buildings at Hamilton, London, Regina, Vancouver, Winnipeg and Windsor are excellent examples of work carried out by the various practising members of the architectural profession outside.

It is interesting to note the trend of architectural taste as evinced from period to period by the buildings erected. There is no doubt that the natural topography of Ottawa with its commanding view calls for a skyline of pointed roofs and towers for its great legislative and departmental buildings, the best way of obtaining which was obviously to adopt a Gothic design. Whether, however, the original adoption of this style was not rather due to the Gothic revival in England at about that date, is a moot question. Suffice it to say that it was chosen, and happily so. In

Fig. 17—Customs and Immigration Building, Douglas, B.C.

later buildings, a tendency towards a Scottish Baronial type with an admixture of Perpendicular Gothic features can be noticed, as instanced in the National Museum, the Royal Mint and the Connaught Building. Today, as the Dominion government departmental buildings are spreading out to the west of Parliament Hill, the Gothic style is still retained, but of the Northern French Chateau type—perhaps the most appropriate style possible for this part of Canada from all points of view—aesthetic, climatic, sentimental and topographical.

What happened in Ottawa in respect to architectural design during the last fifty years has been to a large extent reflected in the designs of buildings throughout the Dominion.

During this period of development advantage has been taken of the opportunities offering to foster the use of building materials of Canadian origin. Sandstone from Nova Scotia; granite from Quebec; limestone from Quebec, Ontario and Manitoba; marble from Quebec and Manitoba, are among the Canadian materials employed.

To members of The Engineering Institute of Canada it is unnecessary to say that the efficient co-operation of members of their various branches of the engineering profession with those of the architectural profession, particularly during the last half century, has had most successful results in the design of the public buildings erected under the Department of Public Works.

ACKNOWLEDGMENTS

The annual reports of the Department of Public Works, both under the Union Government and since Confederation have naturally been the main source of the material used in this paper. Acknowledgment is due to the Dominion Bureau of Statistics' most valuable publications on Canada, in particular the "Canada Year Book" for information used therefrom, to "The Canadian Grain Trade," by Duncan Alexander McGibbon, to which anyone seeking for the knowledge of that subject should refer, and to the "Historical Atlas," by Lawrence J. Burpee.

To C. D. Sutherland, Chief Architect, and F. G. Sims, General Superintendent of Government Telegraphs, the author would express thanks for their invaluable assistance in those parts of the paper dealing with the activities of branches of the Department over which they preside.

# Chemical Engineering

*J. R. Donald, M.E.I.C.,*
*President, Donald-Hunt Company, Montreal.*

This subject is a large one and the broad field of modern chemical engineering makes it difficult to set limits to the scope of the discussion.

It is therefore proposed to deal largely in generalities outlining major developments only. At the end of this article there will be found a list of the more important chemical engineering developments in chronological order. It is not to be assumed that the story as given is complete nor are dates vouched for. It is hoped however that inaccuracies and omissions will be called to the author's attention with a view to their correction or inclusion at a later date.

The question is frequently asked—What is chemical engineering?

The subject has received much attention and discussion. To draw the line between the industrial chemist and the chemical engineer is virtually impossible.

The chemist who develops a process in the laboratory and then transforms it into a commercial operation obviously becomes a chemical engineer. Of necessity the chemical engineer is concerned with plant operations but there are few successful chemical engineers who have not worked in chemical laboratories.

The American Institute of Chemical Engineers has defined chemical engineering as follows:—

> "Chemical engineering as distinguished from the aggregate number of subjects comprised in courses of that name, is not a composite of chemistry and mechanical and civil engineering, but itself a branch of engineering, the basis of which is those unit operations which in their proper sequence and co-ordination constitute a chemical process as conducted on the industrial scale."

Fifty years ago chemical engineering was undefined and unrecognized as a definite branch of the engineering profession. Many of the commoner industrial chemicals of today were not manufactured and in many instances the processes on which their production is now based had been neither discovered nor developed. Canadian chemical industry existed on a small scale only and the application of chemistry to industry was in its infancy.

Fifty years ago sulphuric acid was being manufactured at Capelton, Que., making use of pyrites mined in the vicinity.

The manufacture of wood alcohol by the destructive distillation of hard wood had also been started. Black powder and nitro-glycerine were being produced at Beloeil. Small petroleum refineries existed at a number of points supplying kerosene and lubricants, but the internal combustion engine and the motor car had yet to be developed and to create the modern demand for petroleum products. Other chemical industries of importance were the manufacture of coal gas, and fertilizers, and potash recovery from wood ash, the latter still a substantial industry.

Another important infant industry was the manufacture of sulphite pulp which had just been undertaken in a small way at Hawkesbury, Ontario. Allied chemical industries such as brewing, distilling, sugar refining, tanning and soap manufacture had also been established and supplied the local markets.

The limited scope of the chemical and allied industries is shown in Table I* into which data supplied by the Department of Statistics at Ottawa have been incorporated.

However chemistry was on the march. The great scientific discoveries of the latter part of the 19th century had aroused public interest, and by 1885 chemistry courses had been established at our high schools and universities. There were thus becoming available trained chemists who were in a position to recognize the value of our natural resources, more particularly the mineral resources. Moreover a new industrial tool had just become available with the generation of electric energy on a large scale.

It was thus a logical development that in the years 1890–1900 Canadian chemical industry should enter its first marked period of expansion; it was in this period that some of the more important of our modern chemical engineering industries secured a firm foundation or had their origin.

The most outstanding feature of these years was the inauguration of electro-chemical processes based upon the hydro-electric energy made available for the first time. This led to the manufacture of phosphorus at Buckingham, utilizing the local phosphorus ore apatite. These operations, today greatly expanded, constitute one of our important chemical industries, although the phosphorus ore is now imported. It also led to the manufacture of calcium carbide at Niagara Falls in 1896.

Progress however was not limited to the electro-chemical field.

The Portland cement industry was founded in the early nineties replacing imported Portland cement.

In 1894 the commercial production of glucose from starch was undertaken at Cardinal, Ontario, one of the first instances in Canada of the revolutionary changes chemical engineering was to bring about in many of the older industries. Another development of the period was the firm establishment of the wood distillation industry and the production of acetic acid.

By the turn of the century we thus find a number of well established chemical industries and it is interesting to note how these industries had been built up around our natural resources.

An important professional development of the period was the gradual emergence of chemical engineering as a separate branch of the engineering profession. By 1900 courses in chemical engineering had been established at some of the American universities and the chemical engineer as distinguished from the chemist or mechanical engineer had become identified with the chemical and allied industries.

The period from 1900 to the outbreak of the war in 1914 was one of active and rapid development professionally

and industrially. At this time the formation of the American Institute of Chemical Engineers and the Institution of Chemical Engineers of Great Britain definitely settled the status of the chemical engineer, and chemical engineering courses were established at our Canadian universities.

Industrial developments were numerous and it is again interesting to note how these were associated with our natural resources and involved newly discovered methods and processes.

In 1901 the manufacture of aluminum was undertaken, using the newly developed hydro-electric power at Shawinigan Falls. This was the beginning of one of our most important electro-chemical industries with a world wide market.

A few years later the Canada Carbide Company was formed to undertake the manufacture of calcium carbide also at Shawinigan, an electro-chemical development which was the forerunner of the important contemporary synthetic organic chemical industry for which Shawinigan Chemicals Limited is justly famous.

Electrolytic refining of lead was undertaken in 1904 at Trail, B.C.; the production of cobalt and arsenic compounds at Deloro, Ontario, followed shortly afterwards, utilizing the famed Cobalt silver ores.

The first cyanamid plant on the American continent was built and started operations at Niagara Falls, Ont., in 1909. This event is of particular interest as it represents one of the first answers of the chemical engineer to the old bogey of a world wide shortage of nitrogen fertilizers.

Other milestones of chemical engineering progress were the establishment of the first contact sulphuric acid plant in Canada at Sulphide in 1908, making use of locally mined iron pyrite, the installation of an electrolytic caustic soda and bleaching powder plant at Windsor in 1912, utilizing local salt deposits, the introduction of the revolutionary process of oil hydrogenation at Toronto in 1914.

It was also in this period that the petroleum industry entered that stage of expansion and technical development which was eventually to make it one of the greatest of chemical engineering industries.

These years were also marked by the generally increased application of chemical engineering methods to industry. There was substantial chemical engineering progress in such widely diversified industries as pulp and paper, vegetable and animal oils, textiles, and compressed gases.

The war period 1914–1918 imposed heavy responsibilities upon chemical engineering. Chemicals and explosives were required for military purposes on a previously unthought of scale and many metallurgical and chemical products heretofore imported had to be made in this country. Such wartime emergencies and demands afforded the chemical engineer opportunities of demonstrating his versatility and ingenuity and the flexibility of chemical industry.

Some developments were essentially of a wartime nature, such as the manufacture of cordite, nitro-cellulose powder, trinitrotoluene, etc., and were discontinued with the termination of the wartime demand. Others were of a fundamental nature and were to become a permanent part of our chemical engineering industries. The list is too long to cover in detail but certain accomplishments were of particular importance.

**Fig. 2—Canada Carbide Company Limited, Shawinigan Falls, Que. 1904.**

An outstanding achievement was the development at Shawinigan Falls of the processes by which acetylene was synthesized to acetic acid and acetone to supply much needed raw materials for aeroplane manufacture and explosives. By intensive research textbook reactions were developed to large scale production in record time.

Another outstanding achievement of this period was the research and plant development which led to the electrolytic production of zinc at the plant of the Consolidated Mining and Smelting Company at Trail, B.C. This process put into operation in 1916 has since been widely adopted elsewhere and has made possible the commercial production of the exceptionally pure zinc now widely used in the die casting industry. It was also in the same period and by the same organization that methods of differential flotation were applied to the highly complex ores of the Sullivan mine, a development of outstanding importance to Canada's mining industry.

**Fig. 3—Sarnia Refinery of Imperial Oil Company Limited. 1903.**

Fig. 4—Sarnia Refinery of Imperial Oil Company Limited. 1937.

Further important new activities were the refining of nickel at Port Colborne and the establishment of a magnesia refractory industry utilizing the magnesite deposits of the Calumet district.

In addition to such developments, heavy wartime demands also involved increased production of acids, large scale production of ferro alloys by electro-thermic methods and the production of metallic magnesium as well as many other products.

The rapid progress of chemical engineering industry during the war was a forcible demonstration of the national importance of chemical industry and aroused increased public interest. Much of the air of mystery which to the public mind pervaded chemical operations was dispelled. More particularly business men became familiar with chemical industry and learned to associate it with large industrial developments using raw materials on an extensive scale.

The close of the war brought a period of readjustment in which chemical engineering played an important part. It was necessary to develop new markets and new products to utilize wartime plants and organizations. The chemical engineer again demonstrated his ability to meet the needs of the situation.

Fig. 5—Sulphuric Acid Contact Plant, Canadian Industries Limited, Sudbury, Ont. 1936.

Chemical research was diverted from wartime problems into peaceful channels, resulting in new processes and new products. The chemical engineer rapidly transferred these from laboratory to plant and in this way many chemical industries which had undergone a mushroom growth during the war were re-established on a firm and sound industrial basis.

The period 1919-1929 was one of general industrial expansion and chemical engineering progress was rapid. The older chemical industries expanded and improved processes and products. At the same time they developed new products and processes.

New chemical industries were created, in some instances producing standard products from new raw materials and in others manufacturing entirely new products. Excellent examples are the synthetic ammonia plant utilizing the nitrogen of the air and the artificial silk industry manufacturing a new textile fibre.

Equally important was the penetration of chemical engineering into industry at large, resulting in the application of scientific methods to technical operations formerly carried out in an empirical manner. The recovery of waste products and their conversion into valuable by-products has been typical of chemical engineering activities in many of the older industries. There are now few industries which can afford to be without chemical engineering service.

Some of the developments of this period, 1919-1929, were as follows:—

In 1919 the manufacture of soda ash by the ammonia-soda process was undertaken at Amherstburg making use of the natural salt deposits of the district.

In 1922 a plant for the manufacture of liquid chlorine was installed at Windsor and in 1924 the manufacture of phosphoric acid from phosphorus was undertaken at Buckingham.

A spectacular chemical engineering development was the installation of the rayon plant at Cornwall in 1925.

The same year a contact sulphuric acid plant was installed at Coniston, Ont., utilizing waste smelter gases as a source of sulphur, thus converting a waste product and nuisance into a valuable product. It is significant of the times that although these waste gases had been available for many years it was not until 1925 that chemical engineering initiative and growing demand brought about this development.

By 1926 the world wide demand for aluminum had so increased that its manufacture was undertaken at Arvida, Que., on a large scale, utilizing the hydro-electric power available in the district. This additional aluminum capacity made Canada one of the world's largest producers.

In 1929 a sulphuric acid plant, utilizing waste smelter gases, and a synthetic ammonia plant were installed at Trail, B.C. in connection with large scale plans for fertilizer production. This development is of particular interest as it represents a profitable chemical engineering solution to the waste smelter gas problem at the Trail smelter.

Other important developments of the same year were the erection of a plant for the manufacture of cellulose acetate silk (celanese) at Drummondville, Que., the manufacture of synthetic ammonia at Windsor and the catalytic production of nitric acid from ammonia at Beloeil.

The growing penetration of chemical engineering into many industries has been referred to. While this trend was very general certain examples stand out prominently.

The great expansion of this period in the pulp and paper industry was accompanied by many chemical engineering improvements resulting in greater efficiency and improved products. Of great importance to the industry was the realization that pulp and paper processes were essentially chemical engineering processes.

In the petroleum industry application of chemical engineering technique revolutionized refining practice, introducing cracking processes and modern methods of distillation, thus greatly improving efficiency and the quality of the products.

Similar achievements in many industries served to further increase the prestige of the chemical engineer and by 1929 chemical engineering as a branch of the engineering profession had assumed a role of major importance.

There was a general realization of the necessity of science in industry and this recognition was being fostered by government agencies and other public bodies. Moreover, the highly technical requirements of the chemical and allied industries led to the rapid promotion of chemical engineers to operating and executive positions of importance.

With the onset of the depression in 1929 the chemical engineer again found opportunities of demonstrating his ability and versatility. It is noteworthy that even in the depression years the chemical industry continued to make progress, much of which resulted from the development of new products and new processes. Demands for economy and the pressure of competition also claimed attention and in the rebuilding of many industries chemical engineering played a predominant part.

Certain accomplishments of these depression years are of particular interest. In 1931 the Canada Cement Company Limited developed a special Portland cement to withstand the corrosive action of the alkali soils of western Canada, thus considerably enlarging the field of usefulness for this important material.

The recovery of metallic selenium from electrolytic copper slimes was first undertaken at Sudbury in 1931. In 1934 the large scale production of selenium and tellurium commenced at the Canadian Copper Refinery at Montreal East. Canada is now the leading world producer of these comparatively rare metals and it is significant of the trend of chemical industry that markets have developed as rapidly as these metals have become available.

In 1933 the production of radium and uranium salts from the pitch-blende silver ores of far northern Canada was undertaken commercially at Port Hope, Ontario, a matter of world wide interest as it represents a new source of these important and rare elements.

Another interesting development of the depression years was the erection of a cellophane plant at Shawinigan Falls.

Other recent advances have been the production of hydrogen peroxide, sulphur chloride, trichlorethylene, acetic anhydride and the recovery of liquid sulphur dioxide and elemental sulphur from waste smelter gases.

Current recovery from the depression finds the chemical engineering industries in a strong position with demand

**Fig. 6—Shawinigan Chemicals Limited, Shawinigan Falls, Que. 1936.**

taxing existing capacities. Many plans for expansion are being made.

Professionally, chemical engineering was never in higher repute than at the present time. Engineering courses at our universities are turning out chemical engineering graduates in numbers greater than in other branches of engineering. What slight unemployment existed in the profession during the depression has practically disappeared, with a shortage of trained chemical engineers and chemists in prospect.

Chemical engineers in Canada have no exclusive professional organization but are associated in professional matters with The Engineering Institute of Canada or the chemical societies of Canada. Many of them are also members of the American Institute of Chemical Engineers or the Institution of Chemical Engineers of Great Britain. It is to be hoped that further professional developments will continue to proceed within existing professional bodies.

It is difficult in a brief survey of this sort to convey an adequate conception of the progress that has been made in the last fifty years. Reference to Table I will give some idea of the tremendous growth of the chemical industries

**Fig. 7—Fertilizer and Chemical Plant, Consolidated Mining and Smelting Company, Trail, B.C. 1936.**

and their importance in the economic life of the country. Industries such as the pulp and paper industry and the petroleum industry of no importance fifty years ago have now become leading industries.

Even more significant of chemical engineering activities are the new industries which have been created, such as the electro-chemical industries and the organic chemical industry.

It is a well recognized fact that some of the finest fundamental research is carried out by industrial research organizations who recognize its value and necessity and who do not look for immediate financial returns from it.

Industrial research of a high order has been carried out in Canada by such companies as Consolidated Mining and Smelting Co. Limited, Imperial Oil Limited, Shawinigan Chemicals Limited, Canadian Industries

**Fig. 8—Explosives and Chemical Plant, Canadian Industries Limited, Beloeil, Que. 1936.**

Limited and others. The pulp and paper industry has accomplished much, both through co-operative research and also through the research departments of individual companies.

The technical progress involved in such operations is so remarkable as to be difficult to appreciate. The individual developments which go to make possible such a process as the manufacture of ammonia from hydrogen and the nitrogen of the air are numerous and complex. They have all been made effective in less than fifty years.

Much of the credit for the progress made must be given to the scientific worker in the research laboratory and the industrial laboratory whose fundamental scientific work has laid the foundation.

Chemical research in the broadest sense has of necessity gone hand in hand with the work of the chemical engineer, making available the information which has been translated into industry. Not only has it been necessary to develop in the laboratory the processes of modern chemical engineering industry but in many instances these processes demanded new types of equipment and new materials of construction which also had to be worked out in the laboratory.

Excellent examples are those chemical engineering industries requiring high pressures and high temperatures with close control of temperature and pressure. Without the development of new ferro alloys and automatic regulating devices these processes would be inoperative on an industrial scale.

Little resemblance exists between the apparatus in use fifty years ago and today. Older types of operation such as filtration, evaporation and distillation have been revolutionized by basic research and new materials of construction and new types of apparatus have been created utilizing new scientific principles.

It is consequently not surprising that research has become highly organized and a recognized function of the chemical engineering industries.

Industrial research organizations have been developed by industry, by universities and by Government institutions; actually there are few important industries which have not research facilities of some sort at their disposal.

Endowed industrial research as undertaken by the National Research Council, the Ontario Research Foundation and other Government departments has stimulated industrial research throughout industry, in addition to the important direct results obtained from it.

Canada also benefits substantially by industrial research carried out in the United States and Great Britain by industries with Canadian affiliations. The importance of such co-operative research is apparent in view of the large industrial research programmes carried out in the United States, it being estimated that in 1937 about $250,000,000 will be expended for this purpose.

What are the prospects for the future?

It is difficult to write of the progress of the past fifty years with a first hand knowledge of events and the men who made them possible without a feeling of great optimism as to the future. Just as chemical engineering has expanded in the past by making itself indispensable to the older industries and by creating new industries so it will develop in the future.

The intimate association between the natural resources of Canada and the development of the chemical engineering industries has already been pointed out. In the further exploitation of our natural resources chemical engineering is bound to assume an even more important role.

The motto of the chemical engineer might well be "To Learn is to Live." Chemical engineering has not stopped learning and it is far from a rash prophecy to predict a future of continued progress resulting in processes and products unknown today and destined to add greatly to our national well-being.

## APPENDIX

### Table I

Some Statistics of the Chemical Engineering Industries in Canada, 1890-1935

| | 1890 | 1935 |
|---|---|---|
| Abrasives, artificial | nil | $ 7,188,672 |
| Acids, alkalies and salts | $ 2,161,541 | 19,012,615 |
| Aluminum | nil | 9,200,000* |
| Breweries | 5,717,873 | 40,699,040 |
| Coke and gas | 2,886,697 | 38,474,789 |
| Distilleries | 2,199,600 | 16,114,361 |
| Dyeing and finishing of textiles | 345,504 | 4,004,734 |
| Explosives, ammunition, fireworks | 1,060,855 | 8,537,514 |
| Fertilizers | 280,829 | 6,075,616 |
| Gases, compressed | nil | 3,007,765 |
| Glass | 697,150 | 7,337,260 |
| Inks | 55,500 | 2,886,850 |
| Linseed oil and cake | 377,000 | 3,068,776 |
| Medicinals and pharmaceuticals | 789,400 | 21,292,751 |
| Paints, pigments and varnishes | 1,936,825 | 20,341,400 |
| Petroleum refining | 2,064,115 | 79,176,081 |
| Pulp and paper | 1,057,810 | 162,651,282 |
| Rubber goods | 2,059,320 | 55,949,570 |
| Silk, artificial | nil | 3,722,419* |
| Soap and washing compounds | 2,152,960 | 16,002,040 |
| Starch and glucose | 489,950 | 5,082,694 |
| Sugar refining | 17,127,100 | 36,597,997 |
| Tanneries | 11,422,860 | 20,497,553 |
| Waters, aerated | 946,715 | 13,851,785 |
| Wineries | 441,724 | 3,152,238 |

*Estimated.

The figures given are selling values at the plant and, with a few exceptions, have been obtained from the Department of Statistics, Ottawa.

### Table II

Chronological Table Showing Date of Establishment of Various Chemical Industries in Canada

Prior to 1885—
Sulphuric acid and nitric acid manufacture, nitro-glycerine, black powder, wood alcohol, brewing, distilling, soap, starch, sugar refining, tanning, etc.

1885—Sulphite pulp at Merritton, Ont.
1889—Portland cement at Hull, Que. and Napanee, Ont.
1894—Glucose at Cardinal, Ont.
1895—Chlorate of potash at Buckingham, Que.
1896—Calcium carbide at Merritton, Ont.
1897—Phosphorus by electro-thermic process at Buckingham, Que., utilizing Canadian apatite.
Establishment of petroleum refinery at Sarnia, Ont.
1899—Ferro-chrome at Buckingham, Que., utilizing Canadian chromite.
Acetic acid as a by-product of wood distillation.
1900—Carbon dioxide from Grecian magnesite.
1901—Aluminum at Shawinigan Falls.
Hydrochloric acid at Capelton, Que.
1902—First large sulphite pulp operation in Canada at Hawkesbury.
1904—Calcium carbide manufacture undertaken at Shawinigan Falls, Que.
Electrolytic lead refining at Trail, B.C.
1907—Production of arsenic and cobalt compounds from ores of the Cobalt district at Deloro, Ont.
Chemical engineering course established at the University of Toronto.
1908—First contact sulphuric acid plant in Canada at Sulphide, Ont.
1909—First cyanamid plant on the American continent at Niagara Falls, Ont.
Sulphuric acid plant at Barnett, B.C.
Manufacture of formaldehyde from wood alcohol.
1910—Manufacture of oxygen and nitrogen by liquefaction at Montreal.
Canadian magnesite used to replace Grecian magnesite in manufacture of carbon dioxide.
1912—Manufacture of electrolytic caustic soda and chloride of lime at Windsor, Ont.
Carbon dioxide by coke process at Toronto, Ont.
1914—Hydrogenation of vegetable oils at Toronto, Ont.
1916—Electrolytic refining of copper and zinc at Trail, B.C.
Manufacture of acetone and acetic acid from acetylene at Shawinigan Falls, Que.
Production of butyl alcohol and acetone by fermentation process at Toronto.
1917—Manufacture of cyanide at Niagara Falls, Ont.
1918—Production of refined nickel at Port Colborne.
1914-18—War period.
Manufacture of explosives, solvents, ferro-alloys, metallic magnesium, alloys, etc., for war purposes.
1919—Soda ash at Amherstburg.
1922—Liquid chlorine at Windsor, Ont.
1923—Acetylene black at Shawinigan Falls.
1924—Large scale production of nitro-cellulose lacquers for the paint trade.
1925—Manufacture of "Rayon" (viscose silk) at Cornwall, Ont.
Erection of contact sulphuric acid plant utilizing waste smelter gases at Coniston, Ont.
1926—Production of ethyl acetate and butyl acetate at Shawinigan Falls.
1928—Metallic cadmium at Trail, B.C.
1929—Manufacture of "Celanese" (cellulose acetate silk) at Drummondville, Que.
Manufacture of vinyl acetate resins at Shawinigan Falls.
Synthetic ammonia, sulphuric acid from smelter gases and ammonium sulphate at Trail.
Synthetic ammonia at Windsor.
Nitric acid from ammonia at Belœil.
1930—Portland cement resistant to western Canada alkaline soils.
1931—Selenium from electrolytic copper slimes at Sudbury.
1932—Phosphates of soda and lime at Buckingham.
"Cellophane" at Shawinigan Falls, Que.
1933—Radium and uranium salts from Canadian ores at Port Hope, Ont.
Nicotine sulphate manufactured at Montreal.
Sodium silicate at Niagara Falls, Ont., by electric furnace process.
1934—Selenium from electrolytic copper slimes at Montreal.
1935—Tellurium from electrolytic copper slimes at Montreal.
Hydrogen peroxide at Shawinigan Falls.
Elemental sulphur from waste smelter gases at Trail, B.C.
Electrolytic caustic soda and chlorine at Cornwall.
1936—Acetic anhydride and acetone from acetylene and steam at Shawinigan Falls.

# Urban Transportation

*A. Duperron, M.E.I.C.,*
*Chief Engineer, Montreal Tramways Company, Montreal, Que.*

"The streets of a city may be compared to the veins and arteries of the human body, especially if we include under the title of street not only the open right-of-way, but subways and elevated roads. So long as these function properly the community will be healthy. Nothing can take the place of good circulation in a city any more than in a human body."

R. L. Duffus.

Fifty years ago corresponds very nearly to the date of the discovery of electric street cars. In fact the decade beginning with 1880, was a period of pioneering in that field.

As early as 1884, Van Depoele ran an electric railway line at the Toronto Exhibition, 3,000 feet long, using an under-running trolley wire. This line was used until 1892 to facilitate access from the horse-car line of the Toronto Railway Company, to the exhibition grounds. It is claimed that this was the first, purely commercial adaptation of the electric railway in America. In June 1886, Van Depoele also operated a 1.2 mile line in Windsor, Ontario. The equipment consisted of two cars, each equipped with one 20 hp. motor. The current was collected as in Toronto, from an overhead wire with an under-running wheel, the return of the current being made through the rails. In 1887, the same engineer built and operated a line seven miles long in St. Catherine, Ontario, with two cars.

It is generally recognized that the first large commercial electric railway was built and operated by Frank J. Sprague in Richmond, Va., in 1888, and that its success was the foundation of the electric street railway. It was a complete installation, including eleven miles of track, overhead lines, generating station, and forty cars.

The Vancouver Street Railway Company, was organized in 1888 to construct and operate tracks in the city of Vancouver for horse-car operation, but before the initial work had been completed it was decided to change to electric traction, even though the stables for the horses had actually been built. Operation of the first electric railway lines in the city of Vancouver, totalling about six miles, was commenced on June 28th, 1890, and has continued ever since.

In the year 1891, through the energy and courage of two enterprising pioneers, Messrs. Ahearn and Soper, the Ottawa Electric Railway began operating electric cars on regular schedule in the city of Ottawa. On August 15th, 1892, the first electric car in Toronto was placed in service on Church street, and within the next two years, the whole system was electrified. On September 21st, 1892, the first electric cars were operated in the city of Montreal, around the belt line, via: Craig street, Park avenue, Mt. Royal avenue, St. Lawrence boulevard, Rachel street, Amherst street, to Craig and Côté streets. The city of Winnipeg also started to operate electric street cars during 1892—the city of Saint John, New Brunswick, in the year following—the city of Quebec, in 1897.

Thus the Canadian companies were amongst the first to adopt electric traction as a means of urban transport, and it is becoming here to pay tribute to the enterprising spirit of those pioneers, and also to the Canadian engineers of that time, who were responsible for its development in Canada.

## ROLLING EQUIPMENT

### Street Car Motors

The great difficulty with which the engineers in the early days had to contend, was to develop a motor suitable for car operation. Van Depoele's first motor was mounted on the platform of an existing horse-drawn car and belted to the axle of the car. It is said that it soon shook to pieces both the platform and the car itself.

Sprague, in 1886, was the first to develop the method of supporting one end of the motor on the axle and the other on the truck. The motors that he used in Richmond, Va., consisted of two 7½ hp. series-wound bi-polar motors per car. The motors were centred on the axles and geared at first by single and then by double reduction gearing. None of the manufacturing companies at that time were able to design a motor to run at the speed required for single reduction which would be small enough to be placed in the space available under the floor of the car and between the axles. As one may imagine, the motors of that time were a never-ending source of trouble, because they were of insufficient power, and were not protected against dust, mud and water.

The Westinghouse Electric Company entered the electric railway field in 1890, and brought out in 1891 their No. 3 motor, a four-pole slow speed motor with single reduction gears. While sturdy and reliable, the cast-iron frame and slow speed (about 385 r.p.m. at 10 miles per hour) made it quite heavy.

Fig. 1—Single Horse Car, Toronto. 1890.

Fig. 2—Vancouver Street Railway Cars. 1890.

MODERN car as used in Montreal.

ONE OF the new trolley buses recently put into service in Montreal.

TYPE OF bus used in Toronto on feeder routes to trunk rail lines.

THE PAST half century of engineering advance has seen the passing of the horse car with a few miles of travel and in its place the development of great systems with hundreds of miles of track and bus routes handling the transportation of hundreds of thousands of people, without which the growth of great cities could not have taken place.

*Illustrations through the Courtesy of the* TORONTO TRANSPORTATION COMMISSION *and* MONTREAL TRAMWAYS COMPANY

The Edison General Electric Company also brought out in the same year, a single reduction four-pole motor which was one of the best of its day. The design of single reduction motors marked a distinct improvement in the street railway motors of that time.

In 1892, the Thomson-Houston, Edison, Sprague, and a few other interests were combined to form the General Electric Company. All of the earlier lines of motors manufactured by the above mentioned concerns were abandoned, and were replaced by a new line of motors of which the GE-800 was typical. It was claimed at that time to be the lightest motor for a given output. Rated at 25 hp., its weight was 1,455 lb. The closing of this motor made it quite water and dust proof.

In 1894, the Westinghouse Company brought out their No. 12-A motor, completely enclosed, with the armature shortened and all bearings carried in the motor casing. This type of motor for 25 and 30 hp. ratings was standard for many years. During the years 1894 and 1895, the same company developed their 50 hp. motor No. 38 for larger output.

In 1895, the General Electric Company replaced their GE-800 motor by a new line, of which the 50 hp. GE-57 was the earliest.

These lines of motors, the Westinghouse 12-A and 38, and the GE-57 were typical of the revised design which embodied every essential for successful operation, and which continued practically standard for many years. They were enclosed motors, with frame made of steel casting, series connection of field and armature, ventilated armature windings, four poles and single reduction gearing.

It will be noted from the above that the period before 1890, might be called one of experimentation, and that from 1890 to 1895, one of development. The Canadian companies started to electrify their systems from the year 1890 onward, and used motors of the above types.

Series motors were adopted in preference to shunt motors as being especially applicable for work which demands large starting torque. In addition, the series motor has the very desirable characteristic that when a car ascends a grade, the motor will automatically slow down. The drop in speed allows the motor to develop a large torque with but a moderate increase in power. In the case of a shunt motor, it will maintain the speed of the car at approximately the same value that it has when the car is running on level ground; the motor, therefore, will tend to take an excessive current.

The next great improvement in railway motors came in the years 1907-1908, with the use of motors having commutating poles. These, placed between the main poles, and connected in series with the armature, had the effect of neutralizing the distortion of the main flux, and thereby greatly improving the commutation under any conditions of load.

About 1912, improved ventilation was obtained by the addition of a fan on the armature shaft inside the motor case to draw air through the motor. This method of self-ventilation practically doubled the continuous rating of enclosed motors. These features enabled the overall dimensions and weight of motors for a given rating to be reduced, thus permitting the use of smaller diameter wheels on cars, and at the same time lowering the height of the floor and of the steps; an improvement of decided advantage.

The curve in Fig. 3 shows the weight per horse power for different classes of motors used from 1892 to 1936. The weight is that of the motor and the pinion only, and does not include the gear and gear case. It indicates, that for motors of conventional design operating at about 600 volts with single reduction gears, the weight has been reduced from 80 lb. to 32 lb. per hp. The normal speed (one hour rating) has been increased from 500 r.p.m. to 1,000 r.p.m.

During recent years important development has been made in the design of so-called high speed motors. They are designed for 300 volts for better performance, two motors being permanently connected in series for the 600-volt circuit. On the new cars of the type recommended by the Presidents' Conference Committee (to which

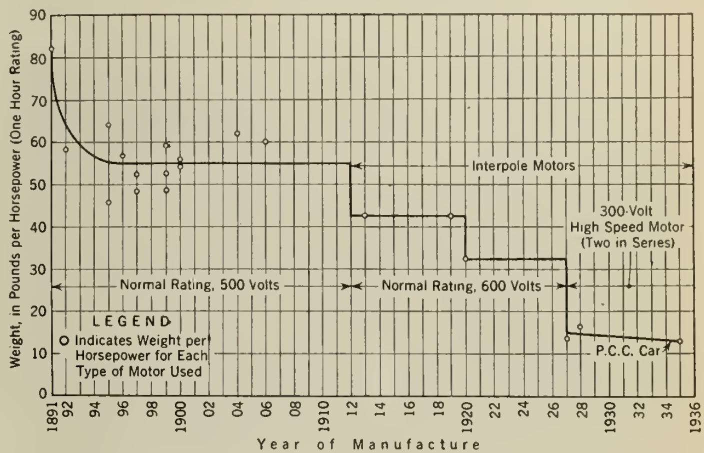

**Fig. 3—Curve Showing Trend in Weight of Street Railway Motors.**

reference will be made later) the motors have a one-hour rating of 55 hp. The weight complete with drive flange varies from 700 to 725 lb. which is about 13 lb. per hp. When this is compared with the 75 lb. per hp. of the year 1892, the progress that has been made in the design of street railway motors can be appreciated.

### Street Car Bodies

The type of body, used at first was that of the horse-car; in fact in some cases the motors were applied direct to the original horse-car bodies. This arrangement did not prove satisfactory. Two types of car soon became of general use. These were the four-wheeled single truck closed car, having longitudinal seats, and the single truck open car, fitted with cross benches and outside longitudinal steps for summer use. The protection offered by closed and heated cars was a necessity in winter, but the popularity of the open car was so marked that it was the usual practice to have two sets of car bodies for each equipment of trucks and motors. These cars measured about 30 feet overall in length, and weighed about 18,000 lb. The motor equipment usually consisted of two 25-hp. series motors. The bodies themselves were practically all wood contruction. The cars were heated by stoves burning coal. Another type of car used was the "convertible car" with removable side panels, making it possible to change these car bodies to the open type in summer, and the closed type in winter.

About 1900, traffic conditions in the central part of the larger cities pointed towards the development of larger cars so as to decrease the number of car units. At about that time the use of the open car was being discouraged, and it was later finally prohibited by various provincial public utility boards.

With the increase in carrying capacity, length and weight of car, the use of the single truck was no longer practical. It was replaced by two trucks with shorter wheel base on which the longer car body rested on pivoted centres. Double truck closed cars were built about 1901, and weighed some 35,000 lb. Then in 1904, the pay-as-you-enter type of car was developed and first used in Montreal. It weighed about 47,700 pounds, and its use quickly spread over the whole continent. Its principal feature was that it allowed, without undue delay at loading points, for the collection of fares at the rear end of the car. The conductor was then able to supervise the movement of passengers, on and off the rear steps, and the reduction in accidents was very marked. The rear end platform was open in those days. The front end was closed and the movement of passengers getting off at that end was under the direct control of the motorman.

Heating by the use of electric current, in place of stoves, was adopted at that time.

It will be noted from the above that the weight of the city cars increased very rapidly from the single truck

**Fig. 4—Street Car Service in Toronto. 1905.**

car of 1901, weighing about 18,000 lb., to the double truck car of 1905, which weighed some 48,000 lb. The weight continued to increase up to about the year 1910, when some of the cars built during that period weighed as much as 56,000 lb. A curve has been drawn showing the trend in weight of cars used in the city of Montreal from 1892 to date. In determining the curve shown in Fig. 6 the weight of cars operating in city streets only was taken, suburban cars and trailers were left out.

The tendency about 1910, was toward cars of large capacity with heavy equipment. These were favoured because of better tractive possibilities on snow covered rails, and because they provided a large margin of inherent heat capacity to meet heavy current demand of operation during heavy snow storms.

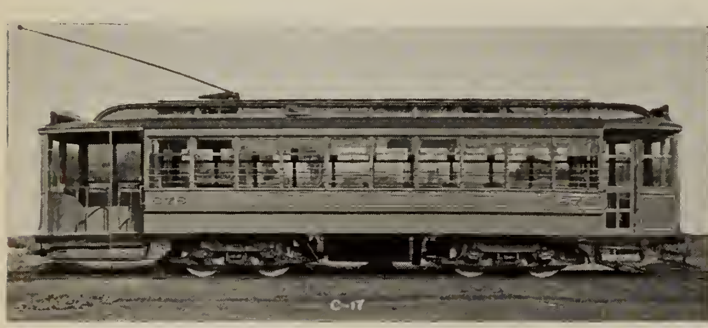

**Fig. 5—First Pay-as-You-Enter Car in Montreal. 1904.**

Beginning in 1907, in Montreal, all the underframes of cars purchased were made of steel up to the window sill. Posts and roof carlins were of composite construction of wood and steel; the roof and the floor were of wood. Some of these cars built at the end of 1907, were 50 ft. 6 in. long, and 8 ft. 9¾ in. wide. Their weight was 56,600 pounds, divided thus: body 29,900 lb., trucks 15,500 lb., equipment 11,200 lb. They were the largest city cars built for that city. Between the years 1910-1915, the car length was reduced to 46 ft. 8½ in. overall, and the width to 8 ft. 4½ in., which is very near the length and width of the two-man cars of to-day. The weight dropped to about 46,000 lb. All of the above cars were equipped with four motors of capacity varying from 40- to 50-hp. each.

During 1914, the use of two-car trains was first tried in Montreal. Twenty-five motor cars, weighing 43,600 lb., and equipped with four 53-hp. motors, were coupled with 25 trailer cars without motors. The trailers weighed 27,400 lb. These were the first cars built with totally enclosed vestibules, and proved to be of real value during rush hours on streets of heavy traffic, and where the headways between cars was short. It was found, however, that these trains were deficient in power capacity and could be operated satisfactorily only on streets where the grade did not exceed six per cent. For that reason, in the next lot of fifty cars and fifty trailers built in 1917, the motor cars were equipped with four motors, 53 hp. each, and the trailers with two motors of the same capacity. The control was of the P.K. multiple unit control type 12 volts, and the cars were equipped with air operated doors. These trains were satisfactory on grades up to 12 per cent.

The above described pay-as-you-enter two-man cars had rear platforms with room for a large number of passengers to board the car, allowing for the collection of fares while the car was in motion, thus preventing delay at busy transfer points. From this idea, the "Peter Witt" type of

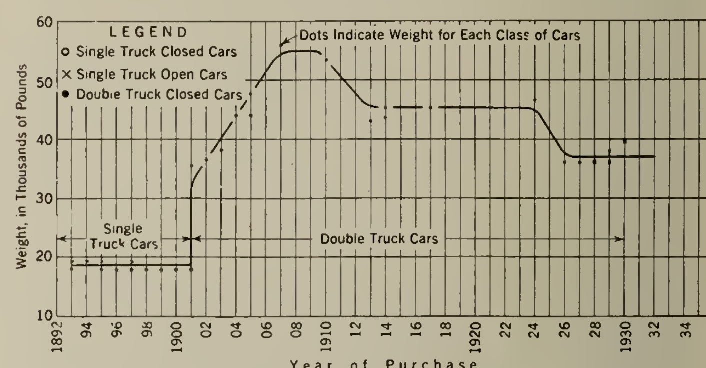

**Fig. 6—Curve Showing Trend in Weight of Street Cars.**

cars was developed. They may be described as front-entrance centre-exit pay-as-you-pass cars. Passengers enter a wide door at the front end without interference from descending passengers. The conductor is at about the centre of the car where two doors are located. He collects the fares of, and issues transfers to, passengers who wish to enter the rear or "paid space in the car"; they are free to leave at any time by one of the exit doors. Those remaining in the front part of the car pay their fare as they pass the conductor when leaving by the exit door immediately next to him. Suitable railings are provided to direct all movements in the desired direction.

This car offers great convenience in case of a large crowd entering a car. On the other hand, it is at a disadvantage when passengers leave the car in large numbers, as all those who remained in the front part of the car have to pay their fare before leaving. In practice it is very difficult to persuade the passengers that it is better for speedy operation not to stay in the unpaid area of the car. Another disadvantage is the opportunity it gives for the abuse of transfer privileges, because the conductor cannot judge when collecting a transfer if the passenger was entitled to its use at the time and place of his entry.

The "Peter Witt" type of car was favoured by a large number of companies on the continent and was adopted in Toronto in 1921.

During 1921-22-23, two hundred and fifty two-man cars of that type were purchased. They were steel frame cars weighing from 47,200 to 50,000 lb. An additional one hundred two-man cars of the same type were also purchased in 1922, but were about 4 ft. shorter than the standard ones. Their weight was 39,700 lb. They have since been transformed into one-man cars.

A large proportion of the new Toronto motor cars were equipped to haul 50 ft. trailers during rush hour periods. One hundred and ninety-five of these trailers were purchased during the period 1921-23. Thirty of them had two centre doors, and weighed 28,600 lb., one hundred and sixty-five had three doors, and were lighter, their weight being only 26,800 lb., all of which had no motor.

During the great war, an interesting development in car design had been made in the United States, with the introduction of what is called the "Birney Safety Car." The object had been to design a single truck car as light as possible, and equipped with the necessary safety measures to permit its operation by only one man. Economy in operation was the main object. Its weight was about 16,500 lb. It served its purposes well, and was valuable to many companies operating in small cities. It was less useful in large cities on account of its small size, except in a few instances, where stub service had to be provided in thinly populated districts.

Its influence, however, was considerable as it led to the development of the one-man car of to-day. It also directed the design of new cars toward a reduction of weight with the object of reducing operating cost.

Another important factor in the development of car design was the increasing use of the private automobile in city streets. The public demand was for speed in transportation and cars had to be built to keep pace in traffic with the automobile. This meant lighter cars, with quick acceleration and deceleration. Fortunately, the development of high speed motors, made possible a reduction in the size of the wheels from 33 in. diameter, to 30 in., and finally to 26 in. diameter by the year 1926. The result was that from that date, two-man cars of standard length could be built weighing only 36,000 lb.

During the years 1927-28-29, one hundred and forty two-man cars of the most modern type were built for the Montreal Tramways Company. Their overall length was 46 ft., their width 8 ft. 3 in., and their weight 36,000 lb. They were equipped each with four 42 hp. 600-volt series-motors with normal speed (one hour rating) of 1,045 r.p.m., and had single reduction gearing. The wheel diameter was 26 in., and they were of all steel construction except for the roof sheeting and the floor.

An important development in urban transportation was brought about by the introduction of one-man car operation. This demanded certain safety features which had not been previously considered necessary for two-man car operation. These included the use of power-operated doors with automatic treadle door exits, and additional precautions such as the dead-man handle, and interlock between doors, brakes and power.

The results of these safety appliances have been very gratifying. The records of accidents of all companies on this continent operating both one-man and two-man cars show fewer accidents per mile run in the case of the one-man car. This decrease in the rate of accidents must be attributed to causes other than mechanical, because in that respect both types of car are equally safe. Outside of a few additional safety appliances and necessary interlocking of power and doors, one-man cars are built exactly along the same lines as two-man cars.

### Brakes

Hand operated brakes of the ratchet type were quite satisfactory for controlling light single truck cars, but when car bodies and equipment increased rapidly in weight, some more powerful and quicker acting form of brake became necessary. Air brakes were, by that time, in common use on steam railways and their application to street cars involved no difficulty. The system first used was what is known as "straight air" in which the air application is made to the brake cylinder from the reservoir through the motorman's valve and is exhausted through the same medium.

Fig. 7—"Peter Witt" Car Built in 1921. Toronto.

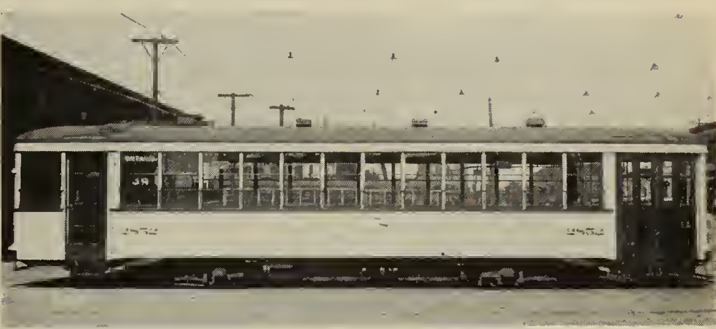

Fig. 8—One-Man Car Built in 1929. Montreal.

The simple straight air brake equipment was standard on all cars until the development of two-car trains. These required the simultaneous application of brakes on both cars in cases of emergency and, furthermore, it was essential that emergency brake application be made in both cars in case of a draw-bar failure.

The Westinghouse S.M.E. system was adopted. This operates as a straight air brake for all mild service applications, but a separate emergency air line is added for the purpose of providing synchronized brake applications on both cars when the air pressure in this emergency line is depleted through a special port in the brake valve or, automatically, in case of accidental separation of the two units.

This same system, slightly modified, has been applied to all single units built since that time, both one-man and two-man cars.

An interesting feature of the newer installations is the Form "E" relay valve. This device obviates the necessity of passing the air through the long pipe line from the reservoir through the brake valve to the air cylinder. The admission of a very small volume of air to the brake pipe acts on a small piston in this relay valve to open a direct connection between reservoir and cylinder. As soon as the air pressure in the cylinder balances with the pressure in the air pipe, the connection is shut off. Any degree of air pressure can thus be obtained in the air cylinder by passing a very small volume of air through the brake valve. Instantaneous release is effected in the same way.

All emergency actions result in the application of sand to the rail, the shortest possible stop being thereby attained.

### Control

A car is started by first impressing a low voltage upon its motors, and then gradually increasing the voltage as the motors speed up until they receive their rated voltage. Hence resistance must be connected in series with the motor armature and is gradually cut out as the armature

**Fig. 9—Two-Car Train. Vancouver.**

comes up to speed and develops a back electromotive force. This operation is performed by what is called a "controller."

As the average current input to each motor during the starting period is usually of the order of the rated current, a considerable loss of energy occurs during the period of acceleration of a car. The efficiency in the case of plain rheostatic control does not exceed fifty per cent. In order to reduce this loss the "series-parallel" method of starting was adopted in the very early days of electric traction, and has continued in use ever since. Its efficiency is 66⅔ per cent.

In the case of a car equipped with four motors, the motors are first divided in two groups, each group consisting of two motors which are always in parallel with each other. In starting, the two groups are connected in series, and also in series with the resistance. The resistance is then reduced step by step until the groups are alone in series across the circuit from trolley pole to ground, each receiving one-half of the line voltage. The motors then run at half their rated speed. When it is desired to further increase the speed, the groups are thrown in parallel with each other and a resistance again introduced. This resistance is then gradually cut-out until the last notch of the controller is reached when each motor receives full line voltage and runs at full speed.

There are two general methods of making the transition from series to parallel connections in series-parallel control. One, Type L, which opens the power circuit during the transition is little used. The other, Type K, does not open the power circuit, but is arranged to cut the current off half the motors during transition from series to parallel. This type has been used almost exclusively in Canada. In it, the main motor-current passes through the controller, which originally had only one blow-out coil to extinguish the arc formed between fingers and sectors as the circuits were opened. About 1910, a radical improvement was made by providing individual blow-out coils, these being fitted to the finger bases of each of the main fingers. With other changes, this improved type is the standard of to-day.

Power-operated control has also been developed, and in general, consists of two parts. There is first, a series-parallel motor controller composed of a number of circuit-breakers, sometimes called contactors, whose function is to effect the different combinations of the motors and regulate the starting resistances in circuit with them. This motor-controller is generally mounted under the floor of the car. Second, there is a master controller located in the vestibule of the car, and operated by the motorman. Its function is to actuate the motor controlling contactors. The current required to operate the master controller is small and ordinarily of the order of two to three amperes per car.

In one system of power-operated control, the motor-controlling contactors are operated electrically by the line current, while in another, the contactors are closed by compressed air and opened by a spring.

The advantages of the power-operated control may be summarized as follows:

(*a*) Multiple-unit train operation is made practicable.
(*b*) All circuit-breakers and other controlling devices which carry the main current motor are removed from the platform and placed beneath the floor of the car.

Power-operated control may be hand-operated when it is wholly under the control of the operator, or automatic, when the control is effected by current-limiting relays and interlocks on the contactors or unit switch.

Such automatic control of the car or of the train, as the case may be, eliminates the variable personal element in the handling of the controller which often results in uneven acceleration. Its disadvantages are that the cost of installation is high, and also that it is difficult to set the limit relay so that the car will be accelerated at the proper rate on different grades, and also under different conditions of track, car loading and street traffic density.

An important development in automatic control was made some eight years ago with the introduction of variable automatic control. (Type VA control).

The essential features of this new type are:
Automatic notching.
Slow, moderate and fast "pick up."
Hold, series and parallel position.

**Fig. 10—Toronto Transportation Company's Hillcrest Car Shops and Davenport Garage.**

In this controller, a variable rate of acceleration is obtained, which is proportional to the advance of the controller. This provides the flexibility so necessary when operating over the typical city route, since the rate of acceleration can be varied in order to conform to the street requirements.

The Montreal Tramways Company was one of the first properties on the continent to make use of the new type of control. Fifty new cars equipped with the variable automatic control were placed in service during 1930.

### The P.C.C. Car

As already stated, the past fifteen years have seen developments in transportation facilities, which have resulted in decided changes in the use of city streets. The private use of automobiles has increased beyond all expectation. The motor bus, and lately, the trolley bus, have definitely taken their place as modern vehicles of transportation.

In view of the above, a committee called The Presidents' Conference Committee was organized in December 1929, through the initiative of the American Transit Association and consisted of representatives of most of the large electric street railway companies in both the United States and Canada.

The object was: "the co-ordinating of efforts toward accelerating and furthering the technical development of the urban railway car and of the apparatus and equipment therein installed, to the end, among other things, that the rates of acceleration and deceleration of said car shall be quickened or improved as much as may be possible; that the car may be made as nearly noiseless as possible in operation; that the weight of the car may be reduced; and that the cost of operation thereof may be as low as possible and that a substantial reduction in the first cost of new cars may be achieved."

The Committee under the guidance of C. F. Hirshfeld, head of the research department of the Detroit Edison Company, who was selected as chief engineer for the Committee, spent four years in research and experimental work of all kinds. Three quarters of a million dollars were expended in designing, experimenting, and building equipment. In 1933, a new car called the Presidents' Conference Car (P.C.C. Car) was introduced, and its performance surpassed that of any previous car.

Four outstanding developments were accomplished:

(*a*) A new type of rubber sprung truck.

(*b*) A new type of rubber-cushioned wheels, also designated "resilient wheels."

(*c*) A motor of greater power and of very high speed, also a radically new control and braking apparatus for smooth rapid starting and stopping.

(*d*) An attractive and modernized car body.

The specification for the P.C.C. cars has been generally accepted as the basis of design for cars built to-day.

Over two hundred cars of the P.C.C. type were ordered during 1936 for Brooklyn, Chicago, Baltimore and a few other American cities. Some of these are presently in service.

A brief description of the main features of these P.C.C. cars, is as follows:—

In general the P.C.C. car is a light weight, four motor, double truck city car, with front entrance and centre exit.

| | |
|---|---|
| Length overall | 46 ft. 0 in. |
| Width overall | 8 ft. 4 in. |
| Wheel diameter | 25 in. |
| Total weight, empty | 33,350 lb. |
| Average accelerating rate (in miles per hour per second) | 4 m.p.h.p.s. |
| Maximum accelerating rate | 4.75 m.p.h.p.s. |
| Service braking rate | 4.75 m.p.h.p.s. |
| Maximum braking rate | 9.00 m.p.h.p.s. |
| Balancing speed in level track | 42 m.p.h. |

**Fig. 11—New P.C.C. Car Built for Brooklyn, N.Y. 1936.**

The average rate of acceleration is more than twice that of the present conventional street car, and substantially greater than that of the ordinary automobile. The service braking rate is also twice that of the present conventional street car.

Experiments made during the research work of the Presidents' Conference Committee show that these rates are well within the limits of human tolerance so long as they are accomplished without jerking or sudden changes in rate.

*Motors*

Special light weight motors were designed for these cars by both the Westinghouse Company and the General Electric Company. Both types, the GE-1198 and the Westinghouse 1432 are designed for 300 volts and are connected permanently two in series for the 600-volt circuit. This is a departure from the conventional 600-volt motor. The high speed motor does not differ fundamentally from that of the conventional type. It is so small, however, that 300-volt design provides better performance than 600-volt design. With the small commutator, the distance between brush holders becomes so short that the motor tends to become more sensitive to flashing, and the voltage to be commutated is also less. Commutator bars are larger and more substantial, and the armature conductor size is doubled by the use of 300 volts. The one-hour rating is 55 hp., or 156 amp. at 300 volts with 120 deg. C. temperature rise (resistance method); speed 1,670 r.p.m. The motor is self ventilated. The continuous rating is 135 amp. at 300 volts with 105 deg. C. rise, speed 1,820 r.p.m. The gear ratio is 7.17 to 1. The weight complete with drive flange varies from 695 to 725 lb. The outside diameter is 15¾ in. The motors are mounted longitudinally for a right angle drive. Transmission is of the right angle hypoid type, which is a special type of spiral bevel gear used in high grade passenger automobiles, and noted for its quietness.

No existing control system was considered capable of providing the smooth and rapid acceleration required for the new car. Both electrical manufacturers produced equipment along entirely new lines. It was considered essential to greatly increase the number of contacts in the controller, and to govern their action automatically. The saving of energy with series-parallel control was considered to be far overbalanced by its complication and the difficulty of obtaining uniform acceleration. The control adopted, therefore is rheostatic, with additional speed points obtained by shunting the motor fields. It is selectively automatic, that is, it produces automatically the performance called for by the position of the operator's control pedal. Unlimited selection of any accelerating rate between 1.5 to 4.75 miles per hour per second can be obtained. There is a switching position for slow movement. The operation of control is by means of a rocking or angle movement foot pedal operated with the right foot.

**Fig. 12—First Gasoline Bus in Montreal. 1920.**

*Braking*

Stopping is effected by a combination of dynamic, magnetic track and air brakes which are brought into action automatically, depending on the depression of the brake pedal. For dynamic braking the motors are used as generators. They are disconnected from the line and short-circuited through resistances, thus generating current by absorbing the energy of the car. The motor field is initially excited by a low voltage battery, and braking is therefore independent of the trolley line.

The magnetic track brake has four shoes, each 42 in. long, and hung between each pair of wheels. When energized they are pulled down to the rail by their own magnetism. The brake shoe itself is an electromagnet energized by a single coil designed for 32-volt current. Each shoe takes some 10 amperes when all resistance is cut out. The track brake is also independent of the trolley wire.

The air brake has four separate cylinders and lever systems, one for each axle, doing away with foundation brake rigging.

The complete operation of the brakes is as follows:—In service braking, as the pedal is depressed the dynamic brake comes into action first and will decelerate the car until the speed falls to about five miles per hour, when the dynamic brake fades out. At this point, the air brake cuts in and completes the stop, in conjunction with the track brake if the pedal is depressed enough to bring it in. The air brake is always available to hold the car. It will be noticed that under normal service conditions, the air brake is relieved by the dynamic braking of the motor of most of the work of the braking operation, and it comes into action only when the car has slowed down to five miles per hour. This arrangement greatly reduces the friction on the car wheels, which must be kept relatively cool to prevent the deterioration of the rubber. It also has the advantage of practically eliminating the skidding of the wheels.

Should an emergency arise, full depression of the pedal causes joint action of all three brakes regardless of the speed, bringing the car to rest in minimum distance.

*Truck and Wheels*

The design of the trucks and wheels differs in practically all essential respects from that used up to the present time.

Rubber was selected instead of steel for all springing. Rubber springs are very effective against high frequency impulses, and also as a noise insulator. Truck springs are made of rubber and steel, so arranged that the metal holds the rubber in place and transmits forces to it. The rubber serves as the resilient member.

The truck is as light as possible consistent with requisite strength. The side frames are two seamless steel tubes of 6¼-in. diameter with ⅜-in. wall. The cross members and supporting brackets are vanadium steel castings all electrically welded to the side tubes.

The resilient wheel, 25 in. in diameter, has a rolled steel web which carries the tread and rim, two outer circular steel plates (one on either side of the web), with disks of rubber held in compression between them and the hub. The construction provides for clamping these rubber disks in such a way that both radial and tangential forces are transmitted to the hub through the rubber.

*Body*

All welded construction is the outstanding feature of the construction of the body, which is light and very attractive in appearance. An alloy steel of high yield point is used in the body underframe, and copper bearing steel in the remainder of the structure. Research indicated that one of the causes of bad riding of the older street car was the high point of attachment between the car body and the truck. Consequently, the design of the new car has

**Fig. 13—29-Passenger Bus. Vancouver.**

been so arranged that the point of attack of the horizontal forces is only 11 in. above the rail.

Lighting has received particular attention. In the Brooklyn cars, luminator lensed globes are mounted one over each seat. Thirty-volt bulbs, 20 in series, give an intensity of 15 foot candles of light on a 45 deg. reading plane, 33 in. above the floor.

### Gasoline Buses

The use of motorbuses by electric railway systems began about 1920. In those early days, the bus consisted of truck chassis running on hard tire wheels, on which were mounted bodies designed for passenger service. This resulted in a vehicle having its floor quite high above the roadway causing inconvienence in riding, loading and unloading of passengers. Four solid tire motorbuses of the "charabanc" type were introduced in Toronto in 1921. A service was also established in Montreal about 1920, on Bridge street, where a small bus of the closed type was used. A second line was established in 1922, to serve streets along the harbour, the service being given by two small buses of the open type with cross benches.

These buses were not satisfactory for city service. It was soon realized that what was required was a bus having a low centre of gravity with floor as low as possible. Safety, comfort in riding, ease in boarding and alighting of passengers could not be obtained otherwise. The use of solid tires had also to be abandoned. A real effort was then made to design a bus to meet these requirements. As was the case in the automobile industry, the development of the bus during the last fifteen years has been really remarkable.

About 1925, Canadian electric railway companies decided that a point had been reached at which they could use buses to advantage. They were all of the closed type, with entrance and exit at the front, capacity varying from twenty-one to twenty-nine seats, and practically all were equipped with six-cylinder engines. Some of the smaller buses were equipped with four-cylinder engines, but it was found that these were subjected to such driving abuses, that the vibration was quickly damaging the chassis. Six-cylinder engines soon became general practice.

With the increase in the use of buses in large cities, traffic developed, and buses of larger capacity were required. Buses of the conventional type, with engine and hood, increased in size and soon reached an overall length of 32 ft.

With buses of this size, the engine became quite large, and it was realized that the space it occupied at the front end of the bus, was wasted as far as floor area was concerned. Buses were then built with the engine underneath the floor, or at the rear end underneath the rear cross bench. Another radical change was also effected some ten years ago, when a chassisless type of bus was brought out. The body and chassis, were built integral as one unit. The "Metropolitan" type or as it is also called the "Transit" type of buses for city service was thus introduced, and is the only type built to-day for city service.

The adoption of the above mentioned type of bus made possible a substantial increase in carrying capacity. Buses of thirty-six, forty and forty-two seats, with a fair amount of standee capacity are now built. The overall length for 36 passenger seating capacity buses varies from 31 ft. 6 in. to 32 ft. 6 in., depending on the position of the engine. That of the 42 passenger seating capacity with engine located under the floor is about 33 ft.

Fifteen years ago, no one would have believed that it would become practicable to drive a steered vehicle of that length in the congested streets of our large cities, especially when they have to go around parked or slow moving vehicles, and draw near the curb to load and unload passengers.

Six-cylinder engines are still generally used on the large buses. Their maximum capacity varies from 130 to 180 hp. The White Company of Cleveland, Ohio, has developed a twelve-cylinder horizontal opposed engine (six cylinders on each side of the shaft), called the twelve-cylinder "Pancake" engine, which is located under the floor of the bus.

The remarkable improvements in bus design, together with improved methods for maintenance have considerably increased the life of the modern bus. A first class bus to-day can run in city service at least 400,000 miles. The basis of depreciation is generally taken at eight years, but a bus is still useful for a few years after on secondary or emergency service.

### Oil Engine Buses

In the Diesel type of engine, the air is compressed in the cylinders to a high pressure, of the order of 500 to 700 lb. per square inch, thereby raising its temperature to a point where it is more than sufficient to ignite the fuel which is sprayed into the cylinder.

Engines of this type have been known for a long time, but as heavy slow speed engines they were not applicable to automotive work.

The development of a Diesel engine of low weight and high speed, suitable for use in buses and trucks, started some ten years ago. An engine was soon developed whose weight was not much above that of the gasoline engine, and of speed varying from 1,800 to 2,400 r.p.m.

**Fig. 14—36-Passenger Gas Bus, Transit Type. Montreal. 1936.**

On account of their fuel economy oil engines of the Diesel type are used to a great extent in Europe. Buses equipped with these engines are numerous in Great Britain. In London, where they have the largest fleet of buses in operation in the world, all new bus engines since 1934, have been of the Diesel type.

A bus equipped with this type of engine will run about twice as many miles per gallon as one equipped with the present gasoline engine. As fuel oil is cheaper than gasoline, the economy in fuel cost is still greater.

The Montreal Tramways were the first on this continent to install the Diesel engine on their buses. In December 1932, one bus was equipped as an experiment. The results obtained were good, and in 1935, fifteen buses were fitted with Diesel engines of English make.

Results to date have been satisfactory, with a saving in fuel cost, at current prices, of from two to two and one-half cents per mile. Indications are that maintenance will be no higher than that of the gasoline engine. Buses equipped with Diesel engines have also been used in Vancouver, where a somewhat greater saving was obtained than in Montreal; due to the greater difference between the cost of oil and gasoline.

It may be of interest to mention that in the United States, urban transportation companies started last year to equip buses for city service with engines of the Diesel type.

### Trolleybuses

The body and chassis of the trolleybus is that of the gas bus of the metropolitan type, but it is driven by an electric motor taking current from a positive trolley wire, like a street car. As there are no tracks to serve as return conductor there must be a second trolley wire, and consequently two trolley poles are required. The trolleybus is not obliged to travel in a fixed direction as a street car, since it can move at will, right or left, to a distance of 12 feet each side of the trolley wires. On streets of ordinary width it can, therefore, move as freely as an ordinary gas bus, and draw to the curb to load and unload passengers.

The principle of the trolleybus has been known in Europe for a long time. As far back as 1899, Siemens and

Halske experimented with one in Berlin. In 1900, Mr. Lombard Gérin built an experimental line 3,000 ft. long along the Seine, just outside the limits of Paris; and also in the Vincennes Park during the Paris Exhibition. A notable installation was also made in the Biela Valley, Germany, in 1901. It had an overhead structure very similar to that used to-day, and the vehicle had two separate trolley poles with shoes for current collection. Several other early trolleybus lines were also experimented with in England, and in the United States. In Canada, two small lines were operated for a short time, fifteen years ago, in Toronto and Windsor, Ont. The Toronto Transportation Commission placed four vehicles in service, and in Windsor a four-vehicle system was operated over two routes.

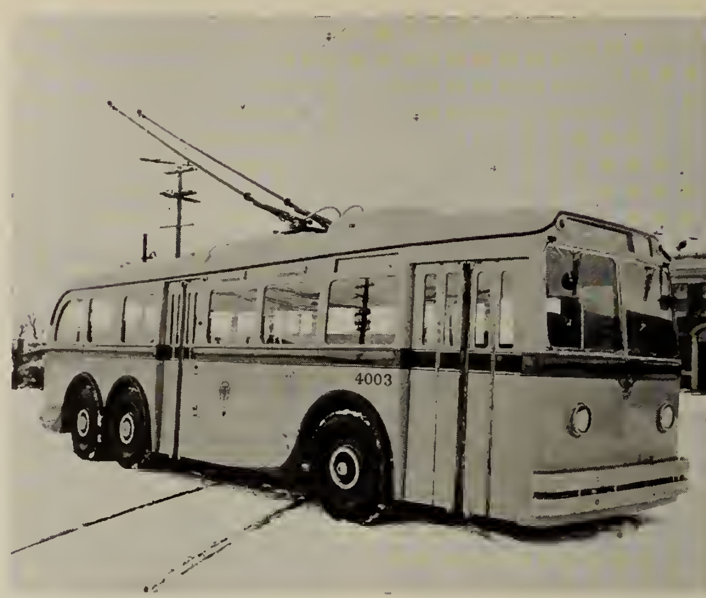

Fig. 15—40-Passenger Trolleybus, Montreal. 1937.

At that time the vehicle consisted of an ordinary four wheel omnibus with hard rubber tires, driven by an electric motor, and collecting its current through two trolley poles.

What was really lacking, was a chassis and body properly designed to suit mass transportation. The great improvements made along these lines for the gasoline bus were to be responsible for the renewal of interest in the trolleybus. In fact the modifications of design in 1928 and the years following have been so revolutionary that the trolley bus can now properly be termed a modern unit of transportation.

Its success and popularity for the last few years have been great, especially in Great Britain and in the United States. Canada's first modern trolleybus line was inaugurated in Montreal, March 22nd, 1937, giving a cross-town service on a street of medium traffic. Seven trolley buses, 40-passenger size, have been purchased in England by the Montreal Tramways Company.

These are single-deck, three axles, the two rear wheels being arranged in tandem, 40-seat capacity. They measure 32 feet in length over bumpers and the width over side sheeting is 8 feet. The wheel base is 16 ft. 2 in., and the weight 17,700 lb.

The bodies are of the all-metal type. The design is such that the riveted constructional sheets and members form the inner skin. The exterior sides and ends are sheeted with aluminum sheets secured in position by wood screws, and may be repaired or replaced easily. The roof carlins are of high tensile aluminum channel-section, and the roof is sheeted with aluminum. Insulation against cold is provided in the body and roof by the insertion of aluminum foil between the inner and outer panels.

The front entrance door has a clear width of 46 in.; the centre exit door is 26 in. wide and is fitted with low voltage treadle plate.

The frame is built up of nickel steel side members, section eleven by three inches, flitched over front and rear axle and down-swept at front to provide single step front platform. Three differentials are provided, ensuring equal distribution of driving torque to all four wheels of the rear bogie. Compressed air braking operates on all six wheels.

The power equipment consists of one compound-wound motor, 80 hp., 550/600 volts. Provision is made for regenerative braking, which though now first used in North America, is used almost universally in Great Britain. When the motor is running at speed, without resistance in circuit, it is generating a back E.M.F. nearly equal to the line voltage. With constant speed any increase in field strength will raise the back E.M.F. above the line voltage, and return current to the line. When the driver allows his master controller to return one or more notches, the corresponding shunt field contactors close and strengthen the shunt field. The motor voltage tends to rise, current is returned to the line, and the energy generated retards the vehicle. As the field falls, continued backward movement of the master controller pedal increases the strength of the motor shunt field step by step, and keeps the generated E.M.F. above the line voltage until the speed is reduced to approximately twelve miles per hour, at which speed the motor is in full field. If further reduction of speed then occurs, the generated volts are no longer higher than the line voltage. The equipment is designed to give rheostatic braking at speeds below the effective range of regenerative braking down to about four miles per hour. Below four miles per hour the electric braking falls away, and the vehicle is finally brought to rest by the foot brake. The master controller is operated by a foot pedal and its operation is very simple. Forward depression of the pedal applies power, and electric braking is effected by releasing the pedal slowly. To prevent excessive voltage being generated when applying the regeneration feature, an overvoltage relay is provided. In the event of the trolley coming off the line, or the line voltage failing at a time when the vehicle is regenerating, the overvoltage relay operates a contactor which closes the motor circuit through a resistance, thereby providing automatically a rheostatic electric brake.

All of the electrical equipment is mounted under the rear cross-seat. The contactor panel and resistances are located behind hinged doors in the back panel. The equipment is mounted on a frame and can be withdrawn as a unit.

One former deficiency of the trolleybus, which also applies to the street car, was due to the fact that current was collected from a trolley wire. Any serious obstruction along the route, such as an accident, a fire, etc., meant that the service was interrupted. The new trolleybus has batteries of sufficient capacity to drive the motor so that the bus may be operated on side streets at slow speed for a maximum distance of one mile on level ground, thereby assuring continuity of service. This feature will also be of assistance for short movements of the vehicle in yards or garages.

Many variations in design and operating characteristics appear in the trolleybuses of to-day. Those of American makes are entirely of metal, with the exception of the flooring. Most of them utilize steel, though some employ a combination of steel and aluminum. The body and chassis are built in one unit, following in that the practice for gasoline buses of the Metropolitan type. Some trolleybuses are equipped with a single motor, others have two motors. The tendency favours the use of one motor of large capacity, with the advantage of lower first cost, lower overall weight, and less apparatus to be maintained. Motors of 125 hp. have been developed for this purpose. Regenerative braking has not yet been adopted by the United States manufacturers, and the deceleration and stopping of the vehicle has to be performed by the air brake, which in the case of an electric vehicle is hard on the brake shoes. The control is fully automatic and sufficient accelerating steps are provided to accelerate the bus smoothly and confortably giving a maximum acceleration of 4 miles per hour per second. Overall lengths vary in proportion to the seating capacity, and are not very different from those of the gasoline buses of the Metropolitan type. The largest single deck trolleybuses in service to-day are the 42-passenger vehicles built for Youngstown and Milwaukee. Their overall length is 36 ft., and the width for the Youngstown units is 106 in. Generally the overall width is 8 ft.

POWER

When the operation of electric cars started in 1892, power for this purpose was generated only by large, slow

Fig. 16—William Street Power House, Montreal. 1894.

speed steam engines, to which were connected or belted direct current generators. The advent of the power generated by turbo-generators and especially by hydro-electric plants superseded those early steam plants, and led up to the automatic converting substations of to-day.

The history of the production of power for the use of street cars can best be outlined by giving that of the two largest cities in Canada; Montreal and Toronto. Development in other cities has been along similar lines.

City of Montreal

In Montreal, the power supply for the first operation of electric cars in 1892 was delivered from two 200 kw. 400 r.p.m. 600 volt Edison bi-polar generators belt driven by two Robb-Armstrong engines. This plant was located in the south-east corner of the Côté street car barn. In addition to the above plant, two similar 200 kw. units at the Royal Electric Company's, Queen street plant, were belt-driven by a vertical cross-compound engine, the generators being operated in parallel with those at Côté street.

Both these plants were abandoned when displaced by the William street station which was put into commission in 1894. The above mentioned four 200 kw. Edison units were transferred to William street station, along with eight additional Edison 200 kw. 600 volt generators driven by three 650 hp. engines (4 on each 650 hp. engine). There were added six 300 kw. 400 r.p.m. multi-polar Thomson-Houston type 600 volt generators belted to three (2 on each) 650 hp. cross compound horizontal engines. Thus in December 1894, the capacity of William street station was 4,200 kw.

From 1894 to 1901, the William street plant capacity was further increased by the addition of one 1,500 kw. multipolar generator, 75 r.p.m., direct connected to a 3,000 hp. horizontal cross compound condensing engine, and of two 850 kw. multipolar, 85 r.p.m. 600-volt generators, direct connected to two 1,500 hp. engines. This installation was accompanied by the necessary boiler plant, stack, economizers, piping and condensing equipment. On account of their slow speed the above units were of very large size.

This made the total capacity of William street steam plant 7,400 kw. at the end of 1901. This plant was in operation up to about the year 1917, when it was replaced by the new Hochelaga high tension steam turbo generator plant.

The original installation at the Hochelaga plant consisted of one 17,000 hp. 1,800 r.p.m. turbine, direct connected to a 15,600-kva. 3-phase, 60-cycle, 13,000-volt generator. A similar unit was added during 1923, which brought the total capacity of the plant to 25,000 kw. The a.c. power generated was distributed to the several substations at 13,000 volts through the Montreal Tramways Company's underground conduit system.

The purchase of alternating current from hydro-electric plants began in 1901. Its use steadily grew until in 1925 it totally displaced power produced by steam. The Hochelaga plant has since been used only as standby.

In March 1901, the first hydro-electric power was first used at William street station, one Westinghouse 375-kw. 600-volt generator being belted to two Stanley 2,200-volt, 2-phase, 60-cycle synchronous motors coupled in parallel.

During the same year, seven additional 500-kw. direct connected motor generator sets were installed, also using two-phase 2,200-volt, 60-cycle current.

The above equipment was in constant operation until 1930, when the plant was abandoned and the machinery discarded.

Until 1904, all the production and conversion of the power required for the operation of the tramways in Montreal was centred at one point; William street

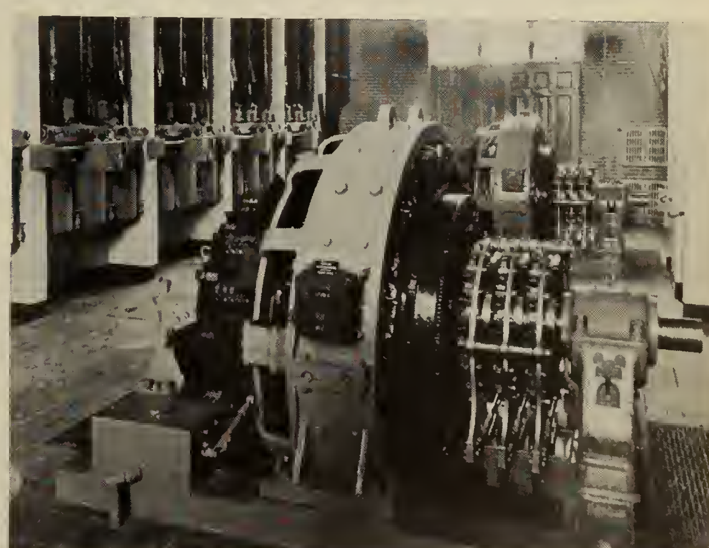

Fig. 17—Guy Street Substation, Montreal. 1929.
Two 2,000 kw. Rotary Converters.

Fig. 18—Queen Mary Road Substation, Montreal. 1930.

station. As the city grew it became uneconomical to distribute current at 600 volts to such great distances, so that converting substations properly distributed over the system became necessary.

During the years 1904-1905, both St. Henry and St. Denis substations were erected. They were equipped originally with induction motor-generator sets of 500 kw. capacity each.

Some of these machines are still in service. The year 1913 marked the arrival of machines of greater capacity One 1,500-kw. 2,300-volt, 3-phase, 60-cycle synchronous motor-generator set, 600-volt, compound wound, was installed at William street substation. Installations of similar machines were made at St. Henry and St. Denis substations during the following years.

It may be of interest to note that in 1906, in order to increase the capacity during the hours of peak loads, 280-cell Exide storage batteries were installed in each of the above two substations—St. Denis and St. Henry, also in the Shawinigan substation. Each of these batteries had a maximum discharge rate of 1,400 amperes for twenty minutes at 600 volts; they were operated in parallel with the motor-generator plant. One renewal of the positive plates was made during the year 1912. These battery plants were abandoned and scrapped in 1916.

The first rotary converters used in Montreal were installed by the Shawinigan Water and Power Company, at their substation on Orleans street, during 1905 and 1906, and consisted of three 1,000-hp. units. They delivered d.c. power to the Montreal Tramways Company, for its street car service. The above machines were in continuous service until the year 1930, at which time the contract terminated.

The first substation of the Montreal Tramways Company, in which rotary converters of large capacity were installed, was located on Côté street, and was built during the years 1920-1921. Four units, each 2,000-kw. 3-phase, 60-cycle, 600-volt d.c. Canadian General Electric Company, rotary converters were installed.

This was followed by the erection of Mount-Royal substation in the years 1924-1925, where three similar units were installed.

The year 1927 marked the appearance of metallic tank mercury arc rectifiers for street railway service. During that year Verdun substation was built and equipped with three Brown Boveri, double tank, 600-volt, 1,200-kw. mercury arc rectifiers. This was also the first station to be made fully automatic.

This was followed by the erection of several other fully automatic mercury arc rectifier substations, but using single tank rectifiers, as follows:—

| | |
|---|---|
| Year 1928—Rockfield Substation...... | 2—Brown Boveri 1,200-kw. rectifiers. |
| Year 1929—Viau Substation.......... | 2—12 Anode, General Electric 1,500-kw. rectifiers. |
| Year 1930—Queen Mary Substation... | 2—1,500-kw.—12 anode, General Electric rectifiers. |
| Year 1936—Ahuntsic Substation...... | 1—Brown Boveri 1,200-kw. type B-612-C rectifier. |

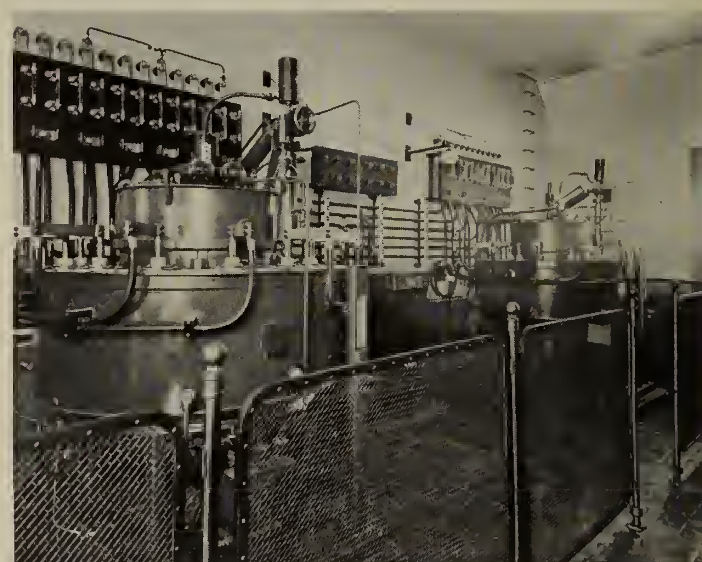

Fig. 19—Queen Mary Road Substation, Montreal. Two 1,500-kw. Mercury Arc Rectifiers. Operation Fully Automatic and Supervisory Controlled.

During 1929, a fully automatic substation was also built on Guy street, equipped with two 2,000-kw., 12-pole Canadian Westinghouse, compound 600-volt d.c. synchronous rotary converters.

Three of these substations, Guy, Queen Mary, and Viau, are supervisory-controlled from the Côté street central station.

To illustrate the functions of these substations (which do not require any attendant), the main features of the fully automatic rectifier substation located on Queen Mary road, may be noted as follows: This station can function on load responsive impulse; by supervisory control from load dispatcher's office, or manually from the switch-board in the substation. When operating automatically, the starting indication is given when the direct current trolley current falls below a predetermined value, provided that the high tension supply has the proper phase and voltage conditions. The second unit is started when the load on the first has reached a predetermined value for a certain definite time. Should the first unit fail to start the second unit is set in operation and entirely replaces the first unit. The second unit shuts down when the load on the station decreases sufficiently to be carried by one unit only, and the first rectifier is shut down when the load has fallen below a suitable value, provided the d.c. bus voltage is above a certain amount.

The above description will be sufficient to show the trend of development in the conversion of alternating to direct current used on this important street railway system.

Another interesting development is the present practice of building substations of smaller capacity, thereby restricting the feeding area of the station. These are located at the centre of gravity of the load, so that less feeders are required and the difficulties with the return current are also lessened.

The amount of capital invested in substations and distribution lines necessary for the operation of a tramway system is quite large. The value of receiving and converting substations, high tension transmission lines, d.c. feeders and returns, and trolley lines, including all equipment from the point of delivery of hydro-power to the trolley wheel of the car, runs from 15 to 20 per cent of the value of the entire tramway system.

Since 1925, all the power used by the Montreal Tramways Company, has been furnished and delivered by Montreal Light, Heat and Power Cons., at two main points: Hochelaga and St. Henry. From these points it is distributed to the several substations at 13,200 volts. The Montreal Tramways Company owns and maintains 16.3 miles of underground conduits, used exclusively for its 50.6 miles of high tension underground substation tie-cables, together with its 12.5 miles of underground control cables, radiating from the load dispatching office at Côté street, to the various automatic substations. The aerial substation high tension distribution is 8.8 miles long. There are 106 miles of 600-volt feeder and return cables installed in the municipal conduit system. The aerial 600-volt d.c. feeders and returns have a total of 250 miles of cable distribution.

There are at present fourteen converting substations spread all over the system with a total rated capacity of 49,000 kw.

The maximum daily peak load on the system during the winter months at 6.00 p.m., is generally around 45,000 kw., and a maximum of 49,225 kw. was reached in February 1935. In Fig. 20, a graph is shown of the daily load curve of the Montreal Tramways Company, during a typical winter month. It is interesting to note the great increase in power demand during rush hours, morning and evening. It amounts to some two to two and a half times the power requirement during other hours of the day.

### City of Toronto

The following historical notes have been kindly furnished by the Toronto Transportation Commission.

The Toronto Railway Company, in the year 1892, established a steam plant of their own at Frederick and Front streets. It consisted of four 450-hp. Armington and Sims condensing high speed steam engines, belted to two Edison 200-kw. 550-volt generators, and one 350-hp. engine belted to one 200-kw. and one 125-kw. Edison generator.

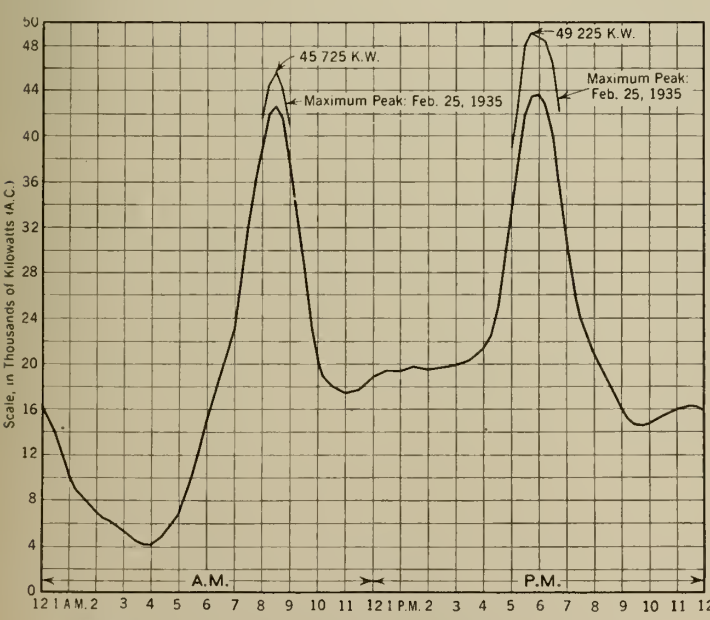

**Fig. 20—Typical Load Curve in Winter. Montreal Tramways Company.**

The plant was steadily increased and by 1905 had reached a capacity of 6,000 kw. The equipment consisted of six 26 by 52 by 48 Corliss compound engines direct connected to six 850-kw. 85-r.p.m. generators.

Niagara power arrived in November 1906, and the load was gradually transferred to Canadian General Electric 12-pole - 1,000-kw. - 250-r.p.m. - 25-cycle - 6-phase rotary converters (575 volts d.c.). All steam plant equipment has been scrapped subsequently.

The converting equipment was built up to sixteen rotary converters, all of which are in operation at present.

In 1921, when the Toronto Transportation Commission took over and consolidated all the street railway lines around Toronto, it became necessary to arrange for additional power. This was obtained by purchasing direct current power from the Toronto Hydro-Electric System, who own and operate for that purpose seven converting substations.

Six stations are equipped with rotary converters, of which two are fully automatic. The capacity of these stations varies from 2,000-kw. to 4,000-kw.; rotary converters are 1,000-kw. each.

In 1929, the Ossington substation was built. It is equipped with two 1,100-kw. Brown Boveri rectifiers, and its operation is fully automatic.

The total capacity for the system, as of December 1st, 1936, was 36,700 kw.

### PERMANENT WAY

Previous to 1892, when horse cars were operated, track construction was quite primitive. The rail was a rolled section consisting of an iron strap 4½ in. wide, ⅜ in. deep on the flat part, with a lug on one side 1¼ in. deep, and weighed about 30 lb. to the yard. It was fastened to longitudinal stringers, generally 4 in. by 6 in. or 6 in. by 8 in., by countersunk spikes at intervals of 18 in. The stringers rested on wooden ties spaced about six feet apart. No special foundation was provided, the ties being set only on a bed of gravel ballast. The paving surface consisted of macadam or cedar pole blocks, six inches deep, the space between the blocks was filled with sand.

### Trackwork

When the horse car systems were electrified this track design proved to be totally inadequate and unsuitable for the return of the electric current. A different type was needed.

The new trackwork for electric railway systems used grooved rails, 6½ in. deep and weighing from 70 lb. to 73 lb. to the yard. They were laid on wooden pole ties, 6 in. by 8 in. by 7 ft. long, spaced on 2-ft. centres. No special foundation was provided at that time, and the ties often rested on natural ground. In other instances, however, the subgrade was covered by a layer of 3 to 4 in. of gravel or of excavated macadam material. The pavement consisted of macadam, wooden blocks or stone blocks. A concrete paving base was first laid filling the space between the ties and covering them by an inch or so. The blocks were then laid on a layer of sand, one inch thick. The above structure was not quite satisfactory, except when it was built on exceptionally good soil, as it lacked proper foundation. It gave rise to a good deal of movement of the rail, causing a rapid deterioration of the pavement.

About 1900, another type was developed. The base was made of concrete in the shape of a concrete floor with stringers and slab. The stringers built longitudinally under each rail measured from 20 to 24 in. wide, and 8 to 12 in. deep below the base of the rail; the slab, between and on each side of the stringers, was from 6 to 8 in. thick and served as paving base. The whole was concreted in one operation from the subgrade to the top of the slab, the base of the rail being thus embedded in the concrete. Wooden ties or steel ties were used, though in some instances the ties were totally dispensed with. The pavement consisting of blocks was laid in the usual way. The above type of track structure also developed certain weaknesses, and was discontinued about 1910.

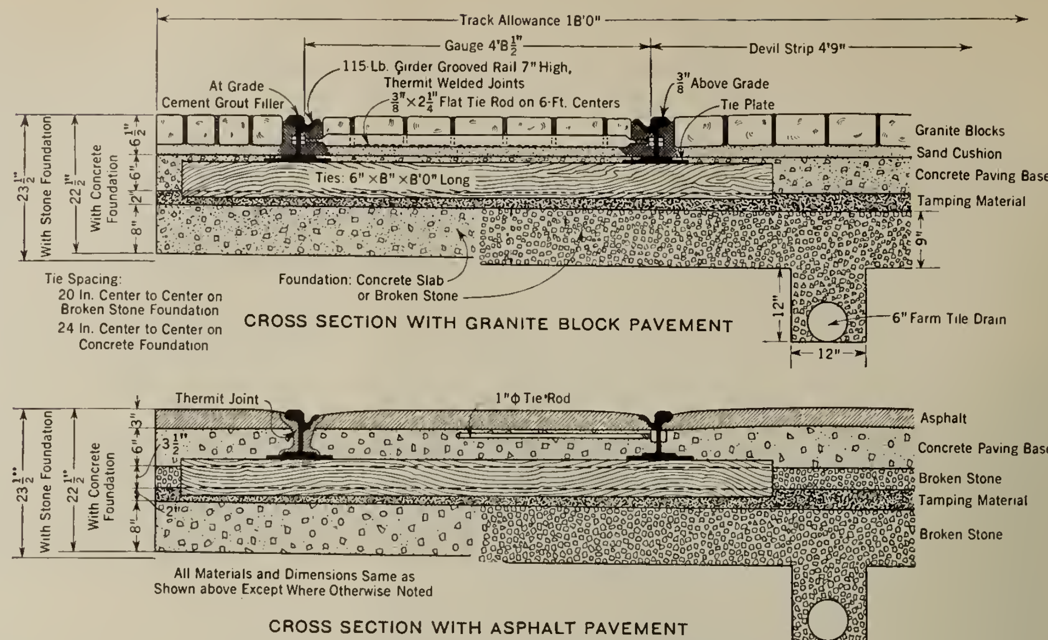

**Fig. 21—Standard Track Construction, Montreal. 1932.**

An important change was made about 1906, when it was decided that the "devil strip" must be widened in order to allow the use of wider cars. In Toronto, the width of the devil strip was increased from 3 ft. 10 in. to 5 ft. 4 in., and in Montreal, from 4 ft. to 4 ft. 9 in. These are standard to-day.

About 1910, in order to properly distribute the load on the soil, the practice of building a suitable separate foundation was commenced. It developed along two lines, one in which the ties rested on a continuous layer of broken stone, and the other in which a concrete mat was constructed on the whole width of the track structure. These types of foundation have given good results; they are still standard to-day. The thickness of the stone foundation is ordinarily 9 in. and the concrete mat, 8 to 9 in. The above mentioned track structure requires an excavation 22 to 24 in. below the level of the surface of the roadway. Beneath the level of the subgrade in the centre of the devil strip, a sub-trench 12 in. by 12 in. is excavated, and drainage is provided by inserting in this trench a 6 in. tile drain embedded in crushed stone, and connected to the sewers at convenient points.

*Ties*

Wooden pole ties have remained the accepted practice in Canada, since the advent of the system, although, steel ties embedded in a concrete base were used in a few instances. The use of treated ties has not been greatly favoured in Canada when laid on streets with permanent pavement, where the ties are sealed by the concrete paving base. However, in open track, their use is general. Ties, 6 in. by 8 in. by 8 ft. long, are laid on a layer of tamping material and are spaced generally at 20 in. centres in the case of crushed stone foundation, and 24 in. in the case of concrete foundation.

A new design of track structure for street railways has been developed during the last few years, in which the rails are laid on light steel cross-ties spaced on 4-ft. to 6-ft. centres, and the whole is concreted from the subgrade to the surface in one operation, forming a monolithic rigid structure. The concrete would be some 3 in. below the surface. The concrete slab is reinforced near the bottom with steel fabric, and additional anchorage for the rail is provided by round bars, spaced about two feet, which are inserted through holes in the web of the rail.

This type of construction has some good points, but has only been used in a few cities, and is still in the experimental stage. It has not been used in Canada.

*Rails*

The weight of grooved rails since 1892 has steadily increased from 72 lb. to the yard, to 83, 88, 96, 115 and 122 lb. to the yard. A certain amount of 87 lb. and 90 lb. high tee rail was also used, but since about 1916, its use has been practically discontinued on streets where permanent pavement is laid, grooved girder rail being substituted. It is of interest to note that in Montreal, since 1918, the use of tee rail on paved streets is not permitted. In the early days, the rails were laid directly on the wooden ties, but with heavier rolling equipment, it became necessary to place bearing tie plates between the rail and the tie.

Not only has the weight of the rail been increased, but the composition of the steel has been changed somewhat. The carbon content has been increased gradually from approximately 0.4 per cent to 0.7 per cent, while the manganese content has been slightly decreased. Some years ago, some intermediate manganese rail with a content bearing approximately 1.5 per cent of manganese was installed in Montreal, as an experiment. Results obtained up until now promise increased life, though the harder rail has shown a tendency to brittleness by an increase in the number of fractures. Rail treated by the Sandberg sorbitic surface hardening process has been laid at test locations, but results are not yet conclusive.

*Joints*

Since the inauguration of the electric system the tracks have been utilized as a conductor for the return current. As bolted joints were standard practice in the earlier days, the rails were connected at each joint with copper bonds soldered to the rails. With the introduction of the seam-welded joint, about twenty-five years ago, copper bonds were abandoned and the connecting side plates were welded to the rail, the parallel rails being connected together however, with cross bonding every 400 feet.

One of the most important developments in track construction has been the adoption of the thermit welding process for rail joints, which has been standard practice since 1931. In this process, the ends of the rails are welded together, forming a continuous head section. The result is a continuous surface on which the car can run smoothly, thus greatly lessening the noise of the car. The cost of track maintenance is also materially decreased. The question may be asked, what is the result of the expansion and contraction of the steel? It must be noted that the rail is embedded in the pavement, and rigidly fixed to the track structure. Actually the rail is so well held in position, that the tendency toward expansion and contraction results only in increase or decrease in internal tension in the steel. It may be of interest to add, that rail welded by the thermit process has been used even in open trackwork, in several instances. In Montreal, in the Wellington tunnel under the Lachine canal, for a length of 1,473 feet (including the two ramps), the rail joints are thermit welded, and no break has yet occurred. Another piece of open trackwork, 900 feet long, on Cote des Neiges private right-of-way, was similarly constructed recently.

### Special Trackwork Layouts at Intersections

These special trackwork layouts are very costly, and deserve special attention. The cost of the steel alone for a grand union intersection layout, viz: with eight curves, is in the neighbourhood of thirty thousand dollars. The cost of the complete structure, including the pavement, amounts to some forty-five thousand dollars.

Curves for intersection layouts were originally designed with one radius throughout, and switches were made with a 45 ft. radius. About 1900, the radius of switches was increased to approximately 100 feet, and easement curves were installed between the heel of the switch and the main central arc. Some twenty-five years ago, clearance curves with long easement ends were introduced, and a 200 ft. radius switch was manufactured to permit clearance of cars in any position. This was of great value in the operation of cars at busy intersections.

The designs of the switch, mate and frog pieces have been constantly improved and standardized to secure interchangeability and ease of replacement from material in stock. In fact the Canadian companies, in respect of the standardization of special layouts, are far in advance of American companies, who are presently working toward the same goal.

Switches, mates and frogs were originally manufactured of cast steel. About 1895, the tongues and part of the head were made of manganese steel, and by 1900, the entire switch, as well as mates and crosses, was being constructed of this metal. Experimental installations were also made with alloy steel of nickel, chrome nickel and high silicon content. To-day the general practice is to use manganese steel with a manganese content of 12 to 14 per cent.

On account of the high cost of special steel layouts, it is important that their life be prolonged. Welding has been of great value in this regard. It was first thought that manganese steel could not be welded with good results, but about 1920, experiments were made with success. This led to further improvement, and today, the practice of welding manganese steel has extended the life of these expensive pieces by almost 75 per cent.

### Pavement

The type of paving most used to-day is of granite blocks and asphalt; in both cases a concrete paving base is built. The blocks are laid on a cushion of sand or of a dry mixture of sand and cement; concrete surfacing has not been used to a great extent in Canada.

What is also worth noting, is that the maintenance of the surfacing of the roadway in the track area, which is to-day solely used by vehicles other than street cars, is in most cities done at the expense of the tramway companies. This is a relic of the time of the horse cars, and though fifty years have since elapsed, and conditions with respect to the use of the pavement have totally changed, this practice has not changed. The enormous increase in traffic, and the use of chains in winter by automobiles and heavily loaded trucks, have rendered the upkeep of the pavement very onerous. The street car passenger through his fare has to pay for that, and fifty years of progress has not helped him at all in this respect; on the contrary the situation has grown worse.

### Cost of Trackwork

The high cost of intersection layouts has already been noted. It may be of interest to mention that the cost of a double track street car line, with paving, poles and trolley wires, built under average conditions, is not less than one hundred and fifteen thousand dollars per mile of street.

The total cost of trackwork of a street railway runs from 25 to 30 per cent value of the entire system

### Economics of Transportation

With the advent of new types of vehicles, the economics of mass transportation have necessarily been modified.

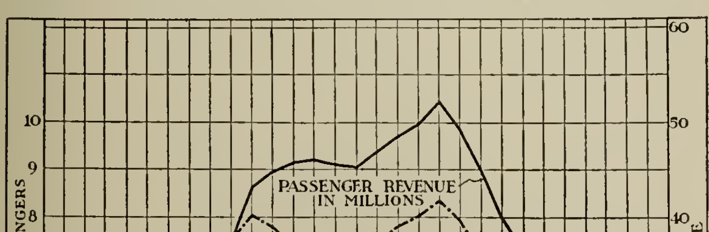

Fig. 22—Passenger Revenue. Canadian Electric Railways.

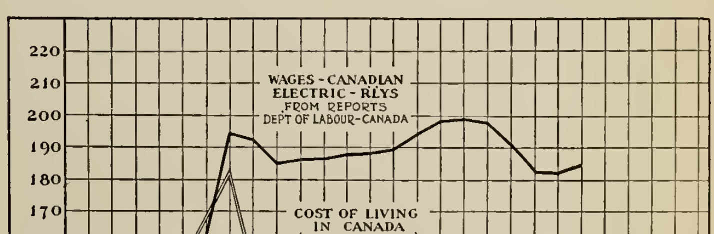

Fig. 23—Fares and Wages. Canadian Electric Railways.

Up to about 1920, street railways were the only practical type of urban transportation on surface streets, large, medium, or small cities had to use the same system. To serve suburban localities, long mileage of trackwork with electric lines had to be installed, which were used only to a limited extent. Maintenance, interest and overhead charges were abnormally high in these cases, due to the small amount of traffic to be handled.

At the present time, three different kinds of service are available on surface streets, depending on the density of traffic: that of the street car, the trolleybus and the autobus. Each of these types has a definite place in a modern system of transportation.

Transportation by subway is not included, as no city in Canada has a sufficient population at the present time, to justify subway construction. In order to have a return sufficient to meet the expenditure, the fare would have to be so high that it would not be practicable. An elevated railway in the heart of a city, though less expensive than a subway, is no longer favoured, as it kills the development of the street along which it is built. Cities where they exist are either tearing them down or propose to do so.

In our large cities the street railway is still the backbone of mass transportation. Due to the large carrying capacity of street cars, and due to the fact that they operate on a track, they can move more passengers for a fixed area of street occupancy than any other type of surface vehicle that can be operated in this country. In the heart of the larger cities having a population near or exceeding the million mark, the interval between cars at certain points is as low as twenty to thirty seconds. To this stream of street cars must be added the steady flow of automobiles. As most of the streets in the heart of our cities only allow for four lanes of traffic, two in each direction, it is easily understood that the street space must be economized to the limit. It has been said that the roadways built over half a century ago, are not an inch wider to-day, and modern traffic leaves them sadly unable to carry their load. As the late Mr. Seurot, of the Montreal Tramways Company, used to say, "we are now facing the arteriosclerosis of circulation." The solution of the problem is certainly not to substitute for the street car on main arteries of traffic, any type of vehicle which will occupy more space per passenger, as is sometimes suggested.

It is important to note that for all cities of a population over 500,000 on the American continent, during 1936, for mass transportation on surface streets, 77.74 per cent of the passengers were transported by street cars, 1.19 per cent by trolleybus, and 21.07 per cent by autobus. This proves conclusively, that for cities of that size, electric railways are still the backbone of mass transportation. They are also the most economical means, when headways are sufficiently short to distribute the cost of the trackwork over a large number of car-miles. There are, however, certain routes on which the movement of passengers is sufficiently heavy to bear the cost of poles and trolley lines, but which cannot economically support the cost of the trackwork. These are better served by the trolleybus, which under these conditions will be the most economical of all. The trolleybus is certainly the finest type of vehicle there is, and for medium traffic on streets where there is no objection to the erection of poles and trolley wires, it offers the best mode of city transportation.

Then comes the third division, viz. routes on which the number of vehicles in service is not large enough to justify economically the erection of trolley lines, and streets where there are objections to doing so. This is the place for autobuses. They offer the special advantage in newly developed districts of not requiring any capital investments other than the purchase of the vehicles.

The development of these new vehicles has brought a great change in transportation systems in the last fifteen years. In large cities, the electric railway companies early realized that autobuses could be used with success as feeder lines to their main tramway system, or on routes where the construction of tracks was not necessary. Many street car lines were changed to bus routes when the tracks had to be rebuilt. To-day the necessity of any proposed renewal of trackwork must be carefully examined.

A great number of cities have totally abandoned their street car services and substituted motorbuses. It may be stated that for all cities of a population not exceeding 150,000 the construction of an electric railway system cannot be justified. Those still in existence will not be

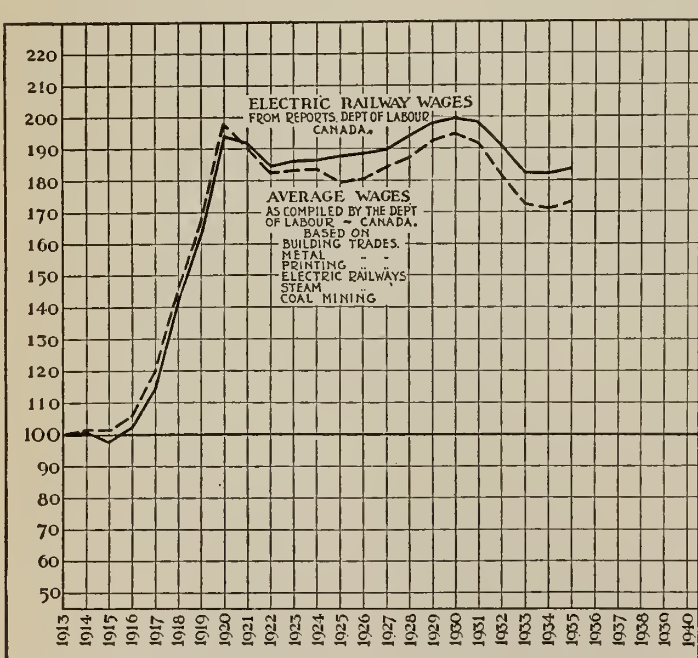

**Fig. 24—Canadian Electric Railways Wages Compared with Average Wages of Railways and other Trades in Canada.**

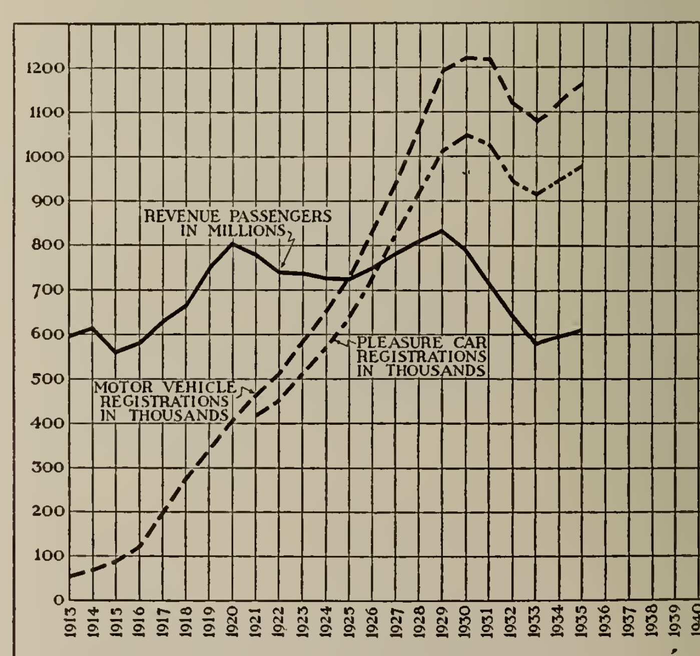

**Fig. 25—Revenue Passengers. Canadian Electric Railways.**

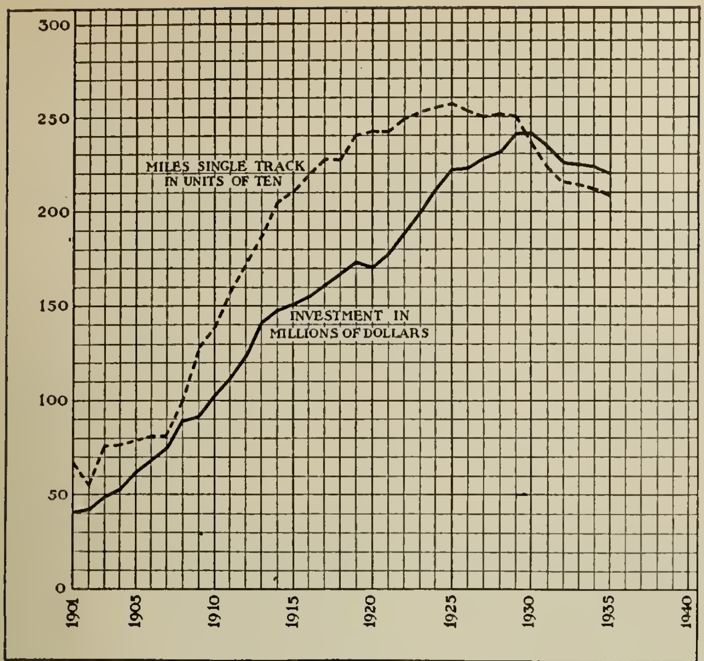

**Fig. 26—Investment in Canadian Electric Railways.**

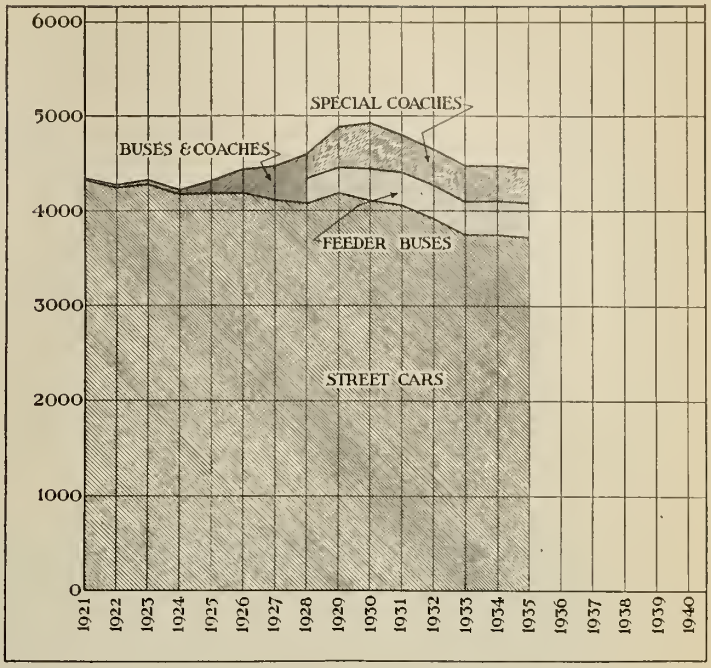

**Fig. 27—Street Cars, Buses and Coaches in use by Electric Railways in Canada.**

renewed when the expenditure for maintenance and replacement becomes too onerous.

During the year 1936, mass transportation traffic in cities of 100,000 population and under on the American continent, was divided as follows: tramways 48.2 per cent, trolleybus 1.8 per cent, and motorbuses 50 per cent.

### Statistics

Through the courtesy of the Canadian Transit Association, a number of important electric railway statistics are reproduced in graphic form in this paper. Being all in the form of charts, they speak for themselves, and no comment need be added.

### GENERAL CONSIDERATIONS ON STREET TRAFFIC

It is not necessary to describe the traffic conditions existing to-day in the main arteries of our large cities. In the central districts, the streets are choked with vehicles, and an average speed of five miles per hour is not uncommon in certain congested sections.

Under such conditions, are we at least making the best use of what we have? On the contrary, we have permitted a practice to be introduced, the parking of automobiles, which often reduces by one half the capacity of streets already too narrow

From an economic point of view, this is a fundamental error; the value of the space occupied in main arteries by parked vehicles is out of all proportion to the service rendered. A city possesses no more valuable property than its streets. The result is that cities are called upon to build ahead of time subways to provide the service that could be given on surface streets.

Every year more citizens use the private automobile to travel from their homes to their places of business or vice versa, so that during rush hours, the main arteries of circulation are flooded with private cars. There is a definite limit to the number of vehicles which can move through streets at reasonable speed. Large cities were not built, and cannot be transformed economically, to permit the transportation of their citizens on a large scale by individual automobiles.

To remove the trouble by providing additional streets or widening existing ones, with provision for grade separation at many points, would require a tremendous capital expenditure. The building of subways, thereby releasing the streets for the balance of the traffic, would also be very costly. The method to be adopted should be one which will give the best results for the amount of capital invested, due consideration being given to the interests of the citizens at large.

For instance, in several cities, huge expenditures have been made to provide street facilities which are used almost exclusively by private automobiles. This may have been justified to a certain extent in exceptional cases, but it is doubtful if in a great number of them this was sound economically. It has even happened that the opening of the new arteries only invited more cars to travel, with the result that soon afterwards, the general traffic conditions were no better than before.

The question may be raised as to whether it would not have been preferable in many cases to spend that money on subways. It must not be forgotten that 75 to 80 per cent of the population of large cities has to be carried by mass transportation agencies; special counts made in different cities have substantiated this statement beyond a doubt. Eighty per cent of the population would have benefited from the construction of the subway, against the 10 or 15 per cent who use automobiles for individual transportation. Besides as already mentioned existing streets would have been relieved for automobile use. The objective should be to co-ordinate the construction and operation of these new facilities in such a way as to provide a maximum of public benefit.

All cities to-day, medium or large, should give special attention to their traffic problem, first to improve their existing facilities, and secondly to provide, within reason, for the probable conditions of the future. It is certain that Canada is going to expand extensively during the next fifty years. In the future as in the past, the question of urban transportation will be of vital importance for the proper development and functioning of our centres of population.

* * * *

Note:—The author desires to thank the officers of the several tramway companies operating in Canada, who have kindly furnished him with data required for the preparation of this work. Information was also taken from several journals and books dealing with urban transportation during the last fifty years.

# Waterways Development

*The Hon. C. D. Howe, Hon. M.E.I.C.,*
*Minister of Transport, Ottawa, Ontario*

The development of waterways along the St. Lawrence river and through the Great Lakes has been so extensive that they dwarf all other inland waterways, not only in Canada but in the entire world.

Some idea of the extent of the traffic carried may be obtained by comparison with the traffic carried by the great inter-ocean canals of the world, the Suez and the Panama.

For this purpose, as the St. Lawrence-Great Lakes waterways are international in their character, the tonnage through the Sault Ste. Marie canals, both Canada and United States is given below as an index:—

Table I

| Year | Sault Ste. Marie Canals | | Suez Canal | | Panama Canal | |
|---|---|---|---|---|---|---|
| | Vessels number | Freight tons (2,000 lb.) | Vessels number | Freight tons (2,000 lb.) | Vessels number | Freight tons (2,000 lb.) |
| 1928 | 19,286 | 86,994,254 | 6,084 | 35,959,231 | 6,253 | 33,169,529 |
| 1929 | 19,794 | 92,618,898 | 6,274 | 38,046,868 | 6,289 | 33,525,500 |
| 1930 | 16,820 | 72,897,895 | 5,761 | 31,427,675 | 6,027 | 33,620,640 |
| 1931 | 13,056 | 44,606,325 | 5,366 | 27,924,000 | 5,370 | 28,073,117 |
| 1932 | 8,679 | 20,484,169 | 5,032 | 26,050,000 | 4,362 | 22,174,864 |
| 1933 | 12,100 | 40,303,398 | 5,423 | 29,669,000 | 4,162 | 20,340,505 |
| 1934 | 11,395 | 42,247,556 | 5,663 | 31,359,000 | 5,234 | 27,668,490 |
| 1935 | 12,959 | 48,292,973 | 5,992 | 29,074,000 | 5,180 | 28,346,670 |
| 1936 | 16,614 | 69,528,795 | 5,877 | 28,221,500 | 5,382 | 29,686,152 |

The season of navigation on the Great Lakes is about seven months or two hundred and forty-three days per year. Nevertheless during the years 1928 and 1929, the Sault Ste. Marie canal carried about three times as much freight as either the Suez canal or the Panama canal. The depression hit this lake traffic more severely than the ocean traffic, but the above table shows it is rapidly recovering its pre-eminence over the great inter-ocean canals.

St. Lawrence River and Great Lakes

The St. Lawrence river is the natural route from the Atlantic to the Great Lakes, and with the lakes provides a course of water communication extending 2,218 statute miles through Canada, from the Strait of Belle Isle to Port Arthur and Fort William on the west coast of Lake Superior, about 600 ft. above sea level.

The St. Lawrence river is naturally divided into two sections, the lower extending from the Gulf of St. Lawrence to Montreal, and the upper, from Montreal to Lake Ontario.

The lower section was, until the organization of the Department of Transport, more or less controlled by the Department of Marine and was officially known as the "St. Lawrence Ship Channel."

A considerable amount of dredging work was done prior to 1887 (from 1850 the channel under the control of the Montreal Harbour Commissioners was deepened from stage to stage), and in 1888 there was 25 ft. draft available which had been obtained at a cost of three million dollars.

In 1889 the control and management of the channel was transferred to the Department of Public Works, and work was started on a 27-ft. channel which was completed in 1898 but in 1899 it was decided that the channel should be 30 ft. The Department of Marine took over this work in 1904 but before the 30-ft. channel was completed, owing to the rapidly increasing size of vessels, it was decided in 1910 to increase the depth of the channel to 35 ft. at low water. It is expected that this 35-ft. channel will be completed during the current year.

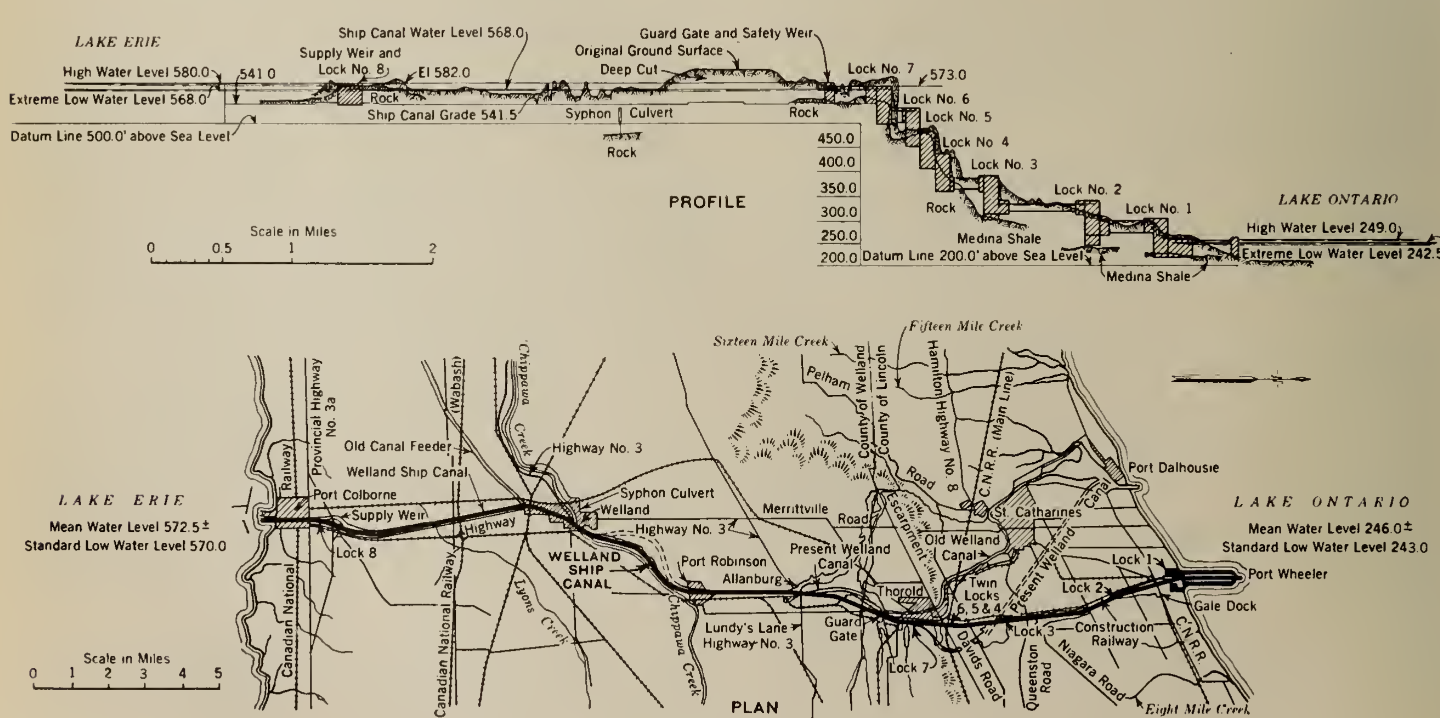

Fig. 1—Plan and Profile of Welland Ship Canal.

Welland Ship Canal at Syphon Culvert

The Canal crosses Chippawa Creek at this point, which necessitated the construction of an inverted syphon culvert to carry the river water under the Canal. The foundations of this structure stand at a depth of 86 feet below the level of the water of the Canal, and six tubes, each 22 feet in diameter, form the water passage by which Chippawa Creek flows on to the Niagara River.

Fig. 2—Flight Locks, Welland Ship Canal.

Ice breakers have been employed for thirty years on the St. Lawrence river, primarily to prevent floods, but a secondary result has been to lengthen the season of navigation.

The average date of the first arrival at Montreal during the past five years has been April 26th, and the average date of the last departure, November 26th, which is an average increase of nineteen days in the season of navigation compared with the previous years.

The upper section, because of its necessary canals, has been almost entirely within the jurisdiction of the Department of Railways and Canals, with the Department of Marine furnishing aids to navigation in the way of buoys and lights and the Department of Public Works doing the dredging in uncanalized stretches.

Fifty years ago, between Montreal and Lake Ontario, the St. Lawrence river, with the aid of a number of canals, provided a draft of 9 ft., and the provision for 14-ft. draft was under way, but this undertaking was not completed until 1904.

A short outline of these various canals, with the important improvements during the period 1887-1937, is as follows:—

The Lachine canal was built to overcome the Lachine rapids, and extended from Montreal harbour to Lake St. Louis, 8.74 miles long with 14 ft. depth in the locks, but only 12 ft. in the canal. The work of enlarging the canal to 14 ft. depth was completed in 1899.

The Beauharnois canal, which provided navigation past the Cedar Rapids, extended from Lake St. Louis to Lake St. Francis, 11¼ miles long, 9 ft. depth. It was replaced in 1899 by the Soulanges canal, 14.67 miles long and 14 ft. depth.

The Cornwall canal was built to overcome the Long Sault rapids, and extended from the town of Cornwall to the village of Dickenson's Landing 11.00 miles long, 9 ft. depth. It was enlarged to give a 14-ft. depth, completed in 1904.

Farren's Point canal, 1.28 miles long, 9 ft. depth, built to pass Farren's Point rapids, was enlarged to provide for a 14 ft. depth, completed in 1901, and the upper entrance was extended 1,700 ft. up stream.

The Rapide Plat canal, 3.89 miles long, 9 ft. depth, built to pass the Rapide Plat rapids, was enlarged to 14 ft. depth, completed in 1904.

The Galops canal was built to pass the rapids at Iroquois Point, Cardinal Point, and the Galops. This canal, 7.36 miles long, 9 ft. depth, was enlarged to provide a 14-ft. depth completed in 1904, and, in 1907-1908, the north channel was dug to provide a better entrance to the canal at the upper end, and Gut dam between Galops and Adams island was built to improve conditions at the upper entrance.

Between Prescott and the junction of the St. Lawrence river and Lake Ontario at Kingston, a distance of 66 miles, improvements in the alignment of the ship channel have been made between 1887 and 1937, and a considerable quantity of solid rock has had to be excavated to make these improvements. The Canadian channel in this stretch now provides a navigable depth of 27 ft. below Lake Ontario elevation 244.5.

The canals on the St. Lawrence river, as at present constructed, control the size of vessel that can traverse the through route and the limiting lock in this respect is situated at Cornwall on the Cornwall canal. This lock has the following dimensions: length between hollow quoins of gates 270 ft., width at bottom 43 ft. 8 in., width at coping 45 ft. 3 in., depth of water over mitre sills 14 ft. It will accommodate vessels having the ordinary perpendicular and pointed bow and rounded stern up to an overall length of 255 ft.

The Welland canal connected Lake Erie with Lake Ontario, the difference in levels being 326½ ft. In 1887 this canal was in operation for 14-ft. navigation, locks 270 ft. long and 45 ft. wide. The normal time required to navigate the canal in 1930 was eighteen hours.

In 1913 work started on the Welland Ship Canal. The ship canal follows the valley of Ten Mile Creek between its mouth (Port Weller on Lake Ontario), about three miles east of Port Dalhousie, and Thorold. From Thorold to Port Colborne, the alignment has been changed in several places, and the canal now takes a much straighter course than that of the previous waterway. The general dimensions are as follows:—

| | |
|---|---|
| Length lake shore to lake shore | 27.6 miles |
| Minimum width of canal prism at 25-ft. depth | 200 ft. |
| Minimum width of canal prism at water level | 310 ft. |
| Minimum depth of canal prism | 25 ft. |
| Number of locks including Port Colborne Guard Lock | 8 |

Fig. 3—Locks 4 and 5, Welland Ship Canal.

| | |
|---|---|
| Length of guard lock | 1,386 ft. |
| Length of locks No. 1 to 7 inclusive | 859 ft. |
| Width of all locks | 80 ft. |
| Depth of water over sills of locks | 30 ft. |
| Lift of locks, except guard lock | 45.5 ft. |
| Normal time for a vessel to traverse the canal | 7.5 hrs. |

The construction of the Welland Ship Canal, which cost $132,070,236.46 to March 31st, 1936, was, of course, the outstanding work in waterway development in Canada during the period from 1887 to 1937, and a plan and profile of this canal has been included in this paper (see Fig. 1). Figures 2 and 3 show the S.S. *Lemoyne* passing through the waterway on the day of the official opening, August 6th, 1932. Figure 4 is a view of bridge 5, opened for the passage of the S.S. *Dow Chemical.* These illustrations give some idea of the magnitude of the work.

**Fig. 4—Bridge 5, Welland Ship Canal.**

During the period from 1887 to 1895 the Canadian canal at Sault Ste. Marie was constructed, with a lock 900 ft. long, 60 ft. wide and a normal depth of 18¼ ft. over sills, giving navigation through a Canadian lock from Lake Huron to Lake Superior.

### Other Canals

The Richelieu river to Lake Champlain route, commencing at Sorel on the St. Lawrence river, 46 miles below Montreal, extends along the River Richelieu through the St. Ours lock to Chambly Basin; thence by the Chambly canal to St. Johns, and up the river Richelieu to Lake Champlain. The distance from Sorel to the International Boundary is 81 miles. The maximum depth of water is normally 6 ft. 6 in. At Whitehall, at the southerly end of Lake Champlain, connection is made by means of the Champlain canal with the Hudson river which has 12 ft. draft available to Albany the head of ocean navigation. St. Ours lock (and dam) was rebuilt in 1930-32 and now has a depth of 12 ft.

The question of further improvements to this route is under consideration by the International Joint Commission.

In 1882-1889 the Murray canal was built through the Isthmus of Murray, giving connection westward between the Bay of Quinte and Presqu'ile Bay. The overall length of canal and entrance channels is 7.53 miles, depth 11 ft., with no locks.

The term "Trent canal" is applied to a series of navigable rivers and lakes connected by short canals forming a continuous system, with a minimum depth of 5 ft. 10 in. navigation, for 224 miles from the Bay of Quinte, Lake Ontario, to Swift Rapids on the Severn river. From the latter point vessels of smaller sizes can be passed over the marine railways, for a further distance of 16 miles to the outlet into Georgian Bay at Port Severn. Of the 240-mile route only 33¼ miles are artificial canal prism. The canal was completed, substantially as at present, in 1918.

### Red River

The St. Andrews lock and dam, built by the Department of Public Works, were opened for traffic in 1910. It is situated on the Red river 20 miles North of Winnipeg and 27.4 miles from Lake Winnipeg, providing through navigation with 9 ft. draft between the city and the lake. Lake Winnipeg is almost 300 miles long and covers 9,398 square miles, so that it is larger than Lake Ontario and only slightly less in area than Lake Erie. The St. Andrews lock and dam now provide a substantial link in one of the routes to the recently developed Gods Lake mining area.

### Mackenzie River

From the town of Waterways, about 300 miles north of Edmonton, Alberta (at the end of steel), a number of steam boats are operated in the District of Mackenzie. From Waterways by way of the Clearwater and Athabaska river, Lake Athabaska, the Rocher and Slave river navigation extends to Fitzgerald, Alta., at the head of a series of rapids extending to Fort Smith, N.W.T. This series of rapids is sixteen miles long, and at this point all the traffic must pass over a sixteen mile waggon road as the rapids are not navigable.

From Fort Smith, the boats operate on an unbroken chain of waterways, comprising the Lower Slave river, Great Slave lake and Mackenzie river to its mouth at Mackenzie bay on the Arctic ocean. The distance by water from Clearwater river to the Arctic coast is 1,662 miles.

From Norman on the Mackenzie river, traffic goes by Bear river to Great Bear lake, and by this route water transportation service is supplied to many mining properties, including the Eldorado gold mines at Labine Point, which is famous as a large producer of radium. Great Bear lake is the fourth largest lake on the continent.

The boats on the Mackenzie river have a draft of from 2 to 4 ft. and a capacity of from 70 to 225 tons. This shallow draft is necessary principally because of bars at the entrances to the large lakes. The season of navigation begins at Waterways about May 15th and the boats follow the ice down the river, reaching Aklavik at its mouth about June 17th. The last boat leaves for the south about September 1st, reaching Waterways early in October.

**Fig. 5—Peterborough Lift Lock, Trent Canal.**

During recent years there has been a considerable development of water traffic along the Mackenzie river, and since 1930 the Department of Transport has furnished a skeleton buoy and beacon service along this route, which is being increased as necessity requires.

### Principal Waterways Development 1887 and 1937

Table II gives a schedule of Waterways Development in Canada, 1887 and 1937, which shows clearly the facilities on the principal water transportation routes in 1887 and also in 1937.

On the routes shown in the schedule, the St. Andrews lock is under the Department of Public Works, while on the Mackenzie river no important development has been carried out. All the other developments are now under the Department of Transport, the St. Lawrence Ship channel having been under the late Department of Marine and the balance under the former Department of Railways and Canals, both of which are now merged in the Department of Transport.

### Traffic Carried and Cost to the Dominion

There are available very complete statistics of the traffic and expenditures on the canals under the old Department of Railways and Canals, and these comprise practically all the important inland waterways. Table III gives a schedule of Canal Traffic and Expenditures, which shows for each year 1887 to 1936 the traffic carried by these canals, the expenditures made, and the revenues received. The drop in revenues shown in 1904 is due to the abolition of canal tolls at that time, and the indirect revenues from canals since that date have been received principally from hydraulic and land rents. The indirect revenue of Canada for inland waterways development is almost incalculable, as the economical transportation afforded by water carriage is a primary factor in the industrial development of eastern Canada, and the agricultural development of western Canada.

The best index of the natural growth in waterways traffic, that is increased traffic not the result of improved facilities, is probably furnished by the St. Lawrence river canals. These waterways had a 9-ft. draft available in 1887 and during 1904 through navigation with a 14-ft. draft was furnished. They are not influenced materially by the heavy United States bulk freight traffic in coal and ore on the Great Lakes. Since 1904 there have been no major improvements between Montreal and Lake Ontario, nevertheless the traffic which amounted to 1,427,316 tons in 1904, that is with 14-ft. navigation, had increased to 8,411,542 tons in 1928, and this pre-depression maximum was almost equalled in 1936 with 8,288,416 tons. The traffic through the Welland canal has shown a correspondingly steady increase, being approximately equal in value to that of the St. Lawrence canals until 1930, when the improved facilities due to the opening of the Welland Ship Canal gave it a further decided increase. The construction of the St.

Fig. 6—"S.S. Distributor" at Aklavik, MacKenzie District.

Lawrence waterways, for which a treaty has been negotiated with the United States of America (subject to ratification by both countries), would enable full advantage to be taken by through traffic of the facilities provided by the Welland Ship Canal and a further corresponding increase in Welland Ship Canal traffic could then be expected.

Traffic through the Canadian Sault Ste. Marie canal reached a maximum of 42,699,324 tons in 1914 but since that date, owing to the diversion of traffic to the new American canal, it has only amounted to comparatively moderate proportions.

Traffic through the various secondary canals reached a maximum of 1,507,879 tons in 1910, and since then has shown a falling tendency with a moderate recovery from the low of 365,338 tons in 1933 to 467,692 tons in 1936.

Passenger traffic on canals reached a maximum of 320,574 passengers during 1910 and since then has fallen

Table II
Waterways Development in Canada—1887 and 1937

| Inland waterways | Location | 1887 | | | 1937 | | |
|---|---|---|---|---|---|---|---|
| | | Locks | | Normal depth | Locks | | Normal depth |
| | | Length | Width | | Length | Width | |

off to a maximum of 38,493 in 1933 with recovery to 59,645 in 1936.

During the fifty years from 1887 to 1936, inclusive, the Dominion Government spent, through the Department of Railways and Canals, $199,213,819.36 on capital account for canals, $77,960,589.72 for maintenance and operation and received revenues amounting to $25,087,449.16.

During the same period about $68,000,000 was spent on improving the St. Lawrence River ship channel which, now, on account of increased depth required by the larger vessels navigating it, extends from Father Point to Montreal instead of from Quebec to Montreal as in 1887. Of this amount, $56,684,054.14 has been spent during the period July 1st, 1904, up to March 31st, 1936, that is since the ship channel was taken over from the Department of Public Works.

The St. Andrews lock and dam was built by the Department of Public Works at a capital cost of $1,569,776.99 to March 31st, 1936. During 1936, 10,063 tons of freight and 2,250 passengers were carried on this route.

### Special Features of Great Lakes Traffic

All statistics bring out prominently, that, in the Lake traffic, three great classes of freight predominate, viz. ore, coal and grains. These are shipped in bulk and to them must be added some other classes also handled in bulk. In effect, bulk freight now constitutes 98 per cent of the total, and the peculiar nature of this traffic has resulted in special developments which are to be seen nowhere else in the world. To give some idea of these, it need only be stated that no less than 12,508 tons of ore have been loaded into one vessel in the short space of sixteen and a half minutes. The same cargo of 12,508 tons was unloaded in

Table III
Canal Traffic and Expenditure—1887 to 1936

| Year | Freight Tons | | | | | Number of passengers | Expenditures (Exclusive of St. Andrews lock and dam) | | |
|---|---|---|---|---|---|---|---|---|---|
| | St. Lawrence | Welland | Sault Ste. Marie (Canadian lock only) | Other Canals, (Including St. Andrews lock and dam) | TOTAL | | Capital expenditure | Operating and maintenance cost | Revenue |
| 1887 | 886,982 | 777,918 | | 926,790 | 2,591,690 | 82,914 | $ 1,783,698.16 | $ 549,944.52 | $ 321,784.88 |

*Canal tolls abolished.

three hours and five minutes. Loading at the rate of 5,000 tons per hour is common. Vessels of the self-unloading type are used in the coal trade, and coal is loaded at rates up to 3,100 tons per hour. In loading grain an exceptionally fast rate was achieved at Port Arthur, where 355,000 bushels were loaded in five hours. Other figures are 130,000 bushels in one hour at Fort William, and 150,000 in seventy minutes (2,143 per minute) at the same point.

The boats plying in the bulk trade, on the Great Lakes, have steadily increased in size, and the largest vessels now carry 15,000 to 16,000 tons. Such vessels have a length of 633 ft. and a beam of 70 ft. and the number of 600 footers is constantly increasing and is now well over 300. Deck hatches are placed at 12-ft. or 24-ft. centres, the large boats having 36 or 38 hatches at 12-ft. centres. The machinery is right aft, and is usually steam, though motor vessels are increasing in number.

At the opening of the Welland Ship Canal, August 6th, 1932, the S.S. *Lemoyne*, 633 ft. long, 70 ft. beam, carried 530,000 bushels of grain or 15,900 tons, with a draft of 19 ft. 6 in. through the canal. Figures 2 and 3 refer to this particular movement.

During recent years there has been a very large development in the movement of gasoline and oil and package freight, both through the St. Lawrence River canals and on the Great Lakes. On account of the accompanying hazard gasoline and oil can be shipped much more cheaply by water than by rail while the extension of the area tributary to the waterways has been increased many times by motor transportation, thus extending this advantage to a much larger volume of package freight. Fifty years ago, in 1887, on the St. Lawrence canals 631,997 tons of freight moved east and 254,985 tons moved west or almost 3 to 1, while last year 1936, 4,093,041 tons of freight moved east, and 4,195,371 tons moved west, that is, the large wheat export moved amounting to 2,354,877 tons last year is more than balanced by upward freight.

### Conclusion

In a continental country such as Canada the importance of waterways in its development can hardly be overestimated. The great development of the prairie provinces is based for the provinces of Manitoba and Saskatchewan entirely, and to a lesser extent for Alberta, on the Great Lakes and St. Lawrence river. Without these waterways and their facilities the development of the western plains would have been impossible. Now the great waterways are lending their aid in the mining explorations of the Precambrian shield which covers so much of this country.

# Hydro-Electric Progress

*J. T. Johnston, C.E., M.E.I.C.,*
*Controller, Dominion Water and Power Bureau, Surveys and Engineering Branch, Department of Mines and Resources, Ottawa.*

**Fig. 1—Chaudiere Falls, Ottawa River, Site of First Hydro- Electric Installation in 1882. Present Installation 109,000 hp.; Plants Both Sides of River.**

At the World Power Conference held in Washington in September last, it was well said that—"Power has become the most efficient tool of the machine age, enormously lessening manual labour and quickening and rendering more efficient almost every productive activity." In Canada this basic tool is hydro power. Low-cost power has been Canada's key both to industrial progress and to the domestic comfort and well-being of its people.

This Semicentennial Celebration of The Engineering Institute of Canada affords a fitting opportunity to review the development of this basic instrument throughout the past fifty-year period. The opportunity is particularly appropriate inasmuch as the life of The Engineering Institute of Canada and its predecessor the Canadian Society of Civil Engineers covers almost the entire life of modern electricity.

Nature has been generous in its allotment and distribution of these water-power resources throughout the Dominion. The wide domain, favourable topography, ample and well distributed precipitation, and innumerable lakes and rivers all combine to provide a wealth of water-power resources which are capable of furnishing a dependable flow of low-cost hydro-electric energy to practically every centre of population in the Dominion and for the development of the industries of mine and forest in our great hinterland. This widespread availability of a low-priced power resource has been the basis of the remarkable development of the past fifty years and in this period has brought Canada from almost a purely agricultural country to one of outstanding industrial importance.

## HISTORICAL OUTLINE PRIOR TO 1887

Before proceeding with an outline of the growth of hydro-electric development and utilization in Canada during the past fifty years, it is desirable to sketch briefly the progress which had been made, prior to that period, in the knowledge and utilization of the two primary factors, electricity and water power.

### Electricity

The discovery of electro-magnetic induction was announced by Faraday in 1831 and led to the construction of alternating current dynamos. Practical progress was slow and it was over twenty-five years before these alternators were put to practical use for the arc lighting of lighthouses. At that time most electricians were accustomed to direct currents, so far as these were available from electro-chemical cells, and although a number of brilliant minds were delving into the theory of alternating currents the majority were thinking in the terms of direct currents and were awaiting a satisfactory generator. This was provided, in 1872, by the Gramme direct current dynamo. The fact that a dynamo would function as a motor if supplied with current was observed the following year.

The chief public familiarity with electricity in these early years was for lighting but, admirable though the arc lamp was, it was realized that a smaller and less intense illuminant was necessary. However, it was not until 1880 that an incandescent lamp was evolved which could be manufactured on a commercial basis. This lamp gave rise to the central station constructed to furnish power for lighting and, as in the daylight hours battery charging was the only load available, an impetus was provided for the development of motors and other devices for the daytime use of power. The first commercial electric tramway opened in 1881.

With so many minds engaged on the problem, logical conceptions of the magnetic circuit began to take shape and, about 1886, electrical progress began to evolve as an exact science. Electrical engineers began to acquire knowledge of the element with which they were dealing and to adapt other machines and materials to their needs.

The high speed necessary for dynamo driving led to the development of high speed prime-movers and we read that in 1887—the beginning of the period we are reviewing—Parsons produced a small steam turbine-dynamo set which was used to light the Exhibition at Newcastle, England.

While direct current was more popular at this time, the alternator had powerful supporters, particularly on this continent, and there were many alternating systems of lighting.

In 1887 then, although much ground work had been accomplished, the practical achievements were not yet remarkable. A 500 hp. dynamo was a colossus; transmission was restricted to two or three miles; aluminum was an interesting laboratory material available in small quantities only and at great expense, the Hertzian wave, Roentgen ray, wireless, Diesel engine and a great many other necessities of nowadays existence had not yet been heard of. In fact, in 1887, electricity was more or less confined to the telegraph and cable, a few telephones, a small but growing lighting business and a few electric tramways.

### Hydro Power

Water has been used as a source of energy since the earliest times. In early Canadian settlement, long before the advent of electricity, the use of small heads on rivers and streams throughout the settled areas, by means of wooden water-wheels of various design, formed the driving power for the operation of saw mills, grist mills, and other local industries. The earliest known development was made about 1607 by the early French settlers to drive a small mill near Annapolis Royal in Nova Scotia at the mouth of the Lequille river.

Even today we find large and important industries located in areas in which they were originally established to utilize the power of some now almost forgotten creek. In Canada, early routes of travel were by waterway and, as was natural, early settlements grew up on these waterways and promptly availed themselves of any nearby fall to operate local industries.

When the dynamo was first invented it was quickly realized that water turbines, which had already been developed, were extremely suitable for their operation and the hydro-electric relationship was early established. Fifty years ago there were already a number of hydro-electric plants in Europe and the United States whilst

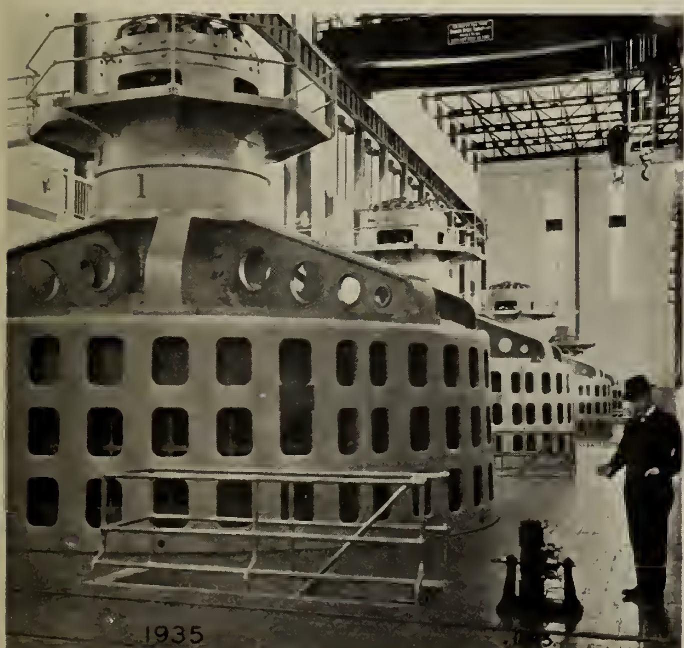

**Fig. 2—1.6 hp. Dynamo, Installed 1885, Compared with Modern 34,000-hp. Generators, Chelsea Plant, Gatineau Power Company.**

a beginning had been made in Canada. The earliest recorded utilization was the lighting of Young's saw mill at Ottawa in 1882.

In these early days electrical power transmission was not available for more than a mile or so and many engineers still favoured tele-dynamic, hydraulic or pneumatic means of transmission. It was not until 1891 that an experimental transmission of 300-hp. 3-phase alternating current at 16,000 volts (later raised to 30,000 volts) for a distance of 112 miles was made in Germany and drew the comment in an electrical journal of the time that "Since the transfer of work by electrical means has become an actual fact, the question of the transmission of power to great distances, especially by the use of remote water-powers comes more and more to the front." Though this comment was made in 1891 there

**Fig. 3—De Cew Falls, Welland Canal, in operation 1898. Installed Capacity now 45,000 hp. H.E.P.C. of Ont.**

still remained much to be done to develop reliable equipment capable of dealing with high voltages and, step by step, transmission voltages and distances gradually increased.

### OUTLINE OF GROWTH—1887-1937

Turning to the actual fifty-year period under review, it has been noted that, in the early years, interest was developing in the application of hydro power to the generation of electricity.

By 1887, public distribution was in progress in Ottawa, Cornwall, Peterborough, Sault Ste. Marie and Pembroke in Ontario and in Quebec and Hull in Quebec

During the period 1887-1900, distribution of hydro-electric power at generator voltage continued where conditions were favourable. In 1893 the International Railway Company installed two 1,000 hp. units at Niagara Falls to operate its electric tramway and to supply electric light and power for distribution. The following year, 1894, three units of the same size were installed at Montmorency Falls to replace an earlier installation, the power being transmitted for distribution in Quebec city, seven miles distant.

In 1897, following the development of the electrical transformer, the first long distance transmission in Canada and, it is believed, in the British Empire, was initiated when a 1,200-hp. development was completed on the Batiscan river and power transmitted 18 miles at 11,000 volts to Three Rivers, Quebec. This heralded the inauguration of modern hydro-electric development in the Dominion. Other systems soon followed: Montreal received power from Lachine and Chambly; Hamilton, Ontario, from DeCew falls; Victoria, British Columbia, from the Goldstream river and Nelson, British Columbia, from the Kootenay river, all in the year 1898. By the end of 1900, water-power installation had reached a total of 173,000 hp.

The next decade, 1900-1910, witnessed a very substantial increase in development, the installation at the end of 1910 having reached a total of 977,000 hp. This was a net increase for the period of more than 803,000 hp., more than a quarter of which was installed in three

The Queenston Power House of the Queenston-Chippawa Development. Its completed length, to house the ten main units and two service units which it now contains, exceeds 590 feet and operates under a head of 294 feet. If the building were placed in front of the American Falls it would nearly hide them. The total capacity of the development is 550,000 horse power.

hydro-electric stations at Niagara Falls from which power was first transmitted to Toronto in 1906. At Shawinigan Falls the Shawinigan Water and Power Company installed its initial units in 1901, and in 1903 power was transmitted to Montreal supplementing the supply already being received from Lachine and Chambly. Fort William, Ontario, received power from the Kakabeka Falls plant of the Kaministiquia Power Company in 1906 and in the same year the Winnipeg Electric Railway Company brought hydro-electric power to Winnipeg from its plant on the Winnipeg river. Vancouver received its first supply of hydro-electric power in 1904 from the first Coquitlam-Buntzen plant of the Vancouver Power Campany, and the mining district in and around Rossland, British Columbia, was supplied by the West Kootenay Power and Light Company from the Kootenay river in 1906.

The decade 1910-1920 showed an increase in development of 1,538,000 hp., more than sixty-two per cent of which took place in the first four years. The growth in the last six years was retarded by war and post-war conditions The period is notable as marking the commencement of power delivery by the Hydro-Electric Power Commission of Ontario, which took place in October 1910 with the bringing into operation of a line extending from Niagara to Kitchener. The Commission secured its first supply by purchase from plants at Niagara Falls, but in 1914 commenced the production of power by building a small plant at Wasdells Falls which was quickly followed by others and in 1917, construction was begun on the great Chippawa-Queenston project, from which power was first delivered in 1922. The installations in the period 1910-1920 included substantial additions to existing stations at Niagara Falls, Shawinigan Falls and elsewhere, while several large new undertakings were completed including developments at Cedars rapids and at St. Timothee on the St. Lawrence, at Grand'Mere on the St. Maurice, in the Lake St. John district in Quebec, at Pointe du Bois on the Winnipeg river and on the Jordan river in British Columbia.

In the next decade, 1920-1930, water-power development far outdistanced anything that had gone before. In this ten-year period, installations totalling more than 3,609,000 hp. were brought into operation. Among the many developments included in this total were such large stations as the Queenston plant of the Hydro-Electric Power Commission of Ontario with 560,000 hp., the 495,000-hp. plant of the Duke-Price Power Company on the Saguenay river, the three Gatineau river plants of the Gatineau Power Company with installations totalling 436,000 hp., the 120,000-hp. plant of the Shawinigan Water and Power Company at La Gabelle on the St. Maurice, the Great Falls plant of the Manitoba Power Company on the Winnipeg river with 168,000 hp., two new plants of the West Kootenay Power and Light Company on the Kootenay river in British Columbia totalling 135,000 hp., the 90,000-hp. plant at High Falls of the MacLaren Quebec Power Company on the Lievre river, the 47,000-hp. plant of the British Columbia Power Corporation at Ruskin on the Stave river, the 42,000-hp. plant of the Churchill River Power Company at Island Falls, the 54,000-hp. Alexander development on the Nipigon river of the Hydro-Electric Power Commission of Ontario, and many others.

Finally in the period 1930-1937, development fell under the influence of conditions brought about by the world-wide economic depression. This period witnessed the initiation of very few new developments of magnitude but in these six years a number of large undertakings, commenced before the depression, were brought to completion. The total increase in installation was 1,820,000 hp. including such developments as the 260,000-hp. plant of the Alcoa Power Company on the Saguenay river, the 224,000-hp. plant at Chats Falls on the Ottawa river jointly owned by the Hydro-Electric Power Commission of Ontario and the Ottawa Valley Power Company, the 330,000-hp. development of the Ontario Government at the canyon on the Abitibi river, the 400,000-hp. plant of the Beauharnois Light, Heat and Power Company on the St. Lawrence, the Rapide Blanc plant of the Shawinigan Water and Power Company on the St. Maurice of 160,000 hp., the 136,000-hp. Masson plant of the MacLaren Quebec Power Company on the Lievre river, the 57,000-hp. Corra Linn plant of the West Kootenay Power and Light Company on the Kootenay river, the Seven Sisters plant of the Northwestern Power Company on the Winnipeg river with 55,000 hp. installed, the Slave Falls plant of the city of Winnipeg on the same

Fig. 5—Coquitlam-Buntzen Development No. 1 of British Columbia Power Corp. first operated 1904, Present capacity 43,500 hp., Head 395 ft.

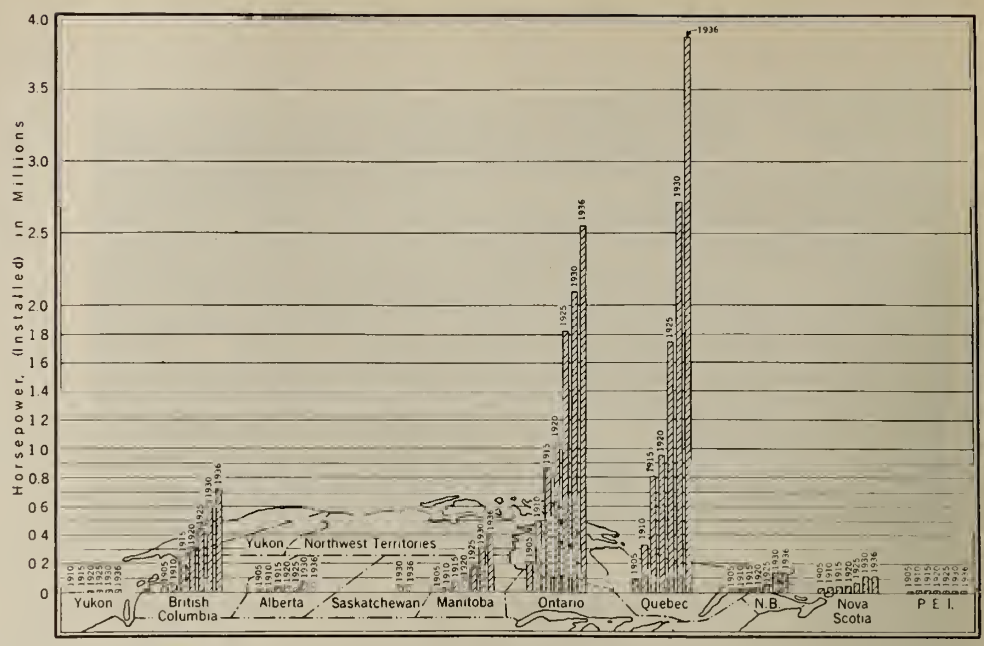

Fig. 7—Growth of Water Power Development in Canada by Provinces.

river with an initial installation of 24,000 hp., and numerous other lesser plants and additions to existing stations.

This brief review gives but a bare outline of the great water-power development that has taken place in the past fifty years. Figures for the earlier years of the period are indefinite but a quite accurate record is available from 1900 onward. This is given in Table I which shows the figures of installation at the end of each year from 1900 to 1936 for each province and for the Dominion as a whole. The growth is also shown graphically by provinces and for the Dominion in Figs. 6 and 7. It is seen that from a modest beginning of 173,000 hp. in 1900 the total had grown at the end of 1936 to a figure of 7,945,000 hp.; a very remarkable achievement.

The series of photographs accompanying this paper are illustrative of typical power installations brought into operation throughout the period under review. Particular attention is called to the photograph showing a row of modern 34,000-hp. vertical type water-wheel driven generators in the Chelsea plant of the Gatineau Power Company and, alongside, the little dynamo of 1.2 kw. used at the same site to operate two arc lamps half a century ago. This photograph which epitomizes fifty years of progress was kindly furnished by John Murphy, M.E.I.C., of Ottawa.

## WATER-POWER DEVELOPMENT IN THE PROVINCES

The growth in the utilization of water-power in the various provinces has been influenced by many factors, the dominating one, of course, being the availability of such water powers to existing and prospective markets. These markets are chiefly the centres of population where domestic, commercial and general manufacturing requirements provide an ever increasing demand for low-cost power, the pulp and paper industry which is by far the largest consumer of power and the mining, metallurgical and electro-chemical industries. It is not proposed to deal with progress in water-power development in the provinces in detail but to give very briefly an indication of the outstanding features.

### British Columbia

Water-power development in British Columbia has grown up chiefly in the Victoria, Vancouver and Nelson districts although there have been, in addition, substantial installations elsewhere for municipal, pulp and paper and mining purposes. With little more than 9,000 hp. installed in 1900 the total had increased to 64,000 hp. in 1910, to 309,500 hp. in 1920, to 631,000 hp. in 1930 and 719,000 hp. at the end of 1936

The Vancouver and Victoria districts are served by the British Columbia Power Corporation. The Vancouver district has been progressively supplied first in 1904 from the Coquitlam-Buntzen developments on Burrard Inlet, then from Stave Falls in 1912, from the Alouette station in 1927 and finally from the Ruskin station on Stave river in 1930. These five stations have a combined installation of 219 000 hp. The Victoria district received its first power from the Goldstream station in 1898 followed by power from two stations on the Jordan river. The three stations now have an installed capacity of 42,400 hp.

Fig. 8—Pinawa Channel Plant, Winnipeg River, Man. In operation 1906, with 37,800 hp. Winnipeg Electric Co.

In the Nelson and southern boundary district, power is supplied chiefly from four plants on the Kootenay river of the West Kootenay Power and Light Company. From a small beginning in 1897 with a plant of 2,368 hp. at Lower Bonnington Falls additional plants have been progressively added at Upper Bonnington, South Slocan and Corra Linn until at present they have a combined capacity of 226,000 hp. In addition, the city of Nelson has its own plant at Upper Bonnington with a capacity of 6,570 hp.

**Fig. 9—Pointe du Bois Falls, Winnipeg River, Man. City of Winnipeg Plant in operation 1911. Present Capacity 105,000 hp.**

The Fernie and Eastern boundary district is served by the East Kootenay Power Company from two plants, one of 7,200 hp. on the Bull river installed in 1922 and the other on the Elk river with 15,000 hp. installed in 1923. An auxiliary fuel station with a present installation of 12,500 kva. was erected at Sentinel, Alberta in 1927.

Elsewhere in the province, smaller systems or individual developments bring the benefits of hydro-electric power to municipalities and industries. Kamloops, Nanaimo, Revelstoke and Prince Rupert are served in this way, while large pulp and paper mills at Powell river and Ocean Falls and numerous mining centres are also supplied with hydro power.

### Alberta

Hydro-electric development in Alberta began at an early date with a 270-hp. development on the Bow river in Calgary in 1893. No appreciable increase, however, took place until 1911 when the Calgary Power Company brought its first plant into operation at Horseshoe falls on the Bow river with an installation of 20,000 hp. The Company's second plant of 11,600 hp. at Kananaskis falls on the same river followed in 1913 and a third plant also on the Bow came into operation in 1929 with 36,000 hp. The Company also controls a 780-hp. development in Calgary and has a widespread transmission system serving about one hundred municipalities from Edmonton to the United States border. Several other small developments, notably those at Banff and Lake Louise, make up with the Calgary Power Company's plants the total for the province of 71,597 hp.

### Saskatchewan

The only hydro-electric development of note in Saskatchewan is that at Island Falls on the Churchill river where in 1930 an installation of 42,000 hp. was made by the Churchill River Power Company to furnish power to the Flin Flon mining area on the Manitoba-Saskatchewan boundary, distant about 60 miles from the plant. A further unit is being installed in 1937 which will bring the total installation to 61,500 hp.

The southern and populous part of Saskatchewan is one of the few areas in the Dominion where conditions for water-power development are not commercially favourable. As a result, the power needs in this area are met from fuel-power stations.

### Manitoba

Water-power development in Manitoba began in 1900 with an installation of 1,000 hp.; by 1910 this had grown to 38,800 hp., to 85,300 hp. in 1920, to 312,000 hp. in 1930 and at the end of 1936 had reached a total of 393,000 hp.

The first development, one of 1,000 hp. on the Minnedosa river, was made in 1900. This was operated seasonally, usually from April to November, and in conjunction with a steam station served the city of Brandon. The plant has not been used since 1924.

In Winnipeg, fuel power supplied the needs of the community from 1892 until 1906 when the first hydro-electric plant was brought into operation at Pinawa on the Winnipeg river with an installation of 37,800 hp. This plant of the Winnipeg Electric Company inaugurated a programme of development on the Winnipeg river which has not only met the expanding power needs in Winnipeg but has been extended to serve almost the entire southern part of the province and the mining district in central Manitoba.

The second plant came into operation in 1911 when the city of Winnipeg completed an initial installation of 26,000 hp. at Pointe du Bois to which additions were made from time to time until in 1926 the plant reached its ultimate capacity of 105,000 hp. In 1922 the Winnipeg Electric Company through a subsidiary brought into operation a development at Great Falls which reached its final installed capacity of 168,000 hp. in 1926. Through another subsidiary the company's third development at Seven Sisters Falls commenced operation in 1930 with an initial capacity of 55,000 hp.; the ultimate installation to be 225,000 hp. In the next year the city of Winnipeg's

**Fig. 10—Stave Falls, Stave River, B.C. Completed 1912. Present installed Capacity 77,500 hp. B.C. Power Corp.**

second plant at Slave Falls started delivery of power with a capacity of 24,000 hp. This is being enlarged to 36,000 hp. in 1937 and the plant has a designed capacity of 96,000 hp.

In the north-eastern part of the province the Gods Lake Gold Mining Company in 1935 completed a 1,900-hp. installation at Kanuchuan rapids on Island Lake river to serve its mining property with power.

Power distribution in Winnipeg and its environs is carried out by the city of Winnipeg and the Winnipeg Electric Company. Elsewhere in the province the Manitoba Power Commission, created in 1919, maintains a widespread and growing transmission system. The power supply for this system is mainly derived by purchase from the plants on the Winnipeg river supplemented by a small hydro plant of 125 hp. at Minnedosa and several small fuel plants.

Fig. 11—Cedars Rapids, St. Lawrence River, Que. M.L.H. and P. Co. In Operation 1914. Present installed Capacity 197,400 hp.

### Ontario

Water-power has been utilized in Ontario since the days of pioneer settlement but it is only during the present century that extensive development has taken place. In 1900 the total installation in the province had reached a figure of about 54,000 hp., much of which was applied mechanically in many small industrial establishments. The stimulus of electrical development increased this total to 491,000 hp. in 1910, and the figures rapidly grew to 1,057,000 hp. in 1920, to 2,088,000 hp. in 1930 and in 1936 had reached a total of 2,562,000 hp.

In southern Ontario many of the cities and towns received their early supplies of electric energy from fuel-power plants, as hydro-electric plants were limited in scope until the advent of long distance transmission.

At Niagara Falls all the early developments were made by private companies with most of the power being exported to the United States. The Canadian Niagara Power Company's plant came into operation in 1904 with 10,250 hp. and with later enlargements reached an ultimate capacity of 121,000 hp. The Ontario Power Company's plant followed with an initial installation of 34,800 hp. in 1905, later to reach a total of 208,200 hp. Then the Toronto Power Company brought its plant into operation in 1906 and following systematic additions reached a total installed capacity of 164,500 hp. Adjacent to Niagara on the Welland canal a subsidiary of the Dominion Power and Transmission Company had brought its plant at DeCew falls into operation in 1898 with 3,000 hp., later to reach a total of 45,000 hp. Power from these plants served a limited area in Ontario including the city of Hamilton and certain municipalities in the Niagara peninsula with service eventually being extended to Toronto in 1906.

In 1906 the Hydro-Electric Power Commission of Ontario was established—a public ownership enterprise which was to become one of the greatest power distributing undertakings in the world. From then on, the Commission's activities dominated all others in southern Ontario. Transmission lines were constructed and distribution to the municipalities commenced in the autumn of 1910, the power being purchased from Niagara. Fuel power stations were rapidly superseded as hydro-electric energy spread throughout the south-western peninsula from Toronto to Windsor. The Commission completed its first development at Wasdells Falls on the Severn river in 1914, the Big Chute plant on the Severn was purchased in the same year, the Eugenia plant on the Beaver river was completed in 1915, plants on the Trent, Muskoka and South rivers were taken over in 1915 and 1916, control of the Ontario Power Company at Niagara was acquired in 1917, the great Queenston enterprise at Niagara was started in the same year, brought into operation in 1922 and finally completed with an installed capacity of 560,000 hp. in 1930; the Toronto Power Company's plant was purchased in 1922, that of the Dominion Power and Transmission Company in 1929, the Chats Falls plant on the Ottawa river was brought into operation in 1930-31 with an installed capacity of 112,000 hp. and numerous other plants were either built or acquired by purchase on the Muskoka, South, Mississippi, Madawaska

Fig. 12—Iroquois Falls, Abitibi River, Ont. Installed 1914. Present Capacity 28,000 hp. Abitibi P. and P. Co.

Fig. 13—Eugenia Falls, Beaver River, Ont., H.E.P.C. of Ont. Installed 1915. Present Capacity 8,500 hp. Head 549 ft.

and other rivers. At the present time the Commission has, in that part of the province south of North Bay, almost a monopoly of power distribution with a total installation of more than 1,190,000 hp. supplemented by a substantial amount of purchased power from companies in Quebec province.

Apart from the Commission's plants in southern Ontario there are a number of municipally and privately owned plants such as those of the town of Orillia on the Severn and Gull rivers, the town of Almonte on the Mississippi, the town of Campbellford on the Trent, Parry Sound on the Seguin river, the Canadian Niagara Power Company at Niagara Falls, the Ottawa Electric Company on the Ottawa river, the St. Lawrence Power Company at Cornwall and several others

In northern Ontario, hydro-electric development has taken place chiefly in connection with mining and the pulp and paper industry. While much of this development has been made by private enterprise, the activities of the Hydro-Electric Power Commission have been increasingly extensive both in plants it has itself constructed and those it has built and operated in behalf of the Ontario Government. On the Nipigon river the Commission has two plants, Cameron Falls brought into operation in 1920 and later enlarged to 75,000 hp. and Alexander Falls with 54,000 hp. completed in 1930. Power from these plants goes to Fort William and Port Arthur and also to the gold-mining district east of Lake Nipigon. In the Sudbury district, three plants totalling 16,900 hp. on the Wanapitei river were acquired in 1929 and have since been operated by the Commission to serve Sudbury and the adjacent copper-nickel mining area with power. Similarly in 1933 the Ontario government acquired a plant under construction at the canyon on the Abitibi river. This was brought into operation by the Commission as agent for the government in the same year and completed in 1935 with an aggregate installation of 330,000 hp. Power goes from the canyon plant to Sudbury and to the mines in the Porcupine and Kirkland Lake mining areas. The Commission also constructed and operates plants for the government at Ear falls on the English river and at Rat rapids on the Albany river to supply power to adjacent gold-mining areas. The Ear Falls plant of 5,000 hp. was brought into operation in 1929 and is being doubled in 1937. The Rat Rapids station, built in 1934-35 and enlarged in 1936, has a total capacity of 2,950 hp.

Under private enterprise the principal developments in northern Ontario are as follows: At Kenora at the outlet of Lake of the Woods a plant established in 1892 and replaced in 1906 was purchased by the Keewatin Power Company in 1922. The plant was enlarged in 1923-24 and a second station built in 1924-25; the combined installation being 30,875 hp. The power is sold for municipal purposes and for the operation of paper mills. At Fort Frances the Ontario and Minnesota Power Company built a plant on the Rainy river in 1910 where the installation now aggregates 15,350 hp. and later in 1927-28 constructed three plants on the Seine river with capacities totalling 36,500 hp., this power is largely used to supply pulp and paper mills. At Fort William the Kaministiquia Power Company developed power at Kakabeka Falls in 1906 and has now an installed capacity of 35,000 hp. At Sault Ste. Marie the Great Lakes Power Company acquired a development first installed about 1901 and has carried out reconstruction which gives the plant a present capacity of 29,200 hp. The company also has a plant of 22,000 hp. on the Michipicoten river completed in 1930 and one of 10,000 hp. on the Montreal river brought into operation in 1937. Power is used for municipal supply and for steel and paper mills at Sault Ste. Marie, also for mining in the Michipicoten and Goudreau districts. The International Nickel Company has five stations on the Spanish and Vermilion rivers aggregating 63,100 hp. These were progressively installed from 1905 to 1929 and serve the company's mines and smelters with power. The Canada Northern Power Corporation has nine stations on the Montreal, Metabetchouan and Mattagami rivers with an aggregate installation of 106,340 hp. serving the mines in the Cobalt, Gowganda, Porcupine, Kirkland and Larder Lake areas. The first of these developments was made in 1910 and the last in 1930. The Abitibi Power and Paper Company has eight plants, three on the Abitibi river, two on the Sturgeon, one on the Spanish, one on the Mattagami and one at Sault Ste. Marie with installations totalling 176,340 hp. The Spruce Falls Power and Paper Company has a 2,500-hp. plant on the Kapuskasing river and a 56,250 hp. plant at Smoky Falls on the Mattagami river completed in 1928.

### Quebec

Water-power development in Quebec exceeds that of any other province. As in other parts of eastern Canada, water powers have been utilized since the early days of settlement but the great growth has occurred in the present century. In 1900 the installed capacity had reached a total of almost 83,000 hp. This grew to 335,000 hp.

Fig. 16—Cameron Falls, Nipigon River, Ont. H.E.P.C. of Ont. Installed 1920. Present Capacity 75,000 hp.

in 1910, to 955,000 hp. in 1920, to 2,718,000 hp. in 1930 and at the end of 1936 aggregated 3,883,000 hp.

Practically all this development has taken place in the St. Lawrence river watershed, the major undertakings being on the St. Lawrence itself, on the Ottawa and its principal tributaries, on the St. Maurice, the Saguenay and its tributaries, and on the Richelieu and St. Francis rivers.

In the city of Montreal and on Montreal Island, power is distributed by Montreal Light, Heat and Power Consolidated from plants of its own and from power purchased from other companies. Its first plant at Lachine came into operation in 1898 with 10,000 hp. later enlarged to 15,800 hp., the Chambly plant on the Richelieu followed in 1901; this has a present capacity of 31,600 hp.; then the Soulanges plant was installed in 1906 with 5,350 hp. later increased to 16,050 hp. and finally the Cedars plant on the St. Lawrence came into operation in 1914 with 97,200 hp., later to be enlarged to 197,400 hp. Latterly the Lachine and Soulanges plants have been inactive.

Other plants in the vicinity of Montreal selling power to Montreal Light, Heat and Power Consolidated are those of the Canadian Light and Power Company at St. Timothee on the St. Lawrence with 28,000 hp. installed 1911-15, the Montreal Island Power Company at St. Vincent de Paul on Des Prairies river with 45,000 hp. installed 1929-30 and the great Beauharnois plant of the Beauharnois Light, Heat and Power Company on the St. Lawrence with a present capacity of 400,000 hp. installed 1932-35.

In the territory along the north shore of the St. Lawrence from Montreal to Murray Bay and south of the St. Lawrence from the St. Francis river easterly to Riviere du Loup, power development and distribution are largely in the hands of the Shawinigan Water and Power Company and its subsidiaries. The company's first development at Shawinigan Falls on the St. Maurice commenced delivery of power from an installation of 20,000 hp. in 1902; transmission to Montreal followed in 1903. Installations at Shawinigan Falls have been systematically increased until at the present time they aggregate 278,500 hp. In 1928 the 176,000-hp. plant of the Laurentide Power Company at Grand'Mere was acquired and enlarged in 1931 to 188,500 hp. The La Gabelle plant was brought into operation in 1925 with 120,000 hp. and enlarged in 1931 to 152,000 hp. Finally Rapide Blanc, the fourth development on the St. Maurice, was brought into operation in 1934 with an installed capacity of 160,000 hp. The company also owns or controls a 22,200-hp. plant on the Batiscan river completed in 1926, two on the Montmorency and one each on the Jacques Cartier, Chaudiere, Ste. Anne de Beaupre, du Sud and La Fourche rivers with an aggregate installation of 43,750 hp.

To the south of the St. Lawrence a considerable area lying between the Richelieu and St. Francis rivers is served by the Southern Canada Power Company incorporated in 1913. Of the company's seven hydroelectric stations aggregating 60,780 hp., the two largest are on the St. Francis river at Drummondville with 19,500 hp. and at Hemming Falls with 33,600 hp.

In the Saguenay-Lake St. John district the first development took place on the Au Sable river at Jonquiere in 1906 and by 1923 nearly 85,000 hp. had been developed in the region chiefly for the manufacture of pulp and paper. Then followed the great development on the

Fig. 17—St. Margaret Bay, N.S. Tidewater Plant, N.S. Power Comm. Installed 1922 with 6,900 hp.

Fig. 18—Musquash Development of N.B. Electric Power Comm. Completed 1922. 11,100 hp.

Saguenay. In 1925 the Duke-Price Power Company (now the Saguenay Power Company) brought its plant at Isle Maligne into operation with 360,000 hp., later to be enlarged to 495,000 hp. and in the period 1931-1934 the Alcoa Power Company completed a development of 260,000 hp. at Chute-à-Caron. This power supplies pulp and paper mills in the district, the reduction works of the Aluminum Company of Canada at Arvida and a considerable portion is transmitted to Quebec where it supplements the supply of the Shawinigan Water and Power Company.

On the Metis river to the south of the St. Lawrence the Lower St. Lawrence Power Company has a plant of 9,600 hp. brought into operation in 1923 and enlarged in 1930. The company serves a territory extending from Trois Pistoles to Matane and down the Matapedia valley to Matapedia.

In the Ottawa valley and in the territory immediately west and north of Montreal, power supply is mainly in the hands of the Gatineau Power Company. The company was incorporated in 1925 and, in addition to acquiring a number of developments already in operation, immediately commenced construction of three large developments on the Gatineau river at Chelsea, Farmers and Paugan Falls. These were brought into operation in 1927-28 and later enlarged to an aggregate capacity of 470,000 hp. Two stations on the Ottawa river in Hull were acquired with installations totalling 36,600 hp., one on the same river near Bryson which has a present capacity of 51,400 hp. and another on Gordon creek at Temiskaming where 24,000 hp. is developed. In addition to these there are ten small plants on the Rouge, Blanche, North and other rivers which tie into the system furnishing power to most of the towns and villages of the lower Ottawa valley. The company's principal customers are the Canadian International Paper Company with large mills at Gatineau, Temiskaming and Hawkesbury and the Hydro-Electric Power Commission of Ontario.

In the same territory the MacLaren-Quebec Power Company has two large plants on the Lievre river, 120,000 hp. at High Falls and 136,000 hp. at Masson installed in 1930 and 1933 respectively. These plants furnish power to pulp and paper mills at Buckingham and Masson and to the Hydro-Electric Power Commission of Ontario. The Commission also receives the entire output of the 112,000-hp. plant of the Ottawa Valley Power Company at Chats Falls on the Ottawa river installed in 1931-32.

The mining district in the north-western part of the province is served by the Canada Northern Power Corporation from a plant on the Quinze river with 40,000 hp. installed in 1923 and 1928.

The largest municipally owned enterprise in the province is that of the city of Sherbrooke with five plants on the St. Francis and Magog rivers totalling 18,050 hp. These installations were progressively made from 1888 to 1929.

A very material contribution to hydro-electric development and the conservation of water-power resources in the province of Quebec has been made by the Quebec Streams Commission by its policy of promoting the creation of storage reservoirs for the purpose, mainly, of increasing the minimum flow of power rivers in the interest of primary power production. The Commission's reservoirs in the St. Maurice watershed have practically trebled the minimum flow in the power reach of the river and similar benefits have accrued on the Gatineau, Lievre, St. Francis, Ste. Anne de Beaupre, Metis and other rivers where reservoirs have been created.

### Prince Edward Island

The water-power resources of Prince Edward Island are not large, the rivers are small and water-power develop-

Fig. 19—Queenston Development, Niagara River, H.E.P.C. of Ont. In Operation 1922. Capacity now 560,000 hp.

Fig. 20—La Gabelle, St. Maurice River, Que. S.W. and P. Co. Installed 1924. Present Capacity 152,000 hp.

Fig. 21—Isle Maligne, Saguenay River, Que. Installed 1925 by Duke-Price Power Co. Capacity now 495,000 hp.

Fig. 22—Chelsea and Farmers, Gatineau River, Que. In Operation 1927. Capacity now 232,000 hp. Gatineau Power Co.

ment is mainly used for the operation of local mills. Eight hydro-electric plants have been built but only one of these, serving Montague, Georgetown and Cardigan, has an installation in excess of one hundred horse-power, the two stations on the Montague river having a combined capacity of 245 hp. The total water-power installation in the province is 2,439 hp., having increased to this figure from a total of about 1,500 hp. in 1900.

New Brunswick

Early water-power development in New Brunswick was chiefly in connection with local industries. In 1900 there was a total installation of 4,600 hp.; by 1910 this had grown to 11,200 hp., in 1920 to 22,000 hp., in 1930 to 133,700 hp. and remained the same at the end of 1936.

One of the earliest hydro-electric developments was that of the Maine and New Brunswick Electrical Power Company on the Aroostook river. The first installation of 1,500 hp. was made in 1906 and additions and alterations were made until it reached its present capacity of 11,400 hp. in 1925. The plant is near the international boundary and power is distributed in Canada and the United States.

The largest development in the province is that of the Gatineau Power Company at Grand Falls on the St. John river with an installation of 80,000 hp. The plant was brought into operation in 1928 and units were added in 1929 and 1931. Power is sold chiefly to paper mills at Edmundston and Dalhousie.

In 1918 the New Brunswick Electric Power Commission was created and since that time has taken a major part in the distribution of electrical energy in the more populous parts of the province. A hydro-electric development of 11,100 hp. was completed on the Musquash river in 1922 and a fuel-power station constructed at Grand Lake in 1931 has now a capacity of 16,330 hp. To supplement its supply, the Commission purchases power from private sources.

Among other hydro-electric developments in New Brunswick, the Bathurst Company has a 14,500-hp. plant on the Nipisiguit river, the municipality of Edmundston one of 1,475 hp. on Green river, the Fraser Companies 2,060 hp. on the Madawaska river, the St. George Pulp and Paper Company 4,134 hp. on the Magaguadavic river and Canadian Cottons Limited 3,500 hp. at Milltown on the St. Croix river.

Nova Scotia

Many small powers were utilized in the pioneer days in Nova Scotia and by 1900 there was a total installed capacity of 19,800 hp. In 1910 this had increased to 31,500 hp., to 37,600 hp. in 1920, to 114,200 hp. in 1930 and 120,700 hp. at the end of 1936.

It is apparent from these figures that most of the growth has taken place since 1920. This has been due chiefly to the activities of the Nova Scotia Power Commission, a public ownership enterprise established in 1919. The Commission's first developments at St. Margaret Bay came into operation in 1922 with 10,820 hp. and was enlarged in 1927 to 15,820 hp., the power being sold in Halifax. Developments followed on East River Sheet Harbour in 1924-25 totalling 11,840 hp., power going to Pictou county and a local paper mill. Three stations were constructed on the Mersey river in 1929 and two others were later acquired and reconstructed, giving a total present capacity of more than 32,000 hp. These installations are primarily to supply a paper mill at Brooklyn but furnish power as well to Liverpool and the surrounding district. A plant of 3,000 hp. on the Tusket

Fig. 23—South Slocan, Kootenay River, B.C. Completed 1928, with 75,000 hp. West Kootenay Light and Power Co.

river near Yarmouth was completed in 1929 and other smaller plants have been built or acquired in other parts of the province. The Commission at present generates about 56 per cent of the electrical energy produced in Nova Scotia.

Next to the Commission, the Nova Scotia Light and Power Company has the most extensive development. Ten hydro and two fuel plants supply its system which extends from Halifax to Windsor and west to Lawrencetown. The White Rock station on Gaspereau river of 1,105 hp. was installed in 1919, the Hemlock Falls station on the Avon river, 2,500 hp. in 1924; the Falls River station, 4,350 hp. in 1928 and the Black River station, 4,500 hp. in 1930. Smaller plants are maintained on the Nictaux, Falls, Bear, Currell, Philip and East rivers and fuel stations at Halifax and Barrington.

Yukon

In the Yukon Territory, the Yukon Consolidated Gold Corporation operates a hydro-electric development near the North Fork of the Klondyke river. The plant was installed in 1911 with 10,000 hp. and enlarged in 1935 to 15,000 hp. Power is supplied to the city of Dawson and for the operation of the gold dredges of the company.

Fig. 24—Grand Falls, St. John River, N.B. In Operation 1928. Capacity now 80,000 hp. Gatineau Power Co.

## GROWTH BY BASIC INDUSTRIES

It is of interest also to make brief reference to the growth of the use of hydro-electric power in certain of the basic industries of Canada during the fifty-year period. It is furthermore indicative of the general interdependence of basic industry and low-priced power. Detailed statistics are not available for the earlier years. Sufficient are available, however, to present a picture of the relationship of hydro power to the industrial growth of the Dominion.

### Central Electric Station Industry

By the end of 1890, three years after the beginning of the fifty-year period, the central electric station industry had achieved a total hydro-installation of only 1,165 hp. This did not represent quite the entire utilization of water power for electric distribution, as in the earliest stages of the industry there was some purchase of hydraulic power from lumber and other mills for the operation of electric generators by central stations. As of the same date, 10,967 hp. were installed in pulp and paper mills and 59,383 hp. or 83 per cent of the total installation, in saw, grist and grinding mills and miscellaneous industrial plants. Probably a very small proportion of the hydraulic installation of the pulp and paper mills and general industrial group was used for electric generation.

At the present time there is a complete reversal in position. Now, 88 per cent of the total installation is developed for central electric station use, and a large proportion of the pulp and paper and other purpose installation also drives electric generators to provide electricity for plant lighting and operation.

In the central electric station industry the capital invested has grown from $401,942,402 in 1918 to $1,459-821,168 in 1935. A consideration of the growth of the industry by five-year periods from 1890 to date, discloses the revolutionary effect upon hydraulic development resulting from the application of electricity to public use. As already stated, the central electric station installation at the end of 1890 was 1,165 hp. or only 16 per cent of the total installation. In the following five-year period, 1890-1895, 39 per cent of all new development was for central station purposes, this proportion increasing to 64 per cent for the second period, 1895-1900, and to 70 per cent for the next period, 1900-1905, before the end of which the central station installation exceeded the combined installation for all other purposes. The proportion rose steadily until, for the last complete period, 1930-35, 97 per cent of all new installation was for central station use. For the year 1936 an even higher ratio obtains.

The production of electricity is now considered a very significant barometer of commercial and industrial conditions. This is illustrated in Fig, 6, the lowest line showing the growth of production of kilowatt hours from hydro central-electric stations during the period 1920-1936. Depressed business conditions in 1921 caused a small decrease in production that year while the pronounced decrease in 1931 and 1932 reflected the much more serious condition brought about by the depression commencing in 1930. The diagram indicates the very substantial increase in production that has taken place in the past sixteen years.

### The Pulp and Paper Industry

The pulp and paper industry increased its newsprint production from 350,000 tons in 1913 to 3,190,599 tons in 1936, a more than ninefold growth. Successive increases in installation are recorded in each of the five-year periods up to the end of 1915 when a peak in growth of direct power installation was reached, apparently largely due to a new policy of organizing an affiliated

| 1935 | 19,309 | 178,453 | 9,069 | 206,831 |

central station company in conjunction with its parent pulp and paper company and in many cases of buying part or all of the power required from existing central stations. Since 1915, while there has been a falling off in new direct power development, there has been steady growth in power demand by the industry, resulting in the development to date of more than 600,000 hp. by the industry itself and the purchase of more than 55 per

**Fig. 27—Island Falls, Churchill River, Sask. Installed 1930. Capacity 42,000 hp. Churchill River Power Co.**

cent of all power sold by central stations for industrial purposes. The total hydro power used in the pulp and paper industry at the present time is in the neighbourhood of 1,635,000 hp.

### The Mineral Industries

The mineral industries have increased in value of product from $10,221,000 in 1889 to $361,394,000 in 1936. The general availability of low-cost hydro energy in ready accessibility to mining centres has been a prime factor in the development of the industry to its present high position in the industrial fabric of the Dominion. Low-cost hydro power has made possible the exploitation of Canada's low grade ore deposits, thus adding immeasurably to the national wealth. While a considerable installation has been placed by the mining industry for direct operation in the course of its development during the past fifty years, here again the practice of forming a power company in conjunction with the mining company and of purchasing power for operation, has been followed. At the present time more than 1,000,000 hp. of hydraulic power is used by the mineral industries.

The foregoing brief comment is indicative of the manner in which the growth in the use of hydro-electric power has kept pace with the growth of the basic industries of the Dominion. It is safe to say the low cost of hydro-

**Fig. 26—Upper Lake Falls, Mersey River, N.S. One of Three Plants Installed 1929 by N.S. Power Comm. Combined Capacity 29,300 hp.**

**Fig. 28—High Falls, Lievre River, Que. In Operation 1930, Capacity now 120,000 hp. McLaren-Quebec Power Co.**

electric energy has been largely instrumental in making possible the remarkable growth of these basic industries.

### Fuel-Electric Power

A review of fifty years of hydro-electric development in Canada would not be complete without some eference to the situation with respect to fuel-electric power development in the same period.

While more than 98 per cent of the electrical energy generated in Canada is from water power nevertheless fuel power plays an important part in certain sections of the country, particularly in the Maritime Provinces and in Alberta and Saskatchewan where native fuels are readily available.

It is not possible to trace the growth of fuel power as applied to the generation of electricity throughout the past fifty years, as reliable statistics only date from the year 1918, following the inception of the annual census of the central electric station industry. However, it is known that many of the early electric generating installations were supplied by fuel power, as they could be quickly installed in the communities to be served and could be readily enlarged to keep pace with the modest growths in load that took place in these early years. With the development of high tension transmission these pioneer fuel stations were largely superseded. This change marked the early growth of the industry in Ontario and Quebec where no native fuels existed and where an abundance of favourably situated water powers stimulated the development and transmission of hydro-electric power and has been a more recent development in Manitoba and Alberta following the development of three very extensive transmission systems.

**Fig. 30—Chute-à-Caron, Saguenay River, Que. In Operation 1931. Present Capacity 260,000 hp. Alcoa Power Co.**

**Fig. 29—Chats Falls, Ottawa River, Ont. Jointly Owned by H.E.P.C. of Ont. and Ottawa Valley Power Co. Operated in 1931. Capacity now 224,000 hp.**

While much of the replacement of fuel stations by hydro power had taken place before 1918, when reliable statistics first became available, certain replacements continued to be made in the subsequent years and had an appreciable effect on the progress of fuel power development from year to year. Table II shows the installed fuel-power capacity in main plant equipment for the years 1918 to 1935 inclusive while Table III indicates the installed fuel-power capacity in equipment auxiliary to hydro-electric stations. The installation in both tables has been classified under the headings: steam reciprocating engines, steam turbines and gas and oil engines.

It is seen that during the period 1918-1935 an increase of 87 per cent took place in main plant equipment in fuel central electric stations while in auxiliary plant equipment the increase was 77 per cent. The figures indicate a gradual reduction in the total installed capacity of steam reciprocating engines and a steadily increasing growth in the capacity of steam turbines and gas and oil engines.

In regard to the average capacity of generating units the 1935 figures indicate in main plant equipment 4,292 hp. for steam turbines, 220 hp. for steam reciprocating engines and 82 hp. for gas and oil engines while in auxiliary plant equipment the corresponding average figures are 3,432, 439 and 178 hp. respectively. These figures illustrate that steam turbines are being utilized where loads of considerable magnitude are encountered. Gas and oil engines are meeting the smaller demands and steam reciprocating engines are falling into disuse.

Among fuel-electric stations generating primary power the outstanding installations are found in Nova Scotia, New Brunswick, Saskatchewan and Alberta.

In Nova Scotia the Seaboard Power Corporation which operates the power plants of the Dominion Steel and Coal Corporation has a 38,760-hp. steam turbine installation in the Sydney - Glace Bay area, the Acadia Coal Company 9,000 hp. in steam turbines at Stellarton, and the Canada Electric Company 19,000 hp. in steam turbines at Amherst.

In New Brunswick the New Brunswick Electric Power Commission has a steam turbine station at Grand Lake with 16,330 hp. installed which delivers power to its transmission line network serving the southern part of the province. The New Brunswick Power Company has a 13,700-hp. steam turbine and a 2,900-hp. reciprocating engine installation in Saint John while the Canadian International Paper Company (New Brunswick) has a 16,750-kw. steam turbine installation at Dalhousie to supplement its hydro supply from Grand Falls.

In Saskatchewan the National Light and Power Company has a 31,265-hp. steam turbine installation at Moose Jaw, the Saskatchewan Power Commission a 27,033-hp. steam turbine installation at Saskatoon, a 3,900-hp. steam turbine and 950-hp. reciprocating engine installation at North Battleford and 6,050-hp. in various internal

Fig. 31—Beauharnois, St. Lawrence River, Que. In Operation 1932. Present Capacity 400,000 hp. Beauharnois Light Heat and Power Co.

Fig. 32—Canyon, Abitibi River, Ont. In Operation 1933. Capacity now 330,000 hp. H.E.P.C. of Ont.

combustion engine plants throughout the province. The city of Regina has a 46,619-hp. steam turbine installation, Canadian Utilities 4,000-hp. in steam turbines at Prince Albert and 4,679-hp. in various internal combustion engine plants. The Dominion Electric Power has 3,780-kva. steam turbo installation at Estevan and 4,360-hp. in internal combustion engines at various stations.

In Alberta the city of Edmonton has an installation of 1,560 hp. in steam engines and 31,100 hp. in steam turbines, the city of Medicine Hat 8,350 hp. in steam turbines, the city of Lethbridge 750 hp. in reciprocating engines and 7,300 hp. in steam turbines and Canadian Utilities 5,300 hp. in steam turbines at Drumheller.

In addition to the fuel stations referred to above, a number of the hydro-electric distributors maintain auxiliary fuel power stations for emergency use. While there is also some use of this equipment during periods of peak demand, its auxiliary nature is indicated by its unit output being only about one per cent of that of the main plant fuel equipment. The largest auxiliary station is the 29,500-hp. Hamilton, Ontario, station acquired by the Hydro-Electric Power Commission of Ontario in its purchase of the Dominion Power and Transmission Company. The British Columbia Power Corporation has a 24,200-hp. steam turbine plant in Vancouver and a 6,000-hp. plant at Victoria. Montreal Light, Heat and Power Consolidated has a 22,000-hp. station at Montreal and the municipality of Winnipeg one of 14,740-hp., the Winnipeg Electric Company maintaining a similar standby of 12,000-hp.

The Calgary Power Company operates two auxiliary plants in Calgary, one of 14,650-hp. and one of 4,500-hp. and a number of smaller stations at various points throughout its transmission area. At Sentinel, Alberta, the East Kootenay Power Company has a steam turbine plant of 13,334 hp. to supplement the output of its Elko and Bull River, British Columbia, hydro plants. The city of Westmount has 10,724-hp. steam turbine equipment in connection with its refuse disposal plant to supplement power purchased from Montreal Light, Heat and Power Consolidated for distribution.

The Associated Gas and Electric Company has a 8,500-hp. station in Halifax, Nova Scotia, and the Moncton Electric Company a 3,600-hp. station in Moncton, New Brunswick.

### Conclusion

In conclusion, it may be said that the extraordinary development of power in Canada during the past fifty years, as briefly reviewed in this paper, has profoundly altered conditions throughout the Dominion. In this relatively short period, indeed, electric energy has so revolutionized our manner of living and has enabled us to develop our natural resources to such an extent that Canada today is scarcely recognizable as the country it was fifty years ago. The development and distribution of this power has brought to more than sixty per cent of our population the boon of electricity for light and for the many conveniences and labour-saving devices which so greatly ameliorate our living conditions today. It has penetrated extensively into our rural districts bringing to farm dwellers the conveniences and comforts already enjoyed by our urban population. It furnishes the low-cost energy so necessary for our basic industries and has enabled Canadian products to attain a prominent place in world export markets. It has brought entirely new communities into being. It has resulted in the direct

Fig. 33—Rapide Blanc, St. Maurice River, Que. In Operation 1934. Installed Capacity 160,000 hp. S.W. and P. Co.

expenditure of more than $1,600,000,000 of capital in power plant and distribution facilities. It has, in fact, been a tremendous factor in our entire national development influencing the growth of our population, our transportation systems, our home markets, our external trade and our national income. Who, fifty years ago, could have foreseen that the crude dynamos of the day would father the vast progeny of machines and facilities we are now using. Who, today, would venture to predict what another half century will bring forth. Canada, however, with her great undeveloped reserves of power is strategically situated to hold and to improve her position in the march of world progress.

*"Canada, in a very special way, may be considered the child of modern engineering. The growth of land, sea and air transport during the last half century, and, above all, the use of hydro-electric power in recent years, have made it possible to build from the scattered colonies of British North America one of the foremost industrial nations of the world."*

*(Vincent Massey, high commissioner for Canada in Great Britain, 1936.)*

*"There could be no better instance of engineering as a factor in nation or empire-building."*

*(Sir Alexander Gibb, President, Institution of Civil Engineers—November 1936.)*

---

Industry in Canada's early days was mothered by necessity and fathered by courageous initiative, and throughout has been fostered by nature, increasingly bountiful. During the fifty years under review the engineer—electrical, mechanical, mining, chemical—must be credited with a contribution that has been a determining factor in manufacturing progress.

The field has been lavish and above all else in value, the sea supplied generously, the mine a rapidly expanding contributor, but the forest has been the stand-by of industry in Canada. The fur trade was its offspring. The earlier settler was enabled to endure adverse conditions because of its beneficence. Shipbuilding, a once leading activity, found in the forest its sturdy materials, the important lumber and wood-using concerns a ready source of supply. The water that furnishes power to its great consumer, the pulp and paper industry, is conserved in its shade. To many manufacturers the forest provides the major raw material and no industry is independent of it.

### IN 1887[1]

Canada was in a period of depression. The gay and prosperous Nineties were not anticipated. Queen Victoria celebrated the fiftieth year of her reign. The Marquess of Lansdowne was Governor-General. John A. MacDonald was returned to power confirming the national policy for the protection of industry. The total revenue of the Dominion was thirty-five million nine hundred thousand dollars. The seven provinces of the Dominion had an income of twelve million nine hundred thousand dollars. The gross value of manufactured products was around four hundred million dollars in 75,000 establishments. During the year 84,526 settlers arrived in Canada, bringing goods valued at nearly four million dollars, Manitoba receiving half the number. Montreal had a population of 200,000, Toronto 66,000, Winnipeg 22,000, and in Vancouver, which had been reduced to ashes the year before, the citizens, numbering about 2,000, were living mostly in shacks and tents. The steam engine and small water powers turned the wheels of industry. Pride of craftsmanship prevailed. The apprenticeship system was universal. The first sulphite paper-making mill in Canada was installed at Merritton in the Niagara Peninsula.[2] The electric light had made its appearance on the streets of Montreal the previous year and was a novelty. There were 13,950 telephones in use in all Canada. The year saw the first C.P.R. transcontinental train from Montreal to Vancouver, and cotton cloth shipped to the Orient. The horse furnished the motive power for the street cars in Montreal, Ottawa and Toronto. The Street Railway Company of Montreal built that year a new stable to accommodate four hundred horses. The winter carnival with its ice palace was an outstanding social event. The tallow candle had all but disappeared and homes throughout the country, except those few contiguous to a gas main, were illuminated by the coal oil lamp. Canning was done at home. The coal oil lantern was in common use. The livery stable flourished and the horse and buggy or cutter were highway transportation de luxe. Highways were not surfaced and sidewalks were of wood. The high-wheeled bicycle, the forerunner of the pneumatic tired safety, was a proud vehicle for both touring and racing. Many men wore whiskers; their favourite head-gear was a bowler hat. The business and professional man wore a boiled shirt and a black string tie. While the crinoline had gone to the attic, red flannels had not been entirely discarded, and the well-dressed woman wore a bustle. The business woman had not arrived. Manual labour earned less than one dollar a day. Wages were paid in cash. Eggs were fourteen cents a dozen, butter was seventeen and one-half cents, and cheese nine and one-half cents a pound. Whisky was five cents a glass. A letter press was standard office equipment. Correspondence was by hand, the typewriter a new-comer. Hydro-electric power was unknown. There was no wireless telegraphy or telephony; no gramophones, kodaks, motion pictures, automobiles, radios, television, aeroplanes, submarines; no adding machines, cash registers, mechanical accounting or teletype; no gas engines, no roller bearings, individual machine drives, high speed steel, arc welding, acid resisting alloys or synthetic resins; no cellophane, no rayon. There were no electric household appliances, no electric refrigerators, vacuum cleaners, toasters, ironers, hot water heaters; no air conditioning, no oil burners, no robots, no electrical eyes. Rugged individualism flourished. Sixty hours was the minimum week's work.

### INDUSTRIAL SEQUENCE SINCE CONFEDERATION[3]

This country has seen twelve eras or industrial cycles since Confederation. The first of five years after the birth of the Dominion was prosperous. There followed seven lean years from 1873 to 1879. Expansion was a trend until '84, when another depression set in, lasting five years. The seven years following '89 saw prosperity return, and for the seventeen years from '96 there was a golden period in manufacturing, which even the brief depression, 1907-08, did not halt. In 1913 many great projects were completed. Since that year conditions have been abnormal. In 1914 industry saw inactivity. The war boom lasted five years, until 1919; then, nearly four years of retrogression. The six years, 1923 to 1929, brought the great boom; the next four years—the great depression. The twelfth era is with us and industry accelerates rapidly.

[3]Canada and its Provinces, General Economic History, Volume 9; The Monetary Times; Canadian Manufacturer; The Canada Year Books; Census of Industry, General Manufacturer's Branch, Dominion Bureau of Statistics; Industrial Canada; Montreal Gazette; "The Manuacture of Munitions in Canada"—Presidential Address, H. H. Vaughan, M.E.I.C., 1919—In this paper the story of how Canadian enterprise, inspired and directed by engineers, made industrial history, is well told.

The first five years in Canada's history after Confederation brought national prosperity, in which the manufacturer shared as he did in the seven lean years that followed. Farm products held first place. The depression following 1873 affected most industries with foreign markets —the lumber trade, textiles, hardware, furniture and the boot and shoe industry. Flour mills, distilleries and breweries used local supplies. Cheese factories made rapid growth. The pork packing industry was transferred from the farm to the factory. Manufacturers of grey cottons increased four-fold in the ten years following Confederation and drove out competition. Dye houses were introduced and checks and coloured shirtings made. The McKay sewing process in place of wooden-pegging methods transformed the boot and shoe industry. Canada ranked fifth among the nations in registered shipping, and in proportion to population, in shipbuilding and navigation Nova Scotia led the world.

* * *

The next five years up to 1884 saw a period of expansion in which the national policy was given credit for bringing the depression to a close in 1879. Good harvests in Canada coincided with the worst in Great Britain during the century. The country enjoyed the expansion brought about by railway construction. The West was having a boom. The investment in favoured industries added stimulus. The milling industry was being transformed by the adoption of the roller mill process. Binder twine and cordage pools formed in Quebec and Maritimes.

* * *

The years 1884 to 1889 were again years of depression. A period of foreign trade expansion ended in 1882 and commenced again in 1892. The national policy did not prove a panacea. A small and stagnant market faced the manufacturer. The prices of farm produce decreased. Foreign trade fell below the mark of 1873. There was bitter discord—religious, racial, political.[4] A strong agitation for commercial union with the United States became a major controversy. Relations with our southern neighbour were not happy—disputes over transportation, fisheries, the tariff.

* * *

The year 1889 saw the beginning of prosperity. The increase in the production of leather goods, cotton, agricultural implements, musical instruments, liquors, woodpulp, and household effects was notable. The McKinley tariff in 1890 brought the country closer to Great Britain and increased British trade in 1895-96 to sixty-two million dollars compared with thirty-four millions purchased by the United States. Over-production capacity for cotton and agricultural implement manufacturing brought about consolidations. A Canadian's experiments produced calcium carbide in 1892.

* * *

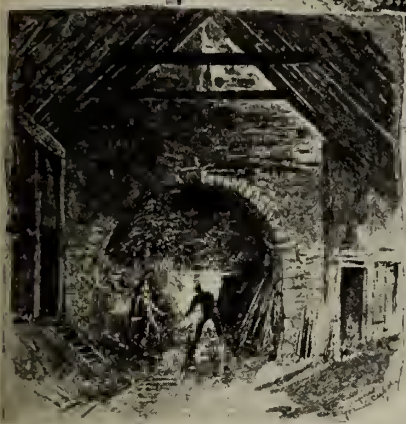
An era of progress, hitherto unexperienced in the Dominion, commenced its upward swing in 1896 and continued until 1912. Factories employing five hands or over increased production from three hundred and sixty-eight million dollars in 1890 to four hundred and eighty-one million in 1900. This, ten years later, had expanded to one billion one hundred and sixty-five million. Many new subsidiary industries were established. Combinations in industry increased. Labour unions increased in power, employers' associations were organized. Transportation facilities improved. Electricity revolutionized production. Capital amounting to one and one-half billion dollars was invested, largely by Great Britain. Population increased nearly two million from 1901 to 1911. New customs tariffs were introduced in 1907—British, intermediate and general. Industries founded on farm products continued to have the greatest value. Milling increased rapidly, capital investment in the first decade from fourteen to forty-three millions, output value thirty-one to eighty-two millions. Industries based on other products of the farm, cheese and butter-making, canning and preserving and meat-packing, expanded, but were unable to supply markets due to the diversion of raw materials. Notable advances were made in manufactures of leather goods. Domestic tobacco came into greater use, and cigar and cigarette making advanced more rapidly than smoking and chewing tobacco. Cotton manufacturing thrived. The cloth-making branch of the woollen industry declined, owing to British woollen competition, made possible by the preferential tariff of 1897. Production in hosiery and knitting factories trebled between 1900 and 1910, and the making of carpets, blankets and flannels expanded. Tailoring to order was largely superseded by factory-made clothing. The demand for timber increased and prices soared. Regulations by the provinces requiring sawing of timber cut on crown lands, and that forest products be manufactured to the most advanced stages, hastened the union of water-power and forest wealth —two major factors in Canada's tremendous production during this century. There were seven millions invested in the pulp and paper industry in 1900, and over twenty millions five years later. Thirty thousand tons of steel and fifty thousand tons of pig iron grew in production from 1896 till 1911 to eight hundred and seventy-six thousand tons of the former and nine hundred and seventeen thousand tons of the latter. Those who dreamed of the self-sustaining iron and steel industry in Canada in 1887 did not realize their ambitions. Canadian ores were not produced in sufficient quantities to meet furnace needs. Water powers of the St. Maurice made possible the production of aluminum, and together with those of Niagara, produced calcium carbide and carborundum on a large scale. Oil refining came under the control of outside oil interests. The explosive industry prospered due to railroad construction and mining. The oil paint and varnish business benefited from manufacturing and building activity. The early years of the century brought prosperity to the agricultural implement industry. The home market was for the most part held by Canadian companies, who exported in some cases up to fifty per cent of their output to Australia, South America and Europe, in spite of the keen competition of the United States. By the adoption of modern improvements, manufacturers of machinery and tools—a pioneering industry in the country—continued their success. The output of electrical apparatus, valued at two million dollars at the beginning of the century, advanced to fifteen million dollars in ten years. Outstanding in its significance and in its influence on industry in Canada, the manufacture of motor-cars was initiated in this period, commencing as assembly plants, subsidiaries of United States automobile companies. Plants for the production of rolling stock for railways were unable to supply the demand. A proposal to renew the Reciprocity Treaty of 1854 to 1864 with the United States was defeated by popular vote in 1911.

* * *

The short depression of 1907 and 1908 inaugurated an orgy of mergers which saw some forty-one industrial combinations formed,[5] absorbing one hundred and ninety-six separate firms or companies. The products affected by these amalgamations were steel and coal, cement, asbestos, rolling mills, steel and screw works, railway rolling stock, breweries, canneries, rubber goods, knit goods, foundries,

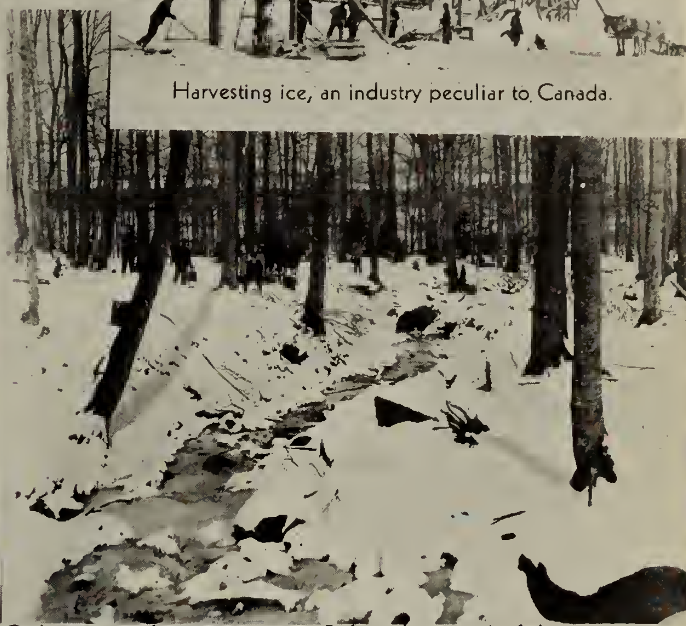
[4]"The mephitic vapours that emanate from 'Globe' editorials when advocating annexation are more nauseating than any that are diffused in the atmosphere by any polecat that ever offended the olfactory organs of mankind." (Editorial Comment, The Canadian Manufacturer, January 3, 1890).

[5]Compilation of Monetary Times.



The Old Forges of the St. Maurice, Quebec. Here in 1733 during the French regime the first metal-working industry on the continent was established and continued for 150 years.

Harvesting ice, an industry peculiar to Canada.



Gathering sap for maple sugar. Before the arrival of the white man the Indians made sugar and syrup from the sap of the hard maple. Today sugar and syrup are the products of 50,000 farms.

Shipbuilding at Lunenburg, N.S. Canada's wooden clippers were world famous. In 1878 the Dominion of Canada possessed over 1,300,000 tons registered shipping. No better vessels sailed the seas.

The old mill with its overshot water-wheel around which the villages of early days sprang up.

French-Canadian peasant, 101 years old, at her spinning-wheel.

Typical salmon cannery on Fraser River near New Westminster, B.C. The salmon fishery of British Columbia gives to that province first place with respect to value of production.

In the earlier days in French Canada almost every house possessed a spinning-wheel and hand loom, providing clothing and all the fabrics needed for the home. The Ursuline nuns taught spinning and weaving. These home industries still exist.

**Industries of Earlier Days.**

spinning and cotton, packing, paint, coal and coke, milling, boot and shoe, and to a lesser degree bread, milk, ice, fish, lumber, explosives, felts, soaps, jewellery, carriages, silk, thread, and wood-working machinery. Navigation companies and railroads joined the procession, power companies followed, and in the merging of banks this movement reached its summit. While the majority of these mergers were subjected to the criticism of being over-capitalized and of providing unwarranted profits to promoters, it would appear that many of these did justify their existence, for industry in strong hands was enabled to take advantage of the opportunities offered by the requirements of the Great War, the record of which presents an epic in industrial history.

* * *

With the collapse of the land boom in the West in 1912, the completion of railroad construction in 1914, with few new enterprises contemplated, depression faced Canada's apparently over-expanded industrial establishments—and 1914 was a depression year.

* * *

The war years and after proved to be most momentous in Canada's industrial history. The enormous production of war munitions is attributed alike to the co-operation of manufacturers and the genius of the Canadian engineer. The Shell Committee, responsible for initial production, was largely a body of engineers. The Imperial Munitions Board, formed later, carried on. One thousand members or twenty per cent of the Canadian Society of Civil Engineers went to the front. Feverish activity featured the metal-working industry. Many new plants were built. Industry, which absorbed many women, worked at high pressure, in many instances twenty-four hours a day, three hundred and sixty-five days a year. Manufacturers of machine tools were unable to supply the demand. Of munitions alone, Canada produced in all forty-seven million shell cases and in the year 1917 fifty-five per cent of the 18-pounder shrapnel, forty-two per cent of the 4.5-inch, twenty-seven per cent of the 6-inch, twenty per cent of the 60-pounder, fifteen per cent of the 8-inch and sixteen per cent of the 9.2-inch shells obtained by the British Government. The value of Canadian manufactured goods rose rapidly until 1920.

* * *

The first three years of the Twenties were reactionary, production dropping from a peak of over three and three-quarter billion dollars in 1920 to two and one-half billion dollars in 1922. The number of establishments decreased but slightly. Wages decreased over twenty per cent. Significant was the introduction in 1921 of the electric boiler, invented by a Canadian.

* * *

Well-equipped and efficiently organized from the prosperity of war years, the country's industrial establishments were ready and able to take advantage of the enormous demand required to replenish war depleted world markets. Her great supply of raw materials—mineral, agricultural and forest products—combined with low-priced power, brought Canada rapidly forward as an exporting nation. The years 1923 to 1929 saw unprecedented metal production, mining output increasing from a value of approximately one hundred and seventy-five millions to well over three hundred millions. During this period Canada became temporarily a capital exporting country, over one and one-quarter billion dollars having come into the country during the war. The huge investment of United States capital from 1914 to 1920 was now increasing the nation's output. Successive large harvests at relatively high prices were a foundation of prosperity. A boom greater than those of the war years continued until 1929, when production rose to a peak of four billion dollars in spite of the forty-one per cent reduction in the price of manufactured goods — an all-time record.

* * *

What might be rightly called the great depression, lasted from 1929 to 1933, during which latter year, due to lessened production and lower values, the total amounted to slightly more than half of that of the year of greatest output.

The present era, which commenced four years ago, referred to later in this article, is of the same order as that of the middle and late Twenties.

## THE ENGINEERS' CONTRIBUTION TO INDUSTRY[6]

The contribution of the engineering profession to the expansion of industry during the past fifty years is not only outstanding but revolutionary.

### Mechanical

In the machine tool realm the engine lathe had already been provided with a quick change gear box, more accurate feed and threading stops. At the beginning of this period, the turret lathe was just coming into use. Soon the power and rigidity of the machine were increased. Tool posts with curved blocks allowed tools to be adjusted vertically. Compound rests were introduced. In the first decade of this century high speed steel revolutionized the lathe as it did all production machine tools. The mechanical engineers have made continuous progress. During this period the individual motor drive was introduced, which together with geared heads became common during the next decade, and the forest of belts thinned out. Antifriction spindle bearings and pneumatic chucking were the next improvement. The automatic screw machine invented in the 70's continued as such for twenty years, when it became more highly developed and capable of turning out quantities of articles much more complicated than simple screws. The capacity, the speed and the accuracy, as well as the capabilities of these automatics were increased year by year. A vertical turret lathe was introduced, lending speed and convenience to heavy chucking work. Boring mills carried on a single bed and grouped about a massive central standard, with a ring of revolving chucks indexing around the tool slide, marked a further advance. Individual drive has become almost universal, and the screaming of belts has disappeared. Reversing motors have been adopted along the lines of those used in rolling mills. Planers and shapers have improved comparably with the lathe. Their work has been supplanted for production purposes by the milling machine. The universal milling machine with hydraulic feed occupies a prominent place in the production line. Jigs, fixtures and gauges have developed with the machine tool and have gained constantly in accuracy.

The production of munitions during the war and the requirements of the automotive industry have created a major revolution in metal production. The advent of tungsten carbide relegated all existing machine tools to obsolescence. Heavier machines requiring great power were built to obtain the benefit of this cutting material. Great power projects with exceptionally large units demanded machine tools of extreme size and accuracy. Special mention of the copying type die sinking machines is made, for without these the forming dies for metal tops, mudguards and streamlined body parts of automobiles would be cut only at great cost and at an extremely low rate of production. To utilize these dies, tremendous presses, some as much as forty feet in height, were designed to press and draw the material.

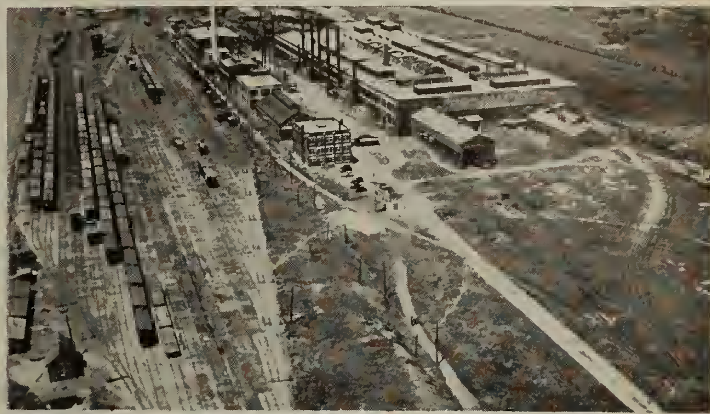
Canadian Vickers Limited owns and operates a floating dry dock and shipbuilding yard at Montreal, and produces industrial and mining machinery, structural steel, aircraft and kindred products. Plant covers 28 acres and employs 450 hands.

Canadian Car & Foundry Company, Ltd.—Longue Pointe plant, Montreal. Part of the steel foundry division of The Canadian Car & Foundry Company. Capacity over 30,000 tons of finished steel castings per annum, used in the manufacture of freight and passenger cars in other of the company's seven plants located at Montreal, Fort William, Brantford and Welland.

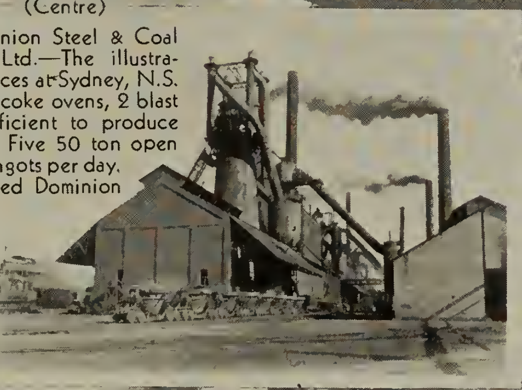


View of the Canadian Ingersoll-Rand Company, Ltd. works at Sherbrooke, Que., as they exist in 1937, and as seen from the Sherbrooke-Montreal highway. This picture shows the extensive buildings which cover an area of over 30 acres, including foundry, pattern shops, machine shops and other buildings. (Below)

Jenkins Brothers, Ltd.—This is the first unit, opened officially on April 6, 1932, in an extensive development program on a 500,000 square foot site at Lachine. The photograph shows the modern bronze and iron foundry building and power house, where valves and goods are manufactured principally for export. (Below)

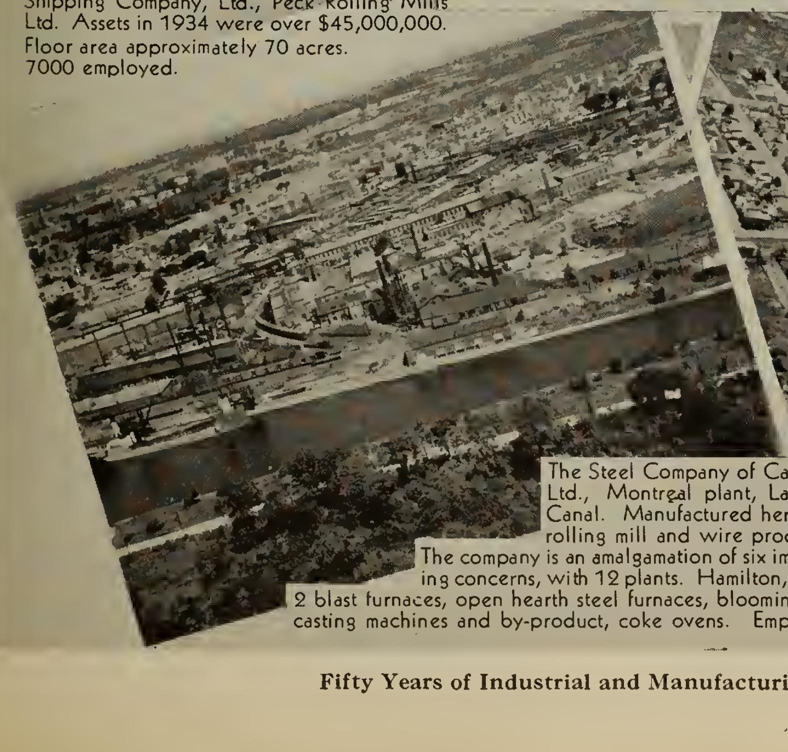
(Centre)

Dominion Steel & Coal Corporation, Ltd.—The illustration shows blast furnaces at Sydney, N.S. This plant comprises 150 coke ovens, 2 blast furnaces and equipment sufficient to produce 300 tons of pig iron per day. Five 50 ton open hearth furnaces in addition produce 600 tons ingots per day. The company, incorporated in 1928, acquired Dominion Iron & Steel Company, Ltd., Dominion Steel Corporation, Ltd., and British Empire Steel Corporation, Ltd., and control of Cumberland Railway & Coal Co., Halifax Shipyards Ltd., Nova Scotia Steel & Coal Company, Ltd., Eastern Car Company, Ltd., Dominion Coal Company, Ltd., Sydney Lumber Company, Ltd., James Pender & Company, Ltd., Dominion Shipping Company, Ltd., Peck Rolling Mills Ltd. Assets in 1934 were over $45,000,000. Floor area approximately 70 acres. 7000 employed.



(Below)

Dominion Bridge Company, Ltd.—View of works and head office at Lachine, Que. Here are fabricated bridges, structural steel work, and electric and hand power travelling cranes. Dominion Engineering Works, seen in the background, manufacture paper mill machinery, turbines and special equipment. The company built in 1929 a fabricating shop in Calgary and a plant in Vancouver. About 1500 people are employed in ten plants.



The Steel Company of Canada, Ltd., Montreal plant, Lachine Canal. Manufactured here are rolling mill and wire products. The company is an amalgamation of six important metal working concerns, with 12 plants. Hamilton, Ont., plants include 2 blast furnaces, open hearth steel furnaces, blooming, billing and rod mills, rolling mills, pig casting machines and by-product, coke ovens. Employs over 4,000. (Left)

Fifty Years of Industrial and Manufacturing Development in Canada.

In the field of quantity production the automobile has imposed on the engineer the task of constructing single purpose machines, such as cylinder block milling machines, cylinder boring machines, tappers and reamers, crankshaft turning machines, multiple drills and many others, which will do only one job. Hence the change in design of any part has meant the scrapping of existing special equipment or heavy alteration charges.

The process of broaching has been elevated to a very important degree. Centreless grinding has come into great prominence in the last three or four years, and with straight or formed faced wheels cylindrical work is produced at rates of speed and limits of accuracy undreamed of by the old method of turning and grinding. Wrist pins, front and rear axles and spring rods are examples of work done by centreless grinding.

In view of the extreme precision to which multiple production is now held, standard micrometer and "go and no-go gauges" are entirely too slow and variable for accurate results. A system of electrical gauges is in use in many instances which measures diameter, length and weight. The readings are entirely visual, these scales being calibrated much the same as on a voltmeter. In many cases these gauges are magazine fed and the operators, frequently girls, have only to watch the scales. Some are automatic and defective parts are knocked out of production when they fail to measure up to required limits.

The use of alloy steel has aided designers in producing articles, strong and light. It is reported that there are approximately 500 different alloys in use in the automobile industry. The use of steel has been greatly influenced by autogenous welding which has come into general use during the last quarter century. Electric and oxy-acetylene welding of steel has reduced fabrication costs by superseding riveting and other mechanical methods of joining metals, so that fabricated parts often replace iron castings. Oxy-acetylene cutting has practically eliminated mechanical methods of severing steel plate of all thicknesses, cutting off risers, and removing defects in billets.

High specifications of quality and accuracy are now firmly entrenched in all engineering work. The mechanical engineer in the motor industry has pioneered these standards. As a result, engineers in all branches of industry are producing work of the highest quality at moderate costs in this time of large power units, high speed transportation equipment, and general engineering, with great endurance and a maximum of safety.

### Power in Industry

The water wheel was the prime mover for the flour and grist mills around which the earliest towns and villages in Canada grew, but for a considerable period, including most of the first decade of this century, the steam engine played an important role. Its use is now largely confined to districts remote from hydro-electric energy or to industries requiring steam for processing. In 1887 most factories used steam engines, the power being transmitted by shafting and belting, gearing or rope drives. Small plants were equipped with simple non-condensing engines, while large mills experimented with compound-condensing. The efficiency of mills increased where exhaust steam could be used in process work. The smaller manufacturer depended upon the slide-valve engine controlled by throttling governor. Working pressures of between 60 and 75 lb. per square inch were common and over one hundred pounds exceptional. About 1900 some of the larger engines developed an indicated horse-power hour with from 15 to 16 lb. of steam at a gauge pressure of 140 lb.

The high speed automatic cut-off engine was developed to operate electric generators. Edison bi-polar dynamos required speeds of 800 to 1,200 rev. per min. The construction of multiple generators with greater capacities and decreased speed was the solution of direct-connected engine drive. These engines were the horizontal single cylinder automatic cut-off type. A vertical single acting type with a closed crank case was produced. Single and compound engines of this category were extensively used in the early Nineties.

The years between 1890 and 1900 saw a vast improvement in the high speed steam engine. Steam pressures rose from 70 to 175 lb. Early forms of steam turbines made their appearance in 1896, but did not prove adaptable to industrial work. Keen interest was shown in superheated steam. Improvements made in water tube boiler construction and under-feed stokers were favourably received. The use of cheaper grades of fuels and anthracite screenings was made possible. Vacuum returns came into vogue. Between 1900 and 1910 high speed turbines were introduced. Steam pressures up to 200 lb. were used and temperatures of between 500 and 550 deg. prevailed. The introduction of pulverized coal necessitated redesigning furnaces. Between 1910 and 1920 smaller turbines, geared, were direct connected and supplanted high speed turbines for many purposes. Fuel oil appeared in competition with coal and treatment of feed water was studied. During the past seventeen years great strides have been made in the design of boilers and stoking equipment. Pressures of between 450 and 600 lb. became common with temperatures as high as 700 to 750 deg.

Designed to use by-products of the manufacture of kerosene, the forerunner of the present gasoline engine appeared in the 80's, and weighed about 1,000 lb. per horse-power up to a three horse-power capacity The present day cost of a three horse-power engine is about $60; in 1887 it was about $2,000. Refinement of the internal combustion engine commenced at the turn of the century. It has revolutionized transportation and, combined with electricity, powers the automobile, and has made possible the science of aviation.

The first Diesel engine appeared in the United States in 1898. In Canada it is used to a considerable extent to supply the motive power for the mining industry, and in districts where hydro-electric power is not available. Since 1930 refinements of this type of engine have been so great, coupled with its much lower cost of operation, that it now looms as a competitor of the gasoline engine for heavy highway transportation.

### Electrical

During the decade preceding 1887, the commercial application of electricity in the industrial field had received considerable impetus and alternating current transmission and distribution by means of transformers had been accomplished on a commercial but limited scale.

The fundamental conception of the magnetic circuits in rotating equipment was not yet clearly understood, and the years following produced marked changes in the physical construction of generators and motors. The alternating current generator of that period was of the rotating armature type with open or face wound coils, and the construction of slotted armatures providing greater mechanical and electrical security for the windings, was a development of the early nineties. The design of modern rotating field generators was evolved from the early hydro-electric installation at Niagara Falls which utilized this form of construction, excepting that the field coils rotated on the outside of the armature and were supported from the shaft by an umbrella-like structure.

Before the end of the 19th century the generating equipment had assumed much of its present form. Later developments have been toward larger capacities with refinement in the materials, and higher speeds with the

The Canadian Marconi Company, Montreal, erected this handsome new plant in the Town of Mount Royal, Que., in 1930. Equipment embodies complete facilities for the manufacture of radio receivers, transmitters and specialty apparatus, which includes direction finding equipment, audiphones and public address systems. This year ground was broken for a considerable addition to this factory.

Montmorency plant, Montmorency Falls, Que., of Dominion Textile Company, Ltd., an amalgamation of many cotton mills, which, with those of its subsidiaries, are equipped with approximately 600,000 spinning spindles, 38,700 twisting spindles and 11,380 looms, giving employment to about 8,000 operatives.

Interior of first glass walled factory building in Canada, completed in 1937 as a 4-storey and basement addition, 63 ft. by 220 ft., to the Imperial Tobacco Company of Canada, Ltd.'s extensive factory system. The building is of reinforced concrete, the walls on 3 floors glass brick, 2 in. thick, 12 in. by 12 in. Cost of building is 3 cts. per cu. ft. more than if steel sash were used. Advantages claimed are high insulating qualities, contribution to humidity control, light giving properties, and beauty. (Above)

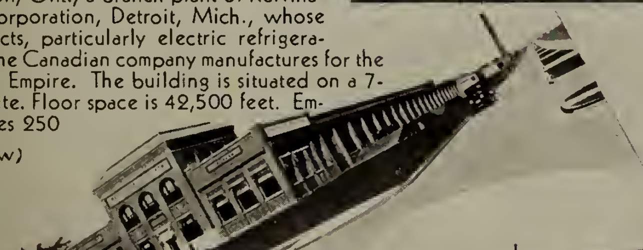
Canadian Industries Limited. On this site at Shawinigan Falls, Que., are located three distinct "C.I.L." plants manufacturing cellophane, hydrogen peroxide and trichlorethylene, the latter a cleaning fluid. The "Cellophane" plant occupies the bulk of the picture with the hydrogen peroxide unit visible in the extreme background at the left. These plants have been continuously expanded since the first cellophane machine was installed in 1932, and now employ over 250 persons.

Western Clock Company, Ltd., Peterborough, Ont., a branch plant of a United States concern, established there during the depression following the war boom, to manufacture trade marked clocks and timepieces. Employee comfort and safety have been given special consideration. (Above)

(Left)

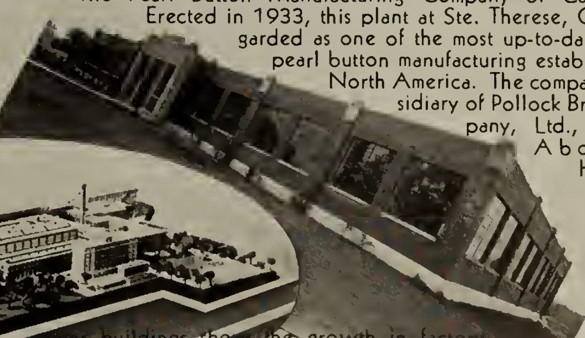
Collins & Aikman Canada, Ltd., Farnham, Que. This substantial plant, 400 ft. by 250 ft., houses an industry engaged in the manufacture of velours and plushes. This establishment has led to the production in Canada of yarns not previously spun in this country, while the industry itself makes certain fabrics hitherto imported. Approximate employment 100 people.

Modern plant of A. Wander Limited, Peterborough, Ont., in which a patented vegetable product is made.



New plant of Kelvinator of Canada, Ltd., London, Ont., a branch plant of Kelvinator Corporation, Detroit, Mich., whose products, particularly electric refrigerators, the Canadian company manufactures for the British Empire. The building is situated on a 7-acre site. Floor space is 42,500 feet. Employees 250

(Below)



The Pearl Button Manufacturing Company of Canada, Ltd. Erected in 1933, this plant at Ste. Therese, Que., is regarded as one of the most up-to-date specialty pearl button manufacturing establishments in North America. The company is a subsidiary of Pollock Bros. & Company, Ltd., Montreal. About 100 hands are employed.

Expansion of electrical industry in Canada is illustrated by the plaster model of the Canadian Westinghouse Company, Ltd. plant at Hamilton, Ont., the original buildings of which are centered around the chimney at the right. The other buildings show the growth in factory operation, in the manufacture of electrical machinery, equipment and apparatus, that has taken place in this important Canadian industry since it was incorporated in 1903.

**Fifty Years of Industrial and Manufacturing Development in Canada.**

advent of the steam turbine. The first alternating generators were of the single phase type and were utilized for supplying current for lighting. The single phase induction motor followed rapidly and enabled the alternating supply of current to be used for motive purposes as well. It was not until the development of the polyphase motor in the early nineties, that much progress was made in the application of electricity to industrial requirements for motive power. Since that date electrical engineers have designed and constructed motors to meet every conceivable requirement of industry in regard to capacity, speed and performance. From the minute motor driving the hands of a synchronous clock to the largest motors on rolling mills and hoists, the engineer has contrived to find a running mate for every job.

The first alternating current generators were built without much regard to the frequency of alternations. The design of the machines supplied by each manufacturer was based on considerations of safe speed of operation and physical construction with the number of poles or magnetic circuits which would lend themselves to convenient manufacture. Consequently, a wide variety of frequencies existed, which in themselves, created no particular hardship since interconnections between generating plants were not required. With the advent of the polyphase motor and the rotary converter for supplying direct current to railway systems a standardization of frequency was inevitable. After much controversy as to the most suitable frequency, opinion crystallized on 60 cycles as most desirable for motive purposes and lighting, and 25 cycles for electro-chemical, long distance transmission and conversion to direct current. Technical developments and improvements in the art have practically eliminated the advantages which were considered inherent to 25-cycle frequency, with the result that 60 cycles is the predominant frequency of today.

For the benefit of industry, as well as the large number of domestic consumers, power companies now maintain a precision control of the frequency. Speed variation in motive equipment, which is so important to the textile, paper and other industries, is now reduced to negligible proportions, and such momentary changes now rarely exceed three-tenths of one per cent of the synchronous speed.

One of the earliest applications of electric motive power was for traction purposes in the operation of street railways by direct current. The growth of alternating current power systems, however, and the improvements in flexibility and control of the induction motor have led to some use of alternating current for heavy traction on railroads. The development of the mercury arc rectifier with its increased efficiency and lower operating costs, has given new life to direct current systems for heavy traction purposes. The mercury arc rectifier with the refinement of grid control, is also coming into increasing favour with the heavy industries using direct current for electro-chemical processes.

The thermal conversion of surplus power from hydro-electric developments by the electric steam boiler has been undertaken in Canada during the past ten years on a very large scale. Steam is produced by electro-thermal process in the plants of industries requiring large amounts of process steam, thus enabling both the manufacturer and the supply company to benefit by the arrangement.

The industries have not been slow in recognizing the speed and accuracy of electric control devices. Practically every industry finds use for one or several of the refinements for automatically timing, regulating or controlling some operation in manufacture.

### INDUSTRY IN 1891[7]

The table of industrial statistics, 1891, lists 75,741 establishments in Canada, with an invested capital of $345,526,259, employing 370,104 hands, distributing to wage-earners $100,656,502 a year, and producing articles valued at $476,183,356. Ontario with 32,150 plants leads Quebec with its 23,011 by a considerable margin. The other provinces follow in order:—Nova Scotia 10,496, New Brunswick 5,429, P.E. Island 2,679, Manitoba 1,031, British Columbia 770, Territories 375. Of the total employed, 273,327 were male over sixteen years of age and 70,156 female. Boys employed numbered 19,556 and girls 7,065. Average yearly earnings including all classes were for the year 1891, $272.

An explanation of some of the industries enumerated in Table I is given because the classifications differ entirely from those of 1935. The item "foods—vegetable" includes 2,550 flour and grist mills, with an output of $52,423,000, and 1,656 bakeries. Confectionery was also included. The animal food industry is represented chiefly by 4,627 fish curing and 1,565 cheese factories. Sawmills, numbering 5,666, with an invested capital of over $50,000,000, employing over 50,000 people and an output of over $50,000,000 led the list in "matters—vegetable," and were followed by carpentering with 4,618 factories. Of cooperages there were 1,524 establishments, and shingle mills, planing and moulding factories, and pump and wind mills were the most important of the balance. Brush and broom making was the principal item in "matters—animal," which includes soap and candles, glue factories, and tallow refineries. Aerated waters, brewers and maltsters, cider making and cigar factories accounted for 626 of the total 769 plants in "drinks and stimulants." Wine making, coffee and spice mills, distilleries, sugar refineries, and cocoa and chocolate making were other items. Cabinet and furniture factories led in "furniture and houses and buildings," followed by lime kilns, and sash, door and blind factories had the greatest volume of output. Paints and varnish, plaster, mattress making, cement mills, and roofing materials were also included. The 621 foundries and machine shops, with an output of $16,400,000, were the foremost industry in "machines, tools and implements," while 1,500 tinsmith shops, employing 3,800 people, produced $4,793,000 worth of products. This classification also included tin and sheet working, iron and brass fittings, edge tools, locksmithing,

Table I

Industrial Statistics—1891

| Industry | No. of establishments | Capital $ | No. of employees | Wages $ | Value of output $ |
|---|---|---|---|---|---|
| Arms and ammunition | 54 | 1,107,011 | 495 | 175,394 | 1,105,205 |
| Books and stationery | 723 | 10,540,431 | 9,906 | 3,875,553 | 10,553,487 |

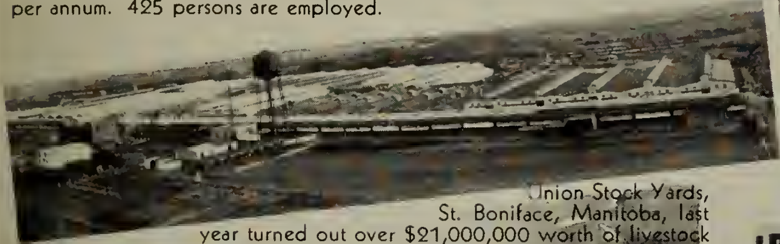
[7]Nearest date to 1887 for which complete statistics are available.

Head office and works of The John Bertram & Sons Company, Ltd., at Dundas, Ont. Manufactured in this large plant are the Pratt & Whitney line of machine tools, as well as mine hoists, winders, presses and rock drills. The approximate output of the plant is $1,000,000 per annum. 425 persons are employed.

Ogilvie Flour Mills Company, Ltd., operate plants at Fort William, Winnipeg, Medicine Hat, Edmonton, Montreal. The plant at Medicine Hat, Alberta, is illustrated. In these mills are manufactured flour, feed, rolled oats, wheathearts and other cereals, cattle and

poultry feeds, of which are exported flour, feed and rolled oats. Approximate value of output of the company is $12,000,000 giving employment to 1,750 people.



Union Stock Yards, St. Boniface, Manitoba, last year turned out over $21,000,000 worth of livestock products in this 52 acre plant. Approximately 300 persons are employed. The tremendous floor area of the plant is clearly visible in the photograph.

Campbell Soup Company, Ltd., New Toronto, Ont. This modern plant started operations during 1931, occupying over 110,000 square feet of floor space for the packing of soups, pork and beans, spaghetti and tomato juice. About 150 operatives are employed.

Typical of modern trends in construction is this recently completed new streamlined plant of Duplate (Windsor) Limited at Windsor, Ont., where safety glass will be produced.

Plant of the Canadian Sugar Refineries, Ltd., at Raymond, Alberta. The production of sugar beet is centered in south-western Ontario and near Raymond, Alberta. Refined beetroot sugar amounting to 119,857,668 lbs., valued at $4,617,733, was produced in 1935.

American Can Company's handsome plant at Simcoe, Ont. Completed in the spring of 1930, this plant manufactures cans of all kinds. The building is constructed of concrete and steel, and provides over 110,000 square feet of floor area, in addition to warehouse capacity of 100,000 square feet.

**Fifty Years of Industrial and Manufacturing Development in Canada.**

furnaces, stoves and heaters, engine building, rolling mills, iron and steel bridges, and type foundries.

### NUMBER OF MANUFACTURING ESTABLISHMENTS

The striking decrease in the number of manufacturing establishments from over 75,000 in 1891 to approximately 25,491 in 1935, is evidence of the elimination of many of the small local industries which flourished in every town and village fifty years ago, the majority of which supplied local needs.

Mergers, consolidations, increased factory production and the growth of individual manufacturing units in the larger centres, made it impossible for most of these small industries to exist, although some did grow and prosper to a point of securing markets from coast to coast, and doing an export business as well.

### EMPLOYMENT IN MANUFACTURING

The manufacturing industries of Canada employed in 1887 some 335,000 people. The curve of employment in manufacturing shows a steady and consistent advance from the year 1870 to 1910. In those years there was no unemployment in Canada. The decade from 1900 to 1910 saw an increase in industrial employment of over 45 per cent. Economic depressions exerted little or no influence on the continued increase. The years 1910 to 1920, the decade in which the gross value of manufactured products rose to hitherto unknown peaks, found the number of employees the same at the end as at the beginning, with a slight increase up to 1917. Then came reaction. During the first of the depression years 1921, over 150,000 of the 620,000 workers, or more than 25 per cent of all gainfully employed in industry were idle. From this time until 1929, with a slight dip in 1923 and 1924, employment increased at the most rapid rate in the history of Canada, reaching the peak of nearly 700,000 in 1929. The collapse from that date to 1932 to 1933 was as precipitous as the previous increase. Since then, however, employment is increasing at the same rate as that of 1924 to 1929. The curve does not indicate the industrial boom of the war years, because mechanical equipment promoting mass production had become an increasingly greater factor in output. The depression following the Great War is clearly indicated, the boom of the twenties, the greatest depression in Canada's history from 1929 to the early thirties, with its attendant lowered production, unemployment, the dole, and general industrial upheaval. The trend of the curve at present, if continued during the next few years, would indicate that industry will again absorb many unemployed.

### SALARIES AND WAGES

From 1870 to 1880 the total annual wages and salaries paid to Canadian workers increased very slowly. From the year 1880 to 1900 increase was more pronounced. From 1900 to 1916 there was a rapid acceleration in the amount paid and the industrial boom years of the war saw an increase greater than the total increase of the previous forty-five years. The depression from 1920 to 1922 is strikingly illustrated in a decrease from $733,000,000 to slightly over $500,000,000. Increased production was shown from 1922 with a slight dip in 1924 up to the peak production in 1929, when wages were approximately $815,000,000. From that year to 1933 the decrease was rapid, but since then the amount of wages has been going rapidly forward until in 1935 we see it approximating that of 1918, but far below the peaks of 1919 and 1928. Salaries and wages for 1935 were $590,300,000.

The average employee in industry receives four times as much as his grandfather earned fifty years ago.

### BRANCH PLANTS IN CANADA

The establishment of manufacturing plants in Canada by companies already existing in other countries had commenced when the present century began, and the number and variety of these concerns, coupled with the value of their output, have had a noteworthy influence in bringing this country to its position as an exporter of manufactured goods. No other nation has had such an experience.

The major influences in this movement were the tariff policy, the requirements imposed by patent laws, and the desire to take advantage of the valuable trading position of the country, due to raw materials, favoured nation treaties with numerous non-Empire countries, and Empire trade agreements. While the contribution from Great Britain has been of no small importance, the proximity of the parent plants in the United States, together with the reasons already cited, accounts for the great majority of these industries in the Dominion.

The importance of the branch plant as a factor in Canada's impressive industrial growth since 1900 may be appreciated when it is realized that from the year 1900 to 1934, capital invested in branch plants amounted to well over two billions of dollars, compared with a total investment in all industries in the same period of approximately four and one quarter billions of dollars.

The curve of branch plant growth in Canada, plotted from 1900 to 1935, graphically shows the progress in such plant establishment. The period from 1900, at which time there were 132 branch plants in Canada, to 1918 is one of almost uniform location of new industries. Following the war, however, a great acceleration took place, which extended until 1932, when there were 1,852 branches of foreign firms in the Dominion. Since then there has been a lessened increase. Latest returns for the current year, however, lead to the conclusion that the branch plant will continue to play a progressive part in Canada's path to further industrial diversification.

### COST OF ELECTRICITY IN INDUSTRY

Electricity's quickening impulse to industry is largely due, in the industrial portions of Canada at least, to its availability in any amount, the flexibility of its service, and its low cost. In an estimate made[8] of the cost of electricity in relation to the value of the output, covering thirty-seven industries, in only four of these does that cost exceed two per cent. Pulp and paper heads the list with 9.76 per cent, acids, alkalies and salts 7.45 per cent, compressed gases 3.53 per cent, and electrical apparatus and supplies 2.03 per cent. Of the industries where the cost exceeds one per cent and is less than two, there are eight. Of the remaining twenty-five the cost ranges from 0.97 per cent for woollen textiles to cotton and jute bags 0.18 per cent.

### ORGANIZED LABOUR

The Dominion Trades and Labour Congress, established in 1873, is the head of the internationally organized workers in Canada, and represents them in legislative matters. The National Catholic Union dates from 1901, when it came into existence in Quebec City. Other national Catholic unions were formed in the province of Quebec, and these were co-ordinated in 1921 by the Confederation of Catholic Workers in Canada. In 1927 the All-Canadian Congress of Labour was organized at a meeting of national representatives held in Montreal. There were in the Dominion in 1935, 1,794 international locals with 143,570 members and 934 non-international unions with a membership of 437,134. Labour is forty-eight per cent unionized.

At the present time there is a war between rival factions of the American Federation of Labour, which has caused serious industrial unrest in the United States. An attempt was made by one faction, the Committee for

[8]The Dominion Bureau of Statistics, Mining Metallurgical and Chemical Branch, March 30, 1937.

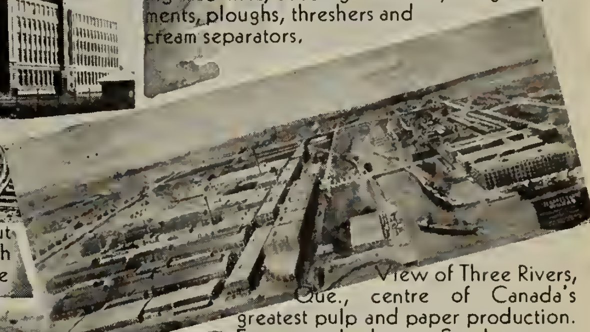
The largest sawmills in Canada are located on the Pacific coast of British Columbia, where the heaviest stands of large timber exist. The mills of the Powell River Company at Powell River, B.C. are shown. Of 2,578,000,000 feet board measure of lumber cut in Canada in 1934, British Columbia produced 1,464,000,000, of which Douglas fir was over 1,000,000,000.

The Goodyear Tire & Rubber Company of Canada, Ltd., has three factories, the one illustrated is at New Toronto. Floor area is 17 acres. Products are automobile, truck, bus, tractor, and motor cycle tires and tubes, also repair materials. Export all lines. Salesvalue of output of this plant is in excess of $1,000,000 per month. Employees March, 1937 were 1,300.

Rayon plant of Courtaulds Limited, located at Cornwall, Ont., manufactures rayon yarns, none of which is exported. The floor area of the plant is 260,000 square feet, the number of employees 2,000, and the approximate value of output $6,000,000 per annum. The growth of this plant in 10 years is a romance in Canadian industry.

Buildings and grounds of Canadian Kodak Company, Ltd., Kodak Heights, Toronto. Floor space 500,000 square feet; employment 800. The power plant has latest equipment, automatically controlled; will develop 1800 h.p.; operates at steam pressure of 450 lbs. and steam temperature of 560° F. A 750 kw. turbo-generator, speed 8,000 r.p.m., supplies electrical power.

Below—International Harvester Company of Canada, Ltd. at Hamilton, Ont., make harvesting machines, seeding machines, tillage implements, ploughs, threshers and cream separators.



View of Three Rivers, Que., centre of Canada's greatest pulp and paper production. Foreground shows St. Lawrence Paper Mills Company, Ltd. Floor area 560,000 square feet; employees 500; daily output 450 tons of newsprint; approximate value of yearly output $4,000,000.

Canadian International Paper Company's mill at Three Rivers, Que., known as the world's largest paper mill with a rated capacity of 750 tons per day. The approximate value of output is $11,000,000 at present prices, and the average number of employees is 900.

General Motors of Canada, Ltd. Oshawa, Ont. Floor space 2,400,000 square feet. Production capacity 750 cars a day.

E. B. Eddy Company, Ltd., plant at Hull, Que., manufacturers specialty papers, toilet and tissue paper products, paper bags, newsprint and sulphite and groundwood pulps. Export toilet paper, towels, serviettes and newsprint. The ground floor area of plant is 458,500 square feet. Approximate value of output $5,000,000. Employees 1000

The Dominion Oilcloth & Linoleum Company, Ltd. Montreal. Area 544,200 square feet. Products linoleums, marble tile, wall coverings.

Below—Located at Ocean Falls on the Pacific coast about 300 miles north of Vancouver, B.C., the plant of Pacific Mills Limited turns out newsprint, kraft wrapping and paper specialties to an amount of 350 tons per day. The harbour is on tide water and is open all the year.

Plant at Drummondville, Que., of Canadian Celanese Limited; silks from cellulose acetate. Employ 2,300 people. Payroll $2,700,000 a year.

**Fifty Years of Industrial and Manufacturing Development in Canada.**

Industrial Organization, to impose its will on Canadian workmen. This group initiated a strike in the automobile industry in Ontario, which was settled without recognition of the trouble fomenters. There is considerable unrest in labour circles.

## INDUSTRY IN 1935—A REVIEW

Nearly two thousand distinct articles or products are listed as being manufactured or processed in Canada in 1935. A tabulation showing forty leading industries, giving the number of establishments, capital invested, number of employees, salaries, cost of materials and gross value of products, as well as the same statistics for the total of all industries, is given in Table II.

This tabulation shows the industries in order of the gross value of their output. For the first time non-ferrous metal smelting and refining has exceeded that of pulp and paper. If, however, we add the output of sawmills to that of pulp and paper, these two exceed the smelting and refining group by over forty million dollars. According to salaries and wages paid, pulp and paper leads, followed in order by printing and publishing, central electric stations, automobiles, railway rolling stock, sawmills, electrical apparatus and supplies, bread and other bakery products, clothing factory (women's), hosiery and knitted goods. In order of gross value of products, pulp and paper is second, printing and publishing fourteenth, central electric stations third, automobiles fifth, railway rolling stock seventeenth, sawmills ninth, electrical apparatus and supplies tenth, bread and other bakery products eleventh, clothing factory (women's) fifteenth, and hosiery and knitted goods sixteenth.

The 25,491 Canadian industrial establishments had in 1935 a capital investment of $4,698,991,853, employed 582,874 people, paid out in salaries and wages $590,326,904, used materials to a value of $1,420,885,153, and turned out a gross value of products of $2,807,337,381.

Table III shows the distribution of industry by groups for 1935.

In the production and exportation of many staple products, including asbestos, newsprint paper and nickel, Canada led the world in 1935 and still does. In output of copper and zinc she occupied third place; fourth place in the production of gold and lead; fifth place in the manufacture of automobiles; and seventh place in yield of wheat. In that year the Dominion was first in the exports of asbestos, newsprint paper, nickel and wheat; occupied second place in the export of wheat flour; third place in the export of automobiles; and fourth place in the export of rubber tires and wood pulp. In world trade Canada in 1935, as well as in 1934, occupied sixth position in total

Table II

Principal Statistics of the Forty Leading Industries of Canada, 1935

| Industry | Establishments Number | Capital $ | Employees Number | Salaries and wages $ | Cost of materials $ | Gross value of products $ |
|---|---|---|---|---|---|---|
| 1. Non-ferrous metal smelting and refining | 15 | 145,686,299 | 8,944 | 12,687,356 | 126,804,075 | 186,245,658 |
| 2. Pulp and paper | 95 | 545,572,938 | 27,836 | 35,893,313 | 57,995,037 | 162,651,282 |
| 3. Central electric stations | 1,041 | 1,459,821,168 | 15,458 | 22,519,993 | | 137,114,911 |
| 4. Slaughtering and meatpacking | 139 | 58,207,715 | 10,674 | 12,448,347 | 108,191,810 | 133,379,312 |
| 5. Automobiles | 20 | 40,765,548 | 13,095 | 18,797,599 | 75,645,998 | 106,624,445 |
| 6. Butter and cheese | 2,589 | 58,291,763 | 14,786 | 13,905,135 | 69,953,193 | 99,888,971 |
| 7. Flour and feed mills | 1,127 | 56,475,315 | 5,454 | 5,165,507 | 78,071,667 | 97,567,868 |
| 8. Petroleum products | 58 | 64,707,454 | 4,856 | 7,153,224 | 58,869,814 | 79,950,525 |
| 9. Sawmills | 3,698 | 75,973,627 | 25,727 | 17,711,657 | 35,927,884 | 65,905,132 |
| 10. Electrical apparatus and supplies | 182 | 75,499,255 | 15,549 | 17,594,759 | 25,409,806 | 61,152,834 |
| 11. Bread and other bakery products | 3,045 | 43,788,924 | 19,167 | 16,369,912 | 28,343,545 | 59,400,678 |
| 12. Cotton yarn and cloth | 35 | 70,741,613 | 18,121 | 13,206,265 | 33,689,873 | 59,378,664 |
| 13. Rubber goods including footwear | 45 | 63,435,798 | 11,023 | 11,017,431 | 20,258,774 | 55,949,570 |
| 14. Printing and publishing | 793 | 53,721,846 | 16,889 | 23,061,512 | 11,197,377 | 55,832,925 |
| 15. Clothing factory, women's | 591 | 22,668,528 | 17,894 | 14,593,861 | 31,642,215 | 53,796.274 |
| 16. Hosiery and knitted goods | 163 | 50,048,900 | 18,511 | 14,252,653 | 22,948,056 | 46,390,103 |
| 17. Railway rolling stock | 37 | 86,547,010 | 16,921 | 18,785,671 | 20,769,208 | 41,213,039 |
| 18. Biscuits, confectionery, cocoa, etc | 234 | 37,779,319 | 10,446 | 9,315,563 | 19,231,189 | 41,197,833 |
| 19. Breweries | 73 | 57,928,298 | 4,460 | 6,155,642 | 15,024,625 | 40,699,040 |
| 20. Tobacco, cigars and cigarettes | 116 | 58,178,513 | 8,145 | 7,221,048 | 19,701,385 | 39,103,875 |
| 21. Castings and forgings | 303 | 63,585,479 | 13,760 | 14,138,972 | 14,042,882 | 38,779,813 |
| 22. Primary iron and steel | 53 | 86,465,490 | 9,523 | 12,279,390 | 18,539,072 | 38,700,961 |
| 23. Coke and gas products | 44 | 98,939,160 | 4,107 | 5,627,861 | 15,233,519 | 38,474,789 |
| 24. Fruit and vegetable preparations | 298 | 38,272,379 | 7,912 | 5,063,481 | 22,252,826 | 38,276,487 |
| 25. Sugar refineries | 8 | 33,017,874 | 2,134 | 3,086,691 | 25,137,568 | 36,597,997 |
| 26. Clothing factory, men's | 170 | 16,271,865 | 9,296 | 8,990,370 | 20,676,934 | 36,578,897 |
| 27. Boots and shoes, leather | 217 | 24,313,445 | 15,930 | 11,742,871 | 19,431,799 | 35,989,912 |
| 28. Sheet metal products | 129 | 47,369,004 | 6,580 | 6,802,698 | 18,971,146 | 33,564,302 |
| 29. Printing and bookbinding | 1,182 | 40,331,944 | 12,194 | 13,707,159 | 11,653,559 | 33,188,331 |
| 30. Machinery | 211 | 59,899,705 | 8,949 | 10,531,251 | 12,194,263 | 32,856,175 |
| 31. Automobile supplies | 82 | 23,260,333 | 6,614 | 7,411,434 | 18,528,296 | 32,684,252 |

The Manufacturing Industries of Canada, 1935, Dominion Bureau of Statistics.

Quarry and mill of the Quebec Asbestos Corporation, Ltd. at East Broughton Station, Que. The asbestos mines of Quebec have long supplied a major part of the world's demands. One company has sufficient asbestos-bearing property to last, at present rate of output, 100 years. Over 100,000 tons of asbestos valued at $5,300,000 were exported in 1935. Employment was provided in the mines and mills for 2,072 persons.

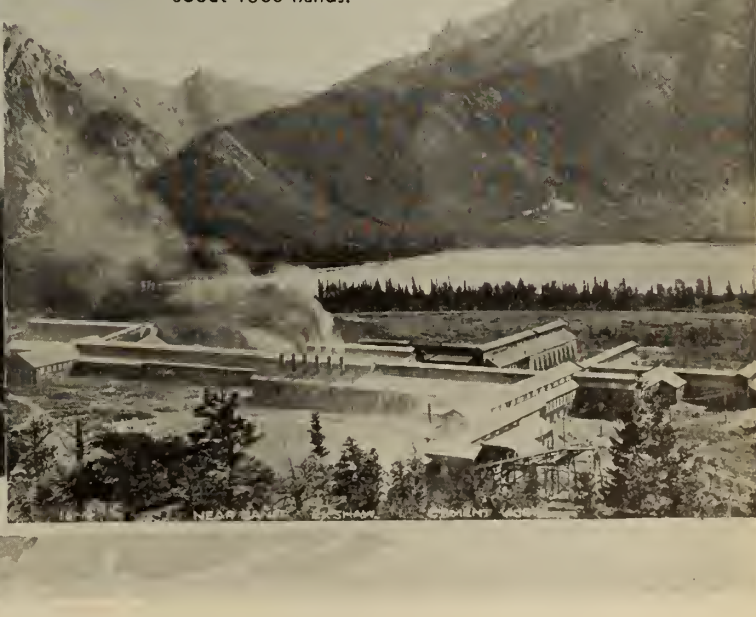
Noranda development in north-eastern Quebec of Noranda Mines Limited. This mine produces gold, silver, copper, selenium and tellurium; recovered (1936) metal to a value of $18,315,000. It exports copper, selenium and tellurium. Over 2,000,000 tons of ore were mined in 1936.

The smelter, lead refinery, zinc refinery, precious metals refinery and copper refinery of the Consolidated Mining & Smelting Company near Trail, B.C., is the largest non-ferrous metallurgical works in the British Empire. This Company is a subsidiary of the Canadian Pacific Railway Company, and owns the Sullivan mine, which is one of the most valuable mineral deposits in America, if not in the whole world. A $10,000,000 plant built a few years ago manufactures fertilizers. Smelter gases are used to produce sulphuric acid, surplus power to make electrolytic hydrogen, nitrogen is extracted from the air, and together with phosphate rock imported from the United States, large tonnages of ammonium sulphate, ammonium phosphate and super-phosphate are made.

The works of Shawinigan Chemicals Limited, producing calcium carbide and glacial acetic acid, is one of the largest in the world and the greatest of its kind in the Empire. Carbide is made from limestone and coke in electric furnaces. The acetylene gas therefrom is the base for acetic acid. Products are shipped to all parts of the world. The company employs about 1000 people and uses 75,000 h.p. of electricity.

The plant of the North American Cyanamid Limited at Niagara Falls, Ont., is the largest cyanamid works in the world. The products manufactured are cyanamid, cyanide and silicate of soda. Cyanamid is used as a fertilizer and is made by absorbing nitrogen in powdered calcium carbide at white heat. The capacity of the plant is over 350,000 tons. Nearly 1000 people are employed.

Exshaw Cement Works of the Canada Cement Company, Ltd., near Banff, Alberta. Canadian cement plants produced 3,648,000 barrels, valued at $5,580,000 in 1935. There were nine plants in operation, employing about 1000 hands.



Fifty Years of Industrial and Manufacturing Development in Canada.

trade; ninth position in total imports; and fifth position in domestic exports.

The year 1936 saw an advance to fourth place among the trading nations of the world in export and fifth place in total trade, the latter amounting to $1,663,093,000, an increase of $274,435,000 over the previous years, showing a favourable balance of $617,000,000 over imports.

## WOOD AND ITS PRODUCTS

As already mentioned, the products of the forest have been of the greatest importance to industrial Canada. They provided for the construction of homes and buildings, the manufacture of furniture, vehicles, cooperage, shipbuilding, and during the period of this review have been the source of supply upon which mighty industries have developed.

When machinery was introduced and power replaced hand labour, the wood-working industry developed rapidly. The manufacture of horse-drawn vehicles was a leading industry when the Canadian Society of Civil Engineers was formed. Mass production and standardization of styles of doors and sash resulted in enormous increases in the product of the factories. Although much of the wood used in the manufacture of furniture is imported at the present time, factories using Canadian woods constitute an important industry. The proximity of great water powers to the pulp wood forests has made Canada the world's chief producer and exporter of newsprint.

The manufacture of sawn lumber is the second of the industries in Canada, which depend on the forest for their raw material. It is carried on by over three thousand establishments, from the gigantic mills of the Pacific coast, cutting as much as half a million feet board measure in a shift, to little custom mills on the Gaspé peninsula operated by windmills, cutting one or two thousand feet a day, with favourable winds.

Due to its importance, the pulp and paper industry deserves special mention. The superior quality of Canada's pulp and paper products has created a world demand. In 1935 Canada produced 3,868,341 tons of pulp, about 79 per cent of which was made in pulp and paper mills and used by them in paper making. Of the total pulp production 64 per cent was ground-wood, 17 per cent unbleached sulphite, 10 per cent bleached sulphite, 6 per cent sulphate. The total production of paper in 1934 was three million tons, of which newsprint and similar paper made up 84 per cent, paper boards 10 per cent, wrapping paper 3 per cent, book and writing paper 2 per cent, and miscellaneous paper the remainder. Conversion of many of these papers results in such products as napkins, towels, packaged toilet papers, coated and treated paper, envelopes, stationery and other cut paper and boards. Early in 1925 Canada's output of newsprint surpassed that of the United States. Since 1926 production in the United States has decreased, amounting in 1936 to slightly over 900,000 tons, while Canada's output was approximately 3,200,000 tons. Of the total Canadian newsprint exports of 2,993,000 tons last year 20 per cent went overseas and 80 per cent to the United States—new high figures to both destinations. Canadian overseas exports have more than doubled since 1928. They passed 500,000 tons for the first time in 1935 and reached 594,000 tons in 1936.

In 1935 wood and its products was Canada's leading industry in number of plants (8,186), employment (123,724 people), salaries and wages ($128,196,000) and in volume of output ($441,160,000) second only to that of vegetable products, and in invested capital ($873,757,000) second to that of central electric stations. While sawmills in 1934 were 43 per cent of the total number of establishments in this group, the ninety-five pulp and paper mills had an invested capital of over 60 per cent of the total and produced over 35 per cent of the value of manufactured products. Sawmills were second in output followed closely by printing and publishing, printing and bookbinding, boxes and paper bags; furniture; planing mills; sash and door factories; and other branches of the industry.

## TEXTILES IN CANADA

The Intendant Talon believed that French-Canadian colonists should clothe themselves either with the consent of the French authorities or in spite of them. He favoured domestic industries, and in 1671 wrote that he had caused druggets, coarse camlet, bolting cloth, serge, woollen cloth and leather to be made in the Colony, stating: "I have of Canadian make wherewithal to clothe myself from head to foot." Spinning and weaving were taught at their schools by the Ursuline Nuns. Almost every house had a flax spinning-wheel, a wool spinning-wheel and a hand loom, so that industrious women provided all the fabrics needed in the home, for bedding, carpeting and clothing.[9] The blanket coat of the snowshoers, the pattern of which is still preserved, was a production of that era.[10] The

[9] "Progress of Canadian Industries" by E. B. Biggar, from Castell Hopkins' "Canada, an Encyclopaedia of the Country."

[10] Young men might have been seen going about in colours that brightened the winter landscape. Gay belts of green, blue, red or yellow enriched the waists of their thick overcoats; their scarlet leggings were laced up with green ribbons; their moccasins were gorgeously embroidered with dyed porcupine quills; their caps of beaver or marten were sometimes tied down over their ears with vivid handkerchiefs of silk. The habitants were rougher and more sombre in their dress. A black homespun coat, grey leggings, grey woollen cap, heavy moccasins of cowhide—this grave costume was usually brightened by a belt or sash of the liveliest colours. The country women had to content themselves with the same coarse homespuns, which they wore in short full skirts, but they got the gay colours, which they loved, in kerchiefs for their necks and shoulders. (History of Canada by Charles G. D. Roberts, M.A.)

clothing mentioned in Roberts' history was made entirely of wool.

In 1768 Guy Carleton sent a report about the manufacturing situation to the colonial secretary, Lord Hillsbury, who was alarmed by the Canadian production, as he meant to keep the privilege of clothing the subjects of the Empire for the textile plants of England.

The manufacture of textile fabrics long continued to be a domestic industry. By the middle of the last century there were in Upper and Lower Canada and the Maritime Provinces, 385 carding and fulling mills and about 250 establishments where weaving was carried on in addition to the hand-loom weaving in the homes. The factory system in textile manufacturing increased with the growth of population, while home production diminished. We find in 1871 a yearly production of 7,640,000 yards of home-made cloth in the four provinces of the Dominion. By 1891 the production had dwindled in every province, having a total of only 4,300,000 yards, of which one-half was made in Quebec.

### Primary Textiles

*Woollens*

Ontario played a pioneering part in the establishment of the woollen industry in Canada. In Eastern Ontario at Galt and other places, at Cobourg in Central Ontario, and in Lanark County the woollen industry grew to an extent that the district was known as the Yorkshire of Canada. The largest woollen factory in Canada was located at Sherbrooke, Quebec. In 1891, the census year nearest to the period under review, there were 377 woollen mills; total hands employed—7,156; annual wages—$1,884,483; total products—$8,087,871. The output of the woollen establishments in Canada in 1920 was $28,000,000, which is the peak year in woollen cloth production. In 1934 it was less than $18,000,000, and has not increased with population or in proportion to the growth of textile industries as a whole.

*Cottons*

The cotton industry had its genesis in the middle of the last century.[11] There were in all Canada in 1889 twenty-five mills with 11,282 looms and 519,700 spindles. For twelve years there was no increase in the number of mills, then capable of supplying twice the population. This over-production resulted in amalgamations. Canada exported grey cottons to China in 1887. The cotton textile industry comprises: cotton yarn and cloth, cotton thread, cotton and wool waste, cotton batting and wadding, and cotton textiles.

*Linen*

The introduction of linen and hemp manufacturing in Canada was contemporaneous with that of the woollen industry. Records show that linen cloth making was introduced as early as 1668. Hemp growing was encouraged by both the French and English regime. The manufacture of home-made linen reached a total of one and three-quarter million yards in 1871, which in 1891 had decreased to 630,000 yards The attempts made to manufacture linen by machinery in Canada failed.

*Silk*

At a time when practically all other industries were experiencing a diminishing demand for their products, or were struggling hard to regain the 1929 level of production, this industry has since then recorded an increase of twenty-four per cent in capital investment, 131 per cent in number of employees, 119 per cent in salary and wage payments, 80 per cent in cost of materials used and 93 per cent in gross value of production.

The principal products of this industry are:—real silk, artificial silk, real and artificial silk mixed, including velvets, artificial silk and cotton mixed.

Ontario and Quebec accounted for all manufacturing activities in the silk industry. Of the thirty-three establish-

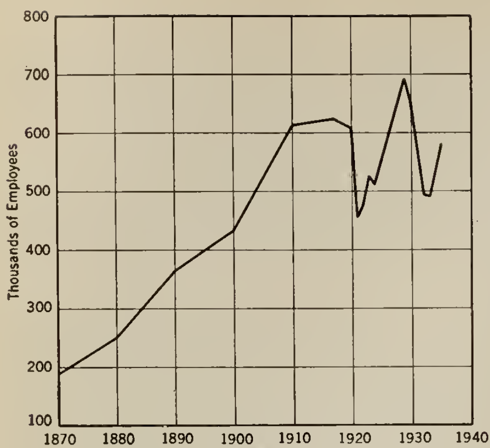

**Fig. 5—Employment in Manufacturing.**

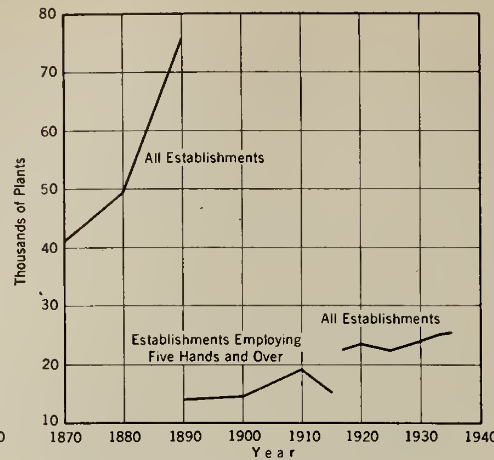

**Fig. 6—Number of Manufacturing Establishments.**

ments, eleven were situated in Ontario and twenty-two in Quebec. The brightest feature of the textile industry during recent depression years was the progress made in the manufacture of that industrial marvel, rayon, and the progressive growth of both the silk and rayon industry.

*Rayon*

The history of Canada's rayon industry is meritorious. Consumption of rayon yarn in this country during the past ten years increased from 3¼ million pounds to 13¾ million pounds, over ten million pounds of which was produced by Canadian plants, one at Cornwall, manufacturing viscose yarns, and the other at Drummondville, manufacturing cellulose acetate yarns. The two plants employed 4,300 workers. Their record is an enviable one, as they have during that period brought into being a major Canadian industry. The increase in volume was paralleled by constant improvement in quality, so that the fabrics made in one plant and the yarns in another, which are woven in many establishments, can compare in quality with anything produced in the world. In its report for the year 1935, the Dominion Bureau of Statistics shows 10,000 persons employed and a total production of $28,045,000.

*General*

The war brought about a modernization of the textile mills of Canada, due to the great demand for the army and civilian population. The depression was responsible for greater efficiency obtained by improvements in plant equipment and organization.

The primary textile industry in Canada comprises a total of 476 mills and includes:— 49 cotton manufacturers; 104 woollen and worsted manufacturers; 180 knit goods manufacturers; 34 silk and rayon manufacturers; 8 plush, velvet and upholstery manufacturers; 1 linen manufacturer; 12 carpet and rug manufacturers; 11 cordage and rope manufacturers; 16 dyeing and finishing; 14 waste and shoddy manufacturers; 34 labels, ribbons and narrow fabric manufacturers; 14 felt manufacturers.

During 1934 the primary textile industry employed 61,061 people and produced a gross value of products of $190,614,000, while the secondary textile industry shows 1,731 establishments and 54,634 employees, and produced a gross value of products of $151,440,000—a total textile production of $342,054,000. Rising commercial prices have given the industry an impetus which indicates that the present year will be the best not only in point of production but from the number employed. The industry employed as at April 1937 sixty-six thousand hands.

During the year ended January 1937 Canada exported fabrics, textiles and textile products to a value of $12,615,000.

### Clothing

In the period of Canadian history until about 1870 there is no record whatever of the establishment of what might be described as "clothing factories." Until that time clothing was either made in the homes of the people or in the case of men's clothing, made by tailors who operated small shops, making clothing to measure for individual customers. In the country districts, itinerant tailors journeyed from village to village and from house to house, carrying with them their shears and tailors's goose. They were supplied with cloth, usually made in a local woollen mill, frequently from wool supplied by the farmer from the backs of his own sheep. Women's clothing was made at home or by dressmakers, sometimes employing a number of other women in their own homes or small shops, but usually by women who visited the homes of those who required and could pay for their services.

The first census of Canada which makes any mention of clothing factories is the census of 1901. Earlier census records show large numbers of clothiers, tailors and dressmakers.

Strong contrasts are found in what is known as the secondary textile industry of Canada. In the primary industry some of the shrewdest business minds of the

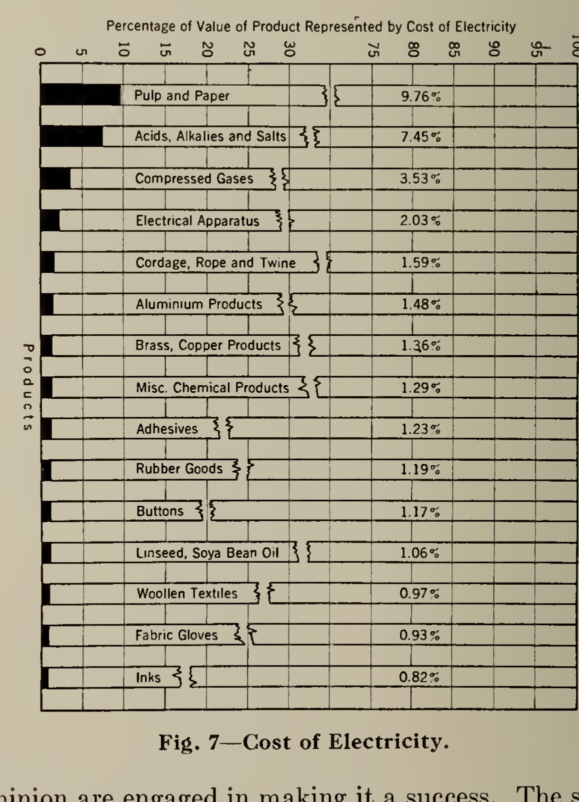

**Fig. 7—Cost of Electricity.**

Dominion are engaged in making it a success. The same is true of some well-organized establishments in the secondary industry. There are about one thousand[12] manufacturers of wearing apparel of one kind or another, the outcome of the contract shops and the establishment of the manufacture of shirtwaists in the "nineties." This industry employed 54,634 people in 1934, being second only to the primary textile industry with its 61,000.

---

[12]Fraser's Directory.

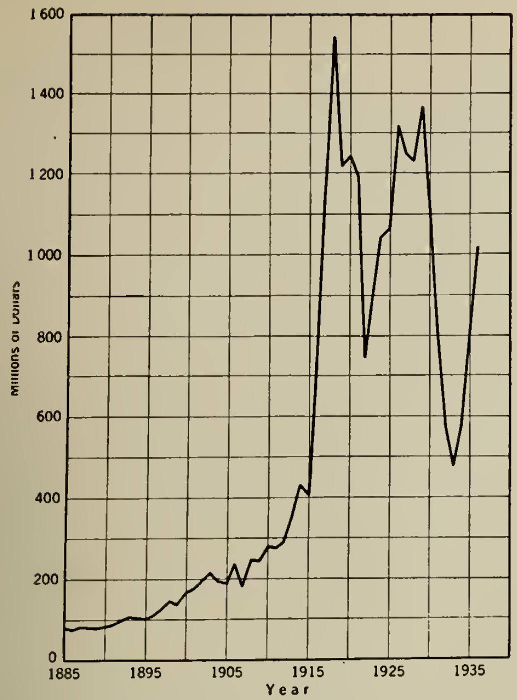

Fig. 8—Exports of Canadian Products.

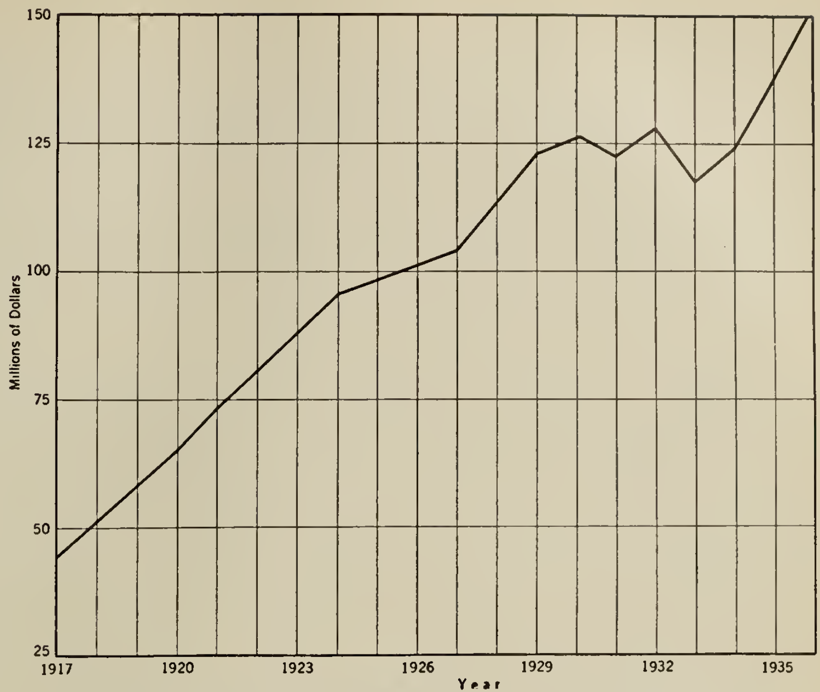

Fig. 9—Central Electric Stations value of Power Produced.

The Price Spreads Commission, appointed to investigate industrial profits, as well as the economics of labour conditions of the industries, in its report said of the secondary textile industry:—"Characterized by economic instability and excessive competition with contract shops and 'home workers' alongside the usual type of manufacturer, this industry though it includes many progressive and socially minded members, has had on the whole a doubtful record. The evidence we have taken shows that in many cases this record is only too well deserved."

There is a high mortality in the clothing industry.[13] Reports show that about 12 per cent of the firms engaged in men's wear industry and 18 per cent in women's wear industry fail each year. A great majority of establishments are conducted by men with little business experience, small capital and lacking in organized leadership.

From the homespun of the pioneer this industry has evolved through a remarkable cycle. The influence of the chemical engineer, the electrical and the mechanical engineer on the textile industry during the past fifty years has been profound.

## IRON AND STEEL AND THEIR PRODUCTS

Canada has pioneered in the metal-working industry. In 1733 the first metal-working industry on the continent was started at the Old Forges, on the St. Maurice river, a few miles north of Three Rivers. The quality of the iron manufactured from these ores was excellent, rivalling the finest made in Sweden. It is recorded[14] that in 1737 one hundred men were working at the plant, which was capable of supplying the working tools and household utensils required by the pioneers in their every day life.

In 1887 iron ore was produced to an amount of 76,330 tons, valued at the mines at $146,197. Four blast furnaces were operated, one at Londonderry, Nova Scotia, two at Drummondville, Quebec, and the Radnor furnaces at Three Rivers. The amount of pig iron produced was 24,827 tons.

The manufacture of machinery, tools and implements was a considerable industry in 1891. Nearly fifty thousand people were employed in over twelve thousand establishments, which had an output of over sixty million dollars. Thus, while industries employing wood products then led, the metal-working industry was already becoming an increasingly important factor.

At present three companies in Ontario and one in Nova Scotia are the only concerns in Canada making pig iron. The Ontario works depend upon foreign ore and coal, but the Nova Scotia plant uses local coal and iron ore from Newfoundland. The capacity of the blast furnaces operated is one million and one-half long tons of pig iron per annum. These companies, which represent the primary iron and steel industry, also operate open hearth steel furnaces and rolling mills, which produce steel ingots, blooms and billets, bars, rods, rails, structural shapes, plates, sheets and other material.

The selling value of the products of the iron and steel industry at the works, according to the preliminary statistics of 1935, is $388,542,774, from a total of 1,261 plants, employing 94,786 people, a capital investment of $548,467,111, and paying salaries and wages of $110,341,786. Castings and forgings number 275 plants, employ 10,701 people, while railway rolling stock with thirty-seven plants employs 16,921, and the twenty automobile establishments 13,095. The primary iron and steel industry employs 9,777 people in fifty-three plants. Machinery manufacturing numbers 202 plants, hardware and tools 134, metal plants 128, automobile parts 81, wire and wire goods 69, boilers, tanks and engines 51, agricultural implements 34, bridge and structural steel 18, bicycles 4, miscellaneous iron and steel 94. Exports advanced from $37,402,000 in 1934 to $50,027,000 in 1935. The number of establishments since 1917 has decreased by 150 and the number of employees is two-thirds of that in 1917 and 35,000 less than in 1929.

During the year ended January 1937, Canada imported iron and its products to a value of $139,616,000, of which $22,157,000 was from the United Kingdom and $112,097,000 from the United States. During the same period Canada exported iron and its products to an amount of $52,382,000, of which $12,674,000 went to the United Kingdom and $5,958,000 to the United States.

## CHEMICAL PRODUCTS

As is the case with many other industries, the availability of hydro-electric power and the demands created

[13]Manual of the Textile Industry of Canada, 1936.

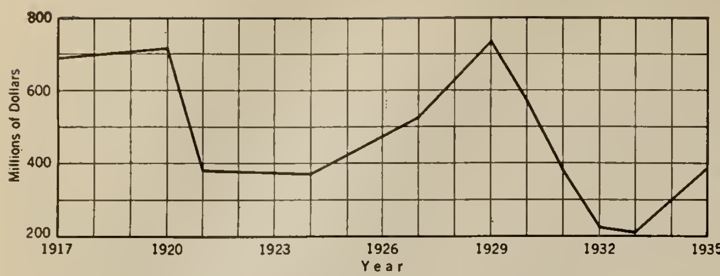

Fig. 10—Iron and Iron Products, Gross Value.

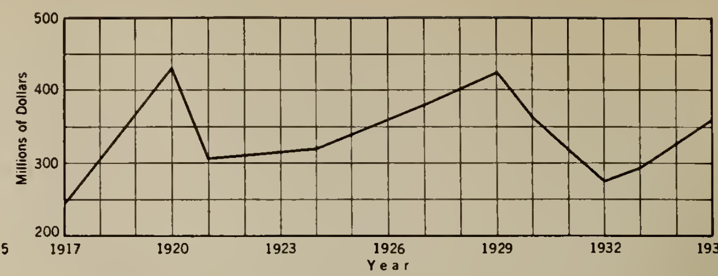

Fig. 11—Textile and Textile Products, Gross Value.

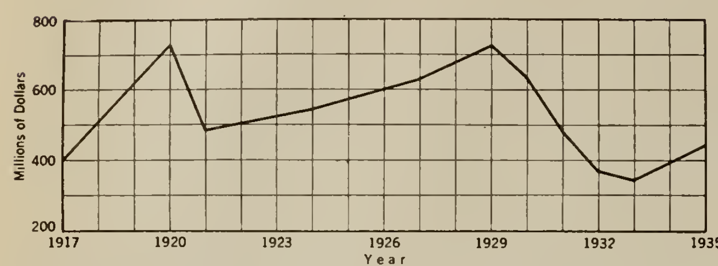

Fig. 12—Wood and Paper Products, Gross Value.

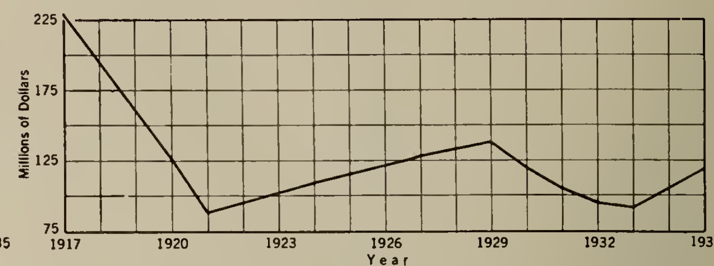

Fig. 13—Chemicals and Allied Products, Gross Value.

by the war have been the great contributing factors to an industry which today plays an important part in Canada's economic welfare. Eighty per cent of the country's requirements for chemicals and allied products are manufactured in the country, in addition to which the export trade has assumed considerable proportions, amounting to $16,372,000 in 1935, which was about 15 per cent of the production.

PETROLEUM

As one of the non-metallic group of minerals, petroleum is important. Many industries have been stimulated by the automobile, but its use has really created the petroleum products industry as we know it today.

There were, in 1921, eleven petroleum refineries in Canada. 1935 records report forty-five, distributed as follows:—Saskatchewan 14; Alberta 9; Ontario 7; Quebec 4; Manitoba 4; British Columbia 4; other provinces 3. These refineries used 1,196,411,000 gallons of crude oil, with operation to 58 per cent of capacity. Gasoline production amounted to 513,716,000 gallons, which was the highest on record. The industry gave employment that year to 4,771 people and had a selling value of products at the works of $79,175,000.

THE FISHING INDUSTRY

Fisheries of the Maritime Provinces, British Columbia, Yukon, the North-West Territories and the Magdalen Islands are controlled by the Dominion government. The non-tidal fisheries of the Maritime Provinces, Ontario, the Prairie Provinces, and the tidal and non-tidal fisheries of Quebec are controlled by the respective provinces. The Dominion operates twenty-four main hatcheries, nine subsidiary hatcheries, eight salmon retaining ponds, and distributed in 1933, 109,500,000 pounds of eggs, fry, and fish, both salmon and trout. Biological research stations are established at Halifax, St. Andrews, Nanaimo and Prince Rupert. The Canadian fishing grounds are among the most valuable in the world.

Fishing is one of the oldest and most historical of Canada's industries, having been carried on since the earliest days of the French regime. Deep-sea fishing commenced in 1873. There are nearly sixty different kinds of fish on the list, the most important of which are:—salmon, lobster, cod, herring, whitefish, halibut, haddock, pickerel and trout. In 1935 there were 68,557 fishermen employed, and in addition 14,360 in fish-canning and curing establishments. The industry has an investment of $43,617,000 and the output a market value in 1935 of $26,677,801, the greater part of which is exported.

THE FUR TRADE

The furs of the forests were the most esteemed of all their assets in Canada's early adventurous days. The northland still contributes liberally,—at present 66 per cent in value—but the largest single item—silver fox—is now a farm production, showing an increase in every year since 1920. The fur trader of the early days secured his pelts from the Indians. Since the Great War, Montreal has become an international fur market, the first Canadian fur auction being held in 1920. Fur auction sales are held also at Winnipeg, Edmonton and Vancouver. All provinces in Canada have enacted laws to regulate the capture of fur-bearing animals, provide for closed seasons, and work in co-operation with the Dominion government.

Besides the fox—mink, racoon, skunk, marten, fisher, muskrat and beaver are raised in captivity. In 1935, 4,926,413 pelts came on the market, valued at $12,843,000. The highest priced fur is the fisher, averaging $45.62 per pelt; the second is the silver fox at $36.06. In value the silver fox leads, followed in order by the muskrat, marten,

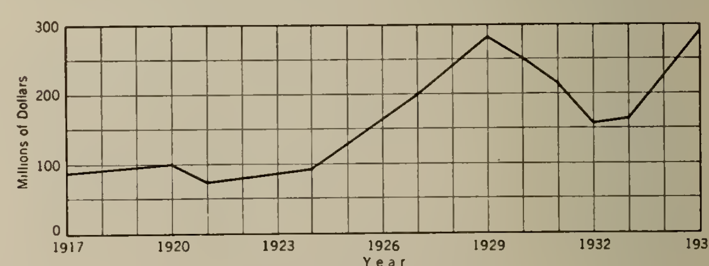

Fig. 14—Non-Ferrous Metals, Gross Value.

white fox, the red fox, and the cross fox. Of the nearly five million pelts marketed in 1935, Alberta led with 1,850,000, followed by Saskatchewan supplying over 1,000,000, and the yield from the other provinces is, in order:—Ontario with 686,342, Manitoba 490,295, Quebec 299,279, North West Territories 212,414, British Columbia 200,351, Nova Scotia 66,828, New Brunswick 55,184, Yukon 41,309, Prince Edward Island 19,828.

### MAPLE SUGAR AND SYRUP

The foundation of the maple sugar and maple syrup industry in the Dominion was laid in Canada by the early French settlers some two hundred and thirty years ago. It is now a substantial industry and guarded by a special act. Quebec is the centre of the industry and accounts for 75 per cent of the marketed Canadian production. Fifty thousand Canadian farmers produce syrup or sugar from twenty-four million trees, being only one-third of possible use. This industry produced a revenue of $3,714,000 in 1936, over eight million pounds of this sugar being shipped to the United Kingdom during that year.[15]

### EXPORTS OF CANADIAN PRODUCTS

In 1887 Canada's total exports were $89,515,000. These continued to increase with declines in 1905 and 1907 until 1914, the year in which Canada entered the Great War. The tremendous requirements for Canadian products, coupled with the manufacture of munitions, a heretofore unbelievable industrial expansion, and the rapid increase in cost of materials, brought the exports of Canada to a record peak in 1918 of $1,540,000,000. In 1922 this had fallen to $740,000,000, increasing rapidly in 1926 to $1,315,000,000, decreasing in 1927 to 1928 and reaching in 1929 a total of $1,363,000,000. Then followed a rapid decline until 1933, when the total had dropped to $473,000,000. Since then the improvement has been almost as rapid as that of the war years, so that in 1936 Canada's exports have again exceeded one billion dollars. Forest products—newsprint paper, wood pulp, planks and boards, and shingle wood exports—amounted to $154,163,000. exceeding in value that of wheat which was $148,577,000.

In 1936 total exports of Canadian merchandise were $1,027,902,000, which was an increase of 22.6 per cent over the preceding year. The total of twenty-four leading nations showed an export increase of only 6 per cent. The imports were $635,191,000.

### THE PRESENT ERA

A general economic recovery, existing reciprocal trade agreements with many countries, notably the British Empire and the United States, war preparedness demands, exchange stability, modern mechanical equipment, efficient industrial processes, higher prices and greater markets for wheat and other food products, for nickel, asbestos, aluminum, zinc, lead, iron and steel products, chemicals, textiles, lumber, pulp and paper, and the tourist trade, have rapidly improved Canada's position during the present era, which commenced four years ago. An agricultural yield of over one billion dollars in 1936, increased production of pulp and paper, chemicals and chemical products, record output of non-ferrous metals and other products, of central electric stations, and monthly increases in exports during 1937, indicate a condition comparable with the boom period of the Twenties.

### CONCLUSION

Facts and figures, already given, leave no doubt as to the material progress made in industry and manufacturing in Canada during the half century just past, in which electricity and the engineer have played principal parts. The engineer has yet another rôle if he would fulfil his destiny. Twenty years ago the author, at a meeting of the Ottawa Branch of The Engineering Institute of Canada, uttered these, so far not prophetic, words:—

> "The lawyer and the politician have admittedly failed to solve the industrial relations of man to man and the relations between capital and labour. The very qualifications of mind and training that have enabled the engineer to so successfully grasp and solve any problem set before him will be called upon and required to solve and to deal with what will be, after the war, the greatest problem which we have to face."

Today's worker in Canada produces four times as much in value of output as his grandfather did. He is paid four times as much. He works fewer hours. He enjoys standards of living then unknown. Labour on this continent is being organized and misled by leaders, whose lust for power knows no limitations. The labour situation grows more and more like that which created dictatorships in Europe, which, having used labour to gain power, later regimented and made it inarticulate. This country's population has doubled since 1887. Now, there are only 57 per cent more workers engaged in industry, which produces six times as much in value of output. Mechanical-electrical engineer-created machines and appliances have done much to create a social situation that needs a remedy and towards which the engineer has a responsibility.

The problem of stabilizing our whole production machine and rationalizing the human element, which includes putting youth to work, retirement of older men, employee-management relations, employee welfare, time and wage schedules, needs scientific treatment and the application of the engineer's mind. The present economic system requires more basic interpretation and more definite codification. The mechanism of human relationships in industry is due for overhauling and neither legislation nor labour organizations can do it.

If those who are guiding the destinies of The Institute were to make the solution of this unsettled problem a principal item on its programme, and its members succeed in finding that solution, which assuredly they can, The Institute will not only have increased its prestige, but the engineer will have exalted his profession by giving direction to a troubled humanity, that needs leadership to bring into being a new order in social affairs.

#### Illustrations

The illustrations, besides giving a glimpse of industry in Canada's earlier days, are included for the purpose of showing, even briefly, the style of modern factory buildings and the extent of some of Canada's industries.

#### Acknowledgments

In addition to the references already mentioned, acknowledgment is made of photographs supplied by the Canadian Manufacturers Association; Canadian Pacific Railway; National Development Branch, Department of the Interior; Natural Resources, Intelligence Service, Department of the Interior; Canadian Airways Limited; and many companies whose plants are illustrated. Appreciation of information supplied and assistance rendered is expressed particularly to Dr. R. H. Coats, and the able members of his efficient department, The Dominion Bureau of Statistics; to the McGill Library; to The Engineering Institute library; to the Public Library of Toronto; to the Library of the Legislative Assembly of Ontario; to the Statistical Department, Province of Quebec; to the Secretary of the Montreal Board of Trade; to the editors of Industrial Canada, Monetary Times and the Montreal Gazette to Mr. Frank Whitcomb and Mr. E. V. Leipoldt.

---

[15] The chemical industry, fast becoming great, and mineral production, making new records every year, are important features of Canada's industrial fabric. As each of these is a subject of a separate paper of this series they are mentioned but not in proportion to their industrial significance. Individual industries such as boots and shoes, which has an interesting historical background, and those non-ferrous metals, asbestos, nickel and aluminum, which are of such economic importance, and others of a lesser value, might well have been included in a more extended review.

Fig. 1—Seymour Falls Water Intake, Vancouver, B.C.

# Progress in Sanitation

*Theo. J. Lafreniere, M.E.I.C.,*
*Chief Engineer, Quebec Ministry of Health, Montreal, Que.*

A review of the developments which have occurred, during the last fifty years, in the "adoption of sanitary measures conducing to the preservation of health" would mean writing the history of modern sanitation. The use of solid culture media in bacteriology and the germ theory of disease date back to the early eighties.

In 1874, the Rivers Pollution Commission of England stated in its Sixth Report that "the existence of specific poisons capable of producing cholera and typhoid fever is attested by evidence so abundant and strong as to be practically irresistible. These poisons are contained in the discharges from persons suffering from these diseases." It had been observed that sewage polluted waters could be the cause of disease, but foul air was also considered dangerous.

The same report contained this historical statement, well known to sanitarians: "There is no river in the United Kingdom long enough to secure the oxidation and destruction of any sewage which may be discharged into it, even at its source."

The studies made in England were closely followed in America, and the State of Massachusetts, where sanitary conditions resembled those prevailing in England, became a leader in sanitation on this side of the Atlantic. The State Board of Health, created in 1869, had advisory rather than executive functions, and one of its first circulars contained this declaration of rights as regards public health: "We believe that all citizens have an inherent right to the enjoyment of pure and uncontaminated air, water and soil, —that no one should be allowed to trespass upon it by his carelessness or his avarice or his ignorance."—These high ideals could not be put into force, and numerous recommendations contained in subsequent reports of the Board show that its work remained of an educational nature for several years.

In Canada, public health measures were taken at times of epidemics only, through a Central Board which Parliament could appoint. The English practice of creating local boards of health was largely followed. Sanitary conditions were better than in England and Europe, due to our small population scattered over a large territory.

Modern sanitation began with the creation of Provincial Boards of Health in Ontario in 1882, in Quebec and New Brunswick in 1887, and later in the other provinces. The powers granted were of an advisory character at first, but it was soon felt that more than persuasive action would be necessary to secure better co-operation from the local boards of health.

In 1895 the Boards of Health of Ontario and Quebec required that plans of water supplies and sewerage systems be submitted for approval; however in 1908, sanitary engineering divisions were created in order to secure better control of new works, and to apply remedial measures to some of the previous works.

### Water Supplies

In 1885, there were sixty water-works plants in Canada. The larger towns had realized early the necessity of such a public service; the systems were mostly of the gravity type and fed by springs or lakes. Improvement in pumping machinery and the introduction of cast iron pipe so facilitated the installation of new works, that twenty-five years later, the number of plants had reached the figure of four hundred and twenty.

The transmission of electricity and the advent of the centrifugal pump, reducing the cost of pumping installation, permitted the smaller municipalities to build water-works. The total number of works in Canada to-day is twelve

Fig. 2—McTavish Reservoir and Pumping Station, Montreal.

hundred and sixty, serving a population of 6,000,000 people, 54 per cent of the total population of the country.

The following statement is taken from a report of Sir John Simon published in 1867:— "My reports are incessantly showing the foulness of private supplies, while as regards public water supplies—it has again and again been shown that their conveniences and advantages are

THE HEAD OFFICE of the Sun Life Assurance Company of Canada—a magnificent monument to Canadian business enterprise and engineering skill. The corner-stone of the first part of the building was laid in 1914 and the corner-stone of the present structure in 1923. The ground area is 80,000 square feet and the total gross floor area (exclusive of three basements) is 1,174,000 square feet. The height is 399 feet (24 storeys).

*Illustration through the Courtesy of the*
SUN LIFE ASSURANCE COMPANY OF CANADA

countervailed by dangers to life on a scale of gigantic magnitude."

Sir. John Simon was referring to the numerous epidemics of cholera in London, where the relation between the prevalence of the disease and the impurity of the water supply had been observed.

Filters were first used to remove turbidity. Chemical improvements as shown by analysis were disappointing, though filtration seemed to be beneficial to health. Bacteriology revealed the removal of germs. Until 1870, there were no water filtration plants in America. The results of the Lawrence Experiment Station in Massachusetts in 1890 proved the efficiency of slow sand filtration and led to the installation of several plants in United States.

At the same time rapid filters had been installed in various municipalities, but it was after the classic experiments of Geo. W. Fuller, on the purification of the Ohio river at Louisville and Cincinnati in 1895 and 1898, that this type of filtration was placed on a par with the older type.

The American practice was adopted in Canada whenever filtration was required. The necessity for the purification of public water supplies was felt only after 1900, as up till then many sources of supplies were not seriously contaminated. However, numerous epidemics of typhoid fever were necessary to convince municipal corporations that a pure water supply was a good investment.

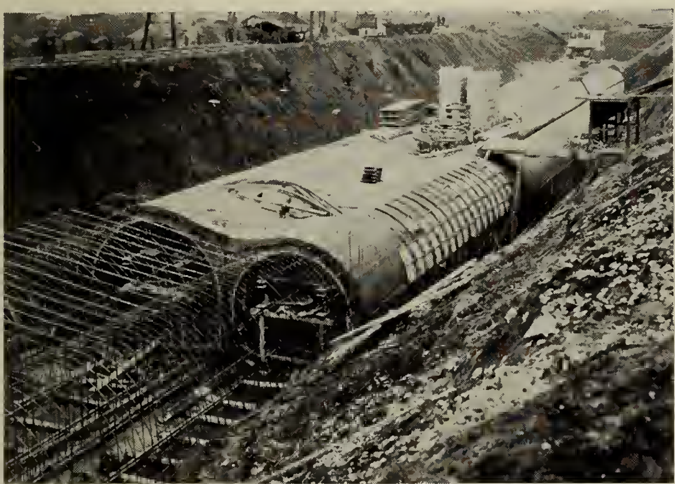

**Fig. 3—St. Pierre River Collector, Montreal. Inside dimensions of Twin Section 14 ft. by 14 ft. 6 in. and 16 ft. by 17 ft. 6 in.**

The first large slow sand filter was built in Toronto in 1912, and Montreal commenced a similar plant of a modified type the following year. The cost of these filters precluded their use by small towns, which resorted to rapid sand filters of the pressure or gravity type. Pressure filters were first used around 1905, in New Brunswick, and gravity filters in Quebec, in 1910. There are in Canada to-day, one hundred and twenty-five filtration plants, serving a population of approximately 3,000,000 people.

Chlorination has been a great help in bringing improvement to many small and large supplies. After the use of chloride of lime by Colonel Geo. A. Johnson, in Chicago and Boonton, in 1908, the adoption of the process spread very rapidly. Montreal thus treated its water in 1910, pending the construction of its filtration plant.

Liquid chlorine soon replaced hypochlorite of lime and it is used to-day in 260 plants, either alone or in conjunction with filtration. The total population thus protected is over 4,000,000.

The art of water purification has reached a high degree of development. Bacteria, colour, turbidity, and odour can be removed with assurance. Its application has reduced typhoid fever death rates in Canada from 30 per 100,000 in 1910, down to less than 2 in 1937.

### Sewerage

Strangely enough it was strictly forbidden to discharge any sewage into the first sewers built. Their object was to remove surface and drainage waters only. However, the temptation was too great, not to so dispose of wastes, and the sewers became elongated cesspools.

Water courses receiving the natural drainage of the land were first walled in, and finally covered, when too foul. Smaller drains built by private initiative or otherwise were soon connected to the larger sewers, and effluents from overflowing cesspools were finally admitted into the system. The water carriage system has been developed by the method of trial and error, by experience more than by experiment.

Flooding of basements and cellars was of frequent occurrence with the early systems; the capacity of sewers as well as the amount of sewage and storm water to be transported were poorly established. Silting of sewers was too frequent, causing the sewer gas which was so much feared.

The installation of sewers in Canada followed the construction of the water-works. English and American practice largely inspired the Canadian works; conditions requiring sewerage arose in the United States several decades before they did in Canada. Moreover, large rivers and smaller centres of population facilitated the solution of such problems.

Reliable statistics showing the growth of sewerage systems in Canada are difficult to obtain. A compilation made by the Conservation Commission in 1915 gives a total of two hundred and eighty systems and 75 disposal works. Today, all cities and towns are sewered and most of the villages are served by private or public sewers. Interceptors are built to reduce the number of outlets or to collect the sewage preparatory to treatment.

The important question of how to deal with the sewage at the outfall was easily solved in most cases: disposal by dilution. Montreal and one inland town applied the sewage to the land after the early English fashion, and with similar results. The soil being unsuitable, the system had to be abandoned.

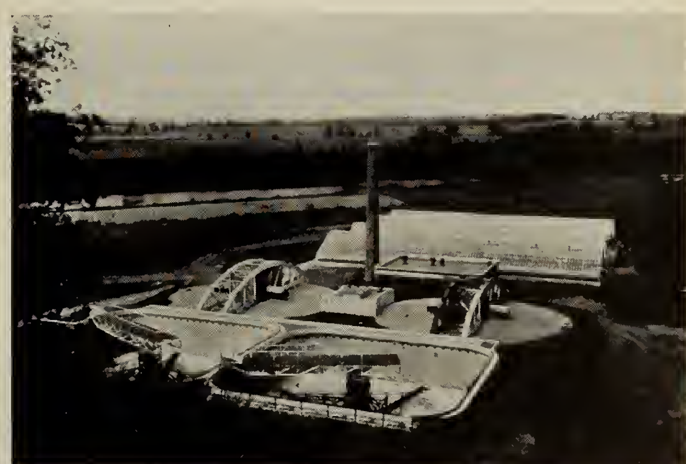

**Fig. 4—Separate Sludge Digestion Plant, 4 m.g.d., Kitchener, Ontario.**

The biological decomposition of sewage in tanks instead of on filters, developed by Cameron in 1895, was expected to produce complete liquefaction. The "septic tank" held public favour for over a decade, and several installations were made even in places where not needed. The problem had not been solved; the effluents were dark offensive liquids and the sludge difficulty remained. The Imhoff or two-storey tank, which is a modification of the Travis tank, was a marked improvement over the septic tank. It was eagerly adopted in Canada and especially in the United States, after 1910.

Contact beds were never popular in this country; percolating filters offered a better means to obtain oxidation of the organic matter, when low dilution required a high degree of purification. The filter area needed for the treatment of large volume of sewage brought the activated

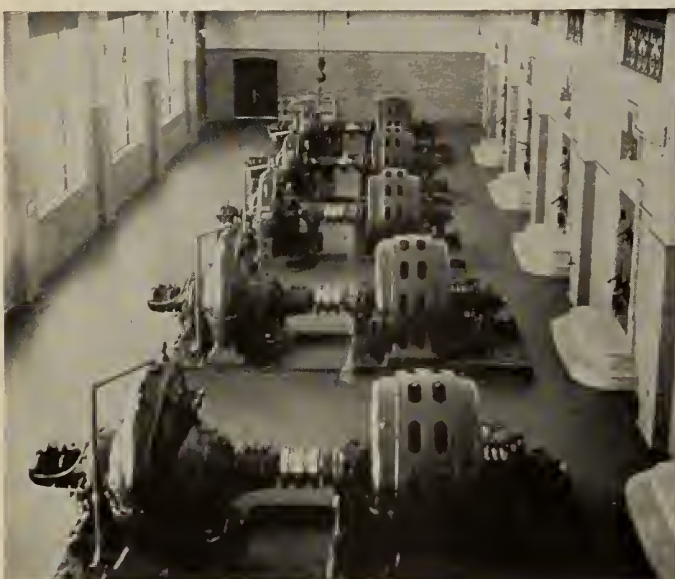

**Fig. 5—Main Pumping Station, Montreal. Highlift Pumps.**

sludge process, which consists in the oxidation of the sewage in tanks instead of on solid material. Experiments made about 1916 proved successful and the method was readily adopted.

The process consists in bringing the sewage into intimate contact with the proper kind of micro-organisms in the presence of an excess of air; it produces a stable effluent and removes a large percentage of the bacteria present in the raw sewage. An activated sludge plant requires expert supervision and can be more easily abused than a percolating filter. The latter still offers a better solution to the sewage disposal problem of the small town.

In recent years the mechanization of the sewage disposal plant has come to the fore. The importance of the object to be obtained has been given more consideration. A method of treatment is no longer adopted simply because it has been successful elsewhere. Each problem is studied and a selection or a combination of proved methods is chosen to satisfy the requirements. Chemical precipitation, which had been abandoned, is receiving favour; new chemicals and a better knowledge of the chemistry of sewage have brought the change. Chlorination of partly clarified sewage is used to protect beaches or prevent undue bacterial pollution of water courses.

There is a public demand for cleaner streams; methods have been devised to purify sewage to any desired degree before it reaches the stream. Disposal by dilution offers economic advantages which are lost to the community at large, when the method is abused.

### Garbage Disposal

The collection and disposal of garbage has retained the attention of the engineer. The dumping ground has been abandoned by large and medium size towns. The hog farm which has always been a messy method of reclaiming value from garbage has lost its glamour. The Beccari process of garbage digestion requires a climate that a northern country does not enjoy.

The incineration of garbage has progressed since the first installation made in Montreal in 1885. Better furnaces have been devised, producing higher temperatures. Recent developments make it possible to burn sewage digested sludge with the garbage, and to use the gases produced by the decomposition of the sludge as additional fuel.

During the last three years a new process has been tried in the United States. It consists in collecting the garbage at a receiving station, where it is ground to a pulp and then discharged into the nearest sewer. The operation is reported to be successful and does not interfere with the subsequent treatment of the sewage—provided the plant has sufficient capacity.

The discharge of ground garbage into sewers, however, must not be attempted until all factors have been studied and the method proved to be economically sound.

### Conclusion

Fifty years ago bacteriology, although in its infancy, had demonstrated the germ theory of disease. The sanitation engineer was called upon to apply this new knowledge, as well as the subsequent discoveries of the biologist, to the solution of sanitary problems. The suppression of many scourges which afflicted humanity proves how well he has succeeded.

The engineer can well be proud of the part he has played in reducing the general death rate in Canada from 14.4 per thousand in 1887, to 9.2 in 1936. He has also contributed his share in increasing the expectation of life at birth, from forty-seven years to sixty years. If health is the capital of the labouring class, he has also contributed to the wealth of his country.

# Lighthouse Engineering

*J. G. Macphail, M.E.I.C.,*
*Chief of Aids to Navigation, Department of Transport, Ottawa.*

There is a convention governing every human enterprise. The convention in this case is that every discussion of lighthouse affairs begins with the Pharos at Alexandria, 280 B.C. But lighthouse engineering is older than that, as witness the excellent device which served to guide the Israelites on their memorable voyage across the Red Sea, 1491 B.C, namely the pillar of cloud by day, of fire by night. Between those dates there is no record of lighthouse engineering and little attention was given to the science for more than thirty centuries. Little definite progress was made until within the last two hundred years, and apart from lighting little was achieved prior to fifty years ago. In 1887 the lighthouse service had but recently emerged from the era of the tallow candle and the sperm-oil lamp; petroleum had come into general use only within the preceding ten years.

But lighthouse engineering is not singular in respect of rapid development in the last half century. Like every other forward step it has depended upon effective application of science in other directions, for example, in the petroleum industry, particularly the "cracking" of oil into gases; the unfolding knowledge of electricity; the evolution of the internal combustion engine; the rediscovery of Fortland cement; application of science to optics and acoustics; the contribution of chemistry in calcium carbide, acetylene, and acetone; vast progress in metallurgy; the miracle of radio.

### Lighthouse Towers

Important lighthouse towers, a hundred years ago, were built of stone and many of these fine structures are still in use. For the past thirty-five years all important towers have been built of reinforced concrete, some of the flying buttress type, as for example that at Cape Anguille, Newfoundland, shown in Fig. 1. The older light station at Cape Race is shown in Fig. 3. For lighthouse purposes concrete is a convenient medium for the reason that light stations are usually in isolated places, but sand, gravel, and water are generally available on the site and the proportion of skilled labour required is small. Waterproofing of old stone towers and recent concrete towers has presented a difficult problem, but is being solved by the use of plastic materials applied under pressure in the case of stone structures, and sealing compounds on concrete.

The distance lights can be seen is limited theoretically by the horizon, or the curve of the earth, and the distance of the horizon depends on the elevation of the observer. The higher the light the farther it can be seen. But as in every other art or undertaking many problems enter, with the result that it is convenient to adopt a mean or middle course. Lighthouse engineers are agreed that a first order light should have an elevation of one hundred and fifty feet above the sea.

### Foundation Piers

Suitable lighthouse sites are usually found on headlands or islands, but in many cases it has been necessary to build submarine foundations on shoals sometimes miles from shore. While no unsurmountable problems present themselves in this regard, construction work is rendered difficult on account of exposure to the sea, and the necessity of carrying on the work, especially in the earlier stages, by "tide work." At Brulé Bank, below Quebec, two such piers were built on pile foundations. As the name implies, the site consists of a sandy shoal and much difficulty was

**Fig. 1—Tower at Cape Anguille, Newfoundland.**

encountered during construction by scouring. The rise of tide is twenty-one feet and the current four knots at ebb and flood. The difficulty was overcome by the use of brush mattresses of special design.

South East Shoal offers another good example of this sort of construction, the foundation pier being built in twenty-one feet of water six miles south of the extremity of Pelee Point, Lake Erie. This structure also is on a sandy shoal, and consists of pile and crib foundation supporting reinforced concrete pier, power house, living quarters, and tower. It has withstood the full force of Lake Erie storm and ice these ten years, and shows no sign of movement or settlement. There is some slight scour, but that is corrected by stone rip rap.

### Optical Apparatus

Fifty years ago the Fresnel lens was in general use. The property of this optic was to gather the rays of light from the source into a horizontal focal plane, thereby greatly increasing the power of the light in the focal plane as compared with the source of light not so directed. In this case, three hundred and sixty degrees of horizon were illuminated, and, in order to make the light distinctive in character, various types of mechanism were used to revolve screens or shutters around the source of light and thereby give the character of one, two, three, or more flashes, or groups of flashes, the purpose being to enable the navigator to identify each light by the advertised characteristic of it. These Fresnel lenses were quite effective optically and of considerable size, built up of central lens belt and refracting prisms mounted in brass framing and measuring five or six feet in diameter and, possibly, eight feet in height.

A great advance was made thirty-five years ago by the adoption of an optic, then lately developed in France and England, which gathered the rays of light not only into the horizontal plane but into a vertical plane also, that is, the optical apparatus consisted of two or more faces, each face being of the nature of a very powerful searchlight. Appropriate clock work causes this optic to revolve, and, according to the angular arrangement of the faces, presents a characteristic to the navigator of one, two, three, or four flashes, or groups of flashes. Such an apparatus is shown in Figs. 5, 6 and 7. The largest of these modern optics is over eight feet in diameter, ten feet high, and the optic itself, that is the glass and gunmetal framing, weighs five

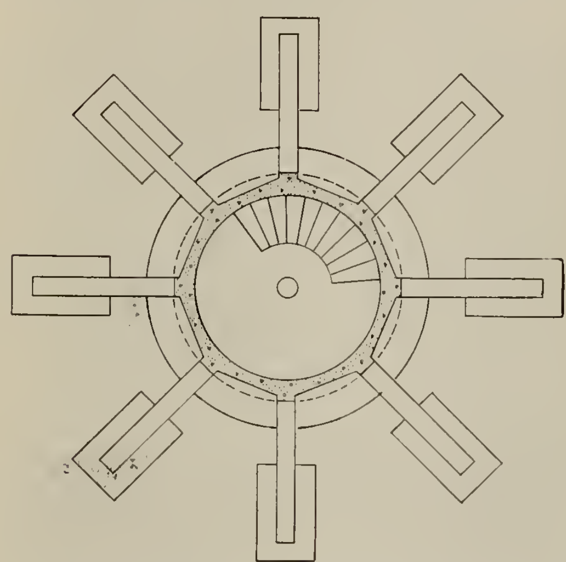

**Fig. 2—Plan of Tower at Cape Anguille.**

and one-half tons. In order to reduce friction and the effect of tower vibration, the optic is mounted on an annular cast-iron float which floats in an annular cast-iron bath of mercury. Although the weight floated, including the cast-iron float, is about seven tons, the quantity of mercury required is, by reason of the peculiar design of float and bath, only nine hundred and fifty pounds. The pedestal and clock weigh eleven tons, which, with the weight of the optic and lantern, makes a total load of forty-two tons on the top of the tower. The beam candle power is about four million candles. The cost of this lantern and optic when purchased in 1905 was $40,000.

The geographical range of a light depends on elevation above the sea, both of the light and of the bridge of the steamer from which it is observed. The light here described is one hundred and sixty-five feet above the sea, and the bridge of an ocean liner may be reckoned at sixty to ninety feet. On these factors the geographical range would be about twenty-five miles. The light has actually been seen seventy-six miles by reason of atmospheric refraction.

Extensive use is made of parabolic reflectors, particularly for range light purposes, but, on account of the flexibility, adaptability, and high candle power obtained from electricity, revolving reflectors are now being used in conjunction with electric lighting for principal coast stations.

In the matter of reflectors, a useful and interesting improvement was made some twenty-five years ago. For centuries, lighthouse reflectors were of the type commonly used for motor car headlights, the depth being large compared with the diameter. The distance of the focus of the parabola from the back of the reflector was relatively short. For example the focal distance of a twenty-four-inch diameter reflector would be only about three inches. It was consequently necessary to cut a hole above and below through which to pass the lamp burner and chimney. This seriously reduced the reflecting surface. Also it was necessary that each reflector should have its own source of light. In order to light the horizon it was necessary to revolve the reflector, the common practice being to mount three groups of reflectors disposed axially one hundred and twenty degrees apart, on a revolving mechanism driven by clock work. This gave the mariner the effect of a series of flashes, the interval between the flashes depending on the speed of the revolving system of reflectors. It was not uncommon to find five reflectors in a group or fifteen in the system, each of the fifteen equipped with its own source of light.

The late L. E. Coté, M.E.I.C., an engineer in the lighthouse service, and later chief engineer of the Marine Department, discovered that a relatively shallow reflector with relatively long focal distance would be equal optically to the age old deep type. A parabolic curve was adopted which placed the focus fifteen inches from the back of the reflector. While in the old type reflectors were circular, the new "long-focus" was made in the form of what might be described as a section of one-sixth of an orange peel as shown in Fig. 8. In width the section was made to subtend an angle of sixty degrees at the focus and the height of the section was thirty inches, the whole stiffened by ribs on the back—top, bottom, and sides. The reflectors were mounted on a revolving table, and, having a common focus, one source of light served all the reflectors of the system. By disposing these sixty degree segments axially sixty degrees apart and revolving the system, a single flashing light was obtained, the beam from each reflector passing through the opening opposite it between the other two segments. By placing the same three segments side by side a triple flashing light was produced, that is three quick flashes and a long interval between the groups.

**Fig. 3—Light Station at Cape Race, Newfoundland.**

Courtesy of Royal Canadian Air Force

**Fig. 4—Lighthouse, Point Atkinson, B.C.**

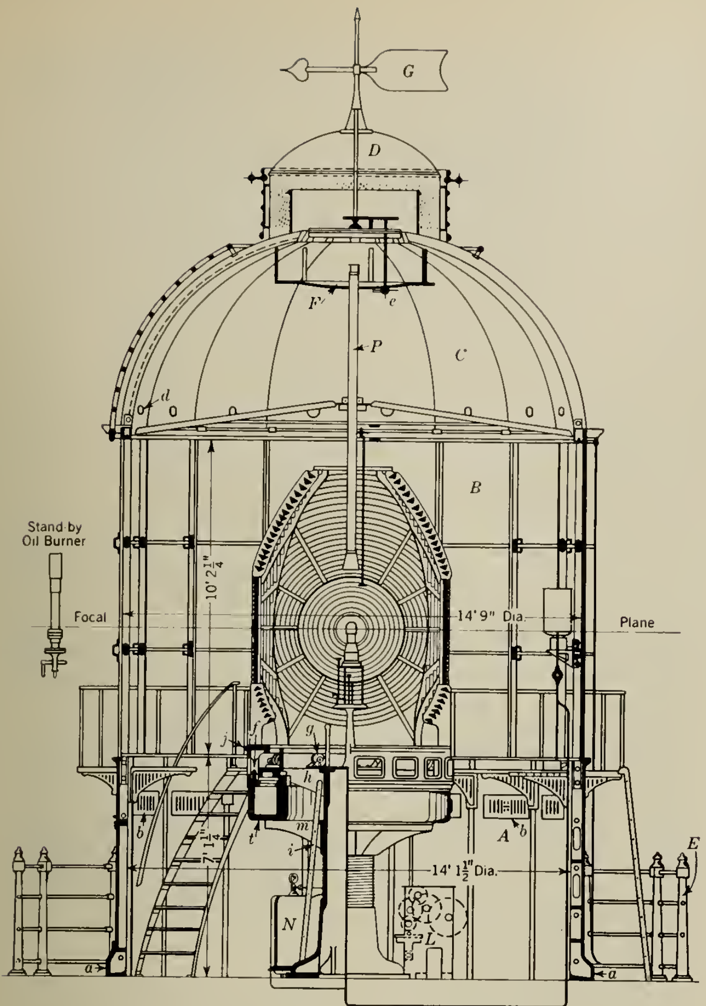

**Fig. 5—General Arrangement of Lighthouse Lantern.**

The double flash was obtained by adopting two segments subtending an angle of ninety degrees horizontally at the focus. In like manner the quadruple flash used four segments each subtending an angle of forty-five degrees.

A great advantage of this system is that by reason of the long focus, all portions of the source of light are approximately equally distant from all parts of the reflecting surface. The divergence is thereby greatly reduced and consequently a narrow beam of light is obtained, comparable to that of the cut glass lens and prism arrangement mentioned earlier. The reflector apparatus is inexpensive, costing only about six hundred dollars, compared with six thousand dollars for equivalent power in the case of a cut glass optic.

Another engineer in the lighthouse service, H. deMiffonis, M.E.I.C., latterly acting chief engineer of the Marine Department, now retired, also made an important departure in the use of reflectors. His contribution was to revolve a single deep short focus reflector, using electricity as driving power and source of light. The electric current to the lamp is interrupted by a system of contacts, which admits of producing any predetermined characteristic of light. A variation of his system is to use two deep short focus reflectors joined back to back with the apex of each cut away so as to admit of a common focus and a single source of light serving the two. Any characteristic may be had as in the case of the single reflector. This arrangement is powerful, flexible in respect of characteristic, and also inexpensive.

### Illuminants

Fifty years ago lighthouse illumination was confined to kerosene burned on a cotton wick, the Argand circular wick burner being then still in use. It was not until the early years of the present century that a notable improvement was made by the use of kerosene oil vapour burned under an incandescent mantle.

This improvement was made possible by the invention of the Welsbach mantle, which placed at the disposal of lighthouse authorities the means of producing a light of high intensity combined with compactness. The vapour burner consists essentially of means of vaporizing kerosene and burning the vapour under a mantle. The mantles vary in size, those in use being respectively 25 m.m. 35 m.m. 55 m.m., and 85 m.m., diameter, yielding respectively 250, 500, 750, and 1,000 candles. The size of the mantle to be adopted is governed generally by the focal length and design of the optic.

In the vapour burner, the vaporizing tube, one half inch to one inch diameter and eight to twelve inches long, is preheated by methylated spirits. When the tube acquires the correct temperature, the kerosene is admitted under thirty pounds air pressure and is vaporized. The vapour issues through a small aperture, part being led to the mantle and part directed against the vaporizing tube to maintain the vaporization temperature. Originally the tubes were made of seamless steel with 3½ per cent nickel content, and much trouble was encountered through rapid oxidation due to the high temperature. After persistent research, and test, an alloy tube of 18 per cent chromium has been evolved, with the notable result that whereas the earlier tubes would last only for a few nights, the chromium alloy is good for five to six months.

Some of the more important lighthouses are illuminated by electricity generated on the premises by internal combustion engine power. Commercial current where available and reasonably reliable is used. In all cases a specially designed electric lamp is used, the special features being that the filament is disposed as to arrangement or form to accord with the optical design of the lens. Also the filament is made in two halves in parallel so that in case of a filament failing the remaining half is still serviceable.

**Fig. 6—Optical Apparatus, Outside View.**

In the case of less important stations, the lightkeeper is not required to be in constant attendance, and so various devices are employed to guard against interruption. The commonest are warning bells which come into action on failure of current, and then the keeper puts in the standby emergency lamp. In cases where an interruption of even a minute or two would be dangerous to shipping, and this refers particularly to range lights leading through long, narrow, dredged, rock channels, interruption of light is provided against by the use of a battery, governed by a relay, which comes into action automatically immediately the current fails and supplies light until the regular current is re-established. These arrangements have regard to brief interruptions due to electrical disturbances in the atmosphere. Use also is made of time clocks to turn the current off by day.

Less important lights, particularly marking isolated rocks where daily attendance is not convenient, are lighted by gas stored according to one of the standard systems and burn continuously for predetermined periods commonly up to twelve months. In order to conserve gas, sunvalves are used to turn the gas off by day. These valves are actuated by sunlight and are very useful especially at points far distant from district headquarters and difficult from the point of view of replenishing the gas supply.

### Fog Signals

Fifty years ago fog signal stations were few in number, the instrument being either a cannon, gun cotton bombs, steam whistle, or compressed air trumpet. The cost of steam power, requiring transportation of coal to isolated points, difficult landings, and lack of sufficient fresh water, limited the establishment of mechanically operated sound signals. There was little or no progress until Mr. J. P. Northey, of Toronto, invented the diaphone about 1903. After some years of experiment and development the diaphone was adopted as the standard instrument, power being furnished by internal combustion engine to compress the necessary air. The power required depends on air consumption and this depends on the size of the diaphone and length and frequency of blast. Engines vary from six to thirty-five horse power.

The diaphone is shown in section in Fig. 9 and consists essentially of a piston reciprocating in a cylinder, in both of which are cut circumferential slots or ports. The piston is fitted with an operating head to which compressed air is admitted first on one side and then on the other, thus producing the reciprocating motion. As the ports in the piston pass and repass the corresponding ports in the cylinder, air at thirty pounds per square inch pressure is admitted, the speed of the piston being one hundred and eighty strokes per second, thus setting up one hundred and eighty vibrations per second in the atmosphere corresponding to the musical note F sharp in the tenor clef. The blast terminates in a quick descending note known as the grunt. This grunt is a very valuable distinctive feature and can sometimes be heard when the first part of the blast is inaudible. After years of observation and trial the diaphone has become the standard fog signal instrument throughout the world. Ordinarily the sound from the larger size of diaphone carries ten to twelve miles. Under favourable conditions it has been heard forty-five miles. Where shorter range is sufficient, smaller sizes of the diaphone are used and also electrically operated vibrators good up to six miles. The acetylene gun, too, is a useful instrument. Here acetylene is automatically mixed with air in suitable proportion, and exploded at predetermined intervals. (See Fig. 10.)

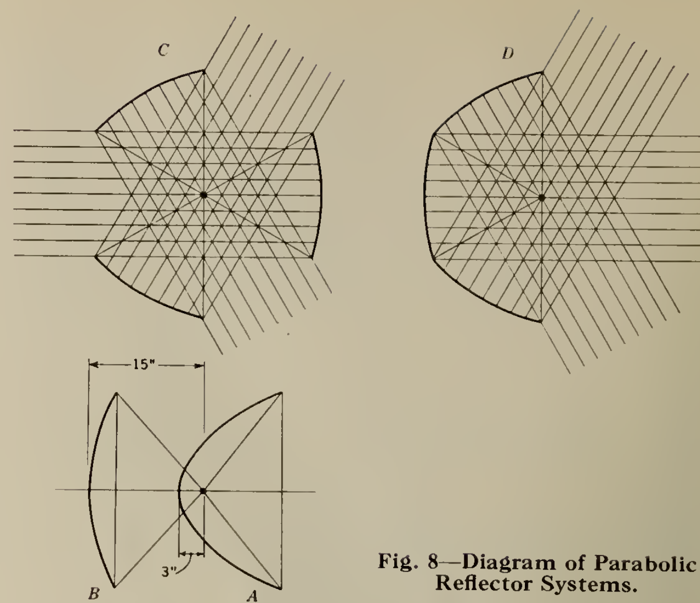

**Fig. 8—Diagram of Parabolic Reflector Systems.**

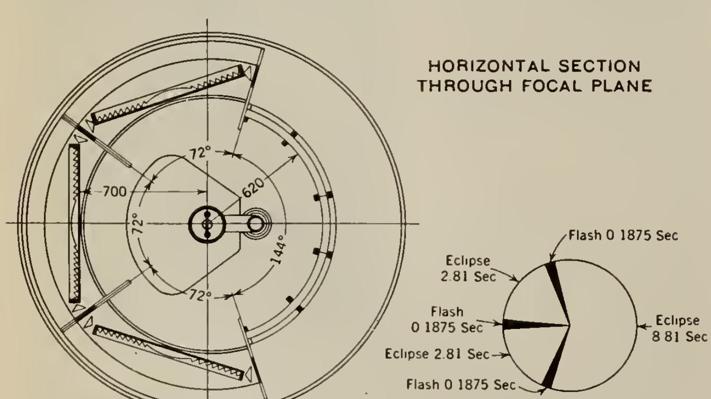

**Fig. 7—Section of Second Order Flashing Light.**

Air compressor equipment has passed through several stages in the last thirty years. In the early days use was made of the straight line compound steam engine with direct connected reciprocating compressor. Later separate engines and compressors were used with belt drive to accommodate the respective speeds, the kerosene engine being used for power purposes. Today advantage is being taken of the medium speed Diesel engine direct-connected to a rotary compressor.

It may be worthy of remark that loudness is not of paramount importance in the matter of the carrying quality of sound signals. Half a dozen riveting hammers, or a passing street car seem to fill the universe with sound, while in reality the sound is not heard a hundred yards away. A church bell of fine tone and consuming little energy may be heard for miles. Lying in a hotel in Halifax one can hear, through all the city noises, the pure musical note of the Chebucto Head diaphone nine miles away. Purity of tone is of first importance, strength of vibration or sound impulse next.

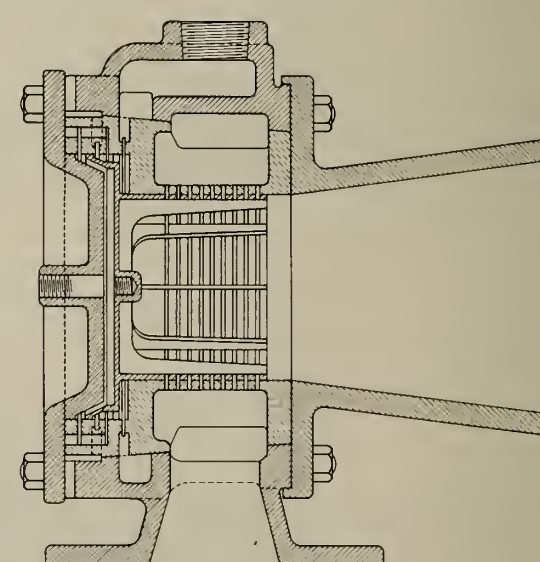

**Fig. 9—Diagram of Diaphone.**

Fig. 10—Automatic Acetylene Fog Signal Gun.

### Buoys

While bells of various sorts have been in use since the time of the worthy Abbot of Aberbrothock, and later whistling buoys, it was not until the nineties of the last century that gas buoys made their appearance. The first buoys operated on oil gas, known as Pintsch gas, stored in the buoy float under a pressure of ten atmospheres. The buoy lantern consisted essentially of a cut-glass lens, wind and waterproof housing and occulting mechanism whereby the flow of gas to the burner was interrupted for predetermined periods and relighted by a small pilot burning continuously. This arrangement served at once to conserve gas and to provide a light of distinctive characteristic. The disadvantage of this system lay in the relatively feeble light and necessity for frequent replenishing of gas.

With the advent of the manufacture of calcium carbide in commercial quantities, acetylene was seized upon as illuminant for gas buoys, the advantage being the relatively brilliant light and the possibility of storing a large quantity of gas, in the form of carbide, in a relatively small space. The smaller type of carbide buoy is eight feet in diameter and twenty feet over all. Within the float chamber is a carbide chamber holding one ton of carbide resting on a grating some three feet above the bottom of the chamber. A port in the bottom of the chamber admits sea water. When the buoy is placed in the water the air imprisoned in the carbide chamber prevents the water entering, or rather water enters only until equilibrium is established between the water pressure and the air pressure within the carbide chamber. When the valve in the lantern is opened the imprisoned air escapes, the sea water gradually rises in the carbide chamber until it reaches and attacks the carbide, immediately generating acetylene. The pressure set up by the acetylene thus generated forces the water out of the carbide chamber. As the gas is consumed the water gradually rises in the carbide chamber and the process is repeated over and over again. One charge of carbide is sufficient to operate a buoy of this type for twelve months. This type of buoy, in addition to being lighted, is commonly equipped with a bell which is operated by the motion of the buoy on the waves. Such a buoy is shown in Figs. 11 and 12.

The larger type of carbide buoy is eleven feet in diameter and fifty feet in length. This larger type of carbide buoy is always fitted with whistling tubes, two in number, twenty-six feet long, twenty-four inches in diameter. By the design of this buoy, of relatively small diameter compared with the length, the motion of the buoy in the sea is approximately vertical. As the buoy rises, air is drawn in through check valves; as the buoy falls, this air is expelled under water pressure through the whistle.

A later development in the use of acetylene is that whereby the acetylene is dissolved in acetone under one hundred and fifty pounds pressure. Acetone has the property of absorbing twenty-five times its own volume of acetylene per atmosphere pressure, with the result that relatively large quantities of acetylene can be stored in relatively small space. In this case also, the larger acetone buoys carry sufficient gas for twelve months burning.

Yet another type of gas buoy is the development of the original oil gas system which was made possible by liquefaction of oil gas. In this case the original buoys are used, but the gas is supplied in steel flasks under a pressure of fifteen hundred pounds to the square inch. The flasks are connected by hose to the buoy float and the gas is allowed to flow into the buoy to a pressure of ten atmospheres. A buoy so charged is good for three months.

Buoy moorings generally consist of close link chain, and granite, concrete, or cast-iron anchors. The chain varies from one inch to one and one-half inch stock, and the anchors from one to six tons depending on the size of the buoy and the exposure of the position to heavy seas. Some of these buoys are anchored in two hundred and fifty feet of water, the weight of chain and anchor approximating twelve tons, the weight of the buoy itself up to sixteen tons.

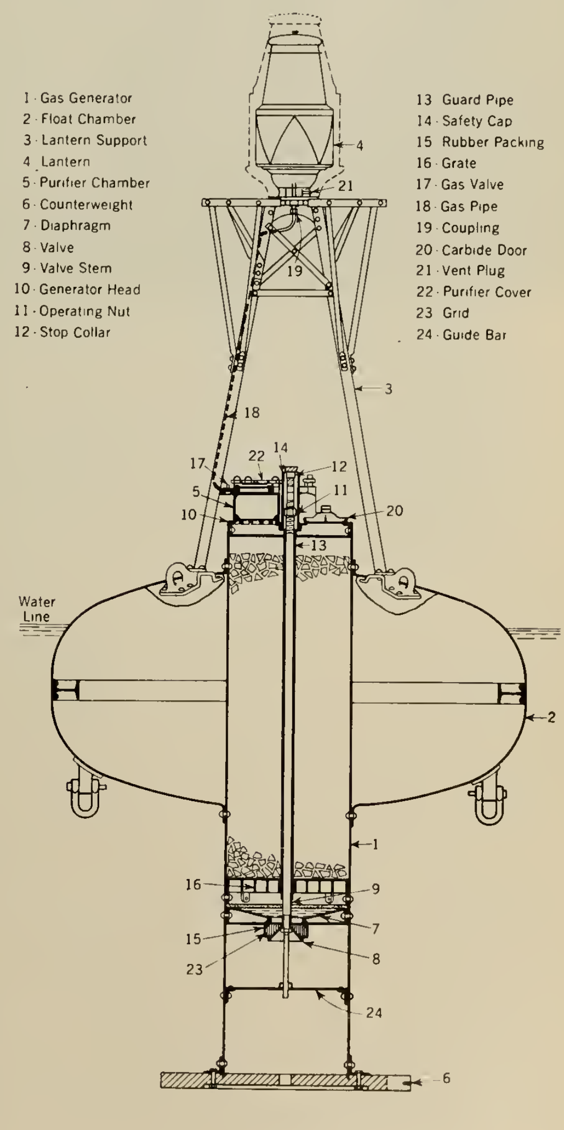

Fig. 11—Diagram of Gas Buoy.

### Lightships

Lightships, of which there are twelve in service, are seagoing vessels for the most part of the trawler type, but special design and construction is required in the case of lightships exposed to the open sea. The essential features of design are full lines of hull, high topsides, central hawsepipe opening at the water line and sufficient power to make head against the heaviest seas in order to relieve the strain which would otherwise come on the mooring cable. This design enables the vessel to surmount the seas, whereas, if built on finer lines, the seas would carry over her and tend to part the mooring, or carry away her upperworks. Lightships occupying ocean positions are equipped with light, fog signal and radio beacon. The first seagoing lightship was built and stationed in 1904.

Fig. 12—Handling Gas Buoy under Winter Conditions, Lake Erie.

### Radio Beacons

The most recently devised, and perhaps the most important, aids to navigation are the radio direction finding station and the radio beacon. In the case of the direction finding station a ship at sea, perhaps five hundred miles away, wants to determine its position. The captain sends a wireless message to a direction finding station asking what his bearing is. As the message is being received the operator at the station by turning a dial determines the bearing and replies immediately. The captain then sends the same message to another direction finding station and receives his bearing from that station. The two bearings intersect and thereby determine the position of the ship. In the case of a radio beacon, the apparatus is in continuous operation during fog and automatically sends out a signal at intervals of two to three minutes. In this case the ship is equipped with a mechanism whereby the bearing of the beacon may be determined. The captain takes radio bearings from two or more radio beacons and thereby determines his exact position. In fair weather the radio beacons send out signals for four or five minutes every hour, each beacon working on a definite time schedule. For example: the Halifax lightship fair weather signal begins one minute and thirty seconds past the hour; the Lurcher lightship in the Bay of Fundy begins four minutes and thirty seconds past the hour; and so on throughout the entire system.

A recent development is the combination of radio with aerial sound signals. The radio signal is synchronized with the diaphone sound signal. For practical purposes radio signals may be regarded as being received instantaneously. Sound travels through air at say 1,140 ft. per sec. Both the radio signal and the sound signal are emitted at the same instant. The radio signal is heard instantly, the sound signal several seconds later. The lag or elapsed time indicates the distance the navigator is away from the lightstation and the radio compass gives him the bearing. A lag of five seconds between the radio signal and the sound signal represents one statute mile. For example: if the lag is thirty seconds the distance off is six statute miles. This is correct within 10 per cent.

### General

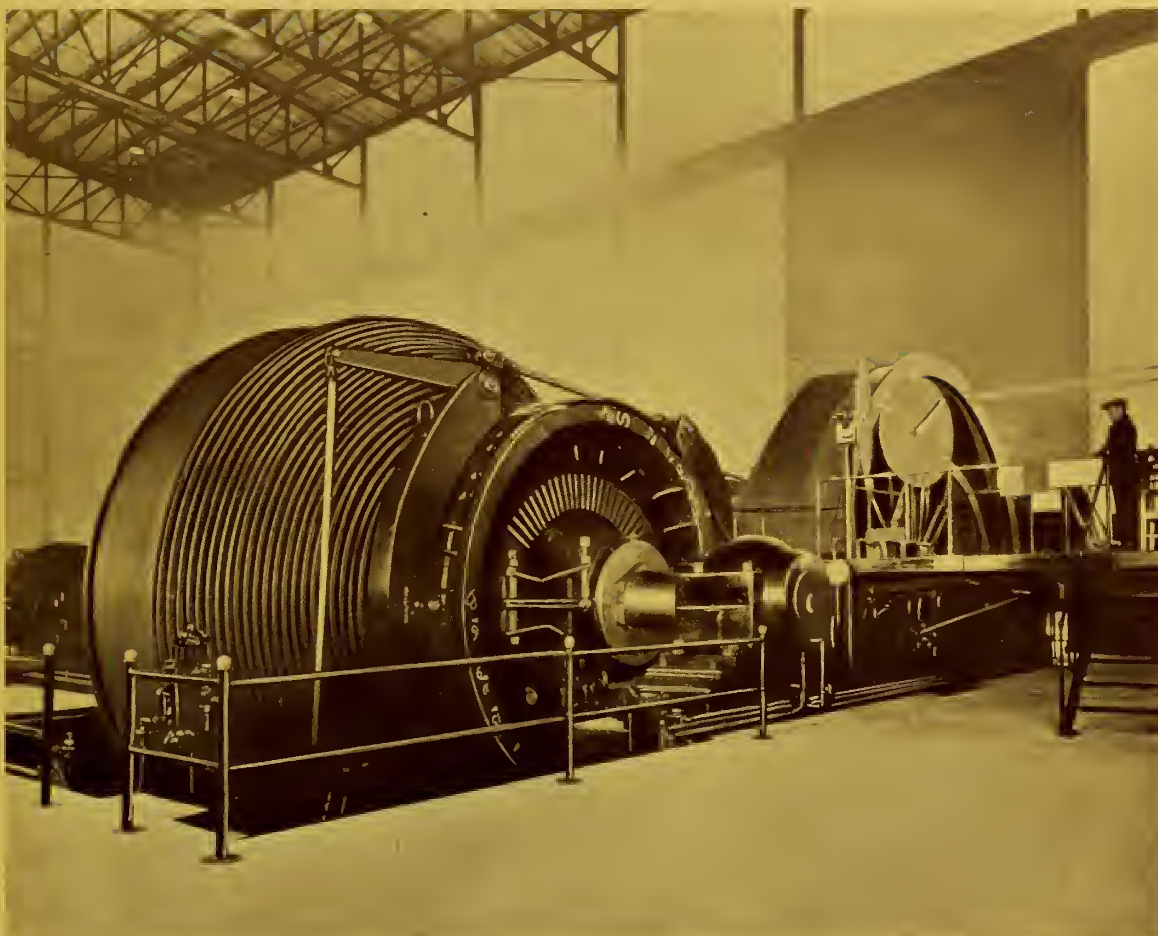
It will be apparent that lighthouse engineering is inseparable from lighthouse administration. The lighthouse service of Canada lies along many thousands of miles of coast and lake and river and has finally reached the Arctic ocean by way of the Mackenzie. The service consists, in round numbers, of 2,000 lights; 400 fog signals; 600 gas and signal buoys; 12 lightships; 9,000 unlighted buoys, beacons, and day marks; a total of 12,000 individual establishments. The staff numbers 2,500 persons.

The administration is constantly pressed to establish additional aids to navigation or to replace older equipment with new. Shipping interests in common with other classes demand the latest, not only in respect of necessities, but conveniences. Conditions, too, have changed. Ships are larger, of deeper draft and faster. The shoal that did not matter fifty years ago is a deadly menace to-day. Fifty years ago it did not matter much whether a vessel reached Montreal to-day or to-morrow or next week. In these times hours are a cause of concern. And so the lighthouse service is involved in the general competition.

The first problem of the lighthouse engineer is to determine what the requirements are in the matter of aids to navigation, then to determine how those requirements can best be met, having regard to the volume of traffic to be served, the dangers to be avoided, the probable consequences of shipwreck, whether loss of property only, or of life also, and the cost, both of the establishment and the annual maintenance of it.

A particular and unusual adaptation of aids to navigation, to suit particular requirements, has been made in Hudson Bay and Strait. The route is important and the season is short. Delay must, therefore, be minimized. While the vessels using the route are large, they are few in number. The Strait is well marked by radio direction finding stations and by a few small unattended gas lights. In ordinary circumstances a series of coast lightstations would have been established at intervals of thirty or forty miles along both sides of the five hundred and fifty mile Strait. Instead the Marine Department, looking back across the waste of more than thirty barren centuries, adapted the pillar of cloud by day, of fire by night idea, to provide a moving protective guide for voyagers.

The C.G.S. *N. B. McLean*, a powerful ice breaking steamer, occupies a stated position in the Strait. Her equipment includes lights, sound signals, radio, echo sounder, gyro compass, salvage pumps, hospital and surgeon. Last season a member of the crew of an inward bound vessel from France, suffering from acute appendicitis, was taken aboard the *McLean* and the necessary operation performed with complete success. The *McLean* supplies commercial vessels with radio bearings and information as to ice fields, and, if necessary, convoys them through the Strait—truly a pillar of cloud by day, of fire by night.



Canada's Largest Mine Hoist

Tandem conical, 25-foot double-drum, electric hoist, built at Rockfield Works, Lachine, Que., and installed at the Creighton Mine of the International Nickel Co. of Canada Ltd.

*Professor of Mining Engineering, McGill University, Montreal.*

During the period under review the production of metallic minerals in Canada has had a very large and fairly uniform growth. In 1887 the total value of metallic minerals produced was $2,073,746; by 1900 it had grown to $40,408,676; and in 1936 it reached the sum of $256,335,000. The increase in the price of gold accounted for $53,419,000 in the 1936 production, but low prices were received for all other metals except nickel. Even after deducting the extra value of gold due to increased price the ratio of 1936 production to that of 1937 is roughly 100 to 1. It is notable that in 1887 no nickel or zinc was produced in Canada.

The great wealth of metallic minerals which is being developed in Canada lies in the pre-Cambrian or oldest rock formations. In these ancient rocks mineral deposits are not only frequently found, but are remarkably persistent and give long life to the mines which operate them. This is not only true in Canada but in other parts of the world where rocks of this age occur. Metallic deposits in the younger formations are frequently shallow and are rapidly worked out. Fifty years ago most of our metal mines were in the younger formations and consequently were short lived. Today the developments are coming largely in the pre-Cambrian and many of them have already been proved to great depth, and there is decided evidence that in many mining districts the limit of depth to which the mines may be carried will be the ability of our engineers to meet the problems of increasing rock pressure and temperature involved in deep mining. This is a most important and encouraging development and must be given due consideration in any attempt to evaluate the mineral development of our country. This Canadian Shield, as it is commonly called, occupies about two-thirds of our country. Most of it is remote from existing transportation facilities and it is difficult to prospect. But new and important mines are being brought in every year, and it will take many generations to develop it fully.

### Mining and Metallurgical Education

Fifty years ago engineers and geologists played a very small part in mining, probably as great as they deserved. Their knowledge and training were insufficient and when it came to management they had difficulty in competing with the practical man. Economic geology was in its swaddling clothes and geologists were chiefly interested in mineralogy, petrography and stratigraphy. Mining engineers were largely surveyors, assayers or draftsmen. Neither knew much about the genesis of ores or the rock alterations accompanying mineralization. Mineral discovery was almost entirely a matter of chance, while mining and reduction of the ore was quite unscientific and largely governed by rule of thumb.

### Transportation

Transportation may seem foreign to this article, but it has such a profound effect on the development of the industry and is in so many cases a problem for the mining engineer who has to provide his own transportation facilities that it cannot be omitted. Even yet the greater part of the Canadian Shield is not served by railways nor highways. Falls and rapids interrupt water transportation and the distances by water are sometimes great. Bush and swamp make the use of pack animals impossible. The Canadian miner must improvise transportation facilities to suit his conditions. His greatest aid is the aeroplane. Planes equipped with pontoons in summer and skis in winter give rapid and safe transportation of men, mail, food and light supplies at reasonable costs, and in emergencies they are used for machinery and heavy supplies. Where possible, other means are used for heavy haulage and the plane for auxiliary service.

Where rapids or falls interrupt water haulage the so-called marine railroad is used to haul barges from one level to another, thus avoiding the necessity of two transfers. The rails are run into the water at each end and the barges are floated onto cars which have been submerged on the tracks. At the other end the process is reversed. Haulage is by cable and hoist, so that heavy grades may be used. By this means supplies for the Red lake area are transported one hundred and ninety miles from the railway, at a cost of $20.00 per ton, or 10.5 cents per ton-mile. The outboard motor has speeded up canoes and other small boats to a point which makes them very useful for prospecting and light haulage.

Where railroads are distant and water communication impossible, winter roads are cheaply constructed by cutting out the trees and cutting down steep grades. Rivers and lakes offer no difficulties and in most cases are a great help. Haulage is done on sleighs pulled by caterpillar tractors. These beat down the snow as it falls, and occasional dragging to fill up chuck holes is all that is required in the way of maintenance. On rare occasions shovelling may have to be resorted to. On long hauls tractors run night and day. In some cases one sleigh is equipped with kitchen and sleeping quarters; a cook prepares meals for the drivers, who take turns at the controls. Costs vary widely, but will run somewhere between 15 and 25 cents per ton-mile. Where there is uninterrupted water haulage from railhead costs are very much lower. Even with these moderately high costs, gold, silver and radium mines may be operated at long distances from railroad or ocean transport.

### Prospecting

Constant and active search for new mineral deposits is essential to replace worked-out mines and to provide for expansion of the industry. The art of prospecting has made many important advances and a technique has been developed to meet the conditions in our north country, which are different in many respects from those existing in other countries. The element of chance has been greatly reduced by the application of sound scientific principles. Rumours started by Indians, trappers and other travellers in the north country still play a part, but a much less important one than formerly. The prospector, partly from association with engineers and geologists of the mining companies and partly from schools for prospectors conducted by some of the provinces, has learned something of minerals, rocks and geological formations and is able to read a geological map sufficiently well to be able to pick out the areas which present conditions favourable to mineralization. The Geological Survey of Canada and the geological departments of several provinces lend invaluable aid by preparing, each year, geological maps of areas which have previously not been mapped in detail. From the air geological conditions can be recognized, in some cases, in a way and with a speed that is impossible from the ground. The air view of Outpost Islands shown in Fig. 1. illustrates this admirably. It can readily be seen that these islands are the upturned edges of steeply pitching sediments and that there is a decided bend in the strike of the beds. The only other probable explanation is a great zone of brecciation due to rock movements. In either case it is obviously a good place to search for mineral. The aeroplane is also serving a very wonderful function in quickly placing or moving prospecting parties, supervising their work and keeping them in supplies. The speed at which modern prospecting in Canada is done offers an amazing contrast with the slow progress of half a century ago.

Where outcrops are few and the country is largely covered with water, muskeg or wet soil, geophysical surveys offer a very important aid in tracing out concealed parts of the ore bodies, in discovering related but totally concealed ore bodies or in tracing out faults, shear zones or contacts with which the mineralization is associated. For metallic minerals the electrical and magnetic methods have been found the most helpful. These geophysical surveys are not positive but are, when intelligently used, a great help to the geologist and engineer in deciding on where and how to attempt further work to prospect beyond the definite showings of mineral. Diamond drilling has been perfected to a point where it gives a very useful method of cheaply proving up geological conditions under water or other overburden. In some cases it gives a fair idea of the size and grade of an ore body, but diamond drill results should be regarded as indicative rather than positive.

### Mining

There has been improvement all along the line in mining. Each mine is a problem in itself and it is difficult to reduce mining to a definitely scientific basis, but progress is being made and in some cases it is quite revolutionary. Standardization has helped in some things but in others the progress has come from breaking away from accepted practice and developing new methods based on a study of the conditions peculiar to the mine. It is impossible to even mention all the improvements that have been brought about as a result of engineering study, in the period under review, but a few of the outstanding developments are listed. Electrification of all machinery, except for drilling rock, and electric lighting have greatly reduced general power costs and improved operating conditions. Improvement in the development, distribution and use of compressed air, in the placing of holes, in the strength and distribution of explosives and the speed of detonation have greatly speeded up development and reduced the cost of breaking rock or ore. Improvements in ventilation have permitted mining to greater depths, and have made working conditions safer, more pleasant and conducive to greater output. Increased knowledge and use of economic geology have greatly reduced the number of failures in prospecting and the amount of development work necessary to prove up and prepare the ore for mining. Geological study has also greatly assisted in working out more economical methods of stoping the ore. Mechanical means of loading and transporting the broken rock and the self-dumping skip for hoisting have cheapened and speeded up the handling of broken rock. Larger scale of operation has reduced overhead, made possible greater capital outlay in labour-saving machinery and made possible many improvements to promote the safety and welfare of the workmen.

In stoping, successful efforts have been made to reduce the amount of timber necessary to support the ore and walls,

Courtesy of Royal Canadian Air Force.

**Fig. 1—Air View of the Outpost Islands.**

to secure as complete extraction of the ore as conditions will permit, to reduce dilution of the ore by low grade or barren material, to provide mechanical aids to the miner and to make use of gravity as an aid to handle the broken ore and even to break it. It is in these uses of gravity that the greatest strides have been made. In the rill method the operations are so arranged that the ore, when broken, flows down an incline to a chute, where it is guided into a car. Similarly, barren material is brought into the stope by gravity to fill the place formerly occupied by the ore. Shovelling of ore and fill is thus eliminated.

Perhaps the most revolutionary method is the "block caving" used at the King mine of the Asbestos Corporation; an isometric sketch of this is shown in Fig.2. As will be noted the ore is mined in large blocks. Suitable raises are provided to conduct the ore from the stope to a "grizzly" or grating, where the oversize boulders may be broken by hand hammers or blasting. Material passing through the grizzly flows down inclined raises to the haulage level for loading into cars. A section of ore, a few feet high, is broken out on the "undercut level" over the entire area of the block. As this is drawn down and support removed, the overlying ore breaks of its own weight, or "caves." Control of the drawing at the raises above the grizzly level makes it possible to cause this caving to occur at a fairly uniform rate over the stope section and it is held within pre-determined lines by weakening the boundaries of the stope by drives at vertical intervals around the stope. The amount of blasting necessary at the grizzlies varies with the nature of the ore but is comparatively small, as the ore is not only subject to tension strains due to its own weight, but to the shattering of its own fall and the fall of other boulders. It will be observed that not only does this method eliminate

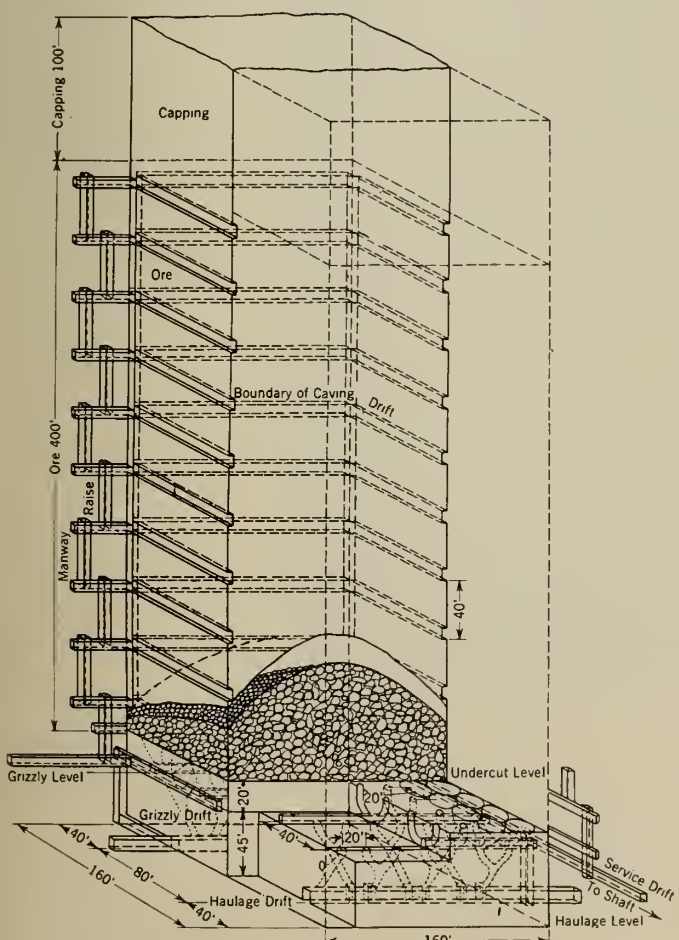

Fig. 2—Isometric Drawing of Stope Block, 160 ft. by 160 ft.

shovelling but that a large proportion of the ore does not have to be blasted but is broken by gravity. Mining by this method is very cheap, its only disadvantage being that some ore is mixed with the overlying waste and must either be left behind or is diluted.

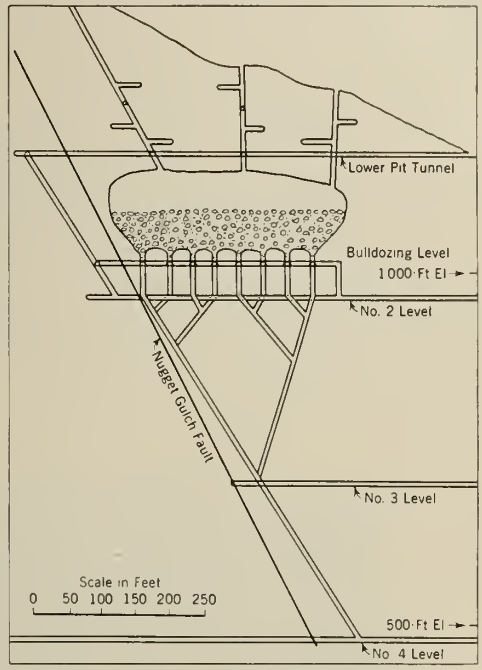

Fig. 3—Longitudinal Section Through Stope at Alaska Juneau Mine.

Figure 3 shows the method used at the Alaska Juneau mine, where the ore is more resistant to caving. In this, raises are driven into the ore and caving is assisted, where necessary, by large charges of dynamite placed in short drifts from these raises. Similar methods are used at the Britannia mine.

In still stronger ore the sub-level and spiral raise methods have been evolved to secure large scale production and efficient use of explosives. In these, gravity does not play such an important part in breaking the ore but it does away with shovelling and stope tramming.

Although there has been a remarkable development of new stoping methods the square set, the stulled stope, the shrinkage stope and the underhand open stope still survive and each has its field of usefulness. They have been greatly improved, however, and are used only for the particular cases where conditions make newer methods inadvisable or to supplement newer methods.

### Concentration and Milling

In concentration, smelting and refining, engineering advances have been quite revolutionary. The cyanide process has increased the recovery of gold from the 60 to 85 per cent formerly made, to from 90 to 99 per cent. Moreover, the process has been made continuous, almost automatic and consequently cheap. Flotation has almost entirely replaced gravity methods for the concentration of sulphide minerals and is also extensively used on non-metallic minerals and native metals. It gives a more complete recovery, a higher grade concentrate and lower cost than any other method. The flow sheet of a flotation mill is remarkably simple, the space occupied per ton of capacity is low and the amount of labour and power required is small. But by far the most important feature of this truly remarkable process, is that it can be made selective, that is, one mineral at a time can be floated away from the gangue and from valuable minerals of like specific gravity and other physical characteristics. This makes it possible to treat complex ores which were valueless to the miner of twenty-five years ago. For example, the great Sullivan mine at Kimberley was of no commercial value until selective flotation was developed. Its ore is a complex mixture of sulphides of lead, zinc and iron. In the smelter no two of these elements could be saved simultaneously, and in fact two of them were always detrimental to the extraction of the third. With selective flotation the lead sulphides are first floated out of the ore, which has been ground in water to a fine ground pulp; then the zinc sulphide ground in water to a fine pulp; then the zinc sulphide is separated from the residue and the iron sulphide allowed to accumulate as "tailing" until such time as there is a demand for it. As many as six different products may be made from one ore by selective flotation.

In the mechanics of milling there have also been important changes in methods of crushing, grinding, classification, handling, sampling, dewatering and drying, but these have had a less profound effect than the introduction of cyanidation and flotation.

### Smelting

In smelting perhaps the most important innovations have been the introduction of the converter, the sintering machine, the electric dust precipitator and the continuous roaster. Blast furnaces have been greatly improved and the reverberatory furnace revolutionized. The improvements in smelting have been great, but have been largely in perfecting details rather than in the introduction of metallurgical processes based on new basic principles.

### Refining

Refining or purifying the metals has gone ahead, but like smelting the changes have been largely in improvements in processes or their adaptation to new uses. Electrolytic refining has been adapted to lead, zinc and other minerals. Greater attention has been paid to purity of product and to by-products. The copper, lead and zinc refineries are producing important amounts of cadmium, selenium, tellurium and many of the rarer metals.

Fundamentally, the greatest forward step that has been made in milling, smelting and refining during the past fifty years is the study of the basic scientific principles and reactions involved. This has led not only to the discovery of new methods but to improvement in details and more accurate technical control of operations, with consequent improvement in results. Formerly, operating control was almost entirely based on the judgment of an experienced operator; today it is pre-determined by calculation or is based on the results of frequent tests, using sound scientific methods.

### Conclusion

The results of this improvement in engineering practice in mining and treatment of ores have been an improved product, lowered cost of production and, most important of all, increase of output and future reserves through obtaining a more complete extraction and bringing into the profitable class many ore bodies which, due to low grade or complex mineralization, were valueless under the old methods. Without the cyanide process few Canadian gold mines could produce profitably, despite the higher price for gold, and none could maintain the present scale of operations. Without flotation the Sullivan, Flin Flon, Britannia, Sterling and many other important mines would never have been profitable.

It is interesting to note that the cyanide process was patented in 1887 and its first commercial application made in 1889. The first patent bearing on flotation was granted in 1860, but it was not until 1902 that patents were granted for the use of gas as a buoyant medium for the flotation of heavy minerals. In 1913 came the first recognition of selective flotation, and its first application in Canada came in 1920 in a pilot plant at Trail, B.C. The first successful commercial application of flotation to the treatment of complex ores in Canada was at the Chapman concentrator of Consolidated Mining and Smelting Company in 1923.

AERIAL photograph of Mercier Storage Dam on the Gatineau River, Province of Quebec. This dam was constructed in 1926-27 by The Foundation Company of Canada Limited for the Quebec Streams Commission and the Gatineau Power Company. The building of this dam created one of the largest storage reservoirs in the world, its capacity being approximately one hundred billion cubic feet of water.

# Irrigation Engineering

*S. G. Porter, M.E.I.C.,*
*Manager, Department of Natural Resources, Canadian Pacific Railway Company, Calgary, Alta.*

Early explorations and surveys in Western Canada, almost without exception, referred to a large area in the southern portion of what is now the provinces of Saskatchewan and Alberta as an arid or semi-arid belt. Its boundaries naturally varied according to the nature of the seasons in which the observations were made, but the average content may be defined as that portion of the provinces of Saskatchewan and Alberta lying south of a line running northwesterly through North Portal, Weyburn, Moose Jaw and Rosetown to a point on the Saskatchewan-Alberta interprovincial boundary near Macklin, 240 miles north of the International Boundary, thence southwesterly towards the foothills of the Rockies, say 40 miles northeast of Calgary, thence straight south through Macleod to the International Boundary—the area containing between 40 and 50 million acres. It is a part of the Great Plains area which stretches all the way from the Mackenzie Basin to central Texas, all of which is an area of low average rainfall. It is also known as "the shortgrass country" and corresponds closely with what has been termed the Drought Area of the past few years. It possesses two of the essential elements for successful agriculture—good soil and abundant sunshine—but is lacking in the third essential—moisture.

It is not arid in the sense of being barren and unproductive. Until broken by the plough it produces good range grass, and in all except the driest portions has periods of good grain crops, alternating with periods of drought.

The completion of the Canadian Pacific Railway across the prairies in the early eighties was followed by the westward movement of settlers. As settlement increased and spread farther and farther westward, the necessity and the possibilities of irrigation on these fertile plains between Moose Jaw and the mountains did not escape the attention of railway and government officials and engineers. This interest increased to such an extent that in 1893 an act was introduced in the Dominion Parliament dealing with the matter. The act was not passed at that session, but J. S. Dennis, Chief Inspector of Surveys, was commissioned to visit the western United States for the purpose of studying and reporting on the irrigation laws and practice in that country. His report was submitted to Parliament at its next session, and upon the recommendations contained in it, was founded the Northwest Irrigation act passed by Parliament July 23rd, 1894. This act has been the legal basis of all subsequent irrigation legislation and development in Canada, and was recognized by authorities in the United States as being much superior to their irrigation laws at that time.

**Fig. 1—Truss Bridge Carrying Inverted Siphon across Okanagan River.**

In speaking of the developments which led up to this result, Mr. Dennis in his report to the Government on irrigation in 1894, said, "The existing climatic conditions, and the necessity for irrigation, have been frequently referred to in the reports of Dominion Land Surveyors employed in surveying this arid region into townships and sections, but it is probably due to the lengthy reports upon this subject and to the persistent advocacy of the principle by Mr. William Pearce, Superintendent of Mines, more than to any other cause, that the public has at last recognized the necessity for irrigation and the benefits to be secured therefrom."

The necessity and advantages of irrigation were given first official recognition by Mr. Pearce in his report for 1885. Mr. Dennis also mentions it in his report for 1886. The Deputy Minister, in his report for 1885, says, "Mr. Pearce raises what is practically a new question when he discusses the irrigation of comparatively dry tracts in the grazing country," and comments that "it will be a long time . . . before . . . settlement . . . will reach the class of country to which Mr. Pearce's suggestions relate." But these two men continued to raise the question and it was not so long after all before it was a live and practical issue. These men were responsible in large measure for the development of irrigation in western Canada during the next thirty years.

The year 1894 therefore may be taken as marking the beginning of any definite government policy in the matter of irrigation. In that year the Northwest Irrigation act became law, and the Dominion Government began its general irrigation surveys under the direction of J. S. Dennis. In his report for that year he presents a list of ninety-three canals in operation, under construction, or projected in that portion of Alberta and Assiniboia known at that time as the "Arid Region." These were all for small areas with the exception of the Calgary Irrigation Company, the Alberta Irrigation Company, and the Springbank Irrigation Company, and only the first one of these three had at that time started construction. Sixty-three projects are shown as being constructed and in operation in 1894, ranging in area irrigated from seven acres to 2,500 acres.

In May of the following year an Irrigation Office was established in Calgary by the Department of the Interior of the Dominion Government, in charge of J. S. Dennis, for the administration of the Northwest Irrigation Act.

The foregoing refers entirely to the country east of the Rockies, but before proceeding with the details of the development of irrigation on the prairies, a brief reference should be made to still earlier work which was going on west of the Rockies where the administration of land and other resources was under the control of the provincial government.

## IRRIGATION IN BRITISH COLUMBIA

The first record of an application for the right to use water for irrigation in Canada was in 1858 when British Columbia was still a Crown colony. This was for the use of water from Nohomeen creek near Lytton and is recorded in the official records dated at Fort Yale October 30th, 1858, in the name of George K. MacCulloch. Likewise, the first act in Canada providing for the acquisition of a water right and for the issuing of rules and regulations governing the use of water was proclaimed in British Columbia by Governor Douglas in 1859 and known as the

"Goldfields Act." While this act was apparently intended to apply primarily to the diversion and use of water for gold mining, a number of applications for water for irrigation were dealt with under it, until in 1865 the Land Ordinance was enacted which provided more definitely for the requirements of irrigation.

### The Doctrine of Beneficial Use

An important feature of the Goldfields Act of 1859 was the provision that the applicant for a water right was entitled only to the amount of water which he put to beneficial use, the surplus being forfeited to the Crown and becoming available for grant to another applicant. Thus was established at this early date an important principle which has been recognized in all subsequent irrigation legislation in Canada—the doctrine of beneficial use.

Another provision of significance and importance was contained in the Water Privileges Act of 1892. That was the declaration that the right to the use of all water not at that time recorded and appropriated was vested in the Crown in the right of the province. This likewise is the underlying principle of the Irrigation Act passed by the Dominion Government two years later.

### Riparian Rights

The old English common law doctrine of riparian rights gave to the owners of land abutting on streams the right to use the water of the stream for domestic or milling purposes, but any water diverted from the stream must be returned to it undiminished in quantity and unpolluted in quality. As irrigation developed on this continent it became evident that its requirements were in direct conflict with this doctrine, for when water was diverted for irrigation it could not be returned to the stream.

In the early development of irrigation in the Western United States water rights were acquired by posting notices at or near the source of supply, like the old system of posting mineral claims. They were often extravagant, inaccurate and overlapping in their claims—in some cases ten or even twenty times the flow of the stream being claimed by rival interests. Complications, confusion and litigation necessarily followed, and it was not an uncommon experience for the cost of litigation establishing the legality of a water right to exceed the cost of the construction of the system.

Canadians had the opportunity of observing the confusion which existed in the early stages of the development of irrigation in the United States and were wise enough to profit by their experience and mistakes. The benefit of these observations is reflected in the provisions of the Water Privileges Act of British Columbia and the Northwest Irrigation Act of the Dominion Parliament. The fact that practically no litigation has grown out of the establishing of water rights under these acts is evidence of the wisdom of their underlying principles.

### Difficulties Encountered

The topography of British Columbia prevents the irrigation of any large areas such as are found on the prairies. The valleys as a rule are narrow. Where they expand into broader stretches, they are frequently covered by lakes or are subject to flooding. The bench lands suitable for irrigation are too high above the main streams to be served by gravity and the cost of pumping as a rule is prohibitive. This makes them dependent for water supply on the small lateral streams, which because of the rugged topography and steep slopes have a rapid runoff. Consequently only a small percentage of their total flow can be utilized unless storage can be provided to supplement the period of low flow. Again, the topography is unfavourable because suitable sites for storage usually exist only near the heads of the streams at points where the catchment areas above them are too small to be of great value.

These natural features add immensely to the problems of irrigation development in British Columbia, but in spite of them the pioneers and engineers accomplished much.

In the early stages of irrigation development in any pioneer country, it is natural and necessary that the first efforts are confined to small individual schemes bordering immediately on the streams, where diversions can be made easily and at little cost. Next come partnership or small community enterprises where neighbours combine their resources. These types have usually served their purpose successfully, because their cost of construction and of operation was low and they had a priority of right to the water supply.

The next step in development was usually a more pretentious one, undertaken by individuals or companies who acquired ownership of large areas of land and built irrigation works to serve them, expecting to reap a profit on the sale of the land with water rights. These enterprises, large or small, have nearly always ended in financial disaster. Many factors have contributed to these results. Among them may be mentioned—(1) Insufficient knowledge of the sources of water supply and its seasonal variations in flow; (2) An under-estimate of the time and cost of placing settlers on the land and bringing it into profitable production. A large part of the cost of operating the system during this period must be borne by the promoters—in fact, the whole proportion chargeable to the unsold area, and frequently a large proportion on the sold area because of inability of the new settlers to meet their payments; (3) For like reason, the inability to dispose of their lands quickly and reimburse themselves for the cost of the enterprise often finds the promoters still carrying the burden when heavy repairs and renewals become necessary. Their cost is frequently beyond the financial ability of either the promoter or the settlers, and disaster results.

### Development in the Okanagan Valley

While irrigation is practised in many valleys in the interior of British Columbia, its most extensive development has been in the Okanagan Valley. The first water right recorded in the valley was by Charles A. Vernon, on Coldstream creek, in 1868. In 1872, William Smithson took out a water right on Mission creek, and in 1874 Andrew Brown filed on Mill creek, both near Kelowna.

The first venture in what has been described in a previous paragraph as the second step in irrigation development, was made by Lord Aberdeen, when in 1891 he purchased the Coldstream ranch near Vernon, constructed an irrigation system, and offered it for sale in 1893 in small tracts as irrigated orchard land. This was followed during the first decade of the present century by the construction of many irrigation systems throughout the valley to serve areas which were subdivided and put on the market, usually as five and ten acre orchard lots, to meet the boom demand for fruit lands.

### Co-operative Enterprises and Government Assistance

The fruit land boom collapsed just prior to the Great War and these projects entered the period of financial difficulties. The struggle for existence which followed led to the formation of co-operative organizations for operating the irrigation works. The legislative machinery at first was inadequate to deal with the situation, but gradually there was evolved the principle of ownership and operation by the water users themselves through the medium of Irrigation Districts. This evolution in legislation as well as in operation has been the outstanding feature of irrigation development since 1920.

The problem was a difficult one. Irrigation structures had deteriorated, the companies which had built them were bankrupt, inadequate and unprofitable market outlets for fruit and other produce made it impossible for the farmers themselves to meet the necessary costs of rehabilitation and continued operation. Under the stress of such conditions it was necessary to appeal to the Government for financial assistance, and as a result the province has since 1918 loaned more than three and a half million dollars to Irrigation Districts.

But there are compensating factors. Thousands of people have built up homes on these projects and have produced millions of dollars of agricultural wealth. It is to be hoped that better markets and general improvement in conditions will soon restore these potentially wealthy districts to a position of economic independence.

#### South Okanagan Project

Before leaving the province of British Columbia mention should be made of one project which differs in many characteristics from the typical ones already referred to. This is the South Okanagan project at Oliver, developed by the provincial government in 1919-1920.

It has been stated that most of the irrigated land in British Columbia is in small broken areas, too high above the main streams to be served by gravity ditches from them. The South Okanagan project is one exception. It covers an open valley about 25 miles long, lying between the outlet of Okanagan lake and the International Boundary. A concrete dam diverts the water from the Okanagan river at a point two miles below Vaseau lake. The canal is concrete lined for a distance of about seven miles and has a capacity of 170 c.f.s. An inverted syphon 3,578 ft. long of 80-in. steel and 78-in. wood stave construction crosses the Okanagan river to the west side of the valley. Many flumes of wood stave and of metal construction are required for side hills and ravine crossings. Pumping plants at three points serve lands above the main canal. Engineering work was done by the provincial government staff and was of a high order throughout. (See Figs. 1, 2 and 3.)

### IRRIGATION ON THE PRAIRIES

The earliest use of water for irrigation in Alberta of which there is any record was by John Glen, who in 1879 built a small ditch out of Fish creek, eight miles south of the present city of Calgary, and irrigated fifteen acres in section 3, township 23, range 1, west of the 5th meridian, with "satisfactory results." Prior to this a ditch had been started from Beaver creek and carried down the flat on the north bank of the Oldman river in what is now the Peigan Indian Reserve. This ditch was started by two Americans who came in with a band of horses and settled there, but before they had it completed, the land they intended to irrigate was set apart as an Indian Reserve, so they abandoned their enterprise and returned south. As the treaty under which the Peigan Indian Reserve was set apart was concluded on September 22nd, 1877, it must have been in that year that the ditch was built. During the next fifteen years there was more or less activity, chiefly among ranchers in the construction of small irrigation works, mainly for the irrigation of hay meadows.

The next event was the passing of the Irrigation Act and the beginning of general irrigation surveys by the Dominion Government under J. S. Dennis in 1894. These surveys indicated the feasibility of irrigating large areas in southern Alberta east of the foothills of the Rockies, and it is proposed to follow briefly the history of the development of some of these schemes.

The first authorization by Act of Parliament for irrigation in Canada was given when the Macleod Irrigation Company received its charter in 1891. The main object of the company was to secure the unoccupied available land in eight townships around Macleod, namely, township 8, ranges 25 and 26; township 9, ranges 23, 24, 25 and 26, and township 10, ranges 24 and 25, west of the 4th meridian, with a view of putting whatever area was susceptible of irrigation under water. The project was examined and reported on jointly by J. S. Dennis, then Chief Inspector of Surveys, and William Pearce, D.L.S., who recommended the sale at one dollar per acre under certain regulations regarding the construction of irrigation works. No construction was undertaken, however, and in January 1896, G. A. Kennedy, secretary of the company, was advised by the secretary of the Department of the Interior that the time for commencement of the works had lapsed and that the matter of reservation of the lands would be held in abeyance until such time as the company again approached the department.

In 1892 the High River and Sheep Creek Irrigation Company was incorporated, but no construction was ever undertaken. In 1893 three charters were granted—The Alberta Irrigation Company, the Calgary Irrigation Company, and the Calgary Hydraulic Company. The first of these was an outgrowth of plans of Mormon settlers to acquire and colonize a large area in southern Alberta. Their application to Parliament set out that their purpose was to construct and operate irrigation ditches in that portion of the District of Alberta lying south of the 50th parallel of latitude. Political and financial difficulties hindered them so that they did not succeed in starting construction work until 1898. Further reference to this company will be made later.

#### Calgary Irrigation Company

The Calgary Irrigation Company proceeded promptly with their plans. They located their headgate on the Elbow river, in section 4, township 24, range 4, west of the 5th meridian, 18 miles west of Calgary. By the end of the year 1893 they had completed their headworks and six miles of main ditch. This company was the pioneer irrigation company in the Prairie Provinces, and constructed altogether 81 miles of main and distributing ditches to serve 45,000 acres of land south of the Elbow and Bow rivers in the neighbourhood of Calgary. The first irrigation water was applied in the summer of 1894, but unfortunately the completion of their works was followed by a cycle of

Fig. 2—Main Canal Looking North towards Oliver.

Fig. 3—Metal Flume, South Okanagan Project, B.C.

wet seasons, during which irrigation was not required, the works were very little used, and were finally abandoned.

### Calgary Hydraulic Company

The Calgary Hydraulic Company, also chartered in 1893, proceeded vigorously with their plans, and by August of that year had commenced construction. Their headgate was located on the south bank of the Bow river in the southwest quarter of section 4, township 25, range 2, west of the 5th meridian, seven miles west of the city of Calgary. At a point about three miles below the headgate the ditch crossed to the north side of the river by means of 1,500 feet of 30-in. wooden pipe supported at the river crossing by a truss bridge of two spans. This is reported to be the first structure of its kind to be erected in the Northwest Territories and attracted considerable interest. (See Fig. 4.)

Fig. 4—Bridge and Barrel Flume across Bow River. Constructed 1894.

The works were completed in September 1894 and water was supplied in the fall of that year for fall irrigation. The main canal had a capacity of 25 c.f.s. and was built to serve 2,500 acres, a portion of which was within the limits of the city of Calgary.

The bridge carrying the pipe line, or barrel flume as it was termed, across the Bow river, was destroyed by flood in June 1897 and was not rebuilt. Thus the irrigation system was abandoned after two years of operation, but the upper end of the canal is still used to supply water to the lagoons and pools used extensively for canoeing, wading and swimming in Bowness Park, owned and operated as a recreation park by the city of Calgary.

### Springbank Irrigation District

About this same time an agitation was initiated by the farmers west of Calgary who wished to irrigate their lands lying between the Elbow and Bow rivers in what was known as the Springbank district. This agitation led to the enactment of the Northwest Irrigation District Ordinance in 1894, which provided for the erection of an irrigation district with powers to levy assessments against lands within the district for the purpose of the construction and operation of irrigation works. It was the first act of its kind in Canada and was patterned after the Wright Act in California, prescribing a method of operation similar to that in the case of a school district or municipality. An interesting feature of this act was that it placed a limit of $6 per acre for cost of construction and $1 per acre per year for operation, maintenance and sinking fund. It was argued that any cost in excess of these figures was prohibitive.

Pending the formal erection of the district a memorial was filed in the Land Titles Office at Calgary on November 5th, 1894, for permission to divert water from Elbow river on the southwest quarter of section 4, township 24, range 4, west of the 5th meridian to irrigate 21,200 acres. A second memorial was filed February 13th, 1895, to divert water from Jumping Pound creek on the southeast quarter of section 13, township 24, range 5, west of the 5th meridian, to irrigate 30,778 acres. An Order-in-Council was passed February 25th, 1896, authorizing the construction of the proposed works. The project was never completed, but its history is recorded here for the reason that it was the first canal projected in Canada as a mutual undertaking under the provisions of an Irrigation District Act, and consequently was looked upon as an event of more than ordinary interest.

### Alberta Irrigation Company

The only one of the early projects of any size which continued in operation was the one under the charter of the Alberta Irrigation Company.

As already noted, the Mormons had settled around Cardston. Being accustomed to irrigation they saw great possibilities in the vast fertile plains to the east and north of their settlement if the deficient rainfall could be supplemented by irrigation. With a view of colonizing and irrigating these lands Charles Ora Card undertook to purchase 116,000 acres and John W. Taylor 595,000 acres on the terms of a rental payment of two cents per acre per year for four years from 1892 to 1895, and then a purchase price of $1 per acre, spread over eight years, with interest at six per cent.

These contracts were made in December, 1891. In December of the following year notice was given that application would be made to Parliament at its next session for "an Act to incorporate a company for the purpose of constructing and operating irrigation ditches or canals in that portion of the district of Alberta lying south of the fiftieth parallel of latitude where it passes through the said district." The original purpose of this application was to obtain an act which would assist Mr. Taylor and his associates in their colonization and irrigation enterprise. Sir Alexander and Elliott T. Galt allowed their names to be used in the application to assist in getting the act through Parliament, but they did not intend to take an active part in the affairs of the new company. However, when the act was assented to in April 1893, and the Alberta Irrigation Company was formed, Sir Alexander Galt was made President. Upon his death in September of the same year, he was succeeded as President of the Alberta Railway and Coal Company (and presumably of the Alberta Irrigation Company) by Mr. Peter Redpath, who died three months later, when Elliott T. Galt became President.

By this time the agitation for irrigation in this district was so well advanced that in the Lethbridge Board of Trade in 1893, it was moved by C. A. Magrath, seconded by W. A. Galliher, that "the promotion of irrigation in this district of Southern Alberta is absolutely necessary for the development of the district, and it is deemed advisable to place the matter properly before the Government and that a Joint Commission, composed of men from Lethbridge, Macleod and Calgary, be appointed to collect evidence, statistics, etc., and that we set aside $200 to cover our share of the necessary expenses."

*Surveys Undertaken*

As already stated an irrigation act had been passed in 1894. At the same time the Government adopted the policy in connection with irrigation development that it would determine what was feasible in the way of irrigation and then leave it to private enterprise to do the rest. In line with this policy, Mr. J. S. Dennis undertook topographical surveys and stream flow measurements to determine what water supply was available and what land could be irrigated. But it did not prove to be an easy matter to interest sufficient capital and enough people to construct a big irrigation system and colonize the lands. So John W. Taylor failed in his ambitious enterprise and his contracts for the purchase of the land were cancelled in 1895.

One of the difficulties encountered by Taylor and by the company was that the lands were located in blocks of alternate townships which made irrigation development in a practical way impossible. Repeated representations to the Government and frequent visits to Ottawa by Mr. Galt and Mr. Magrath were made in this connection, but it was not until 1896, when a western man, the Honourable Clifford Sifton, who was familiar with the conditions, was appointed Minister of the Interior, that the company's land grant was consolidated into a solid block and the irrigation scheme became feasible.

In the meantime the Alberta Irrigation Company had not exercised the functions for which it was organized and as the time for beginning construction had been limited to three years from the date of the incorporation and was now about to expire, a new act was passed in April 1896 to revive and amend the previous act. In the following year Mr. George G. Anderson, an eminent irrigation engineer of Denver, Colorado, was engaged to report on the feasibility and cost of an irrigation system to serve the company's lands. So in 1896 the actual location of the canal was started by the Alberta Irrigation Company. E. T. Galt was then president, C. A. Magrath, manager, G. G. Anderson, consulting engineer, C. F. P. Conybeare, solicitor, and Hugh MacBeth, accountant.

*Work begun on the Big Ditch*

Mr. Anderson started work with his parties in July 1898, A. M. Grace being chief assistant engineer; and by December they had about forty-five teams at work on the first division.

The chief contractors for the ditch were the President and High Council of Latter Day Saints—The Mormon Church—and the sub-contractors, labourers and teamsters were principally Mormon farmers who came to settle in Canada. These men were paid one-half in cash and one-half land; the land with water right being valued then at $3.00 per acre, and located at Magrath and Stirling. These towns were then just being started by the men working on the ditch. Cardston was an older settlement.

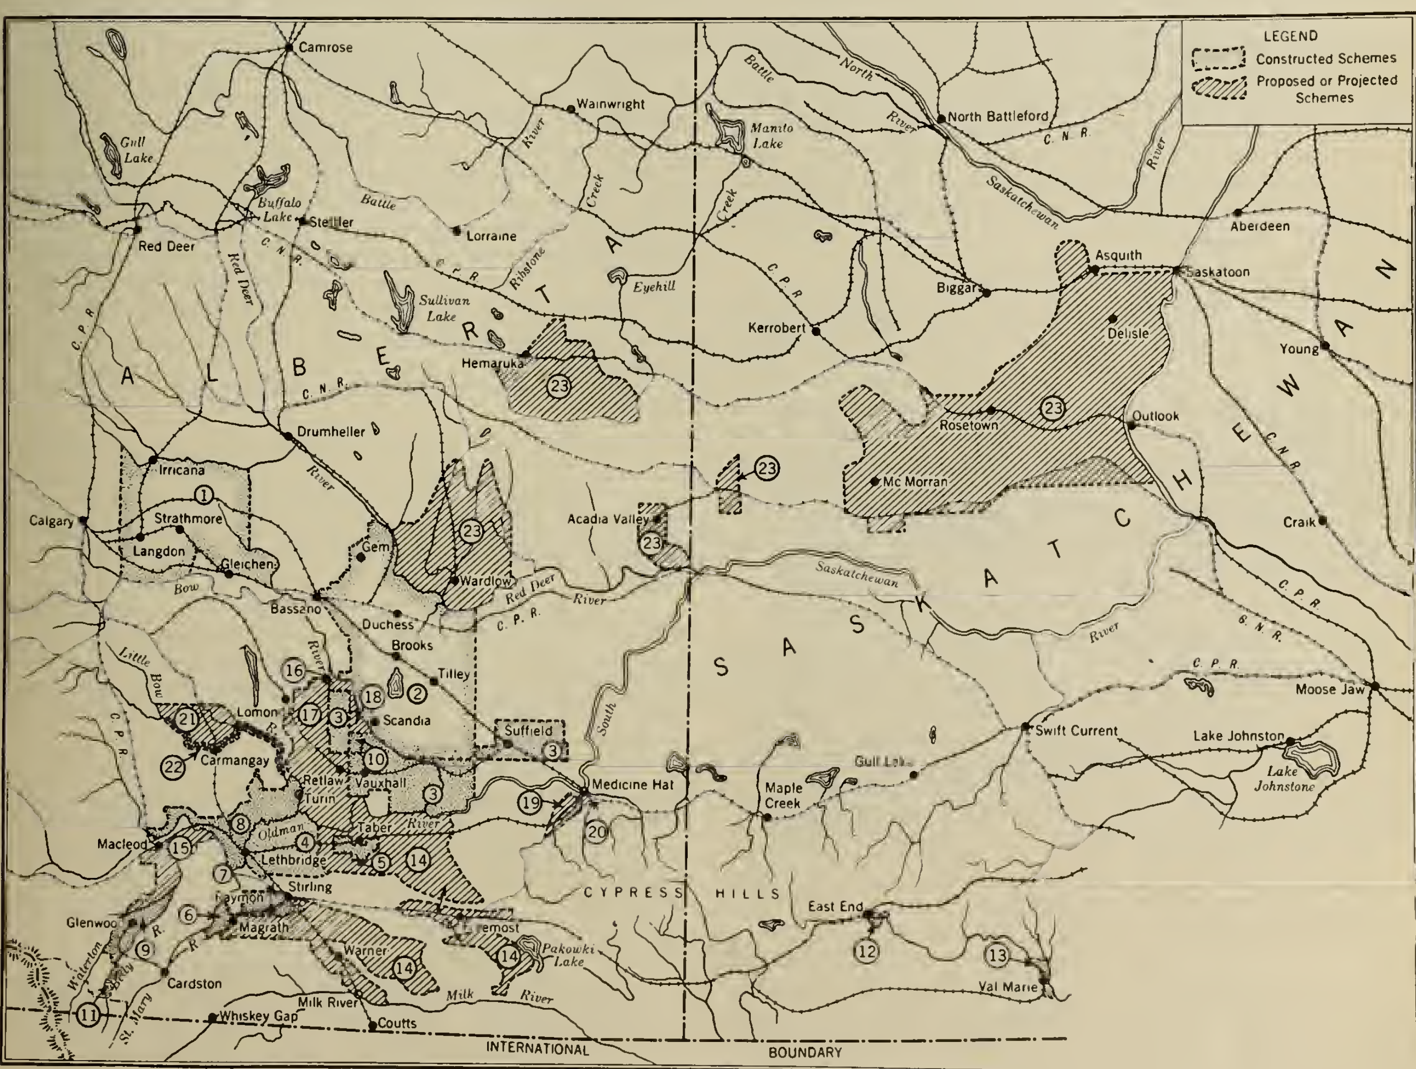

Fig. 5—Map showing Irrigation Projects in Alberta and Saskatchewan.

The whole work was done with teams, and all supplies and lumber for the structures had to be teamed from Whoop-up, a siding on the old Crow's Nest line about five miles south of Lethbridge. The intake on the St. Mary river at Kimball was about 40 miles south and 18 miles west of that point. Over a million feet of lumber was required, most of it being used in the headworks and flumes near the upper end of the system. In wet seasons the work of teaming presented serious difficulties, as some of the creeks and coulees were at times like rivers, and there were no bridges. Indians and anyone else with teams could get work. It is said that lumber was scattered over the prairie all the way from Whoop-up to Kimball where the Indians had got stuck and thrown off and abandoned part of their load. Neither steam shovels or dredges were employed in the excavation, which amounted to 1,121,000 cu. yds.

In 1899 by Act of Parliament the name of the company was changed from the Alberta Irrigation Company to the Canadian Northwest Irrigation Company. In the meantime construction was progressing rapidly.

*Contract with the City of Lethbridge*

As projected the canal was to irrigate land adjacent to Magrath and the valley running between Milk River ridge and the Rolling Hills, with Stirling as the terminal point. When the people of Lethbridge found that the company did not intend to build the canal to Lethbridge, they were much exercised. So the town, under Dr. Mewburn as mayor, induced the company under certain conditions as set forth in By-law No. 107, to build into Lethbridge. This by-law provided that "in consideration of $20,000 paid by the town to the company, they would build the canal to the town limits and deliver for the use of the inhabitants for fire, domestic and cultivation purposes, five cubic feet a second during the irrigation season, for twenty-five years, free of rental, and spend $4,000 in making ditches in town." The ratepayers voted on this by-law on June 29th, 1899, the vote being 85 for and 1 against. The company therefore changed its plans accordingly and brought its main canal into the Lethbridge district.

*First irrigation water reaches Lethbridge*

Water was turned in at the head of the canal on July 4th, 1900. It reached the limits of the town of Lethbridge at three o'clock in the afternoon of September 4th, 1900, and to the particular delight of the small boys, as well as the citizens in general, it flowed through the ditches along the streets of the town. The laterals into Magrath and Stirling were not completed until the following year, water reaching the town of Stirling July 12th, and Magrath July 25th, 1901. The canal was formally opened by His Excellency the Earl of Minto, Governor General, on September 14th, 1900.

### The Alberta Railway and Irrigation Company

In September 1904 the Alberta Railway and Irrigation Company was formed, being successor to the Alberta Railway and Coal Company, the Canada Northwest Irrigation Company and the St. Mary River Railway Company. In 1912 the Canadian Pacific Railway Company took over all the interests of the A. R. and I. Co., and has since that date operated the irrigation works which are, however, still known as the A. R. and I.

As first constructed, the A. R. and I. canal had a capacity of 400 c.f.s. It has been enlarged and extended from time to time until it now has a capacity of 1,200 c.f.s. As already stated, the original construction required a million feet of lumber and the excavation of 1,121,000 cu. yds. of earthwork. Later enlargements and extensions called for 3,250,000 ft. of lumber and 3,800,000 cubic yards of earth, or a total for the system as it now is of four and a half million feet of lumber and nearly five million cubic yards of earthwork.

Including the Magrath, Raymond and Taber Irrigation Districts, which are supplied by it, the A. R. and I. system serves an irrigable area of approximately 120,000 acres east and south of the city of Lethbridge.

### The Canadian Pacific Railway Irrigation Project

The most extensive irrigation enterprise in Canada is the system constructed by the C.P.R. to serve a large tract of land along its main line between Calgary and Medicine Hat.

When the Canadian Pacific Railway was constructed, a part of the consideration was a land grant of some 22,000,000 acres in the provinces now known as Manitoba, Saskatchewan and Alberta. The land was to be given in alternate sections, 20 miles each side of the main line, and the Company had the privilege of rejecting any land which was not reasonably fit for agriculture, making up the deficiency elsewhere. Under this clause the company declined to accept land between Moose Jaw and Calgary, and when the time came for final settlement there was still a large area wanting to complete the grant. The company then agreed to take some 3,000,000 acres in a solid block between Calgary and Medicine Hat, and construct an irrigation system to serve it.

The feasibility of diverting water from the Bow river near Bassano had been investigated by William Pearce as early as 1893 and a comprehensive report on the irrigation block as a whole was made in 1901 by George Anderson, consulting engineer, of Denver. His plan was that the whole block should be served from one intake on the Bow river near Calgary. The final result of further surveys and investigations was that the intake near Calgary should serve the western and central sections, and that Bassano was chosen as the point of diversion for the eastern section.

When the C.P.R. decided to undertake this large project it engaged J. S. Dennis to make further detail surveys and carry out the construction of the project. William Pearce also joined the C.P.R. service about the same time. The responsibility for carrying out this great undertaking may be largely credited to their efforts. Other engineers who figured prominently in the construction days were A. S. Dawson, M.E.I.C., chief engineer, and H. B. Muckleston, M.E.I.C., assistant chief engineer, under whose direction preliminary and final surveys were made and construction carried out.

The Irrigation Block is divided into three sections, namely—

The Western Section, comprising a total of 1,022,300 acres, of which 218,980 acres were classified by the government as irrigable. This project lies immediately to the east of Calgary with operating headquarters at Strathmore, supplied by direct diversion from the Bow river near Calgary.

The Eastern Section, comprising a total of 1,245,730 acres, of which some 400,000 acres were classified by the government as irrigable. This project lies to the east of Bassano, with operating headquarters at Brooks, and is supplied by direct diversion from the Bow River near Bassano.

The Central Section lies between the Western and Eastern Sections and some 240,000 acres were classified as irrigable. Upon further study it was found that on the whole the natural features, topography and cost were not favourable, and so no development was undertaken in this section.

*The Western Section*

This project was started first on account of its proximity to Calgary; construction was commenced in 1903 and completed in 1910. The altitude of the Western Section varies from about 3,315 ft. above sea level, where the irrigable lands begin on the western side, to 2,650 ft.

Fig. 6—Diversion Weir and Main Canal Headgates, Bow River, Calgary.

at the eastern limit. The gate sill of the intake on the Bow river at Calgary is at elevation 3,354.

The canal system as constructed consists of the main canal, with a maximum capacity of 2,100 sec. ft., running from Calgary headworks for 16 miles to Chestermere lake—a balancing pool, about 3 miles long and 1½ miles wide—three secondary canals taking out of Chestermere lake, branch canals from the secondary canals, and a network of distributary ditches and spillways. The total length of all constructed canals, distributary ditches and spillways is approximately 1,733 miles.

The original intake on the Bow river near Calgary was a timber structure diverting directly from the river through 20 gates, 3 ft. wide and 10 ft. high. This structure was replaced by reinforced concrete headgates and a diversion weir of three parts, completed in 1914. The present headgate structure has four openings, each 18½ ft. clear width, with Stoney sluice gates operated either by hand or electrically.

The diversion weir, extending across the river from the headgates, consists of a movable sector weir 152 feet long, a stoplog section 550 ft. long and an earth embankment containing a breaching section 200 ft. long. (See Fig. 6.) The sector is a steel trussed frame covered with skin plate on the two exposed sides. It is hinged to the floor and operated by hydraulic pressure from the water admitted to the concrete chamber in which it moves. (See. Fig. 7.) The stop-log section is built of reinforced concrete and contains twenty-three openings, each 20 ft. wide. The stop-logs are handled by an electrically operated traveller on the concrete deck of the weir.

The control structures on Chestermere lake are of timber construction, but most of the structures on the principal canals are built of reinforced concrete, many of them replacing old timber structures.

A number of the reinforced concrete drops on the larger canals are of the Indian notch type, from which in subsequent years the intermediate piers have been removed, so as to avoid weed jams which have frequently occurred and caused trouble in operation.

Most of the smaller structures in the distribution ditches were constructed of timber, but since the project has been in operation nearly all of them have been replaced at least once and many additional structures have been built in an adjustment of grades and in taking up the fall in natural channels. Replacements were mostly of timber, a large quantity of which included lumber pressure-treated with creosote oil.

In the original construction of the Western Section, a total of over 10,000,000 cu. yds. of earth was excavated and the timber in structures required about 9,000,000 ft. for division gates, drops, flumes, bridges, culverts, turnouts, etc. Capital expenditures for construction and subsequent improvements have amounted to nearly six million dollars.

The climate is favourable for grain growing and stock raising. Grain being the principal crop, and most of the farms being in large units, comparatively few of the farmers make a serious attempt to practise irrigation. Many of them have petitioned to have their water rights cancelled and as a consequence the total area served has been considerably reduced.

*The Eastern Section*

The Eastern Section (now the Eastern Irrigation District) lies between the Bow river and the Red Deer river and extends eastward from Bassano to the line between ranges 10 and 11, west of the 4th meridian, a distance of 48 miles. The topography is favourable to irrigation development, the surface slopes being moderate, making the delivery of water comparatively easy. The altitude varies from about elevation 2,550 at the western edge to 2,350 at the eastern limit.

The average precipitation recorded at Brooks is approximately 12 in. per annum. Extreme temperatures vary from a maximum of nearly 100 deg. F. in the summer to −40 deg. F. in the winter, but rarely occur, the average mean annual temperature being about 40 deg. F. Hours of sunshine and evaporation are high. The frost-free period averages about one hundred and twenty-one days in the year. Snowfall is not heavy and most of the roads are passable in the winter.

Authorization for construction of the project is dated April 21st, 1904. Construction was commenced in 1910, beginning with the Bassano dam and the project as a whole was completed in 1914.

The duty of water and the duration of the irrigating season is the same as for the Western Section, namely 2 acre feet per acre applying to irrigable contracts entered into prior to March 25th, 1919, and 1.5 acre feet per acre applying to contracts made subsequently. The irrigating season is from May 1st to October 1st.

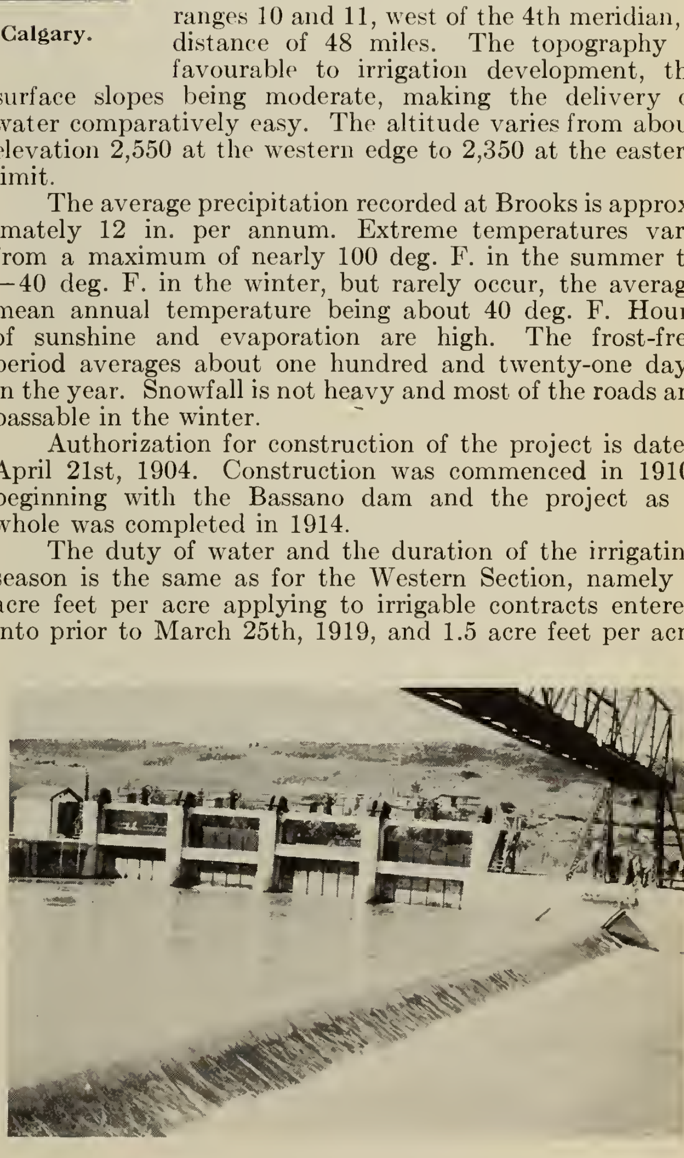

Fig. 7—Headgates of Main Canal and Movable Sector Weir, Bow River Canal.

The main canal, with a maximum capacity of 3,800 sec. ft., runs easterly from Bassano dam about 4½ miles to Little dam where a balancing pool is created at the head of the two principal canals—the East Branch and the North Branch canals. The total length of constructed main, secondary and smaller laterals in the system is approximately 2,250 miles.

Lake Newell reservoir is filled through the East Branch canal. It is approximately nine miles long and four miles wide. At full supply it has a storage capacity of 259,600 acre feet over the sill of Bantry canal headgates and a surface area of 16,666 acres. Its maximum depth is about 52 ft. The structures on the East Branch canal were designed for winter operation.

All the important structures and many of the lesser ones were built of concrete, there being a total of approximately 100,000 cu. yds. placed in structures, including Bassano dam and Brooks aqueduct. The total amount of lumber used in the construction of timber structures was about 9½ million feet. The three most important structures on the project are Bassano dam, Brooks aqueduct and Antelope creek siphon.

Bassano dam, which at one time was rated as one of the most important structures of its kind in the world on account of its composite character, great length, peculiar foundations and the depth of water which flows over its crest in flood periods, consists of a long, high earthen embankment on the south bank of the river and a reinforced concrete spillway in the existing river channel, connected at its northerly end with the headgate structure for the main canal. (See Fig. 9.)

The embankment is 7,200 ft. long with a maximum height of 45 ft. and contains approximately 1,250,000 cu. yds. of material, which was mostly transported from the main canal cut on the opposite side of the river.

The spillway portion of the dam is of the so-called Ambursen hollow type. It is 720 ft. long, with a maximum height of 65 ft. to the lowest foundation and 40 ft. from the bed of the river to the crest, the controlled water depth on the crest being 11 ft. There are twenty-four openings in the spillway, each 27 ft. clear width, with electrically operated structural steel sluice gates of the Stoney type at crest level. Electric power for operating the gates and for illumination is generated in the dam. A roadway ten feet wide extends across the top of the structure. This type of dam is hollow and derives most of its stability from the weight of the water on its back. The foundations are in a thick blanket of clay overlying a more porous sub-stratum.

Fig. 8—Winona Semi-circular Metal Flume, 7 ft. 2 in. diameter, Arch Span 64 ft.

The main canal headgate structure, an integral part of the dam, has five openings, each 20 ft. clear width, with steel gates of the Stoney type, which can be operated either by hand or by electricity. The concrete portion of the dam contains approximately 55,000 cu. yds. of concrete, 3,000,000 lb. of reinforcing steel and 500 tons of structural steel. The total cost of the complete structure was about $1,500,000.

Brooks aqueduct, on the main Bantry canal, carries the water for the Bantry system across a valley about four miles down stream from Lake Newell reservoir. The problem of crossing this valley was one of the most difficult engineering problems encountered in the whole system. The valley is two miles wide and 60 ft. deep and the main line of the C.P.R. runs through it.

The aqueduct is a reinforced concrete grade flume on a concrete trestle, having its section shaped to the hydrostatic catenary—the shape the water would assume in a flume running full, if a flexible material were used for the barrel. A rigid shell of reinforced concrete five inches thick was constructed to this shape, having an interior width at full supply level of 21 ft. 4½ in. and a maximum depth of 8 ft. 8¼ in. The advantage of this particular section in concrete construction is that under full load, moment and shear in the shell are zero. (See Fig. 10.)

The water is passed under the railway through an inverted siphon designed on the Venturi principle, the section of the barrel immediately under the track being 9 ft. 9 in. in diameter.

The total loss of head in the complete length of the aqueduct, including the siphon and reducing channel at inlet, is 4.85 ft. The maximum rated capacity is 700 c.f.s. The aqueduct contains 25,000 cu. yds. of concrete and 4,000,000 lb. of steel. The total cost was approximately $700,000.

Antelope Creek siphon is located on the East Branch canal about 30 miles below Bassano dam where it crosses one of the main divides of the country. Its maximum capacity is 1,200 sec. ft. The original structure consisted of five reinforced concrete pipes, 5 ft. in diameter, 1,740 ft. long, with inlet control, built in 1914. In 1917 it was found necessary to replace 850 ft. of two of the pipes with wood stave pipes in the lowest part of the valley, where rapid deterioration had taken place from alkali in the soil in which they were buried. In 1921 the three remaining pipes were replaced with one large wood stave pipe 90 in. in diameter on pile foundations.

In addition to the above, there are many important structures which vary considerably in design to suit the conditions for which they are required. Some of the more recently constructed gates are of the radial type, and a few have automatic control.

There are a number of large timber flumes on pile foundations over depressions and natural water courses, the two most important being the Lathom and Crawling valley grade flumes of wood stave construction, both 15 ft. diameter at full supply level, with capacities of 978 and 673 c.f.s., and lengths of 2,593 and 1,388 lineal feet respectively. (See Figs. 11 and 12.) All the timber was pre-cut and the staves milled to radius and cut to length

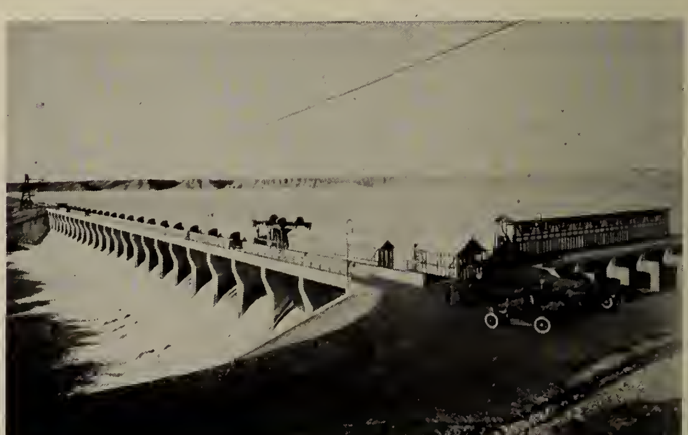

Fig. 9—Bassano Dam and Main Canal Headgates, Bow River.

Fig. 10—Brooks Aqueduct during Construction.

before pressure treatment. This is a very satisfactory type of construction. Gravity tends to keep the staves in close contact and the flume watertight, even when the staves shrink from long periods of dryness and the flume bands get loose.

Also the simplified design of the structure is interesting and is both effective and economical. The pile supports are cut off at subgrade and the tops treated with hot creosote and pitch and then covered with a metal plate before being capped. This is the only field cut in erection, aside from a few bolt holes to be bored. There are no framed bents so the number of end joints is reduced to a minimum. Cradles are not attached to pile caps so that adjustment can be made by wedging if ever necessary. Cradles are held in place by cleats nailed to pile caps, both sides and end. Overturning of flume by wind is prevented by long rods from top of flume to pile caps.

For general irrigation construction, particularly in alkali soils, treated timber has been found very satisfactory. It is readily adaptable to varying requirements of construction and repairs, and has long life.

Capital expenditure for original construction and subsequent improvements had amounted to more than $12,000,000 when the Eastern Irrigation District took over the project on May 1st, 1935.

### The Canada Land and Irrigation Company

The project of the Canada Land and Irrigation Company was formed by the amalgamation of three predecessor companies, namely, the Southern Alberta Land Company, the Alberta Land Company and Canadian Wheat Lands. The two first named companies had obtained from the Dominion Government an agreement to purchase approximately 450,000 acres of land for $1.00 per acre on condition that the companies would construct irrigation works, satisfactory to the Government, to irrigate one quarter of the irrigable area. An additional area of approximately 80,000 acres of land was purchased, consisting largely of school, Hudson's Bay and privately owned lands, thus bringing the total area in the project, including canal right of way, to over 532,000 acres. Out of this area it was found that about 210,000 acres could be irrigated. As the lands were largely contiguous and could be irrigated by only one canal system and point of diversion for water supply from the Bow river, the Southern Alberta Land Company, subject to agreements with the other companies for reimbursement for costs, undertook the construction of works to serve all of the irrigable lands. Work of surveys and construction started about 1909 and progressed rapidly until the advent of war in 1914. Work was stopped in September 1914. In 1917 the three companies were amalgamated, forming the Canada Land and Irrigation Company. Work was resumed by this company in the latter part of that year and the settlement of irrigable land started in 1919.

*Description of works*

By this time the construction of the main canal had been extended for a distance of over 200 miles through the country, in addition to which there were many miles of branch canals, laterals and appurtenant structures. The main feature of the work consists of two dams across two channels of the Bow river, each about 10 feet high and 550 feet in length. From the point of diversion from the river a supply canal, 44 miles in length, was built to a reservoir, Lake McGregor. This reservoir was formed by two concrete paved earth dams respectively 44 ft. and 41 ft. in height and 3,580 and 1,993 ft. in length. The dams form a reservoir about 25 miles in length and one-half to three miles in width and at maximum capacity would store 300,000 acre feet of water. From the outlet structure of this reservoir a canal 14 miles long extends to a second

Fig. 11—Lathom, Semi-circular Wood Stave Flume 15 ft. diameter, 2,593 ft. long.

reservoir, Little Bow reservoir. This section of canal, approximately eight miles, is along the steep side hill slopes adjacent to the Little Bow river and involved a difficult and hazardous location for canal construction. Deep cuts and high embankments of 50 ft. for long stretches are a frequent occurrence in this eight miles. The canal at the lower end of the 14 miles emerges from the Little Bow canyon and enters the Little Bow reservoir. This reservoir was made in a saucer-like basin by excavating a channel to the bottom of the basin and by the construction of an earth dam 24 ft. maximum height and 3,963 ft. in length across a low part of the rim of the basin. It has a capacity of 30,000 acre feet and serves largely as a regulator in the supply of water for irrigation. From the Little Bow reservoir the canal extends approximately 27 miles to the first irrigable lands of the project, making a total of 110 miles from the point of diversion of water to the first point of use. Thence the main canal was extended an additional 100 miles through lands of the holding companies. A fall of approximately 600 ft. occurs in the total length of canal, of which about 200 ft. is taken up by 14 drops and the remaining fall is in canal gradient. From this main canal 78 miles of branch canals were built and approximately 200 miles of lateral ditches have been built to date. Over 100 main canal structures, flumes, siphons, bridges, drops, etc., and nearly 1,400 lateral structures of concrete and wood are in the irrigation system.

The cost of these works probably exceeded $7,000,000 and all costs including land investments, interest on debentures, colonization and other costs to date approximate $17,000,000. At this time 40,000 acres of land are irrigated out of the 210,000 for which the project was originally planned. It would take $3,000,000 to complete the scheme to the ultimate possibilities of the project.

### Irrigation Districts

In 1915 the Alberta Legislature enacted the Irrigation

Districts Act. All new irrigation enterprises in Alberta since that date have been carried out under its provisions.

### Taber Irrigation District

The Taber Irrigation District was the first one to be established under the Irrigation Districts Act of Alberta. The farmers in the district began negotiations with the C.P.R. about 1913 for a water supply for their lands. The company had constructed reservoirs in Chin Coulee for the storage of the waste and surplus water from their Lethbridge system, and surveys had shown that this water could be economically applied to the lands around Barnwell and Taber. The original proposal was that the company should build the irrigation works and accept contracts from the individual land owners, the contracts to be secured by mortgages on the farm lands. But this proved to be impracticable, so the Alberta government was asked to pass legislation which would enable the farmers to organize a district and issue bonds to cover the cost of irrigation works. The Irrigation Districts Act was passed by the Alberta Legislature in 1915 and in the same year the Taber Irrigation District was erected. After a number of delays, negotiations with the C.P.R. were completed in the spring of 1919, and in July of that year the land owners voted unanimously for the issue of bonds for the construction of their canals. The C.P.R. accepted the bonds for the actual cost of the construction of the works, which amounted to $16.50 per irrigable acre. Construction was started July 24th, 1919, and completed in October 1920. The first water was turned into the canal September 10th, 1920, and the canals were primed and about 2,000 acres of land were fall irrigated that season. The original contract called for the delivery of 34,000 acre feet per annum at the headgate of the Taber canal for the irrigation of 17,000 acres. The area entitled to irrigation was afterwards increased to 21,661 acres. The system is operated by the farmers themselves, and has been successful from the start.

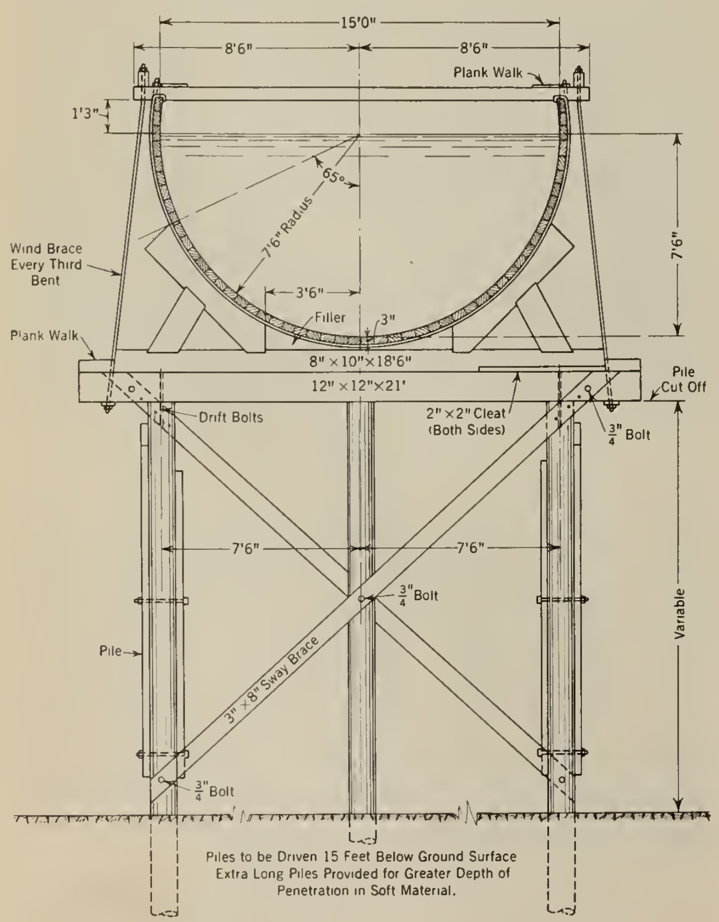

**Fig. 12—Section of Lathom Flume.**

### Lethbridge Northern Irrigation District

As early as 1910 a petition was forwarded to the Government by settlers in the Iron Springs District for the construction of an irrigation system to supply water to their land. Their proposal was to pump water from the Oldman river immediately south of Iron Springs, but as this involved a lift of 300 feet, little study was required to show that it could not be done within the limits of reasonable cost.

Several other possibilities were inquired into but the first actual surveys were made by the Dominion Government in 1913 when the plan of taking water from the Oldman river on the Peigan Indian Reserve, about 10 miles west of Macleod, was recommended as the most feasible scheme. The surveys were continued each season to define in greater detail all the elements of location, cost and areas which could be irrigated.

The Lethbridge Northern Irrigation District was erected by vote of the land owners on September 20th, 1919, the vote being 288 in favour to 8 opposed. It covers an irregular tract of land lying on the north side of the Oldman river extending from Macleod on the west to Turin on the east. The district contains about 230,000 acres of which 105,000 were classified as irrigable. Reclassification has reduced the irrigable area to about 93,000 acres.

The bonds could not be disposed of on acceptable terms until they were guaranteed by the provincial government. This was done in the spring of 1921 and a contract was let on June 1st, 1921, covering the excavation of 7,300,000 cubic yards of material. The earthwork contract was completed October 19th, 1922, and the structures by May 1923. The cost of construction, apart from interest and carrying charges, was $4,171,580.35. The total bond issue which covered construction costs, engineering, interest, administration and other costs during construction, and discount on sale of bonds was $5,400,000, in thirty-year 6 per cent bonds guaranteed as to interest and principal by the provincial government.

Water was turned into the canal May 1st, 1923, but on the last day of May and the first few days of June an unprecedented flood in the Oldman river washed out two or three miles of the main canal and two sections of the flume over the Oldman river. These damages cost the district nearly $100,000 and required all summer to repair, so that no more water was run until October. In 1924 the system was operated for the full season and nearly 30 per cent of the total irrigable area was irrigated.

The diversion dam on the Oldman river is a concrete structure 524 ft. long and 6½ ft. high. (See Fig. 13.) The headgate structure is also of concrete, the gates being of the Stoney type. The main canal is 33 ft. wide on the bottom and designed to carry 800 c.f.s. at a depth of 7 ft. Four miles from the intake the canal passes from the south to the north side of the river through a semicircular galvanized sheet iron flume 14 ft. wide at the top and 3,322 ft. in length. Approaching the river it is supported on wooden trestles resting on concrete pedestals, and it crosses the river by a steel bridge (see Fig. 14). Other important structures on the main canal are the Willow creek flume similar to the one just described, and the Rocky Coulee and White lake inverted siphons, each being of wood stave pipe construction 10½ ft. in diameter and 2,855 ft. and 930 ft., respectively, in length. Hundreds of other structures of various types carefully designed to meet their particular requirements are found on the main and distribution canals. The larger and more important ones as a rule are of concrete construction, the smaller ones of timber. (See Fig. 15.)

The main canal empties into Keho lake, southeast of Barons, which provides storage capacity for about 40,000 acre feet for the eastern end of the district.

H. B. Muckleston, M.E.I.C., was chief engineer during

**Fig. 13—Diversion Dam, Sluice Gates and Headgates on Oldman River.**

**Fig. 14—Metal Flume on Timber Trestle at Oldman River Crossing.**

construction. P. M. Sauder, M.E.I.C., has been project manager in charge of operation.

### The United Irrigation District

A large tract of land known as the Cochrane Ranch, lying between the Belly and Waterton rivers in southwestern Alberta, was purchased and colonized by the Alberta Stake of Zion (The Mormon Church in Alberta) and as early as 1906 the Stake made application to the Dominion Government to irrigate it, and went to considerable expense making surveys for the irrigation of some 45,000 acres. Authorization was granted in 1907 for the diversion of water from the Waterton river for this purpose but the surveys showed that the cost would be excessive so no construction was undertaken and the authorization was cancelled in 1910.

Afterwards another survey indicated that it was feasible to divert water from the Belly river to serve a large portion of this land, and in the dry season of 1918 the farmers in the neighbourhood of Hill Spring and Glenwood, having lost their crops through drought, determined to build the ditch themselves and actually started work on it. But proper surveys had not been made and the authority of the Government had not been obtained, so that little was accomplished.

In March 1919, the Alberta Stake of Zion made a new application for water, this time from the Belly river instead of the Waterton, and the Dominion Government undertook to make a complete survey of the scheme.

In August 1919, the United Irrigation District was erected. In March 1920, another district comprising lands adjoining the United District on the north and east was erected under the name of the Lone Rock Irrigation District. Since these two districts would be served by the same system of canals, the majority of the land owners in the Lone Rock district petitioned the Minister of Public Works of Alberta to be included in the United District. Consequently, by order of the Minister, signed March 2nd, 1921, the Lone Rock Irrigation District was dissolved and the lands which it comprised were added to the United Irrigation District.

Construction work was commenced in October 1921 and completed in the fall of 1923. A feature of the construction of this system was that the contracts were let to the ratepayers in preference to regular contractors. The system covers some 36,000 acres of irrigable land, and cost about \$15 per acre which was covered by the issue of \$550,000 in thirty-year 5½ per cent bonds guaranteed by the provincial government.

### Other Irrigation Districts

Other irrigation districts smaller than the ones above described, have been organized in Alberta, as follows:

The New West Irrigation District was erected in 1923 to irrigate about 4,500 acres north of Retlaw. It gets its water supply from the Bow river through the main canal of the Canada Land and Irrigation Company.

The Little Bow Irrigation District, erected in 1923, diverts water from the Highwood river to the Little Bow river at High river. It was contemplated that individual water users would pump this water from the Little Bow river for the irrigation of about 2,800 acres, but no pumping plants have yet been installed. The diversion serves however to keep up the flow of the Little Bow river for livestock and domestic supplies.

The Mountain View Irrigation District was erected in 1923 for the irrigation of about 2,500 acres east of the Belly river in township 2, range 28, west of the 4th meridian. Construction work was allotted to each of the various interested parties to carry out themselves without the issue of debentures. It has proceeded spasmodically ever since, some progress being made in dry years and practically none in wet years.

The Magrath Irrigation District was organized in 1924 to irrigate about 5,000 acres near the town of Magrath. It gets its water supply from the Alberta Railway and Irrigation system. The C.P.R. constructed the works, accepting the debentures of the District in payment.

The Raymond Irrigation District was erected in 1925 to irrigate about 6,400 acres near Raymond in addition to that already irrigated under the A. R. and I. system. This district also receives its water supply from the A. R. and I. canal.

### Eastern Irrigation District

In 1934 the farmers in the Eastern Section of the C P.R. Irrigation Block approached the company with a proposal for the organization of an Irrigation District and the transfer of the irrigation system to the District. These negotiations resulted in the erection of the Eastern Irrigation District and the transfer of the entire holdings of the C.P.R. within the boundaries of the District, including a million and a quarter acres of lands as well as the entire irrigation system to the Board of Trustees of the District. The agreement was ratified by a special Act of the Provincial Legislature and became effective May 1st, 1935. The system has already been described under the title of the C.P.R. Eastern Section.

### Irrigation in Saskatchewan

Irrigation development has not been so extensive in Saskatchewan as in Alberta, largely because of the absence of an adequate or readily accessible water supply. A large number of small schemes have been constructed in the southwestern part of the province, utilizing the runoff from the Cypress Hills. They are mostly individual flood-water schemes, built at a low cost, in connection with ranching operations. Some of them date back to the 1890's or earlier, but no accurate records seem to be available. The period of greatest activity seems to have been from 1908 to 1912. The Irrigation Branch of the Dominion Government reported in 1915 that there were some ninety-three projects in operation in this district, comprising some 28,000 acres, but that by no means all of this area had been actually irrigated. The area irrigated in 1914 was reported to be 11,959 acres. The area irrigated in 1918, which was a dry year, was reported to be only 4,511 acres.

Reservoirs must be constructed for the conservation of flood waters before any substantial improvement in the situation can be expected. Some progress has been made in this direction, particularly during the past two years, under the Prairie Farm Rehabilitation Act. Among them were two projects completed in 1936 on the Frenchman river. The Val Marie project, the larger of the two, provides storage capacity of 9.000 acre feet for the irrigation of 6,000 acres near Val Marie. The East End project has a storage capacity of 5,000 acre feet and will serve 2,500 acres near East End. A very large number of small irrigation schemes varying in size from a few acres up to several thousand, are being developed at this time through the assistance of the P.F.R. Act. The Natural Resources Department of Saskatchewan estimates that an area of fully 70,000 acres can be irrigated economically in southwestern Saskatchewan. (See map in Fig. 5.)

At least two very large schemes have been suggested in Saskatchewan. One would take water from the South Saskatchewan river near Elbow and serve a large area north and west of Moose Jaw. The other would divert water from the North Saskatchewan river near Rocky Mountain House, Alberta, utilize Buffalo and Sullivan lakes for storage, and irrigate a large area, possibly more than a million acres, between Rosetown and Saskatoon. They have received some preliminary field study dating back as far as 1912, but no complete survey or estimate has ever been made. It is certain, however, that they would be very expensive.

### The Present Trend in Irrigation Policy

Although irrigation is one of the oldest arts practised by civilized man, it must go through a pioneering stage in every new country. The half century, more or less, of its development in Canada has been largely of a pioneering nature. It is a significant fact that the highest development in agriculture, both in ancient and modern times, has been in countries where nature has failed to provide adequate rainfall and where it was necessary to supply the deficiency by the artificial application of water. And when agriculture was highly developed the other arts and sciences also flourished. Such was the history of the great valleys of the Euphrates, the Nile, the Ganges, and the Yang-Tse, where the civilizations of ancient times had their beginnings. They were all arid valleys dependent on irrigation for their success. It is an outstanding fact in history that the human race has never made material progress in countries where nature is too lavish in her support.

The first ventures in irrigation in a new country, as has been stated, have been small individual ones, constructed at very little outlay of money and as a rule serving a temporary purpose successfully. So also with the small community schemes. Then came the private or corporation schemes promoted for profit, nearly all of which met with financial failure, for reasons already stated. Then, for the past twenty years, practically all new development in Canada has been under the Irrigation District plan where the cost of construction and operation is assessed against the land on which the water is used. This seems to be the logical and democratic method for the administration of irrigation works, but up to the present time it has failed to recognize, except indirectly, one very important factor, and that is the general public benefit.

All irrigation construction in Canada to date has been based on the theory that the irrigated lands must bear all the costs. Within certain limitations this theory is correct, but in a broad sense there are many beneficiaries besides the particular land irrigated and the farmer who irrigates it. If a large section of country which in its natural state can provide only precarious support for a sparse population, can be converted into a wealth producing community supporting a large population, it becomes an asset to the whole country. The benefits are distributed through all the industries of the country and to all the people of the country, through increased ability to buy and sell and pay taxes.

Irrigation for big scale grain growing is not economically feasible. Where markets are available for higher priced crops such as fruits, sugar beets, peas and other vegetables, it is profitable. But its greatest value lies in the fact that with its aid comfortable homes can be established, feed for livestock can be produced, and the ravages of drought largely avoided.

Fig. 15—Concrete Drop near Picture Butte, Alta.

Further irrigation development by private capital probably cannot be expected in western Canada for the reason that its benefits are too widespread to be readily assessed. There is no practical way for an individual or corporation to levy and collect its costs. But it is a safe prediction that where a water supply is available and can be developed at reasonable cost its wealth producing value and possibilities of general benefits will be recognized and will result, sooner or later, in development under a policy whose aim will be to distribute the burden of cost more evenly over all who enjoy its economic benefits.

### Acknowledgments

This resumé of Fifty Years of Irrigation in Canada is largely historical rather than technical. It is a compilation of information gathered from many sources. Some of the contributions the author has used almost verbatim, and herewith expresses his thanks and acknowledgments to the following who have assisted him.

Dr. E. A. Cleveland, M.E.I.C., consulting engineer, Department of Lands, Province of British Columbia, Vancouver, B.C.
Major J. C. MacDonald, M.E.I.C., comptroller, Water Rights, Province of British Columbia.
O. H. Hoover, M.E.I.C., engineer in charge, Water Power and Hydrometric Bureau, Dominion Government, Calgary.

# Communications Engineering

*P. F. Sise, M.E.I.C.,*
*President, Northern Electric Company, Montreal, Que.*

### General Principles of Communications Engineering

The remarkable developments in electrical communication which have taken place in the last half century have been largely due to equally noteworthy progress made in this field in the search for new knowledge. As communications engineering is such a specialized branch, it seems desirable to outline a few of its theoretical principles (largely discovered during the past fifty years) before going on to the history of the developments in Canada during this period.

Communications engineering is usually considered as relating only to methods of communication by electrical signals. That telephony is a form of signalling may not be obvious because the telephone, like the teletypewriter, automatically translates its messages into code and back again into intelligible language. In the telephone code, the signal for each sound is made up of many component waves of different frequencies and of different relative powers instead of being composed of dots and dashes. As a matter of fact, the dots and dashes of the telegraph code, and of the teletypewriter code (which is composed of dots or dashes of five different lengths), may also be analysed into a wave code. Communications engineers are usually more interested in the wave frequencies than in the equivalent dots and dashes or speech sounds because the problem of transmitting irregular telegraph and telephone currents can be resolved into one of transmitting regular alternating currents of various frequencies. This leads to the consideration of two important principles involved in the transmission of information by electrical signals.

The first principle may be stated as follows: "In order that a received signal may be a 'true copy' of the transmitted signal all the component waves of the signal must be transmitted at equal velocities and with equal efficiencies." Except for very long distances, the time of transmission is so short for all frequencies, that effects due to differences in velocity are negligible, and the transmission characteristics of a line or piece of equipment may be

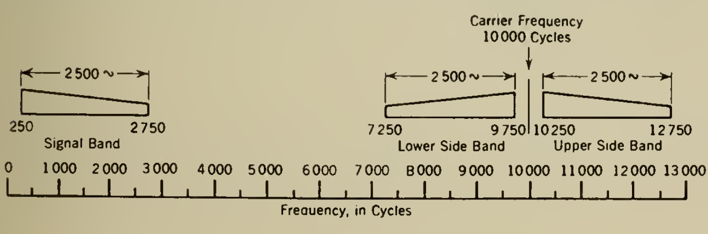

**Fig. 1**

judged from a curve showing the transmission efficiency of the line or equipment over the range of frequencies involved. For distortionless transmission, such a curve should be "flat," and the more nearly it approaches this ideal, the more exactly will the received and transmitted signals agree.

The second principle is as follows: "The amount of information that can be transmitted over a transmission system in a given time by means of a given type of signalling code, is proportional to the range of frequencies." At ordinary speeds, a telegraph message requires the transmission of frequencies ranging from zero to about 100 cycles. It might be thought that by doubling the speed of transmission the same range of frequencies could be used to transmit twice as much information. Actually, however, with the higher rate of transmission, the range of frequencies contained in the component signals is doubled, and will now extend from zero to about 200 cycles. Similarly, in the case of speech, if a phonograph record were run at twice its normal speed and the resulting sound transmitted, all the component frequencies would be doubled so that instead of extending from about 250 to 2,750 cycles they would extend from about 500 to 5,500 cycles, with the result that the frequency range utilized would be doubled.

Increasing the speed of transmission is not the only method, however, of getting more information per minute over a line. Another method is to transmit two or more messages simultaneously by using a different band of frequencies for each message. It should be noted that the total range of frequencies utilized is proportional to the number of simultaneous messages, so that in this case, also, the amount of information transmitted is proportional to frequency range utilized.

A simple example of this form of multiplex transmission is the composited telephone line, whereby telegraph and telephone currents may be transmitted simultaneously over the same line. A selective circuit known as a composite set separates the low telegraph frequencies (approximately zero to 100 cycles) from the higher frequency telephone currents (250 to 2,750 cycles, approximately).

More extensive applications of multiplex transmission have been made possible by the development of processes for shifting the bands of frequencies representing telegraph and telephone signals to any desired position in the frequency scale before transmission, and for shifting them back to their normal position after transmission. These developments have led to the form of multiplex transmission known as carrier telegraphy and telephony.

For wireless transmission, the use of high frequencies in place of the original dot-and-dash or voice frequencies is essential, and to prevent interference, different radio stations in the same area use different radio frequencies. Each radio receiver is able to select one programme or message from the many by means of tuned circuits, and translates the high frequencies back to the original signal frequencies.

The translation of a band of signal frequencies to a new position in the frequency scale is known as modulation.

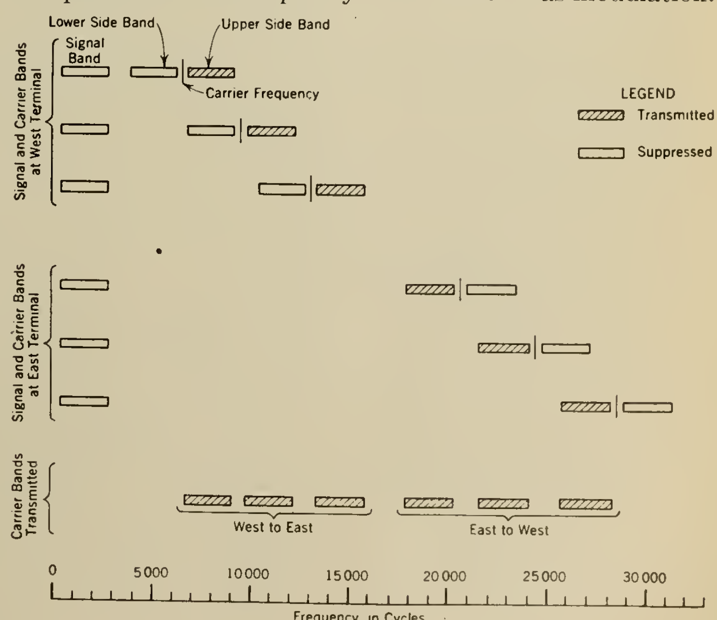

**Fig. 2**

This process combines each frequency of the signal band with a new frequency called the carrier frequency, which is generated for this purpose. From the combination there are obtained two new bands of frequencies, one above and one below the carrier frequency, as shown in Fig. 1; these frequency bands are known as the upper and lower side bands. Each frequency of the upper side band is equal to the sum of a corresponding signal frequency and the carrier frequency, and each frequency of the lower side band is equal to the difference between its corresponding signal frequency and the carrier.

One speech sound differs from another in the relative amounts of power in its different component frequencies. For simplicity, a signal in which the power decreases uniformly towards the high frequency end of the band is illustrated, the height of the band at each point indicating the relative amount of power at each frequency. It will be seen that the upper side band represents the signal band simply shifted up the frequency scale while the lower side band corresponds to the signal band raised up the scale and inverted.

The converse operation to modulation is called demodulation or detection, and translates the side band frequencies back to the original signal frequencies. Demodulation can derive the signal frequency band either from the upper or lower side band, or from both, and does so by combining the side band frequencies with the carrier frequency so as to obtain sum and difference frequencies as in modulation. The band of difference frequencies will be identical with the original band of original frequencies.

To avoid using a greater range of frequencies than necessary, it is customary, in carrier telephony, to transmit only one side band. Figure 2 illustrates the various frequency bands involved in the type C-4-S carrier telephone system, showing which side bands are suppressed and which are transmitted. In carrier telegraphy both side bands are transmitted because the frequency bands are so narrow that the cost of providing sufficiently selective circuits to pass one band and suppress the other is not justified. Figure 3 illustrates the progress which has been made during the past fifty years in adding to the number of communication channels available over one pair of wires

In the transmission of electrical signals by wire or by radio each method has certain characteristics which make it more suitable for some purposes than for others. Wire transmission is essentially more private as the signals follow the conductors from the sending to the receiving station, whereas radio signals are radiated into space and can be picked up at a large number of receiving stations. On account of this, radio transmission is particularly suitable where publicity is desired, as in the case of an SOS call and for the broadcasting of entertainment and advertisements. Secrecy can be obtained in radio transmission by using a private code. In radio telephony, the voice frequencies can be converted into a private code of frequencies and the result is popularly known as "scrambled speech." Radio must also be used where either or both stations are mobile. With wire transmission, switching centres can be conveniently introduced for establishing connection between any two of a large number of stations. It is only necessary to compare the fifteen lines needed to completely interconnect half a dozen points on a sheet of paper with the half dozen lines needed to connect them to one central point, to realize that a large saving in communication channels can be obtained with switching facilities, and the savings increase with the number of points to be interconnected.

With both forms of transmission, the signals become weaker as they travel away from the transmitting station, but in the case of wire transmission over land, repeaters can be conveniently introduced at intermediate points to amplify the attenuated signals and thus restore their original strength. It requires much less power to periodically amplify the signal in this way than to provide sufficient power at the transmitting station to give the same signal strength at the receiving end without repeaters. As an example to illustrate this, let us assume that in travelling 100 miles the power of a signal decreases to one tenth of its initial value, and let us consider a transmitting and receiving station 600 miles apart. If a signal is transmitted with a power of 1,000 watts, the power will fall to 100 watts at the end of the first hundred miles, to 10 watts at the end of the second hundred miles, and so on. Thus when it arrives at the receiving station, its power will be only a thousandth of a watt, or one milliwatt. By installing a repeater every hundred miles that will multiply the power of the signal by ten, it is only necessary to transmit ten milliwatts in order to receive one milliwatt, the power of the signal being alternately reduced to one milliwatt in travelling a hundred miles and then raised to ten milliwatts again. By using repeaters, therefore, the total expenditure of power is reduced from a thousand watts to a small fraction of a watt (10 milliwatts at the transmitting station

| Year | Type of Communication | Graphical Presentation | Number of Channels: Single Morse Telegraph | Duplex Telegraph | Two-Way Telephone | Total |

Fig. 3

and 10 milliwatts at each of five repeater stations, making a total of 60 milliwatts).

It may be of interest at this point to explain the communication engineer's unit of transmission loss and gain, known as the decibel and abbreviated as db. In this unit a line which delivers one tenth of its power input causes a loss of 10 db. and an amplifier, which has a power output of ten times greater than its power input, introduces a gain of 10 db. Expressed in this unit, therefore, the transmission loss for each hundred miles and the offsetting transmission gain at each repeater, for the example which we have just considered, is ten decibels. Thus the transmission loss for the 600 miles without repeaters is 60 db. and with five repeaters is reduced from 60 db. to 10 db.

One other comparison should be noted between wire and radio transmission, namely, the means which are available for obtaining more than one communication channel between two points. With wire transmission it is possible to furnish a separate circuit for each channel and to use as many circuits as desired. If more are required than can be conveniently run as open wire, or if it is desired to place the conductors underground, multi-conductor cables can be used. The use of carrier frequencies for obtaining additional channels is an alternative to the use of additional circuits and permits savings in capital expenditure on long distance circuits. With radio transmission, the use of different frequency bands is the only means of obtaining multiple channels.

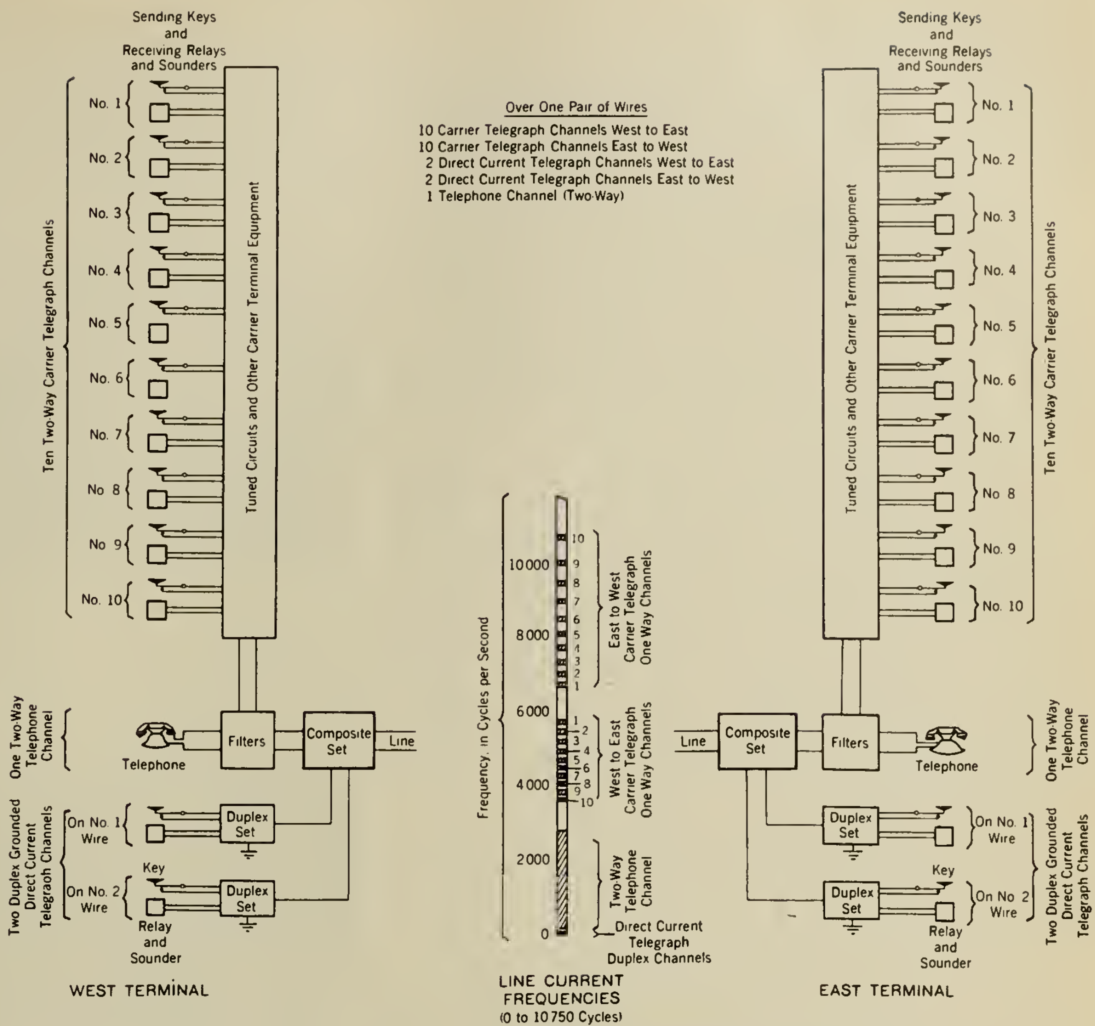

**Fig. 4—Diagram Illustrating Open Wire Carrier Telegraph System (Type 50-B-H).**

The total range of frequencies used for radio transmission has been extended to much higher frequencies than for wire transmission, it being now practicable to use frequencies as high as from three to five hundred megacycles. The range of frequencies used for carrier transmission over the usual type of open wire circuit has not until recently extended beyond about 30,000 cycles. Recent developments in this field, however, have made it practicable to use frequencies as high as about 110 kilocycles on the usual type of open wire and cable, and by the use of a special type of transmission line known as a coaxial cable, consisting of a central wire enclosed in a tubular return conductor, it will be possible to extend the upper limit for practicable wire transmission to at least 1,000 kilocycles.

### Wire Telegraphy

The year 1887 marked the fiftieth anniversary of the invention of the electric telegraph by Cooke and Wheatstone in England and by Morse in America, and at a meeting of the Society of Telegraph Engineers and Electricians (later to become the Institution of Electrical Engineers) held in January of that year, Sir Charles Bright reviewed the history of land and submarine-cable telegraphy during the fifty years then completed. It is interesting to take note of a few of his remarks that throw a light on the state of the art in 1887, at the end of *his* fifty years and at the beginning of *ours*.

". . . on investigating the practical application of electricity for general use of mankind during the last half-century, we find nearly the whole of the work done and capital invested has been connected with electric telegraphs, at all events until 1878, since when a material movement has taken place in the development of electric lighting and telephones . . . the beautiful and rapid instrument of Sir C. Wheatstone and Mr. Stroh now used at the Post Office, the latest speed of working which I am informed by Mr. Preece is four hundred and thirty-five words per minute . . . making a total of 107,000 miles of submarine communication with all the important parts of the world in which more than £37,000,000 capital is invested . . . Duplex telegraphy as applied to cables has been brought to a high degree of perfection judging from results obtained on the Mackay-Bennett cables recently laid across the Atlantic. . . At the present time the Post Office have no less than 153,153 miles of wire used for commercial purposes with 5,097 offices . . . Nor have I been able to refer to telephones which may be regarded as a branch of the telegraphs."

Turning now to the field of Canadian communications, the completion of Canada's transcontinental railway line in 1885 by the Canadian Pacific Railway Company provided in addition to the railway, a transcontinental telegraph line as a link between the east and west. This line was opened for commercial business the following year, and in December, 1886—just about a month before the meeting of the Telegraph Engineers in Westminster, England, from which we have quoted—the inauguration of this "all red" route was commemorated by the following telegraph message from New Westminster on the Pacific to old Westminster in London:

> December 20, 1886—New Westminster, British Columbia, sends greetings to old Westminster, 12.20 p.m. weather cloudy, light rain, thermometer 44 degrees, above. What is weather with you? We are working with cable office in Canso over circuit of 4,600 miles.

In her reply old Westminster sent the compliments of the season to her sister namesake and remarked that the weather was heavy and foggy with the temperature at about 32 degrees.

About two years later, when a direct transcontinental line reached Fredericton, New Brunswick, communication from coast to coast was still so novel that this event also was commemorated by an interchange of greetings, which took place on February 20th, 1889, between the mayors of Vancouver and Fredericton. Said the Mayor of Vancouver, with civic pride and perhaps foreseeing the television of a future age; "Wish we had transcontinental telescope as well as telegraph so you could take a peep at our gardens and fields this morning. Take my word they look glorious."

Said Fredericton's mayor, knee deep in eastern Canada's snow, "On receipt of your telegram several of the audience fainted and the few remaining got up and left for Vancouver."

At this time the transcontinental line was of iron, No. 6 BWG gauge, and local lines were of No. 9 iron wire. In 1898, a copper wire was strung from Montreal to Vancouver. This wire weighed 300 lb. per mile, and was drawn in Canada.

In 1902, the culmination of a long felt desire for an "all red" route for British Empire communications was seen in the completion of a cable between Canada and Australia by means of which communications could be transmitted to different parts of the Empire without passing through foreign territory. The British, Canadian, Australian, and New Zealand governments formed the Pacific Cable Board for the purpose of operating the cable, and the land wire facilities for transmission across Canada were supplied by the Canadian Pacific Railway Company. The completion of this cable in November 1902 was made the occasion of the first around-the-world telegrams ever transmitted. Two messages were sent, one to the east and the other to the west, and were addressed to the Governor General from Sir Sandford Fleming, who had played a great part in bringing about this development of Imperial communications. By 1910 the traffic over this "all red" route was so great that the Pacific Cable Board found it necessary to lease a wire from the Canadian Pacific for its own exclusive use.

The extensive programme of railroad construction involved in building the two additional transcontinental lines which Canada now possesses was accompanied, of course, by associated telegraph lines. In 1915, the Canadian Northern Railway obtained control of the Great North Western Telegraph Company, and combined its own telegraph system with the G.N.W. Company's under the name of the latter. In 1918, when the Canadian Government took over the Canadian Northern and the Grand Trunk Pacific Railways, it also took over their telegraph systems, forming what is now the Canadian National Telegraphs.

Great as had been the growth of Canada's telegraph network in the early 1900's, making it in proportion to her population one of the most extensive in the world, the traffic between the larger cities began to tax the capacity of the available lines. Many operators started using typewriters, so as to be able to receive at high speeds more easily, and before long the use of a typewriter became compulsory on commercial wires.

The printing telegraph was first put into service by the Canadian Pacific Railway Telegraphs between Montreal and Toronto in 1912. Its use was gradually extended during the following years, until now the printer is in service between all important Canadian cities.

The post-war era of prosperity which began for Canada about the year 1922 and ended about 1929 brought to the telegraph systems more traffic than their lines could handle. Means were available, however, in the newly developed carrier telegraph system, for obtaining additional message channels without constructing new lines, and both the Canadian National and the Canadian Pacific Railways took full advantage of this new system. The first installation to be put into operation was a circuit between Montreal and Toronto for the Canadian National Telegraphs, which was opened in April 1927. By the end of 1927 the Canadian National, and by the end of 1929 the Canadian Pacific, had carrier circuits in operation from Montreal to Vancouver. Since a carrier telegraph circuit can also be used as a high grade telephone circuit, both companies installed telephone repeaters as well as the carrier equipment and thus obtained long distance telephone circuits for their official business.

At about this time telephone circuits began to be used for transmitting radio programmes to distant radio stations, and the two large telegraph systems found themselves in the strategic position of having transcontinental circuits available that could be readily arranged for this service. The success of the Jubilee Broadcast in 1927 (of which more will be said under Radio Telephony) showed the possibilities in this field, and from that time the telephone and telegraph companies have both had a share in supplying lines for transmitting radio programmes.

### Wire Telephony

Alexander Graham Bell's early experimental work at Brantford, Ontario, in which speech was first transmitted over distances measurable in miles rather than feet was carried on in the summer of 1876. In 1887, therefore, the telephone was eleven years old, and networks of telephone wires were rapidly spreading over all large towns and cities. One of the most important problems engaging the attention of telephone engineers was the development of a satisfactory multi-conductor cable as a substitute for open wire construction, as the congestion of these lines threatened to limit the growth of the industry. With a view to developing the most suitable type of cable, a conference was held by representatives of the various American companies in 1887, and a specification for a standard cable known as Conference Cable was issued in the following year. The largest size of this cable contained fifty pairs of 18 gauge conductors, the conductors being wrapped with cotton, twisted in pairs, and cabled in reverse layers. The cable thus formed was impregnated with an insulating compound and pulled into a lead pipe having an outside diameter of two inches. The lead was alloyed with 3 per cent tin, as experience had shown this alloy to have less tendency to crystallize and crack, and to be less subject to corrosion than commercially pure lead.

During the next few years, trials were made of dry core cables using paper insulation without any filling, or sealing, compound. These tests showed that the lead sheath, if properly sealed at the ends, could be relied on to exclude moisture, and in 1891 dry core cable was adopted as standard in place of the original "Conference Cable." The new specifications also reduced the conductor size from 18 to 19 gauge and specified a capacitance of 0.080 mf.

per mile between any one conductor and all other conductors grounded to the sheath, which was approximately equivalent to a mutual capacitance of 0.054 mf. per mile between the conductors of each pair. Cable with these characteristics came to be known very definitely as "standard cable" and the transmission efficiencies of later cables were compared with that of standard cable as a reference standard. This gave rise to the transmission unit known as the "mile of

**Fig. 5**
**Telephone Call Bell Switch**
**The Equipment for Six Telephone Lines of the First Exchange in Canada (Hamilton, Ontario, 1878).**

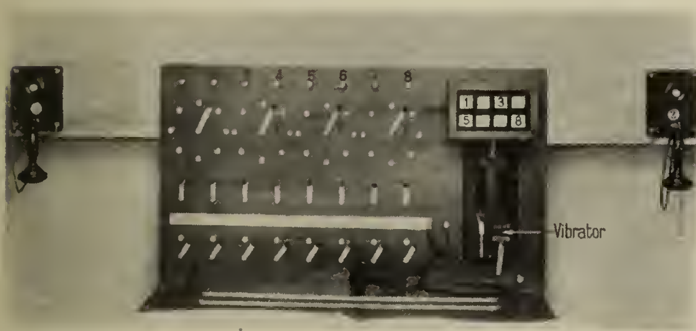

**Fig. 6—Typical 8-Line Telephone Switchboard of about 1880.**

standard cable" which remained in use until the adoption of the transmission unit now known as the decibel. The two units are approximately equivalent for average voice frequencies, one mile of standard cable having a transmission loss of 1.056 db. at 800 cycles.

In 1892 the largest telephone cables contained a hundred pairs and were 2½ in. in diameter. By 1901, cables of the same diameter were available containing 300 pairs of 19 gauge conductors.

The maximum outside diameter of telephone cables has been fixed at 2⅝ in. as this is the largest size that can be accommodated in existing underground ducts, and also because this is about as large a cable as can be satisfactorily handled by present methods. In order to accommodate more pairs it has been necessary to use smaller gauge conductors. The first of these was a 606-pair, 22-gauge cable which was introduced in 1902. This was followed by a 909-pair, 22-gauge cable in 1913, a 1,212-pair, 24-gauge cable in 1915, and an 1,818-pair, 26-gauge cable in 1927. The largest of these to be made in Canada up to the present has been the 1,212-pair, 24-gauge cable, the production of which was commenced in this country in 1921.

In 1907 research work was undertaken with the object of finding a substitute for the lead-tin alloy used for the cable sheath that would be equally satisfactory and less expensive. After extensive field trials, a lead-antimony alloy was adopted. In Canada the lead-antimony alloy has been in use for new cables since 1916.

In the early nineties, telephone companies encountered a serious difficulty as a result of the introduction of electric street railways. Until that time, although two-wire circuits were becoming standard practice for long distance lines, the local exchange lines were single wires, the earth being used as a common return conductor. The heavy earth currents of the street railways, however, caused so much noise on the telephone circuits that it became necessary to convert the grounded single wires to two-wire circuits.

Switchboards arranged to operate with a common central office battery in place of individual batteries at the subscribers' premises were introduced in Canada in the early 1,900's. Queen Exchange, Ottawa, was probably the first Canadian exchange to have a common battery switchboard, and this was cut into service in 1900. Automatic systems whereby calls can be established without the services of an operator were also being introduced at about this time. One of the first automatic offices in Canada was installed in Edmonton in 1905 and was of the Strowger step-by-step type.

Important improvements in telephone transmission were made possible by the invention of the loading coil in 1900 by Pupin. It had been shown by Heaviside that by adding inductance to a telephone circuit the transmission loss caused by the mutual capacity between the conductors could be greatly reduced, and Pupin's invention of the loading coil provided a practicable means of adding this inductance. The application of loading to open wire circuits permitted the distance over which long distance service could be provided to be approximately doubled. Before the introduction of loading, the longest toll circuit over which commercial service could be given was about 1,000 miles long. The development of loading allowed the line to be extended to about 2,000 miles. For these long distance circuits, it was necessary to use No. 8 gauge copper. The advent of telephone repeaters and of carrier telephony caused the loading of open wire circuits to be abandoned,

**Fig. 7—Three Sections of Winnipeg's Switchboard in 1896, with one hundred Subscribers' Lines per Section.**

and smaller gauge wires to be used, but loading is still an important aid to telephone transmission over cable and is used both for toll cables and exchange area cables.

The earliest loading coils used a core of fine iron wire. Greatly improved coils were made possible, however, by the introduction of the compressed powdered iron core in 1916. The development of the permalloy dust core, which was introduced in 1927, has greatly reduced the size and cost of loading, and a still further reduction in the size of loading coils has now been made possible by the development of a new molybdenum permalloy.

Although loading had extended the range of telephony, it was not until the vacuum tube telephone repeater had been developed that continent-wide service became practicable. The telephone repeater became available in 1913, and two years later transcontinental service was inaugurated in the United States.

The first telephone repeaters used in Canada were installed at Kingston in 1917, and the first step towards a Canadian transcontinental circuit was taken in 1921, when the Telephone Association of Canada was formed. This association was composed of members representing the seven major telephone systems in the Dominion, and at its first annual meeting a committee was formed to investigate the possibility of providing transcontinental service over an all-Canadian circuit. The report of the committee indicated difficulties in providing lines through the Rockies, around Lake Superior, and through a stretch of almost uninhabited country extending east of Quebec to the boundary of New Brunswick. Further discussion of the project took place at later annual meetings, but little progress was made until 1928. In that year an engineering study of the problem was begun and two years later, in 1930, work on the undertaking was started. Finally, on January 25th, 1932, the Trans-Canada Telephone System was formally opened by Lord Bessborough.

During the interval that had elapsed between the time that transcontinental telephony had been made possible by the development of the voice-frequency telephone repeater, and the time that the layout of the Trans-Canada Telephone System was begun, the technique of long distance

Fig. 8—Telephone Repeater Equipment used in Transmitting Radio Programmes for Network Broadcasting.

telephony had been considerably changed by the development of the carrier telephone system. Several types of carrier telephone systems have been developed, but the one in most general use is the Type C. This system provides three carrier frequency channels in addition to the regular voice-frequency channel on one pair of wires, and utilizes a maximum frequency of about 30,000 cycles. At each repeater station it is necessary, of course, to amplify the carrier-frequency currents as well as the voice-frequency currents. At these points, the carrier-frequency currents are separated from the voice-frequency circuit, a voice-frequency telephone repeater being used for the voice-frequency circuit, and a carrier repeater consisting of two amplifiers with electrical filters to separate the two directions of transmission, being used for the three carrier channels as a group. After amplification the carrier and voice-frequency currents are again brought together for transmission over another section of line.

With carrier-frequency currents, the tendency for currents in one circuit to induce currents in nearby circuits is greater than at voice-frequencies. For this reason new transposition systems employing transpositions at more frequent intervals are necessary to prevent crosstalk. It is also desirable to reduce the spacing between the two wires of each pair from 12 in. to 8 in., at the same time increasing the spacing between different pairs on the same crossarm.

The carrier telephone system is used extensively for the Trans-Canada Telephone System and on a transcontinental call, transmission is at carrier frequencies for nearly the entire distance. The total length of the Trans-Canada line is about 4,200 miles, of which it was necessary to completely rebuild about 2,000 miles and to carry out pole work for carrier transpositions on some 1,500 miles.

Turning now from long distance to local telephony, a major change that has taken place in recent years is the gradual superseding of the manual system by the dial system in urban areas. Beginning, as has already been mentioned, with Edmonton in 1905, most of the larger cities of Alberta and Saskatchewan had dial telephones before the war, and soon after the war Manitoba also began to adopt the dial system. In Ontario and Quebec, the change to dial operation began in Toronto with the cutover of Grover Office in July 1924, and in Montreal with the cutover of Plateau Office in January, 1925. The Maritime Provinces and British Columbia have also adopted the dial system in some of their cities.

The change to dial operation is still in progress and has begun to penetrate rural areas as well. Various types of equipment, which can be left unattended except for occasional visits. have been developed for use in such areas.

### Public Address Systems

With the facilities for increasing the power of telephone currents, made possible by the vacuum tube amplifier, it was not long before loud speaking telephones, capable of converting the amplified electrical energy into amplified sound, was developed. One of the earliest demonstrations in Canada of the utility of loud speaking equipment was on the occasion of President Harding's visit to Vancouver in July 1923, while returning from Alaska. During this

**Fig. 9—Route of Trans-Canada Telephone System, showing Terminal and Repeater Points.**

visit he delivered an address to a large gathering in Stanley Park and by the use of a public address system the entire audience was able to hear him clearly.

Loud speaking equipment was again used during Lloyd George's visit to Montreal in October of the same year, making it possible for an audience of 11,000 people to hear him without difficulty when he spoke at the Mount Royal Arena.

Though novel in 1923, loud speaking equipment soon became another commonplace facility of communication engineering, the use of which was to be expected whenever conditions made it desirable. Many permanent installations have been made in large auditoriums, churches, and hotels.

An outstanding example of a hotel installation is that of the Royal York Hotel in Toronto, which until eclipsed by the one at the Waldorf Astoria, was the largest and most up-to-date installation in the world. In each of 1,600 bedrooms a loud speaker is provided, with switching facilities by means of which guests may listen to either of two programmes. These may be received by radio or by wire from an outside point, or they may be music or speeches originating in one of the public rooms of the hotel. In addition, all large public rooms are equipped with concealed loud speaking equipment permitting amplification of a speaker's voice so that he may be clearly heard, no matter how large the gathering. There are microphone outlets, also, in all the public rooms permitting speeches or music originating therein to be picked up both for the hotel loud speakers and for radio broadcasting.

*The Recording and Reproduction of Sound*

The problems involved in designing mechanisms for recording and reproducing sound are quite similar to those involved in the designing of telephone transmitters and receivers, and communication engineers have naturally taken an interest in this allied field. When the vacuum tube amplifier became available and led to the introduction of electrical recording and reproduction, the two arts became even more alike, so that to-day the recording and reproduction of sound is usually considered as a branch of electrical communication.

After loud speakers capable of high volume reproduction with good fidelity had been developed, communication engineers began to study the problem of recording and reproducing sound in synchronism with the photographing and projecting of motion pictures, with the object of making possible the production of talking motion pictures. Success was finally achieved and the first theatres to show the resulting sound pictures did so before capacity audiences.

In Canada, the first theatre to be equipped for showing the new "talkies" was the Palace Theatre in Montreal, which opened with sound pictures on September 1st, 1928. Many more installations quickly followed and it was not long before silent films practically disappeared.

**Fig. 10—Amplifying Equipment for Public Address and Music Reproducing System, Royal York Hotel, Toronto.**

Sound recording equipment for the making of sound pictures has also been installed in Canada by such organizations as the Canadian Government Motion Picture Bureau and the Associated Screen News Limited.

WIRELESS TELEGRAPHY

Marconi applied for his first British patent on wireless telegraphy in 1896. Three years later, he succeeded in transmitting messages across the English channel. After further experiments, he succeeded in spanning a distance of 150 miles, and becoming convinced that the curvature of the earth would not prevent wireless communication over still greater distances, he boldly decided to make an attempt at spanning the Atlantic. In 1900 the erection of a powerful transmitting station at Poldhu in Cornwall was begun and in December 1901 he was successful in receiving faint signals from that station in Newfoundland.

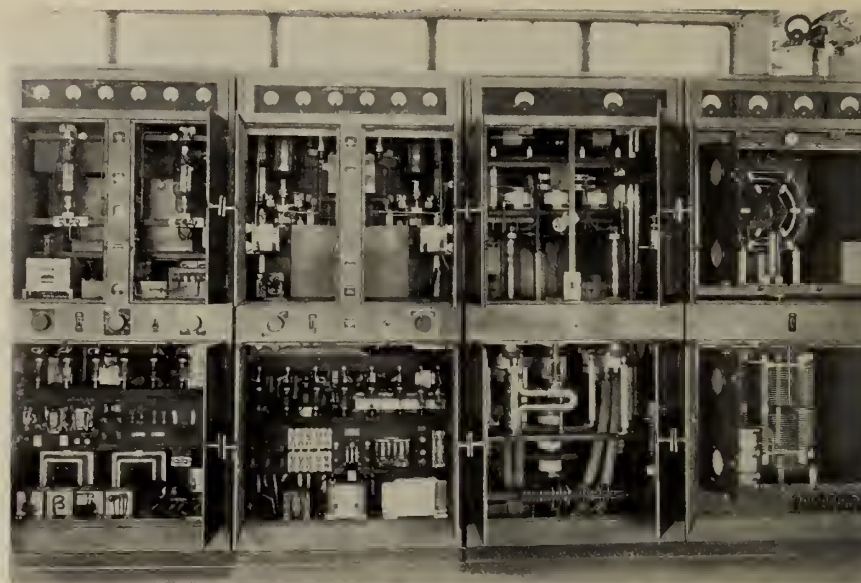

Fig. 12—Radio Transmitting Equipment for a Modern Broadcasting Station.

Experiments between England and Newfoundland were stopped, however, due to a notice from the Anglo-American Telegraph Company to the effect that they had a monopoly of telegraphic communication in Newfoundland. The Canadian Government at once invited Marconi to Canada and in February 1902 an agreement was made, and ratified by the House of Commons, whereby a sum of £16,000 was granted for the erection of a station on the Canadian coast on condition that the wireless rates for telegrams across the Atlantic should not exceed 10 cents a word. Quoting from R. N. Vyvyan's "Wireless over Thirty Years":

Fig. 11—Edmonton heard the Diamond Jubilee Broadcast by means of a Public Address System.

"The Canadian Government by this far-sighted and public spirited action in the cause of technical advancement and public welfare, played a very large part in bringing about the remarkable developments in long distance wireless communication which took place during the next few years, because it was at the Canadian station erected at Glace Bay, Cape Breton Island, that most of the experimental work that led to a regular transatlantic service originated, and it was from this station that the first wireless transatlantic messages were successfully transmitted."

In October, 1902, the construction of the Glace Bay station was completed, and the first messages successfully transmitted in December of that year. Transmission was not sufficiently reliable, however, for commercial service and in 1904 a more powerful plant was installed, but results were still disappointing. For another three years, experiments were carried on, and further improvements made, until success was finally achieved and transatlantic service opened to the public in 1907.

For the period of the war, the British Admiralty closed down wireless service between England and Canada so as to prevent enemy countries from picking up information transmitted over this channel. After the war, development centred at first on the vacuum tube and its application to transmitters and receivers. One of the first long distance circuits to use vacuum tube transmitters for commercial radio telegraphy was the one between Canada and Great Britain. The transmitting set at Glace Bay used forty-eight 500-watt tubes in parallel when this circuit was changed over from damped wave "spark" transmission to continuous wave operation using vacuum tubes.

The next important development was the Imperial short wave beam system. The value of a chain of wireless stations throughout the Empire had been pointed out as early as 1908 in an article entitled "Imperial Wireless Communications" by R. N. Vyvyan, which was published in *The Times*. At the Imperial Conference held in 1911, the proposal to develop an Imperial wireless telegraph system was discussed and after the scheme had been investigated by several Parliamentary committees, a contract with the Marconi Company for an "Imperial Wireless Chain" was ratified by the British House of Commons in August, 1913. The war, however, led to the cancellation of this contract.

After the war, new proposals were made by the Marconi Company and at the Imperial Conference of 1921 it was agreed that a chain of Imperial stations should be proceeded with as rapidly as possible. Questions of State versus private ownership prevented a definite agreement being reached until 1924, and in the meantime, the development of the short wave beam system changed the picture. To determine the possibilities of this system, Marconi had erected a short wave beam transmitting station at Poldhu, and in 1923 and 1924 he carried out a series of tests between this station and the yacht *Elettra* and also between Poldhu and stations in Canada and Australia. During these tests, signals were clearly received in Montreal on a single tube receiver with little or no aerial. The success of these experiments led the Marconi Company to open negotiations with the British Government with a view to using the Beam System for the Imperial Chain, and in

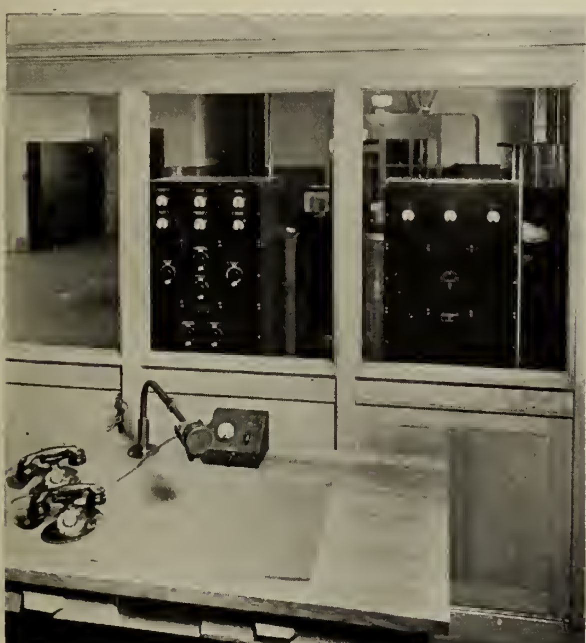

Fig. 13—Police Radio Transmitter.

July, 1924, an agreement was finally reached and a contract made with the British Post Office for Imperial Wireless Communications by means of the short wave beam system. Canada's links in this highly successful Imperial Chain were opened for service between Canada and England, and between Canada and Australia, in October, 1926, and in July, 1928, respectively.

### Wireless Telephony

Besides being the first to transmit speech by wire, Alexander Graham Bell was also the first to demonstrate "wireless" telephony. He accomplished this by causing the sound vibrations at the transmitting point to modulate a beam of light; at the receiving point, by making use of the property of selenium whereby its resistance varies with varying illumination, he obtained a varying current for operating a telephone receiver. His experiments with this invention, which he called a Photophone, were made in the years 1878-1880. It is interesting to note that in recent years practical use is being made of beam transmission, and also of radio waves so short as to be termed "quasi-optical," thus bringing modern radio closer to Bell's early form of radio transmission.

The first radio broadcast in Canada, and sometimes claimed as the first in the world, was originated by the Canadian Marconi Company at Montreal in May, 1920, as a demonstration for a meeting of the Royal Society of Canada which was being held at the Chateau Laurier in Ottawa. The first United States licenses for broadcasting stations were issued in September, 1921, and the winter of 1922-23 saw radio broadcasting assume the proportions of a "craze." Like all such outbursts of enthusiasm, however, this one had its day, after which the new industry settled down to steady progress.

At first the radio listener was most interested in "logging" as many, and as distant stations as he could. After the novelty of radio reception began to wear off, however, its entertainment value began to be more fully appreciated, and the public began to ask for high quality reception of entertaining programmes at loud speaker strength. This led to rapid improvement of radio receivers and transmitters, and was also one of the influences that resulted in network broadcasts whereby high grade programmes could be given to continent-wide audiences.

Fig. 14—Police Radio Automobile Receiver.

The first network broadcast in Canada was given in December, 1923, when a telephone circuit was used to link Ottawa and Montreal for a programme sponsored by the Canadian National Railways. An early network broadcast which was given considerable publicity as the first "International Broadcast" took place on January 1st, 1927, when a programme offered by the Victor Talking Machine Company of the United States and of Canada was broadcast from a network of twenty-five American and three Canadian stations, the latter being at Montreal, Toronto and Ottawa.

On July 1st of the same year, as a part of the celebrations for the Diamond Jubilee of Confederation, a Dominion-wide broadcast "From Sea to Sea" carried the first sounds of Canada's Peace Carillon, and a programme of speeches and music to all parts of the Dominion and to many foreign lands. The radio transmitting stations used for this broadcast were tied together by a network of lines made available by Canada's various telephone and telegraph systems, all of which gave their full co-operation to make the tremendous undertaking a success.

With the growing use of wire lines for linking together radio broadcast stations, it was natural that telephone companies should also consider the possibility of using radio links in their telephone networks, where conditions were unfavourable for building wire lines. The first radio telephone link to be put into service in Canada was one between Campbell River on Vancouver island and Powell River on the mainland, by the Northwest Telephone Company (a subsidiary of the British Columbia Telephone Company). This link was opened in June, 1930, and handled between twenty and forty calls a day until replaced by a submarine cable in July, 1931. The success of this first radio link led to the installation of a number of others, with the result that to-day many isolated points on the rugged coast and in the mountainous hinterland of British Columbia have telephone communication with the outside world. Besides its use by telephone companies, for public service, point to point radiotelephony has also been put to private use by such interests as pulp and paper, mining and aerial transport companies, operating in the new Canada lying beyond the end of steel rail and copper wire.

Commercial telephone service between Europe and United States was initiated in January, 1927, over a long-wave radio circuit, and was extended to Canada in October of the same year. This service was supplemented in the following year by additional short-wave channels. The success of direct short-wave radio telegraph service between Canada and Great Britain, which had been initiated in October, 1926, led to the desire for similar direct telephone service, and on January 29th, 1931, although not ready for commercial service, a direct transatlantic telephone circuit was made available by the co-operation of the British Post Office, Imperial and International Communications Ltd., Canadian Marconi Company and the Bell Telephone Company of Canada for a joint meeting of the Engineering Institute of Canada in Montreal and the Institution of Electrical Engineers (the same body which in 1887 had been known as the Society of Telegraph Engineers and Electricians) in London, England. Although transmission was poor, due to an exceptionally severe atmospheric disturbance, the meeting marked another step in the progress of communications engineering in Canada.

The transatlantic circuit was not opened for commercial service until July 11th, 1932. Seeing that the Imperial Conferences of 1911 and 1921 had played an important part in initiating the plan for an Empire-wide system of Radio Communications, it was rather appropriate that one of the first uses of this new telephone link in the Imperial Chain should be to join together Canadian and British broadcast stations for a transatlantic broadcast of the opening of the Imperial Conference at Ottawa, July 21st, 1932. That year gave us also the first of those Christmas Day Empire Broadcasts which, during the closing years of King George V's reign, brought at each Christmastide to every listening home in the Empire, feelings of common fellowship and goodwill—the strongest bond of our Empire—and closed each year with the voice of the King.

### Television and Telephotography

A review of developments in electrical communication would not be complete without some mention of telephotography and television. The transmission of pictorial or visual images requires the representation of light and shade variations over an area by current variations over an interval of time. To do this, the area is subdivided into narrow strips and by a process known as scanning, the variations of light and shade along each strip in turn are translated into variations of an electric current. In telephotography, one scanning is sufficient, but in television, where the visual image changes from moment to moment, the scene to be transmitted is scanned repeatedly so as to give the illusion of motion by a rapid succession of still pictures.

Telephotography has been in commercial use since about 1925 and television has begun to emerge from the experimental stage. One of the difficulties in television is the wide band of frequencies required. For radio transmission, the wide bands required are only available at what are known as ultra-high frequencies. For wire transmission, a special type of transmission line known as a coaxial line will probably be used, consisting of a tubular conductor enclosing a concentric return wire. As an indication of the relative band widths required for telegraphy, telephony, and television, it is interesting to note that the frequency range of a million cycles that can be transmitted over a coaxial line is sufficient for either 2,880 telegraph channels, 240 telephone channels, or one television channel.

The author desires to express his appreciation of the information made available to him by the officials of the Bell Telephone Company of Canada, Canadian Pacific Railway Company's Telegraph, Canadian National Telegraphs, Canadian Marconi Company, British Columbia Telephone Company and Maritime Telegraph and Telephone Company, Limited, and to Mr. J. S. Cameron, Mr. W. I. Brebner and Mr. E. S. Kelsey of the Northern Electric Company, Limited for assistance in compiling the paper.

# Railway Construction

*V. I. Smart, M.E.I.C.,*
*Deputy Minister, Department of Transport, Ottawa, Ont.*

Fifty years ago in Canada, or in 1887, the year in which the Canadian Society of Civil Engineers was incorporated, the Canadian Railways had already attained a considerable development. During the previous year, the Canadian Pacific had completed its line from Montreal to Vancouver and had inaugurated a daily passenger train service between the Atlantic and Pacific coasts.

The best description of the condition of the Railways in Canada in 1887 is probably given by Collingwood Schreiber, one of the Charter Members of the Canadian Society of Civil Engineers, in his report accompanying Railway Statistics of Canada, 1887, in which he says:—

"The year under consideration has been marked by much enterprise and activity in construction, and by a prosperity quite without example to the lines in operation. Thirteen new lines appear in the tables submitted herewith. Others, under construction last year, are now wholly or partially in operation. Iron rails are fast disappearing. The equipment of railways has received notable additions and improvements. The increase of the traffic has been such as no former year can show amounting to nearly $5,500,000."

figures, (mileage placed in operation) down to the present time shows a close co-relation with the business activity of the period but with a lag of about four years as, of course, the construction usually took place several years before the line was placed in operation. The depressions of 1895, 1911, 1919 and 1929-33, show up very clearly in these figures and accentuate the intervening boom periods.

The completion of the National Transcontinental, Grand Trunk Pacific and Canadian Northern lines, during the war, rather over emphasizes the boom during that period as the lines were started during the previous boom. The considerable increase of mileage during 1935 is due to the Hudson Bay Railway being placed in operation, as previously this had been shown as under construction.

During the decade following 1887 the two large railway companies, the Canadian Pacific and the Grand Trunk, developed their systems and acquired a number of the smaller railroads in their territories. The Canadian Pacific had a monopoly of the western traffic and developed feeders in the east with a winter port at Saint John, N.B. The Grand Trunk developed its system in the east with a winter port at Portland, Me.

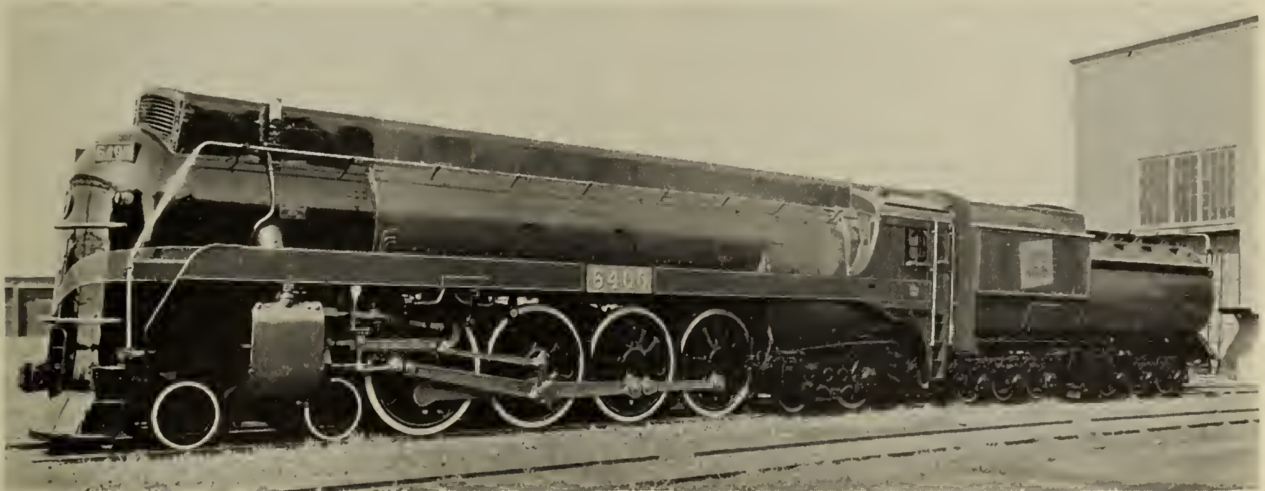

**Fig. 1—Canadian National Passenger Type Locomotive 6400, Built in 1936.**

In order to visualise the railway progress a schedule of railway construction and traffic in Canada has been prepared showing, for the period 1886 to 1936, the mileage placed in operation, the total mileage, the passengers carried and the freight carried. The maximum figure in each column has been underlined. These figures have been extracted from Statistics of Steam Railways of Canada published by the Dominion Bureau of Statistics and, as the final 1936 figures are not available yet, these have been estimated from figures for 1936 recently published by the Bureau of Statistics covering railways in Canada with annual operating revenues of $500,000 or over.

Very complete statistics covering the operations of steam railways are available during recent years and even in 1887 the statistics filled a standard blue book containing 56 pages. The figures selected are comparable over the whole period and show concisely the progress of railway transportation.

The large mileage (1,020) placed in operation during 1886 is due to the completion of the Canadian Pacific main line to Vancouver. Following this second column of

The prairies felt that the monopoly of the Canadian Pacific was not in their interests and the government of the province of Manitoba, which was the only organized provincial authority then in existence in the west, guaranteed the bonds of competing railroads to break the monopoly, finally getting a branch of the Northern Pacific into their province and also another outlet to the Great Lakes, the Canadian Northern to Port Arthur on Lake Superior, which latter line was completed in 1902. Even before this competitive outlet was available, the Dominion Government, in return for a subsidy of $3,360,000 to the Canadian Pacific for the construction of a line through the Crow's Nest Pass, had obtained a decided reduction of freight rates in the west by means of the famous Crow's Nest Pass Agreement which became effective January 1st, 1898.

During the second decade, the Canadian Pacific continued to make large profits and the Canadian Northern, although only in process of development, also showed large profits. The Grand Trunk system was very anxious to share in this western traffic, which was proving a veritable gold mine to the other companies, and in 1903 signed an agreement with the Government to construct a transcontinental railway from Prince Rupert to Moncton. The Grand Trunk undertook to construct the western section through a separate company, known as the Grand Trunk Pacific, from Winnipeg to Prince Rupert while the Dominion undertook to construct the Eastern section, known as the National Transcontinental Railway, and agreed to lease it to the Grand Trunk Pacific on its completion.

The close of the second decade found the Canadian Northern developing rapidly and both the Canadian Pacific and Canadian Northern making large profits in which the Grand Trunk was hurrying to share by building a complete transcontinental system as outlined in the previous paragraph.

The rapid growth of the Canadian Northern, in the prairie provinces, was made possible by these governments guaranteeing its bonds to a large extent and as this system developed it desired outlets of its own and endeavoured to obtain support for such developments.

In 1910 the British Columbia government guaranteed the Canadian Northern bonds for a line from Vancouver to the Alberta Boundary while the province of Ontario had in 1904 guaranteed the Company's bonds between Toronto and Sudbury. In 1911 the Dominion Government guaranteed the bonds for 1,050 miles of line east of Port Arthur, including the gap between Port Arthur and Sudbury, and made it possible to complete a third transcontinental system.

It is interesting to note that the route of the Grand Trunk Pacific Railway, through the continental divide, follows the earlier surveys for the location of the Canadian Pacific Railway, through the Yellowhead Pass, with the rails only 3,720.5 ft. above sea level, and provides the lowest pass for any railroad across the Rocky Mountains in the continent of North America. West of the Rocky Mountains the Grand Trunk Pacific diverges to Prince Rupert, but the Canadian Northern, built later, follows the old Canadian Pacific proposed location down the North Thompson river and provides a line with a maximum grade of five-tenths per cent westbound to Vancouver, and seven-tenths per cent eastbound, which ruling grades are much superior to those of the other lines through the British Columbia mountains.

The large mileage of railway construction, which was put in operation during the year 1912 to 1917, was made possible only by the assistance of the Dominion and provincial governments, as outlined above, during the period 1903 to 1911.

While the Grand Trunk and Canadian Northern were building up transcontinental systems the Canadian Pacific was expanding steadily by improving its main line and building an extensive branch line system.

In the year 1911, also, construction was started on the Hudson Bay Railway, surveys for which had been made in 1909; construction of this road was suspended in 1918 and not resumed till 1926.

The outset of the pre-war depression found the Grand Trunk Pacific and the Canadian Northern both with a large mileage of line under construction. Both these railroads got into financial difficulties and in 1914, all other sources having been exhausted, the Dominion Government stepped in and assisted both these companies to obtain funds to complete their lines under construction by guaranteeing their bonds.

The war came on and, even with a Government guarantee, it became impossible to obtain funds, so the Dominion made advances to the companies, taking whatever securities they could obtain, and enabled the Canadian Northern and Grand Trunk Pacific to complete their lines so that they could be placed in operation.

In 1915 the National Transcontinental and the Grand Trunk Pacific were completed, but the Grand Trunk, on the ground of excessive cost of construction, refused to take over the National Transcontinental, which was left on the Government's hands and subsequently operated as part of the Canadian Government Railway system.

In 1916 the Canadian Northern Transcontinental line was declared open for traffic and these new railways all found themselves in further financial difficulties.

The condition of the railways was so serious that, on July 13th, 1916, the Government appointed a Royal Commission to enquire into Railways and Transportation in Canada and this body, known as the Drayton-Ackworth Commission, made its report in April 1917. The majority report, signed by Sir Henry Drayton and Mr. W. M. Ackworth, recommended that the Government should take over the Canadian Northern, Grand Trunk and Grand Trunk Pacific properties, while the minority report, signed by Mr. A. H. Smith, recommended that the Canadian Northern properties in the east should be turned over to the Grand Trunk, that the Grand Trunk Pacific properties in the west should be turned over to the Canadian Northern and that the Dominion should operate or assist in the operation of the connecting lines between the east and the west.

The recommendations of the Drayton-Ackworth Report were adopted to the extent of the Government taking over the Canadian Northern on November 16th, 1917, while on March 10th, 1919, the Minister of Railways was appointed receiver for the Grand Trunk Pacific and on May 1st, 1920, under an agreement for acquisition, financial control of the Grand Trunk was taken over by the Dominion. At the same time as these large systems were being acquired by the Government nine short lines in the Maritimes were purchased and added to the Canadian Government Railway system.

The management of all the railways, controlled by the Dominion, was placed under the Canadian National Railway Company, which had been incorporated by Act of Parliament during 1919, and on January 1st, 1923, all these lines were consolidated for unified operation under this Company.

Large expenditures were, of course, required to consolidate this conglomeration of railroads into a reasonable system, but, in addition to this original problem, a large branch line development, particularly for the prairies, was entered into, resulting in the construction, by the Canadian National, of 1,895 miles of line between the years 1923 and 1931, while the Canadian Pacific entered into a similar branch line construction programme requiring the construction of 2,265 miles of line in the same period. In addition six short lines of railway in the Maritimes were taken over by the Canadian National and added to the system as branch lines.

During the post war boom period, 1923-1929, when these large branch line programmes were inaugurated, the railway freight transportation tonnage showed steady improvement and appeared to warrant the development, though passenger traffic was showing a slight decline due to the competition of the private motor car. However, when the severe decline in business set in, which reached its worst in 1933, it became evident that the railways were over developed, and on November 20th, 1931, the Government appointed a second Royal Commission to enquire into Railways and Transportation in Canada, known as the Duff Commission, under the Chairmanship of Sir Lyman Duff, Chief Justice of Canada. This Commission recommended a trustee form of management for the Canadian National Railways and also that machinery should be provided to enforce co-operation between the Canadian National Railways and Canadian Pacific Railway. These recommendations were duly accepted by the Canadian National-Canadian Pacific Act of 1933, but the sections of

Table I
Railway Construction and Traffic in Canada

| Year | Mileage placed in operation | Total railway mileage | Traffic carried | |
|---|---|---|---|---|
| | | | Passengers number | Freight revenue—tons |
| 1886 | 1,020 | 11,793 | 9,861,024 | 15,670,460 |
| 1887 | 391 | 12,184 | 10,698,638 | 16,356,335 |

| 1934 | − 66 | 42,270 | 20,530,718 | 75,746,093 |
| 1935 | 646 | *42,916* | 20,031,839 | 77,081,057 |
| 1936 | −208 | 42,708 | 20,455,000 | 84,677,400 |

Note: In 1919 the end of the statistical year was changed from June 30th to December 31st, the two sets of figures given for that year are both for twelve-month periods. Italics indicate *maximum* figure in each column.

the Act requiring enforced co-operation between the railroads have never been put in effect. An amendment to this Act was passed in 1936 revising the form of management of the Canadian National Railways and this new management took over on October 1st, 1936.

The financial condition of the railways has improved somewhat since the low of 1933 but it is still by no means rosy, particularly when compared with Collingwood Schreiber's description of 1887 conditions. During 1936 the Canadian National earned $6,408,911.26 available for interest but required contributions for deficits amounting to $43,303,393.82 from the Dominion and had, in addition, net charges during the year in its profit and loss account amounting to $12,684,818.25, while the Canadian Pacific paid its fixed charges amounting to $23,913,298.24, and transferred $6,029,183.92 to profit and loss, but the Company made various charges amounting to $7,001,168.68 against that account that making a net reduction of $971,984.76 in the profit and loss balance for the year.

It is apparent that the railways are equipped to handle much more traffic than they receive. This condition has been caused by various reasons, the principal ones being, over development of railway mileage, slowing up of development of the country, the existing depression of world trade, and diversion of traffic to competitive transport facilities both highway and waterway. An examination of the last two columns of Table I, Railway Construction and Traffic in Canada, shows that the passenger traffic reached a maximum in 1920 of 51,318,422 passengers but that, due principally to the diversion of this traffic to private motor cars, this had been reduced in 1936 to 20,455,000 passengers and it does not appear likely that any large portion of this loss can be regained. The freight traffic reached a maximum in 1928 of 141,230,026 tons and, owing chiefly to world conditions and partly to diversion of traffic to competitive transport facilities, this had been reduced in 1936 to 84,677,000 tons which, however, is a considerable improvement over the 1933 traffic of 63,634,893 tons.

The development of railway mileage compared with railway traffic is hardly a fair index of conditions, as the considerable improvement in grades and alignment, structures and locomotive equipment makes each mile of railway in 1937 able to handle many times the traffic of a mile of railway in 1887.

Statistics as to train loads are only available for thirty of the fifty years but these show that the average train load, which was 260 tons in 1907, had increased to 528 tons in 1935, while in 1928, due to the heavy wheat crop, an all time maximum average of 557 tons per train, was handled and during recent years there has been a steady increase in the average train loads as shown below.

**Fig. 2—Grand Trunk Passenger Type Locomotive 2196, Built in 1888.**

Average Tons per Freight Train

| | | | | | |
|---|---|---|---|---|---|
| 1927 | 514 | 1930 | 509 | 1933 | 521 |
| 1928 | 557 | 1931 | 514 | 1934 | 522 |
| 1929 | 523 | 1932 | 517 | 1935 | 528 |

The 1936 figures are not available yet for all railroads but for railroads with an operating revenue over $500,000 the 1936 average figure is 593.4 tons per train compared with 596.0 tons per train during 1935 or a slight decrease.

The principal reason for increased train loads is of course, improvements in motive power and some idea of these may be obtained from the two pictures of locomotives, which appear in this text—Grand Trunk locomotive No. 2196, built in 1888 and Canadian National locomotive No. 6400, built in 1936. This immense increase in the size of locomotives has, of necessity, required corresponding improvements in alignment, both grades and curvature, or possibly it might be better expressed by saying that improvements in alignment have made possible the increase in size of locomotives. In any case, the low grades and curvature on recently constructed railroads, as compared with those built fifty years ago, have increased the capacity of these lines for railway freight or passengers many times.

The high standard of construction and equipment in Canada has kept the freight rates at a low figure, amongst the lowest in the world, and this despite low traffic density, high wages, and the disadvantages of extreme climatic conditions.

This point of the low cost of railroad transportation in Canada is best set out by comparison with other countries and these figures are given for the year 1932 from the last issue of "Railway Statistics of the United States of America and recent statistics of Foreign Railways."

Receipts per Ton Mile (Cents)

| | | | |
|---|---|---|---|
| Canada | 0.94 | British India | 0.83 |
| United States | 1.052 | Mexico | 1.49 |
| Great Britain | 1.87 | Victoria | 2.15 |
| Germany | 1.49 | New South Wales | 1.92 |
| South Africa | 1.35 | South Australia | 2.33 |
| New Zealand | 3.41 | West Australia | 2.08 |

The only country among the above which shows a lower average freight rate than Canada is British India and, in that country, labour is so cheap and climatic conditions are so moderate that a low freight rate follows automatically.

Transportation in Canada has always been a serious problem, the small population being spread over a vast expanse of territory, so that geographical characteristics call for means of ready movement between the widely separated areas.

No country in the world, perhaps, is so dependent on transportation for the opening up of its undeveloped areas and the railways are and have been the greatest single agency in this respect.

With a further improvement in world conditions there is no doubt that there will be a corresponding improvement in the railway traffic available in Canada, but, even with this, it must be admitted that the railway mileage of Canada has been over developed and will require very careful administration and economical operation over a long period to preserve these assets for the benefit of the country as a whole, bearing in mind that the development of an extensive continental area like Canada is based entirely on the development of its railways.

# Road Building

*R. M. Smith, A.M.E.I.C.,*
*Deputy Minister, Department of Highways of Ontario, Toronto, Ontario.*

Fifty years, in most history, is a comparatively short space of time. But insofar as road building in Canada is concerned, it is almost impossible to describe a history of even fifty years. The last decades of the past century marked the era of railroad building on this continent and the construction of highways was at almost a complete standstill. As an illustration of conditions which existed one need only refer to the province of Ontario. In 1913 a commission was appointed to study the road needs of that province. Included in the report of this commission was a summary of the history of Ontario roads. The period from the seventeenth century to about 1850 was covered in a matter of some twenty pages, the following years up to 1913 occupied three paragraphs! Could anything describe more vividly the lack of interest in roads during this period?

In this brief review of road development in Canada during the past fifty years it is not proposed to go into technical developments, but to give a short description of the actual expansion of highway mileages and to the factors which led to that expansion. The technical features of the development have been covered minutely in the discussions of various bodies and need no elaboration here. But there is a certain romance in the building of roads, a romance which is evident in the parallel between the growth of the country and the growth and development of highways in Canada and these have coincided with the expansion of transportation.

A study of our road building cannot however begin in 1887. We must go farther back if we are to appreciate the circumstances which placed our roads where they are to-day. Some certainly would follow different routes were modern engineers turned loose this year to locate new highways most advantageously.

Water-borne transportation was the first important factor in the growth of Canada. The earliest roads were only feeders or auxiliary routes. The bulk of movement was by lake and river. It is difficult for the average citizen of Toronto in 1937 to realize, when he sees a constant stream of traffic flowing into and out of the city on Yonge street to points in Muskoka and farther north, that Yonge street was first laid out merely as a short cut between Lake Ontario and Lake Simcoe, in order to shorten the water passage to Georgian Bay. To-day it provides a means and an end in itself. Then it was only a short cut for faster movement of light goods.

Later roads were built for military purposes, to permit the movement of troops and supplies along a route more remote from possible southern invasion than was afforded by the waterways of the boundary.

Finally there were colonization roads, but as in the case of the earliest highways, their principal object was to provide access to the nearest waterway. They were seldom constructed as a primary means of transportation. They were still only feeders and connecting links.

In the middle of the nineteenth century the railroad began to supplant the waterway. And with the coming of the railway road building in Canada almost ceased. Waterways did not always reach the necessary areas and formerly some roads had been built of necessity. But the railroad, which could be taken to any point (and unfortunately sometimes was), provided better and faster transportation than horse-drawn vehicles and, in that era, could be financed much more easily than any road. For almost fifty years the only interest in roads that remained was confined to whether or not there was a passable road from a given point to the nearest railroad station.

Highway Views in the Province of Ontario

*First*—Highway No. 2, looking East towards Etobicoke Bridge, one of Ontario's four-lane highways.

*Second*—Oakville Bridge, looking North on Toronto-Hamilton Middle Road.

*Third*—Highway No. 2, East of Oakville, showing standard three-lane highway.

*Fourth*—Snow Plow clearing Ontario Highway following mid-winter storm.

*Illustrations through the Courtesy of the* Department of Highways of the Province of Ontario

During all this time there was practically no road improvement in any part of Canada, except in British Columbia where topographical conditions made the construction of railways extremely difficult and where pack trains were still the most practical means of transportation. In the period around 1870 some effort was made to construct a military road from Winnipeg to the Lake of the Woods, but this was abandoned when it was found that the last thirty miles were impassable. However, something was accomplished and the present highway route No. 12 of the province of Manitoba is located on a part of this early road.

Of course, similar sporadic and purely local undertakings of minor importance were carried out in many districts but there was no widespread demand for road construction. However, a little more than forty years ago there may be discerned the beginning of the good roads movement as we know it to-day. That beginning was the foundation of the Ontario Good Roads Association in the year 1894. The demand then was not for improved trunk highways as we build to-day, but for the improvement of local roads, feeders for railroads and contacts with market towns, the idea of a network of roads forming a complete and comprehensive transportation system not having at that time been envisioned. Nor could such a system be foreseen before the development of the motor vehicle made it practicable.

However, the year 1894 saw the awakening of the public mind to the value of good roads and the false economy of neglected highways which resulted in increased transportation costs. The vision was purely local but it was the seed that was to eventually produce the branches and trunk roads on which modern motor cars travel. This start was made in Ontario and it may be said without any suggestion of prejudice that the lead which was assumed in Ontario at that time has never been relinquished. In Ontario up to this time, and indeed for many years afterwards, road building continued to be a purely local responsibility, though provincial governments did contribute some financial assistance to the construction of some roads and assumed a large interest in bridge construction. Practically all work was done by statute labour and very frequently was productive of no lasting improvement.

About the year 1912, however, the motor car had been developed to a degree which, while giving no hint of the actual progress to be made, did give rise to a new demand for improved roads. It was not an entirely unopposed demand either. Farmers living along the more important roads protested that the fumes and dust from the operation of these vehicles would destroy their crops and ruin their land. Others, and in greater numbers, fortunately were able to see the advantages to be gained by convenient transportation, and supported the demand. In Ontario a Royal Commission was appointed to enquire into the whole situation, and the report of this commission, submitted in 1914, formed the basis for the establishment of the present King's Highway system, and led directly to the construction of the Toronto-Hamilton highway, the first paved rural road in Canada of any importance.

From that point roads have progressed along with the motor car. And it is perhaps only fair to say that the development of the motor car has been quite as important to road building as has the improvement in the science of road building. This is especially true in relation to motor trucks. Had adequate shock absorbers and springs as well as pneumatic tires not been developed for heavy vehicles, freight transportation by highway never could have been accomplished. Engineers could have built roads to carry these loads on solid tires but the cost of such highways would have been prohibitive. For the improvement in our highway systems a substantial share of credit must therefore be accorded to the automotive engineer.

The great diversity of problems and conditions makes consideration of the Dominion as a whole impossible excep under very general headings. The first of these is the contribution made by the Dominion government to road building. As mentioned before, until the second decade of this century road building, except for financial assistance given by the provinces was purely a local responsibility. About this time, however, the provinces began to assume direct or full responsibility for many of the most important roads, and under the Canada Highways Act of 1919 the Federal Government took over, in a very restricted measure, the job of fathering, financially, the most important projects. (The position might perhaps be better described as grandfather, instead of father.) Since that time the Dominion contribution to highway construction has mounted to a very large sum, particularly the contribution to Trans-Canada Highway construction, but the amount so contributed is in no way comparable, even yet, to the amounts spent by the provincial governments, and the heavy financial interest of the Dominion in railway ownership makes very doubtful the prospect of Federal road-building assistance ever reaching the proportions now contributed by provincial treasuries.

There is one very interesting feature revealed by the statistics covering the entire Dominion which should be mentioned before undertaking a brief review of regional progress. It is evident that, though road building was a neglected art in earlier days, road planning was not neglected. The first bulletin of the Dominion department with reference to roads contains a table showing a total road mileage of 447,384. In view of the fact that thousands of miles of highway have been constructed since then, it is amazing to find, in the 1935 report, that the total road mileage of Canada open to traffic in that year was 410,808. It must be that the earlier figures included thousands of miles of roads which had been laid out on plans but never opened.

More significant of progress, however, is the fact that in 1922 there was no effort made to classify roads by types of surface. Presumably paved roads were practically non-existent and the only designation of quality provided was the information that in the entire Dominion 8 per cent

**A Retread Road, Ontario.**

of the roads were described as "very fair to good." In 1935 approximately 25 per cent were shown as paved, gravelled, or otherwise surfaced.

### British Columbia

As pointed out previously, in earlier days road building in British Columbia suffered less from the progress of the railway than in any other province. The topography of the country was such that rail construction was difficult and expensive, beyond the ambition even of those daring pioneers who financed our other railroads. Trails were largely the order of the day. With the progress of road construction these same difficulties have been encountered. Magnificent roads have been built, but the linking up of a comprehensive highway system has been made almost impossible because of excessive costs, estimated in some areas to run as high as $500,000 per mile as compared with the twenty to forty thousand per mile average elsewhere. Despite these difficulties, however, there are over 13,000 miles of surfaced highways in this province.

### Alberta, Saskatchewan and Manitoba

The problems here are almost exactly the reverse of those confronting British Columbia. It is small population, long distances and lack of construction materials which handicap the engineers of the prairie provinces. Despite these obstacles, however, they have constructed long stretches of splendid roads. Because of the fact that these are largely agricultural provinces, it has been necessary to open a very great mileage and this has aggravated the difficulties because concentration on a few roads is impossible. The nature of the country has, of course, made possible the opening of roads at comparatively small expense, but the maintenance of this enormous mileage is a staggering undertaking. The result is that these three provinces enclose roads with a total length of more than 240,000 miles, or more than half in all the Dominion. But of these not quite ten thousand miles have been surfaced.

### Ontario

Ontario has been most fortunately placed in the matter of road building. Large quantities of construction materials are available; the nature of the country makes road building no more than ordinarily difficult; the population of the province, while scattered, is the largest in Canada, and consequently can afford to support a road system beyond the reach of other jurisdictions. With these facts in mind, there may reasonably be claimed for Ontario the position of premier province of this Dominion insofar as road construction is concerned. After making an early start, with an agitation for good roads commencing more than forty years ago, to-day the province has approximately half the total surfaced road mileage of Canada, and about half of all the motor vehicles in this Dominion. It may be added that the province's expenditures on road work total also about 50 per cent of the total Dominion expenditure. This is a position won by long and consistent work backed by sensible but heavy investment. At the present time more than two-thirds of Ontario's 70,000 miles of highways are surfaced, and nearly five thousand miles are paved.

Diversion of New Denver-Rosebery Road, British Columbia.

The province is now undertaking two very great tasks. The first is the paving of many of its northern roads, the second the construction of dual highways in the heavy traffic areas of the south. The first is necessitated by the growing importance of northern development and the failure of gravel roads to withstand the heavy traffic, and the latter by the phenomenal increase of traffic. Both will establish, even more firmly, Ontario's claim to leadership in highway work in Canada.

### Quebec

In this province there has arisen a problem of administration which has handicapped the splendid work done by the engineering departments. Some of Canada's finest highways have been built in Quebec but the absorption into the provincial system of some 18,000 miles of road, or practically half of the total in the province, has placed a financial burden on the provincial treasury which has limited the amount of new construction to be undertaken. Maintenance costs of this extensive system absorb such a large percentage of the total available as to make extensive new work impracticable. However, the highways already constructed and those under way are excellent examples of the finest road building technique.

### Maritime Provinces

Here again there exists a set of conditions differing entirely from those of other sections. The comparatively small area of these provinces makes extensive highway mileages, as we know them elsewhere, unnecessary. At the same time, comparatively small populations create the same problems as throughout the remainder of the Dominion. Except in Prince Edward Island, where the motor car has until recently been an almost negligible factor, a middle course has been chosen. The Maritime Provinces have a total of nearly 30,000 miles of highways, of which about 40 per cent is surfaced. In Prince Edward Island, however, only 16 miles of pavement and 195 miles of gravel highway had been constructed by the end of 1935.

There have been hundreds of outstanding personalities who have lent their assistance in the promotion of better highways in Canada who well deserve mention in an article of this kind. But to attempt such a list would be impossible in a brief review. In conclusion, however, there is one person to whom the author must make reference, since no record of Canadian road building would be complete without the name of A. W. Campbell, the first Canadian Commissioner of Highways and also the first Good Roads Commissioner of Ontario. As Dominion Commissioner of Highways, he was called upon to study conditions in the different provinces and in conference with the various provincial authorities his technical advice and experience proved invaluable. Shortly before his death, in the course of an address, he used the following sentence, which the author believes may well become the slogan of every highway engineer: "After a quarter of a century, a lifetime, I may say that I am still a student of roadbuilding and the man who to-day professes to know all about this question is making the greatest mistake that an engineer can possibly make." Those words were true a decade ago, and they are equally true to-day. Much has been learned, but in fifty years our highway problems have not been solved nor is it likely they will be ever entirely overcome. There has been progress, however, and if we remain students of roadbuilding, we shall see even greater progress during the next half century.

# Harbour Construction

The importance of Canadian harbours to the general welfare of our Dominion is defined by Sir Alexander Gibb, in his National Ports Survey of 1931-1932, wherein he makes the following statement:

"The ports of Canada, although they have a capital value of about $370,000,000 only, are part of a transportation system which, including railways, canals and roads is assessed at $4,500,000,000 and constitutes over a seventh of the country's estimated wealth. The principal ports are not, as in many countries, founded on the service of a great exporting or consuming area in their immediate neighbourhood; nor have they been created and developed by merchant or shipping interests. They exist primarily as the connection between land and sea in the long route that the exports of Canada must take to reach their market; and for that reason, by the terms of Confederation, and in distinction from the position in the United States where the ports have remained almost entirely in the control of individual states and cities, almost all ports in Canada have become federal property."

There are six major seaports in Canada, namely Halifax, Saint John, Quebec, Montreal, Vancouver and New Westminster. Through these ports passes almost fifty per cent of the total foreign trade of our country and over seventy-five per cent of the overseas trade of Canada. There are a number of important harbours on the great lakes, of which Toronto, Port Arthur and Fort William are the principal. In the year 1929, the all time high in Canada's record of foreign trade, the total amounted to 2.65 billions of dollars, of which 1.26 billions passed through the six principal ports.

In dealing with the subject of this paper, the chief engineers of the principal harbours were consulted, and the articles which they kindly contributed are published herewith.

## CONSTRUCTION IN HALIFAX HARBOUR

The port of Halifax is located on the southeast coast of the province of Nova Scotia, in Latitude 44° 30′ north, Longitude 63° 45′ west. With relation to the ports of Europe and Africa it is nearer than any other North Atlantic port. The regular steamship lanes traversed by vessels plying between New York and Great Britain are about one hundred and sixty miles south of Halifax. It is, therefore, favourably situated as a port of call for passenger liners on this route.

The harbour is 7.5 nautical miles in from the open sea. Its entrance channel is from one-half to one mile in width, on a relatively straight course. The depth of water in the channel is from 50 to 110 ft. Including Bedford Basin, which forms an inner land locked harbour, the total area within the harbour limits, having a depth of 45 ft. or more, is about ten square miles. The tidal range at spring tides is 6.7 ft. and currents within the harbour at all stages of tide are negligible, the maximum rate at the Narrows leading to the Basin being less than one knot. Throughout the winter season the main harbour is free from ice.

During the winter season, when the St. Lawrence river ports are ice bound, the port of Halifax handles a large proportion of Canadian freight and passenger traffic.

The first extensive scheme of harbour development for Halifax was considered in 1911. It was proposed to construct four large reinforced concrete piers, with concrete pile substructures, at the deep water terminals. Only one of these piers was built, pier 2, which was begun in 1912 and completed early in 1915 by the Department of Railways and Canals. This pier is 780 ft. long by 235 ft. wide, carried on reinforced concrete piles, 24 in. square, in lengths from 55 ft. to 75 ft. The largest piles weighed about twenty-three tons. Thirty-three vertical and six inclined piles were driven in each bent, the spacing of the bents was 18 ft. between centres.

A two-storey reinforced concrete transit shed was erected on the pier. The building columns were spaced 39 ft. 6 in. transversely and 18 ft. longitudinally, the shed being approximately 680 ft. long and 200 ft. wide. Three piles were driven close together under each of the interior shed columns and two under each wall column, with one inclined pile at each column group. The main deck of the pier was constructed on the ordinary beam and girder system. The upper portions of the piles were cast after driving. They were capped with girders, 12 in. wide by 49 in., 38 in. and 36 in. deep, carrying beams 12 in. wide and 24 in. deep. The deck slab was 8 in. in depth. Two plies of 2 in. creosoted timber lagging, 8 ft. in height, enclosed the piles from low water level to 1½ ft. above high water. This was provided as a protection against erosion by frost action or other causes. The main shed columns in the lower storey were circular, 25 in. in diameter, and the wall rectangular, 16 in. by 20 in. The girders supporting the upper floor were 36 in. wide by 50 in. deep, carrying a 7 in. floor slab with 12 in. by 27 in. floor beams. The main columns of the upper storey were 12 in. square, the roof girders 12 in. by 42 in., carrying a 3½ in. concrete roof slab with 8 in. by 12 in. roof beams.

The live loads provided for in the design of this structure were: deck of first floor, 1,000 lb.; second floor, 500 lb.; and roof, 110 lb.

In 1930, after more than fifteen years of service, due to the severe frost conditions, the underside of the main deck structure had become damaged by spalling of the surfaces to such an extent that corrosion of the reinforcing steel had occurred. Repairs were effected by chipping off all loose concrete, sand blasting the steel and resurfacing all damaged sections with gunite concrete impregnated with finely ground iron. This work, which was done in 1930, is in good condition at the present time.

In September 1933 the upper storey of the transit shed was completely destroyed by fire but very little damage was done to the building below the upper floor level. The structure was stripped down to that level and the upper storey was reconstructed with a structural steel frame, corrugated iron siding, mill type wood roof covered with built-up tar and gravel roofing, and a complete sprinkler system was installed throughout the upper storey.

H. W. Frith, M.E.I.C., Chief Engineer, Vancouver Harbour Commissioners.

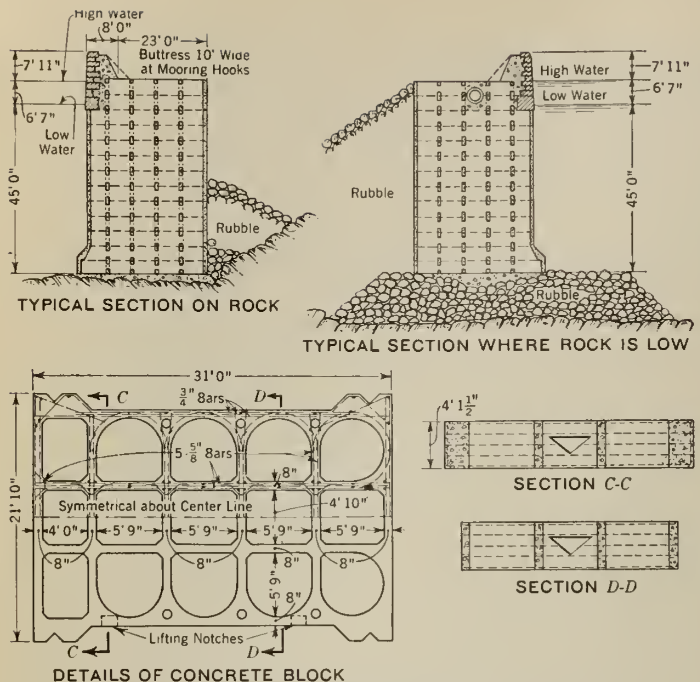

**Fig. 1—Detail of Dock Wall Construction, Ocean Terminals, Halifax.**

The deck of the pier at the north and south sides, and for a width of 24 ft. at the centre of the shed, is depressed 3 ft. 6 in. below the shed floor level. Four standard gauge railway tracks, two at the centre of the shed and one along each side of the pier, were provided. The deck level in way of the tracks is 15 ft. 8 in. above low water.

The depth of water at pier 2 is from 33 ft. to 57 ft.

### Ocean Terminals

Harbour development on a more extensive scale was undertaken in 1913 by the Department of Railways and Canals. This project took in a frontage of over 5,600 ft., the north end of which was about a mile south of the deep water terminals.

The scheme included the building of the connecting railway from Fairview, at the north end of the city, to the south end terminals; the construction of a classification yard along the shore of Bedford Basin, between Fairview and Rockingham; and the construction of docks, including 3,300 ft. of dock wall forming the Bulkhead passenger landing quay, and five piers, each 1,250 ft. long, having a mean width of 340 ft. The basins between piers were to have an average width of 340 ft. The draft to be provided at most of the berths was 45 ft. A breakwater, 1,400 ft. in length, at the south end of the frontage, completed the layout.

Contracts for the dock construction, carried out between 1913 and 1919, included the construction of the Bulkhead passenger landing quay, pier "A," the breakwater, and the two basins adjacent to pier "A." The total length of dock wall completed was 6,522 ft. The depth provided at the east face of the passenger landing quay, for a length of 2,006 ft., and at both sides of pier "A," was 45 ft. For the outer berth at the north side of basin 1, a depth of 35 ft. was provided, and 35 ft. for the inner berth.

The design adopted for the construction of the dock wall is shown in Fig. 1. It consisted of stacks of cellular concrete blocks, 31 ft. long, 21 ft. 10 in. wide and 4 ft. 1½ in. high, each block weighing about sixty tons. The blocks were reinforced to withstand the handling stresses and those which would exist after the dock wall had been completed and backfilled. A large area near the site was used for the casting and storing of the cellular blocks. The minimum thickness of the cell walls of these blocks was 8 in. They were kept in storage for at least three months before being placed in the work.

The harbour bottom at the site of this project consisted of ledge rock overlaid with harbour mud or a layer of clay and mud. The rock was encountered at or above elevation 45 ft. below low water throughout the greater part of the length of the wall, but at the outer end of pier "A" and midway along the front of the passenger landing quay the rock surface was quite a depth below that level. Except at these low places the procedure followed was to excavate the rock to grade and to place concrete pedestals to carry the corners of the blocks. These pedestals were placed by means of a large diving bell, especially constructed for the work, having a working chamber 34 ft. long, 26 ft. wide and 7 ft. high. This permitted accurate setting of the work and thorough inspection.*

Where the rock was only a few feet below the elevation of the bottom of the blocks, a mass concrete foundation was laid under water in a steel sheet-pile cofferdam. For depths beyond 55 ft. a rubble mound of quarry stone was placed and allowed to settle for a year before the concrete pedestals were set on it. This latter method was used for a length of about 600 ft. midway along the bulkhead passenger landing quay and for a length of 300 ft. at each side and across the front of pier "A."

The precast cellular blocks were placed on the prepared foundations by means of a large locomotive crane operated on tracks placed on the completed stacks of blocks. They were kept in vertical alignment by reinforced concrete guide piles placed in the triangular grooves formed in the sides of the blocks. After a stack of blocks, thirteen to a complete stack, was in place, all cells in the lower blocks were filled with concrete and those of the second were half filled. Circular holes extending through all blocks of a tier were then filled with grout, thus filling and bonding the horizontal joints between blocks. The front rows and middle transverse rows of pockets in each tier were then filled to the top with concrete, making a solid concrete buttress in each tier. The other pockets were completely filled with rock, gravel and sand. The two upper layers of blocks were made narrower than those below and set back from the face line. A mass concrete cope wall faced with granite was constructed from one foot below low water to the finished cope level 14.5 ft. above low water. A bank of rubble was placed at the rear of the wall to a height of 20 ft. below low water. Rock, earth and sand fill was used to complete the filling of the reclaimed areas. Work on the various contracts for dock construction was completed in 1919.

During 1917 and 1918 four single storey timber transit sheds were built at the Ocean Terminals, sheds 23 and 24 at berths at the north side of basin 1 and sheds 25 and 28 at the inner berths at north and south sides of pier "A."

Work on the erection of sheds 21 and 22 on the landing quay was begun in 1921. These sheds form one continuous building, 1,262 ft. long and 95 ft. wide. They are of two storey steel frame construction, 40 ft. high from floor to eaves on the west or track side and 54 ft. high on the east or harbour side. The foundations are concrete walls and pedestals on concrete piles, floors of reinforced concrete—the lower floor being surfaced with asphalt mastic. The roof is of mill type timber construction with five ply built-up roofing. The walls of the sheds proper are covered with asbestos protected metal, except at each end and at the central bay section, 100 ft. long, where the walls are of brick. Brick fire walls were constructed midway in each

*A complete description of this piece of equipment was published in The Engineering Journal dated October, 1918, pp. 252-262.

shed. The transit sheds are fitted with continuous sliding doors at each side on the lower floor and on the upper floor of shed 22 on the harbour side. Construction work on these sheds was suspended from 1923-1925 and the work was not completed until 1926.

The landing quay and general arrangement of the various buildings are shown in Fig. 2.

In 1929 two other transit sheds and an office building were built by the Halifax Harbour Commissioners; shed 20 and the Administration Building were constructed north from shed 21, and shed 27 at the outer berth on the south side of pier "A."

The Administration Building, three storeys in height, is of reinforced concrete and tile construction, faced with brick; the concrete foundation walls and pedestals are carried on timber piles driven into the fill. The building is 100 ft. by 66 ft., located at the north end of shed 20 and 60 ft. from the north end of the landing quay.

Transit shed 20, adjoining the Administration Building, extends northward along the landing quay for a length of 596 ft. to the north end of shed 21. Its width is 95 ft., with single span roof trusses. It is of steel frame construction carried on concrete foundations and timber piling. The floor is of concrete, surfaced with asphalt mastic. The height from floor level to eaves is 27 ft. The roof is of timber construction with five-ply tar and gravel roofing. The walls are of corrugated sheet steel fitted with continuous sliding timber doors on the east and west sides.

Transit shed 27 is a single storey building with structural steel wall columns, on concrete foundations. A Lamella type roof of segmental timber construction was erected. Two and three-eighth inch diameter tie rods extend across the width of the building, connecting the wall columns at the top. The timber roof is covered with five-ply built-up roofing. The main shed is 655 ft. long by 90 ft. wide. The floor is of concrete, surfaced with mastic. Along the north side main shed, for its full length, a track shed, 42 ft. wide, was constructed of structural steel frame with corrugated sheet steel siding, timber roof and tar and gravel roofing.

### Construction of Pier "B"

Further development of the ocean terminals was carried out by the Halifax Harbour Commissioners in the construction of pier "B" located about one thousand feet south of pier "A." The contract for this unit was awarded in January 1930 and work was finally completed early in 1933.

This pier, of the solid wall type, is 1,250 ft. long by 300 ft. wide. The cellular concrete-crib type of dock wall construction was used on this project.

The outer berths at this pier, for a length of 700 ft. on the south side and 900 ft. on the north, have a depth of

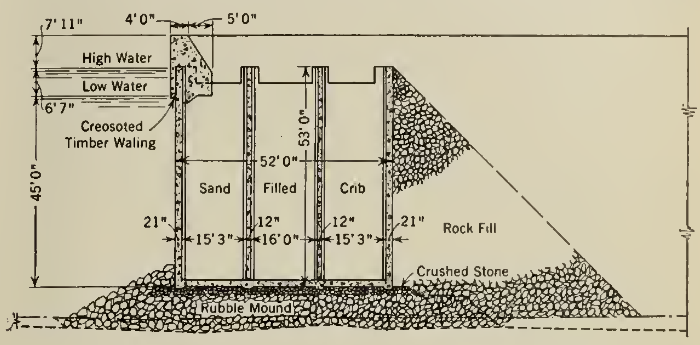

**Fig. 3—Section of Dock Wall, Pier B, Halifax.**

45 ft.; the inner berth sections have 35 ft. The adjacent basins at each side were excavated to these depths; that on the north side is 225 ft. wide and on the south side 255 ft.

Thirty concrete cribs were constructed for the dock wall; sixteen of the cribs were 107 ft. 3 in. long, 52 ft. 0 in. wide and 53 ft. 0 in. high; eleven of them were 107 ft. 3 in. long, 43 ft. 0 in. wide and 42 ft. 0 in. high. Three other cribs, approximately 75 ft. long, were placed, two of the larger section and one of the smaller. The cribs were constructed with concrete bottoms, the bottom slab being 18 in. thick, the outer side walls 21 in., the end walls 18 in. thick and the intermediate cell walls 12 in. thick. The interior cell walls were stopped off four feet below the side walls. Each crib was constructed to a height of about fifteen feet in a large timber pontoon. The bottom slab and the first lift of the walls were poured in fixed forms; sliding forms lined with sheet steel were then erected and the walls poured to a height of fifteen feet.

The pontoon had sufficient buoyancy to allow the crib to be built to that height, at which stage the crib would

**Fig. 2—*Majestic* at Ocean Terminals Wharf, Halifax.**

float with a freeboard of about two feet. It was then possible to remove the pontoon by sinking below the crib bottom. The crib was then moved to another berth and the concreting operations continued with the crib afloat, until the final height was reached. The pontoon on being re-floated was made ready for the next crib.

Ciment Fondu, a rapid setting, high early strength cement, was used in the construction of all of the pier "B" cribs. This cement was purchased in England and supplied to the contractors by the Harbour Commissioners.

In preparing the crib sites the overburden was removed and where the rock surface was above the required elevation it was excavated to two feet below the grade of the bottom of the crib. A course of crushed stone was laid to a depth of two feet and carefully levelled off to receive the crib. At the east end of the pier the rock surface was from 20 to 25 ft. below the grade required for the cushion course, and for a distance of 500 ft. on the north side and 700 ft. on the south side from the outer end the rock surface was below that elevation. Over these areas a rubble mound of quarry stone was placed and allowed to settle before the cushion course of crushed stone was laid. The top of the rubble mound extended out from the line of the cribs at least 17 ft. at the sides and 23 ft. at the outer end of the pier, and the crushed stone cushion was placed to at least five feet beyond the inner and outer lines of the cribs. Crib setting followed immediately after the work of preparing the foundations. (See Fig. 3.)

The cribs were towed into position and flooded by means of siphons. After setting in proper alignment, the cribs were completely filled with sand. The openings between cribs were closed with bagged concrete for a width of eight feet at the front and backfilled with broken stone. The line of cribs thus placed and filled with sand formed a solid wall enclosing the main fill.

All rock and other satisfactory fill material obtained from dredging was deposited within the pier area. Additional rock and earth was obtained from the excavation of the trackage areas immediately west of the pier.

To get proper alignment for the cope wall, it was necessary to construct a curtain wall of reinforced concrete along the face of the cribs from low water to the top of the cribs. A creosoted timber waling was bolted along the face at low water and hook bolts were placed through the wall above the waling to anchor the slab. This varied in thickness from 8 in. to 30 in.

Above the cribs and on the line of the curtain wall, a cope wall of Portland cement concrete was constructed to the finished height of the pier, 14 ft. 6 in. above low water. The filling of the pier was then completed to cope level.

Construction of the transit sheds on pier "B" was begun in April 1934 and completed in December of that year.

Two single storey sheds were erected, each 1,200 ft. long by 94 ft. 6 in. wide, with a connecting shed at the east end, 73 ft. by 80 ft.

The centre line of columns along the dock side was set 19 ft. 2 in. back from the cope line. The concrete pedestals supporting the front columns along the dock side of each shed were either carried on the intermediate walls of the cribs or on creosoted piling driven into the crib fill. At the inner or track sides of the sheds the concrete foundation wall and column footings were carried on spread footings where rock fill was encountered and on creosoted piling in on all other cases.

The shed frame was constructed of structural steel, with single span roof trusses. Corrugated sheet steel siding, steel sash and steel doors were used in the construction of the transit shed walls. Sectional vertical lift doors were provided in alternate bays on the quay side, and single section vertical lift doors in practically every bay along the inner or track sides. All doors are raised and lowered by means of mechanical devices, hand chain operated. The roofs were constructed of timber on steel purlins, covered with five-ply tar and gravel roofing. Concrete slabs were poured over the entire floor area and also between the cope wall and the sheds.

At the west end of each shed a two storey reinforced concrete and brick building was erected, 96 ft. by 22 ft., to provide office accommodation and special storage rooms.

The buildings are completely equipped with an automatic sprinkler system and twenty-six 2½ in. standpipes for fire protection. A brick fire wall was constructed midway in each shed, subdividing each into two 600-ft. sections.

During 1935 two other projects of dock construction were built, a 730-ft. extension to pier 9 at Richmond terminals, and a small pier at the cold storage terminal to serve as a fish pier, 290 ft. wide and 200 ft. long, with bulkhead sections adjacent thereto.

The type of construction used at the fish pier was similar to that used for pier "B," but on a smaller scale. In this case the main cribs were 70 ft. long, 30 ft. wide and 29 ft. high. The outer walls of these cribs were 18 in. thick, intermediate walls 12 in. and the bottom slab 12 in. Portland cement concrete was used in the cribs and cope wall of this pier. Quarry rubble mounds and crushed stone cushions were used in the same manner as for pier "B." The cribs were constructed on the beach, just above high water, on sliding launchways, to a height of 15 ft., and launched from seven to ten days after being built to this height. The remaining sections of the walls were poured with the crib afloat. Gravel filling was used in the cribs after setting. The cope wall was constructed to fourteen feet six inches above low water, corresponding to the cope level throughout the ocean terminals.

The extension to pier 9 at Richmond terminals was constructed of rock filled close-faced timber cribs up to a height of 1 ft. 8 in. above low water and a mass concrete cope wall was built thereon to a height of 14 ft. 6 in. above low water. The depth of water at this berth is 30 ft. There were eight timber cribs constructed for the work, six of them being 101 ft. 8 in. long, 35 ft. wide at the bottom and 31 ft. 8 in. high at the face and stepped at the rear. Creosoted Douglas fir was used for the face timbering and all cross ties entering the face. Untreated hemlock and spruce timber were used throughout the interior and rear of the cribs.

The original harbour bottom at the side consisted of ledge rock overlaid with from two to six feet of mud and clay. The over-burden was excavated from the crib sites and where the rock surface was higher than 31 ft. below low water it was excavated to 31 ft. 6 in. Low places were filled with quarry rubble and the entire area brought to the grade of the crib bottom by placing about eighteen inches of crushed stone cushion. After the cushion course had been carefully levelled off the cribs were sunk in place and completely filled with stone. The concrete cope wall was then constructed.

The reclaimed area at the rear of the wall was filled with the rock and other material from dredging and with earth and gravel deposited from dump trucks.

Other facilities provided at the port of Halifax are the grain elevator and cold storage plant, located at the ocean terminals. The cold storage plant has a million cubic feet of refrigerated storage space for the handling of fish, meats, fruit, vegetables and other food products. The refrigeration plant has an equivalent capacity of over five hundred tons per day. The grain elevator has a storage capacity of 2,200,000 bushels. Conveyor galleries to five berths were provided for delivery of grain to vessels, and one marine leg at berth 25, for unloading grain from vessels, has a capacity of 12,000 to 15,000 bushels per hour.

Of the privately owned piers constructed within the harbour limits, three are of special interest.

The Furness-Withy pier, located a short distance south of deep water terminals, was built in 1917. This pier is 580 ft. long by 90 ft. wide, constructed on concrete cylinders 6 ft. and 7 ft. in diameter. Four cylinders were placed in each bent braced with horizontal and diagonal struts of reinforced concrete. Longitudinal and transverse girders support the reinforced concrete deck. A single storey warehouse, 514 ft. long by 69 ft. wide, of reinforced concrete construction, was erected on this pier.

Immediately south of the Dartmouth ferry landing on the Halifax side of the harbour, a creosoted pile wharf was constructed in 1928 by the Western Union Telegraph Company. It is 360 ft. long by 54 ft. wide. All timber used in this work was creosoted. The deck slab was constructed of reinforced concrete and a timber shed, 280 ft. by 30 ft., erected thereon.

In 1935 the Imperial Oil Company constructed a dock at Imperoyal on the east side of the harbour. This pier has a creosoted pile trestle approach 315 ft. long extending from the shore to the pier head. Four large cribs of Portland cement concrete, 98 ft. long, 44 ft. wide and 44 ft. high, were constructed to form the pier head; sliding forms were used for the construction of these. The cribs were set on a rubble mound, with a crushed stone cushion course. The cribs were completely filled with gravel and sand after placing. A concrete cope was constructed on all four sides and a concrete pipe duct was provided at rear of the dock, and the remainder of the area filled to cope level and covered with a concrete slab. Vertical and horizontal fender timbers were provided along the west side of the pier.

The administration of the port of Halifax is now under the National Harbours Board, Ottawa.

## RECENT CONSTRUCTION IN SAINT JOHN HARBOUR, N.B.

The great tidal range in Saint John Harbour, 28 ft. at spring tides, necessitates the construction of much higher wharf structures than are ordinarily required in harbour development. To provide a berth having 30 ft. depth at low water, with provision for deepening to 35 ft., it is necessary to construct wharf walls at least 67 ft. in height. This, taken in conjunction with the fact that river silt is deposited in considerable depths over a large part of the harbour, greatly complicates the problem of providing structures with the necessary stability, at a reasonable cost.

Two major wharf developments of some considerable interest have been undertaken in this harbour during the past eight years, namely, the Navy Island development, and the reconstruction of berths 1, 2, 3 and 4. Although the structures are founded on rock in both developments, in the former case the rock surface varied from slightly below the berth grade to about coping level, while in the latter case, it varies from slightly below the berth grade to 46 ft. below that level.

### Navy Island Development

The Navy Island development consists of a two-berth pier, 700 ft. in length, and a quay wall 857 ft. 6 in. long, connected by a 300-ft. bulkhead wall. The slip between the pier and quay wall is 300 ft. wide at the bulkhead line, and 360 ft. at the outer end of the pier. Another 300-ft. bulkhead wall forms the head of the slip on the opposite side of the pier. Berth grade level is elevation −35.

On account of the large quantity of submarine rock to be removed, it was decided for economic reasons to carry out the work within a cofferdam, which enclosed an area of 43 acres. This, in addition to greatly reducing the cost of the rock excavation, made it possible to design a much more economical wharf structure. (See Fig. 4.)

In designing the structure, advantage was taken of the fact that the rock surface extended above the berth grade over nearly the whole area. The type of structure adopted also reduced to a minimum the quantity of rock excavation necessary to provide for its foundation.

The lower half of the structure consists of concrete buttresses, 5 ft. wide, spaced at 25-ft. centres. The buttresses are built against the rock slope and support a reinforced concrete arched slab, the rise in the arch being 4 ft. and the crown thickness 2 ft. A cut-off wall is built in with the slab along its back edge and extends down to the spring line. On top of the slab, a mass concrete retaining wall extends up to coping level. The fill immediately behind the structure is rock.

On account of the variation in rock elevation, three widths of structure were established, namely, widths of 28, 32 and 36 ft., and two levels were established for the spring line of the arch, namely, elevations 0.0 and −5.0. The upper level was established in order to reduce rock excavation when the rock surface extended above elevation −5.0. The 28-ft. wide section was used on both levels in order to extend this economical section as far as possible. Where the rock surface was below elevation −5.0, the spring line was carried at this level for both the 32-ft. and 36-ft. widths. Where the rock surface extended so low that the backfill would spill over the top of the excavated rock slope, a retaining wall was constructed between the buttresses, at their base, to prevent the fill from extending out into the slip. Expansion joints were made in the slab and retaining wall over the centres of alternate buttresses. It was found, however, during construction that the top six feet of the retaining wall tended to crack about half way between these joints. In order as far as possible

**Fig. 4—Navy Island Development, Saint John, N.B., before Removal of Cofferdam.**

to prevent these cracks, an additional expansion joint was made in the top section.

The transit sheds are single storey, and are ninety-five feet wide, over all. The frames are structural steel, and the roof trusses span the full width of the shed. The siding is galvanized corrugated steel and the roof is wood three inches thick, covered with a five-ply built-up asphalt and gravel roofing. The shipping doors are of steel and slide horizontally, and are continuous on both back and front of the shed. The floors are concrete. Grain shipping galleries are carried above each shed. The work was completed and in service early in 1932.

Reconstruction of Berths 1, 2, 3 and 4

Berths 1, 2, 3 and 4 were among those destroyed by fire in June 1931. Berths 2, 3 and 4 form one side of Saint Point slip, and berth 1 parallels the harbour channel. Berth 1 is 769 ft. 4 in. long, berths 2 and 3 combined are 753 ft. 4 in. long, and berth 4 is 600 ft. long, the total length of wharfage being 2,122 ft. 8 in. The bulkhead wall between berths 4 and 5 is 324 ft. long. The berth grade level is elevation -35 for berth 1, and elevation −30 for berths 2, 3 and 4.

The depth at which rock was found varied considerably and very irregularly. The highest was at elevation −35, and the lowest at elevation −83.4. The class of material overlying the rock is also variable. In berth 4, and part of berth 3, a six-foot layer of very hard clay, mixed with sand and gravel, lies in contact with the rock, and over this is a deposit of stiff red clay, sloping off from about low water level at the inshore end, to disappear at the outer end of berth 4. Very little hard material was encountered in the other berths, most of the overlying material being silt of various degrees of compactness. A considerable number of boulders were encountered at the inshore end of berth 4 and throughout the length of berth 2. Most of these were removed without blasting.

During the preliminary investigation, various types of construction were studied. The great depth to which the soft material extended over a large part of the site eliminated the more ordinary types, and it was finally decided that some form of construction in which cylinders were sunk to a solid foundation would be the most suitable. Various combinations of cylinders, and cylinders with piles, were considered, the type adopted being found to most nearly combine conditions of satisfactory foundation with reasonable economy.

The structure is made up of a series of transverse bents supporting a reinforced concrete slab and is shown in cross-section in Fig. 5. The bents are spaced 20 ft. apart longitudinally, each bent consisting of two concrete cylinders, spaced at 25-ft. centres, supporting a transverse wall, and two timber pile clusters of 13 piles each, at 24-ft. centres, supporting concrete columns. The units are tied together transversely by concrete struts, and longitudinally by continuous front and rear walls, and by concrete struts. The rear wall is supported on timber piles. The tops of cylinders and pile clusters, and the base of the rear wall are at elevation 15, which is about half tide level. The deck slab is supported on the walls and columns. This slab, excepting the part supported by the transverse walls over the cylinders, is designed as a two-way flat slab. The only girders are two transverse girders at each expansion joint, and one continuous longitudinal girder over the inner row of cylinders. The columns have a circular section. The reason for adopting the flat slab, and making the columns round instead of square, was to eliminate as many sharp corners as possible, these being considered the most likely points of attack by sea water and frost. Expansion joints are 120 ft. apart.*

During the pile driving operations at berth 4, serious ground disturbance took place, resulting in some outward movement of the slopes. After careful investigation it was decided, in order to reduce the horizontal thrust on the slope and structure, to build a 50-ft. wide relieving platform at the rear. This platform is at elevation 15 and consists of a timber deck supported on timber piles.

The cylinders are precast reinforced concrete shells, 12 in. thick and 9 ft. in diameter. They were cast on end in the dry dock in lengths of from 55 ft. to 70 ft., a steel cutting edge being fixed in the base of each. The cylinders were sunk by the open dredging method, kentledge being applied when necessary, after which they were filled with concrete. The very fine floating equipment provided by the contractor greatly facilitated the sinking of the cylinders. This was the most hazardous part of the work, but it has been completed without encountering any serious difficulties. It is expected that the construction of these substructures will be completed during the summer of 1937.

The great tidal range in this harbour exposes large surfaces of the structures to severe frost action as well as to the action of sea water. To resist disintegration of the concrete, its surface must be as nearly watertight as possible. In both the developments described above, great care was used in the control of concrete operations, both as to proportioning the materials and the mixing and placing. At Navy island, the cement content is 564 lb. per cubic

*For a fuller description of this work, see The Engineering Journal, October, 1936, pp. 437-445.

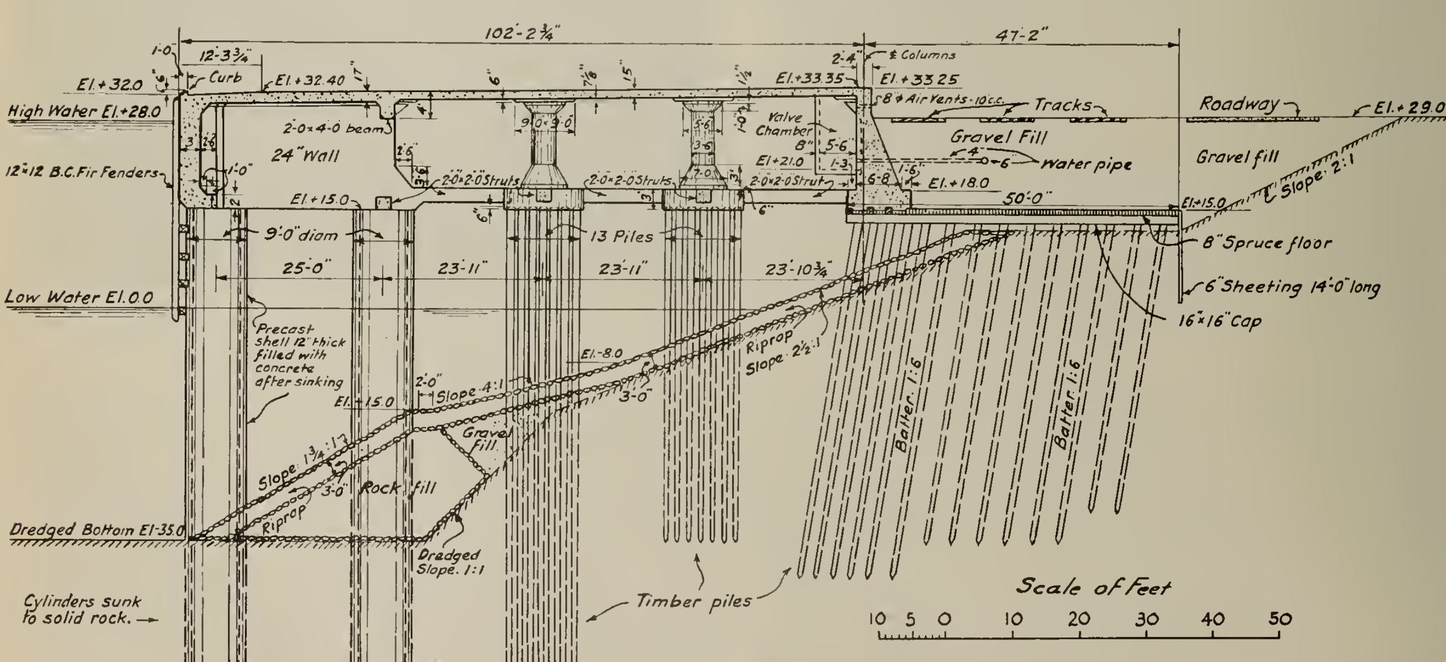

Fig. 5—Section Berths 1, 2, 3 and 4, Saint John, N.B.

yard, except an 18-in. facing within the tidal range, which is 658 lb. At berths 1-2-3-4, the cement content is 658 lb. in all concrete except the cylinder fill, which is 470 lb. The Navy island wharves have now been in service for three years and practically no evidence of disintegration can be found.

### THE PORT OF QUEBEC

The first real development of the port of Quebec began a few years before the appointment of the Quebec Harbour Commissioners in 1876. The general plan comprised practically all the wharves of that time, and also considerable enlargements in the estuary of the River St. Charles. The embankment wall forming the north wall of the inner and outer basins of the Princess Louise docks was completed in 1882, and the cross-wall dividing the two basins in 1886.

Pier 1 is of later construction, having been completed in 1907; and the St. Charles river wharf, a northern extension of the Princess Louise embankment, was built in 1917, and completed at the west end by an extension in 1930.

The latest development of the harbour has been at Wolfe's Cove terminals, where a modern ocean terminal was completed in 1931, for the 42,500-ton *Empress of Britain* and other transatlantic liners.

**Fig. 6—Princess Louise Basin, Quebec.**

#### Quay Wall Construction

In the development of Quebec harbour during the past fifty years, as briefly outlined above, the timber crib gravity has been, with few exceptions, the preferred type of quay wall, as this type of construction has been found most suitable for the local conditions. Of late years the superstructure of the quay walls from low water to coping level has been made of concrete to obviate the necessity of the renewal of face timbers exposed to the air.

Up to twenty years ago the maximum depth of water required at the wharves in Quebec harbour was from 25 to 30 ft. at low tide, but the increasing draft of ocean vessels necessitated providing greater depths at ocean berths and the quay wall at the new Wolfe's Cove terminals was designed to provide a maximum of 40 ft. of water at low tide. This greater depth has considerably increased the cost of gravity quay walls, as with the spring tide range of over 22 ft. at Quebec, the timber cribs with concrete superstructure have a total height of 70 ft., and the width of the timber crib at the base is 60 ft.

The timber used in the construction of the cribs is 12 in. by 12 in. dressed on two sides. Southern pine was used in the St. Charles river quay extensions in 1917-1918, and B.C. fir at the Wolfe's Cove development and in the St. Charles west end extension in 1930.

These gravity timber quay walls are designed to resist overturning, for the bearing capacity of the ground, and to resist sliding. In the most recent designs a surcharge of 1,000 lb. per sq. ft. was provided for. As an added factor of safety against sliding in the quay wall built in the St. Charles river in 1929, anchor piles were driven through the front pockets to a depth of 20 ft. into the crib seat, and pockets were also left open to permit the stone filling to penetrate into the ground.

An exception to the gravity type of quay wall exists at the western extremity of the St. Charles river quay wall, where a steel sheet piling bulkhead wall was erected in 1929. At that location it was imperative that the quay wall should be of impervious construction, and no sliding movement could be tolerated, as the bulkhead formed a protection wall for a marine railway slip.

This steel bulkhead wall, as far as the author is aware, was the first of this type built in this country. The steel sheet piles were driven 15 ft. below the ground elevation, and the lower tie-rod was placed two feet above mean low water, giving a span of 32 ft. Carbon steel of high tensile strength was used to obtain the necessary section modulus without excessive weight. Structural steel was used for all other steel members. The anchor wall was of reinforced concrete on wooden piles, while a concrete coping was placed on the steel sheet piling to complete the wall.*

#### Masonry Walls

Masonry walls were extensively used some fifty years ago, and proved satisfactory and economical for the quay requirements of that time. An example of this type of construction is the cross-wall forming the division between the inner and outer basins, and enclosing the entrance gates to the inner basin at its southern extremity. This masonry wall was built in 1886 and apart from the addition of a few tie-rods has required practically no maintenance; its present condition would indicate a further useful life of another fifty years.

#### Inner Basin Entrance

In 1886 work was started on the entrance gates to the inner basin, as well as the installation of sluice valves between the inner and outer basins. These entrance gates are of timber and are in duplicate. They are operated at high tide to allow navigation between the inner basin or wet dock and the outer basin or tidal harbour, the vessels berthed in the inner basin being kept at the same level with the coping of the wharf, regardless of the stage of the tide.

These wooden gates have been in continuous service since their installation some fifty years ago, and the machinery for the operation of the sluice valves, installed at the same time, has been operated daily during the navigation season over the same period, with only minor repairs.

Fig. 7—*Empress of Britain* at Wolfe's Cove, Quebec.

The draw-bridge over the entrance gates to the inner basin was completed in 1888, and is also still in service. However, the ever increasing auto-truck loads will necessitate its replacement by a heavier structure in the near future.

A single-track railway bascule bridge, having an 88-ft. span, was erected over the entrance to the inner basin in 1912. It has been in continuous service since its construction.

### Graving Docks

Another example of the utility of masonry walls is the Lorne graving dock at Lauzon (Levis) in Quebec harbour, on the south bank of the St. Lawrence river, which was built by the Harbour Commission in 1886, and has been in continuous service since that time. The travelling caisson provided for this dry dock was a decided improvement over the older type of dock gates, and was one of the features of the design of this dry dock at the time.

While the Lorne graving dock, with its 600-ft. length, was adequate at the time of its construction, the increasing length of ocean liners in the early part of the twentieth century necessitated the construction of the Champlain dry dock, on a site near the Lorne dock at Lauzon.

The Champlain dock was built by the Dominion Government under the supervision of the Department of Public Works. It has a total length of 1,150 ft. from the outer caisson to head wall, and a width of 120 ft., with a depth on sill at high water of 40 ft., being the largest dry dock in the world at the time of its construction in 1918.

It is divided into two compartments by a floating caisson, one compartment being 650 ft. and the other 500 ft. in length. It was constructed of concrete, with granite steps, altars and quoins. Its location in solid rock involved the removal of 342,000 cubic yards of rock.

The outer entrance is closed with a rolling caisson. The floating caisson for the inner entrance can also be used to close the outer entrance in case of emergency.

The dock is emptied by three centrifugal pumps, each with a capacity of 63,000 gal. per min., and about two hours is required to empty or fill it.

Fully equipped modern repair plants are provided at both the Lorne and Champlain dry docks.

### Wolfe's Cove Terminals

To accommodate the increasing tonnage of ocean liners, especially in the period following the Great War, and in order to permit the port of Quebec to retain its position as a modern seaport, it was deemed advisable to develop the harbour frontage west of Champlain Market. Here a protected section of the harbour, known as Wolfe's Cove, afforded ample space for extended development for deep draft vessels.

The location of these new developments was selected after an exhaustive study of all the sites in the harbour. Preliminary work commenced in 1924, and construction started in the fall of 1925, a contract having been let covering the necessary dredging and quay construction for the first section of this project. A launchway and trestle were built near the site of the work for the construction of the timber cribs.

The type of quay wall used for the first section of the Wolfe's Cove terminals was a timber gravity crib up to low water level, and a pre-cast concrete superstructure from low water to coping level at elevation 124.00. The main cribs were 202 ft. in length and 60 ft. in depth, with anchor cribs of 60 ft. front and 150 ft. in depth, placed every fourth crib. Each main crib required about 1,200,000 ft.b.m. of B.C. fir, the total amount of timber in the quay wall being 28,000,000 ft.b.m. Some 330,000 cu. yd. of one-man stone were used as fill These cribs were placed in a trench dredged to 45 ft. below low water.

The concrete superstructure is also of the gravity wall type, but was constructed in pre-cast reinforced concrete sections, the wall having been made by placing pre-cast I sections on top of the timber cribs and filling with mass concrete. The facing of the superstructure of the quay wall was made of pre-cast concrete blocks. Some 60,000 cu. yd. of concrete were used in the construction of this superstructure.

The necessary filling back of the quay wall was obtained from the dredged material removed in the crib seats and in the berth areas in front of the quay wall. Over 6,000,000 cu. yd. of blue clay, sand and gravel were dredged and placed for this filling.

A rip-rap embankment was constructed from the south end of the quay wall to meet the shore line near Wolfe's Cove, and provide a storage yard and place for transfer tracks at the southern approach to the terminals. Temporary wooden bulkheads were also provided at the northern and southern extremities of the quay wall to retain the fill.

In 1930 the foundations were laid for a modern two-deck passenger and freight landing shed, 1,380 ft. by 100 ft., with a railway terminal adjacent thereto. This shed was built on the newly constructed quay wall at Wolfe's Cove terminals, and was designed especially for the *Empress of Britain*, then under construction. Special precautions had to be taken in the design of the foundation of the shed to prevent any possible settlement or lateral movement. Wooden piles were driven into the old formation of the ground. A reinforced concrete foundation resting on the pile clusters was chosen as being most suitable to carry the dead load of the shed, and a live load of 450 lb. per sq. ft. for the lower deck and of 250 lb. per sq. ft. for the upper deck was provided for. This shed has now been in operation since 1931, with no appreciable settlement or lateral movement, notwithstanding that some 25,000 tons of newsprint paper have been stored in it during the past few winters.

The lower deck is for freight and the upper deck for passengers and light baggage, although heavy commodities are stored on the upper floor when necessary. Office accommodation and passenger waiting rooms are provided at the east end of the shed. Covered passageways connect directly with the adjoining railway terminal, allowing passengers to board and leave trains rapidly, with no inconvenience from the presence of freight or from the handling of baggage. Provision has been made to accommodate four passenger and one baggage train at one time, and the length of the shed allows two modern liners to berth and handle passengers and freight with dispatch.

The transit shed is provided with two baggage elevators of 5-ton capacity, three large stairways to serve passengers arriving or leaving by taxi or bus, four spiral stairways for longshoremen, and four baggage chutes. A driveway down the centre is sectioned off by the shed columns. The wearing surface of the upper and lower floors is 2-in. sheet asphalt, over a concrete floor.

The outshore wall of the first and second decks, and the inshore wall of the lower deck are fitted with continuous doors of the two-section turnover type. These doors are 18 ft. wide and 16 ft. high on the river side. On the track side the doors are 18 ft. wide and 12 ft. high, except for every fourth door which is 14 ft. high, in order to provide clearance necessary to handle large boxes, crates, etc. These doors are framed by structural steel shapes, diagonally braced, with riveted connections throughout, and covered with steel plates of No. 14 gauge. They were designed to withstand a wind pressure of 30 lb. per sq. ft. They are so counter-balanced as to operate freely and easily in all positions, with a maximum pull of 35 lb. The lower structural members of doors as well as cover plates are of copper-bearing steel.

A heavy-duty cargo beam, of 5-ton capacity, has been constructed the full length of the transit shed to permit placing gangways and handle cargo in conjunction with ship's tackle.

The dock front is provided with all required water and fuel oil outlets, of sufficient capacity to provide rapid servicing of vessels.

## WHARF CONSTRUCTION IN THE HARBOUR OF MONTREAL

Certain physical and especially climatic conditions at the harbour of Montreal were the principal reasons, several years ago, for the choice of the type of wharf structure now adopted there for a group of wharves in the vicinity of the Jacques-Cartier bridge.

The past decade's channel dredging operations have lowered the surface of the river water to such an extent as to render fordable the undredged portion of the stream. In other words, the flow of the river has been mostly diverted into the dredged channel, which is but a fraction of the two miles width of the river at that point. The result has been the acceleration of the current therein, which was already rapid due to the constriction of the river section by the presence of St. Helen's island in its centre.

On the other hand, the territory of the harbour of Montreal was so defined by an Act of Parliament that wharves, piers, rails and driveways had to be and were all reclaimed from the river.

The provision of wharves in the style of piers or slipways was therefore out of the question at that particular section of the harbour, because the establishment of piers in the river would have the objectionable result of greatly reducing the channel width and increasing the velocity of the stream. A narrow shore wharf was the only alternative and in the earlier part of this particular development, that type was adopted. It has many disadvantages however, as well be seen from Fig. 8, when the following points are noted.

With a group of shore wharves established in a straight line and with provision of say 500 ft. berths, the length of the ships berthing at the individual berths cannot exceed 500 ft., otherwise the adjoining ships would overlap. But, assuming that all the ships accommodated at this particular group of wharves are not longer than 500 ft.,

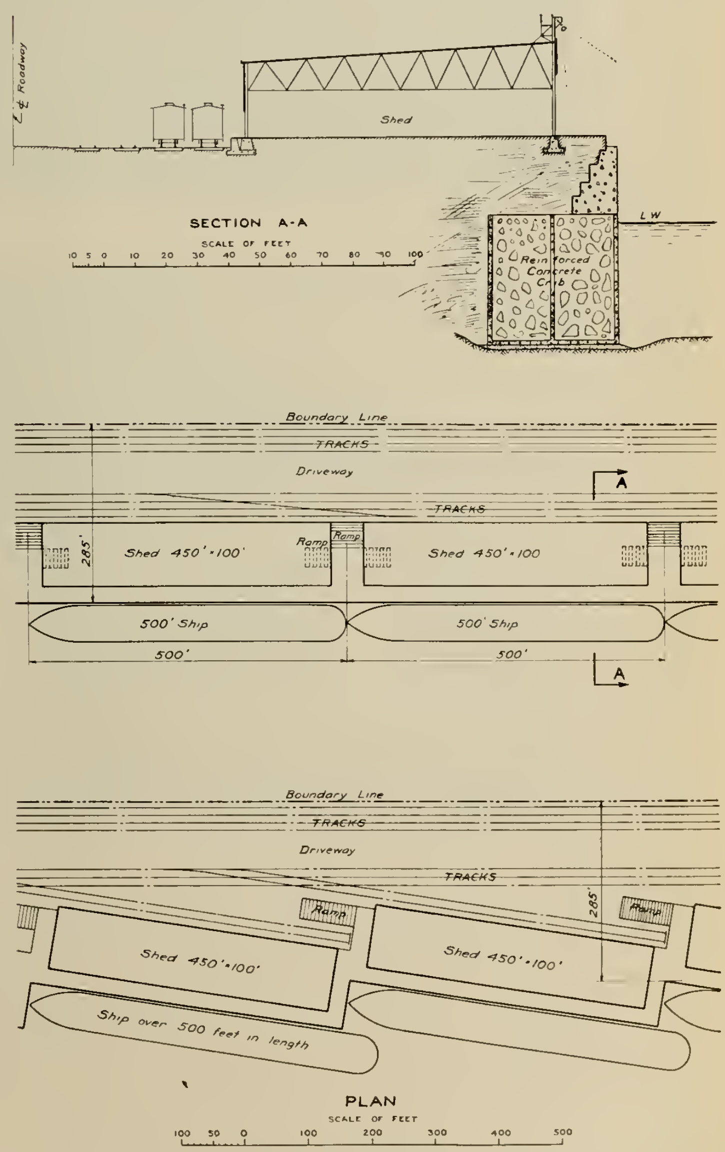

Fig. 8—Two Types of Shore Wharf Construction, Montreal Harbour.

and considering the presence of a strong current at these berths, their berthing and sailing when ships are already berthed at the adjoining upstream and downstream berths becomes a difficult and even dangerous manoeuvre. When berthed at a wharf of this description, ships are, during the whole period of their stay, subjected to the constant strain resulting from the action of the current, and the failure of one ship's moorings would likely endanger those of others moored downstream from her.

Through the rotation of each individual berth at a point located at its extreme upstream end, so as to form a recess between its downstream end and the adjoining berth (as in Fig. 8.), all these objections disappear. Ships of any length can be berthed at a given berth without interference with the adjoining one. Their berthing and sailing can be effected with comparative ease. The failure of the mooring of any particular ship would simply let her drift downstream without exerting any extra strain on the moorings of the ships below. The recess protects the bows of the ships from the effort of the current and creates an eddy counteracting to a certain extent the pull on their sides and sterns.

The retaining walls of these wharves, like many others in the harbour of Montreal, consist of reinforced concrete cribs topped with a gravity concrete wall, as shown in section A-A, Fig. 8. The cribs are founded at a depth of at least 36 ft. below the standard low water elevation and the top of the walls at approximately 25 ft. above the latter. The river bed on the site of the crib seat is first dredged to 12 in. below the elevation at which the crib is to rest. When this operation is completed, careful soundings are taken. When the bed has been found satisfactory, a layer of 2-in to 2½-in crushed stone, at least 12 in. thick, is spread over the seat as a mattress.

For the purpose of obtaining an even surface, a small scow has been fitted with a steel beam 45 ft. long suspended at the proper depth from the surface of the water, and a diver spreads the stone so that the beam can be passed over the mattress. Protuberances are removed and cavities filled. Soundings are taken in order to ascertain the quality of the work when completed.

It has been found necessary at places where there is too strong a current, to build up a wall of bagged concrete on the exterior side of the mattress as a prevention against scouring, particularly when, during the process of crib sinking, the crib nears the bottom. When the speed of the current is excessive, the top layer of the mattress stone must also be bagged for the same reason. The crib, conveniently ballasted, is then towed out, placed in position over the mattress, and sunk by filling it with water. The use of water ballast makes it possible, in the event of the crib not coming to rest on the proper alignments, to float it again for adjustment. Siphons or valves are resorted to for the purpose of filling the cribs with the required quantity of water.

Following the satisfactory placing of the crib on its mattress, it is filled with granular material, preferably of a fine nature which squeezes the water out more completely than a coarse one. The mass concrete cope wall is then constructed over the crib. An interspace of 30 in. is provided between contiguous cribs. It is closed on the outer face of the wharf and below the surface of the water, either by means of bagged concrete, a method suitable to any condition, or by a pre-cast reinforced concrete pile of convenient size and shape. A concrete bilge, integrally provided during the construction of the crib, runs from top to bottom of the crib at each end with its exterior face flush with the exterior face of the crib, in order to maintain in place the keys, whether formed of bagged concrete or pre-cast piles.

The dimensions of the reinforced concrete cribs built for incorporation in these and other wharves and provided therein as a subaqueous understructure, were fixed as height 42 ft., length 112 ft. and width 42 ft. This particular width was adopted as the largest one which would permit floating of the cribs through the Lachine canal along which are the docks where the contractors built the cribs. The length and height were chosen for convenience in the sinking of the cribs, and economy of design, respectively.

The construction of the cribs is not limited to the dry-dock method by any means. As a matter of fact, some of the early cribs were built on a specially built shallow pontoon of dimensions exceeding those of the cribs by approximately 3 ft. on each of the four sides. A sufficiently strong and rigid partition of a convenient height was provided on the four sides of the pontoon and the forms of the actual crib erected with both the pontoon and forms concentric. The concreting of the forms had for obvious effect the gradual submersion of the boat, consisting of the pontoon and its side walls, in the water. When the subsidence became sufficient for the water to invade the open space between the crib and the exterior wall over the latter, the crib was of a sufficient volume to float by itself. The pontoon was then loaded by means of heavy weights under which it sank to a depth not exceeding that necessary to pull the crib off the float or the float with its walls from under the crib. The removal of the weights caused the pontoon to rise to the surface ready for the start of a new crib construction.

Cribs have also been started on three scows tied together side by side so as to form a pontoon, the width of which was the length of the scows and its length the combined width of the three scows, an integral stiff deck being provided over the group of scows. When the cribs were of sufficient height to permit self floating, water was admitted into the scows, conveniently partitioned crosswise, and the eccentric weight of the volume of water, through the consequent canting on one side of the group of scows, allowed the crib work to slide into the water over a slipway provided and greased for the purpose.

Cribs have also been partly built over a convenient platform erected on the shore so designed as to allow canting sufficient for the sliding off of the crib work. When leaving the platform, the crib became supported on a greased slipway carried on a slant to a sufficient distance in the water as to allow the crib to float when reaching the end of the slipway.

In all instances, the floating cribs were raised to their definite height of 42 ft. in lifts so calculated as not to allow any fresh concrete to become submerged prior to its having had two days curing in the air.

In the design of the different parts of the cribs, consideration must be given to the following factors:—

The concrete and reinforcing steel of bottom slab or bilge which is required primarily for the sake of flotation of the crib prior to its sinking in place, must resist part of the reaction of the water against the weight of the completed crib. When the crib is floating, it is necessary to admit some water so as to maintain its stability and verticality during the raising and sinking processes. The weight of this volume of water reduces by so much the reaction the bottom slab would have to resist if the crib were maintained in an empty condition until sinking.

The crib has in plan the character of a series of contiguous bins, much like an ordinary reinforced concrete grain elevator. The transverse walls, 12 in. thick, are computed as retaining walls for a 5 ft. excess of fill between consecutive bins during the filling process only, the water admitted in the cribs prior to and during the sinking

Isle of Orleans Bridge, (*top*) over St. Lawrence River, six miles below Quebec City. Total length including approaches, 1½ miles. Suspension span, longest of its type in Canada, 1,059 feet centre to centre of main piers. Two side spans 419½ feet each.

Jacques Cartier Bridge, (*bottom*) built by the Board of Harbour Commissioners of Montreal over St. Lawrence River. Total length 8,817 feet including main span of 1,937 feet overall and 1,097 feet centre to centre of piers. Height above high-water 163 feet.

Dominion Bridge Company Limited

process being maintained at a practically even level in all the bins, and also as buttresses taking the reaction of the water pressure on the front and rear walls during the flotation period.

Consideration must be given to the horizontal component of the stress in the front wall due to the interior fill and the pressure when the crib is finally part of the wharf structure, as affecting the design of the reinforcing steel of these walls and their end enchorage.

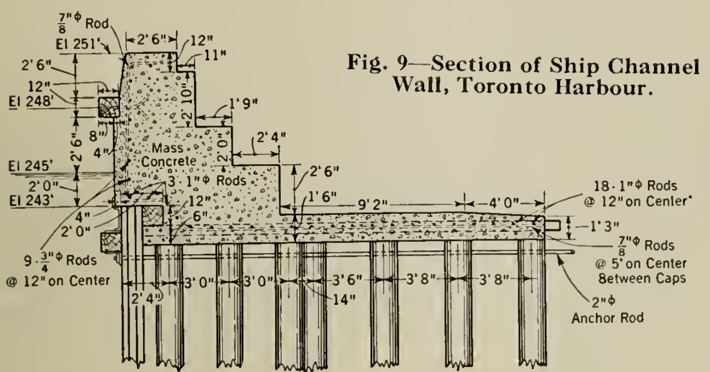

Fig. 9—Section of Ship Channel Wall, Toronto Harbour.

The central longitudinal wall is provided, at least in the central bins, merely as a stiffener for the cross walls. Being required for that purpose it is computed to resist the side pressure of a possible 5 ft. height difference of fill between the two sections of the bin it separates, and is used in the design of the bottom slab to take its proportioned share of the latter's upward reaction. Further, this wall strengthens both ends of the crib.

The rear and end walls are designed to resist part of the water pressure when afloat, that of the fill prior to the backfill behind and at each end of the cribs.

In the front wall consideration is given to exterior water pressure when afloat, and interior resultant of fill and superloads, plus vertical pressure of cope wall.

This wall is thickened by 6 in. as a protection for the reinforcing steel, laid 6 in. clear of the exterior face, against possible breakage of the concrete facing by shocks. It was also necessary to thicken the rear wall for the sake of stability when afloat during construction and sinking. The four exterior walls have a double horizontal reinforcing system, also the bottom slab, the others a single, while vertical spreader rods are provided. The front and rear walls are 22 in. thick, the end walls 24 in., the interior walls and the bottom slab 12 in.

A sufficient number of rods is also provided protruding past the top of the cribs, imbedded in the top wall concrete to resist the pull of the mooring cables on the bollards. The vertical rods, where the quay wall is resting on the walls, are left protruding over the top of the cribs.

Towing rings are provided for use in mooring or towing the cribs.

## TORONTO HARBOUR

During the past fifty years, the material changes which have taken place in the construction of ships have brought about the necessity of harbour improvement to keep pace with such changes. Vessels have kept on increasing in size and speed, the self-unloader has made its appearance and canals are continually being enlarged and deepened to meet the ever-growing demands of navigation.

In 1910, through lack of proper vessel accommodation, Toronto harbour was in some danger of losing what waterborne trade it possessed. Adequate improvement to meet the demands of navigation was an impossibility without legislation, which was obtained with the passing of The Toronto Harbour Commissioners' Act on May 19th, 1911. Under the provisions of this act five commissioners were appointed, three by the city council and the other two by the Dominion Government, one of the latter being nominated by the Board of Trade. They hold office for three years, are eligible for re-appointment, elect their own chairman and act without remuneration. The act gave them very wide powers and they were authorized to develop their properties.

Surveys were made and plans prepared, the latter being approved by the city council in November 1912, and by the Dominion Government in June 1913. This was immediately followed by the awarding of contracts and the commencement of the work which has been carried on continuously since that date. As a result Toronto now has a practically new harbour, modern in all respects and capable of accommodating the largest vessels which can pass through the Welland ship canal, as well as those which may, in the future, navigate a completed St. Lawrence deep waterway.

The carrying out of the above work comprised the construction of a ship channel and turning basin in the eastern section together with retaining walls on the Don Channel and Marginal Way, and the reclamation of the adjoining lands. Single leaf bascule bridges were erected over these channels.

This area, known as the Eastern Harbour Terminals, reclaimed from marsh lands and lands covered by water, now comprises 580 acres of land for industries, and is served by 20 miles of steam railway tracks, 8 miles of wide paved streets and 6½ miles of permanent concrete wharves. Nearly all of the area was non-revenue producing in 1915.

In the central section a new harbourhead line, at a maximum distance of approximately 1,100 ft. south of the old pierhead line, has been constructed easterly from the western entrance of the harbour to Yonge street. There is a bulkhead line from Yonge street to Parliament street, and the land to the north of it, from Bathurst street to Parliament street, has been reclaimed. Practically all of this was covered by water and non-revenue producing in 1917. This area, known as the Central Harbour Terminals,

Fig. 10—Marginal Way Pier, Toronto Harbour.

contains 260 acres of land for industries and is served by 8 miles of steam railway tracks, 4 miles of wide paved streets and 4 miles of permanent concrete wharves.

In the west end some 330 acres have been developed, of which 217 acres were reclaimed for park and recreational purposes and 113 acres for an improved waterway formed by the construction of a breakwater paralleling the shore at a distance of about 350 ft. and extending from the Humber river to the western entrance to the harbour, a distance of approximately four miles.

The retaining walls which formed a very large part of the work presented the most interesting features, their design being dependent upon the depth of rock below mean water level. The ultimate navigable depth of the harbour was thirty feet and where the rock was about this depth the crib type wall was necessary. Where the depth to rock exceeded 40 ft., a navigable depth of 30 ft. could be obtained by dredging; here the pile type of wall could be used and still leave 10 ft. for the penetration of the piling.

### Ship Channel Walls

The ship channel walls consisted of tongued and grooved close sheet piling of B.C. fir made up of 12 in. by 12 in. timber with strips spiked to both sides to form a close sheet piling. These piles were 40 ft. long and were driven along the front of the structure. They were then cut off square at an elevation of 243 ft., or two feet below the zero of the Toronto Harbour Commissioners' gauge. (Fig. 9.)

Along the top of this close sheet piling two stringers were placed, one along the inside or rear face of the pile and the other along the outer or front face; the rear stringer was 12 in. by 12 in. timber and the front stringer a 15-in. steel channel, and these two stringers were fastened together by one inch bolts.

Pile bents were driven at right angles to the line of the work to form the foundation and brace the sheet piling. These piles are of spruce 14 in. at the large end and 8 in. at the small end.

Anchor rods two inches in diameter and 50 ft. long were placed on 10-ft. centres extending from the front face of the timber sheet piling back to two anchor piles driven at 2-ft. centres, and each rod was provided with a turnbuckle.

The ship channel was unwatered to enable the proper cutting off of the piles, the setting of cap timbers and placing the superstructure, which latter was formed of reinforced mass concrete, and it also permitted a close inspection of the various stages of the work. The concrete was mixed in the proportion of one part cement, two parts sand, four parts broken stone or gravel and moulded in 50-ft. longitudinal sections with provision for expansion and contraction at each joint.

Cast iron bollards of the Scotch type were placed at distances of 75 ft. along the ship channel and turning basin walls.

Variations of this construction are to be found in the Polson Extension and Don Channel walls, parts of which were constructed with steel sheet piling, but the greatest variation is in the Marginal Way pier which has been recently constructed by the Dominion Government.

In this latter pier (Fig. 10), steel sheet piling was used throughout. A section, 31¾ lb. per sq. ft. and varying in length from 44 ft. to 56 ft., formed the outer face or front wall of the pier. This was cut off at an elevation of 248 ft. Six inches below the top of the pile a stringer formed of 12-in. by 4-in. steel channel weighing 36½ lb. per lineal foot was placed along the outer face of the front sheet piling and from the face of this stringer, two inch anchor rods 50 ft. long with turnbuckles and spaced at 8-ft. centres extended back to two anchor piles in a manner similar to the ship channel wall. Bents formed of round wooden piles 38 ft. to 45 ft. in length were driven at 5-ft. centres, at right angles to the sheet piling and carried back a distance of 21 ft. These piles, with the exception of the rear pile, were cut off at elevation 243.5 ft., the rear pile was cut off at elevation 246.5 ft., and along the rear face of the top of the rear piles was placed a 6-in. by 8-in. waling, forming a guide for an inner row of sheet piling, 18½ lb. per sq. ft. and 40 ft. long which was cut off at elevation 247 ft.; along the outside of the top of this sheet piling another 6-in. by 8-in. timber waling was placed. Half way between each anchor rod a 1½-in. tie rod extending from the face of the front stringer to the last mentioned waling fastened the two together. The superstructure was of reinforced mass concrete similar in proportions and form to that of the ship channel.

Along the inner harbour front where rock was encountered at a depth of about 30 ft. or less, the crib type of wall was used. It consists of rock filled cribwork in sections of standard length of 100 ft. and special lengths as required to make up odd distances. The section of these cribs was square, varying from 18 ft. to 26 ft. by two-foot intervals. In addition to the timbers shown on the general cross-section (Fig. 11) longitudinal ties were placed in all cribs over 24 ft. in width. Berths or trenches were dredged to bed rock. Before placing the cribs the rock was cleaned and levelled, careful soundings were taken and the crib constructed to fit the bottom as accurately as possible. After being sunk and held in place by sinking blocks, the cribs were lined and filled with stone; the various sections of the crib work were fastened together by interlocking end posts; and shoes, fastened to the face of each crib at every cross tie, were bolted to the rock with 2½-in. bolts.

A reasonable time for settlement was allowed before the vertical posts were cut off and capped and the flooring laid to receive the concrete superstructure. The elevation of the top of the wooden substructure is 243 ft. or 2 ft. below the zero of the Harbour Commissioners' gauge.

The superstructure consists of pre-moulded reinforced concrete blocks 8 ft. by 5 ft. by 5 ft. with sides bevelled front to back to ensure as far as possible a perfect alignment. After being placed and lined the blocks were keyed to the plank flooring and to each other. The concrete mass as shown in Fig. 3 was then placed on the

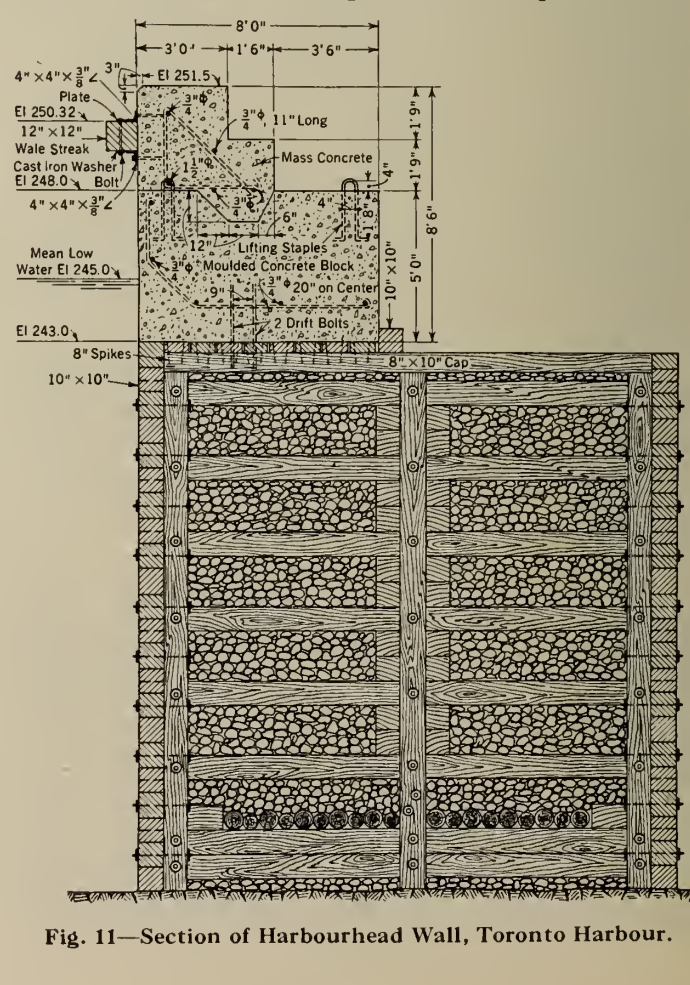

**Fig. 11—Section of Harbourhead Wall, Toronto Harbour.**

blocks and tied to them by reinforcing steel. Expansion joints were placed at every 50 ft. and mooring bollards every 75 ft. as in the case of other walls.

A similar type of wall with the exception of the extreme western section which is on sand, was used in the construction of the western breakwater (Fig. 12) which differed only in height and the form of superstructure. It is a structure 18,500 ft. long and extends from the mouth

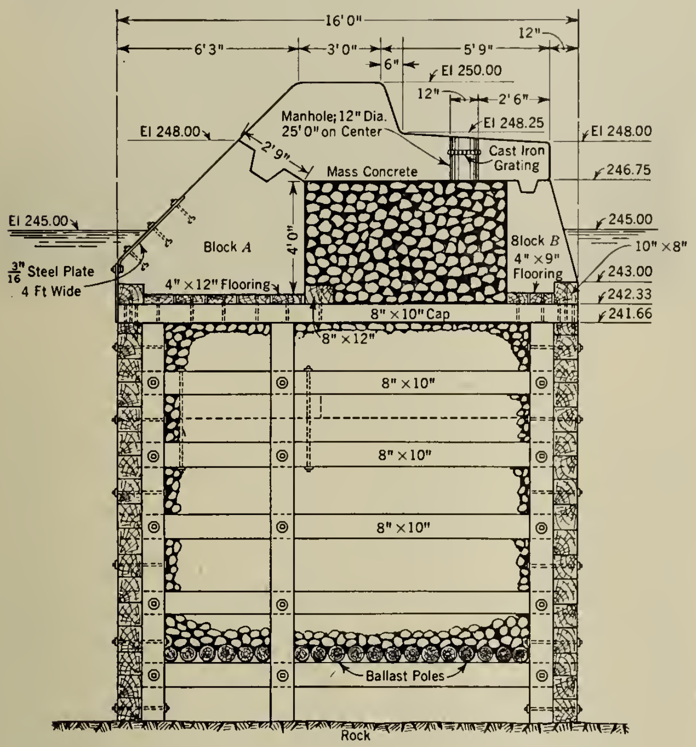

Fig. 12—Section of Western Breakwater, Toronto Harbour.

of the Humber river easterly to the western entrance to the harbour with intervening openings and was built for the purpose of preventing the erosion of the shore line from southerly gales and as a protected waterway.

As a result of the carrying out of these improvements the assessed value of the occupied harbour properties has increased from $1,976,804 in 1912 to $20,937,721 in 1936, and, during the same period, the city has received in taxes from above-mentioned properties the total sum of $7,355,740. The cargo tonnage in 1929 totalled 959,234 tons; in 1930 the Welland ship canal was opened to navigation, following which the cargo tonnage increased to 3,382,830 tons in 1936.

## DEEP SEA PIERS AT THE PORT OF VANCOUVER

### Lapointe Pier

The first permanent deep sea pier constructed in Vancouver harbour, now known as Lapointe pier, is located on the south shore of Burrard Inlet, and was designed by the Department of Public Works. Construction was commenced in October 1913 and completed in the fall of 1915. The pier, as constructed at that time, was 800 ft. long and 300 ft. wide. The berths are dredged to a depth of 35 ft. below low water, or to elevation 49.77, using the National Harbours Board datum. Thus elevation 84.77 is low water level and 97.77 high water. The cope level of the pier is 106.00. In order to obtain the required depth of water in the berths, it was necessary to dredge some 127,000 cu. yd. of material. At approximately 25 ft. below low water rock was encountered and a special drill scow with five drills was built with which some 200,000 yards of rock were removed and dumped in deep water. The pier is constructed with reinforced concrete faced timber cribs, consisting of twenty-three sections, each 99 ft. long, 40 ft. wide, and 39 ft. high. Each section of crib used approximately 500,000 ft.b.m., of B.C. fir. 1,550 cu. yd. of reinforced concrete, and 28 tons of reinforcing steel. The crib sections were constructed on launching ways to a height of 10 ft. and the concrete facing to a height of 8 ft., after which they were launched and then built up to their full height of 35 ft., floated into location and sunk into position. Upon the crib-work substructure was built a solid mass-concrete gravity retaining wall with a height of 18 ft., base of 13 ft. and top of 6 ft. This wall runs around the two sides and north end and forms the cope of the pier. Approximately 15,000 cu. yd. of concrete were used in this portion of the work. 400,000 cu. yd. of gravel were used to fill the cribs and bring the core of the pier up to cope level. The Lapointe pier, as built in 1913 and described above, is provided with grain galleries and the necessary spouting for loading grain direct to ships. Two sheds were built of mill construction, shed No. 1 being 676 ft. long by 79 ft. wide, and shed No. 2 being 842 ft. long by 98 ft. wide. The pier is provided with the usual trackage, which connects to the National Harbours Board Terminal Railway. The aerial view in Fig. 13 shows the pier before extension.

Due to the increasing length of the modern deep sea vessels, it was found that the pier was of insufficient length to accommodate two vessels on each side, and it was accordingly decided in 1933 to extend it by 310 ft., making the total length 1,110 ft. The type and method of construction was somewhat similar to the original work but in place of facing the four sides of each crib with concrete, only the water side was provided with a concrete face, the other three sides, which were eventually embedded in the fill, were merely sheathed with a double layer of creosoted lumber and made sufficiently water-tight to keep afloat during construction. 127,000 cu. yd. of mud and silt were cleaned from the site in order to obtain a solid bottom on which to place the foundation fill. The removal of soft material was essential by reason of the depth of water (90 ft. at low water), and to obviate the possibility of the gravel foundation fill and structure sliding after construction. The quantity of material used in the extension, comprising eight cribs, was approximately 4¼ million feet of B.C. lumber; approximately 300 tons of reinforcing steel, drift bolts, etc., and 9,000 cu. yd. of reinforced and mass concrete. The gravel fill required, including foundations, filling of cribs, and bringing the core to cope level, was 432,000 cu. yd.

It is interesting to note that the maintenance on the original structure built in 1913 and the extension built in 1933 has been very small.

### Ballantyne Pier

The Ballantyne pier is also located on the south shore of Burrard Inlet, and was designed and the work supervised by A. D. Swan, M.E.I.C., of Montreal. Construction was commenced in 1920 and completed in 1923. The length of the pier is 1,200 ft. on the east side and 1,070 ft. on the west side, the width of the pier being 341 ft. The inner berths are dredged to 35 ft. below low water and outer berths dredged to 45 ft. below low water. The elevation of the cope of the pier, N.H.B. datum, is 106.00. The pier is of reinforced concrete—beam and slab construction—supported on concrete cylinders, carried down to bed rock. The cylinders are seven feet in diameter, with a 9-in. wall. They were pre-cast in sections averaging 17 ft. in length. The bottom section was provided with a steel cutting edge which, in some instances, was enlarged to 9 ft. outside diameter, where additional bearing area was advisable. The cylinders were sunk through the fill by open dredging method, orange-peel buckets being used. The cylinders were located 20 ft. centre to centre longitudinally with the pier and 32 ft. transversely, to conform with the positions of the transit shed columns. They were sunk in position and filled with concrete. Approximately 85,000 cu. yd. of soft material was removed and 70,000 cu. yd. of rock excavated. The gravel core fill approximated 700,000 cubic yards. The pier is provided with three two-storey reinforced concrete sheds 108 ft. wide by 400 ft. long. The pier and sheds are served by seven railway tracks running its full length, and connecting with the National Harbours Board Terminal Railway. Thirteen electrically operated travelling cranes of three-ton capacity are provided for the handling of ships cargo. Grain conveyor galleries are located on the roofs of the sheds and several of the cranes on each side of the pier have been specially adapted for carrying grain from the galleries by means of spouting to the ships. This enabled the grain galleries to be carried at a low level, thereby very materially reducing the height of the steel towers and the overturning moment due to wind load. This in turn substantially reduced the foundation requirement. Approximately 96,000 cu. yd. of concrete were used in the entire works, and 6,100 tons of reinforcing steel. The pier is shown in Fig. 14 and is equipped with every modern appliance for the expeditious handling of cargo.

It was found during construction that all phases of the work proceeded in accordance with schedule except that of sinking the cylinders. Below the stabilizing fill and lying above the sandstone and conglomerate foundation, a considerable number of boulders were encountered. These materially delayed the completion of the sinking operations. Considerable time and expense would have been saved had the entire area been dredged free of these boulders before placing the stabilizing fill. This was done with satisfactory results on the No. 2 elevator foundation nearby, the construction of which followed the building of the Ballantyne pier.

Fourteen years of maintenance have shown some minor defects but in general the pier construction has remained in exceedingly good condition. The only deterioration in the concrete sub-structure has been found where the pre-cast trusses join the cylinders. Here some repair work has been necessary due to corrosion of the reinforcing steel.

Fig. 14—Ballantyne Pier, Vancouver Harbour.

The stabilizing fill continued to settle for several years after completion of the work and several breakages occurred in the flanged watermains which were laid in the fill. A flexible joint, or preferably a separate trench in which the watermains could have been suspended would have been advantageous. The same subsidence also caused a settlement of the inner bay in the transit sheds, resulting in a fracture of the floor slab along the line of the inner row of columns. Concrete roadways were constructed approaching the pier structure and between the transit sheds. Considerable abrasion resulted from the use of trucks and trailers in handling cargo between sheds, and this section of roadway had finally to be paved with an asphaltic concrete. Sand lime brick was used in the inside panels of the wall construction. These were unable to resist the driving rains of the coast and a plaster coat for waterproofing purposes had later to be added. The drainage system has had to be amplified to take care of the heavy rainfalls, the down spout system being materially increased over the original.

Fig. 13—Lapointe Pier and No. 1 Grain Jetty, Vancouver Harbour.

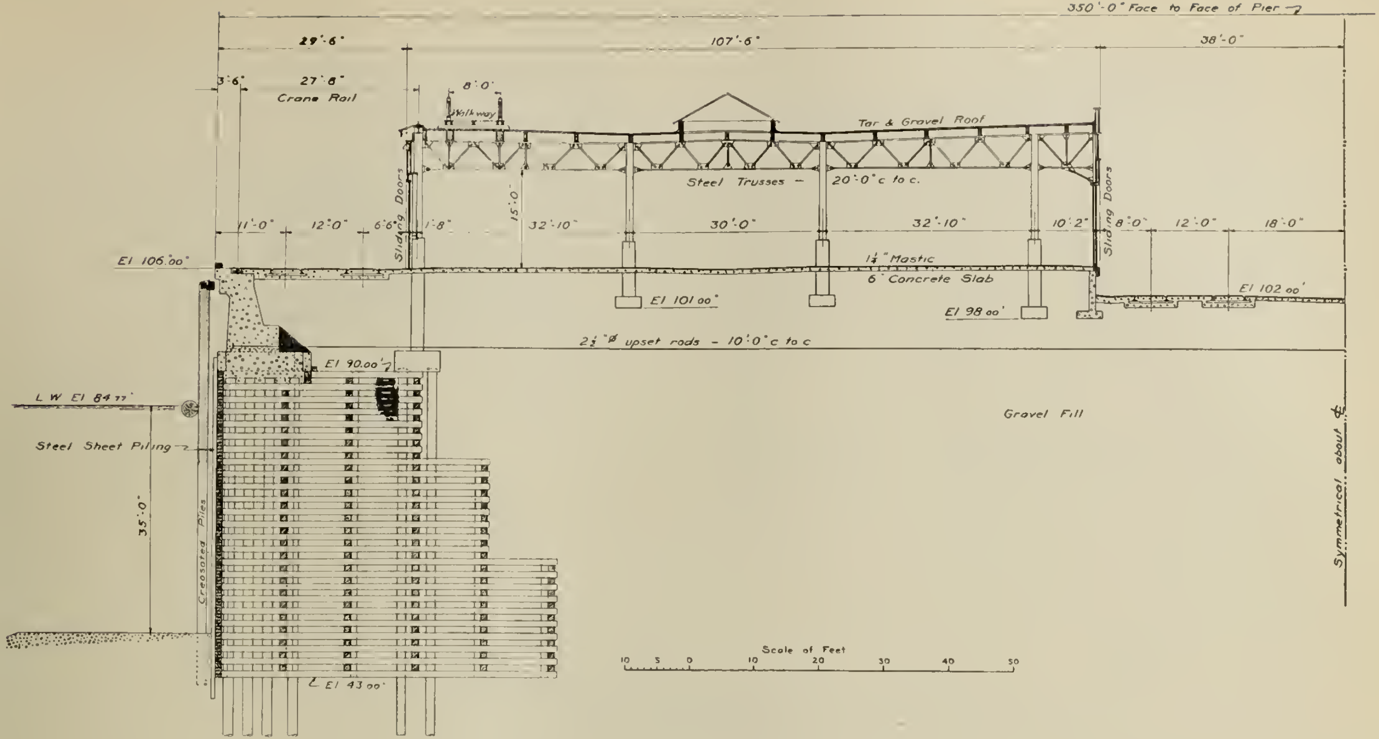

Fig. 15—Proposed Deep Sea Pier, Vancouver Harbour.

The value of the second storey in the transit sheds has been open to considerable discussion. At times the space had been almost entirely occupied with canned salmon storage. Its principal value lies in storing cargo where delayed shipment occurs. The lighting system has been entirely satisfactory in permitting the convenient handling of cargo. The wide pier apron has also been valuable for the expeditious handling of cargo. The width of the pier is ideal for the Pacific coast type of cargo.

### Proposed Deep Sea Pier, Vancouver Harbour

In the year 1929 Sydney E. Junkins, M.E.I.C., and the author were commissioned by the Vancouver Harbour Commissioners to prepare plans and specifications for a new deep sea pier to be located in the inner harbour of Vancouver on a centrally situated property of the Commissioners. Fig. 15 represents this pier in cross section.

The plans provide for the accommodation of deep-sea ships by the construction of a pier to the west of and adjacent to the existing Ballantyne pier. They contemplate a pier 350 ft. in width with a length of 1,547 ft. on the east side and 1,100 ft. on the west side, together with a connecting quay wharf, 320 ft. long. of creosoted piling and creosoted lumber across the end of the basin between the proposed pier and the Ballantyne pier.

The substructure of the pier will consist of a gravel fill retained by timber cribs surmounted by concrete walls on the outer edge. The timber cribs will be sheathed on the outboard face with interlocking steel sheet piling to protect them from marine borers. The space between the sheet piling and the timber cribs will be filled with sand. The substructure will have a spring fender system of creosoted piling.

The superstructure of the pier will consist of two transit sheds each 107 ft. 6 in. wide by approximately 1,062 ft. long. There will be a walkway along the roof of each shed on the outboard side for the accommodation of passengers.

At the south end of the westerly shed the necessary passenger accommodation will be provided, consisting of a baggage room and lunch room on the ground floor and a concourse, toilets, customs examination room and offices on the upper floor. The upper floor will connect with the walkways on the roof.

Along the outboard side of each shed there will be two railroad tracks and a track for semi-portal cranes.

Between the sheds there will be an area 76 ft. wide which will be depressed approximately 4 ft. below the floors of the sheds. In this area there will be a centre drive-way with two railroad tracks on each side adjacent to the sheds.

The surface of the pier and connecting roadways will be paved with concrete which will have a bituminous wearing surface.

The mechanical equipment of the pier will include a number of semi-portal cargo cranes and four marine elevators.

Crib construction of the type contemplated for this project has been used on several occasions in water front works in Vancouver harbour. Generally the cribs are partially completed on marine ways, launched and completed as a floating undertaking near by the site of the works. They are sunk by adding to the compartments a sufficient amount of sand and gravel filling to accomplish this purpose. In the case of the design in question certain parts were only to be partially filled originally, with the flooring of such thickness that the anchor and bearing piles would pierce these floors in driving.

In Vancouver harbour it has been the custom to protect the face and ends of these cribs against teredo action with concrete curtain walls. The principal variation in this case consists of the employment of interlocking steel piling driven around the entire outer face of the pier structure, having a minimum clearance of 3 in. from the crib timber, the top made fast to the concrete gravity section wall and the space between the steel piling and the crib timbers filled with sand to act as a filter for protection against marine borers.

The plan provides for the filling of the enclosed area hydraulically with sand and gravel of suitable consistency.

With respect to equipment, cargo cranes are fairly well known in Canadian harbours. Marine elevators,

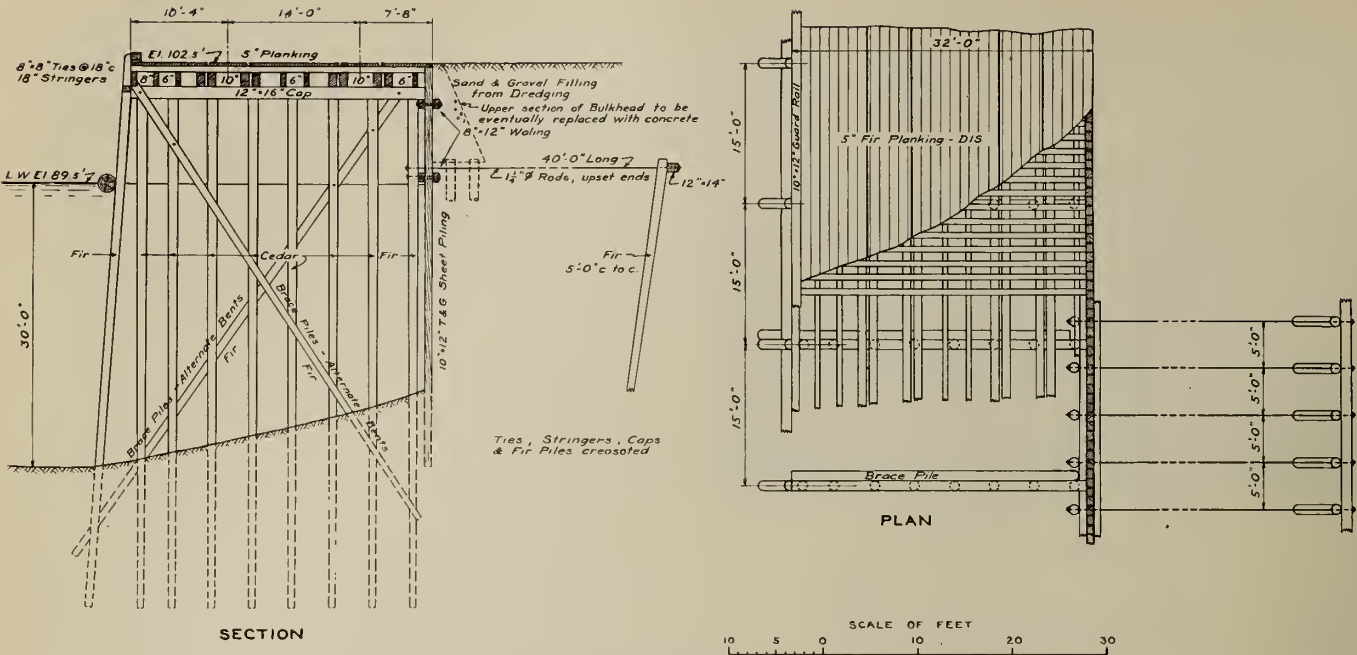

**Fig. 16—Typical Wharf and Bulkhead Construction, New Westminster, B.C.**

however, appear at the present time to have been made use of to any great extent in Vancouver harbour only. These consist of heavy platforms operating from the apron level of the pier to the deck level of lighters or of ships provided with side hatches, the stage of tide determining the extent of the lift. They are built of sufficient strength to permit the movement thereon, when resting at apron level, of railway cars and switching locomotives. They may be altered to act as ramps when the deck of the ship on which discharge and loading of cargo is proceeding is reasonably close to the apron level.

Due to the falling off of business in the year 1930 and the subsequent years of less than normal trade, the Commissioners decided to postpone indefinitely the construction of this pier. The site was, however, dredged free of soft material and the stabilizing fill, consisting of 1,200,000 cu. yd., has been completed.

## NEW WESTMINSTER HARBOUR

### Typical Wharf Construction

The port of New Westminster comprises the main channel of the Fraser river from the mouth to the confluence with the Pitt river, a total distance of 22 miles. In the past year, 1936, the business of this port in tons of cargo handled stood third in the Dominion.

Wharf or shore quay construction alone is suitable for the lower Fraser river. In many cases a wharf built on the bank of the river answers all requirements, but more frequently dredging is required. This can be economically combined with filling in rear to complete the area required for tracks, storage and other industrial purposes. The development cost is low, and except where heavy erosion of banks threatens, is very satisfactory.

The type of wharf construction shown in Fig. 16 has been satisfactorily employed in several projects, although generally creosoted materials are not initially adopted. There are no marine borers present so far in the lower Fraser river. Red cedar piling is therefore very durable and many structures of twenty-five years' life and over are to be found with 12 in. to 15 in. only of deterioration of cedar pile tops under the cap. The balance of the piling shows very little deterioration.

Many types of timber bulkheading have been used but the design in question has been tried and found eminently satisfactory. It is designed not only for the final loading but to resist hydraulic pressure during construction, since most of the dredging and filling operations in the port are carried out by hydraulic equipment. Care is taken, however, during the filling operations to avoid impounding water from the pumping behind the bulkheading.

Provision has been made in this design for cutting off and replacing by a concrete retaining wall that portion of the bulkhead above the lower tie rod connection. This is due to the deterioration and eventual destruction of the timber above the permanent wetted level.

Untreated wooden flooring has been found to be decidedly uneconomical and is giving way to an asphaltic concrete suitably supported on laminated construction. It has been found imperative to leave a half inch air space in the laminated base, otherwise dry rot is inevitable. This type of wharf is in general designed for standard railway loading less impact allowance, and where tracks are omitted for 500 lb. per sq. ft. live load. The foundation material is fine river sand, progressive refining occurring towards the mouth of the river. Skin friction alone supports piling which has an average penetration of 35 ft. Maximum pile loading of 25 tons per pile has been adopted as having a sufficient factor of safety. Piling varies from 9 in. tops to 15 in. butts. Eight pound creosote treatment of timbers appears to be satisfactory.

# Surveying and Mapping

*J. M. Wardle, M.E.I.C.,*
*Director, Surveys and Engineering Branch, Department of Mines and Resources, Ottawa, Ont.*

Probably no science can claim progress that is not intimately linked with agencies developed by other sciences and in few engineering activities is this more emphasized than in Canada's progress in surveying and mapping through the past fifty years. Progress in these related activities has been tremendously increased, methods improved and costs reduced by practical and far reaching discoveries in the fields of electricity, metallurgy, chemistry and physics, and mechanics.

In the electrical field, communication by wireless through radio signals has brought speed and accuracy to astronomical observations; in metallurgy the discovery of invar with an almost negligible coefficient of thermal expansion has given increased accuracy in the direct measurement of distance; in chemistry and physics the introduction of infra-red photography and echo-sounding apparatus respectively have had tremendous beneficial effects; and in the great field of mechanics the internal combustion engine, the aeroplane and the modern aerial camera have combined to give swift transportation and accurate and extensive topographical information at greatly reduced costs. Yet in looking back over fifty years, there is the striking fact that while modern instruments have given increased precision, the spectacular advance has been made in the use of faster and less costly methods.

The surveyor or engineer of fifty years ago was as interested in keeping the human factor of error to a minimum as his successor of to-day and the results obtained in the early surveys command admiration and respect.

Many years before 1887 Canada's surveyors were busy with the opening up of a new country, some on land surveys, some on river control and reclamation projects, some on road and railroad location. Many went west during the early eighties when the Canadian Pacific Railway was under construction. In British Columbia they followed the Royal Engineers who in 1858 brought the first surveyors to that province. Throughout Canada and particularly in the western provinces these pioneer surveyors contributed greatly to the country's development. Their works bear witness in many localities and their names are perpetuated by river or mountain or town across the Dominion.

Because of her youth and tremendous unmapped areas, Canada has perhaps benefited more than any other nation through the development of modern survey and mapping methods. Nor has this country failed in itself to contribute substantially to such development. Possibly the greatest single advance in mapping work, namely, photo-topographical surveying, was developed for practical use in Canada by the late Dr. E. Deville, for many years Surveyor General of Dominion Lands. Another important contribution towards placing surveying practices on a sound basis was that of the late Dr. W. F. King, Chief Astronomer, International Boundary Commissioner and Superintendent of the Geodetic Survey of Canada. A bronze tablet on the summit of King Mountain, a few miles north of Ottawa, marks the beginning by Dr. King at that point of the geodetic triangulation network in Canada.

### Survey Organizations—Historical

To obtain a clear picture of the advances in surveying and mapping during the last half century, one must understand something of the evolution of the Canadian

**Fig. 1—Map of Eastern Canada. Reproduced from a Map by Duchesneau dated 1681.**

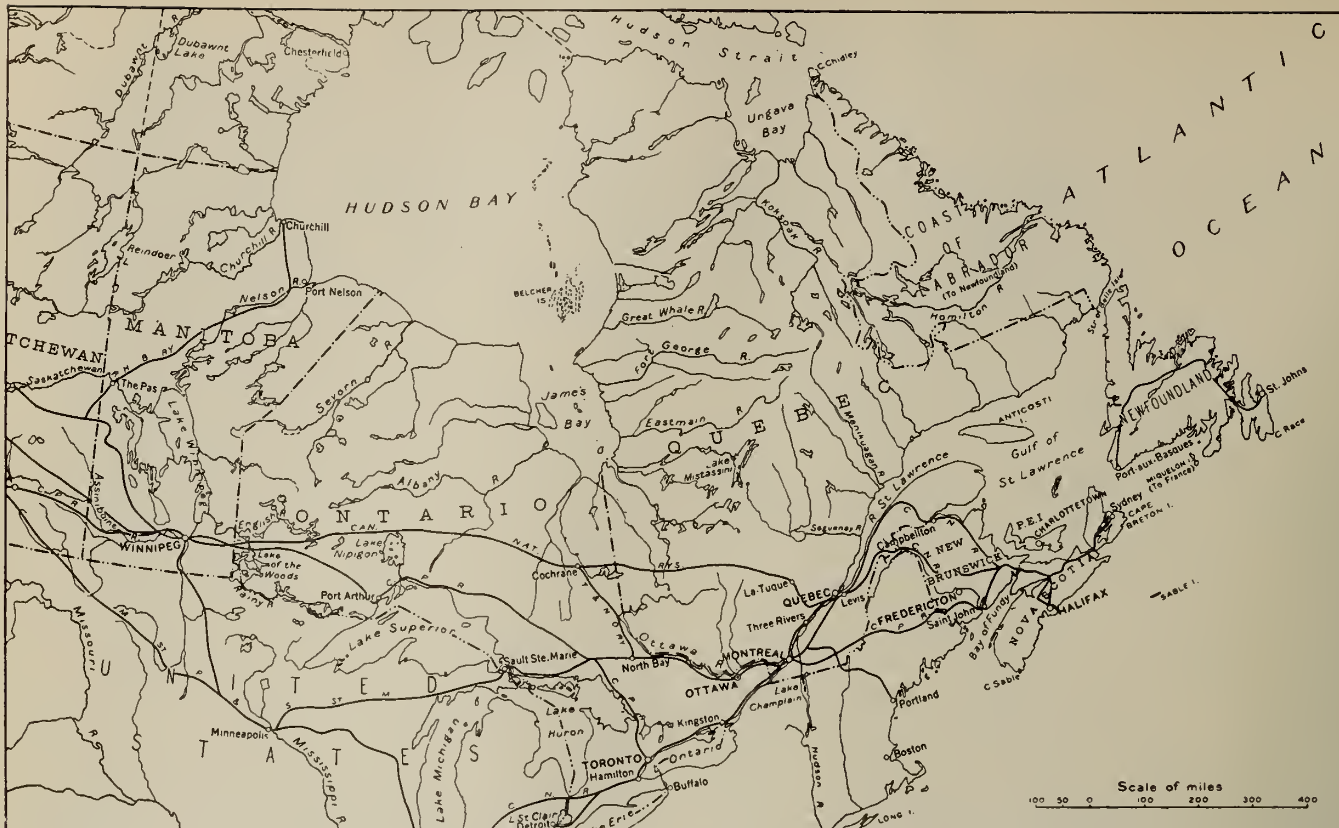

Fig. 2—Map of Eastern Canada 1937.

Survey organizations. Under the terms of Confederation the administration of their natural resources was a responsibility of the various provinces of the Dominion and hence the execution of the cadastral surveys, that is, the subdivision of provincial land into units for agriculture, forestry, mining or other uses was and still is a function of the provincial governments. Federal authorities, however, continued these surveys in the provinces of Manitoba, Saskatchewan and Alberta and in the Railway Belt and Peace River Block of British Columbia until 1930. In that year the four western provinces, under the Transfer of Natural Resources Agreements, took over the administration of all provincial lands within their boundaries, including the undertaking of land surveys.

Much of the mapping done prior to 1887, and for many years afterwards, was thus based on information secured by Dominion Land Surveyors in carrying on cadastral surveys and from other surveys undertaken by Provincial surveyors. An exception to this was the topographical work undertaken by the Geological Survey of the Dominion Government. Established in 1842, this organization issued topographical maps in order to locate and show geological data. For the next fifty years many of the best topographical maps that were available came from this source and at the present time a large proportion of topographical surveying in Canada is undertaken in connection with the work of this unit.

While surveys of water routes and other physical features naturally supplied additional information, topography was for many years more or less a secondary consideration.

After the first organized land survey in Canada was commenced in Prince Edward Island by Captain Samuel Holland in 1764, the magnetic compass continued as an important survey instrument for over a hundred years, or until 1870. The following year, 1871, the first monument of the Dominion Lands Survey System was placed on the Principal Meridian.

Prior to 1883 all charting of Canadian waters was carried on by the British Admiralty. In that year the Hydrographic Service of Canada was organized. Its operations were confined to the Great Lakes until 1904. In that year the Canadian organization commenced operations on the Atlantic coast and in 1906 undertook the work on the Pacific coast.

In 1886 a start was made in mapping sections of the Rocky Mountains by photo-topographical methods. This method of mapping has been much more extensively used in western Canada than in any other country and with some improvements has remained in use to the present time.

While by 1887 the several sections of the International Boundary between Canada and the United States had already been defined in a series of treaties, demarcation was only partial, and the nature of the marking was such that it was in many cases rapidly disappearing. Water sections of the boundary were practically unmarked, no accurate maps of them were available, and in addition the boundary between Canada and Alaska had yet to be determined. As a result of these conditions, the past fifty years has seen the entire International Boundary between Canada and the United States and between Canada and Alaska surveyed. and a belt along the boundary mapped.

Figure 3 is a view looking eastward along the International Boundary at Fort Frances, Ontario, and International Falls, Minnesota; Rainy river in the foreground, Rainy lake in the distance.

In 1891 the first sectional sheets on a scale of three miles to one inch were prepared from Dominion Lands Surveys and additional information gradually made possible accurate topographical maps of the settled lands in the prairie provinces. Compiled maps of Canada and of sections of Canada were being prepared from time to time so that in 1903 the first standard topographical map appeared which covered a portion of Ontario. This type of map, issued by the Chief Geographer of Canada, eventually covered most of eastern Canada and parts of British Columbia.

The Geodetic Service of Canada was officially created in 1909 but had already begun in 1905 the precise levelling and primary triangulation that were to form the framework of accurate control for all survey work in Canada. While proved in value by world experience and while particularly necessary because of her tremendous areas, Canada was nevertheless one of the later countries to initiate national geodetic control.

Following the Great War, national mapping in Canada was given its greatest impetus through the agencies of the aeroplane and the aerial camera. Experiments in vertical and oblique photography initiated by an Air Survey Committee appointed in 1919, showed in succeeding years the great possibilities of the new methods; the year 1924 saw the practical adaptation of aerial photography to surveying and mapping on a large scale. In the thirteen years of the new science of mapping, areas have been photographed to an extent undreamed of—and in fact impossible—with the old ground methods.

By vertical photography there have been covered to date 187,800 square miles; by oblique photography 505,000 square miles, or a total area almost equal to the combined areas of France, Spain, Germany and Italy.

No outline of the past fifty years of surveying and mapping in Canada would be complete without some mention of precise levelling and of the compilation "Altitudes in Canada." In early days elevations in the interior were at best approximations only, being based on aneroid readings or level lines of the early railroads. Levels for engineering projects were based on the best datums available and in many cases assumed datums were the basis for all levels in a locality.

The first precise levels in Canada were run by the Department of Public Works in 1883 to furnish accurate vertical control for harbour and river improvements, this net being largely confined to the St. Lawrence river and the Great Lakes. In 1931 this levelling system was amalgamated with that of the Geodetic Service.

In 1912 the Topographical Survey of Canada started precise levelling in the three prairie provinces to check and reduce to mean sea level datum the great mass of levelling information resulting from tertiary levels which were being carried on with the original land surveys. In 1925 this system of levels was also amalgamated with that of the Geodetic Service.

The original "Altitudes in Canada" appeared in 1901 and was compiled by the late James White when a member of the Geological Survey of Canada. Probably no government publication has been received with greater avidity; practically every engineer in the country had long felt the need of such information. Following the great expansion of railroads between 1901 and 1915, the second edition of "Altitudes in Canada" was printed in 1915 and contained much more than double the information available in the first work. In 1925 all of Mr. White's records were turned over to the Geodetic Service and several volumes covering parts of Canada have lately been issued or are in course of preparation.

In 1936 the survey organizations of the Federal Government were brought under the newly created Department of Mines and Resources, with the exception of the Geographical Section of the General Staff of the National Defence Department which undertakes considerable topographical work in order that a survey nucleus may be available in times of emergency.

To summarize the situation it might be said that at the present time all the cadastral survey work in the provinces is undertaken by them or under their control. The Dominion Government undertakes all cadastral surveys in Dominion areas including the Northwest and Yukon Territories. The Dominion also undertakes the main geodetic nets of triangulation and precise levelling and all hydrographic surveys.

In the field of mapping, British Columbia through photo-topographic surveys in her mountain areas makes an important and extensive contribution. The province of Quebec also issues a number of maps based on aerial photographs and other survey information. Elsewhere mapping is largely being undertaken by the Dominion, particular attention being paid to areas where natural resources such as mining and water power promise development. Excellent co-operative assistance is provided by the provinces through their cadastral and other organizations. At least three provinces—Quebec, Ontario and British Columbia—publish geographically compiled provincial maps, but otherwise the issuing of topographical and geographical maps, and of charts, is largely undertaken by the Dominion.

### Progress of Mapping

Some idea of the achievement in mapping to date may be given by a brief description of the three most important series of systematized topographical map sheets that have been issued by Dominion organizations. The sectional map sheets of western Canada, which have been extremely useful over many years, cover about 4,320 square miles. A total of 121 sheets have been issued. The Geographer's Standard Topographical Map was issued at scales of 3.95 miles to the inch and 7.89 miles to the inch, each sheet covering 7,500 square miles and 30,000 square miles respectively. A total of 56 of these sheets has been issued, mainly covering eastern Canada. This class of maps has now been discontinued and is replaced by what is called the National Topographic Series. The sheets of this series are of uniform size. The one mile to one inch sheet covers about 400 square miles, areas of other sheets varying with the scale. Of the large scale mentioned—one mile to one inch—150 sheets have been issued, chiefly by the Geographical Section of the National Defence Department. Of the two miles to one inch

**Fig. 3—International Boundary between Ontario and Minnesota at Fort Francis.**

sheet, 62 have been published; of the four mile sheets—58; of the eight mile sheets—9.

For convenience a table has been prepared—Table I—giving the area of Canada that has been covered by accurate maps at varying scales up to four miles to one inch.

Among important topographical maps that naturally have not been produced in a systematized or grid series are those of the Geological Survey for depicting geological information, and the hydrographic charts which cover Canada's sea coasts, waterways and harbours. The latter number some 480 and include standard mariners' charts for navigation, special charts for radio direction finding purposes, current charts and charts for general marine information.

## COMPARISON OF SURVEY METHODS—1887-1937

### Magnetic Surveys and Azimuth Determinations

Although the magnetic compass and the magnetic meridian had been partially superseded for the running of survey lines by the transit theodolite and astronomical meridian in 1887, yet the former has continued, to a small degree, even to the present time.

The uncertainty of compass readings due to diurnal and yearly variation, but more, perhaps, to the local attraction of magnetic substances, is very great, and many compass lines, if viewed from above, would appear snake-like instead of straight. It is easily realized that in any compass survey of large areas, when linear inaccuracies are also taken into account, errors of position of the order of several miles may easily result.

Although the use of the astronomic meridian as the basis of azimuth was in use fifty years ago, the instruments and methods were cumbersome and slow as compared to present-day practice. The telescopes of the average surveyor's transit of that day were not sufficiently powerful to observe on the Pole Star in the day time, and even if they had been considerable computation was necessary, so that surveyors in those days usually preferred to observe at night when the star was at elongation. Many surveyors will vouch for the inconvenience and tribulations attendant upon these night observations.

Let us consider now the advantages the present-day surveyor has over his predecessor of fifty years ago. Improvements in optical parts of theodolites now permit a sight on Polaris at any time of the day. There is no difficulty in seeing a star with any present-day surveyor's theodolite within an hour or two before dusk, or after dawn, when there is still sufficient daylight for all ordinary operations. Surveyors are further provided with mathematical tables that give the azimuth of the star at each ten minutes of time within the twenty-four hours and for different latitudes. With a modern transit-theodolite and sidereal watch a surveyor can orient his telescope to sight on the star in broad daylight, take one or two observations by the most approved methods in a few minutes, and by the aid of astronomical field tables quickly reduce the observations, the resulting azimuth being correct to within a few seconds.

The changing of the basis of direction for survey lines from magnetic to astronomical bearings, and the simplifying of the azimuth observations, are perhaps among the most important developments of the past half century in the improvement of cadastral and mapping surveys.

### Longitude Determinations

Modern agencies have also greatly simplified the determination of longitude as compared with fifty years ago. At that time astronomical observations for latitude had already reached a high degree of precision, but those for longitude were seldom as satisfactory.

The most accurate method of determining longitude required an exchange of time signals over a telegraph line between a point of known longitude and the one whose position was required. Consequently north of the telegraph lines near Canada's southern border, the only methods of determining differences of longitude were by the transportation of chronometers and by lunar methods, both of which were subject to considerable errors, and the latter method was arduous and slow.

Unknown variation in the rating of chronometers could result in large errors. This is exemplified in the case of early charts of the east coast of Hudson Bay where recent determinations of longitude show an error of the shore line given on the old charts of some 30 miles. In determination of longitude by lunar methods the most painstaking care was necessary to ensure reasonable accuracy. This is well illustrated by the accomplishment of the late William Ogilvie just fifty years ago in determining the point where the 141st meridian crossed the Yukon river in the Yukon Territory, information which was to be used in fixing the Canada-Alaska boundary. Lacking telegraphic communication and with the transport of chronometers not feasible, Mr. Ogilvie was dependent on lunar methods for his determination of longitude. Following a micrometer traverse from Lynn canal over Chilkoot Pass and down the Yukon river, Mr. Ogilvie established winter quarters at the 141st meridian as determined from his traverse. During the winter of 1887-88, he determined the longitude of his station by the method of moon culminations. When eighteen years later the longitude of the meridian was determined through telegraphic exchange of time signals,

Table I

Areas Mapped in Canada to Various Scales

| Scales | Accurate contours Sq. miles | Percentage of Canada | Approximate contours Sq. miles | Additional Accurate planimetry Sq. miles | Total Accurate planimetry Sq. miles | Percentage of Canada |
|---|---|---|---|---|---|---|
| Up to and including 1 mile to 1 inch | 71,960 | 1.9 | 4,800 | 700 | 77,460 | 2.1 |
| Between 1 and 2 miles to 1 inch (including 2 miles to 1 inch) | 25,800 | 0.7 | 9,800 | 48,800 | 84,400 | 2.3 |
| Between 2 and 3 miles to 1 inch (including 3 miles to 1 inch) | 9,800 | 0.3 | 155,200 | 8,200 | 173,200 | 4.7 |
| Between 3 and 4 miles to 1 inch (including 4 miles to 1 inch) | 63,000 | 1.2 | 66,000* | 310,900 | 388,600 | 10.6 |
| Totals = Areas up to, and including 4 miles to 1 inch | 170,560 | 4.1 | 235,800 | 368,600 | 723,660 | 19.7 |

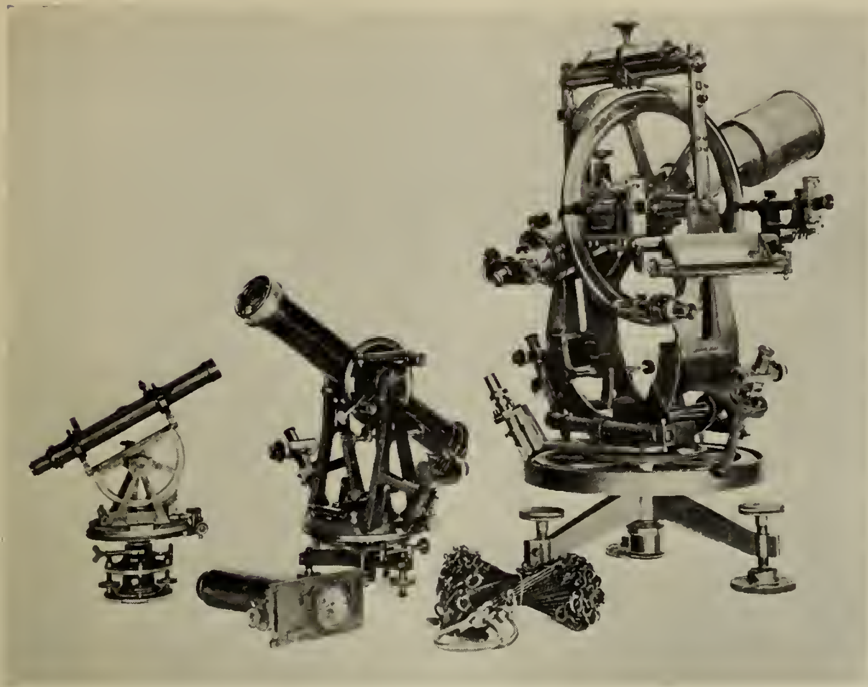

Fig. 4—Old Types of Surveying Instruments.

In Fig. 4 reading from left to right the instruments are: old type of theodolite; split lens type of micrometer used for distance measurements, accuracy about 1 in 200; micrometer theodolite for running governing survey lines, horizontal circle reading to 10 seconds, vertical circle reading to one minute; 100-link Gunter's chain; 12-inch altazimuth used for high precision astronomical work and primary triangulation, horizontal and vertical circle readings to one second. The old instruments are all characterized by great weight and long telescopes, and may be compared with the lighter short telescope modern instruments shown in Fig. 5. The scales of Fig. 4 and 5 are approximately equal.

Figure 5 shows: upper row—sounding sextant reading to one minute; precise level. Lower row—Prismatic astrolabe for astronomic latitude and longitude; surveyor's transit, horizontal circle reading to 20 seconds, vertical circle to one minute; transit theodolite for high class surveys, horizontal and vertical circles reading to one second; primary triangulation theodolite both circles reading to 0.2 seconds. The introduction of the internal focusing lens permitted great shortening of telescopes, and this and other improvements have allowed great reduction in size and weight to be made, with increased precision.

Mr. Ogilvie's position was in error only 218 feet, a truly remarkable achievement, but one involving a large amount of time and labour.

Present-day methods after fifty years are startling in their ease and simplicity. In 1936 during aeroplane mapping by oblique photography of the Northwest Territories, and with astronomical latitude and longitude used as a basis for aerial mapping, two observers determined the positions of thirty points in two summer months. Aeroplane transportation was provided by the photographic planes; each party was equipped with a radio transceiver with which the observers were able to receive accurate time signals from sending stations on two continents; and daily two-way telegraphic communication was maintained with the aeroplane base.

Precision of astronomical observations for latitude and longitude is not absolute, due to the deflection of the gravitational force, and the average station error of many astronomical positions in Canada amounts to about 600 feet However, accuracy of position of even the above order is a tremendous improvement where land features on existing maps may be many miles in error, and this means of control is exceedingly useful for small-scale maps in northern Canada where geodetic control has not yet been laid down.

### Instruments

The surveyor of 1887 generally used the old-fashioned theodolite for cadastral work, although even then the transit was coming into use. On Dominion Lands Surveys of that time both 3-inch and 6-inch transits were in use, the latter instrument reading to 20 seconds of arc. The replacement of the theodolite by the transit on legal survey work was, however, not rapid, and even in recent years surveyors in private practice have continued the use of the original instrument. As would be expected, present-day transits embody radical improvements in design as compared with the types of fifty years ago. Important developments include large telescope apertures with decreases of focal length, internal focussing lenses and increased precision in circle graduation and circle readings. The most noticeable change of all is the smaller, more compact and much lighter instruments, beautifully machined and modelled.

### Linear Measurements

A vital factor in survey practice, fifty years ago, as now, was the linear measurement of distances. The old wire chains, on which the surveyor of fifty years ago relied for his distance measurements, are familiar to everyone. Manufactured in 66 and 100-foot lengths and consisting of 100 links, each chain had 600 or 800 bearing surfaces to wear and gather mud or ice, and 400 or 500 loops which might stretch or open under tension. Variations in measurements were consequently inevitable even apart from lack

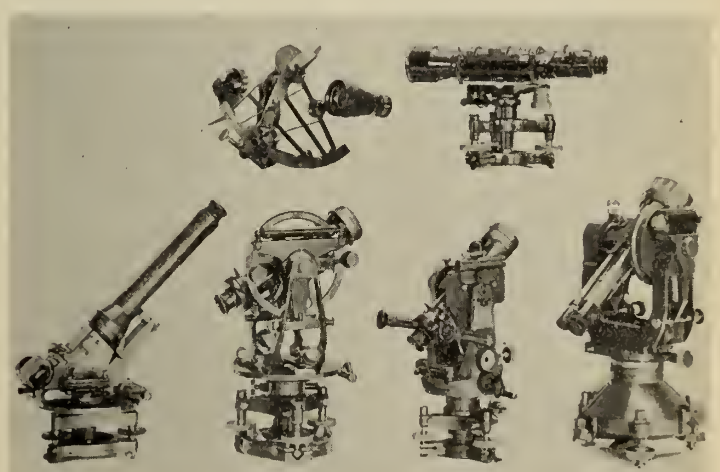

Fig. 5—Modern Surveying Instruments.

of standardization in chain lengths. An interesting example of chainage error in early surveys is provided by the results of the retracement of parts of the Principal Meridian which runs northward a short distance west of Winnipeg. This line was first run in 1871 and was retraced in 1912. The length of each section along this meridian (excepting the road allowances) was supposed to be exactly 80 chains, or one mile. Actually the retracement showed the lengths of the sections to be those given in Table II.

Courtesy of Royal Canadian Air Force.

**Fig. 6—Looking eastward up the Vermillion Pass in the Rocky Mountains, Kootenay National Park. Banff-Windermere Road in the Foreground.**

Table II

Actual Lengths of One-Mile Distances Obtained on Resurvey

| | Tp. 6 Chains | Tp. 9 Chains | Tp. 13 Chains | Tp. 15 Chains |
|---|---|---|---|---|
| Section 1......... | 80.25 | 80.12 | 80.18 | 80.20 |
| Section 12......... | 80.23 | 80.20 | 80.21 | 80.20 |
| Section 13......... | 80.24 | 80.21 | 80.19 | 80.22 |
| Section 24......... | 80.26 | 80.23 | 80.21 | 80.23 |
| Section 25......... | 80.24 | 80.20 | 80.20 | 80.28 |
| Section 36......... | 80.26 | 80.21 | 80.20 | 80.23 |

The chain used in the original survey was a Gunter's 66-foot chain. On the retracement a 300-foot steel tape was used which had been carefully standardized. Considering the conditions under which the original survey was made, the uniformity of the figures in Table II shows that a great amount of care was taken in the actual field measurements; also that the chain must have be n too long by a ratio of approximately 1 in 400, an error which might be compared with the present precision of similar surveys of 1 part in 2,000 to 1 part in 5,000 or better.

Improvement in the mechanics of linear measurement while not enjoying the scope of instrument design and manufacture, has been very noticeable. The development of the steel tape, the standardization of chain and tape lengths, and the use of alloys with a low coefficient of expansion are important factors of progress in the last half century. Corrections for temperature, sag, stretch and slope must, however, still be made.

The first record of steel tapes on surveys in the Dominion was in 1886 when a 66-foot steel band was used on a traverse of the Canadian Pacific Railway through the Rocky Mountains. Today steel tapes varying in length from 66 feet to 500 feet are used entirely. For extremely accurate measurement, such as geodetic base lines, invar tapes or wires are used.

### Hydrographic Survey and Charting

In no branch of surveying is accuracy and reliability put to a more definite test than in the survey and charting of Canada's coastal and inland waterways. With the development of modern navigation, involving greater draught, higher speed and more intense competition, modern accurate charts are a necessity and in constant demand. Improvements in ships and increased sea traffic must be met with improvements in navigation safeguards. Comparatively fast speed in fog and cutting of corners may save for a ship the fuel and other expenses that will turn loss into profit. To carry on this practice safely, there must be absolute reliance on the accuracy of the marine chart. So great has been the progress in charting over the past fifty years that not only is it difficult to cover it briefly, but the methods of 1887 seem primitive and inadequate. The magnetic compass has been replaced by the gyroscopic compass, and the sounding lead by the echo-sounding instrument. In both hydrographic work and navigation the direction of the course is checked and determined with the highly developed radio direction finder.

Of all charting aids, that of the echo-sounding instrument for determining depth is without doubt the greatest and most important innovation. In speed, scope and accuracy the modern method far surpasses the old hand-line and wire sounding devices. A ship equipped with an echo-sounding instrument can follow a charted channel under the worst fog conditions. Canadian hydrographers have been among the first to adopt this method of accurately plotting sea-floor topography. Today all hydrographic steamers are equipped with this modern instrument and many of the launches as well.

While the sea floor is plotted through the mechanics of sound, plotting of the coast line has kept pace through aerial photography. Used in conjunction with triangulation along the coast, topographical features can be accurately plotted in the detail desired and in addition a saving in cost effected. The responsibilities of Canada's Hydrographic and Map Service include not only marine charts, but the collection in the field of the necessary information for the compilation of publications important to navigation interests, such as Sailing Directions and Tide Tables. In addition the Precise Water Levels Division of the Hydrographic Service records and analyses the fluctuations in levels of the Great Lakes and St. Lawrence Waterway System from Port Arthur to Quebec. Probably no branch of surveying more quickly reflects its value in the commercial world than does hydrographic survey work, the accuracy and completeness of which is very definitely reflected in marine insurance rates.

### Aerial Surveying

The limits of this paper do not permit adequate expression of the tremendous advance in topographical and other survey methods made possible by aerial photography. So young is the science, so rapid the developments in planes, cameras and plotting equipment and so great the possibilities of application that any description of present practices can only be regarded as depicting a transition stage. Already ground methods of mapping in Canada, except in mountainous areas, have practically disappeared. Control points are of course still fixed by ground methods.

There is no fair comparison between ground and aerial mapping. Under ground methods only those features a surveyor actually locates by measurement or indicates by sketches can be mapped. The proposed scale of the map governs the number of measurements to be secured and the cost of the work is dependent upon the area to be covered, the character of the country and its accessibility. Even in settled or open country, the wealth of accurate detail that is on call to the surveys engineer from aerial photographs, and the speed with which an area can be covered, gives the advantage to the aerial method.

In Canada vertical photography is used in rough country where a stereoscopic examination of over-lapping photographs enables inequalities of the ground surface to be portrayed. Oblique photography has been found most suited for country of minor relief and where small scale maps will meet requirements.

Control for plotting from aerial photography is taken from geodetic triangulation wherever available. Such control is generally extended by subsidiary triangulation, traverses, cadastral survey data and photo-topographical surveys. On small scale maps plotted from obliques, adequate control is cheaply provided through astronomical observations of latitude and longitude made at intervals of from 50 to 75 miles.

Many instruments have been developed to facilitate plotting and contouring from aerial photographs, some of which are complicated and expensive. Less elaborate machines, suitable to Canadian conditions are now being developed, some of them in Canada.

Aerial surveying is naturally a field undreamed of by the surveyor of fifty years ago. The production of the topographic map is only one of its uses. The photographs themselves are a veritable mine of information and one trained in their interpretation can extract valuable and definite information relative to geology, forestry, highway, railway and transmission line location, flood control, water power, irrigation and other fields too numerous to mention. These multiple uses of aerial photographs provide an entirely new field of basic information for design and cost analysis. The extensive information available has already effected startling savings. In one recent case a map plotted from aerial surveys showed a possible reduction in the length of a projected road which saved, in construction costs, an expenditure equivalent to a substantial part of the cost of aerial photography for a whole season. Such possibilities must be kept in mind when the cost of mapping from aerial photographs is under consideration. Estimates of mapping cost naturally vary but the figure most commonly used in Canada is about $6.00 per square mile for uncontoured maps, excluding any other uses for the photographs. Contracts at $7.50 per square mile for flying only were made in 1936. Recent United States figures for aerial photographs vary from $3.00 to $18.00 per square mile, depending on the scale and the size of the area to be covered.

To what extent these figures will be changed by the rapid development of aerial surveying no one can accurately foretell. Almost within the last year the nine lens camera, covering some 550 square miles in one exposure, has been developed. Automatic taking of photographs with timing set to provide any desired overlap and the subsidiary camera to automatically record time, temperature, altitude, tilt, etc., are already accomplished facts.

### Geodetic Surveys and Control

Accurate horizontal and vertical control are vital factors in the survey of a large country. Detail surveys of small areas are naturally made with a degree of precision suitable only to local requirements, but the accumulation of errors when extended to large areas produces compilation anomalies and difficulties of major importance. Such has been Canada's experience, and the Geodetic Service was established to provide a national network of permanently marked points whose accurate relative positions (altitude, longitude and elevation) are determined. By this means the accuracy of other surveys by government or private organizations can be checked, their errors segragated, and the results of disconnected and frequently conflicting surveys co-ordinated.

Continuous geodetic surveys have not yet been extended much beyond the limits of the area served by railways, so that in northern Canada control for mapping

Fig. 7—Survey Party using Scow Transport down Peace River, 1916.

and charting operations is based on astronomic positions and, for altitude, on local level datums.

For geodetic surveys, triangulation methods are generally employed. Stations are placed on the highest hills, and are, in work of greatest precision, preferably spaced at approximately 25-mile intervals. Distances as great as 150 miles between stations are occasionally necessary in Canadian practice, such as those spanning Cabot Strait between Cape Breton island and Newfoundland, across the Gulf of St. Lawrence west of Anticosti island, across Lake Superior and between Queen Charlotte islands and the British Columbia mainland.

The angles of primary triangulation are measured at night when air conditions are more conducive to accuracy,

Fig. 8—Loading Surveyor's Equipment for Transport by Air. Fort Smith, N.W.T., 1936.

sights being made on electric signal lamps operated by dry cells.

The high accuracy of the primary triangulation nets is not required for most purposes of control. Consequently, secondary nets adequately serve local purposes and are much in demand for topographic, hydrographic and other requirements. In this class of triangulation work, stations are spaced at intervals of 5 to 15 miles and sights are made in daylight by cotton signals. Positions of latitude and longitude are calculated on the North American Datum established in Kansas, to which all geodetic work in Canada, the United States and Mexico is referred.

No important change in standards of accuracy has occurred in geodetic practice in the last half century, although remarkable improvements in methods have taken place. Electric signal lamps of increased power and penetration have displaced kerosene and acetylene lamps. The aeroplane has been used in the selection of sites for triangulation stations with remarkable success. The introduction of invar tapes has greatly reduced the cost of base lines and the heavy instruments of the past have been replaced by smaller, lighter and more quickly operated theodolites.

The Canadian precise level system is based on Mean Sea Level as determined at three tidal stations on the Atlantic and two on the Pacific established by the Hydrographic Service. When the first transcontinental line of levels was completed in 1916, the discrepancy between Atlantic and Pacific amounted to only six-tenths of a foot.

There has been little or no change in the standards of levelling accuracy since the beginning of the century.

The importance of permanent bench marks is now more fully appreciated and the supporting structures are very carefully chosen. These consist of building foundations, bridge abutments, bed rock, or especially built concrete piers. In large towns and cities, bench mark piers of great permanence are established at selected sites.

### Transport and Communication

The exploratory engineer or surveyor usually precedes settlement and as a consequence has been largely dependent upon the more primitive forms of transport. Until a very few years ago the transport and maintenance of a survey party in our Canadian hinterland was a greater problem than the carrying on of the survey itself. In common with his predecessor of 1887, the surveyor of a few years ago relied upon the man, the horse and the dog for motive power, using such overland equipment as carts, wagons, sleighs and toboggans. The pack train was common, as well as the earliest form of transport, namely back-packing. Canada's numerous and far-reaching waterways gave, in many cases, the sometimes fortunate alternative of the river boat, canoe, scow or raft. Base line surveyors easily recall the year-long field expeditions which, coupled with almost absolute lack of communication, entailed nearly as much planning and forethought as the Arctic expedition of the present day. Nearly every surveyor remembers his dependence upon the head-packer and the relief felt when the pack-train returned on schedule with its supplies from the frontier town, where perhaps the arrival of the pack-train had coincided with a local celebration.

But science and modern methods have revolutionized survey transport. The automobile and tractor, the outboard motor and most wonderful of all, the aeroplane, have largely relegated the problem of transport to the background. Journeys that formerly required weeks or months of travel are now accomplished in a few hours. Canada's northland, so recently remote, vague and inaccessible, has been brought through the agencies of aerial flight and water almost to the back door of her towns and cities. Air transport of animals, supplies, and equipment and machinery of all kinds is now commonplace.

Radio transmitting and receiving sets ensure instantaneous communication and coupled with aeroplane service, save time and money, rectify mistakes and reduce personal hazard. In the past winter between December and March a survey party completed a 115-mile north-easterly extension of the Ontario-Manitoba boundary line. An aeroplane took in personnel and equipment, moved camp when requested through radio communication, brought in further supplies at the same time, and brought out personnel and equipment when the winter's programme was completed; a modern accomplishment that could not be visualized fifty years ago.

In conclusion it can be said that Canada's progress in surveying and mapping has, through the past half century, kept pace with her needs. With her increasing development will go an increasing need for additional surveys, maps and charts. Even with the much older development of European countries, it is recognized that the mapping of their comparatively small areas will never be wholly completed. Canada is a huge country with great natural resources that depend for development on transport by air, land and water. In mapping the tremendous areas covered by these resources and in mapping and charting their routes of travel, Canadian surveyors seem to have an almost unlimited field of service.

# The Development of Aviation

*J. A. Wilson, M.E.I.C.,*
*Controller of Civil Aviation, Department of Transport, Ottawa, Ont.*

THE PRE-WAR PERIOD

A century before the foundation of the Canadian Society of Civil Engineers, the Montgolfier brothers made the first balloon ascents in France. During the nineteenth century Lilienthal in Germany, Pilcher in England and Chanute in the United States experimented with gliders. These activities in lighter- and heavier-than-aircraft were the foundation on which was built our modern aviation.

Canada took little part in this work. Though no doubt occasional balloon ascents were made, the only record of the design and construction of an original flying machine in Canada during the nineteenth century, which can be traced, is that of Mr. Charles Pagé, of Montreal. His invention was a dirigible, cigar shaped balloon, from which was suspended a nacelle. Descriptions of the machine and the method of operation were published in two articles in the Montreal Witness on May 14th and June 18th, 1879.

A trial flight was made on June 21st, 1879, using an ordinary spherical balloon. No hydrogen was available and city gas had to be used, which made it necessary to discard part of the propelling machinery to lighten the load. The ascent was made from the Shamrock Lacrosse grounds in Westmount. An exciting landing not without risk in the darkness, was made 45 miles away near Ste. Hyacinthe. The flight led to no practical result, but showed that even in those days Canadians were not insensible to the importance of aviation.

As the new century dawned, experiments in both Europe and North America intensified. Mr. W. R. Turnbull was the father of aeronautical research in Canada. In 1902 he constructed the first Canadian wind tunnel, at Rothesay, New Brunswick, and commenced the research work which established him as the Canadian pioneer in this field and later brought him into prominence in the science of aeronautics. His wind tunnel was powered by a heavy four-bladed fan-propeller driven by an electric motor. The fan was mounted at one end of a rectangular box 6 feet long and 22 inches square, and pushed the air through this "tunnel" at about 10 miles per hour. Thin baffle plates were employed to take out the propeller swirl from the air stream.

In 1907 he published the first Canadian Aeronautical Research paper in the Physical Review, entitled "Researches on the Forms and Stability of Aeroplanes." The term "aeroplanes" was used at that date to designate what are called aerofoils. This paper described experiments in which the lift, drag and centre of pressure movement were measured for aerofoils of zero camber, positive and negative camber and reflex camber.

Turnbull discovered the laws of the centre of pressure movement on aerofoils and made deductions from these laws which explained the longitudinal stability of aeroplanes. He showed in particular how the aerofoil with reflexed trailing edge had automatic stability while the conventional single curvature aerofoil had unstable characteristics due to the movement of the centre of pressure with change in angle of incidence.

He published a paper entitled "Efficiency of Aeroplanes" in the Aeronautical Journal for July, 1908, and in October, 1908, in "Aeronautics" a report on French motors, made at Dr. Graham Bell's request for the Aerial Experiment Association.

Turnbull constructed an experimental track for testing air propellers in the open, and in April, 1909, he published a paper in the Scientific American Supplement on the "Efficiency of Aerial Propellers" and in the Aeronautical Journal for October, 1910, and January, 1911, two more on the "Laws of Airscrews." For these papers Turnbull was presented with the bronze medal of the Royal Aeronautical Society. He showed that the efficiency of airscrews varies with the forward speed, attaining a maximum value depending on the percentage of apparent slip. The thrust r.p.m. brake horsepower and axial speed of the propellers on test were measured and he estimated that a limit of 80 per cent efficiency was indicated, a figure not much exceeded in modern design.

Perhaps Turnbull's greatest contribution to aviation was his controllable pitch propeller. His work on this subject dates from 1918; at that time the possible need for a controllable pitch propeller was so remote that tribute must be paid to his far-sighted vision.

His ideas on controllable pitch were strongly backed by the Associate Air Research Committee of the National Research Council and a grant for their development was made. A full-size propeller was constructed by Canadian Vickers and tests were carried out at Camp Borden. The results were encouraging and demonstrated the feasibility of controlling pitch, though the advantage of controllable pitch propellers could not be demonstrated with the aircraft used in the tests, owing to its small speed range. The American rights to the Turnbull controllable pitch propeller are owned by the Curtiss-Wright Company and his fundamental ideas are embodied in the controllable propeller now in common use.

In 1900 the Wright Brothers began their work at Kitty Hawk, North Carolina, which led to the first power driven flight on December 7th, 1903. Samuel Langley, of the Smithsonian Institution, working on similar lines, had built a man-carrying aeroplane which he tried without success on the Potomac river in the same year. The veteran inventor of the telephone, Dr. Graham Bell, a Regent of the Smithsonian Institution and an intimate friend of Langley, had for some years been experimenting

**Fig. 1—First Military Aircraft Trials, Petawawa, Ont. August 1909.**

with kites and airscrews in his private laboratory at his summer home near Baddeck, Cape Breton Island. Mr. J. A. D. McCurdy, a local boy, had played as a child in the laboratory and as he grew older had helped Dr. Bell in his work. In 1907 he graduated from the School of Practical Science at Toronto University and returned to Baddeck, taking with him another graduate, F. W. Baldwin, of the same school. Both were enthusiastic believers in the future of flying.

During the summer of 1907, Dr. Bell saw that if his aeronautical experiments were to serve any practical end, he must have the help of a trained engineering staff. He naturally turned to McCurdy and Baldwin. On October 1st of that year, he formed the "Aerial Experiment Association," with the objective of constructing "a practical aerodrome or flying machine driven through the air by its own power and carrying a man." The five members of this Association were Dr. Bell, Messrs. McCurdy, Baldwin, Glen Curtiss and Lieutenant Selfridge. Glen Curtiss was then building motor-cycle engines in a small factory at Hammondsport, New York, and his assistance was sought on account of his special experience in the construction of light power plants, as it was realized that without a suitable power plant little progress could be made. Lieutenant Selfridge was granted leave from the United States army to participate in the work of the Association. Mrs. Bell, always keenly interested in her husband's scientific work and confident that the Association would produce practical results, supplied the working capital—$35,000. The full story of the Association is recorded in a series of bulletins, of which five were typewritten, one for each member. Two copies of these bulletins still exist, one in the Smithsonian Institution, and the other, given by Mr. McCurdy, in the aeronautical museum of the National Research Council in Ottawa.

During the summer of 1907, Dr. Bell designed and built in his laboratory at Baddeck a large tetrahedral kite known as the "Cygnet." It was ready for trials late in the year and on December 6th it was successfully flown with Lieutenant Selfridge as passenger from the surface of the Bras d'Or Lakes, the motive power being supplied by a steam tug. It rose to a height of 170 feet and made the first recorded flight carrying a passenger of any heavier-than-aircraft in Canada.

The Association decided that each member should design a flying machine on his own ideas. Dr. Bell continued his kite experiments in the hope that he would get one to fly under its own power, while the four other members built gliders equipped with a motor, following the example of Langley, the Wright Brothers and contemporary European experimenters.

The work of the Association was continued during the winter at the Glen Curtiss factory at Hammondsport, New York. On March 12th, 1908, the first aeroplane was completed and was successfully flown from the ice at Lake Keuka, New York. The machine had been provided with skis and glided over the ice for a hundred feet or more before it rose and then flew steadily at an elevation of ten to twelve feet above the ice, carrying Mr. F. W. Baldwin as pilot. This was the first flight by a British subject. The "Red Wing," designed by Baldwin and built in the Glen Curtiss factory was ready for flight with an engine which Curtiss had specially designed for it. On May 18th, it was successfully flown. Later in the summer Curtiss' "June Bug," the third of the Association's aircraft, was ready for flight. He entered it in a competition announced by the "Scientific American" for a trophy for the first heavier-than-air machine to fly one kilometer. Many machines were entered, but few were successful in flying the required distance, and the "June Bug" was awarded the trophy.

McCurdy's "Silver Dart" was completed in November and assembled at the Bell laboratory in Baddeck for trials from the ice there. On February 23rd, 1909, Dr. Bell was able to cable to the London "Times" in part as follows:—

> "First flight of a flying machine in Canada occurred here today when Mr. Douglas McCurdy, native of Baddeck, Nova Scotia, flew a distance of about one-half mile at an elevation of about thirty feet above the ice on Baddeck Bay in an aerodrome of his own design, named the 'Silver Dart'."

The following day a flight of four and a half miles at a speed of 40 miles an hour was made in a circle round Baddeck Bay. On March 8th a distance of eight miles was covered in the fast time of eleven minutes and fifteen seconds.

Aviation history was made rapidly in the little town of Baddeck that winter. The "Silver Dart" was without doubt an advance on any aircraft previously flown. It embodied several new and very important features, notably a three-wheel undercarriage, tapered wings and the use of aileron control.*

Dr. Bell then felt that the purpose for which the Association had been formed had been accomplished. Lieutenant Selfridge had been killed while flying with the Wright Brothers near Washington, and he was anxious that the three remaining members should all be free to take advantage of the results of their work in the Asssociation. It was accordingly dissolved on March 31st, 1909.

The Association's life was short but brilliant. No contemporary work was more successful or productive of lasting results and Canadians are beginning, after a generation has passed, to recognize the contribution made to aeronautics by this little band of workers in far off Cape Breton Island. Dr. Bell has, of course, long passed to his rest, full of honours and world-wide renown. Two of the members are, happily, still with us—Messrs. McCurdy and Baldwin—and still actively interested in aviation.

Messrs. McCurdy and Baldwin continued their activity in Canada and endeavoured to interest the Department of Militia in their work. Lieutenant Colonel G. S. Maunsell, M.E.I.C., then Director of Engineer Services at militia headquarters, had followed with interest the early development of aeronautics and had contributed two papers on the subject to meetings of the Ottawa Branch of the Engineering Institute. He strongly backed their efforts and approval was finally given for trial flights to be conducted at Petawawa in August, 1909. Unfortunately, the available landing areas there had a very different surface from that of the smooth ice at Baddeck. Had a good aerodrome been available, the trials might have had a very different result. As it was the frail aircraft could not stand the rough landings and after a series of early morning successful trial flights, both aircraft crashed on landing, fortunately without injury to their pilots. The military authorities remained unconvinced of the practical value of aircraft in military work and refused further assistance.

It is unfortunate that the Militia Department refused to take cognizance of McCurdy's and Baldwin's two hundred successful flights made under proper conditions and adopted a conservative attitude, based on the reports of the trials made from rough ground at Petawawa. Their lack of vision had an influence detrimental to the development of Canadian aviation.

Nineteen hundred and ten saw a renewal of aviation activity and the holding of the first flying meet at Montreal. The famous young French pilot, Jacques de Lesseps, brought his Bleriot monoplane to Canada and made flights at Montreal and Toronto in July.

The first aeroplane built and flown in western Canada was a 35-40 hp. Anzani engine biplane constructed in 1910 out of Sitka spruce and ash, with silk covered wings, from their own designs by William Templeton, William McMullen and Winston Templeton, of Vancouver. This

*A full description of the aircraft will be found in the January, 1937, issue of "Canadian Aviation."

home-made aeroplane, after many weeks of trials, finally made a few successful, though short flights from the race track on Lulu Island, B.C.

McCurdy's next activity was his flight from Key West, Florida, to Havana, on January 30th, 1911. This was the longest overseas flight made up to that date, It was made at a speed of fifty miles an hour, at an elevation of about one thousand feet, in a plane of his own design. He was forced down short of fuel within sight of the crowds waiting his arrival on the shore and was picked up by a

Courtesy of Royal Canadian Air Force.

**Fig. 2—Royal Canadian Air Force Camp and Aerodrome, Camp Borden, Ont.**

destroyer following him. For this flight, McCurdy was awarded a prize of $8,000 and was given a tremendous welcome in Cuba. Fortunately, the plane was undamaged and the next day he made several successful flights from an aerodrome which had been prepared near Havana.

Air meets were held in Toronto and Hamilton in August, 1911, and many successful flights were made, including a race between Charles F. Willard, a United States pilot, and Mr. McCurdy, from Hamilton to Toronto, which was won by the latter in the fast time of thirty-six minutes for thirty-five miles. There was then a lull in activity until the spring of 1914, when flying was again resumed in Toronto and Hamilton.

Improvement in the strength, reliability and efficiency of aircraft was rapid between 1908 and 1914. Each new model built showed advances in reliability, speed, carrying capacity and manoeuvrability. The progress made in these years is best exemplified by the fact that an attempt to fly the Atlantic from Newfoundland to Ireland was being organized by Lieutenant-Commander John Porte, R.N., in August, 1914, when the outbreak of war abruptly changed the whole course of aviation.

### THE GREAT WAR, 1914—1918

The record of Canadians in the air was remarkable. It was, however, due to the efforts of individual Canadian officers and men serving in the British air services. Even the training organization in Canada, which grew to large proportions in 1917 and 1918, was under British direction.

None of the allied powers had realized in advance the important part aircraft would play in the world war and at first all were reluctant to divert men and material to the air arm. The British services were only able to muster a score of aeroplanes to accompany the British Expeditionary Force to France in 1914 and the other armies were no better prepared. Experience soon showed the value of aircraft. Observation was at first the only use. Soon the rival observers took to fighting in the air, and aircraft were armed with machine guns. As their power and speed increased, bombing was added. Special recruitment, both of pilots and mechanics, soon became necessary as the air services expanded rapidly and the casualties in the air were heavy. An increasing stream of transfers from the Canadian Expeditionary Force to both the Royal Naval Air Service and the Royal Flying Corps commenced. In addition, both services readily accepted young Canadians who had learned to fly in private schools.

#### The Curtiss School

The Curtiss Flying School in Toronto was established in the spring of 1915, with J. A. D. McCurdy in charge, to meet this demand. The following description by one of the first dozen pupils gives a picture of conditions at that time:—

> About the 1st of May 1915, a news item appeared in the Victoria papers to the effect that the Royal Navy needed air pilots and if any Canadians of good family, preferably with engineering training and who were physically fit, would learn to fly at their own expense and would pay their way over to England, they would be taken on strength as Chief Petty Officers, and if they served for so long as their services were required, their way would be paid back to Canada and they would be granted a gratuity of £150.
>
> On the strength of this news item, I reported to the Senior Naval Officer at Esquimalt and was accepted as the first candidate from the west on the 6th of May, 1915.
>
> The Curtiss school was then giving a course in flying on Curtiss flying boats in the Toronto Bay, with hangars at Hanlan's Point, with the promise of landplane training at a later date at Long Branch. The fee was $400 for 400 minutes with a rebate at the rate of a dollar a minute if for any reason the course was given up.
>
> J. A. D. McCurdy was in charge of the school, but did no active flying himself.
>
> We did not go solo on the flying boats, but when in the opinion of our instructor, we were capable of handling them, we were transferred to the landplane school which had then opened at Long Branch. Once again we did not go solo until it came time to take our tests, our first solo flying time being our official test.
>
> Taken all round I considered it was a well run flying school and that we got excellent value for our money.
>
> During our days at Long Branch the Royal Flying Corps sent representatives to Canada and offered us commissions as Second Lieutenants if we completed our course. Most of us, however, stayed with the R.N.A.S. who, in turn, raised the ante by making us "Flight Sub-Lieutenants, R.N., probationary, temporary"! They also paid for our passage to England but did not refund any of the cost of learning to fly.

Through this school, nearly seven hundred young Canadians were accepted in Canada for the Royal Naval Air Service and proceeded overseas, the candidates being examined and tested by the Royal Canadian Navy. Many others joined the Royal Flying Corps but no exact record is apparently available.

#### The Royal Flying Corps in Canada

The intense air activity in the latter half of 1916 during the battle of the Somme was the principal factor which led to the establishment of Royal Flying Corps recruiting and training units in Canada. The exploits of Canadian pilots soon drew attention to their natural ability in air warfare. After negotiations between the representatives of the Canadian and British Governments, authority was given in December, 1916, for the establishment in Canada of Royal Flying Corps training units. The Imperial Munitions Board added an Aviation Branch under Mr. G. A. Morrow to their many activities, and, with the consent, approval and assistance of the Canadian Government, the training units and the necessary recruiting agencies, technical services for the preparation of aerodromes, the construction of quarters and other accommodation and the purchase of supplies were rapidly organized.

In January, 1917, the nucleus of a Royal Flying Corps training and administrative section arrived in Canada. Camp Borden, hitherto used as an infantry training camp for the C.E.F., was placed at their disposal by the Government and a contract was immediately let for the construction of fifteen hangars, barrack buildings, water supply, and all the requirements for a flying training unit. At the same time, the military property at Long Branch, west of Toronto, was taken over and there was formed the first flying unit of the Royal Flying Corps in Canada.

Sites for additional training camps were later selected at Leaside, Armour Heights, Mohawk and Beamsville, and a ground school opened at Toronto University. Wholehearted co-operation was given in all this work by the Canadian Government, who assisted the organization in every way and provided the funds through advances by the Finance Department to the Imperial Munitions Board.

Space will not permit any detailed account of the training activities of the Royal Flying Corps in Canada, nor a discussion of the many engineering problems involved in the construction, equipment and maintenance of the bases and shops.*

The organization ceased its work at the armistice in November, 1918, and was disbanded. Its record is as follows:—

| | |
|---|---|
| Pilots trained and sent overseas | 2,539 |
| Pilots trained and ready, waiting to go overseas at the armistice | 240 |
| Pilots retained in Canada as Instructors. | 321 |
| Pilots trained for United States Air Services | 370 |
| Pilots partially trained at armistice | 587 |
| Cadets in ground training courses at armistice | 3,500 |

### Canadian Aeroplanes, Ltd.

Canadian Aeroplanes, Ltd., was organized in December, 1916, by the Imperial Munitions Board under the presidency of Sir Frank Baillie to build the aircraft for the Canadian training units. A large number of aeroplanes and spare parts were also supplied for the training services in the United States. In the twenty-one months of its existence it built 2,900 aeroplanes, valued at $14,000,000. It took over from the Curtiss Flying Service a small factory but in April, 1917, the need for expansion forced the acquirement of larger premises on Dufferin Street, Toronto.

Their shops covered some six acres of floor space, and were built in two and a half months. The aircraft adopted for training in the Royal Flying Corps in Canada was the Canadian J.N.4, or Curtiss "Jenny." Supplies of materials for this new industry had also to be organized, including the cotton cloth for the covering of the wings (the Irish linen hitherto used was unobtainable), silver spruce, not only for Canadian requirements, but for those of all the allied powers (this item alone involved an extensive organization in British Columbia), ash for the longerons and white oak for the building of propellers.

In addition to the 2,900 "J.N.4" aircraft, Canadian Aeroplanes built 30 "F.5" twin engined flying boats for the United States Naval Service during 1918. This was the largest type of flying boat then in existence. Mass production of the "Avro" trainer was just beginning when the armistice closed this chapter of aeronautical activity in Canada.

The combined expenditure by the Imperial Munitions Board on the training organization and Canadian Aeroplanes Limited, to December 31st, 1918, was approximately $40,000,000.

### The Royal Canadian Naval Air Service

Submarine warfare on the North Atlantic forced consideration of plans for the protection of the constant stream of supplies passing overseas from North America to the United Kingdom and French ports. Late in 1917, the convoy system was instituted and immediately the marine casualty rates fell.

The visits to Atlantic coast waters of long range U boats early in 1918 (an oil tanker was torpedoed and sunk within ten miles of Halifax harbour on one occasion) made air patrols necessary at Halifax and Sydney for the protection of the convoys which gathered there.

Two years earlier the Admiralty had advised the Canadian Government of the conditions which might result from the extension of submarine warfare and suggested that Canada should organize a Naval Air Service. Two flying boats were shipped to Halifax in 1916 but no action was taken in the matter till March, 1918, when the Admiralty again raised the question and the Canadian Government agreed to organize the Royal Canadian Naval Air Service, for which suitable bases were located at Dartmouth and Sydney.

As the United States were sending large numbers of their troops overseas through Canadian ports they were desirous of having aerial patrol protection for the troopships. The Canadian and United States Governments combined efforts to put the Canadian air bases into commission until such time as Canadians could be trained to carry out the air patrols. Under this arrangement, the United States Government supplied the following for the unit established at Halifax:—

Courtesy of Royal Canadian Air Force.

Fig. 3—Royal Canadian Naval Air Service Base, Dartmouth, N.S. 1918.

(1) Twelve "H.S.2 1" flying boats complete with all necessary spares.
(2) Two kite balloons, complete, with necessary additional spares, winches for same, and hydrogen plant.
(3) Steel portable hangars for housing flying boats.
(4) Complete U.S. Navy personnel for the base.

*See "Aviation in Canada, 1917-18" by Allan Sullivan.

Similar arrangements were made for the North Sydney base, as it was believed that the enemy submarines would choose the St. Lawrence route for operation in September and October.

On August 16th, 1918, the American advance party, with two flying boats, arrived at Halifax. The personnel were, pending completion of their buildings, put under canvas, the machines were assembled and on August 25th, 1918, the first convoy patrol was carried out. Regular patrols and convoy flights were flown from both stations, until the signing of the armistice.

On September 5th, 1918, the general outlines of regulations governing the Royal Canadian Naval Air Service were approved by the Canadian Government. The recruitment and training of personnel and equipment of the stations with Canadian aircraft was provided for.

Up to the time of the armistice, eighty-two cadets had been recruited; sixty were under training in the United States, nineteen were in England training for service in the "Lighter-than-Air" section.

Immediately after the signing of the armistice, the Department of Public Works was instructed to stop construction at both bases. Store houses, hangars, sleeping and recreation buildings had, by that time, been completed at both Dartmouth and Sydney. The Dartmouth base is still in use by the Royal Canadian Air Force and is today being modernized and enlarged.

The R.C.N.A.S. was demobilized after the armistice. All flying material, including 24 "H.S.2.L." flying boats and 25 Liberty motors, was presented by the United States to Canada. These flying boats later proved invaluable and were the foundation on which was built the forest patrol systems organized in the succeeding years.

## POST-WAR PERIOD

Canada was in an excellent position after the armistice to deal with aviation intelligently. The statutes contained no reference whatever to aeronautics and the war organizations at home and overseas had been disbanded. Freedom of action was complete.

There was little recognition on the part of the public generally that flying would soon become as important in peace as it had been in war, but men of vision had been watching with increasing interest the conquest of the air. As early as the fall of 1915, Dr. Charles Camsell, M.E.I.C., Past President of The Institute and now Deputy Minister of Mines and Resources, had made inquiries about obtaining flying boats for use in northern Canada to ease the burden and increase the efficiency of scientific parties working in the remoter parts of the Dominion. Concentration of every effort on "winning the war" prohibited any progress on these lines before the armistice.

Canada was fortunate in having, not only a great fund of energy and enthusiasm for aviation in the thousands of young Canadians who made such a brilliant record in the air services, but a virgin field for the useful and economic employment of air services in the exploration and development of the northern areas, where there were no roads or railways, where travel was a slow and arduous business and where better means of access and observation were the key to development.

Within a few days of the armistice a meeting was held in Ottawa under the auspices of the Dominion Land Surveyors' Association to discuss the future of aircraft in such work. Surveyors, foresters and geologists eagerly lent their knowledge to planning these new developments with the airmen. Enthusiastic young men were returning from overseas and demanding that their opportunities for flying should be continued and extended. Surplus aircraft and war disposal stock were coming on the market and available at low prices, necessitating action to control flying in Canada. Canadian representatives at the Peace Conference were assisting to draft the International Convention for Air Navigation to determine the principles underlying the regulation of civil aviation in all parts of the world. In March, 1919, the Canadian Pacific Railway asked Parliament for an extension of their powers to include the operation of aircraft. This brought the matter directly to the Government's attention. To meet the situation, the Air Board Act was introduced, passed rapidly through all its stages and received Royal Assent on June 6th, 1919.

By the Air Board Act a Board on Aeronautics was established which had broad powers of control over all forms of aeronautics. Doubts were expressed as to the jurisdiction of the Dominion, and this question was not finally settled till 1931 when the Privy Council decided that aeronautics lay wholly within Federal jurisdiction.

The Air Board Act provided in detail for the regulation of civil aeronautics and it was framed primarily for this purpose. Powers to deal with military aeronautics were less well defined and were then regarded as temporary pending the post-war re-organization of the defence forces, which appeared inevitable.

### The Air Board 1919-1922

The first Air Board was appointed by an Order-in-Council dated June 23rd, 1919. The Honourable A. L. Sifton was chairman, Colonel O. M. Biggar, who had acted for Canada on the sub-committee of the Peace Conference in Paris dealing with Air Conventions, Vice-Chairman, the Honourable S. C. Mewburn, Minister of Militia and Defence, the Honourable C. C. Ballantyne, Minister of the Naval Service, together with the Deputy Postmaster General, the Chief Inspector of the Department of Customs and Inland Revenue, and the author were the other members.

No time was lost in organizing the necessary staff for the duties imposed by the new Act. Four civil branches were created:—

- (*a*) Secretary's Branch, dealing with organization, finance, staff and departmental duties generally.
- (*b*) Certificates Branch, dealing with the licensing of aircraft and personnel.
- (*c*) Flying Operations Branch, to conduct any flying operations required for other Government Services.
- (*d*) Technical Branch.

Before the close of 1919 the preliminary organization was completed. Air Regulations based on the International Convention for Air Navigation governing civil flying in Canada had been approved by Order-in-Council. An Aerial Survey Committee was appointed, representative of the survey services of the Government. Its Chairman was the late Dr. E. Deville, Surveyor General. Dr. Deville, as a young man, had taken the lead in the development of photo-topography. In his old age he had the satisfaction of introducing new methods of surveying from aerial photographs, widely used, not only in Canada but in many other countries.

A survey had been made to ascertain "what public services could be more efficiently, and, in the broader sense, more economically performed by air than by existing methods." Provision had been made for scientific research in aeronautics by the formation, under the Council for Scientific and Industrial Research, of an Associate Air Research Committee. Arrangements had been completed with the Dominion Meteorological Service, looking towards the necessary extension of the existing meteorological services to serve the requirements of aviation, and with the Government Radio Telegraph Service of the Department of Naval Service for co-operation in the development of any radio services required for air navigation.

The Board also took over from the Department of Naval Service the seaplane stations erected during the war at Halifax and Sydney, and from the Department of Militia and Defence that portion of Camp Borden which had been developed as a flying training base by the Royal Air Force.

The Imperial Government generously gave from their surplus war stock, eighty aeroplanes, fourteen flying boats, twelve airships, six kite balloons and much miscellaneous equipment of inestimable value in enabling the Air Board to start its work. In addition, sixteen aircraft were received from the Air Ministry to replace those presented from time to time during the war to Canadian forces and used by the Royal Flying Corps. The flying boats and Liberty motors left at Halifax and Sydney by the United States Naval Air Service were available and the new organization was, therefore, well provided with equipment.

When the preliminary work of organization had been completed towards the close of 1919, the original Board resigned and a new Board was formed, with the Minister of Militia and Defence as Chairman. Colonel O. M. Biggar remained as Vice-Chairman. The Controller of Civil Aviation and Director of Flying Operations were appointed members of the Board, together with the Director of the Naval Service, the Surveyor General and the Inspector General of the Canadian Air Force.

The formation of a Canadian Air Force under the Aeronautics Act was approved on February 18th, 1920. The Service authorized was on a wholly temporary basis. No permanent officers or men were appointed. Its immediate duty was the provision of refresher training for officers and men who had served during the war pending action on the constitution of a permanent Air Force. These refresher courses were established at Camp Borden in July, 1920, and were maintained in active operation until the close of 1922.

Previous to the appointment of the first Air Board, Ellwood Wilson, M.E.I.C., Chief Forester of the Laurentide Company at Grand'Mère, applied to the Department of Naval Service for two flying boats to make trials of aircraft in forest protection and forest survey work. The loan was granted. The two flying boats were flown from Halifax to Lac à la Tortue, P.Q., by Stuart Graham and successful flights were made in August and September. These were followed with general interest by the Dominion and Provincial Forest Services.

The results of these experiments, combined with those of the Air Board surveys, led to the conclusion that the needs of the forest service for improved methods of transportation, observation and travel were of immediate importance.

An Interdepartmental Conference, convened in January, 1920, for the consideration of proposals for the institution of air services, recommended the establishment of air bases at Vancouver, B.C.; Morley, Alberta; Ottawa, Ontario; and Roberval, P.Q., for co-operation with the forest services—Provincial and Dominion. The provincial governments co-operated wholeheartedly. British Columbia supplied a site for a suitable seaplane base at English Bay, and volunteered to defray a substantial part of the cost of the operation. The base at Morley was established for the purpose of better fire protection in the Dominion Government forest reserve on the eastern slopes of the Rocky Mountains. (This station was later moved to a better site at High River.) The operation at Roberval was undertaken at the request of the province of Quebec to provide forest fire patrols, forest surveys, and to facilitate the exploration of forest areas surrounding Lake St. John. The buildings and slipway required were erected by the provincial government. These bases provided facilities for flying operations, not only for the forest services, but for much other government work in these areas.

Consideration was also given at that time, in conjunction with the officers of the Postal Service, to the establishment of air mails. In most countries, inter-city services were the only outlets for aviation after the war. Such services required heavy subsidies from the governments concerned, as in most cases they were not (and still are not) self-sustaining. It was decided that the carriage of mail by air in Canada could well await further development. Until public opinion was riper and experience had been gained in other countries, the operation of such services would be costly and premature. It was not, in fact, until 1927 that inter-city air mails again received active consideration.

In January 1921, a second Interdepartmental Conference on air operations was held in Ottawa to consider the results of the previous year's work and make recommendations as to future progress. The experience of the past year had been so satisfactory that greatly increased demands were received. New bases were established in Manitoba for the patrol and survey of the forest areas surrounding Lakes Winnipeg and Winnipegosis, in conjunction with the Dominion Forest Service, and also at Sioux Lookout, Ontario, with the help of the Provincial Forest Service of Ontario, for similar work in northern Ontario. In 1922 this work was continued on a larger scale at all bases and further new operations were commenced.

The discovery of crude oil at Fort Norman, N.W.T., late in the fall of 1921, led to the first large-scale attempt to establish long range air transport in the Far North. The Imperial Oil Company purchased two all-metal Junkers planes with the object of establishing more efficient communication to the new oil field from Edmonton. The story of this pioneer effort is an epitome of the difficulties to be overcome. Intense cold, Arctic blizzards, rough landings in unknown country, inadequate supplies and unsuitable equipment, all were mastered by hard work and indomitable perseverance. (A new propeller was built on one occasion at a Hudson's Bay post from oak sleigh boards and glue made on the spot from moose hide!)

The results of these first three years' of trial and experimental work proved that aircraft could play a most important part in transportation in the outlying districts of Canada; in forest patrol and exploration; in aerial surveys, by photography and sketching; and other similar work. The use of air transport in the North had, in fact become firmly established.

The question of training a new generation of pilots to take the place of those who had served during the war first received consideration during the year. It was decided that the best personnel for the Canadian Air Force could be drawn from the engineering and science schools of the Canadian universities. Under this scheme a selection was made each year of a number of students in the first year of their course in science or engineering who would, during their summer vacations for three or four years, go to Camp Borden and undergo a thorough training in aeronautics in all its phases. A selected number would be granted commissions in the Air Force on graduation.

One further activity in 1922 calls for mention. The most direct routes between North America and Europe and Asia all pass through northern Canada. As these might become of international importance, it was considered that no time should be lost in making a preliminary investigation of flying conditions in the Arctic. R. A. Logan, a highly qualified pilot who was a Dominion Land Surveyor and had long experience of travel and conditions in the North was selected to make this reconnaissance and accompanied the supply and relief ship on her annual visit to posts in the Arctic Islands. Much valuable information was obtained, but it was not possible, under the re-organization of the Air Services which followed, to continue this investigation.

### Department of National Defence

On January 1st, 1923, the Act creating the Department of National Defence became effective. Under this legislation the Air Board ceased to exist and its functions were assumed by the Minister of National Defence.

In the re-organization of the air services under the new Department, practically all civil positions were abolished. No recognition was given to the patent fact that a large part of the administration of aeronautics dealt with purely civil functions which had little relation to the Air Force.

The necessity for a change in this organization soon became apparent and in 1927 the administration of the aeronautical activities of the Department was divided into four directorates:—

(*a*) The Royal Canadian Air Force.
(*b*) Civil government air operations.
(*c*) The control of civil aviation.
(*d*) Aeronautical engineering.

The Royal Canadian Air Force was continued as part of the Branch of the Chief of the General Staff and the three others, which dealt with civil matters in large measure, were placed directly under the Deputy Minister, as civil head of the Department.

This new division of duties was satisfactory as far as the administration of the Royal Canadian Air Force and Civil Aviation was concerned but left a measure of divided responsibility in regard to the other two branches. A more satisfactory solution was found in 1930, when, with the transfer of the natural resources to the provinces, Civil Government Air Operations were greatly reduced and that Branch and the Aeronautical Engineering Service were again absorbed by the Air Force, Civil Aviation remaining as a separate civil branch under the Deputy Minister until its transfer to the Department of Transport on its formation in 1936.

*Royal Canadian Air Force*

Under the Department of National Defence the Air Force was re-organized as a permanent force. The highest

**Fig. 4—Expenditure on Air Services.**

educational and physical qualifications were set for entry of both officers and men. Wider experience was gained by the training of selected officers by special courses in Royal Air Force training establishments, the Air Force Staff College and later the Imperial Defence College, and by a system of exchange of officers with the Royal Air Force.

Space will not admit of following its history through the intervening years. It must suffice to say that today the Royal Canadian Air Force is coming to be recognized as perhaps the first line of Canada's defence. It is being strengthened materially by the provision of modern aircraft. New bases are rapidly being built for training its increased personnel. Non-permanent squadrons have been formed in the principal cities where young Canadians,

Courtesy of Royal Canadian Air Force.

**Fig. 5—R.C.A.F. Base on Hudson Bay Railway, Cormorant Lake, Man.**

normally employed in civil pursuits, can participate in the work of the Air Force as they have done for generations in the non-permanent Militia. The authorized strength is today 155 officers and 969 men.

*Civil Government Air Operations by the Royal Canadian Air Force*

The usefulness and practical nature of the civil government air operations developed by the Air Board and the support they had received from all quarters made their continuance necessary, and for some years a large part of the funds available for Air Force purposes was devoted to such operations. This tended to prevent the development of the Air Force on a scale commensurate with its position in a well balanced defence programme.

The work between 1923 and 1930 was based on the forest services in the prairie provinces, which were still under Dominion jurisdiction. The provinces of Ontario, Quebec and British Columbia had assumed responsibility for their own flying when the Air Board was abolished. With the development of new methods of aerial survey this interesting phase of the work increased rapidly and was extended to include surveys in all provinces and territories. In 1931, with the transfer of the natural resources from Dominion control to the provinces, the forest operations came to an end. Civil Government Air Operations are now confined almost wholly to photographic surveys and transportation for Dominion services in the remoter regions. (See Fig. 6).

Arrangements were made with the governments of Manitoba and Saskatchewan to help them establish provincial air services to carry on part of the work hitherto undertaken in their northern areas by the Royal Canadian Air Force. Certain bases and equipment were turned over to them for this purpose.

*Control of Civil Aviation*

The control of civil aviation under the Department of National Defence was, at first, a relatively small matter. The administration of the air regulations and licensing of civil aircraft and aviation personnel were provided for in the Branch of the Secretary of the Royal Canadian Air Force, and Air Force officers were lent for the performance of these duties. The re-establishment of the

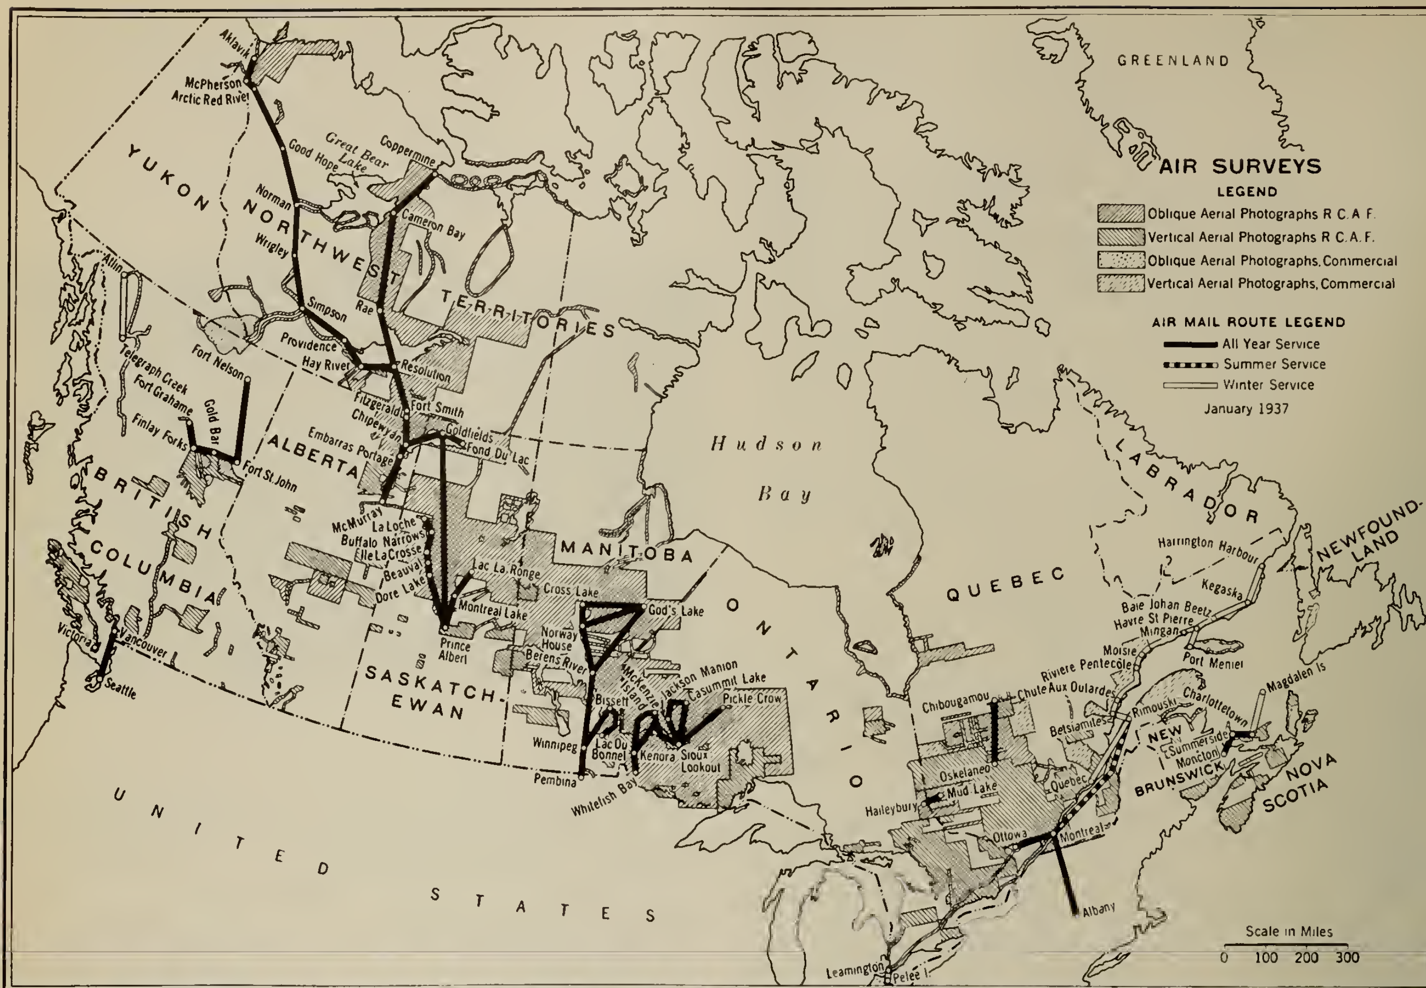

**Fig. 6—Air Surveys and Air Mail Routes in Canada.**

Civil Aviation Branch under the Deputy Minister was found necessary in 1927. The Secretary's Branch of the Royal Canadian Air Force became the Civil Aviation Branch and from that time all appointments were filled by Civil Servants.

In 1928, when construction of the trans-Canada airway was decided on, the division of the branch into separate Air Regulations and Airways Divisions became necessary. The former is charged with the inspection and licensing of aircraft, the examination of pilots and air engineers and the supervision of the Air Regulations generally, while the latter is charged with airway and airport surveys, the location and construction of aids to navigation on the airways, including intermediate aerodromes, lighting, the co-ordination of the radio and meteorological services and the licensing of airports and seaplane bases.

*Aeronautical Engineering Division*

The Aeronautical Engineering Division developed gradually from the appointment in 1920 of a civilian Director, Lieutenant Colonel E. W. Stedman, O.B.E., M.E.I.C., of the Technical Branch of the Air Board. The Air Board commenced to investigate the structural design of aircraft for airworthiness purposes, but progress was slow owing to the necessity for training a technical staff, for technical and supply duties.

From the earliest days the Branch has worked in the closest liaison with the Air Research Committee upon research problems connected with flying conditions which are peculiar to Canada, particularly those problems involved in winter flying.

In 1922 the Air Board was transferred to the Department of National Defence and the Technical and Equipment Branch was re-organized from a civil to an Air Force basis under an Assistant Director, C.A.F. During this year a supplementary estimate was obtained for the construction of a building at Toronto University to house the wind tunnel, thus allowing the only wind tunnel then available in Canada to continue in operation.

The next few years were mainly noteworthy for the training of personnel and the building up of a staff capable of undertaking any investigations that might be required. This staff was obtained by sending Air Force officers to England for training in aeronautics at the Imperial College of Science and Technology, and by the appointment of civilian engineers, or junior engineers for training in this highly specialized branch of engineering.

On July 1st, 1927, the Air Force was re-organized and the Technical and Supply Branch was renamed the Aeronautical Engineering Division "to act in a consulting capacity respecting all technical and engineering matters pertaining to the Air Services, and the carrying out of duties prescribed by the Air Board Act and Regulations thereunder."

With the re-organization the Aeronautical Engineering Division was formed into three main sub-divisions. (1) *The Research and Design Branch* to take charge of all engineering matters in connection with aircraft used by the Department of National Defence, modifications, design of camera mounts and skis, supervision of type trials, collection and distribution of technical information and co-operation with the Air Research Committee. (2) *The Airworthiness*

*Branch* to check the design of aircraft for which application for type certificates of airworthiness had been received by the Civil Aviation Branch, and the study of new methods of calculation to deal with progress in the art of aircraft construction. (3) *The Aircraft Inspection Branch*, divided into a number of detachments distributed throughout the country, to inspect aircraft under construction or during overhaul at manufacturers' works and to assist the Civil Aviation Inspectors.

An agreement in 1928 with the United States Government for the mutual recognition of certificates of airworthiness necessitated a study by the Airworthiness Branch of the methods of calculation used in the United States. Since that date both British and United States methods of calculation have been used in the Airworthiness Branch for domestic certificates, but for export purposes the British methods of calculation and International Convention for Air Navigation factors have always been employed.

The expansion of the National Research Council in 1929 to include a section devoted to Aeronautic Research provided much better equipment than had previously been available in Canada, and this has been of great assistance to the Aeronautical Engineering Division.

With the formation of the Department of Transport in 1936, the Division was divided to provide some of the personnel required for a separate aeronautical engineering staff for the new Department, which will in future handle all Civil Aviation questions.

### The Department of Transport

Stability in the organization of the air services of the Dominion was finally reached after the many changes, of which an outline has been given above, by the complete separation of its civil and military functions. The former was transferred to the new Ministry of Transport on its formation on November 1st, 1936, and the latter remained with the Army and Navy in the Department of National Defence. As long as both services were small, the advantages of combining their administration in one department were manifest. Civil aviation has now become so important a part of the transportation system of the Dominion that it can best be administered by the organization dealing with the railway, canal, marine and highway services, to which it is complementary.

No duplication of effort follows this change. The only new service required is the formation of an Aeronautical Engineering section in the Department of Transport, which will deal with civil aircraft, relieving the Royal Canadian Air Force engineering staff of much work which had no relation to its proper functions.

### Provincial Air Services

After the Air Board's operations were discontinued at the close of 1922, the Ontario government contracted with the Laurentide Air Service for their flying. In 1924 they established their own air service as part of the Provincial Forest Branch and have continued it on this basis until the present time. A central depot and base was established in 1924 at Sault Ste. Marie and ten sub-bases and many refuelling bases in the forest areas in the northern and western parts of the province have been provided, as required.

In 1931, when the control of the natural resources of the Prairie Provinces reverted to the provinces, the Royal Canadian Air Force withdrew their forces and these provinces accepted responsibility for their own forest fire protection.

The province of Manitoba during 1931 contracted with Canadian Airways for this work but in 1932 followed the example of Ontario and formed its own air service, with its principal base at Lac du Bonnet.

The province of Saskatchewan also operated its own flying service from 1933 to 1935. In both cases flying boats were given by the Department of National Defence to help start the new organization.

### Commercial Flying

After the armistice, aircraft were cheap, as governments were disposing of surplus war stocks. Pilots invested their war gratuities in the hope of establishing successful air transport companies. Their only outlet was exhibition flying, joy riding and flying instruction. Once the first curiosity of the public was satisfied the demand for such flying fell off and many of the smaller companies were forced out of business. Their sponsors forgot that time was required to build up the ground services, evolve new types of aircraft and convince the public that air transport could play a useful part in the normal life of the community. Those who were content to confine their activities to work for the forest services and transportation in the northern parts of the country reaped their reward and were able to operate on a self-sustaining basis.

As has been noted earlier in this review, the first tests of aircraft in civil work were made at Grand'Mère in the summer of 1919. The example of the Laurentide Company was followed by Price Brothers, who purchased aircraft for the use of their forestry service in Quebec. In 1922 these companies felt that their flying could be done to better advantage by separate organizations, which would be free to expand their field of operation and so reduce the cost to the parent company.

The Laurentide Air Services Limited was established in 1922 with six aircraft and during that year did over

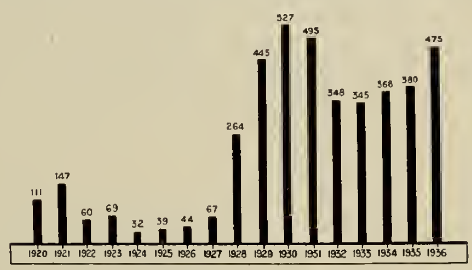

Fig. 7—Registered Aircraft.

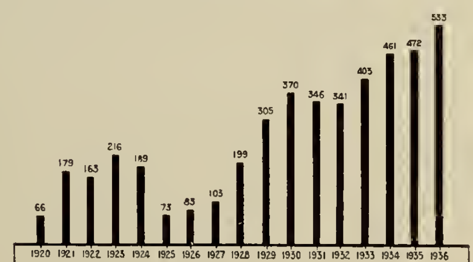

Fig. 8—Licensed Air Engineers.

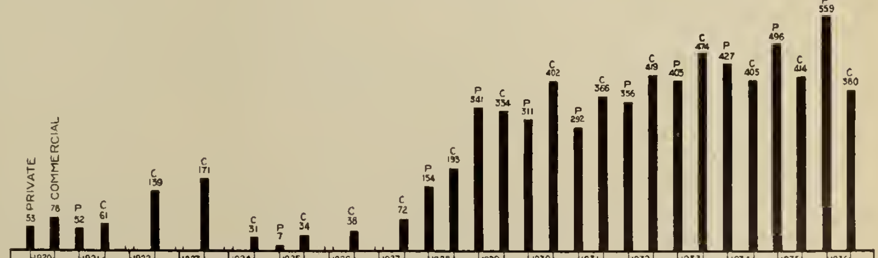

Fig. 9—Licensed Pilots.

seven hundred and eleven hours flying, including work for the Laurentide Company in Quebec and a large contract for the provincial government of Ontario for mapping the forest types in northern Ontario between the National Transcontinental Railway and James Bay.

In 1923 the company increased their fleet to twelve aircraft and obtained a contract from the Ontario government for fire patrols as well as for type sketching. Their flying time was approximately fifteen hundred hours for the year.

Fig. 10—Junkers 52, Payload on Floats 4,500 lb.

A new company, Dominion Aerial Explorations Limited, was formed in 1923 by the late Captain H. S. Quigley, A.M.E.I.C., who had been chief pilot for Price Brothers. In addition to contract work for Price Brothers, they took over, on a contract basis, the work hitherto done by the Air Board in the Roberval district for the Provincial Government of Quebec and extended their forest reconnaissance flights to the little known and remote areas on the north shore of the Gulf of St. Lawrence as far east as the Straits of Belle Isle.

The Fairchild Aerial Surveys Company was also formed in this year and, like the Laurentide Air Services, had its inception in the interest of Mr. Ellwood Wilson, Grand'Mère, in forest conservation work. The company was formed primarily to do photographic work and not flying, but it found that the ordinary aircraft available had not sufficient ceiling to undertake photography to good advantage. They, therefore, were forced to purchase their own aircraft and took over the original base at Grand'-Mère when the Laurentide Air Services moved its headquarters to Three Rivers.

From these modest beginnings commercial aviation has made rapid progress in all parts of the Dominion and by hard work, resourcefulness and concentration on immediately practical and economic operations, has maintained itself wholly without subsidy to the present day.

The first regular freight and passenger service was inaugurated in 1924 by the Laurentide Air Service, using H.S. 2L boats in summer and ski planes in winter. Over 1,000 passengers, 78,000 pounds of freight and 15,000 letters and telegrams were carried between Haileybury and Rouyn during the first six months of operation. Rouyn is still a centre of flying activity from which radiate regular services to the many new mining fields since discovered in northwestern Quebec.

In 1925 further pioneering was done by an expedition organized by Lieutenant-Colonel Scott Williams to prospect in northern British Columbia. Flying a Vickers Viking he penetrated from Wrangell, Alaska, into Dease Lake, and from a base there explored the upper waters of the Liard and Yukon Rivers, hitherto almost inaccessible.

Seaplanes were flown during the spring of 1924, 1925 and 1926 for the owners of the Newfoundland sealing fleet to spot the herds of seals on the ice floes and guide the sealers to them. This meant flying from continually shifting ice floes off the Labrador and Newfoundland coasts over vast stretches of water covered with ice floes in the early spring of the year.

Nineteen twenty six saw an all round increase of fifty per cent in the amount of flying done by commercial operators in Canada. Gold discoveries at Red Lake and elsewhere in northwestern Ontario made new outlets for commercial air services similar to the organization at Rouyn; Hudson and Sioux Lookout, Ontario, became centres of activity for these.

Mr. J. V. Elliott, of Hamilton, was a pioneer in this venture in which he was joined by a new Fairchild Company formed for the purpose. They took over the Rouyn service and also established another in the Red Lake district, carrying 576 passengers and 24,000 pounds of freight before the end of the season.

Aircraft re-entered the Mackenzie River basin in this year. The Vickers Viking used the year before in northern British Columbia was flown from Lac la Biche into the Great Slave Lake district by C. S. Caldwell and a base established at Fitzgerald, from which exploration flights were made into the country north and east of the Slave river, transporting prospecting parties in the area.

Commercial flying was also started by D. R. MacLaren on the Pacific coast and Captain H. A. Oaks, an ex-war pilot and a mining engineer formerly pilot with the Ontario Air Service, began a passenger, express and mail service from Sioux Lookout to Red and Woman lakes, with a Curtiss Lark seaplane. Later in the year he took over the management of Western Canada Airways Limited, which had been formed by Mr. James Richardson, of Winnipeg, to engage in air transport in western Canada.

Nineteen twenty seven saw the rapid expansion of work to meet the growing needs of the prospectors and mining companies. A study of the statistics on page 471 will show the continuous increase in the carriage of passengers, freight and mail, almost wholly due to such services. They show the early flow of the post-war tide, the ebb after the first enthusiasm was spent, then a lull, and from 1926 on a steady growth which still continues.

No factor has had a greater effect in the expansion of our mining industries than the adoption of air transport by the prospector and the mining companies. Aircraft now penetrate with ease and certainty to the remotest parts of the Dominion, and travel and transport by air all through the North has become commonplace.

The pioneer companies in eastern Canada were merged in 1928 into Interprovincial Airways by General MacBrien, including Dominion Aerial Exploration Limited, the Fairchild companies, the Laurentide Air Services and J. V. Elliott, while Western Canada Airways extended their operations from northwestern Ontario into Manitoba and the Mackenzie area and later absorbed Commercial Airways, of Edmonton, and Pacific Airways, of Vancouver. Two years later Canadian Airways Limited was formed by the union of Interprovincial Airways with Western Canada Airways and became a Dominion-wide organization.

Many companies have been organized since to participate in this work and have played an important part in its expansion. These include General Airways Limited, formed in June, 1928, by Captain A. Roy Brown, and Dominion Skyways Limited, formed in 1935 by H. de M. Molson and Air Vice-Marshal W. A. Bishop. Harvey St. Martin, a pioneer in the work in Quebec, has continued his independent operations from year to year with a high measure of success. In the west mention should be made of Mackenzie Air Services Limited, formed by W. Leigh

Brintnell in 1932; Starratt Airways and Transportation Limited, formed in 1932; Arrow Airways, by Harvey Webber and Jack Hone in The Pas in 1932; Wings Limited, Winnipeg; and United Air Transport Limited, formed in 1934 by G. M. G. McConachie, of Edmonton.

### Air Mails

The transport of mails by air in Canada has two phases:—

(1) Service to outlying communities not now served by roads or railways. In such cases there is no need to consider flying by night and favourable weather may be waited for. Such services are flown by seaplane in summer and skiplanes in winter. The surfaces of the many lakes and rivers in northern Canada provide admirable bases without expense, although flying is liable to interruption for a few weeks in the spring and fall during the break-up and freeze-up periods. Notwithstanding this drawback, remarkable efficiency is attained.

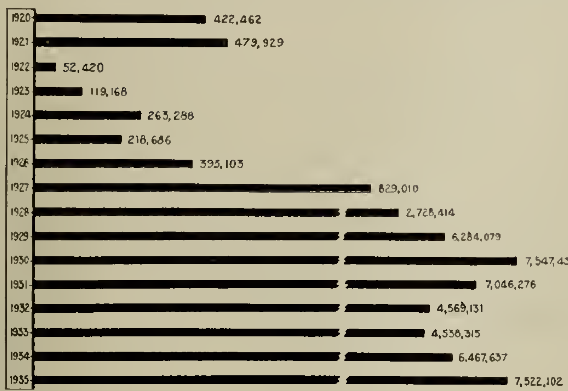

**Fig. 11—Aircraft Mileage.**

(2) Inter-city air mail services require a very different form of organization. They must show a material saving of time over the present railway or road services. To do this night flying is essential on many airways. The service must be maintained all the year round, in all weathers, and success depends on regularity and punctuality.

Regular scheduled services cannot be operated without adequate terminal airports and intermediate aerodromes, lighted for night flying; efficient communication and radio services and an extensive meteorological organization. They call for speedier aircraft of higher horse power and can only be operated successfully under mail contracts with the Post Office or other forms of government subsidy.

As has been previously noted, a study was made of the possibilities of inter-city air mail services in 1920 and it was decided that these were too costly for consideration at that time. The development of air mails to outlying districts had been growing up naturally with the inauguration of air transport services to the mining communities. The Post Office Department had, in 1924, given permission to northern operators to carry mails and had permitted them to issue twenty-five cent "stickers" to pay for the service. The regularly with which the mails had been carried under difficult conditions with no assistance or subsidy proved that the carriage of mail was not only feasible in northern Canada, but was much more efficient than the means hitherto used. Contracts were let in the autumn of 1927 for air mail services in outlying districts as follows:—

(*a*) *Murray Bay - Seven Islands and Anticosti (Winter Service)*

The scattered communities on the River and Gulf of St. Lawrence are accessible in summer by water but in the winter were dependent on mails drawn by sleigh as far as Bersimis and thence by dog team twice during the winter as far as the Straits of Belle Isle. The time taken for the conveyance of mail was six weeks and the cost high. The whole area is now served regularly by air, receiving mails twice a week. Travellers can come and go along the coast; facilities for medical aid and the hospitalization of serious cases have proved of great value.

(*b*) *Moncton - Magdalen Islands*

The Magdalen Islands were isolated for several months in the year and were wholly dependent on radio for communication with the outside world. Winter mails were occasionally floated ashore in barrels and picked up on the north coast of Prince Edward Island. Mails, passengers and express now pass regularly by the winter air service.

(*c*) *Rolling Portage - Red Lake*

This was the first of the regular air mail services to the mining areas and is typical of that class of work. The convenience to the inhabitants of these mining districts is very great.

(*d*) *Leamington - Pelee Island*

Each winter communication between Pelee Island with the mainland in Ontario is interrupted by ice floes on Lake Erie. The mails used to be carried by row boats, which could be hauled over the ice and launched again in the open water. This cumbersome method has been completely superseded by the carriage of mail by air. The distance is short and the cost is small.

The advantages of such air mails are obvious. The Post Office has extended these services year by year until

**Fig. 12—Pounds of Freight Carried.**

**Fig. 13—Pounds of Mail Carried.**

Fig. 14—Trans-Canada Airway Intermediate Aerodrome, Caddy Lake, Man.

they now serve all outlying parts of the Dominion. The Postmaster General stated recently in the House of Commons that the air mail business for the fiscal year 1936-37 had been profitable, the cost being $284,000 and the revenue $605,000. (See Figs. 6 and 13.)

The Post Office Department have an agreement for the interchange of air mail traffic with the Postal authorities of the United States. This gives Canada the full advantage of the air mail system in the United States and its extensions abroad in Central and South America and later on the trans-Pacific service. International services giving air mail connections in western, central and eastern Canada have been made from Vancouver to Seattle, Winnipeg to Chicago and Montreal to New York.

In regard to trans-Atlantic mail service it was found that incoming and outgoing trans-Atlantic mails could be materially hastened by flying the urgent matter from Rimouski to Montreal. Arrangements were made with the British Post Office to pouch special mails separately. These are transferred to the aircraft waiting at Rimouski and flown to Montreal. In the same way, mails received in Montreal after the steamer had sailed can be placed on board at Rimouski. Experimental flights were made in the fall of 1927 by seaplane but it was found that the absence of a sheltered base near Father Point prevented the maintenance of a regular schedule. A suitable aerodrome was located near Rimouski Wharf and since 1928 this service has been continued each year during the summer season of navigation.

Experiments were made in September, 1931, and again during the Imperial Conference in 1932 to make a further saving of time by the extension of the mail service to the Straits of Belle Isle, where contact was made with the incoming and outgoing steamers. Thus one-third of the trans-Atlantic journey was made by air. During the past two years an all-air trans-Atlantic mail service has been under consideration and plans for the extension of the ship to shore service have been abandoned in favour of the all-air route.

A preliminary conference was called in St. John's, Newfoundland, in 1933, to consider the trans-Atlantic air service, and at a conference of representatives of the Canadian, United Kingdom, Irish Free State and Newfoundland Governments in Ottawa in November, 1935, an agreement for co-operation was reached. The Canadian Government has accepted responsibility for the radio and meteorological services in Newfoundland and eastern Canada necessary for its efficient operation and preparations on the ground are well advanced. It is expected that trial flights will commence in June, 1937. Trans-Atlantic air services are the subject of a special paper in this series and therefore will not be considered at greater length.

### The Trans-Canada Airway

The success of the inter-city air services in Europe and the steady growth of the United States airway system led in 1927 to a reconsideration of Canada's position

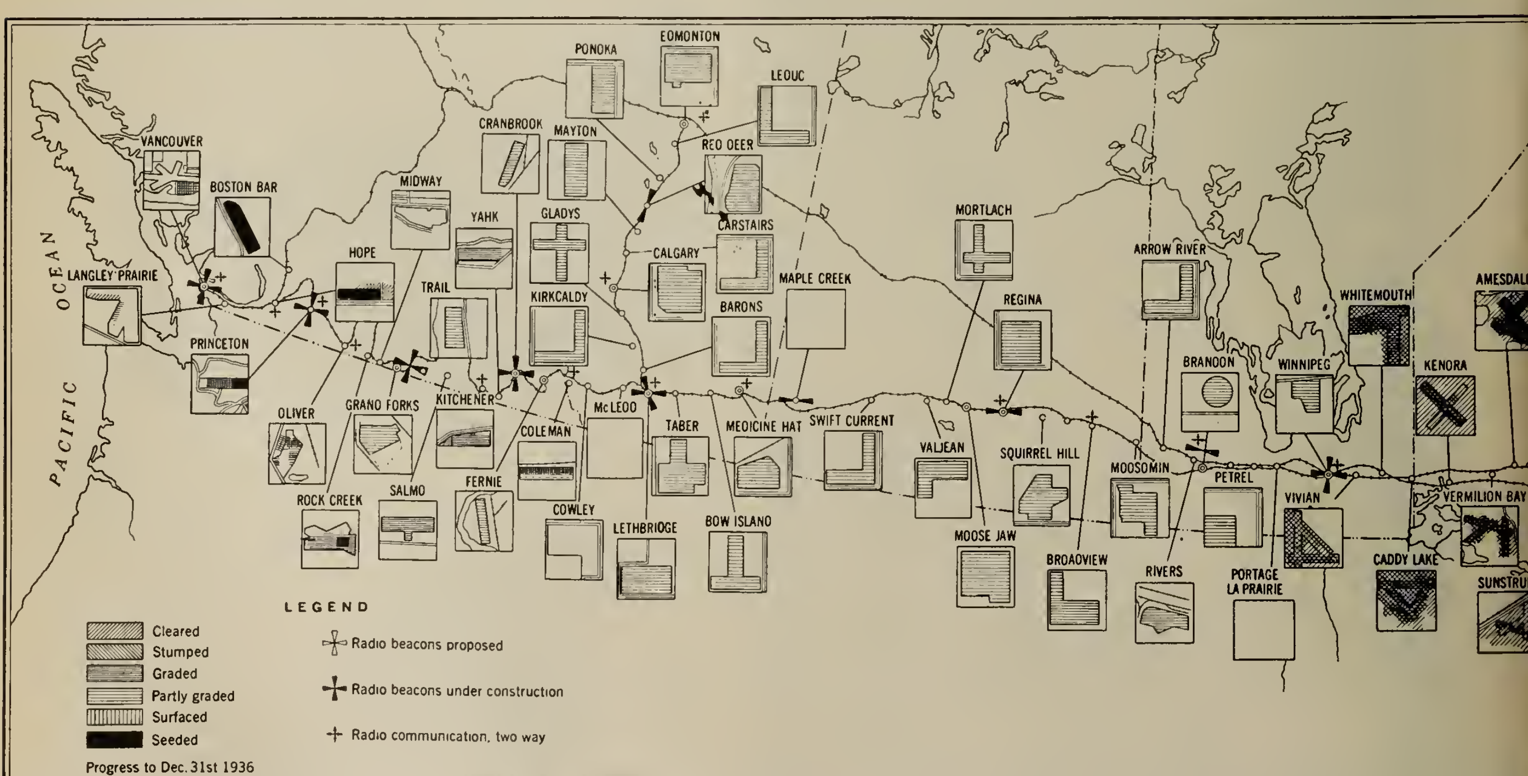

Fig. 15—Map showing

in regard to inter-city air mails. The cost of building the trans-Canada airway was estimated at from $5,000,000 to $6,000,000 but revenues were buoyant and it was felt that it would become an essential part of our transportation system before many years had passed. Canada, as one of the great trading nations of the world, must move with the times. Signs were evident of the desire of the United States air transport companies to tap traffic in the main centres of population and industry in Canada, which are not far from the international boundary, and to feed it into the United States airway system. In 1928 permission was given to commence the survey for a Canadian transcontinental airway.

Due to the activities of the flying clubs and the support they were receiving from their communities, a chain of airports was coming into being from coast to coast. In the Maritime provinces, Sydney, Halifax, Saint John and Moncton all secured sites and were busy constructing airports. In Ontario, Kingston, Hamilton, St. Catharines, Brantford, London and Windsor were all moving, while in Toronto the club had secured premises which, with improvement, would serve the purpose, and at Montreal the airship base at St. Hubert made an admirable site for an aerodrome. In western Canada all the principal cities were active, so that the foundation for the trans-Canada airway was provided by the municipalities it would serve when completed.

Intermediate aerodromes to fill the gaps between these major airports, the lighting required for night flying, and the radio and weather services would be the contribution of the Dominion Government, who also pay for the carriage of the mails by contract with the Post Office Department, which stoutly backed the project.

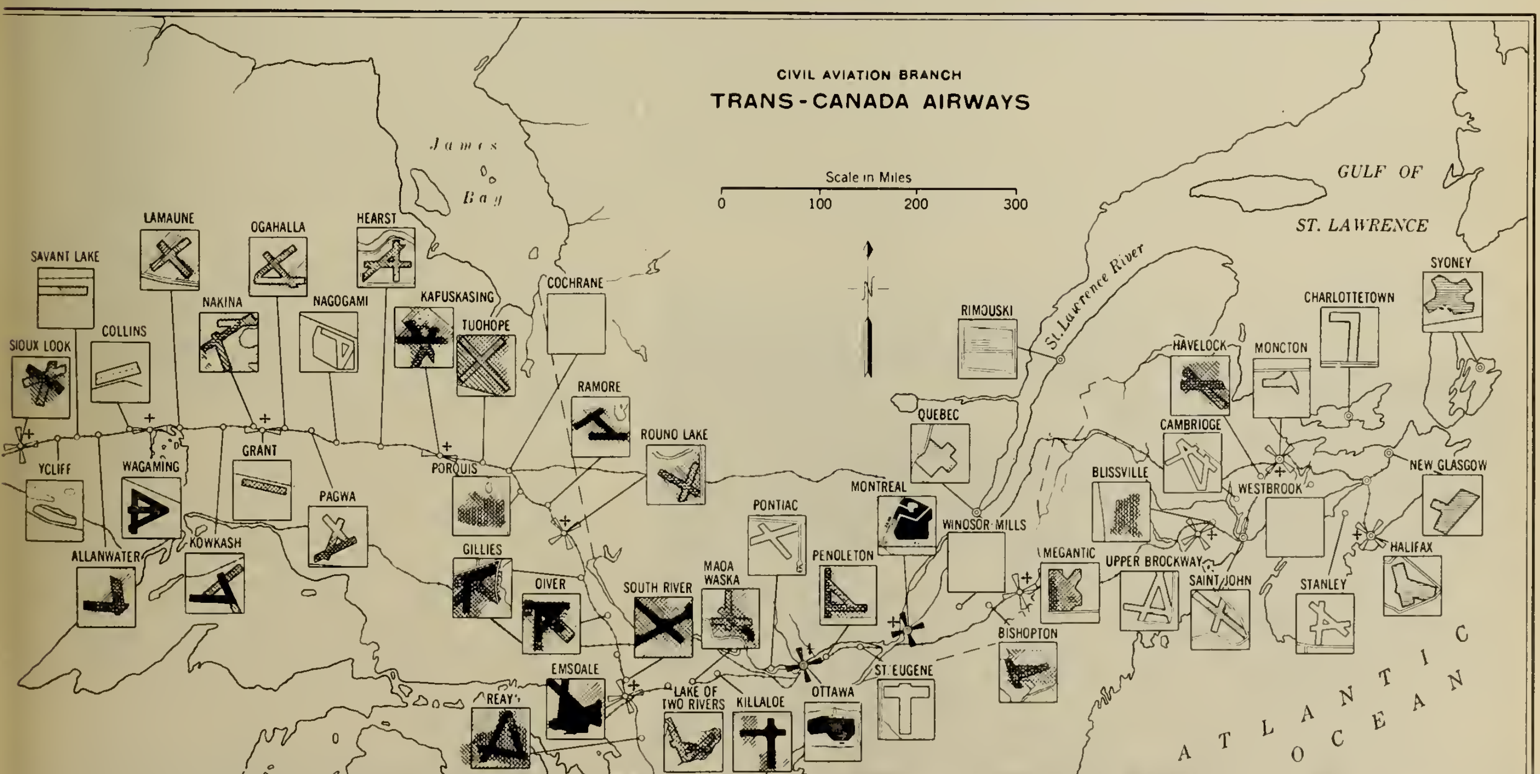
That section of the airway lying in the prairie provinces presented the simplest problem and was tackled first. By flying the mails over night between Winnipeg and Calgary a twenty-four hour saving in the transcontinental journey could be made without waiting for the completion of the more difficult sections through the mountains and the rugged section in northern Ontario. The location of the intermediate aerodromes in the prairie section, the leasing and improvement of the necessary properties, and the installation of the lighting, radio and meteorological services were completed in March, 1930, and a nightly service was inaugurated under contract with the Post Office between Winnipeg and Edmonton, via Calgary, in the first place, and later via Lethbridge and Calgary.

A contract for a daily air mail service from Moncton to Montreal, Kingston, Toronto, Hamilton, Brantford, London, Windsor and Detroit was let by the Post Office at the same time and arrangements were made with the United States air mail service for the conveyance of mail between Detroit and Pembina, south of Winnipeg, over the United States airway, so that there was a through connection by air between Moncton and Edmonton by the spring of 1930.

Surveys were continued through the Rocky Mountains to determine the best route from the prairies to Vancouver and also east of Winnipeg. These showed that the Crow's Nest route through southern British Columbia was shorter, the climate was better, it passed through a more settled area and the difficulties of constructing aerodromes were less there than on the alternative routes via the Yellowhead and Kicking Horse Passes. Aerodromes were already in existence on the route at Fernie, Cranbrook, Trail, Grand Forks and Chilliwack.

On March 31st, 1932, the necessity for economies in all public services forced the Government to discontinue the inter-city air mail services. Permission was given to maintain intact those sections of the airway which had been constructed and to continue surveys for its completion.

A year later, the need for finding suitable employment for the many thousands of single, homeless men in different parts of the country led to the establishment of construction camps on various projects. Airway construction work was specially suitable for this purpose and authority was given to commence construction of the intermediate



the Trans-Canada Airway.

aerodromes in British Columbia and in Ontario, Quebec and the Maritime provinces. The locations for all intermediate aerodromes in British Columbia had by that time been fixed, so that clearing and grading could be proceeded with at once.

In northern Ontario the task of finding the best route through the thousand miles of forest, lake and rock of the Precambrian Shield was a difficult one. It was advisable that the airway should keep in close touch with existing railway lines there. The airway surveys had showed that the route along the line of the National Transcontinental Railway from Winnipeg east to Cochrane was preferable to that followed by the C.N.R. line or the C.P.R. line. It passed through easier country; the climate, though colder, was more even than on the route by the shores of the Great Lakes, and it would serve the growing mining districts in northern Ontario and Quebec. Sites on which aerodromes could be constructed at a reasonable cost in the Laurentian country at approximately thirty-five mile intervals were hard to find. The clearing, stumping and grading of the sites provided a suitable task for the re-employment of single, homeless men and camps were established at all sites during 1934 and 1935 and much valuable work was done through this scheme. Construction was extended also through the eastern townships of Quebec and the Maritime provinces. On July 1st, 1936, the Government decided that the camps should be closed. The Civil Aviation Branch has continued construction by day labour or contract since then.

By July 1st, 1937, the western section should be ready for operation, complete with lighting, radio and meteorological services, and one year later the remainder of the airway from coast to coast should be sufficiently far advanced to enable safe operation to be conducted by night or day.

Legislation is now before Parliament creating a trans-Canada operating company, which will be entrusted by the Government with the operation of the airway. Tentative schedules arranged with the Post Office Department call for mail posted at the close of the business day in Montreal, Ottawa, Toronto and other eastern cities to be delivered by first mail the next morning on the prairie and first afternoon post in Vancouver.

### Airship Services

At the Imperial Conference in 1926 the support of Canada was promised by the Prime Minister in the development of a system of Empire air communications by airship. Under this agreement Canada constructed an airship base at St. Hubert, seven miles east of Montreal. The site was chosen by Major Scott, Director of Airship Development in the Air Ministry, after a survey of all likely sites in eastern Canada.

The construction of the base was undertaken in conjunction with the Public Works Department, who became responsible for the engineering work involved, the design and construction of the mooring tower and other facilities, including a hydrogen plant and mooring winches. The construction work was completed early in 1930.

The crew for the mooring tower was lent by the Royal Canadian Navy. Lieutenant-Commander A. B. Pressy, R.C.N., and four experienced naval ratings had been sent to the Royal Airship Works at Cardington to gain experience in airship operation during the trial flights of H.M. Airships R.100 and R.101.

The wireless system was organized by the Royal Canadian Corps of Signals and the Meteorological Branch of the Department of Marine arranged for a special study of trans-Atlantic weather in co-operation with the Meteorological Service in the United Kingdom.

On the evening of July 28th, 1930, notification was received that H.M. Airship R.100 would leave Cardington for St. Hubert early on the morning of the 29th. The airship arrived over Montreal on the evening of the 1st of August and was successfully moored at dawn the next day. During her stay at St. Hubert, a successful flight over Ottawa, Toronto and Niagara was made and the airship was then refuelled, regassed and reballasted and was ready for departure on August 13th. She slipped her mooring cable at 9.30 p.m. Quebec was passed before midnight, Father Point at 2.00 a.m. and Belle Isle on the 14th. On the morning of August 16th she was reported over Lundy Isle in the Bristol Channel and before noon was safely moored again at Cardington.

Many valuable lessons were learned during the flight. So far as the Canadian part in the experiment was concerned, the handling of the airship, her servicing and repair at the mast and the ease with which she was moored and unmoored proved conclusively that the design and construction of the Canadian base was sound. A crew of fourteen men, of whom only five had ever seen an airship before, handled this airship with ease and certainty.

The destruction of the sister airship R.101 in France in the fall of 1930 while en route to India led the Air Ministry to reconsider their plans and no further use has since been made of the airship equipment at St. Hubert; it has been maintained in working order pending a final decision on airship services.

Courtesy of Royal Canadian Air Force.

Fig. 16—H.M. Airship R.100. St. Hubert, 1930.

In justice to the staff of the Air Services in Canada, civil, military and technical, it should be stated that their unanimous opinion was that while airships might prove efficient under certain conditions, the North Atlantic ocean was not a suitable proving ground for their development.

### Flying Club Movement

In the fall of 1927, two urgent problems faced the Civil Aviation Branch. The first was the provision of municipal aerodromes in all parts of the Dominion. Flying had been confined to seaplane and ski operations and there were no improved aerodromes in the country, though a few fields had been licensed for use. Before any Dominion-wide inter-city services could be inaugurated, proper airports were essential. The Dominion Government could not build airports in every municipality and the responsibility must be shouldered by the municipalities as their contribution to the airway system.

The other problem was the acute shortage of Canadian pilots. Even the Dominion and provincial government services had had to send to Great Britain to recruit the pilots they required for their work. There were practically no flying instruction facilities in the country and experience had shown that flying instruction was not a profitable venture. The flying club movement in Great Britain had been successful and it was considered that if a flying club could be organized in every important Canadian centre, both needs would be met.

The standard conditions, as approved by Order-in-Council, provide that any community pledging itself to provide the services of an instructor and an air engineer, a licensed aerodrome and adequate accommodation for the housing and maintenance of the machines, would be issued with two light aircraft by the Department in the first year, and in each subsequent year, if they supplied from their own resources a machine of an approved type, the Department would issue one further light aircraft. Further, the Department would pay to the club a grant of $100 for each *ab initio* pupil obtaining a private pilot's certificate.

Sixteen clubs were started during 1928 and in 1929 seven additional clubs. Their success has fully met the expectations of the Department. The following Table I shows the progress of the club movement:—

Table I

Summary of Flying Club Activities 1928-1936

| Year | Members | Aircraft in use | Members under instruction | Hours flown | Licences obtained | |
|---|---|---|---|---|---|---|
| | | | | | Private | Commercial |
| 1928 | 2,403 | 34 | 598 | 8,124.30 | 111 | 28 |
| 1929 | 5,233 | 65 | 904 | 16,612.50 | 175 | 58 |
| 1930 | 3,643 | 70 | 703 | 14,686.44 | 178 | 59 |
| 1931 | 2,915 | 72 | 673 | 11,507.32 | 111 | 48 |
| 1932 | 2,703 | 68 | 872 | 10,450.55 | 129 | 27 |
| 1933 | 2,075 | 68 | 499 | 9,971.59 | 120 | 26 |
| 1934 | 2,200 | 82 | 535 | 10,581.33 | 133 | 21 |
| 1935 | 2,400 | 81 | 536 | 13,819.31 | 165 | 33 |
| 1936 | 2,492 | 66 | 645 | 17,324.01 | 210 | 34 |

It may be noted that during the years of the depression the average cost to the Government of maintaining the flying clubs was little more than a thousand dollars per club per annum.

### Aircraft Industry

An aircraft industry to construct in Canada the aircraft required for military and civil flying was essential for the sound development of flying.

After the armistice, surplus war types of aircraft were thrown on the market at sacrifice prices and there was little or no demand for new aircraft. The industry ceased for the time being, but by 1923 the demand for civil aircraft built in Canada to meet Canadian conditions was such that the manufacture of aircraft began again.

Canadian Vickers were the pioneers. Their first contract was for eight "Viking" amphibians, a type which had been produced by the parent company in England. In 1924 they added a design staff to their organization and undertook the development of special types to suit Canadian conditions. Their first production was the "Vedette," a three-seater flying boat specially built for forest sketching, light transportation and aerial photography. This type has been most successful and is still in use for seaplane flying, instruction, forest patrols and forest type sketching. In 1925, the "Varuna," a twin engined flying boat, specially built for forest fire suppression in the prairies, and other types, were designed and built. Later the company built "Fokker" types and during 1936 the Northrop "Delta" under licence. They are now engaged on a contract for five "Stranraer" twin engined flying boats for the Royal Canadian Air Force in addition to other work.

Fig. 17—De Havilland Dragon "Rapide" Twin Engined Aircraft.

In 1927, with marked activity in flying and promise of further extensions, other companies entered the field, including the de Havilland Aircraft of Canada Limited, a branch of the parent company in Great Britain, and makers of the popular "Moth" aircraft. They built a plant for the service and assembly of aircraft in Toronto and during 1928 delivered sixty-two aircraft to users in Canada, including "Moths," the D.H. 61, a larger, general purpose biplane suitable for northern transportation and forest fire suppression work, and have since then continued to play an important part in the supply of aircraft in Canada, including the "Tiger," "Puss," "Hornet" and "Hawk" Moths; the "Dragon," "Dragonfly" and "Rapide" twin-engined types.

The Reid Aircraft Company established a plant at Cartierville aerodrome, Montreal, in February, 1928, and commenced the manufacture of aircraft to their own designs. In January, 1929, the Curtiss Aeroplane and Motor Company entered into an agreement with the Reid Aircraft Company and this firm was afterwards known as the Curtiss-Reid Aircraft Company, and later as Montreal Air Industries Limited. Finally, in 1935, the plant was taken over by the Noorduyn Aircraft Company Limited to manufacture the Noorduyn "Norseman" general purpose transport, designed specially to meet Canadian conditions. (See Fig. 18.)

In 1928 Armstrong-Siddeley Motors established a branch in Ottawa for the service, assembly and repair of their aero engines in Canada, including the well known 750 hp. "Leopard"; 455 hp. "Jaguar"; 225 hp. "Lynx"; 140 hp. "Mongoose"; and 85 hp. "Genet," while the allied interests of the Ottawa Car Company arranged with the A. V. Roe Company to establish a plant for the manufacture of the "Avro" types.

The two leading engine manufacturers in the United States also established assembly and service plants for their engines at Montreal—the Canadian Wright Company, the makers of the famous "Whirlwind" cyclone series of engines, and the Canadian Pratt & Whitney Company, the "Wasp" and "Hornet" engines.

The Fleet Company of Buffalo established a Canadian branch at Fort Erie in 1930. It was re-organized in 1936,

**Fig. 18—Noorduyn "Norseman" General Purpose Single-Engine Aircraft.**

is now wholly controlled in Canada and builds the well known "Fleet" trainer and is agent for "Waco" types.

The Boeing Company of Seattle established a branch plant in Vancouver in 1929 for the manufacture and service of their aircraft in Canada in co-operation with the Hoffar-Beeching Shipyards of Vancouver, who had previously acted as their agents to build flying boats and mail planes.

In co-operation with the Fairchild Aviation Corporation of New York, a group of Canadian business men organized the Fairchild Aircraft of Canada Limited early in 1929. A modern aircraft factory was constructed and production commenced in April, 1930. The Fairchild Company had, since the earliest days, been interested in Canadian aviation through the Fairchild camera. They became closely identified with the early experimental work, and later, in practical operations in transport and air services, they obtained a wide experience of Canadian operating conditions and have built their aircraft to suit them. Fairchild types—F.C.2 or "Razor Back," the "51," "71" and "82"—are known in every operating field. The design and production of a twin engined plane suitable for northern operations and a large, single engine freight carrier are now in hand.

Table II

Aircraft Industry—Statistics of Production
1923-1936

| | Number of aircraft built or assembled in Canadian factories | Number of aero engines built or assembled in Canadian factories |
|---|---|---|
| 1923 | 10 | |
| 1924 | 13 | |
| 1925 | 11 | |
| 1926 | 5 | |
| 1927 | 17 | |
| 1928 | 83 | |
| 1929 | 175 | 70 |
| 1930 | 116 | 32 |
| 1931 | 64 | 55 |
| 1932 | 12 | 3 |
| 1933 | 15 | 3 |
| 1934 | 21 | 10 |
| 1935 | 62 | 33 |
| 1936 | 86 | 53 |
| Total | 677 | 259 |

Table II gives some statistics of Canadian Aircraft production.

In addition to these aircraft manufacturing companies, other firms have specialized in the manufacture of floats and skis, including MacDonald Brothers in Winnipeg, who commenced with the manufacture of Edo floats and now do a general aircraft servicing business in addition to their float work. Elliott Brothers of Sioux Lookout were originally boat and toboggan builders. With the development of the mining industry in northern Ontario they had ample opportunity of studying the practical requirements for winter landing gears and have specialized in this work with notable success.

**Fig. 19—Fairchild Super "71" on Floats.**

Aeronautical Research

In 1919 the Air Board requested the Honorary Advisory Council for Scientific and Industrial Research (now the National Research Council) to organize an Associate Air Research Committee whose function would be the fostering of aeronautical research in Canada and the supplying of technical assistance to the Air Board in solving its problems.

The Committee was similar to the other associate committees of the Advisory Council which had been formed to deal with chemistry, mining and metallurgy, etc., and reported directly to the Advisory Council; copies of all its proceedings were sent both to the Advisory Council and to the Air Board. The members of the Committee were qualified by familiarity with scientific or aeronautical work.

The first meeting of the Committee was held on February 7th, 1920. The problems awaiting solution and those likely to arise in the near future were reviewed. Steps were taken to obtain information as to experimental work accomplished and in progress in England, France and the United States in order to avoid duplication. The aircraft industry was notified of the formation and objects of the Committee and suggestions were invited as to the lines of work which would be of assistance to the industry.

The next step was to discover what research facilities existed in the Dominion and what men were available to work in the field of Aeronautical Research. Enquiries were sent out to all the Canadian universities asking what their facilities were, what aeronautical research work had been done, what work was in progress or what work, if any, was contemplated in aeronautics.

In the years that followed the Committee were able to make financial grants to assist aeronautical researches carried out in various parts of the Dominion. The facilities of the University of Toronto wind tunnel were valuable both to the Committee and the industry, as likewise were those for engine research at McGill University and the University of Alberta, and the co-operation given by other universities and scientific men throughout Canada.

Some of the more important problems dealt with by the Committee are as follow:—

1. The winter operation of aero engines with special reference to starting conditions. This work covered an investigation of the running conditions, lubrication, cooling, etc., of aero engines at low temperatures. The starting and early running technique developed from this work was made a routine in the flying service for a number of years.
2. Effect of low temperature on lubricating oils and on the strength of materials such as spruce, ply wood, streamline wire and rubber shock cord.
3. Development of a controllable pitch propeller. Funds were provided for the construction of the experimental propeller and arrangements were made for it to be tested. The propeller was successful and has now been commercially developed.
4. The elimination of magneto noises in the radio-telegraphic receiving equipment for aircraft.
5. The development of a piezo-electric engine indicator.
6. The development of the most efficient type of windmill, a research that has a direct commercial and utilitarian value.
7. Aerodynamic investigations on tapered wings, wind-tunnel wall interference and the stability of flying boats.

The Committee now functions as a liaison between the aircraft manufacturers and operators on the one hand and the aeronautical laboratories of the National Research Council on the other, thus bringing together representatives of all organizations interested in Canadian aviation problems.

### The Engineering Institute of Canada and Aviation

This review of aeronautical activity in Canada would not be complete without a reference to the relations between the older, well established branches of engineering and The Institute itself to the new science. All aviation services, civil, military and technical, owe much to the interest, helpful support and ready co-operation received from engineers in all parts of the country and from them, in a corporate capacity, through The Institute. From the earliest days Institute meetings in all parts of the country have welcomed speakers on aviation and have provided a platform from which our work and aims might be made known.

Aeronautics is not a self-contained science, and calls for contributions from all branches of engineering: mechanical in its engine development, structural in aircraft design, electrical in lighting and radio, civil in aerodrome and building construction. Forest engineers and surveyors gave the air service its first opportunity to prove its value in Canada. In the development of aviation in Canada, engineers of all branches have played a notable part.

The Institute has been generous in welcoming as members many engaged in aviation. Co-operation between the Royal Aeronautical Society of Great Britain and The Engineering Institute of Canada has been close. It was decided some years ago that where a branch of The Institute desired to form an aeronautic section, this section would become automatically a branch of the Royal Aeronautical Society. The Montreal and Ottawa Branches immediately formed such sections, which hold meetings regularly for consideration of this particular phase of engineering work. The papers presented are printed in special supplements to the Engineering Journal.

Any member of The Institute can become a member of the aeronautic section, and by an exchange arrangement copies of the aeronautic section reprint of the Journal are sent to the Royal Aeronautical Society in return for copies of the Journal of the Royal Aeronautical Society, which are issued to members of The Institute belonging to the aeronautic sections. This arrangement also provides a much larger circulation for papers presented in Canada before the comparatively small audience of a local aeronautic section.

The election to the Presidency of The Institute in this, the Jubilee year, of G. J. Desbarats, C.M.G., Hon.M.E.I.C., is particularly gratifying to everyone connected with flying. As Deputy Minister of the Naval Service during the war, he administered the first Canadian air service. In the drafting of the Air Board Act in 1919 he lent advice and guidance. In the same year he encouraged the first trials of aircraft in forestry by authorizing the loan of two flying boats for this purpose. From 1923, when he became Deputy Minister of National Defence, till his retirement from the public service in 1933, he was responsible for the administration of aeronautics in Canada. His patience and imperturbability in the face of difficulty and discouragement, his balanced judgment and wise counsel in times of prosperity, and his ready sympathy at all times have gained for him the respect and affection of everyone in aviation. His great gifts as an administrator and his high conception of duty as a servant of the State have been a constant inspiration to those who had the good fortune to serve under him.

# Bridge Building

*C. R. Young, M.E.I.C.,*
*Professor of Civil Engineering, University of Toronto*

During the fifty years that have elapsed since the predecessor of The Engineering Institute was founded, the science of bridge building, along with whatever of art there is in it, has moved forward with amazing strides. Records of boldness, ingenuity and originality unsurpassed in any other country have been established in the bridge work done within our own borders.

### Fifty Years Ago

The late eighties found many new developments of importance under way. More permanent forms of construction had been forecasted in the construction of many iron bridges for the Grand Trunk Railway in the early fifties and, thanks to the pertinacity of Sandford Fleming, in the construction of many more for the Intercolonial Railway in the early seventies. Nevertheless, by far the greater number of bridge structures in Canada had been built of timber—the material that was closest at hand and easiest to work. Stone masonry had been used for piers and abutments, but, in strong contrast with the practice in Europe, very little use had, or has subsequently, been made of the masonry arch type of superstructure. Concrete was still a material to be used with great caution and seldom permitted to show itself above water level. As late as 1898, concrete closer to the surface than 20 ft. was not allowed in the substructure of the Alexandra cantilever bridge over the Ottawa river, at Ottawa.

**Fig. 1—Three Bridge Types at Windsor, N.S.**
**Half-deck plate girder spans, English riveted lattice truss spans of 1880, and pin-connected Pratt truss spans.**

As the nineties approached, fire hazards and short structural life were forcing the Canadian Pacific Railway to consider the replacement of many of its timber bridges. In order to speed up construction, and incidentally to lessen interest charges, much temporary work had been done on the transcontinental line, involving long, high timber trestles, timber truss spans up to 180 ft. in length and many timber pile or crib substructures. It was not long before these were forced to give way to steel.

Things were stirring, too, in the field of highway bridge construction. In Nova Scotia steel highway bridges had been built as early as 1883 and thereafter the use of wood for such structures rapidly decreased. In Ontario, the progressively poorer quality of local timber had reduced the life of wooden bridges to from eight to twelve years and the activities of the amateur bridge-builder, accepted for this type of construction, had greatly shortened the expectancy. Faulty joints, lack of counterbracing and excessive deflections soon racked many structures to pieces, if they by chance survived the passage of the neighbourhood traction engine.

A strong incentive towards the application of metal to bridge construction in bolder and more massive forms had been given in the successful completion of the famous Kentucky river cantilever in 1876, and the St. Lawrence river continuous bridge at Lachine, in 1886, according to the designs of C. Shaler Smith, as well as in the signal achievement of Sir John Fowler and Sir Benjamin Baker at the Firth of Forth. Steel was beginning to come to the fore with all of its fascinating possibilities, and, as the decade drew to a close, the first reinforced concrete bridge built in America was completed in Golden Gate Park, San Francisco.

With such a background the drama of Canadian bridge building rapidly unfolded. New materials, new forms, and new methods were devised and applied, with an outcome that we continue to contemplate with professional pride. In the pages that follow the progress during the half century now completed will be examined primarily in relation to the material of the superstructure and, within this classification, in accordance with the structural type. Substructures will be mentioned in a separate classification.

## STEEL SUPERSTRUCTURES

### Simple Plate Girder Spans

As a derivative of Robert Stephenson's tubular bridges, simple plate girder spans of considerable length had been built some time before the organization of the Canadian Society of Civil Engineers and many followed soon thereafter. C. Shaler Smith employed 80-ft. spans with rocker supports in the St. Lawrence bridge at Lachine, in 1886. The long span Howe truss wooden bridge of the Canadian Pacific Railway over the Jacques Cartier river, P.Q., was replaced in 1887 by 85-ft. deck plate girder spans on stone

**Fig. 2—Champlain Bridge, Ottawa River, Ottawa.**
**A highway deck plate girder structure, including four 125-ft. spans. 1929.**

**Fig. 3—C.N.R. Subway at Breslau, Ont.**
**Steel girders and floorbeams with reinforced concrete stringers and deck. 1931.**

masonry piers, giving an appearance in elevation strikingly like modern plate girder bridges. In the ensuing years, an increasing number of railway plate girder spans were

**Fig. 4—C.P.R. Half-Mile Bridge, Don Valley, Toronto.**
**Girder spans weighing 105 tons handled by single derrick. 1928.**

erected, both as replacements and as original structures.

Such novelty as has been associated with plate girder bridge construction in recent years has generally gathered about the method of erection. An unusual plan was followed in 1912 by the Dominion Bridge Company, Ltd., in the case of the C.P.R. bridge at Ste. Rose, P.Q., when 78-ft. deck plate girder spans replacing old 157-ft. through truss spans were moved along the old structure on flat cars, slung up to the trusses and lowered in place on their piers after the floor and lateral system had been taken out of the span to be removed. About the same time, the half-deck plate girder spans of the Dominion Atlantic Railway bridge at Windsor, N.S., shown in the foreground of Fig. 1, were erected by the same company, utilizing a light erection truss span which was dropped in place by a derrick and upon which the girders were end launched. It is incidentally of interest to note the contrast of types in the illustration. The truss spans in the near bridge are light pin-connected railway spans removed from the bridge at Ste. Rose, P.Q., already mentioned, the middle structure is of English riveted lattice truss spans, built about 1880, and the bridge in the background is a light pin-connected highway structure, of about the year 1900.

Although size, weight and erection difficulties generally preclude the use of long plate girder spans for highway bridges, there have been some notable exceptions to the rule. The main highway between Toronto and Montreal now crosses the Ottawa river over two large deck plate girder bridges separated by Ile Perrot. The westerly bridge, built in 1924, contains, in its 17 spans, 7 spans 101 ft. long, while the easterly one, built somewhat later, contains 11 plate girder spans and 3 truss spans. For the plate girder spans no stringers were used, the floor slabs resting on floorbeams cantilevered over the main girders and spaced at 5 ft. centres. Both structures were designed by L. V. Denis, A.M.E.I.C., of the Department of Public Works of Canada.

Another notable highway bridge utilizing deck plate girder spans is the Champlain bridge (Fig. 2) over the Ottawa river, at Ottawa, built under the direction of A. K. Hay, A.M.E.I.C., in 1929. Of the 26 spans, 4 are 125 ft. long and 12 ft. deep, with bottom flanges sloping near the ends. The superstructure was fabricated and erected by the Dominion Bridge Company, Ltd.

Extensive use of the simple plate girder type of bridge has been made in grade separation structures. By reason of the ever pressing problem of reducing the distance from base of rail, or finished roadway, to the underside of the superstructure to an absolute minimum, much attention has been given to the design of shallow floor systems. In the early years of the present century considerable numbers of grade separation bridges were built without stringers, but with closely spaced transverse floorbeams of rolled I-sections with concrete filling between and a concrete deck over them on which the ballast and trackage were placed. The soffits of the floorbeams were left exposed. Examples of this type of construction are to be seen in the grade separation structures along the C.P.R. line through North Toronto. In the case of the Mountain street and Guy street grade separation bridges of the Canadian National Railways, at Montreal, built in 1931, with closely spaced floorbeams and no stringers, the steel below the sidewalk level was given a 2-in. gunite coating over mesh reinforcement.

**Fig. 5—C.P.R. Viaduct at Lethbridge, Alta.**
**Longest and highest viaduct in Canada. 1909.**

**Fig. 6—Original C.N.R. Bridge over the St. Lawrence at Coteau, Que. 1889.**
**Early example of fully riveted work. Thirteen out of seventeen spans erected by flotation.**

A variation of this type was developed in accordance with which closely spaced I-beam stringers, encased and covered as in the type above mentioned, were used. These stringers were supported at the middle of the highway by a bent parallel to the highway and composed of deep and heavy plate girders supported by H-section columns. On account of the depth of the girders no bracing was found to be necessary in the plane of the bent. Examples of this type are to be seen in the Kenilworth avenue subway, Hamilton, built in 1915, and in the grade separation structures over Bloor street west, Toronto, built in 1925.

An important development in the plate girder type of grade separation bridge is seen in the use of reinforced concrete T-beam construction for stringers and slab with transverse floorbeams of structural steel. Several such structures have been built in the Central Region of the Canadian National Railways, of which C. P. Disney is bridge engineer, as, for example, the subways at Breslau, Ont. (Fig. 3), Shannonville, Ont. and Charlesbourg Road, P.Q. A very important feature of these structures is that the rails rest directly on the concrete deck except for interposing steel chairs, oak cushions, or rubber cushions. The total depth of the floor construction is by this means greatly reduced, with an important resultant economy for the whole work.

A number of ingenious features are contained in the Vidal street grade separation bridge over the C.N.R. at Sarnia, built in 1932, and utilizing Canadian-rolled steel only. The floor framing consists of transverse floor beams, stringers heading into these floorbeams and 6-in. secondary I-beams running transverse'y across the tops of the stringers

**Fig. 7—Erection of the C.P.R. Bridge over the French River.**
**Span end-launched across the river in three hours. 1907.**

and carrying ¼-in. deck plates welded to their top flanges. To the top surface of the plates grids were welded and in and over these an asphaltic floor surfacing was laid. Both the main floorbeams and the transverse 6-in. beams were designed to utilize the floor plates as flange section, thus constituting an application of the battledeck type of construction. The 72-ft. centre span of the main supporting girders of the bridge is of the cantilever type, with a 48.5 ft. suspended span. Temperature changes are accommodated in the supporting bents by fixing the columns at the bottom and allowing them to bend. This constitutes a treatment

**Fig. 8—C.P.R. Bridge over the St. Lawrence, Lachine, Que.**

similar to that given the approach viaducts of the Hawkesbury bridge, over the Ottawa river, and the Canadian approach of the Detroit-Windsor bridge. The superstructure was designed and erected by the Sarnia Bridge Company, Ltd.

### Plate Girder Viaducts

For many years one of the most important uses of plate girders has been in the construction of steel viaducts. The wide and deep valleys of Canada invite crossing by structures of this type.

At the beginning of the half century period under review, numbers of tall steel railway viaducts were being built. These were generally of the deck type with noisy, pin-connected rod bracing that would not be tolerated today. Several of them were built for the C.P.R. near Toronto, on the Toronto-Montreal line.

In the Don Valley, a C.P.R. viaduct, known as the "Half-Mile Bridge," was built in 1888 and, forty years later, due to the added demands of traffic, was replaced, under the direction of P. B. Motley, M.E.I.C., engineer of bridges for the railway, in a manner calculated to excite the admiration of all bridge engineers, as well as laymen. Concrete piers were built without disturbing the existing steel towers and, between trains, plate girder spans 112.25 ft. long, riveted up complete and field painted, weighing 105 tons, were dropped into place by a single derrick, as shown in Fig. 4. The between-train task of the Canadian Bridge Company, Ltd., was to remove four plate girder spans and the tops of three bents, to run out and drop the new span into place, and erect and connect up the deck and rails. This was done with a maximum time from each breaking of track to the restoration of traffic of two and one half hours.

Incidental to the construction of the National Transcontinental Railway, now incorporated in the Canadian National Railways, a number of important steel viaducts were built. One of the most interesting of these is the Cap Rouge viaduct, some three miles west of the Quebec bridge, erected in 1906, by the Dominion Bridge Company, Ltd. It is distinctive in that the transverse bracing of the bents is of the stiff diagonal type without horizontal struts. A significant fact is that in spite of certain advantages that may be claimed for the bracing system it has not been widely adopted.

The longest steel viaduct on the National Transcontinental Railway is the Little Salmon River viaduct in New Brunswick, built in 1910. It has a length of 3,918 ft. and a height of 200 ft., with late girder spans of the half-through type. Horizontal struts with diagonals designed for tension only were used in this structure.

The longest and highest steel viaduct in Canada, and apparently the most massive one in the world, is the justly famous Lethbridge viaduct, which carries C.P.R. trains over the Belly river. This structure, 5,328 ft. long and 314 ft. high from river bed to base of rail, was built under the direction of the C.P.R. bridge engineer, then C. N. Monsarrat, M.E.I.C., and was fabricated and erected by the Canadian Bridge Company, Ltd., in 1909. Partly to safeguard the structure against serious damage due to derailments and partly for the psychological benefit to the traveller, the construction is of the through type. Tower spans are 67.1 ft. and intermediate spans 98.8 ft. The transverse bracing of the bents is of the conventional type, and while both the transverse and longitudinal systems are stiff they are figured for tension only. The manner of erection is indicated generally in Fig. 5.

**Fig. 11—Yonge Boulevard Bridge, near Toronto.**
**Heavy Warren truss structure on reinforced concrete H-piers. 1928.**

Many steel viaducts have been constructed by utilizing, in whole or in part, truss spans supported by either steel towers or concrete piers, or arch spans on a concrete substructure. Such bridges will be discussed under the superstructure type predominating in the bridge.

### Simple Truss Spans

Fifty years ago the employment of multiple intersection trusses was much more frequent than it is to-day. The deck spans of the C.P.R. bridge built over the St. Lawrence at Lachine were, therefore, not unnaturally of this type. In highway bridge practice the use of the double intersection Warren truss persisted for some time. For

**Fig. 12—Bayview Avenue Bridge, Toronto.**
Three lines of stringers with cantilevered end panels of end truss spans. 1929.

**Fig. 13—Burrard Bridge, Vancouver, B.C.**
An instance of the successful collaboration of engineer and architect. 1932.

example, the two 370.9-ft. spans of the highway bridge built at Richmond, P.Q., in 1903, were of this form. Nowadays, Pratt or single intersection Warren trusses, subdivided if need be, are commonly employed. The use of very long parallel chord trusses, such as were used in the Richmond bridge, is less frequent. For through construction, sloping top chords are often employed for spans as short as 150 ft.

Pin-connected trusses, with their rattling eyebars, counters and rod laterals, have long since given way to stiff riveted structures, except for the very longest spans. A record was established with the construction of the Richmond bridge in that the 370.9-ft. spans continued for many years to be the longest riveted highway spans in existence. When European fabricators, who never succumbed to the American fondness for the pin-connected type, furnished superstructures for Canadian crossings they were always provided with riveted connections.

A number of important simple truss span railway bridges were completed in the late eighties and early nineties. Amongst these may be mentioned the International bridge of the C.P.R., with 240-ft. fixed spans having curved top chords, at Sault Ste Marie, in 1889; the Fredericton bridge over the St. John River, in 1887; the C.P.R. bridge over the Portneuf river, P.Q., in 1890; and the Grand Narrows bridge, Cape Breton, about 1890.

Especially noteworthy was the construction of the well known railway bridge over the St. Lawrence river, at Coteau, P.Q., built in 1889. This structure, composed chiefly of 217-ft. double intersection Warren truss spans with sloping top chords, as shown in Fig. 6, was riveted throughout, a distinct departure for Canadian-fabricated work at that time. A mass-production type of erection was adopted, in that thirteen of the seventeen spans were assembled, riveted up completely, and stored on trestles from which they were taken off by barges and floated into position on their piers. The erection of the superstructure, carried out by the Dominion Bridge Company, Ltd., was probably the most rapid piece of work of its kind that had been performed up to that time. The Coteau bridge and the Grand Narrows, C.B., bridge were amongst the first bridges in Canada to be erected in this manner. Due to increasing live load the whole superstructure was renewed in 1910 and the erection done in very much the same manner as for the original bridge.

A very extensive piece of work involving simple truss spans was the rebuilding of the Victoria bridge over the St. Lawrence, at Montreal, in 1898, during which the 25 tubular spans were replaced by an equal number of simple Pratt truss spans. The old piers, built in the late fifties, had only to be extended a short distance up stream. The truss spans were erected around the old tubular spans with only slight disturbance to the traffic, this being possible by ingenious special construction at the tops of the piers.

Difficult erection problems involving simple truss spans were met admirably in floating into place the spans of the Northwest and Southwest Miramichi river bridges of the Intercolonial Railway, in 1901, and of the Shubenacadie river bridge, N.S., in 1903.

A special constructional feature exists in the simple truss combined railway and highway bridge across the Fraser river, at New Westminster, B.C., built in 1903, according to the design of Waddell and Harrington. The northerly span is a spread or Y-span, and although only 225 ft. in length is 19 ft. wide at the river end and 135.5 ft. wide at the shore end. This arrangement was necessitated by the bifurcation of the railway.

One of the cleverest erection procedures that has ever been carried out in this country was the erection of the C.P.R. bridge across the French river, in 1907, by the Canadian Bridge Company, Ltd. The main span is 412.7 ft. in length and riveted throughout. It is one of the longest

**Fig. 14—Reinforcement of C.P.R. Stoney Creek Arch, B.C.**
Stresses in new and old arch trusses equalized by weighting and special details. 1929.

**Erected as 3-hinged arch and transformed to 2-hinged condition. 1915.**

riveted railway spans ever built and at the time of construction was the largest and heaviest single track fixed span yet completed in Canada or ever erected by the end launching method. Moreover, it is believed that the record still stands. The forward end of the structure was carried on a scow, as shown in Fig. 7, and the rear end slid on greased rails. The load was transferred to the scow by a 155-ft. steel truss span designed for the Wanapitae crossing, and the heavy span was pulled forward by a hoisting engine utilizing as the pulling links a string of bottom laterals borrowed from the 250-ft. span designed for the Pickerel river crossing a short distance away. Once all the material and equipment, borrowed or otherwise, was assembled, the span was moved across the river in only three hours. C. N. Monsarrat was the engineer of bridges for the Railway.

Another ingenious method of erection was that for a 200-ft. C.P.R. truss span at Kenora, built about 1907. In the process of double tracking, the span had to be placed alongside an existing span. No falsework being possible in the river, suspended needle beams from each of the floorbeams of the old span were installed and stringers and rails were laid on these to form a skidway. Each truss was assembled separately on shore and hauled across the opening, after which it was jacked sideways and lowered into position on its bearings.

Replacement of the old continuous bridge of the C.P.R. across the St. Lawrence at Lachine, in 1913, was characterized by a particularly bold erection procedure for the two 408-ft. through spans. In double-tracking the line the railway bridge department, of which P. B. Motley was, and continues to be, the head, found that the most practicable plan was to construct two independent single-track bridges on the one set of piers, as shown in Fig. 8. The channel spans, weighing 1,300 tons each, were erected on the adjacent deck spans and were then end-launched into their final positions, the forward end of each span being carried on a specially constructed scow and the rear end on an ingenious truck or buggy. To avoid overstressing the side spans a special distributing frame was devised by F. P. Shearwood, M.E.I.C., whereby a three-point bearing with equal reactions was produced at the rear end of the span. So accurately was the work organized by the Dominion Bridge Company, Ltd., who fabricated and erected this structure, as well as its predecessor, that it was possible by signalling the operator of the hauling engine 800 ft. away to spot the forward end of the moving span on its exact final location.

An important aspect of the work of the railway bridge engineer is to utilize to the full the service life of structures. A characteristic example of this was the installation, in the C.P.R. bridge over the South Saskatchewan, at Outlook, of eight 240-ft. multiple intersection deck truss spans removed from the Lachine bridge.

In the Nipawin bridge of the C.P.R. (Fig. 9), erected over the Saskatchewan river, in 1932, the accommodation of highway traffic was provided for on a lower deck by the device of carrying the roadway along a part of the approach railway viaduct on brackets cantilevered from one side of the steel bents. The arrangement is essentially a Y, and similar to the one employed for the railway approach of the Fraser river bridge at New Westminster, B.C., already mentioned. To avoid foundation uncertainties the truss spans were made as long as could be erected by cantilevering the full length without introducing special erection features of high cost. Temporary harness was employed by the Dominion Bridge Company, Ltd., for deepening the trusses over the piers.

In highway bridge practice, the use of pony spans with T-chords for lengths greater than 100 ft. has been abandoned, and this type of chord is rarely seen now except for

Visibility improved by omission of diagonals. 1935.

the shortest spans. One cause of this is the disappearance of the unsightly wing, or outrigger, type of bracing for the top chord, which persisted until the use of the 1922 Specification for Steel Highway bridges of the Canadian Engineering Standards Association became generally recognized. Lateral support of the chord is now generally provided by stiff verticals capable of withstanding a large moment without much deflection.

An important development in steel highway bridge construction was the substitution of reinforced concrete floors for timber floors. The first structure of this kind with a concrete floor built in Canada appears to have been that built at Thornhill, near Toronto, in 1903. It was a 35-ft. span with a reinforced concrete slab deck carrying paving brick surfacing. The following year Musson's bridge with a 124-ft. span was built near Weston, Ont., with the same type of deck. The credit for this innovation belongs to James McDougall, then engineer for the County of York.

The end-launching method of erection on high viaducts was employed with conspicuous success in the building of the Twelve Mile creek and the Sixteen Mile creek bridges on the Dundas Highway, between Toronto and Hamilton, in the years 1917 and 1921. The superstructures of these bridges were built of old 108-ft. Intercolonial Railway iron lattice girders, which had already put in one life time in the railway service, thereby justifying the confidence that had been reposed in them by Sandford Fleming. Norman McLeod, alert contractor for the Dundas Highway bridges, unearthed the girders and brought about their installation for another life time in the highway service. Triangular pilot trusses were bolted to the forward ends of each girder span, which had been riveted up completely with its bracing. The whole span was then hauled forward into position, the pilot trusses serving as guides and coming in contact with the forward pier before the permanent trusses became overbalanced.

Much steel viaduct work involving the use of deck truss spans has been carried out in the neighbourhood of Toronto in the last fifteen years. In this category might be mentioned the Rouge river bridge, completed in 1920, by the Ontario Department of Highways, of which A. B. Crealock, M.E.I.C., was then bridge engineer. This structure, on a 5 per cent grade, was characterized by marked economy in both steel and masonry. The tower columns were somewhat novel for that time, of H-section, and the floorbeams heavy rolled Bethlehem beams.

The easterly entrance to Hamilton of No. 2 highway from Toronto contains two economical viaducts, of a type similar to that at the Rouge river, one of which is shown in Fig. 10. Both viaducts were fabricated and erected by the Hamilton Bridge Company, Ltd.

A particularly massive viaduct combining deck Warren trusses and reinforced concrete piers is the Yonge Boulevard bridge, constructed in 1928, by the Ontario Department of Highways, and erected and fabricated by the Canadian Bridge Company, Ltd. As will be seen from Fig. 11, this structure utilizes reinforced concrete piers of H-section similar to those adopted by Frank Barber for the East York-Leaside viaduct built the previous year.

The Bayview avenue bridge, Toronto, built to the design of Margison and Babcock, in 1929, is characterized by novel features in the form of the supporting reinforced concrete towers, as will be seen from Fig. 12, and by marked economy in the steel superstructure. Only three lines of stringers were used and the end steel spans were cantilevered out one panel to meet the abutment at one end and the concrete approach at the other. The Dominion Bridge Company, Ltd., erected the steel.

In steel truss viaduct work mention should be made of the Englehart bridge built over the White river on the Ferguson highway, in 1932, utilizing Canadian steel

**Fig. 20—Quebec Cantilever Bridge.**
**The world's longest cantilever span. First use of K-trusses. 1917.**

throughout, the sections being built up satisfactorily of plates and angles.

A feature of interest in connection with the design of the Perley bridge over the Ottawa river at Hawkesbury, was the notable economy in the approach viaduct structure. As many as six spans in series are without longitudinal bracing, the columns having been designed with fixed bases and allowed to take the calculated bending. This structure, built under the direction of the Dominion Department of Public Works, of which K. M. Cameron, M.E.I.C., is chief engineer, was erected by the Canadian Bridge Company, Ltd., in 1931.

As an example of the attractiveness that is possible with deck truss span steel bridges the Burrard bridge over False creek, Vancouver, might be cited. This was constructed in 1932 under the direction of J. R. Grant. M.E.I.C. On account of the especially prominent location of the bridge, architectural collaboration was sought, with the excellent result evident from Fig. 13. The main piers, extending above the roadway as pylons, were made particularly massive and connected across the roadway by decorated galleries.

### Arch Spans

In the replacement of timber bridges on the C.P.R. in British Columbia, the steel arch was early adopted as a particularly suitable form of structure. A 336-ft., 3-hinged, latticed-rib arch, replacing a long span Howe truss structure carried on timber towers, was erected over Stoney Creek in 1893, in accordance with the design of that gifted engineer, H. E. Vautelet, M.E.I.C. The steel arch was built around the old timber structure without interruption of traffic, the loads being applied to the rib at every third panel point along the haunches and four panels apart adjacent to the crown. For this reason the stringers were very long, in fact, truss spans in themselves.

Spectacular reinforcement of this early arch was carried out in 1929 according to the general plans of the railway bridge engineer by the Canadian Bridge Company, Ltd. New arch trusses were erected outside of the old ones, equalizers were inserted connecting the adjacent trusses and on them the transverse bents carrying the track spans rested, as shown in Fig. 14. The new arch trusses were weighted to deflect equally with the old under their proper dead load, and connection was then made between the new and the old trusses, so that the entirely new floor system and the live load could be carried equally by the new and old ribs.

Displacing the Edward Serrell suspension bridge, built in 1852, a 2-hinged, spandrel-braced arch, designed by C. C. Schneider, was erected over the Reversible Falls, at Saint John, N.B., in 1915, by the Dominion Bridge Company, Ltd. This structure, shown in Fig. 15, has a span of 565 ft. and a rise ratio of 1 in 9.2, which is next in order of flatness to the short span of the Peace bridge between Fort Erie and Buffalo. The arch ribs were erected as cantilevers and connected up to a temporary crown hinge, thus making the structure 3-hinged for a large part of the dead load. Subsequently, by the insertion of an accurately fitted piece in the top chord, the arch was made 2-hinged for the remainder of the dead load, for live load and for temperature changes.

The Niagara river, particularly the gorge below the Falls, has been an attractive location for steel arch bridges. In 1897, the Grand Trunk Railway replaced the Roebling suspension bridge by a 2-hinged, spandrel-braced arch span of 550 ft., which was heavily reinforced for intensified traffic in 1919. Farther up, at the site of the old Samuel

**Fig. 21—C.P.R. Cantilever, Saint John, N.B.**
**Novel through truss form with horizontal top chord. 1921.**

Keefer suspension bridge, the 840-ft. Niagara Falls and Clifton arch was erected in 1898, holding the record of span length for arches until displaced by the Hell Gate arch at New York, in 1917. The 640-ft. Michigan Central Railroad arch at Niagara Falls was erected in 1924 in the same manner as the Saint John arch, in that the structure was made 3-hinged for most of the dead load and 2-hinged for all subsequent loads. The floor system consists of independent plate girder spans for each panel, thereby eliminating the participation of the floor system in the arch rib stresses and obviating much uncertainty in the behaviour of the structure as a whole. The most recent of the Niagara river bridges, the Peace bridge between Fort Erie and Buffalo, erected in 1927, contains a series of 3-hinged, solid-ribbed arches. The shortest of the spans, next the Canadian shore, has a rise ratio of only 1 in 11.3, the smallest rise ratio of any steel arch in this country.

Typical of double-deck arch construction is the Prince Edward viaduct over the Don river on Bloor street, Toronto, shown in Fig. 16. This structure, built in 1918, according to the design of the late Thomas Taylor, M.E.I.C., and erected and fabricated by the Hamilton Bridge Company, Ltd., is of the 3-hinged type, with the hinges in the top chord. The crescent form of arch rib grew out of the provision for a lower deck to accommodate subway trains, should they ever have to be operated over the structure.

Hingeless steel arches are sufficiently rare in Canada to merit special mention. An important structure of this type (Fig. 17) was built over the Grand river, at Paris, in 1931, according to the design of Arthur Sedgwick, bridge engineer for the Ontario Department of Highways. The arches are not only hingeless but are on a skew, which naturally complicated the work of detail and fabrication. The whole work was completed, however, at the very low price of about $6 per sq. ft. of floor surface. Another novel feature was the use of 36-in. rolled I-beams as rib segments.

Improved visibility was secured with the attractive 140-ft. tied steel arch (Fig. 18) built at Ormstown, P.Q., in 1935, by the Dominion Bridge Company, Ltd. Absence of diagonals confers upon the structure some of the simplicity of the commonly occurring reinforced concrete tied arch.

### Cantilever Spans

Although an important cantilever bridge had been built for the C.P.R. over the Reversible Falls, at Saint John, N.B., in 1885, the type was infrequently employed in Canada for some time subsequently. In the year 1900, however, the Alexandra, or Interprovincial, bridge (Fig. 19) was erected over the Ottawa river, at Ottawa, under the general direction of Guy C. Dunn. The main span is 555.75 ft. Frazil ice troubles complicated the work of erection, carried out by the Dominion Bridge Company, Ltd. The plan followed was to erect the anchor arms on falsework carried on distributing Howe trusses to floating scows which were towed as a unit from one erection position to another. The cantilever arms and suspended span were erected to a junction at the centre by the ordinary cantilever method.

The high-water mark of achievement in cantilever bridge construction for Canada, as for the whole world, was reached with the completion of the Quebec bridge, in 1917. While its central span of 1,800 ft. does not greatly exceed the two main spans of the Forth bridge, the live load for which it was designed was 2¼ times that for the older structure. The suspended span, 640 ft. in length, continues to hold the record for Canada for a simple truss span. Many novel features characterize the structure, the most important of which is the K-arrangement of diagonals in the main trusses, proposed by Phelps Johnson. In contrast with the Forth bridge, the trusses were made parallel rather than battered, thus giving simpler detail and facilitating erection. The Board of Engineers under whose direction the structure was finally completed consisted of C. N. Monsarrat (Chairman), Ralph Modjeski and C. C. Schneider. The St. Lawrence Bridge Company, whose design for the superstructure was adopted by the Board, fabricated and erected the structure. Figure 20 shows the completed bridge.

**Fig. 23—High Level Cantilever Bridge, Hamilton, Ont.**
**Artistic short-span cantilever simulating an arch. 1932.**

Consequent upon increasing traffic demands, the light pin-connected cantilever of 1885 at Saint John, N.B. was replaced by the C.P.R. in 1921, under the direction of P. B. Motley, engineer of bridges. As will be seen from Fig. 21, it is totally unlike the old cantilever, seen in the background. An unusual feature for a through bridge is the horizontal top chord for both cantilever arms and suspended span. Another, is that it is riveted throughout. The main span, 450 ft. in length, was erected by cantilevering from both ends to a junction at the centre. The contractor for the steel was the Dominion Bridge Company, Ltd.

The most modern of the large cantilevers is the Jacques Cartier bridge between Montreal and the South Shore, completed in 1929, under the direction of Monsarrat and Pratley. It has a central span of 1,097 ft., and is fully riveted, except at the top and bottom of the main vertical posts over the piers.

Fig. 24—Kettle Rapids Continuous Bridge, Hudson Bay Railway. Most important existing continuous bridge in Canada. 1917.

Profiting by favourable experience with the Quebec bridge in respect of erection and deformation, the K-system of trussing was adopted. Silicon steel was employed in all main truss members, in flanges of the floorbeams and of a number of stringers, and in the main material of most of the bottom lateral system. Elsewhere, a special carbon steel was used. As will be seen from Fig. 22, the varying length of the panels for the cantilever arms resulted in a pleasing general outline. The Dominion Bridge Company, Ltd. fabricated and erected the steel.

Short span cantilevers, simulating arches, may often be employed advantageously in steel, as in reinforced concrete. Such a one is the highway bridge over the Desjardins Canal, Hamilton (Fig. 23), built in 1932, under the direction of James, Proctor and Redfern, Ltd. It has a central span of 220 ft. and a suspended span of only 55 ft. To lighten the suspended span and the cantilever arms the flooring was made of haydite concrete. Particular attention was given to the architectural features of the design, with the result that the bridge was awarded honourable mention by the American Institute of Steel Construction for bridges in its class in the 1932 competition. The general contractor was E. P. Muntz, Ltd., the contractor for the steel work being the Hamilton Bridge Company, Ltd.

### Continuous Spans

In conformity with the North American neglect of the continuous type of bridge, there have until recently been few steel bridges of this type built. Given foundations that do not yield appreciably, there are distinctive advantages in continuity. Cantilever erection, with little or no addition of material for erection stresses, reduction of positive moments, lessening of deflection, narrowing of piers and simplification of bearings outweigh the additional difficulties of design.

For many years the continuous spans of the St. Lawrence River railway bridge at Lachine, P.Q., built in 1886, to the design of C. Shaler Smith, remained the most outstanding example in America, if not in the world, of the continuous type. This structure contained four spans in a continuous series, the two central 408-ft. spans being of through construction and joined up cleverly to the deck side spans. As has already been mentioned, this notable structure was replaced in 1913 by the present C.P.R. bridge.

The marked advantages of the continuous type where cantilever erection is imperative were exemplified in the Hudson Bay Railway bridge over the Nelson river, at Kettle Rapids (Fig. 24). This structure, designed by W. Chase Thomson, M.E.I.C., and fabricated and erected by the Canadian Bridge Co., Ltd., was completed in 1917. It is composed of three fully riveted subdivided Warren truss spans of 300, 400 and 300 ft. in length. All material for the north end of the bridge had to be transported across the river by cableway, the middle span being cantilevered each way to closure at the centre.

The three-span continuous bridge, shown in Fig. 25, was erected over the Saguenay river, at Kenogami, in 1922,

Fig. 25—Saguenay River Continuous Bridge at Kenogami. Economical structure with low piers. 1922.

by the Eastern Canada Steel and Iron Works, Ltd., for Price Bros. and Company, Ltd. It is of the double-intersection Warren type with trussed legs, which markedly reduce the height of the piers.

A continuous structure was also found best for the crossing of the Chibougamau Railway over the Saguenay river. Three spans of 190, 270 and 190 ft. were found best suited to the crossing by the engineers, Monsarrat and Pratley. The structure was erected in 1929 by the Dominion Bridge Company, Ltd.

An unsymmetrical structure of two continuous spans was designed and built by the Dominion Bridge Company, Ltd., in 1930 for the Shawinigan Power Company, over the St. Maurice river, at Rapide Blanc, about 28 miles north of La Tuque, P.Q. The 260-ft. span was erected by cantilevering it full length, using the 78-ft. span as an anchor arm. The appropriate reaction for the normal weight of steel was produced at the forward end by adjustment, and the stresses for the remaining load were calculated as for a continuous structure of two spans.

Suggestive of the European "dinosaur" type is the main span (Fig. 26) of the Honoré Mercier bridge over the St. Lawrence river, a short distance below the C.P.R.

Fig. 26—Honore Mercier Bridge, Lachine, Que. Contains a unique continuous tied arch span. 1934.

bridge. This important structure was completed in 1934, under the direction of O. O. Lefebvre, M.E.I.C., chief engineer, with W. Chase Thomson M.E.I.C., as structural engineer, the Dominion Bridge Company, Ltd., fabricating and erecting the steel work. The main span is a 400-ft. continuous through tied arch, a type unique in Canada. Splayed truss spans connect the northerly span of the continuous unit to the simple span portion of the bridge, and the latter to a possible future vertical lift span at the proposed deepened St. Lawrence waterway channel close to the North shore. The reinforced concrete viaduct on the South shore was built with the use of light structural steel Kane trusses as reinforcement, which at the same time carried the weight of the forms and of the green concrete. All steel used in the structure was rolled in Canada.

A notable recent development in continuous construction is the use of welded plate girder spans. The six continuous all-welded 107-ft. deck plate girder spans over the Ste. Anne river at La Perade, P.Q., built in 1936, form the most outstanding example of this kind of work yet carried out in North America. Minimum depth is provided at span centres, as shown in Fig. 27, with a pleasing arch profile between piers. An apparent saving in weight of 27 per cent, compared with simple span riveted girders, was effected, according to the Dominion Bridge Company, Ltd., who built it. L. F. Gaboury was the engineer for the owners.

### Suspension Spans

Despite its manifest merits, the suspension type of bridge has not been widely adopted in Canada. Apart from the three frontier suspension bridges over the Niagara river—the Roebling bridge which stood on the site of the present C.N.R. arch from 1855 to 1897, the Samuel Keefer bridge on the site of the Niagara Falls and Clifton arch (1868-1898), and the Queenston-Lewiston bridge (1851-1864 and 1899 to the present), the only other important suspension bridge built before 1887 was the Edward Serrell bridge at Saint John, N.B. (1852-1915).

Appreciating the advantages of the suspension type of highway structures, Frank Barber built three such structures in York County, near Toronto, between 1910 and 1920, with spans varying from 90 to 150 ft., one of them having a reinforced concrete floor.

A light suspension bridge of 451 ft. span employing 2.5-in. locked coil cables and wooden towers was built across the Bulkley River canyon, at Hagwilget, B.C. in 1913. Proving too light, the structure was replaced by a heavier one of the same general type, in 1931. The 1.5-in. wire ropes employed for the cables—nineteen in each—were prestressed at the site, using a weight box suspended in a pit and filled with gravel. The process was repeated three times for each rope, and when the actual dead load was applied in the structure the cable sag came to within ½ in. of the calculated sag. The structure was designed by the Department of Public Works of British Columbia, of which Patrick Philip, M.E.I.C., was Deputy Minister and chief engineer at the time.

Canada has an important professional, as well as economic, interest in the Ambassador suspension bridge between Windsor and Detroit, completed in 1929. Its main span of 1,850 ft. was the longest suspension span and the longest highway span in existence at the time of completion. The cables, of the unloaded backstay type, are now of cold-drawn wire, replacing the heat treated wire which developed alarming breakages under partial dead load near the point of tangency with the strand shoes, both in this structure and that at Mount Hope, R.I. Silicon steel was used in the towers and in the chords of the stiffening trusses, which have a depth of only 1/84 of the span, the smallest depth ratio used in any important suspension bridge up to the time of building. The approach viaduct on the Canadian side, fabricated and erected by the Canadian Bridge Company, Ltd., has very little longitudinal bracing. The columns, like those for the Hawkesbury bridge, were figured to bend longitudinally.

In recent years, the use of a group of twisted wire ropes, rather than parallel wires, for suspension bridge cables has greatly extended. An important example of this kind of construction is that shown in Fig. 28, the Grand'-Mère bridge over the St. Maurice river, built in 1929. Robinson and Steinman and Monsarrat and Pratley were the engineers, and the Canadian Bridge Company, Ltd., the contractor for the steel. The structure is of the unloaded backstay type, with a central span of 948.8 ft. Taking advantage of the severity of the Canadian winters, rather than being hampered by it, the cables and stiffening trusses were erected from the ice, the cable ropes having been prestressed at the mills to 60,000 lb. per sq. in. and then slacked to 20,000 lb. per sq. in., at which they were measured and marked. The towers are pivoted at the base, the shoe castings being finished convex downward and bearing on base casings finished with a level surface.

The most recent of the large Canadian suspension bridges is that over the North branch of the St. Lawrence river to the Island of O leans (Fig. 29), completed in 1935, for which the main span is 1,059 ft. The two cables, each 10 in. diameter, are composed of 37 prestressed twisted wire ropes, 1⅜ in. in diameter. The structure was designed by the deflection theory of stress analysis by Monsarrat

and Pratley, the engineers for the suspended part of the bridge. The towers, which are of Chromador steel, are of the flexible type, with fixed base, both pedestals and saddles being built up of steel plates welded together and stress-relieved. The contractor for the steel work was the Dominion Bridge Company, Ltd.

### Movable Spans

Movable spans of any importance in Canada have almost wholly consisted of the swing, bascule or vertical lift types.

At its completion in 1887, the 234.75-ft. "Menomonee" swing span over the Lachine canal on the north approach to the St. Lawrence river railway bridge at Lachine was deemed by its designer, C. Shaler Smith, to be the latest word in movable bridges. In elevation, it was of the shape of a deep isosceles triangle, the low position of the top chords at the ends being intended to reduce the wind resistance to turning.

In 1915 this old structure was replaced by a deck plate girder swing 239.6 ft. long, operating on the old pivot pier, as shown in Fig. 30. The utilization of this pier for a double track structure of the type selected—the longest span of the kind in existence—was justly regarded as a remarkable achievement. Four main girders, 13.5 ft. deep at the centre, were used, as it was essential to maintain traffic during the replacement. The work was done under the general direction of P. B. Motley by the Dominion Bridge Company, Ltd.

In the meantime, in 1896, an important bobtailed swing span had been erected over the Burlington channel, near Hamilton, Ont. in conformity with the design of H. E. Vautelet. At that time it was the only bridge in Ontario to be operated electrically, with the exception of the one at Sault Ste. Marie. It was a pin-connected, rim-bearing structure, actuated by a sprocket on the land arm travelling along a fixed chain. The bridge has since been replaced by the present twin Strauss bascule spans, erected in 1922 and 1931 by the Hamilton Bridge Company, Ltd., and resting on a rest pier between the two channels.

Many bascule spans of the multiple-trunnion type have been erected in Canada during the past fifty years. The C.P.R. bridge over the Kaministiquia river at Fort William, erected in 1913, is a good example of a heavy bridge of this type. It is a single-leaf, double-deck Strauss with a clear span of 200 ft. At the time of its construction this structure held the size record for a double-deck bascule. Another sizable Strauss is the 160-ft. Cataraqui river bridge, Kingston, erected in 1917 by the Hamilton Bridge Company, Ltd. The main trunnions were placed above the level of the roadway, thereby making them freer from dirt and more accessible for greasing.

**Fig. 30—C.P.R. Swing Bridge over Lachine Canal.**
**Longest deck plate girder swing span in existence. 1915.**

An example of the rolling lft type of movable bridge is the 114-ft. single-leaf, four-track Scherzer erected in 1913 for the C.P.R. over the McKellar river, at Fort William. Bridge No. 1, over the Welland Ship canal, at Port Weller (Fig. 31), is a 93.6-ft. rolling lift span designed by Harrington, Howard and Ash. Altogether, there are seven rolling lift bridges over the canal.

Of late years there has been a strong disposition to simplify bascule bridge design by reverting to the original simple trunnion idea. Three recent structures of this kind are the 80-ft. single-leaf Norwood street bridge, Winnipeg, built in 1931, to the design of A. J. Taunton, M.E.I.C., Department of Public Works of Canada; the 90-ft. double-leaf bridge at Gaspé, P.Q., designed by Baulne and Leonard, and built in 1932; and the 165-ft. double-leaf structures at Sorel, P.Q. (Fig. 32), built in 1932, to the design of the Department of Public Works of Quebec, with Monsarrat and Pratley as consulting engineers. These structures were fabricated and erected by the Dominion Bridge Company, Ltd.

Vertical lift bridges are by no means new in Canada. One was built at Shubenacadie, N.S., in 1899, but up to 1914, few others had been built. In that year the Canadian Northern Pacific Railway bridge over the North Thompson river, at Kamloops, B.C., was erected, containing a 93-ft. Waddell and Harrington vertical lift span. The vertical tower legs stand on the piers and the rear or battered legs, stand on the side plate girder spans. The lift is operated by a gas engine.

**Fig. 31—Rolling Lift Bascule, Welland Ship Canal.**
**Simple modern type for moderate spans. 1929.**

A simple vertical lift of Strauss design is the Pretoria avenue bridge at Ottawa, built in 1916. As the lift is only 20 ft., a system of levers was profitably substituted for cables.

Of the eleven vertical lift bridges over the Welland Ship canal, the 209-ft. structure at Allanburg (Fig. 33) may be taken as a representative example. To lighten the dead load, the floor was made of haydite concrete. The design is that of Harrington, Howard and Ash.

An undertaking of especial difficulty, involving the installation of a vertical lift span, was the reconstruction of the Second Narrows bridge at Vancouver, B.C., in 1935. According to the plans of Monsarrat and Pratley, who were in charge of the work, a new lift span had to be inserted where the old wrecked 300-ft. span had been, substituting a clear waterway of 272 ft. for one of 175 ft. The old bascule span was cut down by two panels and made fixed, the counterweight being left in position, as shown in Fig. 34. For the new lift span the counterweight ropes were prestressed, thus making it possible to dispense with equalizers. Chromador, a chrome-copper-silicon steel, was extensively employed. The contractor for the superstructure was the Dominion Bridge Company, Ltd.

### CONCRETE SUPERSTRUCTURES

As a material for bridge superstructures, concrete made no appreciable impression on Canadian engineers until about 1907. Very properly, they proceeded with caution. In consequence of this attitude, only two concrete bridges had been built on the provincial highway system of Ontario up to the end of 1923, although much work in this material had been done in the municipalities. In the following year, however, the province built ten bridges of moderate size of this material. In Manitoba, numbers of concrete spans up to 30 ft. in length had been built prior to 1915. As the war proceeded, steel for bridge construction became scarcer and dearer, and longer and longer spans of concrete appeared in the form of through and tied arches. When, by 1920, all material and labour had risen about equally in price, steel resumed something of its old place in the construction of the longer spans. Concrete was slow to arrive in Saskatchewan. Up to 1919, practically all important highway bridge construction had been in the form of standard steel spans on pile bents. The railways throughout the country were still more cautious in applying concrete to bridge work.

Employment of concrete for the main superstructure elements of bridges may be in the form of simple beams or girders, viaducts, untied arches, tied arches, rigid frames, cantilevers or continuous spans.

#### Simple Beam and Girder Spans

In 1907 James McDougall designed and built a 50-ft. through girder span for highway use at Unionville, Ont. About the same time James A. Bell began to build girder spans in Western Ontario, so that in a few years there were a great many examples of them to be seen. No attempt has been made to rival the 142-ft. girder spans of the Salt river bridge, in California, but frequent and appropriate use is made of the girder type for highway bridges in those parts of Canada where the snowfall is not excessive. Mani-

toba found that through girders acted as collecting troughs for snow, and had to abandon them.

The railways have found simple reinforced concrete beams and slabs of great value in grade separation structures. For example, the Ontario street subway under the C.P.R. tracks, at Montreal, was built in 1924 by placing precast slabs 6.5 by 3.1 by 23.25 ft. on precast reinforced concrete columns, using a locomotive crane. The work, which was done under the direction of L. J. Leroux, A.M.E.I.C., was carried out with trifling disturbance to traffic.

Typical of the practice of the Central Region of the C.N.R. is the poured-in-place slab subway at St. Lambert, P.Q., built in 1931, with a depth of 4 ft. and a clear span of 49.4 ft. As the rails were fastened directly to the slab without ties or ballast, and with nothing more than an oak cushioning strip embedded in the concrete, the depth from base of rail to underside of the superstructure is scarcely more than the slab depth.

The use of reinforced concrete beams and girders in viaduct and continuous construction is now extensive and will be discussed separately under these headings.

### Viaducts

A comparatively early use of concrete for railway viaduct construction was in the Weston road viaduct of the C.P.R. at West Toronto, built in 1911. It was of the now familiar beam and slab type.

Two viaducts of much bolder construction were erected in the C.P.R. between Toronto and Leaside Junction, in 1918. One of these, shown in Fig. 35, is over the abandoned belt line railway, and the other over Reservoir Park. Precast T-beam units 6.5 ft. wide, 4.7 ft. deep and 35 to 37 ft. long, weighing up to 55 tons were placed by a wrecking crane on the caps of reinforced concrete bents cast in place. Up to that time no reinforced concrete beams of greater length than 25 ft. had been employed for railway bridges. As will be seen from the illustration, the lateral and longitudinal bracing consists of staggered horizontal struts, haunched top and bottom.

The merits of the flat slab system were utilized in the construction of the Fourth Avenue viaduct, Moose Jaw, Sask., in 1929, by C. A. P. Turner. Columns were spaced at 30 ft. centres and the reinforcement was arranged in accordance with that engineer's well-known mushroom pattern.

### Arches Without Ties

Most of the early activity in concrete bridge construction centred upon the arch. The first arch of considerable size erected in Canada appears to have been the 92-ft. earth-filled one at Massey, Ont. (Fig. 36), built in 1906 under the direction of W. A. McLean, M.E.I.C., then

chief engineer of the Ontario Department of Highways. In the Lyndhurst bridge at St. Thomas, built in 1908, by James A. Bell, the span record was raised to 116 ft. Two years later, Barber and Young built the 118.5 ft. Wadsworth arch at Weston, Ont., probably the first open spandrel reinforced concrete arch in Canada. In 1913 Frank Barber constructed the King George arch on the Middle road, over the Sixteen Mile creek, near Oakville, Ont., with a span of 135 ft. This structure, as good as new, was blown out in 1935 to make way for the much wider and higher bridge necessitated by rebuilding the road as a first-class highway.

Fig. 39—Ashburnham Bridge, Peterborough.
Longest concrete arch span and first use of temporary hinges in Canada. 1921.

The University bridge over the South Saskatchewan river, at Saskatoon, was the most extensive piece of reinforced concrete construction undertaken in Canada up to the date of its completion in 1916. As is seen from Fig. 37, it consists of ten open spandrel arch spans, four of which are 150 feet. in the clear. On account of the extreme severity of the winter in Saskatchewan, the arch rings were left for summer work. The temperature stresses in the rings of certain of the arches exceed all other stresses combined. D. B. Luten was the consulting engineer to the Board of Highway Commissioners, under which the bridge was constructed.

At almost the same time the very attractive Centre street bridge in Calgary (Fig. 38) was completed. It is a double-deck skew structure containing, amongst others, three spans of 150 ft. John F. Greene was responsible for the design.

One of the outstanding concrete bridges of Canada for structural and architectural merit is the Ashburnham bridge at Peterborough, completed in 1921, to the design of Frank Barber. This structure, shown in Fig. 39, contains a clear span of 234 ft., the longest span in Canada. For aesthetic reasons secondary spandrel arches were used, decreasing in span towards the crown of the main arch, and above these the structure was cinder filled. Temporary hinges were used at the skewbacks and at the crown for the first time in Canada. There is no reinforcing in the main arch ribs except that for the hinges, the analysis indicating no possibility of tension.

Another structure of attractive appearance is the bridge at Elora, Ont., built according to the plans of A. W. Connor, M.E.I.C., in 1921, and shown in Fig. 40. Two 80-ft. spans meet on an 80-ft. stone masonry pier that had served the lifetime of the steel bridge displaced by the concrete arches. The trusses of the old bridge were used to support the forms for the concrete ribs which came outside the trusses. To supplement the capacity of the trusses, the forms for the ribs were built to act as arches, the lateral rods from the old bridge serving as ties.

Knox bridge, over the Montreal aqueduct, built in 1926, was constructed with Mesnager temporary hinges at the skewbacks and crown of the three arch spans, the notches being left open for thirty days after the completion of the deck and ninety days after the ribs were placed. J. F. Brett, A.M.E.I.C., was the designing engineer.

Not often has the three-hinged type been employed for reinforced concrete arches in Canada, but the Ahuntsic bridge, over the Back river, near Montreal, shown in Fig. 41, is an important instance. This structure, built in 1930, under the direction of L. J. Leroux, by the Dufresne Construction Company, Ltd., contains five spans, the longest of which is 222 ft. The hinges are steel castings abutting on centre pins at the rib axis. A very unusual feature, which apparently worked, is that the arch ribs were not placed in voussoirs, but each half rib was concreted fully in one operation, thereby saving the trouble of symmetrical pouring. The centring was kept in place until the deck structure was concreted.

Very careful thought was given to the design of the Wellington ravine arch bridge, Edmonton, Alta., by the consulting engineer, Professor I. F. Morrison. The ribs of the main span are much shallower than they are wide, in conformity with the modern effort to reduce temperature and deformational stresses. Floorbeams are closely spaced and there are no stringers. Provision was made against sideways bending of the ribs due to lateral temperature effects by inserting single lines of 60-lb. rails near each vertical face. The structure was completed in 1932.

The Broadway bridge at Saskatoon, Fig. 42, like its mate, the University bridge, is a large and important structure. It contains five arches of varying span and six girder spans, the maximum arch span being 201 ft., centre to centre of piers. The arches have approximately the same rise ratio and wide, shallow ribs. No reliance was placed by Dean C. J. Mackenzie, M.E.I.C., the engineer in charge, on possible deck participation, as the deck was poured after the falsework had been removed. On the other hand, the temperature moments and thrusts at the springing were arbitrarily increased about 75 to 150 per cent, respectively. To reduce spandrel post flexural stresses, some of the posts were hinged. The expansion of the approach viaduct was looked after by flexure in the slender columns, and the position of the columns on the shifting south bank was secured by a line of reinforced concrete struts extending downhill to the first main pier. The structure was completed in 1932, as an unemployment relief project.

**Fig. 40—Twin Arches on 80-ft. Masonry Pier, Elora, Ont.**
**Trusses of old bridge supported forms which were built as a tied arch. 1921.**

Another instance of a three-hinged reinforced concrete arch is the 66-ft. pipe line bridge built over an inlet to Esquimalt harbour, in 1928. Brass-bushed steel pins turning in steel castings were used at the springings and crown. Each half rib was cast on the flat and erected by derrick.

Three similar multiple-span arch bridges were built in the years 1934-1936 at the crossings of the Middle Road over the Credit river, Sixteen Mile creek and Twelve Mile creek, under the direction of Arthur Sedgwick, bridge

engineer for the Ontario Department of Highways. The Twelve Mile creek bridge is shown in Fig. 43. The maximum arch span in any of them is 145 ft. and they are all characterized by wide shallow ribs. Internal vibration of concrete was carried out for the last two bridges, completed in 1936.

### Tied Arches

Recognizing the advantages of the reinforced concrete arch but being frequently unable to build the regular type because of low available rise, engineers in Canada, following the lead of Considère, set about to adapt the arch to crossings where low banks existed by using a horizontal tie, thus transforming it into a bowstring truss.

The first reinforced concrete truss bridge built in Canada was the 80-ft. Middle road bridge across the Etobicoke river, near Long Branch, Ont., constructed in 1909 by Barber and Young. As will be seen from Fig. 44, diagonals were used to stiffen the compression chord against distortion, the chord then being proportioned for area and not for moment of inertia. In order to reduce the probability of cracking in the concrete of the bottom chord, the steel reinforcement in it was prestressed. Bond of the concrete between the work of one day and that of the next was promoted by placing cracked ice in bags on the work when stopping at night. The material was then found to be plastic on the resumption of work next morning. This structure was removed in 1932 to give way to a much wider bridge for the newly rebuilt Middle road.

The first pure bowstring truss span, or tied arch, constructed of concrete in Canada was that at Riverview, Man., built in 1917, under the direction of P. Burke Gaffney. The span, 86.5 ft., was the longest of any tied arch in America at that time.

**Fig. 43—Twelve Mile Creek Bridge near Bronte, Ont.**
**Typical of three recent arch bridges on the newly rebuilt Middle Road. 1936.**

As an incident to the construction of the concrete highway between Toronto and Hamilton, four tied arches were built in 1918-1919 at Mimico creek, Etobicoke river, Credit river and Twelve Mile creek, all of them except the one at Mimico creek, being 119.1 ft. in clear span. Splices in the bottom chord were provided by staggered turnbuckles, the rods being attached by nuts to anchor plates at the ends. These bridges were built in accordance with the designs of F. G. Engholm, and proved to be eminently satisfactory. Due to the widening of the highway, the structures at Mimico creek and the Etobicoke river have recently been removed, but were found to be in excellent condition, never having required any expenditure for maintenance. Figure 45 shows the bridge at the Credit river, which is still standing.

Favourable experience with the tied arch type has brought about its application to bridges containing many

**Fig. 44—Middle Road Concrete Truss Bridge, Etobicoke River.**
**First use of the type in Canada. Tension chord steel prestressed. 1909.**

spans. One at Freeport, Ont., built in 1925, under the direction of A. B. Crealock, bridge engineer for the Ontario Department of Highways, has seven tied arch spans, 71.75 ft. centre to centre of piers. Floorbeams and hangers were spaced 6.2 ft. apart and no stringers were employed. A 9-span structure, with spans of 72.6 ft., was built at Caledonia, Ont. in 1927 under the same auspices. This bridge is shown in Fig. 46. A similar structure with five

82.2-ft. spans was built at Bridgeport, Ont., in 1934, by D. J. Emrey, A.M.E.I.C.

An interesting detail in connection with some of the tied arches recently built by A. B. Crealock, as at Belleville, Ont. and Galt, Ont., is the use of precast splash panels suspended in the plane of the hangers with a view to preventing the splashing of pedestrians on the sidewalks and making it impossible for children to dart out on the roadway from behind the hangers.

A tied arch with very unusual features was erected across the Montreal aqueduct at Du Bois street in 1930, to the design of J. F. Brett. It is 146 ft. in span from centre to centre of piers and the top chord is cantilevered at each end 13 ft. over the piers. As indicated in Fig. 47, there is no top bracing. To facilitate simple arch action the hangers were made as flexible as possible in the plane of the rib. Each of these ribs has a dumb-bell cross section, each bulb of the dumb-bell being heavily reinforced as a spiralled compression member. The rocker bearings consist of transverse steel flats between two heavy steel billets and temperature effects are provided for by allowing the piers to rock on thin sand cushions between the bottom of the pier and the top of its footing. All long steel reinforcement was spliced by welding.

As is recounted in a special paper presented to the Institute on the occasion of the present celebration, Dean C. J. Mackenzie has recently designed and supervised the construction of a three-span tied arch structure at Borden, Sask., containing a centre span 213 ft., centre to centre of piers, the longest on this continent.

### Rigid Frames

The credit for introducing to Canada the reinforced concrete rigid frame, which is really only an arch with a sudden change of rib alignment at the knees, belongs to the Ontario Department of Highways, of which Arthur Sedgwick is bridge engineer. Three such structures of single span and one of two spans were built under the auspices of the Department of Essex county, in 1931. Another one with three spans of 50 ft. was built in the same year over the Scugog river, near Lindsay, Ont. Since that time all concrete structures with spans of 20 to 60 ft. have been designed by the Department according to this type wherever it was applicable. The impetus thus given the rigid frame construction has resulted in the building of about forty such highway bridges in varicus parts of the province of Ontario during the past six years.

One of the important recent rigid frame bridges is the structure built in 1935 over the Etobicoke river, near Toronto, on Highway No. 2, in accordance with the design of the Ontario Department of Highways. This bridge, shown in Fig. 48, contains two 75-ft. spans, the maximum spans so far built by the Department. Whereas all of its previous rigid frame bridges were of the solid type, the Etobicoke river structure is of the thin, multiple-rib type, giving a very small quantity of concrete, but requiring a considerable quantity of closely grouped steel at the compression faces of the ribs. This is the first example of the rib type of rigid frame in Canada.

About 1931 the Central Region of the C.N.R. began building 2-span rigid frame structures for carrying highways over the railway right of way. These had a very shallow depth in the centre span and, due to the omission of abutment wing walls, have a small yardage of concrete.

A novel application of the rigid frame type of a 2-span structure for railway use is found in the C.N.R. crossing over St. Clair avenue, W., Toronto. This bridge, built in 1931, rests freely on a centre pier and has a total depth from base of rail to soffit of only 4.33 ft. The rails rest on shallow concrete ties placed directly on the deck slab without the employment of ballast. The structure is shown in Fig. 49.

As an example of long span railway rigid frame construction, the grade separation bridge of the C.N.R., shown in Fig. 50, over Petite Cote road, near Vaudreuil, P.Q., built in 1933, may be cited. This structure has a clear span of 72.7 ft. and was built in two parallel units, in order that traffic might be diverted to one while the other was being constructed. Incidentally, the bridge being on a skew, the stress situation was definitely simplified and helped by the use of two parallel structures.

### Cantilever Spans

The frequently arising desire to utilize an arched structure in reinforced concrete, in spite of unsatisfactory foundation conditions, may be met in many cases by the construction of a cantilever bridge of this material. Reactions are vertical and moderate settlement of the piers or abutments will not produce any particular harm.

An early use of the cantilever principle is found in the Mount Pleasant road bridge, Toronto, built in 1918, in accordance with the design of J. S. Burgoyne, now engineer of railways and bridges for Toronto. The bridge looks in elevation like a 3-span arch structure, but is in reality two single span rigid frames with the rib of each projecting over the inner pier to a free joint at the centre of the middle span. At this joint the steel reinforcement was allowed to project from the concrete at one side of the gap into the concrete at the other side, bond being prevented by wrapped tar paper.

An application of the cantilever principle similar to that followed in the construction of the Mount Pleasant bridge was made in the Assiniboine Park bridge, Winnipeg, built in 1932. It is composed of three units of 172 ft. with a free expansion joint at mid-length of every third span, the maximum spans being 86 ft.

Designed in 1930, and built in 1933, the Cockshutt bridge near Brantford represents an important example of pure cantilever construction in reinforced concrete. The bridge contains three spans of 113 ft., two of 99 ft., and two shore cantilever spans of 40.2 ft. Two of the 113-ft. spans are cut and contain suspended spans 65.7 ft. in length. Provision was made for longitudinal movement at piers by carrying the reactions into a pier through heavily reinforced concrete rockers 5.7 ft. deep and operating in a recess in the top of the pier. The reactions of the main girders are transmitted by means of inverted corbels, through long, hard lead plates placed transversely to the direction of the bridge. The structure was built under the direction of R. M. Lee and F. P. Adams, A.M.E.I.C., with C. R. Young, M.E.I.C., as the designing engineer for the substructure. It is shown in Fig. 51.

### Continuous Spans

A unique form of continuous construction is seen in the Governor's bridge built at Toronto, in 1923, in accordance with the design of F. G. Engholm, A.M.E.I.C., and shown in Fig. 52. The main span, 200 ft. in the clear, was designed to act partly as the centre span of a continuous unit and partly as an arch. Very heavy tensile reinforcement, consisting of 2½-in. round rods with welded splices, is inserted at the top of the main supporting ribs. Transverse floorbeams are used, but no stringers, the space between the floor framing and the soffit of the arched structure being hollow.

One of the most important of the continuous bridges in reinforced concrete is that built at Lambton, Ont., in 1928, to the design of Frank Barber. It is of the continuous beam type, comprising three units of three spans each and one unit of two spans. The spans vary from 56 ft. to 84 ft. By reason of continuity and the use of a square floor panel reinforced both ways the design proved to be very economical.

**Fig. 48—Two-Span Rigid Frame, Etobicoke River.**
First use of multiple-rib type in Canada. 1935.

**Fig. 50—C.N.R. Rigid Frame, Vaudreuil, Que.**
Heavy long-span grade separation structure. 1933.

An application of the continuous type to grade separation structures was made in the building of the Yonge street subway, Toronto, in 1929. The structure is 80 ft. in the clear between abutments with a centre row of columns along the axis of Yonge street. A slab depth of only 4.33 ft. was required.

Cast-in-place continuous construction for grade separation work is also well illustrated by the Richmond street subway at London, built by the C.N.R. in 1931. Like the St. Clair avenue subway, there is no integral connection of the superstructure to the centre pier. Precast reinforced concrete ties were employed to give greater flexibility for track changes.

Of great convenience to traffic is the plan of erecting precast slabs on cast-in-place abutments and a centre pier by the use of wrecking cranes. Such a structure is the one built near St. George, Ont., in 1932, and shown in Fig. 53. This slab was dropped in place by two cranes between trains. Extreme shallowness of the floor was made possible by placing the rails directly on the slab. Similar construction was adopted for the St. Francois street subway in Sherbrooke, P.Q., which was erected in twenty minutes between trains.

### TIMBER SUPERSTRUCTURES

It may not be generally known that considerable use of timber for bridge superstructures still persists in Canada. In Quebec covered timber bridges are still being built. Rather remarkably, the government of New Brunswick found, in 1919, that the neglect of maintenance of steel bridges was playing such havoc with them that it reverted to wooden superstructures for spans up to 180 ft. Wood was still plentiful and of good quality in the province.

With the comparatively recent development of timber connectors the application of timber to important bridge construction has revived. An instance of this is seen in the 210 ft. span of the Sioux Narrows bridge, Ont., built in 1935, as shown in Fig. 54. The life of the timber for this structure was considerably lengthened by creosoting. Another creosoted timber bridge is that at Quesnel, B.C., consisting of five through Howe truss spans, three of which are 180 ft. in length.

Where timber of sufficient dimensions and satisfactory quality can be obtained locally, it may prove economically practicable in many cases to construct timber bridges of substantial span lengths, but this will not be the case where timber must be brought very great distances at high expense.

### SUBSTRUCTURES

Engineers in Canada, as elsewhere, have learned from long, and sometimes bitter, experience the need for adequate exploration of the material upon which substructures are to rest. One of the most striking of these mishaps was the collapse of two spans of the bridge across the St. Lawrence at Cornwall, in 1898. The pier common to the two spans had been founded on what appeared to be a satisfactory bed of hardpan, but unfortunately this bed was only 2 ft. thick. When the erection load had reached a certain stage, the pier punched through the thin layer of hardpan and quickly sank 15 ft. into the soft clay beneath.

#### Pile Foundations

During the pioneer stage of bridge building in Canada it was natural to construct substructures by the driving of pile bents. Many fairly important steel bridges in the west were carried in this way. Apart from the shortness of life of piling timber at levels that are alternately wet and dry, there is always the risk of long piles being pushed sideways by the weight of the superincumbent earth filling. Several instances of damages to bridge superstructures have arisen from the lateral displacement of piles.

As a means of transmitting loads from piers or abutments to solid material beneath, piles still continue to serve an important role. During the last twenty-five years, however, there has been an increasing disposition to use concrete piles, either cast-in-place or precast and driven in the same way as wooden piles. The permanence of such piles makes it possible to seat the footings at a much higher level than would be possible with timber piles.

#### Open Caissons

Fifty years ago the art of employing open caissons for bridge foundations had been well established. They had been successfully used in the construction of the Intercolonial Railway bridges in the early seventies and in the St. Lawrence river bridge at Lachine, in 1886. It was consequently well-tested practice to employ this method in the construction of the piers of the Coteau bridge over the St. Lawrence, in 1888. Improved manipulation of the caissons for this structure was devised by towing the caissons out between barges, and on the anchoring of the latter in the proper position, weighting the caisson and letting it down to its position on the bottom by means of tackle on the decks of the barges.

**Fig. 51—Cockshutt Cantilever Bridge near Brantford, Ont.**
**Expansion by reinforced concrete rockers in pier recesses. 1933.**

In sinking the bottomless caissons through the ice in water as deep as 57 ft. for the foundations of the Alexandra cantilever bridge at Ottawa, in 1898, eight to twenty feet of sawdust, slabs and water-logged timbers were encountered. Despite the difficulty of removing such material the caissons were finally seated at their proper level and on being cleared out by divers the concrete was placed under water to a point 20 ft. below water level.

Reinforced concrete open caissons with removable bottoms were successfully employed in the construction of the foundations for the Welland Ship Canal bridges. The caisson was landed on the cut-off piles by flotation, the timber bottoms were removed and the caisson then partly filled with concrete placed underwater. It was then unwatered and the remainder of the concrete placed in the dry.

#### Pneumatic Caissons

Increased certainty and safety in manipulating pneumatic caissons has developed in Canada in the last twenty-five or thirty years. For example, in the pneumatic caisson work for the Quebec bridge, in which the caissons were carried down to a depth of over 100 ft. below high water level, there were no lives lost and only a few cases of illness resulting from working under air.

In the construction of the Honoré Mercier bridge over the St. Lawrence at Lachine, in 1933, a number of improvements in foundation construction by the pneumatic method were introduced. Welded steel caissons were adopted, new methods were devised for guiding and sinking the caissons and forming breakwaters, and a specially designed deflector was used in combination with a powerful shear-leg boat.

#### Combination Methods

Very frequently the inevitable variation in foundation conditions from pier to pier requires differentiation of foundation procedures.

**Fig. 52—Governor's Bridge, Toronto.**
Combined continuous frame and arch structure. Hollow spandrels and piers. 1923.

**Fig. 53—C.N.R. Precast Slab Bridge, St. George, Ont.**
Placed between trains. Rails rest directly on slab. 1932.

For example, in the reconstruction of the C.P.R. bridge over the St. Lawrence at Lachine, in 1912, all piers but the seven in the deepest water were built in open cofferdams with puddled walls. For the seven piers where the depth of water was from 20 to 27 ft. the work was done by a combined pneumatic and open process. In order to reduce the current from 8 to 12 miles an hour to about 2 or 3 miles an hour, wing rock-filled cribs were constructed at 45 deg. immediately up stream on each side of the old piers. The caissons were built in place on pontoons and, when ready, the latter were allowed to fill with water and were then pulled out from under the caisson as it settled.

In the case of the Jacques Cartier bridge at Montreal the foundation work included open crib, pneumatic caisson and pile foundations. Similarly, in the construction of the two new piers for the Second Narrows bridge, at Vancouver, one was built by the open caisson method and the other by the pneumatic method.

The foundations for the tower piers of the Detroit-Windsor bridge were each composed of two cylindrical reinforced concrete open caissons carried to 105 ft. below water level. In accordance with the plan of operation the caissons were sunk part of the way by open dredging and were then converted into pneumatic caissons and the sinking finished under air.

### Substructure Materials

Although up to about 1900 the use of concrete as an above water material for piers and abutments was not prevalent, some engineers were beginning to advocate its more extensive use. Dr. Martin Murphy, M.E.I.C., for many years provincial government engineer for Nova Scotia, was a pioneer in concrete construction, and many of his structures were of this material. Although concrete had first been employed in highway bridge construction in Nova Scotia, somewhat hesitatingly in 1883, by 1888 it was being used widely and with confidence.

The matter was examined with particular care in the Maritime Provinces by reason of the great disruption of masonry structures across tidal waters, in the vertical zone subjected to alternate exposure and submersion by the tides. It was found, however, that good concrete did not behave any worse than stone masonry, although as an extra precaution the piers of certain structures, as for example the Annapolis-Granville bridge, were sheathed with hardwood for that portion of the height within the tidal range.

Practice generally requires the use of stone masonry facing for those portions of important bridge substructures subjected to direct ice action, as for example in the piers of the two St. Lawrence bridges at Lachine, the Jacques Cartier bridge, and the Detroit-Windsor bridge.

### Substructure Forms

Forms of piers have naturally changed greatly during the past fifty years, as a result of the effort to cut down weight and cost. Suggested, no doubt, by the old twin-cylinder piers filled with concrete, which had some vogue many years ago, piers have taken on the dumb-bell or H-form. Instances of this form are to be found in the East York-Leaside viaduct piers and those for the Yonge boulevard bridge, already mentioned. A web continuously connected to the two flanges of the pier was used in these cases, but in many cases, such as for the Mercier bridge over the St. Lawrence, and the Galipeault bridge over the Ottawa between Ste. Anne and Ile Perrot, the connection of these flanges is not made continuous. In other words, the pier under lateral load is, in effect, a Vierendeel girder.

# Authors of Semicentennial Papers

K. M. Cameron

A. Duperron

The Hon. C. D. Howe

J. T. Johnston

Cameron, K. M., M.Sc., M.E.I.C., chief engineer of the Department of Public Works, Ottawa, received his early education at the Strathroy Collegiate Institute and at London, Ont., graduated from the Royal Military College at Kingston in 1901, and in 1902 from McGill University. He joined the Department of Public Works at London, going to Ottawa in 1912 and acting as assistant chief engineer until 1923.

Donald, J. R., B.Sc., M.E.I.C., President of Donald-Hunt Limited, Montreal, graduated from McGill University in 1913. From 1916 until 1918 he was chief inspector of explosives and chemicals for the Ministry of Munitions, Canada. When Donald-Hunt Limited, inspecting engineers and metallurgists, was formed in 1934 Mr. Donald became president of that organization.

Duperron, A., B.A.Sc., M.E.I.C., chief engineer of the Montreal Tramways Company, graduated from the Ecole Polytechnique, Montreal. In 1912 he was on hydro-electric surveys and was later with the Canadian Pacific Railway Company. In 1927 he was appointed chief engineer of the Montreal Tramways Commission and received his present appointment early this year.

Howe, The Hon. C.D., M.P., B.Sc., Hon. M.E.I.C., Minister of Transport, was born at Waltham, Mass. and graduated from the Massachusetts Institute of Technology in 1907. In 1916 he established the firm of C. D. Howe and Company, consulting engineers, Port Arthur, Ont. In 1935 he was elected to Parliament as Liberal Member for Port Arthur, later entering the cabinet.

Johnston, J. T., B.Sc., C.E., M.E.I.C., Controller, Dominion Water and Power Bureau, Surveys and Engineering Branch, Department of Mines and Resources, Ottawa, graduated from the University of Toronto in 1910. He has published several works on power storage and related studies and was granted the post-graduate degree of Civil Engineer in 1916 by the University of Toronto.

Keith, Fraser S., B.Sc., M.E.I.C., manager, the Department of Development of the Shawinigan Water and Power Company, Montreal, graduated from McGill University with honours in 1903. In 1917 he assumed the duties of general secretary of the Canadian Society of Civil Engineers, and in 1925 resigned to accept his present position.

Lafreniere, T. J., B.A.Sc., M.Sc., M.E.I.C., chief engineer, Bureau of Health, Province of Quebec, Montreal, graduated from the Ecole Polytechnique, Montreal, in 1909, and in 1912 received the degree of M.Sc. from the Massachusetts Institute of Technology. Upon graduation he was appointed sanitary engineer to the Board of Health of the Province of Quebec.

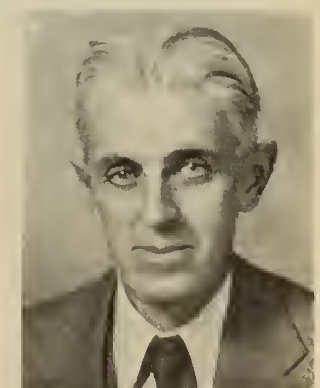
Macphail, J. G., B.A., B.Sc., M.E.I.C., Chief of Aids to Navigation, Department of Transport, Ottawa, graduated from Queen's University in 1905. Following graduation he joined the staff of the Marine Department, Ottawa, and was on the Commissioner of Lights' staff. In 1911 he was appointed Commissioner of Lights and received his present appointment in 1936.

McBride, W. G., B.Sc., M.E.I.C., Macdonald professor of mining engineering at McGill University, Montreal, graduated from McGill University in 1902, and subsequently spent a number of years in mining activities. From 1917 until 1927, when he received his present appointment, he was general manager of the Old Dominion Company of Arizona.

Fraser S. Keith

T. J. Lafreniere

J. G. Macphail



W. G. McBride

S. G. Porter

P. F. Sise

V. I. Smart

W. G. Swan

Sise, P. F., B.Sc., M.E.I.C., President of the Northern Electric Company, Montreal, is a graduate of McGill University of the year 1901. From 1914 to 1919 he was vice-president and general manager of the company, and in 1919 was appointed to his present office.

Smith, R. M., B.Sc., A.M.E.I.C., Deputy Minister, Department of Public Highways, Ontario, graduated from Queen's University in 1914, and joined the Department of Public Highways, Ontario in the same year. In 1920 he was appointed divisional engineer in charge of construction in the north and central portions of the province, and received his present office in 1930.

Swan, W. G., Major, D.S.O., B.A.Sc., C.E., M.E.I.C., consulting engineer, Vancouver, graduated from the University of Toronto in 1906, and received the degree of C.E. in 1911. In 1920 he was appointed chief engineer of the Vancouver Harbour Commissioners, and in 1925 resigned to enter private practice.

Porter, S. G., A.B., S.B., M.E.I.C., manager of the Department of Natural Resources of the Canadian Pacific Railway Company, graduated from Baylor University, Texas, in 1898, and from the Massachusetts Institute of Technology in 1903. In 1913 he came to Canada, and joined the staff of the Canadian Pacific Railway in 1918. Mr. Porter was President of The Engineering Institute of Canada in 1931.

Wilson, J. A., M.E.I.C., Controller of Civil Aviation, Department of Transport, Ottawa, received his education at University College, Dundee, and St. Andrews University. From 1923 to 1927 he was secretary and assistant director for the Royal Canadian Air Force, Ottawa; in 1927 became controller of civil aviation with the Department of National Defence, and received his present appointment in 1936.

Smart, V. I., B.A., M.E.I.C., Deputy Minister of Transport, Ottawa, graduated from Queen's University in 1887. From 1907 until 1912 he was professor of railway engineering at McGill University, and then was vice-president and general manager of the General Railway Signal Company, Montreal, and member of the firm of Smart and Burnett, Montreal.

Wardle, J. M., B.Sc., M.E.I.C., Director, Surveys and Engineering Branch, Department of Mines and Resources, Ottawa, Ont., graduated from Queen's University in 1912. In 1920 he became chief engineer of the Canadian National Parks Branch, and held that position until 1935 when he received his present appointment.

Young, C. R., B.A.Sc., M.E.I.C., professor of civil engineering at the University of Toronto, was a graduate of that University in 1903, and has been a member of the faculty since 1907. He was for some years professor of structural engineering, and in 1929 received his present appointment.

# Investigations of Canadian Coals Including Their Testing, Classification and Utilization*

## Conducted by the Staff of the Division of Fuels, Department of Mines and Resources, Ottawa.

*B. F. Haanel, M.E.I.C.,*
*Chief of Division, Division of Fuels, Bureau of Mines*
*and*
*R. E. Gilmore, M.E.I.C.,*
*Senior Engineer, Division of Fuels, Bureau of Mines.*

**Paper presented at the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

In this paper the nature, scope and summary results of recent investigations involving testing, classification and utilization of Canadian coals conducted by technical officers of the Division of Fuels of the Department of Mines and Resources are considered briefly. For those readers desiring more complete details regarding certain investigations or phases of investigations, references to various reports are given at the conclusion.

While not indicated the paper is divided into two parts or sections. The first section, in addition to a few introductory paragraphs on Canadian coal resources and production, deals with the smaller laboratory scale chemical and physical tests employed by fuel technologists together with a discussion of the significance and relative importance of these tests. This section also briefly summarizes the laboratory investigations of friability, size stability, and grindability of coal conducted at the Fuel Research Laboratories, and illustrates the application to Canadian coals of the rank, grade, and use classification specifications recently promoted by the American Society for Testing Materials, in whose classification activities representatives from Canada had a prominent part.

The second section of the paper reviews the recent large scale investigations conducted by officers of the Fuels Division, at the Fuel Research Laboratories, at collieries, and at by-product coke oven plants. These investigations comprise coal seam survey work, physical and chemical analysis survey of screened sizes of coal from Canadian collieries, washing, sizing and storage investigations, combustion tests in an experimental domestic furnace—hand, blower and stoker fired, pulverized fuel tests, briquetting, coking tests at high, low and medium temperatures, and high pressure hydrogenation tests. The objective of these investigations, in which a few coals from Great Britain and the United States have been included for comparative purposes, has been to obtain results that will serve for a more efficient and greater utilization of Canadian coals.

In preparing this paper the aim of the authors has been to present a comprehensive review of recent investigations for prospective readers and particularly for engineers, generally and specifically interested in fuel technology.

*Published by permission of Director of Mines and Geology Branch, Department of Mines and Resources.

### Coal Production

Canada's coal resources[1]† are confined almost entirely in the extreme eastern and western provinces: in Nova Scotia and New Brunswick in the east and in British Columbia, Alberta and Saskatchewan in the west. Accordingly it is in these provinces that the producing mines are located, leaving the central provinces of Quebec, Ontario and Manitoba dependent on coal mined outside their borders. In Manitoba and Ontario appreciable deposits of lignite have been located but their production is relatively negligible.

The total Canadian coal production in 1935 was nearly fourteen million short tons. Of this total approximately forty-two per cent was mined in Nova Scotia, thirty-nine per cent in Alberta, ten per cent in British Columbia and seven and two per cent from Saskatchewan and New Brunswick respectively. Nearly ninety-six per cent of the coal mined in Canada is consumed in the country, but the production represents only about fifty-five per cent of the total consumption, consequently nearly one-half of our coal requirements are imported.

The trend of the production, importation, and consumption of coal in Canada[2] may be gathered from perusal of Table I covering the ten-year period from 1926 to 1935.

Table I

Production, Exports, Imports and Consumption of Coal in Canada—Millions of Short Tons

| Year | Production | Exports | Imports | | Consumption |
|---|---|---|---|---|---|
| | | | Bituminous | Anthracite | |
| 1926 | 16.5 | 1.03 | 12.4 | 4.2 | 31.6 |
| 1927 | 17.4 | 1.11 | 14.6 | 4.1 | 34.1 |
| 1928 | 17.6 | 0.86 | 13.4 | 3.7 | 33 0 |
| 1929 | 17.5 | 0.84 | 14.2 | 4.0 | 34.1 |

†References to the bibliography at the end of the paper are indicated by superscript numbers thus [1].

The production for 1935 according to province, area and kinds of coal mined is shown in detail in Table IV, a summary of which is as follows:—

| | |
|---|---|
| *Bituminous coal* | |
| Nova Scotia | 5,808,420 tons |
| New Brunswick | 342,333 tons |
| Alberta | 2,248,685 tons |
| British Columbia | 1,329,379 tons |
| Yukon | 825 tons |
| *Sub-bituminous (and lignite) coal* | |
| Manitoba | 3,984 tons |
| Saskatchewan | 919,477 tons |
| Alberta | 2,645,917 tons |

*Coking and Non-coking Coals*

Most bituminous coals since they cake and form coke when burned are said to be coking coals whereas the high rank anthracites and the lower rank sub-bituminous coals are non-coking. The terms "hard" and "soft" which referred originally in this country to Pennsylvania anthracite and to ordinary bituminous steam coal respectively, are now more or less obsolete since it is generally realized that there are hard and soft varieties of both of these kinds of coal. The term coking as used here is general rather than specific and refers to all those coals that have poor, fair, and good coking properties as judged by the "coke" button residue obtained in proximate analyses.

Of the total reserves in Canada only about seven per cent belong to the bituminous coking coal class. The remaining ninety-three per cent belong to the non-coking classes of which less than one-half of one per cent is anthracite. This implies that approximately 92.5 per cent of the country's resources are non-coking, sub-bituminous and lignite coals. Of the total production of coal over three-quarters is bituminous, and it is likely that this ratio of coking to non-coking coals will continue for several decades. When, therefore, the supply of the higher rank coals nears exhaustion practically all of the country's coal resources will consist of the lower rank non-coking coals.

The coal mined in the Maritime provinces is almost entirely bituminous, the geological age of which is known as carboniferous. In British Columbia also, practically all the coal is bituminous but its geological age and characteristics are different to those in the east and moreover vary widely among themselves. In Alberta, where all classes of coals are produced, about one-half of the coal mined is coking bituminous coal, the other half comprising the non-coking varieties. In this province certain of the non-coking coals, on account of their free burning properties, freedom from smoke, etc., find extensive use for household heating, and for this reason are known as domestic coals. They also find extensive use for steam raising, for which the cost in comparison with other suitable coals available is the deciding factor. The coal mined in Saskatchewan is lignite which is also the designation of the coal deposits recently discovered in Northern Ontario.

## Chemical and Physical Laboratory Analyses

The analyses of Canadian coals have been reported from time to time in Department of Mines publications [3,4] These are what are ordinarily known as chemical analyses and are to be considered separate from, or rather supplementary to, physical tests to which a coal should be subjected in order to ascertain its relative suitability for a given use. A laboratory chemical analysis is conducted on the finely divided pulverized coal, whereas most of the physical tests are carried out on the sized coal sampled at any stage on its course from the producer to the consumer. At this point it may be emphasized that for the proper interpretation of the chemical analysis of a coal for commercial use, its general physical characteristics should be known. Furthermore it should be remembered that the "as received" basis on which analyses are reported means as received at the laboratory, and does not allow for changes in respect to moisture, calorific value, etc., that may have taken place in the transit of the sample to the laboratory.

*Proximate and Ultimate Analyses*

As is generally known the proximate analysis comprises determinations for moisture, ash, and volatile matter contents, with the fixed carbon percentage obtained by difference; and the ultimate analysis includes determinations of carbon, hydrogen, ash, sulphur, nitrogen, and oxygen by difference. The ash content in both analyses is assumed to be the same, and when the only item of the ultimate analysis called for is the sulphur content, it is a usual laboratory practice to report it separately from the four items of the proximate analysis. In the proximate analysis the sulphur is assumed to be equally distributed between the volatile matter and the fixed carbon. A complete analysis of a coal, or other solid fuel, includes calorific value, the results of which are usually expressed as B.t.u. per pound.

All of these determinations are chemical when judged by the criterion that a chemical change takes place, but strictly speaking most of them are physical-chemical in nature. Other chemical determinations are the fusion point of ash (F.P.A.) and the analysis of the ash involving determinations for part of all of the following elements, viz., silica, iron, aluminum, calcium, magnesium, sodium, potassium, titanium, phosphorus, and sulphur, all of which are usually reported as oxides. Additional tests are often necessary to ascertain general caking or coking, potential smoke producing and storage properties.

*Physical Analyses*

Determinations of the physical properties of coal, coke or other solid fuels include a screen analysis for size, specific gravity—true and apparent, bulk density for weight per cubic foot and cubic feet per ton, friability or its complement size stability, and grindability or pulverizability. These determinations as mentioned above are made on the fuel either in the lump form or after being either crushed or pulverized. The preparation of the sample for laboratory analysis is physical rather than chemical and involves crushing, riffling, and pulverization according to standardized laboratory procedure. Sampling which also may be classed as physical is a very important item as a pre-requisite to analysis in the laboratory. The importance of sampling will be evident when it is realized that it is subject to greater errors than the subsequent analysis.

The theory of sampling is, that in the final pulverized laboratory sample amounting generally to less than one-half pound each particle represents a lump, before or after crushing, of the original lot of fuel sampled. Hence when a single laboratory sample is to represent quantities as large as a railway carlot or a steamship cargo, great care is necessary in the sampling procedure. According to good sampling practice, the original gross sample should be an aliquot portion of the lot sampled, and as the gross sample is reduced in amount by progressive "quartering," the size of the lumps should also be uniformly reduced.

## Standard Methods of Analyses

Standardized methods for analyzing coal, coke and other solid fuels have been prepared and published by different standardization organizations. The most important of these, so far as Canada is concerned, are:—

American Society for Testing Materials . . (A.S.T.M.)
American Standards Association . . . . . . . . . (A.S.A.)
British Standards Institution . . . . . . . . . . . . (B.S.I.)

The specifications for coal and coke analyses recently advanced tentatively by the British Standards Institution follow generally the respective A.S.T.M. standard methods with slight variations in the procedure details. For coal and coke it is the practice of the American Standards Association to select and adopt A.S.T.M. methods, under their "K—Chemical Industry" designation, rather than to develop separate A.S.A. methods. Methods adopted and published either as A.S.T.M. "Standards" or "Tentative Standards" by the American Society for Testing Materials are as a matter of general interest tabulated below:—

*Methods of sampling and analyses (see footnote)*

| | |
|---|---|
| †D 21–16 | Sampling Coal. |
| D 346–35 | Sampling Coke for Analysis. |
| *D 271–33 | Laboratory Sampling and Analysis of Coal and Coke. |
| D 410–35T | Test for Screen Analysis of Coal. |
| D 311–30 | Test for Sieve Analysis of Crushed Bituminous Coal. |
| D 197–30 | Test for Fineness of Powdered Coal. |
| D 293–29 | Test for Sieve Analysis of Coke. |
| D 431–36T | Designating the Size of Coal from its Screen Analysis. |
| D 310–34 | Test for Size of Anthracite. |
| *D 291–29 | Test for Cubic Foot Weight of Crushed Bituminous Coal. |
| *D 292–29 | Test for Cubic Foot Weight of Coke. |
| *D 167–24 | Test for Volume of Cell Space of Lump Coke. |
| D 408–35T | Grindability of Coal by the Ball-Mill Method. |
| D 409–35T | Grindability of Coal by the Hardgrove Machine Method. |
| *D 141–23 | Shatter Test for Coke. |
| *D 294–29 | Tumbler Test for Coke. |
| . . . . . . . . . | Test for Agglutinating Value of Coal (Proposed Draft). |
| . . . . . . . . . | Drop Shatter Test for Coal (Proposed Draft). |
| . . . . . . . . . | Tumbler Test for Coal (Proposed Draft). |

*Specifications for:*

| | |
|---|---|
| D 166–24 | Gas and Coking Coals. |
| D 17–16 | Foundry Coke. |
| E 11–26 | Sieves for Testing Purposes. |
| E 17–36 | Round-Hole Screens for Testing Purposes. |
| †D 388–36T | Classification of Coals by Rank. |
| †D 389–34T | Classification of Coals by Grade. |

*Definitions of:*

| | |
|---|---|
| D 121–30 | Terms Relating to Coal and Coke. |
| D 407–35T | Terms Gross Calorific Value and Net Calorific Value of Fuels. |

Note—Printed copies of each of these documents are available at 25c. each in pamphlet form from American Society for Testing Materials, 260 South Broad Street, Philadelphia, Penna., U.S.A. The whole set is published as a separate volume under the title "A.S.T.M. Standards on Coal and Coke—Prepared by Committee D-5" and priced at $1.00.

The D prefix means that the corresponding standard methods of test, specifications, and definitions, were developed by Committee D-5 on Coal and Coke of the American Society for Testing Materials, the middle number, e.g. 21, 346, etc., is the serial number of the test and the suffixes are the years in which they became standard or were last revised. T, following the year, signifies that the method of test is as yet a tentative standard and † and * mark those methods that have been approved as "American Standard" and "American Tentative Standard" respectively by the American Standards Association.

At the Fuel Research Laboratories of the Division of Fuels at Ottawa the A.S.T.M. methods listed above have been largely adopted and extensively used in the chemical and physical testing of coal and other solid fuels. These methods are subject to revision at any time in accordance with the rules of the Society, which revisions and also the development of new methods are made by standing sub-committees of Committee D-5, which sub-committees are at present fifteen in number and in numerical order are: Advisory, Methods of Testing, Nomenclature and Definitions, Agglutinating Value, Pulverizing Characteristics of Coal, Foundry Coke Specifications, Coke Sampling, Editorial, Coal Friability, Sampling Coal at Coal Cleaning Plants, Mechanical Sampling, and Reduction of Samples, Dustiness of Coal and Coke, and Plasticity and Swelling. The second named author of this paper, in addition to being a member of Committee D-5 and of four of the sub-committees, is chairman of the Sub-Committee on Coal Friability and accordingly has a direct interest on behalf of the newly created Bureau of Mines in the A.S.T.M. standardization of methods for testing solid fuels and in the development of new methods of test.

## SIGNIFICANCE OF TESTS

It is to be noted that only one of the above listed methods concerns chemical analyses, viz., D 271-33, the others being physical tests. This one standard method is, however, very important since it comprises the proximate and ultimate analyses, calorific value, fusibility of ash, and the preliminary preparation of the laboratory sample. A treatise of considerable length could be written on the significance of tests for coals, but in view of articles already available,[5,6] in addition to a contemplated publication on this subject now being prepared by A.S.T.M. Committee D-5 only some aspects of the more pertinent tests will be discussed here.

### *Preparation of Sample for Analysis*

This concerns the sample after it is received in the laboratory, and involves its reduction both in size of particle and in amount, by means of either a crusher or grinder, large and small riffles, and a pulverizer of the "bucking board," planetary disc crusher, or porcelain ball-mill type. The sampling part of this preparation is of course separate from the collection of the sample and its reduction prior to sending it to the laboratory. If conducted according to standardized procedure, any errors in the final analysis due to sampling are as a rule attributable to the sampling before it reaches the laboratory. For samples appearing wet special care is taken either to air dry the sample before crushing and record the air drying loss, or to take a special (aliquot part) sample for the determination of the moisture content on the as received basis.

On the pulverized laboratory sample, prepared with or without preliminary drying, determinations for moisture, ash, and volatile matter are made separately on different portions of approximately one gram each. Of these, the volatile matter determination is perhaps the most important. In this determination, in which the coal is heated in a covered platinum crucible at 950 deg. C. for seven minutes, the gases given off consist of the moisture and volatile matter contents of the coal, leaving behind the combined ash and fixed carbon. Having previously determined the moisture and ash contents, the four components constituting the proximate analysis are recorded and reported. The per cent fixed carbon which is not determined directly is the difference between one hundred and the sum of the moisture ash and volatile matter percentage contents.

### *Volatile Matter and Fixed Carbon*

These serve, either before or after they are calculated to the pure coal basis, for classifying coals according to rank primarily for scientific purposes—for example into low, medium and high volatile bituminous coals, and into the high rank anthracite coals. The residue left in the platinum crucible after the volatile matter determination may be graded to indicate the general characteristics of a coal in respect to caking or coking. The gradings[30] reported include non-coking, agglomerating, and poor, fair or good coking.

### *Moisture, Ash and Calorific Value*

These indicate the grade of a coal so far as its chemical characteristics are concerned. The calorific value alone may be considered as representing the grade, since it is determined on the raw (air dried) coal containing moisture and ash and it is, therefore, influenced by these constituents. It is the gross calorific value as per D 407-35T that is shown in a report of analysis of a coal. The net calorific value is calculated from the gross value by making a deduction for the water formed by combustion, for which it is necessary to know the hydrogen content as determined in the ultimate analyses. The calorific value on the basis of the freshly mined coal, free of ash and mineral matter, is used for classifying the lower rank coals into different classes and groups.

*Sulphur Content*

This is an important grade specification and for accurate calorific value determinations, corrections are necessary to allow for the difference between complete oxidation when burned in the calorimeter bomb and partial oxidation when the coal is burned in an ordinary furnace. Usually only the total sulphur is shown in an analysis report, but in investigational work three different forms are determined and noted, viz., sulphate, pyritic and organic sulphur. The total, and in particular the pyritic sulphur content indicates relative ash fusion temperature—high pyritic sulphur usually means correspondingly low fusion points.

*Fusion Point of Ash (F.P.A.)*

This determination gives a general indication of the tendency of a fuel to form clinkers when burned. It affords a means of dividing coals into low, medium, and high ash fusion grades—the respective ranges recognized for these three grades being: below 2,200, 2,200 to 2,600, and above 2,600 deg. F. The ash content has an important bearing on the interpretation of the ash fusion temperature and its relation to clinkering properties, and ash fusion temperature specifications may be lowered in accordance with lowering of the ash content below that considered normal or average. Other factors allowing lowered F.P.A. specifications are physical and chemical characteristics that influence reactivity and rate of burning such as structure of a coke fuel and rank of a coal. Quality of the volatile (combustible) matter in high rank coals, e.g., in non-coking semi-anthracites, and the oxygen content of the non-coking lower rank coals, influence rate of burning; and generally, for free burning fuels the fuel bed temperature is appreciably lower than normal, thus allowing a relatively low fusion point of the ash. In an ash fusion determination three points are determinable, viz., the initial deformation temperature of coal ash cone, its softening point, and the fluid point. It is the middle temperature, viz., the softening point, that is reported as the "F.P.A." For low and certain medium ash fusion coals and cokes the softening and melting ranges are significant. These ranges are respectively the difference between the initial and the softening points and the difference between the softening and fluid points. A fuel may have a relatively low F.P.A. and still not give clinkering trouble on account of its high fluid point and consequent wide melting range.

*The Relation of Chemical Composition of Coal Ash to Its Fusion Temperature*

Within recent years this has been the subject of much research but as yet no very definite relation has been found to hold universally true. High silica and alumina contents indicate high fusion temperatures and the addition of either or both of these oxides to low F.P.A. coals, viz., those below 2,000 deg. F., has been suggested for improving their general burning qualities in respect to general clinkering properties and especially the tendency of the ash to melt and run on account of a narrow melting range. For this purpose, indications are that alumina would be about five times as effective as silica. Lime and combinations of sodium and potassium compounds, on the other hand, have the effect of lowering the ash fusion temperature. An analyst can make fifteen or more ash fusion determinations in the time required for a complete analysis of a coal ash, hence the rapid and more practical F.P.A. determination is usually requested and the chemical analysis, if made, is then useful as supplementary information.

*Screen (and Sieve) Analyses*

These tests are important for checking the sizing of coals, cokes, etc., as prepared at the mine, as delivered on the market, and as used for different purposes. In heating installations and power plants requiring pulverized fuel, a sieve analysis of the boiler feed serves to ascertain if the fuel is sufficiently fine for good combustion, and as a check on the performance of the pulverizer unit. For good combustion the fineness may be as low as forty per cent through 200-mesh sieve for certain low rank coals, but for ordinary medium to high volatile bituminous coals the percentage passing this sieve should range from seventy to eighty.

For screen analysis and size designation as per A.S.T.M. Nos. D 410-35T and D 431-36T round hole screens from eight-inch diameter down to and including ⅜-in. sized openings are specified below which the ordinary small wire cloth sieves with square openings are used. These are laboratory or plant tests for comparing coals in respect to average size and although they may be used for checking preparation at the mine they are separate from the colliery preparation where large mechanically operated screens of various types are employed. By these methods, applicable mainly to bituminous coals, the range of size is indicated by giving the lower and upper limiting screens between which 80 per cent of the sample is retained. Examples of size designations are 2-4-in. and ½-3-in. in which the order is from the lower to the upper limiting screen; "in." being the abbreviation for inches. The standard and condensed size designations proposed are applicable for testing run-of-mine, slack, and other commercial sizes of coal.

*Standard Anthracite Sizes*

For anthracite a different set of round hole screens have been adopted, as per D 310-34, in which the screens and sizing conform to the specifications of the American Anthracite Institute which are:—

| Passing | Retained on | Size Designation |
|---|---|---|
| 4⅜ inch screen | 3¼ inch screen | Broken |
| 3¼ inch screen | 2 7/16 inch screen | Egg |
| 2 7/16 inch screen | 1⅝ inch screen | Stove |
| 1⅝ inch screen | 13/16 inch screen | Chestnut |
| 13/16 inch screen | 9/16 inch screen | Pea |
| 9/16 inch screen | 5/16 inch screen | No. 1 Buckwheat |
| 5/16 inch screen | 3/16 inch screen | No. 2 Buckwheat (Rice) |
| 3/16 inch screen | 3/32 inch screen | No. 3 Buckwheat (Barley) |

While these sizes apply primarily to American anthracite, they may be of service for Welsh, Scotch and other European anthracites on the Canadian market and especially the buckwheat sizes marketed as blower fuels. When, however, a screen analysis is made on other than American anthracite it should be clearly stated and emphasized that the percentages of the stove, nut, pea, buckwheat, etc., sizes reported are equivalent to, or in terms of the respective sizes specified by the American Anthracite Institute. To the authors' knowledge there are no similar size specifications governing the British, European and Asiatic anthracite imported into Canada.

*Bulk Density*

Tests to determine weight per cubic foot of crushed bituminous coal and of coke comprise the weighing of repeated lots into a box of known volume and calculating the weight (in pounds) per cubic foot to obtain an average value for reporting. For crushed coal, less than 1½ in. in size, a cubical iron box holding exactly one cubic foot is specified and for coke a two cubic foot cubical box made of wood is recommended. In making the test the fuel is allowed to flow gently into the box which is not to be shaken or tapped during the falling and levelling off procedure. Knowing the weight per cubic foot, the cubic feet per ton can be readily calculated. Bulk density values are useful for estimating the storage space required for different fuels. A large number of these values have been made at the Fuel Research Laboratories, some of which have been published.[26,27] The bulk density varies somewhat for different sizes of clean lumps of the same fuel, due to their shape and intervening air spaces—the space required for a given weight being greater for the smaller sizes than for the larger lumps. For mixed sizes this variation tends to disappear due to the filling of the voids between the larger lumps by the smaller sizes. Domestic sizes of anthracites and bituminous coals will average about fifty pounds per cubic foot equal to 40 cu. ft. per ton. The smaller sizes of by-product coke will range from 67 to 77 cu. ft. per ton with the average about midway between these values.

*Volume of the Cell Space of Lump Coke*

Test D 167-24 (A.S.T.M.) involves the determinations of both "apparent" and "true" specific gravity, from which percentage of cell space is calculated. In this test the water displacement principle is utilized and the apparent specific gravity determination requires a correction for the water absorbed. For this test lump coke is required whereas in the determination of true specific gravity the specifications call for pulverized coke passing a 200-mesh sieve. The apparent specific gravity of the lump coke, on the market as domestic household fuel usually ranges from 0.80 to 1.00.

*Density of Coal*

For lump coal and particularly the denser, non-porous and non-friable varieties, the apparent gravity closely approaches the true specific gravity. The test, for which clean lumps two to four inches in size are recommended, may be employed for making rough estimates of the bulk density of coal "in situ"—with allowance to be considered for the compressing effect of pressure in the mine. In making "gravity" determinations at the Fuel Research Laboratories, incident to the physical and chemical survey of coals from Canadian collieries outlined in the section below dealing with coal preparation and storage, certain improvements have been effected in the apparatus and procedure. A full description of these improvements is now in manuscript form ready for publication. The cubic feet per ton values obtained show considerable variation according to ash content, and in respect to the proportion of bright and dull coal, and the fusion constituents. The lower ash coals from the Sydney and Springhill areas in Nova Scotia, for example, have specific gravities averaging 1.30, the corresponding weight per cubic foot and cubic feet per ton "in situ" values averaging 81 and 24.7 respectively. Other Nova Scotia (normal ash) coals show specific gravities ranging from 1.3 to 1.4 with corresponding cubic feet per ton values of 24.5 to less than 23.5.

*Grindability*

Tests D 408 and 409 (A.S.T.M.) are for indicating the relative amounts of energy required to pulverize coals to a given fineness using a coal of known commercial performance as a standard. Hence these tests are useful for dividing coals into different grades in respect to pulverizability. It is to be noted that the results obtained by the two methods are interchangeable by the use of a factor, so that a laboratory may choose the method preferred. The Fuel Research Laboratories (F.R.L.) at Ottawa are equipped with apparatus for making grindability tests according to both the "ball mill" and the Hardgrove machine method and also according to the F.R.L. method. This latter method was developed in the early stages of the activities of A.S.T.M. sub-committee of pulverizing characteristics of coal, as a forerunner to the ball mill method adopted, to which the F.R.L. method is similar in many respects. Results of tests on several Canadian coals by both the Hardgrove and F.R.L. method have been published[7] and the results on many more coals are on record. A grindability index of 100 or higher by the Hardgrove machine method indicates an easily pulverized coal, while indices of 30 and lower represent coals that are comparatively hard to pulverize. The values by the ball mill method corresponding to these two indices are 80 and 21 respectively.

The sieve test, as per D 197-30, is employed for determining the fineness of powdered coal and in a heating or power plant requiring pulverized fuel the test will indicate whether or not the fuel is sufficiently fine for good combustion. It also serves for checking the performance of the pulverizer. The fineness required appears to vary considerably and in accordance with the rank of coal. The manufacturers of pulverizers guarantee as high as 85 per cent through a 100 mesh. For bituminous and sub-bituminous coals, degrees of fineness down to 80 per cent through 100 mesh—with corresponding percentages through 200 mesh of 55 per cent—have been found to assure good combustion while for low rank lignite coals which are comparatively hard to pulverize percentages as low as 65 per cent through 100 mesh are allowable.

*Shatter and Tumbler Tests for Coke and Coal*

These tests are useful for indicating relative strength and handling properties. They were originally developed for testing the strength of metallurgical coke for use in a blast furnace, but they have become generally serviceable for domestic coke and lump coals.

The shatter test as applied to coke consists of dropping 50 lb. of lumps larger than two inches in size a distance of six feet onto an iron plate base of a specially constructed apparatus. The unbroken and broken lumps resulting from the first drop are returned to the box container and again dropped. This procedure is repeated until four drops have been made after which the resultant coke is subjected to a screen analysis using square hole screens. The percentage of lumps remaining on the two inch screen is the main result sought which percentage is sometimes known as the "Shatter (2 in.) Index." The proportions remaining on the smaller screens are also recorded to indicate the extent of breakage taking place in the test and accordingly to further judge the quality of the coke tested. In the tumbler test for coke 22 lb. (10 kg.) of two to three inch lumps are tumbled for fourteen hundred revolutions at 24 r.p.m. in a three-foot diameter steel drum fitted on the inside with lifting shelves. After tumbling the broken coke is screened on the same two inch square hole screen as used in preparing the sample, and then on smaller size screens. The total percentage retained on the one-inch screen is reported as the stability factor and the total on the one-quarter-inch screen as the hardness factor.

Another tumbler test applicable to coke, coal and briquettes is the "Sheffield" coke abrasion test.[8] In this test two cubic feet of 2 to 3 in. lumps of coke are rotated at a specified r.p.m. and total number of revolutions in a steel drum, without shelves, nearly filled with the charge. The total percentage of the broken coke retained on the smaller screen used in preparing the sample, viz., 2-in.

(square hole) is recorded and reported as the "Abradability Index" and the percentage passing a $\frac{1}{16}$th in. screen the "Dust Index."

A test for "dustiness" recently proposed may be mentioned here. In this test a given charge of fuel is dropped in a specified closed vertical chamber and the amount of dust formed is determined by allowing it to settle on a horizontal shutter inserted immediately after the fuel dropped has released its dust to the chamber atmosphere. The amount of dust so formed is, of course, collected and weighed, and the results are serviceable for indicating the relative dust producing qualities of various fuels and in particular the domestic sizes of coke and coal used as household fuels. This test which is now being developed by Committee D-5 as an A.S.T.M. tentative standard is useful for checking the efficiency of dedusting processes now in extensive use for domestic fuels.

In the smaller abrasion (tumbler) test the breakage taking place is considered to be largely due to the abrasive action of the lumps rubbing against each other and to a lesser extent to the shattering effect of the lumps dropping short distances against each other and against the walls of the tumbler. The breakage in the larger (coke) tumbler test is both by abrasion and shattering, whereas in the shatter test apparatus the breakage is considered to be effected largely by shattering, with a small amount only of the breakage being caused by abrasion or attrition. It is for this reason that the shatter test has been selected as applicable for testing the relative friability of coals, since it is considered that the breakage taking place during commercial handling is by shattering to a much larger extent than by abrasion. All of the above shatter and tumbler test machines and apparatus, including the apparatus for dustiness, are installed at the laboratories in Ottawa and are extensively used for testing cokes, coals, and other solid fuels.

### Coal Friability Tests

A large number of coal friability tests[9] were made at the Fuel Research Laboratories during 1932, 1933 and 1934. These were supplementary to similar tests previously made at the University of Illinois,[10] the Seattle Experiment Station of the U.S. Bureau of Mines[11] and elsewhere, and were for the purpose of comparing different laboratory friability methods in connection with the programme of the "Coal Friability" sub-committee of the American Society for Testing Materials. The tests also served for selecting a method for testing the comparative handling properties of coals incident to "an investigation of the physical and chemical characteristics of different sizes of coal from Canadian collieries' outlined below.

By friability as applied to coal is meant its liability to break and crumble into smaller pieces. Hence a friability test, which is physical in nature, serves to compare relative handling properties. The more practical method of ascertaining the handling properties of a coal in respect to friability is to examine by screening, shipments at different stages during its mining, preparation and transportation from the mine to its ultimate consumer. Comparing coals by this method, however, is too costly and what is required is a laboratory method or methods to serve as a definite measure of the comparative friability of coals. In the development of laboratory friability methods, the principle followed has been that of performing a uniform amount of work on the sample and then measuring the reduction in the average size of the lumps. Seven different methods, five tumbler and two shatter, were tried out in the experimental work in which an endeavour was made to ascertain to what extent the apparatus and methods for coke, outlined above, would be suitable for coal.

Working on seven different standard coals varying from hard non-friable anthracite to soft quite friable bituminous coals, it was found that certain variations of all seven methods could be considered satisfactory in that they placed the seven coals in the same order as to friability. Concluding that there was a need for two methods, one tumbler and one shatter as with coke, it was necessary to select these from the seven. The two methods selected are listed above as Proposed Drafts. They have recently been adopted as A.S.T.M. Tentative Standards but the designation of each has not as yet been published.

*The Tumbler Test Method for Coal*

This method employs a porcelain (pebble mill) jar, the same as is used in many laboratories for preparing coal samples, that is for pulverizing them, for analyses. For the friability test the jar is fitted with an iron frame with lifting shelves constructed according to definite specifications. The standardized procedure requires the preparation of an adequate supply of 1.05 to 1.5-in. lumps using square hole screens. A single test consists of rotating 1,000 grammes of these sized lumps for one hour at 40 r.p.m. and two or more series of quadruplicate tests are recommended. After tumbling, the contents of the jar either singly or in sets of four are screened on a specified set of ordinary screens and sieves ranging from one inch down to 50 mesh. From the screen analysis of the broken material the average size of lumps before and after tumbling is calculated and the result of the test expressed as friability per cent. This is simply the average size of the broken coal expressed as a percentage of the average size, viz., 1.275, of the lumps taken as sample. In this method both shattering and abrasion takes place and it has been suggested that the fines and dust through the 50 mesh sieve, which is considered to represent the breakage due to abrasion or attrition, be reported as the "dust index." This method, which was originally developed[12] and employed for comparing the dust producing properties of coals and cokes as delivered as household fuels, may be termed a small laboratory scale friability method. While serviceable for measuring the relative friability of coals at the mine and during subsequent handling it may also serve to indicate the extent to which lump coals will suffer degradation in certain mechanical feed devices. By this method the friability percentages range from about 20 for a low friable coal such as Pennsylvania anthracite to 60 and higher for very friable coals.

*Drop Shatter Test for Determining Size Stability of Coal*

In this test the same shatter test machine as adopted for coke (D 141-23) is used but the number of drops specified for coal are two instead of four as for coke. The breakage taking place in this test is mostly by shattering and it is considered that the extent of breakage is more in accordance with that in the ordinary handling of lump coal than in the tumbler test. The reporting of the results in terms of size stability is preferred to the term friability in that the producers of coal would more than likely favour consideration of their lump product in degree of size stability, that is its resistance to breakage, rather than in respect to degree of friability or size degradation. The size stability per cent is the difference between one hundred and the friability per cent, that is, the one is the complement of the other.

Round hole screens are used in the drop shatter test method, these being recommended in accordance with the adoption of round hole screens for the screen analysis of coal and its size designation as per D 410-35T and D 431-36T. The size of coal selected as standard for the test are 2 to 3-in. lumps and supplementary specifications are given for testing smaller and larger sizes than the standard and for mixtures of two or more of these sizes. Hence the method is considered applicable to different sizes of the same coal as well as to the same size of different coals. In addition to reporting the size stability per cent which represents the average reduction in size or rather the average overall stability of the lumps tested as ascertained by a screen analysis of the "dropped" coal, it is recommended that the "slack index," namely, the percentage through the ¾ in. screen be reported as supplementary information. This would be specially applicable when testing the relative size stability of freshly mined coal at the mine.

The size stability per cent of different coals when tested by the drop shatter test method varies from 93 to 95 for a hard (non-friable) coal to 65 and lower for very friable coals, that is when testing standard 2- to 3-inch lumps. The corresponding stability values for this and other larger and smaller sizes of a typical medium-friable bituminous coal from the Sydney area in Nova Scotia are tabulated here as a matter of general information.

| Size of Lumps (round hole screens) | Size Stability Per cent |
|---|---|
| 8 in.-12 in. | 39 |
| 6 in.- 8 in. | 46 |
| 4 in.- 6 in. | 56 |
| 3 in.- 4 in. | 66 |
| 2 in.- 3 in. (standard) | 74 |
| 1½ in.-2 in. | 79 |
| 1 in.-1½ in. | 84 |
| ¾ in.-1 in. | 88 |
| ½ in.- ¾ in. | 91 |

This illustrates how the stability varies with the size of lumps from large to small of the same coal and that the smaller lumps of a soft bituminous coal approach a stability value of hard anthracite coal, evidently due to the fact in the smaller lumps the fracture lines so apparent in the larger lumps have disappeared. On account of the effect of the cushioning effect of the "smalls" and "fines" the size stability per cent of a minus 4 in. (run-of-mine) coal mixture by this test will be as high as 95. This observance is decidedly in favour of always shipping and handling mixed sizes in which a goodly proportion of "slack" is present but for particular uses a uniformly sized product free from fines is required and the above data show that a stable lump product in the smaller sizes can be prepared from a friable coal.

## COAL CLASSIFICATION ACTIVITIES

The specifications for classification of coals by rank and by grade as per A.S.T.M. D 388-36T and D 389-34T represent committee work on coal classification inaugurated in 1927 and continuing up to the present time. This work was conducted mainly by the "Sectional Committee on Classification of Coals" functioning under the sponsorship of the American Society for Testing Materials and according to the procedure of the American Standards Association. In accordance with the rules of the latter the membership of the Sectional Committee was, and still is, composed of representatives of different interests. Out of a total membership of twenty-eight, seven represent the producers of coal, eight the consumers, two the distributors and the remaining eleven the "general interests." The detailed work involved was accomplished by three "Technical Committees" and seven sub-committees. "Coal Classification," "Nomenclature," and "Marketing Practice" are the designations of the three technical committees and of the seven sub-committees that "on correlation of scientific classification with used classification of coal" is worthy of special mention in this paper as below.

The organization just outlined has been concerned with the classification of the coals of the North American continent, including Canadian coals of course. While the membership* of the American Committees was predominantly from the United States and they were primarily concerned with their own coal classification problems, the Canadian classification interests had a prominent part in the detailed committee work. To this end the "Associate Committee on Coal Classification and Analysis" of the National Research Council of Canada, was organized in 1928 since when it has been primarily concerned with the classification of Canadian coals in co-operation with the "American" Sectional Committee. The co-ordination of the coal classification activities of the Dominion Department of Mines, the Alberta Research Council, and other Canadian research organizations has been the function[13] of the "Associate Committee" of the National Research Council. The membership of this committee includes ample representation from these organizations and from Canadian coal producers and consulting analysts as well. Although the Canadian representatives have concurred in the findings of the Sectional Committee the Canadian "Associate Committee" as a whole has yet to sanction and adopt the A.S.T.M. specifications for the classification of Canadian coals.

### *Classification by Rank*

According to the A.S.T.M. classification, rank is based on the fixed carbon and calorific value calculated to the mineral-matter-free basis—the higher rank coals being classified on the dry basis and the lower rank coals according to B.t.u. per pound on the moist (as mined) basis. Agglomerating properties, that is, weakly caking properties, and slacking indices, the tendency for certain low rank high moisture coals to slack and crumble due to weathering, are used to differentiate between certain adjacent groups. The classification into four classes and thirteen groups is summarized for ready reference in Table II.

Table II

A.S.T.M. Classification by Rank—as per Designation D 388-36T

| Classes and Groups | Limits of Fixed Carbon (f.c.) and B.t.u. (Mineral-matter-free basis) and Requisite Physical Properties |
|---|---|
| I. Anthracite class | |
| 1. Meta-anthracite group | Dry f.c. 98 per cent or more |
| 2. Anthracite group | Dry f.c. 98 to 92 per cent |
| 3. Semi-anthracite group | Dry f.c. 92 to 86 per cent, non-agglomerating |
| II. Bituminous class | |
| 1. Low volatile group | Dry f.c. 86 to 78 per cent |
| 2. Medium volatile group | Dry f.c. 78 to 69 per cent |
| 3. High volatile A group | Dry f.c. less than 69 per cent and moist B.t.u. 14,000 or more |
| 4. High volatile B group | Moist B.t.u. 14,000 to 13,000 |
| 5. High volatile C group | Moist B.t.u. 13,000 to 11,000 either agglomerating or non-weathering |
| III. Sub-bituminous class | |
| 1. Sub-bituminous A group | Moist B.t.u. 13,000 to 11,000 both weathering and non-agglomerating |
| 2. Sub-bituminous B group | Moist B.t.u. 11,000 to 9,500 |
| 3. Sub-bituminous C group | Moist B.t.u. 9,500 to 8,300 |
| IV. Lignite class | |
| 1 Lignite group | Moist B.t.u. less than 8,300 (consolidated) |
| 2. Brown coal group | Moist B.t.u. less than 8,300 (unconsolidated) |

*Canadian representatives on the "American" Coal Classification Technical Committees and Subcommittees are:—Prof. E. Stansfield of the Alberta Research Council, Dr. B. R. MacKay of the Dominion Geological Survey, and R. E. Gilmore, the latter being the sole Canadian member on the A.S.T.M. Sectional Committee and its Executive Committee. F. E. Lathe represented the National Research Council at most of the meetings of the Technical Committees.

In interpreting the limits of fixed carbon and B.t.u. specified in this classification scheme, it must be borne in mind that these values are on the mineral-matter-free basis, that is, on the basis of "pure" carbonaceous coal matter free from both ash and the mineral matter. The ash content as determined in the laboratory is always less than the mineral matter originally in the coal due to decomposition of certain constituents, and in the ordinary proximate analysis the volatile matter percentage reported on the dry coal basis is high to the extent of the mineral matter to ash, decomposition loss. As a result of considerable experimental work it was concluded that for classification purposes a ratio of 1.1, that is, eleven parts of mineral matter to ten parts of ash represents the average relation of these criteria. Immediately below are the approximation formulae recommended for correcting proximate analysis from the values as determined to the mineral-matter-free basis, in which it will be noticed the sulphur as well as the ash content is taken into account.

Dry Mineral-matter-free Fixed Carbon

$$= \frac{\text{Fixed Carbon}}{100 - (\text{Moisture} + 1.1\ \text{Ash} + 0.1\ \text{Sulphur})} \times 100$$

Dry Mineral-matter-free Volatile Matter

$$= 100 - \text{Dry Mineral-matter-free fixed carbon}$$

Moist, Mineral-matter-free B.t.u.

$$= \frac{\text{B.t.u.}}{100 - (1.1\ \text{Ash} + 0.1\ \text{Sulphur})} \times 100$$

Proximate analyses with sulphur and calorific values, on the determined, and on the calculated mineral-matter-free bases, for a typical bituminous coal from Nova Scotia and for a typical sub-bituminous (domestic) coal from Alberta are as follows:—

Typical Bituminous Coal

| | As Determined (Moist) | As Determined Dry | With m.m.* (Dry) | Dry m.m.* Free |
|---|---|---|---|---|
| Moisture..............per cent | 2.8 | | | |
| Ash (or m.m.)*........per cent | 8.6 | 8.8 | 10.0 | |
| Volatile matter.........per cent | 33.5 | 34.5 | 33.3 | 37.0 |
| Fixed carbon..........per cent | 55.1 | 56.7 | 56.7 | 63.0 |
| Sulphur...............per cent | 2.7 | 2.8 | 2.8 | |
| Calorific value B.t.u. per pound. | 13,450 | 13,850 | 13,850 | 15,390 |

Typical Sub-bituminous Coal

| | As determined (Moist) | With m.m.* (Moist) | Moist m.m.* Free |
|---|---|---|---|
| Moisture...................per cent | 18.0 | 18.0 | 18.0 |
| Ash (or m.m.)*............per cent | 5.5 | 6.0 | |
| Volatile matter.............per cent | 31.2 | 30.7 | 33.2 |
| Fixed carbon...............per cent | 45.3 | 45.3 | 48.8 |
| Sulphur...................per cent | 0.4 | 0.4 | |
| Calorific value B.t.u. per pound..... | 10,030 | 10,030 | 10,670 |

*m.m. means mineral-matter.

Referring to the A.S.T.M. Classification, it is evident that the typical Nova Scotia bituminous coal belongs to the High Volatile Bituminous A Group and the typical Alberta "domestic" coal to the Sub-bituminous B Group.

*Specific Volatile Index (S.V.I.) Classification*

This is the designation of a classification[14] devised by technical officers of the Fuel Research Laboratories, primarily for use in the by-product coking industry. The "Specific Volatile Index" is in reality the heat value expressed in B.t.u. per one per cent volatile matter content of the coal as determined in the laboratory, and is expressed as follows:—

$$\frac{\text{Determined B.t.u. per lb.} - (14{,}500 \times \text{wt. of Fixed Carbon})}{\text{Per Cent Volatile Matter}}$$

The calorific value and other chemical criteria used in this formula are on the Parr[15] "unit coal" basis in which the analyses are corrected to the basis of coal substance free of ash and mineral matter. By this scheme coals, peat and wood, are divided into eleven classes or sections, as outlined in Table III. The nomenclature shown in brackets is that of Seyler[16] whose classification was advanced particularly for English coals.

Table III

S.V.I. Classification—"Unit Coal" Basis

| Section | Name of Class | S.V.I. Limits |
|---|---|---|
| A | Woods.................................... | under 50 |
| B | Peat...................................... | 50 to 82 |
| C | Brown lignites (lignitious)................ | 82 to 99 |
| D | Black lignites (ortho-lignitious)........... | 99 to 125 |
| E | Sub-bituminous (meta-lignitious)........... | 125 to 160 |
| F | Bituminous (para-bituminous)............... | 100 to 175 |
| G | Bituminous (ortho-bituminous).............. | 175 to 190 |
| H | Bituminous (meta-bituminous)............... | 190 to 210 |
| I | Semi- or super-bituminous.................. | 210 to 230 |
| J | Semi- or sub-anthracite.................... | 230 to 255 |
| K | Anthracites................................ | 255 to 300 |

Features of the S.V.I. Classification, part only of which is shown here, are that the different sections and corresponding classes can by means of a chart be delimited by rectangular spaces, and that for typical coals in certain sections, the approximate yields and quality of the gas, tar and coke products when coked in a by-product oven can be predicted. This is specially applicable to sections E to I inclusive, in which are to be found all the coking coals—those in sections A to D inclusive and in sections J and K being non-coking.

Classification of Canadian Coals

The application to Canadian coals of both the A.S.T.M. and the S.V.I. classification systems is shown in Table IV where the arrangement under provinces and districts is that at present in use by the Canadian Bureau of Statistics. This table, which deserves detailed study, illustrates the need of a revision of the classification now used by the Bureau of Statistics, and especially for Alberta coals. By the new A.S.T.M. classification, certain of the Alberta "sub-bituminous" coals become high volatile bituminous, either Group C or B, and most of the so-called "lignite" coals of this province become sub-bituminous and are distributed into Group A, B and C of this class. Likewise, certain of the higher rank Saskatchewan coals may be classed in the sub-bituminous C group. This general promotion in classification by rank is evident also for British Columbia coals. Coals in those districts designated by the Bureau of Statistics as bituminous, however, remain as such, but are subject to sub-division into low and medium volatile groups and into high volatile A, B and C groups. It is significant to note that whereas, as previously stated, the major portion of the coal mined is bituminous and that the largest portion of the country's coal resources belong to the sub-bituminous and lignite classes, anthracites occur to a small extent in Canada. These belong to the semi-anthracite group, e.g. some of those in the Cascade (Canmore) district and certain coals found in the Colchester area in Nova Scotia and in the Kathlyn area in British Columbia.

Other classification systems[17] have, from time to time, been advanced for classifying Canadian coals, but with the exception of certain government classifications

### Table IV

Classification of Canadian Coals, Showing "S.V.I." and "A.S.T.M." Class and Group Designations

Arranged according to the Districts at present adopted by the Dominion Bureau of Statistics

| Province, District and present (1) Bureau of Statistics Classification | Production (1) in 1935—tons | S.V.I. (2) Limits and Class Designation | A.S.T.M. (3) Classification Class and Group Designation |
|---|---|---|---|
| Nova Scotia—"Bituminous" | | | |
| Cape Breton District | 4,413,570 | 147–173 (Para-) and sub-bituminous | Bituminous—High volatile A and B |
| Inverness District | 116,978 | 115–142 Sub-bituminous and black lignite | Bituminous—High volatile C |
| Cumberland (Springhill) District | 702,496 | 152–172 (Para-) and sub-bituminous | Bituminous—High volatile A |
| Pictou (Westville and Stellarton) District | 589,031 | 154–181 (Ortho-para) and sub-bituminous | Bituminous—Medium and high volatile A |
| New Brunswick—"Bituminous" | | | |
| (Minto District) | 346,024 | 153–179 (Ortho- para-) and sub-bituminous | Bituminous—High volatile A and B |
| Ontario—"Lignite" | | | |
| (Onakawana District) | | 75–101 Brown lignite and peat | Lignite—(Brown coal) |
| Manitoba—"Lignite" | | | |
| (Turtle Mountain District) | 3,106 | | Lignitic |
| Saskatchewan—"Lignite" | | | |
| (Estevan District) | 921,785 | 86–112 Black and brown lignite | Sub-bituminous C and lignitic |
| Alberta—"Bituminous" | | | |
| Cascade District (Canmore) | 152,924 | 187–259 Anthracite, semi-anthracite, Semi- (meta- and ortho-) bituminous | Anthracite—Semi and Bituminous—Low volatile |
| Crowsnest District (Bellevue to Coleman) | 1,297,394 | 158–196 (Meta- ortho- para-) and sub-bituminous | Bituminous—Medium and high volatile A |
| Mountain Park District (Cadomin and Luscar) | 651,270 | 166–209 (Meta- ortho- and para-bituminous) | Bituminous—Low, medium and high volatile A |
| Nordegg District | 147,032 | 213–239 Semi-anthracite and semi-bituminous | Bituminous—Low volatile |
| Alberta—"Sub-bituminous" | | | |
| Coalspur District | 413,489 | 105–129 Sub-bituminous and black lignite | Bituminous—High volatile C |
| Pekisko District | 4,284 | 147–159 Sub-bituminous | Bituminous—High volatile B |
| Pincher District (Lundbreck) | 1,405 | 147–159 Sub-bituminous | Bituminous—High volatile B |
| Prairie Creek District (Hinton and Jasper) | 110,192 | 147–159 Sub-bituminous | Bituminous—High volatile B and C |
| Saunders District | 37,055 | 116–134 Sub-bituminous and black lignite | Bituminous—High volatile C |
| Alberta—"Lignite" | | | |
| Ardley District | 25,778 | 97–108 Black and brown lignite | Sub-bituminous—B |
| Big Valley District | 2,651 | 94–108 Black and brown lignite | Sub-bituminous—B |
| Brooks District | 8,043 | (107*) Black lignite | Sub-bituminous—B |
| Camrose District | 57,613 | (96*) Brown lignite | Sub-bituminous—C |
| Carbon District | 95,295 | 102–118 Black lignite | Sub-bituminous—B |
| Castor District | 34,823 | 90–100 Black and brown lignite | Sub-bituminous—C |
| Champion District | 20,841 | (113*) Black lignite | Sub-bituminous—A |
| Drumheller District | 1,261,447 | 99–114 Black lignite | Sub-bituminous—B |
| Edmonton District | 493,884 | 85–103 Black and brown lignite | Sub-bituminous—B and C |
| Gleichen District | 9,172 | (108*) Black lignite | Sub-bituminous—B |
| Halcourt District | 3,753 | 128–133 Sub-bituminous | Bituminous—High volstile C |
| Lethbridge D strict | 351,004 | 110–136 Sub-bituminous and black lignite | Bituminous—High volatile C |
| Magrath District | 1,282 | 140–146 Sub-bituminous | Bituminous—High volatile B |
| Milk River District | 4,492 | (115) and (131) Sub-bituminous and black lignite | Sub-bituminous—A and B |
| Pakowki District | 2,803 | (89*) Brown lignite | Sub-bituminous and lignite |
| Pembina District | 72,163 | 82–98 Brown lignite | Sub-bituminous—B and C |
| Redcliff District | 34,150 | (100*) Black lignite | Sub-bituminous—C |
| Sheerness District | 88,877 | 93–108 Black and brown lignite | Sub-bituminous—C |
| Taber District | 14,819 | 101–123 Black lignite | Sub-bituminous—A and B |
| Tofield District | 59,500 | 91–105 Black and brown lignite | Sub-bituminous—C |
| British Columbia—"Bituminous" | | | |
| Crowsnest Pass District | 457,149 | 160–206 (Meta-, ortho- and para-bituminous) | Bituminous—Low and medium volatile |
| Inland District (Coalmont) | 93,821 | 133–142 Sub-bituminous | Bituminous—High volatile B |
| Inland District (Nicola) | 28,691 | 138–160 Sub-bituminous | Bituminous—High volatile A, B and C |
| Inland District (Princeton) | 42,003 | 111–124 Black lignite | Sub-bituminous—B |
| Inland District (Telkwa) | | 166–178 (Ortho- and para-bituminous) | Bituminous—High volatile A |
| (Vancouver) Island District (Comox) | 704,729 (Comox and Nanaimo combined) | 154–171 (Para-) and sub-bituminous | Bituminous—High volatile A |
| (Vancouver) Island District (Nanaimo) | | 142–160 Sub-bituminous | Bituminous—High volatile A and B |
| Yukon—"Bituminous" | | | |
| (Tantalus) | 835 | 141–157 Sub-bituminous | Bituminous—High volatile A |
| North West Territories | | | |
| (Great Bear Lake) | | 74–103 Black and brown lignite and peat | Lignite—(Brown coal) |

(1) The district and colliery designations shown in brackets in the first column, are added for explanatory purposes, and the coal production figures shown in the second column are those reported by the Bureau of Statistics—the producing mines for each district being listed in the annual "Coal Statistics for Canada" report of the Bureau. (2) S.V.I.—means Specific Volatile Index; the class designations shown in parentheses are according to Seyler and the S.V.I. values in this column in brackets and marked with asterisks are for single samples only from the respective districts. (3) A.S.T.M.—means American Society for Testing Materials and the class and group arrangement shown is according to Designation D 388-34T, viz., "Tentative Specifications for Classification of Coals by Rank" The calculations necessary to convert analyses from the normal ash to the "Unit-Coal" and the mineral-matter-free basis required respectively in the S.V.I. and A.S.T.M. classifications were made by G. P. Connell and the analyses used in the preparation of this Table were selected by J. H. H. Nicolls from those on record at the Fuel Research Laboratories

regulating the importation (and exportation) of coal, no complete system has as yet been adopted. The government classifications just referred to, which are in reality merely regulations, pertain to the importation of duty-free anthracite, including semi-anthracite, as distinct from dutiable bituminous coals coming under the Customs item "Coal n.o.p.," and to the exportation and importation of lignite and lignitic coal, duty-free under a reciprocity agreement between Canada and the United States. A review of these regulations is available in published[18] form, hence they need not be further discussed here.

*Type, Rank, and Grade Classifications*

In both the A.S.T.M. and S.V.I. classifications, coals are arranged according to rank, that is, according to the progressive alternation of coal constituents from peat and lignite to anthracite. The arrangement according to rank, on the mineral-matter-free basis, may be described as a classification devised by the chemist primarily for scientific purposes. The geologist is concerned with the nature of the material from which coal was originally formed, and in collaboration with the microscopist is responsible for devising "type" classification. Designations such as common or bright banded coals, splint coals, non-banded cannel coals, and algal or boghead coals, represent different types or varieties, but this subject need not be discussed further here except to say that as a result of several years study the A.S.T.M. Sectional Committee expect soon to agree on a type classification that will serve for both academic and practical purposes. A third classification is that "by grade," which is determined principally by the amount and nature of the ash, and by the sulphur content of the coal. Improvement in the grade of a coal over that as mined, may be, and is usually made in its preparation for the market. These three classifications, viz., by type, rank and grade, to which may be added a "use" classification as outlined below, are designed for use by fuel technologists, and it is hoped will be found to be of great practical value in the industrial and commercial use of coal.

*Symbols for Grade and Rank Classification*

In the specifications for classification by grade as per A.S.T.M. Designation D 389-34T, symbols are shown for grading coal according to ash, softening temperature of ash, and sulphur, the analyses being expressed on the basis of coal as sampled. A coal designated as 132–A8–F24–S1.6 indicates a heating value of approximately 13,200 B.t.u., an ash content of 6.1 to 8.0 per cent, a F.P.A. of 2,400 to 2,590 deg. F. and a sulphur content of 1.4 to 1.6 per cent. When it is desired to express both the grade and rank classification of a coal in symbol form it is suggested that the symbols indicating rank be shown in parentheses prefacing those for grade, as illustrated in the following example

(62-146) 132-A8-F24-S 1.6

The numbers in parentheses are the fixed carbon to the nearest whole per cent and the B.t.u. to the nearest hundred, on the dry mineral-matter-free basis and indicate the rank of the coal—in this case High Volatile A Bituminous.

*Use Classification*

As a conclusion of this outline of classification activities special mention should be made of the work of the sub-committee of the A.S.T.M. Sectional Committee on the Classification of Coal known as Sub-committee VI—on the Correlation of Scientific and Use Classification. The second named author of this paper, in collaboration with other technical officers of the Fuel Research Laboratories has been intimately associated with the work of this sub-committee of which he is a member. Under the title "Factors Recommended for Consideration in the Selection of Coal" a comprehensive report[19] has recently been published. This report contains seven charts illustrating the relative importance of various physical and chemical factors as applied to the following uses, viz., stationary steam generation—hand fired, stoker fired, and pulverized fuel fired, coke and gas making, ceramic products, domestic, bunker and cargo, and miscellaneous. The data shown in this report are of particular value to both the producers and consumers of coal, especially the latter, in that they designate the factors which are to be stressed in the selection of a coal for a given use. Examples showing the factors for a single variation of three different uses, viz., for steam generation (underfeed stoker), high temperature (domestic) coke making, and ceramic (terra cotta) manufacture are illustrated in Table V. The examples shown represent only one each of fifty-four, fifteen, and twenty-one different variations respectively of the three uses just specified.

TABLE V

Physical and Chemical Factors in the Selection of Coal showing their relative importance for three uses, as examples. (* means of ordinary importance, ** more than ordinary importance, *** very essential, dash means not important and blank indicates future development.)

| Factors in coal selection | Steam generation-underfeed stoker, excessive load | Domestic coke making in high temperature by-product oven | Ceramic-terra cotta manufacture in induced draft, muffle kiln |

## COAL PREPARATION AND STORAGE INVESTIGATIONS

The preparation of coal is conducted mostly at the colliery, and involves screening, sizing and beneficiation by either wet or dry cleaning processes. With the exception of washing operations at Sydney, N.S. for preparing coal for the manufacture of metallurgical coke special preparation of coal has received but scant attention in Canada until quite recently. Coal was generally shipped or disposed of as it was produced at the mine—the only cleaning resorted to being that by the use of the picking belt. Today, however, the demand is both for a clean coal and for special sizes to serve the particular purpose for which it is intended, and this has compelled colliery operators to clean and size their coal not only to meet demands for a sized product for steam generation, by-product oven and other uses but also to insure good storage properties. The total and percentages of run-of-mine, screened, and slack grades representing the shipments from Canadian mines, together with a list and type of coal washeries operated in Canada is given in a recent publication[20] by the first named author of this paper. Of a total of 12½ million tons shipped in 1934 from Canadian mines, 29 per cent was run-of-mine, 38 per cent designated as "screened" and the remaining 33 per cent was slack coal.

### *Phalen Seam Survey*

An investigation under this designation was conducted during the five-year period of 1928 to 1933—and concerned a general study of chemical and microscopical characteristics of this extensive and most important coal seam in the Sydney area in Nova Scotia. In addition to the (then) Division of Fuels and Fuel Testing, the Geological Survey and the Dominion Coal Company co-operated in this investigation, in which twenty series of columnar and sectional samples from as many different locations in the seam were collected and examined. Among the results of the investigation, certain phases of which have been published,[21,22] may be mentioned the following: The microscopic study by means of thin sections showed the relative proportions of bright and dull coal, and fusain, and indicated the nature of the coal as originally deposited in the seam. The proportions of fusain (also known as mineral charcoal) and of the sulphur content, and its forms, in the columnar samples from the different locations gave valuable information in respect to variation of type and grade of the coal in the seam as the workings progressed seaward. And the analyses of the high ash content sections near the floor and roof and also of the partings, indicated to what extent the grade of the run-of-mine coal could be improved by selective mining.

### *Physical and Chemical Survey of Coal from Canadian Collieries*

This project, begun in 1932, is a comprehensive investigation designed to include all Canadian collieries working from east to west. To date the survey has covered all the collieries in the Sydney and Springhill areas, Nova Scotia, and two collieries in the Minto area, N.B. From each colliery five to ten tons of coal representing the run-of-mine coal produced, are collected, from which after screening over a four-inch (round hole) screen a ton lot, or more, of the minus-four-inch coal is shipped in boxes to the Fuel Research Laboratories. Here by means of a screen analysis it is separated into its component sizes on which physical and chemical tests are made. The physical tests conducted, in addition to the screen analyses on standard screens, comprise bulk density, specific gravity and weight per cubic foot friability and size stability, and grindability. The chemical tests made include proximate and ultimate analyses, ash fusion and composition of ash, forms of sulphur, and the distribution of fusain. Float and sink tests according to standard small scale laboratory procedure are also made from which the amenability of the coal to commercial cleaning is predicted. Certain of these tests are also made on representative samples of the plus-four-inch lumps, so that the results can be reported on the run-of-mine basis as well as on the minus-four-inch product.

The purpose of this investigation is primarily to afford fundamental information on the characteristics of different screened sizes as produced at the mine and as a result of the study of the physical and chemical properties of the coal, to predict for what uses it is most suited, either in raw state or after special preparation by sizing, washing, etc.

### *Large Scale Storage Tests*

Two series of storage tests[21] on "Dominion" Nova Scotia coal, conducted by officers of the Fuel Research Laboratories may be reviewed here. These were on "screened" run-of-mine and slack coal stock piles at Windmill Point, Montreal, during the 1928 to 1929 autumn and winter seasons, and on specially washed and sized coal at the LaSalle coke plant of the Montreal Coke and Manufacturing Company in 1931 and 1932. Storage for a period of seven months, of the screened run-of-mine coal piled fourteen feet high and provided with ventilation holes eighteen inches apart, showed practically no alteration in quality in respect to calorific value. The slack coal, however, piled to the same height, but not so ventilated did show an average loss in heating value ranging from 300 to 450 B.t.u. per pound, with no appreciable increase in ash content but with a noticeable increase in moisture content. The increase in moisture was accounted for by absorption from the air by the fines in the slack; and the decrease in calorific value was evidently due to oxidation which in turn is influenced by moisture in the finely divided coal.

The second series of storage tests served to demonstrate how the smaller sizes of coal from the Princess and Waterford mines in the Sydney area could be stored in piles thirty-five to forty feet high as required at the LaSalle coke plant. These results were effected by first washing the coal and then sizing within certain limits. The average screen analysis using square hole screens showed less than 5 per cent on one inch, about 57 per cent of one-half to one inch lumps, 35 per cent of the one-eighth to one-half inch sizes and less than 3 per cent through the one-eighth inch screen. By means of thermocouples placed at different horizontal locations and at different levels in piles varying in size from 4,000 to 35,000 tons, the absence of any appreciable heating was indicated over a period of nearly a year from the time the coal was put into storage. This was a remarkably successful result in view of the failure of unsized freshly mined coal previously tested to be stored, without heating, under the conditions prevailing. Washing effected reductions in ash and sulphur contents to less than 3 and 1.5 per cent respectively, so that the special preparation served for complying with the specifications required not only for ash and sulphur contents but also with the rather stringent storage requirements.

## COAL COMBUSTION INVESTIGATIONS

Since 1925 coal combustion investigations have comprised mainly tests on coals and coke in lump form as domestic (household) fuels and on coals as pulverized fuel for steam raising purposes. Prior to that date tests[23,24] had been made on a large number of Canadian coals in experimental gas producer and boiler installations. These were preceded by a comprehensive investigation[25] of the coals of Canada, with reference to their economic value, conducted at McGill University under the auspices of the Dominion Government. Only those combustion investigations made since 1925 and particularly since 1929 will, however, be reviewed here.

### Tests in Domestic Furnace

Two series of burning tests have been conducted in an experimental domestic hot water boiler, which may be described as the old series made in 1925 and the new series inaugurated in 1935. The new series is still in progress. The boiler used, or rather the furnace as known by the public, is an ordinary round hot water boiler of a size suitable for heating a house of eight or nine rooms. Accessory equipment used in making the tests included a radiation tank and cooling water system, scales for weighing fuel and refuse, thermometers, pyrometers, draft gauges, gas sampling and analysis apparatus and water meter calibration apparatus. In both series of tests the objective was to determine the relative value of different fuels, one with another and with a standard coal.

Pennsylvania anthracite was adopted as the standard fuel. In the old 1925 series the anthracite used averaged 14.5 per cent ash with a calorific value of 12,090 B.t.u. per pound as fired whereas in the new 1935 series the average ash content is 9.6 per cent with a corresponding calorific value of 13,190. This improvement in quality, as demonstrated in an anthracite and coke analysis survey[26] made in the 1932-33 winter season, was a factor prompting the new series of tests.

In both series a single test was conducted weekly on an individual fuel, but there were considerable differences in the method of operation, rate of combustion, etc. The old series comprised tests requiring day and night shifts, and each test was made at a constant rate of firing during the week. The feature of the tests in the new series is a changeable rate of combustion in which the coal is fired at low, medium and high rates combustion similar to actual household firing on a typical mid-winter day. During the night hours the furnace operation is automatic with test data obtainable by means of recording instruments. The new method of testing is conducted in two parts, namely, four (twenty-four hour) days to serve as a general burning observation test, followed immediately by a twenty-four hour thermal efficiency test. Even on the same standard coal, the relative results obtained by the two methods of testing would be different, but it is considered that the results of the new series of tests are more acceptable than those of the old series in that they can be interpreted more readily in terms of actual household burning conditions.

The final result sought, in a single test, is the average amount of fuel fired per therm (that is, 100,000 B.t.u.) delivered to the cooling water. From this result the tonnage of each fuel, equivalent to ten tons of American anthracite is calculated. In Table VI are listed the fuels tested in the two series of tests together with their gross calorific values as determined by laboratory analysis, and their relative actual heating values in comparison with the anthracite standard. It will be noted that in addition to anthracites, cokes and peat, the first series contained several non-coking Alberta sub-bituminous domestic coals and that the second series included several coking bituminous coals mostly from the Maritime provinces. For these coals the kind of coal and the area from which they originated are given rather than their trade and colliery names. Detailed results of the old 1925 series of tests have been published[27] but the results of the new series have been supplied from time to time to the interested parties only, subject to eventual publication to the general public when the series is completed.

The overall thermal efficiencies, as expected, varied indirectly with the volatile matter content of the different fuels and hence directly with their fixed carbon contents. The thermal efficiency in the new series averaged 66 per cent for five individual tests on the standard Pennsylvania anthracite with a volatile matter content of 5 per cent. For three different samples of by-product oven coke with less than 2 per cent volatile matter, the thermal efficiencies ranged from 72 to 76 per cent, while the average efficiency

| Peat—briquettes | 5.5 | 57.1 | 8,145 | 19.6 |

of two samples of "semi-bituminous" coals with 16 and 19 per cent volatile matter was 58 per cent. The corresponding overall thermal efficiencies for the high volatile bituminous and sub-bituminous coals ranged from 50 to 60 per cent with an average of 55 per cent, which figure also represents the efficiency obtained with peat, both air-dried and machine made partially dried briquettes.

For the lower rank bituminous and sub-bituminous coals, tested in the domestic furnace, the overall thermal efficiencies varied as much as 5 per cent from the average, for approximately the same rank classification. These variations are accounted for by varying ash contents and varying physical properties such as average size of lump, and friability or tendency to crumble during handling and burning. By means of a curve obtained by plotting thermal efficiencies against fixed carbon, preferably on the dry mineral-matter-free basis, for a series of fuels varying in rank from anthracite to peat, it is possible and often practical to predict the approximate efficiency with which a given coal or coke of which the proximate analysis and calorific value is known, can be burned. Knowing the gross calorific value, and assuming a thermal efficiency, the amount of fuel required to deliver a therm to the cooling water and the consequent tonnage equivalent to the standard (anthracite) fuel can thus be calculated. However, for the bituminous and lower rank coals, an actual burning test is necessary for determining overall thermal efficiencies which vary plus or minus 5 per cent from the known average, since the variations in physical properties mentioned above, it has been found, affect the burning efficiency to that extent.

### Blower and Underfeed Stoker Tests

The hand fired tests in the domestic hot water boiler, outlined above, have been supplemented by tests in the same experimental furnace equipped first with automatic blower and then with a domestic type automatic underfeed stoker. The coals used in the blower fuel tests comprised the buckwheat sizes of anthracite marketed in Ottawa as "blower" coals—including Welsh, Scotch, Indo-China, and Pennsylvania anthracites—and two different lots of by-product oven coke. These buckwheat anthracites and pea size cokes were burned alone and in admixture with specially prepared bituminous slack coal from the Sydney area, Nova Scotia. The overall thermal efficiencies obtained averaged slightly over 68 per cent for Welsh and Pennsylvania buckwheats and from 70 to 72 per cent for the Scotch anthracite and the pea coke, all of which were judged satisfactory blower fuels for household heating purposes.

The corresponding efficiency for the screened bituminous slack was 57½ per cent. It was confirmed that such specially prepared bituminous slack coal can be used alone in blower equipped domestic furnaces, but in comparison with anthracite buckwheat it has certain disadvantages including dirty handling properties, smokiness and soot requiring the furnace to be cleaned at short intervals and caking trouble requiring constant slicing with poker—in addition to a comparative low overall thermal efficiency. Mixtures of ½, ⅓, and ¼ of the bituminous slack with Welsh buckwheat showed progressively better results as the proportion of the bituminous coal to anthracite was reduced. The use of ⅓ bituminous slack gave better results than the ½ proportion but not as good as the ¼ mixture. The general conclusion drawn is that whereas by householders accustomed to burning Welsh or other anthracite buckwheats alone the admixture of bituminous coal may not be attractive, the use of mixtures of bituminous slack with buckwheat anthracite should be considered favourably as blower fuel in localities where bituminous lump coal is now solely and satisfactorily employed as a domestic fuel.

Only a few underfeed stoker fired tests have been made using a commercial grade of bituminous slack coal from the Sydney area, Nova Scotia, and selected slack coals from two mines operating on different seams in that area. Despite soot deposit trouble requiring frequent cleaning, smoke conditions were improved, and the overall thermal efficiencies were in the range stated above for mixtures of bituminous slack with buckwheat size anthracites.

### Pulverized Fuel Tests

Pulverized fuel tests were made during 1930, 1931 and 1932 on twelve British Columbia coals, ten Alberta coals, and on four different lots of Onakawana lignite from Northern Ontario. The testing equipment was a Babcock and Wilcox marine type water tube boiler mounted over a solid refractory wall furnace haivng a hollow air-cooled floor, together with an Aero-size B high speed paddle type mill pulverizer rated at 1,000 lb. per hour, which prepares and mixes the fuel with the primary air and transmits the air-heated coal to the furnace. Three complete tests were made on each of the coals tested, one test at high rate, one at medium rate and one at low rate of feed, at approximately 20, 40 and 60 per cent of the rated capacity of the pulverizer. The objective was to obtain comparative results, one with another and with a standard operating coal selected on account of its known characteristics and its extensive industrial use as a pulverized fuel.

Detailed reports on each coal were supplied to the interested parties, including the British Columbia government for whom the tests on the coals from that province were made. A summary report on the thirteen coals from B.C. was published[28] in mimeographed form but the detailed results on the Alberta coals and on the Ontario lignite have yet to be published.

The results of these tests demonstrated that Canadian coals of varying rank and grade, with consequent wide variations in moisture, volatile matter and ash contents can be considered as suitable for use in the pulverized state. Although the thermal efficiencies of the experimental boiler used ranged roughly from 61 to 66 per cent, this being low in comparison with the better modern commercial boilers, the results do show the comparative value of the coals tested. In Table VII are shown certain selected and salient items for the different coals arranged generally in order of their rank from high to low, as indicated by their increasing moisture content and decreasing calorific values.

## COAL CARBONIZATION INVESTIGATIONS

The term "carbonization," when applied to bituminous coals in general, means the heating of the coal with exclusion of air, to distil off the liquid (tar oils and ammoniacal) products, to leave a coherent coke residue appreciably higher in carbon content than in the raw coal started with. The residue from certain non-coking varieties of the bituminous class, and from non-coking sub-bituminous, lignite, and anthracite coals is not a coke properly speaking, but is to be described as a char or carbonized residue. Carbonization investigations comprise the treatment of coals at high, medium, and low temperatures. In Canada the manufacture of coke and gas in by-product coke ovens and city gas plant is effected by high temperature carbonization, where mid-temperature and low temperature carbonization has not developed beyond the experimental stage.

### Coking Tests in By-Product Coke Ovens

A comprehensive programme of coking tests has been conducted on Canadian bituminous coals for the purpose of determining to what extent native coals may be employed in place of imported coals formerly used for the manufacture of domestic coke and city gas. These tests

Table VII

Summary of Steaming Tests on Various Canadian Bituminous, Sub-bituminous and Lignite Coals in Experimental Pulverized Fuel Fired Boiler at the Fuel Research Laboratories

| Designation of coal, name, province and rank | Rate of feed | Moisture in fuel as fired per cent | Ash content of fuel as fired per cent | Average volatile matter content on the dry coal basis per cent | Calorific value of fuel as fired (B.t.u.—gross) | Pulverized fuel passing through 200 mesh per cent | Water evaporated per lb. of fuel fired lb. | Percentage of rated boiler capacity developed |
|---|---|---|---|---|---|---|---|---|
| Standard (high volatile bituminous) operat- | Low | 3.7 | 9.5 | | 13,240 | 67.9 | 9.17 | 77 |
| ing coal | Medium | 3.3 | 8.7 | (32.5) | 13,470 | 60.3 | 8.88 | 149 |
| | High | 1.8 | 8.3 | | 13,700 | 69.5 | 8.69 | 223 |
| Low volatile bituminous | | | | | | | | |
| Canmore coal, Alta | Medium | 1.4 | 10.9 | (14.5) | 13,580 | 85.3 | 9.53 | 162 |
| Brazeau coal, Alta | Medium | 1.9 | 12.7 | (15.5) | 13,370 | 79.8 | 9.52 | 163 |
| Medium volatile bituminous | | | | | | | | |
| Luscar coal, Alta | Medium | 2.0 | 16.0 | (20.0) | 12,780 | 82.1 | 8.69 | 148 |
| Greenhill coal, Alta | Medium | 1.4 | 11.8 | (22.5) | 13,330 | 87.0 | 9.45 | 162 |
| McGillivray Creek, Alta | Medium | 2.1 | 13.4 | (24.0) | 12,810 | 78.3 | 8.93 | 152 |
| Denison coal, Alta | Medium | 1.9 | 14.4 | (24.5) | 12,660 | 79.4 | 8.68 | 148 |
| Corbin washed steam coal, B.C. | Medium | 3.8 | 13.1 | (23.5) | 12,610 | 79.6 | 8.74 | 149 |
| | High | 3.9 | 12.7 | | 12,540 | 80.9 | 8.54 | 219 |
| Cadomin coal, Alta | Medium | 2.0 | 12.7 | (25.5) | 13,110 | 87.6 | 9.58 | 163 |
| Mt. Park (M) coal, Alta | Medium | 3.0 | 12.3 | (28.0) | 13,080 | 81.0 | 9.50 | 162 |
| Michel coal, B.C. | Medium | 2.0 | 5.9 | (28.0) | 14,280 | 79.2 | 9.63 | 165 |
| | High | 1.7 | 7.7 | | 13,950 | 78.6 | 9.46 | 222 |
| High volatile bituminous | | | | | | | | |
| Hillcrest coal, Alta | Medium | 1.4 | 17.2 | (28.0) | 12,330 | 77.8 | 8.71 | 150 |
| Telkwa coal, B.C. | Medium | 5.0 | 12.8 | (32.0) | 12,470 | 71.6 | 8.48 | 145 |
| | High | 3.2 | 12.8 | | 12,820 | 66.1 | 8.49 | 216 |
| Comox coal, B.C. | Medium | 3.9 | 14.3 | (31.5) | 12,290 | 63.9 | 8.22 | 140 |

have been made both at different by-product oven coke plants and at the Fuel Research Laboratories—where facilities are available for conducting tests on small, intermediate, and large scales—and may be listed as follows:—

(1) 1923—Coking tests on four coals from the Maritime Provinces, three from Nova Scotia and one from New Brunswick, in the ovens of the Hamilton By-Product Coke Ovens, Limited, Hamilton, Ontario.

(2) 1930 and 1931—Coking tests at Ottawa on eight coals from British Columbia, on six coals from Alberta, and on a specially prepared Nova Scotia coal from the Sydney area—the latter when blended with certain imported coals in comparison with the standard mix of American coals.

(3) 1930 (December)—Coking tests at Winnipeg on Michel, B.C. coal in comparison with Allison, Pennsylvania, coal. These tests were made in the ovens of the Winnipeg Electric Co., and were preceded in 1927 by special small-scale box coking tests on several coals from western Canada.

(4) 1931 (September and November)—Coking tests at Montreal on washed Princess coal, a specially prepared bituminous coal from the Sydney area, Nova Scotia, in admixture with certain American coals. These tests were made in the ovens of the Montreal Coke and Manufacturing Company.

(5) 1933 (April)—Coking tests at Vancouver on selected coals fromBritish Columbia and Alberta in the (new) ovens of the British Columbia Power and Gas Company.

(6) 1933 (May)—Coking tests at Brandon on Michel, B.C. coal at the gas plant of the Manitoba Power Commission.

(7) 1936 (October)—Coking tests at Hamilton on a mixture of Princess and Waterford coals from the Sydney area, N.S., in the ovens of the Hamilton By-Product Coke Ovens, Ltd.

(8) 1933, 1934, and 1936—Coking tests at Ottawa in two different 500-lb. capacity ovens, for studying the characteristics of coals when blended with one another and with inert coke breeze, and for testing the amenability of Canadian coals to mid-temperature carbonization.

Summaries of the results of all these coking tests have been published,[29, 31, 32] hence only the salient points of this series of investigations will be reviewed here.

For the manufacture of high quality domestic by-product coke, a coal must comply with quite rigid specifications if it is to be coked alone. Such coals, native to Canada, are somewhat limited in number, for which reason the usual practice is to use a two, or three, or even a four coal blend. In plants where gas is considered the main product and coke secondary, a bituminous coal with 33 to 35 per cent volatile matter may be used. But in plants where either domestic or metallurgical coke is the main product and gas secondary, a coal or coal blend with about 30 per cent volatile matter is required. The following table gives the composition of typical one, two, three, and four coal blends.

| Kind or rank of coal | High volatile bituminous | Medium volatile bituminous | Low volatile (semi) bituminous |
|---|---|---|---|
| Volatile matter content. per cent | 33 to 35 | 29 to 31 | 16 to 18 |
| One coal.............. per cent | | 100 | |
| Two coal blend........ per cent | 55 | | 45 |
| Three coal blend....... per cent | 56 | 28 | 16 |
| | or 35 | 50 | 15 |
| | or 40 | 40 | 20 |
| Four coal blend........ per cent | 40 of (*a*) | 25 | 20 |
| | 15 of (*b*) | | |

(*a*) and (*b*) designate two different high volatile bituminous coals.

The usual practice is to crush each of the coals before blending, and typical screen analyses of the coal mix charged to the ovens show from 40 to 80 per cent through a ⅛ in. round hole screen. This practice, adopted generally for by-product oven coking, is different from that employed in vertical gas retorts when run-of-mine or specially prepared lump coal is charged without crushing.

A prerequisite characteristic of prime importance when a bituminous coal is coked alone or blended with one or more coals is that the coal or coal blend will have the desired contracting properties in the latter stages of coke formation, suitable for use in the particular type of by-product oven in which it is used. The structure and other physical characteristics of the coke produced are also very significant, with the chemical properties of secondary importance.

The structure specifications of a high grade by-product oven coke, for use as a domestic household fuel, are different from those for a metallurgical or foundry coke mainly in respect to shape and strength. A properly-sized metallurgical coke, however, makes a good domestic coke. Significant physical properties of run-of-oven coke influencing general structure, include appearance, size and shape, cross and longitudinal fracture, cell structure, sponginess, hardness, and ring when struck. A good domestic coke as marketed, should be square or rectangular in shape, and when the large run-of-oven coke is crushed and screened into the different egg, stove, nut, and smaller sizes, the structure should be such that a maximum proportion of the higher price larger sizes are produced, with a minimum amount of low price smaller sizes and breeze.

The ash content, and in particular the fusion point of ash, are important, but in Canada the requirements, or rather the allowable specifications in this respect, for a domestic coke may vary considerably according to the part of the country in which the coke is marketed. The reason for this is that the properties of the fuel accepted as standard in a given locality regulate the specification requirements of domestic coke as a substitute fuel in that locality. For example, in the localities in the extreme eastern and western parts of the country, in the coal mining areas, bituminous lump coal is the standard domestic fuel. Such bituminous coal has varying coking or caking properties when burned and is smoky to varying degrees. A characteristic of the coals mined in the Maritime provinces is their relatively low fusion point of ash, and householders using these coals as domestic fuel have become accustomed to, and have learned how to burn them without experiencing troublesome clinkering. Hence, there, a domestic coke with ash fusion temperatures in the lower range, from 2,300 deg. F. to as low as 2,000 deg. F. will likely be found acceptable as a substitute fuel, providing the ash content of the coke is low, say not over seven to nine per cent. With the exception of certain coals in the Crow's Nest Pass area, the coals of British Columbia and especially those from Vancouver Island have medium ash fusion temperatures, from 2,300 deg. F. to 2,400 deg. F., with relatively high ash contents. These coals have free burning characteristics, and are not strongly caking. For these reasons a substitute coke fuel, in Vancouver and neighbourhood, need comply with less dense structure specifications than required elsewhere for by-product coke. The ash content also may range as high as 15 to 18 per cent, and still be quite satisfactory for household heating purposes.

The requirements for coke in Winnipeg and other large centres of Manitoba, in respect to structure, ash content, fusion point of ash, etc., are intermediate between those for coke on the Pacific coast and in Central Canada The extensive use of Alberta "domestic" grades of sub-bituminous and lignite coals in that district has accustomed householders to a free-burning fuel, for which oversize furnaces are in extensive use. For these users, a free-burning coke with medium to low ash fusion temperature would be acceptable. However, for those who require a substitute for imported anthracite, the best grade of by-product coke in respect to structure, ash fusion and general burning qualities is required.

These are also the requirements of a by-product coke in Central Canada, from Montreal to the Great Lakes. In this central portion coke has to compete with Pennsylvania, Welsh, Scotch, and European anthracites. Hence, a coke fuel must be dense to keep its bulk density in terms of cu. ft. per ton as low as possible, and be of the proper cell structure and density to permit the desired rate of burning. It must be low in ash content and high in ash fusion temperature. An ash fusion temperature of 2,700 deg. F., or higher, signifies a high grade coke fuel, but it has been ascertained by burning tests that for a coke with seven to nine per cent of ash, an ash fusion temperature as low as 2,500 deg. F. will insure comparative freedom from clinker trouble.

*General Coking Test Conclusions*

The tests in 1931 on specially prepared coal from the Sydney area showed that as high as 35 per cent of the specially washed and sized Nova Scotia coal could be used in the coal blend without reducing the ash fusion temperature of the coke seriously below 2,500 deg. F., and that the coke produced was equal in all respects to that from the blend of one hundred per cent imported coals formerly used. As a result of the test in 1936 at Hamilton it was found that selected unwashed run-of-mine "Sydney area" coal could be blended in proportion up to 35 per cent to give a satisfactory by-product, providing the medium and low volatile bituminous coals used in the blend had certain stipulated high ash fusion temperatures. The tests in 1930 at Winnipeg demonstrated that a selected coal from the Crow's Nest area in British Columbia could be satisfactorily employed in place of the imported coal formerly used. Likewise the tests at Brandon in 1933 showed that a Crow's Nest Pass (B.C.) coal could be satisfactorily substituted for the formerly used Pennsylvania coal for the manufacture of city gas and "gas" coke. The tests in Vancouver in 1933 were comprehensive and demonstrated what inland British Columbia and Alberta coals could be employed in admixture with Island coal to obtain different grades of coke in respect to structure, ash content, etc., satisfactory for the Vancouver market, and still give the desired yield and quality of city gas.

Prior to about 1923 the only public utility plants using Canadian coals for the manufacture of city gas and domestic coke were those at Halifax and Vancouver. These were primarily city gas plants with coke as a by-product. The status of the Halifax plant, which has Glover-West retorts, has not changed materially, its present coal consumption being about 12,000 tons annually; in Vancouver, the old gas retorts have been replaced by new (vertical) by-product ovens, with an annual coal consumption of over 56,000 tons. In the Woodhall-Duckham retorts at Quebec, Nova Scotia coal is used exclusively to the extent of nearly 20,000 tons. 185,000 tons is the approximate annual consumption of Canadian coal at the LaSalle plant, Montreal, representing approximately one-third of the total coal used in the Koppers (Becker) horizontal by-product ovens there. The amount of coal coked annually in the Koppers by-product ovens at Winnipeg is over 50,000 tons, where Canadian (B.C. Crow's Nest) coal has recently been used exclusively. Hence, the economic significance to date of the trend towards a greater use of Candian coal for the manufacture of domestic coke and gas, in which the coking tests referred to above have played an important part, is represented by a total increased annual consumption of nearly 300,000 tons.

Coking plants, up to the present, not using Canadian coal are the city gas (and coke) plants at Ottawa and Toronto, the coking plant of the Algoma Steel Corporation, at Sault Ste. Marie and the two large by-product coke plants at Hamilton, viz., those of the Hamilton By-Product Coke Ovens, Ltd., and the Steel Company of Canada. As indicated above, large scale tests have, however, been made at both Ottawa and Hamilton, and it is hoped that Canadian coal can be introduced in plants in these centres as well as in Toronto in the not too distant future. The 300,000 tons annual consumption of Canadian coal for domestic coke mentioned above is, of course, exclusive of slightly under 500,000 tons of Nova Scotia coal used annually in the manufacture of metallurgical coke in the Koppers ovens of the Dominion Steel and Coal Corporation at Sydney, and of nearly 150,000 tons of British Columbia coal used in bee-hive ovens in the Crow's Nest Pass area for the production of metallurgical coke.

The commercial plant scale tests at Montreal and Winnipeg confirmed the results obtained in the experimental oven of two-ton capacity at the Fuel Research Laboratories at Ottawa. Supplementary information is obtained at the Ottawa laboratories as to the comparative yields of gas, tar oil, and other products, by testing individual coals, or coal mixtures, on a small 20-gram scale by what is known as the tube test, which is in reality a high temperature carbonization assay. By means of this test, together with a laboratory swelling index test,[33] the carbonization engineers are able to predict the general coking characteristics, the yield, and general physical properties of the coke, the yields of light and heavy tar oils, and the yield and thermal value of the gas, that may be obtained when a coal or coal blend is coked in a commercial by-product oven. Ability to make such predictions, however, it should be mentioned, has resulted from a comprehensive study of the results obtained in the experimental and commercial ovens on a large number of coals, and depends on the accumulated knowledge of the engineers making the small scale laboratory tests.

### Special Blending and Mid-Temperature Carbonization Tests

The coking tests listed under (8) above were carried out for the purpose of ascertaining the coking properties of coal on a smaller scale than that allowable in the large experimental oven at Ottawa and in commercial ovens. Two ovens each having a capacity of approximately 500 lb. of coal were built and experimental tests were made in them, Two ovens having a capacity of approximately 500 lb. of coal were built and experimental tests were made in them, these ovens being known as the high temperature 16 in. wide oven and the other the mid-temperature 12 in. oven. The feature of these ovens is that sufficient coke is produced from individual 500 lb. coal charges for examination as to structure and other physical properties and for chemical properties as well, the coke obtained being similar in quality to that produced in commercial ovens.

Tests in the 16 in. high temperature oven operated at an average flue temperature of about 2,200 deg. F. are for the purpose of studying the coking characteristics of coals, before and after washing, when blended with one another and with inert material. Coals from western Canada, not previously tested in the large ovens, have been tested in this oven and the results show that a large proportion, when either washed or properly prepared, or blended with other suitable coals, are suitable for the manufacture of city gas of the required quality and of coke entirely satisfactory for the domestic market.

Tests in the 12-in. mid-temperature oven operated at an average flue temperature of 1,400 deg. F. are carried out for studying the effect of the blending of inert material such as coke breeze, anthracite fines, fusain, etc. with Canadian and other coals. The results of the tests carried out in this oven have indicated how a particular coal from New Brunswick, previously considered unsuitable for carbonization on account of its high ash and sulphur contents, can be first washed and then blended with coke breeze from a former test on the same coal, to produce a high quality coke, quite different and equal to (if not better than) the better grades of high temperature coke, in respect to physical properties. This has proved to be one of the most important results of these tests. Some of the principal features of these improved qualities of the coke are the remarkable uniformity of cell structure, the absence of minor fissuring common to high temperature coke, and the high apparent specific gravity.

### Low Temperature Carbonization

By low temperature carbonization is generally meant carbonization at temperatures varying from 500 to 600 deg. C., that is from about 900 to 1,100 deg. F. Generally speaking, the relative temperatures for low and high temperature carbonization may be kept in mind as 1,000 deg. F. for low temperature and 1,000 deg. C. for high temperature. The latter temperature, equivalent to 1,800 deg. F. is, however, the approximate flue temperature of the coke oven rather than the average maximum temperature within the oven during the progressive coking of the coal from the hot walls to the centre of the charge which ranges from 1,500 to 1,600 deg. F. For mid-temperature carbonization which may be interpreted as midway between high and low temperature, the flue temperature may vary somewhat from 1,400 deg. F., stated above, with a corresponding average maximum temperature within the oven 200 to 300 deg. F. lower.

The literature on low temperature carbonization is very extensive, and since the scope of this paper does not allow space for its review, only some salient points as applied to Canadian coals will be mentioned here. The present status of low temperature carbonization in Canada is that all attempts to introduce it on a commercial scale have so far met with failure. Its main disadvantage for bituminous coals is that very few of the processes promoted will produce a coke product as satisfactory for the domestic fuel market as the ordinary by-product oven domestic coke. The low temperature product is grayish-black in colour, and as a rule has poorer handling qualities than the high temperature coke. It is free burning and quite serviceable for open grates and cooking purposes for which it was originally promoted in England where also its smokeless properties were in its favour.

The high temperature yield of gas is such that a surplus over and above that required for heating the ovens of 7,000 cu. ft. of 500 B.t.u. gas or more, is available for sale, whereas by low temperature, there is no such surplus, despite the fact that the heating value of the low temperature gas is appreciably greater. The doubled yield of tar oil which is a feature of low temperature carbonization is not specially attractive since its value in the raw state is not greater than that of fuel oil. The yield of coke is appreciably higher by low temperature but unless the coke produced can be sized and marketed at a greater profit per ton of coal carbonized than by the high temperature process thus offsetting the deficiency in surplus saleable gas, any advantages claimed for low temperature carbonization disappear.

A considerable number of low temperature carbonization tests on Canadian coals have been made at the Fuel Research Laboratories (F.R.L.). These have been on small and large laboratory scales and the results have been published.[34,35] The results of assays are on record for a large number of coals varying in rank from lignite and peat to semi-anthracite, by a recently developed F.R.L. low temperature carbonization assay method. These results are being specially correlated with the classification by rank of the coals tested and will be the basis of a manuscript for publication in the near future.

The first named author of this paper during his visit in 1928 to Europe inspected several low temperature carbonization plants, then in the development stage, including the retorts developed by the Fuel Research Board at Greenwich, the Illingworth plant at Pontypridd, the Turner, Sutcliffe, Babcock Wilcox, the L and N plants, all in Britain, and four plants in Germany including the Lurgi retort plant. A summary was published[36] of the relative merits of these processes and the reasons for selecting the Illingworth process as the most suitable for Canadian bituminous coals. The application of low temperature carbonization to the coking and non-coking (domestic) coals of Alberta has recently been described.[37] Significant points stressed in the references 36 and 37 may be summed up as follows:—Attempts to adopt processes which have been successful in one country to conditions in another country have rarely succeeded and claims that a process is universal in application are a proof of ignorance or worse: the best processes are liable to fail to pay dividends in any but the most favourable locations. Furthermore the success of any low temperature carbonization process in Canada will depend on low capital cost of plant per ton year—materially lower than the present cost of either by-product oven or gas plants—and on the ability to utilize a low grade and inexpensive raw fuel.

The results obtained in some large scale tests made on selected Canadian coals in the experimental plant of the Illingworth Carbonization Company in South Wales are worthy of special mention here. These tests, which were made on unwashed and washed Sydney, Nova Scotia coals were planned and witnessed by officers of the Fuels Division of the Canadian Department of Mines and the detailed results have been published,[38] reprints of which are available. The yields and certain chemical characteristics of the coke and other products obtained by the Illingworth low temperature process in comparison with the corresponding results in a high temperature coke oven, using two different washed coals from the Sydney area Nova Scotia are shown in Table VIII and the relative low temperature carbonization laboratory results on typical Alberta bituminous, sub-bituminous and domestic coals are given in Table IX.

Table VIII

Results of Carbonization of two different samples of washed Sydney, N.S. Coal, by low-temperature carbonization in comparison with those at high temperature.

| | High-temperature carbonization in by-product oven | Low-temperature carbonizaiton by Illingworth process | |
|---|---|---|---|
| Analysis of coal | | | |
| Ash (dry coal basis)....per cent | 3.5 | 5.8* | (4.3) |
| Volatile matter....per cent | 38.0 | 28.0* | (31.0) |
| Products obtained, per ton of dry charge | | | |
| Coke (dry)....lb. | 1,340 | 1,590 | (1,550) |
| Ash in coke....per cent | 4.8 | 7.7 | |

| B.t.u. per pound.... | | 13,850 | |
| Sulphur in coke....per cent | 1.0 | 2.4 | |
| Tar oils....Imp. gal. | 11.0 | 14.0 | (15.5) |
| Gas (including light oils)....cu. ft. | 12,700 | 5,500 | (6,085) |
| B.t.u. of gas.... | 595 | 705 | |
| Light oils extractable from gas....Imp. gal. | 2.5 | 2.9 | (3.2) |

*This is the analysis of the coal charged after admixture of ten per cent breeze from a previous test, hence the coke yield of 1,590 lb. is subject to correction. Figures given in brackets in the last column to the right are the calculated analyses and yields based on one hundred per cent dry coal without the breeze. The volatile matter content of both the coal and the coke is low, as it was determined in silica crucibles at the Illingworth plant in England.

The tar oil yield by the laboratory low temperature carbonization assay from the washed Sydney, Nova Scotia coal on which commercial yields are reported in Table VIII is 26 Imperial gallons, practically equal to that for high volatile bituminous from the eastern border of the Crow's Nest area in Alberta reported in Table IX. It is further noted that the tar oil yields of the typical medium volatile, and of the sub-bituminous and domestic coals from Alberta are comparatively low, ranging from 18.5 to 11 Imperial gallons per ton; and also that the carbonized residue from the sub-bituminous and low rank domestic coal is a char rather than a coke. For these reasons as referred to below and also because of their relatively low char yield, as well as the lower heating value of the gas, low temperature carbonization for the lower rank non-

Table IX

coking coals is not an especially attractive proposition, since for these coals it is often difficult to realize the main objective of carbonization which is to convert coal into new products of greater value than the raw fuel carbonized

### FUEL BRIQUETTING INVESTIGATIONS

Briquetting is applicable to several different kinds and forms of fuel including anthracite fines, coke breeze from bituminous coals, petroleum coke breeze, char resulting from the carbonization of non-coking coals, the fines from low-volatile bituminous, sub-bituminous and domestic coals in the raw state, and in addition such materials (either raw or carbonized) as peat, sawdust, straw and grain screenings. The purpose of briquetting is obviously to convert either the raw or carbonized fuel, usually in the form of slack, fines or breeze, into a more saleable lump product. The size and shape of briquette varies from small size oval or pillow shaped briquettes corresponding to ordinary nut and stove size anthracite, to much larger cylindrical and cubical shaped briquettes that are either burned as such or broken down at the time of firing.

The briquetting process consists of intimately mixing while hot the suitably sized coal or other raw material with a binder and then feeding the hot mass to a powerful press where it is moulded into the briquettes. Careful handling of the briquette is usually required during the cooling stage between the briquetting press and the storage bin. Such binders as petroleum asphalt, and coal tar pitch are most commonly used. Other binders that have merits are pitch or powder from sulphite liquor, and flour, either alone or as a paste emulsion with oil binder. The admixture of a coking low volatile bituminous coal is often used to improve the internal caking strength of the briquette during the first stage of burning and to increase the calorific value of the briquette. Oxidized pitch from Alberta bitumen has also been found, both in tests at Ottawa and Edmonton, to be as satisfactory a briquette binder as pitch from either petroleum or coal tar.

A feature of the briquetting facilities at Ottawa is the commercial size briquetting plant with a capacity of five tons per hour capable of either continuous or intermittent operation. A Mashek roll press is used in conjunction with three mixers, two of which are steam jacketed, elevators, conveyers, and suitable binder tanks and feeding devices. For batch (intermittent) tests a steam jacketed mixer with a capacity of 50 to 75 lb. of coal is employed for preparing the charge for the briquetting press. A variable pressure plunger press, a hand operated hydraulic press, together with adequate steam boilers complete the briquetting equipment.

Briquetting tests have been conducted at the Fuel Research Laboratories intermittently since 1918. These have included briquetting tests on (*a*) carbonized lignite incident to carbonizing and briquetting investigations on lignite from southern Saskatchewan and northern Ontario, (*b*) Welsh anthracite screenings, (*c*) petroleum coke breeze, (*d*) hardwood charcoal breeze, and (*e*) fines from eight British Columbia coals.

In a recent publication[39] entitled "Fuel Briquetting" the results of these tests are given in detail and the status of fuel briquetting in Canada and in the United States reviewed. The comprehensiveness of this publication which includes a complete review of recent literature on the subject as well as a list of briquetting patents with special reference to binders may be indicated by stating the titles of the six chapters. They are as follows:—History of briquetting, Processes for briquetting various classes of fuel, Binders and processes for briquetting, Equipment used in briquetting, Investigations on briquetting, and Economics of briquetting.

As a part of the briquetting investigational programme conducted at the Fuel Research Laboratories, a survey was made of commercial briquettes on the market in both Canada and the United States. The chemical analyses of the briquettes have been reported[40] and their physical properties are given in the "Fuel Briquetting" publication. As with sized coal and coke it is mainly the physical characteristics that determine the relative merits of different briquetted fuels, although the chemical properties in respect to ash content, volatile matter, smokiness and calorific value are important. Accordingly the briquettes included in the survey and those produced in the laboratory briquetting tests, were examined in respect to the following physical properties, viz., apparent specific gravity; bulk density in terms of weight per cubic foot; waterproofness and shatter; abrasion and compression tests to indicate comparative handling properties. Depending on the quantity available, the usual practice is to make either small or large scale burning tests to determine the smokiness of the briquettes and the degree to which they soften and coalesce in the fire. The survey indicated a wide variation as to type of briquette marketed, which variation was accounted for by the variation in the fuel accepted as standard in the different localities. The relative heating values of two different lots of anthracite briquettes, one made from Pennsylvania semi-anthracite fines and the other produced in Western Canada from low volatile bituminous coal, in comparison with Pennsylvania anthracite and other domestic fuels are shown in Table VI.

A study of the results of the briquetting tests on eight coals from British Columbia ranging in rank from lignite to medium volatile bituminous revealed that the physical properties in respect to strength, etc., of the briquettes, made with a constant proportion of (145 deg. F. melting point) coal tar pitch, varied directly with the rank of the coal. The shatter index, as indicating resistance to breakage, increased from low to high rank and the dust producing properties of the briquettes, when subjected to a standard laboratory tumbling test, decreased according to rank, being the greatest for the non-coking lignite and sub-bituminous coals and the least for the coking medium volatile bituminous coals.

The beneficial results of blending a good coking coal with the non-coking coals for briquetting purposes was confirmed and it was found that the optimum quantities of the coking coal to be added ranged from 25 per cent for the non-coking sub-bituminous (and lignite) coals to as low as 5 per cent for anthracites. The addition of a coking coal to the non-coking lower rank coals, it was also confirmed, improved their general burning qualities. In fact without the admixture of a coking coal these lower rank coals are unsuitable for briquetting since briquettes made from them disintegrate badly when burned, due to their high volatile matter contents.

#### Briquetting of Carbonized Residue

The merits of the double treatment of carbonization and briquetting versus the briquetting of the raw coal fines has received considerable attention at the Fuel Research Laboratories and elsewhere in Canada. In this connection the relative calorific values of typical coals of different rank in the raw, dried and carbonized states, as tabulated below, are significant.

The data in this table indicate generally what ranks of coals may best be briquetted in the raw or dried state and what ranks may be suitable for the double treatment of carbonization and briquetting. It is to be noted that the calorific values of the char are progressively higher than those of both the raw and dry coal as the rank decreases from noncoking high volatile bituminous coal to lignite, whereas in the high rank anthracites (and low volatile bituminous coals) the reverse is the case. The increase of calorific value by drying alone in comparison with the added increase by carbonization is also illustrated.

TABLE X

| Selected typical coals (Moisture, ash and volatile matter contents in brackets) | Calorific Values—B.t.u. per lb. | | |
|---|---|---|---|
| | Raw coal as mined | Dry coal basis | Char after carbonization at 600 deg. C. |
| Alberta—Semi-anthracite (3–8–11)* | 13,900 | 14,300 | 14,200 |
| Alta.—High volatile bituminous (10–8–38) | 11,550 | 12,850 | 13,750 |
| Alberta—Sub-bituminous (15–9–38) | 10,150 | 11,950 | 13,050 |
| Alta.—(Sub-bituminous) domestic (25–10–37) | 9,300 | 11,250 | 12,780 |
| Saskatchewan lignite (35–11–43) | 7,150 | 11,000 | 12,500 |
| Northern Ontario lignite (50–11–44) | 5,250 | 10,500 | 12,220 |

*Example—3 per cent moisture, 8 per cent ash and 11 per cent volatile matter, with the ash and volatile matter on the dry coal basis.

The char resulting from carbonizing the lower rank non-coking coals is porous and therefore requires appreciably more binder when briquetted than the raw coal, both low and high rank. This porosity of the char, which tends to increase with decrease in rank, is influenced appreciably by the temperature of carbonization. For lignites in particular, the maximum calorific value in the char is obtained at 550 to 600 deg. C., but the fact that char produced at higher temperatures, say up to 850 deg. C., has appreciably better briquetting properties must be taken into account.

In the establishment of briquetting plants in Canada, and also in the United States, the same degree of success has not materialized as in Europe. This is mainly due to the difference in the available fuels and their method of utilization. In Europe the briquetting industry seems to have been established for converting the fines from all ranks of coals into a more useable form irrespective of a specific standard, whereas in North America fuel briquetting has been confined almost exclusively to the production of a domestic briquette in competition with anthracite. In Canada recent briquetting ventures have been mainly associated either with the carbonization of lignite of the grades found in Southern Saskatchewan and in Northern Ontario, or with the semi-anthracite and low volatile bituminous coals of Alberta. Anthracite briquettes, imported from either the United States or Great Britain, are marketed in Central Canada, where recently cubical shaped packaged briquettes made mostly from low volatile ("semi") bituminous coal are also on the market.

Briquetting was conducted in conjunction with carbonization operations at Bienfait, Saskatchewan, intermittently from 1918 to 1930, first by the Lignite Utilization Board[41] and then by the Western Dominion Collieries.[42] While it is understood that financial considerations were mainly responsible for the discontinuance of operations, it is believed other factors such as competition of Alberta and other domestic fuels, and also the increased use of Saskatchewan lignite in the raw state in Winnipeg, Regina and other centres in Manitoba and Saskatchewan, have been partly responsible for the non resumption of carbonization and briquetting operations there. Two briquetting plants are reported in operation in Alberta—one at Canmore and the other at Nordegg—the raw material briquetted being low volatile bituminous fines.

FUEL HYDROGENATION INVESTIGATIONS

The hydrogenation of coal and other fuels consists of heating them under high pressure in the presence of hydrogen and a catalyst. The reaction may take place in the solid, liquid, or gaseous state. By the hydrogenation treatment heavy liquid hydro-carbon fuels are transformed into lighter liquid fuels usually with the production of hydrocarbon and other gases. In the hydrogenation of high molecular weight petroleum, bitumen and coal tar, the aim is to produce lighter hydrocarbon oils with an average molecular weight approximating that of gasoline, with a minimum amount of solid and gaseous products. When applied to coal the objective is to produce a maximum yield of motor fuel with minimum amounts of coke and waste gases. For best heat transfer conditions coal in the pulverized state is mixed with a heavy coal tar oil and fed to the reaction chamber in the form of an emulsion or paste. In the hydrogenation reaction the solid coal particles are first converted into heavy (tar) oils and then into lighter oils, and the proper temperature and pressure conditions to obtain maximum yields of motor fuel of desired properties from a given coal are determined by experiment.

The investigational programme on fuel hydrogenation at the Fuel Research Laboratories was begun in 1929 since when it has comprised the following series of batch and continuous tests:—

*Small Laboratory Scale Tests in One Litre Bomb*

(*a*) On bitumen from Alberta bituminous sands.
(*b*) On coal tar from a Nova Scotia coal by low temperature carbonization.
(*c*) On several Canadian coals of varying rank in admixture with coal tar.

*Intermediate Scale Tests in Large (4 Litre) Bomb*

(*d*) On bitumen, coal tar and suspension of powdered coal in coal tar.

*Large Laboratory Scale Tests in New Vertical Reaction Chamber*

(*e*) On typical bituminous coals from Nova Scotia and British Columbia.

The programme outlined in (*a*), (*b*) and (*c*) which were intermediate batch tests in a small (Cook) bomb of one litre capacity, served to demonstrate the amenability to hydrogenation of the fuels tested. These tests, the detailed results of which have been published[43,44] demonstrated that both Alberta bitumen and low temperature tar from Nova Scotia coal were eminently suitable for high pressure hydrogenation. With the bitumen, laboratory yields of 65 to 75 per cent by weight, equal to 90 to 100 per cent by volume, of the unrefined gasoline fraction were obtained, in comparison with the 30 to 40 per cent by weight yield by the "Cross" pressure cracking process. Optimum results were obtained on the coal tar at approximately 450 deg. C. and 250 atmospheres pressure, using molybdic oxide as catalyst. On each material the coke formation by hydrogenation was reduced to about one-half of 1 per cent as compared with 17 per cent by ordinary pressure cracking without hydrogen. The yield of the gasoline fraction by hydrogenation was double that by pressure cracking, with total oil recoveries of 90 and 78 per cent respectively.

The intermediate scale tests[45] in a large four litre (Cook) bomb on coal tar, as per (*d*) above, were intermittent batch tests each of eight hours duration, but the apparatus was capable of continuous operation. On the three different materials tested with molybdic oxide as catalyst, the pressures of the reaction chamber ranged from 183 to 187 atmospheres with temperatures varying from 428 to 452 deg. C. The net yields of "dry volatile oil" obtained were 102 per cent by volume from the bitumen, 90 per cent from the coal tar, and 89 per cent from the coal tar-coal emulsion. These yields are based on the net material charged, that is, the total amount charged minus the partly converted oil left in the reaction chamber at the end of the run—which represents the yields that could be obtained in continuous runs of long duration. The yields from the bitumen and coal tar previously obtained in the small bomb were thus confirmed, with the conversion yield from the mixture of coal and coal tar practically equal to that of the coal tar oil. Another noteworthy result was that carbon formation was avoided in all of the three test runs and the volatile products from the three different raw materials had quite similar distillation ranges—with a 45 per cent gasoline fraction below 410 deg. F. and a 90 per cent combined gasoline and kerosene yield below 472 deg. F.

The tests in the small bomb as per (*c*) were planned for the purpose of ascertaining the relative amenability to hydrogenation of typical Canadian coals varying widely in rank. The results obtained were not entirely satisfactory, due, it was judged, to the tendency of the catalyst and other solids to settle out and form a cake in the bottom of the bomb below the paddle stirrer, thus preventing uniform heating of the charge. This effect took place particularly with the high rank semi-anthracite coal, with two lignites and with peat, all of which are non-coking. The results, however, do indicate that generally speaking the suitability of six other coals to hydrogenation was directly according to their rank classification. The highest coal-to-oil conversion, viz., 70 per cent by weight, was obtained from a medium volatile bituminous coal, with yields of 64, 51, and 46 per cent from three different high volatile bituminous coals, and of 22 and 13 per cent from a typical sub-bituminous and a domestic coal respectively. These results are of comparative value only and subject to confirmation on a larger scale.

*Continuous Hydrogenation Tests in Vertical Reaction Chamber*

For the tests referred to in (*e*) above, an apparatus with a throughput capacity of one Imperial gallon of raw material per hour is used. The main part of this apparatus, or rather equipment, consists of an externally heated vertical reaction chamber 10 feet long and 2.74 in. inside diameter, made from chrome nickel steel and equipped with temperature controller and recorder. Accessory equipment which has been described[46] in detail with illustrations, is comprised of the following pieces of apparatus, viz., on the raw material feed portion:—portable hydrogen (shipping) cylinders, three-stage compressor, two high pressure hydrogen storage cylinders, feed tank and liquid feed pump; and on the product side of the reaction chamber operated under high pressure, a cooler, receiver, hydrogen recirculating pump and flow meter. In this experimental equipment capable of operation either continuously for long periods of several days or intermittently continuous for shorter periods of eight to twelve hours, the shortcomings of the batch test runs in the autoclave bomb reaction chamber are remedied, and results more applicable to commercial conditions are obtainable.

In brief a hydrogenation test on a coal consists of mixing the pulverized coal with a heavy oil from a previous run as vehicle, and pumping the coal-oil paste into the system just prior to the reaction chamber, into which the charge is carried by the hydrogen from the high pressure storage cylinders. The current of hydrogen and other gaseous products augmented by the hydrogen recirculating pump also serves for removing the hydrogenated liquid product from the reaction chamber into the cooler and high pressure receiver, from where by a gradual reduction of pressure it is removed for subsequent examination. On a given coal a series of eight-hour test runs are necessary in order to accumulate sufficient hydrogenated heavy oil vehicle to make a final hydrogenation test on that coal. Hence allowing time for the proper examination of the products from each eight-hour test run it requires a month or longer to complete a test on a coal.

To date only three coals have been tested in the continuous vertical reaction chamber equipment, viz., on two high volatile bituminous coals, one each from Cape Breton and Vancouver Island, and on a medium volatile bituminous coal from the Crow's Nest area, British Columbia. Of these coals, which were included in the batch tests in the small bomb mentioned above, the best yields have been obtained from the one from Nova Scotia, viz., the washed coal with 3.5 per cent ash content from the Sydney area reported in Table VIII. The best results on this coal were obtained at a reaction chamber temperature of 443 deg. C. and 2,940 lb. per square inch pressure (that is 200 atmospheres). It was found that at this pressure for this particular coal slight changes in temperature and certain other operating conditions reduced the net coal-to-oil conversion yield from a maximum of over 77 per cent to less than 54 per cent.

Tabulated below are the results from the Sydney Nova Scotia coal in comparison with those from a Yorkshire coal, which shows that the yields from the English coal reported by the Imperial Chemical Industries can be closely approached on a Canadian coal in our equipment at the Fuel Research Laboratories.

Table XI

| | Per cent weight of coal charged | |
|---|---|---|
| | Yorkshire coal | Sydney, N.S. coal |
| Hydrogen used | 7.5 per cent | 7.4 per cent |
| Solid residue | 4.0 per cent | 6.2 per cent |
| Aqueous liquor | 8.0 per cent | 7.0 per cent |
| Gas produced | 15.5 per cent | 16.8 per cent |
| Oil produced | 80.0 per cent | 77.5 per cent |

Sufficient information has been obtained to show that each coal tested requires a different set of conditions for optimum results. Hence the main purpose of the hydrogenation tests now in progress is to ascertain these conditions by experimentation. It is planned to test first a series of typical coals varying widely in rank from the different eastern and western Canadian coal producing fields, after which a second series on particular coals of the rank showing the best results will be in order. Furthermore it is anticipated that several Canadian coals will be found suitable for the production of motor fuel and other (petroleum oil) products by hydrogenation.

# Characteristics and Quality of Nova Scotian Coals

*F. H. Sexton, LL.D.,*
*President, Nova Scotia Technical College, Halifax, N.S.*

**Paper presented at the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

SUMMARY.—Describes recent investigations on Nova Scotia coals as to their characteristics and performance when used for domestic heating and steam boiler firing. Tests of the effect of weathering on stock piles were also made.

Although extraordinarily rich in almost all other kinds of minerals, the eastern half of Canada has no coal except near the Atlantic coast. Most of the deposits of this mineral are in Nova Scotia, and are situated so close to the shore that the waves break over a good many of the outcrops. The greater portion of the beds extend out under the ocean and over half of the output is taken from under the bed of the Atlantic. Some of the working faces of the collieries are nearly three miles from the shore. It seems as though Nature had been chiefly concerned in Nova Scotia with creating the greatest fishing grounds in the world, and had grudgingly lifted only enough land to show on the beaches the outcroppings of the seams of coal that extended out under the waves. On the east and west coasts of Cape Breton island the coal beds lie exposed in the cliffs of the shore and the surf almost literally breaks at the foundations of the colliery hoisting head frames. There are two important coal fields in the interior of the mainland of Nova Scotia in Pictou and Cumberland counties, but neither is very far from tide-water.

These deposits have been worked for well over two centuries and were yielding coals before the famous Pennsylvania fields were discovered. The extent of the beds is not known nor the economic limits to which they can be exploited. It has been estimated that the province contains over two billion tons of coal in beds that are one foot or over in thickness less than four thousand feet in depth and within three miles of the shore. This actual reserve is large enough to supply coal at the present rate of production for more than three hundred years. Most of the seams lie in the rocks of the Upper Carboniferous and are all classified as bituminous coal. Almost all the fuel requirements of the Maritime Provinces, Quebec, and Newfoundland are supplied from these areas because of the ease and economy of transportation by water. Large steamers can carry cargoes up the St. Lawrence as far as Montreal. At this point begins a severe competition with coal carried by rail or rail and water from Pennsylvania, West Virginia, and Ohio, all of which lie not far south of Ontario. That province imports far more bituminous coal from the United States than the entire production of Nova Scotia.

In recent years the Dominion Government has become increasingly conscious of the national importance of maintaining the coal mining industry of the eastern provinces in a reasonably healthy condition. There has also grown up a better feeling on the part of the highly industrialized central provinces in respect to a responsibility for purchasing fuel from the east as a partial compensation for the large sales of manufactured articles there. There have been established federal subventions to the railroads for payment of freight charges to equalize the prices of coal from the Maritimes in Quebec and Ontario with those from the United States. This has led to a slow but steady increase in the production of Nova Scotian coal with satisfactory related economic advantages to Canada. No one can predict how far or how fast this movement will proceed because there are so many sudden changes that disturb the equilibrium in the central Canadian coal market and also other factors such as, (1) the increasing use of oil for fuel and power, (2) the greater efficiencies obtained from the combustion of coal in the more modern plants, and (3) the wider use of energy generated from hydro-electric plants.

During the past few years great advances have been made in the production of steam power from coal. The improvements in efficiencies from pulverization, higher pressures, greater ratings, better mechanical stokers and boiler accessories, and other changes in practice are well known to all engineers. Increasing costs of raw coal and competition from power manufactured in hydro-electric plants have been generally met so that steam still holds its dominant position in this field. When new stations are now built or additions made to existing plants, the problem of securing the most economical fuel and equipment for the special conditions to be met is one which involves the most careful analysis and engineering design. After the fuel which will be used has been selected, the apparatus to be installed is often modified largely in order to secure the best results.

In the light of these existing conditions it becomes necessary for a coal-producing area to have available all the scientific and technical data concerning the fuels which it markets so that the combustion engineer may give them full consideration for use in plants where they are available. This is especially true with Nova Scotian coals, which are shipped to inland points nearly 1,000 miles away from the mines to meet competition with the American coals from Pennsylvania and West Virginia. The data on the fuels mined in eastern Canada were comparatively meagre and scattered through many publications. From 1906 to 1910 a thorough investigation had been carried out by the Dominion Department of Mines on Canadian coals and the results published.[1] Since that time, however, the working faces of the mines in Nova Scotia had been advanced for miles in some cases and the data in this report referred to coal which had long been extracted. The figures could not be used by the combustion engineer who wished to know what kinds of coal were available in the market when he was planning his plant for present use.

These facts led the Nova Scotian government in 1928 to carry out a fresh investigation into the characteristics and qualities of the coal being produced in the province. An advisory board was created which included representatives of the two Canadian railway systems, the coal-producing companies, practising combustion engineers, members of the staff of the Federal Department of Mines, and professors from the Nova Scotia Technical College. A programme of action was planned and carried out during the years 1928 to 1931.

The complete results have been published in the annual report of the Nova Scotia Department of Public Works and Mines for the year 1933.

The programme included four distinct branches of effort:

1. Chemical analyses on representative samples taken directly from the working faces in the producing collieries throughout the province.
2. Evaporation tests in standard boiler trials of large-scale samples taken from the working faces.
3. Radiation tests in common types of domestic hot-water boilers to ascertain comparative heating values between fuels produced locally and imported fuels.

4. Weathering characteristics of Nova Scotian bituminous coals when stored in stock piles.

### Chemical Analyses of Nova Scotian Coals

In each mine two separate samples were taken from the working face. One was from a channel, three inches deep and four inches wide, cut by hand from the roof to the floor. All splint and pyritic bands such as would be removed on a picking belt were rejected and the coal placed immediately in air-tight cans. At the same spot a large 5-ton sample was taken which was bagged and shipped to the Technical College for boiler trials. This latter sample was again cut down and analyzed after it had arrived at its destination.

The laboratory work included the following determinations:

1. Proximate analysis for moisture, volatile matter, fixed carbon, and ash.
2. Ultimate analysis for carbon, hydrogen, oxygen, nitrogen, and sulphur.
3. Calorific power.
4. Fusibility of ash.

The methods followed were those which had been set forth as standards by the American Society for Testing Materials. The calorific values were determined by means of an Emerson-Daniels oxygen-bomb adiabatic calorimeter. The analyses are reported on the "as received" and "moisture-free" bases. The letters "R" and "D" respectively refer to the samples in these conditions.

The results of the analyses included here are limited to those mines in the three areas of Sydney, Pictou, and Springhill from which considerable amounts are exported to other provinces. Coal from the other mines is mostly consumed in Nova Scotia.

The samples selected are as shown in the following tabulation:

Table I

| No. | Mine | Coal seam | Area |
|---|---|---|---|
| 1-16-01 | No. 16 | Lingan | Sydney |
| 1-1B-02 | No. 1B | Phalen | Sydney |
| 1-02-03 | No. 2 | Phalen | Sydney |
| 1-04-04 | No. 4 | Phalen | Sydney |
| 1-11-06 | No. 11 | Emery | Sydney |
| 1-Pr-07 | Princess | Main | Sydney |
| 1-Fl-08 | Florence | Main | Sydney |
| 4-24-16 | Albion | Third | Pictou |
| 4-24-17 | Albion | Cage-pit | Pictou |
| 4-22-12 | McGregor | McGregor | Pictou |
| 4-22-13 | McGregor | Fleming | Pictou |
| 4-23-15* | Allan | Foord | Pictou |
| 4-23-16* | Allan | Foord | Pictou |
| 4-23-17* | Allan | Foord | Pictou |
| 4-23-18* | Allan | Foord | Pictou |
| 5-02-22 | No. 2 | | Springhill |
| 5-06-20 | No. 6 | | Springhill |
| 5-07-21 | No. 7 | | Springhill |

*The four samples, 4-23-15 to 4-23-18, were taken from the Foord seam which is 40 ft. thick and each sample represents a 10-ft. section progressing with the successive numbers from roof to floor. Each of these was a 5-ton sample.

It is interesting to note the variations in composition in the four samples taken from the 40-ft. Foord seam in the Pictou area. The differences between 10-ft. sections are greater than in the case of coal samples taken from different mines in the Sydney area.

If the analyses of the channel samples are carefully compared with those of the 5-ton samples, it will be seen that the former indicate a slightly better coal in most cases. This is probably due to the care with which impurities such as splint and pyrite are discharged when cutting the channel by hand. The coal as mined is not picked so carefully although the sampler tries to simulate closely the regular rejections that would take place on the picking belt. The results secured in the analyses of the 5-ton lots would approximate the constitution of the run-of-mine coal as marketed in large quantities more closely than would those obtained from the channel samples.

The fusibility of the ash has become an important value in recent years, especially where the fuel is being considered for use in high boiler ratings. Most of the coals in the Sydney area have ashes that are classed as easily fusible. The Springhill coals are better in this characteristic and have ashes that are designated as of medium fusibility. The Pictou coals show a still higher temperature of ash fusibility and that from the Foord seam is almost up to the refractory level.

### Comparative Tests of Fuels in Domestic Hot-water Heating Boilers

The purpose of these tests was to find the relative values of various fuels that were commonly used in Nova Scotia for house-heating in the winter months. Not many years ago most homes used Pennsylvania anthracite for this purpose. The price of this coal steadily advanced and caused people to turn to other forms of fuel. Coke from gas works and by-product ovens, sized bituminous coal, and briquettes came to be widely used. With the wide distribution of electrical power at low prices many small stokers were developed for household use and an even wider range of fuels was employed. Furnace design was improved concurrently so that even for domestic heating the small sizes of anthractie were successfully burned. Oil burners with blowers and regulating thermostats were put on the market for those people who were willing to pay a higher cost for the extra convenience and close temperature control. All this has led to new practices of coal producers in the careful preparation of a wide variety of fuels to meet the demands of the users. In eastern Canada the imports of anthracites in small sizes from Great Britain has largely increased in recent years. This movement has spurred the coal operators of Nova Scotia to new efforts to meet the competition by promoting the use of metallurgical coke, by offering more closely sized soft coal, and by sponsoring certain types of mechanical apparatus and furnaces suitable for the efficient burning of coke and bituminous coal in house-heating.

The householder himself has become more acutely aware of the scientific and economic aspects of the problem of keeping warm during the winter, and is keenly interested in the apparatus and the fuel he should use to procure the best result with the maximum of convenience he can afford. Under these conditions it seemed the part of wisdom for the provincial government to conduct some tests in regard to the relative heating values of the common solid fuels available, in order to supply information to the householders on how to solve their heating problems. It was hoped that the results would show that the economic advantages would be in favour of using local soft coals or the cokes manufactured from them. Accordingly, authority was given to carry out a series of trials on domestic hot-water boilers at the Nova Scotia Technical College.

In 1925 the testing laboratories of the Mines Branch of the Federal Department of Mines had conducted an elaborate series of tests[2] of this nature. The fuels used included Welsh, Scotch, and American anthracites, gas coke, by-product coke, American and Alberta semi-bituminous, and Alberta bituminous. Nova Scotian coals were not included in this programme. It was thought best to carry out the local investigation as closely as possible with apparatus and procedure followed by the workers in Ottawa so that the results obtained would be closely comparable.

[2]Results reported in Mines Branch Investigations of Fuels and Fuel Testing, 1925, Bulletin No. 671, pp. 33-63.

The boilers used for domestic hot-water heating systems were the ones selected for the trials, because this kind lent itself best to securing the most accurate results and this type of heating is used widely throughout the province. Three common types of hot-water boilers were installed for the investigation, known in the trade as the horizontal-section, vertical-section, and drop-tube. The last mentioned form is designed for using bituminous coal and is not as widely employed as the two preceding ones, so that it was not used to any great extent in the tests. The size of the furnace is that which is usually provided to heat a house of eight rooms.

The method of firing in the boiler followed closely the practice of the householder in maintaining heat in his home. The furnace was run for a period until a good fire bed had been formed and the rate of combustion approximated that of the test. This brought all the parts of the heating system to a stable working condition. At the actual beginning of tests, the grates were shaken and a charge of fresh fuel fired that would last from four to ten hours according to the kind that was being used. At the end of the run the fire bed was brought to approximately the same condition as at the commencement.

Natural draft was used in all trials and the drafts were altered only to maintain a steady rate of combustion. Most of the tests were conducted so that 50,000 to 70,000 B.t.u. per hour were delivered to the cooling water. In some trials the rate was increased to 100,000 B.t.u. or more per hour for experimental reasons. The grates were shaken when necessary to maintain a good fire except in the case of metallurgical coke made by the Dominion Steel and Coal Corporation, with which another method known as the "still-grate" practice was found to give better results.

Preliminary tests indicated that reliable results could be secured by runs in which 500 lb. or more of the fuel were burned if the rate of combustion was not pushed above 100,000 B.t.u. per hour.

The fuels were all carefully sampled and analyzed chemically, both by the proximate and ultimate methods, and are reported on the dry basis. The refuse of ash and clinker from each trial was also sampled and the amount of combustible material retained was determined by analysis.

In the trials it was found that the best results in the use of Dosco metallurgical coke could be secured by the "still-grate" method. The grates were not shaken at all during the run and any clinker formed was lifted out through the fire door with tongs. Any ash that fell through the grate was put back on top of the fire bed after fresh fuel had been charged. In this way the ash was kept at a minimum and the method is one that can be easily followed in practice by any householder. It keeps the refuse to a small quantity and reduces the amount of combustible matter retained by the ash and clinker to a very small proportion.

### The Experimental Plant

Figure 1 shows the arrangement of the apparatus and measurements used in the investigation. The layout of the equipment is easily understood by reference to the following explanation of the meaning of the letters on the diagram.

A —Drop-tube boiler
B —Horizontal-section boiler
C —Vertical-section boiler
D —Receiving tank
E —Main weighing tank
F —Auxiliary weighing tank
G —Radiation tank
H —Radiators
J —Flue to chimney
K —Boiler flue connections
L —Riser to radiation tank
M—Return from radiation tank
N —City water supply
O —Water meter
P —Cooling water inlet
Q —Cooling water outlet to weighing tanks
R —Cooling water inlet and temperature recorder
S —Room temperature recorder
T —Tag mono carbon dioxide recorder
U —Draft gauge
V —Flue temperature pyrometer
W—Flue-gas sampling tube
X —Copper-pipe connections to flue
Y —Leads to boiler-flue connections.

The three types of boiler used in the trials are distinctly different in their design and construction. They are rated in the trade according to the number of square feet of radiator surface which they are supposed to serve efficiently. The vertical two-pass boiler has a rating of 750 sq. ft. with a grate area of 3.305 sq. ft.; the horizontal-section furnace has a rating of 1,025 sq. ft. with a grate area of 3.34 sq. ft.; and the drop-tube boiler has a rating of 1,100 sq. ft. with a grate area of 5.32 sq. ft. The first two types are widely distributed throughout Nova Scotia. All the furnaces were thoroughly lagged to diminish the amount of heat radiated from the walls.

Close to the back of the flue damper a high-range thermometer was inserted to measure the temperature of the flue gases. At the same point a sampling tube was joined through which a constant flow of flue gases was maintained for a number of hours to a sampling tank. Gas samples were analyzed for carbon dioxide, oxygen, carbon monoxide, and nitrogen by means of a Hays Orsat apparatus. In addition a Tag Mono carbon dioxide analyzer was connected to give a continuous record of the amount of this gas throughout each trial. An Ellison draft gauge furnished the means of reading the chimney draft with various damper adjustments to maintain this factor as nearly constant as possible during a test.

The water in the boilers was piped to the radiation tank above which contained nine cast iron radiators with a heating surface of 9 sq. ft. each and connected in parallel. The cooling water was supplied from the city service. The temperatures at the inlet and outlet were continuously recorded by a Tycos double-pen instrument which was frequently checked by a mercury thermometer. The amount of cooling water from the outlet of the radiation tank was all weighed. A water meter was used for this purpose in preliminary trials, but it was found to be too difficult to keep it in adjustment so that its readings could be relied upon. The radiation tank was thoroughly insulated to keep this source of heat loss to a minimum. In each trial the flow of water was closely adjusted to produce a constant temperature difference between the cooling water and the outside air.

### Fuels Tested

The different fuels tested were mostly of the varieties available to the householders in Nova Scotia. For the sake of closer comparison with the results of the domestic hot-water boiler trials made in Ottawa by the Federal Department of Mines, a few tests were made on La Salle by-product coke which is manufactured in Montreal. In all cases except this, the fuels were purchased from or donated by local dealers. There follows a list of the variety of the fuels used in these trials.

1. Gas coke manufactured by the Nova Scotia Light and Power Company, Limited, Halifax, Nova Scotia, by the horizontal retort process from Nova Scotian coal for gas utility purposes.
2. Dosco coke manufactured by the Dominion Steel and Coal Corporation, Limited, Sydney, Nova Scotia, in by-product ovens.
3. Scotch semi-anthracite.
4. Welsh anthracite.
5. Pennsylvania anthracite.
6. Nova Scotian bituminous coal, "Acadia" run-of-mine, produced by the Nova Scotia Steel and Coal Company, Limited, at Stellarton, Pictou County, Nova Scotia.
7. Nova Scotian bituminous coal, "Springhill" run-of-mine, produced by the Dominion Steel and Coal Corporation, Limited, at Springhill, Cumberland County, Nova Scotia.
8. English coke imported from Great Britain.
9. La Salle coke produced in Montreal, Quebec, in vertical by-product ovens from American bituminous coal.

The chemical constitution of the fuels on a dry basis is given in Table III.

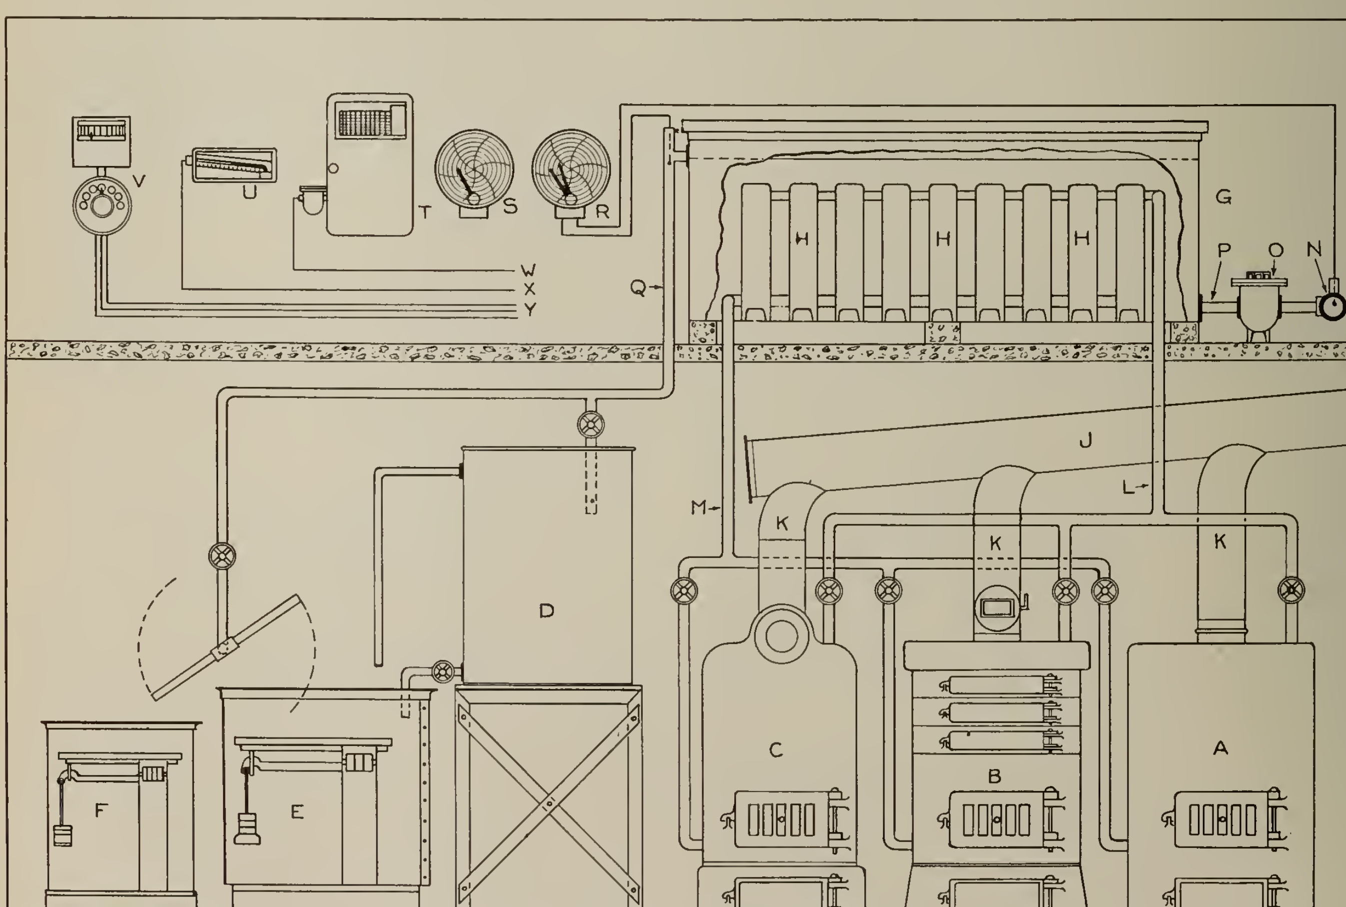

**Fig. 1—The Experimental Plant.**

## Results of the Trials

The most significant figure secured in the investigation was the amount of dry fuel fired per therm* delivered to the cooling water. The overall thermal efficiency gives a fair indication of the comparative values of the various fuels for heating purposes, but closer valuations may be made by using the dry fuel per therm. The salient characteristics of the different fuels tested in the boilers are shown in Table IV.

The horizontal-section boiler shows greater efficiency in burning all the fuels except one than the vertical-section type. The drop-tube furnace is best adapted for the use of bituminous coal with a fairly high percentage of volatile matter and its performance in this case excels that of the other two.

Dosco by-product coke compares favourably with the imported anthracites in the amount of heat delivered per pound of dry fuel as well as in its rating on the basis of thermal efficiency. It has advantages over Pennsylvania anthracite in that it produces only about one-third of the refuse and this is in the form of a solid heavy clinker that is easily disposed of by the householder. The American fuel gives a large volume of dusty ash which is disagreeable to handle and contains a good deal of unburned carbon. The coke ignites easily and responds quickly to changes of draft when it is desired to force or check the fire. The coke is sold at a much lower price and thus seems to possess such advantages from nearly all standpoints that it should displace the imported anthracites for domestic heating purposes.

The Nova Scotian bituminous coals can be secured at such prices that the householder can heat his home with these at less cost if he is willing to sacrifice some convenience that is available in using coke or anthracite. The furnace fire needs more frequent attention when soft coal is employed, and the interior sections of the furnace must be cleaned oftener to remove soot and dust. Acadia run-of-mine has a comparatively high percentage of ash which is disagreeable to handle. In Nova Scotia the bituminous coals are used successfully for domestic heating in the neighbourhood of the mines, but outside of these areas the imported and prepared fuels are most commonly employed. Anthracite has dominated the market for many years in the past and the home owner has become accustomed to the practice needed to get good results from it. The burning of coke requires a totally different technique and this is a handicap to its more rapid acceptance. People are becoming more concerned in improvements and economies in the heating of homes and are more amenable to experimenting with new methods and fuels.

The results of these trials are directly in line with those secured by the Dominion Department of Mines in its testing laboratories in Ottawa. They both point clearly to the advantages of replacing imported anthracite by coke which is manufactured in Canada. Hard coal is used widely in Ontario and Quebec for house-heating, and enormous quantities of this fuel are imported for this purpose. The impetus gained from long habit makes a change difficult, but the economic advantages to the individual and to the nation by using a fuel prepared in Canada are so evident that this should be a great influence toward changing over to coke for domestic heating. There has been a good deal of experimental work and development in the effort to make a small automatic stoker that will burn low grades of bituminous coal in the home under automatic thermostatic control. Progress is being made in this direction, and when satisfactory apparatus is available for a reasonable cost the use of both anthracite and coke may be sharply curtailed in house-heating.

*One therm = 100,000 B.t.u.

### Standard Boiler Trials

Boiler trials were run on all the 5-ton samples of coal which had been taken directly from the advanced working faces of the producing mines. The trials were conducted at the Nova Scotia Technical College according to the revised codes adopted for such tests by the American Society of Mechanical Engineers. The boiler used was of the horizontal return tubular type rated at 100 hp. and manufactured by I. Matheson and Company, Limited, New Glasgow, Nova Scotia. The method of hand firing was followed throughout. The boiler was equipped with Tupper grates and had means for forced draft by a Carling turbo-blower. The dimensions of the boiler were as follows:

Length—16 ft.
Diameter—60 in.
Heating surface—1,043 sq. ft.
Grate surface—22.90 sq. ft.
Volume of combustion space—800 cu. ft.
Distance from centre of grate to bottom of boiler—6 ft. 7 in.
Furnace volume per sq. ft. of boiler heating surface—0.144 cu. ft.

The setting had raised the boiler to a much greater height than was the customary practice. This was done for experimental purposes, because it was believed that a comparatively large space should be provided in the furnace so that the volatile gases distilled from the coal would be thoroughly mixed with air to promote complete combustion before being drawn through the tubes. It was found that the setting was too high for the greatest efficiency. After the standard trials were completed, the boiler was lowered and better heating results were secured. It was found that the distance from the grate to the boiler in plants using this type of boiler should vary according to the composition of the coal used.

The smoke connection from the boiler was 3 ft. in diameter and 50 ft. long with one right-angle bend. The Custodis brick stack was 3 ft. 6 in. in diameter at the top and 85 ft. high. The feed water was weighed from a large head tank, which served also as a feed water heater, and discharged into a hot well from which a Weir pump delivered the supply to the boiler. The temperature of the feed water was recorded continuously by a Tycos thermometer. The rate of steam flow was measured by a Bailey steam flowmeter. An artificial load for the boiler was provided by blowing the excess steam through a four-inch valve fitted with a Maxim silencer.

The combustion performance of the furnace was measured for carbon dioxide content in the flue gases by a Tag Mono recorder. A sampling tank was connected to the smoke uptake from which samples of flue gas could be obtained continuously. These were analyzed as a check on the recorder readings for carbon dioxide content and for percentages of carbon monoxide, oxygen, and nitrogen. Recording thermometers and draft gauges were also inserted at the other points where it was necessary to measure these factors.

The coal was weighed as fed to the boiler, and was fired by hand under the supervision and direction of the chief operator in charge of the trial. The first part of the run was made with the boiler kept at normal rating for ten hours and then the equipment was pushed up to a forced rating of approximately 150 per cent for as many hours as the remainder of the 5-ton sample would last. This latter period usually consisted of about six hours. The coal was sampled as it was fed into the boiler and the amount reserved was further crushed and divided to prepare the final sample for chemical analysis. The ash and clinker were weighed and sampled for a like purpose and were analyzed for the amount of remaining combustible matter as well as for calorific value.

The actual detailed data of the standard trials are too voluminous for a paper of this nature so that a statement of the comparative values of the different samples for steam-raising purposes as shown by these tests is all that is included. The results given cover both the runs at normal rating and in forced ratings. The fuel which gave the best performance is placed first and the others in succeeding order. The comparative efficiencies obtained are reported on a scale which is based on the assumption of 100 per cent for the coal which stood highest. The list is given for both normal and forced ratings, and appear in Tables V and VI.

### Weathering Characteristics of Nova Scotian Coals in Stock Piles

Since most of the coal mines of Nova Scotia are at or near tidewater, most of the product is transported to the consumers by boat. The St. Lawrence river is navigable as far as Montreal for large steamers, thus the bulk of exports to Quebec and Ontario are sent by this route. It is frozen over between the middle of November and the middle of April so that it is necessary to store large quantities of coal in stock piles both at the mines and in Upper Canada for comparatively long periods.

For many years there has been a persistent belief that the Nova Scotian coals deteriorated considerably when left out in the weather in a stock pile for several months. In

NOTE:—R—as received; D—dry basis.

the mine itself there is a constant exudation of gas from the working faces of the coal seam underground. In a mine a good deal of this is caused by the great pressures existing in such places and action of this kind does not continue to any considerable extent after the coal is broken up and raised to the surface. There is direct oxidation of very fine coal when it comes in contact with the air and the pyrite in coal weathers fairly rapidly when it comes under the influence of moisture and oxygen as it does in stock piles. These chemical reactions may cause heating and spontaneous combustion in piles of coal in small sizes especially with slack. Different coals have widely varying characteristics regarding their liability to spontaneous combustion and stock piles must be watched and occasionally tested for local heating.

Part of the investigation was devoted to tests under practical weathering conditions to find out how much change in composition took place in the stock piles at the mines and elsewhere. The tests were limited to a few samples of slack. A skeleton box frame, 2 ft. by 1½ ft., was made by welding ¾ by ¾ in. angle iron together at the corners. This was covered first with copper wire screening which had 16 meshes per inch and then with strong galvanized iron wire with 2 meshes per inch to protect the contents when roughly handled. The boxes were filled with freshly mined slack and buried at varying depths in the regular bank of slack that was built up during the winter at the mine. When the coal was lifted by the steam shovel during the next spring the box was recovered and a chemical analysis of it was made. These boxes were exposed to the regular influences of frost, snow, rain and air which acted on the bank as a whole for periods varying from two and a half to five months.

The results are set forth in Tables VII and VIII.

If the analyses of the samples of the different boxes are averaged and compared with that of the original sample in both tests, the results shown in Table IX are obtained.

A test of longer duration was run on a sample of Acadia coal from the Pictou area. A sample of freshly mined run-of-mine coal was taken from a carload shipped to Halifax and four boxes were buried in the stock pile at the Round House of the Canadian National Railways on the outskirts of the city. They remained there out of doors under the influences of the weather for two years and two months before they were lifted, sampled and analyzed. (See Table X.)

The indications are clear that the chemical composition of these Nova Scotian coals is altered to only a slight degree by exposure to the weather for those periods for which it is ordinarily necessary to bank it at the mine or in the yard of the consumer. The weathering improved the quality of the fuel somewhat, because some of the pyrite was oxidized to reduce the sulphur content and the calorific power is slightly increased because of the greater percentage of fixed carbon.

Summary

The purpose of the investigation was to secure scientific data on the characteristics and qualities of the coals that are being mined and distributed from Nova Scotia at the present time. These should be of definite value to the consumers in the province, but especially to those in Ontario and Quebec where there is a large variety of fuels available for power and heating purposes.

Table X

| | Analysis original sample | Average analysis weathered sample |
|---|---|---|
| Moisture......................per cent | 3.0 | 2.7 |
| Volatile matter..................per cent | 29.8 | 28.1 |
| Fixed carbon....................per cent | 53.9 | 56.0 |
| Ash...........................per cent | 13.3 | 13.4 |
| Sulphur.......................per cent | 1.25 | 1.09 |
| Calorific power.............B.t.u. per lb. | 12,170 | 12,230 |

Chemical analyses were made of both channel and large scale samples taken from the advanced working faces in all the important producing mines and these results may be taken as indicative of the composition of shipments at the present time. The proximate analysis, ultimate analysis, calorific power, and the temperature of fusion of the ash of each coal that is shipped to central Canada in any considerable quantity have been made available for reference.

Trials were run on a number of fuels which are commonly used in domestic hot-water boilers for house-heating and the results show that coke prepared from Nova Scotian coal will give satisfaction and efficiency equal to the results secured from imported anthracites. If cost is an important factor with the householder he can save money by using the fuel that is produced from the local soft coals.

Standard boiler trials were run on all the coals in an ordinary horizontal return-tubular boiler fired by hand and run at both normal and forced rating. The results are given in a sequence of comparative efficiencies, but this order might be considerably altered in other types of boilers run under other conditions. The cost of the fuel is an all-important factor in steam generation and this varies widely according to the geographical position of the place where the coal is consumed.

Tests were made on the effects of weather on Nova Scotian coals that must be banked for a few months while the St. Lawrence river is frozen up. These show that the coal under these conditions does not deteriorate in its composition to any great extent and the small change that does take place is in the direction of improving the quality.

The data are presented for the use of the combustion engineer or the industrial manager in making plans for new steam-power plants, additions or changes to present plants, or for the adaptation of special mechanical boiler-room apparatus in that part of Canada where Nova Scotian fuels are available. This is a time when many changes and additions to steam generating plants are being planned and contemplated and it is important from a provincial and national standpoint that Nova Scotian fuels should have the most thorough consideration wherever they might be used. Technical and scientific data of all kinds are accessible regarding all the American coals which are brought into Ontario in such large quantities. The results of the tests on those produced from the deposits on the Canadian Atlantic seaboard should serve as reliable basis of study for purchasing agents, engineers, and other consumers who are in a position to secure bituminous coal mined in Nova Scotia.

# An Economic Use for New Brunswick Coal

## The Grand Lake Plant, New Brunswick Electric Power Commission

*John Stephens, D.Sc., M.E.I.C.,*
*Professor of Mechanical Engineering, University of New Brunswick, Fredericton, N.B.*

**Paper presented at the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

**SUMMARY.—Deals with the successful use of a local slack coal, high in ash and moisture, in pulverized form in a modern steam plant of 12,500 kw. capacity. Five years' experience with furnace walls, air preheating, superheat, fans, mills and burners is described; tables of costs and operating results are given.**

The following facts and conclusions about efficiency and economy in the use of New Brunswick coal from the Minto field, are based on the design and performance of the steam plant of the New Brunswick Electric Power Commission at Grand Lake.

The Grand Lake, or as it is now called, the Minto Coal field, contains the oldest workings in America. Situated in the D'Amour Seigneury, and close to old Acadian settlements on navigable water, the deposit was discovered in 1620 and a shipment of coal was made to the Colony of Massachusetts Bay in 1628. In his diary, in 1665, Samuel Pepys expressed regret that France had been left in possession of the debatable ground of the St. John Valley as the "only coal in the North American Colonies is on the Great River of Acadia."

Notwithstanding its early development, the use of Minto coal extended slowly. The discovery of the great deposits of Nova Scotia and Pennsylvania and the natural provision by manufacturers of combustion equipment for these lower volatile and more uniform coals account for the neglect of the New Brunswick field. But since the completion of a railway to the mines about twenty-five years ago, the coal has found a much more extended use for railway and industrial purposes.

The plant of the New Brunswick Electric Power Commission at Grand Lake, however, affords the only example of the exclusive use of the lowest grades of slack coal from this area, on a comparatively large scale, and under modern conditions of rating and efficiency. It is hoped that the methods used and the results obtained may be of some interest, especially as concerning the only coal mined in Canada between Nova Scotia and Saskatchewan.

In 1928 it became evident to the New Brunswick Electric Power Commission that its hydraulic plant at Musquash would soon prove unable to supply the expanding needs of its customers and the future demands of industry. Consequently an estimate of the energy requirements up to 1937 was made and this has, luckily, proved to be substantially correct.

An investigation of the available hydraulic sites resulted in the conclusion that none was economically sound or even physically adequate. Thus the construction of a fuel plant became a necessary part of the Commission's programme and its engineers and consultant had to arrive at decisions on the following points:—

1. Fuel to be used and its cost per kw.h. at the load factors expected.
2. Location of plant with respect to fuel, water and point of delivery of energy.
3. Steam conditions justified by fuel cost and load factor.
4. Capital, sinking fund and maintenance costs implied by previous decisions.
5. Terms on which new contracts could be made, notably for the supply of Fredericton and of the factory of the Canadian Cotton Company at Marysville.

This list of interdependent factors had to be dealt with definitely, as the work could not be justified without the completion of long term contracts for the Fredericton district. That the estimates made at this time proved substantially correct is due rather to good fortune than to the possession of the gift of prophecy which every good engineer should have.

The accompanying map (Fig. 1) shows the districts served by the Commission and the location of the Grand Lake plant.

After a preliminary investigation lasting for over a year, it was decided to advise the Commission to construct a plant on the shore of Grand Lake, in the centre of the mining area and designed to burn the local slack coal in any of its various grades.

The advice then given that a plant could be built, with reasonable capital and maintenance charges, to generate a kw.h. with 2 pounds of wet slack, involved a decision which would inevitably determine the future usefulness of the Commission's work.

Methods of purchasing and continuous sampling and testing, as will appear, had to be devised at this stage. In fact, the major part of the engineering for the combustion side of the undertaking was done in this preliminary study.

The information kindly given by the engineers of the Nashwaak Pulp and Paper Company at this time was of vital importance. This company, from 1928 to 1930 used Minto coal in pulverized form at its mill at Fairville, N.B. It then suspended operation, at this location, but not for reasons of suitability or economy of fuel. The Combustion Engineering Corporation, of Montreal, who made the Nashwaak equipment, also supplied information of the greatest use.

The pioneer work done by and for these companies provided the Commission with data which otherwise could hardly have been acquired in time for its undertaking.

After the completion of these preliminary studies, and when the Commission had made the necessary financial arrangements, the initial development was proceeded with.

This first installation, completed in 1931, contains two 2,500-kw. Oerlikon generating units. These do not come within the scope of this paper and will not be referred to again, but it is fair to state that their efficiency and remarkable durability played an essential part in the economic success of the original scheme.

The addition, in 1936, of a 6,250-kw. Parsons turbine with a Combustion Engineering steam generating unit with Kidwell boiler, was made by the Commission's engineers and consultant. The building, piping, auxiliary lay-out and electrical work were the particular work of the Commission, while to the contractors for the turbine and steam generating unit belongs, rightly, the responsibility for design in their respective fields. They both fully met their performance guarantees.

Table I

Steam Generating Units

Steam condition—440 lb. per sq. in.—650 deg. F.
Vacuum 28.5 in. in summer
Vacuum 29 in. in winter
1931—Two 600-h.p. Kidwell boilers, each with two Foster-Wheeler mills and burners.
Combustion Engineering water walls and preheaters.
Capacity of each 62,000 lb. per hr.

1936—One 800-h.p. Kidwell boiler with three mills, boilers and water walls and preheaters.
Capacity 100,000 lb. per hr.

The actual peak capacity has now been found to be 12,500 kw. Boiler ratings of 325 per cent are maintained with slack coal containing 22 per cent ash and 8 per cent water.

### The Minto Coal Deposit

The Minto coal deposit, which is of unknown extent, occurs and is worked at depths from outcrop to 180 ft., the latter being about 40 ft. below sea level.

The seams are thin, averaging perhaps 20 in. A 5-in. seam is also present but is not worked. "Sulphur balls" which are extremely hard and cannot be crushed or pulverized are sometimes present. Slack coal, which generally means passage through a 5/8-in. screen, will absorb and hold up to 10 per cent water. Careful mining is required to prevent the accidental inclusion of bone which is contiguous to the coal but which will not burn. The ash fusion temperature is as low as 1,700 deg. F. in some instances.

Analyses similar to the following were available in great numbers and similar variety during the preliminary studies. It was also known, from experience in various industrial and heating plants, that the source of origin did not determine quality and that the percentages of water given by the authority quoted were inherent moisture and bore no relation to the water or ice, in slack from a wet working, shipped in an open car. It was known that slack could hold and retain up to 10 per cent water.

Table II
Typical Proximate Analyses*

| Origin | Per cent | | | | | B.t.u. per lb. | |
|---|---|---|---|---|---|---|---|
| | Water | Volatile | Carbon | Ash | Sulphur | (a) | (b) |
| A | 2.0 | 29.0 | 50.6 | 19.5 | 6.5 | 11,800 | ..... |
| B | 1.1 | 30.1 | 51.0 | 18.9 | ... | 12,000 | ..... |
| C | 1.3 | 30.5 | 51.4 | 18.1 | 11.3 | 12,100 | 11,830 |
| D | 1.1 | 32.3 | 54.0 | 13.7 | 6.3 | 12,800 | 13,030 |
| E | 0.7 | 29.8 | 48.8 | 23.4 | ... | 11,400 | ..... |
| F | 1.4 | 33.8 | 60.4 | 5.8 | 2.0 | 13,900 | 14,170 |

*All data are from the Department of Mines except B.t.u. (a) which are calculated.

Since, however, it was necessary to describe the coal to contractors who wished to submit proposals and yet not encourage design solely for extreme conditions, the following typical proximate analysis was given in the Commission's specification:—

| Water | Volatile | Carbon | Ash | B.t.u. approx. |
|---|---|---|---|---|
| 4 per cent | 32 | 48 | 16 | 12,000 |

Sulphur (separate determination) may be from 6 to 10 per cent, and the equipment must work (at less efficiency

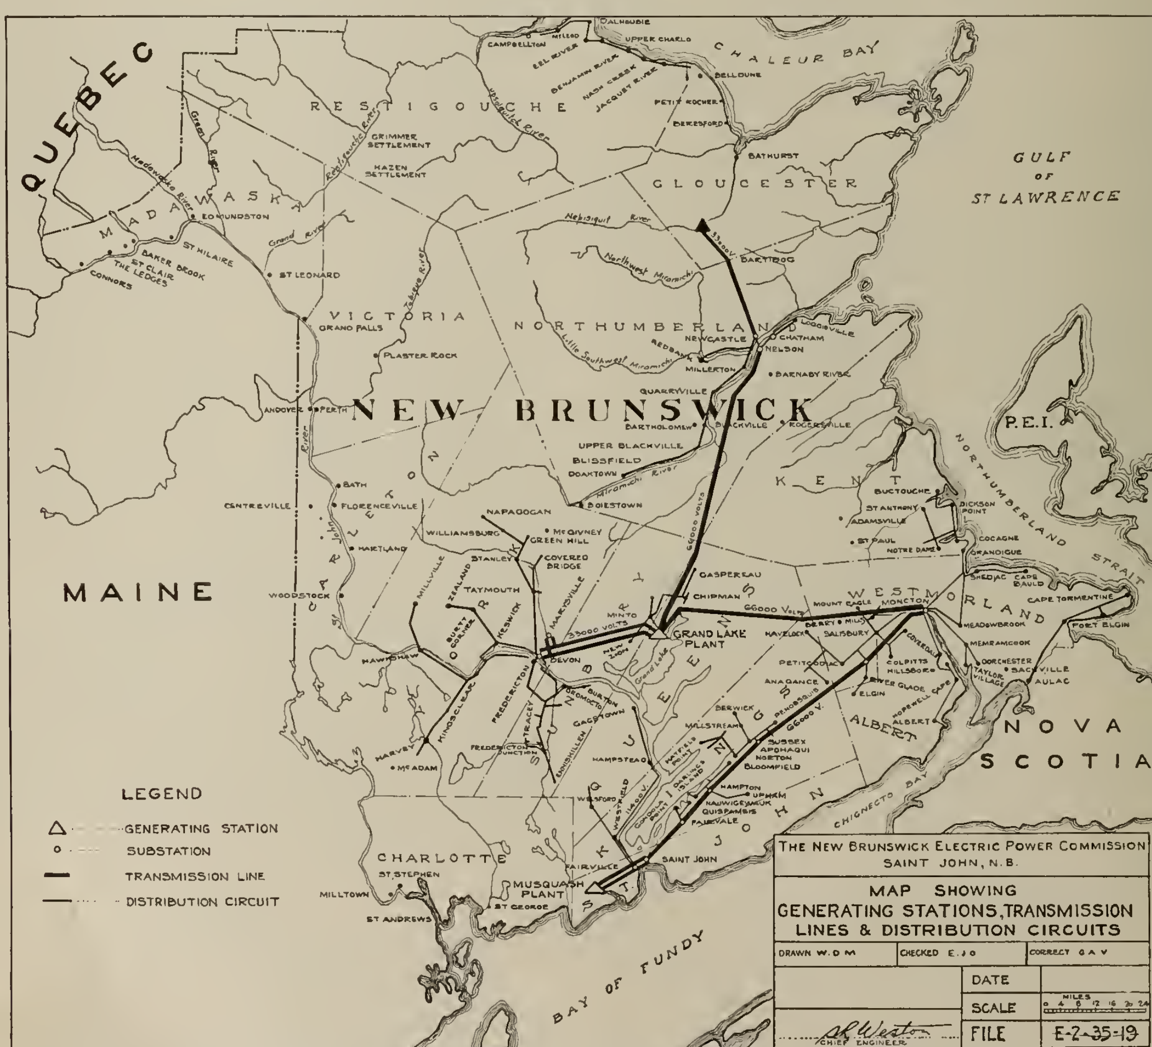

Fig. 1—District Served by New Brunswick Electric Power Commission.

of course) with a maximum of 8 per cent water and 24 per cent ash.

From the above, it may be understood that the problem is in no way similar to that of purchasing and using non-absorbent dry coal from a thick uniform seam. In fact it is hard to make engineers realize that a coal will absorb so much moisture.

One prospective contractor offered to design equipment if sent "a 30 pound sample of coal," another expressed the

**Fig. 2—Grand Lake Power Plant.**

opinion that "all Maritime coals are very much alike." These examples serve to show that there is need for knowledge of eastern coals among Canadian manufacturers.

### Sampling and Testing Coal

In buying this coal the most important measurement is the determination of water. Should 1,000 lb. of coal be taken as a sample and quartered in the usual way, the absorbed moisture is largely lost. Therefore it has been necessary to develop a method of sampling and testing which could be applied readily and cheaply, and which would meet the peculiar local conditions.

For sampling, twelve pieces of two inch pipe, each two feet long, are driven into the coal, six on each side of the car. The cores thus obtained are mixed as quickly as possible, and a sample weighing about 5 lb. is placed on a shallow tray and oven dried.

Frozen slack with 7 to 10 per cent ice still presents an unsolved problem.

Ash is determined in the usual way from a small ground sample. The Commission only pays for combustible.

The B.t.u. value is not determined at the plant. Experience of many years indicates that this determination requires the services of a very skilful and devoted laboratory worker. The four or five significant figures in which results of energy content are so often given indicate a general ignorance of the actual precision of this test.

As Minto coal, unless very high or very low in sulphur, contains approximately 15,000 B.t.u. per lb. of combustible, calorimeter tests seem superfluous except as an occasional check on the general character of the combustible.

The Commission was advised, in 1931, to buy on a percentage of combustible basis. The base price is paid for coal of 16 per cent ash, the average value for the area. A bonus is given for less and a penalty is exacted for more ash. The specification, which has been used successfully for the past six years, is omitted for the sake of brevity, but it is available to anyone who is interested.

### Quality of Coal Used at Grand Lake

The quality of coal actually in use can now be given from the experience of six years. For the year June 1st, 1932 to May 31st, 1933, the results are as follows, six independent mine operators supplying various quantities of coal.

Table III

| Operator | Tons | Average per cent combustible | Average per cent combustible for all operators | Deduction for quality under contract | Average cost per ton combustible including freight |
|---|---|---|---|---|---|
| A. | 6,568 | 80.87 | 82.2 | 8.6c. per ton | $4.03 |
| B. | 3,050 | 84.4 | | | or |
| C. | 3,426 | 81.5 | | | 74,000 |
| D. | 522 | 85.5 | | | B.t.u. |
| E. | 1,217 | 83.1 | | | for |
| F. | 1,048 | 82.2 | | | 1 cent |

During this year run of mine coal was used when slack was not available. The results naturally show the influence of a less absorbent form of coal. Also, the cost is somewhat higher than for all slack.

During the year ending October 31st, 1936, corresponding results from thirteen independent mine operators were:

Table IV

| Tons | Average per cent combustible for all operators | Deduction for quality under contract | Average cost per ton combustible including freight |
|---|---|---|---|
| 24,310 | 79.4<br>Max. 92.4 per cent (51 tons)<br>Min. 76.4 per cent (8,550 tons) | 20.05c. per ton | $3.64 or 82,000 B.t.u. for 1 cent |

This year, screening was practised on a larger scale and slack was available from more operators. Thus, the plant is fulfilling one of the reasons for its inception and is enabling the coal operators to sell slack for use in power production and dispose of screened sizes at a much higher price than formerly obtained for run of mine.

The quality of the coal actually burned has proved substantially the same as had been anticipated, thus there is no excuse for faulty design of combustion equipment. The mistakes made in the first installation were minor but will be indicated.

### Essential Factors in Design of Grand Lake Plant*

1. *Extent and Character of Furnace Water Wall Surface*

Experience at the Nashwaak plant indicated positively that slagging of the fusible ash occurred on all refractory surfaces near the flame, and notably on the front wall which was not water cooled. Thus it was determined to cool all four walls at the Grand Lake plant. A certain weight of opinion was advanced to the effect that this would cause extinction of the flame and danger of serious puffs. This idea has proved to be unfounded.

The fin tube type of water wall was adopted, and, whatever may be the merits of other walls, in this case it has proved successful. Where there are fin tubes there is no slagging. In the first installation, there is some exposed refractory on the front wall near the burners. This has slagged and required maintenance.

After five years experience, it was decided to cool the front wall as completely as possible. This has prevented slagging and the new unit may be left on the line indefinitely as far as combustion conditions are concerned. There has been no maintenance of fin walls.

*See Fig. 3.

The original value for energy release in relation to cooled furnace wall surface is 35,000 B.t.u. per hr. per sq. ft. This proved successful, and is the same in the new unit. The distribution of the surface, however, has been changed in the front wall design.

2. *Energy Release and Furnace Volume*

A low value for energy release (16,000 B.t.u. per cu. ft. per hr.) was used as a basis of design. This has proved satisfactory and has been adhered to in the new boiler. Indeed it is believed that no furnace or boiler has been operated yet to its limit, although all have produced more steam than promised in the contracts.

The effect of this low energy release on superheater design will be referred to. Otherwise, the large furnace volumes are only objectionable as they affect capital cost.

3. *Air Preheating*

Again, from the Nashwaak experience, as well as from obvious theoretical reasons, the need of ample air preheater capacity was recognized. The first installation has 3,960 sq. ft. surface for each unit, or 64 sq. ft. per 1,000 lb. of steam per hr. This has worked well. There is no visible depreciation in five years. The corrugated plate surfaces remain clean and an air temperature of about 340 deg. F. is maintained at all loads.

But, from extreme conditions of wet coal, it was decided to try to get a higher air temperature in the new plant. Consequently, the new preheater has a surface of 10,900 sq. ft. or about 110 sq. ft. per 1,000 lb. of steam. An air temperature of about 420 to 450 deg. F. is maintained and it is believed that this increase has been justified by results. It represents a maximum however, as no risk must be run of approaching the dew point in the steel stack. The formation of sulphuric acid from the high sulphur content of the fuel would cause destructive corrosion. For this reason, also, the omission of an economizer may be necessary.

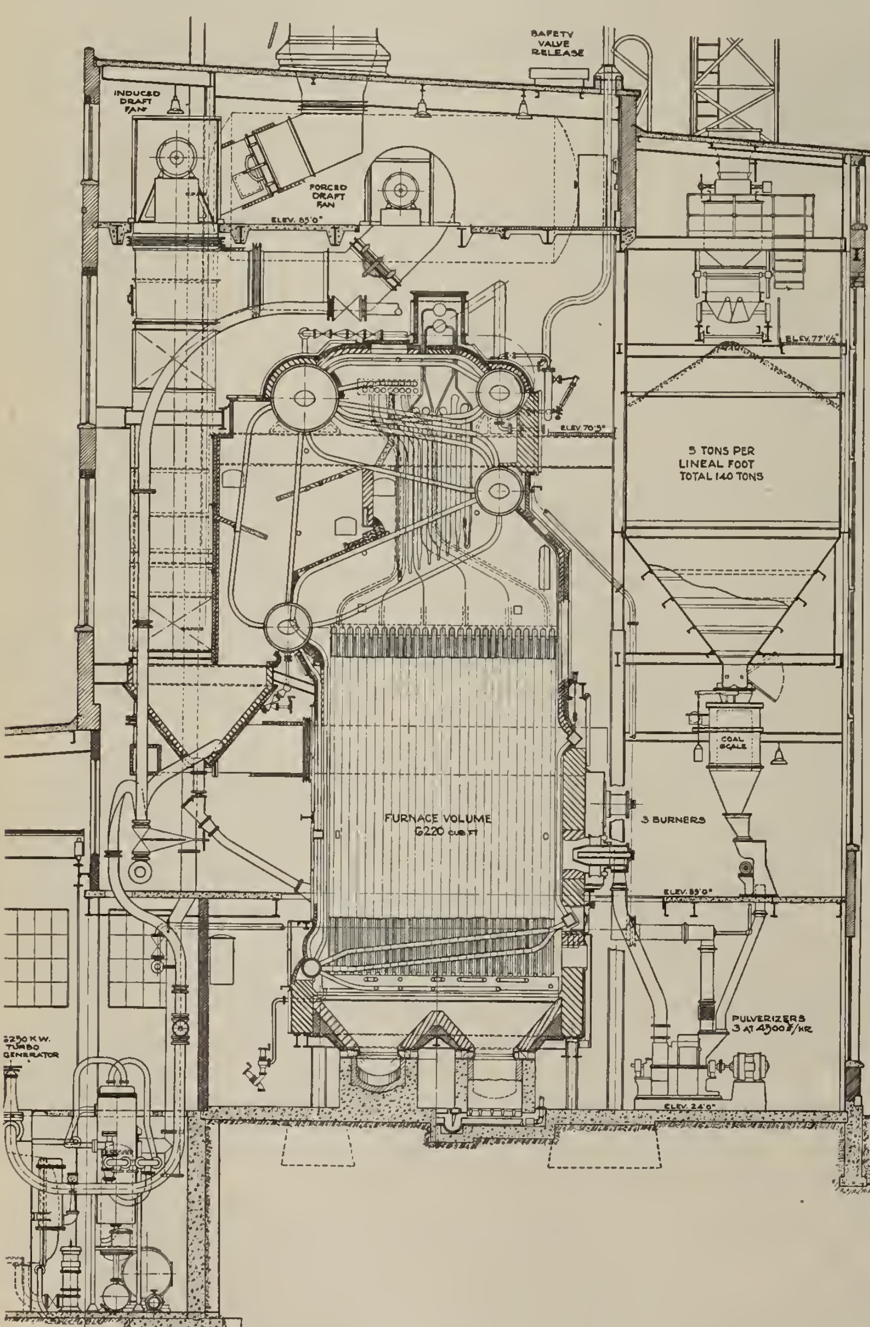

Fig. 3—Cross Section Showing General Arrangement, No. 3 Boiler.

4. *Superheat*

The large furnace volume in the original boilers and the consequent low temperatures in the first tube bank produced the superheat condition illustrated in the accompanying performance chart (see Fig. 4). This condition was afterwards improved somewhat, but persists still in kind, if not in degree.

Therefore it was determined to have enough surface to ensure 200 deg. superheat. The new unit, although the largest which could be used, has failed to realize expectations. While it is satisfactory, its performance shows that high temperatures cannot be obtained by this type of superheater with a Kidwell boiler. It appears that the superheater at about 650 deg. F. radiates back to the first bank tubes at about 450 deg. F. This is pointed out as a warning to other users of large furnace volumes.

No solution of the problem is offered here as, if one were known it would have been applied at Grand Lake. It was claimed that fin wall slagging would improve superheat. Slagging has not occurred.

5. *Fans*

Owing to the large percentage of fly ash, rapid erosion of the induced draft fans was expected. This has not occurred. Rotors last nearly two years and are then successfully repaired by building up with electric welding.

In the first installation, constant speed fan drive was adopted. This was a mistake. Auxiliary power was excessive and damper erosion occurred very rapidly. The old fan units have now been fitted with variable speed hydraulic couplings and these were included in the new specifications. This method has given much better draft control and a marked economy in auxiliary power.

It is believed however that all fans are too large, even for extreme conditions, with what once was erroneously believed to be a difficult coal.

6. *Mills and Burners*

Impact mills were advised on account of the wet coal condition. The first boilers had each two mills and burners made by the Foster Wheeler Company of Montreal. These have worked satisfactorily to date. The power requirement is in excess of that of the new mills, but the grinding appears to be finer. Plugging with wet coal occurs with a lower percentage of moisture than with the new mills. This, no doubt, is influenced by the smaller preheaters. The original burners required modification during preliminary operation and water cooling had to be employed. One water jacket has been repaired in six years operation.

The new mills and burners, of which there are three, were made by the Combustion Engineering Corporation, of Montreal. Operation was successful from the first run, power requirements have been reduced and water cooling is not employed.

Mill maintenance is easy, but, where loads are not under the control of the management, the frequent necessity of taking a mill off to change hammers creates some anxiety. So far, however, these changes have been made without difficulty.

It is believed that the use of three burners and the increased space for flame travel are good features in the new unit. The mills have handled coal up to 9.6 per cent moisture in an emergency and the boiler has operated at loads of from 10 to 110 per cent of its contract capacity.

In connection with the subject of mills and burners, it may be of interest to note that no interruption of service has occurred in connection with fuel preparation and combustion, since 1931, except in one instance when wet coal plugged a spout.

Table V-Typical Results of Mill Operation

| | 9.30 to 11.30 Oct. 26 | 2.30 to 3.30 Oct. 27 | 10.00 to 11.00 Oct. 27 | 9.00 to 10.00 Oct. 28 |
|---|---|---|---|---|
| **Mill 3A** | | | | |
| Feed | 7.39 | 5.56 | 5.17 | 5.20 |
| Amperes | 45. | 38.5 | 29.2 | 30. |
| Coal......lb. per hr. | 8,400 | 3,800 | 3,400 | 3,400 |
| Pri. air | 5.9 | 5.76 | 6.56 | 6.4 |
| Sec. air | 1.9 | 2.4 | 1.96 | 1.5 |
| Temp. to mill | 220 | 274 | 180 | 201 |
| Temp. from mill | 140 | 161 | 149 | 140 |
| **Mill 3B** | | | | |
| Feed | | 6.52 | 4.70 | 5.25 |
| Amperes | | 56. | 42.6 | 44. |
| Coal......lb. per hr. | | 3,800 | 2,800 | 3,200 |
| Pri. air | | 5.62 | 7.0 | 6.12 |
| Sec. air | | 1.84 | 2.0 | 1.5 |
| Temp. to mill | | 169 | 160 | 162 |
| Temp. from mill | | 147 | 143 | 146 |
| **Mill 3C** | | | | |
| Feed | 6.72 | 6.20 | 5.98 | 5.2 |
| Amperes | 44. | 43.5 | 43.5 | 38. |
| Coal......lb. per hr. | 8,000 | 3,800 | 4,700 | 4,000 |
| Pri. air | 5.92 | 5.6 | 6.84 | 6.76 |
| Sec. air | 1.7 | 1.76 | 1.96 | .8 |
| Temp. to mill | 209 | 224 | 208 | 175 |
| Temp. from mill | 139 | 145 | 142 | 146 |
| Steam flow...lb. per hr. | 64,000 | 90,000 | 93,000 | 93,000 |

Coal samples were taken from mills 3B and 3C at 10.00 a.m. on October 27th in order to get a comparison of the grinding obtained when using twelve hammers and sixteen hammers. At this time mill 3B had been running approximately thirty-four hours and mill 5C approximately forty hours. The following results were obtained:—

Table VI

| | Mill 3B | Mill 3C |
|---|---|---|
| Through 48 mesh | 98.4 per cent | 94.3 per cent |
| Through 100 mesh | 94.0 per cent | 83.9 per cent |
| Through 200 mesh | 88.2 per cent | 73.3 per cent |

The above results are not necessarily examples of good operation. The runs were made to determine doubtful points about operation and to determine mill power and performance.

7. *Explosion Doors*

Only one puff, so far, has occurred which could be the cause of any alarm. It was caused by a mistake made during preliminary operation in 1931. No damage was done.

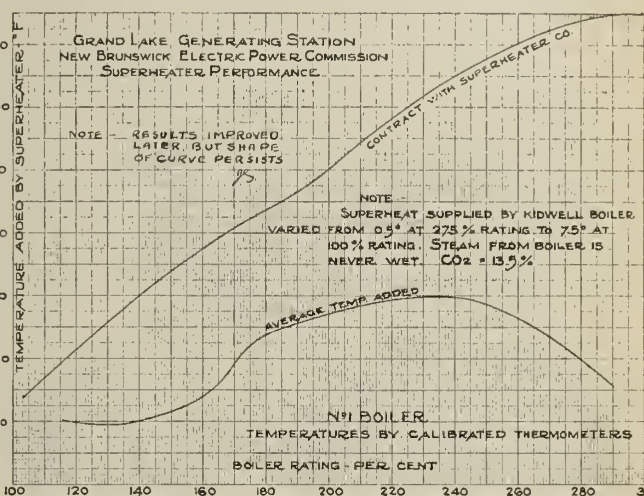

**Fig. 4—Superheater Performance, Grand Lake Generating Station.**

Nevertheless, in the new unit, a change was made from the conventional door to simple pot lids. These are believed to exclude air better. The complete steel casing is also a change which has improved operation.

8. *Ash removal*

The staggered water screen at 14-inch centres in the initial plant has been embodied in the new. Ash removal presents no difficulty and no manual work is required.

9. *Soot blowing*

The large percentage of fly ash keeps the surfaces clean. Blowing is done with a pressure of 100 lb. per sq. in. Very little blowing is effective. Although abrasion keeps the surfaces clean it is not apparent that erosion occurs.

Plant Performance

The tabulations of performance and cost which appear in the Appendices are based on routine operation over long periods. Coal is weighed by scales which are correct to at least three figures.

Steam flow is measured by Bailey meters but, with the new unit, the flow values have been checked by a 2-in. orifice, calibrated by direct weighing, on the condensate. Flow values are correct to two and one half significant figures.

No numerical reference is made to the somewhat cryptic term "boiler efficiency." The author does not understand it, and, even were this not so, operation with variable coal, mixed in a bunker, would make values misleading on any basis.

Capital overheads are computed on the cost of the whole plant and will diminish. The first installation required the purchase of land, the construction of a railroad, the provision of circulating water canals and many items of permanent value. The new installation cost $74 per kw. of peak capacity. This includes building, coal handling and every physical item, ready to run. It also includes organization, preliminary operation, engineering and every indirect overhead which can be found.

Of the cost of the new unit, the steam generator, complete with mills and burners and all auxiliaries connected with combustion cost $20 per kw. Material and supervision were supplied by the contractor, labour by the Commission.

Interest, sinking fund and maintenance is allowed for at a total of 9 per cent. This leaves provision for a maintenance reserve well over actual costs so far. The other cost items, are it is hoped, self explanatory.

The Commission designed and constructed everything except items directly a part of the boiler and turbine contracts.

### Conclusion

Fuel preparation costs about 23c with the old and 21c with the new equipment. Auxiliary power has been reduced from about 9 to about 5.5 per cent.

It will be noted, in the cumulative tabulation for 1935, before the operation of the new plant, that with 39.1 per cent load factor, 2 lb. of coal were used per kw.h. This is a fortunate agreement with the estimate of 1930.

A comparative value of 1.53 lb. was attained in October 1936. This improvement is rather due to better load factor, lower auxiliary power and better heater and evaporator layout than to any want of specific efficiency in the old main units. Although it is hoped that this paper is free from matter not pertinent to the use of a particular coal, it should be stated that the new 6,250-kw. unit with its condenser, heaters and evaporator contributes materially to the result and has shown economy better than contract figures.

After six years experience, it has been found that the use of New Brunswick coal, in a centrally located plant, is justified.

From no other source can energy in the form of prepared coal be obtained so cheaply within reach of the Commission's customers. It is felt that there may be other power users, so geographically placed that this may be of interest.

In the preparation of the above, the writer is indebted to S. R. Weston, M.E.I.C., chief engineer of the New Brunswick Electric Power Commission, and his staff.

### Appendix I

Grand Lake Generating Station

Operating summary for the month of October, 1936

| | October 1936 | October 1935 | Cumulative 1936 | Cumulative 1935 |

# The Use and Production of Coke in Canada

*D. G. Munroe,*
*Vice-President and Managing Director, Montreal Coke & Manufacturing Company, Montreal.*

**Paper presented at the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

SUMMARY.—Sketching the earlier situation as regards gas-coke production in Canada, particularly for domestic use, the author describes the measures taken by the Dominion Government to encourage the use of Canadian coals in the manufacture of by-product coke, and explains the nature of the competition which Canadian producers have to meet.

The first use of coke in Canada was coincident with the establishment of artificial gas plants in the older and larger cities in eastern Canada. This coke was called "gas-house" or "retort" coke. Little attention was paid to its quality by the makers, who considered it to be a residue, a by-product, in the manufacture of coal gas. It was sold in territories adjacent to the point of manufacture for whatever price it would bring. Wood was then the principal fuel used for domestic heating. Later, wood was largely supplanted in the cities and towns of Ontario, Quebec and New Brunswick by American anthracite coal. "Gas-house" or "retort" coke, strictly limited in quantity as it was by the amount of gas manufactured, remained a very minor factor in national fuel economy. It was not suitable for metallurgical purposes.

### Coke for Metallurgical Use

As the metallurgical industry developed, first in the melting of metals for foundry purposes, and later for the smelting of ores in Ontario, Nova Scotia and British Columbia, coke was imported, especially into Ontario, from the United States. No other source of supply was available.

The first by-product coke ovens in Canada were built primarily to produce metallurgical coke. Those at Sydney, N.S., and those at Anyox, B.C. (the latter now shut down), used local bituminous coals. Those constructed at Sault Ste. Marie, Ont., for the Algoma Steel Corporation and at Hamilton, Ont., for the Steel Company of Canada, naturally use American bituminous coal on account of their geographical location. The gas produced by these coke-ovens is used almost exclusively by the metallurgical companies themselves; but in their operations gas is not a necessity. It is only a useful convenience or by-product. Hence the use-value to them is that of coal or other fuel which would be consumed if no gas were available. The coke too small for metallurgical use formerly was largely used for steam generation. Only a very small quantity was sold for domestic heating.

### Coke for Domestic Use

The first use of coke as domestic fuel, aside from the small quantities produced by the gas companies, was in Ontario. It was introduced by owners of by-product coke-ovens in Detroit.

Good by-product coke has practically the same qualities as the very best grades of American anthracite. It is cheaper and it is a satisfactory substitute for anthracite which by 1900, in cities at least, had come to be considered almost a necessity.

In ensuing years the quality of anthracite steadily became worse. Actual shortages occurred from time to time due to labour disputes in the mining regions of northeast Pennsylvania, then the only available source of supply. Several times there was even danger of an embargo on the export of anthracite from the United States to Canada. In 1923, the Pennsylvania anthracite reserves were estimated at thirty-six years' consumption. Anthracite prices became much higher.

About this time the Dominion Government took cognizance of the serious situation and of the resulting hardship in the "acute fuel area." It made thorough investigations which resulted in the conclusions that the situation could be improved, even if not wholly cured, by a more widespread use of coke as a substitute for anthracite, and that the coke should be made in Canada, preferably from Canadian bituminous coal, but even if the coal had to be imported, the coke should be made in Canada.

The demand for coke in Ontario was growing rapidly. It could not be met by Canadian steel and gas companies and so, naturally, extensive imports were made. They originated in American points of production on or near Lake Erie, where large supplies had become available —thanks to the rapid expansion of the American by-product coke industry. This condition and the known attitude of the Government led to the formation of the Hamilton By-Product Coke Ovens Limited, which in 1924 put into operation at Hamilton, Ontario, the first merchant by-product coke plant in Canada, i.e., one not owned by a company using most or all of the coke and gas made, in its own metallugical operations. It had to depend for its coke market on domestic and industrial (other than metallurgical) consumers, and it had to sell its surplus gas, some 35 to 40 per cent of the total evolved by coal in the coking process. The gas was bought by the local gas company which mixed it with natural gas for distribution in and about Hamilton.

It is most important to understand this dual necessity, which is the fundamental commercial difference between *merchant* by-product coke-oven plants and those owned by metallurgical companies. The steel companies themselves consume most or all of the two principal products, coke and surplus gas. The merchant plant cannot be established or, if established, cannot continue to exist without the sale of both coke and gas to others.

The Government was greatly interested in this undertaking and took measures to aid its success, in the hope that others would be encouraged to established similar plants elsewhere in Canada.

As a result the Hamilton By-Product Coke Ovens Limited doubled its plant in 1926; a by-product recovery coke-oven plant was completed in 1924 by the Winnipeg Electric Company in Winnipeg and in 1928 a much larger one, having a capacity of 400,000 tons of coke per year, was constructed just outside the city of Montreal by the Montreal Coke & Manufacturing Company. These plants were built in conformity with the publicly expressed policy of the Dominion Government. They are fulfilling the purposes for which they were constructed and are valuable assets to the country.

The steel companies having by-product coke-ovens also aided materially in providing additional domestic coke supplies by operating their coke plants at rates often far greater than would have sufficed for their own metallurgical coke needs, and by altering and increasing their coke screening equipment so as to be able to make as much domestic coke as possible.

Some gas companies also did their utmost to increase domestic coke supplies—the British Columbia Electric Power and Gas Co. Ltd., by building a by-product recovery coke-oven plant in Vancouver in 1931; the Quebec Power Company, a new coal gas plant in Quebec in 1929; the Nova Scotia Light and Power Company of Halifax, a new coal gas plant in 1927; and the Ottawa Gas Company by converting their already installed retort equipment into coke-ovens.

## THE USE OF CANADIAN COAL FOR DOMESTIC COKE PRODUCTION

### Objects of Fuel Investigations

The Dominion Government investigations above referred to had two aims, viz., to free Canada from dependence on Pennsylvania anthracite and to find substitutes for it, if possible of Canadian origin.

### Possibilities

There were only three possibilities which gave any hope of fulfilling both objects. These were:—

- Utilization of peat and/or lignite;
- Production of coke from Canadian coal by low temperature distillation;
- Production of coke from Canadian coal by the by-product recovery coke-oven process.

There is no need to say more about the first two than that they were thoroughly investigated and found impracticable under present Canadian conditions.

The third seemed to offer greater promise. Coke made in by-product recovery coke-ovens from 100 per cent Canadian coal was being used in a small way in some areas in the country. Large reserves of coking coals occur in Canada, though unfortunately principally far from the principal centres of population. It was thought that under the circumstances of national necessity existing in the period between the close of the war and 1925 these difficulties might be overcome with financial and other assistance from the Dominion.

### The First Duncan Report

These ideas are well summarized in the report of the first Duncan Commission dated January 8th, 1926, "Report of the Royal Commission Respecting Coal Mines of Nova Scotia," 1925, Halifax (pp. 57, 58 and 59).

The Commission, which was considering the situation principally from the standpoint of increasing Maritime coal production, took a very optimistic view of the potentialities. Its conclusions follow closely those contained in Publication No. 5 of the Dominion Fuel Board—"Coke as a Household Fuel in Central Canada," Ottawa, 1925 (pp. 136-138). These tentative plans contemplated the construction of seven coke plants. They were to be located in Quebec, Montreal, Ottawa, Toronto, Hamilton, Port Colborne and London. Their potential consumption of Canadian coal was estimated at 1,904,000 tons per year with a resulting production of 1,376,000 tons of domestic coke. As the necessary coal was thought to be available from existing mines in Cape Breton, the Commission recommended that the provincial government should enter into active co-operation with the Dominion Fuel Board further to explore the possibilities of immediate development.

### The Domestic Fuel Act

As a result of these recommendations and of similar related efforts, the Dominion Government passed the Domestic Fuel Act—17 George V, Chapter 52, which received assent April 14th, 1927.

The Act provided for the payment, under certain conditions, of subsidies based on the capital cost of the works, to private companies or to municipalities and other public corporations erecting carbonizing plants to make domestic coke. In order to receive the subsidy, the carbonizing equipment had to be so constructed that 70 per cent of Canadian mined coal could be used. The subsidy might extend to a term of fifteen years. Advantage of it was not to be taken after June 30th, 1932.

### Results of Domestic Fuel Act

The results of this legislation were far from what had been hoped. So far as eastern Canada is concerned, two small plants were built under it—one at Halifax, N.S., and one at Quebec City, between them using only some 35,000 tons of Canadian coal, instead of seven plants using 1,904,000 tons.

In 1928 the plant of the Montreal Coke & Manufacturing Company with a capacity of over 500,000 tons of coal was completed. This company did not make application to benefit under the Act although the subsidy it could have received would have been around $225,000 per year. Obviously the conclusion that the conditions for receiving the subsidy could not successfully be met, was reached only after mature and careful consideration.

One other undertaking qualified for and is receiving the subsidy, viz., that of the British Columbia Electric Power and Gas Company, Ltd., in 1931 in Vancouver. This, of course, had no bearing on the situation in the "acute fuel area," Ontario and Quebec.

### Why the Domestic Fuel Act Fell Short of its Objective

There was great disappointment, specially in Nova Scotia, that the results of the Act came so far short of what had been anticipated. Much agitation arose for the enactment of compulsory or punitive measures. There were even accusations of deliberate unwillingness on the part of potential or already established manufacturers to use Nova Scotia coal for coke making. All this, however, came from lack of knowledge of the severity of competition in quality as well as in price among the various kinds of domestic fuels, which has to be met by coke makers, and from the faulty premise that any kind of coal that cokes will make a fuel satisfactory to all householders.

### Satisfactory Coals for Domestic Coke Manufacture

Beside the property of coking, there are three other essential qualities coal must have to make it available as the raw material for domestic coke:

- It must be of the proper quality to produce the desired kind of coke;
- It must store in quantity for long periods without damage from heating;
- It must be purchasable at a price which will permit the manufacture of coke at a cost which makes successful competition with other fuels possible.

### Efforts to Get Satisfactory Coal in Nova Scotia

The Nova Scotia coal available at the time of the passage of the Domestic Fuel Act filled none of these three requirements so far as the Montreal Coke & Manufacturing Company was concerned. This is the reason no attempt was made to take advantage of the Domestic Fuel Act. This Company had confirmed by large scale practical experiments in 1930—part of the cost of which was defrayed by the Dominion Government—its previous conclusions on the subject. However, it continued to try to find some way which would permit the purchase of at least a substantial part of its coal requirements in Nova Scotia. It shared actively in the attempts of the Dominion Coal Company, aided by the Technical Staff of the Division of Fuels, Department of Mines, to effect a satisfactory solution of the problems of quality and storage. Without this, no price—no matter how low—could be attractive.

### Technical Success

These experiments were eventually successful. By special methods the Dominion Coal Company was able to prepare from certain mines coal of such a quality that at least 35 per cent of it could be used with mixtures of other coals to produce the desired quality of coke. The storage of this specially prepared coal was also satisfactory. Its utilization then became a matter of cost.

### Employment Given by the By-Product Coke Industry in Canada

In 1934, the Montreal Coke & Manufacturing Company produced 393,000 tons of coke, about one-sixth of the Canadian total. In this year its total disbursements for Canadian labour and materials were $2,672,000.

Its payrolls were $500,000. This sum is equivalent to approximately one million man hours or 125,000 man days of labour. Taking three hundred working days per man per year, direct employment was given to 417 persons.

This is by no means the total Canadian labour to be considered. In 1934 the company used 185,000 tons of Canadian coal which had it not been for its operations would not have been mined. Taking the approximate output per man per day in Nova Scotia mines at two tons, 92,500 man days of employment resulted. At two hundred and thirty working days at the mines in 1934, employment for 400 men resulted.

Twelve Canadian owned and Canadian operated vessels each having a crew of twenty-one men were employed to carry the coal used by the Montreal Coke & Manufacturing Company from Nova Scotia and from ports of Lake Erie and Lake Ontario to its plant at Ville Lasalle, P.Q. Therefore, in the direct operation of the boats 252 men were employed for the season of navigation.

The total of these three items is 1,069 men. Assuming that the remainder of the expenditures made up of smaller items gave as much employment per dollar as those just cited, the Montreal Coke & Manufacturing Company in all, directly and indirectly, gave employment to about 1,540 men in Canada. If the other five-sixths of the coke industry in Canada employed labour in the same ratio, the total for the industry would be around 9,000 persons.

## THE NATURE OF COKE COMPETITION IN CANADA

Sellers of coke, whether it be of Canadian or foreign origin, under ordinary circumstances naturally try to sell it for its value.

The market value of coke is governed by the selling price of competitive fuels. In the populous sections of Central and Eastern Canada the determining fuel has been anthracite coal. Formerly American anthracite was decisive but now foreign anthracite also has weight.

### How Coke Prices Are Established

The Canadian coke producer in deciding upon the price to ask for his product first considers the price of anthracite and makes up his mind how much less he must quote in order to do business. When the coke is to be sold at a distance from the point of production he deducts from this amount the cost of transportation and other expenses incident to moving the coke from his plant to the point to which it is to be shipped. The remainder is all that he can receive. If it is too low to be attractive he names a higher price and resigns himself to the possibility of not doing business at the point in question.

This is a normal economic way of arriving at prices. Insinuations and statements that Canadian manufacturers of coke are charging outrageous prices are without foundation. To sell an article for its value is not extortion nor profiteering. The consuming public has ample and automatic protection against exploitation in the price of coke because there are everywhere several other fuels available if too high a price is asked for coke.

Since coke cannot be manufactured at every point where it is consumed, all producers take different prices when the cost of transportation to the point of consumption is different. Generally, the greater the distance from the point of production the less the manufacturer gets for his coke. The market nearest the point of production is almost always the most important and most profitable. Remote markets are desirable only when production exceeds local demand.

### Importations of European Coke

Competition of any consequence due to the importation of European coke first occurred in 1931 when Great Britain abandoned the gold standard and the pound sterling fell to as low as $3.70. British coke manufacturers were quick to see the possibilities and looked eagerly to St. Lawrence ports as an outlet. Montreal was particularly attractive because of its size and because a well established coke trade already was in existence. Indeed several cargoes of English coke were put into Montreal at prices Canadian manufacturers could not meet permanently. The extent and the duration of this menace were not known, so one Canadian coke maker actually decreased its operations to about 60 per cent of its capacity. British coke was duty free, as it is now. Had there been a duty of $1 per ton, coke manufacture in Montreal and Canadian enterprises serving it would have proceeded at a normal rate.

There is at present increasing actual competition and vastly greater potential competition from Continental Europe. This is coming to some extent from Poland and Belgium, but more especially from Germany. It is non-economic in the sense that it is not made possible by cheaper production, but is the result of the dire need these countries have for foreign exchange with which to purchase goods they are unable to produce or to find substitutes for at home.

The prices of exports from these countries have simply nothing to do with costs of production or internal prices, nor with the motive of profit on which all trade is ordinarily based. Losses on such sales are not borne by individual industries or manufacturers, but are spread over the whole national economic structure because they are incurred as a national necessity. The extent to which this condition can develop is well shown by the London dispatch appearing in the "Montreal Standard" of November 22nd, 1936, which reads as follows:—

> "London, Nov. 21—On the Thames wharves first consignments of 100,000 tons of foreign coke are waiting to be unloaded.
>
> In the mining districts of South Wales, Scotland, and Durham, miners and coke-oven workers have just been told that there is no work for them.
>
> To produce this 100,000 tons of coke at home would employ 330 British miners and 330 subsidiary workers. In other words, this cargo in the Thames throws 660 men idle.
>
> Counter plans have been laid by the coal owners and distributors to stop this foreign coke buying. Representations are being made to the Minister of Mines and the subject will be raised in Parliament.
>
> It is stated that no justification can possibly exist for importing a single cargo of coke while thousands of British miners are still without work, and while sufficient supplies of suitable fuel are easily available."

Such occurrences are bound to impress us forcibly that private manufacturers, who are necessarily in business to make profits, have no chance whatever to compete with the whole resources of a foreign government which has real or fancied national needs as a price mover. Consequently, it is for those who direct and formulate national policies to decide what measures to take in face of conditions which have been almost unknown up to the present time.

Conclusions

The studies on which the foregoing is based lead to the following definite conclusions:—

1. The governmental policy designed to free the "acute fuel area" from almost complete dependence on Pennsylvania anthracite is sound.
2. The governmental policy of encouraging the establishment of by-product recovery coke-oven plants to aid in attaining this end has been well justified.
3. The by-product recovery coke-oven industry is a distinct national asset because of its domestic fuel production, because of its direct and indirect employment of Canadian labour and because of its consumption of Canadian raw and finished materials, especially of Canadian mined coal.
4. The sympathetic attitude of the government toward this industry ought to be continued.

---

# Some Observations on the Use of Bituminous Coal as Locomotive Fuel

*John Roberts,*
*Chief of Motive Power, Canadian National Railways, Montreal.*

**Paper presented before the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

SUMMARY.—A brief account of the conditions of combustion in locomotive boilers and the method of selecting coal for locomotive use.

The purchasing, distribution and economical consumption of coal on any large railway system presents a vast and complex problem. Its vital importance may be gauged from the fact that the total coal bill for the Canadian National system—all inclusive—for the year 1936, amounted to over $18,000,000, and this figure does not include the cost of "on company's service" haul.

While there is an abundance of coal within the Canadian borders, nature unfortunately located the coalfields in the extreme east and extreme west, leaving the central provinces with no domestic source of supply. The Canadian National policy has been to extend the use of domestic coal to the economic limit and Maritime Province coal is being used from the Atlantic coast to Toronto and Cochrane, and western Canadian coal from the Pacific coast to Winnipeg and sometimes even farther east.

The quality of coal obtained from the different seams varies through a very wide range. There are coals rating about 14,500 B.t.u., 37 per cent volatile, less than 4 per cent ash and between 1 and 1½ per cent sulphur, which compare favourably as locomotive fuel with the best on the continent, and from this peak they vary all the way down the scale to a quality which we would much prefer to leave underground until someone happens to need it.

In order to distribute the various grades of coal from the mines to the points of consumption in such a manner as to give the best results, close co-operation between the mechanical department and the fuel department of the railway is essential, and a great deal of study has been given to this phase of the question by both departments during the past fifteen years. By means of evaporation tests under service conditions the mechanical department have rated the relative fuel value of every grade of coal used for firing locomotives, from coast to coast. In the first place a very good grade of coal was selected, tested and given an arbitrary rating of 100 per cent. As the other grades were tested the results were compared with the 100 per cent test and a separate fuel value rating given to the coal from each mine contributing to the railway's requirements. The quality of coal from any mine is liable to vary over a period of years and, when any change is noticed or suspected, check tests are made and the rating varied, if necessary, to keep all rated comparative values in line with present day quality.

One of the principal functions of the fuel department is to select the right coal for each terminal, and having all coal test reports and ratings at their disposal is of great assistance in making the best selection. In the first place the grade of coal selected must be suitable for the class of service required and, assuming this condition as having been met, the next consideration is economy. At terminals which are located at a considerable distance from the source of supply, the cost of haulage is a large percentage of the final cost of the coal loaded on the tender. Speaking in a general way then, the problem of the fuel department is to take into consideration the pit-head cost, the hauling and handling cost and the percentage rating of the fuel, and then supply a coal suitable for the class of service required, and which will give the maximum number of pounds of steam per dollar of expenditure.

The burning of different qualities of coal, with widely varying characteristics, in locomotive service, presents an almost unlimited array of problems, and these difficulties have to be overcome without interruption of service. Some coals will clinker the grates, some will build up ash at a rapid rate, some will plaster the back tube sheet with slag, some show a tendency to plug flues, others to plug spark arrester netting, and any of these troubles will kill an engine in a very short space of time, unless the conditions are watched closely.

There are few engineers outside the field of the railways and locomotive builders who realize what a marvellous piece of equipment is the modern locomotive boiler. When limiting dimensions and weights are taken into consideration together with tremendous capacity, rapid flexibility and withal a very respectable efficiency, it must be admitted that there is nothing just like it in the whole field of steam generation. The steam demand of the engine on the boiler may vary as much as 3,000 h.p. within a few minutes, and the rate of combustion and evaporation must vary coincidentally with the demand, in order to maintain a constant steam pressure.

The evolution of the locomotive boiler has been a gradual process during the past hundred years and, while the fundamental principles with regard to arrangement of grates, firebox, barrel and smokebox still remain, the proportioning and construction of the present day boiler bears little resemblance to the boiler of a few years ago.

Grate areas have been increased to bring the maximum combustion rate per square foot of grate within the desired limit; air openings in grates have been greatly reduced to combat the wasteful effect of excess air; firebox heating surfaces and combustion chamber volumes have been enlarged to obtain the maximum benefit of radiant heat; brick arches have been introduced to increase the length of the flame way, to direct the gases evenly over the whole tube sheet area and improve the distribution of radiant heat to the firebox and combustion chamber walls; arch tubes and syphons have been applied to improve water circulation and further increase the absorption of radiant heat; mechanical stokers have been developed which will maintain a thin fire evenly spread over the total grate area, and drafting appliances so proportioned as to induce the required flow of air through the grates with the least possible back pressure on the engine. Apart from the steam generating equipment there are other important economy devices such as feed water heaters and superheaters, which assist materially in keeping combustion rates within the economical range, and the cumulative effect of all these refinements in design is shown in a marked improvement in fuel performance.

Calculated on the basis of fuel consumption per 1,000 gross ton miles, the improvement in fuel performance on the Canadian National system from 1923 to 1936 amounted to over 22 per cent, notwithstanding the adverse effect of higher operating speeds. The average freight-train speed during the same period increased by over 39 per cent. The records of the Canadian National system, as at present constituted, only date from 1923 and there is no doubt that, if the records were available for the previous ten years, the figures would be even more impressive.

Combustion conditions in locomotive service are entirely different from those in any other type of steam generator, and on this account a coal which may give good results in other classes of service may be unsuitable for locomotive use. The comparative ratings assigned to the output of various mines are therefore based on the results of road tests rather than on calorific values and analyses. This statement is not intended to convey the impression that the laboratory figures have no value. The heat content and analyses are always obtained, and in many cases the laboratory tests are carried through to the ultimate analysis, ash analysis, fusing point of ash, etc. These figures give definite clues to the general characteristics of the fuel and to whatever troubles may be anticipated in service. For instance, a high sulphur content will always indicate trouble from the formation of clinker in the firebox and also liability to spontaneous combustion in the storage pile. A high ash content is never desirable in coal for any purpose and least of all for locomotive service. If the percentage of combustible volatile is low, it indicates a short-flame coal, which will not permit of taking full advantage of the increased combustion volume and firebox heating surface of the modern locomotive boiler. The more information the railway officer has of the characteristics of the grades of coal he has to use, the better position he is in to overcome any troubles which may develop, but, as stated before, the final percentage ratings are based directly on results obtained under service conditions.

Perhaps the most remarkable characteristics of locomotive combustion conditions are the very high maximum combustion rates, high maximum firebox temperatures and the capability of varying these rates and temperatures in instantaneous response to variations in the steam demand upon the boiler. The use of the main exhaust as a jet through the petticoat and stack, to induce the necessary draft through the fuel bed, is the simplest, most effective and in fact the only satisfactory method ever evolved of maintaining a constant balance between the supply and demand for steam. The elementary principle was used on George Stephenson's "Rocket" and on this account there have been periodical outbursts of criticism of what is regarded by the critics as an antiquated method. The idea generally advanced is that a steady, controlled draft, such as might be produced by a fan, would be less liable to tear the fire, thus effecting a reduction in spark losses, etc. Experiments have revealed the rather surprising fact that a pulsating draft is a decided advantage when burning coal under locomotive operating conditions. The steady draft required to support a given rate of combustion is considerably higher than the average of a pulsating draft, in fact the steady vacuum will often run higher than the peaks of the pulsations. Under these conditions it will be readily understood that, when a steady draft picks up the fines from the fuel bed, they whirl right out of the stack without any pause, whereas when the fines are picked up at the pulsating peaks, the tendency is to drop back, and a considerable proportion will be burned in suspension over the fire. It is absolutely essential, however, that the pulsations be reasonably mild and perfectly even, as there is nothing which will tear a fire in holes quicker than uneven exhaust beats from the engine.

The problem of induced draft on locomotives is not one that can be solved by mathematical methods. Various empirical formulae have been used through the various stages of development of the locomotive boiler, but perhaps the most valuable contribution in recent years is the report which was issued last year by the Locomotive Construction Committee of the Association of American Railroads. The practice outlined in this report was based on the results obtained from several years of experimental work on the Chesapeake and Ohio Railway, and it was found possible to recommend a definite proportioning of the various gas passage areas between the firebox and the stack. By this method the area over the brick arch, the area under the table plate, the area under the draft sheet, the net area through the smokebox netting and the cross-sectional area of the stack are all based on the net gas area through the tubes and flues, and results obtained to date on engines with the recommended proportioning have been entirely satisfactory.

In addition to providing for the efficient generation of steam, there are other difficulties which have to be faced, such as fire hazard and smoke nuisance. To support combustion, and also to keep grate bearers and grates reasonably cool, a free flow of air is essential through the ash pan. It is often a difficult matter to provide for unrestricted air flow in such a way as to prevent the possibility of live coals dropping to the track or being blown out of the pan by a strong cross wind, but nevertheless it has to be done. Any sparks which are ejected from the stack must be broken up to such a size that they will be dead before they reach the ground. The small cinders which are drawn through the flues cannot be allowed to accumulate in the smokebox and they are therefore kept in a constant swirl by a strong draft directed along the bottom of the smokebox, to be broken up by the spark arrester netting and discharged to the atmosphere. These complications increase the difficulty of designing a free steaming boiler but it is essential that such conditions be met and there is no desire to side-step the issue.

The emission of black smoke was a common, every day occurrence in the old days of narrow fireboxes and banked fires but, with the thin fires and large grate areas and combustion chamber volumes of present day practice, there should be no difficulty in keeping the stack clear, provided the coal is of such quality that a thin fire can be maintained throughout the run. The gospel which was preached to the old-time engine crews, that black smoke meant waste, and a clear stack indicated economy, probably did a lot of good, but without proper qualification it might be very far from the truth. Black smoke certainly indicates incomplete combustion, but the number of B.t.u. wasted in the unconsumed combustible given off with the smoke does not approach the waste of B.t.u. which is possible with large volumes of excess air and a clear stack. The stack should be clear at all times, which means that sufficient air must be provided to support complete combustion; the excess air, however, must be kept down to the practical minimum and this is accomplished by restricting the percentage of air opening through the grates to a fraction of what it was a few years ago.

Taking into consideration the steady improvement in combustion conditions, the coal operators would probably like to know why the railways, during the past few years, have been insisting on an increasingly better grade of fuel. The answer is that exigencies of traffic are constantly becoming more severe, trains are heavier, running times are shorter and avoidable delays are not tolerated. The more the locomotive is improved, the more work is expected from it and, unless a reasonably good grade of fuel is available, it is impossible to keep traffic moving at the speeds which are required today. The use of an inferior grade of coal becomes increasingly difficult with faster service; if a clinker forms on the grates, the best a fireman can hope to do with it is to hook it into one of the back corners until he has an opportunity to get it out, and if clinkers form too rapidly a steam failure is sure to follow. If the ash builds up too quickly the fireman can move his grates once in awhile and shake the ash into the pan; the pan, however, has only a limited capacity and, if it should happen to be filled to such a level that the grate bearers become overheated, the results are disastrous.

The shipper is constantly pressing the traffic department for improved service, the traffic department turns the pressure on to the transportation department, who in their turn make increased demands on the mechanical department. The mechanical department make every effort to improve their equipment to meet the situation, but at the same time pass some of their troubles along to the fuel department. The fuel department follow the situation to its logical conclusion by imposing more exacting conditions on the coal operators. The struggle for improvement is unceasing—one cannot afford to stand still as there is always the danger of slipping back. Yesterday's peaks are today's averages, today's peaks will be demanded as tomorrow's averages, and so the battle goes on.

# The Burning of Low Rank Alberta Coals

## Combustion and Control

*Edgar Stansfield, M.Sc., M.E.I.C.,*
*Chief Chemical Engineer, Research Council of Alberta, Edmonton, Alta.*

**Paper presented at the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

SUMMARY.—Contains brief introductory notes on coal classification and analysis, with data and charts relative to combustion, referring particularly to Alberta coals of low rank.

This paper is planned to enable combustion engineers to become more familiar with recent developments in the methods and conceptions of coal analysis, and with their significance in combustion problems, as well as to supply them with data, equations and charts relative to combustion. The title of the paper limits its range to the combustion of low rank coals, but it has appeared necessary to study low rank coals by comparison and contrast with high rank ones. It is hoped that the paper will be of general value; but since Alberta possesses a wide range of coals, and the author has access to far fuller details of these than of other Canadian coals, the examples given are entirely, and the charts are largely, based on Alberta coals. Certain phases of the problem have been omitted to reduce probable overlapping with other papers to be presented at the same convention.

### Rank and Grade of Coal

Coals are ranked according to their degree of metamorphism or progressive alteration, in the natural series from lignite to anthracite; a low rank coal has undergone less metamorphism than has a high rank coal. Coals are graded according to their calorific value, ash and sulphur content, screen size, ash softening temperature, etc., that is, in general, according to their commercial value. Low rank coals may be high grade with respect to purity, screen size, etc., but are always low grade with respect to calorific value. A low grade coal may be of either high or low rank.

### Coal Classification

There is no internationally accepted classification of coal by rank, and Canada has not yet adopted any classification. In the United States coals are classified by the fixed carbon in the pure, dry coal and by the calorific value of the pure, moist coal, with some reference to physical properties, according to a specification[1]* of the American Society for Testing Materials (A.S.T.M.). In England coals are classified by the carbon and hydrogen in the pure, dry coal according to Seyler's classification.[10] The Provincial Mines Branch in Alberta[4] classifies coals for statistical purposes as bituminous, subbituminous and domestic, but no specifications have been given for these classes.

### The Coal Band

If charts are prepared to show graphically the composition of a large variety of coals—by plotting carbon against hydrogen in the pure coal as in Seyler's chart, or volatile matter against calorific value of unit coal as in Parr's chart,[5] or dry fixed carbon against moist calorific value of pure coal as in the A.S.T.M. classification, or by many other methods of plotting—the resultant points are found to lie along a band which has a sharp bend. This band is called a coal band. In Figs. 3, 5 and 6, such a band is shown for a number of Canadian coals.

It can be seen that a criterion which cuts across one limb of the band, and is therefore good for classifying those coals, may lie almost parallel to the other limb and is therefore useless for classifying the coals in that limb; this explains why two independent variables, or criteria, have always to be used for a full coal classification. In the same way it will be shown later that combustion factors which differentiate the high rank coals may show little variation in the low rank coals, and vice versa.

### Analyses of Coal

Three types of analyses are commonly made of samples of coal, proximate, ultimate and calorific analyses. The first, which is empirical in character, determines moisture, ash, volatile matter, and fixed carbon. The second, which gives absolute results, determines the actual percentages of carbon, hydrogen, sulphur and nitrogen in coal. The ultimate analysis also includes the ash, and oxygen by difference. The third analysis, also absolute in character, determines the heat value or calorific value of the coal,

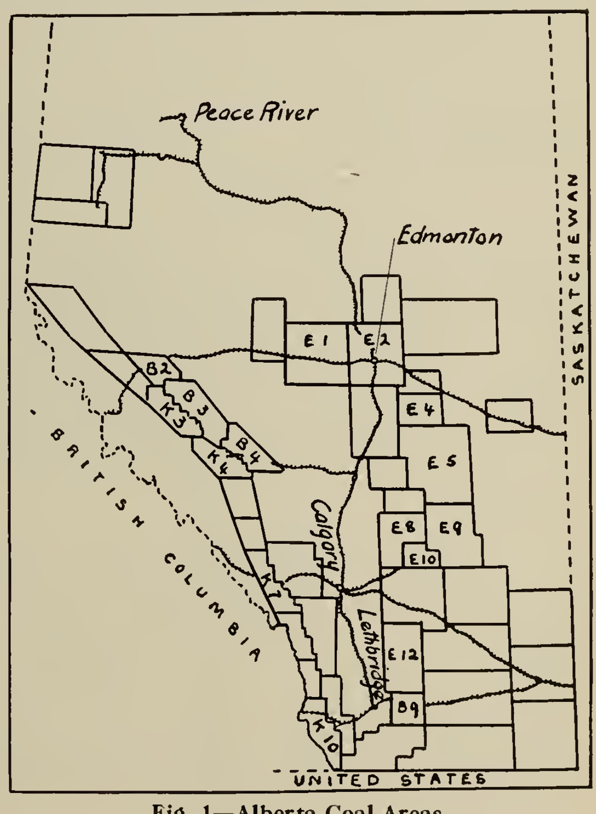

Fig. 1—Alberta Coal Areas.

usually as British thermal units (B.t.u.) per pound of coal burned. The specifications of the A.S.T.M.,[2] with minor modifications, are generally employed in Canadian laboratories.

### Mineral Matter and Ash

All coals contain mineral impurities in greater or less amount, and when burned an ash is left behind. The weight of ash, however, is rarely the same as that of the mineral impurity. It is easy to determine the percentage of ash by burning the coal, but it is almost impossible to

*References to the bibliography at the end of the paper are indicated by superscript numbers, thus [1].

make a direct determination of mineral impurity. The relation between the weight of mineral matter and the weight of ash of any coal can be studied by means of calorific value determinations.

If sugar were mixed with 20 per cent by weight of chalk, its calorific value would be reduced by 20 per cent, but if the ash of this sugar-chalk mixture were determined

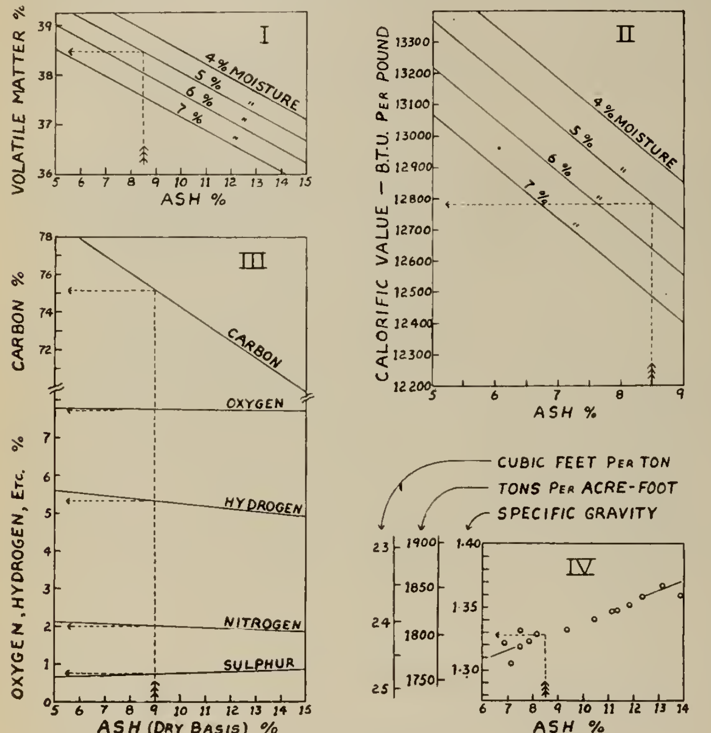

Fig. 2—Coal Charts.

it would be found to be only 11.2 per cent, since 100 parts of chalk when heated, as in the ash determination, lose 44 parts of carbon dioxide and leave behind only 56 parts of lime (ash). It would thus be found that a 20 per cent reduction in calorific value was found in a sugar-chalk mixture showing 11.2 per cent ash; but as a 20 per cent reduction in calorific value must be caused by the addition of 20 per cent of mineral matter to the sugar it is obvious that the ratio of mineral matter to ash is in this case 20 ÷ 11.2 or 1.79.

In the laboratories of the Research Council of Alberta (R.C.A.) a method[14] has been developed in which samples of coal are separated into a number of fractions of varying ash content—floats and sinks—by means of liquids of suitable densities. Each fraction is then analyzed and each percentage of ash plotted against the corresponding B.t.u., both calculated to the dry coal basis. It is found that, within experimental errors, the points lie along a straight line. This line, if extrapolated to the zero ash axis, gives the calorific value of the pure, dry coal; and the mineral matter to ash ratio can be calculated from the slope of the line.

It follows from the above that if two samples of the same dry coal have ash percentages of $A_1$ and $A_2$, and calorific values of $CV_1$ and $CV_2$ respectively, and if the ratio of mineral matter to ash is $F$

then $$CV_2 = CV_1 \frac{100 - FA_2}{100 - FA_1} \quad \text{(I)}$$

Or, if the ash percentages and calorific values are those of moist samples with $M_1$ and $M_2$ percentages of moisture,

then $$CV_2 = CV_1 \frac{100 - (M_2 + FA_2)}{100 - (M_1 + FA_1)} \quad \text{(II)}$$

The factor $F$ varies from coal to coal, but an average value of 1.1 is often assumed. Some determined values are given in the last column of Table II.

It must be noted that although the ratio of mineral matter to ash can be used in calculations of calorific values, the presence of mineral matter in the coal, as distinct from the ash of the coal, may affect other analytical values of the coal in unpredictable ways. Thus the mineral matter may contain a lower percentage of moisture than does the coal, so that the cleaner the sample the higher the moisture. Sometimes the mineral matter contains the higher percentage of moisture, so that the reverse is the case. It is commonly assumed that the difference in weights of mineral matter and ash affects the volatile matter as determined, but not the fixed carbon; this is often not correct. Again, if the mineral matter contains water of hydration not removed in the moisture determination, the hydrogen as determined is not all hydrogen from the coal; similarly carbonates in the mineral matter will increase the determined carbon of the coal. All these factors cause uncertainty in computations based on coal analyses.

The float and sink fractions of coal described above can be subjected to full proximate and ultimate analyses, and the determined values of the different constituents, together with any other available comparable analyses, all calculated to the dry coal basis, can be plotted against the corresponding ash percentages. As before, these points will be found to lie along straight lines, and these lines can be extrapolated to the zero ash axis and thus furnish a good estimate of the complete analysis of the pure coal.

### Capacity Moisture in Coal

All coals contain some moisture which is commonly regarded as inherent in the coal. Since coal mines are frequently wet, and mined coal may be exposed either to rain or to dry air, different consignments of the same coal may show notable variations in moisture content. It might be suggested that it matters little to the consumer whether the water delivered in his coal really belongs there or not, if he has to pay for it, and for its evaporation, in either case. Nevertheless it is useful to know the true, inherent moisture

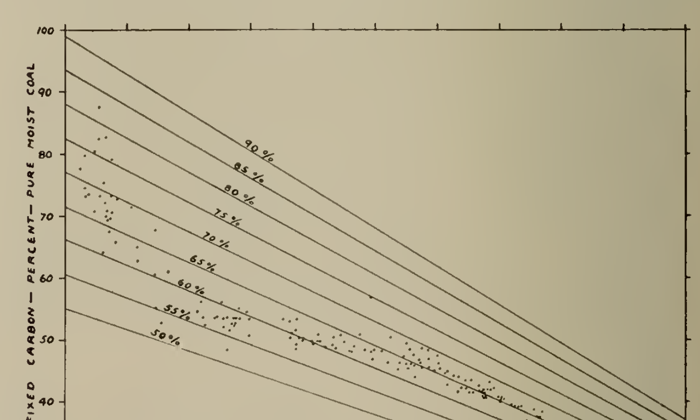

**Fig. 3—Canadian Coal Band and Percentage of Heat in Non-Volatiles.**

of the coal; and this moisture is an important factor in the classification of the coal by rank. The free surface water of a coal also will dry off faster than will the inherent water.

In the work of the Research Council of Alberta the capacity moisture of a coal is defined as the least amount of water in the coal that will show the same vapour pressure as does free water at the same temperature. A simple method has been devised for determining the true or capacity moisture of any coal, in accordance with this definition.[13] In later tables, wherever data with respect to moist coal are given, the values are for coal with its capacity moisture.

### Gross and Net Calorific Values, and the Therm

When coal is burned in a bomb calorimeter, as in the determination of calorific value, the products of combustion are cooled to room temperature and the steam is condensed to water and gives up its latent heat to the calorimeter. In ordinary combustion of coal, on the contrary, the products

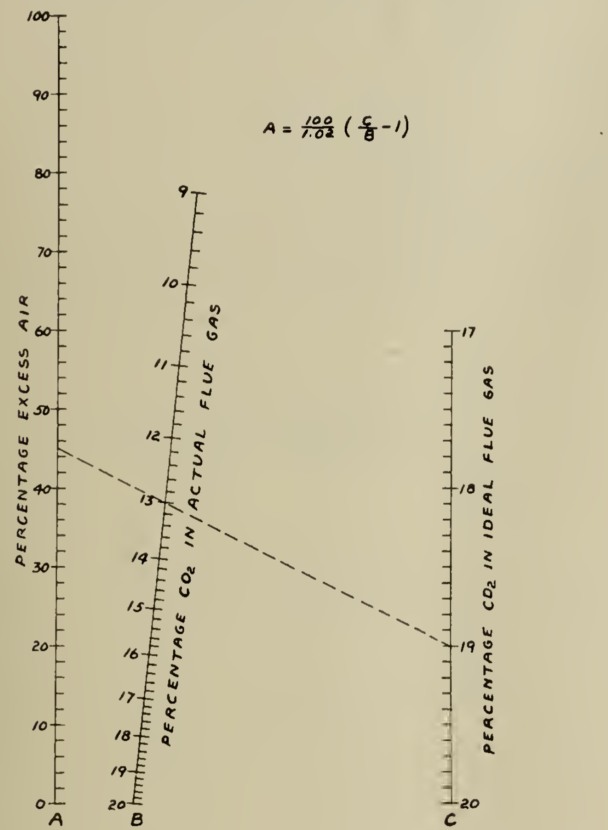

Fig. 4—Excess Air in Combustion of Coal and $CO_2$ in Flue Gases.

of combustion escape up the chimney at too high a temperature to permit the condensation of the steam; there is thus lost not only the sensible heat of the gases but also the latent heat of the steam. A boiler maker, in tests of the efficiency of his equipment, may feel that he is correctly charged with the loss of sensible heat and yet resent being charged with the loss of latent heat that he has no reasonable chance to recover even in part. Two forms of calorific value therefore are recognized—gross calorific value in which the products of combustion are cooled to ordinary temperatures (about 60 deg. F.) and the steam condensed to water, and net calorific value in which the products of combustion are cooled to ordinary temperatures but with the steam uncondensed. The gross values are generally used in Canada, but the net values give a better picture of the relative commercial values of different types of coal, and are often used in other countries.

The net calorific value of a coal may be calculated from the determined gross value by subtracting 94 B.t.u. per pound for each one per cent of hydrogen in the coal as fired. The percentage of hydrogen must include both the hydrogen of the coal itself and the hydrogen of the accompanying water. The last column of Table IV shows the approximate percentage of the gross calorific value to be subtracted from that value to give the net calorific value of each coal cited, when burned with its capacity moisture. With a natural gas this reduction may be over ten per cent, so that the correction is of considerable importance in considerations of the relative values of coal and gas as fuels. It also will be shown later that true combustion relations between the lower rank coals are only shown when the net heat value is taken.

Since the ordinary unit of heat, the B.t.u., is rather small a larger working unit has been created and called a therm; this value is used in one of the tables. The therm is equal to 100,000 B.t.u., and is approximately equal to 30 kw.h. or to 40 hp.h.

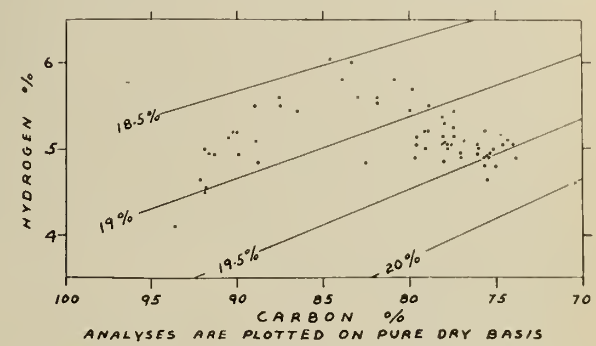

Fig. 5—Canadian Coal Band and Iso-Carbon Dioxide Lines for Dry Flue Gas.
(Plotted on Seyler's Classification Basis.)

### Ignition Temperature of Coal

This can only be an empirical value, as the time factor plays an important part in the ignition of coal. Thus a pile of coal out of doors may catch fire, but no one would suggest that the ignition temperature of any coal is as low as the temperature of the atmosphere. Wheeler has devised a test[15] in which dry, powdered coal is slowly heated in a stream of dry oxygen and the temperature measured at which rapid oxidation commences. This temperature is capable of exact determination, but it might better be regarded as the temperature of acute danger in a stock pile than as the temperature of ignition. An R.C.A. method[6] has been devised and constructed by H. Stansfield for measuring the lowest temperature of an air current in which small particles of the raw coal will catch fire within a couple of minutes. This temperature is not capable of exact determination, but it does indicate the temperature at which open combustion will commence. Some values by the Wheeler method are shown in column 5 of Table IV. No values by the R.C.A. method are available for tabulation;

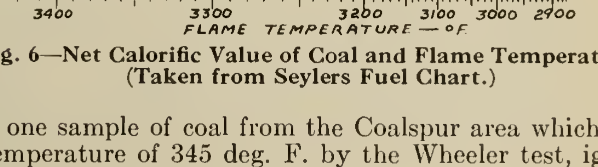

Fig. 6—Net Calorific Value of Coal and Flame Temperature.
(Taken from Seylers Fuel Chart.)

but one sample of coal from the Coalspur area which gave a temperature of 345 deg. F. by the Wheeler test, ignited in air at 705 deg. in the R.C.A. test.

### Oxidizability and Storage of Coal

This large subject can hardly be more than mentioned. The R.C.A. has examined many methods for evaluating the oxidizability of coals, but only one method[7] will be described. An air-dried sample of fresh coal is ground for about one hundred and twenty hours in a ball mill filled with air, and maintained at exactly 86 deg. F. Oxygen enters the mill through a gas meter to replace the oxygen absorbed by the coal, and the volume absorbed is thus calculated. The measurements with some coals are complicated at the beginning of a test by the evolution of occluded gas from the coal. A standard procedure was therefore adopted for evaluating oxidizability by the oxygen absorbed by the coal between the twenty-fourth and the ninety-sixth hour, expressed as a weight percentage of the pure, dry coal. Values obtained by this method are shown in column 2 of Table IV.

It is useful to have a measure of the heat evolved by the slow oxidation of stored coal; and unpublished experiments are in progress to measure this heat. It has been found that if the heat generated is measured in terms of the volume of oxygen absorbed, the value is almost independent of the rank of the coal. The average value found to date is about 465 B.t.u. per cubic foot of oxygen absorbed, measured at normal temperature pressure, or 98 B.t.u. for the oxygen in a cubic foot of air. This is about 90 per cent of the heat which would be generated by complete combustion, as shown in column 6 of Table IV.

Agglomeration, friability and pulverizability are important characters of coals in relation to their use in furnaces, but they will not be discussed here.

## COAL ANALYSIS CHARTS AND SELECTED ANALYSES OF ALBERTA COALS

There are at present some thirty-three coal-producing areas in Alberta. The fifteen areas with the largest outputs in 1936 have been selected, and tabular data for the coals in these areas are given, to illustrate the different points discussed. The areas are listed in Table I and are indicated by reference numbers in the coal areas map of Alberta, Fig. 1.

Table I

Selected Coal Areas

| Area | Geological Horizon | Reference Number | Alberta Classification |
|---|---|---|---|
| Mountain Park: | | | |
| Higher volatile coals.. | Kootenay | K 3, A | Bituminous[4] |
| Lower volatile coals... | Kootenay | K 3, B | Bituminous[2] |
| Nordegg............... | Kootenay | K 4 | Bituminous[2] |
| Cascade: | | | |
| Higher volatile coals.. | Kootenay | K 7, A | Bituminous[2] |
| Lower volatile coals... | Kootenay | K 7, B | Bituminous[1] |
| Crowsnest............. | Kootenay | K 10 | Bituminous[3] |
| Prairie Creek........... | Belly River | B 2 | Subbituminous[5] |
| Coalspur............... | Belly River | B 3 | Subbituminous[6] |
| Saunders............... | Belly River | B 4 | Subbituminous[6] |
| Lethbridge............. | Belly River | B 9 | Domestic[6] |
| Pembina............... | Edmonton | E 1 | Domestic[7] |
| Edmonton.............. | Edmonton | E 2 | Domestic[7] |
| Camrose............... | Edmonton | E 4 | Domestic[8] |
| Castor.................. | Edmonton | E 5 | Domestic[8] |
| Carbon................. | Edmonton | E 8 | Domestic[7] |
| Sheerness.............. | Edmonton | E 9 | Domestic[8] |
| Drumheller............ | Edmonton | E 10 | Domestic[7] |

The areas are arranged geographically in each geological horizon; that is roughly in a northwest to southeast direction. The order has no other significance. The way in which these coals probably would be classified according to the A.S.T.M. specifications is indicated by the reference numbers and the following key:—

(1)Semianthracite; (2)Low volatile bituminous coal; (3)Medium volatile bituminous coal; (4)High volatile A bituminous coal; (5)High volatile B bituminous coal; (6)High volatile C bituminous coal; (7)Subbituminous B coal; (8)Subbituminous C coal.

Some of the coals, however, lie across a boundary line and might be classified in two classes.

The analyses of coals from an area will vary from mine to mine, but even from the same mine may vary notably in ash and moisture according to local conditions and degree of cleaning. It is therefore very difficult to state a typical analysis for an area, and such analysis, if published, is apt to be taken more seriously than is warranted. Even if a typical analysis of the clean, dry coal were stated, it would not be possible to calculate therefrom the analysis for any particular ash and moisture because of uncertainty with regard to mineral impurities, as discussed above. It is possible, however, to construct charts[8] showing the way the different constituents in a coal vary with the ash percentage and the moisture percentage. If the latter factor is not represented on the chart, correction for moisture can be made by simple calculations, as will be shown later.

A set of four charts for one (subbituminous) coal are shown in Fig. 2. A dotted arrow in each chart illustrates its use for ascertaining the analysis of a sample with 8.5 per cent ash and 5 per cent moisture—or with 9 per cent ash in the dry coal. Chart I gives the proximate analysis; the volatile matter corresponding to 8.5 per cent ash and 5 per cent moisture is shown to be 38.4 per cent and the fixed carbon is found to be 48.1 per cent by subtracting the sum of the other percentages from 100. Chart II gives the gross calorific value and Chart III gives the ultimate analysis of the dry coal. If it were desired to determine the ultimate analysis of a coal with 8.5 per cent ash and 5 per cent moisture, it would be necessary first to calculate

Table II

Data for Construction of Coal Charts

All values on the dry coal basis

| Area | Percentage | | | Percentage | | | | | C.V. | F |
|---|---|---|---|---|---|---|---|---|---|---|
| | Ash | V.M. | F.R. | C | H | S | N | O | B.t.u. per lb. | |
| K 3, A | 0 | 33.3 | 2.0 | 87.8 | 5.5 | 0.3 | 1.4 | 5.0 | 15,660 | 1.10 |
| K 3, A | 20 | 24.2 | 2.3 | 69.8 | 4.0 | 0.5 | 0.9 | 4.8 | 12,200 | |
| K 3, B | 0 | 24.2 | 3.1 | 89.9 | 4.9 | 0.3 | 1.4 | 3.5 | 15,830 | 1.13 |
| K 3, B | 20 | 19.3 | 3.1 | 71.0 | 3.8 | 0.3 | 0.9 | 4.0 | 12,250 | |
| K 4 | 0 | 18.1 | 4.5 | 90.6 | 4.7 | 0.5 | 1.4 | 2.8 | 15,930 | 1.13 |
| K 4 | 20 | 14.5 | 4.5 | 71.6 | 3.6 | 0.4 | 0.9 | 3.5 | 12,330 | |

Both volatile matter (V.M.) and fuel ratio (F.R.) are given for interest, although these are interrelated. The fuel ratio is the fixed carbon divided by the volatile matter. The carbon, hydrogen, sulphur, nitrogen and oxygen are indicated by their chemical symbols, C, H, S, N, and O. The symbol F is used for the mineral matter-to-ash ratio. The data given are for fresh coal, and are not applicable to weathered coals.

(1)In this area (K 10) the values are representative of the coals from the centre of the area, where the larger mines are located. The coals from some small mines in outlying districts are notably different.

(2)The values cited for E 1 are based on analyses from a mine which is now shut down, they are not representative of the whole area.

(3)In these areas (E 4 and E 5) sufficient data are not available for plotting the ultimate analysis charts, but values at one ash content are given.

the corresponding ash in the dry coal; thus $\left(8.5. \times \frac{100}{100-5}\right)$ gives 8.95 per cent ash. The ultimate analysis of the dry coal with that ash could then be read off from the chart. This dry coal analysis would then be adjusted to the 5 per cent moisture basis by simple calculation in the case of carbon, sulphur and nitrogen:—thus,

$$\text{Carbon per cent (dry)} \times \frac{100-5}{100} = \text{carbon per cent (moist).}$$

In the case of hydrogen and oxygen a further adjustment is needed to include the hydrogen and oxygen in the 5 per cent of water:—thus

$$\left(\text{hydrogen per cent dry} \times \frac{100-5}{100}\right) + \frac{2.016 \times 5}{18.016} = \text{hydrogen per cent (moist);}$$

the corresponding addition for oxygen is $\frac{16.0}{18.016}$ times the moisture per cent. It is not proposed to discuss Chart IV; the values given refer to tons of 2,000 pounds, and to the solid coal as it occurs in the seam.

Charts of the type shown, when used for fresh coal from a single mine, are generally accurate enough for all ordinary use. Thus if a coal seller specifies the ash and moisture for the coal he tenders, the consumer can obtain from the charts the complete analysis of the coal he is to receive; this system allows for ready adjustment by both parties according as to whether cleaned coal, run-of-mine, or slack coal is to be supplied.

The coal charts are less accurate for individual coals when drawn to represent the average coal of a district or area, but they can be used for general discussions as in this paper.

Data are given in Table II from which charts could be drawn to represent the average coal for each of the seventeen areas, or sub-areas, listed. Straight lines may be drawn in such charts from the values given at 0 per cent ash to those at 20 per cent. Considerable experience with Alberta coals has shown that the values for all the constituents given, when plotted against ash, lie in a straight line within the limits of probable errors.

## DECOMPOSITION OF COAL WITH HEAT

### Decomposition and Softening Temperatures

When a coal is heated, in the absence of air, it soon loses moisture and may slowly lose carbon dioxide and other gases. This slow decomposition increases with temperature, and finally a temperature is reached at which decomposition is quite rapid, with the evolution of gas and tar. Some coals, called coking coals, soften or become plastic when heated, finally hardening with further heat into the hard, cellular material called coke. It is not easy to specify any determinable temperatures as decomposition and softening temperatures, but a method[3] was developed in the R.C.A. laboratories and values determined for a number of coking, or of near-coking, coals. Some average values thus obtained are shown in columns 3 and 4 of Table IV.

It has been suggested that a coal will coke readily if the softening temperature is distinctly below the decomposition temperature. However, a coking coal may be heated above the softening temperature without the formation of coke, if the heating is carried out so slowly that the fusible matter decomposes before it softens. The low rank coals, as a class, have a low decomposition temperature and do not coke.

### Volatile and Non-Volatile Fractions of Coal

When coal is heated strongly, as in the determination of volatile matter in the laboratory, volatile products of decomposition are driven off and a non-volatile coke or char is left behind in the crucible. The recorded loss in weight is for analytical purposes divided into two parts, moisture and volatile matter, whilst the weighed coke or char is taken as made up of ash and fixed carbon. The sum of the four percentages therefore must equal 100.

Low rank coals are characterized as being high-volatile coals. It is therefore important to consider the relative amounts of volatile and non-volatile fuel in such coals; as well as to consider the distribution of the total heat of the coal, and of the total volume of air required for combustion, between the volatiles and non-volatiles.

In the laboratory test for volatile matter a small sample of powdered coal is heated for seven minutes at 1,742 deg. F. (The lower rank coals have to receive a preliminary heating at a lower temperature to avoid mechanical loss of non-volatiles with the otherwise too rapid evolution of gases.) Since there is no reason why this temperature of 1,742 deg. F. should have any significance in boiler practice, its suitability for use in combustion studies was investigated experimentally by heating a series of five coals at three temperatures, 1,112 deg. F. 1,472 deg. F. and 1,742 deg. F. (600, 800 and 950 deg. C.), and subjecting the residues to ultimate and calorific analyses. Some of the results obtained are shown in Table III.

The yields of non-volatiles shown indicate that, on the average, the five coals lost 28 per cent at the lowest temperature, 7 per cent more to the next temperature, and only 2 per cent extra for the last stage; the losses of heat values in the volatiles show similar conditions. The ultimate analyses of the residues show that after heating to 1,742 deg. F. the aggregates of the elements hydrogen, sulphur, nitrogen and oxygen have been reduced to about 3 per cent, so that the fixed carbon left at that temperature is nearly pure carbon. It is therefore safe to assume that little further change would occur at the higher temperatures of the furnace, so that there is no serious objection to the use of 1,742 deg. F. in these studies; furthermore, the selection of this temperature makes possible the use of a large amount of available laboratory data.

Less comprehensive tests were made on some forty-one other coals; the results from all the tests showed that the heat of the non-volatile part of any coal could be calculated with considerable accuracy by multiplying the determined percentage of fixed carbon by 145.5. The

Table III

Decomposition of Coal With Heat

| Source of coal sample—Area | K 10 | B 3 | E 2 | E 10 | E 12 |
|---|---|---|---|---|---|
| Yield of non-volatiles—from dry coal | | | | | |
| Treated at 1,112 deg. F. (600 deg. C.) % | 76.8 | 73.3 | 71.1 | 70.2 | 69.1 |
| Treated at 1,472 deg. F. (800 deg. C.) % | 72.4 | 65.2 | 63.7 | 62.4 | 61.0 |
| Treated at 1,742 deg. F. (950 deg. C.) % | 70.6 | 61.6 | 62.1 | 60.8 | 60.0 |

| In residue at 1,472 deg. F. % | 4.5 | 3.9 | 3.6 | 6.1 | 3.7 |
| In residue at 1,742 deg. F. % | 2.9 | 2.9 | 3.0 | 3.4 | 2.5 |
| Combustion of non-volatiles (1,742 deg. F.) | | | | | |
| B.t.u. liberated per cu. ft. of oxygen required | 490 | 490 | 491 | 494 | 492 |

These values were obtained from single samples and are not area averages.

Area E 12 is Champion area.

The treatment, with only three exceptions, was seven minutes heating in a platinum crucible at the full heat for the treatment. The last three coals, however, for the highest treatment, were given a preliminary heat for five minutes at 1,472 deg F. followed by the full heat treatment for six minutes at 1,742 deg. F.

The percentage of heat in non-volatiles is based on the gross calorific value of the coal.

product shows the heat units (B.t.u.) available from the non-volatile residue from one pound of the coal. This makes it easy to calculate the distribution of calorific value between the volatile and non-volatile fractions of any coal.

The bottom set of figures in Table III show that in the combustion of the cokes or chars (made at 1,742 deg. F.) the heat liberated, when stated in B.t.u. per cubic foot of the oxygen required for the combustion, varied very little from the average value of 491. The volume of oxygen required was calculated from the ultimate analysis of each coke. This value of 491 B.t.u. per cubic foot of oxygen, taken with the calculated heat of the non-volatiles, makes it now possible to calculate the volume of air required to burn the non-volatiles in any coal. The total air requirements of the original coal can be calculated from its ultimate analysis, as shown later, so that the percentage distribution of the air for combustion between the volatiles and the non-volatiles can also be calculated. Some of these calculated values are shown in Tables IV and V.

The results are rather surprising, for example in the percentages of gross heat in the non-volatiles, shown in column 7 of Table IV, it can be seen that whilst the semi-anthracitic coal of area K 7, B has the highest value, some of the domestic coals have higher values than have some of the bituminous coals. The same is true even if the net calorific value is considered as in column 8. Quite similar results are found in the values for the percentages of total air required for non-volatiles, as shown in column 2 of Table V.

In Fig. 3 average analyses of coals from a number of Canadian coal districts or coal mines have been plotted. The values chosen for plotting this coal band are the fixed carbon percentages and gross calorific values in B.t.u. per pound, both on the moist coal basis. In the same chart are plotted lines drawn through calculated points where the percentage of the heat in the non-volatiles is 50 per cent, 55 per cent, and so on, respectively. It can be seen that the 65 per cent line, for example, lies along the lower end of the sloping limb of the band and then cuts across the nearly vertical limb. It is thus easy to see how it is that quite different coals may show the same percentage of non-volatile heat. Similar conditions could be charted for air requirement distribution.

Gas volumes all measured at N.T.P., 32 deg. F. and 29.92 in. mercury.

Dry flue gas refers to flue gas as analyzed in the laboratory, i.e., with the steam condensed to water and therefore not occupying volume in the gas.

Wet flue gas refers to flue gas with steam as it leaves the furnace. When the volume is computed to N.T.P. the steam is assumed to remain uncondensed.

The above discussions consider distributions between the volatile and non-volatile portions of coal in simple form; in the furnace fire the conditions are more complicated. If air is passed up through a bed of hot fuel, the carbon dioxide produced at the bottom may higher up be partially reduced to carbon monoxide by the hot carbon. Some of the non-volatile fuel is thus converted to a volatile fuel which burns in the flames above the fuel bed. Similarly, if steam is blown into the ash pit this reacts with the hot carbon to form water gas, and again non-volatile fuel is converted into volatile fuel. These two reactions are probably more affected by the firing conditions than by the rank of the coal, but in any case they could not be evaluated and considered in the present discussions.

## COMBUSTION CALCULATIONS—AIR AND FLUE GAS VOLUMES

In the following calculations the atomic symbols $C$, $H$, $O$ and $S$ are each taken to represent the percentage of that element in the coal. Whole figure atomic weights have been taken for sake of simplicity, since the differences from the correct values are less than the probable errors of analysis. Thus carbon is taken as 12, hydrogen 1, oxygen 16 and sulphur 32. The nitrogen in the coal can be neglected as in many cases can also be the sulphur. It is assumed that air contains 21 per cent of oxygen and 79 per cent of nitrogen (N). One pound-molecule of any gas occupies 359.0 cu. ft. at Normal Temperature and Pressure (N.T.P.), that is at 32 deg. F. and 29.92 in. of mercury (0 deg. C. and 760 m.m.); thus, for example, 44 lb. of carbon dioxide (12 + 32 lb.) occupies 359 cu. ft. at N.T.P.

One hundred pounds of coal contains $\frac{C}{12}$ lb.-atoms of carbon, $\frac{H}{1}$ of hydrogen, $\frac{O}{16}$ of oxygen, and so on. This weight would require for its combustion $\left(\frac{C}{12}+\frac{H}{4}+\frac{S}{32}-\frac{O}{32}\right)$ lb.-molecules of oxygen, and this oxygen would be accompanied, in the air for combustion, by 79/21 times this volume of nitrogen, if the theoretical or ideal amount of air only were supplied. The products of combustion would be, in lb.-molecules, $C/12$ carbon dioxide, $H/2$ steam and $\left(\frac{C}{12}+\frac{H}{4}+\frac{S}{32}-\frac{O}{32}\right)$ 79/21 nitrogen. In dry flue gas (as analyzed) the steam is condensed to water (of negligible volume); whilst in wet flue gas it is considered present as steam even though cooled to 32 deg. F.

The equations involved can be simplified to show gas volumes in cubic feet at N.T.P. per pound of coal, as follows:

$$\text{Air required} = \frac{359}{400}\left(\frac{C}{3}+H-\frac{O-S}{8}\right)\frac{100}{21} \quad \text{(III)}$$

Since the term $\left(\frac{C}{3}+H-\frac{O-S}{8}\right)$ occurs in nearly every equation it has been replaced by the letter $Z$ for sake of brevity.

$$\text{Carbon dioxide produced} = \frac{359}{400}\times\frac{C}{3} \quad \text{(IV)}$$

$$\text{Dry flue gas} = \frac{359}{400}\left(\frac{C}{3}+\frac{79\,Z}{21}\right) \quad \text{(V)}$$

$$\text{Wet flue gas} = \frac{359}{400}\left(\frac{C}{3}+2H+\frac{79\,Z}{21}\right) \quad \text{(VI)}$$

$$\text{Per cent } CO_2 \text{ in dry flue gas} = \frac{100\,C/3}{C/3+79/21\,Z} \quad \text{(VII)}$$

If instead of the theoretical or ideal air only being supplied for combustion, $X$ per cent of excess air is supplied, then:—

$$\text{Air supplied} = \frac{359}{400}\times\frac{100+X}{21}Z \quad \text{(VIII)}$$

$$\text{Dry flue gas} = \frac{359}{400}\left(\frac{C}{3}+\frac{79+X}{21}Z\right) \quad \text{(IX)}$$

$$\text{Wet flue gas} = \frac{359}{400}\left(\frac{C}{3}+2H+\frac{79+X}{21}Z\right) \quad \text{(X)}$$

Per cent $CO_2$ in dry flue gas

$$= \frac{100\,C/3}{\frac{C}{3}+\frac{79+X}{21}Z} \quad \text{(XI)}$$

$$\frac{\text{Per cent } CO_2 \text{ with ideal air}}{\text{Per cent } CO_2 \text{ with } X\% \text{ excess air}} = \frac{\frac{C}{3}+\frac{79+X}{21}Z}{C/3+79/21\,Z} \quad \text{(XII)}$$

Exception might be taken to volumes of flue gases being stated at N.T.P., particularly when it involves the assumption of the presence of steam at that low temperature. However, Normal Temperature and Pressure is well known, and it is easy to calculate the volumes given from this base to any other temperature and pressure. Thus, if $V_{ntp}$ is the volume at N.T.P. and $V_{tp}$ the volume at any other temperature and pressure $t$ and $p$, where the temperatures are in degrees Fahrenheit and the pressures in inches of mercury, then:—

$$V_{tp} = V_{ntp}\left(1+\frac{t-32}{491.56}\right)\left(\frac{29.92}{p}\right) \quad \text{(XIII)}$$

Values were worked out for the ratio shown in equation XII for three coals of widely varying proportions of carbon, hydrogen and oxygen. It was found that if $X$ = per cent of excess air, $B$ = per cent of $CO_2$ in actual flue gas and $C$ = per cent of $CO_2$ in theoretical flue gas, the following equation was correct, within the limits of experimental errors of analysis, for all three coals regardless of their different compositions:—

$$X = \frac{100}{1.02}\left(\frac{C}{B}-1\right) \quad \text{(XIV)}$$

The alignment chart, based on equation XIV, shown in Fig. 4 was kindly prepared by Dr. A. J. Cook, Associate Professor of Mathematics at the University of Alberta. In this diagram the dotted line shows, as an example of its use, that if the actual flue gas from a furnace is found to contain 13 per cent carbon dioxide (line $B$), when a coal is being burned which would give 19 per cent carbon dioxide (line $C$), with perfect combustion when the theoretical amount of air is employed, then the excess air actually supplied in the furnace is 45 per cent (line $A$).

Values of carbon dioxide percentages in dry flue gas, with theoretical air, are shown in Table V, column 3, whilst air requirements and flue gas volumes, per pound of pure dry and of pure moist coal, are shown in columns 4, 5 and 7. The moist coal is coal with its capacity moisture.

The values for carbon dioxide percentages in the ideal, dry, flue gas (column 3) are rather surprising. In the high rank coals this percentage falls with decreasing rank of coal, but it can be seen that, instead of continuing to fall with the rank, a minimum is reached with the high volatile bituminous coals and that the domestic coals give higher percentages even than the semi-anthracitic coals. This variation in percentages is shown graphically in Fig. 5. A number of Canadian coal analyses are here plotted on the Seyler chart basis,[10] and calculated lines for equal carbon dioxide percentages are drawn on the chart. It can be seen that the minimum carbon dioxide is found near the bend of the coal band, and that the percentages of carbon dioxide increase in either direction along the limbs.

## FLAME TEMPERATURES

If no heat were lost by radiation or otherwise when a fuel is burned, the sensible heat of the flue gases produced should equal the heat of combustion of the fuel. Therefore, if the volume of flue gases were calculated and their mean specific heat known, and if suitable units were used throughout, a flame temperature might be calculated by dividing the product of the volume of the gases and their specific heat into the available amount of heat. This is the problem reduced to its simplest terms; actually an estimation of flame temperature is a complicated problem. Thus, radiation can not be neglected, particularly in a boiler furnace where it is planned to radiate the maximum heat possible to the water tubes. Moreover, combustion can not be complete at high temperatures; this is usually stated in reverse order by saying that the products of combustion, carbon dioxide and steam, dissociate at high temperatures into carbon monoxide, hydrogen and oxygen. The extent of dissociation, or loss of combustibles from the high temperature zone of the fire, depends on the temperature and on the concentrations of all the gases involved in the reactions. It is therefore doubly dependent on the amount of excess air employed. The extent of the dissociation factor may be guessed at from the statement that at atmospheric pressure pure carbon dioxide dissociates 0.2 per cent at 2,550 deg. F., 1.5 per cent at 3,090 deg. F. and 6.0 per cent at 3,630 deg. F. The corresponding values for pure steam are 0.08, 0.5 and 1.9 per cent. It is not suggested that the dissociation factor involves a permanent loss of heat, since the carbon monoxide and hydrogen may continue burning, to completion, as the gases cool. A further complication in flame temperature calculations is the fact that the specific heats of the different gases included in the flue gases vary with the temperature, and that the relation is not a simple one. Finally, and particularly with long-flame coals, combustion is not something which happens and is completed in, or just over, the fire bed; so that any theoretical calculations are liable to be in error. Nevertheless, it is suggested that the calculated flame temperatures of a series of coals may give a good insight into their comparative values as furnace fuels, if the calculations are all based on the same assumptions. Flame temperatures are also of value when taken in conjunction with the ash fusion temperatures of the same coals. Seyler[12] in his Fuel Chart relates the flame temperature to the net calorific value of the coal as fired. This relation, copied from his chart, is shown in Fig. 6. Thus a coal with a net calorific value of 14,000 B.t.u. might give a flame temperature of 3,700 deg. F., one of 11,000 B.t.u. a temperature of 3,580 deg. F., and one of 6,000 B.t.u. a temperature of 3,200 deg. F. Seyler does not show how his flame temperatures were calculated, nor what allowances, if any, were made for radiation and dissociation losses; but it may be safely assumed that the use of this graph, with the net calorific values of a series of coals as fired, will give reasonably comparative flame temperatures when the coals are burned with the ideal volume of air. Seyler gives some minor adjustments which should be made, and also equations for correcting the flame temperatures for different amounts of excess air, and for preheat in the air, but for these the original paper must be consulted.

It is obvious that the flame temperature goes down with the rank of the coal, and that it is reduced by the presence of water in the coal and by the use of excess air for combustion; it can be raised by preheating the air. The flame temperature is extremely important in its influence on the transmission of heat from the furnace to the boiler tubes by means of radiation. According to the Stefan-Boltzmann law radiation is proportional to the difference between the fourth power of the absolute temperature of the radiating body and the fourth power of the absolute temperature of the receiving body. Thus if the heat absorbing surfaces of the boiler had a mean temperature of 500 deg. F., raising the temperature of the furnace flame from 2,500 deg. F. to 3,055 deg. F. would approximately double the transmission of heat by radiation.

## ASH FUSION TEMPERATURES

In the A.S.T.M. specifications[2] for the determination of ash fusibility, small cones of the ash, of standardized size and shape, are heated with a definite rate of rise in temperature, in a mildly reducing atmosphere. The cones are carefully watched and the three temperatures noted at which specific changes occur. These are:—(1) The Initial Deformation Temperature, the temperature at which the first rounding or bending of the apex of the cone takes place. Such bending must not be confused with a shrinking or warping of the cone. (2) The Softening Temperature, the temperature at which the cone has fused down to a spherical lump. (3) The Fluid Temperature, the temperature at which the cone has spread out over the base in a flat layer.

The softening temperature is the temperature normally indicated in references to ash fusion temperatures.

In the laboratories of the R.C.A. a modified method has been developed[9] and is frequently employed. In this method the above specifications with respect to cones, rate of heating, and atmosphere, are followed exactly; but instead of only heating 3 or 4 cones at once and watching closely their behaviour, a batch of 20 or more different cones are simultaneously heated to some prearranged temperature, and then rapidly cooled and withdrawn from the furnace. Similar batches are likewise heated to other temperatures, until for each ash a series is obtained of cones heated to temperatures at 45 deg. F. (25 deg. C.) intervals. The

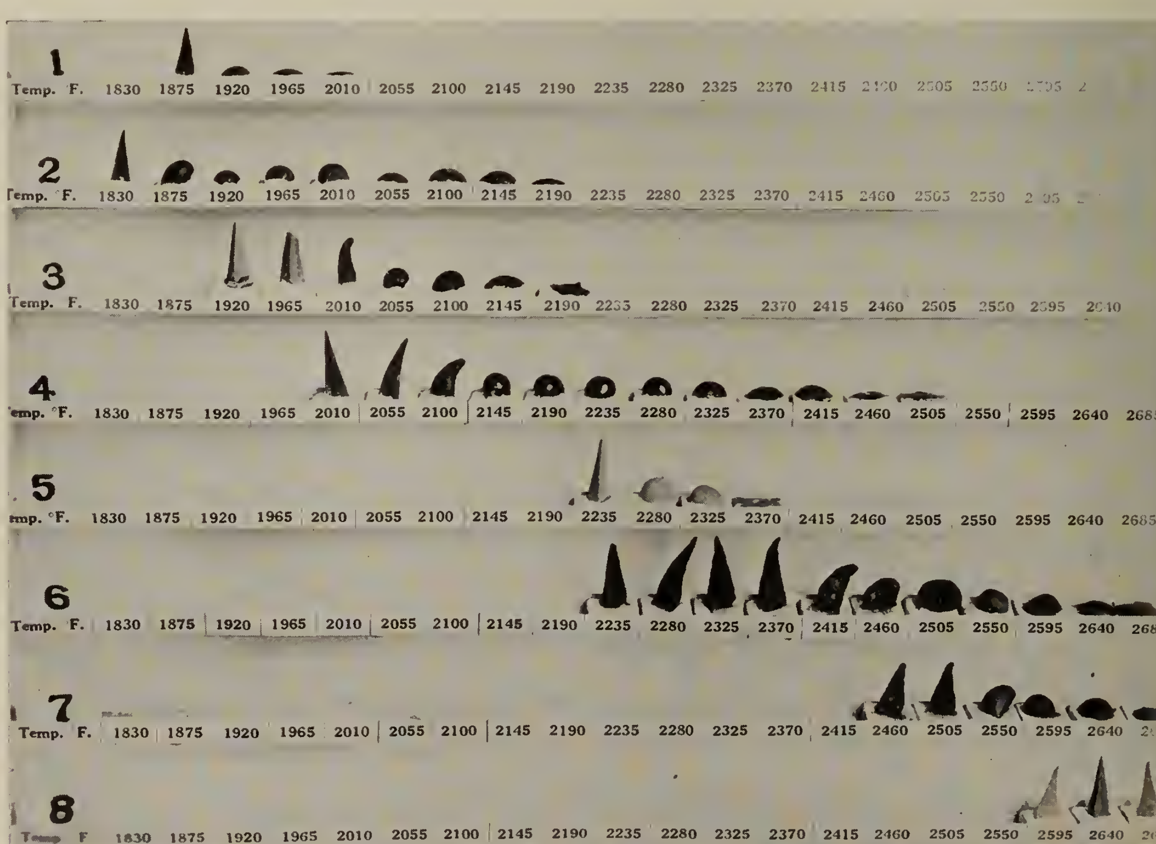

Fig. 7—Ash Fusion Cones.

series can then be arranged in order and examined at leisure for the fusion characteristics of the ash.

Figure 7 shows eight such series of ash cones. In series 4 initial deformation is just visible at 2,055 deg., the softening temperature is shown at 2,145 deg. and the fluid temperature at 2,460 deg. F. In some cases the temperatures must be estimated, as in series 1, for example, the initial deformation and the fluid temperature both occur between 1,875 deg. and 1,920 deg. It might be pointed out that in the regular method it is not easy to control all the conditions simultaneously, and also to identify exactly all three temperatures for 3 or 4 cones in an intensely hot furnace. The R.C.A. method has the advantage of giving a permanent picture of the ash character.

In the figure, series 1 and 2 show ashes with low fusion temperatures, but in series 1 the complete range from initial deformation to fluid temperature is not more than 90 deg. whilst in 2 it is about 360 deg. In series 3 and 4, and in 5 and 6, similar contrasts of short and long ranges of softening and flowing are shown for higher fusion temperature ashes. Series 8 shows an ash which only just reached the initial deformation at the highest temperature tested, 2,685 deg. F. In series 3 there is a marked change in colour at the temperature of initial deformation. Series 8 also shows a colour change. Series 6 is characterized by swelling of the ash cone when heated—all the cones shown were the same size when made.

It is not easy to correlate with furnace practice laboratory data obtained with small ash cones. It would seem probable, however, that ash 1 of the figure would give little trouble in a stoker furnace because it would melt completely and run through the grates; ash 8 should give little trouble because it would not clinker except in a very hot fire. Ashes 4 and 6 would be more likely to give trouble on account of the probability of their reaching the pasty stage and yet not reaching the fluid stage. Ash 5 could probably be handled easily either in a fairly cool fire, or in a hot fire. Similar considerations would affect the use of the coals, corresponding to these ashes, in powdered coal equipment.

The low rank coals of Alberta have, in general, lower ash-fusion temperatures than the high rank coals of the province; this can not be a definite characteristic of all low rank coals. It should be noted, however, that a coal with a low ash-fusion temperature and low flame temperature may give less trouble due to clinker than coal with a medium ash-fusion temperature and a high flame temperature.

The ash of plants is comparatively fusible; so that it is to be expected that where such ash is little mixed with other mineral matter, as in a low ash coal, this ash also will be fusible. The ash of a cleaned coal is commonly more fusible than the ash of the raw coal, although the reverse is sometimes the case. The ash from separate lumps of coal from the same mine may sometimes show marked differences in fusion character; but nevertheless there is commonly enough uniformity in the mine run of ash, for coal from one mine, or even district, to be known to have a high fusion ash and coal from another mine or district to be known to have a low fusion ash. Blending two coals may have little influence on their ash fusibility, or it may produce an ash more fusible than either ash alone.

## GENERAL DISCUSSIONS AND CONCLUSIONS

The Alberta coals discussed, and for which values are given in the tables, cover a very wide range, although this is not quite as wide as it could be if all Alberta coals were included. The coals listed are all of cretaceous age (post-carboniferous), but are representative of three geological horizons. They rank as follows:—from semi-anthracite to (or nearly to) lignite, in the ordinary use of these terms: from semi-anthracite to sub-bituminous C coal, in the A.S.T.M. classifications; and from semi-anthracitic species to ortho-sub-lignitious, in Seyler's classification.

The ranges of variations in the analytical and combustion data of Tables II, IV and V are given in Table VI, with a few supplementary ranges. The values given in the actual range column are, whenever possible, the limit value of the high rank coals followed by the limit value of the low rank coals. In the percentage range column the maximum value of the actual range is in each case taken as 100.

The first eight items of analytical data in the table confirm the claim as to the wide range in character of the coals; this range is particularly shown by items 7 and 8. Study of the combustion values show a more varied picture. Items 9-12 have wide ranges, but this merely indicates that, just as the higher rank coals have higher heat values than the low rank coals, so also they require more air per pound for their combustion and produce more flue gas per pound of coal burned. Item 13 shows that there is a quite narrow range in the carbon dioxide percentages with ideal air, and, as already pointed out, this percentage does not vary regularly with the rank of the coal. Items 14-16 show very narrow ranges; there is remarkably little variation in the heats of combustion, throughout the whole range of these coals, if these heats are expressed either as gross or net B.t.u. per cubic foot of air required, or are expressed as gross B.t.u. per cubic foot of flue gas produced from the dry coal. In fact it might be concluded that there was little difference between the combustion of high and low rank coals, except that more pounds of the latter must be fired.

TABLE VI

ANALYTICAL AND COMBUSTION RANGES

| | Actual range | Percentage range | Reference* |
|---|---|---|---|
| Analytical values for pure, dry coal | | | |
| 1. Carbon........per cent | 92.4–73.7 | 100–80 | II–5 |
| 2. Hydrogen........per cent | 4.0– 5.7 | 70–100 | II–6 |
| 3. Oxygen........per cent | 1.6–19.5 | 8–100 | II–9 |
| 4. Fixed carbon........per cent | 89.3–56.5 | 100–63 | |
| 5. Gross calorific value........B.t.u. | 15,930–12,550 | 100–79 | II–10 |
| 6. Net calorific value........B.t.u | 15,490–12,090 | 100–78 | |
| Analytical values for pure moist coal (capacity moisture) | | | |
| 7. Capacity moisture........per cent | 1.5–27.3 | 5–100 | |
| 8. Net calorific value........B.t.u. | 15,240–8,500 | 100–56 | |
| Combustion values | | | |
| 9. Air required, per lb. pure, dry coal..cu. ft. | 147–115 | 100–78 | V–4 |
| 10. Air required, per lb. pure, moist coal. cu. ft. | 145– 83 | 100–57 | |
| 11. Flue gases (wet) per lb. pure, dry coal........cu. ft. | 151–121 | 100–80 | V–5 |
| 12. Flue gases (wet) per lb. pure, moist coal........cu. ft. | 150– 94 | 100–63 | V–7 |
| 13. Carbon dioxide in dry flue gases (ideal air)........per cent | 18.65–19.55 | 95–100 | V–3 |
| 14. Heat available per cu. ft. air required ........gross B.t.u. | 106–109 | 97–100 | IV–6 |
| 15. Heat available per cu. ft. air required........net B.t.u. | 103–106 | 97–100 | |
| 16. Heat available per cu. ft. flue gas from dry coal........gross B.t.u. | 104–102 | 100–98 | |
| 17. Heat available per cu. ft. flue gas from moist coal........net B.t.u. | 101– 89 | 100–88 | V–9 |
| Heat decomposition values | | | |
| 18. Heat of non-volatiles as per cent of total gross heat of coal........ | 82.7–58.0 | 100–70 | IV–7 |
| 19. Heat of non-volatiles as per cent of total net heat of moist coal........ | 84.8–60.5 | 100–71 | IV–8 |
| 20. Air for non-volatiles as per cent of total air required for coal........ | 84.9–61.1 | 100–72 | V–2 |

*The references are to the tables and columns from which the values have been taken.

The same number of cubic feet of air must be supplied for, and (from item 16) the same number of cubic feet of flue gas would be produced by, the generation of one therm of heat with any coal. It would therefore appear that the same furnace volume would be required regardless of the rank of the coal to be burned. Study of items 18-20 would not add much to change the above conclusions. They show that there is a notable range in the distribution of heat production and air requirements between the volatile and non-volatile fractions of the coals; but from Tables IV and V it can be seen that, although in every case the semi-anthracite has the highest values for the non-volatiles, there is little relation between distribution and rank with the bituminous and lower rank coals.

One combustion value was omitted above, item 17, the net B.t.u. available per cubic foot of flue gas from the combustion of coal with capacity moisture; this has a 12 per cent range. A study of Table V, column 9, shows that these values vary little with the high rank coals, but with the lower rank coals decrease with the rank of the coal. This value, Seyler's calorific intensity,[12] classifies the lower rank coals in approximately the same order as the A.S.T.M. classification. It is thus evident that, when net heat and the moisture in the coal as fired are given due consideration, even if other things were equal, a larger furnace volume would be required for the lower rank coals.

Other factors, however, also must be considered, factors which can not be stated numerically. It has been pointed out earlier that net calorific values fall rapidly with rank, that flame temperature falls with net calorific value, and that transmission of heat by radiation falls with the flame temperature; less heat will therefore be transmitted by radiation from a low rank coal and greater heating surface must be provided in consequence. A high preheat would raise the flame temperature, but this possibility may be restricted by ash fusibility. Careful avoidance of unnecessary excess air will also raise the flame temperature. In a powdered coal plant the use of heated air in the pulverizers and the consequent drying of the coal will also tend to raise the flame temperature.

Low rank coals are more easily oxidized, and have lower ignition temperatures than the higher rank coals, so that it is easier to burn the coal and there is less need for excess air. On the other hand the decomposition temperature is lower with low rank coals, so that volatile matter will be given off more rapidly and at a lower temperature than with high rank coals and there may be some risk of such volatile matter escaping unburned.

Data and an alignment chart have been provided to permit the estimation from a flue gas analysis of the excess air supplied to the furnace. These were prepared on the assumption that no unburned gases were present. If the percentage of excess air is reduced too much, unburned gases will result; increasing the excess air, on the contrary, increases the loss of sensible heat in the flue gases. Full flue gas analyses and flue temperature measurements make it possible to ascertain the optimum conditions for any coal.

It has already been pointed out that the heat generated per cubic foot of air supplied is remarkably constant, and is almost independent of the coal; in other words the air supplied and steam generated are very closely related and are independent of the quality of coal burned. This is, of course, the basic fact in the control of a steam plant. An air flow meter and a steam flow meter can be set to register on the same recorder chart, and be so adjusted that the two pens will record on the same line with optimum conditions of firing and air supply. The maintenance of matched readings by these meters then ensures the continuation of optimum conditions.

This paper is limited in its scope and falls far short of adequate treatment even of the subjects considered; it is hoped nevertheless that it may prove of some value along the lines of its stated objective.

The writer wishes to acknowledge gratefully the valuable assistance of his colleagues, Mr. W. A. Lang and Mr. K. C. Gilbart, in the investigations involved as well as in the preparation of this paper and its charts.

# The Burning of Low Rank Alberta Coals

## The Steam Generating Plant

*C. A. Robb, M.E.I.C.,*

*Professor of Mechanical Engineering, University of Alberta, Edmonton, Alta.*

**Paper presented at the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

**SUMMARY.—This paper deals with the development in Alberta and Saskatchewan during the past decade of steam generating plants equipped for burning low-rank Alberta coals; notes on these plants and their equipment are given, with some performance data and suggestions as to trends of design.**

The World Power Conference of 1936 provided an opportunity for the publication of material dealing with the developments which have taken place in connection with the generation of electric energy, constituting the first comprehensive survey in regard to plant, equipment, performance and trends in design since the Berlin conference of 1930. This material yields a fair picture of the "state of the art" at this time. With the celebration by The Engineering Institute of its Semicentennial it seems fitting that local plant and methods should be reviewed and that possible applications of these new developments in the broader field to Canadian stations receive consideration.

### Power

Discussion will be limited to plant in which power is generated for public use. Published statistics[1] show that, at the end of 1934, the installed capacity of hydraulic stations in Alberta and Saskatchewan was 71,590 kva., an increase of 38,070 kva. over 1927. The capacity of fuel stations was 166,959 kva., an increase of 35,000 kva. for the same period. Consumption of electricity for domestic use was 65,284,000 kw.h. in 1934. The average annual domestic use was 520 kw.h. in Alberta and 785 in Saskatchewan, at a cost of 4.99 and 5.81 cents per kilowatt hour respectively. Revenue of hydraulic stations in 1934 was $1,687,310 and of fuel stations $5,623,724.

The trend in recent years has been to consolidate power generation in a small number of relatively large plants, both fuel and hydraulic, and to operate as an interconnected system, fuel plants operating on base load during low water periods in the winter months, and as standby only during the balance of the year. Other fuel plants are on a standby basis throughout the year. Interconnected lines extend westward to the British Columbia boundary. In certain cases these arrangements for interconnection have been interrupted and in others, fuel plants have been required to provide pumping service for domestic water supply throughout the year. In general, interconnection of plant has resulted from economic studies. However, certain plants have retained the interconnection for the purpose of mutual assistance in case of trouble and to avoid interruption of the service.

Note:—References to the bibliography at the end of the paper are indicated by superscript numbers, thus [1].

A low head (14-ft.) 10,000-kw. pumping unit, operated from a hydraulic power station for irrigation in a dry area, is a recent development. The experiment is interesting in that the intention is not to encourage the intensive farming methods characteristic of irrigation projects, but rather to serve areas which are above the main irrigation ditch, with a view to growing regular prairie crops on land which would otherwise be too dry for this purpose. Such devices have advantages as load builders. They may be operated as off-peak load and are on demand

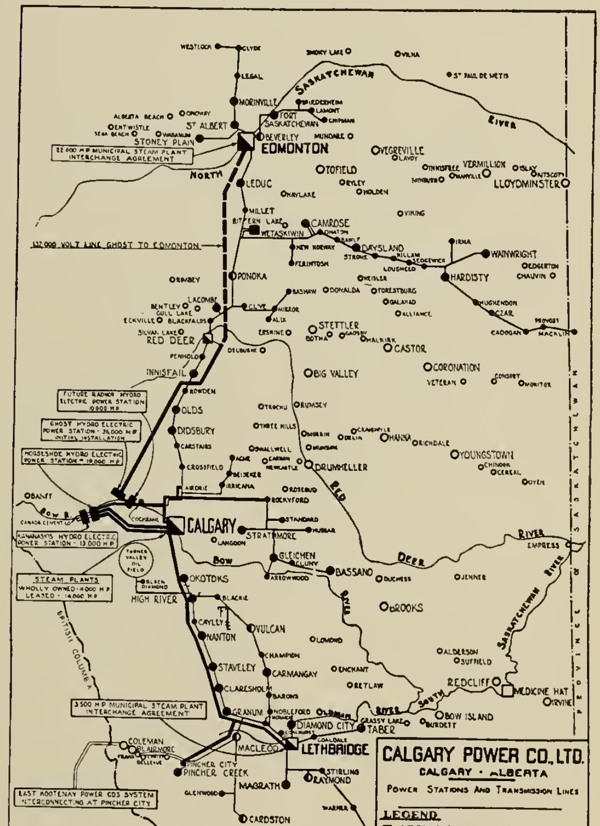

**Fig. 1—Calgary Power Company System in 1930.**

during periods of high water only. This is important in an area where climatic conditions and mountains place limitations on hydraulic power station output during the winter peak load period.

During the past decade many small steam, natural gas, semi-Diesel and Diesel plants have been taken out of service and dismantled. Privately owned companies have constructed transmission lines reaching the towns and villages formerly served by these small fuel plants. The extent of the activities in Alberta of one of these

public utility companies is shown, as at 1930, in Fig. 1. The system includes about 1,700 miles of transmission lines and reaches 136 communities with a combined population of more than 250,000. The installed capacity of this company's hydro-electric plants comprises more than 98 per cent of the developed water power in the province.

The larger fuel plants which have been retained in service, have undergone a gradual and normal process of development. Higher pressures and temperatures have been adopted and steam generating plants have been equipped for burning the cheaper fuels as they have become available. One of the earlier plants to adopt pulverized coal has reverted to standby service. A limited number of plants have been designed to operate on alternative fuels including bituminous and lignite* coals,[1] and oil. The majority of the plants are equipped with forced draft chain-grate stokers. One plant has been designed to burn low rank pulverized coal.

Of the six larger fuel stations, four are owned and operated as municipal enterprises. One is operated by a provincial power commission; two are privately owned and operated.

Old plant in fuel stations is characterized by lower operating pressures and temperatures, smaller boilers and furnaces, and fewer heat-recovery devices than have been provided in the modern equipment installed in the larger stations. Three of the plants operate at 400 lb. per sq. in. and 700 deg. F. Two of the 3,600 r.p.m. condensing turbines were the first to operate at capacities of 10,000 kw. and 15,000 kw.; the former is at Edmonton (1928) and the latter at Regina (1930).

### Thermal Station Performance

Thermal performance of certain Canadian stations for the period, November 30th, 1934 to November 30th, 1935, is summarized in Table I. The performance may be expected to show improvement as a larger fraction of the station operates at the higher pressures and temperatures, and advantage is taken of available heat cycles,[2] heat-recovery devices and superposed plant.[3]

Superposition consists in the addition of new high-pressure, high-temperature, low heat-drop turbines which receive high-pressure steam from new high-pressure boilers, exhaust into the old low-pressure mains and, through the serviceable old low-pressure turbines, to the condenser. The combination is equivalent to a compound unit. An extraction feedwater heater may be provided to operate at the throttle pressure of the low-pressure turbine. Superposition has the advantage of increasing station capacity of high performance equipment, and of improving the station performance. The cost is limited to the turbine, generator, piping and switching arrangements. The turbine may be placed near the new high pressure boiler plant and thus save the cost of extension of high pressure piping.

The electric energy generated and the distribution between fuel and hydraulic stations for the period 1926-1936, is shown in Fig. 2. The net annual output of five stations is shown in Fig. 3; annual load factor in Fig. 4; station performance in Fig. 5; auxiliary power in Fig. 6; feedwater make-up in Fig. 7; fixed charges on plant in Fig. 8 and fuel cost in Fig. 9. The outage of the largest turbine appears in Fig. 10 and the outage of the largest boiler in Fig. 11.

### Steam-Generating Plant

The coal consumption in pounds per kw. hour has been reduced from 3 to about 1½ during the last twenty-five years. Contributing factors are the practical application of the regenerative cycle, higher pressures and temperatures, and increase in the size and efficiency of steam turbines. Improvements in the turbine room have been followed by a similar transformation in steam-generating plant. A high pressure boiler having an output of 1,250,000 lb. per hour is in service. In one of the newer stations of the United States, the 80,000 kw. turbine is served by a single boiler. The station has set a record of 11,166 B.t.u. per kw. hour for the first five months of operation. Average boiler plant efficiency for 1935 in large modern stations ranges from 83 to 87.5 per cent. Pressures have increased to 1,400 lb. per sq. in., temperatures to 1,000 deg. F. and ratings to 500 per cent.

Modern steam-generating plant, with a view to a minimum cost per unit of steam generated, is characterized by an equitable distribution of the heating surface between the waterwalls, boiler tubes, superheater, and heat-recovery devices such as the economizer and air preheater, having regard to the individual conditions of operation, choice of fuel or fuels, and fuel burning equipment.[4] Economic operating conditions of pressure and temperature are determined by the turbine heat balance.[5] The central stations with which this paper is concerned, having an installed turbine capacity of 20,000 kw. or over, have adopted a pressure of 400-430 lb. per sq. in. and temperatures of 700-825 deg. F. Earlier experiences in the burning of low rank Alberta coals, early designs of boilers, furnaces and stokers and their performance have been discussed[6] elsewhere by the author.

Typical steam-generator installations are shown in Figs. 12 to 18. One of the largest steam generators in Canada is the 1,650 hp. unit in the Regina station, shown in Fig. 12. This generator is designed to produce a maximum of 205,000 lb. of steam per hour at a pressure of

*The term "lignite" coal is taken from "Central Electric Stations in Canada."

400 lb. per sq. in. and 743 deg. F. with gas as fuel (although a natural gas supply was contemplated it has not been provided at Regina to date) or to burn powdered bituminous coal or lignite. It consists of a water and steam cooled furnace, 4-drum bent tube boiler, combination superheater and tubular air preheater. A new unit now being installed at the Regina plant is described[7] in another paper in this symposium.

Data for certain western Canadian steam generating plants are shown in Table II for the period November 30th, 1934 to November 30th, 1935. Approximate performance data for four units are shown in Table III; operating conditions of seven units installed 1928-30 are given in Table IV.

### Boilers

The bent-tube type of boiler has been chosen for all recent installations of large high pressure units. The majority are of the Stirling type, with the exception of Regina, Fig. 12, and Moose Jaw, Fig. 18, which burn pulverized coal, all are equipped with chain or travelling grate stokers. In certain cases, stokers were installed in place of pulverized coal for the reason that it was not desirable to discharge powdered coal ash from the stack over the surrounding city. At that time methods for dust removal from flue gases had not been successfully developed. Today the efficiency of dust recovery with precipitators ranges from 90 to 95 per cent. It is noted that when the design conditions of a boiler differ from those on which it is operating, this difference has an effect on the performance of the boiler.

Moderate ratings of 200-300 per cent are favoured. Boiler drums are of liberal proportions and are riveted. The average availability of the Edmonton boiler was 96 per cent in 1933 and 97.5 per cent in 1936. The Regina boiler is shut down twice a year for cleaning and inspection, each period usually taking two weeks. The Lethbridge boiler is shut down for cleaning and inspection every three months. The one-boiler one-turbine system is favoured as the modern trend and has been adopted in certain plants. One station has operated with one boiler and one turbine for over five years, excepting for the periods of shut down of each, and has never had a shut down due to a fault in either boiler or turbine. Availability of the Saskatoon boilers is about 97½ per cent. Steam scrubbers, or steam washers for removing moisture and avoiding the carry-over of dissolved solids, have not been adopted but dry pipe separators are used.

*Superheaters*

With the single exception of Regina, all superheaters in recent installations are of the convection type described as "pendant." The Regina boiler has the combination of convection and radiant types which has the advantage of producing a flat superheat curve with a varying steam output. Experiences with combination superheaters are described[8] elsewhere. As an alternative to the radiant superheater, a disposition has been shown, notably at the Picture Butte plant of the Canadian Sugar Factories, to place the convection superheater nearer the fire so that less boiler surface is between it and the furnace, as shown in Fig. 17. One plant reports that a damper regulator limits the variation of superheat, over the operating range, to 10 deg. F. One plant reports drainage facilities for the convection superheater. The combination type is drained. One operator of a stoker-fired plant reports trouble in controlling superheat and is inclined to blame the furnace design in which laning or streaking

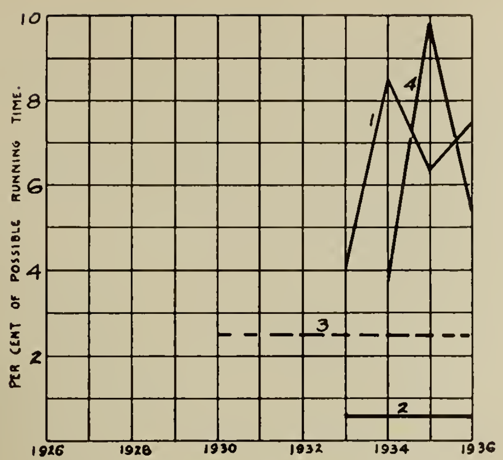

**Fig. 11—Outage of Largest Boiler.**

of the fire occurs. Provision for dust and slag removal from the superheater tubes, is usual.

*Air Preheaters*

In the case of stoker installations, preheated air is often used in conjunction with an economizer to insure proper heat-recovery. The distribution of heating surfaces between these units depends upon their respective costs in individual cases. One of these units may be omitted. At the Delray station of the Detroit Edison Co. preheated air at 500 deg. F. has been used.[9] Stoker grate bars must be properly ventilated to withstand the temperatures involved. Not less than four air preheaters are in service in the stations under review and the plate, regenerative and tubular types are represented. Temperatures range from 300 to 400 deg. F. One of the smaller stations omitted the air preheater, the economizer serving instead for heat recovery. The stoker, however, is designed to permit the use of preheated air to 450 deg. F. One of the larger plants, in which the furnace walls are air-cooled, omitted the economizer. No trouble has occurred from wear or fouling with flue dust.

*Economizers*

Both the integral and external types of economizer are in service. An example of the former is shown in Fig. 15. The feedwater is supplied to this economizer at 210 deg. F. and no trouble arises from corrosion or deposit of flue dust. This temperature is within 10 degrees of the 220 deg. F. commonly adopted.

*Boiler Feedwater*

The adoption of high pressures and temperatures requires very careful attention to the quality of the feedwater for the boiler and the conditions which obtain in the boiler itself. A notable reduction in the percentage of make-up required to compensate for leakage, soot blowing and vent losses, is shown by certain representative plants during the last five years in Fig. 7. The practice of supplying only deaerated distilled water to the boiler is usual in the larger high-pressure, and some of the smaller, stations. Substantial returns are yielded even in the smaller low-pressure plants in the form of reduction in costs for boiler cleaning, replacements due to corrosion, and excessive blowing down of the boiler to avoid high concentration of solids and carryover.

Single- or double-effect evaporators, having effective descaling features are added to the turbine heat balance, together with an evaporator condenser and raw water heater. Mechanical deaeration of all feed to the boiler is provided by an open deaerator heater in which high pressure steam is bubbled through the feedwater. The feedwater in the heater requires to be at the same temperature as the steam in the heater. The air is entrained by the bubbles of the high-pressure steam and discharged to the atmosphere through the heater vent, which is equipped with a gleaner condenser. The purpose of this condenser is

to recover heat otherwise wasted through the heater vent. By this process the oxygen content of the feedwater is reduced to 0.03 c.c. per liter. Residual dissolved oxygen is removed by adding sodium sulphite to the feedwater as it enters the boiler, and should be practically zero by the Winkler test. Where economizer protection is desired, a continuous feed of sodium sulphite before the boiler feed pump suction, is preferred. The use of sodium

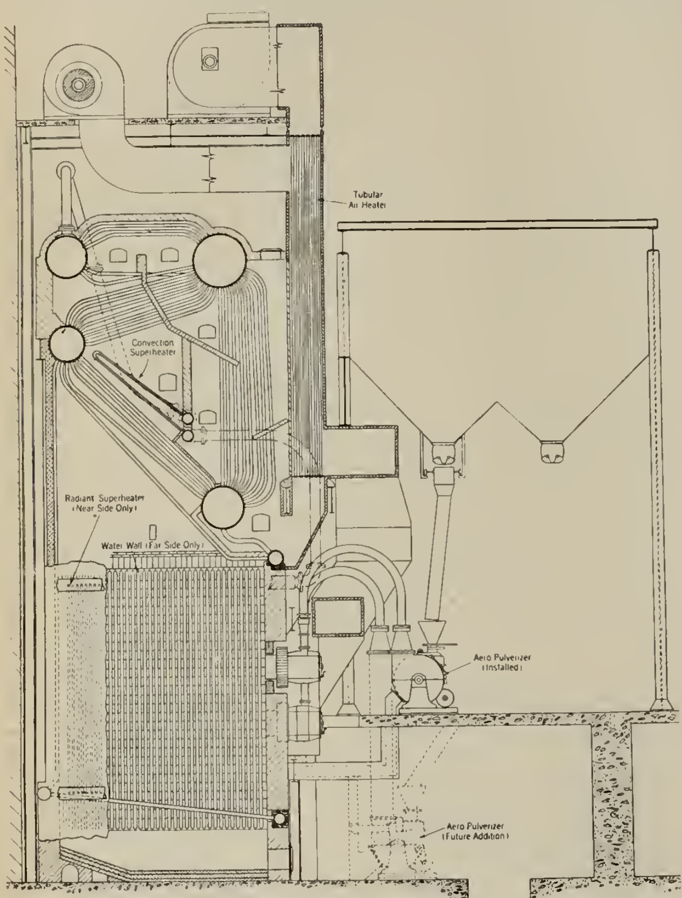

**Fig. 12—Boiler 9, City of Regina Municipal Power Plant.**

sulphite has been reported[10] as satisfactory in laying up idle boilers filled with water when a *pH* or "acidity index" value of 11.6 or higher and a residual of 20 p.p.m. or more of sodium sulphite were maintained throughout the boiler.[11]

The boiler damage, which has been ascribed to the condition of the feedwater in the boiler and named "caustic embrittlement," has been observed in certain areas of this continent and abroad. The earlier investigations have been discussed[12] elsewhere. This phenomenon was exhibited as higher pressures and temperatures were adopted in boilers having riveted drums. The conditions which cause caustic embrittlement of boiler material, its detection and the control of feedwater conditions to prevent its action are now understood and have been discussed[13] elsewhere. Current practice in the central stations of the United States has been summarized.[14] High alkalinity of the water in the boiler drum is maintained to reduce corrosion. A *pH* value of 9.6 is considered necessary and with high silicates may be as high as 11. High alkalinity at high boiler pressures requires a large amount of sodium sulphate to maintain the A.S.M.E. sulphate-alkalinity ratio to inhibit caustic embrittlement. Sodium phosphate is used at times to reduce the quantity of sulphate necessary to control residual hardness from condenser leakage and to lessen boiler-water concentration. An example of the variation in the composition of river water is shown[15] in Table V.

Reduction in the percentage of make-up of feedwater necessary simplifies the problem of chemical treatment. Pieces of polished boiler plate have been used as detector rods for corrosion. The importance of an accurate knowledge of the conditions of the feed- and boiler-water and adequate means for its control cannot be stressed too strongly.

Reserve storage of distilled feedwater amounts to from 0.5 to 1.35 imperial gallons per kw. of capacity as compared to 2 U.S. gallons in some of the large stations.

A classification of Canadian coals has been proposed,[18] and the composition of Canadian coals has been described[19] elsewhere. Coal friability tests have been conducted[20] and reported on.

*Coal and Ash Handling*

Clam shell buckets are in use for handling both coal and ashes. Crushers have been located over the coal bunkers and under the firing floor. In one plant the coal is burned as received and without crushing. Roll jaw crushers and ring crushers are used. A skip or bucket is used to elevate the coal, and a belt conveyor for distribution to the bunker. A suspended catenary bunker has been provided in one of the recent installations. Coal storage areas range up to 1.25 acres. High moisture coals tend to give trouble from spontaneous ignition in storage piles. It has been stated that the size and temperature of the coal when it is put into the pile are important factors in determining the heating effect, and coal between ¾ in. and 1½ in. in size stored during warm weather gives the greatest amount of trouble. Further, that fine coal stored during the winter months gives little trouble even over a period of months. During very cold weather, high moisture coal supplied from a storage pile which has become mixed or impregnated with snow requires heating to prevent caking or arching in the hopper of the stoker.

Three methods of removing ash are employed, by car from ash pits in dry form, by steam jet conveyor and by hydraulic sluice. Trouble has resulted from the freezing of discharged ash. When the ashes are handled in dry form adequate ventilation of ash tunnels is required. Ashes and cinders are used for street maintenance in certain cases.

Trouble has been experienced with segregation of the coal in the pipes leading from bunker to stoker, causing an uneven fire. Segregation of the fuel may occur in the stoker hopper as a result of poorly sized and prepared fuel. Laning or streaking of the fire has been ascribed to this segregation. A device, installed at the Picture Butte plant to prevent segregation is illustrated in Fig. 19.

*Pulverizers*

The two pulverized coal stations in active operation are Moose Jaw and Regina. The performance of the former is shown in Table I, and that of the latter is discussed[7] elsewhere.

At the National Light & Power Company plant at Moose Jaw are installed two C-E (Heine) bent tube, 4 drum, boilers (shown in Fig. 18), 7,000 sq. ft. heating

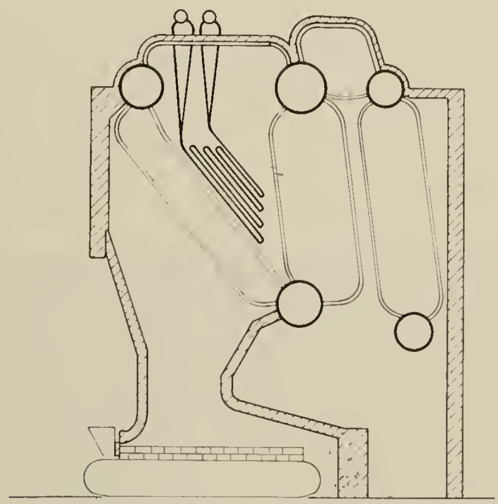

**Fig. 15—Stirling Boiler with Economizer Coxe Stoker and Rear Arch Furnace. Lethbridge Station.***

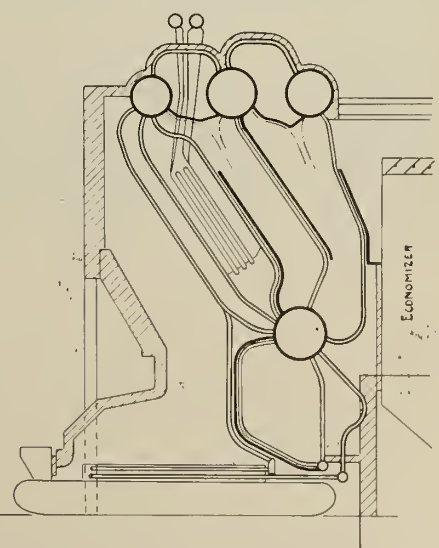

**Fig. 16—Stirling Boiler, Water-cooled Rear Arch and Side Walls along Stoker Grate Line. Prince Albert Station.**

*See Table II for details.

surface each, design pressure 275 lb. per sq. in. with 260 lb. at the superheater outlet. Both side walls are water cooled with finned tubes, while the rear and bottom have plain tubes. Each unit has two Raymond No. 50 high speed (impact) pulverizers and two type "D" 20 in. burners. The first unit installed in 1929 is equipped with a Riley (Thermix) air preheater, and the second (1930) a C-E plate type air preheater of 7,040 sq. ft. heating surface. The capacity of each unit is 45,000 lb. per hour

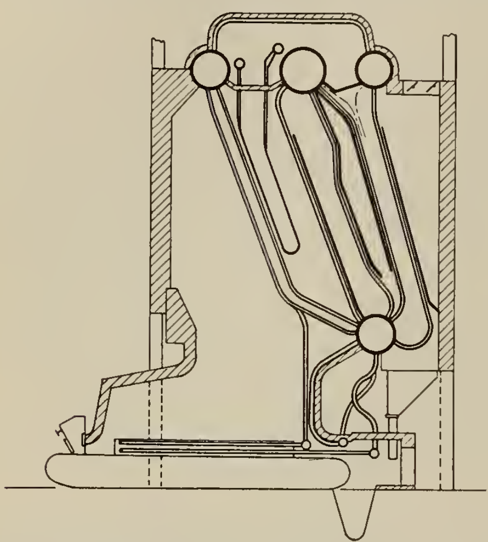

**Fig. 17—Stirling Boiler with Dutch Oven, Water-cooled Rear Arch and Side Walls above Stoker Grate Line. Picture Butte Station.**

with a maximum of 60,000 lb. per hour. This plant burns all western Canadian coals as well as fuel oil or natural gas, if available.

At the city of Regina plant in Regina the pulverized coal equipment consists of a Foster-Wheeler (Kidwell) 4-drum bent tube boiler (shown in Fig. 12), 16,500 sq. ft. heating-surface, design pressure 400 lb. per sq. in.; water walls with tile back 1,452 sq. ft.; ash pit screen 1,349 sq. ft.; furnace volume 13,000 cu. ft. above ash pit screen; convection superheater extended surface, one loop, 66 units 35 ft. long; radiant superheater in furnace, 34 units 2 in. diameter, 19 ft. long; air heater 20,240 sq. ft.; pulverizers, B-W pressure type ball mill rated at 12,000 lb. per hour on coal having a grindability factor of 82 per cent.

This plant also is capable of burning all Western Canadian coals and/or oil.

Lignite coals grind easily in spite of the high moisture content. It is necessary, however, to pass about 50 per cent more air through the pulverizer on account of the high moisture content, it being necessary to furnish the larger weight of air in order to remove sufficient moisture to grind the coal. There is probably about 7 to 10 per cent of moisture remaining in the coal in its pulverized form. 18 to 19 kw.h. per ton are required for certain Alberta lignite coals compared with 12 to 14 kw.h. per ton for Alberta bituminous coals and 19 kw.h. per ton for Saskatchewan lignite. Analyses of these coals have been published.[16] Pulverizing capacity of the mill is reduced about 25 per cent when grinding lignite coal as compared with bituminous coal. The percentage of pulverized lignite coal passing through the 40,100 and 200 mesh screens is reduced considerably. One of the Regina mills has ground more than 70,000 tons of fuel with the original grinding elements, and has done this without a decrease in the original fineness.

### Furnaces

Zoned air control in chain grate stokers which burn lignite and sub-bituminous coals is generally satisfactory. Difficulty arises when more than the requisite number of zones are provided, in that it takes too long for the fireman to examine the fire and then rearrange the dampers to suit conditions in the furnace. This condition results in a lack of flexibility. In one case the design provided for combustion rates from 15 to 57 lb. of coal per sq. ft. of grate surface per hour and a good average is 40 to 45 lb. The latter gives a heat release per foot of width of 7.4 million B.t.u. per hour.

One of the recent stokers burned an average of 37 lb. of lignite coal per sq. ft. of grate surface in 1936, with a heat release per foot of width of 5.75 million B.t.u. per hour. A smaller stoker burned a maximum of 52 lb. of sub-butiminous coal with an average of 17 lb. The maximum heat release per foot of width is 6.85 million B.t.u. per hour. No recent installations of underfeed stokers have been made in central stations. One of the older stokers, installed to provide flexibility, exposed capacity limitations at a moderate rating. Difficulty arose from slagging due to the moderate fusion temperature of lignite coal, as follows: Tofield, 2,000 deg. F.; Edmonton, 2,100 deg. F. and for slack, 1,800-2,000 deg. F.; Coalspur, 2,000-2,300 deg. F.; Pembina, 2,400 deg. F.; Lethbridge sub-bituminous, 2,100 deg. F.; and bituminous, 2,200-2,800 deg. F. Satisfactory performance was not obtained, for example, with slack from the Edmonton area, although this trouble does not occur when the slack is burned on chain grate

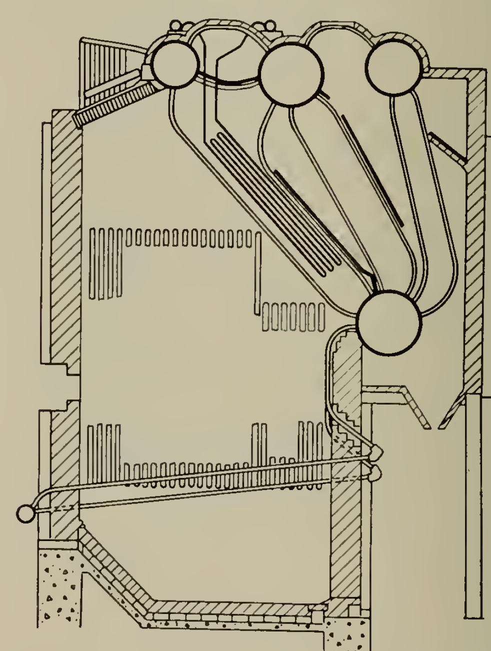

**Fig. 18—C-E Bent Tube Boiler, Waterwalls, Type D Burners and Air Preheater. Moose Jaw Station.***

stokers. The recent developments of providing water-cooled piping above the tuyères,[21] overfire air, carborundum extension grates, and water-cooled side walls are promising in view of the lower cost of underfeed stokers. Two pulverized coal plants are equipped for burning oil simultaneously with the coal.

In one station automatic draft-control equipment is provided in connection with an automatic stoker in an old plant. In new steam-generating plant, hand control is adopted for the stoker and combustion-control,

*See Table II for details.

the latter being the usual arrangement. Maintenance cost on this equipment is reported as low.

The trend in furnace design is toward a completely water-cooled furnace, with combustion space of ample proportions to allow combustion to be completed before the tube bank is reached. Furnace temperatures are maintained by employing refractory or cast iron protection for the tubes on the furnace side.

Table I shows a tendency to high values for heat release per cubic foot of furnace volume. The practice has been to allow higher values of heat-release with coals in which the fusion temperature of the ash is low, and lower heat-release values when the fusion temperature of the ash is high; the older values for design are 12,000, 17,000 and 34,000 B.t.u. per cu. ft. of furnace volume per hour for refractory, air-cooled and water-cooled furnaces respectively. Recent installations have lower values as, for example, at Port Washington, a large steam generating unit with water cooled walls, in which the heat release is only 15,000 B.t.u. per cu. ft. per hour. Excessive heat release values tend to shorten the path from the grate to the tube bank and result in imperfect combustion. They also lead, especially in the case of refractory walls, to abnormal maintenance costs.

*Stoker Fired Installations*

Typical stoker fired units are to be found at Edmonton, Lethbridge, Picture Butte and Prince Albert. The Edmonton unit, Fig. 13, consists of a Harrington travelling grate, 20 ft. wide by 18 ft. long, driven by a 10-hp. motor through a Reeves variable-speed reduction gear. Forced draft is supplied through six compartments. A large triangular front arch facilitates ignition. Side walls are air cooled and fitted with shaped carborundum bricks, intended to prevent building up of ash and slag on the furnace walls. The bricks begin 2 ft. from the hopper and extend for 13 ft. 6 in., to a height of 10¾ in. above the grate. Rear arches are also installed. Air to the stoker is at 300 deg. F. The fuel is Edmonton lignite coal, crushed to 1 in. and under. The furnace volume is 3,800 cu. ft.

At the city of Lethbridge plant, two Coxe travelling grate stokers, 9 ft. 8⅝ in. wide and 13 ft. 8 in. long, have been installed under two bent tube Stirling type boilers, shown in Fig. 15. These have 5,000 sq. ft. heating surface each. The boilers were designed for 272 lb. per sq. in. and 580 deg. F. and have a maximum rating of 48,000 lb. per hr. each. The furnace volume is 2,000 cu. ft. The fuel burned is Lethbridge high ash clinkering coal.

The Picture Butte boiler of Canadian Sugar Factories and the Prince Albert boiler of the Dominion Gas and Electric Company, have been equipped with water-cooled bridge walls of the stud-tube type shown in Fig. 20. This construction eliminates the structural difficulties often encountered in supporting a large refractory bridge wall, and maintenance at this point.

*Waterwalls*

Waterwalls of bare tubes, fin-tubes, block-covered, and stud-tubes are in use. Stud-tubes, covered with refractory material, have less tendency to overcool the furnace than the bare tubes.

Trends in furnace design are toward completely water-cooled furnace walls. Nearly one-sixth of the total heating surface is installed in the furnace and this radiant heating surface yields about half of the boiler capacity. It has been stated that, for western coals, a completely water-cooled furnace cannot be justified on a stoker installation, and water-cooling of the side walls, at least along the stoker grate line, will probably be essential on large installations. This eliminates the trouble caused by ash and slag building up on the furnace walls and interfering with the movement of the fuel along the stoker.

*Dust Removal from Flue Gases*

Considerable progress has been reported from England and the United States in the removal of flue dust discharged from pulverized coal furnaces and in the design of cinder catchers to remove cinders which are characteristic of certain stoker installations. Electro-static precipitators have an efficiency of from 90 to 95 per cent, and dust catchers of the cyclone type, 70 to 90 per cent. Film and spray washers, cinder traps, dust catchers, cinder vane fans and other devices are also in use.

Consideration of this rather costly service will be required in future installations of large steam-generating plant located within or close to city limits.

*Boiler-Auxiliary Plant*

Soot blowers continue in common use and the practice of employing the hand lance as a finishing operation in places not reached by the soot blowers has not been adopted. Some difficulty has been caused by failure of the blowing elements. Loss of treated condensate is offset by the added convenience of the soot blowers. Hydraulic couplings for fan regulation have not been employed. A single preference has been expressed for this device on future installations.

Forced draft fans have been operated by a turbine operating at high pressure and exhausting into the mains of the old low pressure plant. Induced draft fans are served by two direct connected motors, one having two and one half times the capacity of the other.

### Piping

Welding of boiler drums (to prevent caustic embrittlement) and of piping throughout the plant has not been generally adopted. The art of welding and methods for inspection of welded joints have been highly developed in recent years and offer useful benefits in the case of larger installations. Piping materials and welding practice, piping experiences at 1,000 deg. F., and corrugated and creased-bend piping have been discussed[22,23,24] elsewhere.

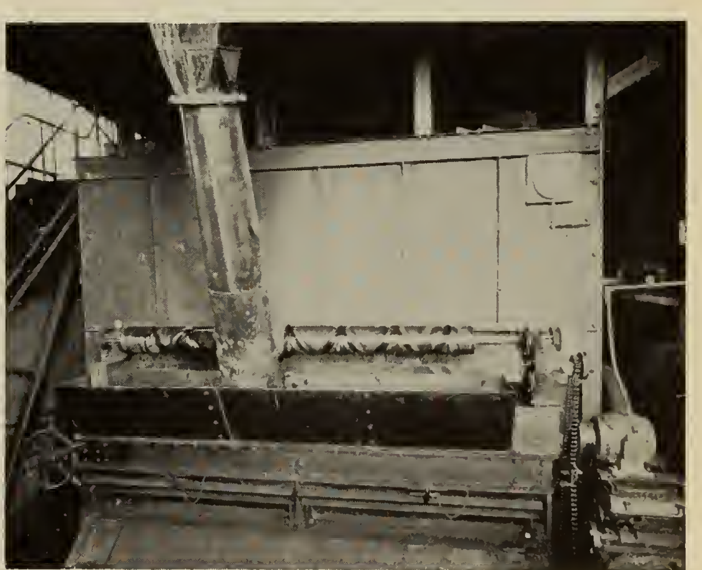

Fig. 19—Traversing Coal Chute.

### Personnel

Large new central station plant offers attractive opportunities for men with scientific training to act as operatives, chemists, etc. Such personnel require laboratory facilities for testing of feedwater, fuels, gases and lubricants. Persistent vigilance in the steam-generating plant is required if satisfactory results are to be obtained.

### Conclusions

Evidence of improvement in the operation of typical central stations is shown in the annual reduction of the station performance and percentage of feedwater make-up. Station load has resumed a normal upward trend. Increased fixed charges reflect the introduction of modern equipment, are moderate and in some cases low. Heat release values tend to be high and furnace volumes low, as compared with modern practice in the larger stations in other places. Low rank Alberta coals are being burned successfully in underfeed stokers at rather low ratings. For larger plants and at medium ratings the forced draft, chain grate stoker is preferred, and where a variety of coals are in competition the pulverized coal furnace is used. The economy to be obtained by the generation of electric energy in high pressure steam turbines which exhaust into low or moderate pressure mains for factory processes or heating, is not generally appreciated, as shown by the fact that various establishments have discontinued generation of power in their own plants and have reverted to the purchase of their energy requirements while operating their steam-generating equipment as a heating system only.

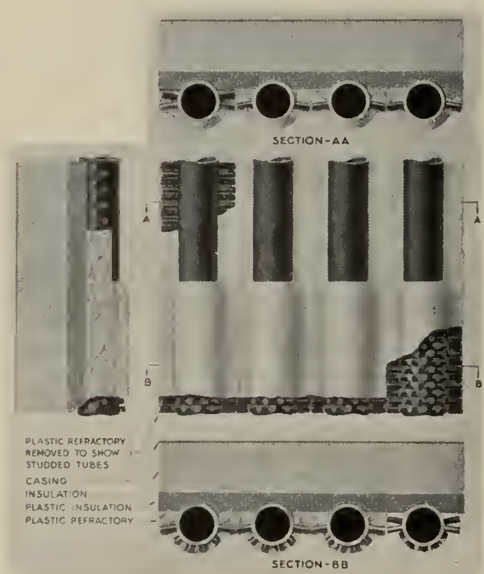

**Fig. 20—B-W Bailey Stud-Tube Furnace Wall. (See Figs. 16 and 17.)**

Architectural design of new station buildings and landscaping of the station grounds have produced more beautiful surroundings. The use of light paint and the omission of partitions have resulted in cleaner and more pleasing interiors. Attention is required in the design of coal and ash handling equipment to insure a fair harmony with station buildings. Recent developments in the art of welding offer advantages which may well receive consideration in the construction of new plant.

# The Saskatchewan Lignite Industry

## An analysis of recent developments in the industry and the effect of production methods on employment and earnings of labour.

*R. L. Sutherland,*
*Combustion Engineer, Truax-Traer Coal Company Limited, Winnipeg, Man.*

**Paper presented at the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

SUMMARY.—Statistics of production are given. The paper discusses causes of the recent expansion of the industry, noting unsatisfactory conditions as to employment and earnings of workers and the provincial legislation which followed. Satisfactory continued development is possible with a smaller number of adequately equipped mines.

The Saskatchewan lignite industry owes its existence to the geographical position of the field in relation to other producing fields and proximity to the more densely populated areas of the prairie provinces. Its future development will depend on the extent to which production methods are adopted which require the minimum capital investment in relation to production value and which, at the same time, reduce the present seasonal fluctuation in employment to a practical minimum. These conditions are essential to the financial stability of the industry and the building of a self-sustaining industrial community.

During the past six years of general economic depression, aggravated locally by crop failures, production in the lignite field has doubled, in competition with overdeveloped production capacity in other fields, for a shrinking market. The increase in production facilities during this period has followed two distinctly different lines, (1) an extension of existing underground methods dependent largely upon hand labour, and (2) mechanized strip mining. The increase in production from the field has been divided about equally between the two methods.

Analysis of statistics covering the past decade shows the trend of development along these two lines and the effect of each on employment. While the available statistics are general in nature and do not permit complete accuracy of analysis, the trends show definitely the dangers of uncontrolled development, and the type of development required for stability of the industry.

An unhealthy condition of employment and earnings of the workers in the underground mines has developed in recent years due to (1) an increase in the range of seasonal production, (2) lack of supervision over wage schedules and working conditions during the earlier years of the period of depression and (3) stabilization of mine prices by operators of the larger mines at levels permitting normally uneconomical operations to develop.

Lignite, as the name implies, is a low rank coal characterized by high moisture and oxygen content. It disintegrates on exposure to weather or heat. The volatile constituents of the lignite found in the northern great plains region contain relatively small proportions of hydrocarbons recoverable as liquid distillates. Its heat value is the lowest of the coals mined commercially in Canada. The characteristic property which offsets the physical and chemical disadvantages and permits its use in the natural state is the greater relative reactivity of the carbon content.

The coal is favourably located for economical recovery, lying in relatively thick horizontal beds, close to the general surface level but protected from weathering by a tight clay cover. In underground workings, roof and floor conditions are favourable and there are no complications from gas or excessive water. Much of the coal lies sufficiently close to the surface to be recovered by strip methods.

The average cost of production, as shown by statistics published by the Dominion Fuel Board, is the lowest in Canada both in actual cost per ton and in relation to heat value.

Capital employed per ton of annual production is lower than in the other western provinces or the average for Canada, but is higher per dollar of value on account of the lower unit value of the coal.

Factors affecting the rate of development of the Saskatchewan industry in recent years may be summed up as follows:—

1. Earlier development of production facilities in competing fields with control of the market;

**Fig. 1—Ten-ton Electric Stripping Shovel Removing Clay Overburden up to 65 Feet in Depth.**

2. A shrinking total market in the western provinces;
3. A localized market due to the low heat value of the product;
4. Seasonal market;
5. Available burning equipment.

1. While the history of the Saskatchewan industry covers practically as long a period as in the other western provinces, production figures are still small by comparison. In British Columbia the peak of production and value was reached in 1920; the peak of value was reached in Alberta in 1920 and of output in 1928. Production and value in Saskatchewan have been increasing to date. Production for use in the natural state has doubled since 1929.

2. Between 1929 and 1935, the last year for which complete data are available, coal consumption in Saskatchewan, Manitoba and Western Ontario, exclusive of locomotive fuel, decreased 900,000 tons or 24 per cent. The total decrease was made up of

(*a*) A reduction of 437,000 tons in shipments from Alberta and British Columbia, and
(*b*) A reduction of 803,000 tons in imports for other than railroad use, offset in part by an increase of 340,000 tons from the Saskatchewan field, which was further increased by 90,000 tons in 1936.

A part of the decrease in coal consumption is accounted for by an increase in the use of wood available because of a temporary employment and economic condition;

part represents reductions due to more economical or efficient use of coal in industrial plants and for domestic heating. An increase in the use of competitive fuels, oil, and electric energy from hydro-electric plants, has also contributed to the reduction in total fuel burned.

3. The practical market available to Saskatchewan lignite is limited by its lower heat value in relation to competitive western coals and coal imported through the western lake ports, to an area roughly determined

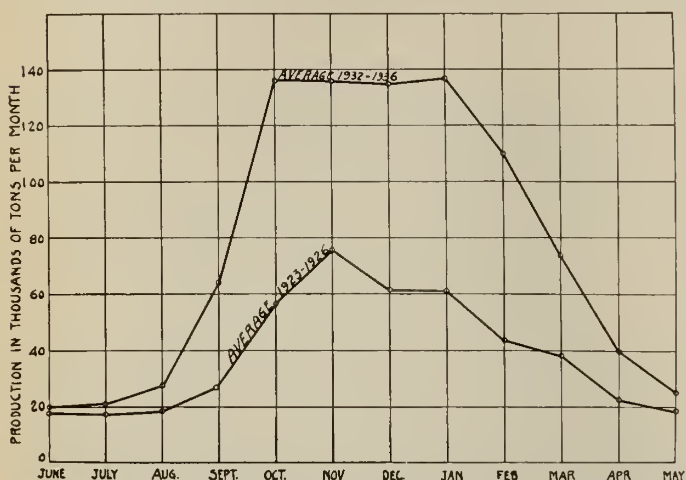

**Fig. 2—Average Monthly Production of Saskatchewan Lignite.**

by a $2.30 freight rate on the east and north and a slightly lower rate to the north-west and west. This potential market area covers approximately 50,000 square miles with a population of about 700,000 people. Freight rates to the larger cities, from Moose Jaw on the west to Winnipeg on the east, range from $1.90 to $2.30 per ton.

4. Production of all coal mined in Alberta and Saskatchewan for domestic and most industrial uses, except part of the locomotive coal, is seasonal and follows weather conditions as measured by degree-day-deficiency. Production in Saskatchewan follows weather conditions more closely than in the other western provinces because,

- (*a*) lignite weathers when stored in open sheds in mild weather;
- (*b*) the additional cost of handling the lower rank fuels through storage adds a greater proportion to the delivered cost than is the case with higher rank fuels;
- (*c*) steam generation of power in the more industrialized portion of the market territory is limited by the availability of low cost hydro-electric power.

Table I and Fig. 2 show production by months for two periods in which annual production for each period was approximately uniform, the average of three and four year periods being used to equalize the effect of variations in monthly temperatures from year to year. It will be noted that while winter production increased about 80,000 tons per month, midsummer production increased less than 4,000 tons per month.

Table I and Fig. 3 show the close relation between monthly production above the midsummer minimum, and degree-day deficiency, when both are expressed as percentages of the total for the heating season. It will be noted that the production curve rises in advance of the degree-day-deficiency curve, due to stocking of coal in the rural districts during the period of grain movement from the farms, and falls off only slightly earlier than the temperature curve toward the end of the season. The degree-day-deficiency curve is based on Winnipeg weather data.

Table I

Production by months for two periods showing relative increase in summer and winter output. Also showing excess of monthly production above midsummer average as a percentage of the seasonal excess by months.

| Month | 1923–1926 | | | 1932—1936 | | | Deg. day deficiency average per cent |
|---|---|---|---|---|---|---|---|
| | Tons | Tons less midsummer average | Per cent of tons for heating season | Tons | Tons less midsummer average | Per cent of tons for heating season | |
| June | 17,606 | | | 20,074 | | | |
| July | 17,373 | | | 21,262 | | | |
| August | 18,034 | 544 | 0.2 | 27,696 | 7,028 | 1.1 | |
| September | 27,724 | 10,234 | 4.1 | 64,672 | 44,004 | 6.4 | 3.65 |
| October | 56,805 | 39,315 | 15.7 | 136,596 | 115,928 | 17.0 | 7.15 |
| November | 76,209 | 58,719 | 23.5 | 136,716 | 116,048 | 17.0 | 11.35 |
| December | 61.746 | 44,256 | 17.7 | 135,455 | 114,787 | 16.8 | 16.35 |
| January | 61,175 | 43,685 | 17.5 | 137,081 | 116,413 | 17.0 | 18.25 |
| February | 43,529 | 26,039 | 10.4 | 110,860 | 90,192 | 13.2 | 17.20 |
| March | 38,327 | 20,837 | 8.4 | 74,553 | 53,885 | 7.9 | 13.40 |
| April | 22.639 | 5,149 | 2.1 | 40,104 | 19,436 | 2.9 | 8.05 |
| May | 18,441 | 951 | 0.4 | 25,797 | 5,129 | 0.7 | 4.60 |

Figure 4 shows the similarity between the production curves for the Saskatchewan and Alberta lignite fields. Production of Alberta lignite leads that in Saskatchewan in the early part of the season and falls off earlier at the end of the season, the slight differences being due to the better storing qualities of some of the Alberta lignites. The production curve for the Alberta bituminous coals, used chiefly for locomotive fuel, shows an almost negligible dependence upon weather conditions.

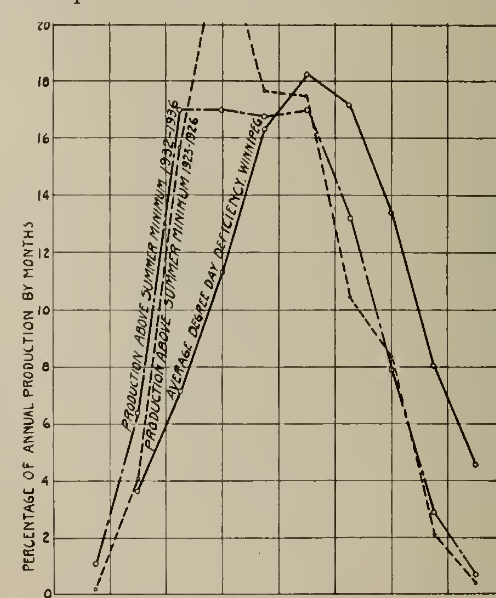

**Fig. 3—Relation of Monthly Production of Lignite to Weather Conditions.**

5. Prior to 1930 the burning equipment installed in industrial plants was designed primarily for burning the higher rank western and imported coals. Since that time many plants, both large and small, in which burning equipment had become obsolete or worn out, have been equipped to burn lignite efficiently.

Lignite production for use as mined has increased from 500,000 tons in 1929 to 1,014,000 tons in 1936. While no accurate data are available it is estimated that of this increase approximately 400,000 tons has been absorbed by the industrial market. At the present time not less than half of the production from the field is used in industrial plants. The large increase in the use of wood due to a temporary economic condition has retarded the rate of increase of lignite for domestic heating.

The increase in the use of Saskatchewan lignite, particularly in industrial plants, has been brought about through

1. Improved preparation of the coal at the larger mines to suit market requirements;

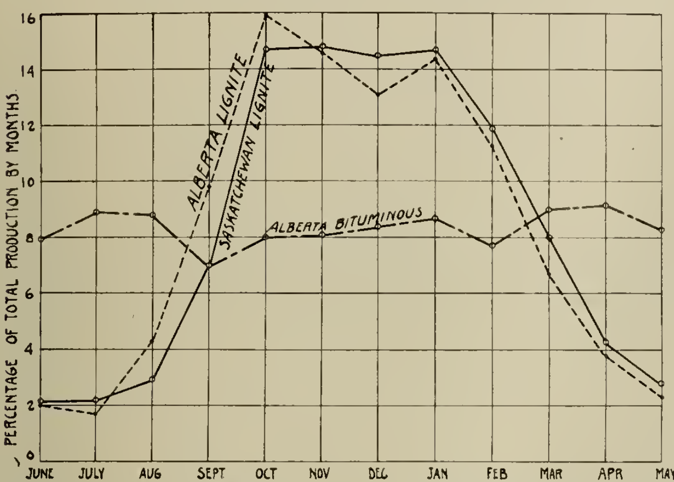

**Fig. 4—Comparative Production for Alberta Bituminous and Lignite and Saskatchewan Lignite Mines.**

2. Promotion of the installation of burning equipment suitable for use with lignite;
3. Co-operation of the Saskatchewan government;
4. Assistance given by the Dominion government in the form of subventions.

Lignite is now available from the larger shipping mines in a range of sizes designed to meet all normal market requirements. The larger sizes are used principally for domestic heating and the smaller sizes for hand fired and stoker fired industrial plants.

The industry has co-operated with manufacturers and plant owners in the design or modification of industrial plants to ensure the maximum economy with the fuel. Several new plants have been designed and built in recent years.

Equipment which has proved most suitable for developing high efficiency with lignite as well as with other available western coals is of two general designs, both of the overfeed type. In smaller plants, or larger plants in which the load factor is relatively low, mechanical coal feeders with non-sifting grates and forced-draft fans have proved most economical. In larger plants, under more nearly continuous load, non-sifting, forced-draft, travelling-grate stokers have been installed. In most cases air-preheaters and induced draft fans have been included with the latter type.

In many hand-fired plants, lignite has displaced coals of higher rank, without change in equipment other than the installation of forced-draft fans. The additional labour for handling the increased quantity of the lower rank fuel has been offset by the reduction in labour for maintaining the fuel bed and breaking up coke.

In plants equipped with underfeed stokers, not suitable for developing maximum capacity or economy with lignite alone, mixtures of lignite and coking coal are being burned at higher efficiencies than could be obtained with either fuel alone, and at substantial reductions in the cost of steam. The proportions of the two coals vary with plant conditions but in every case best operation and lowest steam cost are obtained with mixtures in which the lignite predominates.

The use of lignite in industrial plants in Saskatchewan has been stimulated by the action of the provincial government in equipping the power and heating plants under its control in the southern part of the province to burn the native fuel. The economies effected have more than repaid the entire investment cost of the improvements.

The granting of subventions by the Dominion Government on coals mined in western Canada for shipment to industrial plants in eastern Manitoba and western Ontario, has resulted in the displacement of large tonnages of imported coals by Canadian coals, in which the Saskatchewan industry has participated. Present subventions are based on transportation cost and since Saskatchewan coal moves relatively shorter distances to market the per ton subsidy is less than for other fields.

Total shipments of Saskatchewan coal into Manitoba and Ontario increased from 230,929 tons in 1929, without government assistance, to 408,822 tons in 1935, an increase of 177,907 tons. Of this increase 138,584 tons moved under subventions ranging from fifteen cents per ton to thirty-five cents per ton, with an average for 1935 of twenty-three cents per ton. The average subvention paid on all Canadian coals in 1935 was ninety-four cents per ton. Increases in shipment of bituminous and sub-bituminous coals from other western provinces into the same territory were 147,285 tons less than the total shipments under subventions in 1935. Lignite shipments from Alberta to Manitoba and Ontario decreased 228,917 tons or 45.7 per cent in the same period.

### Recent Trends in Development of Production Plants

The lignite area is divided naturally into two producing fields, viz.,

1. A field in the south-western part of the province in which smaller deposits are mined for local use. Production in this field in 1936 was approximately 10 per cent of the total.
2. A field at the eastern end of the area, served by both railroads, from which practically all of the coal shipped by rail or commercial truck is produced. Production from this field in 1936 was approximately 90 per cent of the total.

**Fig. 5—Loading Lignite into 4-ton pit Cars at Opencast Mine.**

Prior to 1930 about 90 per cent of the total tonnage was produced by six underground mines. Production from these mines in 1936 represented about 50 per cent of the increased total for the province. In 1930 a mechanized strip mine was opened, production from which accounted for the greater part of the increase in field output for two years. Since that time the increase has been taken up largely by smaller underground mines. The increase in production from these smaller mines has been made possible by an abnormal labour condition.

Of the present total field production, approximately 10 per cent is produced for local use in small operations, labour for which supplements employment on the farms or in other local industries; 25 per cent is produced by one fully mechanized strip mine having a minimum of seasonal fluctuation in employment; 50 per cent is produced by four underground mines having annual outputs from 60,000 to 200,000 tons each, with some power equipment; 15 per cent is produced from smaller operations without trackage facilities and dependent almost entirely on hand labour.

As the result of the findings of the Royal Commission which investigated labour conditions in the underground mines in 1931, operators of larger mines agreed to maintain prices at a level which would permit payment of a fair wage scale at the mines affected by the investigation. Operators of the small mines were not affected by the agreements nor did many of them come under the provisions of the Workmen's Compensation Act until after a second investigation in 1935 which resulted in legislation setting up a Provincial Coal Administration.

While the increase in production has provided part time employment for more than six hundred men during a period of economic stress, the trend of the development has not been conducive to a stable industry, from the standpoint of either mine operator or labourer.

The entry of these small mines into the more profitable domestic market has prevented increase in, and in some cases has reduced, shipments of these sizes from the larger and better equipped mines. Increased production from the larger mines has been limited chiefly to the lower priced industrial sizes, with a corresponding reduction in average realization per ton. The reduction of 18 per cent in average realization per ton since 1929 has been due in large part to the increased proportion of coal shipped to the industrial market.

For the purpose of this study the statistics for the more recently developed strip mining section of the industry have been deducted from the total to permit direct comparison of conditions prior to 1930 with those existing in 1935, following a substantial growth in production totals. Figures for capital employed in 1934 are used, as the total for 1935 is incomplete due to the temporary elimination of the capital for one of the larger mines not operating at the end of the year.

Total capital employed in the underground mines increased about 7 per cent between 1929 and 1934. Capital employed per ton of production decreased from $6.88 in 1929 to $6.48 in 1934, but increased from $4.02 to $4.53 per dollar of value due to decreased average realization per ton. The corresponding figures for the strip mining section for 1934 were $3.46 per ton and $2.95 per dollar of value. Comparative averages for Canada in 1929 and 1934 were respectively $8.11 and $8.57 per ton and $2.25 and $2.82 per dollar of value.

### Trends in Employment

As indicated above, average changes in the relation of capital invested to tonnage and value of production in the underground section of the industry were more favourable in Saskatchewan than in the other western provinces, or the average for the Dominion. The change in employment conditions constitutes a more serious danger to the building of a self-sustaining industrial community, without which any industry is of doubtful value.

Comparing production and employment figures for the underground mines for 1929 and 1935, production increased 19.4 per cent with an increase of 20.4 per cent in man days worked. Total value of production increased 3 per cent, with a decrease of 14.8 per cent in earnings of workers. Average realization per ton decreased 23 cents while labour cost decreased 26 cents.

The trend in employment with increasing production in the underground mines is shown in Table II below:—

Table II

| Month | Underground Mine Section | | | | | | Strip Mine Section | |
|---|---|---|---|---|---|---|---|---|
| | 1925–1926 | | 1928–1929 | | 1934–1935 | | 1934–1935 | |
| | No. of men | Av. days per man | No. of men | Av. days per man | No. of men | Av. days per man | No. of men | Av. days per man |
| June | 309 | 14.0 | 298 | 10.7 | 339 | 8.0 | 51 | 20.2 |
| July | 324 | 15.7 | 304 | 11.9 | 351 | 9.1 | 48 | 22.4 |
| August | 309 | 15.5 | 318 | 15.6 | 460 | 11 3 | 47 | 26.4 |
| September | 431 | 17.6 | 457 | 15.2 | 1,031 | 17.3 | 63 | 23.6 |
| October | 731 | 22.7 | 738 | 21.2 | 1,339 | 19.4 | 69 | 29.1 |
| November | 768 | 20.9 | 773 | 17.9 | 1,254 | 17.5 | 65 | 25.4 |
| December | 727 | 17.0 | 719 | 15.6 | 1,158 | 19.3 | 67 | 25.2 |
| January | 650 | 16.3 | 711 | 19.8 | 1,084 | 20.2 | 68 | 29.4 |
| February | 614 | 14.7 | 691 | 17.6 | 946 | 13.3 | 62 | 19.1 |
| March | 537 | 16.1 | 592 | 15.1 | 777 | 14.6 | 57 | 20.5 |
| April | 366 | 13.4 | 413 | 22.7 | 505 | 13.1 | 51 | 21.6 |
| May | 336 | 13.9 | 373 | 17 4 | 397 | 10.6 | 46 | 20.9 |
| | | 197.8 | | 200.7 | | 173.7 | | 283.8 |
| Maximum men | 768 | | 773 | | 1,339 | | 69 | |
| Minimum men | 309 | | 298 | | 339 | | 46 | |
| Ratio—max.-min. | 2.48 | | 2.59 | | 3.96 | | 1.5 | |
| Average earnings per man per day | $4.39 | | $4.46 | | $2.96 | | $4.18 | |
| Tons per man day | 4.34 | | 4.65 | | 4.45 | | 14.2 | |
| Tons produced | 453,732 | | 513,843 | | 694,544 | | 235,685 | |

Table III shows the effect of seasonal production on earnings per man per year. Increase in the seasonal range and dispersal of production among a greater number of smaller operations have both acted to spread employment over a greater number of men and to decrease the employment available to each man. It will be noted that as production has increased, the percentage of the total men working in all twelve months of the year has decreased and the number of man-days worked by this group has shown a slight progressive decrease over the ten-year period. The trend is shown graphically in Fig. 6.

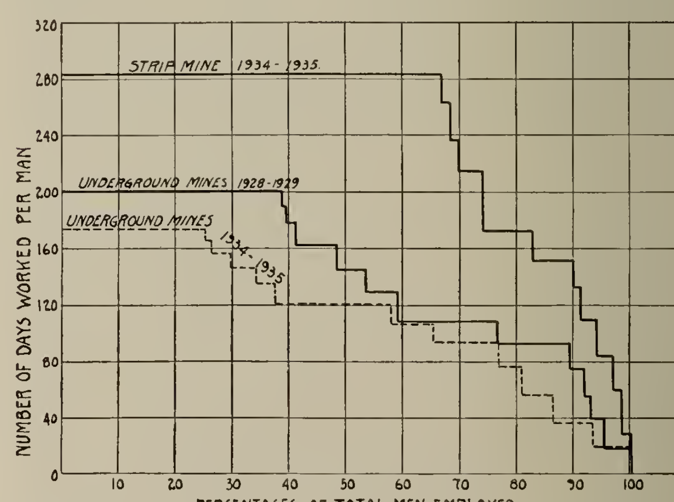

Fig. 6—Employment in Underground and in Strip Mines.

### Stabilization Methods

A Royal Commission was appointed in 1934 to investigate the lignite industry as a result of threatened labour

Table III

Underground Mine Section

| No. of months worked | 1925–1926 | | | | 1928–1929 | | | | 1934–1935 | | | |

disturbances at some of the larger underground mines. Following the submission of the report of the Commission the Saskatchewan Coal Mining Industry Act was enacted in 1935.

By virtue of this legislation the provincial government exercises supervision over wage schedules, and payment of wages, rentals due to the Crown, royalties on coal mined on Crown lands, and Workmen's Compensation assessments. The Lieutenant Governor in Council is authorized "to give force and effect to agreements between groups or associations of operators approved by the minister (of Natural Resources) for stabilizing of conditions in the coal mining industry of Saskatchewan which will ensure fair wages to employees for their labour, fair returns to operators on their investment and fair value to consumers in the form of a more uniform and standardized product. Such agreements may provide for:—

(*a*) minimum prices at the minehead in Saskatchewan for the different grades and sizes of coal;

(*b*) standards of grades and sizes upon which such minimum prices shall be based; and

(*c*) conditions under which such minimum prices shall be observed and maintained."

All mines are operated under licenses issued by the Coal Administrator.

The Act provides machinery for correcting such abuses as were indicated by evidence submitted to the Commission. Other evidence submitted indicated that annual earnings of the men were inadequate on account of short time employment. In the report of the Commission, Mr. Justice Turgeon quoted the following from evidence submitted:—"A large number of the men employed in and about the mines are unable to support themselves and their families while working and practically all of the men are unable to support themselves and their families when laid off or only working part time; and these men and families require to be assisted by their respective municipalities under such conditions;"

With respect to employment, Mr. Justice Turgeon stated "Insofar as these men are concerned the general attitude in respect to wages is not that the schedules of wages are too low, but that the number of working days in the year are too few to allow them to make a fair annual living wage."

Enforcement of the Act can provide increased daily earnings and improved conditions of employment at mines where adequate wages were not paid and where safe working places were not provided. No statistics are available covering employment and earnings since the Act has been in force by which its effectiveness can be measured. It will be evident from the previous comparative employment data that a return to the higher wage schedules of 1929 would not provide an adequate annual income for many of the additional part time workers employed in recent years as a result of increased seasonal production.

No practical method of reducing the seasonal range of production appears possible at this time. Continued increase in production can be expected to further increase the seasonal range of employment. The situation has been aggravated by the general depression and local crop failures, preventing men from obtaining supplementary employment in other industries. It is apparent that a self-sustaining industrial community cannot be maintained under the scale of employment and average earnings indicated by the employment data. The comparative records of recent years indicate that reduction in the proportion of short time employment and increased average earnings require the adoption of production methods less dependent upon hand labour.

The record of development in the lignite mining industry of the adjoining state of North Dakota, in which all physical factors are directly comparable with those in Saskatchewan, shows an increase in the proportion of total production coming from strip mines and an increasing production per man per year in both strip and underground mines due to the use of an increasing amount of

Table IIIA

Strip Mine Section

| Number of months worked | 1934-1935 | | | |
|---|---|---|---|---|
| | Number of men | Per cent of max. number | Number of days | Annual earnings |
| 12 | 46 | 66.7 | 283.8 | $1,185 |
| 11 | 1 | 1.4 | 262.9 | 1,098 |
| 10 | 1 | 1.5 | 236.5 | 989 |

| Total | 69 | 100.0 | | |

power equipment. Detailed data of employment and earnings are not available, the records showing only the maximum number of men employed in each mine. The trend of development over a fourteen-year period is shown in Table IV.

Table IV

Production Statistics for the North Dakota Lignite Industry

| | 1922 | 1929 | 1935 |
|---|---|---|---|
| Total production, tons | 1,057,823 | 1,902,593 | 1,828,213 |
| Value of production, dollars | 2,616,802 | 3,473,658 | 2,385,229 |
| A—Local mines producing less than 5,000 tons per year: | | | |
| Number reporting | 78 | 185 | 320 |
| Tons produced | 236,766 | 214,368 | 242,849 |
| Per cent of total field output produced | 18.0 | 11.2 | 13.0 |
| B—Mines producing more than 5,000 tons per year: | | | |
| Number of strip mines | 6 | 6 | 11 |
| Number of underground mines | 33 | 22 | 26 |
| Output of strip mines, tons | 186,500 | 837,267 | 1,004,045 |
| Output of underground mines | 741,123 | 850,958 | 581,319 |
| Per cent of total field output: | | | |
| From strip mines | 12.5 | 43.9 | 55 |
| From underground mines | 69.5 | 44.9 | 32 |
| Maximum number of men employed in mines producing more than 5,000 tons per year: | | | |
| Strip mines | 297 | 805 | 560 |
| Underground mines | 1,196 | 1,088 | 585 |

Trends in production per man per year, based on the maximum number of men employed, for North Dakota and Saskatchewan, are shown in Table V. The figures for North Dakota include only mines producing more than 5,000 tons per year; figures for Saskatchewan include all mines. Production from mines having annual outputs less than 5,000 tons were 3.4 per cent in 1922, 6.5 per cent in 1929, and 10.2 per cent in 1935, of the totals for underground mines only.

Table V

Comparative Production per Man per Year

| | 1922 | 1929 | 1935 |
|---|---|---|---|
| North Dakota: | | | |
| Strip mines | 628 | 1,040 | 1,790* |
| Underground mines | 620 | 728 | 993† |
| Saskatchewan: | | | |
| Strip mine | | | 3,320 |
| Underground mines | 597 | 788 | 575 |

*Maximum: 2,970 tons. †Maximum: 1,600 tons.

Comparative values of the coal produced in North Dakota and Saskatchewan are shown in Table VI.

Table VI

Comparative Per Ton Values of Coal Produced (All Mines)

| | 1922 | 1929 | 1935 |
|---|---|---|---|
| North Dakota | $2.46 | $1.83 | $1 30 |
| Saskatchewan | 2.10 | 1.71 | 1.40 |

Comparative statistics for the underground mine and strip mine sections of the Saskatchewan industry show that the basic requirements of minimum capital investment in relation to production value, combined with minimum seasonal fluctuations in employment, are best met by the mechanized strip method. Some increase in mechanization has been effec ed in the larger underground mines during the period under review, but the effect on employment in these mines has been masked by the disproportionate increase in the use of hand labour in the smaller mines. While strip methods are not applicable in all cases, production records indicate mechanization in underground operations has increased production per man per day, in some instances to a point comparable with average strip mine production.

Summary

Social legislation provides protection for the workers during the time they are employed. The present need is for greater continuity of employment. The interests of the workers and of the community can be best served by the adoption of production methods which provide the maximum number of days work for a smaller number of men rather than by distribution of a greater total number of days work among such a large number of men that the combined total earnings are inadequate to maintain a reasonable standard of living for the whole community.

Fig. 7—Tipple at Truax-Traer Opencast Mine, showing Rotary Pump (left) and Pneumatic Cleaning Plant (right).

Such production methods, calling for an increased use of power equipment, require the concentration of commercial production into a smaller number of adequately equipped mines with minimum overall costs, and the elimination of unsafe and uneconomical operations.

Provision for adequate annual earnings for the maximum proportion of the men employed, which is essential to the development and maintenance of a self-sustaining industrial community, under existing natural limitations of the industry, is a problem calling for solution by the managements of the several mine operations.

The experience of the past seven years indicates that stabilization of the industry to ensure fair wages to the employees for their labour, fair returns to the operators on their investments and fair value to the consumers, can best be effected, during the present formative stages of development of the commercial section of the industry, by (1) voluntary co-operation between the managements of the several operations in the formulation of a sound policy of development, (2) consolidation of management and of production facilities into units large enough to permit efficient and economical use of power equipment, and (3) maintenance of mine prices at levels which will permit payment of fair wage schedules and fair returns on efficient operations, but which will not encourage the development of unsafe or uneconomical operations dependent upon abnormal labour conditions for their existence.

Physical conditions affecting production and geographical position of the field in relation to markets are sufficiently favourable to permit continued development and growth of an economically sound industry serving alike the interests of the workers, the operators and the consuming public.

# Experience in Burning Western Canadian Coals

*E. W. Bull,*
*Superintendent, Light and Power Department, City of Regina, Sask.*

**Paper presented at the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

**SUMMARY.**—Describes the original boiler and furnace equipment and that later installed in the Regina city power plant, discussing the operating difficulties and the results obtained with underfeed stokers and pulverized fuel when burning Alberta bituminous coals and Saskatchewan and Alberta lignites.

In giving results of burning Western fuels in the Regina city power plant, it is best to outline conditions generally.

Regina's geographical location is far from any reliable water power site, but as a compensating feature is in the competitive centre of several coal fields, being 125 miles from the lignite fields in the south eastern part of Saskatchewan; some 600 miles from the Crow's Nest field of bituminous coal in Alberta and about 500 miles from the Drumheller lignite fields in Alberta, with some of the Edmonton district coal being competitive at times.

All four fields have by-product coal of extremely fine size, which is the present class of coal burned in the Regina city plant in pulverized form.

This competitive condition of by-product fuel has not always prevailed, for at the time of design of the present plant in 1913, the then outstanding value in fuel was the bituminous coal from the Crow's Nest field in Alberta. Consequently the stokers selected for the plant were the incline underfeed type with moving side bars of retorts, which stokers at that time and even yet, are eminently suitable for burning reasonably low ash and slightly coking bituminous coal.

### Original Equipment

The present power house, located on the shore of Wascana lake, is the second power plant built by the city and followed an earlier plant built in 1904 on a site without liberal circulating water supply, power demands on which soon expanded beyond the cooling pond capacity. Rather than be tied to cooling towers and poor vacuum for the steam turbines, then the outstanding prime mover, a new site close to a large body of water was selected.

The plant was designed on the bus system, in that the building was arranged with turbine room and boiler room with their lengths parallel, with circulating pumps, boiler feed pumps, and induced draft fans and stack located at the adjacent ends of the two rooms.

The boiler room was arranged for two rows of boilers facing on a firing aisle, over which were coal bunkers of 1,500 tons capacity with eight separate coal pockets and outlets for each boiler of the original design of sixteen boilers, although only the row of boilers next to turbine room was developed on this plan.

The Babcock-Wilcox boilers with longitudinal drums in 500-hp. units were arranged in batteries of two boilers each with a six foot space between batteries with four batteries on each side of firing aisle occupying a panel of 28 ft. 6 in. each battery. Each boiler has a feed water section of 160, 12-ft. cast iron economizer tubes set in the same setting.

The boiler room floor is set 14 ft. above the basement floor and the space between is utilized for ash hoppers, air chamber for stokers and ash removal equipment, with a gas flue running below the boiler room floor with gas damper in passage from each boiler, as in Fig. 1, which shows the whole plant as planned in 1913.

The gas flues next to the building wall lead to induced draft fans at the end of the boiler room, with additional dampers making it possible to have gases flow direct to fans or through gas passages and a group of 320 standard 9-ft. tube economizers on way to the induced draft fan suction. This economizer group was operated with no pressure, but with condensate flowing through on the inverted siphon principle on the way from the condensate pumps to the open feed water heater, into which heater all feed pump and fan driving engines exhaust was directed.

The 160 economizer tubes acting as a feed water section of each boiler were all set in line with the under floor gas passages, and additional dampers so arranged that the feed water sections of idle boilers could be made to be included

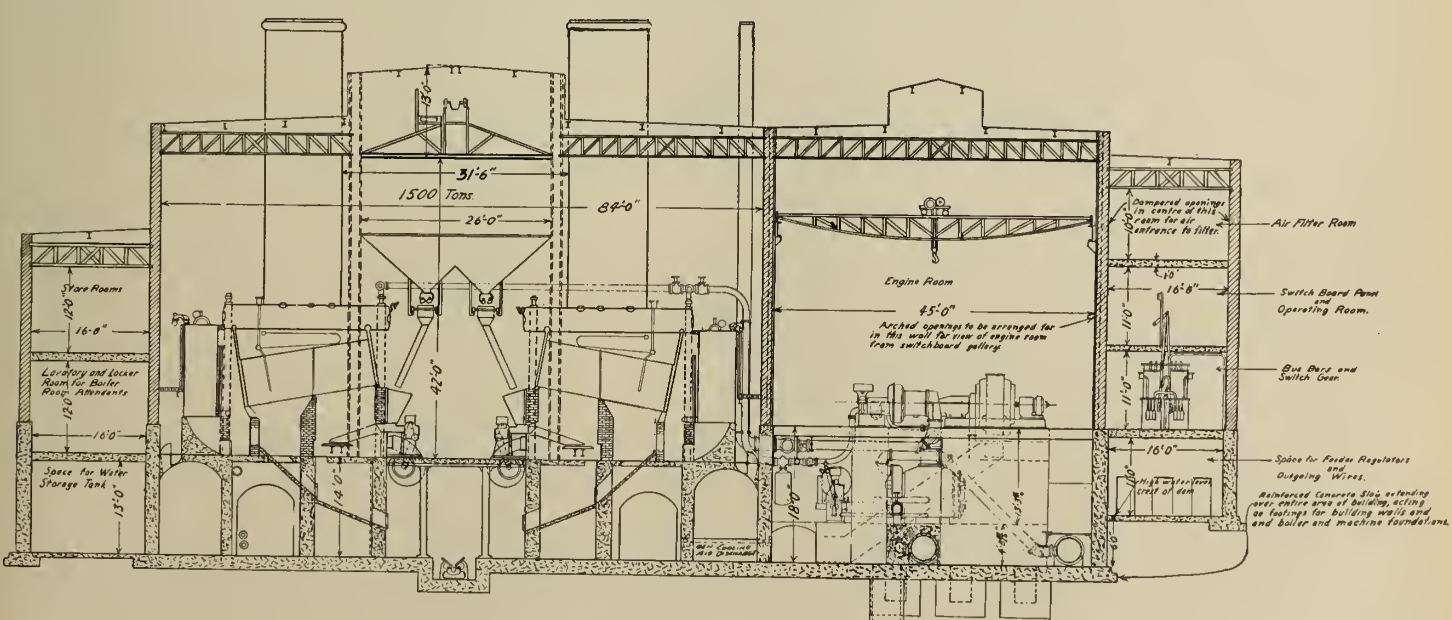

**Fig. 1—Arrangement of Equipment for Regina City Power Plant.**

in a gas passage parallel to the main under the floor flue, thus making it possible to bring the greatest amount of economizer surface in service with gases passing on way to induced fan and stack, and feed water directed in contraflow on its way to the active and more efficient boilers furthest away from fans and stack which were always operated as base load equipment.

With this arrangement of equipment with a complete building provided for two rows of eight 500 hp. boilers and six turbines, installations were made as load conditions required, both in boilers and turbines, each new installation successively occupying the next vacant space nearest to the fans, circulating pump and feed pumps at one end of the building.

By 1914, four 500-hp. boilers and three turbines, aggregating 6,000 kw., had been installed.

Load increase continued despite the war conditions and in 1921 boilers 5 and 6 were installed. In order to try out the possibilities of burning the local Saskatchewan lignite, the stokers were increased to seven retorts wide and a longer type of stoker installed with a total of 132 sq. ft. of grate surface, whereas the original short stokers were six retorts wide with only 82 sq. ft. grate surface.

The water cooled ash pits were then placed in service, all as shown in Fig. 2.

In order to assist in burning the high moisture lignite, a form of arch was placed to join up the new bridge wall located for the long stoker and the regular vertical baffle that was immediately above the original bridge wall when the short stokers were in use. This flat arch was supported by an air-cooled box girder and gave satisfaction in burning the high moisture lignite by its reflecting power concentrated at the proper section of the fuel bed.

When the lignite, due to price variation, ceased to be the best fuel, low ash bituminous coals were burned with complete success on the same equipment up to reasonable rates of burning on the grate. Eventually the bridge wall was rearranged and continued upwards to a point near the lower boiler tubes and a tile baffle placed above the lower row of tubes to connect the bridge wall with the original vertical boiler baffle was constructed, as shown by dotted lines in Fig. 2.

With the removal of the reflecting arch, burning of even bituminous coal was not so good at light loads.

The side wall surfaces at the fuel bed line was severely punished whenever high ratings had to be taken from the boilers.

The answer to this condition, was to install Carbofrax bricks on the hot zone of the furnace at side walls to a point above the regular height of fuel bed.

### Principles Involved in Burning Coal on Stokers

In operating highly forced draft underfeed stokers a closed ash pit is required, which in this case evolved from a brick lined concrete pit into a closed water-cooled ash pit of fire box construction with properly arranged doors to drop ash to a drag chain conveyor.

It was early found that the capacity limiting feature of underfeed stoker operation was the discharge of the ash without allowing too much burning coke to discharge in quantities, which would not only result in a loss of heat by reason of the carbon not being consumed in the furnace, but would cause the ash pit to act as a gas producer when leakage of air from the forced draft plenum chamber filtered through the racks required for adjustment of the ash discharge section of the Riley underfeed stokers. Under certain conditions the smallest opening from the ash pit was a liability, and tongues of blue flame would come from every leak around ash pit doors.

As a result of these experiences, in an effort to protect the equipment, the ash pit was vented to the furnace side above the fuel bed to convey any combustible gases along with the air leakage to the furnace, as shown in Fig. 2.

This condition of burning prevailed during the tests made in 1922 and 1925–26, results of which are shown in Tables I and II.

The cooling of the ash pit and stoker discharge backing box by condensate was a regular operating condition, and the heat absorption of the cooled ash pits figured in the efficiency obtained, as shown in Table II, when the whole boiler plant was tested to determine operating efficiency.

The principles of burning coal on underfeed stokers are well known, in that the volatile constituents of the fuel are distilled below the surface of the fuel bed and are

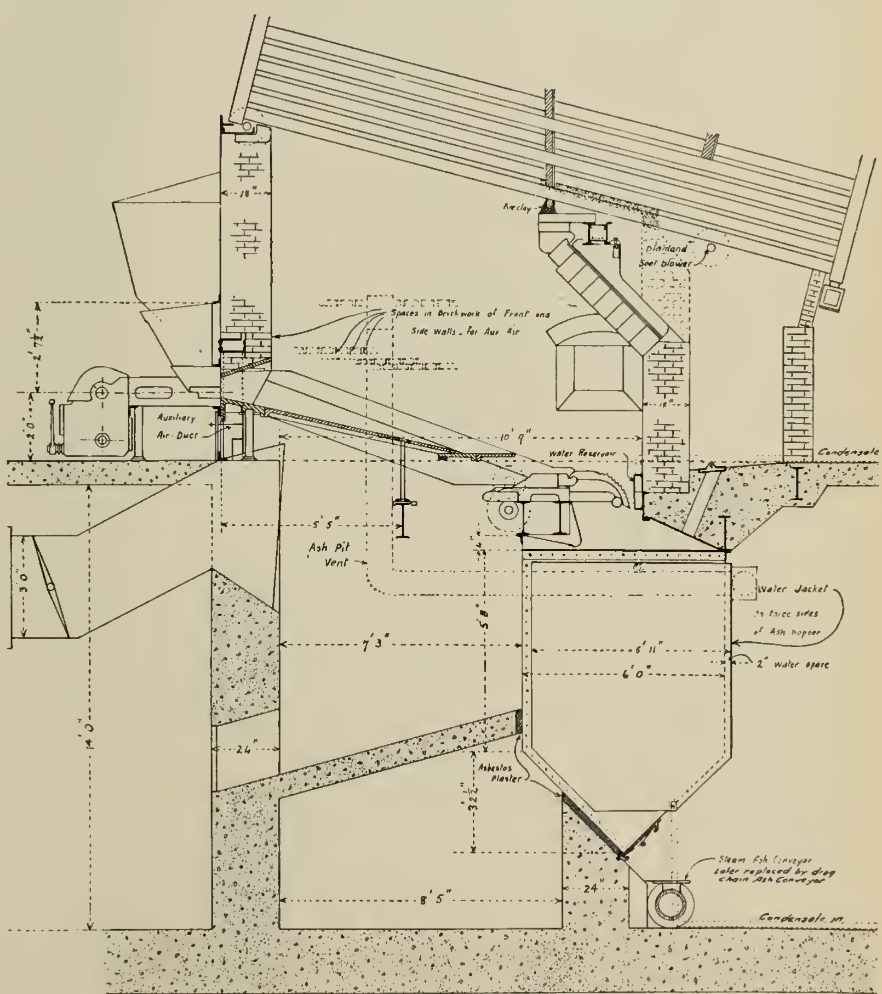

**Fig. 2—Stoker Arrangement for Boilers 5 and 6.**

thoroughly heated and mixed with the air as it passes through the spaces between the coal of fuel bed on the way to the finishing combustion spaces above the fuel bed.

In this system (or any grate system with a forced draft) of burning, the combustion air and expanded gases in their rush through the coal spaces carry with them small particles that are thrown off the coal pieces by spalling due to heat.

These particles, consisting of carbon, in size approximately 1/50th to 1/100th of an inch in diameter, are carried above the fuel bed and between the boiler tubes and, if considerable furnace volume is not available for combustion, are eventually cooled below combustion temperature.

With longitudinal drum Babcock and Wilcox boilers in 500-hp. units set eleven feet above fire floor, allowing a furnace depth between fuel bed and lower boiler tubes of six feet, it was found that with some coals, enough particles were carried over to require considerable handling of second pass and flue accumulation.

Analysis of these accumulations showed a high carbon content, running as high as 70 per cent combustible with certain coals.

The method of recovery was by extracting this accumulation from flues and boiler passes with screw conveyors, returning this extracted material to the coal being fed to the stoker, thus again passing the particles through the fuel bed.

While lignite was burned on the underfeed stokers in considerable quantities, its low heat value and the low melting point of the ash did not make for success. Any forcing to high rating of grate surface burning not only caused slagging of grate tuyeres, but fine particles of the low melting point ash were projected into the banks of tubes six feet above, eventually causing clogging of spaces between tubes by gradually building a collar or sleeve around each tube.

Despite efforts made to locate soot blowers to prevent this accumulation, this condition required that at intervals the boilers and furnace be laid idle and cooled for mechanical cleaning by men with lances working from the furnace space.

The results obtained, as shown on Table I, did not warrant continuing burning lignite with the underfeed stokers except when purchasable at a very low price.

The bituminous coal was considered best for the existing conditions so that prices were obtained competitively from time to time and tests made to determine the best fuel to purchase.

A series of tests of coal to operate the complete plant including banked boilers and based on using the complete equipment of economizers was made. The results of long period tests of three bituminous coals made early in 1926 are shown on Table II, from which may be noted the effect of a great area of brick walls of gas passage and economizer scraper openings in the low percentage of $CO_2$ registered. This low $CO_2$ was partly due to banking the fires for considerable periods, a procedure made necessary by the cyclic variations in load demand.

In 1926 the complete year's operation of the plant while burning Crow's Nest coal (the first of the tests in Table II) resulted in a coal consumption of 1.375 lb. per kw.h. generated with an average load on the turbo-generators of 55 per cent of their capacity.

This year's operation showed probably the best result obtained from the 200-lb. pressure plant operated with a great extent of economizer surface. Even before this date the regenerative cycle of feed heating was fast proving its worth and in 1924 when an additional turbine of 5,000 kw. capacity was purchased, the specifications called for its design for ultimately operating with 400 lb. pressure with a steam temperature of 750 deg. F. and for regenerative feed water heating with two points of extraction.

### Fuel Characteristics

In considering the fuel characteristics, it was found that the lightly coking bituminous coals from the Crow's Nest field in Alberta, with ash melting point from 2,300 to 2,700 deg. F., were well adapted to the underfeed stoker installation, which has moving tuyeres on retort sides within the furnace with adjustable lengthwise movement to allow of breaking up any coke that may form and keep the deep fuel bed free by constant movement of its coal lumps.

The only serious variation in these bituminous coals was in the percentage of ash, and in the melting point and constituents of the ash. Operation with a standard of 20 per cent carbon in ash pit refuse is feasible under good operating conditions. On this basis it is apparent that for each ton burned, coal that contains 15 per cent ash will discharge at least twice as much unburned carbon to the pit as a coal with 7.5 per cent ash, assuming the same excellence of separation at the ash discharge point of the stoker.

This proportion cannot be realized with high-ash coal, as the efficiency of ash and coke separation is really a function of the amount of refuse discharged in a given time from a definite volume of discharge space. The results establish that the low-ash coals, all other characteristics being equal, are definitely better coals to operate with.

There are other important characteristics besides the melting point of the ash. The ash composition may be such as will have a fluxing action on refractory lining of furnace, or again the ash may melt and run together in large clinkers. Other coals have ash that forms clinkers in lumps of walnut or golf ball size that do not adhere strongly to each other, consequently the discharge of clinkers is more readily effected.

In the original installation, as in Fig. 2, the ash discharge space did not have the benefit of the deep ash pit discharge pockets with rotary clinker grinders which were used in many underfeed stoker installations made at a later date. Nevertheless reasonable success was attained and the 1926 year's consumption of coal per kilowatt hour is evidence of this.

### Stoker Fired Lignite Characteristics

While the best success was with bituminous coals, there were times when price conditions made it advisable to burn lignites, whose operating characteristics varied considerably. In the original plant, without preheated air and with a high moisture content reducing the furnace temperature, lignites were successfully burned up to moderate rates of combustion without undue clinkering.

All the fuels were of the slack variety and on underfeed stokers behaved fairly well, but on occasion some of the fine free burning lignite ran in the stoker retorts like sand, with a considerable loss to the ash pit, as evidenced by the high percentage of combustible in the ash pit refuse, as shown on the 1922 tests of the lignite coals.

It is quite evident that the underfeed stoker is not the best equipment to burn fine size lignite and it appears that the travelling grate stoker with preheated forced draft is the logical equipment for burning such fuel if conditions are such that grates must be used.

### Pulverized Coal Equipment

When additional boiler capacity was required in 1927, burning of pulverized coal was fast coming to the fore. A study of the relative costs and efficiencies of stoker and pulverized fuel systems resulted in pulverizing equipment being purchased and installed in lieu of stokers for two of the 500-hp. boiler units already on hand. These were raised to secure sufficient furnace volume, and complete furnace wall cooling of the resulting 3,600 cu. ft. furnaces was applied to the installation by regular four-inch boiler tubes set behind the face of refractory tiles, which together with water tubes were applied to the walls as a separate nine-inch furnace lining.

These two boilers continued to operate with 200-lb. pressure and liberal economizer surface until 1930, when a new large steam generating unit for pulverized coal with no economizers, but with air preheater, operating at 430-lb. pressure and 750 deg. F. steam temperature, was purchased, together with a 15,000-kw. turbine. Extraction and deaerating heaters were provided for three points of extraction for feed heating for complete operation on the regenerative cycle, this new high-pressure section of the plant starting operation early in 1932.

In installing larger high-pressure steam generating units, the space in the boiler room formerly laid out for eight 500-hp. boilers was used, each steam generator occupying a panel that had been provided for a battery of two 500-hp. units.

The furnaces were extended to the basement, and the upper parts of the unit, consisting of forced and induced draft fans, projected through the original boiler room roof in the case of boiler 9. In the case of boiler 10, which is now being erected, the forced and induced draft fans are set in the space to the side of the boiler and below the original roof.

These two units occupied alternate original battery spaces within the building, thus leaving plenty of space on either side of each boiler unit. Each unit had an individual stack extending 125 ft. above basement floor.

Boiler 9 is arranged with both forced and induced draft fans installed above the boiler proper, with the natural route of the gases upward to the induced draft fan and stack and the passage downward from the forced-draft fan through the tubular air preheater to the burner.

The whole boiler is incased in sheet metal plates attached to the steel frame work supporting the boiler.

With the natural convection currents of air ascending on all sides of the boiler, and with the forced-draft fan taking its air from this elevated position, it was natural to install a large umbrella-shaped casing around the induced draft fan and stack, from the top of which all air is drawn by the forced-draft fan. This arrangement resulted in the unavoidable loss from the boiler setting being turned back to the air on its way to the air preheater.

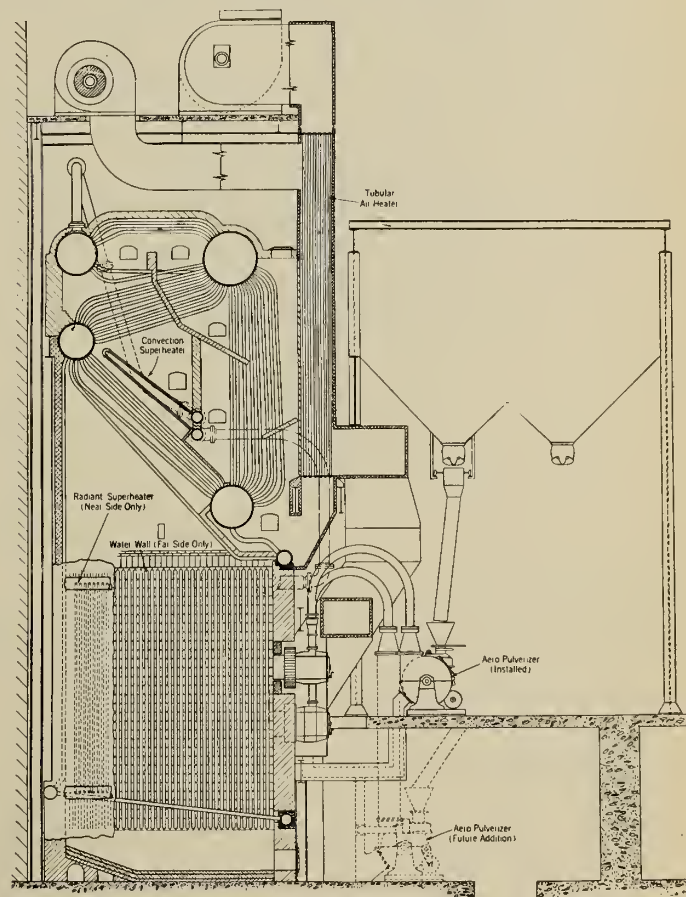

**Fig. 3—Sectional View of Boiler 9.**

In these units no gas dampers of any kind are used, the whole control of draft and air to the air preheater being effected by changes of fan speeds and by operating air foil louvres of the intervane burner.

The fans are driven by separate field supply direct current motors fed from a separately excited shunt current generator, which is part of a motor generator set. In operation, with separate field control to all three d.c. machines (two fan motors and one d.c. generator), the

voltage is varied on the generator for general changes in capacity required from fans, and the motor fields are changed to produce the required relative speeds for forced-draft and induced draft fans to secure the proper draft or air pressure to burners.

The general arrangement of these two units is shown on sectional views of boilers 9 and 10. (Figs. 3 and 4).

It will be seen that boiler 9 has a 13,000 cu. ft. furnace with water cooled walls on back and one side, with steam cooling in the form of superheater tubes on one side wall and with a water cooled ash pit screen in the form of 4-in. tubes on one-foot centres placed about six feet above the ash pit floor.

The burner wall is entirely of refractory material, with six 27-in. Foster Wheeler intervane burners in this wall, all supplied from three pulverizers. Each pulverizer supplies two burners, each of which may be shut off independently. Two of the pulverizers are rated at 8,000 lb. per hour each, one motor driven and the other steam turbine driven and operated at 1,200 r.p.m. The third pulverizer, rated at 12,000 lb. per hour is for base loads and is a motor driven ball mill operating at 138 r.p.m. This pulverizer supplies two main burners and also a smaller half size burner within one of the main burners which is closest to the radiant superheater at one furnace side wall.

This small burner is operated or not operated to give a measure of control of the superheat at the boiler steam outlet.

The burners as originally supplied, which were used during the 1933 coal tests, are shown in Fig. 3 in the front wall of boiler 9.

The arrangement of burners shown in Fig. 4 for boiler 10 was applied to boiler 9 in October, 1935 with a marked improvement in efficiency over the original burners used during the tests reported on in Table III, which is verified by the improved results obtained in the 1937 series of tests.

Boiler 10 has only four burners of the same size as boiler 9 burners, two of which are supplied by a ball mill driven by a 100-hp. motor.

The two remaining burners are to be supplied by one No. 4 Riley Attrita and an oil atomizer for emergency operation in case of the single pulverizer having to be suddenly taken out of service for any reason.

### Pulverized Coal Burning

Burning coal in pulverized form presents its own problems, as the pulverized coal is floated into the furnace by air. Although the coal is finely divided, the necessary scouring action of the air on the coal cannot be readily attained even by the turbulent burners which only give a difference of velocity of coal and air for a short distance from the burners. Even this turbulence, if given in a whirl, and if at excessive speed, will throw coarse particles of coal outside the flame, resulting in loss of fuel to the ash pit.

In any case the coal particles are soon surrounded by an envelope of carbon dioxide and inert gases that prevents maintenance of the first rapid phase of combustion.

This slowing up process of burning is in practice compensated for by having large furnace volume to allow of particles remaining in the heated portion of the furnace for sufficient time to allow of reasonably complete combustion.

The author's experience has been that with rates of combustion varying through a range of four to one, really fine pulverization (85 per cent through a 200-mesh screen) is necessary to prevent particles of carbon falling to the ash pit or being caught up as second pass grit.

The natural laws supporting this improved condition of burning with finely pulverized coal are well known in that the finer particles expose an increased surface for a given weight of coal particles and also a smaller weight of each particle has to be consumed in a given unit of time.

The percentage of volatile constituents of the coal has a marked influence on speed and completeness of burning, the higher percentages of volatile having the advantage, although some compensation is effected in low volatile coals when their nature or grindability allow of a product with a high percentage of extreme fines.

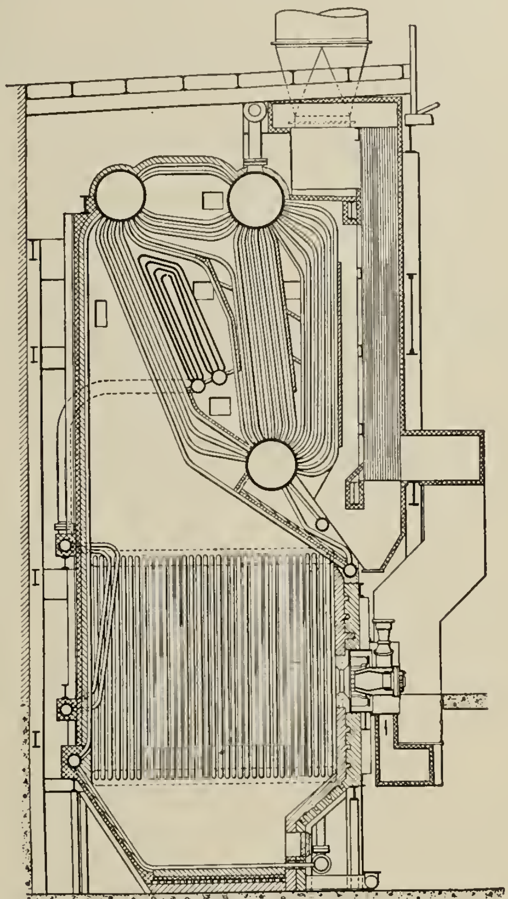

**Fig. 4—Sectional View of Boiler 10.**

### Experience with Pulverized Coal

The author's first experience with pulverized coal burning was with the low ash bituminous coals formerly burnt on stokers. In the first pulverized fuel installation, in which Riley Attritas were used without preheated air, a limited number of trials on other coals indicated that the use of low ash bituminous coals should be continued with the pulverized system burning equipment.

With the installation of boiler 9, with preheated air, it was felt that further trials should be made and during 1933 the tests, results of which are reported in first section of Table III, were completed. The latest trials have now been completed with the results shown in the second section of Table III.

After about nine years' experience with pulverized fuel burning, the outstanding conclusion is that the fuel should be ground to extreme fineness with the rather low volatile content of our western Canadian bituminous coals.

Another conclusion is, that despite almost similar analysis, the coals have widely different characteristics of 'grindability.' Even with an equipment having plenty of adjustment for carrier air to lift the pulverized coal from the pulverizer, it seems at times impossible to secure uniform fineness in some coals, because their fracture results in the formation of thin flakes that are lifted out of the pulverizer by carrier air before sufficient work has been done on them to reduce to a smaller size.

This characteristic of fuel cleavage at the final stage when reducing to fine particles will be realized when the result of the second test in the first section of Table III is noted. This coal, although of the highest B.t.u. and lowest ash content of the series of tests in April and May, 1933, gave the lowest efficiency of the series, probably due to the high percentage of combustible in the ash pit refuse and possibly a greater percentage of combustible carried through the boiler.

It was evident that the nature of the cleavage of coal in pulverizing resulted in a large percentage of flakes, indicated by the rather low power consumption per ton of coal pulverized.

On the other hand some coals will grind to fines readily, most likely by fracturing to produce particles more cubical in shape, and consequently not so readily lifted out of the pulverizer by the carrier air. These will require more work to reduce to a high percentage of fines.

An example of this condition is the Saskatchewan lignite used during the test of May 3rd and 4th, 1933, shown in the first section of Table III, in which the highest percentage of fines resulted. This lignite required over 50 per cent more power to pulverize than some of the bituminous coals, but the fact that it could be pulverized with a higher percentage of fines allowed it to be used successfully despite its high moisture content.

On this series of 1933 tests, the only bituminous coal (or rather a coal approaching a semi-anthracite) that shows such a freedom from large particles is the Brazeau coal tested on April 21st and 22nd, which is really of a friable nature and readily breaks into fines with a low power consumption per ton; this almost neutralized the disadvantage of having a volatile content of only 16 to 18 per cent. This coal is from the Edmonton field, the mine being located at Nordegg, southwest of Edmonton, Alberta.

This same condition is shown also in the results with the Fernie or Crow's Nest coal in the last test but one of the 1937 series, as shown on Table III.

From experience the author believes that with coals of similar general chemical characteristics, trials of their grindability and observation of the nature of the pulverized product, such as the amount of coarse particles carried to furnace, and the combustibles in the ash pit and second passes of boiler, a definite judgment of their relative value can be arrived at without the necessity of evaporation tests, of course after considering the B.t.u. per dollar of total cost of fuel, which must include all transportation and handling of coal, pulverizing, and removal of eash.

### Burning Lignite in Pulverized Form

*Results with Saskatchewan lignites*

The Saskatchewan lignite of 35 per cent moisture, 8 per cent ash, 7,000 B.t.u., with an ash melting point below 2,000 deg. F. has been successfully burned in the raw state with boiler 9 and the ball type pulverizer, with results as shown on Table III under date of May 3rd and 4th, 1933. The conclusion was reached that the raw state is the proper state to consider for grinding and preparing for furnace.

Many attempts had been made to reduce the amount of moisture in the lignite before shipment, as the transportation charges to Regina equal approximately five times the cost of the lignite at the mine. It was naturally assumed that if the 35 per cent moisture content could be reduced considerably, the benefit from lower freight charges would allow of the lignite competing with other coals to a greater radius from the mine district.

The first trial was to reduce moisture to approximately 25 per cent by drying at the mine, and make trial shipments and burning tests of the lignite with this reduced moisture content. Shipments of the partly dried lignite did not have a happy time, as even in the two days' journey from the point of shipment to the plant, self-ignition often occurred with dire results to the lignite and sometimes the car used for transport.

In addition to this hazard, it was found that the partly dried lignite had a toughened condition that made it resist pulverization, with the result that a given pulverizer apparently had no greater capacity in heat value of the product than could be obtained with the undried lignite.

Trials were then made to obtain partial drying at the plant by passing the raw fuel over an idle underfeed stoker with warm air fed through the tuyeres and through the fuel bed, but with no lighting of fires.

With this system of drying it was not possible to feed the heated lignite (which was reduced to mush or small size) to the pulverizer, as in the experiment the temporary course of transfer allowed the lignite to cool off. The only result of these trials was a confirmation of the opinion that a greater pulverizer capacity could not be obtained with the partly dried lignite when the processes of drying and pulverizing are not made sufficiently continuous to avoid the toughening and resistance to grinding which occurs when the lignite is allowed to cool.

Other attempts were made to have the lignite not only dried, but carbonized, with the resulting char shipped to the plant.

This condition did not bring freedom from self-ignition of the product in shipment. The attempts made to burn it in pulverized form in boilers 7 and 8 served by Riley Attritas, which furnaces had large areas of the water walls in the hot zone of furnace covered with about one inch of refractory, resulted in such a high furnace temperature being attained that the low melting-temperature ash was carried through the boiler and interdeck superheater tubes, repeating the experience with underfeed stoker conditions, and blocking the gas passages from the furnace.

Thus attempts to avoid the freight on the moisture content of the lignite were not successful and it was decided only to consider burning in the natural raw state.

Tests of preparing and burning from the raw state showed an efficiency upwards of 81 per cent, which was considered satisfactory for operation at times when load conditions did not exceed the capacity of the pulverizer to prepare the lignite.

To allow of a quick or gradual change from the bituminous coals that were required on peak load to the lignite which could only be used at times of very light load for about seven hours each day, an arrangement of divided coal pocket and separate feeder was installed with the result that a mixture of coal and lignite in any proportion could be fed to the base load pulverizer.

This arrangement worked satisfactorily with the division of the two fuels shown on a typical chart for Sunday, January 25th, 1934. (See Fig. 5).

The economical results that can be expected from burning a high moisture lignite and a low moisture bituminous in proportions to allow of furnace condition of somewhere near the optimum amount of 6 per cent water vapour for maximum speed of combustion have been verified in actual practice, in that long period tests with the mixture and similar periods of operating on straight bituminous coal show a drop in boiler efficiency of less than 0.5 per cent below that reached with bituminous coal alone.

This is best illustrated by the following table showing the result of operating with the original burners on boiler 9.

Table IV

Summary of Operating Results Comparing Mixed and Straight Bituminous Coal

| | Jan. 31st, Feb. 1st and 2nd 1934 | Feb. 5th, 6th and 7th 1934 |
|---|---|---|
| Steam pressure (gauge).......lb. per sq. in. | 412 | 409 |
| Steam temperature....deg. F. | 757.3 | 755.2 |
| Average feed temp.....deg. F. | 242.4 | 241.7 |
| Total steam flow..........lb. | 3,430,000 | 3,460,000 |
| Total pounds of coal:— | | |
| Bituminous................ | 314,270 | 384,800 |
| Lignite.................... | 119,700 | none |
| Total heat given to feed water and steam...........B.t.u. | 4,056,318,000 | 4,090,412,000 |
| Total heat in coal......B.t.u. | 4,806 014,700 | 4,829,240,000 |
| Greenhill 12,550 B.t.u. per lb. | | |
| Lignite 7,200 B.t.u. per lb. | | |
| Boiler and air heater efficiency —per cent................ | $\frac{4,056,318,000}{4,806,014,700} = 84.4$ | $\frac{4,090,412,000}{4,829,240,000} = 84.7$ |

The first test on the 1937 series shown in Table III, gives the result obtained when burning the two fuels in the same furnace, but prepared in different pulverizers and fed through separate burners.

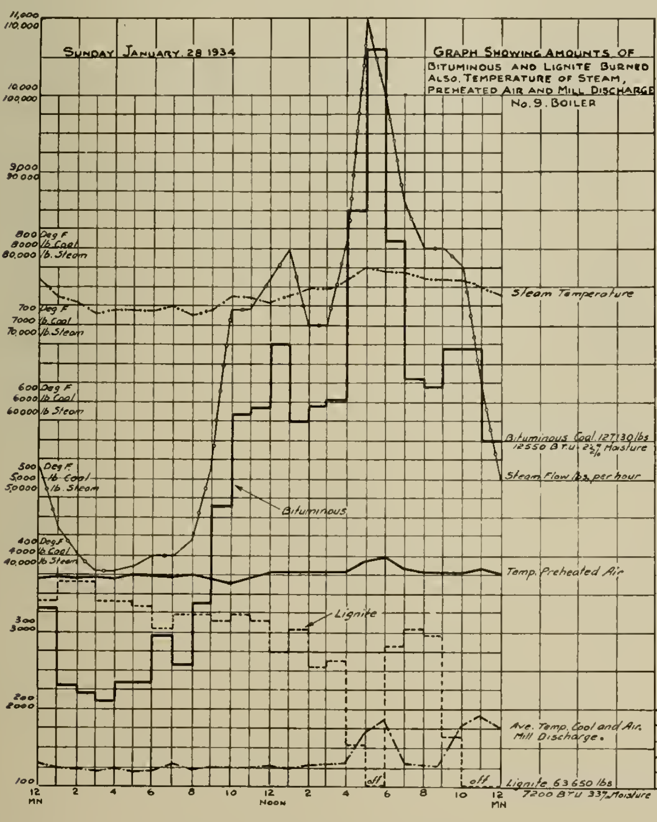

**Fig. 5—Coal Burned and Temperatures of Steam, Preheated Air and Mill Discharge on Boiler 9.**

This method of burning gives a lower efficiency than when the mixture can be made in one pulverizer and fed thoroughly mixed through the same burner.

Due to the nature of the lignite there were other conditions to be met in burning in pulverized form that only became apparent after extended experience.

In burning with preheated air in boiler 9 the intervane burner bodies are located in and supplied with secondary air from a plenum chamber with tangential louvres that have variable openings for secondary air control for operation and could be shut off completely in case the burner is out of service.

The primary or carrier air is fed with a tangential whirl close up to the refractory-formed mouth of burner in furnace wall, the whole being whirled through the opening into furnace. In practical working some very small quantities of siftings of the fine coal are not carried into the furnace, but drop to the bottom of the plenum chamber.

With bituminous coal no detrimental effect from this condition was noticed other than the necessity of cleaning out whenever access to the plenum chamber was required at period of boiler shut downs. With lignite, however, the temperature of the preheated air, together with its drying effect, was sufficient to cause self-ignition, which resulted in the slow burning of these siftings, a shower of sparks being carried through the duct which leads from the bottom of the plenum chamber to the pulverizer carrier-air fan suction.

No explosion resulted, but to avoid any possible danger, the plenum chamber bottom was made in steep hopper form with the lower parts vented to the furnace bottom with a 2-in. pipe connection, with the result that the fine siftings were carried to the furnace by the flow of forced-draft air through that pipe.

In continued burning of mixed lignite and bituminous coals in the large cooled-wall furnace at the capacity required to carry the regular load, no trouble was encountered by ash slagging on walls or being carried through the boiler to form bird-nesting, troubles sometimes encountered where high furnace temperatures must be maintained. But lignites were not fed at times when high average furnace temperatures were required, as in the regular routine the lignite feed was reduced as greater capacities were required from the boiler, and completely stopped at times of heaviest load when furnace temperatures were highest.

### *Results with Alberta lignites (Drumheller Field)*

While no extended operation of the pulverized fuel section of the plant has been undertaken with Alberta lignite, three sample cars from this field were burned in order to see if the characteristics of this lignite were suitable to burn in pulverized form and if any slagging or bird nesting in boiler tubes would result if a fair rating were attained in the furnace.

The pulverizing was done in the ball type pulverizer with the results as to grindability and capacity of pulverizer shown in Table V, which also includes supporting conditions during the burning.

It will be noted that a high percentage of the product would not pass a 40-mesh screen, which condition was reflected in the percentage of combustible in the last pass of the boiler. On the other hand, the ash pit refuse showed a small percentage of combustible, as with all lignites small particles continue combustion at low temperatures on the ash pit hearth where small leaks of air at doors, and air deliberately let in through ash pit door register, flows over the ash pit floor in a layer, absorbs radiant heat from the flame above, burns the unconsumed carbon, and thus shows low percentage of combustible when the ash pit refuse is analysed.

The later passes of boiler tubes have no such condition of large amounts of free oxygen and active radiant heat to continue the combustion process.

There was no indication of slagging of furnace or tubes in the rather short periods of burning these lignites.

### Oil Equipment

In addition to coal and lignite another form of by-product fuel is available, as with several oil refineries located in proximity to Regina, still-bottoms or bunker "C" fuel

Table V

Observation Runs on Drumheller Lignite, December 15th, 16th and 17th, 1936

Furnace volume, cu. ft., 13,000.

All walls of furnace, except burner wall, water or steam cooled and ash pit water tube screened.

Type and capacity of boiler: four drum, bent-tube, 150,000 lb. steam per hour (rated capacity) at 430-lb. pressure, 750 deg. F. final steam temperature.

Type and capacity of No. 3 pulverizer: pressure type ball mill, 6 tons per hour on coal having grindability factor of 82 per cent.

oil can be obtained in considerable quantities at a price to compete with the by-product coal fuels.

In order to provide for the use of this oil fuel as found desirable, the necessary tanks, heaters and other essentials are installed and oil burners or atomizers are fitted to all boilers with furnaces for pulverized fuel operation.

The burner equipment in boilers 9 and 10 consists of four burners in each furnace, namely two Peabody wide range burners with a capacity of 250 Imp. gall. per hour each and two non-variable Monarch atomizer tips with a capacity of 150 gall. per hour each.

These oil atomizers are fitted within the coal burners and the same secondary air and control serves for both oil and coal.

The furnace being 18 ft. deep from burner wall, excellent burning conditions with oil prevail and it is possible to burn oil and coal in the same burner simultaneously; it is more usual to operate with some coal burners and oil burners in the same furnace.

In regular practice changes are made from coal to oil or reverse in about one minute.

The supply of oil is not sufficient for continuous complete plant operation.

### Condition of Progress

As first stated Regina is situated far from any available water power and has, therefore, developed a steam plant to meet its power requirements. The results are best shown on the 1937 coal tests, which do not cover a full twenty-four hour period of plant operation, but do represent in the statement of boiler efficiency and coal per kilowatt hour the results obtainable with the average loading on boiler and turbine shown.

The steam turbine in regular service during the 1937 tests was designed for 360 lb. gauge pressure and 725 deg. F. temperature and an absolute back pressure of one inch mercury, but during these tests the vacuum maintained was less than 0.6 in. back pressure.

The by-product fuels are available at such a price, including all costs of transportation, handling, pulverizing and removal of ash, that 5,000,000 B.t.u. can be fed to the furnace for $1 cost.

The plant now in use cost less than $90 per kw. of modern equipment installed.

# British Columbia Coals in Metallurgy

*R. R. McNaughton,*
*Smelter Metallurgist, Consolidated Mining and Smelting Company of Canada, Limited, Trail, B.C.*

**Paper presented at the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

**SUMMARY.—After discussing briefly the objectives desired in metallurgical furnaces of various kinds, the paper deals with powdered coal burners, particularly those for small furnaces (down to one ton per day). Notes are also given on storage, drying and pulverizing equipment for bituminous and lignitic coals.**

A search of the literature on the utilization of coal reveals a wealth of information on almost every phase of the subject with one exception. This exception lies in the part played by coal in metallurgy. Some aspects of this application in connection with British Columbia coals will be submitted in this paper.

### Coal Fields in B.C.

The coal fields are liberally distributed in this province. There are three principal producing areas so located as to supply the consuming centres with the minimum freight haul. The Vancouver Island district, oldest and largest producing field in the province, is located on the east coast on tide-water in close proximity to the larger centres of population on the island and mainland. The interior of B.C. has several sources of supply; in the south, Merritt and Coalmont, with Princeton and Tulameen. The Crow's Nest Pass district on the eastern boundary of the province is close to the industrial centre of Trail. In the north there are known coal fields which have not been developed to any extent as yet, but which are available if the need arises.

The coal produced from these districts has been estimated for 1936 as follows*:—

| | |
|---|---|
| Vancouver Island | 712,913 tons (2,240 lb.) |
| Crow's Nest Pass | 459,073 tons (2,240 lb.) |
| Nicola-Princeton | 158,365 tons (2,240 lb.) |
| Northern | 5,559 tons (2,240 lb.) |

In character the coal produced in B.C. ranges from low-volatile high-rank bituminous to high-volatile sub-bituminous and lignitic. Some anthracite has been found on the Queen Charlotte Islands and in the northern part of the province, but these districts supply only the local needs and are largely undeveloped. Much of the coal found in B.C. is suitable for the manufacture of coke, the beehive ovens in the Crow's Nest Pass area having long supplied the requirements of the metallurgical industry in the Boundary District. These coals are all low in sulphur content, rarely showing more than 1 per cent.

Cleaning plants have been installed by several of the larger producers and low ash coal is available.

Some years ago twelve representative coals were sent to Ottawa at the instigation of the British Columbia government. These were tested as pulverized fuel under a boiler in the Fuel Research Laboratories, and the data gathered were fully set out in a paper by E. S. Malloch.† Ash in the test coals ranged from 7.7 per cent in a Crow's Nest coal to 17.2 per cent in an Island coal. Moisture varied from 1.7 per cent in a Crow's Nest coal to 22.9 per cent in an interior coal. Thermal value was lowest in the high moisture coal at 8,110 B.t.u. and highest in a Crow's Nest coal at 13,950 B.t.u. Evaporation varied from 5.34 to 8.54 lb. of water per lb. of fuel fired. Ash fusion temperature varied from 2,032 deg. F. to over 2,700 deg. F.

### Selection of Coal

Every fuel problem has its own variables and factors which can be determined and which should be developed before any binding decision regarding the type of fuel to be used is reached. If coal is selected as the most economical and most suitable fuel for a particular purpose adequate consideration should be given to the type of coal which will best satisfy the specific requirements. It is highly unsatisfactory to judge the merits of a coal on its proximate analysis or thermal value alone because there are other properties which may have a greater bearing on the success or failure of the fuel. For instance, if the coal is to be pulverized the grindability is an important factor. If it is to be burned on a chain grate or travelling stoker it is essential to know the coking properties. Another point which might easily assume a vital magnitude is ash fusion or softening temperature.

Coals which are satisfactory when used on one type of equipment are not necessarily so on other equipment of similar although slightly different type. There is also a best technique for burning each coal and this technique will vary with the duty and type of equipment used. Available equipment, available fuel and required duty should all receive careful consideration. The variation of several factors which may be of very minor individual importance may, when developed collectively, exert a profound influence on the fuel problem.

The preparation of the coal, the design of plant and its operation are not static and it would be impossible to compile a code or set of rules which would be flexible enough to cover all the factors involved in the selection of coals. The burning characteristics of a coal are frequently altered by sizing and cleaning. It is not uncommon for the ash-softening temperature to be changed in this way to such an extent that the lower ash cleaned coal is unsatisfactory for use under the same conditions in which the high ash uncleaned coal was eminently suitable. An examination of the ash analysis might explain this phenomenon.

Once the coal from any particular source has been selected and found to be satisfactory in use, the proximate analysis can usually be relied on for checking purposes.

In actual practice there is only one way to discover the most suitable among a number of similar coals for any specific purpose and that method is the time-tested one of trial and error.

### Metallurgical Coal Problems

From a fuel standpoint metallurgical furnaces are usually operated with two objectives in view: first, a certain optimum temperature is required; and second, a certain furnace atmosphere is desired. The first objective is not necessarily the development of the highest possible temperature, although this may be required in certain instances. In the non-ferrous industry the volatilization of metal is an important consideration and it is desirable on this account to maintain the lowest temperature which is compatible with the operation being carried out in the furnace. The second consideration, the furnace atmosphere has an important bearing on the type of reaction going on in the furnace. The atmosphere desired may be reducing, oxidizing or neutral and its character may be altered from time to time to suit the condition of the furnace charge.

If pulverized coal is used these two primary objectives are relatively easy of attainment, but several other factors complicate the situation. It may be essential to keep the charge as free as possible of coal ash, either because ash is objectionable in the charge or on account of the ash being refractory. In either case the remedy is obvious. But it may be necessary to use the same coal on a number of furnaces, each of which is doing a different job. Under these conditions the problem becomes rather complicated and the best compromise may not be entirely satisfactory.

A specific instance may be indicative of the way a problem may be attacked. Some years ago a relatively short reverberatory furnace was built to smelt wet copper concentrates using pulverized coal as the fuel. A great deal of trouble was almost immediately experienced when the coal ash melted and slagged the flues. A search revealed an available coal having a high melting point ash and the difficulty was alleviated somewhat by this expedient. Unfortunately this new coal was of high-rank bituminous type and it was difficult to secure complete combustion in the furnace, so that hot flues persisted. (It should be pointed out at this time that local knowledge of the principles of powdered coal combustion was in the course of development.) Further testing evolved a turbulent burner which so improved combustion that the flues ran cool and no further slag troubles were encountered with any kind of coal.

It is unusual to specify colour in coal ash, although this may be important. One furnace in the Trail smelter is producing a leaded zinc oxide which may be used as a pigment, in fact it is so used for locally made paints. Pulverized coal is burned in this furnace and the colour of the coal ash shows up very prominently in the oxide. A considerable search was carried on before a neutral coloured ash was discovered.

When absolutely no coal ash is allowable in furnace gases or charge, the operator must turn to the use of coal or coke on grates, unless oil, gas or electric heating are economic alternatives. In this case ash content and fusion temperature and coking characteristics require the usual consideration.

### Powdered Coal Burners

A great deal of excellent work has been done on the development of powdered coal burners for steam raising where fuel consumption exceeds 50 or 100 tons a day. But progress in the design of a burner for the consumption of a ton or so of coal a day has been slow. One reason for this has undoubtedly been that unit mills were usually installed on jobs of this small size. In an industrial plant there may easily be fifteen or more individual coal burning units and the bin and feeder system with central crushing plant has certain advantages which make its use attractive. In this case every effort should be made to find and use the type of burner which is best suited to the characteristics of the available coals.

When the use of powdered coal first became general at the Trail smelter, the most economical coal was a low-volatile high-ash slack from the Crow's Nest Pass district. It was difficult to initiate combustion and still more difficult to burn in small quantities. In the course of an extended investigation a suitable burner was developed, the basic design of which has not been altered. (Figs. 1 and 2.)

This burner was the answer to a demand for a high combustion rate in a very small furnace which required quite high temperatures for successful operation. The furnace was smelting copper dross from the lead drossing plant, with the object of making a matte which was low in lead and high in copper. It had been found that higher furnace temperatures were conducive to the production of this higher grade matte and this inducement initiated the development work. It turned out that the furnace capacity was greatly increased in addition to making a better product.

Adjustments are provided which allow alteration of the flame characteristics to suit local conditions. The size sketched is burning 7 tons a day of coal on which the ash is 19 per cent with 21 per cent volatile in a very small melting furnace. A similar burner, of smaller size of course, is burning one ton of the same coal in another furnace. One advantage of this burner is that no hot spot or ignition chamber is required to promote combustion. With proper adjustment a stable flame can be made to break within 6 inches of the burner tip.

In burning a coal of this nature the importance of fine grinding must be stressed. Experience shows that 80 per cent through a 200 mesh screen is the minimum requirement for the grade of coal mentioned and that this fineness may vary inversely as the volatile matter content. High ash coals are not necessarily hard to pulverize but high volatile coals are usually so.

In adapting this burner, which was designed for use with 60-80 lb. primary and 40 oz. secondary air, to different conditions where these particular air supplies are not available, it should not be necessary to alter the basic design. A slight alteration in the angle and number of secondary air vanes will compensate for lower air pressure. It is particularly desirable, however, to retain the high pressure primary air supply. Consumption on a single unit is only 30 c.f.m. for a 50-ft. straight run. Another

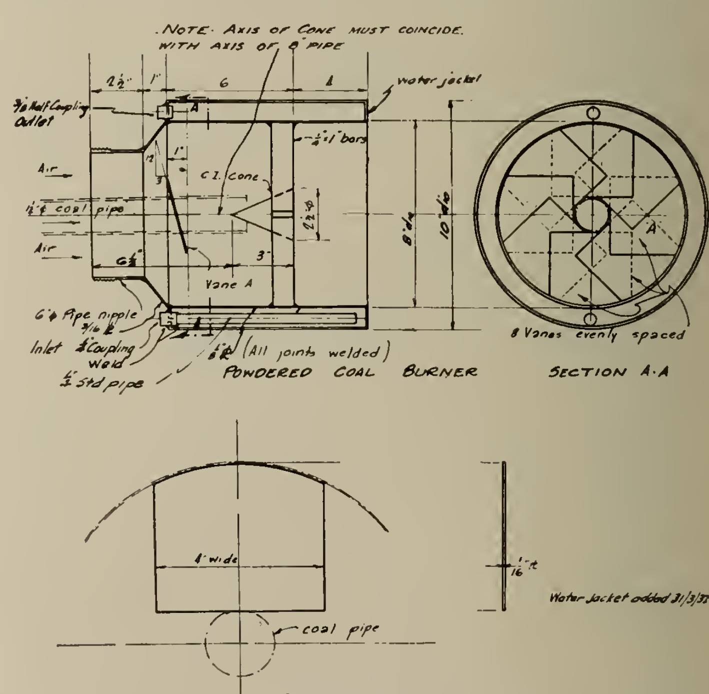

**Fig. 1—Detail of Powdered Coal Burner.**

advantage of using high pressure primary air on small furnaces is that the coal delivery line may be made of quite small and easily handled pipe. Ordinary black iron pipe is found to have a surprisingly long life on these installations.

It used to be customary to think of pulverized coal furnaces as being excessively large to burn a certain tonnage of coal. The author believes in making the radiant heat in a powdered coal flame do as much useful work as possible.

A powdered coal installation was arranged to fire a pair of 8 ft. by 60 ft. single shell rotary dryers and the fire box was made quite large. The job was reasonably successful but had a major disadvantage in the cost of fire box maintenance. One obvious way out of this difficulty was to reduce the amount of brickwork exposed to the flame but it was only possible to accomplish this and still secure good ignition by installing an adaptation of the turbulent burner shown in the sketch. The secondary air supply in this case was at 4 oz. pressure. These dryers now burn about 8 tons of coal per twenty-four hours with an ignition chamber of 48 cu. ft. and secure a heat efficiency of some 45 per cent. The material being dried varies in consistency from a thick mud to chunks of clay and the flame persists for a considerable distance into the dryer. The same type of installation is used for firing two double drum coal dryers.

Another type of burner which has enjoyed some success at this plant is similar in design to that developed by the Fuel Research Board and described as the "Z" burner in the 1933 report. The simplicity of this burner makes its use attractive in certain applications. It has been used for firing lead kettles at a feeding rate of 1 ton per day where a "lazy" flame is desirable in order to avoid local overheating of the kettle where the combustion volume is restricted. In another furnace, where a long luminous flame is desired for the drying and melting of slimes, it has obvious advantages.

The largest individual powdered coal consumer at the Trail plant is the slag fuming furnace. The application is unusual in that the coal is injected into a bath of liquid slag through tuyeres located some two feet below the surface of the bath. The operation has as its object the release of zinc from the slag and its recovery as zinc oxide. Furnace gases pass through a waste heat boiler and the oxide is eventually collected in a baghouse.

### Powdered Coal Plant

In a bin and feeder system the design of a preparation plant requires careful consideration. The types of coal likely to be used must be borne in mind. In general the plant will consist of receiving bins, coal dryers and pulverizing mills with a distributing system supplying the furnace bins. If the coal has much inherent moisture and is lignitic in character, the dryer and mill installation will be large in comparison with that required for a bituminous coal. It will not be good practice to operate the coal dryer at much over 200 deg. F. with lignite coal, since it has an unfortunate tendency to spontaneous ignition after the inherent moisture has been removed. This further reduces dryer capacity.

In handling high-ash low-volatile coals, which are difficult to ignite, the operator may easily acquire a certain carelessness about respecting the ordinary precautions which should be observed with any coal. A test shipment of high volatile coal was received at this plant about a year ago and the whole operating procedure had to be changed in order to operate safely. Dryer temperatures required very close control to avoid fires and still get capacity. Bin fires in the dried coal and powdered coal, while not frequent, were a constant source of concern. Experience at this time showed the truth of the ancient maxim that the only safe coal plant is a clean one.

Storage for dried coal should be small, particularly if lignite is being prepared. Once the coal is dried it should be kept moving until it is burned in the furnace.

At one time it was necessary to use up a supply of coke breeze by mixing it with the feed to the coal pulverizing plant. Although up to 20 per cent of the pulverized fuel was coke, the only particular difficulty that developed was

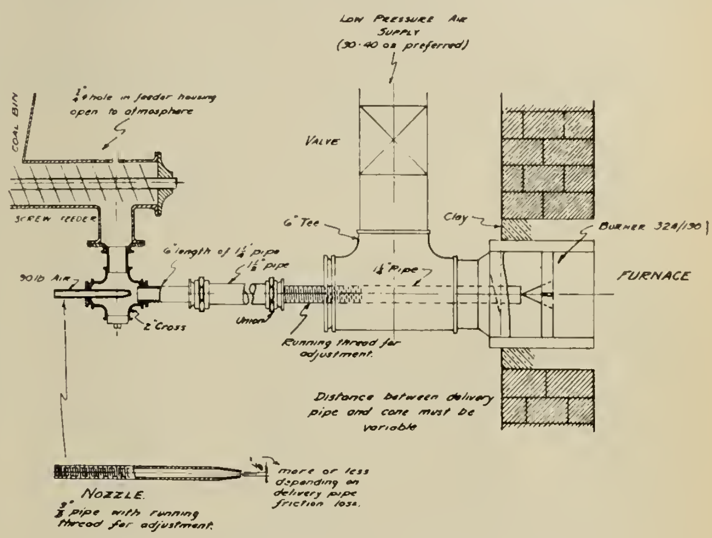

**Fig. 2—Arrangement of Powdered Coal Burner.**

in the crushing operation. The coke tended to hang back and load up the mill while the coal went through. This particular breeze contained 23 per cent ash.

Pulverizing mills are of various types, most of which have been developed to the point where maintenance is very low. Slow speed mills usually require more power than high speed mills for the same capacity.

The air pressure system of coal distribution has the advantage of being comparatively foolproof, since there are no moving parts to require adjustment. All that is necessary is a pipe line and pressure tank.

The furnace bins are usually vented through bags at the top and have some type of coal feeder mounted on the bottom. For the consumption of small tonnages of coal, the design of the feeder becomes important. Screw feeders have several disadvantages with one saving grace, simplicity. There is a field here for the development of a non-flooding feeder that will deliver a small quantity of coal to the burner at a constant rate.

The use of pulverized coal for heating has distinct advantages over the use of coal in any other form in a great many fields, both in large and small scale operations. It is flexible, efficient and can be made foolproof. It is one easy way of getting the greatest thermal value out of the fuel dollar.

# THE ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE OF CANADA

"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."

VOLUME XX JULY, 1937 No. 7

## The Utilization of Canadian Coals

The ten papers on Canadian coals published in this issue of The Journal treat of a number of live problems which arise in the study of this important division of the fuel resources of the Dominion. They really form a symposium on the subject, and naturally fall into groups corresponding roughly with the widely separated eastern and western areas in which nature has placed our coal deposits.

Three of them deal with coal classification and investigation, and more particularly with recent advances in this difficult field. The article by the Director of the Division of Fuels of the Dominion Department of Mines is itself a mine of ably selected information; Mr. Haanel's data are well supplemented by those of Dr. Sexton from Nova Scotia and by Mr. Stansfield's as regards Alberta coals. From the particulars given it will be evident that the public money devoted to these inquiries has been judiciously spent, both by the Dominion and the Provincial Governments concerned.

The technique of coal utilization is discussed by five authors. Conditions in many parts of Canada are such that if we are to avoid resorting to imported fuel, whether for power generation or for domestic heating, low rank coals, or a higher rank coal possibly having some difficult moisture, ash or sulphur characteristics, must be used in many places. Actual experiences in New Brunswick, Saskatchewan and Alberta (in power generation practice), and in British Columbia (in metallurgical work) are recounted by the men who have themselves been responsible for many of the successful results they report, and for the means adopted to overcome operating difficulties. Their methods of burning certain coals in pulverized form and with mechanical stokers are of considerable interest.

There are other papers of somewhat different scope. As the demand for coke for domestic purposes in Canada grew—particularly in Ontario where the competition from American anthracite was severe—the Dominion Government endeavoured to encourage the use of Canadian coals in the manufacture of by-product coke. Requirements could not be met by coke produced by the metallurgical companies, who needed practically all they could make. This led to the establishment of coke-producing companies, who succeeded in meeting the competition of imported European coke. Mr. Munroe describes the vicissitudes of their enterprise, and incidentally throws an interesting light upon the local and international factors which affect an industry of this kind.

Mr. Sutherland's story of the Saskatchewan lignite industry shows how the utilization of an abundant and easily mined natural resource may prove to be dependent on labour conditions, legislative enactments, the scale on which individual enterprises are operated, and on the transportation facilities available.

The importance to Canadian industry, and to the country at large, of the proper utilization of our coal resources is self-evident. The papers here presented bring up to date the creditable record of coal investigations in Canada, explain some of the difficulties and successes experienced in coal-burning practice, and show the decisive effect which economic conditions may exert in certain phases of the Canadian fuel industry.

## Institute Problems Considered at Recent Meetings of Council

Members will be interested to learn of the action taken by the Council, following the announcement of the result of the ballot on the amendments to by-laws, which was reported at the Council meeting of April 30th, 1937. At this meeting the Council's attention was drawn to the proposals for local co-operation which had been put forward, more particularly in Nova Scotia and Manitoba, in 1934 and 1935, and had necessarily remained in abeyance pending the result of the work of the Committee on Consolidation. As already noted in the Journal, arrangements were at once made for visits by members of Council to Winnipeg, and to Saint John and Halifax, by President Desbarats and Mr. J. L. Busfield respectively, and reports of these visits were presented at the Council meeting of May 28th, 1937.

In these reports the Council was informed that the local schemes were still under consideration. The proposals differ somewhat in the two localities, but in general involve a common executive committee and secretary, and the encouragement of local engineers to belong to both the Association and The Institute, an arrangement being also proposed for the local collection of a single fee. In Nova Scotia the scheme under discussion is one of amalgamation rather than co-operation and is being further considered there by a committee of seven members, two representing the Association, two the Halifax Branch of The Institute, one the Cape Breton Branch, and two appointed by the Council of The Institute. Professor H. W. McKiel and Mr. C. A. Fowler are acting in the latter capacity.

At this meeting of the Council Mr. R. A. Spencer reported on conditions in Saskatchewan, where a plan for local consolidation is also being studied. He then stated that there was a feeling that the Council of The Institute in the past few years had done very little to further the professional interests of members. Mr. Spencer was asked to indicate some definite lines of action by the Council which would meet the views he had expressed, and after considerable discussion the President suggested that all these matters should be referred to a small committee which would report thereon at the Plenary Meeting of Council to be held on June 14th. Upon this committee he named Messrs. F. S. B. Heward, J. L. Busfield and R. A. Spencer.

At the Plenary Meeting of Council this committee reported accordingly, suggesting a comprehensive scheme involving the establishment of the following committees:

(1) A main 'Committee on Professional Interests' (of three members) which will co-ordinate the activities of provincial sub-committees of which one should be formed in each province. This Committee on Professional Interests is also to act in all negotiations with the Provincial Associations of Professional Engineers. In addition to carrying out discussions with the several Professional Associations as regards co-operation with The Institute, these sub-committees will deal with the following other questions of interest to our members: (*a*) Salaries and Remuneration; (*b*) Professional Practice; (*c*) Junior Engineers, and (*d*) Public Education, the latter term involving action to acquaint the general public with notable achievements in engineering and the advantages of employing qualified engineers to deal with industrial and civic problems of an engineering nature, and also to promote local publicity in the various centres.

(2) It was further recommended that a 'special committee of a temporary nature' be set up to investigate and report upon the management and membership of The Institute. This committee would examine and report on such questions as possible improvement of the organization of the Council and in the conduct of Institute affairs; the standards of admission and of fees; the suitability of the present classes of membership to existing conditions; the desirability of setting up Provincial Divisions, etc.

(3) It was further recommended that there should be a 'Special Committee on Closer Relations with Other Engineering Organizations,' with a view of leading to closer relations with other engineering organizations operating in Canada, this committee to have sub-committees in provinces where such engineering organizations are active.

(4) Finally, with regard to the question of closer working arrangements with the Provincial Associations, it was recommended that the Council adopt the following resolution as a statement of its policy, this resolution to be communicated to each of the eight Provincial Professional Associations:

> "Whereas, the closest possible co-operation with Provincial Professional Associations is desirable,
>
> Now therefore, to permit of said closer relationships the Council of The Institute is prepared to negotiate agreements with the Provincial Professional Associations along the following lines:
>
> (*a*) Provision for such mutual recognition of each other's membership as may be found possible.
> (*b*) Provision for joint collection of fees where desirable.
> (*c*) Provision for reduction of fees of members belonging to both organizations.
> (*d*) Provision for liaison between the respective Councils.
> (*e*) Provision for joint operations."

All the above suggestions were adopted by the Plenary Meeting of Council, and the following committees were appointed accordingly:

(1) *Main 'Committee on Professional Interests'*

This committee also to act in any negotiations with the Professional Associations.

F. A. Gaby, *Chairman*
F. Newell
O. O. Lefebvre

*Chairmen of Provincial Sub-Committees of C.P.I.*

P. H. Buchan, British Columbia
R. M. Dingwall, Alberta
R. A. Spencer, Saskatchewan
T. C. Main, Manitoba
J. A. Vance, Ontario
J. A. McCrory, Quebec
E. J. Owens, New Brunswick
H. S. Johnston, Nova Scotia

These councillors to form their own sub-committees.

(2) *Committee on Membership and Management of The Institute*

| | |
|---|---|
| Dr. L. F. Goodwin, *Chairman* | A. J. Taunton |
| E. A. Wheatley | Brian R. Perry |
| P. M. Sauder | V. C. Blackett |
| D. A. R. McCannel | R. R. Murray |

(3) *Special Committee on Closer Relations with other Engineering Organizations*

The Institute's existing 'Committee on Relations with National Societies' (under the chairmanship of Mr. John Murphy) was appointed a Special Committee to investigate and report on the feasibility of closer co-operation with other engineering organizations. Its membership is:

| | |
|---|---|
| John Murphy, *Chairman* | A. B. Crealock |
| R. W. Angus | J. M. R. Fairbairn |
| A. B. Cooper | H. J. Roast |

Sub-committees in each province to be appointed by the above committee.

The present situation as regards The Institute's relations with the Provincial Professional Associations is, therefore, that all the Associations will receive the resolution referred to above, and in each province a local sub-committee will report to the Committee on Professional Interests the nature and results of their negotiations with the local Professional Associations.

During the discussions it was made clear that the establishment of this Committee and its sub-committees will in no way affect the discussions now being carried on by the local committee in Nova Scotia on which Messrs. McKiel and Fowler are serving. It was also agreed that none of the recommendations or agreements of these committees should become effective unless endorsed by a Plenary Meeting of Council or a majority on a letter ballot of the whole Council.

In addition it will be noted that Mr. Spencer's suggestions have led The Institute Council to appoint committees dealing with four separate groups of subjects:

(1) Means of furthering the professional interests of members.
(2) Membership and management of The Institute.
(3) Relations with other engineering societies operating in Canada.
(4) Relations with the Provincial Associations of Professional Engineers.

---

## Past-Presidents' Prize 1937-1938

The subject prescribed by Council for this competition for the prize year July 1st, 1937 to June 30th, 1938, is **"Stream Control in Relation to Droughts and Floods."**

The rules governing the award of the prize are as follows:

The prize shall consist of a cash donation of the amount of one hundred dollars, or the winner may select books or instruments of not more than that value when suitably bound and printed, or engraved as the case may be.

The prize shall be awarded for the best contribution submitted to the Council of The Institute by a member of The Institute of any grade on a subject to be selected and announced by Council at the beginning of the prize year, which shall be July 1st to June thirtieth.

The papers entered for the competition shall be judged by a committee of five, to be called the Past-Presidents' Prize Committee, which shall be appointed by the Council as soon after the Annual Meeting of The Institute as practicable. Members and Honorary Members only shall be eligible to act on this Committee.

It shall be within the discretion of the Committee to refuse an award if they consider no paper of sufficient merit.

All papers eligible for the competition must be the bona fide work of the contributors and must not have been made public before submission to The Institute.

All papers to be entered for the competition must be received **not later than June 30th, 1938,** by the General Secretary of The Institute, either direct from the author or through a local Branch.

**SEMICENTENNIAL BANQUET—THE ENGINEERING INSTITUTE OF CANADA**

**Head Table Guests:**—*Left to right at top of table:* Brigadier-General C. H. Mitchell, C.B., C.M.G., C.E., D.Eng., Dean of the Faculty of Applied Science and Engineering, University of Toronto, Past-President of The Engineering Institute, Toastmaster; Sir Alexander Gibb, G.B.E., C.B., F.R.S., Hon.M.E.I.C., President of the Institution of Civil Engineers, representing the Institution of Civil Engineers and the Newcomen Society (England); The Right Hon. Lord Tweedsmuir, P.C., G.C.M.G., C.H., Governor-General of Canada, Guest of honour and principal speaker; G. J. Desbarats, C.M.G., Hon.M.E.I.C., President of The Engineering Institute of Canada; Edward P. Lupfer, vice-president of the American Society of Civil Engineers, representing the American Society of Civil Engineers; Dr. A. Surveyer, Past-President of The Engineering Institute of Canada; E. A. Cleveland, LL.D., immediate Past-President of The Engineering Institute of Canada. *Left to right around the circle:* A. M. McCutcheon, President of the American Institute of Electrical Engineers, representing the American Institute of Electrical Engineers; C. E. Davies, M.E., M.E.I.C., Secretary of the American Society of Mechanical Engineers; Brigadier-General Magnus Mowat, C.B.E., T.D., F.R.S.E. A.K.C., Secretary of the Institution of Mechanical Engineers, London; H. H. Vaughan, Past-President of The Engineering Institute of Canada; Canon H. J. Cody, President, University of Toronto; G. H. Duggan, D.Sc., LL.D., Hon.M.E.I.C., Past-President of The Engineering Institute of Canada; Dr. W. H. Brittain, Acting Principal of McGill University; A. R. Decary, D.A.Sc., Past-President of The Engineering Institute of Canada, and President of the Corporation of Professional Engineers of the Province of Quebec; J. C. Irwin, President American Railway Engineering Association; A. Frigon, D.Sc., M.E.I.C., Past-President, The Engineering Institute of Canada, representing the Ecole Polytechnique, Montreal, and the Société Française des Electriciens; W. T. B. McCormack, representing the Institution of Engineers, Australia; Major Geo. A. Walkem, Past-President The Engineering Institute of Canada; Johnstone Wright, Vice-President, Institution of Electrical Engineers, representing the Institution of Electrical Engineers; Julian C. Smith, Past-President, The Engineering Institute of Canada; F. N. Jean Gindorff, representing the Newcomen Society (United States); The Hon. C. D. Howe, Hon.M.E.I.C., Minister of Transport, Ottawa; H. E. Wimperis, President, Royal Aeronautical Society.

# The Celebrations of the Semicentennial of The Institute

The ceremonies which have just taken place in Montreal and Ottawa to commemorate the completion of fifty years of The Institute's activities will long be remembered. They were attended by members from all over the Dominion and by a host of distinguished guests from all parts of the English speaking world, while His Excellency the Governor-General honoured The Institute by his presence and his address to the members and ladies at the banquet. At the technical sessions more than twenty important papers were presented on subjects of marked interest and variety. The many official delegates brought greetings from nearly fifty sister institutions, universities and professional associations, many of them in the form of illuminated addresses.

The organization and arrangements were in the hands of a Semicentennial Committee of Montreal and Ottawa members under the chairmanship of J. L. Busfield, M.E.I.C. The Committee's activity and efficiency may be judged by the fact that, almost without exception, the various events commenced exactly at the times specified in the programme, and all were carried out with smoothness and despatch.

Several hundred delegates had registered by the time the first session opened in the Rose Room of the Windsor Hotel on the morning of June 15th, and their first act, on the call of the President, was to stand in silence for a minute as a tribute to the memory of Harrison P. Eddy, of Boston, Mass., an eminent American engineer who had come to participate in the jubilee proceedings and to receive an honorary membership in The Institute. Mr. Eddy had died early that morning in his hotel room. In announcing the sad event, the President expressed the profound regret of all present and tendered their sincerest sympathy to Mrs. Eddy and the members of the family.

The official visitors, headed by Sir Alexander Gibb, President of the Institution of Civil Engineers, James H. Herron, President of the American Society of Mechanical Engineers, H. E. Wimperis, President of the Royal Aeronautical Society and Director of Research at the Air Ministry, and Brigadier-General Magnus Mowat, representing the Institution of Mechanical Engineers, were then introduced to the meeting by F. S. B. Heward, chairman of the Reception Committee, who gave a brief outline of their careers and the organizations they represented. An interesting presentation was that by Charles Penrose, a vice-president of the Newcomen Society in the United States, who presented a letter from Sir Herbert Marler, Canadian Minister to the United States, conveying his congratulations to The Institute on its half century of existence.

On the completion of this ceremonial Past-President H. H. Vaughan officiated in announcing the award of Honorary Membership in The Institute to the following eight distinguished engineers:

R. W. Angus, Toronto, Ont.
George H. Duggan, Montreal, Que.
Harrison P. Eddy, Boston, Mass.
Sir Alexander Gibb, London, England
The Hon. C. D. Howe, Ottawa, Ont.
S. J. Hungerford, Montreal, Que.
Jacques Rabut, Paris, France
The Hon. Grote Stirling, Kelowna, B.C.

Of these, Past-President Duggan, Sir Alexander Gibb, the Hon. C. D. Howe, and Mr. Hungerford were present to receive their diplomas, which were handed to them by Mr. Vaughan with a few words of welcome in each case.

Past-President George A. Walkem took charge of the presentation of The Institute prizes and medals, which was the next item on the programme. The awards included that of the Sir John Kennedy Medal to Past-President J. G. Sullivan of Winnipeg, the Duggan Medal and Prize to P. L. Pratley of Montreal, the Gzowski Medal to David Boyd of Lachine and the Plummer and Leonard Medals to C. R. Whittemore of Montreal and L. S. Weldon of Tanganyika respectively.

Past-President H. H. Vaughan took the chair at the luncheon which followed, and the gathering was addressed by James H. Herron, President of the American Society of Mechanical Engineers, who spoke on social progress as affected by mechanical advancement, the dispersion of education and culture, and the increased responsibilities now imposed upon government. He was followed by H. V. Potter, representing the Society of Chemical Industry, who told of the efforts being made in Britain to co-ordinate and link in some central organization the work of three great chemical societies, the Society he represented, the Institute of Chemistry, and the Chemical Society, the latter being mainly interested in problems of pure science.

After luncheon the delegates adjourned to an 'Overseas Session,' at which three papers were presented by British contributors. General Mowat, secretary of the Institution of Mechanical Engineers, spoke on British Engineering Societies and Their Aims; Hugh Beaver dealt with Industrial Zoning and predicted the eventual establishment of centralized control of all forms of transport in Great Britain; and Johnstone Wright, chief engineer of the Central Electricity Board, described the construction and operation of the Grid system of main electrical distribution in Great Britain. Active discussion followed on all these papers. Canadians were particularly interested to note that the British Grid system was designed, constructed and operated under the supervision of outstanding professional experts, who were in no way subject either to governmental direction or political interference.

The first day of the meeting closed with a Semicentennial Ball in the Windsor Hall, at which the guests were received by President and Mrs. Desbarats. The decorations of the hall and of the Rose Room, where supper was served, featured the beaver-emblem of The Institute, and a striking record of names of the forty-seven Past Presidents of The Institute was displayed as a frieze round the room.

On Wednesday, June 16th, the technical sessions of the meeting began. The delegates divided into two sections to hear papers on such diverse subjects as the Utilization of Canadian Coals, the Use of Electric Power in Metallurgy, Electric Relaying, and Welding. At the luncheon which followed, the Hon. C. D. Howe presided, the guest speaker being A. C. Gardner, chief engineer of the Clyde Navigation Trust, Glasgow, Scotland. Mr. Gardner gave a fascinating history of the Clyde's development over the last two hundred years.

He was to have been followed by Mr. Harrison P. Eddy, whose untimely death was referred to by the chairman. Fortunately Mr. Eddy had prepared excellent notes of his address, and these were impressively presented to the meeting by F. S. B. Heward. In this message, which so unexpectedly proved to be his last, Mr. Eddy traced the probable sociological results of the far-reaching developments now taking place along engineering lines, holding that mass production will be extended to many more industries than at present; that conditions of agricultural production will change due to the adoption of methods of control and mechanization, and that these factors will inevitably lead to a reduction in the work-time required to satisfy the demands of the public. "What will be the result," asked Mr. Eddy, "of providing the resulting surplus of spare time?" In his view increased facilities for recreation and education must be available for everyone, a longer period of education for youth will be needed, and the development of scientific and literary occupations must be continued through adult life.

During the afternoon the technical sessions were continued, the papers treating of Concrete Construction, Freight Hauling in Undeveloped Territories, the Measurement of Stream Flow, the North Atlantic Air Service, and Modern Railway Motive Power.

The Banquet held in the evening was honoured by the presence of His Excellency the Governor-General, who was also the principal speaker. President Desbarats was in the chair, and was supported by Past-Presidents C. H. Mitchell, Arthur Surveyer and E. A. Cleveland. The former acted as toastmaster. The Governor-General's address, which appears on another page of this issue of the Journal, was followed by a toast to "Our Guests" proposed by Dr. Surveyer, the reply to which was given by Sir Alexander Gibb in his usual happy vein. The toast to "The Institute" was proposed in an eloquent speech by Mr. Edward P. Lupfer, representing the American Society of Civil Engineers, and was replied to by Past-President Cleveland. Greetings were heard from Sir Henry Barraclough, Past-President of the Institution of Engineers, Australia, speaking from Sydney, Australia; W. G. Sutton, President of the South African Institution of Engineers, speaking from Johannesburg; S. N. Ghose, Vice-President of the Institution of Engineers (India), Calcutta, and J. McGregor Wilkie, President of the New Zealand Society of Civil Engineers, speaking from Wellington.

The arrangement of the head table was unusual and most effective. Upon an elevated dais there had been placed a bank of peonies, white and pink, surrounding the beaver of The Institute worked in dark foliage and cutting a tree trunk of red peonies. Round this great mass of flowers sat the head table guests and officers of The Institute.

The proceedings were broadcast over the network of the Canadian Broadcasting Commission.

Thursday, June 17th, was devoted to a series of well organized visits to industrial and engineering works in and near Montreal, the tours being arranged so as to return in the afternoon in time for a Garden Party on the Campus of McGill University, which had been made possible through the courtesy of the University authorities. The gathering was addressed by Dr. W. H. Brittain, Acting Principal of the University, and afforded a pleasant opportunity for renewing acquaintanceships and comparing notes on the events of the day.

In the evening, the closing event of the Montreal celebrations was a very successful and well attended smoking concert in the Windsor Hall, held under the direction of C. C. Lindsay, at which President Desbarats took the opportunity of expressing to Mr. Busfield the appreciation of The Institute Council and members of The Institute at large, of the services of himself and the Semicentennial Committee of which he was chairman. This gratitude was indicated in a very practical fashion by the presentation of a silver cigar box.

During the Montreal meetings a number of events were arranged specially for ladies, including a tea and bridge, and a drive to Macdonald College and Senneville, which were well attended and greatly appreciated.

On the morning of the following day, Friday, June 18th, the visiting engineers and many Montreal members proceeded to Ottawa, where the celebrations were continued by a luncheon at the Chateau Laurier, afternoon tours of inspection to power plants, industrial establishments, government laboratories and buildings, and by a dinner in the evening. At the luncheon gathering, the presiding officer was J. G. Macphail, chairman of the Ottawa Branch, and the speaker was H. Gerrish Smith, vice-president of the Society of Naval Architects and Marine Engineers, New York, who gave an interesting historical resumé of the development of shipping, with particular reference to the contributions of the engineer to safety and comfort at sea.

In the evening, President Desbarats took the chair at a dinner where the members and guests were addressed by the Hon. C. D. Howe on Air Transport in Canada. Mr. Howe gave an account of the remarkable developments which are culminating in the establishment of a modern air line route across Canada. It was evident that before hearing Mr. Howe few of his listeners had realized the extent and scope of this great undertaking. The dinner was followed by a very enjoyable dance, which was the final function of the Semicentennial week of meetings and festivities.

On Saturday morning, officials of the principal Government Departments in Ottawa kindly received delegates who were interested in departmental work of an engineering character.

Those who were fortunate enough to be present agreed that the celebrations as a whole, and particularly the

Garden Party on McGill University Campus—June 17th, 1937.

Proceedings at the opening session and at the banquet were impressive as a demonstration of the solidarity of The Institute, its position among the engineering societies of the world, and its friendly relations with sister organizations on this continent, in Europe, and in the other countries of the British Commonwealth of Nations.

Our visitors from overseas and from the United States were most kind in their many expressions of appreciation of the welcome they received and the manner in which the various functions were conducted.

All arrangements were carried out by the Semicentennial Committee whose membership follows:

| | | |
|---|---|---|
| Montreal — | A. Cousineau, A.M.E.I.C. | Executive |
| | J. M. Fairbairn, A.M.E.I.C. | Publicity |
| | R. H. Findlay, M.E.I.C. | Executive |
| | W. McG. Gardner, A.M.E.I.C. | Hotel |
| | F. S. B. Heward, A.M.E.I.C. | Reception |
| | C. C. Lindsay, A.M.E.I.C. | Smoking Concert |
| | H. Massue, A.M.E.I.C. | Branch Delegates Conference |
| | G. Midgley, A.M.E.I.C. | Visits |
| | C. K. McLeod, A.M.E.I.C. | Dance |
| | J. F. Plow, A.M.E.I.C. | Registration |
| | T. C. Thompson, A.M.E.I.C. | Technical Sessions |
| Ottawa — | A. Ferrier, A.M.E.I.C. | Luncheon |
| | W. H. Munro, M.E.I.C. | Visits |
| | J. L. Rannie, M.E.I.C. | Dinner Dance |
| | A. K. Hay, A.M.E.I.C. | Chairman |
| | J. L. Busfield, M.E.I.C. | Chairman |

As regards attendance, it may be said that the total registration of members, ladies and guests was fully as large as anticipated. Some four hundred and fifty attended the Banquet in Montreal. At the luncheons at Montreal and Ottawa the attendance was from two hundred and seventy-five to three hundred and fifty. Two hundred and fifty were present at the garden party, three hundred at the smoking concert, and approximately the same number at the dinner and dance at Ottawa.

## Special General Meeting of The Institute

**June 21st, 1937**

The Special General Meeting of The Institute, notice of which was published on page 257 of the May issue of The Engineering Journal, was duly convened at ten a.m. on Monday, June 21st, at Headquarters, Vice-President J. A. McCrory, M.E.I.C., in the chair. Thirty-nine corporate members were present.

The Secretary having read the notice calling the meeting, the chairman stated that the objects of the meeting were as set forth in the notice, and that discussion would be in order.

Mr. Challies enquired whether any of the petitioners for the meeting were present.

Gordon McL. Pitts, A.M.E.I.C., as one of the petitioners, stated that the meeting was intended to provide an opportunity for the ordinary membership to express their wishes or thoughts. Since it was found impossible to make arrangements exactly in accordance with the intentions of the original petitioners, the present meeting did not fulfil the purpose for which it was called. He and his fellow petitioners, however, had held an informal meeting of their out-of-town representatives during the Semicentennial week at which there had been a very satisfactory discussion and very interesting points had been brought out.

There being no further discussion, J. L. Busfield, M.E.I.C., moved the adjournment of the meeting. His motion having been seconded by Mr. Gordon McL. Pitts, was carried unanimously.

The proceedings terminated at 10.17 a.m.

R. J. Durley,
*Secretary.*

## The Recent Ballot on Amendments to The Institute By-laws

At its meeting on May 28th, the attention of Council was drawn to certain statements which are reported to have been made at recent meetings, and which purported to give information as to the result of the voting in each province. The Council accordingly directed me to ask the scrutineers whether such information existed, and in reply the following letter was received:

June 3rd, 1937.

The Secretary,
The Engineering Institute of Canada,
Montreal.

Dear Sir:—

In reply to your letter of May 31st, with reference to the results of the canvass of the ballot on amendments to the By-laws, we would say that we have no information further than is contained in our report to Council dated April 30th. *In particular we would say that we are unable to give any statement as to the totals of the vote by provinces, since this information was never obtained.*

Yours truly,
R. E. Jamieson, M.E.I.C.
J. B. D'Aeth, M.E.I.C.,
R. H. Findlay, M.E.I.C.,
*Scrutineers.*

This letter is now published, by direction of Council, for the information of the membership.

The report dated April 30th to which the scrutineers refer, will be found on page 256 of the May issue of The Engineering Journal.

R. J. Durley, *Secretary.*

## The Semicentennial Meetings

### Acknowledgments

The Semicentennial Committee gratefully acknowledges the help so generously provided by the following organizations, without which it would have been impossible to have conducted the Semicentennial in such a satisfactory manner:—

Contributions in Service or Material—
- City of Westmount—Floral decorations for head table for banquet.
- Anglin Norcross Ltd.—Construction of head table for banquet.
- Bell Telephone Co.—Communications requirements.
- Northern Electric Co.—Equipment.
- R.C.A. Victor Corpn.—Special record.
- Montreal Tramways Co.—Transportation.

Contributions to Semicentennial Fund—
- Babcock-Wilcox & Goldie-McCulloch Limited
- Canada Cement Co. Limited
- Canadian Car & Foundry Co. Limited
- Canadian General Electric Co. Limited
- Canadian Industries Limited
- Canadian Ingersoll-Rand Co. Limited
- Canadian National Railways
- Canadian Pacific Railway Company
- Canadian Westinghouse Co. Limited
- E. G. M. Cape and Company
- Combustion Engineering Corpn. Limited
- Dominion Bridge Co. Limited
- Dominion Engineering Works Limited
- Dominion Steel & Coal Corp. Limited
- Foundation Co. of Canada Limited
- Fraser Brace Engineering Co. Limited
- General Dredging Contractors Limited
- Montreal Engineering Co. Limited
- Montreal Light, Heat & Power Consolidated
- Montreal Tramways Company
- Northern Electric Co. Limited
- Power Corp. of Canada Limited
- Shawinigan Water & Power Company
- Steel Co. of Canada Limited
- Superheater Co. Limited

J. L. Busfield,
*Chairman.*

# Address of His Excellency the Governor-General of Canada, Lord Tweedsmuir, P.C., G.C.M.G., C.H., Hon.M.E.I.C.

**At the Semicentennial Banquet of The Engineering Institute of Canada, Montreal, June 16th, 1937**

I am honoured to be here tonight as your guest at your jubilee dinner, and to congratulate The Engineering Institute of Canada on fifty years of vigorous and fruitful life. Some time ago you honoured me by making me an Honorary Member of The Institute, a distinction of which I am very proud, for I have no knowledge of engineering to justify it. I have had a good many different professions in my life, and at different times I have had inclinations to many more. But I cannot ever remember wishing to be an engineer. I always felt that your world was a world quite beyond me. I admired it profoundly, but I admired it from afar, as the ignoramus admires the expert.

Most professions, it seems to me, are empirical things and deal largely in speculations and generalities. The business of a lawyer, for example, is to give practical application to general principles, but he is not dealing with an exact science. No legal doctrine is really precise in its application. The work of a doctor, too, must be largely experimental. As for the politician, the terms he uses can never be accurately defined—that is part of the fun of politics. Therefore in nearly every profession you have faddists and theorists. But the engineer is wholly different. He has to deal with hard facts. He knows that if he is not exactly right in his calculations he will be wholly wrong. That gives his mind, I think, a clearness and precision which is not common in other walks of life. I have had the good fortune to know a fair number of eminent engineers, and I have always been struck by the masculine firmness of their intelligence. There are no vague patches, no loose ends in their methods of thought.

Your profession, gentlemen, has always been the foundation of any civilized society. You provide the basis, the physical basis, which makes government possible. That was so in the ancient monarchies of the East and especially in ancient Egypt. There were not many greater engineers in history than the Egyptians. The Greeks, it is true, were no engineers. They were interested more in the human mind than in the physical conditions of life. But they had to borrow a physical basis from their predecessors, and without these predecessors there would have been no Greek civilization. When you come to the Romans, the real makers of the world as we know it, we find that they were above all things a race of engineers. The Roman roads, the Roman aqueducts, the Roman bridges still stand to-day in the Old World as a memorial of a people who based their society firmly on engineering science.

Here, in Canada, the engineer is very much in the position of the ancient Romans. In the settled countries of Europe to-day I think one might say that nature has been largely conquered by the engineer. He has constantly to adjust and modify his science as new needs arise. But the initial problems have been solved. But here in this vast Dominion you have still the same kind of problem to face as the Romans had. You have to conquer space and you have to adapt landscape to human needs. Your profession must always be a matter of expansion and constant pioneering, and therefore a live profession. You have already had many great engineering achievements to your credit; your trans-continental railways, your harnessing of water powers are among the miracles of modern science.

But, gentlemen, I think your work has only begun. I am convinced that the future will hold for you still far greater triumphs than you ever contemplated. The future of the British Commonwealth depends largely upon applied science and now, when the old days of territorial expansion are over, you may fairly say that the engineer is the true empire-builder.

May I be allowed to say one word on a subject which concerns us deeply in Britain and which is of some importance to Canada. The beauty and dignity of Nature are among the chief assets which any country can possess. In a small, closely settled country, this beauty must be carefully preserved and it is most important to keep the balance between the aesthetic and the utilitarian point of view. The secret and subtle loveliness of the English countryside and of the Scottish Highlands can easily be ruined if the only consideration is utility.

Now, on this matter, it is important not to be pedantic. I have no patience with people who see in every modern development an outrage on nature. When railways were first started in England there was a loud outcry that the beauty of the countryside was gone. But nature has a wonderful power of absorbing human inventions. It was a foolish outcry, for it has added to its charm. It has proved the stability of nature, for it has absorbed the railways and made them a part of it.

The same I have no doubt will be true of the great arterial motor roads of the future. Take an achievement like the Forth bridge. I remember in my boyhood how people declared that such a bridge would ruin the amenities of the Firth of Forth. The exact opposite is the truth. These great piers, with the sea below them and the Highland hills as their background, have enormously added to the beauty and picturesqueness of Scotland because it has brought the human interest in touch with the mysteries of nature, just as the pyramids have added to the wonders of the Egyptian desert. In Switzerland the pylons marching down the countryside carrying electric power, so far from destroying the grandeur of the Alps have added to them by placing homely human interests in contrast to their immensity. It is necessary in these matters to get rid of shallow aesthetic fads and take a robust view of what constitutes the picturesque.

But at the same time the human construction must keep in some kind of harmony with nature. This is true even in Canada where you are dealing with nature in its wildest form. Even in Canada the engineer should also be something of an artist. As I have said, I think the introduction of a human interest does not spoil but rather dignifies any landscape. For example, I have been greatly impressed with the beauty in the west, of the grain elevators, with their white domes and towers, which carry the eyes from the immense prairie levels to the blue prairie sky. I do not suppose there was any conscious artistic purpose in the building of these elevators, but I can testify the result is excellent.

This morning I went for a trip around Montreal harbour and again was enormously impressed with the beauty of the elevators. They make a most dignified entrance and gateway to this great city. But there is one point of which I think the Canadian engineer should have some consciousness of his purpose, and that is in connection with bridges. Canada is a country of bridges, and the bridge is one of the most beautiful of human creations. I hope that your great profession will create bridges worthy of that august natural setting. Canada will be, and indeed Canada is already, the natural playground of North America, and those who visit us will demand beauty as well as usefulness.

Your profession, gentlemen, has a great mission, you have in your hands the furnishing of the material background of a great nation. You are the pathfinders, the roadmakers, the Cyclopean architects of a land whose horizons are not limited, and whose future no man can assess. I congratulate you most warmly upon a half century of brilliant achievement, and I am very certain that when you come to celebrate your centenary you will look back even upon this year of your jubilee as no more than a day of small things.

## Honorary Memberships Presented at Semicentennial Meeting

### Harrison Prescott Eddy, M.E.I.C.

A sketch of the career of Harrison P. Eddy, M.E.I.C., Past-President of the American Society of Civil Engineers, appears on page 593 of this issue of The Journal.

Mr. Eddy came to the Semicentennial Meeting to receive his Honorary Membership in person and died suddenly soon after his arrival in Montreal.

A man of high professional attainments, few engineers in North America were more greatly esteemed. His loss is deplored by a host of Canadian friends.

### Robert William Angus, M.E.I.C.

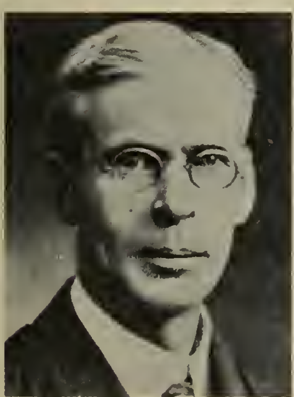
Robert William Angus was born in 1873 at St. Thomas, Ontario, and educated at the University of Toronto, graduating B.A.Sc. in 1897, and later receiving the degree of M.E.

His early engineering experience was with E. Leonard and Sons, London, Ontario, and in Pittsburgh and Cleveland, Ohio, where he was engaged in the design of automatic screw machines, steel plant equipment, and internal combustion engines.

In 1905 he was appointed Professor of Mechanical Engineering at the University of Toronto; he has occupied that position continuously since that time. He also practises as a consulting engineer and is a recognized authority on hydraulic problems, particularly those connected with surges and water hammer. He has done special consulting and investigating work for the City of Toronto and the Hydro-Electric Power Commission of Ontario.

Professor Angus' published works include, "Theory of Machines" (1915) and "Hydraulics for Engineers" (1931); he has presented many papers on his special branches of work before scientific and engineering societies.

He joined The Institute as a Member in 1921. He also holds membership in the Institution of Mechanical



R. W. Angus

G. H. Duggan

Engineers, the American Society of Mechanical Engineers (of which he was a Vice-President from 1924 to 1926), the American Water Works Association, and the Ontario Association of Professional Engineers (serving as President of that body in 1936).

### George Herrick Duggan, D.Sc., LL.D., M.E.I.C.

George Herrick Duggan, D.Sc., LL.D., M.E.I.C., the donor of the recently established Duggan medal and prize, was born in Toronto in 1862; graduated from the University of Toronto in 1883, and commenced his engineering career with the Canadian Pacific Railway Company. In 1886 he joined the staff of the Dominion Bridge Company, and was appointed chief engineer in 1891. In 1901 Mr. Duggan became assistant to the president of the Dominion Iron and Steel Company and the Dominion Coal Company, and was promoted to second vice-president and general manager of the Dominion Coal Company in 1904. In 1910 he returned to the Dominion Brigde Company as chief engineer, and later became general manager and vice-president, being appointed president in 1918. He held that office till 1936, when he resigned and became Chairman of the Board of Directors.

Mr. Duggan joined the Canadian Society of Civil Engineers as an Associate Member in March 1888 and was elected a Member in 1890. He served on Council for nine years, was vice-president for five years, and President in 1916. He was the recipient of the Sir John Kennedy Medal in 1931.

He is a vice-president of the Royal Bank of Canada, and director of numerous Canadian organizations, including the Steel Company of Canada, the Dominion Steel and Coal Corporation, the Montreal Trust Company and the Wayagamack Pulp and Paper Company.

Mr. Duggan is a Doctor of Science of the University of Toronto, and has received the honorary degree of LL.D. from both McGill and Queen's Universities. In 1936 he was elected an Honorary Member of the American Society of Civil Engineers.

Sir Alexander Gibb

The Hon. C. D. Howe

### Sir Alexander Gibb, G.B.E., C.B., F.R.S., M.E.I.C.

Sir Alexander Gibb, G.B.E., C.B., F.R.S., M.E.I.C., President of the Institution of Civil Engineers, has been the recipient of many honours, and has rendered to his country and to the public distinguished service, both in peace and in war time.

Born in Scotland in 1872, Sir Alexander started his professional career as a pupil of the late Sir John Wolfe Barry. He is now the senior member of the firm of Sir Alexander Gibb and Partners, and has held such appointments as consulting engineer to the Admiralty for the Singapore Naval Base; chief engineer for ports construction to the British Armies in France and Belgium, 1916-1918; civil engineer-in-chief to the Admiralty, and chief engineer for the reconstruction of the ports of Belgium (with rank of Brigadier-General), 1918-1919. In 1931-1932 he came to Canada and reported to the Dominion Government on the harbours of Canada, his report being published as the National Ports Survey in 1932.

Sir Alexander is a member of many engineering and learned societies, and his firm, which is of acknowledged eminence, is actively engaged in all forms of civil engineering. He joined The Institute as a Member in 1932.

### The Hon. C. D. Howe, M.P., M.E.I.C.

The Hon. C. D. Howe, M.E.I.C., was born at Waltham, Mass., in 1886. He graduated from the Massachusetts Institute of Technology in 1907, and was subsequently assistant in the structural engineering department of the same university. From 1908 until 1913 he was professor of civil engineering at Dalhousie University, Halifax, and also acted as a consulting engineer on important factory and warehouse structures. From 1913 until 1916 Mr. Howe was chief engineer of the Board of Grain Commissioners of Canada and was in charge of the design and construction of terminal grain elevators at Saskatoon, Moose Jaw, Calgary and Vancouver. In 1916 he established the firm of C. D. Howe and Company, consulting engineers, at Port Arthur, Ont., and since that time has designed and superintended the construction of many large grain elevators. He also surveyed the grain handling situation in the Argentine for the government of that country. Mr. Howe has travelled extensively, studying world trade, particularly factors affecting the grain business, becoming a recognized authority on that class of engineering work.

S. J. Hungerford

Hon. Grote Stirling

In 1935 he was elected to Parliament as Liberal Member for Port Arthur, and on the formation of the Mackenzie King government he entered the Cabinet as Minister of Railways and Canals and Minister of Marine. Under his direction these important departments have now been consolidated and enlarged, resulting in the formation of the new Department of Transport over which he presides as Minister. Mr. Howe joined The Institute as a Member in 1922.

### Samuel James Hungerford, M.E.I.C.

Samuel James Hungerford, M.E.I.C., was born at Bedford, Quebec, in 1872. His first railway work was as machinist apprentice with the Canadian Pacific Railway at Farnham. From 1891 to 1910, he remained with the Canadian Pacific Railway and held such positions as master mechanic of the western division, with headquarters at Calgary, and superintendent of the large locomotive shops at Winnipeg. In 1910 Mr. Hungerford entered the service of the Canadian Northern Railway, becoming superintendent of rolling stock with headquarters first at Winnipeg and later at Toronto. Following the organization of the Canadian National Railways, he was appointed in November 1917 general manager of the eastern lines, and in the following year became vice-president and general manager. In 1923 he was appointed vice-president in charge of operation, maintenance and construction, and in 1934 the Board of Trustees, named to administer the affairs of the railway, appointed him as President. In 1936 he became chairman of the new Board of Directors of the Canadian National Railways.

Mr. Hungerford joined The Institute as a Member in 1919.

### The Hon. Grote Stirling M.E.I.C.

The Hon. Grote Stirling, M.E.I.C., was born at Tunbridge Wells, England, in 1875, and was educated at University College School, London, and the Crystal Palace School of Engineering, graduating from the latter institution in 1895. Following graduation he was for several years occupied in railway work as assistant resident engineer and resident engineer with the Midland and Great Northern Joint Railways, and in 1907-1911 he was in private practice in Norfolk, England. Coming to this country in 1911, Mr. Stirling was resident engineer during 1912-1913 on the construction of the Black Mountain Water Company's main irrigation system at Kelowna, B.C., and has since been engaged in private practice in that part of the country.

In 1901 Mr. Stirling was elected an Associate Member of the Institution of Civil Engineers, and joined The Institute as a Member in 1927.

He was first elected to Parliament in November, 1924, when the seat at Yale, B.C., was vacated by the death of J. A. McKelvie, and he was re-elected in the three succeeding general elections of 1925, 1926 and 1930. In 1934 he was appointed Minister of National Defence and acting Minister of Fisheries in the Bennett Cabinet.

### Jacques Rabut

**Chevalier de la Légion d'honneur, Croix de Guerre**

M. Jacques Rabut, whose age is fifty-two, graduated from the Ecole Nationale des Ponts et Chaussées in 1909. and is a prominent Member of the Société des Ingénieurs Civils de France. He is at the head of the firm Société Ch. Rabut et Cie, in Paris, which carries on an extensive practice in consulting engineering.

During the winter of 1934 he visited Canada and gave a series of twelve lectures to the graduates of the Ecole Polytechnique, Montreal. The series dealt with the Technique of Great Modern Public Works, and its scope may be judged from the title of the opening lecture which was "The Scientific and Industrial Evolution of the Art of Construction." M. Rabut described construction methods used in twelve of the principal public works carried out in Europe during the past decade, and he was good enough to repeat one of these lectures in English at a meeting of the Montreal Branch of The Engineering Institute of Canada.

## Results of May Examinations of The Institute

The report of the Board of Examiners, presented at the meeting of Council held on May 28th, 1937, certified that the following candidates, having passed the examinations of The Institute, have satisfied the examiners as regards their educational qualifications for the class of membership named:

Schedule "B"—For admission as Junior:

John Jomini, Grand'Mere, Que.

J. Philias Villemure, S.E.I.C., Grand'Mere, Que.

## OBITUARIES

### Harrison Prescott Eddy, Hon.M.E.I.C.

It is with the deepest regret that we have to announce the death at Montreal on June 15th, during the Semi-centennial Meeting of The Institute, of Harrison Prescott Eddy, Hon.M.E.I.C., a distinguished leader of the profession and a man of acknowledged eminence in sanitary engineering. Mr. Eddy had come to Montreal to receive an Honorary Membership in The Institute, and to be one of the guest speakers at the celebrations. He had driven from Boston with his family and was stricken with a heart attack not long after his arrival.

Harrison Prescott Eddy, Hon.M.E.I.C.

Mr. Eddy had been outstanding in civil engineering for forty years; in his special field he was probably the most eminent American practitioner of his day. Born in Millbury, Mass., on April 29th, 1870, his early training and practical experience was gained in New England, where he took up sanitary engineering work immediately upon graduation from the Worcester Polytechnic Institute in 1891. In that year he was appointed superintendent of the sewage treatment plant at Worcester, and the following year became superintendent of the sewer department of the city, work which included entire charge of design and construction.

Mr. Eddy continued at Worcester until 1907, when he went into private practice with Leonard Metcalf under the firm name of Metcalf and Eddy. That association was dissolved by Mr. Metcalf's death in 1926, but the firm name was continued. As a member of the firm of Metcalf and Eddy, he acted as consultant on problems of water supply, sewage and waste disposal for nearly one hundred cities, including Chicago, Cincinnati, Buffalo, Dayton, New Orleans, Detroit and Washington. Outstanding among these undertakings was his work on the design of the sewerage system of Louisville, which brought him national recognition, and his study of sewage disposal and water supply for Milwaukee. He also served in an individual capacity as a member of numerous boards and commissions, most notable of which was the engineering board of review of the Sanitary District of Chicago. In recent years he was a member of the P.W.A. board of review.

Mr. Eddy was widely known as the co-author of a standard work on American Sewerage Practice and Sewerage and Sewage Disposal, and many technical papers and reports also have appeared under his name.

He took an active part in the affairs of technical and professional societies, including the American Society of Civil Engineers and the Boston Society of Civil Engineers, of which organizations he was a past-president; the American Water Works Association, the American Institute of Consulting Engineers and the American Public Health Association.

Mr. Eddy became a Member of The Engineering Institute of Canada on March 23rd, 1926.

### Charles Louis Arcand, A.M.E.I.C.

Regret is expressed in placing on record the death in Montreal on March 31st, 1937, of Charles Louis Arcand, A.M.E.I.C. Mr. Arcand was born at Three Rivers on November 22nd, 1880, and graduated from the Classical and Business College of Three Rivers in 1899. In 1900 he was appointed by the Department of Public Works of Canada to the district engineer's office in Three Rivers, and in 1907 became assistant engineer for the Department, which position he held up to the time of his death.

Mr. Arcand joined The Institute as an Associate Member on June 24th, 1919.

### Charles Bruce Daubney, A.M.E.I.C.

It is with deep regret that we place on record the death at Norwood, Mass., on May 12th, 1937, following a long illness, of Charles Bruce Daubney, A.M.E.I.C., of Ottawa. Mr. Daubney was returning to Ottawa from the southern United States, where he had been at a health resort.

Born at Cummings' Bridge, Ontario, on November 28th, 1889, he graduated from McGill University in 1910, with the degree of B.Sc. Following graduation he was instrumentman on the Fort William terminals, and subsequently was with John S. Metcalf Company Limited, engaged on elevators at Montreal and Saint John, N.B. In 1913-1914 Mr. Daubney was demonstrator in civil engineering at McGill University. In 1915 he joined the Department of Railways and Canals, and was assigned to harbour terminal construction at Port Nelson. During the World War he enlisted with the Canadian Expeditionary Force, holding the rank of lieutenant with the engineers. On returning to the Department of Railways and Canals following his discharge, he was appointed engineer for the St. Lawrence waterways. In 1924 Mr. Daubney was promoted to the head office staff of the chief engineer of the Department, and a few years later became general assistant engineer, an office he still held after the Department of Railways and Canals became part of the newly created Department of Transport.

Charles Bruce Daubney, A.M.E.I.C.

Mr. Daubney joined The Institute as an Associate Member on March 21st, 1916.

### Richard Adams Davy, M.E.I.C.

It is with deep regret that we place on record the death at Ottawa on May 1st, 1937, of Richard Adams Davy, M.E.I.C., one of the original members of the Canadian Society of Civil Engineers.

Born at Penzance, Cornwall, England, Mr. Davy was educated there and in London, commencing the study of civil engineering in 1870 under the borough engineer of Penzance. Coming to Canada in 1873, Mr. Davy made a number of mine surveys on the north shores of Lake Superior, and in 1875 was on the Canadian Pacific Railway's survey between Finmark and Lake of the Woods. With H. I. Mortimer he laid out the Fort Francis locks. In 1881 he was engaged on the location and construction of the Canadian Pacific Railway Kingston-Pembroke line, following which he was made division engineer in charge of the construction of the 25-mile line between Hawk Lake and Kenora. His division was later extended to Eagle Lake, a total distance of 67 miles. Upon completion of the railway between Port Arthur and Winnipeg, Mr. Davy made an exploratory survey for the line between Richelieu and Lennoxville, Que., and in 1887 went to Riviere du Loup to revise the location of the Temiscouata Railway. In the following year he was made chief engineer on the construction work, and during this time also ran a preliminary line for a railway between Edmundston, N.B., and Moncton, a distance of 250 miles. In 1892 Mr. Davy was engaged in Exchequer Court cases and was sent by the Department of Railways and Canals to supervise the boring for the projected Prince Edward Island tunnel. In 1894 and 1895 he assisted in irrigation construction work between Gleichen and Lethbridge, Alta., and in 1896 made a joint report with C. H. Keefer for the Ottawa main drainage. In the following year Mr. Davy was appointed assistant engineer on the enlargement of the Iroquois canal. He was then stationed in the district office of the Department of Railways and Canals until 1901 when he took charge of the construction on the Simcoe-Balsam Lake division of the Trent canal. Some years later Mr. Davy had charge of the construction of the Bank Street subway in Ottawa for the Grand Trunk Railway, and then made a survey for a railway between Meaford and Owen Sound. In 1907 he was given charge of the Buckborn dam and bridge and in 1908 went to Lindsay to supervise the reconstruction of the locks, dams and bridge there, being transferred to the Heeley Falls section in 1910. Mr. Davy retired about twelve years ago, and has since lived in Ottawa.

Richard Adams Davy, M.E.I.C.

Mr. Davy became a Member of the Canadian Society of Civil Engineers on its foundation on January 20th, 1887. Together with the late Colonel W. P. Anderson, he took an active part in the discussions in Ottawa which led to the participation of many Ottawa engineers in the formation of the Society. He was greatly interested in its early history, and his reminiscences form a valuable record of its establishment.

### John Smythe Hall, A.M.E.I.C.

We regret to announce the death at Montreal on May 8th, 1937, of John Smythe Hall, A.M.E.I.C.

Mr. Hall was born at Montreal on January 27th, 1894, and graduated from McGill University in 1914 with the degree of B.Sc. Following graduation he joined the staff of the Canadian Pacific Railway Company, and had only been in that service for a short time when war broke out. He enlisted in the 148th Battalion, C.E.F., in 1915, but was later transferred to the Light Railway Operating Company, and afterwards to the Royal Tank Corps, with which unit he served in France until the end of the War. Returning to Canada, Mr. Hall resumed his connection with the Canadian Pacific Railway, and with the exception of two years with the Franklin Railway Supply Company, served with that company until the time of his death. He was last stationed at Calgary.

Mr. Hall joined The Institute as a Student on December 14th, 1912, and became an Associate Member on April 18th, 1922.

### Lewis W. Toms, A.M.E.I.C.

Members of The Institute will learn with regret of the death at Victoria, B.C., on May 15th, 1937, of Lewis William Toms, A.M.E.I.C., a member of very long standing.

Mr. Toms was born in England at Combe Martin, North Devon, on December 25th, 1857, and was educated at Marlborough College and at the Crystal Palace School of Engineering. In 1877-1879 he was with Whitehead and Company, torpedo manufacturers, Fiume, Austria, and subsequently took a course in civil engineering at Glasgow University. From 1881 to 1884 Mr. Toms was with Mirrlees, Watson and Company, Glasgow, and in 1885 went to Australia, where he was engaged on the erection of a sugar mill plant for the Colonial Sugar Refining Company. He returned to England, and in 1888 went to Kauai, Hawaiian Islands, where he erected a cane sugar diffusion plant for the MacKee Sugar Company. In the same year Mr. Toms came to Canada, and entered the drawing office of Miller Bros. and Mitchell, Montreal, becoming a member of the firm of Miller Bros. and Toms in 1889. In the late 90's, Mr. Toms went to Vancouver and conducted prospects and inspection for eastern mining interests in the Cariboo and Kootenay districts. In 1904 he returned to fruit-farming on Vancouver Island. During the War, Mr. Toms worked as a shell inspector in Vancouver and Victoria.

Lewis W. Toms, A.M.E.I.C.

He became an Associate Member of The Institute (then the Canadian Society of Civil Engineers) on November 14th, 1889.

### Leslie Lucas, A.M.E.I.C.

Regret is expressed in placing on record the death at Montreal on June 23rd, 1937, of Leslie Lucas, A.M.E.I.C.

Mr. Lucas was born at Annan, Dumfrieshire, Scotland, on August 13th, 1896, and was educated at the Royal Technical College, Glasgow. He served a five-year apprenticeship with Mavor and Coulson Limited, Glasgow, and served with the Imperial Army from 1914 to 1919, first with the Seaforth Highlanders, and holding the rank of Captain with the Highland Light Infantry after 1917. Coming to Canada in 1923, Mr. Lucas was on the staff of Fraser Brace Limited, Montreal, as a draughtsman, and in 1924-1926 was superintendent of plant and transmission lines with the Great Northern Power Company at Indian Chutes, Ont. In the latter year he became plant manager for the Northern Canada Power Company Limited, Timmins, Ontario, and in 1929 was connected with the Sun Life Assurance Company, Montreal. Mr. Lucas then joined the staff of the Northern Electric Company, Montreal, and was with that firm at the time of his death.

Mr. Lucas joined The Institute as a Junior on January 27th, 1925, and became an Associate Member on February 10th, 1928.

### Coote Nisbitt Shanly, M.E.I.C.

Deep regret is expressed in placing on record the death at Kingston, Ont., on May 5th, 1937, of Coote Nisbitt Shanly, M.E.I.C.

Mr. Shanly was born at Montreal on January 29th, 1889, and following two years at McGill University was from 1905 until 1908 with the Canadian Pacific Railway Company, the Dominion Bridge Company, and the Prince Edward Island Railway. In 1909 Mr. Shanly was in charge of a plane table party for the Irrigation Department of

Coote Nisbitt Shanly, M.E.I.C.

the Canadian Pacific Railway, and in 1910 was in charge of a railway location party for the Kananaskis Coal Company. From 1911 until 1912 Mr. Shanly was in the city engineer's office, Vancouver, and in 1913-1914 was engaged on the design of concrete railway structures for the Canadian Northern Ontario Railway. He served in England, France and Salonika with the Royal Engineers from 1914 to 1918, in the latter year commanding the railway survey and reconnaissance section, R.E., handling all railway location for the British Salonika Force. Returning to Canada in 1919, Mr. Shanly was connected with the Department of Soldiers Civil Re-establishment in the Montreal Retraining Centre. He joined the engineering staff of Price Brothers and Company Limited in 1920, subsequently being assistant resident engineer for the Kenogami paper mills, resident engineer on the hydro-electric development at Chute aux Galets, in charge of preliminary studies for mill and town sites, in charge of construction of the hydro-electric development at Chicoutimi, and town manager at Kenogami. Latterly Mr. Shanly was engaged on insurance work for the Imperial Life Assurance Company, at Quebec, and as manager at Kingston, Ontario.

Arthur Langley Mudge, M.E.I.C.
Whose Obituary appeared in the May, 1937, issue of The Journal.

Mr. Shanly became a Student of The Institute on April 17th, 1909, was elected a Junior on March 11th, 1913, an Associate Member on May 25th, 1920, and a Member on June 7th, 1924. He took an active interest in Institute affairs, and was chairman of the Saguenay Branch in 1925.

### Silfroy Joseph Fortin, M.E.I.C.

It is with regret that we announce the death at Montreal on May 17th, 1937, of Silfroy Joseph Fortin, M.E.I.C.

Mr. Fortin was born at St. Sebastien, Iberville county, Que., in 1867 and graduated from the Ecole Polytechnique, Montreal, in 1889. Following graduation, he was, until 1899, engaged on structural steel design, working in New York, Philadelphia and Chicago, in turn with Levering and Garrigues, the American Bridge Works, the Riverside Bridge Works, and C. O. Brown, New York. He next spent two years in Honolulu, then two years in Japan and China, subsequently becoming resident engineer and representative of Milliken Brothers of New York City, in Mexico. From 1914 until 1918 Mr. Fortin was employed by the Federal Government at Ottawa to supervise the building of bridges and jetties, as well as a number of hydraulic projects throughout the Dominion. He joined the city of Montreal Public Works Department in 1918 as Deputy Director of Public Works, and in 1922 was appointed Deputy Chief Engineer and chairman of the Techincal Commission of Montreal, which body he originated. Among his achievements may be named the supervision of the building of an arsenal and drydocks for the Russian government at Port Arthur, and the Post Office, Marine and Public Works buildings, the Legislative Palace and the National Theatre in Mexico City for the Mexican government. He was the author of two monographs, one dealing with the problems of foundations in the volcanic lava at Mexico City, and the other on the organization and functions of a town planning commission for the Island of Montreal.

Mr. Fortin became a Member of The Institute on December 21st, 1915, and was made a life member on June 12th, 1936.

## PERSONALS

W. H. Stuart, M.E.I.C., has resigned from his position as inspecting engineer for the Mines and Geology Branch of the Department of Mines and Resources at Ottawa, and has accepted an appointment with Mr. John E. Hammell in the mining industry. Mr. Stuart's home address will be at 7 High Park Boulevard, Toronto, Ontario.

J. F. McDougall, A.M.E.I.C., formerly highways engineer with the Department of Public Works, Alberta, is on the staff of McDougall and Secord Limited, Edmonton, Alta. Mr. McDougall graduated from the University of Alberta in 1930 with the degree of B.Sc., and obtained that of M.Sc. from McGill University in 1931, and following graduation entered the service of the Alberta Department of Public Works.

S. J. Hungerford, M.E.I.C., chairman of the Canadian National Railways, Montreal, has been named president of Trans-Canada Air Lines, and two other members of The Institute have been appointed provisional directors of the Board: J. A. Wilson, M.E.I.C., Controller of Civil Aviation, Department of Transport, Ottawa, and Lieutenant-Commander C. P. Edwards, O.B.E., A.M.E.I.C., Chief of Air Services, Department of Transport, Ottawa.

J. Hastie Holden, A.M.E.I.C., has been appointed manager of the Geo. W. Reed and Company Limited, Montreal. He was formerly sales manager for the company. Mr. Holden graduated from McGill University in 1923 with the degree of B.Sc. and subsequently became assistant to the plant engineer of the Northern Electric Company. In 1924 he joined the staff of the company with which he is now connected.

S. S. Colle, A.M.E.I.C., of Air Conditioning Engineering Company, Montreal, has moved his office to 2040 Union Avenue. Mr. Colle organized this company during 1936 to design and contract for the installation of ventilation, heating, humidification and air conditioning work. Mr. Colle was principal assistant to the late Frederick B. Brown, M.E.I.C., consulting engineer, up to 1932, and was engineer with the Beauharnois Light, Heat and Power Company from 1932 to 1936.

W. D. Black, M.E.I.C., president of the Otis-Fensom Elevator Company Limited, Hamilton, Ontario, has been elected first vice-president of the Canadian Manufacturers' Association. Mr. Black was chairman of the Hamilton branch of the Association in 1929-1931, and for several years was chairman of the Commercial Intelligence Committee. In 1934, as chairman of the Association's Industrial Relations Committee, he was appointed employers' delegate to the International Labour Conference in Geneva. Mr. Black is a director of the Bank of Canada.

A. H. Harkness, M.E.I.C., consulting engineer, Toronto, was the recipient of the honorary degree of Doctor of Engineering from the University of Toronto recently. Mr. Harkness graduated from the University of Toronto in 1895, returning for the degree of B.A.Sc. in 1897. After graduation he spent some three years in an architect's office, and then joined the designing staff of the Canada Foundry Company in their steel and bridge division. He remained with this company for eight years, holding in the latter years the position of assistant chief engineer. In 1910 he commenced consulting practice in the city of Toronto, and his work since that date has made an outstanding contribution to Canada's growth. The structural features of important buildings from Vancouver to Halifax pay tribute to his ability in that branch of engineering. Mr. Harkness, who was a vice-president of The Institute in 1932, received the Sir John Kennedy Medal, the highest honour which The Institute can bestow, in 1936.

Karel R. Rybka, A.M.E.I.C., was the recipient of the degree of D.Sc. at a convocation held recently at the College of Engineering (Technische Hochschule) in Prague. Dr. Rybka graduated from this college in 1923 in mechanical engineering and was subsequently for three years connected with diverse engineering works in Europe. Since 1928, when he came to Canada, he was on the staff of Walter J. Armstrong, consulting engineer in Montreal and Toronto, except for a short period devoted to private practice, and during the last three years was in charge of the Toronto office of the firm.

M. D. Stewart, A.M.E.I.C., has resigned his position as resident engineer with the Seigniory Club Community Association Limited, Seigniory Club, Que., to become town engineer for the town of Mount Royal, Que. Mr. Stewart graduated from the University of Toronto in 1922 with the degree of B.A.Sc. and during the following year was with Bremner Norris and Company Limited. In 1923 he was for a time inspector for MacVicar and Heriot on the new Caron Building, Montreal, becoming assistant engineer with Price Brothers and Co. Limited at Chicoutimi in 1924. In 1929 Mr. Stewart joined the staff of the Foundation Company of Canada, and in 1930 became connected with the Seigniory Club Community Association Limited.

C. H. Oakes, A.M.E.I.C., is now in the designs office at Woolwich Arsenal, England. Mr. Oakes attended Liverpool University from 1910 to 1915, and was subsequently until 1919 an engineer officer in the Royal Naval Transport Service. From 1919 until 1922 he held the same rank in the Merchant Service. In 1924-1927 Mr. Oakes was resident engineer for Meccano Limited, at Liverpool and Paris, and coming to Canada in the latter year, he became system operator at the Quebec terminal of the Shawinigan Water and Power Company. He was later resident engineer, and works manager with Canadian Industries Limited, and in 1930 joined the staff of the Boiler Inspection and Insurance Company of Canada as engineer and surveyor.

Major A. R. Ketterson, D.S.O., A.M.E.I.C., succeeds Phillips B. Motley, M.E.I.C., as engineer of bridges of the Canadian Pacific Railway Company. Major Ketterson, who is an Associate of the Royal Technical College, Glasgow, entered the service of the Canadian Pacific Railway as bridge inspector in the chief engineer's department, Montreal, in 1907. In 1910 he was engaged on work as a structural draughtsman of bridges in the same department, and in 1912 was appointed assistant engineer, holding this position until 1916 when he went overseas, where he served with distinction and was awarded the D.S.O. On demobilization Major Ketterson returned to the service of the Canadian Pacific Railway, and was appointed to the chief engineer's department, and in 1928 became assistant engineer of bridges.

W. P. Near, M.E.I.C., formerly city engineer of London Ont., and more recently with the motor vehicles branch, Department of Highways, Ontario, has been appointed a commissioner on the Ontario Municipal Board. Mr. Near graduated from the University of Toronto in 1903 with the degree of B.A. and in 1907 received that of B.A.Sc. from the same university. Following graduation he was employed on surveys and track revisions for the Temiskaming and Northern Ontario Railway, and in 1909 joined the engineering staff of the Works Department, Toronto, in the main drainage office, later being appointed engineer in charge of trunk sewer construction. Mr. Near was appointed city engineer of St. Catharines in 1913, which position he held until he received a similar appointment in London in 1923. In 1932 he resigned to become manager of the Toronto division of the Supertest Petroleum Corporation, and two years later accepted the position which he now relinquishes.

### Phillips B. Motley, M.E.I.C., Retires

Phillips B. Motley, M.E.I.C., engineer of bridges for the Canadian Pacific Railway, concluded forty-five years of service with the company when he retired on June 30th, 1937.

Born in Calcutta, India, Mr. Motley completed his general and engineering education in England, and joined the engineering department of the Canadian Pacific Railway Company at Montreal in 1892. He occupied the positions of draughtsman and inspector of bridges both in the shops and during erection until 1903 when he became assistant engineer in the department. In 1908 he was made assistant engineer of bridges, and on June 1st, 1911, received the appointment from which he has now retired. Among the more important bridges for which Mr. Motley has been responsible may be mentioned the Lethbridge viaduct, the Edmonton City bridge, the crossings of various large rivers on the prairies such as at Saskatoon, Outlook, Nipawin and Winnipeg, besides the bridge at Galt, Ontario, and the bridge over the St. Lawrence river near Montreal, which was reconstructed to allow for double tracks, and the Saint John, N.B. cantilever bridge. There were many others of lesser magnitude and of difficult construction, particularly in the Rocky and Selkirk Mountains and the North shore of Lake Superior.

Mr. Motley is a member of the Institution of Civil Engineers, the American Society of Civil Engineers, and the American Railway Engineering Association.

J. W. Orrock, M.E.I.C., for the past fifteen years engineer of buildings for the Canadian Pacific Railway Company, with headquarters at Montreal, has recently retired. Mr. Orrock's retirement comes after forty-six years' service with the Canadian Pacific Railway. He joined the company in 1891 as draughtsman in the chief engineer's office at Montreal, and in 1910 became chief draughtsman. In 1912 he was appointed division engineer at North Bay, and later was promoted to principal assistant engineer at Montreal, and attained the position from which he now retires in 1924. During his occupancy of this position, the engineering department has been in charge of the rebuilding of the Chateau Frontenac hotel at Quebec, the reconstruction and extension of the company's hotels at Banff and Lake Louise, the extension of the Palliser hotel at Calgary and the Empress hotel at Victoria, B.C., and the construction of the Royal York hotel at Toronto, as well as the construction of Digby and Kentville, N.S., and the Maritime hotels at Yarmouth, various station buildings such as those at Three Rivers and Park Avenue, Montreal.

Mr. Orrock is a member of The Engineering Institute of many years standing, having joined as an Associate Member on June 18th, 1896, and transferred to the class of Member on October 24th, 1907.

Jules Joyal, M.E.I.C, has joined the staff of the Consolidated Paper Corporation Limited, and will be located at Escoumains, where he will take charge of works to be in connection with the reopening of the Escoumains river for logging operations. Mr. Joyal is a graduate of the Ecole Polytechnique, having obtained the degree of B.A.Sc. in 1920. Following graduation he was for several years on survey parties for Price Brothers and Company Limited, the Lake Megantic Pulp Company, the Montmorency Lumber Company, and Henry Atkinson Reg'd., and in 1922 was division engineer in the Quebec Roads Department. In the same year he again became connected with Price Brothers and Company Limited, being engaged on survey and storage dam construction, the Kenogami mill extension, and as assistant logging engineer, until 1931 when he joined the staff of the Quebec Public Commission as engineer, from which position he has now resigned. Mr. Joyal has also resigned as secretary-treasurer of the Quebec Branch of The Institute, which office he has held for several years.

## Elections and Transfers

At the meeting of Council held on May 28th, 1937, the following elections and transfers were effected:

*Members*

DAVIES, Clarence Ebenezer, M.E., (Rensselaer Polytech. Inst.), Secretary, The American Society of Mechanical Engineers, New York, N.Y.

POITRAS, Paul E., B.A.Sc., C.E., (Ecole Polytechnique, Montreal), mech. engr., The Steel Company of Canada, Montreal, Que.

VAISON, Albert Felix, (Naval College, Brest), technical adviser, Dept. of National Revenue, Ottawa, Ont.

*Associate Members*

BOUCHARD, Jean, B.A.Sc., C.E., (Ecole Polytechnique, Montreal), city engr., St. Hyacinthe, Que.

HOGG, Thomas, (National Cert., Inst. Mech. Engrs.), dftsman., water rights branch, Dept. Natural Resources, Regina, Sask.

LAVERTY, Clarence Alvin, B.Sc., (Univ. of Alta.), elect'l. inspr., Boiler Inspection and Insurance Co. of Canada, Montreal, Que.

O'SHAUGHNESSY, Patrick Leo, B.Sc., (McGill Univ.), mill foreman, Canada Cement Co. Ltd., Belleville, Ont.

SNYDER, Beverly Wells, B.Sc., (Univ. of Alta.), engr., asst. to the vice-president, Can. Western Natural Gas. Light, Heat and Power Co. Ltd., Calgary, Alta.

*Juniors*

JOHNSON, Robert, M.Sc., (Univ. of Sask.), mech. and bridge dept., Dominion Bridge Co. Ltd., Lachine, Que.

*JOMINI, John Louis, (McGill Univ.), dfting. office, Consolidated Paper Corporation, Grand Mere, Que.

KIRKBRIDE, David Spencer, B.Sc., (Univ. of Sask.), 2229 Cornwall St., Regina, Sask.

McEWEN, Markland Neil, B.Sc., (Univ. of Man.), instrumentman, Dept. of Northern Development, Kenora, Ont.

NESBITT, William P., B.Sc., (Queen's Univ.), junior engr., Fraser Companies Ltd., Edmundston, N.B.

SHERWOOD, Benjamin H., B.Sc. (Univ. of Alta.), dftsman., engrg. dept., Imperial Oil Limited, Calgary, Alta.

*Transferred from the class of Associate Member to that of Member*

BURNS, Charles Henry McLeod, (Mt. Allison Univ.), asst. mgr., Canada Foundries and Forgings Ltd., Welland, Ont.

NICHOLSON, John Billington, B.A.Sc., (Univ. of Toronto), President, The Nicholson Company, Chrysler Building, New York, N.Y.

*Transferred from the class of Junior to that of Associate Member*

LLEWELLYN, Leopold William, B.Sc., (Univ. of Sask.), dftsman. and designer, Northwestern Iron Works Ltd., Regina, Sask.

*Transferred from the class of Student to that of Associate Member*

CAIRNCROSS, Alexander Thomas, B.Sc., (Queen's Univ.), technical adviser, dept. of engrg., Generalissimo's Staff, National Government of China, Chengtu, Szechwan, China.

LAING, David Alexander Shearer, B.Sc. (McGill Univ.), mech. engr., cable engrg. dept., Northern Electric Co. Ltd., Montreal, Que.

WISE, Alfred John, B.Sc., (McGill Univ.), inspr. and elect'l. engr., Canadian Underwriters Association, Montreal, Que.

*Transferred from the class of Student to that of Junior*

CHARLEWOOD, Charles Benjamin, B.Sc., (McGill Univ.), engr., Babcock-Wilcox & Goldie-McCulloch Ltd., Galt, Ont.

KELLAM, George Douglas, B.Sc., (Univ. of Man.), asst. engr., Canadian Western Natural Gas, Light, Heat and Power Co. Ltd., Calgary, Alta.

KERSHAW, Norman William, B.Sc., (Univ. of Sask.), asst. engr., Eagle Pencil Company, Drummondville, Que.

MANN, Oswald Nelson, B.Eng., (N.S. Tech. Coll.), asst. plant engr., Eagle Pencil Company, Drummondville, Que.

McKENZIE, Ralph Boynton, B.Sc., (Univ. of Alta.), elect'l. contracting, estimating, salesman, McKenzie Electric Ltd., Lethbridge, Alta.

ROMBOUGH, Joseph Harold Melville, B.Sc., (Queen's Univ.), tapping dept., Fittings Ltd., Oshawa, Ont.

STANLEY, Thomas Douglas, B.Sc., (Univ. of Alta.), M.Eng., (McGill Univ.), ap'ticeship engr., Calgary Power Co. Ltd., Calgary, Alta.

TWEEDDALE, Reginald Estey, B.Sc., (Univ. of N.B.), instrumentman on highway location, Arthurette, N.B.

*Students Admitted*

BLOCK, Jacob Benjamin, B.Eng., (McGill Univ.), 3511 Jeanne Mance St., Montreal, Que.

CAMPBELL, Gerald Arthur, (Univ. of N.B.), Fredericton, N.B.
EDSON, Ralph Everett, B.Eng., (McGill Univ.), 489 King St., Peterborough, Ont.
HOPKINS, Albert Parker Eugene, (Univ. of Toronto), senior asst., Ontario Geological Survey Party, Substation 98, Toronto, Ont.
LEMIEUX, Roland A., B.A.Sc., C.E., (Ecole Polytechnique, Montreal), 1702 St. Hubert St., Montreal, Que.
McNAUGHTON, Andrew Robert Leslie, (R.M.C.), Royal Military College, Kingston, Ont.
THOMPSON, James William Joseph, B.Eng., (N.S. Tech. Coll.), 7 Payzant Ave., Halifax, N.S.
WILKINSON, William C., (Univ. of N.B.), Campbellton, N.B.

*Has passed Institute's examinations.

# BOOK REVIEWS

## Metallic Corrosion Passivity and Protection

*By Ulick R. Evans. Edward Arnold and Company, London (Longmans, Green and Company, Toronto). 1937. 6 by 9¼ in. $13.50. Cloth. 720 pages.*

Reviewed by Harold J. Roast, M.E.I.C.*

Dr. Evans' previous work on "Metals and Metallic Corrosion" naturally leads one to expect a highly scientific and mathematical treatise in the case of the new book and the reader will not be disappointed. In the preface one finds "The present work is an attempt to summarize the existing knowledge, and is based on the investigations and writings of about seventeen hundred authors whose names appear in the index." When one finds in addition to this that the technical publications quoted number well over three hundred, it is no surprise that the book is one of over seven hundred pages.

The author is to be complimented in the idea followed throughout the book of dividing each subject into three sections (A), (B) and (C). (A) is devoted to the scientific basis, (B) discusses the practical problems and under section C is what the writer pleases to call "A very *elementary* quantitative discussion of those cases which are sufficiently simple to be represented by equations." Actually the mathematical demands made on the ordinary engineer in section (C) will be ample to brighten up his mathematical viewpoint. The book throughout is logical and one can read section (A) throughout, or (B) throughout, and get a very connected idea of the subject, depending on what viewpoint is considered the most interesting.

A comparison of ordinary steel with stainless steel on page 231 is informative and on page 234 "Internal Corrosion of Iron Pipes and Jackets" is an example of the practical way in which the various subjects are treated and in this particular instance the corrosion due to moving liquids. The same might be said of page 253 "Influence of Arsenic on Brass." The discussion on page 650 of "The Fallacy of Anodic Testing" indicates frankness and fearlessness on the part of the writer based on his intimate knowledge of the case.

In the last chapter under "Testing (C)—Quantitative Treatment Statistical Considerations" under the heading "Methods of Minimizing Errors" an interesting and informative discussion is shown.

Some headings from section (B) might indicate a general idea of the work—"Stray Currents, Attack on Metals Underground," "Plain Acid Pickling of Steel," "The Requirements of Heat-resistant Materials," "Public Fuel Policy and Corrosion," "Control of Corrosion by Additions to the Corrosive Liquid," "Materials for Chemical Industry," "Effects of Stress and Strain on Corrosion," "Protection by Metallic Coatings," "Protection by Paints and Enamels," etc.

Anyone who is called upon to give advice on prevention of metallic corrosion should not be without this latest work in this connection. After reading the book one may feel, that in view of the fine points referred to, no form of complete metal preservation is possible. It still remains, however, that the more one takes advantage of the latest scientific knowledge, the more permanent will metal protection become.

**Canadian Bronze Company Limited, Montreal.*

## Asphalt Pocket Reference

*By Prevost Hubbard and Bernard E. Gray. The Asphalt Institute, New York. 1937. 225 pages. Flexible, leather finished, vest pocket edition.*

The new and enlarged Asphalt Pocket Reference for Highway Engineers recently issued contains seventeen chapters, comprising a comprehensive handbook of all phases of asphalt highway construction. Among the chapter headings may be mentioned the following: Terms Relating to Asphalt; Paving Plants; Design of Asphalt Pavements; Condensed Construction Specifications for Asphalt Surfaces and Pavements; Non-Bituminous Bases; Maintenance and Resurfacing; Asphalt Joint Filling and Bedding Courses; Airports; and Asphalt Revetment and Jetty Construction.

Copies of this manual may be secured without charge upon request to The Asphalt Institute, 801 Second Avenue, New York, N.Y.

## JOINT MEETING OF THE INSTITUTE WITH THE AMERICAN SOCIETY OF CIVIL ENGINEERS

### Boston, October 6th, 7th and 8th, 1937

As already announced in The Journal, The Institute, at the invitation of the Board of Directors of the American Society of Civil Engineers, will participate in the Society's Fall Meeting in Boston, Mass., on Wednesday, Thursday and Friday, October 6th to 8th, 1937. The detailed programme is in preparation and will be available shortly.

At the technical session for which The Institute is responsible, the following papers will be presented and discussed:

The Substructure of the New Highway Bridge over the Fraser River at New Westminster, B.C., by W. G. Swan, M.E.I.C., consulting engineer, Vancouver, B.C.

Recent Developments at the Port of Halifax, N.S., by E. H. James, M.E.I.C., consulting engineer, Montreal.

The Conception and Design of the Outardes Hydro-Electric Project, by H. G. Acres, M.E.I.C., consulting engineer, Niagara Falls, Ont.

Announcements will be made later regarding hotel and railway arrangements. The time and place are attractive and a large contingent of Institute members is expected to head for Boston in the first week of October.

# BRANCH NEWS

## Edmonton Branch

*M. L. Gale, A.M.E.I.C., Secretary-Treasurer.*
*F. A. Brownie, Jr.E.I.C., Branch News Editor.*

THE ISLAND OF ORLEANS BRIDGE

The April 9th meeting of the Edmonton Branch, which was held in the Macdonald hotel, had the pleasure of having a paper by P. L. Pratley, M.E.I.C., on "The Island of Orleans Bridge." This paper was published in full in the Engineering Journal for July 1936.

RECENT IDEAS IN EARTHWORK ENGINEERING

The final dinner meeting of the Edmonton Branch for the 1936-1937 season was held at the Macdonald hotel on April 28th, 1937. At the short business meeting a new slate of officers was elected for the ensuing year including J. D. Baker, M.E.I.C., as Branch chairman.

Professor I. F. Morrison of the University of Alberta presented a paper dealing with "Recent Ideas in Earthwork Engineering." The paper was of particular interest due to the fact that in 1936 the speaker had attended the Harvard Conference on Soil Mechanics and Foundation Engineering, the first world conference of its kind ever held.

In pointing out the peculiar position of earth or soil in engineering, Professor Morrison stressed the fact that these materials are the commonest with which engineers have to work and yet they are probably the least well known of all engineering materials. This is because soil is a much more complex and variable substance than other engineering materials. However, recent developments in physical chemistry and increased interest in soil research have so opened up the subject that empiricism in dealing with soils is now being replaced by more rational methods.

An outline of the most important developments to date in the science of soil mechanics was followed by a discussion by the speaker of the fundamental concepts necessary for an understanding of the subject.

Soil being defined as an aggregate of particles, the characteristics of these particles—size, crystalline character, shape and grading—are of great importance. Perhaps more important still however than those fairly obvious qualities is the fact that each soil particle consists not only of the particle proper but of a film of adsorbed water so thin that it behaves quite differently from free water.

Next speaking of the aggregate, Professor Morrison explained its most important properties: cohesion, interparticle friction, interlocking and the density state, "cohesion" between particles arises from molecular attraction and the action of water and colloidal matter surrounding the particles. Particle interlocking along with other qualities governs the ability of a soil to resist shear, or in short, its stability. The importance of this stability in engineering is obvious and the possibility of its being anticipated, through control of soil water especially, offers great possibilities particularly in road building.

Density state in any soil refers to its condition as between a maximum of void space. This quality too is of great importance since for foundation purposes a dense soil should not be deformed while a loose soil may require compaction or other treatment.

The meeting voted its hearty appreciation of the paper and a brief discussion followed in which Professor Morrison answered questions. Branch chairman E. Stansfield, M.E.I.C., presided.

## Hamilton Branch

*A. R. Hannaford, A.M.E.I.C., Secretary-Treasurer.*
*W. W. Preston, S.E.I.C., Branch News Editor.*

AUTOS AND GASOLINES

A popular subject discussed by an authority—that is what attracted an audience of 120, including several ladies, to a meeting of the Hamilton Branch E.I.C. held in McMaster University on May 4th, 1937. The title of the lecture was "Motor Car Engines and Their Fuels," and the speaker, introduced by the chairman, Col. E. G. MacKay, A.M.E.I.C., was Mr. P. B. MacEwen, combustion engineer of the Ethyl Gasoline Corporation. Mr. MacEwen illustrated his lecture with a talkie and slides, and also demonstrated the effect of different fuels on a testing engine which was equipped with a quartz window in the cylinder head, a thermo couple in the combustion chamber and meters to measure h.p., r.p.m., and temperature.

At first engineers thought that the knock in an auto engine was caused by some mechanical defect, but when mechanical improvements offered no solution, they turned their attention to the fuel being used. They decided to see what happened inside the combustion chamber of an engine, and inserted a quartz window in the cylinder head. It was found that under normal conditions the gas exploded with a blue flame, and that under knocking conditions the flame was white. Motion pictures of these explosions have revealed that when the flame is blue the explosion wave leaps across the combustion chamber from the spark plug to the opposite cylinder wall, but with a white flame there are two waves; one wave, ignited by the spark plug, and also a wave that shoots back from the far cylinder wall which is so hot that it sets off a counter explosion. When these two waves collide the engine knocks.

Realizing that excessive heating of the cylinder walls promoted knocking, research engineers sought a fuel which would produce less heat. The speaker demonstrated that gasoline containing ethyl fluid satisfied this condition. Ethyl fluid contains tetraethyl lead, ethylenedibromide, ethylenedichloride and a dye for indication.

The relationship of an automobile engine to its fuel was then discussed. Every gasoline must be blended to give an engine its best performance at all times. For starting, a light gasoline is required; for acceleration, a heavier grade; and for power, a still heavier gasoline. A proper mixture of these component assures the motorist of efficiency. The reason that one does not get more miles to the gallon of gasoline is partially due to the fact that 70 per cent of its potential power is lost to the cooling water and the exhaust. These losses may be decreased by increasing the compression ratio, but as the compression ratio rises there is more likelihood of knocking. Speed of operation has a marked effect on gasoline consumption. Most miles per gallon are obtained at 20 m.p.h., and consumption is doubled at 70 m.p.h. The position of the spark is of utmost importance. There is no advantage in using a better fuel, stated Mr. MacEwen, if the spark is not advanced to permit the motorist to take advantage of the extra power available. Another consideration concerns the valves. As about 60 per cent of the cooling of the valve is through the valve-head, the valve should rest on its seat as long as possible to lower its temperature and lessen the tendency to knocking.

Following the discussion at the conclusion of the lecture, P. Ford-Smith, M.E.I.C., proposed a vote of thanks to the speaker, and the meeting adjourned for refreshments.

## Lethbridge Branch

*E. A. Lawrence, S.E.I.C., Secretary-Treasurer.*
*R. F. P. Bowman, A.M.E.I.C., Branch News Editor.*

On Saturday evening, March 13th, 1937, the Lethbridge Branch held a joint dinner meeting with the Association of Professional Engineers of Alberta and the Rocky Mountain Branch of the Canadian Institute of Mining and Metallurgy. During the dinner music was provided by George Brown's instrumental quartette following which community singing was indulged in. Monologues by A. J. Branch, A.M.E.I.C., 'cello solos by Mr. Gordon Hendersen and vocal solos by Mr. T. Smith were also received with applause.

The Branch's new chairman, J. M. Campbell, A.M.E.I.C., presided over the meeting and called on N. H. Bradley, A.M.E.I.C., to introduce the speaker of the evening, A. W. Haddow, A.M.E.I.C., President of the Professional Engineers of Alberta, who addressed the meeting on "Some Early Examples of Engineering."

Mr. Haddow advanced the theory that the landmarks of civilization are of an engineering nature and developed this theme, by examples from earliest times. The first mile post in the development of man lay in his aquiring control over fire. The development of the bow and arrow which made him more superior in defense and the acquisition of food came next. The use of burnt clay vessels marked another forward step, leading to the storing of water and the boiling of foods and with this stage attained man could be said to have passed from the savage to the barbaric state. In this latter state the development of metals is a predominating characteristie and with the invention of writing it may be said that civilization is attained. The last and most recent stage has been the substituting of mechanical power for man power. Mr. Haddow illustrated the growth of civilization by describing the early civilizations of the Tigris, Euphrates and Nile rivers, where at very early times the construction of canals and dykes was practised with a view to irrigation and flood control. The buildings of Babylon were great feats of engineering achievement, while in Egypt, the erection of gigantic temples and monuments illustrates the great capabilities of the early engineers. Among the Egyptians we also find the early beginnings of marine engineering, together with the use of trusses for stiffening the hulls of ships.

Recently another civilization has been brought to light in Crete where much evidence of engineering development has been found, particularly in the use of terra cotta pipe and stone sewers with arched roofs.

The Greeks, Mr. Haddow said, were too interested in speculation to pay much attention to the concrete problems of engineering but their successors, the Romans, have left us many samples of their engineering genius of which we all know.

At the conclusion of his address Mr. Haddow showed a number of slides of Egyptian engineering works, the projector being operated by Mr. Cyril Watson. J. Haimes, A.M.E.I.C., moved a vote of thanks to Mr. Haddow which was heartily endorsed by those present.

## London Branch

*D. S. Scrymgeour, A.M.E.I.C., Secretary-Treasurer.*
*Jno. R. Rostron, A.M.E.I.C., Branch News Editor.*

The regular monthly meeting of the Branch was held on April 22nd, 1937, in the Public Utilities Commission's Board Room. The speaker of the evening was Mr. R. S. Charles, B.Sc., who gave a travelogue of his experiences while searching for public water supplies in France, Indo-China and Algeria.

The chairman of the Branch, A. O. Wolff, M.E.I.C., presided.

After the reading of the minutes, which were unanimously adopted, E. V. Buchanan, M.E.I.C., introduced the speaker, who in his introductory remarks referred to Professor Reavely's address to the Branch at the February meeting. He discussed the professor's description of ground water and its relation to geology.

The writer very much regrets that owing to a misunderstanding of the date of this meeting he was not present and is therefore unable to give a proper account of the speaker's address.

From outside sources however he learns that in all the countries named a thorough description was given covering the geological formation, the rotary drilling operations, the construction of wells, the quality and quantity of the waters found, climate, water divination, method of financing and labour troubles.

The latter part of the speaker's talk was devoted to a very complete description of the conditions, geological and otherwise, in southern Ontario—also covering methods of finding water, test holes, contamination of water from deep drillings, leaks, methods of modern well construction, large diameter rotary drilling, concreting outer casings, under reaming, etc.

A very animated discussion followed, various members particularly interested in water supplies voicing their experience and opinions.

A vote of thanks was moved by W. C. Miller, M.E.I.C., seconded by W. G. Ure, A.M.E.I.C., and unanimously carried.

Twenty-two members and guests were present.

## Niagara Peninsula Branch

*P. A. Dewey, A.M.E.I.C., Secretary-Treasurer.*
*C. G. Moon, A.M.E.I.C., Branch News Editor.*

An electoral meeting held at the Ontario Paper Company, on May 11th, 1937, reported the result of the ballot and adjourned until May 18th, when the new officials were elected and the results announced.

### Annual Meeting

The annual meeting was held on May 18th at the Leonard hotel in St. Catharines. Some sixty members and friends were in attendance. Paul Buss acted as the Reception Committee perfectly.

Chairman George H. Wood, A.M.E.I.C., presided at the earlier part of the meeting but was called away upon urgent business and handed the reins over to L. C. McMurtry, A.M.E.I.C.

After dinner, past-president Alex. J. Grant, M.E.I.C., said a few words in appreciation of the apparent health and activity of the Branch. He had expected a slump in the affairs following completion of the Ship Canal but was pleasantly surprised at so much interest being taken by the old, as well as the new members. The local industries were evidently doing their part in keeping the Branch very much alive.

A short period of entertainment was then provided, consisting of songs and tap dancing, with Mr. Clarence Colton at the piano.

Dr R. W. Boyle, M.E.I.C., Director of Physics and Electrical Engineering Division of the National Research Council, at Ottawa, was the guest speaker. C. G. Cline, A.M.E.I.C., introduced him as being well known to the Branch and remembered from February 26th, 1931, when his subject was "The Engineer in the Nation."

This year Dr Boyle chose "Technology and Peace and War," thus as usual, giving, his audience a very definite message and leading them towards thoughtful consideration of present day problems.

### Technology and Peace and War

The world is in such an uncertain state to-day, said Dr. Boyle, that people hardly know which way to turn or what is in store for them. The hydra-headed monster of doubt, ignorance and fear rules too extensively.

The gifts which the engineer and scientist have showered upon us are, in the first place, not impartially divided and, in the second place, are often used for the destruction rather than the well being of mankind.

Some are inclined to think that the scientist is to blame for this state of affairs; that he has advanced too fast and too far beyond the moral and political adaptibility of the race; that nations are prostituting his art in the interests of war rather than of peace.

Winston Churchill has said that "Man has not yet learned to conduct his own affairs for his own advantage." Perhaps there is great truth in this aspersion. The scientific mind is necessarily wrapped up and submerged in its own particular field, generally content to trust others in the application of any discovery, taking too little interest in the ultimate result.

There are many pseudo-scientists and charlatans who are quick to take advantage of the devices and principles of science for their own selfish ends or to promote political gain. An example of this is the doctrine of Aryanism and the form of Hitlerism preached in Germany to-day.

Without doubt the pace of living has accelerated, The strain of keeping up with the procession is great. There is little time for rest and meditation, the results are showing in an increase of mental and nervous disorders, disorderly thinking being but one of the symptoms.

While there appears to be little but toil and turmoil in the world to-day, yet there are possibilities of hope. History teaches that many an important discovery has been born in such trying times, undreamed of by those who will be most affected. Napoleon had shaken Europe and the Congress of Vienna was occupying men's thoughts at the same time that modern spectroscopy and Rumford's and Carnot's theories of heat were crystallizing. Which of these had the greatest effect upon the world and human relations?

Mankind is an adjustable animal and, given time, can adapt himself to changed conditions. The adjusting period, however, is always a time of stress. New inventions may create unemployment temporarily, but they lead to other means of occupation and, properly directed, to a higher standard of living and a fuller life.

The crux of the matter is direction, leadership. You may place the blame for our social backwardness where you will, on teachers, politicians, businessmen, clergymen, or scientists as citizens but don't blame science. And don't forget to place the blame where it properly belongs, viz., on yourselves.

Thunder clouds of war hang over the world. Thunder clouds, produced not because there is the "will" to war, but because no one seems to have solved completely the problem of using science and the products of science in such a way that mankind will be benefited and not harmed therefrom, and great sections of the people given employment to keep them from starving in the midst of plenty.

As Julian Huxley says, the realistic but deplorable attitude about war seems to be this—as long as there is a real risk of war, the fullest resources of science should be used (1) to make war militarily as efficient as possible at the least possible cost; (2) make it as merciful as possible (binding up the wounded, curing the sick and easing the dying); (3) make it as unlikely as possible by rapid and varied means of international communication, interchange of personalities and ideas in the spheres of politics, literature, language, art, music and science. But if we will have war we can be quite assured of three things: (1) we cannot have it consciously gentle, it will be mechanical and remorseless with the release of animal passion; and as time advances an increasing proportion of the nation will get killed or become sick and hurt; (2) we cannot have it cheap; (3) its dislocations economically and in society will be deeper and more disruptive than ever before. It is incorrect that there is no better method than to cry "war" and in our search for work create employment only in the manufacture of war materials.

A "Science of Peace" is greatly to be desired. This precious term we should seek to popularize. This science would carry within it the essence of truth and not be mere guesswork by diverse groups who perforce see but their own side of the picture. Society must learn to use, or to make use of, the scientist and direct his trained mind to this purpose. Then will we find a solution for this problem.

A scientific peace and employment clinic—The country which first takes the necessary steps to provide such a clinic of minds trained to search for social truth will confer a boon upon all mankind.

## Ottawa Branch

### Light Waves in Gauge Standardization

At the noon luncheon at the Chateau Laurier on April 22nd, 1937, R. H. Field, A.M.E.I.C., of the staff of the National Research Laboratories, gave an address on the use of light waves in gauge standardization.

Some gauges nowadays, stated Mr. Field, are sold commercially with an accuracy as high as two one-millionths part of an inch; and his address dealt with methods employed at the Laboratory for verifying or standardizing such gauges. In comparing present-day results with those of the days of James Watt, who succeeded in boring the cylinders of his engines to within three-sixteenths inch error from the true cylindrical form, the speaker brought out two points: first, the remarkable advance attained in the precision of machined products; and second, that the necessity for making measurements in the standards laboratory to a one-millionth part of an inch or less is dictated by the needs of hard-headed engineers.

Today, practically all precision machine-shop work is controlled primarily by Johansson gauges. These were first introduced in Sweden in 1910 after many years of development work on the part of their inventor. They are simple in form—rectangular blocks with two opposite faces determining the dimension. These faces are very accurately finished as to distance apart, parallelism and planeness. In fact the finish is really an optical polish. Such surfaces have the valuable property of adhering together when properly wrung. Hence, by wringing two or more gauges together a new gauge is formed, of length equal to the sum of the components. In this way the usual complete set of 81 blocks can be made to form a series of gauges from 0.2 to 10 in. in steps of one ten-thousandth of an inch.

The older micrometric systems of calibration for such gauges in terms of the legal standard are either insufficiently accurate, or their execution too laborious. In nearly every case, nowadays, they are primarily standardized by means of light waves.

The major portion of Mr. Field's address was taken up with a description of the procedure required to effect this standardization by such means.

## Sault Ste. Marie Branch

*N. C. Cowie, Jr.E.I.C., Secretary-Treasurer.*

A general meeting of the Sault Ste Marie Branch of The Engineering Institute of Canada was held in the Windsor hotel, Sault Ste. Marie, on March 19th, 1937.

After a short business meeting the chairman, C. W. Holman, A.M.E.I.C., introduced the speaker, Mr. H. R. Hipwell. Mr. Hipwell, the instructor of machine shop practice at the Sault Ste. Marie Technical and Commercial High School, presented a very interesting paper entitled "The Teaching of Machine Shop Practice."

Mr. Hipwell emphasized that the primary purpose of any school was the development of character and right thinking, and that a community cannot be greater than its citizens. Secondly, they aim to impart knowledge and to teach skill. After outlining the functions of the departments of the Technical School and the academic background given to each course, he gave details of the work covered in a three year course of machine shop practice. He then compared this course with that of the industrial apprentice from the standpoints of shop hours and subject matter. A description was given of the equipment and the details of the different operations which are taught both on the machines and as bench work and the need for co-ordination between the different departments to develop a better insight into the work. The importance of teaching safety measures was mentioned.

The paper was illustrated with shop blue prints and large scale charts, samples of the work done by the students were shown. One of the charts based on a survey in Milwaukee showed that 78 per cent of the apprentices from the Technical School stayed in the industry, whereas but 22.8 per cent of those from all other sources remained in the industry after one year.

The speaker closed his remarks by stating that the records of the students were available to those seeking employees.

Mr. Hipwell was sincerely thanked for his interesting paper by the members and guests present at the meeting.

The Sault Ste. Marie Branch of The Engineering Institute of Canada held a general meeting at the Windsor hotel on Monday, April 26th, 1937.

Fifteen members and guests were present to enjoy the dinner served in the hotel grill room at 6.45 p.m.

Following the dinner a short business meeting was held at which a few routine matters were speedily dealt with.

The chairman, C. W. Holman, A.M.E.I.C., then called the general meeting to order and asked W. A. Dawson, A.M.E.I.C., the chairman of the Papers Committee, to introduce the speaker of the evening.

A very interesting illustrated paper entitled "The Maintenance of Worn Parts by the Oxy-acetylene Process" was then given by Mr. R. J. Anderson of the Dominion Oxygen Co., Montreal.

Mr. Anderson first mentioned the economic factors that should be considered in any application of surfacing for wear, the choice of the surfacing material and typical materials for surfacing operations. With the aid of a number of slides the speaker then outlined many ways in which machine parts were being maintained by this method.

Mr. Anderson was thanked for his interesting paper by the meeting on a motion of J. L. Lang, M.E.I.C., seconded by O. A. Evans, Jr.E.I.C.

## Toronto Branch

*J. J. Spence, A.M.E.I.C., Secretary-Treasurer.*
*D. D. Whitson, A.M.E.I.C., Branch News Editor.*

The regular meeting of the Toronto Branch of The Institute was held at Hart House, with Otto Holden, A.M.E.I.C., Branch chairman, presiding. The speaker, Mr. McKenzie Williams, B.A.Sc., of the class of 1910, Faculty of Applied Science, University of Toronto, delivered a very interesting address on "Some Vital Economic Developments in Relation to Engineering," illustrated with a large number of very carefully prepared graphs and charts. Mr. Williams was for many years with the well known firm, A. E. Ames and Company, and at present is the director of investments and research for Corporate Investors Limited, and from his wide experience he treated those fortunate enough to be present with a store of information that should prove valuable to them to say the least.

The speaker opened his address by commenting on the general lack of information in the inter-relation of all business, and stated that from such records as were available that all the indices indicate that the recent depression in business is definitely over, and that despite our present feelings on the matter, the recent depression was not the worst, for in 1837 all the banks throughout Canada and the United States closed their doors. Cycles of business did not always exist, said the speaker, and at one time, plagues, wars and acts of God were the only upsettors of business activity. It was only when physical power and money power became linked to extend credit to producer, manufacturer and purchaser, that business cycles were born.

The basis of business forecasts, reliable enough to guide a business man's actions, can only be obtained by the accumulation of factual material related to trade, similar to actuarial or insurance knowledge, and then only a proper interpretation will yield a successful conclusion. Building statistics, car loadings, bank clearings are all barometers of business and may be misleading due to unknown quantities of freight and express carried by trucks and airplanes, car loadings no longer indicate business activity the way they did in previous years. Other indices that must be watched are the physical volume of business, the national electric power production, the mineral production, the turnover of bank deposits, bank debits, and the rise and fall of interest rates on loans to finance business and manufacturing. The speaker thought that one of the surest indicators of the future trends in business was the relation of the short term loan interest rate to the long term loan rate. Whenever the short term rate rose near the long term rate it was a sure indicator of an approaching recession in business. Several months before the memorable crash in 1929 the short term rate actually rose above the long term rate, and the same relationship has held good previous to earlier depressions.

The speaker thought bond prices were also a worth while indicator of the state of business, and the best way to conserve capital during a period of insecurity is to purchase high grade short term bonds. Senior gold stocks always decline in value during a period when commodity prices are rising. The most stable securities are those of sound companies in the field of consumers goods, and the most variable are those of companies producing the so-called durable goods and the instruments of production. During a period of rising prices, when a business cycle is emerging from a low point and starting on the way up, one is in a position to increase his capital by buying stocks of sound companies engaged in the production of commodities such as copper, nickel, lead, zinc, rubber, etc., and companies manufacturing "goods" that will become new capital investments such as steel and cement or other products that will enter into the creation of buildings, power plants, railroad equipment, generators and other forms of "capital" because such creations will be needed in the upswing of the next business cycle.

The speaker showed graphs to illustrate that increases in the amounts of gold produced were always the forerunners of an extended rise in commodity prices and that based on the huge increases of gold in the last two years, he predicted a long period of rising prices and increased business ahead. This was certainly good news for engineers in particular, and all present agreed that Mr. Williams' talk was extraordinarily instructive and the Branch would be fortunate indeed if it could secure his services again in the not too distant future.

### Annual Meeting

The annual meeting of the Toronto Branch of The Institute was held on Thursday, April 1st, 1937, at the quarters of the Canadian Military Institute on University Avenue. A large and enthusiastic turnout enjoyed the dinner which preceded the annual meeting, and the Branch was privileged to have as guests R. L. Dobbin, M.E.I.C., of Peterborough, vice-president of The Institute, E. P. Muntz, M.E.I.C., Councillor of the Hamilton Branch, and W. T. Fanjoy, A.M.E.I.C., Secretary of the Peterborough Branch, and Colonel E. G. MacKay, A.M.E.I.C., chairman of the Hamilton Branch. Brigadier General C. H. Mitchell, M.E.I.C., and Dr. F. A. Gaby, M.E.I.C., past-presidents of The Institute, were also present.

Following the dinner the guests were welcomed by Otto Holden, A.M.E.I.C. the Branch chairman, and the business of the annual meeting was commenced.

The chairman reviewed the various activities of the Branch during the past year and referred to the more important matters, including: the work done in the study of various proposals for Consolidation; the request of the Branch Executive to Headquarters to have a study made for presentation to students thinking of entering engineering, of the supply and demand for engineers; a resolution recommending the reduction in size of the Council of The Institute; local arrangements for assisting in the celebration of the Semicentennial of The Institute; a joint luncheon being arranged in honour of Professor R. W. Angus, M.E.I.C. by various engineering societies in Toronto.

The following reports were submitted to the Branch and adopted: (*a*) The Secretary-Treasurer's report by W. S. Wilson, M.E.I.C., showing a small surplus for the year; (*b*) The report of the Membership Committee by W. E. P. Duncan, M.E.I.C.; (*c*) The report of the Committee on Student Relations, by A. M. Reid, A.M.E.I.C.; (*d*) The report of the Publicity Committee by A. U. Sanderson, A.M.E.I.C., stressing a gratifying increase of space in the local press concerning our activities.

J. R. Montague, A.M.E.I.C., and E. A. Cross, M.E.I.C., were appointed and kindly consented to act as auditors and later reported that they had examined the books, pass books, and vouchers pertaining to the Branch and found them correct.

A discussion was then held on the report of the Committee on Consolidation and on the ballot on Consolidation to be returned to Headquarters April 20th, 1937. Mr. Holden read a statement from A. B. Crealock, M.E.I.C., outlining the various steps leading up to the presentation of the final report of the Committee on Consolidation and Council's action thereon. Mr. Holden then outlined the various actions taken by the Branch Executive on the question of Consolidation. Following this, a general discussion developed on various points and on the ballot and was participated in by many of those present including the guests.

The scrutineers then reported the results of the election of officers for 1937-1938.

The incoming chairman, A. U. Sanderson, A.M.E.I.C., then took the chair and spoke briefly.

LOOKING BHCKWARD AND FORWARD

On April 13th, 1937, at the Royal York hotel, Toronto, the Toronto Branch of The Institute had the pleasure of participating with four other local branches of engineering societies in a luncheon held in honour of Professor R. W. Angus, M.E.I.C., head of the department of mechanical engineering, Faculty of Applied Science, University of Toronto.

A large and appreciative audience heard Professor Angus speak on the subject "Looking Backward and Forward—Fifty Years of Engineering."

The societies participating were the American Society of Mechanical Engineers, American Institute of Electrical Engineers, the Institute of Radio Engineers, the Ontario Chapter of the American Society of Heating and Ventilating Engineers and the Toronto Branch of The Engineering Institute of Canada.

Otto Holden, A.M.E.I.C., immediate past-chairman of the Toronto Branch of The Institute, occupied the chair during the gathering.

## Vancouver Branch

*T. V. Berry, A.M.E.I.C., Secretary-Treasurer.*
*J. B. Barclay, A.M.E.I.C., Branch News Editor.*

At a dinner meeting of the Branch on May 4th, 1937, Mr. W. J. Johnson, who is attached to the engineering staff of the British Columbia Insurance Underwriters Association, gave an address on "Automatic Sprinkler Equipment."

Mr. Johnson gave a brief historical sketch of the development of the sprinkler from its humble beginning in the last century, which was just a perforated pipe turned on by hand. In 1861 the first automatic head was used and has improved till we have the type of head used today.

The automatic sprinkler has been the means of saving billions of dollars. Of 60,000 fires where sprinklers were used, 97 per cent have been arrested or put completely under control, in many cases the fires having been put out before the arrival of the fire department. Of the remaining three per cent which were a total loss it was found that one per cent alone was due to the water being turned off and the balance to causes other than the sprinkler equipment.

It has been found that sprinkler heads go wrong only once in 50,000 cases, and the Underwriters laboratories are continually testing new heads, new types of equipment and are always ready to help the engineering profession in installing sprinkler equipment.

Two systems are in general use today. The wet system, which has water in the pipes all the time, and the dry pipe system which has to discharge the air in the pipes before water can take its place. The former is the quicker acting but it is necessary to use the latter where there is danger of freezing in the pipes.

Considerable reduction of insurance rates is allowed in a building, properly designed to reduce fire hazards, and where properly designed sprinkler equipment is used. It is necessary to take care of such details as: sufficient water must be available; enough heads are to be used; feed pipes must be of proper sizes; equipment used must be passed by the Fire Underwriters Association; maintenance of equipment must be kept up.

At the conclusion of the address a vote of thanks was proposed which was heartily endorsed by the members who had enjoyed a most interesting and instructive paper.

## Winnipeg Branch

*H. L. Briggs, A.M.E.I.C., Secretary-Treasurer.*

At the meeting of the Winnipeg Branch of The Institute held on April 15th, 1937, an interim report by J. T. Rose, A.M.E.I.C., chairman of the Research and Investigation Committee of the Branch, announced the appointment of Professor A. E. Macdonald, M.E.I.C., as chairman of a subcommittee to study a matter of importance now before the public eye in that city, namely "Foundation Conditions of Small and Medium Sized Buildings." Mr. Rose also announced the appointment of T. C. Main, A.M.E.I.C., as chairman of a second subcommittee to study the related subject of "Ground Water Conditions in Winnipeg."

Mr. C. S. Landon, Registrar of the Association of Professional Engineers of Manitoba, delivered the paper of the evening on the subject "History of the Association of Professional Engineers of Manitoba." The act incorporating the Association was given Royal assent on March 27th, 1920, the initial registration being one hundred and sixty-eight engineers. In 1935 the act was repealed and a new one substituted, such as gave Council more discretion in their actions. Since formation, the Association has had to go to court only once, and then with favourable results. Mr. Landon said that whatever the result of the present ballot on consolidation, nothing should be allowed to disturb the present very cordial relations between the Association and the local Branch.

After considerable discussion, a hearty vote of thanks to the speaker was moved by Professor G. H. Herriot, M.E.I.C.

A SPECIAL GENERAL MEETING

A special general meeting of the Branch was held on May 20th, 1937, the occasion of the visit of the President of The Institute.

Mr. Desbarats presented the membership with the results of the recent ballot on the consolidation amendments after paying tribute to the enormous amount of work performed by Mr. Pitts, his committee, and others working on the problem. However, the ballot of the membership was unfavourable, and his purpose in coming to Winnipeg was to get a cross section of the opinion of Manitoba engineers as to their stand in the matter, Manitoba having presented a definite consolidation proposal to Council some two years ago.

After his brief address, the meeting was opened for the presentation of views of members, which continued at some length, until the meeting adjourned for coffee and biscuits. The sincere thanks of the Branch to President Desbarats for his visit was expressed by F. G. Goodspeed, M.E.I.C., and endorsed unanimously.

To honour J. G. Sullivan, LL.D., M.E.I.C., upon the occasion of the conferring upon him by the University of Manitoba of the honorary degree of Doctor of Laws, the Winnipeg Branch joined with the Association of Professional Engineers of Manitoba on May 27th, in a well attended dinner at the Royal Alexandra hotel. In attendance were His Honour the Lieutenant-Governor of the Province of Manitoba, and distinguished members of the engineering and sister professions. E. V. Caton, M.E.I.C., and President of the A.P.E.M., acted as chairman of the evening.

Dr. Sullivan is the most recent recipient of the Sir John Kennedy medal.

## Earthquakes and Buildings

A considerable amount of reliable data relating to distant earthquakes has been accumulated and analysed during the past half century, but this is only of secondary value to civil engineers, since there are good grounds to support the view that only near earthquakes cause extensive damage to buildings and structures in general. One important obstacle to progress in earthquake study hitherto has been the want of suitable instruments for recording the intensities of near shocks, and even with our present resources it is by no means easy to construct sensitive apparatus for the purpose. Engineers and architects in many countries will therefore welcome the detailed description of the apparatus mentioned in the report entitled *Earthquake Investigations in California*, 1934-1935, which has been recently issued by the Department of Commerce in the United States of America. In more senses than one the subject dealt with has applications in countries extending from China to Peru, and this goes to enhance the value of an account of the work done by a number of engineers and scientists, under the general direction of Captain N. H. Heck, Chief of the Division of Terrestrial Magnetism and Seismology in the U.S. Coast and Geodetic Survey. The measure of success achieved in work of this magnitude depends mainly on efficient organization, so that it is a matter of congratulation to note that in the year 1932 more than 3,000 completed questionnaires were received from postmasters and employees in both public and private concerns situated in various parts of California, giving information on the intensities of the disturbances felt during the year. While other parts of the country have experienced more severe shocks, California was chosen as the starting point of the survey because the characteristics of the predominant earthquakes offered an immediate return on the funds granted by Congress, though the investigations will, doubtless, be extended so as to cover all the States affected in this way. That the statistical examination of the resulting data should prove to be of the greatest value to all interested in the subject is demonstrated by the fact that the information available, even in the initial stages of the present work, was utilized in the process of designing large undertakings such as the Boulder Dam, and the Madden Dam at Panama.—*Engineering.*

## New Flow Meter Catalogue

A new 40-page catalogue on Bristol's electrical and mechanical flow meters is available for distribution by The Bristol Company of Canada, Ltd. These instruments are for recording, integrating, controlling, and indicating the flow of steam, liquids or gases.

Details are given regarding the new electric flow meter and its operation, using Bristol's Metameter principle of telemetering. Also, complete information is included on Bristol's mechanical flow meters. The publication contains useful engineering data for reference.

# Preliminary Notice

## of Applications for Admission and for Transfer

June 28th, 1937

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

**Communications relating to applicants are considered by the Council as strictly confidential.**

The Council will consider the applications herein described in August, 1937.

R. J. DURLEY, Secretary.

---

•The professional requirements are as follows:—

**A Member** shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years inthe case of a candid ate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

**An Associate Member** shall be at least twenty-seven years of,age, and shall have been engaged in some branch of engineering for at least six years which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch ofengineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more year.

**A Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

**A Student** beshallat least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

**An Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

**The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.**

### FOR ADMISSION

ADAMS—JOHN DEWITT, of London, Ont., Born at Macleod, Alta., July 26tn, 1908; Educ., B.Sc., Univ. of Alta., 1930; Summers: 1925, with the Lethbridge Northern Irrigation; 1926-27, rodman, Reclam. Service, Dept. of the Interior; 1928-29, rodman, Dept. Public Works, Alta.; 1930-32, instr'man., Dept. Public Works, Highways Branch, Alberta; with the Dept. of Highways of Ontario as follows: 1934, tiling inspr., 1935, gravel checker, 1936, grading inspr., 1937, dftsman.

References: A. A. Smith, V. A. McKillop, H. A. Brazier, W. E. Cornish, H. J. MacLeod, R. S. L. Wilson, C. A. Robb, M. L. Gale.

BORBEY, JOHN PIERRE, of 4443 Old Orchard Ave., Montreal, Que., Born at Toronto, Ont., Aug. 6th, 1910; Educ., B.A.Sc., Univ. of Toronto, 1934; 1934-35, survey work, Dept. Northern Development of Ontario; 1936 to date, designer, plate and boiler dept., Dominion Bridge Co. Ltd., Montreal.

References: F. P. Shearwood, F. Newell, R. S. Eadie, A. S. Wall, C. R. Young.

BYERS—WILLIAM CARYL, of Kenora, Ont., Born at Rouleau, Sask., Sept. 1st, 1912; Educ., B.Sc. (E.E.), 1934, B.Sc. (C.E.), 1935, Univ. of Man.; 1935 (May-Sept.), dftsman., highway plans, profiles, bridge plans, etc.; Sept. 1935 to Aug. 1936, instr'man., highway location and constrn.; Oct. 1936, inspr., subway constrn., Winnipeg; Feb. 1937, instr'man., survey of creek and soundings; Mar. 1937, engr.-inspr., i/c river bank protection work constrn., and at present temporarily employed with the Dept. of Public Works at Kenora, Ont.

SAINT JACQUES—JEAN, of Quebec, Que., Born at Montreal, Mar. 22nd, 1909; Educ., B.A.Sc., Ecole Polytechnique, Montreal, 1929. B.Sc. (E.E.), McGill Univ., 1931; 1926 (summer), survey work, Quebec Streams Commn.; 1927 (summer), on Isle Maligne to Dolbeau line for Price Bros. & Co. Ltd.; 1929-32, ap'ticeship course, Shawinigan Water and Power Co.; 1933-36, asst. engr., rates, rate studies, statistical analyses, power sales, supervn. of plant account, secondary power sales, and at present office engr. on similar work, for Quebec Power Company, Quebec, Que. (*St. 1931.*)
References: R. B. McDunnough, E. D. Gray-Donald, R. Dupuis, H. Cimon, A. Frigon, J. B. Challies, C. V. Christie.

VILLEMURE—J. PHILEAS, of Grand Mere, Que., Born at Ste Flore, Que., Oct. 12th, 1910; Educ., Passed E.I.C. Examinations under Schedule "A" 1931 and Schedule "B" 1937; 1929-30, dftsman., Shawinigan Chemicals; 1930 to date, dftsman., rodman, instr'man., City of Grand Mere. (*St. 1931.*)
References: E. B. Wardle, N. J. A. Vermette, W. B. Scott, O. O. Lefebvre, A. Plamondon, A. Valiquette.

## Naval Commissions for University Graduates

Of all the problems associated with a rapid expansion of naval forces in time of peace, probably the most serious is that of providing trained officers and men at a rate commensurate with the completion of the ships. The emergencies of war can be, and have been, met by recruitment on a temporary basis in conjunction with the reserves maintained for the purpose, but a peacetime expansion necessarily requires that the additional personnel shall serve as long as the ships are likely to remain in commission; and under modern conditions, a ship can be built in a third or a quarter of the time necessary to train an officer, especially a technical officer, to the point of fitness for executive responsibility. An announcement now made indicates that, in the case of engineer officers, the anticipated requirements are to be met in part by recourse to the Universities of Great Britain and Northern Ireland, by the offer to engineering graduates in September, 1937, and in each half-year thereafter, of 20 commissions as sub-lieutenant (E). It is specified that applicants must be unmarried British subjects of pure European descent, and the sons of parents who are British subjects at the time of the candidate's entry; that they must be between the ages of twenty-one and twenty-five on July 1 for appointment in the following September, or January 1 for appointment in February; and, after a course of not less than three academic years as an internal student, and a regular training and sufficient practical experience in mechanical engineering, must have obtained a mechanical or electrical engineering degree accepted by the Institution of Mechanical Engineers as exempting from Parts A and B of the examination for associate-membership of that institution. In certain circumstances, the notice adds, the first year at a recognized Dominion university may be counted towards the three years' academic training. Detailed regulations and entry forms are obtainable from the Secretary, Admiralty, London, S.W.1, or from the Universities, but the application must be made, on completion of the form, to the authorities of the candidate's university.—*Engineering.*

## EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

*All correspondence should be addressed to*

**The Employment Service Bureau, The Engineering Institute of Canada**
**2050 Mansfield Street, Montreal**

## Situations Vacant

DRAUGHTSMEN, for a large industrial company in Montreal, architectural, civil and mechanical. Apply to Box No. 1587-V.

RECENT GRADUATES in civil engineering for a large construction company in Montreal. Apply to Box No. 1599-V.

GRADUATE MECHANICAL ENGINEER, 23-26, to work on the development of steam specialties. Must have had two or more years draughting or designing experience. A sound knowledge of physics is particularly important. British subject preferred. Location England. Apply to Box No. 1601-V.

MECHANICAL DRAUGHTSMEN. Situation vacant for experienced mechanical draughtsmen. Permanent employment for suitable men. Applications by letter only, giving full particulars of experience. Dominion Engineering Works Limited, P.O. Box 3150, Montreal, Que.

## Situations Wanted

CHIEF ENGINEER-CONSTRUCTION MANAGER, nineteen years construction maintenance operating, industriel plants, steam and hydro power, canals, water supply, etc., estimates, plans, specifications, supervision of construction. Apply to Box No. 36-W.

PURCHASING ENGINEER, graduate mechanical engineer, Canadian. Married, with fifteen years experience covering construction and operation, principally having to do with specification and ordering of equipment and materials for new construction and maintenance. Details upon request. Apply to Box No. 161-W.

INDUSTRIAL ENGINEERING EXECUTIVE, with wide experience including fourteen years in design, construction, maintenance and operation of pulp and paper mills and power developments. Now employed, desires change of location. Apply to Box No. 320-W.

STEAM AND MECHANICAL ENGINEER. Married. Wants position with industrial company within 100 mile radius of Montreal. Would prefer position in charge of maintenance. Can undertake plant layout work, handling steam lines, look after alterations or extensions, make installations on construction work. Previously in charge of similar work and can prepare own drawings. Have good all round knowledge of all trades. 35 years experience. Apply to Box No. 441-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aero-photographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

ELECTRICAL ENGINEER, B.Sc., E.E., age 38. Married. Ten years electrical experience; including, one year operation, one year maintenance, and four years on construction of hydro-electric plants and sub-stations. Four years electric maintenance and construction in pulp and paper mill. Also experience on highway construction and Geological Survey. Available at once. Apply to Box No. 636-W.

ELECTRICAL ENGINEER, B.Sc. E.E. '28. Two years with large electrical manufacturing company including test course, about two years in supervisory operating office of a large electrical power utility, and considerable experience in electrical and mechanical draughting. Location in Ontario preferable. Apply to Box No. 660-W.

ELECTRICAL AND CIVIL ENGINEER, B.Sc. Elec. '29, B.Sc. Civil '33. Jr.E.I.C. Age 29. Experience includes four months with Can. Gen. Elec. Co., approximately three years in engineering office of large electrical manufacturing company in Montreal, the last six months of which was spent as commercial engineer. For the last year and a half employed in electrical repair shop. Best of references. Apply to Box No. 693-W.

YOUNG CIVIL ENGINEER, B.Sc. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

MECHANICAL ENGINEER, Jr.E.I.C., B.A.Sc., Univ. of B.C. '30. Single, age 30. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

## Situations Wanted

CIVIL ENGINEER, B.Sc., M.Sc., R.P.E.; Lieut. C.E., R.O. 16 years municipal, highway and construction, 5 years overseas. Married. Read, write and talk French. Will go anywhere. Apply to Box No. 737-W.

RADIO AND ELECTRICAL ENGINEER, B.Sc., '31, Jr.E.I.C. Single. Age 30. One year and a half actual field experience in power and lighting equipment. Extensive work in telephone and radio layouts in switchboard and installation depts. Particularly interested and experienced in sales and traffic work in telephone and radio company. At present supervisor over sales and service of radio and electrical company. Available on short notice. Location immaterial. Apply to Box No. 740-W.

PLANT ENGINEER or SUPERINTENDEBT, capable of supervising all phases of industrial plant operation, graduate electrical, eleven years diversified industrial experience including test course, four years on large Quebec industrial development, on construction and operation, also six years with prominent consulting firm supervising electrical and mechanical engineering projects. Age 31, single. Apply to Box No. 795-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. in C.E. (Sask. '32). Single. Age 27. Three years experience includes—instrumentman, compiling reports and draughting with a National Park; in charge of construction of water supply and sanitary sewer systems; assistant on city surveys. Excellent draughtsman. Available at once. Location immaterial. References. Apply to Box No. 818-W.

### Employment Service Bureau

Members are again reminded that we are receiving an increasing number of enquiries for engineers.

If you are registered with the Employment Service Bureau please bring your record up-to-date

The more information you give us, the more intelligently and effectively we can place your record for consideration with prospective employers.

MECHANICAL ENGINEER, Jr.E.I.C., technical graduate, bilingual, age 35, married, experience includes five years with firm of consulting engineers, design of steam boiler plants, mechanical equipment of buildings, heating, ventilating, air conditioning, plumbing, writing specifications, etc. Five years with large company on sales and design of power plant, steam specialties and heating equipment. Available on short notice. Apply to Box No. 850-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

CIVIL ENGINEER, B.A.Sc. (Univ. of Toronto '27). Age 34. Familiar with house building cost, experience combines structural engineering, construction and house building and improvement, interested in obtaining a connection with firms investigating housing problems, making building loans or with a company engaged in construction or building costs. Apply to Box No. 910-W.

ELECTRICAL ENGINEER, B.Sc. (McGill '28), age 34. Experience includes transmission line and rural distribution construction and design. Some installation of motors and equipment, also house wiring. Available immediately. Apply to Box No. 940-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

## Situations Wanted

ELECTRICAL ENGINEER AND GEOPHYSICIST. B.Sc. (Man. '23), A.M.E.I.C. Married. Ten years specialized experience in the practical use of magnetic, electrical and mechanical instruments for the prospecting, surveying and mapping of mineral, oil and gas lands. Five years experience with telegraph, telephone and radio equipment. Capable of giving instruction in theory and practice in these lines and in college physics. Available on short notice. Apply to Box No. 1063-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

ELECTRICAL ENGINEER, B.Sc. '34 (Univ. of N.B.), S.E.I.C. Age 24, single. Desires any kind of electrical work. Will consider any location. Apply to Box No. 1262-W.

ELECTRICAL ENGINEER, B.A.Sc. '29. Hydraulic option. Age 31. Experience includes telephone power plant and switchboard design and supervision of university laboratory and research work. Prefer laboratory test in electrical or mechanical field. Also interested in radio. Location immaterial. Available on short notice. Apply to Box No. 1403-W.

CIVIL AND ELECTRICAL ENGINEER, Univ. of Man. '35 and '36. S.E.I.C. Experience in irrigation and mapping. Available at once. Location immaterial. Box No. 1418-W.

CIVIL ENGINEER, B.Sc. 1910, A.M.E.I.C. Married. Twenty-six years experience on heavy construction work, both field and office; rails, roads, power house, hotels, bridges, etc. Location immaterial. Available at once. Apply to Box No. 1470-W.

CONSTRUCTION SUPERINTENDENT, M.E.I.C. Age 49. Married. Twenty-two years experience as engineer, superintendent and manager in charge of hydro-electric, mechanical production, structural steel erection, also considerable experience in steam plants, combustion, transmission lines, millwright work, complete mine installations, rock work, rock crushers and conveyors. Executive ability. Speaking French fluently. Location immaterial. Apply to Box No. 1482-W.

ELECTRICAL ENGINEER, B.Eng. (McGill '33). One and a half years experience in plant and production routine, and with considerable training in sales work. Bilingual, single, and available at once for any location. Apply to Box No. 1509-W.

ELECTRICAL ENGINEER, B.Sc. '31 (Univ. of Alta.), Jr.E.I.C. Age 28. Married. One year students' test course with C.G.E.Co. including testing and operation of transformers, meters, industrial control and switchgear apparatus. Two years as instrumentman on highway construction. Desires electrical utility, commercial lighting or air conditioning work, location immaterial and available at once. Apply to Box No. 1522-W.

CIVIL ENGINEER, B.Sc. '32, S.E.I.C., P.E.N.B., D.L.S.N.B., age 32. Experience in mining, both coal and metals, private and legal surveys, railroad construction, geology and building construction. At present in private practice in coal mining district. Desirous of changing location for position either in mining field or construction in Canada. or abroad. Apply to Box No. 1562-W.

RESIDENT ENGINEER, familiar with all types of surveys and construction work including, railway, roads, irrigation, drainage, buildings and air ports. Executive ability. Had charge of several large projects. Intimate knowledge of reports and estimates. Available immediately. Any location. Apply to Box No. 1567-W.

CIVIL ENGINEER, B.Sc. '17, O.P.E. Married. Executive and administrative experience. Extensive office and field experience in harbour works, dredging; both steam and electric railways in location, construction and maintenance; telephone works in design, construction and maintenance of pole lines, wire, cable and conduit; highways in location, construction and paving; municipal works in roads, sidewalks, sewers and water mains. Intimate knowledge of estimating, unit costs, cost accounting and analysis. Some knowledge of air conditioning. Willing to locate anywhere. Available at once. Apply to Box No. 1587-W.

ELECTRICAL ENGINEER, B.Sc. '27 (McGill), A.M.E.I.C. Age 36. Married. Bilingual. Three years experience in telephone work (installation of manual and automatic exchanges). One year electrical prospecting. Nine years experience with electrical power company. Apply to Box No. 1601-W.

EXECUTIVE TOOL AND PRODUCTION ENGINEER, desires to make a permanent change, graduate in mechanical (Queen's '23), A.M.E.I.C., married. Well abreast with modern production methods and present competition. Competent supervisor of tool and die design and construction; operations and methods, plant layout, efficiency and time study, toll and production estimating, tooling development foundry, machine shop and designing experience. Best of references. Apply to Box No. 1653-W.

# THE ENGINEERING JOURNAL

VOLUME XX, No. 8 AUGUST, 1937

# Air Transport in Canada

*The Hon. C. D. Howe, Hon. M.E.I.C., Minister of Transport, Ottawa.*

**An address delivered in Ottawa, on June 18th, 1937, during the Semicentennial Celebrations of The Institute.**

Visitors to Canada are somewhat surprised to find that no inter-urban air line service is available, particularly on the coast-to-coast route. From that they often infer that Canada is deficient in aviation services. The latter deduction is entirely incorrect. Canada has an aviation development which is unique in character, and of immense importance to the industrial life of the country.

Approximately three-quarters of the Dominion lies north of railway and highway transportation systems, and it is in this vast area that the use of the airplane has been of chief importance in aiding and advancing prospecting and mineral enterprise generally. Fortunately, this area has numerous lakes and waterways which provide ideal landing places for hydroplanes, so that little expenditure is required for constructing ground facilities.

Planes are equipped with pontoons while the waterways are open, and with skis for winter use. Except for a brief interval in the spring and in the autumn, when neither type of landing gear can be used, northern flying can be carried out safely, with the lakes and rivers available for summer and winter landing fields.

Canada is far in the lead of other countries in the use of the airplane in mineral development, and there are few metal mining areas of importance that are not serviced by airplanes. In the early stages of development, planes were used chiefly in the transportation of passengers, but now they are commonly used in the transportation of diamond drills, machinery of all sorts, food and other supplies, and even small milling plants. They have become indispensable to the development of areas remote from transportation.

In 1920 the first commercial use of the airplane in the far north was developed by the Imperial Oil Company, to service petroleum discoveries at Fort Norman, on the Mackenzie River. In 1922 another phase in the use of the airplane began with experiments by the Dominion Topographical Survey in aerial photography for map-making. Two years later such progress had been made that an extensive programme of aerial mapping was undertaken. In 1928 large scale prospecting by air commenced. Exploration companies equipped with their own planes made criss-cross flights over large portions of the Yukon and the Northwest Territories. In 1929 three mineral exploration companies with 24 planes reported an exploration of a total of 174,000 square miles by air. In carrying out this work, the planes flew a total of 500,000 miles, and carried 1,000,000 pounds of freight, supplies and equipment for the maintenance of prospecting parties.

In the successive stages of mineral development from prospecting to production, the airplane is used.—

1. As a means of making reconnaissance surveys.
2. For the transportation of prospectors and their equipment into promising areas.
3. Diamond drills and their crews are flown in.
4. Freighting of machinery and equipment for the new mine.
5. Gold concentrates and gold bricks are flown out.

There are in Northern Canada a number of fair-sized towns that are wholly dependant on aerial transportation for their existence. Material flown in includes mine cars, steel rails, huge boilers, cement, tractors, air compressors, etc. A team of oxen was recently flown in to one of these towns.

During recent years Canadian airplanes have carried 60 per cent of the total air-borne freight of the Empire and close to five times the total freight of all airplanes in the United States. There are eleven well-established North and south air routes in Canada at present. Edmonton's municipally-owned airport is the busiest in Canada, being the terminal for air routes into Great Bear lake, Yellowknife river, Gordon lake, Outpost Islands mining areas in the Northwest Territories, and into the Lake Athabaska area in Saskatchewan. Freight carried by all commercial aviation companies in 1936 is estimated at about 15,000 tons. It is expected that the current year will exceed that tonnage considerably.

While there has been spectacular Canadian development of transportation of freight by air, these planes also carried mail and passengers. In 1935 these planes carried 1,126,000 pounds of mail and 177,000 passengers.

The need of inter-urban air services has long been apparent, but difficulty of providing necessary landing fields has proved a serious obstacle. Prior to the depression, daily schedule services were provided from Winnipeg to Lethbridge, Calgary and Edmonton across the Canadian prairies, but during the depression years this service was suspended. These flights were made with land machines, and fairly adequate landing fields were constructed.

During the depression years the Government seriously undertook the construction of a series of landing fields across Canada from Halifax to Vancouver and between Toronto and Vancouver as an unemployment relief project. These fields were constructed with runways having a minimum length of 3,000 feet and capable of being extended to 5,000 feet and a width of 300 feet. Wherever possible, each field was provided with three runways of this dimension to permit landing under all conditions of wind and weather. All these fields were well advanced toward completion with relief labour, and all have been further advanced by contract. Today all these fields are practically completed, and it is the intention to undertake schedule flights from coast-to-coast early next year.

The magnitude of the task of providing ground services for a modern airline route across Canada will be apparent to those familiar with our geography. Northern Ontario is a wilderness of spruce forests and swamps, and to locate a field capable of being made level, to cut the trees and remove the stumps, to provide gravel for grading the runways, and to provide adequate drainage has been in itself a major engineering project.

A further and even greater engineering problem is to provide a route through the Rocky Mountains. Two mountain ranges must be crossed, and both have peaks extending far above the highest elevation possible for plane travel. Emergency landing fields must be provided at close intervals across this part of the route. The Crow's Nest Pass route has been chosen as most favourable and the necessary landing fields have been provided and brought to completion.

These fields have special problems due to our climatic conditions. The main stopping places along the route must have hard-surface runways. These are being provided where possible by impregnation of the soil with a bituminous compound; and, where the soil is not suitable for such treatment, runways of tar or asphalt are being built. For emergency fields a coating of grass is provided for summer landings. All the fields have their special snow problems. Experiments are now being carried out to determine whether the best results can be obtained by pressing down the snow with rollers, by the use of mechanical blowers for snow removal, or whether snow-plows will provide higher efficiency.

Lighting must be provided at all landing fields to mark the runways and to guide the pilot to his landing place in the event of radio failures. The main guide for the pilot is, however, a continuous radio beam, which will extend from Halifax to Vancouver. A pilot flying on this beam obtains a steady hum on his earphones. If the wind has drifted him to the north off the beam proper, the monotone disappears and he hears a dot and dash (the Morse letter "A"); while, if he drifts to the south, he hears a dash and dot (the Morse letter "N"). These provide warnings that he is off course, and directions for returning to the course. A pilot flying on his beam and equipped with the usual instruments is independent of visibility except for purposes of actually touching the ground. He requires reasonable visibility within 300 feet of the ground, but, above that, his instruments provide all required information. His landing place is located by the beacon marker situated two miles from the end of the main runway. As he follows the beam over his marker, he finds himself in a cone of silence, and from there he glides at a predetermined angle in a well-marked direction to his field. He will emerge from the clouds directly over his runway, and can land without difficulty. Those of us who have stood at a busy airfield such as Newark, New York, and have seen planes come through the clouds at intervals of fifteen minutes and take their landings without circling the field or other wasted manoeuvres, have some appreciation of the triumph of radio over adverse weather. Often the pilots who are landing have not seen the ground for hours.

While travelling on the beam, the pilot receives weather bulletins over the beam itself, and can return messages over the beam if he so desires. In addition, his plane is equipped with radio telephone, over which he can talk with any of the main or emergency landing fields along the route. Over this telephone he receives weather reports, and telephones conditions to the ground as he is finding them. Thus the pilot is well reinforced with expert advice in case of emergency.

The most important service to be provided for an airline is that of adequate weather reporting. In Canada we are rapidly expanding our weather reporting service, some 900 reporting stations now being in operation. These stations are located at strategic points from the shores of the Arctic Ocean along both sides of Hudson Bay and down to the United States boundary. In addition, we receive reports from all weather reporting stations in the United States. Reports so obtained are interpreted by highly trained analysts, who compile weather forecasts, which are sent to all landing fields every six hours by means of a teletype service connecting all the fields. Observations are not confined to the ground. Upper air observations are made by means of balloons and theremometers, so that the pilot is informed of wind speeds and temperatures for each air layer up to 10,000 feet. He receives, while in flight, instructions as to the most favourable altitude for his purpose. The efficiency of airline operation depends very largely upon the efficiency of its supporting weather service.

The route from Halifax to Vancouver has about 100 landing fields, located not more than 50 miles apart. Some time ago I had a definite impression that such short intervals were unnecessary. My staff took a very effective means of curing me of that impression. I was taken on an inspection trip of the route from Montreal across Northern Ontario. While flying at 6,000 feet the single engine of our plane suddenly sputtered a few times and died. My first thought, of course, was, where would we land? I looked about me, and in all directions I could see nothing but spruce trees, and no sign of a landing field. After a minute or two, the engine started again, and my anxiety was relieved. The pilot explained later that one gas tank had run out and that he had failed to turn on another in time to keep the engine running continuously, but in any event he had convinced me that we needed landing fields at least 50 miles apart, and more frequently if possible.

Toward the end of July, I expect to fly over our new route from Montreal to Vancouver. I will use a twin-engine plane similar to those that will be standard equipment on the route. The plane will have a cruising speed of about 200 miles per hour and will carry gasoline for about 1,000 miles of flight. The distance to be covered will approximate 3,000 miles, and I anticipate that by leaving Montreal in the morning I will be able to dine in Vancouver the same evening at the usual time. I will make the trip in safety, for, in the almost impossible event of both engines failing, I will always be within gliding distance of a well-built emergency landing field. For most of the distance I will be on a radio beam and thus be independent of visibility. I will ride comfortably in a well air-conditioned plane, with most comfortable seats that can be inclined at any angle I wish for reading or sleeping.

The regular schedule will provide for leaving Montreal at eight o'clock in the evening, flying across to Winnipeg in the night, and arriving at Vancouver around the following noon. The return trip will leave Vancouver about three p.m. and arrive in Montreal early next morning. Toronto will be similarly served by planes leaving there in the evening and arriving in Vancouver next noon. Connections will be made at several points with planes for the United States, and the many Northern routes now in operation will have connections with the main artery of travel. Within the next two years Canada will have a modern airline service available for all its principal cities. When that time comes, I trust that some proper recognition will be given to the engineering genius that has been expended to provide the facilities that have made these routes possible.

Some of us are apt to think of an airline as made up of only modern planes and their pilots. The fact is that about ten men are required on the ground for every one man who operates in the air. Overhaul shops, equipped with expert mechanics, must be provided for regular servicing of all planes and engines; and provision must be made for handling passengers and mail expeditiously at stopping places. An aviation route is similar to other competing transportation systems in the complexity of its problems and its need for an experienced personnel. In the neighbouring United States a most efficient practice has been built up over the past ten years at considerable expense, and Canada is fortunately in a position to profit by the experience gained there. It is our intention to obtain as head of our Trans-Canada Air Lines a man fully conversant with the experience of the United States and who will be able to guide our development in a way that will permit us to profit by United States practices in parallel operations.

There has been much discussion recently about the safety of travel by air. Modern invention has provided a very high degree of safe operation. I have every confidence that Canadians generally will adopt this new form of travel, and that ample traffic will offer as soon as the route can be placed in operation.

The Trans-Canada service shortly to be placed in operation will tie together existing operations, and furnish Canada with an airline network that will reach all parts of our vast Dominion. Facilities for rapid travel should do much to knit together our scattered population, and to make for better understanding between far distant centres. There is a demand for this service both for mail and passengers, and I am firmly convinced that the rate at which traffic will increase will tax the efforts of those charged with providing adequate service.

While we in Canada are creating an inter-urban route across this country, our associates in England and in the United States are co-operating to conquer the North Atlantic by air. It is expected that the first of the trial flights across the Atlantic will be undertaken simultaneously from England and from the United States during the latter part of next week. Montreal has been designated as the Canadian terminus of this route, and Canada has undertaken to be ready to transport passengers and mail from the North Atlantic airships across Canada to Vancouver. There can be little doubt that an extension of the route westward will follow, and that within a few years Canada will be an important link in an all-British air route which will touch every country in the British Empire. Developments in modern engineering have removed all doubt that such a route is feasible. Perhaps no more spectacular engineering triumph has been reported at this gathering.

# North Atlantic Air Service[1]

## London - Montreal

*J. H. Parkin, M.E., M.E.I.C., F.R.S.C., F.R.Ae.S.,*[2]

*Director, Division of Mechanical Engineering, National Research Council, Ottawa, Ont.*

**Paper presented at the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

**Deals with factors affecting the success of a commercial air service across the north Atlantic, such as potential traffic, choice of route, weather conditions, terminal organization and facilities, aids to navigation, and type and performance of aircraft.**

The outstanding feature of all recent developments in transportation is speed and in no branch, perhaps, is this feature so impressive and so important as in transport by air.

While, at the moment, air transport is restricted somewhat by meteorological and topographical factors, as are older methods of transportation to a greater or less degree, on reaching its full development in the near future, air transport will undoubtedly surmount these limitations. Full advantage can then be taken of the principal advantage of air transport, namely, speed. Air transport lines of the future will follow the great circle routes unhampered by weather or terrain.

Canada, with respect to some of the more important of the future great circle air routes, occupies a geographical position of great importance. Even before air transport reaches complete independence, and during the development of inter-continental air routes, the geographical position of the Dominion is one of no little strategic value.

It is proposed in this paper to discuss one of the inter-continental air routes, now in process of establishment, of great importance to Canada, that across the North Atlantic ocean.

### Historical

The North Atlantic ocean, the great barrier to communication between Europe and North America, has been successively overcome by sailing vessels, steamships[3] (1827) submarine telegraph (1858), wireless telegraphy[4] (1901), wireless telephony (1915) and aircraft (1919). During 1936, the first regularly scheduled commercial air transport service over the North Atlantic was operated.

Since the first flights across the North Atlantic in 1919, some 85 crossings have been made by air. Of these, 65 were non-stop flights and 20 were made by stages. The non-stop flights included 31 by airship and 34 by aeroplane. Of the latter, 8 were solo flights, 26 were made from west to east and 8 from east to west. Some 68 persons have crossed the North Atlantic by aeroplane, non-stop, and 269 by stages, and about 2,682 by airship. The crossings are listed in Appendix I, and the courses of some of the more important are plotted in Fig. 1, reproduced from a previous paper.

Generally speaking, the crossings by aeroplane have been, with a few notable exceptions, purely stunt flights, undertaken with no scientific or technical objective, and have added little or nothing to our knowledge. In most of these flights, the aeroplane was more or less seriously overloaded compared with normal airworthiness standards. The exceptions include the first non-stop crossing of Alcock and Brown, on June 14th, 1919, the first solo flight of Lindbergh, the first westward crossing of Huenefeld, the east-west flight of Costes and Bellonte, the exploratory flights of von Gronau and of Colonel and Mrs. Lindbergh

[1]Without in any way wishing to detract from the impressive performances of airships over the North and South Atlantic, this paper is confined to consideration of an air service using heavier-than-air aircraft.

[2]The views and opinions expressed in this paper are entirely those of the author.

[3]It may be noted in this connection that the Royal William, a wooden vessel 176 ft. long, of 200 hp., built in Quebec in 1831, crossed to England in 1833 in twenty-five days and was the first ship to make the eastward crossing wholly under steam.

[4]The first transatlantic signal, the letter S, transmitted from Poldhu, Cornwall, was received at St. Johns, Newfoundland, by means of an aerial supported by a kite, on December 12th, 1901. Marconi was immediately invited by the Canadian Prime Minister to proceed to Canada and, as a result, a contract was entered into for the establishment of a transatlantic wireless service between Canada and Great Britain. The first messages were exchanged between the Governor-General of Canada, the Earl of Minto, and King Edward VII, in 1902, and in October 1907, the first long distance commercial service in the world was inaugurated between Glace Bay, N.S., and Clifden, Ireland.

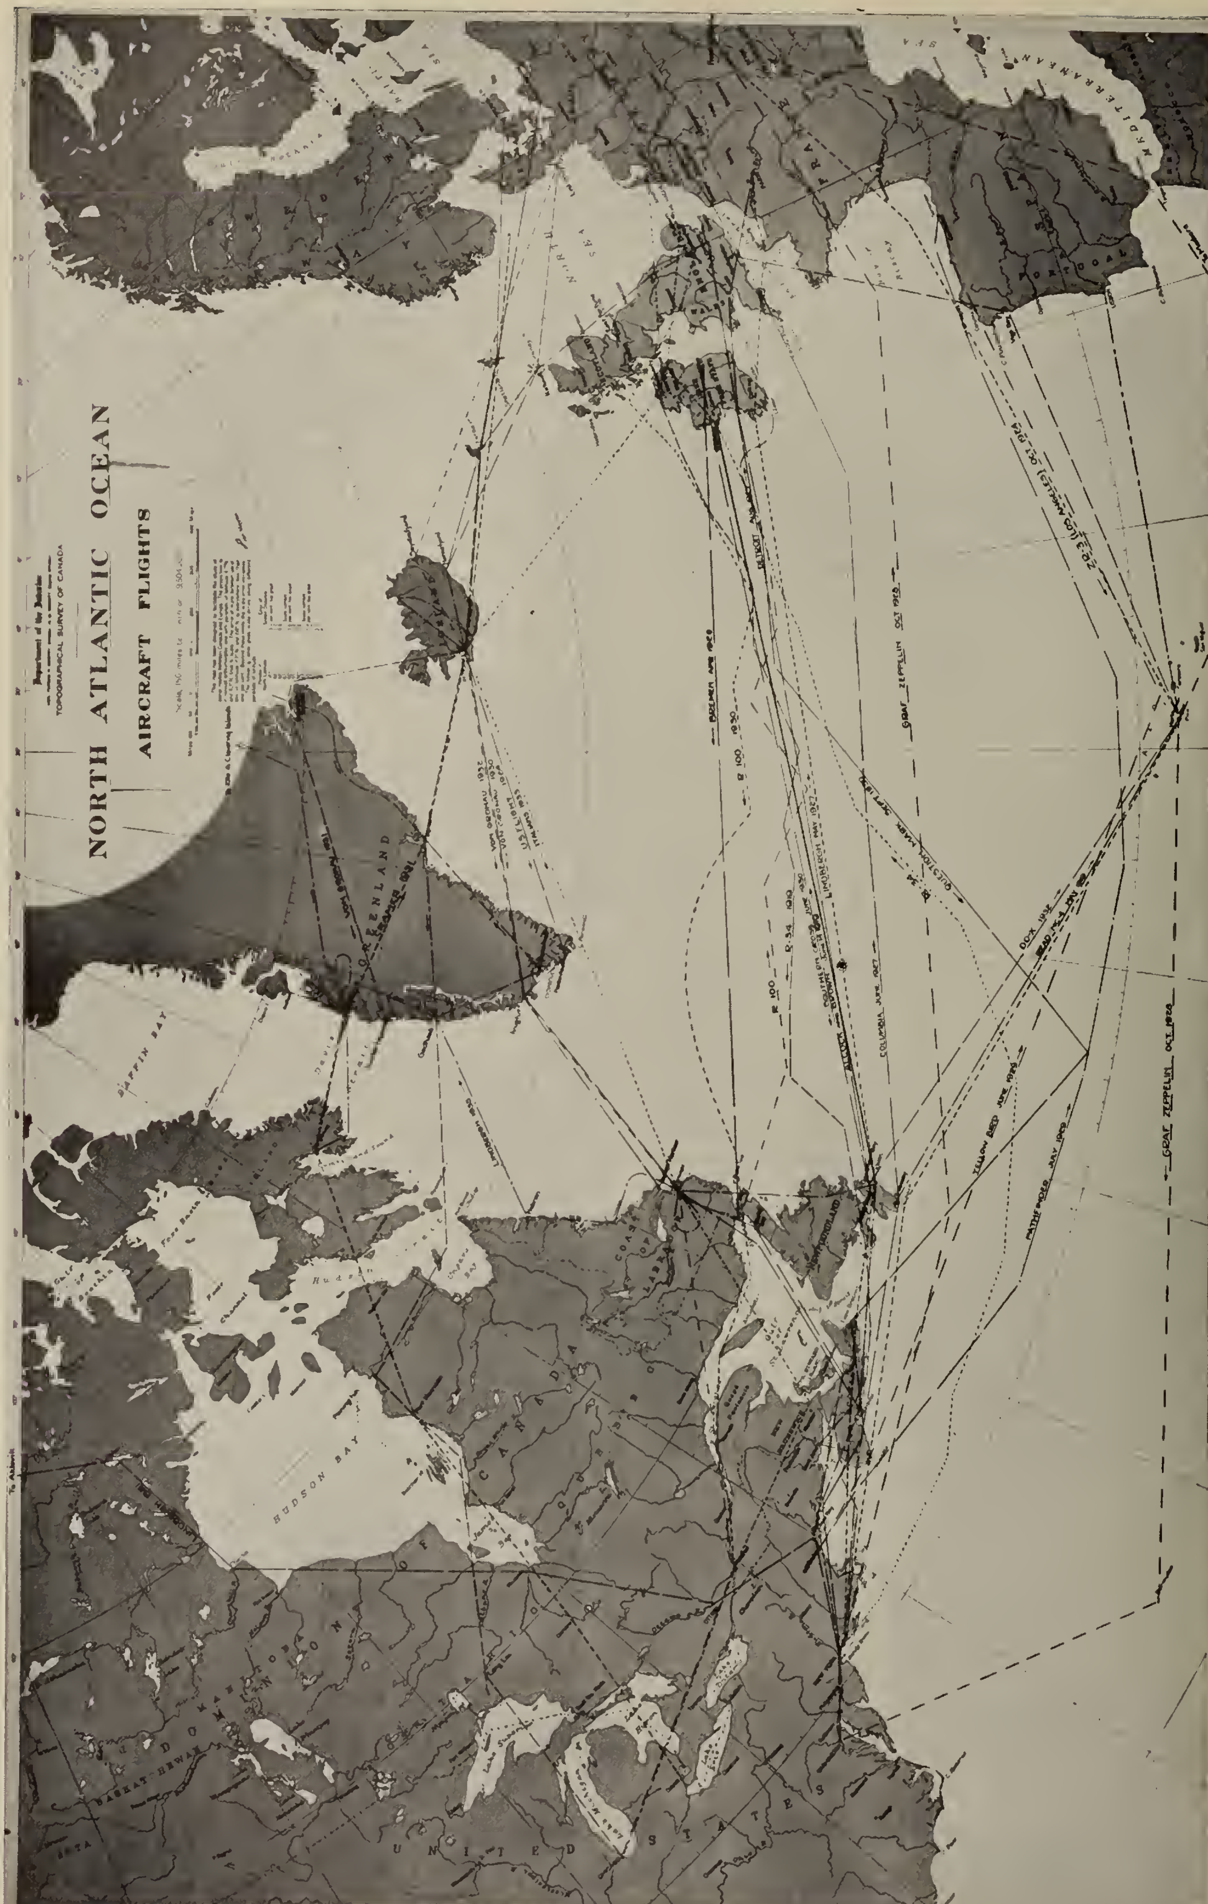

Fig. 1—Aircraft Flights, North Atlantic Ocean.

and the recent flights of the Diesel engined Dornier Do-18 flying boats.

The first and only commercial air service operated to date over the North Atlantic is that of the German airship LZ-129 (von Hindenburg) which, during the period May-October, 1936, flew ten scheduled round trips between Germany and the United States, carrying passengers, mail and express.[5]

### The Barrier of the Atlantic

Regular air services now connect most of the major land bodies of the earth, with three notable exceptions. Although many flights have been made across the North Atlantic, and a smaller number across the North Pacific, regular commercial services by aeroplane are not yet in operation between North America and Europe, Asia[6] and Australia.

The possibilities in the operation of a commercial air service across the North Atlantic have long been recognized and plans for establishment of services have been made from time to time since the first crossings in 1919. Recent years have seen a quickening of interest in the project. Several nations are now actively studying proposals and, in one case, at least, preparations for a service are so far advanced that operation will likely be commenced in 1937.

Considering the inducement offered by the enormous potential traffic, it is evident that the difficulties to be overcome in the establishment of an air service between Europe and North America must be formidable.

The North Atlantic ocean has been termed "the greatest natural obstacle with which air transport is confronted." The barriers to be surmounted in overcoming this obstacle are those due to the length of the land to land flight and to the severe meteorological conditions. Up to the present time, these two have proved unsurmountable obstacles to the establishment of a transatlantic air service.

The minimum land to land distance that must be flown non-stop, if landings are not made on mid-ocean islands, is 1,850 miles, between Ireland and Newfoundland. Solely from the standpoint of non-stop flight, this range presents no particular difficulty for modern aircraft. The economic operation of a commercial service over a non-stop stage of this length and over the open sea, however, does present difficulties at this stage in the development of aircraft. The distance is considerably longer than the longest stage of any commercial air route now in operation and the overseas distance exceeds any flown commercially up to the present time.

It is generally recognized that the meteorological conditions over much of the North Atlantic ocean are, from an aeronautical standpoint, troublesome, not the least troublesome feature being the lack of knowledge pertaining to the upper air. However, as stated by Sir Napier Shaw, it would be difficult to draw a line across the ocean that could be regarded as an impossible course.

General surface climatic conditions over the North Atlantic are to-day reasonably well known. Organized weather reporting from ships at sea, observations at land stations, and the co-operation of the meteorological services of the maritime nations provide more or less adequate

[5]Average figures for this service are:—

| Trip | Miles | Time | Passengers | Crew | Best time |
|---|---|---|---|---|---|
| Westward | 4,351 | 64–35–00 | 48.1 | 56 | 52–48–00 |
| Eastward | 4,091 | 51–53–00 | 53.7 | 56 | 42–52–00 |

[6]The United States have practically completed the organization of a transpacific air service and trial flights have been made, but, at the date of writing, regular operations had not commenced.

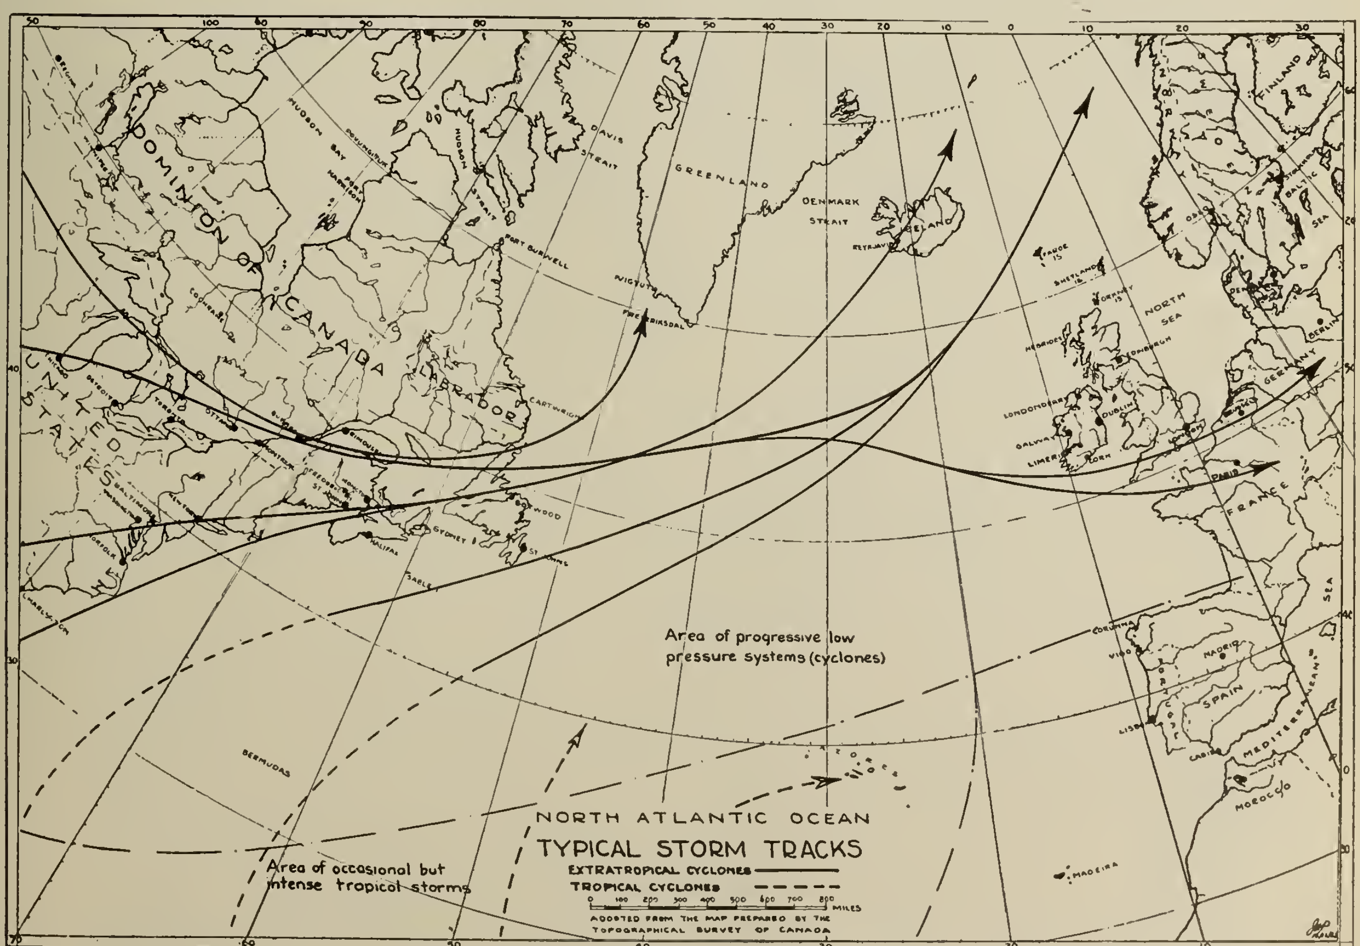

Fig. 2—Typical Storm Tracks.

information for sea-borne transport. On the other hand, knowledge of upper air conditions, so necessary to air transport, is almost completely lacking. The only information available is that collected at coast and island stations, by a few naval vessels and scientific expeditions and that obtained from the relatively few flights so far made.

The stormy character of the Atlantic ocean north of the Bermuda-Azores line is well known. The area below the line, approximately from the Bahama islands to Cape Finisterre, is subject to occasional but intense tropical storms and that above this line is characterized by frequent progressive low pressure systems or cyclones (see Fig. 2).

Perhaps the most striking fact disclosed by a study of the tracks of North Atlantic storms is that a rather well defined corridor is followed from the North American coast to Europe.

The largest number of storms enter the North Atlantic region from the Newfoundland area. Many of these have previously traversed Canada and the Northern United States. Of the storms entering by way of Newfoundland, nearly 50 per cent turn northward toward the west or east coast of Greenland. The remainder move on a course generally somewhat north of east to about midocean. Thereafter, most of these follow paths over the northern parts of the British Isles or north of them, some turn to the north and pass over Iceland and a few veer south to pass over the southern part of the British Isles.

Other cyclonic storms, frequently of great severity, develop in the Florida region or off the Carolina coast and move up the Atlantic coast and across the Atlantic along the corridor already described.

Of over 300 lows studied by Colonel Finley, 10 per cent were traced from the American to the European coast, 21 per cent were observed on one coast or the other and 32 per cent of those reaching the European coast originated over the ocean.

Tropical storms, of which the best known are the hurricanes, originate in midocean north of the doldrum area, move first generally westward and later turn north to pass over the West Indies and Gulf of Mexico. Those forming off the African coast frequently swing north in midocean and later north-eastward toward or north of the Azores. These storms, as a rule, form in September and October and average six or seven per year. They cannot be foreseen since there is little shipping in the region from which they come.

There is a definite seasonal variation in storm frequency. North of latitude 36° N. during the winter (from the middle of October to the middle of April), gales and storms are frequent. Days on which gales (wind force 8[7]

[7] Beaufort Scale

| Beaufort number | Description of wind: Seaman's | Description of wind: U.S. Weather Bureau | Statute miles per hour |
|---|---|---|---|
| 0 | Calm | Light | Less than 1 |
| 1 | Light air | Light | 1-3 |
| 2 | Light breeze | Light | 4-7 |
| 3 | Gentle breeze | Gentle | 8-12 |
| 4 | Moderate breeze | Moderate | 13-18 |
| 5 | Fresh breeze | Fresh | 19-24 |
| 6 | Strong breeze | Strong | 25-31 |
| 7 | Moderate gale (high wind) | Strong | 32-38 |
| 8 | Fresh gale | Gale | 39-46 |
| 9 | Strong gale | Gale | 47-54 |
| 10 | Whole gale (heavy gale) | Whole gale | 55-63 |
| 11 | Storm | Whole gale | 64-75 |
| 12 | Hurricane | Hurricane | Above 75 |

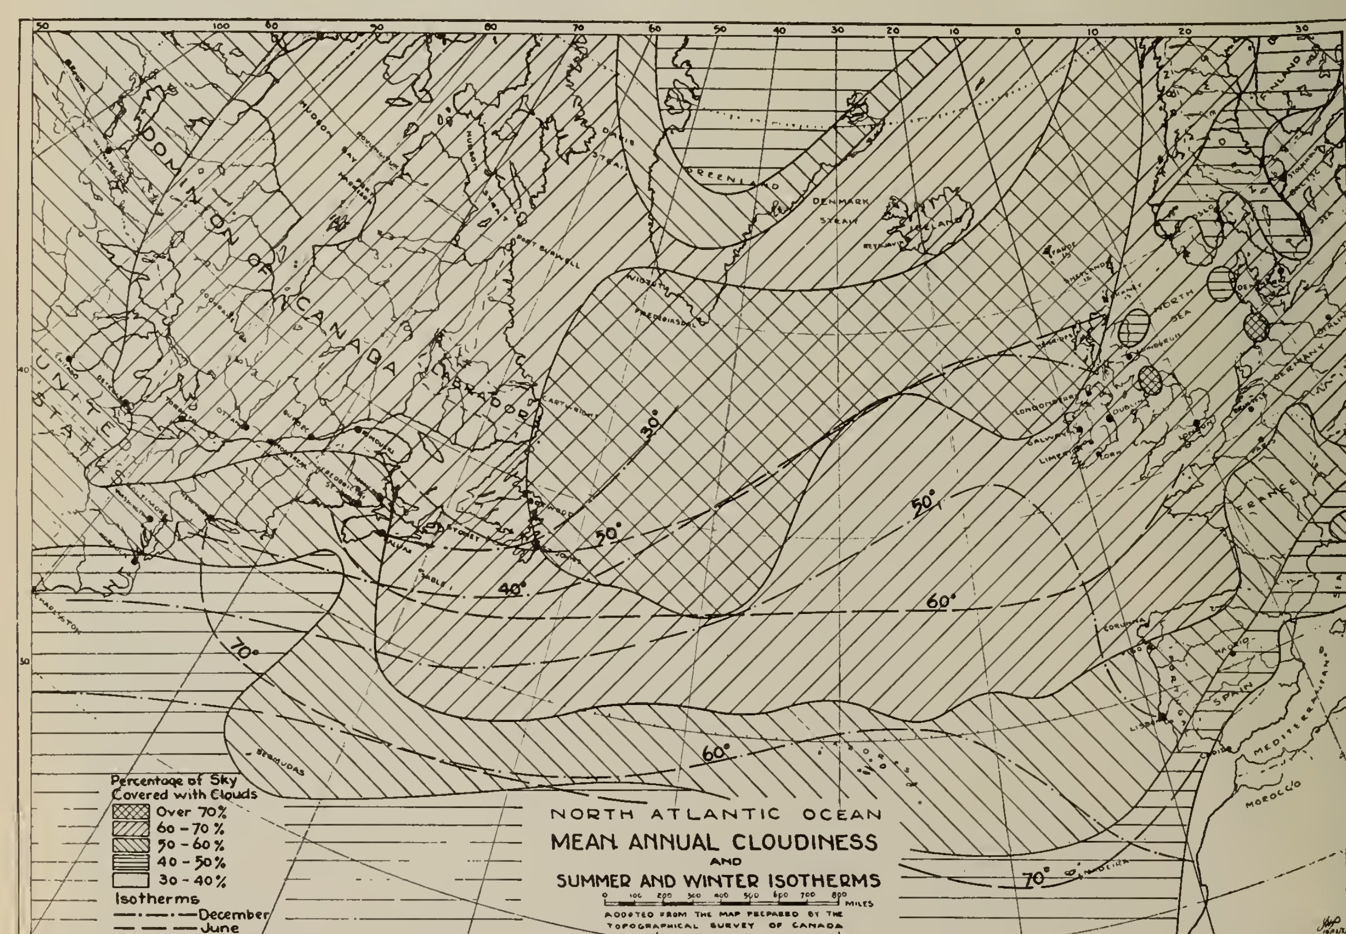

Fig. 3—Mean Annual Cloudiness.

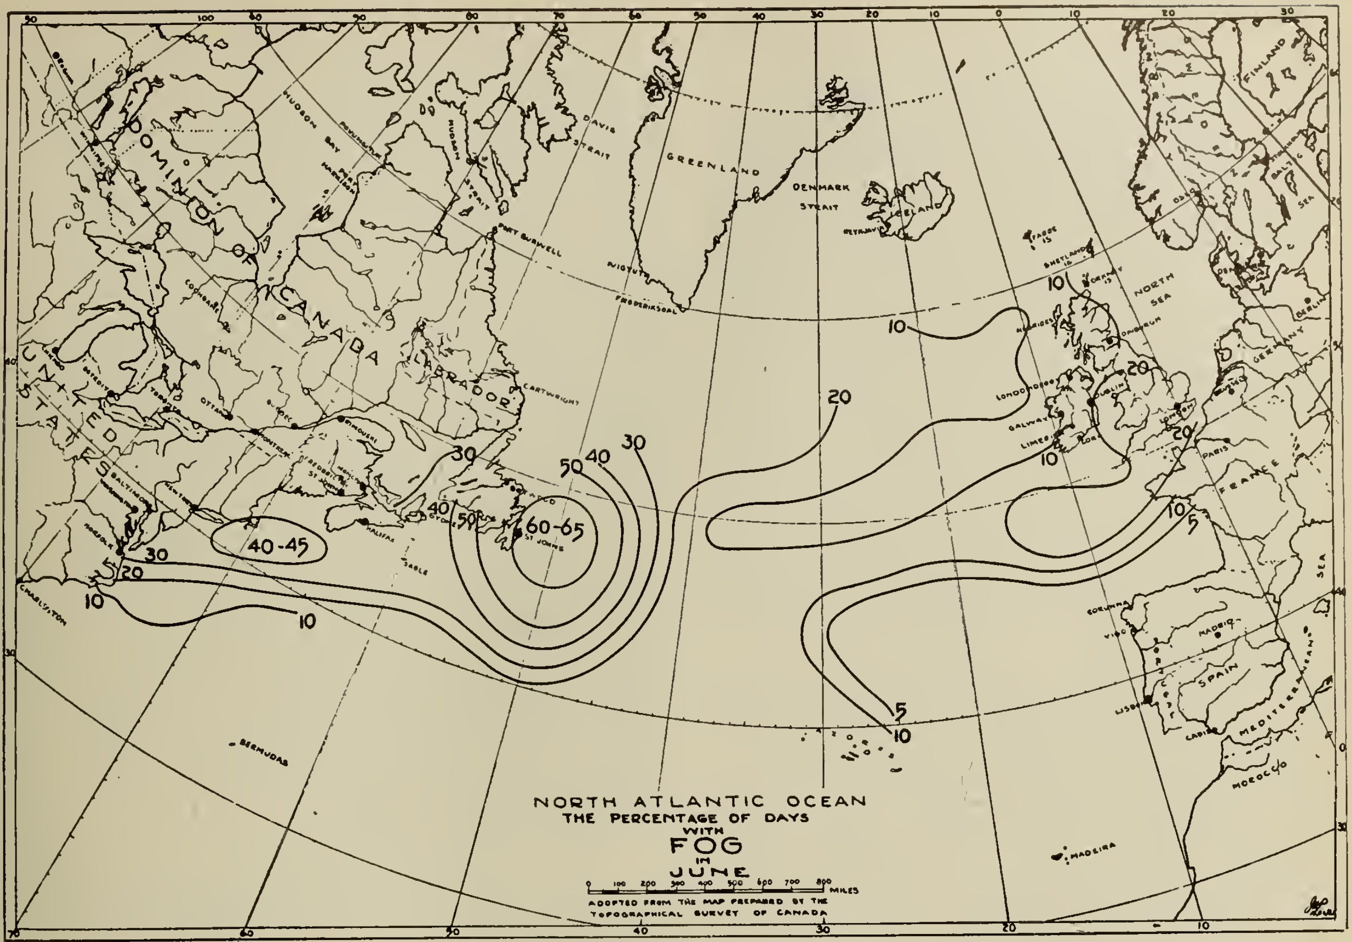

**Fig. 4—Percentage of Days with Fog in June.**

and below) are reported in this region may reach 20 per month; whole gales (force 10) 5 or more and winds of hurricane force (force 12) 1 or 2 and occasionally more per month. There is some indication that the frequency is greater in midocean between longitude 25° and 45° W. than near the coasts.

Information is lacking as to the height to which cyclonic storms extend. Storm areas over the Atlantic have been encountered above 10,000 ft. and in at least one case the top of the storm cloud was estimated to have extended to 20-25,000 ft.

A good deal of information pertaining to North Atlantic surface winds, their strength, direction and frequency has been collected and made available. While the average prevailing wind in the north is westerly, it varies widely in strength and direction. However, winds in the quadrant NW. to SW. predominate.

The wind direction at altitude over the ocean can only be inferred from observations made at coast and a few island stations, knowing that, for the same pressure gradient, surface winds are considerably stronger at sea than on land and blow more nearly parallel to the isobars, and that consequently the increase in speed and change in direction with height are less over the ocean than over land. Also, observed conditions at island stations are applicable to larger adjacent areas than is the case for land stations.

The average veering of the wind with altitude as observed at American coast stations indicates that, up to 2,000 ft., there is a general clockwise rotation and thereafter a veering right and left from the east until, at 12-13,000 ft., wind directions range only from NW. to WSW. Surface winds from the NW. and WNW. change little in direction with altitude. At the same time, the velocity increases with altitude. To illustrate:

A 10-mile E. wind at the surface becomes
at 5,000 ft. a 17-mile SSW. wind
at 10,000 ft. a 20-mile W. wind
at 15,000 ft. a 26-mile WNW. wind

A 10-mile W. wind at the surface becomes
at 5,000 ft. a 23-mile WNW. wind
at 10,000 ft. a 31-mile WNW. wind
at 15,000 ft. a 38-mile NW. wind

Thus easterly winds at the surface are usually shallow.

Another feature of the North Atlantic region is its extreme cloudiness. The cloudiness appears to be related to surface air temperatures. The major axis of the area of greatest cloudiness extends roughly between Newfoundland and the Faroe islands (see Fig. 3) and this line corresponds approximately with the 40 deg. surface isotherm in midwinter and the 50 deg. isotherm in summer. With surface temperatures below 50 deg. in summer, clouds may be expected.

Most clouds apparently lie below 10,000 ft. although some extend higher. The height of clouds may be estimated from the surface air temperature and humidity.

Information regarding the prevalence and seasonal distribution of different cloud types and their relation to thunderstorms, fog and mist would be of considerable value in the operation of ocean air services. Such information, while available in the mass of records of meteorological services from cloud observations made at sea, has apparently not been analysed and published in maps because of its relative unimportance to shipping.

Certain regions of the North Atlantic are characterized by dense and frequent fogs (see Fig. 4). Fogs result when steep temperature gradients of air and water are superimposed, as frequently happens off Newfoundland.

As temperature measurements indicate that the temperature in fog increases from the sea to the top, above a certain height fog is impossible and consequently fogs must be relatively shallow. This conclusion is confirmed by kite observations which show that fogs average in height from 400 to 500 ft. with occasional heights exceeding 1,000 ft. But, should an area of low pressure lie over the fog bank, the low clouds merge with the fog and poor visibility will then extend continuously from the surface to high altitudes.

Air temperatures (see Fig. 3) over the Atlantic, except as they influence other climatic conditions, fog and ice, impose no handicap on aircraft. Atmospheric ice formation is a hazard peculiar to aircraft. For this reason, information pertaining to it has not been collected in the past. Icing has been encountered by aircraft over the Atlantic, even in summer and well south of the steamer lanes.

From the standpoint of icing, a knowledge of upper air temperatures and humidity is important. Overland temperatures decrease roughly 1 deg. per 328 ft. altitude, but this rule is subject to wide variation with latitude and even for the same latitude.

Precipitation over the northern portion of the North Atlantic is high. About one-half of the observations from ships in this region report precipitation. Except as it relates to the formation of atmospheric ice, precipitation is not important to modern aircraft.

Thus the meteorological handicap peculiar to the North Atlantic is the frequency of storms, fog and cloud characterizing certain regions. The prevailing westerly winds, although possibly stronger over the Atlantic, face any east-west service and the extent of the ice hazard has yet to be determined.

The severity of the climatic conditions has not prevented the development of transatlantic shipping until the volume of traffic now exceeds that across any other sea, nor should it obstruct indefinitely the establishment of transatlantic air services.

### Ship-Shore Services

In the past, lacking equipment capable of operating a transatlantic air service, efforts were made, with the available aircraft, to secure some of the advantages of air transport, by operating partial services in conjunction with steamers on the transatlantic routes.

Canada, looking forward to the time when aeronautical development would permit the establishment of transatlantic commercial air services, commenced, in 1927, experimental ship-shore air mail services. The purpose of these services was fourfold, namely:

1. The exploitation of the favourable geographical position of the Dominion with respect to Europe and steamer lanes, as a result of which, of the 3,350 miles of steamer route between Montreal and Southampton (via Belle Isle) some 1,000 miles are within the relatively sheltered waters of the St. Lawrence waterway.
2. The acquiring of experience in the regular operation of a St. Lawrence air service relative to suitable aircraft types, meteorological conditions, routes, organization and operating technique, which would be valuable when operation of a transatlantic air service commenced.
3. The speeding up of the delivery of incoming and outgoing overseas mail.
4. The demonstration of the benefits to be derived from even such a partial air service and the awakening of public opinion to the importance of Canada's position relative to the principal transatlantic air route and to the need for active Canadian participation on a major scale in the development of this route.

Aircraft of the Royal Canadian Air Force made experimental flights between Montreal and Father Point in the autumn of 1927 to advance the delivery of transatlantic mail carried by steamers using the St. Lawrence route. Ten flights were made (8 by aeroplane, 2 by seaplane) and a total of some 2,500 lb. of mail were carried with an average advance in delivery of incoming mail of thirty hours and of outgoing mail of three and a half days.

The success of these experimental flights resulted in the establishment of a regular contract air mail service between Montreal and Rimouski on May 5th, 1928, which has been operated each year since, during the season of St. Lawrence navigation (May-November). The mail is carried by aeroplane and transferred to and from the steamer by pilot tender at Father Point. Up to 800 lb. of mail are carried per flight. A brief record of this service is given in Appendix II.

In December 1929, primarily to continue the summer Montreal-Rimouski service, an experimental service between Montreal and Moncton and Saint John, N.B., was begun. Daily trips (5 days per week) were made by way of Quebec, south shore of the St. Lawrence river, Edmundston, St. John river valley to a point northeast of Woodstock, Fredericton and Moncton. Overseas mail was transferred at Moncton for carriage by rail to Halifax. In 1930, the service terminated at Moncton and on June 1st, 1931, was suspended when a general reduction was made in Canadian air mail services. A brief record of this service is also given in Appendix II.

Later, consideration was given to the extension of the St. Lawrence service to the Strait of Belle Isle and an experimental flight was made in 1930 by two aircraft of Canadian Airways Ltd. from Quebec to Bradore Bay (see Fig. 5) on the Strait just within the Canadian boundary. The 785 miles were flown between 8.30 a.m. and 5.00 p.m. and some 1,000 lb. of mail transferred to the *Empress of Australia* which had sailed from Quebec the previous day, effecting a saving in time of twenty-four hours.

In 1932, in conjunction with the Imperial Conference in Ottawa, a ship-shore air mail service was operated between Red Bay on the Strait of Belle Isle and Ottawa. Ten flights were made by aircraft of the Royal Canadian Air Force.[8] A typical schedule is given in Appendix II. Mail was delivered in Ottawa twenty-seven hours before the ship docked at Quebec, thereby saving thirty-six hours in the delivery of overseas mail. Mail posted in London was delivered as follows:

| | |
|---|---|
| In Montreal | 102 hours later |
| In Ottawa | 104 hours later |
| In New York | 106 hours later |
| In Vancouver | 151 hours later |

Ship-shore services by means of aircraft catapulted from the ship have also been operated from steamers plying between Europe and America. The first liner to be equipped with a catapult for this purpose was the *Ile de France* of the French line. The catapult[9] was mounted on the stern. The first flight was successfully made on August 13th, 1928, when the amphibian aircraft, with wheels removed, carrying three sacks of mail was catapulted some 400 miles at sea and landed the mail at New York sixteen hours before the ship docked. Longer flights, up to 800 miles, using a larger aircraft, were planned, but no further information on the service is available.

---

[8]Another demonstration of the possibilities of Canadian air mail was given in August 1933 when letters were flown from Vancouver to Quebec, placed on the *Empress of Australia*, and reached London in seven days instead of the twelve days ordinarily required for the 6,000 miles.

[9]For details of catapult and aircraft, see Appendix III.

In 1929, the Norddeutscher Lloyd liner *Bremen* was equipped with a catapult mounted on a turntable between the funnels and, in 1930, the *Europa* was similarly equipped.

The service was operated under the joint auspices of the Norddeutscher Lloyd, the Deutsche Luft Hansa and the German Post Office. The aircraft was launched at distances ranging up to about 1,500 miles, but averaging 500-700 miles from the English or American coast, depending on prevailing conditions and, eastbound, flew to Southampton and thence to Bremerhafen, and, westbound, flew via Cape Race to Sydney to land Canadian mail and thence to New York. Occasional landings were made at Boston. While proposed, the despatch of mail by seaplane to overtake the ship was, insofar as is known, not attempted.

The extra fee charged for letters, for carriage by this service, was 75 pfg. per 20 grammes. The British and United States Post Offices did not accept mail for dispatch by the service.

In spite of an early accident, when a seaplane was lost near Newfoundland, the service was operated each summer[10] from 1929 to 1935 inclusive. A brief record of the service is given in Appendix IV. The time saving ranged up to forty-eight hours eastbound and up to seventy-two hours westbound. A five-day service between London and San Francisco was rendered possible.

The service has enabled the Deutsche Luft Hansa to gather information regarding Atlantic weather, radio operation and the economic aspects of Atlantic air mail, of great value in planning a transatlantic air mail service.

[10] The catapults were removed in the fall and reinstalled in the spring.

## THE TRANSATLANTIC AIR SERVICE

### Object

The volume of traffic between European ports and the Atlantic ports of North America greatly exceeds that between any other two continents (see Appendix V). That much of this traffic is of a character which demands and is prepared to pay for the fastest possible service and would hence immediately make use of a reliable air service if it were available is evident from the experience of the N.D.L. ship-shore service and from the steady increase in the volume of traffic carried by long distance air services now operating.

Banks and business houses are quick to take advantage of air mail and news film companies, press photographic agencies and similar organizations use air mail whenever possible.

The transatlantic traffic demanding speed will comprise mail, express and passengers and the ultimate objective should be the operation of a reliable, fast, regular, frequent and economical service for this traffic. However, for a number of reasons, the initial service should be confined to the carriage of mail and express.

In the first place, as the figures in Table I indicate, the revenue is greater for mail and express than for passengers. Mail and express require less space and do not require the food, services, facilities, comfort and entertainment demanded by passengers. The mail aircraft is therefore smaller, more compact, less costly to build and operate, and requires a smaller crew than the passenger carrier. Operation for the first few years will necessarily be largely devoted to the acquisition of experience and information

**Fig. 5—Gulf of St. Lawrence.**

and the crews should be free to devote themselves to this work. There is the further consideration that there will be a certain element of risk during the initial period of operation and the carriage of passengers would impose an additional strain on the crews and in addition the loss of passengers would react much more unfavourably on the project than would the loss of mail or express.

Table I

Comparison of Transatlantic Transport Rates

| | Steamer Present average | | |
|---|---|---|---|
| | Nominal | Rate per lb. | Rate per cu. ft. |
| Mail—letter......... | 3c. per oz. | $1.20 | $18.00* |
| Express.............. | 10c. per lb. | 0.10 | 2.00 |
| Passenger........... | $250.00 | 1.00 | † |

| | Aircraft Proposed rates‡ | | |
|---|---|---|---|
| | Nominal | Rate per lb. | Rate per cu. ft. |
| Mail—letter......... | 15c. per ½ oz. | $6.00 | $90.00 |
| Express.............. | $1.00 per lb. | 1.00 | 20.00 |
| Passenger........... | $500.00 | 1.66 | 4.00 |

Based on 40 letters per pound and a weight per cu. ft. of letters equal to 15 lb., i.e., 600 letters per cu. ft.

Based on average express package weighing 20 lb. and occupying one cu. ft. of space.

Based on average weight of passenger and baggage 225 lb.

Based on an allowance per passenger in aircraft of 75 lb. for furniture, galley equipment, food and service and a space allowance of 120 cu. ft.

*Steamers are paid about 50 cents per cu. ft.

†In steamers, excess baggage, over an allowable of 20 cu. ft., is charged for at a rate of 60c. per cu. ft.

‡Suggested by the author.

## Potential Traffic

The present seaborne traffic between European and North American ports is tabulated in Appendix V. In round numbers, the total yearly traffic each way is:

| | |
|---|---|
| Mail—first class............................ | 3,600,000 lb. |
| prints, etc............................ | 17,000,000 lb. |
| parcels............................ | 11,500,000 lb. |
| Passengers.................................. | 300,000 |

Assuming 2½ per cent of the first class mail, 1 per cent of the parcel mail and none of the prints are carried by air, at the rates suggested in Table I, the volume of air mail traffic and revenue per week would be roughly as follows:

| | Traffic per week Total | By air | Rate | Revenue |
|---|---|---|---|---|
| First class........ | 70,000 lb. | 1,700 lb. | $6.00 per lb. | $10,000.00 |
| Prints............ | 325,000 lb. | 0 | 0 | 0 |
| Parcels........... | 220,000 lb. | 2,200 lb. | $1.00 per lb. | $ 2,200.00 |
| Total.................... | | 3,900 lb. | | $12,200.00 |

On a basis of three trips each way per week initially, the capacity of the aircraft would need to be about 1,500 lb. of pay load and the gross revenue would be about $4,000 per trip.

If passengers are to be carried, the figures indicate that about one-sixth of the total passengers travel first class, or about 1,000 per week each way. If 2½ per cent of these travel by air, the number will be 25 per week or, with three trips per week, about 8-10 per trip, yielding a revenue, at the suggested fare, of about $4,000 per trip.

## Flight Schedule

In drafting the flight time-table, many factors must receive consideration, only a few of which will be mentioned here.

The nature of competitive services may largely determine the terminal to terminal time permissible. In this case, with competition confined to fast liners and airships, adequate time advantage will result from a twenty-four to thirty-hour service.

An important factor is the requirement of the traffic. Contemplating mail and express traffic only, times of arrival and departure should be arranged to permit collection and delivery of mail to suit business hours.

Connections with existing services must also be provided for in arranging the schedule.

Difference in time, on a long east-west service such as this, must not be overlooked.

The service being new and experience lacking, proper allowance must be made in the flight schedule for uncertainties and contingencies.

Initially, the schedule must be arranged to make operation as easy as possible for the personnel. The schedule should not be too close to the limit of which the aircraft are capable. The added strain, due to excessive haste and undue emphasis on the maintenance of schedule, may lead to personnel taking unnecessary risks and inevitably to disaster, as has been recently demonstrated.

As take-off is generally easier than landing at night or under conditions of poor visibility, particularly with catapulting, departures should be scheduled at night to permit landing after the oversea flight in daylight.

A suggested schedule is as follows:

*Westbound*

London—depart 8.00 p.m., permitting collection of mail at close of business day.

Limerick—depart 12.00 midnight.

Botwood, Nfld.—arrive 11.00 a.m., Atlantic Standard time, allowing fifteen hours for flight against headwinds.

Montreal—arrive 5.00 p.m., Eastern Standard time, permitting carriage of mail to many Canadian and United States points overnight, for delivery in morning.

Elapsed time—twenty-six hours.

*Eastbound*

Montreal—depart 2.00 p.m., Eastern Standard time, permitting collection of mail at noon.

Botwood, Nfld.—depart 10.00 p.m., Atlantic Standard time.

Limerick—arrive 4.00 p.m., allowing fourteen hours for flight with following wind.

London—arrive 8.00 p.m., permitting distribution of mail, during the night, to many European points, for delivery in the morning.

Elapsed time—twenty-five hours.

This schedule, based on a cruising speed on the ocean crossing of not less than 180 m.p.h. and providing fourteen and fifteen hours for the crossing, allows ample margin for head winds and deviations to take advantage of weather conditions.

With a tri-weekly service initially, the east and west flights would be made on alternate days.

## The Terminals

The bulk of the North Atlantic traffic is between ports in the British Isles and those adjacent to or reached through the English Channel, and Canadian and North Atlantic ports of the United States. In other words, the heaviest traffic flow is between ports serving the thickly populated and industrial region of Europe and ports serving the corresponding region of North America.

Hence, a transatlantic air service, to carry that portion of the inter-continental traffic demanding speed should operate between terminals convenient to these regions and should ultimately, taking full advantage of the freedom of aircraft, follow the shortest and most direct route between these terminals.

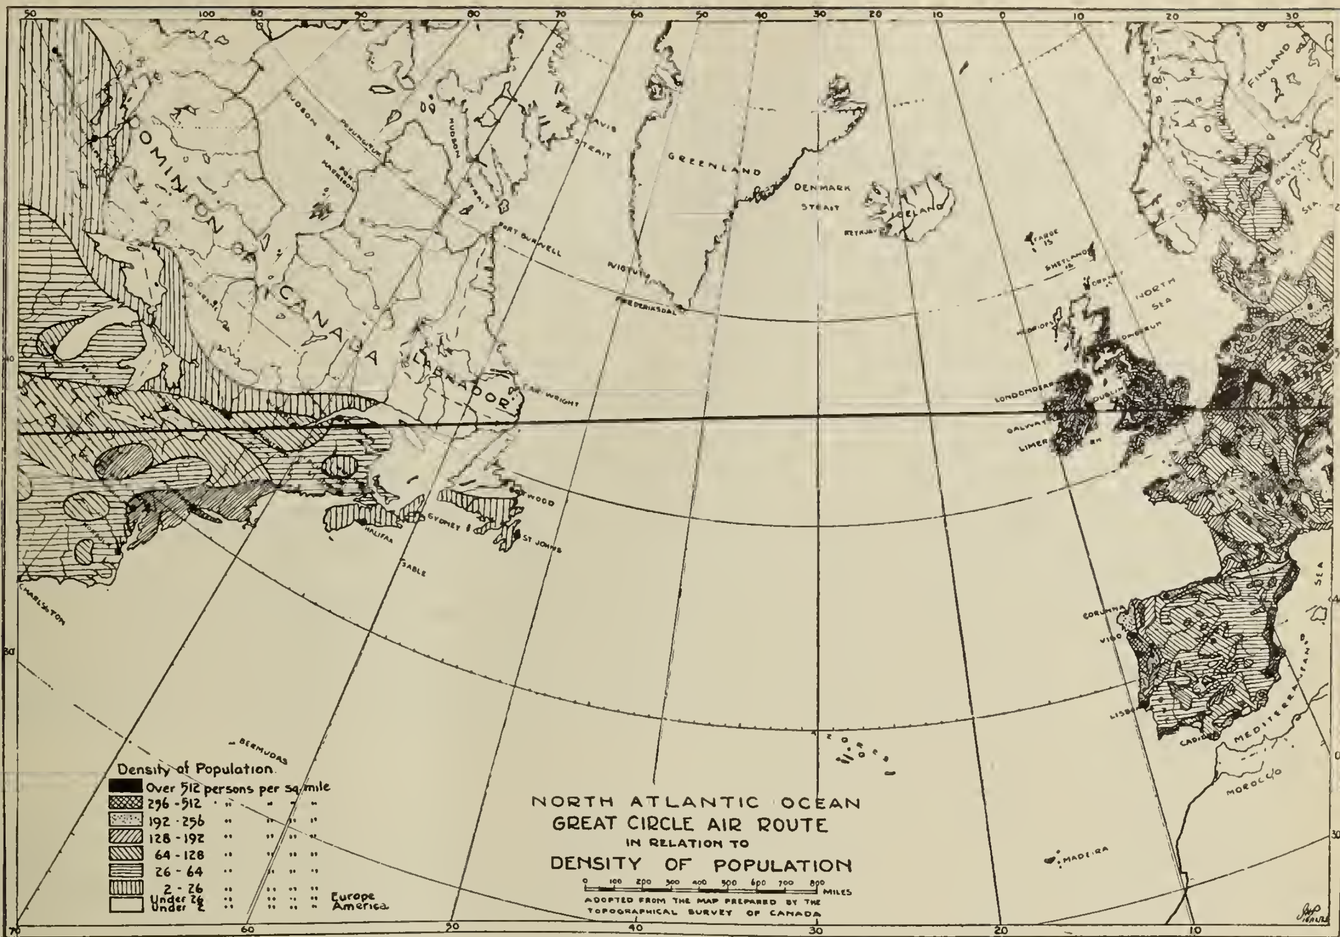

**Fig. 6—Great Circle Air Route in relation to Density of Population.**

The map of Fig. 6, showing density of population, indicates that London is well situated to serve as a distribution point for overseas traffic to the industrial region of Europe and possesses the advantage that it is now the focus of a system of air lines radiating to all parts of Europe. Having due regard for national considerations in the choice of the terminal, it also appears from the map that Montreal is favourably located to serve as the western terminus and centre of distribution for the industrial areas of Canada and of the United States.

### The Route

The ultimate route of the inter-continental air service should therefore be the great circle, between these terminals and the prior routes, established during the development period, should approach the great circle as closely as the capabilities of aircraft at the time permit limitations of range, weather and topography to be overcome.

The courses flown and the air routes proposed across the North Atlantic have been selected generally to circumvent the length of the non-stop oversea flight and to take advantage of favourable or avoid unfavourable weather, or for both reasons. Most successful aeroplane crossings eastward have been from or by way of Newfoundland to take advantage of the short sea crossing and favourable winds and, in the case of flights from the United States, the opportunity, afforded by the long coast flight, to check instruments and motor. All early flights were made in the least stormy season of the year and few, if any, flights have been made starting irrespective of weather conditions. In Fig. 1, are plotted the courses of a number of the more important flights that have been made.

The air routes flown or proposed may be broadly classed as northern, southern and direct.

The northern or Arctic routes are by way of Iceland and Greenland. The most practical of these routes is probably the following (see Fig. 7): London-605[11]-Shetland islands (or Orkney islands)-220-Faroe islands-485-Reykjavik, Iceland-780-Frederiksdal, Greenland-630-Cartwright, Labrador-630-Shediac, N.B.-435-Montreal.

Since the navigation of the North Atlantic was first studied on a scientific basis by Maury early in the nineteenth century, there has been a tendency to recommend shipping routes farther and farther south, despite their great length, to avoid icebergs, fog and storms.

Similarly, the southern air routes, flown or proposed, and based on the Azores, have been selected, not so much to reduce the length of the overseas flight, since little, if anything, is gained in this respect, as to take advantage of more favourable weather conditions.

The southern routes are:

1. That by way of the Azores and Bermuda, recommended by the Hydrographic Office of the U.S. Navy Department (Pilot Chart of the Upper Air—North Atlantic ocean) and partially flown by the Graf Zeppelin in October, 1928. From London to Montreal, this route would be: London-290-Brest-400-Corunna-320-Lisbon-1,050-Horta, Azores-2,050-Bermuda-800-New York-340-Montreal.

   The U.S. Hydrographic Office also recommended routes from the Azores to Cadiz, Brest and Plymouth. Corunna is also a possible European landing point from the Azores and Norfolk and Baltimore alternative points of landing from Bermuda.

[11]Distances are approximate and in English miles.

2. That direct to New York from the Azores, roughly following the New York-Mediterranean steamer lanes, a distance of 2,370 miles.
3. There is also the intermediate route by way of the Azores and Newfoundland, followed on the first Atlantic crossing in 1919 and on several flights since. This route is Lisbon-1,050-Horta, Azores-1,350-St. Johns, Nfld.-355-Sydney, N.S.-660-Montreal.
4. To take advantage of the better weather conditions there existing, routes still further south have been suggested (Verle and Viant 1927, Bleriot 1927). The following commercial route was recently proposed by Musella[12]:—Lisbon (Cadiz in winter)-600-Madeira-1,430-28-0-0 N., 40-0-0 W.-920 (via 28th parallel)-28-0-0 N., 55-0-0 W.-660-Bermuda-800-New York.

Some flights have been made between Europe and North America by way of Africa, the South Atlantic and South America.

The great circle route between London and Montreal crosses Ireland and Newfoundland and passes down the St. Lawrence valley. The approximate length is 3,250 miles. This route is the shortest and therefore the fastest and the land to land distance compares very favourably with that along other practicable routes.

For reasons already mentioned, most transatlantic flights by aeroplane have closely approximated the great circle route.

The great circle route is the commercial air route to be ultimately used when the development of aircraft permits. Immediate complete utilization, non-stop, of the route is impracticable owing to the present limited long range carrying capacity of aircraft which necessitates intermediate landings and imposes limitations on the choice of the location of the intermediate airports. In addition, for the present at least, it is desirable that the transatlantic route connect with and utilize the trans-Canada airway.

To meet these restrictions, intermediate bases in Ireland and Newfoundland must be utilized and the probable route of the air service planned to be inaugurated in 1937 is London-70-Southampton-340-Limerick, Ireland,-2,010-Botwood, Nfld.-470-Shediac, N.B.-435 (via trans-Canada airway)-Montreal.

This route deviates but little from the great circle and its length, 3,325 miles, is consequently little greater than the 3,250 miles of the great circle. At the same time, the length of the oversea flight is practically the same as for the great circle.

The most suitable of the foregoing routes is the one which best permits the requirements of the service—reliability, speed, regularity, frequency and economy—to be met. With the limitations of present day aircraft, all of these requirements will be influenced to a greater or less degree by the length, overall and oversea, and climatic conditions. However, while possible, it is improbable that weather conditions along a shorter transatlantic route would be so much more difficult as to necessitate heavier, slower and more costly aircraft, requiring a longer time for the route than would the lighter, faster and less expensive machines permitted by the more favourable weather of a longer route.

The figures of Table II emphasize the advantage of the great circle route and routes approximating it with respect to overall length. From this standpoint, the northern route is superior to the Azores routes. The shortest of the latter is 30 per cent, or over 1,000 miles longer than

[12] Aeronautica 12, 1932, pp. 1024-37.

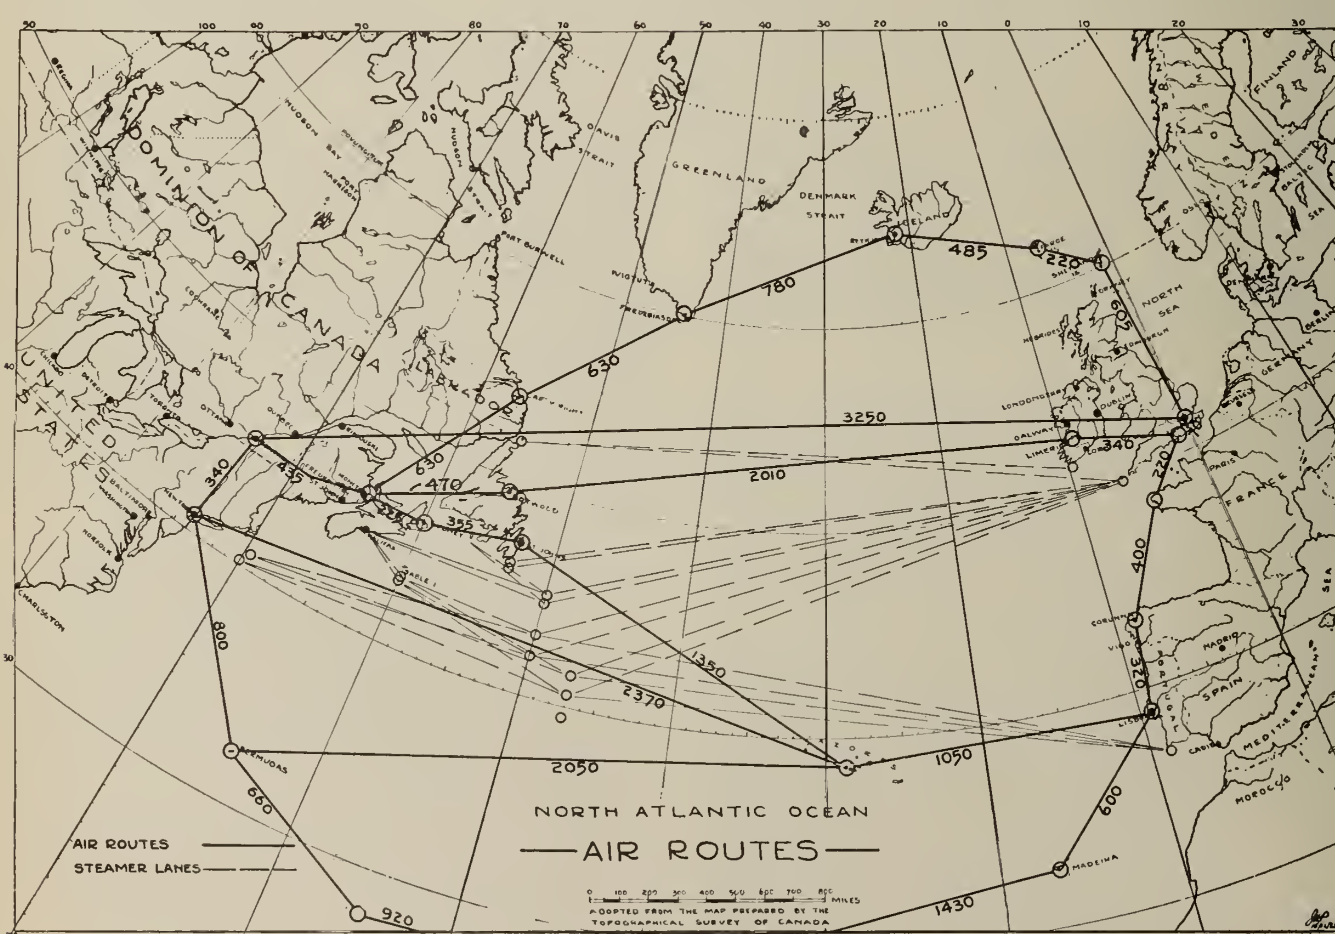

Fig. 7—Air Routes.

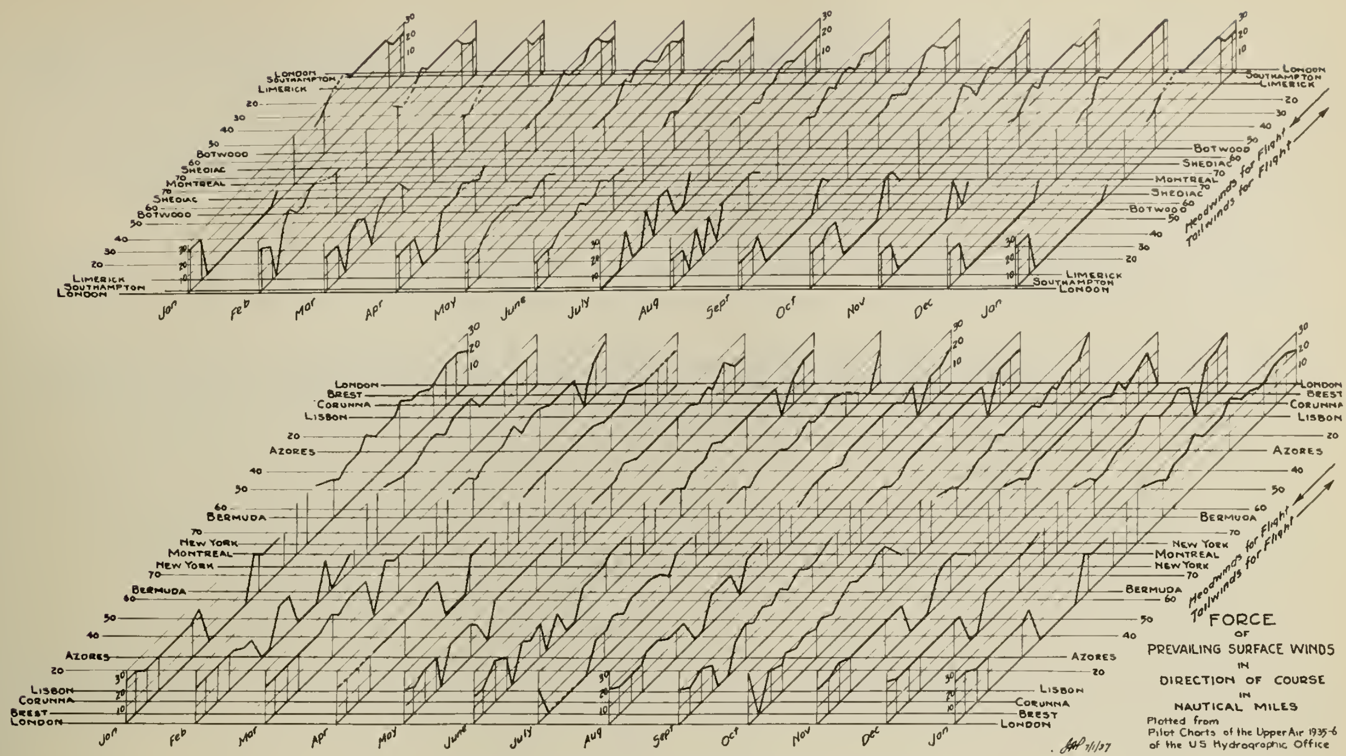

**Fig. 8 —Force of Prevailing Surface Winds.**

the proposed direct route. The overall length of the route, in its bearing on the time from terminal to terminal, is a highly important factor, in view of the keen competition to be met from modern transatlantic steamships and airships.

TABLE II

COMPARISON OF ROUTES—LONDON-MONTREAL

| Route | Overall length miles | Maximum oversea distance miles |
|---|---|---|
| *Northern* | | |
| By way of Iceland-Greenland-Labrador..... | 3,785 | 780 |
| *Southern* | | |
| 1. By way of Azores and Bermuda.......... | 5,250 | 2,050 |
| 2. By way of Azores and Mediterranean steamer lane.......................... | 4,770 | 2,370 |
| 3. By way of Azores and Newfoundland.... | 4,425 | 1,350 |
| 4. By way of Madeira and Bermuda......... | 5,760 | 3,610 |
| *Direct* | | |
| 1. Great circle............................. | 3,250 | 1,870 |
| 2. By way of Limerick and Botwood........ | 3,325 | 1,900 |

While the longest oversea flight of the Arctic route is much shorter than that of any of the others (unless artificial aids are used), it is considered otherwise impracticable for reasons to be given. The 1,350 mile oversea flight between the Azores and Newfoundland is shorter than the 1,900 mile Ireland-Newfoundland flight, but the former route is 30 per cent longer than the latter and will be seen to possess little if any advantage from a weather standpoint. Any advantage possessed by the Madeira route is more than offset by its much greater length and the long oversea flight, and the Azores-Bermuda route suffers from the same disadvantages to a lesser extent.

Thus, on a basis of overall length, the direct route possesses marked superiority, while its inferiority in respect to length of oversea flight, as compared with two of the routes, is more than offset by its superiority in other important respects.

### THE WEATHER

Comparison of the different routes from the standpoint of weather will be confined to two only, the direct and the southern, by way of the Azores and Bermuda, for the following reasons:

Northern, or Arctic routes, have been flown a number of times (see Fig. 1). From the experience of these flights and other available information, it is concluded that these routes, despite the shortness of the oversea flights, are impracticable for regular commercial operation, certainly, in the near future. The disadvantages of the northern routes were dealt with at some length in a previous paper.[13] Such further information as has become available confirms the original conclusion as to the impracticability of the routes. Briefly summarized, the disadvantages of the routes are:

1. Length. The routes lie far from the great circle connecting the thickly populated industrial regions. They are therefore much longer and the resulting greater time between terminals nullifies the principal advantage of air transport, namely, speed.
2. Lack of meteorological information and services (including ships as a source of weather reports) and of reliable charts and maps.
3. Climatic conditions including radio and magnetic difficulties.[14]
4. Difficulties of terrain.
5. Difficulty and cost of establishing and maintaining the necessary ground facilities.

The principal disadvantage of the extreme southern routes is their great length. While the weather is possibly

[13]Transatlantic Air Transport, The Engineering Journal, June 1935, p. 305.

[14]In addition to those mentioned in the previous paper, these conditions include Arctic fog and ice (Amundsen-Ellsworth-Nobile expedition 1936) frequent fog off east coast of Iceland and off the Labrador coast and summer fog south of Cape Farewell.

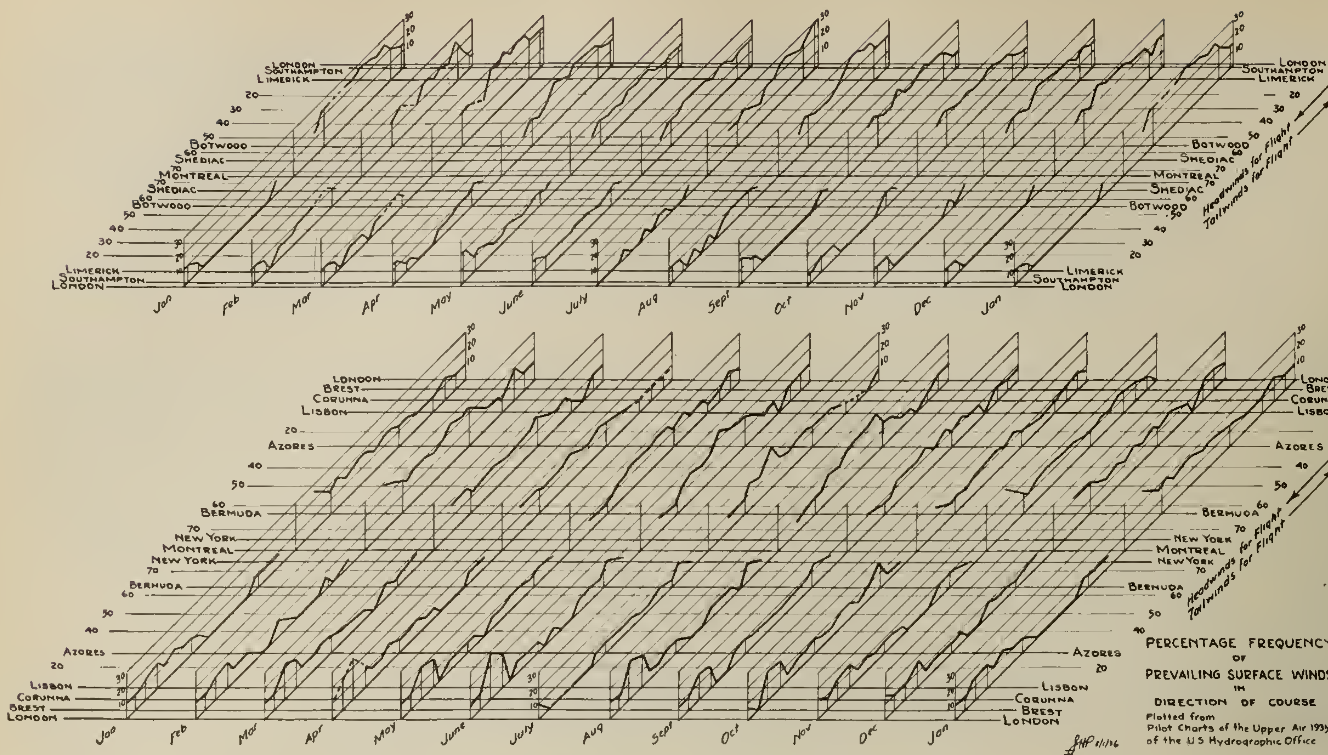

**Fig. 9—Percentage Frequency of Prevailing Surface Winds.**

generally more favourable, there is the hazard of violent tropical storms. These storms are difficult or impossible to predict due to the lack of shipping in and to the south of the region. The length of the oversea flight is generally large.

The route from the Azores direct to New York possesses no advantage from a weather standpoint over the Azores-Bermuda route and the length of the oversea flight is formidable at present. It is somewhat shorter than the Bermuda route, but it is 1,200 miles longer than the direct route. There is the advantage of the presence of shipping since it lies near the steamer lanes.

The one advantage of the Azores-Newfoundland route is the short oversea flight. Otherwise it is long and experiences much the same weather as the direct route. Indeed it traverses the region of greatest fog frequency southeast of Newfoundland (see Fig. 4).

A brief comparison of the weather of the two remaining routes, the direct and the southern by way of the Azores and Bermuda, follows:

*Headwinds*

The strength and frequency of surface head and tail winds for the two routes are plotted in Figs. 8 and 9. Lacking information pertaining to upper air conditions over the Atlantic, the routes must be compared on a basis of surface winds and the known variation with altitude over land.

For the direct route, surface headwinds on the westward flight range from 20 to over 30 m.p.h., with a frequency averaging 20-30 per cent and, on the eastward flight, are, for six months, largely zero and for the remainder of the year average 20 m.p.h., with a frequency of about 20 per cent.

Headwinds average generally over 20 m.p.h., with a frequency of 10-20 per cent on the westbound flight over the whole of the southern route except near Lisbon. Eastbound, the headwinds average 20 m.p.h., with a frequency of about 10 per cent except for sections between longitude 40 and 60 W. where the headwinds drop to zero.

On a basis of upper air observations at American coast stations (see Fig. 11), the westerly winds at 10,000 ft. will range from nearly 40 m.p.h. in winter to about 20 m.p.h. in summer and in frequency from 30-20 per cent. The upper air records for European coast stations are less clear. It appears that, at western stations in England, westerly winds range from 20-25 m.p.h. at 5,000 ft. with frequencies from 40-20 per cent. At the latter stations, easterly winds at altitude are more commonly recorded.

While only direct head and tail winds for the courses have been plotted, the effect of cross winds should not be ignored. A wind from any direction in either quadrant to right or left of the direct head wind and even slightly aft of a direct cross wind, in effect, reduces the distance made good per hour. In a general way, along the ocean section of the direct route, winds from N. to W. to S. predominate in strength and frequency, with west winds generally rather stronger and more frequent than others. Except near the coasts, along the ocean section of the southern route, the strength of the different winds, other than E. and possibly SE., is largely the same, with the frequency higher in the western than in the eastern quadrants.

It should also be remembered that, at altitudes over 12,000 ft., winds probably will range only from NW. to WSW.

As head winds become tail winds for flight in the opposite direction, the disadvantage of the one becomes the advantage of the other. However, tail winds assist less than head winds of equal speed retard flight.

The percentage of calms, light airs and variable winds at the surface (see Fig. 10) averages about 5 per cent for the direct route and 10 per cent for the southern route.

To summarize, on the westward crossing, the head winds encountered are up to 10 m.p.h. stronger and of frequency 10 per cent greater on the direct than on the southern route, but this handicap is experienced for 3,250 miles instead of 5,240 miles (or for 1,870 miles of open sea crossing instead of 3,900 miles from Lisbon to New York).

Eastbound, the average strength of the head winds is about the same for the two routes, but the frequency is less for the southern route. However, the sections experiencing no head winds when eastbound are longer and this condition extends over a greater part of the year on the direct route than on the southern route. Here again the additional 2,000 miles of the southern route must be considered.

In view of the foregoing, the adverse effects of head winds should, on the whole, be more serious for the southern route.

*Storms*

The direct route lies wholly within the region characterized by cyclonic storms (see Fig. 2) and the storm tracks largely follow the route. The occan section of the southern route between Portugal and longitude 20 W. lies wholly outside the cyclonic storm area. The leg between Bermuda and New York crosses the storm corridor up the Atlantic coast. Between longitude 20 and 40 W., the route passes the region subject to occasional but intense tropical storms. Local thunderstorms are also prevalent along the route.

From Fig. 10, it will be apparent that the percentage of days on which winds of gale force and over may be expected ranges, for the direct route, from an average of 1 or 2 per cent in summer, to over 10 per cent in winter, the frequency being highest for the section from the Irish coast to longitude 40 deg. W. where it may reach 15 per cent. The gale frequency is zero for much of the southern route in summer and averages less than 5 per cent in winter. The frequency is highest for the sections in the neighbourhood of longitude 50 deg. W. and of New York and may exceed 10 per cent in these regions.

Thus, along the direct route, the storm frequency is high. Storms are also frequent near the coasts, and particularly the American coast, on the southern route and a section of this route is subject to tropical storms.

The handicap imposed by storms will depend on the height to which they extend. Should cyclonic storms be found to extend no higher than 10-12,000 ft., the handicap will not be serious.

*Visibility*

*Fogs*—Figure 12 clearly indicates that fogs are much more prevalent along the direct route than along the southern in spite of the fact that the route passes to the north of the worst fog area (Fig. 4). The southern route is practically free of fog except near the coasts. In the vicinity of New York, fog frequency may be as high as 20 per cent and the Corunna-Brest-London section, particularly the northern portion, is foggy.

The fogs off Newfoundland are dense and frequent, but seldom, even in the south, surmount the cliffs of the shore and are rarely carried inland. There is often a narrow channel of clear water between the fog bank and the shore. Further north, except in the Strait of Belle Isle, fogs, from a navigation standpoint, are no more serious than in other regions.

Lighthouse records show that fogs are frequent on the east and south coasts of Newfoundland, particularly to the southeast, but the frequency never exceeds 35 per cent and is generally much less (see Appendix VI, Table IIa). The west coast is relatively free of fog. The maximum frequency at points on the west coast may be as low as 2 per cent for the worst month. Sunshine is said to be above the average in Newfoundland and precipitation not large and, while reports conflict as to the degree of prevalence of fog, the foregoing records support the conclusion that there are many fog free areas on the west coast and probably in the interior.

Records (see Appendix VI, Table I) indicate that the frequency of fogs in the St. Lawrence valley is small and less than in the region around New York and portions of the European coast area traversed by the southern route.

As the graphs indicate, little actual fog forms at the Azores. However, strato-cumulus clouds often descend and

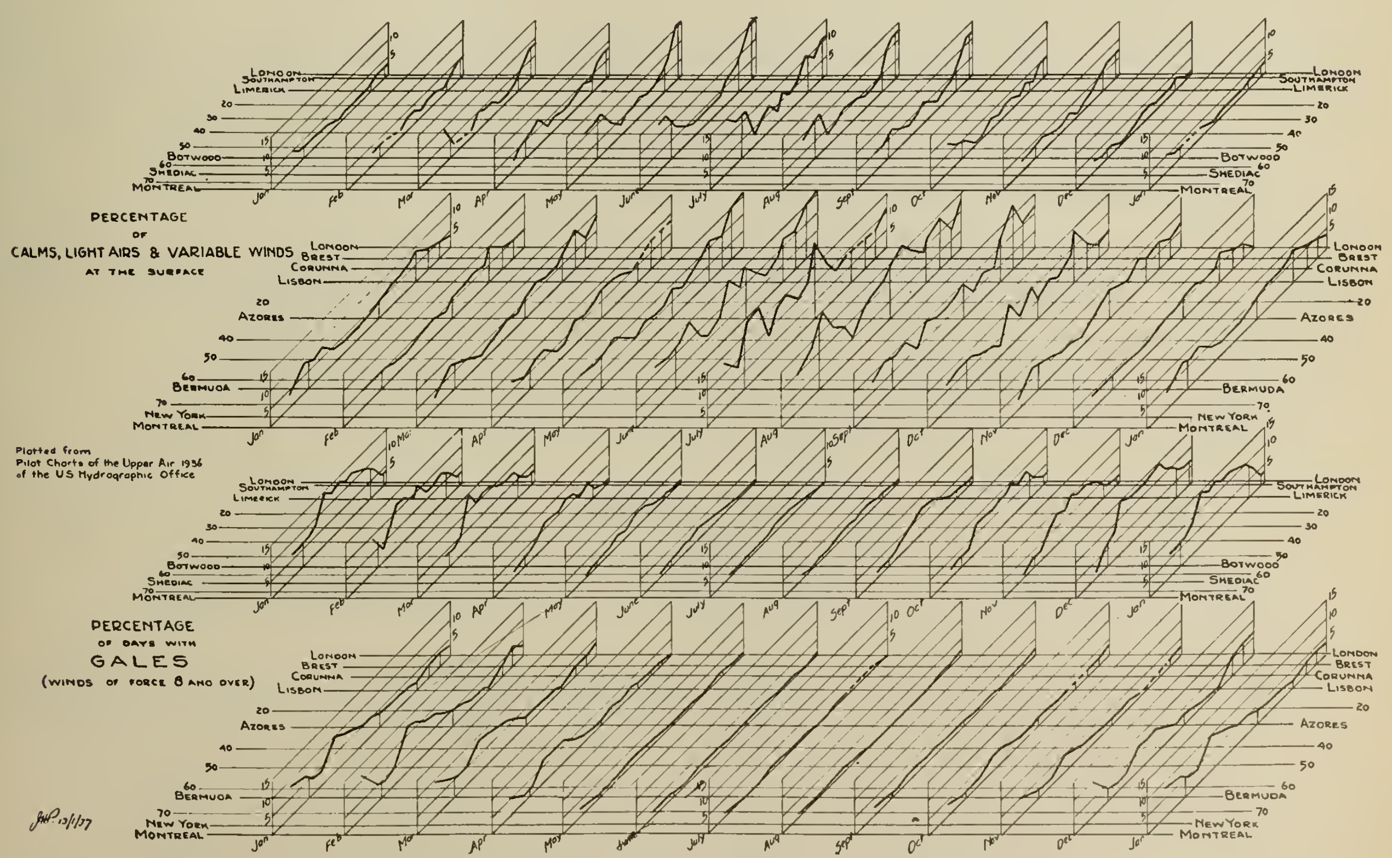

Fig. 10—Percentage of Calms, Light Airs, Variable Winds and Gales.

cover the entire mountainous parts of the islands, rendering them invisible from outside, and even descend to sea level. This occurs principally in June and represents the only lasting "fogs" of the Azores.[15]

*Clouds*—While the region traversed by the direct route is more generally overcast than that of the southern route, the handicap which this greater cloudiness may impose on the direct route will depend upon the height to which the clouds extend and the efficiency of the blind flying equipment.

*Temperatures*

Sea and air surface temperatures along the ocean sections of the two routes throughout the year are plotted in Fig. 12. Generally, sea and air temperatures show the same variations. Air temperatures are higher in summer and lower in winter than sea temperatures for the direct route and are generally lower for the southern route except during May, June and July. Along the direct route, the air temperatures increase from west to east by as much as 10 deg. in winter and 5 deg. in summer. On the southern route, the maximum air temperatures are in the region of longitude 40 deg. W. with a slight gradient to the European coast and Bermuda. A steep gradient of as much as 10 deg. in winter occurs between Bermuda and New York.

For the direct route, temperatures average over 50 deg. in summer and under 40 deg. in winter and, along the southern route, the corresponding average temperatures are nearly 70 and about 50 deg.

[15]According to Director of Meteorological Service of the Azores at Angra.

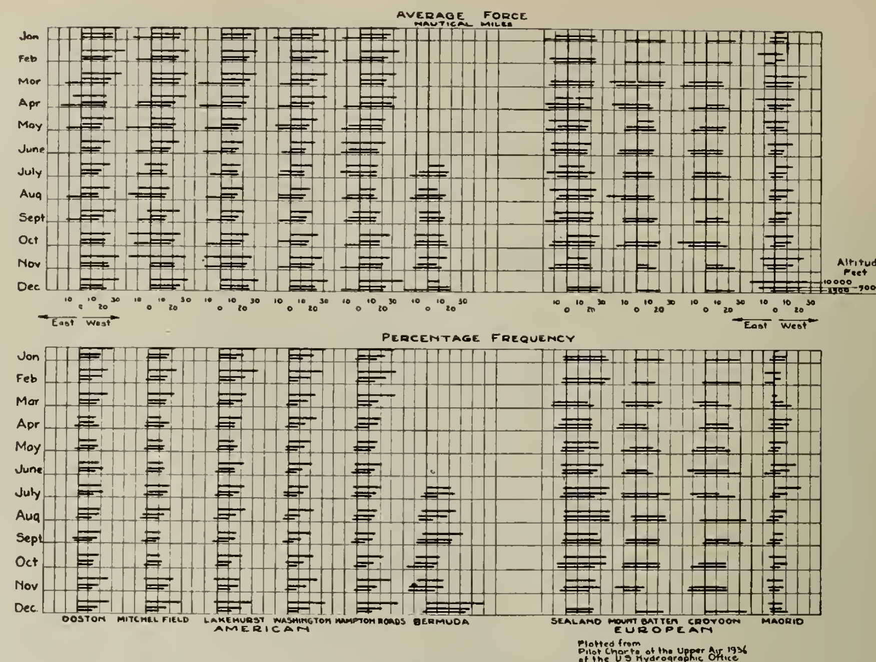

**Fig. 11—Variation of East-West Winds with Altitude.**

*Weather Information*

Reports from ships at sea on the regular steamer lanes to the south of the route and from Canadian and United States stations enable the surface weather along the direct route to be reasonably well forecast, since the weather of this area is generally "made" to the west and south. Numerous reports and hence good coverage results from the density of shipping along the New York-English Channel lanes.

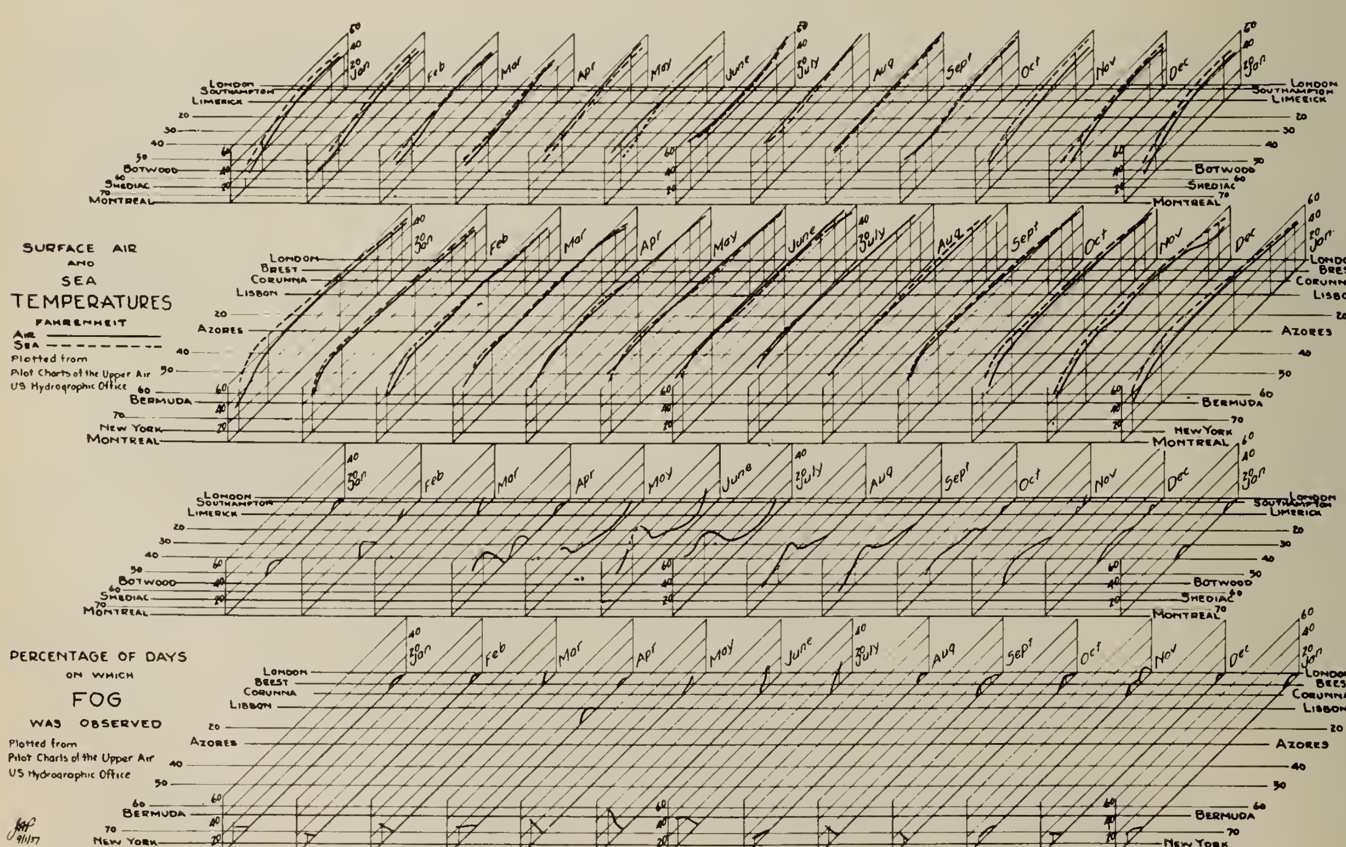

**Fig. 12—Surface Air and Sea Temperatures—Percentage Days with Fog.**

The European coast section of the southern route, the section between the European coast and the Azores, and that between Bermuda and the coast of the United States are satisfactorily served by reports from ships. There is little shipping, however, between Bermuda and the Azores and still less south of this line and it is in this region that the tropical cyclones originate. Forecasting for this section, nearly 50 per cent of the whole route, is therefore unsatisfactory.

*Summary*

On the whole, it is concluded from the foregoing that the southern route, from a weather standpoint, possesses but slight superiority over the direct route. Because of the improvement in blind flying and landing equipment, services and technique, lack of visibility due to fog and cloud is no longer a serious handicap and blind flying is inevitable in the operation of a regular and frequent service. It is not improbable that, in the near future, if not now, fog will be of less menace to aircraft than to ships. Also, the real meteorological hazard, that due to the formation of atmospheric ice, while it may be found to be more frequent on the direct route, has already been encountered in the south.

### Terrain

The southern route is based on the Azores and Bermuda, the former about 850 miles off Portugal and the latter nearly 700 miles from the North American coast.

The Azores, or Western Isles, belonging to Portugal, are (see Fig. 13) a scattered archipelago of some nine small mountainous islands which rise sharply from their scree covered shores. The volcanic peak of Pico, rising to 7,821 feet, is the highest. There is said to be no suitable base for flying boats in the islands. Of the three principal ports, Angra, Ponta Delgada and Horta, the latter is the only one worth considering for aircraft and its effective size is smaller than charts indicate, due to silting.[16] While adequate for ordinary landings, a long take-off run would extend out into the open sea. Considerable expenditure would be necessary to make it a good harbour. Some dredging was

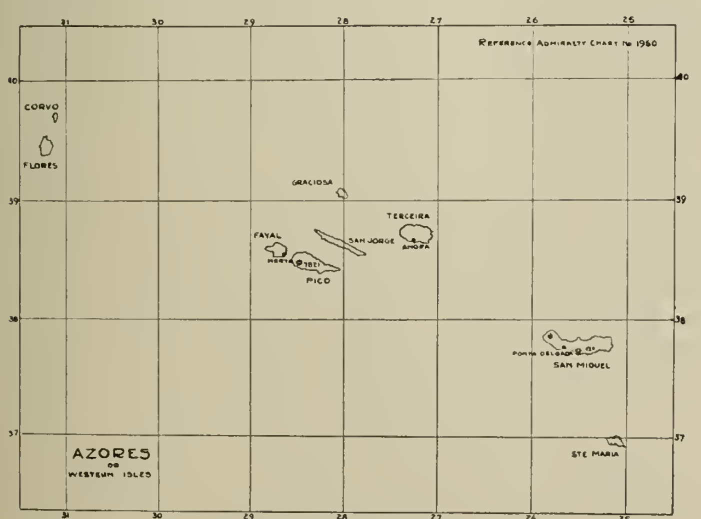

**Fig. 13—The Azores.**

recently done. The inland lakes, surrounded by mountains, are unsuitable for use by large flying boats. The largest lake, Sete Cidades, on San Miguel, the crater of an extinct volcano, is some 10 miles in circumference, and of irregular shape. There is a small landing field on a plateau on the island of Terceira and it was recently reported that the

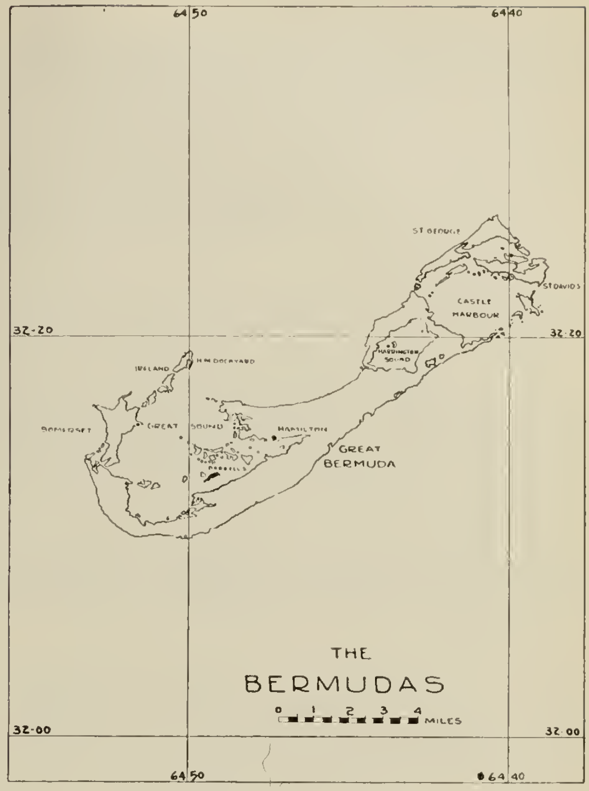

**Fig. 14—The Bermudas.**

French had selected this site as capable of enlargement, at small cost, into an aerodrome for a transatlantic service.

Because of their exposed position, winds from the W. and SW. render navigation dangerous about the islands. Intense squalls in the vicinity frequently cause tide races, the "houle," to sweep about the islands. Under these circumstances, in spite of the fact that the sea is quite calm during part of the year, lacking harbours, the alighting and take-off of large seaplanes would often be hazardous and regularity of services difficult to maintain.

The Bermudas (Fig. 14) comprise a compact group of some 150 sandstone and coral islands, mostly small islets, on a submarine bank and surrounded by a reef of coral covered sandstone. The sandstone of the islands forms irregular hills, some 200 to 250 ft. in height. The group is some 15 miles long and 5 miles in extreme width and encloses several large and well protected harbours. Darrell's island in the Great Sound is being equipped as a base for a Bermuda-New York air service.

The Bermudas are a British possession and the site of a naval station.

In Europe, the southern route, using the stages London-Brest-Corunna-Lisbon involves landings in French, Spanish, and Portuguese territory and, in America, a landing in and flight over United States territory.

The direct route will use bases in Ireland and Newfoundland. Among the many fine natural harbours of Ireland, there are several well suited for air bases. The north and west coasts are high and rocky—those of the east and south less so. The more mountainous areas are in the north and south and the central plain extends, in places, to the east and west coasts.

Promising sites for combined sea and land bases appear to include (see Fig. 15), on the north coast, Lough Foyle, near Londonderry (used by the Italian flight in 1933), on the west coast, Galway Bay and the estuary of the Shannon, and Cork Harbour on the south coast.

---

[16]The Lockheed Sirius of Colonel Lindbergh was unable to take off here, fully loaded, in November 1933. It was used by the Italian flight on the return from Chicago in the same year.

There are high hills (2,000 ft.) west of Lough Foyle. Between Galway Bay and the Shannon estuary, the country is relatively low, few peaks exceeding 1,000 ft. and there is a large percentage of low land. The excellence of Cork Harbour is well known. There is much sheltered water in the reaches of the harbour and many sites suitable for the construction of airports. The surrounding country is low, but the highest hills in Ireland (3,500 ft.) lie between Cork and the west coast. As indicated in the previous paper already referred to, Galway Bay and the Shannon estuary appear most suitable.

The rugged and rocky coast of Newfoundland, with high and perpendicular cliffs in most places and deep water to the edges, is heavily indented (see Fig. 5). There are many large bays and numerous islands, especially on the east and south coasts. The hills are mainly near the coasts and average 1,500 ft. in height. The highest mountains are in a range extending some 200 miles along the northwest coast and rise to over 2,200 ft. almost directly from the sea.

The interior is mainly undulating, much of it heavily wooded, in which there are innumerable lakes and rivers.

In view of the foregoing, it should not be as difficult, as is often assumed, to find ice and fog free harbours suitable for marine bases, or quite satisfactory airport sites in the interior.

From the standpoint of intermediate bases, the southern route is handicapped by the conditions in the Azores, on which the route is dependent, while in Ireland and Newfoundland, on the other hand, there are numerous suitable sites for intermediate bases for the direct route.

### The Better Route

It is concluded from the foregoing brief comparison of the two routes on a basis of length, weather and terrain, that, while some advantage rests with the southern route from the standpoint of weather, the advantage is insufficient to compensate for its much greater overall length, the greater length of oversea flight and the difficulty respecting provision of a suitable base in the Azores and hence, on the whole, the direct route is the better.

**Fig. 15—Ireland.**

It has been suggested that the direct route should be used in summer and the southern route in winter. Admittedly, the climatic conditions are, in some respects, more severe over the former in winter, but here again the decision is the fundamental one as between weather and length and terrain. In the author's opinion, the direct route is superior, even for winter operation.

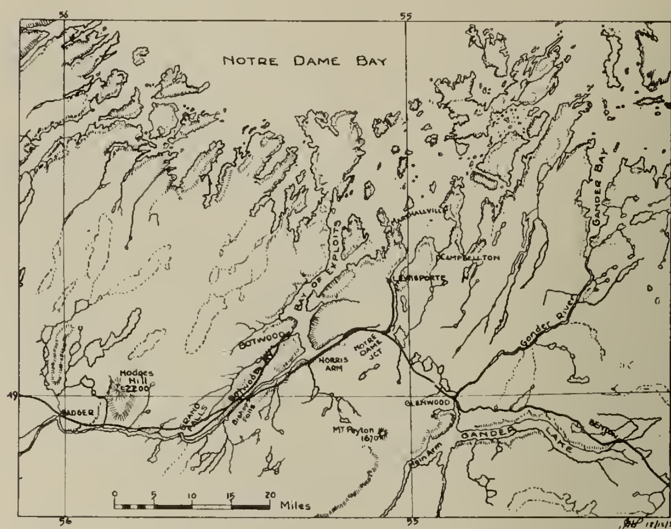

**Fig. 16—Botwood and Vicinity.**

The trans-atlantic service between London and Montreal will be an important part of the network of airlines connecting the various units of the British Empire and, as part of the Empire network, the desirability that the service should be "all-red" is obvious.

## ORGANIZATION OF THE DIRECT ROUTE

### Selection of Intermediate Refueling Bases

Until experience has indicated the most suitable type of aircraft for the service, provision should be made for both landplanes and seaplanes at the terminals and intermediate stations. There is also the possibility that aircraft of both types may continue to be used in the service.

The selection of the particular route to be followed, within the zone of the great circle and of the intermediate stations between terminals, is governed by many factors. Initially, to shorten as much as possible the oversea flight, refueling stations should be established as near as practicable to the west coast of Ireland and east coast of Newfoundland. Nature of terrain, such as adequate area of level ground, sufficient expanse of ice-free sheltered water, low-lying surrounding country, together with the usual requirements as to nature of soil, drainage, access (railroad facilities) must be considered.

Careful consideration has also to be given to meteorological conditions and, from this point of view, fog and ice conditions are important. Ice-free water is necessary for year-round operation of seaplanes and, in Newfoundland, this probably eliminates the use of lakes in the interior.

The relation of the proposed route to existing or projected air services and to other transportation systems must receive attention.

It is obvious that the particular route and sites of stations can only be decided upon after detailed information concerning these various factors has been secured and studied and with full knowledge of the relative importance of the different economic and political considerations involved.

As previously indicated, the reported route of the service planned for inauguration in 1937 is London-Southampton - (Portsmouth) - Limerick - Botwood - Shediac(?) - Montreal.

Portsmouth is contemplated as the marine terminus of the main Empire Air Routes. Temporarily, Hythe or Southampton Water, where slipway and hangar facilities exist, is in use (December, 1936) as a flying boat base for the India service and will be used for the Atlantic service. Langstone Harbour, adjacent to Portsmouth, will probably be made the permanent base. It is said to be fog-free and, by means of barrages across the entrance, or by dredging channels, an excellent marine base can be provided and there are suitable areas available for an aerodrome. A railroad runs close by and the site is close to Southampton, with its many facilities and rail connections to London.

The site of the combined marine and land base, to be named Kilconry, reported being prepared in Ireland, is at Rynanna Point, in County Clare, at the junction of the River Fergus with the Shannon, about halfway between Limerick and the coast. The Shannon is here some eight miles wide and the surrounding land is flat. A temporary base will be at Foynes, County Limerick, on the south shore of the Shannon and permanent wireless stations will be located in the village and on Foynes island in the river.

In Newfoundland, based on the results of special meteorological investigations, both surface and upper air, carried on since 1934, two sites have been selected and are in preparation. Port Botwood, a port near the mouth of the Exploits river (see Fig. 16), chosen as the marine base, is now used for the shipment of pulp and paper and is connected by a branch railroad with the mills at Grand Falls and the main line of the narrow gauge Newfoundland railroad. The river at Botwood is about a mile wide and the harbour is reported to be fog-free and satisfactory for flying boats.[17]

As the topography of the surrounding country is not suitable for the construction of an aerodrome, the site selected for the Newfoundland airport is at Hatties Camp, north of Gander Lake and south of the railroad, some 42 miles east of Botwood and about 30 miles from the east coast where an ample area is available, requiring little levelling and with good drainage. The elevation is 500 ft. above sea level. Clearing and grading started in 1936. Four concrete and tar macadam runways, intersecting at 45 deg., are to be constructed, each 1,500 by 200 yd., and with a load capacity of 5 tons per sq. ft. The main runway, equipped for blind landings, runs NE.-SW. and is to be 1,600 by 400 yd.

In Canada, there are several possible sites for the terminal of the route from Newfoundland, including Shediac, Moncton and Saint John in New Brunswick and Sydney or Louisburg in Nova Scotia. Although no decision will likely be made until after trial flights, Shediac appears to be the preferable site. It possesses adequate facilities for manoeuvering large flying boats and is close to Moncton (which lacks such facilities), on the trans-Canada airway. Shediac was used by the Italian flight in 1933.

### The Fuel Load Handicap in Long Range Flight

Unlike other means of transport, the engines of heavier-than-air aircraft must not only supply the power for propulsion, but also for the support of the aircraft and its load. In consequence, the horsepower required and the fuel consumption are higher for a given payload than for transport in which the weight is supported directly by the earth or by displacement.

The limitation imposed on the payload by the large load of fuel that must be carried for the transatlantic flight is illustrated by the figures of Table III derived from a simple approximate calculation. The magnitute of the necessary fuel load, the possible payload (neglecting weight of crew, etc.) and the influence thereon of structural weight, power loading and cruising speed are shown.

Table III

Payload Capacity

Assumptions:—Distance 1,800 miles, 30 m.p.h., head wind, cruising power 2/3 rated power, cruising fuel consumption 0.6 lb. per hp. per hr.
*W* = gross weight of aircraft.

| | Weight ratio*—1.75 | | | Weight ratio*—2.00 | | | Weight ratio*—2.25 | | |

| 150 | 0.60*W* | 0.40*W* | 0 30*W* | 0.60*W* | 0.40*W* | 0.30*W* | 0.80*W* | 0.40*W* | 0.30*W* |
| 180 | 0.48*W* | 0.32*W* | 0.24*W* | 0.48*W* | 0.32*W* | 0.24*W* | 0.48*W* | 0.32*W* | 0.24*W* |
| **Pay Load Carried—Pounds** | | | | | | | | | |
| 120 | 0 | 0 | 0.03*W* | 0 | 0 | 0.10*W* | 0 | 0.02*W* | 0.15*W* |
| 150 | 0 | 0.03*W* | 0.13*W* | 0 | 0.10*W* | 0.20*W* | 0 | 0.15*W* | 0.25*W* |
| 180 | 0 | 0.11*W* | 0.19*W* | 0.02*W* | 0.18*W* | 0.26*W* | 0.07*W* | 0.24*W* | 0.32*W* |
| **Pay Load Carried—Pounds per Horsepower** | | | | | | | | | |
| 120 | 0 | ·0 | 0.6 | 0 | 0 | 2.0 | 0 | 0.3 | 3.1 |
| 150 | 0 | 0.5 | 2.5 | 0 | 1.5 | 4.0 | 0 | 2.3 | 5.1 |
| 180 | 0 | 1.7 | 3.8 | 0.2 | 2.7 | 5.2 | 0.7 | 3.6 | 6.4 |

$$\text{*Weight ratio} = \frac{\text{gross weight}}{\text{net weight}} \qquad \text{†Power loading} = \frac{\text{gross weight}}{\text{total rated power}}$$

With an aircraft of normal design, in which, for a long non-stop flight, the weight of fuel leaves a very small part of the disposable load available for pay load, the desired pay load capacity can be attained, within certain limits, by increasing the size of the aircraft until the fraction of the disposable load available equals the desired pay load. This procedure is obviously uneconomical. The alternatives are mid-ocean refueling, fueling in the air or a resort to some form of assisted launching.

### Mid-Ocean Refueling

Evidently, if satisfactory refueling facilities could be provided at one or more points in mid-ocean, the fuel load carried could be reduced and the pay load correspondingly increased. Two alternative proposals for mid-ocean refueling have been made, one by the use of ships and the other by the provision of floating islands.

The Deutsche Luft Hansa has employed "depot ships" on the South Atlantic section of its air mail service to South America since 1934 and in the summer of 1936 employed one of these ships in trial flights across the North Atlantic by way of the Azores.

The depot ships of the D.L.H.[18] are each equipped with a compressed air catapult for launching flying boats, a rotating and folding electric crane for lifting the aircraft on board or on the catapult and a trailing apron or "stau-segel" for facilitating the hoisting of aircraft on board in rough weather. The ships also have very complete radio and meteorological equipment.

The depot ship was originally employed as a refueling station in mid-ocean. More recently, having improved the range of the aircraft, the ships have been used for launching the aircraft at each end of the oversea stage. As a refueling station, the aircraft flew to the ship, alighted on the sea,

[17]Colonel Lindbergh refueled his Lockheed Sirius here in 1933.

[18]Details of the depot ships and of the South Atlantic service are given in Appendix VII.

was hoisted aboard, refueled and serviced and launched by catapult for the second stage of the crossing.

The depot ship is mobile, permitting the route to be changed at will, as, for instance, from the direct in summer to the southern in winter. If the aircraft is forced down within reasonable distance (and in fair weather), the ship can proceed to its assistance. The cost of the ship is low, as compared with that of a floating island.

However, as a permanent refueling station, in mid-ocean on a schedule service by the direct route, the depot ship is considered impracticable because of the frequency of gales on the North Atlantic which would render disastrous the alighting of aircraft on the sea.

On the other hand, as a temporary expedient during the initial operation of the service, to serve as a beacon ship and meteorological station, the depot ship possesses attractive possibilities.

Floating islands to serve as refueling stations in mid-ocean have been projected from time to time. Most such schemes were, to use M. Bleriot's description "a little fantastic."

The design to which most careful study and tests have been devoted and which appears the most promising technically is the so-called Armstrong Seadrome, as described in Appendix VIII.

The seadrome is a floating structure, embodying an unobstructed flying deck, with hangar, shop, radio and meteorological facilities and accommodation for crew and passengers. Its design is such that it is claimed to be unaffected by wave action. It is retained in place by special anchoring arrangements.

To provide a flight deck of adequate size for modern high speed, heavily loaded aircraft, the structure must be large and, while possibly technically feasible, the cost will be high and the financial burden on the service excessive.

From the point of view of the direct route, the fundamental obstacle to the use of the seadrome is, that owing to the surface climatic conditions—gales and fog—landing on the restricted deck would be hazardous and often impossible.

It is concluded that the provision of mid-ocean refueling stations on the direct transatlantic route is impracticable.

### Fueling in Flight after Take-Off

By having the aircraft take off and climb to its operational height, without its fuel load, and there supplied from another aircraft with the fuel for the journey, the take-off handicap would be overcome.

Many tests of methods of fueling in flight have been made and endurance records have been established by means of numerous refuelings in the air. The operation is, however, one that so far has only been performed in fair weather. In its present stage of development, it is not considered suitable for use in a regular commercial service, the schedule of which must be maintained irrespective of weather conditions.

### Take-Off Conditions

The take-off speed and the landing speed may be taken as roughly equal to the stalling speed of the complete aircraft. The latter depends on the maximum lift coefficient of the wing, the air density (altitude of the landing point) and the wing loading. The maximum lift coefficient may be increased by such lift increasing devices as slots and flaps and with good control at low speeds, the landing speed, and to a less extent, the take-off speed, can be correspondingly decreased.

Actual take-off speeds may be 10 per cent higher than minimum flying speeds, to provide a reserve of lift at take-off. At the same time, "ground effect" reduces the landing and take-off speeds.

The power required for take-off is greater than for normal flight. For take-off under full load, in a reasonable distance or time, the maximum permissible take-off power of the engines is usually employed, while for cruising in level flight the engines are throttled to cruising power for which the fuel consumption is a minimum. As the maximum take-off power of the engines may be 110-125 per cent and the cruising power about 66⅔ to 75 per cent of rated power, it is evident that the power used for take-off is about twice that for cruising.

With an unlimited take-off run or time, the take-off power would of course be less.

Additional power over that for cruising is also required for climbing, but this need not be large if there are no high obstacles to be cleared in the vicinity of the stations.

A further consideration is that a margin of power over that required for cruising is necessary to enable the aircraft to remain in flight in the event of failure of one or more engines and to permit the engines to operate at reduced power for low fuel consumption and wear on engine.

The approximate analyses of take-off conditions given in Appendix IX indicates, in a general way, the factors affecting take-off and their relative importance.

### Assisted Launching

With assisted launching, by catapult or otherwise, the aircraft for a given long range service will be smaller and of lower power since it can be designed specifically for cruising conditions with very high wing loading and a cruising speed approximating that for maximum aerodynamic efficiency. It is seen, for instance, from the graphs of Fig. 24, that, for a cruising speed of say 160 m.p.h., the pounds of gross weight carried per horsepower at different wing loadings are as follows:

| | | | |
|---|---|---|---|
| Wing loading | 18 | 28.6 | 40 |
| Pounds per horsepower | 15.0 | 21.1 | 26.5 |

The saving in power and consequent fuel consumption thus affected can be used to increase the payload, the range, or both together, or the original power can be used to carry the same load at a higher speed. In this way, long range and large payload can be combined in the same aircraft.

Assisted launching of heavily loaded aircraft is subject to the condition that a large part of the load must be of a consumable or readily dischargeable nature, in order that the landing speed at the end of the flight may not be excessive and that, in an emergency, a safe landing may be made by jettisoning part of the load.

Even with normal aircraft of high wing loading, able to take off unassisted under prescribed airworthiness requirements, the landing speed may exceed safe limits and require jettisoning of fuel if an emergency develops immediately after take-off.[19] For this reason, one noted designer of flying boats has proposed that aircraft should be licensed for a higher load for take-off than for landing.

In the case of marine aircraft, the displacement of the flotation gear will be that required for conditions at the end of the flight and the hull or floats can therefore be smaller, weigh less and have less drag than that necessary for unassisted take-off.

### Catapulting

The launching of aircraft by catapulting is of course not new, since a simple device of this kind was used by the Wright brothers and the system employed in launching gliders is of the same kind.

Naval vessels have long been equipped with aircraft catapults and, as already mentioned, catapults have been employed on liners for launching aircraft in connection with ship-shore air mail services.

It is indicated in Appendix VII that the catapult equipped Deutsche Luft Hansa depot ships now function

[19]Such a situation has occurred on at least one occasion in the case of an aircraft of the type on which the curves of Fig. 24 were based.

as launching stations in the South Atlantic service. From the German standpoint, lacking shore bases, the mobility of the ship is an important consideration. For the operation of a North Atlantic service over the direct route in summer and the southern route in winter, this mobility would also be advantageous, obviating the necessity of duplicate shore launching stations. Further, the use of the depot ship would satisfactorily overcome many of the difficulties arising from conditions in the Azores. But, with a permanent route and fixed stations, the mobility of the depot ship is not necessary.

However, the many catapult launchings that have been made on the D.L.H. South American service without an accident, insofar as is known, do prove that this method of launching heavily loaded aircraft can be safe, reliable and generally satisfactory on a transoceanic air mail service.

The launching of commercial aircraft by means of long run catapults of the car and track type was suggested to the author by Mr. D. S. Atkinson, in January 1935. Similar suggestions have since appeared in the technical press and it is reported that the use of catapults is receiving consideration for the transatlantic service planned for 1937.

The proposal, which is dealt with in some detail in Appendix X, is briefly as follows. The launching runway is a length of track about one-half mile long, laid on land in the direction of the prevailing wind. If for marine aircraft, the track is laid on or near the shore. The car is driven by cable from a fixed prime mover, Diesel or gasoline engines on the car, or by aircraft engines and airscrews. The aircraft cradle is so arranged as to permit the aircraft to align itself with the relative wind. The attachment of the aircraft to the cradle is such that, on attaining a speed in excess of the minimum flying speed, acceleration is reduced to zero and the car speed held constant until the pilot signals and releases the lock. The car then begins to decelerate and the aircraft flies off. After the launch, the car is brought to a stop under the control of the operator.

*Launching from an Aircraft in Flight*

Many years ago, a glider was dropped from a balloon[20] and more recently aeroplanes have been launched from rigid dirigibles. At the present time, two aircraft are nearing completion which are intended to be used in combination, one being launched from the other.

In this so-called composite aircraft, proposed by Major R. H. Mayo, the two aircraft combined function as a single unit for the take-off and later, at altitude, the one serves virtually as a catapult for launching the other. While the detailed arrangement may be varied to suit different conditions, in the composite aircraft under construction, the upper component to be launched is a high performance, heavily loaded seaplane, mounted on top of the lower component or carrier aircraft, a lightly loaded flying boat of more or less normal design. Locked together, the characteristics of the combination are such that the stalling speed is low and a satisfactory take-off, together with good climb, are possible.

The patents associated with the proposal cover principally the method of effecting separation of the components through the medium of aerodynamic forces. Apparently the aerodynamic characteristics of the wings of the two components differ, due either to a use of different basic sections or to the use of slots and flaps and are so chosen as to ensure the upper component carrying a larger and larger share of the combined weight as the speed increases until at launching speed the upper component is lifting more than its own weight so that when released the two components separate. It is understood that the patents also cover separation through the increasing of the incidence of the upper component during flight.

Apparently during take-off all control rests with the pilot of the lower component, the controls of the upper component being locked in neutral and the pilot virtually a passenger. On reaching the proper height, reported to be 10,000 ft., the aircraft levels off and accelerates to a speed well above the stalling speed of the upper component. At this speed (over 100 m.p.h.) the lower pilot signals his colleague, releases one part of a dual device locking the components together and relinquishes control. The upper pilot assumes control, releases a second part of the locking device and, on the machine reaching a speed corresponding to a predetermined separating force, the locking device automatically releases and permits the components to separate.

After the launch, the service aircraft proceeds on its flight and the carrier returns to its base.

It is obvious that the safety of the launch will depend on excellent co-ordination of controls and infallible working of the locking device and severance of all connections on separation. Further, the stability of the composite aircraft on the water, taking-off and in flight, and of the components during separation will require careful study.

The few constructional and performance particulars of the composite aircraft so far made public, are listed in Appendix XI.

*The Composite Aircraft vs Catapult Launching*

As compared with the fixed catapult, the following advantages have been claimed for the composite aircraft:

1. *Lower Cost*—The lower component now under construction is reported to be a four-engine boat similar to the Empire boats. While its cost is not known, it is probably not less than the reported cost of the Sikorsky S-42 flying boats, namely $250,000, and a conservative estimate of the cost of the lower component would be $150,000. It is difficult to conceive of a mile long track and launching car and necessary land costing this much.

   The cost of the upper component will be little, if any less, than that of the similar aircraft for catapult launching.

2. *Greater Mobility*—For operation of an air service over a permanent route with fixed bases, mobility is of no advantage.

   For military and naval use, mobility would be distinctly advantageous.

3. *Elimination of Risk Attendant on Launching at Low Height*—Admittedly, this hazard is present with catapult launching, but its magnitude has been exaggerated. With multi-engined aircraft, the danger of all engines cutting out, particularly immediately after launching, when they are presumably in the best of condition, is remote. As indicated in Fig. 28, an aircraft is easily capable of maintaining level flight and climb with a wing loading 40 per cent greater than normal on three out of four engines operating at 75 per cent power.

   With a car and track launching gear, the catapulting speed can be made considerably higher than the stalling speed of the aircraft and, if the latter is held to the car until this speed, on release it will immediately climb.

   Also, the Deutsche Luft Hansa has proved, in three years of regular use on the South Atlantic under much more difficult conditions than those which will obtain in a long-run fixed catapult, that launching by catapult is safe and reliable in commercial service. It remains to be seen whether the separation of the components of the composite aircraft can be as safely effected in flight and at high altitudes.

[20]Montgomery glider dropped from hot air balloon at 4,000 ft. in California, April 1905.

4. *Permits the Use of Fixed Pitch Airscrews*—For unassisted take-off of aircraft with high wing loading and fully supercharged engines, variable pitch airscrews are essential. With the composite aircraft, the heavily loaded upper component, being relieved of most of the burden of take-off, can be fitted with a fixed pitch airscrew, designed for cruising condition, with less sacrifice of efficiency during take-off. There is therefore a saving in weight and cost.
5. *The Aircraft can be Launched at Higher Speed*—A long-run catapult of the type mentioned can launch an aircraft at quite as high a speed for the same expenditure of effort. For the land catapult considered in Appendix X, the maximum power for the car is seen to be from 2,000 to 3,500 hp. for launching a 25-ton aircraft at 100 m.p.h., compared with a reported power of about 3,500 hp. for the carrier component of the composite aircraft to launch a much lighter aircraft at the same speed.
6. *Reduced Cost of Operation and Maintenance*—It is difficult to see wherein these costs will be less than for a long-run catapult. The same handling will be involved in placing the service aeroplane on the car or carrier aircraft and the cost of operation of the carrier may easily exceed that of the car. The economy of the two service aircraft should not be greatly different if a low rate of climb is permissible for the catapult aircraft. In the case of a marine carrier component, depreciation and maintenance will likely be higher than for the catapult.
7. *Ability to Use Small Aerodromes and Harbours*—It is considered that, in this respect, the advantage would rest with the catapult rather than with the composite aircraft. In any case, for operation over a permanent route, such as the one under consideration, with well selected bases, there should be no necessity to use unduly restricted take-off areas.
8. *Ease of Take-Off—Permits Night Take-Off with Safety*—This advantage applies with equal, if not greater force, to catapult launching, since, with the latter, the car runs on fixed rails and launching from a car should be easier than from another aircraft in flight.

   Blind take-off, under condition of poor visibility, in fog or rain or at night, is part of the regular routine in the D.L.H. service using catapults. Such take-off should therefore be relatively simple and straightforward with larger shore catapults.

   It is clear from the foregoing that the assisted launching of aircraft by means of the composite aircraft possesses, for commercial operation over a permanent route, only the one advantage—that of launching at height—and that this advantage is offset by advantages possessed by the fixed long-run land catapult.

   The economic advantages to be derived therefrom justify the provision of equipment for launching aircraft on the transatlantic service and, from the foregoing, it is concluded that the most promising means of launching is the fixed long-run shore catapult.

### Meteorological Service

An efficient meteorological service for the collection of weather reports and the preparation of forecasts is one of the most vital elements of the ground organization of a transatlantic route.

The service should be equipped and organized to provide the pilot at take-off with a detailed weather forecast for the flight. This forecast should be as complete as possible, not only with respect to surface conditions, but also, insofar as existing knowledge permits, with respect to upper air conditions.

It is reported that the meteorological work on the western side of the Atlantic, for the proposed air service, was undertaken by Canada in 1935 and that the organization of the work is now actively proceeding.

The forecasts of the Meteorological Service of Canada[21] are prepared twice daily, at 8.00 a.m. and p.m., on weather reports received from some 69 Canadian stations and from 159 in the United States. Reports are also received from 4 stations in Greenland and one in Bermuda, together with about 25 daily reports from Europe. An average of 12 to 16 reports are received from ships on the Atlantic, of which 5 or 6 are between Ireland and Newfoundland.

Recently 2.00 p.m. observations have been received from 34 stations in Canada, 135 in the United States and 6 in Newfoundland, for the preparation of 2.00 p.m. weather maps which are used to correct forecasts.

For adequate forecasting for the transatlantic air service, observation and reporting facilities should be increased in the region between Newfoundland and Bermuda and additional facilities provided in the Ungava peninsula, northern Ontario and the Canadian Northwest. Weather observations are now made in these regions from Dawson, Mayo, Aklavik, Fort Norman, Simpson, Smith, McMurray, Coppermine, Chesterfield Inlet, Nottingham island, Cape Hope's Advance, Resolution Island, Churchill, Moosonee, Chibougamau and Cartwright.

It is essential that the number of upper air observations be increased. At the present time, such observations by balloon are made only at Sable island, Fredericton, Clarke City, Dolbeau, Moosonee, Toronto (also by aircraft, to 10-12,000 ft.), Winnipeg, Vancouver and Victoria. Reports of aeroplane observations are received daily from a maximum of 22 upper air stations and of pilot balloon observations from 50 stations, in the United States.

Regular aviation forecasts by the Canadian service are now confined to those for the Montreal-Rimouski, Montreal-Albany, Montreal-Ottawa and the north shore of the St. Lawrence, Rimouski-Harrington Harbour services and for the Rouyn area. Pilots on the Montreal-Rimouski service report in detail the weather encountered.

With the inauguration of the trans-Canada air service in the near future, an extensive and frequent aviation forecasting service will necessarily be organized which will be exceedingly useful in connection with the transatlantic service.

Additional weather reporting facilities, particularly respecting upper air conditions, will be required at the European end of the route. A special forecasting station is being established at the Foynes base in Ireland.

There is a fully equipped meteorological station and forecasting centre at Bermuda at which pilot balloon observations are regularly made. It is being prepared for service in connection with Atlantic air routes.

Since 1934, upper air conditions over Newfoundland and the Gulf of St. Lawrence have been studied at meteorological stations and by means of aircraft. There are now operating, nine stations in Newfoundland. Pilot balloon observations are made from two of these and aeroplane observations at one station. A preliminary analysis of records extending over ten years to determine wind speed and direction was completed in 1936.

Upper air observations should be made, if feasible, by balloon, from transatlantic steamers, preliminary to the establishment of the air service and possibly during the operation of the service. However, knowledge of upper air conditions over the Atlantic will be built up principally on the reports of the crews of aircraft operating the service, when established.

[21]Information kindly furnished by the Director.

A comprehensive weather forecasting system is being arranged, to include the establishment of an extensive network of stations in Newfoundland, for furnishing information to a central forecasting station at Botwood, provision for the training of forecasting personnel and the study of the meteorological problems connected with the operation of the transatlantic service.

With a flight weather forecast, complete in every possible detail, based on the latest weather analysis and using modern forecasting methods, furnished immediately prior to each flight, and with aircraft having a reasonable margin of range over the minimum, rigid adherence to the great circle course will be unnecessary, and the most favourable course and flying levels can be used as was done by Costes and Bellonte on their westward flight and as is being done on the Pacific flights. Not only should the best course and levels to take advantage of favourable and avoid unfavourable winds be worked out in advance, but also all other possible flight details based thereon, such as cruising speeds, engine operation, times, etc.

### Radio Service

The importance of adequate radio services in connection with the operation of a transatlantic air service is obvious. Every effort should be made to provide the most up-to-date and dependable equipment. In addition to equipment of proved efficiency and reliability, provision should be made for service trials of promising new developments.

The function of the radio service will be threefold, namely as a means of communication, as an aid to navigation and as a guide in blind landing.

Two-way communication between aircraft and the route terminals, shore stations and ships at sea is necessary to permit the pilot to secure flight information as to weather ahead and airport conditions, to report his progress and position and weather encountered and to call for help in an emergency.

For this service, there should be provided both short and medium wave equipment for two-way communication, by voice and key, to ensure absolute dependability under all conditions.

Ordinary two-way communication over water, with aircraft equipment is now practicable over distances of 3,000 miles and is possible under certain conditions up to nearly 4,000 miles.

For navigation across the Atlantic and between stations, radio at present will be relied upon primarily to check and supplement navigation by the well tried and proved methods based on celestial observations and dead reckoning, using such new and improved instruments as have been developed for aircraft use.

Radio direction-finding equipment has proved quite accurate, even over long distances, in flight over the South Atlantic and Pacific and indeed it must be largely relied upon for navigation under conditions of poor visibility. For the determining or checking of position and course, dependence will be placed principally on fixes obtained from shore D.F. stations, verified by bearings taken, using direction-finding equipment in the aircraft, on shore stations, steamers or even broadcasting stations.

Long range aviation D.F. equipment now in service is capable of determining bearings within 1° at 250 miles or less and within 3° at ranges from 1,200 to 1,600 miles, at frequencies from 6,000 to 250 kilocycles, and bearings have been obtained at a range of over 2,000 miles. The equipment is relatively free from night effect. A rotatable (and retractable) loop is of course used to permit the taking of bearings without deviating from the course and to permit "homing." Indications are both aural and visual.

While bearings determined at shore D.F. stations are more accurate and will normally be depended upon for fixes, bearings determined with the direction-finding equipment in the aircraft will be found useful and convenient and will doubtless be regularly employed as a matter of routine.

The pilots of the D.L.H. South Atlantic service rely almost wholly on their own bearings taken on the depot ships and shore stations, using medium wave, although the bearings are compared with those obtained by the depot ships.

For the direct transatlantic route to be inaugurated in 1937, large up-to-date D.F. stations are being erected at Foynes, County Limerick and at Ballygirreen, County Clare, in Ireland and at Botwood, Newfoundland. Doubtless other D.F. stations will be provided in Newfoundland and possibly some of the numerous marine D.F. stations of the Department of Transport, along the Atlantic coast and Gulf of St. Lawrence, will be equipped to serve as D.F. stations for the transatlantic service.

Guidance in blind landing is the third duty of radio in the operation of a scheduled commercial air service. The aircraft, having been navigated by means of one or all of the three available methods to within 100-200 miles of the terminal, then picks up the beam from a radio beacon and follows it in. When 10-15 miles from the beacon, the ultra short wave (about 9 m.) fan-shaped landing beam is picked up and followed, passing, at between 1 and 2 miles from the landing area and at about 2,000 ft. altitude, the vertical conical beam of the first marker beacon. Following the curved lower fringe of the landing beam, the second marker beam is passed about 300 yards from the boundary. Continuing to follow the fringe of the beam, the aircraft is brought within a few feet of and parallel to the surface. By slowly throttling and easing back on the control, the aircraft is put down. Both visual and aural indication is provided.

Insofar as is known, blind landing equipment of this kind has not been used over water. The difficulties involved appear to be mechanical since there is nothing to interfere with the electrical principles involved. The fixing of the small transmitters for the beams and markers, to prevent their disturbance by wave action, to allow for tides and so that they may be out of the way presents difficulties.

Several British, most German and many other European airports are now equipped with one or other of the several types of blind landing equipment, now perfected, and blind landings are made as a matter of routine.

Needless to say, the terminals and stations of the transatlantic route should be so equipped.

In this connection, for use, both for navigation and approach to the airport, the direct reading radio compass, using a cathode ray oscillograph tube as an indicator, is very promising. This compass, invented in Canada in 1924, by Major-General A. G. L. McNaughton and Lieut.-Col. W. Arthur Steel is now undergoing development in the laboratories of the National Research Council. It has been improved by Dr. J. T. Henderson to indicate sense as well as direction of the bearing and the sensitivity of the receiver has been increased. The compass possesses a number of points of superiority, including immunity from noise and interference effects, simplicity of operation, ease of reading and the possibility of securing simultaneous bearings on two or more stations. The compass is to undergo service trials in Canada in 1937.

### AIRCRAFT

Aircraft of the heavier-than-air type differ from all other means of transport in which the weight is supported directly by the ground or through displacement, in one very important particular, namely the variation of power with economic speed. With land transport, the power increases rapidly with speed. Similarly with ships there is a limiting economic speed depending on the size and shape of the hull beyond which there is a prohibitive increase in power. On the other hand, there is for every aeroplane a most economic speed in relation to its load and any increase or decrease in this speed adversely affects the economy (see Fig. 24).

The wing characteristics are such that high efficiency is attained only over a limited range of incidence. Operating at this favourable incidence and varying the speed by variation of wing loading or altitude of flight, the power increases only as the speed.

A comparison of air transport with other means of transport is given in Table IV. The figures are approximate only but are probably sufficiently accurate for the purpose.

Table IV Comparison of Means of Transport

(*a*) Passenger

| | Number of passengers | Cost per passenger (dollars) | Weight per passenger (short tons) | Hp. per passenger | Speed (m.p.h.) |
|---|---|---|---|---|---|
| Modern de luxe liner... | Up to 3,000 | 20-25,000 | 40-50 | 80-85 | 30-33 |
| Small liner............ | 800 | 17-19,000 | 35 | 40 | 20 25 |
| Railroad train, steam.. | 400 | 4-6,000 | 0.5-2.0 | 10-20 | 50 60 |
| Railcar, I.C. engine.... | 30-50 | | 2.0 | 10 | 50-60 |
| Motorcar............ | 5 | 150 up | 0.3-0.5 | 10-20 | 30-60 |
| Airship............ | 50-72 | | 2.5-5.0 | 70-130 | 75-86 |
| Aeroplane—boat....... | 30-50 | 6-9,000 | 0.25-0.6 | 75-125 | 150-180 |
| wheeled.... | 8-10 | 5-10,000 | 0.3-0.8 | 90-180 | 180-200 |
| wheeled.... | 5-6 | 2-6,000 | 0.3-0.6 | 75-150 | 180-200 |

(*b*) Freight

| | Capacity (short tons) | Cost per short ton capacity | Weight per short ton capacity | Hp. per short ton capacity | Speed (m.p.h.) |
|---|---|---|---|---|---|
| Freighter............ | Up to 12,000 | Up to 60 | 0.5-1.5 | 0.25-0.6 | 10-18 |
| Railroad train, steam... | 1,500 | 200-250 | 0.3-0.5 | 0.3-0.5 | 30-50 |
| Truck............ | 5-10 | 1,000 | 1-3 | 2 up | 40-50 |
| Airship............ | 15-20 | | 6-10 | 180-250 | 75-85 |
| Aeroplane—boat....... | 2-8 | Up to 70,000 | 2-4 | 500-750 | 150-180 |
| wheeled.... | 1-2 | 20-25,000 | 1.5-2.5 | 200-500 | 180-200 |

## Existing Aircraft

In Tables V-VI, the reported characteristics and performances of some 70 civil aircraft, aeroplanes, flying boats, seaplanes and amphibians, have been tabulated in order of gross weight and in Figs. 17 (columns 1 and 2), and 18 are given, insofar as available, their line drawings, all to the same scale and arranged also in order of gross weight. There have been included long range, large capacity, large size, high efficiency and other aircraft, selected because of their interest in this connection.

These tables and drawings were prepared at the end of 1935. Table VII and Figs. 17 (column 3) and 19, containing particulars of certain aircraft published during 1936 were prepared early in 1937 and hence the aircraft included therein are not in proper order with respect to those of the earlier figures and tables.[22]

In column 29 of the tables is given a figure for the transport efficiency. This figure is the disposable load, in short tons, multiplied by the cruising speed in miles per hour and divided by the total rated horsepower and is therefore expressed in ton miles per hour per horsepower. It is used as a simple and reasonable measure of the value of the aircraft as a means of transport.

[22]The aircraft of Table VII and Figs. 17 (column 3) and 19, have been designated with a number and letter to indicate their relation to those of the other tables and figures.

The particulars of the aircraft listed indicate the recent and present position of commercial aircraft with particular reference to range, capacity and size and may serve as a guide in developing aircraft suitable for the Atlantic service.

### Factors Governing Air Transport Efficiency

The factors controlling the efficiency of air transport are those governing the attainment of maximum range. Improvements and economies which extend range also improve economy of transport over shorter distances. Thus the steady increase in the world distance record is perhaps a surer measure of the progress of air transport than is the raising of the speed record.

A study of the factors affecting range will therefore be useful in considering aircraft for use for the transatlantic service. From such a study, it will be evident that the principal factors affecting economy of operation are the aerodynamic efficiency of the aircraft and airscrew, the structural efficiency of the aircraft, the power plant efficiency and the efficiency of navigation, including choice of height, speed and course with respect to weather conditions.

These and other considerations involved in determining the characteristics of the aircraft to be used for the service are discussed briefly in the following paragraphs.

### Type of Aircraft

In considering the question of the aircraft for the service, the first decision to be made is that of the type of aircraft—aeroplane, flying boat, seaplane or amphibian. On this point, there are two schools of thought, one favouring aeroplanes, the other flying boats.

From the standpoint of efficiency, the modern flying boat, particularly in the larger sizes, is as efficient and may be more efficient than the corresponding land machine, as the figures of Tables V-VII and the plots of Figs. 20 and 25 indicate. Even with undercarriage retracted, the large commercial aeroplane is not more efficient than a well designed boat and it is probable that the efficiency of the latter will be improved still further in the future by fairing the steps in flight, retracting wing tip floats,[23] or improving the stub wings.

From the standpoint of structural efficiency, the modern boat weighing, with load, 30,000 lb. or

[23] This is already being done. See number 11A, Fig. 17.

over, is seen from the tabulated figures for the ratio of gross to tare weight and the plot of Fig. 22 to be generally superior to the wheeled aircraft. There is some indication from the figure that, as the size becomes greater, the structural weight of boats becomes proportionately less.

As the size is increased, the displacement and normal loading of the hull increases as the cube of the linear dimensions. At the same time, the larger the boat, the better the take-off, since the hump speed occurs later when the wings are carrying a larger part of the load and, due to its lower centre of gravity, the stability of the larger boat on the water is better.

Thus the large flying boat is advantageous structurally, hydrodynamically and aerodynamically.

The service being over water, it is considered by some that the flying boat should be used because of its ability to alight and remain afloat in an emergency. This reason in itself is not adequate. A wheeled aircraft, properly designed and with retracted undercarriage, could safely alight on the sea and, if provided with watertight compartments and wings, could remain afloat in fair weather probably as long as a flying boat.[24] It is contended that aircraft forced down at sea have remained afloat and crew, load and machine have been recovered on several occasions in the South Atlantic and, on at least one occasion, a land machine remained afloat some days in the North Atlantic. But in these cases, the weather was fair, with no sea. No existing aircraft, if forced down, could long survive North Atlantic seas in rough weather. The advantage of the boat in this respect is that, if forced down by a minor defect, in fair weather, it can take off again after repairs have been

[24]Service aircraft, operating from carriers, are now built with watertight compartments.

made, or possibly taxi toward a rescue ship. The psychological effect of this factor on the crew should not be overlooked.

The decision as between aeroplane and flying boat thus seems to depend largely on conditions at the terminals. The boat possesses the advantage that, using available harbours, construction of costly aerodromes is avoided. With increase in weight of wheeled aircraft, the cost of constructing runways capable of supporting the heavy wheel loads becomes high. In the case of oceanic or coast routes, harbours are at sea level and a high rate of climb is normally not necessary. The cost of fuel and supplies is generally lower at seaboard.

On the other hand, the use of boats is dependent on the availability of fog and ice-free harbours and on the ability to make blind landings on water. While blind alightings on water, using radio, have not been attempted, insofar as is known, there seems to be no technical difficulty involved. Without radio, dependence must be placed on an accurate and sensitive height indicator. With ample room, blind landings have been made by coming in on a flat glide until a weight hanging a known distance below the hull strikes the water.

The wheel undercarriage of aeroplanes, particularly of large size, is heavy and necessitates heavy structural members to take the landing loads. The working parts of the undercarriage require maintenance. If retractable, the retracting gear adds to the weight, complexity and mainnance of the undercarriage. In addition, for winter operation over the Atlantic, provision must be made for take-off on wheels from land and alighting on skis on ice or snow, or vice versa. Such provision can be made without serious sacrifice of efficiency.

The float seaplane is not considered suitable for the service. Compared with the boat, it is less seaworthy, has less reserve buoyancy (about 100-150 per cent, as compared with possibly 500 per cent for the boat) and is not capable of development to the large sizes possible with the boat. The seaplane is less efficient structurally and aerodynamically in the larger sizes.

Although, in discussions of the type of aircraft for an Atlantic service, the amphibian is generally dismissed as unsuitable, the figures tabulated in Table V for number 17, the Sikorsky S-43 amphibian, indicate that, both structurally and aerodynamically, the amphibian can be made quite efficient, which, coupled with its versatility in landing, amply justifies the amphibian receiving serious consideration. The weight of its landing gear should be little larger proportionately than the retractable undercarriage of land machines and it should possess the low structural weight and other advantages of the flying boat as is indicated by the plots for number 17 in Figs. 20-23.

### Monoplane or Biplane

Present practice in commercial aircraft favours the monoplane. This is indicated in Tables V-VII and the corresponding figures. Insofar as is known, no large commercial biplane is now under construction anywhere. It is also worthy of note that the three major world records are held by monoplanes.

This question is largely associated with that of aspect ratio or span. The span of the equivalent monoplane (same induced drag) is greater than that of the biplane. For maximum economy, flying at maximum $L/D$ aspect ratio is important, but its importance decreases with increase in operating speed and reduction in incidence below that of maximum $L/D$. Aspect ratio is also important in connection with climb and, for boats, take-off. The aspect ratio determined by these considerations has generally to be reduced, for practical reasons, such as housing, or in the case of boats, to provide tip clearance, in roll, on the water.

The parasite drag of the wing bracing of the biplane, even with high wing loading and few interplane struts, reduces the aerodynamic cleanliness as compared with the monoplane and, in consequence, for a given cruising speed, higher power is required, with greater fuel consumption (see Fig. 23).

At the same time, it appears from the weights of the few biplanes tabulated in Tables V and VI and plotted in Fig. 22, that the structure weight of biplanes is rather higher, instead of lower, than that of monoplanes.

The adverse effect on economy of a loss of aerodynamic efficiency is greater than that of the same relative increase in weight.

Figures 20 and 21 indicate that the transport efficiency of biplanes is generally less than that of monoplanes. For economy in long range operation, a good monoplane generally will be superior to a good biplane.

For flying boats, seaworthiness is important and from this standpoint the monoplane is the better. Its stability on the water, as when taxying, is greater since the side area is neither as large nor as high and the rolling moment is therefore less than for the biplane. Good wave clearance is provided by the high wing monoplane.

The cost of construction is largely influenced by the number of parts and hence generally the biplane structure, with its larger number of struts and fittings, will be higher, not only in initial cost, but also in cost of maintenance.

It is therefore evident that, for a service of the nature of that over the Atlantic, the monoplane is preferable.

### Wing Loading

For economy of operation in long range commercial aircraft, high wing loading and moderately high power loading are essential. Generally speaking, the higher the wing loading, the closer does the cruising speed approach the speed of greatest aerodynamic efficiency. But with high wing loading, landing speeds are generally dangerously high and take-off difficult. For instance, with a wing loading of—

20 lb. per sq. ft., the stalling speed is 70 m.p.h. or 101 f.p.s.
30 lb. per sq. ft., the stalling speed is 85 m.p.h. or 125 f.p.s.
40 lb. per sq. ft., the stalling speed is 98 m.p.h. or 145 f.p.s.
50 lb. per sq. ft., the stalling speed is 110 m.p.h. or 162 f.p.s.

These speeds may be lowered and take-off and landing thereby improved by the use of slots, flaps and similar lift increasing devices and by wheel and air brakes. Variable pitch airscrews afford extra power for take-off and increased airscrew efficiency.

Because the weight of the fuel consumed in long flights is large, the gross weight and with it the wing and power loading, are much reduced at the end of the flight and the aircraft lands at a much lower speed than that at which it took off. In other words, the characteristics of the aircraft change during a long flight. If determined by the take-off conditions, the wing loading is unduly low at the end of the flight and the excess area over that required for alighting and the additional power provided for take-off reduce the pay load and range. In a general way, for efficient operation, the wing loading should be determined by conditions at the end of the flight and the power loading by the average cruising conditions during the flight.

Some of the foregoing points are illustrated by the performance curves of Fig. 24. The curves apply in a general way to a well designed modern long range flying boat, of gross weight 38,000 lb., rated power 2,800 hp. and a weight ratio of 2:1. Curves $A$ (full lines) apply to the fully loaded aircraft with wing loading 28.6 lb. per sq. ft. and power loading 13.6 lb. per hp.; curves $B$ (dotted lines) to the same aircraft, after flying at 160 m.p.h. a distance of 1,800 miles against a 30 m.p.h. head wind and using 14,000 lb. of fuel; curves $C$ (dashed lines) to the aircraft with the same engine installation, when loaded up to a gross weight

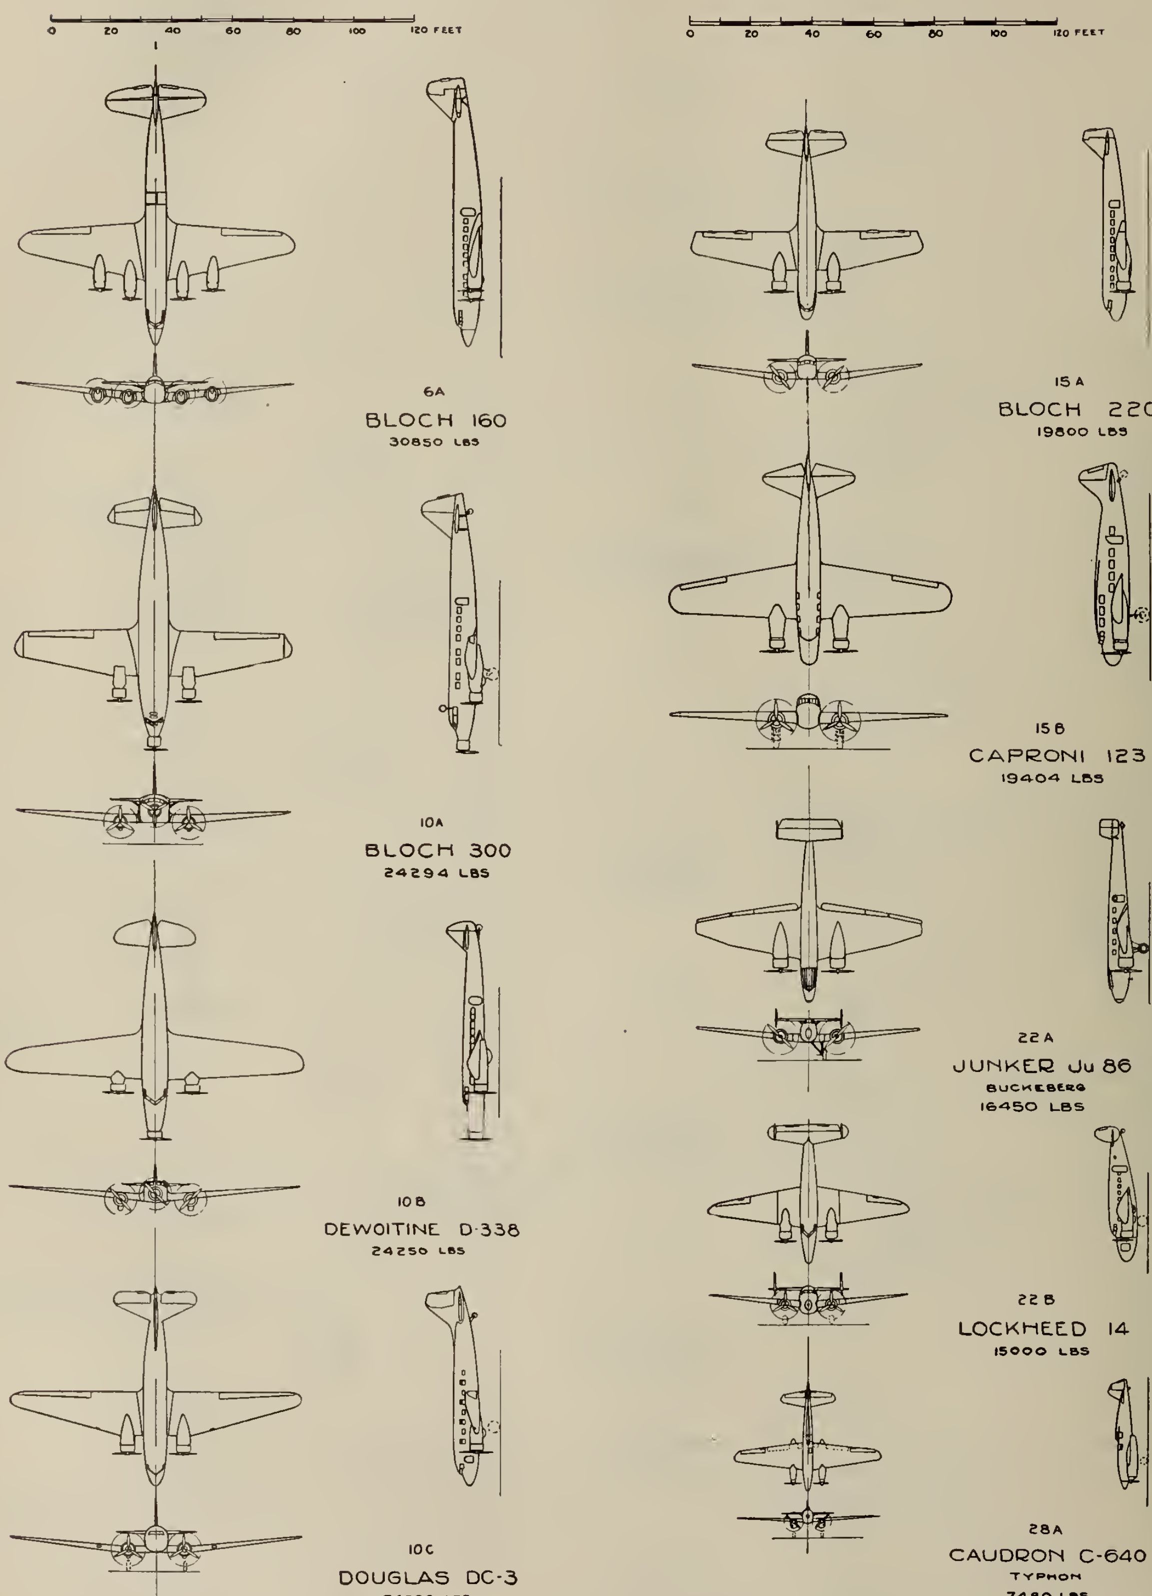
**Fig. 19—Aeroplanes (Civil)**



of 53,000 lb. corresponding to a wing loading of 40 lb. per sq. ft. and curves *D* (dot and dash lines) apply very roughly to an aircraft, otherwise the same, with the wing area reduced, to increase the wing loading to 40 lb. per sq. ft.

The curves illustrate the handicap on efficient operation resulting from the limitation imposed on wing loading by the requirement of safe take-off speed and the advantages that result from high wing loading. It is apparent, for instance, that, if this aircraft could be got into the air, it could fly with the wing area reduced to ½ or ⅓ of the normal area.

Roughly, for condition *C*, the cruising speed is 150 m.p.h., time of flight fifteen hours and fuel burned 15,000 lb., leaving a disposable load in excess of fuel of 11,500 lb., assuming the same weight ratio. For condition *D*, the cruising speed is 180 m.p.h., time of flight twelve hours, fuel consumed 12,000 lb. and disposable load, over and above fuel, 7,000 lb., assuming no change in structural weight. The disposable loads, less fuel, carried per horsepower, for conditions *A*, *C* and *D* are 1.8 lb., 4.1 lb., and 2.5 lb. and the transport efficiencies 0.540, 0.710 and 0.610 ton miles per hour per horsepower respectively.

The higher the wing loading, the smaller is the wing area and the size of all other elements depending thereon—tail area, length of fuselage, etc., and the smaller and lighter the aircraft. Thus, increasing wing loading reduces structural weight thereby improving the transport efficiency.

Increase in wing loading reduces the ceiling and rate of climb. For long range oversea operation from large well located permanent airports or protected harbours, a high rate of climb is not essential. The adverse effect on take-off resulting from reduced rate of climb can be nullified by catapulting and reduction in ceiling can be compensated for by supercharging the engines.

For service over the North Atlantic, good airworthiness is a prime requisite. The higher the wing loading, the less the effect of a vertical gust or squall. Highly loaded aircraft now in service confirm theory in that their flight is smooth and easy and their control characteristics in stormy weather are good. In addition, the smaller wing permitted with high loading is advantageous in flying boats when afloat.

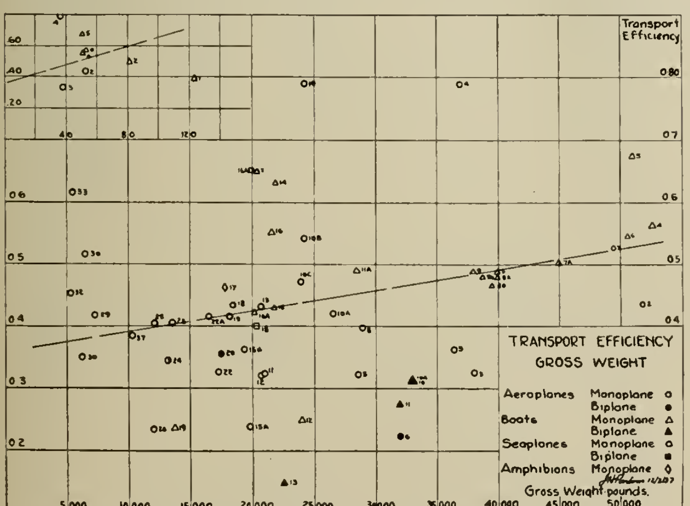


**Fig. 20—Transport Efficiency—Gross Weight**

Thus, with high wing loading, the maximum and cruising speeds are higher, range and pay load are increased, weight of structure is reduced and efficiency of transport, airworthiness and safety are improved. The accompanying loss in ceiling can be compensated, the lower rate of climb can be accepted and the increase in take-off and landing speeds can be counteracted. For these reasons, the aircraft for the transatlantic service should be designed with a high

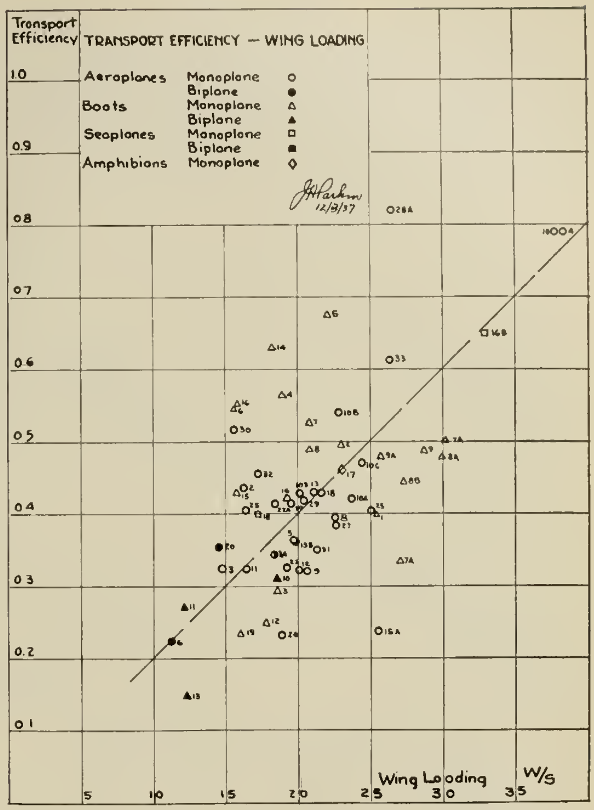

**Fig. 21—Transport Efficiency—Wing Loading.**

wing loading and a loading of 40 to 50 lb. per sq. ft. is suggested.

### Power Loading

The performance characteristics influenced by the power loading are speed, maximum and cruising, take-off, climb and ceiling. For commercial operation, the first two are usually the determining considerations. With an assisted take-off, the power loading will depend on the cruising speed and altitude and the aerodynamic fineness of the aircraft.

The graphs of Fig. 24 indicate the way in which speed is increased by increase in power and reduction of drag, and Fig. 23 illustrates the variation of speed with power loading.

The higher the power, the greater the weight of the power plant (engine, accessories and fuel) and the smaller the pay load. At the same time, the installed power must provide for operation at a cruising power below rated power and a margin of power to take care of failure of one or more engines.

With a high cruising speed, fixed by the service timetable, if the power loading is to be reasonably high and economy of operation attained, the drag of the aircraft must be reduced to a minimum.

### Aerodynamic Fineness

An analysis of the factors contributing to the total drag of an aircraft indicates that, for economy at high speeds, the wing loading must be high and the parasite drag low.

The aerodynamic cleanness of an aircraft is largely bound up with the structural design and it is necessary from an economic standpoint to balance structure weight against drag. An increase in weight must be accompanied by an increase in *L/D*. Very generally a reduction in drag is more effective in this respect than reduction in weight of structure.

The cantilever monoplane permits the cleanest aerodynamic design and, as already seen, the gain in this respect is not offset by an increase in structural weight.

Similarly, the lower drag of liquid cooled engines must be balanced against their somewhat greater weight. From this point of view, the housing of the engines wholly within the wings is desirable.

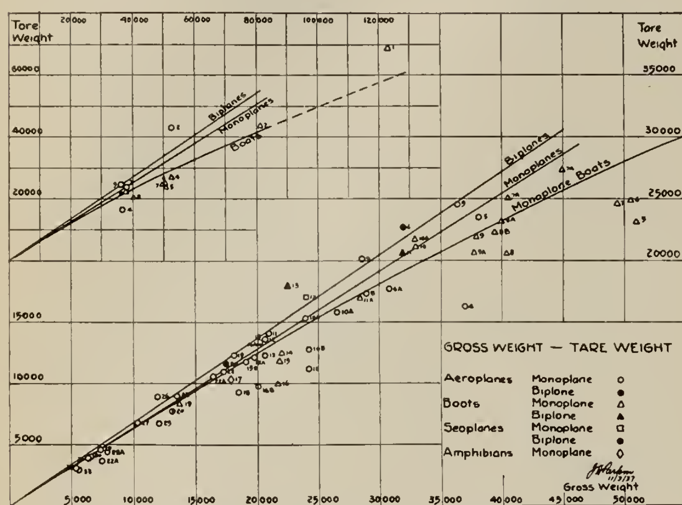

**Fig. 22—Gross Weight—Tare Weight.**

Retractable undercarriages, flush riveting of metal skins and similar means for the reduction of drag should all be employed.

While there is still room for improvement in aerodynamic cleanness, modern commercial aircraft, both aeroplanes and flying boats, possess very high values of $L/D$, ranging from 12-15. Notable performance and high transport efficiency have been attained with some of the aircraft listed in the tables, largely as a result of careful attention to aerodynamic cleanliness.

### Structure Weight

The greater the ratio of gross to tare weight, i.e., the lower the structure weight, the larger the fuel and pay load which may be carried. Reduction of the weight of the structure involves both the type of construction and the size of the aircraft and, at the same time, the drag. With certain types of construction, low structure weight is associated with high drag. As already seen, high wing loading leads to a reduction in weight.

The weights of Tables V-VII are plotted in Fig. 22, excluding those of machines specially designed to establish records and it will be seen that there is some indication, particularly for flying boats, that the structure weight is proportionately less the larger the aircraft. There may be a limit to this condition, but it is not yet evident.

### Power Plant Efficiency

Since range varies inversely as the fuel consumption, maximum range and economy result from the minimum consumption per brake horsepower per hour. This specific fuel consumption depends on a number of factors, including—

1. The power plant, its type, condition, operation and control.
2. The speed of flight.
3. The altitude of flight.

*Type of Power Plant*

Economy of transportation is influenced by the power plant, not only as a result of its effect on the specific fuel consumption, but also, since the power plant contributes a large part of the aircraft weight, through its influence on the gross weight of the aircraft. For economy, a power plant of low specific weight and low specific consumption, i.e., low weight of engine and fuel, is required.

The ratio of the fuel load to pay load varies with the length of the flight. The longer the flight, the less the pay load that can be carried. Fuel load and pay load are, in a sense, interchangeable within a given total disposable load.

At the present time, the electrical ignition gasoline engine, either air or liquid (or steam) cooled is used, with a few notable exceptions, for aircraft propulsion. Gasoline engines, developing up to 1,000 hp. and more, weighing less than 1.5 lb. per hp. and having specific consumptions of fuel and oil of 0.50-0.55 lb. per hp., are in regular production. At the same time, these engines are daily proving themselves possessed of adequate reliability, long life and low maintenance.

The present high state of development has resulted from improvements in design, in materials, in production methods and in fuels. Increased speed of rotation, higher compression ratios and supercharging have raised the output per litre of the cylinders of normal engines to 30-40 hp.

Although the specific consumption of fuel and oil of the liquid-cooled motor is slightly less than that of the corresponding air-cooled (averaging 0.52 as compared with 0.54 lb. per hp. per hr. and is still lower with glycol cooling), its specific weight, including the cooling system, is higher—2.0 lb. per hp.—compared with 1.5 lb. per hp. However, its true weight handicap is less than these figures indicate, if due allowance is made for the weight of the cowling, baffles, additional oil-cooling, etc., so necessary in modern high power air-cooled engines. On a basis of the total weight of the power plant, including fuel and oil, using the foregoing figures and neglecting the effects of differences in aerodynamic resistance, a flight of about twenty-five hours is required before the liquid-cooled motor overcomes its weight handicap. Actually, for the reasons given, a shorter time will be necessary.

While the difference in drag between the modern cowled radial air-cooled engine and an in-line liquid or steam cooled engine, with its radiator or condenser, is

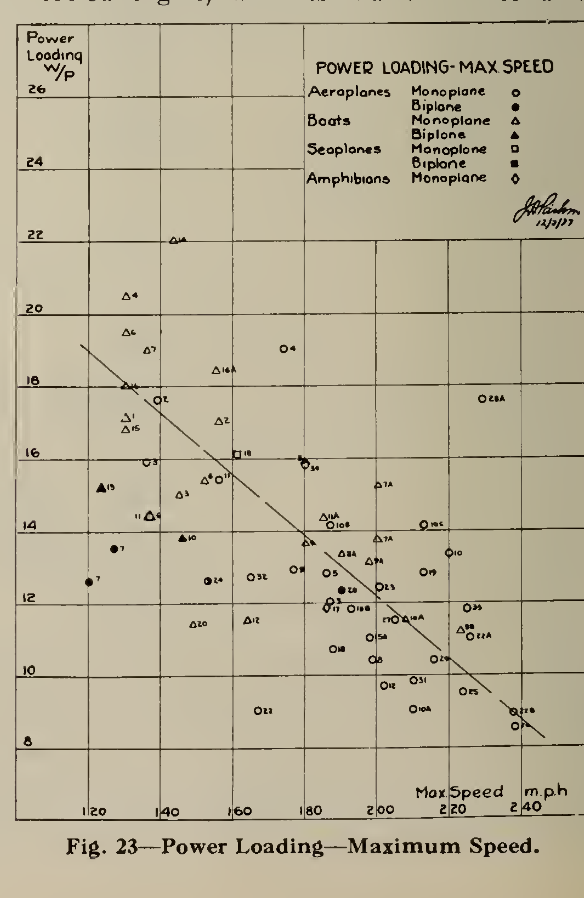

**Fig. 23—Power Loading—Maximum Speed.**

less than formerly, the advantage still rests with the liquid-cooled plant.

The former handicap of the liquid-cooled installation of lack of reliability due to "plumbing" troubles no longer exists, with the modern simplified cooling system; the air-cooled motor is acquiring an analogous handicap in the intricate system of adjustable cowling, intercylinder baffles and special oil cooling, without which high output cannot be maintained and is, at the same time, losing its former advantage of simplicity.

It is significant that, insofar as is known, all long distance world records have been made by aircraft powered by liquid-cooled motors.

For the initial transatlantic service, it is probable that the air-cooled engine will be used, but it is believed that, before the service has been long in operation, aircraft will be used in which the power plant will be housed in the wings or body, using, if air-cooled, forced air circulation through ducts. For such an installation, the radial air-cooled engine is not suitable. If liquid-cooled motors are used, ducted radiators will be employed. In either case, reduced drag and increased accessibility will result and the cooling medium, or air, heated therefrom, in the case of liquid-cooled motors, will be used for cabin heating and ice prevention.

It is further anticipated that the limitation imposed by the exhaust valve on any further large increase in specific output of the poppet valve engine, coupled with other advantages being demonstrated by this motor, will result in the rapid introduction and wide use for commercial service, particularly of the kind under consideration, of the sleeve valve motor. The low fuel consumption (i.e. 0.43 lb. per hp. per hr. at cruising power, recorded for the Bristol Perseus engine), is an important advantage of the sleeve valve motor for long range commercial service.

For commercial service, the compression ignition engine, because of its numerous advantages, is attractive and especially so for a service over long non-stop stages where its low specific consumption is able to offset its present handicap of high specific weight.

Comparison of the principal aviation compression ignition engines with modern electric ignition gasoline engines of 800-1,000 hp. yields the average figures for specific consumption and weight given in Table VIII. An allowance is made of 0.4 lb. per hp. for the weight of the cooling system of liquid-cooled gasoline engines and 0.3 lb. for that of compression ignition engines. The weight of the tankage is taken as 0.8 per cent of the fuel weight.

The weight of the complete plant for a flight of $X$ hours, neglecting effects of reduction in gross weight as fuel is consumed, is shown in the last column. From these figures, it will be seen that the compression ignition engine weighs less than the gasoline engine for flights of more than six to seven hours and possibly less if allowance is made for the better maintenance of power at height of the compression ignition engine. For a 1,000 hp. aircraft

Table VIII

Comparison of Gasoline and Compression Ignition Engines

| Type of engine | Specific weight on nominal B.h.p. — Dry | Specific weight on nominal B.h.p. — With cooling system | Specific consumption on nominal B.h.p. — Fuel and oil | Weight of power plant complete with fuel for $X$ hours |
|---|---|---|---|---|
| Air-cooled | | | | |
| Gasoline | 1.5 | | 0.54 | $1.5 + 0.58X$ |
| Compression ignition | 2.5 | | 0.40 | $2.5 + 0.43X$ |
| Liquid-cooled | | | | |
| Gasoline | 1.6 | 2.0 | 0.52 | $2.0 + 0.56X$ |
| Compression ignition | 2.6 | 2.9 | 0.38 | $2.9 + 0.41X$ |

on a flight of twelve hours, the compression ignition engine will permit, on the foregoing basis, an increase in pay load of 800-900 lb. over that with a gasoline engnie.

In view of the foregoing, it is difficult to understand the apparent lack of interest in the compression ignition engine. If the same effort had been given to the compression ignition engine as has been devoted to the development of the gasoline engine, the superiority of the compression

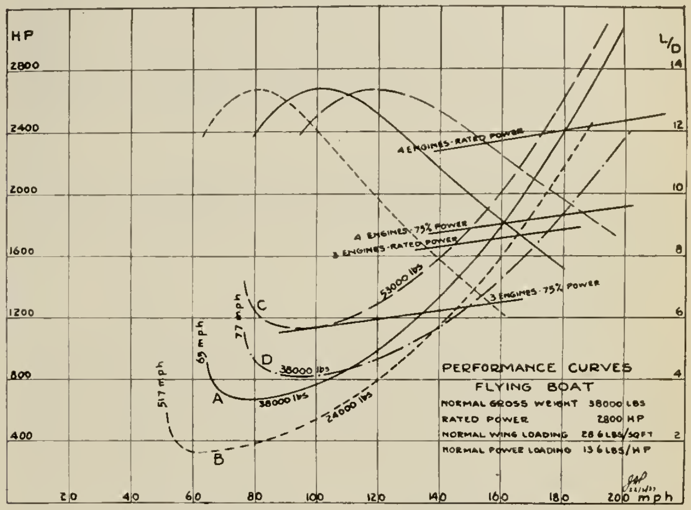

**Fig. 24—Performance Curves, Flying Boat.**

ignition engine for commercial service would be more marked. While compression ignition engines will not likely be used on the initial transatlantic services, except that of the D.L.H., it is considered that their ultimate use for this work is inevitable.

*Power Plant Operation and Control*

Overall economy of operation depends, not only on fuel consumption, but also indirectly on the life of the engine and frequency of overhauls. Aircraft engines will not run indefinitely at full power without damage. The longer and more frequent the periods of high power operation, the more frequent the overhauls. It is therefore customary to cruise with the engine throttled to from 60-75 per cent of full power to prolong its life, lengthen the periods between overhauls and afford a margin of power for use in the event of failure of one or more engines in a multi-engined aircraft. The engine is tuned for minimum specific consumption at this reduced cruising power.

It should be noted that this reduction in power can be secured at full throttle through the equivalent throttling resulting from the reduced density at high altitudes, with, at the same time, a gain in speed. Thus, at full throttle, at constant r.p.m. at 13,000 ft., the power is reduced to 60 per cent and at 8,000 ft., to 75 per cent of rated power.

The specific consumption varies with mixture, throttle and altitude. Consumption can be appreciably reduced by operating on lean mixtures, but it is normally not possible to operate on a mixture much leaner than the theoretically correct. However, engines can be safely operated on mixtures leaner than is customary, especially when throttled, and liquid-cooled motors can, in general, be operated on leaner mixtures than air-cooled.

The specific consumption varies but little with throttle in the region of the minimum, but increases appreciably for full throttle and at small throttle openings.

The more economical the operation of an engine, the less is economy affected by height. Under present conditions, there is possibly a slight gain in economy at altitudes in normally aspirated engines and also in supercharged engines up to some altitude below the rated height.

Theoretically, the reduction in consumption is about 2 per cent for normally aspirated engines and 3 to 4 per cent for supercharged engines at 15,000 ft., but this gain is largely offset by the less favourable carburation and distribution conditions at altitude.

As with manual control, fuel consumption may vary as much as 40 per cent for different pilots under the same conditions, automatic controls are now employed where economy is important. The average figures for consumption used in Table VIII would be somewhat lower with automatic controls or with unusually careful manual control. Actual consumptions in the neighbourhood of 0.4 lb. per hp. per hr. at ⅔ power have been obtained in long distance flights with liquid-cooled motors and a figure of 0.37 is theoretically possible.

Automatic controls and constant speed airscrews are used on the Sikorsky S-42 flying boats and specific consumptions as low as 0.42 lb. per hp. per hr. are reported for the Pacific flights.

*Supercharging*

The drop in power with altitude in a normally aspirated engine (power at 13,000 ft. about 60 per cent of that at sea level) is offset by supercharging. The supercharger maintains the air supplied to the engine at constant pressure (rated boost) up to the limiting or rated altitude beyond which the pressure falls with altitude in the normal way. A rated altitude of 15,000 ft. is generally considered to be about the limit for a single stage centrifugal supercharger (1.85:1 compression ratio).

While the power required to drive the supercharger increases (7.5 per cent at 12,500 ft.) and the thermal efficiency of the engine decreases, there is an actual increase of about 1 per cent per 1,000 ft. in the power developed by a supercharged engine at constant boost and r.p.m. up to rated altitude due to reduction in exhaust back pressure. At the same time, the fuel consumption is increased and the engine weight is greater by the weight of the supercharger.

The alternative to supercharging is the provision of an oversize engine such that the reduced power developed at altitude equals that required. The weight of the engine with supercharger is probably less than that of the oversize engine, but its fuel economy is also lower. On the whole, the power necessary for high speed operation at altitude can be best attained by supercharging. In addition, supercharging enables extra power to be developed at sea level to assist take-off.

For operation of the Atlantic service, cruising at 180 m.p.h. at an altitude of about 12,000 ft., as suggested later, it is considered that moderately supercharged engines of rated altitude of 5,000-6,000 ft. should be used. The throttling effect of reduction in air density above this height will reduce the power at full throttle to a cruising power of about 75 per cent of full power.

*Variable Pitch Airscrews*

For the conditions of high speed, high loading and high altitude suggested for the service, V.P. airscrews are necessary, especially with geared and supercharged engines. The primary consideration for the service is efficient operation at cruising speed and altitude. With fixed pitch airscrews designed for this condition, the loss in efficiency and power at low speeds during take-off and climb is prohibitive. With the V.P. airscrew on the other hand, the pitch can be adjusted to suit both take-off and high speed conditions. The engine therefore holds its speed and power and a large increase in thrust for take-off, 100 per cent or more in average thrust, is provided with V.P. airscrews, particularly with geared and supercharged engines.

The V.P. airscrew permits the engine speed to be controlled by the pitch of the blades as well as by the throttle and, in fact, the most recent development is the constant speed airscrew which, if left alone, maintains constant speed, although the speed may be controlled by the pilot.

Thus, operating at high altitude and full throttle, the normal cruising power results and the engine speed can be held to cruising r.p.m. by the V.P. airscrew, thereby increasing cruising speed.

In the event of engine failure in a multi-engined aircraft, the drag of the idle airscrew can be reduced and the speed and power of the active engine maintained, thereby enabling flight to be continued even with heavy load. This feature is particularly marked in the case of tandem engines. Tests indicate that fuel consumption at a given speed is less with V.P. airscrews than with an equivalent fixed pitch airscrew.

Evidently the V.P. airscrew is advantageous for the high loading, high speed and other conditions of an Atlantic air service.

### Speed

The speed of flight is determined by two principal considerations, economy of operation and the requirements of the service.

The chief advantage possessed by the aeroplane compared with the fast liner and airship for transatlantic service is speed and, if this advantage is to be appreciable, the elapsed time between terminals must be low and the cruising speed consequently high.

The schedule already suggested is based on a cruising speed of not less than 180 m.p.h.

As previously indicated, for high cruising speed, clean aerodynamic design must be combined with one or more of high wing loading, high power and high altitude of flight. The possibilities and limitations of these alternatives have already been briefly reviewed.

Ordinarily, the most economical speed is too low for practical commercial operation. Also, as fuel is consumed during flight, the weight of the aircraft decreases and the speed of maximum efficiency decreases in proportion to the square root of the gross weight, necessitating a progressive decrease in r.p.m., further throttling and increase in specific consumption. On the other hand, the most efficient speed increases with altitude and the effect of decreasing weight can be offset by increasing altitude to maintain constant speed.

To minimize the adverse effects of winds on the flying schedule, the speed must also be high since the higher the speed, the less the effect of winds.[25] This is clear from the following expression for the effective speed or speed made good. For a flight speed of $V$ and a wind speed $v$ m.p.h., at an angle $\theta$ to the course, the effective speed is:

$$V_e = \sqrt{V^2 - v^2 \sin^2 \theta} + v \cos \theta$$

Aside from schedule requirements, a high flight speed is advantageous against a head wind by reducing the time during which the handicap is suffered while, with a favouring wind, the desirable speed is one near that for minimum power, permitting the aircraft to benefit a longer time. The most economical speed is increased by head winds and decreased by tail winds.

Under the foregoing limitations, maximum practical economy is attained by adopting as high a wing loading as permissible and designing and adjusting the engine-airscrew combination to operate with minimum fuel consumption at the speed demanded by the service.

### Altitude of Flight

In the selection of the altitude of flight to be used in the service, there must be considered, economy (i.e.,

[25] In this respect also, ease of navigation is increased.

altitude for most miles per gallon), navigation and weather, personnel and passengers and other factors.

Flying at the altitude of maximum aerodynamic efficiency, the true airspeed and horsepower must be increased, at altitude, to compensate for the decrease in air density. The increase is inversely proportional to the square root of the air density, neglecting the effects of slip stream variation. The effect of altitude on the speed of maximum efficiency is similar to that of wing loading, the increase in the speed at 10,000 ft. being about equal to an increase of 1/3 in loading.

At constant $L/D$, i.e., constant indicated airspeed, economy of flight is dependent only on the specific fuel consumption. The effect, if any, of altitude will be that due to the variation of consumption with height and consumption may decrease slightly with altitude.

On the other hand, to maintain a given true airspeed at altitude (higher than that of maximum aerodynamic efficiency), the power necessary is less than at sea level since the power required depends on the drag, which, in turn, varies inversely as the $L/D$ and, as the incidence must be increased to compensate for decrease in air density, the $L/D$ increases as the angle of maximum $L/D$ is approached. Under these conditions, the power required decreases rather more rapidly than the air density. The air speed will remain nearly constant if the altitude is increased, as the weight decreases with consumption of fuel, to maintain a balance between cruising power of the engine and the power required.

From the standpoint of economy then, the service should be operated at a high altitude.

Lacking definite knowledge concerning upper air weather conditions over the Atlantic, such as the height of storms, it is not possible to predict the best altitude from a meteorological standpoint.

Experience indicates that the air pressure in the cabin must be increased over that outside if passengers are to be carried at altitudes above 12-14,000 ft.

On the whole, it is considered that, with the present state of development of aircraft and equipment, the most favourable altitude of flight for the initial transatlantic service will be about 12,000 ft., for which satisfactory and relatively light superchargers are now developed, at which special provision for the crew (and passengers) is not necessary and which probably exceeds the height of most storms.

### Precautions against Icing

The danger due to the formation of ice is peculiar to aircraft and is, perhaps, the most serious meteorological hazard of the transatlantic air service. The extent and seriousness of the hazard is as yet unknown. It has already been reported by stunt pilots and, with little doubt, has been responsible for the failure of many attempted transatlantic flights.

Ice may form on aircraft in any weather and in any cloud in which the temperature is below freezing. The character and effects of ice formation on aircraft and the conditions favourable to icing are dealt with in Appendix XII.

It is fortunate that serious deposits occur only in some form of visible moisture since the pilot is thereby given visual warning provided he knows the air temperature. The aircraft therefore should be equipped with a distant reading thermometer with metal shield and located outside the zone of influence of the airscrew; and with lights for the detection of visible moisture at night.

*Avoidance*

The best safeguard against the ice hazard is avoidance of the ice-forming region through accurate meteorological prediction of the location and extent of the region. The number and complexity of the factors involved in icing, the difficulty of observation and consequent lack of information renders prediction in particular for the transatlantic service very difficult.

Heaviest icing usually occurs in long extended zones associated with "fronts," i.e., air mass boundaries. Synoptic maps give information concerning such fronts. This is another reason for the provision of the most complete weather maps and forecasts possible for each flight.

The most dangerous condition occurs in low cold air, when warm air meets and over-rides a stationary low flat air mass, or a wedge of cold air pushes under a warm air mass. The former is the condition of a change from frost to thawing weather and the latter from mild to cold. Icing due to supercooled rain is less common in the latter case.

Temperature is the principal criterion of the probability of icing. Lacking upper air information, the air temperatures at altitude must be estimated from surface conditions, assuming a suitable lapse rate. The latter depends on many factors: time of day, season, latitude, surface (land or water) cloudiness, wind, pressure distribution and precipitation. It averages 1 deg. per 328 ft.

Determination from the ground of the size of cloud droplets, which has a bearing on the kind of ice formed, is difficult. An incipient rain condition indicates large droplets. A corona, if small, i.e., close to sun or moon, indicates large droplets. A halo indicates clouds composed of ice spicules.

Low pressure areas being generally associated with cloudiness and precipitation, are usually more favourable to icing conditions than are high pressure areas. Conditions favourable to icing are probable to the leeward of large bodies of water and over high terrain.

When very damp cloud air at subfreezing temperatures is encountered and icing is probable, as a result of cold air inflow or over-running, an attempt should be made to climb above the clouds. This is often successful at heights of 10-13,000 ft., although, in most cases, an altitude of 16,000 ft. is required and even this may not be sufficient. While climbing, the zone of frost should be avoided to escape icing and possible reduction in ceiling of the aircraft.

Ice deposits from freezing rain can often be removed or prevented by flying in the inversion usually existing above such rains.

If ice forming fronts must be crossed, it should be done at right angles, to shorten the period of icing.

*Prevention*

While avoidance of the ice forming zone, through meteorological prediction, is the best safeguard, with existing knowledge, such prediction is uncertain. Preventive measures on the aircraft are therefore necessary to cope with unexpected, heavy and rapid icing. Also, the extent of the zone and the service schedule may be both such as to necessitate flight through the zone.

Many preventive methods and devices have been suggested or tried. Very few have been found reasonably efficacious and have been adopted in service.

The use of coatings of so-called waterproof materials, such as oil, grease and wax, to lower the adhesion of ice has been found ineffective. Resistance to penetration of water at ordinary temperatures is no indication of resistance to ice at or below freezing, in fact, the reverse may be the case.

The adhesion of ice can be definitely lowered, although the rate of formation is little affected, by providing on the surface, a substance which, mixed with supercooled water, lowers the freezing point sufficiently to maintain a liquid boundary layer. Because of their more rapid rate of mixing, liquids miscible in all proportions with water are superior to soluble solids for this purpose, but they must be protected from the scrubbing action of the air and rain. Specially processed rubber and leather have been found the best means of retaining the liquids on the surface.

In the so-called "overshoe" developed in the United States, the coating of specially processed rubber has built into it, for wings, three air tubes and for tail surfaces a single tube weaving back and forth. The overshoe is held to the leading edge of metal wings by means of threaded rivets. Air at 5 pounds pressure is supplied to the tubes through distributing valves in such a way that the tubes are alternately inflated and deflated about every 40 seconds, thereby first cracking the ice, then lifting it so that it is caught by the air and carried away, owing to the reduced adhesion.

The complete installation weighs about 75 lb. There is negligible effect on performance except when the tubes are inflated. The rubber is said to require renewal about once a year. Originally, the rubber was impregnated with pine oil, but the oil has been found unnecessary. The overshoe is widely used on commercial aircraft in the United States and Europe.

In the "anticer" develped at the Royal Aircraft Establishment in England, a porous outer surface of specially tanned leather is employed, to which ethylene glycol alone or mixed with 10 per cent of ethyl alcohol is fed under slight pressure through a perforated tube. The liquid is spread by an under layer of cotton and saturates the leather. As fast as the ice is formed, that next the leather is melted by the liquid, lowering the adhesion and the ice is blown off by the air. The flow of fluid may be varied to suit conditions and is normally about 1½ pints per hour. The anticer is applied to the leading edges of wings and tail surfaces. It is light, easily fitted and has little effect on performance. It has been found effective in service.

Airscrews may be protected in a similar way by means of a porous leather cover over the boss and inner portion of the blades to which the glycol is fed by means of a slinger ring on the back of the hub.

A somewhat similar arrangement has been developed in the United States. The airscrew is fitted with an oil impregnated rubber covered spinner. An 95:15 alcohol glycerine mixture is fed by means of a slinger ring to tubes which deliver the liquid, behind the spinner, to the leading edge of each blade and the liquid spreads over the blade under the combined action of centrifugal force and air flow. The increased centrifugal force, combined with a certain amount of flexing and heat generated in overcoming viscous drag, tend to keep the blade tips free of ice.

In addition to icing under conditions already mentioned, ice formation in the carburettor and induction system, due to cooling caused by evaporation of the fuel, may have serious consequences. Carburettor icing depends on the humidity, temperature and pressure. In an unheated carburettor, dangerous accumulations are probable with high humidity for intake air temperature between 15 and 65 deg. F. It may be prevented by heating the intake air or, more effectively, by heating the carburettor by jacketing. Another effective method is by the addition of alcohol (ethanol and methanol) to the fuel in the carburettor, under the control of an ice detector, which admits alcohol when ice begins to form.

Freezing of radiator shutters is best prevented by placing them back of the radiator.

Airspeed heads are now commonly protected from ice by electric heating. Venturis are replaced by vacuum pumps and windmill drives by positive drives from the engine.

The use of heat for ice prevention is attractive. The large amount of waste heat available (about ⅔ that in the fuel), the fact, proved in hydro-electric plant practice, that the temperature of the surface need be only a minute fraction of a degree above freezing to prevent the adhesion of ice, and the further fact that icing most frequently occurs with temperatures close to the freezing point, are factors favourable to the use of heat.

The amount of heat required will depend upon the meteorological conditions, the wing and the speed. The rate of heat transmission through the brass covering of a Clark Y wing, at 80 m.p.h., has been found to vary from 27 near the leading edge to 19 B.t.u. per sq. ft. per hr. per deg. F. temperature difference near the trailing edge.

Utilization of waste heat from the power plant is considered practicable only for all metal monoplanes. There are a number of promising possibilities.

With liquid cooled (glycol) or steam cooled engines, the jacket heat may be used in wing and tail surface radiators, or possibly leading edge radiators. The reduced drag of the radiators may be more than offset by the greater weight and plumbing difficulties.

The piping of the exhaust gases to a detachable leading edge is perhaps the most direct method of utilizing the heat in the exhaust, but difficulties are involved, including corrosion due to acids and high temperatures, thermal expansion and proximity to wing fuel tanks. The probable reduction in exhaust noise is an advantage of the method.

There is some indication from tests that heating the leading edge is effective only in preventing the accumulation of ice in that region, and that ice will continue to form on the unheated after portion of the wing.

It has been suggested in the National Research Laboratories, Ottawa, that icing of the wings and of the airscrew might be prevented by piping exhaust gases to a leading edge section of the wing and discharging them therefrom through a properly located narrow slot parallel to the span in such a way that a sheet of hot gases flows back over the wing surface. The blades of pusher airscrews sweeping through this sheet of hot gases may have their temperature raised sufficiently, in combination with the temperature increase due to viscous drag, to prevent ice formation.

Rough preliminary tests of such an arrangement made early in 1935 in the National Research Laboratories gave promising results. The wing surface from leading to trailing edge was kept ice free.

National Advisory Committee for Aeronautics tests have indicated that a pusher propeller, driven by an extension shaft from an engine housed in the wing is a more efficient combination than any radial engine driven tractor or pusher airscrew combination tested. There may be additional advantages, both aerodynamic and to the engine, in the discharge of exhaust gases in the manner suggested.

Experience with stainless steel silencers for aircraft engines indicates that the use of stainless steel overcomes corrosion troubles. Stainless steel is now being introduced for aircraft construction.

The driving of an airscrew by means of an extension shaft has been proved feasible by the long service of such drives in the Junker G-38. More recently, military aircraft have been built in which this form of drive is employed.[26]

In addition to other advantages, propulsion of aircraft by means of airscrews, driven through extension shafts from engines housed in the wings, is a convenient arrangement for the prevention of ice by utilization of waste heat. For the method suggested, using a slotted nose section, the connections would be very direct. It makes possible the utilization of heated air from air-cooled engines, or from ducted radiators and condensers in liquid or steam-cooled engines, alone or in combination with air heated by the exhaust.

---

### Instrument Equipment

The success of the transatlantic air service will depend very largely upon the piloting and navigation, and the aircraft must therefore be provided with the best and most comprehensive of instrument equipment.

For a long range service of this kind, an automatic pilot is essential. This instrument automatically maintains the aircraft on a pre-set course and in a given trim, thereby increasing the accuracy of course keeping and of control, improving control in bad weather or conditions of low visibility, reducing the risk of loss of control under such conditions and reducing the strain on and fatigue of the pilot.

The automatic pilot includes two indicating instruments which serve also with manual control, namely the gyro horizon and the directional gyro. It is desirable, however, to provide duplicates of these as a precautionary measure.

In addition to the instruments included in the automatic pilot, essential instruments for blind flying, which may be used in different combinations, include the gyro turn indicator, ball or pendulum type cross level or side slip indicator, rate of climb indicator, or fore and aft level, airspeed indicator and sensitive altimeter.

For navigation, in addition to the foregoing, there should be provided at least two magnetic compasses, one of which may be arranged to control the directional gyro, drift and ground speed indicator, course and distance calculators, chronometer, astronomical instruments such as bubble sextant, radio compass and other radio direction finding equipment to which reference has already been made.

The need for the most complete engine instrument equipment for this service, where proper functioning of the power plant is so important, need not be emphasized. Fuel-air indicators and fuel flow meters should be included.

For catapulting, provision of a fore and aft accelerometer is desirable.

For the detection of icing conditions and ice, a distant reading thermometer and suitable lights are necessary.

### Summary

To summarize the foregoing, the suggested aircraft for the initial transatlantic service should be one designed for the carriage of mail and express, having a pay load capacity of 1,500-2,000 lb., a cruising speed of 180 m.p.h., a range of 2,400 miles against a headwind of 30 m.p.h. and fitted for catapult launching at a speed of 100 m.p.h. The type, either flying boat, amphibian or wheeled aeroplane, will be determined by the terminal conditions. The aircraft should be a monoplane and, if a boat or amphibian, a high wing monoplane. If a wheeled aeroplane, it should be fitted with a retractable undercarriage and provided with ample flotation in the form of water-tight compartments and wings. Provision should be made for landing on snow or ice.

The wing loading should be high—40-50 lb. per sq. ft.—the aerodynamic design clean and the structure weight carefully controlled to permit a weight ratio of not less than 2:1. The aircraft should be multi-engined, with, initially, air-cooled gasoline engines, moderately supercharged to 5,000-6,000 ft., equipped with automatic controls, and fitted with variable pitch or constant speed airscrews. Early consideration should be given to liquid cooled and sleeve valve engines and especially to compression ignition engines.

The aircraft should be fitted with lift-increasing devices to reduce the landing speed after a ten-hour flight to 60-65 m.p.h., with wheelbrakes and with dump valves in the fuel tanks.

Full provision should be made for the detection and prevention of icing.

The instrument equipment should include automatic pilot and complete blind flying, navigation and engine instruments.

### Conclusion

Determined efforts are about to be made to establish a commercial air service by aeroplane across the North Atlantic and thereby surmount one of the last of the great barriers to the linking of the continents by air transport.

In this paper, an attempt has been made to review the different aspects of the problem, the various considerations involved and to outline the organization, in a general way, of a commercial transatlantic air service.

The successful establishment of a transatlantic air service between London and Montreal will mark another achievement in the progress of transportation and one in which Canada will continue her close association of the past with new developments in transportation.

### Acknowledgments

The author desires to express his thanks for their assistance in the preparation of this paper to Mr. J. A. Wilson for information pertaining to the trans-Canada airway, to Mr. G. Herring for information regarding postal rates, etc., and for checking the section dealing with Canadian ship-shore services, to Dr. J. T. Henderson for his checking of the section on Radio Service, to Mr. S. J. Murphy for his suggestions in connection with the section on Instruments, to Mr. K. F. Tupper for his preparation of Table IV and his checking of certain sections of the paper, and to those gentlemen and organizations mentioned in the paper who so kindly furnished information.

## APPENDIX I

### North Atlantic Air Crossings*

(A) Non-Stop

| No. | Date | Pilot | Route | Aircraft | Time | Miles |
|---|---|---|---|---|---|---|
| | 1919 | | | | | |
| 1 | June 14 | Alcock and Brown | St. Johns-Clifden | Vickers Vimy | 16-12-00 | 1,890 |

## APPENDIX II

### Canadian Ship-Shore Air Mail Services

1. *Record of Montreal-Rimouski Summer Service**

| Year | Single trips: Scheduled | Single trips: Completed | Mail carried (pounds) |
|---|---|---|---|
| 1927 | | 10 | 2,469 |
| 1928 | | 94 | 62,834 |
| 1929 | 124 | 114 | 68,672 |
| 1930 | 92 | 72 | 54,044 |
| 1931 | 97 | 87 | 54,801 |
| 1932 | 83 | 69 | 38,987 |
| 1933 | 66 | 54 | 33,253 |
| 1934 | 59 | 50 | 31,546 |
| 1935 | 63 | 60 | 39,390 |
| 1936 | 63 | 54 | 42,676 |

2. *Record of Montreal-Moncton Winter Service**

| Year | Route | Single trips: Scheduled | Single trips: Completed | Mail carried (pounds) |
|---|---|---|---|---|
| 1929 | Montreal-Saint John | 66 | 56 | 4,279 |
| 1930 | Montreal-Moncton | 504 | 358 | 7,256 |
| 1931 | Montreal-Moncton | 206 | 169 | 2,775 |

3. *Schedule of Red Bay-Ottawa Service, 1932*

London—leave 2.00 p.m.—by aeroplane to Cherbourg.
Cherbourg—leave 6.30 p.m.—by *Empress of Britain*.
Strait of Belle Isle—2.30 a.m., third day out—transferred by naval tender.
Red Bay-Havre St. Pierre—by seaplane, 386 miles, 4 hours.
Havre St. Pierre-Rimouski—by flying boat, 290 miles, 3½ hours.
Rimouski-St. Hubert (Montreal)—by aeroplane, 314 miles, 3½ hours, arrive 4.00 p.m.—mail sorted.
Montreal-Ottawa—by aeroplane, 110 miles, 1 hour, arrive 5.30 p.m.
1,100 miles flown in 12 hours' flying time and 15 hours' elapsed time.

*Figures kindly furnished and checked by Mr. G. Herring, Chief Superintendent, Air and Land Mail Services.

## APPENDIX III

### Ship-Shore Catapult Equipment

(A) *Ile de France Installation.*

Catapult—compressed air operated
overall length 111 ft. 7 in.
weight 60 tons
launching capacity 4 tons at 112 m.p.h.

Aircraft— Liore and Olivier amphibian
weight 7,275 lb.
speed 105 m.p.h.
range 7 hours at 90 m.p.h.

later— CAMS—37 amphibian

(B) *Bremen and Europa Installations.*

Catapult—Heinkel K-2
compressed air operated—air pressure 28-78 atmospheres, depending on the wind speed
accelerating distance 65.6 ft.
braking distance 9.84 ft.
weight including catapult, circular rail and pivot and excluding understructure and compressor installation—260 tons
launching capacity 4 tons at 62.2 m.p.h.

Aircraft—Bremen—Heinkel He-12—low wing seaplane
weight empty 3,454 lb., loaded 5,100 lb.
later Junker Ju 46 with extra tanks
range 11 hours at 112 m.p.h. cruising speed
Europa—Heinkel He-58.

## APPENDIX IV

### Record of N.D.L. Bremen-Europa Ship-Shore Service

Westbound*—To New York

| Year | Flights | Flying time | | | Distance | | | Bags and parcels | Weight pounds |
|---|---|---|---|---|---|---|---|---|---|
| | | Min. | Max. | Aver. | Min. | Max. | Aver. | | |

## APPENDIX VII

### Depot Ships of the Deutsche Luft Hansa

In organizing its air mail service to South America, the Deutsche Luft Hansa adopted depot ships as the most satisfactory solution of the problem of operating the service across the South Atlantic under the conditions. The conditions confronting the D.L.H. included lack of aircraft capable of making the crossing non-stop with sufficient payload, lack of colonies and hence sites for bases and lack of airports with adequate facilities to permit the use of large heavily loaded landplanes.

Possessing in the Dornier Wal an efficient and seaworthy, long range flying boat, capable, almost fully loaded, of alighting and remaining afloat for days in South Atlantic weather and of taking off unaided from sheltered water, the use of depot ships enabled the D.L.H. to start the service without waiting for larger aircraft able to make the 1,890-mile ocean flight from Bathurst, Gambia to Natal, Brazil, non-stop.

Following successful trial flights to and from the depot ship *Westfalen*, stationed in mid-ocean, in November 1933, a regular fortnightly service (each way) was commenced February 4th, 1934, and a weekly service in September 1934. The service has been operated, with a high degree of regularity since that time, largely with Dornier Wals improved in 1934, driven by two-geared BMW-VIu motors and having a range of 1,680 miles, cruising at 120 m.p.h., the all-up weight being 22,000 lb. The first night flight was made October 23rd, 1934.*

In April 1934, the 5,500 miles from Pernambuco, Brazil, to Stuttgart were flown in two days, twenty-three hours, forty-five minutes. The average overall time from Stuttgart to Rio is fifty-five to fifty hours.

The mail load, each way, was originally 150 to 175 lb. (about 20,000 letters) and is now 450 to 500 lb., the capacity being 880 lb.

The German air mail letter rate is 1.50 and 1.25 marks for 5 grammes (1.6 oz.) to Buenos Aires and Rio de Janeiro respectively.

Up to the end of 1936, over 200 ocean flights had been made and more than 10,000,000 letters carried, with the loss of one aircraft only.

The D.L.H. now has three depot ships in service, the *Westfalen*, a converted Norddeutscher Lloyd cargo ship, the *Schwabenland*, formerly a cargo and passenger ship of the Dampfschiffahrts Gesselschaft Hansa and the *Ostmark*, a specially built motor ship placed in service in 1936. Particulars of these ships are given in the accompanying table.

The depot ships are fitted with the following equipment: a compressed air operated catapult for launching the flying boats; a rotating and folding electric crane for lifting the flying boats on deck or on the catapult; a trailing apron or "strausegel" to facilitate hoisting the aircraft aboard in rough weather; complete radio and meteorological equipment; accommodation for aircraft on deck to permit servicing and repairs.

The apron, invented by Herr Hein, is of sailcloth some 100 ft. long, with bamboo spreaders and drag pockets on the under side. It trails from a roller at the stern of the ship and, when not in use, is rolled up. When the aircraft alights, the ship reduces way, the apron submerges and the aircraft taxies on it. The ship then speeds up, the canvas becomes taut and raises the aircraft almost entirely out of the water. A secure connection between ship and aircraft is thus provided so that, even in a heavy sea, the aircraft can be lifted inboard by the crane without risk.

The *Westfalen* and *Schwabenland* each have two short wave transmitters (800 watts for distant ground station and 60 watts for aircraft), one medium wave transmitter (key and voice, 300-3,000 m.), duplicate receivers and loop aerial for direction finding.

The aircraft are equipped with 20 watt medium and short wave transmitters and receivers and loop aerial. The normal range of the loop aerial is 600 nautical miles and occasionally up to 900 miles.

The *Ostmark* is equipped with four standard transmitters and six receivers for long and short waves, including an emergency spark transmitter and a radiogoniometer.

The ships are also equipped as meteorological and oceanographic stations, staffed by the Deutsche Seewarte. Weather reports are received from each other, from ships at sea, and from land stations, particularly upper air pilot balloon observations from West African stations. Balloon observations are also made from the ships. Weather maps and forecasts are prepared in each ship for each flight.

Originally, the D.L.H. employed the depot ship primarily as a refueling station. The old 7-ton Wals were unable to fly non-stop across the South Atlantic. The flying boat flew to the depot ship, stationed in mid-ocean, and alighted on the sea. The mail was transferred to a second aircraft, already prepared on the catapult, which was then launched and continued the crossing while the first was hoisted aboard, refueled and made ready to continue the next crossing. Alternatively, on reaching the depot ship, the aircraft was hoisted aboard, refueled and launched to complete the crossing.

With the improved 10-ton Wals, having range sufficient for the whole flight from Africa to Brazil, there was no need for mid-ocean refueling and the depot ships have functioned as launching stations. As such, stationed in sheltered water, and with improved crane arrangements, the need for the trailing apron has largely disappeared. With two depot ships, one is stationed at Bathurst, the second at Fernando de Noronha. At Bathurst, the mail is placed on the aircraft on the ship; the latter leaves port and the aircraft is launched. On reaching the second ship, if enough fuel is left, the aircraft continues to Natal, otherwise it alights and is refueled. From Natal, the aircraft flies to the depot ship, is taken aboard, the ship puts to sea and some hours later the aircraft is catapulted toward Bathurst.

The Deutsche Luft Hansa apparently contemplates initiating in 1937 a North Atlantic service via the Azores and Bermuda, using the same technique which has proved so successful in the South Atlantic. The *Schwabenland* and a sister ship, now building, will be used for launching.

The oversea flight being longer, new aircraft have been built for the North Atlantic. These are the Dornier DO18 flying boats, powered by tandem Junker Jumo 500/560 Diesel engines and designed for the carriage of mail and express over long distances after catapulting, and the Ha139 twin float monoplanes for catapulting, built by the Hamburger Flugzeugbau, weighing 11½ tons, with four Jumo motors and having a top speed of 186 m.p.h. and a range of 3,100 miles.

During September and October 1936, the *Schwabenland*, the largest of the three ships, was used in trial flights across the North Atlantic by two DO18 flying boats, to study flying conditions, equipment, navigation and landing facilities. In these trials, the depot ship functioned as a launching station. Two flights each way were made. First launched westward at the Azores, the two aircraft flew to New York, one non-stop (2,390 miles) and the other via Bermuda (2,063 miles) where it was again catapulted. The *Schwabenland*, having followed to New York, the aircraft were catapulted for the eastward flight via Bermuda to the Azores. The second westward crossing was made non-stop to New York. The aircraft then flew to Sydney, N.S., were launched from the ship and flew to the Azores.

The flights were reported successful. With the exception of a leaking radiator, during one of the first westward flights, there was no trouble and no replacements were necessary in the aircraft or motors and the flights were made, without waiting, in such weather as occurred.

As a refueling base, and for launching aircraft, the catapult equipped depot ship possesses the advantages of mobility and lower cost. If the aircraft is forced down at sea within reasonable distance, the ship can proceed to it and, in a moderate sea, using the trailing apron, the aircraft can be taken aboard. As a launching device, the mobility of the depot ship permits the base to be shifted at will. The cost of the ship is relatively low and the Diesel engined depot ship is economical to operate, due to the absence of standby losses when not under way, the readiness for immediate service and to the economy of and small space occupied by the engines.

### Deutsche Luft Hansa Depot Ships

| *Ship* | *Westfalen* | *Schwabenland* | *Ostmark* |
|---|---|---|---|
| Fitted out or built | 1932 | 1934 | 1936 |
| Type | steam | twin ? Diesel | twin Diesel |
| Gross registered tonnage | 5,124 | 8,188 | 2,000 |
| Power—hp | 2,750 | 3,600 | 1,800-2,000 |
| Speed—knots | 11.5 | 12 | 13½-15 |
| Length—ft | 410-0 | 460-0 | 245-0 |
| Beam—ft | 52-6 | | 37-6 |
| Draught—ft | 28-0 | | |
| Crew | 40 | | |
| Gasoline tankage—gals | 8,800 | 19,800 | |
| *Catapult* | | | |
| Type | Heinkel K-6 | Heinkel | Heinkel K-9 |
| Location | bow | stern | bow |
| Maximum capacity— | | | |
| Gross weight—lb | 30,860 | 30,800 | 33,000 |
| Take-off speed—m.p.h | 93 | 93 | 93 |
| Maximum acceleration | 3.5 $g$ | 3.5 $g$ | |
| Mean acceleration | 2.8 $g$ | 2.8 $g$ | |
| Length of accel. run—ft | 103-9 | 103-9 | 103-9 |
| Length of braked run—ft | 16-5 | 18-0 | 18-0 |
| Total length—ft | 138-0 | 136-0 | 136-0 |
| Width | 6-6 | 7-3 | |
| Weight of carriage—lb | | | 3,960 |
| Stroke of piston | 18-8 | | |
| Maximum pressure—atmos | 150 | 160 | 160 |
| Total weight—lb | 128,000 | 205,000 | |
| *Crane—Electric* | | | |
| Type | rotating | rotating and folding | rotating |
| Maximum load—lb | 33,000 | 33,000 | 33,000 |
| *Aircraft Accommodation* | | | |
| Number | | 3 | 1 |

*For catapulting on moonless nights, a motor drive was fitted to the artificial horizon.

## APPENDIX VIII

### Armstrong Seadromes

In the floating aerodrome as developed by Edward R. Armstrong for use as a refueling station on Atlantic air routes, the flight deck is 1,500 ft. long and 300 ft. wide amidships, and 150 ft. wide at the ends. The deck is supported some 100 ft. above sea level on 32 buoyancy units, in the form of vertical streamlined telescoping columns, the upper portions of which constitute buoyancy chambers and the lower, ballast chambers. When the seadrome is in place the cylinders are extended, the ballast sections sinking to a depth of about 200 ft. The buoyancy units are of streamline section to reduce the resistance to the passage of waves, and are so designed that the centres of buoyancy and gravity are well below the water surface. As a result, it is claimed that tank tests have shown that the seadrome is unaffected by wave motion and has no tendency to roll or pitch. It is said that theory indicates and experience in submarines confirms that wave action is hardly perceptible at a depth of 200 ft.

A second deck, below the flying platform and reached by elevator, carries hangars, workshop, radio and meteorological stations and accommodation for crew and passengers.

The decks and buoyancy units are interconnected by lattice beams to form a rigid structural unit weighing some 28,000 tons. The displacement with full ballast tanks will be about 67,000 tons.

The difficulty of mooring the seadrome under Atlantic conditions is believed to have been overcome. The conditions designed for are: depths of 3-4 miles, 70 mile wind, and 1½ knot current, the latter imposing a cable tension of some 200,000 lb.

The mushroom shaped 1,650 ton anchor will be floated to position, buoyancy chambers will then be flooded and the rate of descent of the anchor checked by canvas drogues.

The anchor will be connected to a triangular buoy of the same type of construction as the seadrome, by means of two suspension bridge type steel cables connected through chains to the anchor.

The triangular anchor buoy will carry beacon light and radio equipment.

The seadrome is in turn connected to the buoy. To provide a further margin under extreme conditions and also for manoeuvring, four of the buoyancy units of the seadrome are fitted with electric motor driven propellers capable of developing a total thrust of 100,000 lb.

The cost of each seadrome unit is estimated to be between six and seven million dollars.

The seadrome project contemplates the stationing of seadromes at approximately 500-mile intervals between Europe and America, in one case along the 38th parallel of latitude to secure better weather conditions, or, as proposed by M. Bleriot, near the latitude of New York. The latter suggested that if initially all seadromes were not constructed, intermediate floating islands equipped as meteorological and radio stations and beacons should be provided, anchored in the same manner as the seadromes, and hence readily replaced by the latter when constructed. A somewhat similar suggestion has been made in connection with the Pacific route; that small structures, resembling the anchorage buoy of the seadromes, equipped as radio and meteorological stations, and with lifeboats and motor patrol boat to send supplies to aircraft forced down, should be provided at a cost of about $200,000 each.

The economics of the seadrome project, as outlined by M. Louis Bleriot, are:

| | |
|---|---|
| Capital cost— | |
| 4 seadromes at 110,000,000 fr. each say.......... | 500,000,000 fr. |
| Yearly revenue— | |
| *Postal* 2/7 of receipts from carriage of 500 tonnes of letters and 800 tonnes of papers and parcels to yield.......... | 90,000,000 fr. |
| *Passenger* 1/5 of receipts from fares of 80,000 passengers at 5,250 fr. each.......... | 60,000,000 fr. |
| *Other* sale of gasoline and oil, rental of hangars and stores, hotels, etc.......... | 12,000,000 fr. |
| Total say.......... | 170,000,000 fr. |
| Operating charges— | |
| Maintenance, salaries, insurance.......... | 33,000,000 fr. |
| Balance..........say | 140,000,000 fr. |

Technically the construction, anchorage and seaworthiness of the seadrome appears practicable and it is reported to have received the approval of the U.S. Navy Department and of marine engineers.

From an aeronautical standpoint experience with aircraft carriers would indicate the plan to be feasible, although the deck area may be inadequate for modern, large, high speed, commercial aircraft with high wing loading, and landing in fog would be hazardous.

A serious obstacle to the project is the uncertainty as to the territorial status of the seadrome. Is it a ship or territory—national or international? What is its status in war? Virtually it appears to be an island, well stocked with fuel and other supplies, but an island capable of being moved and hence a valuable prize.

The lower cost per pound rendered possible by the smaller fuel load for the shorter stages between seadromes is attractive. Whether this reduction in transport cost is sufficient to offset the great cost of the seadromes is doubtful. It appears that the tolls that it will be necessary to impose to make the project pay will be too high for the traffic to bear.

## APPENDIX IX

### Take-Off Conditions

The calculation of the take-off conditions of aircraft requires a detailed knowledge of the particular aircraft, including the aerodynamic characteristics of the aircraft and propeller, hydrodynamic characteristics of the hull, engine performance, condition of aerodrome, and many other factors; and even when these are reasonably well known, certain assumptions still have to be made and these, with the variation in the technique of take-off of different pilots, render close prediction difficult.

For this reason and also because a general outline only is here necessary, the following very rough figures are given to illustrate the take-off limitations.

Although not included in the following, "ground effect" is an important factor in connection with take-off. Ground effect through reducing the induced drag of the wing and the angle of attack for a given lift coefficient facilitates take-off. At the same time, a heavily loaded aircraft, having taken off, may find it impossible to climb beyond the zone of influence of ground effect which is confined to a height above the ground about equal to the span of the wings.

*Symbols*

$W$—gross weight of aircraft, lb.
$P$ —rated horse power of engines.
$D$ —air resistance of aircraft (without hull or floats in case of seaplane) without slipstream, lb.
$R$ —reaction drag—ground or water resistance, lb.
$F$ —effective accelerating force, lb.
$T$ —propeller thrust corrected for slipstream resistance, lb.
$V$ —velocity, ft. per sec.
$S$ —wing area, sq. ft.
$s$ —distance, ft.
$t$ —time, seconds.
$g$ —acceleration of gravity, ft. per sec. per sec.
$q=\frac{1}{2}\rho V^2$—dynamic pressure, lb. per sq. ft.
$\rho$ —mass density of air, slugs per cu. ft.
$\mu$ —coefficient of rolling friction.

*Subscripts*

0 —at beginning of ground run.
1 —at take-off.
$m$—mean during take-off.
$w$ —wind.

The take-off is usually analyzed in three stages, the ground run up to unstick speed, the change of flight path, through an arc to climbing attitude, and climb to clear an obstacle of given height. It will be sufficient to consider only the first stage here.

The minimum speed of flight is simply given by

$$V=\sqrt{\frac{1}{C_{L\max}\cdot\frac{\rho}{2}}}\sqrt{\frac{W}{S}}$$

The aircraft may be stalled off at minimum speed. In the case of a seaplane it may be necessary to stall off the top of a wave. Ordinarily the take-off speed may be possibly 10 per cent higher than stalling speed (which implies that the wing is operating at a $C_L$ about 20 per cent less than $C_{L\max}$), in order that some reserve of lift may be available after take-off. Minimum take-off run or time, however, usually requires that the aircraft be stalled off. As already mentioned, ground effect permits the aircraft to take off at a speed below the minimum for flight at an altitude.

An expression for the length of the ground run has been obtained by integration from the energy equation by Dr. Martin Shrenk, as follows:

$$Fds=\frac{W}{g}\,d\left(\frac{V^2}{2}\right)\quad\text{and}\quad\frac{V^2}{2}=\frac{q}{\rho}$$

$$ds=\frac{W}{\rho g}\cdot\frac{dq}{F}$$

It is assumed that the propeller thrust decreases linearly with $q$ and that the angle of attack is constant during the ground run so that the reaction drag and air resistance are proportional to $q$. Then

$$F=F_0-\frac{F_0-F_1}{q_1}\cdot q$$

and

$$ds=\frac{W}{\rho g}\,\frac{dq}{\left(F_0-\frac{F_0-F_1}{q_1}q\right)}$$

integrating, and determining constant of integration by the fact that $s=0$ when $q=0$

$$s_1=\frac{W}{\rho g}\cdot\frac{q_1}{F_0-F_1}\cdot\log\frac{F_0}{F_1}$$

A simplification can be effected by assuming, instead of a linear reduction in effective accelerating force from $F_0$ to $F_1$, that the mean accelerating force acts uniformly during take-off, then

$$F_m = \frac{F_0 + F_1}{2}$$

and

$$ds = \frac{W}{\rho g} \cdot \frac{dq}{F_m}$$

integrating

$$s_1 = \frac{W}{F_m} \cdot \frac{q_1}{\rho g} = \frac{W}{F_m} \cdot \frac{V_1^2}{2g} = \frac{W}{F_m} \cdot \frac{W}{S} \cdot \frac{1}{C_{L\max} \rho g}$$

The last formulae are in error less than 4 per cent where $F_0$ is equal to or less than twice $F_1$.

Shrenk indicates that the minimum ground run results when the run is made at an angle of attack approximately equal to that for minimum drag in flight, until the minimum flight speed is reached, when the aeroplane is pulled up to an angle corresponding to minimum flight speed and the aeroplane lifts off.

Assuming constant acceleration during take-off,

since $$s = \frac{V_1 t}{2}$$

$$t = \frac{W}{F_m} \cdot \frac{V_1}{g} = \frac{W}{F_m} \sqrt{\frac{W}{S}} \frac{\sqrt{C_{L\max} \rho}}{g\sqrt{2}}$$

*Effect of Head Wind on Take-off.*

The principal effect of a head wind is to reduce the ground speed for take-off to $V_1 - V_w$ together with a minor effect due to the resulting increase in propeller efficiency.

The take-off run is reduced to

$$s = \frac{W}{F_m} \frac{(V_1 - V_w)^2}{2g}$$

It is evident from this formula that the reduction in ground run due to a relatively light wind is appreciable. A wind of velocity equal to 10 per cent of the take-off speed reduces the ground run about 20 per cent.

The effective accelerating force is:

$$F = T - R - D$$

*Air Resistance.*

The air drag $D$ is practically the same for modern aircraft whether seaplane or landplane.

Assuming constant attitude during take-off (angle of maximum lift) which is as accurate as other assumptions that have to be made, the air resistance increases from zero to a maximum in proportion to $V^2$. The resistance at take-off will be

$$D = \frac{W}{L/D}$$

where the value of $L/D$ is that corresponding to maximum lift, which, in modern aircraft, will range from 7 to 9 depending on the cleanliness of design.

As the variation of drag with speed for constant angle is parabolic, the average air resistance during take-off will be $\frac{D}{3}$.

Taking $L/D = 8$ the average air drag is

$$D_m = \frac{W}{24} = 0.04\,W$$

*Reaction Drag.*

It is the difference between the water resistance of seaplanes and the ground resistance of landplanes that is responsible for the difference in the take-off performance of these two types of aircraft.

(a) Landplanes

The friction drag $R = \mu W_m$

$W_m$ is the load on the ground, which equals the difference between the gross weight and the air lift and decreases from $W$ to zero. As the variation of lift follows the same parabolic law as that of the drag during take-off, the average ground reaction during take-off is $\frac{2}{3} W$ and the mean reaction drag is

$$R_m = \frac{2}{3} \mu W$$

$\mu$ depends upon the nature of the take-off surface. For reasonably good conditions, say hard turf and short grass, a conservative value is $\mu = .06$.

Then $R_m = 0.04\,W$

(b) Seaplanes

The familiar form of the curve of water resistance of a hull during take-off plotted on speed has been shown by Gouge to be approximated by a parabola, the maximum hump resistance ranging from 0.16 $W$ for a good hull to 0.25 $W$ for a rather poor one.

On this basis the average water resistance during take-off will be 2/3 of the maximum or say

$$R_m = 0.10\,W$$

The water resistance of the hull includes the air drag.

*Effective Propeller Thrust.*

The thrust can be made sensibly the same for seaplane and landplane.

A reasonable assumption is that

$$T = K \cdot P$$

where the constant $K$ depends on the pitch angle and speed of the propeller and varies from 3.4 for direct drive and fixed or two pitch

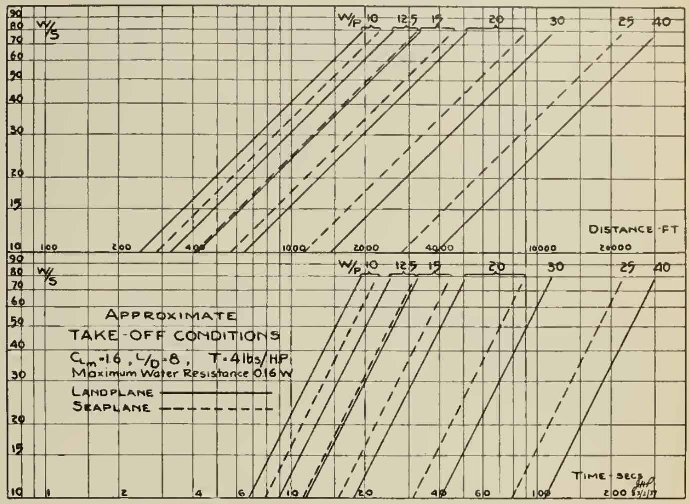

Fig. 25—Approximate Take-Off Conditions.

propellers to 4.2 for geared engines with constant speed propellers. An average value may be taken as 4.

Assume the propeller thrust constant during take-off and equal to $4\,P$.

*Average Effective Accelerating Thrust.*

(a) Landplanes

Using average values

$$\begin{aligned} F_m &= T - R - D \\ &= 4\,P - 0.04\,W - 0.04\,W \\ &= 4\,P - 0.08\,W \\ &= \left(\frac{4}{W/P} - 0.08\right) W \end{aligned}$$

and $$\frac{W}{F_m} = \frac{12\frac{W}{P}}{50 - \frac{W}{P}} \text{ roughly}$$

(b) Seaplanes

$$\begin{aligned} F_m &= 4\,P - 0.10\,W - 0.04\,W \\ &= 4\,P - 0.14\,W \\ &= \left(\frac{4}{W/P} - 0.14\right) W \end{aligned}$$

and $$\frac{W}{F_m} = \frac{7\frac{W}{P}}{30 - \frac{W}{P}}$$

It has been found that in many cases the acceleration during 2/3 or more of the take-off run is sensibly constant and hence the net accelerating force must be approximately constant.

*Finally*

For landplanes

$$s = \frac{12\frac{W}{P}}{50 - \frac{W}{P}} \cdot \frac{V_1^2}{2g} = \frac{12\frac{W}{P}}{50 - \frac{W}{P}} \cdot \frac{W}{S} \cdot \frac{1}{C_{L\max} \rho g}$$

For seaplanes

$$s = \frac{7\frac{W}{P}}{30 - \frac{W}{P}} \cdot \frac{V_1^2}{2g} = \frac{7\frac{W}{P}}{30 - \frac{W}{P}} \cdot \frac{W}{S} \cdot \frac{1}{C_{L\max} \rho g}$$

For landplanes

$$t = \frac{12\frac{W}{P}}{50 - \frac{W}{P}} \cdot \frac{V_1}{g} = \frac{12\frac{W}{P}}{50 - \frac{W}{P}} \sqrt{\frac{W}{S}} \cdot \frac{\sqrt{C_{L\max} \rho}}{g\sqrt{2}}$$

For seaplanes

$$t = \frac{7\frac{W}{P}}{30 - \frac{W}{P}} \cdot \frac{V_1}{g} = \frac{7\frac{W}{P}}{30 - \frac{W}{P}} \sqrt{\frac{W}{S}} \cdot \frac{\sqrt{C_{L\max}\rho}}{g\sqrt{2}}$$

The formulae are plotted in the accompanying Fig. 25.

For landplanes, the take-off distance is important, to reduce the size of aerodromes and runways required, while for seaplanes the take-off time is important to reduce the punishment of the hull by waves and to permit take-off from small or crowded harbours.

It is evident from the foregoing formulae that the take-off distance increases as the gross weight, as the square of the take-off speed and hence as the wing loading and with increase of power loading.

The take-off time increases as the gross weight, as the take-off speed and hence as the square root of the wing loading, and with increase of power loading.

Evidently also cleanness of both aerodynamic and hydrodynamic design improve take-off as does condition of the runway or take-off surface.

## APPENDIX X

### Fixed Long Run Shore Catapult

With the limited space available on shipboard, the accelerations are necessarily high in ship catapults. On the other hand, with relatively unlimited space available on land, the length of the track can be long and the accelerations moderate. This is illustrated by the figures in the following table, for two ship catapults and for a suggested land catapult.

| Catapult | Acceleration run | Weight of aircraft | Launching m.p.h. | Speed f.p.s. | Aver. f.p.s.$^2$ | Accel. $g$ | Time sec. | Accel. force |
|---|---|---|---|---|---|---|---|---|
| *Bremen* | 65 ft. 0 in. | 4 tons | 62.2 | 91 | 63.7 | 1.98 | 1.43 | $2W$ |
| *Ostmark* (Heinkel K9) | 103 ft. 9 in. | 15 tons | 93.0 | 136 | 89.2 | 2.77 | 1.53 | $2.8\ W$ |
| Land | 2,000 ft. 0 in. | 25 tons | 100.0 | 147 | 5.4 | 0.167 | 27.4 | $W/6$ |

Evidently, the accelerations need not be prohibitive in land catapulting. An acceleration of 0.16 $g$ is rather greater than that in an electric train, but less than that possible in a motor car.

The general arrangement of the proposed land catapult is as follows:

*Track*

There are two possible arrangements of the track worth considering: one employing a long fixed track and the other using a shorter track capable of rotation. If the winds at the site of the station are reasonably constant in direction, the former is preferable because of its lower cost and longer possible run. If the winds vary widely in direction, the latter is better, since it permits full advantage to be taken of the assistance of the wind in launching and the car is largely relieved of lateral forces.

The fixed straight track is laid in the direction of the prevailing wind and may have a slope downward in the direction of launching. The track is of standard railroad construction and can be built over quite rough terrain using, where necessary, standard railroad practice in the matter of fills, trestles, etc. Use of the track permits take-off from a site where the cost of construction of an aerodrome would be prohibitive. In the case of marine aircraft, the track and car permits the use of smaller protected waters since an aircraft can alight in a much smaller harbour than that from which it can take-off. In this case, if the prevailing wind direction is suitable, the track can be built along the sandy beach or rocky shore of the harbour or bay or of a stream running into it.

For the rotating track, latticed girder construction is used and rotation provided for by supporting the girder at about the quarter points, on two cars running on a large diameter circular track (complete or arc only) or alternatively, by pivoting at one point and using one car on a track of twice the diameter. Beyond the supporting cars, the girder is a cantilever and, at the launching end, can be relatively light because the weight of the aircraft is here becoming air-borne.

The figure given for the average acceleration, using a track 2,000 ft. long, indicates that a much shorter track can be used without encountering excessive accelerations. A rotating track would necessarily be shorter, possibly not over 1,000 ft. long. In either case, length must be provided for deceleration of the car following the launch.

*Car*

The size, shape and arrangement of the car will depend upon the type of drive, type of aircraft, the track and other conditions.

The external form of the car should be carefully designed, possibly after wind tunnel tests, in order that the resistance and interference with the air flow about the aircraft may be reduced to a minimum. If the car produces much disturbance of the flow of air, a difficult change of flight conditions may be encountered during the launch when the aircraft passes beyond the influence of the disturbance.

For the propulsion of the car, there are several alternatives, depending on the length of the track and local conditions. A cable drive appears promising, particularly for a short track although mine practice proves long high speed cable drives practicable. A cable drive for the car of the model testing basin at Ottawa has proved satisfactory. With cable drive, the car can be light, but the weight of the cables will increase the required accelerating force.

For long tracks, self-propelled cars driven by gasoline, Diesel or even steam engines may be used. The tractive effort required will be equal to the sum of the drag of the aircraft, car resistance and accelerating force. The resistance of the car, including rolling and journal friction and air drag will increase with speed up to about 25 lb. per ton at top speed. This is relatively small and, together with the drag of the aircraft, may be assumed to be taken care of by the thrust of the airscrews of the aircraft.

Assuming constant acceleration, the accelerating force for the suggested catapult of the foregoing cable will be one-sixth the total weight of the aircraft and car. A reasonable value for the coefficient of traction between wheels and rails is 0.25 and, as this exceeds the accelerating force coefficient, it is clear that any weight of car will provide sufficient traction if the lift of the wings does not exceed one-third the weight of the aircraft. To reduce the force and power for acceleration, the weight of the car should be kept low. If it is assumed equal to one-half the weight $W$ of the aircraft, the average total accelerating force will be $W/4$, traction will be $3/8\ W$ and the maximum power (constant acceleration) required will be about 0.07 $W$ hp. For a 25-ton aircraft, the accelerating force will be 12,500 lb. and the maximum power 3,500 hp.

However, the accelerations would not, in practice, be constant, but vary, being high at the beginning of the run and dropping to zero at the instant of launching and the maximum power required would then be much less than that given.

The principal handicap of wheel traction drive for the car is the weight of the motive power and the vicious circle that results from weight requiring power to accelerate and power, in turn, requiring weight.

An attractive form of drive is by means of aircraft engines and airscrews. The aircraft engine is the lightest type of prime mover, hence the car can be very light and traction difficulties are avoided. Airscrews designed for the particular low speed conditions are used and the engines are operated at full take-off power for the short time necessary for the launching.

For the example considered, assuming the car weight is reduced to $W/4$ with airscrew drive, the accelerating force (constant acceleration) will be about $W/5$ and the maximum power about .04 $W$ or, for a 25-ton aircraft, 10,000 lb. and 2,000 hp., respectively. By using four 500-600 hp. engines, mounted on cantilever outriggers on each side of the car, the airscrews will be well below the aircraft wings and an effective drive provided.

An operator, riding on the car, controls the speed, to accelerate in the desired way and, after the launch, brings the car to rest.

*Cradle*

The aircraft cradle is pivoted in the car to permit the aircraft to align itself (weather-vane) with the relative wind. The aircraft is cradled at a fixed incidence, slightly below that of maximum lift and held in place by a locking device. On reaching launching speed, acceleration is reduced to zero and the speed of the car held constant until the pilot signals and releases the lock. The car then begins to decelerate and the aircraft flies off.

With ample accelerating thrust available from the car, there is no need to reduce the aircraft drag during acceleration, by cradling the aircraft on a tilting cradle at the incidence of minimum drag and, at the instant of take-off, increase the incidence by use of the aircraft controls. A slight freedom in tilt may be desirable to enable the pilot to feel if the aircraft controls are set appropriately for the speed at launching.

The aircraft may be lifted from the ground or water and placed on the cradle by means of a rotating crane as in the D.L.H. depot ships.

## APPENDIX XI

### Mayo Composite Aircraft

The reported construction and performance details of the composite aircraft, now under construction, are as follows:

Upper Component—'Mercury'

Four-engined, high wing, float seaplane—span 73 ft. 0 in.; length 51 ft. 0 in.; height 20 ft. 3 in.; wing area 611 sq. ft.; tare weight 9,760 lb.; gross weight 20,000 lb.

Engines—Four Napier Rapier, Series V, 16-cylinder, air-cooled H engines; dry weight 720 lb.

Power—rated 315 hp. at 10,000 ft.
maximum, 340 hp. at 13,000 ft.
maximum r.p.m. 4,000.

Propellers—Fixed pitch, wooden.

Performance—Specified range 3,500 miles with 1,000 lb. of mail. Predicted range 3,380 miles in still air or 2,150 miles against 60-mile headwind, with possibly 4,000 lb. mail.

Lower Component—'Maia'

Four-engined, high wing, flying boat, similar to Short Empire boats—span 114 ft. 0 in.; length 84 ft. 11 in.; height 32 ft. 7 in.; wing area 1,750 sq. ft.

Engines—Four Bristol Pegasus.

Composite Aircraft

Combined horsepower nearly 5,000.

Power loading about 11 lb. per hp.

Combined weight about 42,000 lb.

## APPENDIX XII

### The Ice Hazard

Until the advent of modern commercial air transport, operating on fixed routes, on regular schedules, in all seasons and in all kinds of weather, the ice hazard was not serious. In recent years, however, there have been an increasing number of interruptions to commercial services and forced landings, some disastrous, due to this cause.

The meteorological and physical conditions and processes leading to the formation of ice on aircraft are complex and are not yet properly understood. Hence the hazard is difficult to forecast accurately even with the best of meteorological organizations.

*Character of the Ice Deposit*

The nature of the ice formation varies with the conditions. Three principal types of deposit are generally recognized:

1. Clear ice or "glaze," normally smooth but which may be rough when mixed with snow or sleet or ridged when freezing is slow. The ice builds up on the leading edge in a blunt nosed shape, i.e., "mushrooms," tapering sharply to the rear. Occasionally the wings are covered both top and bottom, and icicles form at the trailing edge. The ice adheres tenaciously. This type of ice has the most serious effects.
2. Hard, white, opaque granular deposit or "rime" which builds forward from the leading edge in a sharp-nosed shape. Rime is encountered more frequently but generally adheres less tenaciously than clear ice, except at very low temperatures, and is less serious.
3. Frost, a light feathery crystalline deposit with little adhesion, which is not dangerous.

*Conditions*

Ice deposition in serious amounts occurs practically only when the aircraft is in some form of visible moisture, cloud, fog, rain or mist, at temperatures below and close to 32 deg. F. and high relative humidity, 90 per cent or over.

Supercooled water droplets in the air remain liquid at temperatures below freezing, and have been observed at surprisingly low temperatures, as for instance −4 deg. F. in America, −29.2 deg. F. in fog in Greenland and −37.2 deg. F. in Antarctica. The supercooled state is unstable, and on collision with the aircraft the droplets freeze. On impact, part of the droplet freezes, forming a slushy mixture at 32 deg. F. which changes to ice as the latent heat is removed through evaporation or conduction to the structure. The rapidity of freezing depends on the degree of supercooling. Droplets at, or a few degrees below 32 deg. F. freeze slowly to form clear ice; if highly supercooled, at several degrees below freezing, the droplets freeze rapidly to form rime. Apparently large droplets, as in rain, generally form clear ice and the minute droplets of clouds form rime. If droplets of different sizes are present, the deposit may be either clear ice or rime and if the former, the coating will be rough. Most rapid icing usually occurs where there is temperature inversion and rain is falling from comparatively warm clouds above on a layer of air or cloud at a temperature below freezing in which the aircraft is flying.

A thin coating of ice may be formed in clear air above cloud, from the moisture collected in passing through the cloud.

Occasionally icing occurs at temperatures above freezing when the aircraft is flying in a layer of dry air on which rain is falling from above. Evaporation of the liquid film on the aircraft causes, as long as the surface is wet, a temperature drop of several degrees depending on the relative humidity, sufficient to result in freezing especially since the rain drops falling through the dry layer are themselves cooled by evaporation, below air temperature, and may be supercooled. Cooling also results from adiabatic expansion of the air flowing over the wing surface. The latter cooling is greatest at the points of highest velocity.

The formation of frost on aircraft is a result of sublimation and therefore dependent on a state of supersaturation with respect to ice. Frosting may occur when, after being cooled to a low temperature in a cold strata, an aircraft descends rapidly into a highly saturated layer at a higher but still subfreezing temperature. Frosting may also occur in flight in nearly saturated air at a temperature below freezing due to adiabatic cooling.

Sleet alone does not collect on aircraft, but mixed with rain may form a rough and dangerous coating. Similarly, dry snow does not adhere, but a mixture of snow and rain or cloud droplets will likely result in a heavy deposit of frozen slush. Clouds composed of ice spicules do not form any appreciable deposit.

The structural material of the aircraft is of importance only insofar as it affects the start of the ice formation. The rate of growth, after the initial coating, varies but little. There is some indication that highly polished surfaces reduce the adhesion of ice, and that roughness such as seams and rivets favour icing. Thick wing monoplanes appear to be less susceptible to icing than thin wing biplanes.

High speeds favour icing through increasing the quantity of moisture encountered in a given time, the rate of heat dissipation, and the adiabatic cooling.

Records of autographic meteorological instruments carried by aircraft indicate that in the United States clear ice may begin to form at temperatures from 33.8 to 1.4 deg. F. and rime from 33.8 deg. F. to −4 deg. F. but that most frequently clear ice commences at 32 deg. F. and rime at 28.4 deg. F. Rime occurs two or three times as frequently as ice. Both types are encountered most frequently at elevations between 1,500 and 5,000 ft. and somewhat less often at 8,000 to 10,000 ft. for clear ice and 13,000 to 15,000 for rime, but icing may be met with at any elevation within the range covered, i.e., up to 18,000 ft. The region from 6,500 to 8,000 ft. is one of low frequency for both types.

Clear ice and rime form most frequently in strato-cumulus clouds, with high frequencies also, for clear ice in alto-stratus and for rime in stratus clouds. No deposits were reported in cumulus clouds doubtless because flights were made before daylight. Cumulus and strato-cumulus are known to be favourable to icing.

*Effects*

The effects of the accumulation of ice on aircraft are numerous and serious.

The most serious effect of icing is the deformation of the aerodynamic forms, particularly of the wing and tail surfaces and the resulting adverse effects on performance. Lift is decreased, and drag increased, to such an extent in many cases that flight cannot be maintained even at full throttle. The cleaner the aerodynamic design, the more quickly are the effects apparent.

The malformation resulting from ice causes vibration of wires, wing tips and tail which, at high speed, may start very suddenly and may cause failure of the part.

The increase in weight due to icing is generally of secondary importance. The additional load is partly offset by the weight of the fuel consumed during the accumulation of the ice. The effect of the weight of the ice is chiefly noticeable in banking.

In spite of centrifugal force, the airscrew is also subject to icing. In addition to the effects on efficiency, deposits on the airscrew constitute a serious hazard if thrown off irregularly. Balance is destroyed and vibrations, in extreme cases of a disastrous character, are caused. To minimize vibration, throttling is often necessary, leading to more rapid icing of the airscrew. The disturbances are amplified by the gears in a geared engine.

Ice may interfere with the movement of control surfaces and of external controls. The latter is not serious in modern aircraft with interior controls.

The power plant may be affected through the freezing of radiator shutters, clogging of air intake screen and closing of tank and crank case vents if they project into the air stream.

Instruments are also affected through the icing of such elements as Venturis, air speed heads, windmills and radio antenna, both trailing and fixed.

Windows may be coated, and, if sliding, may freeze tight and prevent their operation in landing.

# Industrial Zoning

*Hugh Beaver, M.I.Chem.E.,*
*Partner, Sir Alexander Gibb and Partners, London, England.*

**Paper presented at the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

**There has already been definite progress towards the state control of industry in Great Britain, particularly as regards unemployment and the location of industries. The author believes that this will continue and that ultimate success will largely depend on the provision of cheap transport and cheap power.**

In putting forward for consideration on this occasion a paper with this title and subject, some word of explanation, and it may be apology, is needed. A purely technical engineering paper would be much more easily transplanted from one country to another, than can be a paper which deals with the adaptation of engineering experience and training to the economic solution of the particular problems of my own country. This paper does not seek, and could not attempt, to discuss conditions or problems in Canada. It deals specifically with those of Great Britain. But although conditions there are in many ways so different that it might seem no analogies could be drawn, fundamentally the evils of industrial depression and unemployment, and their causes are, I am convinced, the same or very similar on both sides of the Atlantic. If it were otherwise it would be merely to waste your time and your patience, to offer a paper that could have no application to your own conditions, and no interest to yourselves. I believe, however, on the contrary, that there is a good deal that you can learn from our mistakes—and at worst you may be able to offer us useful constructive criticism when you know the facts.

With this explanation and apology, I will proceed to discuss the subject of my paper—Industrial Zoning—wholly and solely from the point of view of my own country, and by way of examination of those conditions, of which alone I have first hand knowledge. In the first place I would explain what I mean to include in "Industrial Zoning." It will, I hope, emerge more clearly in the course of the paper, but it will simplify matters for me to explain at once that I take the title, for want of something better, to refer to the whole question of the economic and technical direction of a nation's industrial activities for the greatest efficiency and greatest convenience.

We have had something like two hundred years of industrialization in Great Britain, certainly one hundred and fifty years of quite intense industrialization. By 1800 there was already the nucleus of a Black Country. It may therefore seem curious and pathetic that at this stage of our history we should be discussing the question of industrial planning—but so it is. The fact is, that it is only in recent years that governments and rulers have found themselves faced with the necessity of making effective decisions and taking active steps on such matters as to how industries shall be encouraged and protected, and where and in what circumstances they shall operate. This is a complete reversal of the whole attitude of our country for the past six generations. It means the definite interference by government in private and business activities to an ever-increasing degree. But in spite of that it is quite generally recognized that the necessity exists; and practically the only debate is how this new obligation of government is to be exercised. And a very grave problem and responsibility it is proving.

May I give you a few facts and figures of our own country, so as to fill in the background to these problems as they present themselves to us in Great Britain.

Figure 1 shows an industrial map of Great Britain. If we exclude all north of a line joining Glasgow with Aberdeen, and all west of a line joining Glasgow with Swansea in South Wales, we shall have an area of approximately 61,000 square miles, which contains almost the whole industrial life of Great Britain, and over 95 per cent of the population. In this area there are 46,000 miles of railway; and 25,000 miles of first-class roads, with a network of good secondary roads. There are more than a thousand miles of modernized and well-used internal navigation. There are at least sixty recognized ports, and there is no spot more than 60 miles from the sea coast. Geographically, therefore, it would seem that there could scarcely be a more ideal position for economical development.

With regard to resources, we have at least 100,000 million tons of proved reserves of coal, the equivalent of, say, four hundred years working at our highest output. We have still extensive deposits of iron ore, including perhaps the cheapest workings in the world—Corby, in Northampton—where the ore is probably mined and delivered at a cost of 1s. 6d. (say 36 cents) per long ton at the adjacent steelworks. Admittedly there are many raw materials and natural resources that we have not. But I would only say this, that the natural riches that first started our industrial developments are by no means exhausted.

Taking another point of view we have probably not much less than £400 per head of population invested in industry and manufacture. We manufacture £2,000,000,000 worth of goods a year—excluding the annual value of food, drink, timber, mining industries, as well as building and contracting, and public utility companies, which between them total another £1,500,000,000 per annum. Our imports and exports approach £1,500,000,000, and our overseas invisible exports, in such services as shipping, banking, insurance, etc., total another £350,000,000. We have the highest value of exports of any country in the world. We are easily the premier ship-building nation. Our steel and iron output in 1936 was the greatest in our history.

By many standards then we are not unsuccessful. Lest, however, you should think that I speak in any spirit of boasting, I now refer you to Fig. 2, which eloquently illustrates the domestic problem which most deeply concerns us now in Great Britain—namely, the existence of large derelict or semi-derelict regions known as the Depressed Areas, or, more euphemistically, the Special Areas. They are shown black, and comprise those parts of the country where, broadly speaking, the unemployed population averages—or until recently averaged—more than 35 per cent of the available labour. In many parts the average unemployment is higher, in a few cases up to 80, 90 and almost 100 per cent.

If one were to include as well, all those areas where the percentage is as high as 25 per cent, very much more of the map would be coloured black. Since 1919 we have never had less than about one and a half to two millions of male unemployed; and when two years ago special action was taken in respect of the distressed areas, the unemployment figure for the whole of Great Britain was 16.3 per cent. In 1931-2, the figure far exceeded three million, and even now when we are in the midst of a kind of a boom, there are still probably over two and a quarter millions. I say "probably," because it is exceedingly

Fig. 1—Great Britain, Areas of Major Industrialization.

Fig. 2—The Special Areas as Defined by the Special Areas (Development and Improvement) Act of 1934.

difficult to interpret all the unemployment figures, and it would merely confuse the issue to descend to details that do not affect the broad principles.

Unemployment has thus apparently become one of the chronic phases of our industrial conditions. For every six men on the pay roll there is one invisible employee permanently to be carried who does nothing for his cost. Our unemployment relief system has been fiercely criticized. But after all, in this as in so many other of our problems, there is no alternative. Civilization and humanity will no longer permit such matters to be ruled solely by the harsh economic laws of nature. Our annual expenditure on unemployment, taking into consideration all the different channels of relief, is not less than £200,000,000, the equivalent of over 20 per cent of our national budget. This, as a serious handicap on industry, needs no emphasis. The deplorable state of affairs is even a greater potential handicap, in its effect on the character and morale of a large part of our citizenship. May I quote from a report that was recently made public, giving the results of a conscientious and sympathetic enquiry by a hard-headed, cold-blooded engineer into the possibilities of reviving industry in one of the hardest hit of all our depressed or special areas—

> "Turning now to more detailed consideration of South West Durham, the most immediate apparent fact in present conditions is that the grouping of population and the location of villages having been fixed solely by the position of coal pits, the result is a haphazard, illogical and now utterly uneconomic state of affairs. Many of the villages have been left as it were by the receding tide, in deserted, stagnant backwaters. No traffic stream will ever come near them again. There is no hope or chance of any industry ever being established in their midst. There cannot even be an efficient supply of ordinary services, schools, drainage, etc. The outlook of people in such circumstances must be hopeless and demoralized in the extreme. They have never had any amenities and but few services; and now they have no prospects.
>
> Since owing to their situation, neither industry nor even civilized conditions can ever come to these isolated spots, it is our suggestion that the worst and most isolated of such villages should be abandoned and demolished and the individuals housed elsewhere, where they can receive the facilities, services and amenities that they should, and at least have some hope of obtaining employment.
>
> Owing to the limited prospects of industrialization within South West Durham, most of such re-housing should be outside it. But a proportion should be in specially selected places within the area. This re-settlement should be made part of a definite and detailed survey and study, so as to plan the district generally on new lines—that is to say concentrate the population from derelict and backwater villages into strategic centres, with good communications and all social services. By this means labour could at least be organized so as to be available, if and when the demand for it arose. In due course, too, if industries should turn to this area, there would be suitable localities for them to go to. Improved roads will in themselves bring increased traffic, which will in turn induce development and business. Moreover, the provision of modern social services would incidentally be much more economical and satisfactory; and the moral and mental deterioration of a considerable portion of the community would be prevented."

That may appear pessimistic, but it has, I think, to be accepted as fundamentally true. In South Wales the position is in some parts even more acute. Although the prospects of revival of industry are more promising, the numbers involved are much larger. In a monumental Survey,* just completed (1937), Professor Marquand sums up as follows—

> "Our Survey of the industrial situation of the Region has revealed that there has been a measure of recovery from the depths of the depression of 1930-1933; but that there still remains a mass of chronic unemployment which is peculiar to this and other depressed regions which have not developed large new industries to compensate for the contraction of basic activities such as coal-mining and steel-making. The population of the Region is rapidly adjusting itself to the changed circumstances by migration from the Region. Such growth of new enterprises as has taken place has been too small to make any appreciable reduction of the surplus of labour attached to the older industries."

Merthyr Tydfil with a population of over 80,000, long since dwindling and now below 65,000, epitomises in concentrated form the experience of South Wales. For one hundred and fifty years the area ranked as one of the most important iron and steel centres in the world. At one time it easily outdistanced all competition. The great Dowlais works where Bessemer carried out his experiments were in operation before 1750. The Cyfarthfa works were in 1803 the largest industrial iron works in the world; and there were at least two other great works at Merthyr. All are now derelict, and there is scarcely a prosperous business in the town. The local rates are now the highest in the whole country—27s. 6d. in the £, as compared with an average throughout the country of probably 9s.; and of these rates 55 per cent is required for Public Assistance.

I will not pursue the matter. I have said enough to show how serious is the problem and to what a considerable degree our industrial plan—so far as any hitherto existed—has broken down. Let me now briefly refer to some of the causes of the breakdown as they appear to me.

Unemployment and depression have been world wide. Every industry and business almost has been affected. In our own country there has in the last three years been a general improvement, led by an unusual and unexpected expansion of speculative house building, and maintained or at least accentuated by the rearmament programme. But this minor boom only serves to illustrate even more clearly how permanently unemployment seems to have become established and concentrated in certain industries and certain localities.

What are the special causes? They may, I think, be summarized as follows:

- Antiquated plant and obsolete processes unable to compete with more modern and more efficient methods.
- Exhaustion of old sources of supply, and the discovery of alternative raw materials; the substitution of new products for old—for instance, of oil for coal.
- Removal of industry to more suitable locations, as the big Welsh steel works from the narrow inland valleys to the sea coast.
- Mechanization.
- Rationalization.
- Political reasons, such as the policies of foreign countries and of our own Government; trade barriers, protection, subsidies, national self-sufficiency.
- Financial reasons, such as deflation and the premature return to the Gold Standard.
- Uneconomic and inefficient administration of many of the great industrial companies.
- Over expansion, required during the war for national reasons, and encouraged by the notorious Excess Profits Duty, led to the creation of fixed assets that subsequently turned out to be heavy liabilities.

And I would venture to add:

- Nepotism in administration. The attempt to retain family control of the big industrial businesses that were started in the latter half of the last century, has almost invariably been disastrous.

Both to employers and employed in some, perhaps most, of the basic heavy industries on which our pre-war progress was based, prosperity and money came too easily. Professor Marquand, in his survey, points out that "although South Wales has a long record of iron and tinplate production, it has never developed an important engineering industry. This failure of South Wales to develop an important engineering industry, like its failure to develop other secondary industries, was caused by the concentration

*The Second Industrial Survey of South Wales, 1937 (Marquand).

on coal and tinplate in the times of prosperity." The position was much the same on the West Durham coal field.

Although there is at the moment such a strain on the resources of our steel and iron industries, that we are experiencing something in the nature of a boom, and all the worries of rationing of steel and other supplies; and although in other directions—such as ship-building—there has been a remarkable improvement in the last two years, yet there are still industries severely hit, such as mining, textiles, railways and shipping. Except in the south-east and round Birmingham, real prosperity is still some considerable way off.

But attention is naturally focussed on the special or depressed areas, and on the many steps that government has taken to alleviate conditions there, and the many plans to that end that have been recommended to government. It is of importance, therefore, to consider exactly what has been the nature and extent of this new form of direct intervention by the State into the promotion of individual industrial activity. The policy of the Government was stated as follows by Mr. Neville Chamberlain at the end of 1934—

> "Although in the present case we need not describe the disease as desperate it certainly is sufficiently exceptional to warrant exceptional treatment. What we want here, as it seems to us, is something more rapid, more direct, less orthodox if you like, than the ordinary plan, and if we are to do what seems to me even more important than the improvement of the physical condition, if we are to effect the spiritual regeneration of these areas, and if we are to inspire their people with a new interest in life and a new hope for the future, we have to convince them that these reports are not going to gather dust in some remote pigeon hole but that they will be the subject of continuous executive action . . .
>
> "We have resolved to cut through all the ordinary methods and adopt a plan which we conceive is more suitable to these special conditions than the methods which, in the ordinary course, would be applied to such a problem . . .
>
> "We are going to give the Commissioners (who were specifically appointed by the Special Areas (Development and Improvement) Act of 1934, a very wide discretion. They must not be afraid of trying experiments even if those experiments fail."

Up to date a sum of about £20,000,000 has been expended under this new legislation, or is pledged for expenditure in the special areas. Considerable assistance has been given to all sorts of social improvement plans, the provision of necessary services, land settlement, remedial work such as the renovation and extension of derelict harbours, the provision of capital at low rates for new speculative and struggling factories with very moderate, or sometimes no, security. There are other and numerous unusual inducements offered to manufacturers to settle in the special areas, provision of free sites, assistance in the building of factories, partial remission of rates and rentals, etc. In addition to such concrete action, there is a vast deal of quiet and unobtrusive persuasion, particularly in regard to foreign immigrants who require permits for permanent residence in Great Britain.

All these efforts, very briefly summarized above, are openly and definitely directed solely to the encouragement of industries to establish themselves in certain parts of the country, for the sole reason that there is in those parts an excess of unemployment. In the circumstances it has not been attempted to take a broader view. In this the government has had the assistance of numerous local Industrial Development Councils and Development Boards—which have had a great value as a focus of local activity and enthusiasm, and whose great advantage is that they have never attempted to take other than very local or wholly one-sided and single-minded views of the problem—that of their own locality.

Without implying any criticism of the special area policy, it must be admitted—and is recognized by government—that to act on these lines to any great extent, might involve an upsetting of the industrial balance; and that government has as yet no means of assessing the claims and rights of applicants on the one hand, and of established and threatened industries on the other. Almost every works so established by government assistance in a special area are in competition with some other works that have not had government assistance. Government has been the first to realize the serious implications and responsibilities that would—if pressed too far—necessarily follow from such a policy, forced on them as it has been by circumstances, but contrary to their old conceptions and traditions.

In this connection it is, I think, worth while to consider in rather greater detail the action that government has taken in regard to the setting up of Trading Estates, because here we come more immediately to the problem of industrial planning and zoning. This is in fact the most interesting and important action that has so far been taken, and involves an ultimate commitment of probably £10 to £15 million pounds. There are three government Trading Estates—one in Scotland in Renfrewshire, one at Gateshead south of the Tyne to serve the North East Coast area, and one in South Wales. The first is as yet only in embryo stage; the other two have already progressed some distance. The underlying policy was that they should be designed to encourage the growth of new types of industry in areas hitherto dedicated almost wholly to heavy industries, and that they should thereby spread the risks, so to speak, and tap new uses for the surplus labour.

There have been a number of so called Trading Estates established in Great Britain in the past twenty to thirty years, promoted by private interests and carried on on purely business lines. There is the big Trafford Park Estate on the Manchester Ship Canal, the Slough Trading Estate, the two industrial garden cities of Welwyn and Letchworth, and the Ford Estate and several others near by on the lower Thames. In every case they provide sites, build factories, and give services. The Trafford Park Estate is largely devoted to heavy industry; the Slough Estate, 20 miles west of London, was more or less started from a famous motor dump after the war. According to the latest published figures, about 300 acres have already been developed, at an average rate of about 15 acres a year, holding altogether some 200 factories, employing directly over 20,000 employees. The Slough Estate is an exceedingly well-managed, and now a very prosperous, business.

The industrial garden cities of Letchworth and Welwyn are on rather different lines. They aimed at providing ruralized industrial areas, the sort of development that had taken place at Bournville round the Cadbury's cocoa and chocolate works, or later at Port Sunlight at the Lever Company's soap works. In them industrialization has been on a comparatively smaller scale. Letchworth, started in 1903, housed by 1936 a population of 16,000 and about 60 industries. Welwyn, established in 1920, had in 1936 a population of about 10,000 and 40 factories.

But it was not really any of these developments that inspired the government's new Trading Estate policy, but rather the intense industrial development during the last ten years in London and the Greater London area.

The Greater London area comprises now about 2,000 square miles, and the diameter of the circle is something like 50 miles. The population has increased a million in a decade. In 1905 there were computed to be 14,500 factories in the area. In 1930 there were 27,000, of a greatly increased average size. These factories are mainly of the semi-luxury and consumer-goods type. The reason why they have been established in such numbers in and near London, is solely the proximity to the immense market of 10 million people. Cost of land, building restrictions, difficulties of transport and travel, severe restrictions in regard to noxious fumes and trade effluents, none of these discouraging factors could outweigh the immense advantage of having the consumer within hourly delivery distance of the manufacturer; and so far labour has always been available and amenable. It is this amazing London development that has given rise to the many alarmist reports of the drift of industry from the north of England to the south.

The location of the first government Trading Estate was at Gateshead, and it was decided after the most careful consideration as to the possibility of repeating the London experience there on a smaller scale.

A ten mile circle can be drawn with its centre approximately at Newcastle, to include a population of over one million people, a population that after years of depression is beginning to benefit by the improvement in the steel trades, armaments, munitions, ship-building, etc. It was argued that there was scope for the establishment of a light-industry trading estate on the outskirts of this big potential market. Although 700 acres in extent, the Gateshead Trading Estate is right on the edge of a most thickly-populated area. It is only ten minutes by motor to the centre of Newcastle. Work was only started in the autumn of 1936, and already over 30 factories are being built. It is true that some were attracted by government's special terms, but broadly speaking the original policy clearly is being justified. The capital has been provided by government, but ultimately a reasonable return has to be obtained for it; and the rents have been fixed accordingly, and accepted without difficulty or demur. It is clear, therefore, that in this respect the government Trading Estate has filled a want. I would like, before passing on, to give a sketch (Fig. 3) showing the planning of this Gateshead Estate, because by the close co-operation of engineer and architect it has in fact been sought to lay it out on lines that will avoid the worst failings of some industrial developments.

The South Wales Trading Estate was necessarily planned on rather different lines. The industrialization of Wales having been based on coal and iron, has taken place in the valleys that run inland from Newport and Cardiff, like the fingers of a hand. The transfer of labour from areas where industry has failed, to those parts where labour is wanted, is the obvious and to some extent an inevitable result and solution of such industrial decay as has taken place in the depressed areas. But South Wales has already lost heavily in population since the war. Nearly a quarter of a million have migrated, being nearly 10 per cent of its population; and there has been an actual net fall of population of at least 100,000. If this drain were not checked Wales would be destined to become depopulated. On the other hand transfer within the area of South Wales itself was considered uneconomic. The houses and the services already existed, and the wholesale abandonment of adequate habitations and their rebuilding a few miles away seemed unjustifiable, and would certainly have been very unpopular. Moreover there is not the concentration of population in South Wales that there is in the Newcastle area. The same objectives could not, therefore, be sought, and it was for consideration whether a Trading Estate was justified. A Trading Estate was ultimately designed on smaller grounds and was located in one of the populous valleys within a few miles of Cardiff, and also within reach of several of the most stricken valleys, there being an unemployed population of 31,000 in a ten-mile circle from it. The arguments then were not the same as on the North East Coast; and they had regard perhaps a little less to the industrial than to the local and psychological aspects. But these too are considerations that must be borne in mind in planning. A senior medical officer in Wales recently found an explanation for some of the abnormal developments in medical history in that country in "the national characteristics of the Welsh, for example, the intense conservatism of their social habits, the closeness and tenacity of their family relationships, and their fatalistic outlook." In those characteristics are to be found, too, many of the causes both of their success and of the exceptional difficulty of their present industrial position. Psychological conditions, in fact, play no small

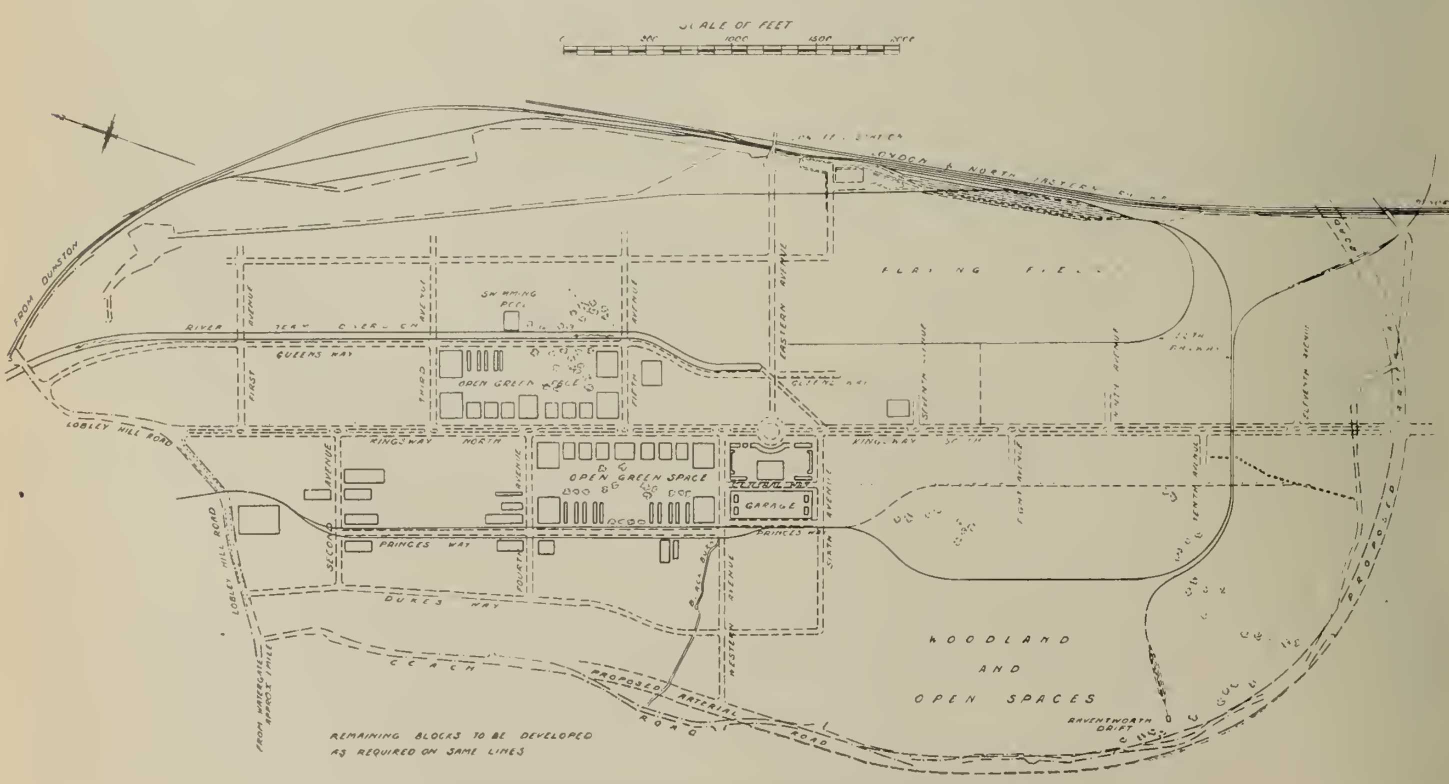

Fig. 3—Government Trading Estate on Tyneside.

part in many of the special areas. In West Durham and West Cumberland, for instance, one of the major difficulties is the absence of big leadership—in which respect the North East Coast has fortunately never failed.

These activities of government have not been made without incurring considerable criticism and doubt. Some critics have been inspired quite naturally by the threat to their own existing interests; others on broader grounds have deprecated the intrusion of government into the industrial arena; others though sympathetic have been unconvinced of the likely success of the measures adopted. But these critics have none of them fully realized how many steps government had already, and long since, taken in this very direction of directly influencing and controlling industry, and in fact actually participating in industrial activity. A few instances will suffice. There is now operating in Great Britain a very close steel federation, which was forced into existence in the teeth of opposition and warring interests, largely by the power of the Bank of England, obviously and admittedly interpreting the views of the government. It was quite openly promised that a measure of protection would be granted by government, as soon as the steel makers had "put their house in order," along lines that met with government's approval—and not otherwise. Government's action in this respect has had the profoundest effect on industrial activity in Great Britain.

Again in connection generally with protective tariffs, which have apparently become part of the permanent policy of all our political parties, there is an Imports Duties Advisory Committee whose primary task it is to examine the arguments put forward by different trades asking for tariff protection; and on their advice government may decide to protect a particular manufacture or not. It has been a natural development for this Committee to be employed by government to examine generally into economic and industrial questions, such as the feasibility or practicability of new manufacturing proposals that are submitted to government by private interests.

Government is in fact increasingly finding itself faced with such problems. Quite recently there has been considerable debate and agitation on the question of the manufacture of calcium carbide in Great Britain, which is at present all imported. It seems practically certain that its manufacture without tariff protection is not practicable, because of the great difference in the cost of power between Great Britain and Norway. Be that as it may, a proposal was brought forward by private interests, which did not immediately ask for any government assistance, beyond the securing of statutory powers to develop hydro-electric power in the Highlands of Scotland. Great pressure was brought to bear on government from different sides to support the scheme as of national importance, and contrariwise to oppose it, unless it were located in one of the Special Areas. The arguments and the struggle were heated in the extreme. They became almost wholly centred on the "special areas plea" without much consideration of any other points. Government itself succeeded in remaining more or less neutral, and the proposal failed in Parliament. But it has now been announced that government will appoint a committee to discover whether or not carbide could or should be manufactured in Great Britain. If it decides favourably, presumably government will take steps to initiate the new manufacture.

A similar investigation is now being made into the question of the development on a large scale in Great Britain of the German Fischer-Tropsch process for the distillation of oil from coal. Another great controversy raged a year ago, again involving government and its advisers, in regard to the proposed establishment of a steel works at Jarrow on Tyne, where grave unemployment had existed, and still exists, by the collapse more than twelve years ago of the great shipbuilding firm of Palmers.

These are only a few instances—but they are sufficient to show that, whether it is theoretically desirable or not, government has already practically become the absolute arbiter to decide, in the final recourse, as to the establishment and location of any new industry. It seems certain that such responsibility will increase; and seeing that obviously there is as yet no sort of definite national policy, nor even the information on which to base such a policy, the appointment of a Royal Commission which was recently announced, to study the question of the location of industry and kindred matters, is clearly not premature.

When that Royal Commission starts its review—or whenever and in whatever way government, or legislators, economists or industrialists seek to reach definite conclusions as to the policy that should govern the establishment and location of industry in Great Britain—then it is essential that the long view rather than the local view shall be taken. It is, for instance, not necessarily to be assumed, because "depressed areas" exist, with large aggregations of unemployed people, that it is ultimately either sound economics or in the widest national interest to re-establish new industries there. It is the natural course; it may seem the most humane; but it may not really be the wisest. I am not saying that I myself would subscribe to such a view but one is not justified in taking it for granted one way or the other, and then basing one's solution of the problem on what may be a faulty premise. Without ceding to anyone in active sympathy with the special areas, it has to be remembered that in population they represent but 7 per cent of the whole population of Great Britain and that while there are something over 350,000 unemployed in the Special Areas, there are five times as many unemployed spread over the rest of the country. There are other areas and other industries that have been for years in only slightly worse state than the special areas.

On the other hand it is equally not to be assumed, for instance, that the boundless extension of London, industrially or domestically, is necessarily advantageous. There are many who think it should be prevented. Others confidently and happily estimate that the growth of the future will far exceed that which has so far taken place. One distinguished economist recently calculated that half the population of England and Wales would be living in London by the end of this century. At present its share is only a little over a quarter. Sir Raymond Unwin, Past President of the Royal Institute of British Architects, has made a careful study of 1,145 entirely new factories that were established in London itself in the ten or twelve years following the war, employing directly 131,569, and thus affecting a population of at least 500,000, a fresh industrial city in itself—fifty times the size of Welwyn. Had it been split up into say five industrial units, he claimed that in all respects the position would have been more satisfactory and sounder. This will provide a knotty problem for the Royal Commission on the location of industry.

But in fact the drawing up of any detailed instructions in such a matter as the location of industry does seem an almost impossible task. If and when the power of decision as to the establishment or prevention of individual industries lies with government, except in special circumstances, it would end all private enterprise. On the other hand, government should be able to ascertain the basic causes that are handicapping existing industry, or preventing new industries from being established; and the main factors that have operated favourably or unfavourably in existing and past industrial developments.

If I may quote from a work to which I have already referred: "Alfred Weber's well-known work on the location of industry* was intended to be the preliminary to a realistic description of the facts of existing industrial location in Germany. He never completed his realistic study; but since he wrote, many descriptive accounts have been written which throw light upon the theory. The time indeed seems ripe for a further careful statement of how the theory of location stands to-day. There is reason to doubt whether the theory can ever become sufficiently positive to be applied without hesitation to any concrete situation. But we ought, nevertheless, to avail ourselves of all the lessons which can be easily derived from past experience."

The root of the whole matter will, I believe, be found to be in cheap transport and cheap power. In 1921 was passed the Railways Act which—more or less compulsorily—amalgamated into four main systems the 123 railways, large and small, which still survived from the many hundreds promoted and built in the years between 1830 and 1910. I would be venturing on a thorny path were I to explore in detail the present railway position. But I venture to say that ultimately government, or at least centralized control, will become complete. The pressure for co-ordination and rationalisation in order to cheapen transport will increase until finally the four railway groups will become one. The complete main line electrification recommended by a commission some years ago at a cost of £250,000,000 would by itself involve government financing and probably government control direct or indirect.

The growing complexity of modern transport and the inter-dependence of all forms of activity, do indeed seem to make it proper that the burden of such an essential service as transport should be undertaken by the State, for not only is the cost of transport the principal item in many manufactures; but is becoming the arbiter of modern life. It is for instance transport alone that makes great cities possible, which in these times provide one of the great social, economic and political problems we have to face. At the same time, nowhere is such hopelessly chaotic and inefficient cross-carriage of goods and passengers to be seen as in our great cities. Mr. Pick, the chief executive of the London Passenger Transport Board, quotes in his presidential address to the British Institute of Transport, the case of two large boroughs of London, Acton and Hammersmith, which are both residential and manufacturing areas, with populations respectively of 70,500 and 135,500. Acton turns out 13,500 workers and takes in 14,500; Hammersmith turns out 32,000 and takes in 29,000. The residents of many of the dormitory suburbs of London spend two to three hours a day travelling to and from their work.

Quite recently the central government has taken over all the trunk roads in the country. This foreshadows a national policy in regard to road transport.

The Road and Rail Traffic Act of 1933 was designed to control to some extent road traffic in order to bring co-ordination between rail and road services. But road transport is still a free agent as regards charges, and for competition for traffic; of the 400,000 or so vehicles on British roads in 1934, 70 to 80 per cent were owned by manufacturers or dealers in commodities. The issue of vehicle licences is now being pretty str'ctly administered; but there is still a great deal of costly and futile competition taking place, to no one's ultimate prosperity.

The ports of Great Britain are not centrally controlled to the extent that the national ports of Canada are. In some ways and for some reasons—but not as yet financial—such a policy may be even more desirable in our country. If a circle of 100 miles be drawn from any of the major ports in England, London, Southampton, Bristol, Liverpool, Hull, Tyne, they will each be found to have a distribution area of about 20,000,000 persons—a total of three times the population of Great Britain. Obviously there must be much overlapping. The benefits of coastwise traffic in permitting the cheapest form of carriage for many things have only been very partially utilized. Tramp shipping has recently been assisted by our government but it is difficult to estimate how this is affecting other classes of transport.

If, as is clear, transport may be the ruling factor in the location of industry; if cost of transport is a preponderating factor in the industrial growth of big cities, which it were desired to limit; if it were decided to simplify the whole position and remove anomalies and handicaps, then there might well be arguments, for instance, for the establishment of flat rates for transport, irrespective of distance, possibly calculated as a percentage on the cost of the material to be transported. At any rate in spite of the fact that we have had a Royal Commission on Transport, we yet lack a national transport policy.

The other direction in which most can be done to create favourable conditions for industry as a whole and particularly for the establishment of new types of industry, is, I believe, the provision of cheap power. We have in Great Britain no low priced hydro-electric power as compared with what Canada is used to. Our cheapest development is probably about £3.10.0 per kilowatt year, say $17. It is certain that no power has been developed in Great Britain at that price since the war, nor can be. Moreover our water power resources are for the most part remote from industry and in areas where industry could not generally be economically established. This means that electro-chemical or electro-metallurgical industries must rely on steam power, the cheapest being about £6 per kilowatt year, say $30. Through the Central Electricity Board, there is already control of the generation and to a considerable extent, of the distribution of power. Very recent announcements indicate the ultimate complete centralized control of all electrical distribution. The establishment of such manufactures as ferro-alloys, and calcium carbide, would require, I think, a guaranteed rate for power of not more than £5 per kilowatt year, or say $25, to be available, whether the factories were immediately adjoining a super-power station or not. Though still high as compared with water power figures, other considerations such as saving in transport, suitability of conditions, raw materials, labour, proximity of markets, the use of process steam, and so on, would, I consider, make that figure economically justifiable as the basis of a new chemical engineering development in Great Britain.

Another direction in which government activity must soon be taken, is in the provision of industrial water and the means of disposal of trade effluent. The control of underground water resources will certainly soon be necessary, since the continuance of uncontrolled competitive boring is likely to prove disastrously costly in the end; while on the other hand the very proper campaign to prevent pollution of streams and rivers, must be accompanied by a policy for handling trade effluent through the common sewerage systems.

Cheap fuel is another vital necessity to industry, that has been recognized by government, but not yet achieved. But the British Government has just acquired by purchase the whole coal royalties in Great Britain, and by recent legislation all underground petroleum and oil has been declared to be the property of the Crown. Pipe lines for transport of refined petroleum would greatly relieve traffic pressure on the roads. There are, I believe, at least 130,000 miles of pipe line in the U.S.A. for crude

*Alfred Weber's Theory of the Location of Industries, translated by C. J. Friedrich (Chicago 1929).

petroleum, and some have more recently been installed there for refined petroleum also. The practicability must be explored of the development on lines that have gone furthest in Russia, of thermal-electric central stations. A Gas "grid" has been established locally in more than one place, but efforts to carry it through on a large scale, making full use of waste gases from blast furnaces and coke ovens, have not yet been very successful.

One other piece of government action I must refer to, the taking over of the greater part of the burden of local rates on manufacturing premises, by what was known as the Derating Act. This remits three quarters of the local rates that would fall to be paid on any building used as a factory. In this, the government in effect undertakes to provide free, such services as sewerage, cleansing, fire protection, watch and ward.

I think enough has been said to show that the government in Great Britain has already moved very far in the direction of the state control of industry and the means of industry. There can be no doubt, I think, that that control will and must increase. It is no longer a question for discussion whether such a policy is wise or not. The question now is as to the lines along which control shall run, and how it can best be used to promote prosperity. Without the wise administration by government of the power of control that it now has, industry—at least in Great Britain—can no longer progress, or indeed survive.

These then are some of the matters that have to be dealt with in Industrial Planning. I have, I fear, merely touched on the fringe, and it is impossible to follow out all the implications and possibilities. There is, however, one final point I would make. In matters of Town and Regional Planning, or in research into the causes for industrial failures, in the replanning of industrial areas, and in the planning of the development of a country's resources—it has been quite rare to find any activity on the part of engineers as a body. The result has been, that rather a one-sided school of thought has grown up regarding Town Planning and Regional Planning. I may quote just one instance—part of the official summary of the results of the International Conference on the subject in Berlin in 1931—

> "The primary aim of planning is to secure the health, comfort and welfare of the people and the first item to be decided should be zoning, that is the disposition of functions: industry, housing, business areas, bulk of buildings, open spaces, etc."

The failures of industrial development in the past have not, however, been due to neglect of amenities—deplorable as that has often been in our country; or to the poor architecture of the factories! It has on the other hand, far too often, resulted from failures in technique, and mechanical inefficiency. Amenities are long since realized as essential even from the most prosaic of manufacturing and business points of view. But amenities cannot dictate the location and operation of industry, on which a country's prosperity ultimately rests.

In Great Britain we have to decide how our main industries are to be strengthened and expanded, how new industries are to be encouraged, how the provision of cheap raw materials is to be safeguarded, how our labour is to be most effectively used, whether we are to change our views as to the concentration of industries in vast manufacturing areas, whether our existing populous areas are to be added to, or decreased—how in fact industry is to be carried on most efficiently and least to the detriment and inconvenience of the people. I imagine that much the same is true in Canada. Those are largely engineering problems, and engineers must take them up.

---

# British Engineering Societies and their Aims

*Brig.-General Magnus Mowat, C.B.E., F.R.S.E., M.Inst.C.E., M.I.Mech.E., M.I.E. and S., Hon.M.Inst.R.E., Secretary, The Institution of Mechanical Engineers, London.*

**Paper presented at the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

**The mediaeval guilds were the forerunners of engineering societies and were followed by scientific bodies. The activities and objects of the Institution of Civil Engineers and the Institution of Mechanical Engineers are described, with notes on other national and local associations in Great Britain.**

Engineers the wide world over form a vast brotherhood, so that when the writer was asked to deal with engineering institutions in Britain he willingly acceded, feeling that such an account would be of particular interest at the Semicentennial gathering of The Engineering Institute of Canada at Montreal in June 1937.

* * * *

Probably the City Livery Companies of London may claim to be the first corporate bodies to give an impetus to the handicrafts which form the basis of engineering as we know it today, and many of these guilds date back to remote times. For instance, the Founders Company (a guild of which the writer is a Liveryman) appears to have existed in an early form as far back as A.D. 1365, that is, in the reign of Edward III. The Armourers and Brasiers Company was granted a charter in 1453 by Henry VI, but long before this it can be proved that it was in existence, since the guild possessed a Hall in 1428, and the Company claim an antiquity at least as ancient as the beginning of the 14th Century. The guild of the Blacksmiths claims by prescription to have been incorporated in the reign of Edward III in 1325, and the first charter was granted to the Company by Queen Elizabeth in the year 1571, which incidentally united the Blacksmiths with the ancient guild of the Spurriers. The Carpenter's Company received its charter from Edward IV in 1477, but the guild was in existence at an earlier period and, in fact, its Hall was begun in 1429 and gradually completed, while the Shipwrights' Company first appeared in the form of a guild as early as 1428, and there is a presumption in favour of it having existed by prescription for some time before that period. In 1661 it claimed to have had a corporate life of 400 years, hence the date of its foundation would be about the middle of the 13th Century. Its Charter of Incorporation was granted by James I in 1605. Nor must we forget the Hammermen of Glasgow, a body which dates back to the Middle Ages. These companies continue to take an active interest in their crafts, distributing their ample funds in prizes and grants to students, and endowments of professorial chairs at colleges and universities.

However, we will leave the Guilds and come to the Royal Society of London, which dates from the seventeenth century, being granted a Royal Charter in 1662 by "Carolus Secundus Rex" whose interest in the Society led him to seek its advice on at least four scientific questions; it was endowed with Chelsea College and lands by him. The terms couching the preface of the Royal Charter are noteworthy as the following translation shows:—

> "We have long and fully resolved with Ourself to extend not only the boundaries of the Empire, but also the very arts and sciences. Therefore We look with favour upon all forms of learning, but with particular grace We encourage philosophical studies, especially those which by actual experiments attempt

either to shape out a new philosophy or to perfect the old. In order, therefore, that such studies, which have not hitherto been sufficiently brilliant in any part of the world, may shine conspicuously amongst Our people, and that at length the whole world of letters may always recognize Us not only as the Defender of the Faith, but also as the universal lover and patron of every kind of truth:

Know ye that We, of Our special grace and of Our certain knowledge and mere motion, have ordained, established, granted, and declared, and by these presents for Us, our heirs, and successors do ordain established, grant, and declare, that from henceforth for ever there shall be a Society, consisting of a President, Council and Fellows, which shall be called and named The Royal Society; And for Us, our heirs, and successors We do make, ordain, create, and constitute by these presents the same Society, by the name of the President, Council, and Fellows of the Royal Society, one body corporate and politic in fact, deed and name, really and fully, and that by the same name they may have perpetual succession;"

Of interest too in the charter is the election of the Royal Society's first president:—

"Our very well-beloved and trusty William, Viscount Brouncker, Chancellor to Our very dear consort, Queen Catherine to be and become the first and present President, and to continue in this office until the feast of Saint Andrew next (if he shall so long live) and till another out of the Council be chosen and sworn."

Amongst other Presidents of the Royal Society have been Sir Christopher Wren, Samuel Pepys, Sir Isaac Newton and Sir Humphry Davy, whose first miner's safety lamp is still in the possession of the Society. It was invented in 1815, simultaneously with George Stephenson's safety lamp. The Royal Society was founded primarily for the advancement of pure science but it embraces the fundamentals of engineering practice and ranks first amongst the British learned societies.

Another society of broad scope is the Royal Society of Arts (1754) which has encouraged various branches of art and manufactures with its awards. Its Repository of Inventions, consisting of mechanical devices which had won the Society's awards, was first held in 1761 and may be regarded as the parent of all great exhibitions. In time these shows so overcrowded the Society's Rooms that its President, the Prince Albert (Consort of Queen Victoria), called a meeting in 1849 at which the Great Exhibition of 1851 was conceived.

Yet one more society of wide scope is the British Association for the Advancement of Science (1851) which has a special Section (G) for Engineering. The origin of the British Association may be traced to the condition of Britain after the Napoleonic Wars, when applied science fell into disrepute and Professor Charles Babbage of Cambridge published his "Reflections on the Decline of Science in England" (1830). This book was reviewed by Sir David Brewster, who appears to have been stirred to take steps which led up to the formation of the British Association, whose members you may remember, have visited Canada on several occasions.

In Scotland, the Royal Society of Edinburgh was established in 1783 from an older foundation, the Philosophical Society of Scotland, which had already been in existence for many years. Its wider boundaries admitted to its fellowship men of letters such as Sir Walter Scott, who was President in 1832. Chemistry, medicine and engineering are also represented on its roll.

The oldest purely engineering society is the Society of Civil Engineers (Smeatonian) founded in 1771, now a dining club of exclusive character at which eminent members of the profession foregather to perpetuate the memory of their founder.

The Institution of Civil Engineers, founded in 1818, and granted a Royal Charter by George IV in 1828, claims priority of the British engineering societies by seniority of foundation and catholicity of aim—the term "civil" being interpreted in its wider sense to embrace all forms of engineering other than "military," but recently this definition has been extended further to include officers of the fighting services, provided their engineering qualifications are satisfactory. "The art of directing the great sources of power in nature to the use and convenience of man" is indeed a noble objective, and one has only to glance through the voluminous Proceedings of this Institution to be assured of the fulfilment of its aims.

Thomas Telford (who became its first president in 1820) has left a tradition seeking perpetuation, and today we are justly proud to have with us the present president —Sir Alexander Gibb—his companion in thought, and by profession his lineal descendant.

The library of the Institution of Civil Engineers contains 61,000 volumes—its archives a treasury of knowledge—and the ample Proceedings give an account of almost every engineering work of importance. "Engineering Abstracts" of foreign technical literature are prepared by a committee of experts, and are available to the profession.

The Institution house in Great George Street has recently been completed by the addition of the west wing, which enhances its external appearance and adds to its dignity. Mr. James Miller, F.R.I.B.A., its architect, is also the designer of the adjacent wing of the building of the Institution of Mechanical Engineers.

A former President of the Institution told the writer that it was his endeavour to make the status of a Member of the Institution of Civil Engineers as high as that of a King's Counsel, and the Associate Membership equivalent to a Junior Counsel on admittance to the Bar. Whether this has been attained is debatable, but the practical and theoretical qualifications required are most exacting, and the status maintained from generation to generation.

Next in seniority among the Founder Institutions of the Engineering Joint Council is the Institution of Mechanical Engineers, which was founded at a meeting of leading members of the profession in Birmingham in 1847, and incorporated in 1878. It received a Royal Charter from King George V in 1930, which set forth the objects for which the Institution is constituted as follows:—

(*a*) To encourage invention and research in matters connected with mechanical engineering and, with this object, to make grants of money or books or otherwise to assist such inventions and research.

(*b*) To hold meetings of the Institution for reading and discuss communications bearing upon mechanical engineering or the application thereof, or upon subjects relating thereto.

(*c*) To print, publish and distribute the proceedings or reports of the Institution or any papers, communications, works or treatises on mechanical engineering or its application, or subjects connected therewith.

(*d*) To co-operate with Universities, other Educational Institutions and public Educational Authorities for the furtherance of Education in Engineering Science or Practice.

(*e*) To do all other things incidental or conducive to the attainment of the above objects, or any of them.

George Stephenson, "Father of Railways," was elected the first president, and generously gave £100 to the funds, taking an active interest in the new body, and reading papers himself. On his death in 1848, Scott Russell wrote of him:—"In our late president, England has lost one of her most distinguished men, the world one of its great benefactors."

His son, Robert Stephenson, was the next in the chair, and other famous presidents in early days were Sir William Fairbairn, Sir Joseph Whitworth, Lord Armstrong, Robert Napier and Sir William Siemens. The Institution of Mechanical Engineers moved from Birmingham to London in 1877, and for years was allowed the the use of the Institution of Civil Engineers' hall for its meetings. Afterwards, it built its own house at Storey's Gate in St. James's Park, and there it has repaid the debt by lending its accommodation for meetings of many of the more recently formed institutions, among which are the Institutions of Gas Engineers, Automobile Engineers, Locomotive Engineers, and Production Engineers.

Accommodation at the Institution of Mechanical Engineers comprises a well-equipped meeting hall (recently oak-panelled), council and committee rooms, reading room, and a refreshment room with walls and floor lined with marble. The library (with its three annexes and two galleries) renders practical service to the members. This will be evident when it is mentioned that over 4,000 technical books per year are lent, and 1,000 searches for specialized information are made. In addition, a list of latest works added is printed monthly in the Journal, with annotations in many cases. There is also a reading room where 350 current periodicals are exhibited.

The monthly Journal contains short summaries of papers to be discussed, particulars of forthcoming meetings, examinations, and other announcements. The principal publication of the Institution of Mechanical Engineers is of the Proceedings which contain the papers and discussions. They are issued in three volumes a year, and have been printed in an unbroken sequence from 1847. Many of these papers represent the acquisition of new knowledge and are not a mere chronology of work already accomplished.

Among other activities are the examinations held twice annually at home and overseas for Associate Members, Graduates and Students. There is, in addition, a scheme of National Certificates in Mechanical Engineering awarded at 168 technical colleges throughout Great Britain and Northern Ireland by the Institution, in conjunction with the respective Government Departments of Education. An important feature of the scheme is the fact that the control or oversight of the examinations (in so far as approval of the question papers and scrutiny of the marking of the answers is concerned) is exercised by Assessors, who are Members of the Institution, and are appointed by the Institution in conjunction with the Board of Education, or other Government Departments. The Principal of the School, or other local official, acts as examinations' officer, and due regard is given to the work done by the students in the class-room, in the laboratory and at home. In no case is the entity of any approved school or college endangered by entering candidates for these examinations —on the contrary, though insisting on a high National standard, the scheme is intended to foster local "esprit de Corps" and bring home to the many centres throughout the country, privileges which have hitherto been restricted to a few. The approved colleges do not find their activities curtailed in any way, but on the contrary receive the benefits resulting from contact with the Institution and the Board of Assessors, and the scheme is a great incentive to students to follow co-ordinated courses of instruction, rather than to attend isolated classes. Many students now follow these courses for six or seven years, or even longer, and obtain endorsements in additional subjects including those concerned with Workshop Organization and Management. The standard of the Higher National Certificate is that of an engineering degree in individual subjects. A student who has gained this certificate is allowed a considerable measure of exemption from the Associate Membership Examination of the Institution, in some cases sufficient to satisfy all the Institution's educational requirements.

The Institution of Electrical Engineers, the Institution of Naval Architects, the Institute of Builders, and the Institute of Chemistry also conduct schemes of National Certificates in their respective subjects; whilst the Institution of Automobile Engineers, the Royal Aeronautical Society, and the Institute of British Foundrymen co-operate with the Institution of Mechanical Engineers by endorsing its National Certificates where candidates have also taken their special subject.

Research has been in the forefront of the work of the British engineering Institutions, and more particularly of the Institution of Mechanical Engineers, for over half a century. The results of the investigations financed by them are recorded in the various proceedings and transactions. The progress of engineering technique, stimulated by the developments in other fields such as in metallurgy, and by inventions such as in new forms of locomotion, is maintained only by continuous attention to means of improvement, and by experimental research directed to the elucidation of phenomena and the rationale of new processes. It is clear that the principles of research must necessarily be abundantly recognized and employed in the newer branches of engineering as, for example, in the development of wireless communication and of aviation, progress in which has been so spectacular. It is perhaps not quite so manifest in the development of mechanical engineering. Nevertheless, it is true that the march of invention, the increasing severity of competition, and the complexity of modern civilization, cause the engineer constantly and tirelessly to pursue scientific investigations to enable him to satisfy the increasingly exacting demands made of him. The Institutions have been in the van of such developments and can point proudly to a list of researches all of which at the time they were in progress satisfied an urgent need for new knowledge and many of which, to this day, have left their mark in the stating of basic scientific principles. This important work is still being carried out by the Institutions and since the war, the Privy Council have set up a special Department of Scientific and Industrial Research, and have encouraged the industries themselves to elucidate their own specific problems, by the establishment of many British Industrial Research Associations initiated by large grants of public money, but continued with more and more support from their respective industries as their worth becomes known and appreciated.

The Institution of Mechanical Engineers has over 12,000 members, having practically doubled its membership since the immediate post-war period in spite of, or perhaps it should be said on account of, the increasingly high standard of admission. It has nine local branches in Britain, one in South America, and one in China, also several Graduates' Sections for the younger men. These local branches which began to be established in 1920 as an activity of the Institution, have become important features in its corporate life. They are made up of the members of all classes of the Institution resident in the districts they cover, and hold series of meetings at some convenient centre or centres under arrangements made by Branch Committees (both of Corporate Members and of Graduates and Students) elected by the members of the Branch. Important papers which have been read at General Meetings in London are frequently repeated at local branch meetings, and the resulting discussions embodied in the Proceedings, while papers of local interest are generally read at local branch meetings only. It occasionally happens that a paper of first-rate importance originates at a local branch meeting and, in this respect, as well as through increased membership as a result of such local activities, the branches act as feeders to the general life of the Institution. The work of the local branch is carried out voluntarily, and the brunt of it naturally falls on the honorary secretary, while the chairman for the time being is ex officio a member of the Institution's Council, and brings his own contribution to the work of that body. In addition, there are advisory Committees or Honorary Corresponding Members in the Dominions. The Canadian Advisory Committee consists of the following:—

Montreal—Mr. H. H. Vaughan, M.E.I.C.
Toronto—Professor E. A. Allcut, M.E.I.C.
Halifax—Engineer Commr. F. H. Jefferson, R.C.N.
Winnipeg—Mr. F. E. Collinson.
Vancouver—Major G. A. Walkem, M.E.I.C.

The third of the Founder Institutions of the Engineering Joint Council is the Institution of Naval Architects founded in 1860, and later came the Institution of Electrical Engineers (originally the Society of Telegraph Engineers and Electricians (1871) which is numerically the largest Institution, its membership amounting to over 16,000), and many specialized or local associations so that there are now over one hundred engineering societies with a total membership of 100,000. It has been estimated by Sir Alexander Gibb that one seventh of the working population of Britain is connected in one way or another with engineering. Other prominent institutions which should be mentioned are:—

The Society of Engineers (1854)
The Institution of Gas Engineers (1863)
The Royal Aeronautical Society (1866)
The Iron and Steel Institute (1869)
The Institution of Municipal and County Engineers (1872)
The Institution of Royal Engineers (1875)
The Institute of Marine Engineers (1889)
The Institution of Mining and Metallurgy (1892)
The Institution of Water Engineers (1896)
The Institution of Heating and Ventilating Engineers (1897)
The Institution of Automobile Engineers (1906)
The Institute of Metals (1908)
The Institution of Structural Engineers (1908)
The Institution of Locomotive Engineers (1911)
The Institution of Production Engineers (1921)
The Institution of Chemical Engineers (1922)

It will be seen that a number of these have already reached their Jubilee, and others are approaching that occasion.

Amongst these bodies is one, the Institution of Mining Engineers, which is a Federation of a number of local associations, each of which retains its own name, but its papers are published in the Transactions of the parent body. Their members are also members of the parent body, which possesses no members apart from those of its constituents.

Another society, the Junior Institution of Engineers (1884), has paid special attention to the development of social intercourse amongst its members, and the help and encouragement of young engineers; and there is the Newcomen Society (1920) which is devoted solely to the fascinating study of engineering history.

Ireland, Scotland and Wales, also have their own national societies, namely, the Institution of Civil Engineers in Ireland (1835) with the younger but virile Belfast Association of Engineers (1892) in Northern Ireland, the Institution of Engineers and Shipbuilders in Scotland (1857), and the South Wales Institute of Engineers (1857). Then there are bodies which are identified with particular districts, such as, the North of England Institute of Mining and Mechanical Engineers (1852) (a constituent of the Institution of Mining Engineers); the North-East Coast Institution of Engineers and Shipbuilders (1854), and the West of Scotland Iron and Steel Institute (1892).

The chief manufacturing towns have their own local societies, such as the Manchester Association of Engineers (1856), the Liverpool Engineering Society (1875) and many others.

It is thought by some that there are too many societies, and indeed, the subjects in which the younger societies specialize are usually branches of general engineering. Most of these, however, cater for those whose practical training or educational qualifications do not, in many cases, reach the general standard of knowledge required by the by-laws and examinations of the senior Institutions, also they allow of more frequent discussion of papers on their specialist subjects than is possible with a body representative of broader interests. Proposals for the affiliation of the younger institutions have so far been unsuccessful. To some extent, the formation of sections solves this problem; for instance, in the Institution of Mechanical Engineers there is an Education Group, an Internal Combustion Engine Group, and a Steam Group, each run by a small committee and each with its own series of meetings, mostly of an informal character, but sometimes consisting of the discussion of a symposium of printed papers dealing with current developments in its particular sphere.

There is a tendency in British societies to hold, in addition to their usual discussions, regular informal meetings at which, instead of a printed paper being presented, a short introduction to a subject is given, and then free and unreported discussion is allowed.

The leading Institutions possess Royal Charters which entitle their corporate members to style themselves "Chartered Civil Engineer," "Chartered Mechanical Engineer," etc. All these bodies are governed by by-laws made under the charters and by councils elected by the corporate members. The councils necessarily have to appoint numerous committees to deal with the various activities, such as Publications and Library, Finance, Research, Examinations, etc.

Social activities, though subservient to technical matters, are not neglected, visits to works, dinners, conversaziones and summer meetings being held regularly. These summer meetings are enjoyable functions, and have formed part of the Institution of Mechanical Engineers' activities since 1856. They provide opportunities for members to meet socially, and visits are made to important engineering works. Visits have been paid to most of the principal cities in the British Isles, and several of the meetings have been held overseas, notably in Europe, the United States and Canada. You may remember the Institution of Mechanical Engineers' visit to Canada in 1932, and very pleasant are the visitors' memories of your kind entertainment on that occasion.

Useful joint efforts are made and there is substantial collaboration amongst the societies, such as the Marine Oil-Engine Trials carried out by the Institution of Mechanical Engineers with the co-operation of the Institution of Naval Architects, the Institute of Marine Engineers and the Admiralty. The British Standards Institution was brought into being with the support of the leading engineering bodies, and still receives financial help from several of the Institutions. The Engineering Joint Council established in 1922 consists of representatives from four Founder Institutions and four co-opted Institutions, and considers matters generally affecting the profession.

Engineering in Great Britain is not a closed profession—it may be practised by anyone, for there is no registration of engineers. However, it may be regarded as a semi-closed profession, since it is advisable for any member of it who aspires to some degree of standing, to join one of the few leading Institutions and thereby gain the necessary status which this confers, besides keeping in touch with both the technical and administrative developments of his profession. The peculiar position of our great engineering Institutions in conferring special status is not always understood abroad, where an engineering degree, coupled with government recognition, is the acknowledged qualification for an engineer. Ours is a typically British system which has grown up with the development of engineering science and practice, and possesses an elasticity which enables it to include engineers of very diverse types of training and education, who are capable of maintaining our high traditions.

This résumé would not be complete without some reference being made to the work accomplished by the engineering societies of the students at the universities and colleges throughout the country. Among these, King's College Engineering Society of London, founded in 1847, may be regarded as the oldest, and has been the training ground of several presidents of the senior Institutions.

In conclusion, the writer would like to emphasize the quiet and unobtrusive work which is being done year by year by the learned societies all over the world. We are working harmoniously for the betterment of mankind—and progrcss, though gradual, is cumulative.

# APPENDIX

Copy of Illuminated Loyal Address on vellum presented to H.M. KING GEORGE VI on his Coronation on 12th May 1937, under Seal of the Institutions and signatures of President and Secretary of each society.

To His Most Excellent Majesty,
King George VI.

MAY IT PLEASE YOUR MAJESTY

We, on behalf of the members of the principal Engineering Institutions and Societies in the United Kingdom of Great Britain and Northern Ireland, desire to tender on the occasion of Your Coronation our heartfelt congratulations and to offer our earnest wish that Your Reign may be long, prosperous and peaceful.

Your Majesty has always evinced a deep interest in the Institutions that exist for the advancement of engineering science and for the better utilization of the forces of nature for the benefit of mankind. In the course of the services which You rendered as Duke of York during the lifetime of Your much beloved Father, His late Majesty King V, You have been brought into direct contact with workshops, with mines and with works of engineering construction, wherein the art of the Engineer and the manual skill of the workman have combined to supply many of the needs of modern civilization.

In the assurance of Your knowledge of and close interest in the work on which we are engaged, we beg leave humbly to express to Your Majesty and to Her Majesty Queen Elizabeth our loyalty and support in the onerous duties consequent upon Your accession to the Throne, and we pray that Almighty God may bestow upon Your Majesties health and strength to bear these responsibilities, and happiness in the knowledge of the devotion of Your people.

List of Signatures:—

The Institution of Civil Engineers:
Alexander Gibb, President; H. H. Jeffcott, Secretary. (L.S.)

The Institution of Mechanical Engineers:
J. E. Thornycroft, President; Magnus Mowat, Secretary. (L.S.)

The Institution of Naval Architects:
Stonehaven, President; C. V. Boys, Secretary. (L.S.)

The Institution of Gas Engineers: Stephen Lacy, President;
J. Terrace, Hon. Secretary, J. R. W. Alexander, Secretary. (L.S.)

The Royal Aeronautical Society:
H. E. Wimperis President; J. Laurence Pritchard, Secretary. (L.S.)

The Iron and Steel Institute:
H. C. H. Carpenter, President; K. Headlam-Morley, Secretary. (L.S.)

The Institution of Electrical Engineers: H. T. Young, President;
Frank Crawter, Member of Council; P. F. Rowell, Secretary. (L.S.)

The Institution of Municipal and County Engineers:
D. Edwards, President; C. W. Scott-Giles, Secretary. (L.S.)

The Institute of Marine Engineers:
Stephen J. Pigott, President; B. C. Curling, Secretary. (L.S.)

The Institution of Mining Engineers:
C. Augustus Carlow, President; C. McDermid, Secretary. (L.S.)

The Institution of Mining and Metallurgy:
Robert Annan, President; C. McDermid, Secretary. (L.S.)

The Institution of Water Engineers:
Neil J. Peters, President; A. T. Hobbs, Secretary. (L.S.)

The Institution of Automobile Engineers:
J. S. Irving, President; Brian G. Robbins, Secretary. (L.S.)

The Institute of Metals:
William R. Barclay, President; G. Shaw Scott, Secretary. (L.S.)

The Institution of Structural Engineers:
C. H. Fox, President; R. F. Maitland, Secretary. (L.S.)

The Institution of Chemical Engineers: Wm. Cullen, President;
(A. J. V. Underwood, M. B. Donald,) Joint Hon. Secretaries. (L.S.)

# THE ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE OF CANADA

"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."

VOLUME XX  AUGUST, 1937  No. 8

## Air Service - Transatlantic - Transcontinental

The successful out and home flights across the North Atlantic of the British Imperial Airways flying boat *Caledonia*, and the Pan American *Clipper III*, which have just been completed, were the first of a series to be conducted by the experts of the two lines in order to gain experience in the operation of the aircraft on that route, and to test the airway facilities, and those navigation aids and meteorological services whose completeness and efficiency are so necessary for the maintenance of a regular transatlantic service on a commercial basis. The service is to be operated by a company with which the governments of Great Britain, Canada, the Irish Free State and the United States will be associated, an arrangement which is an excellent example of international co-operation.

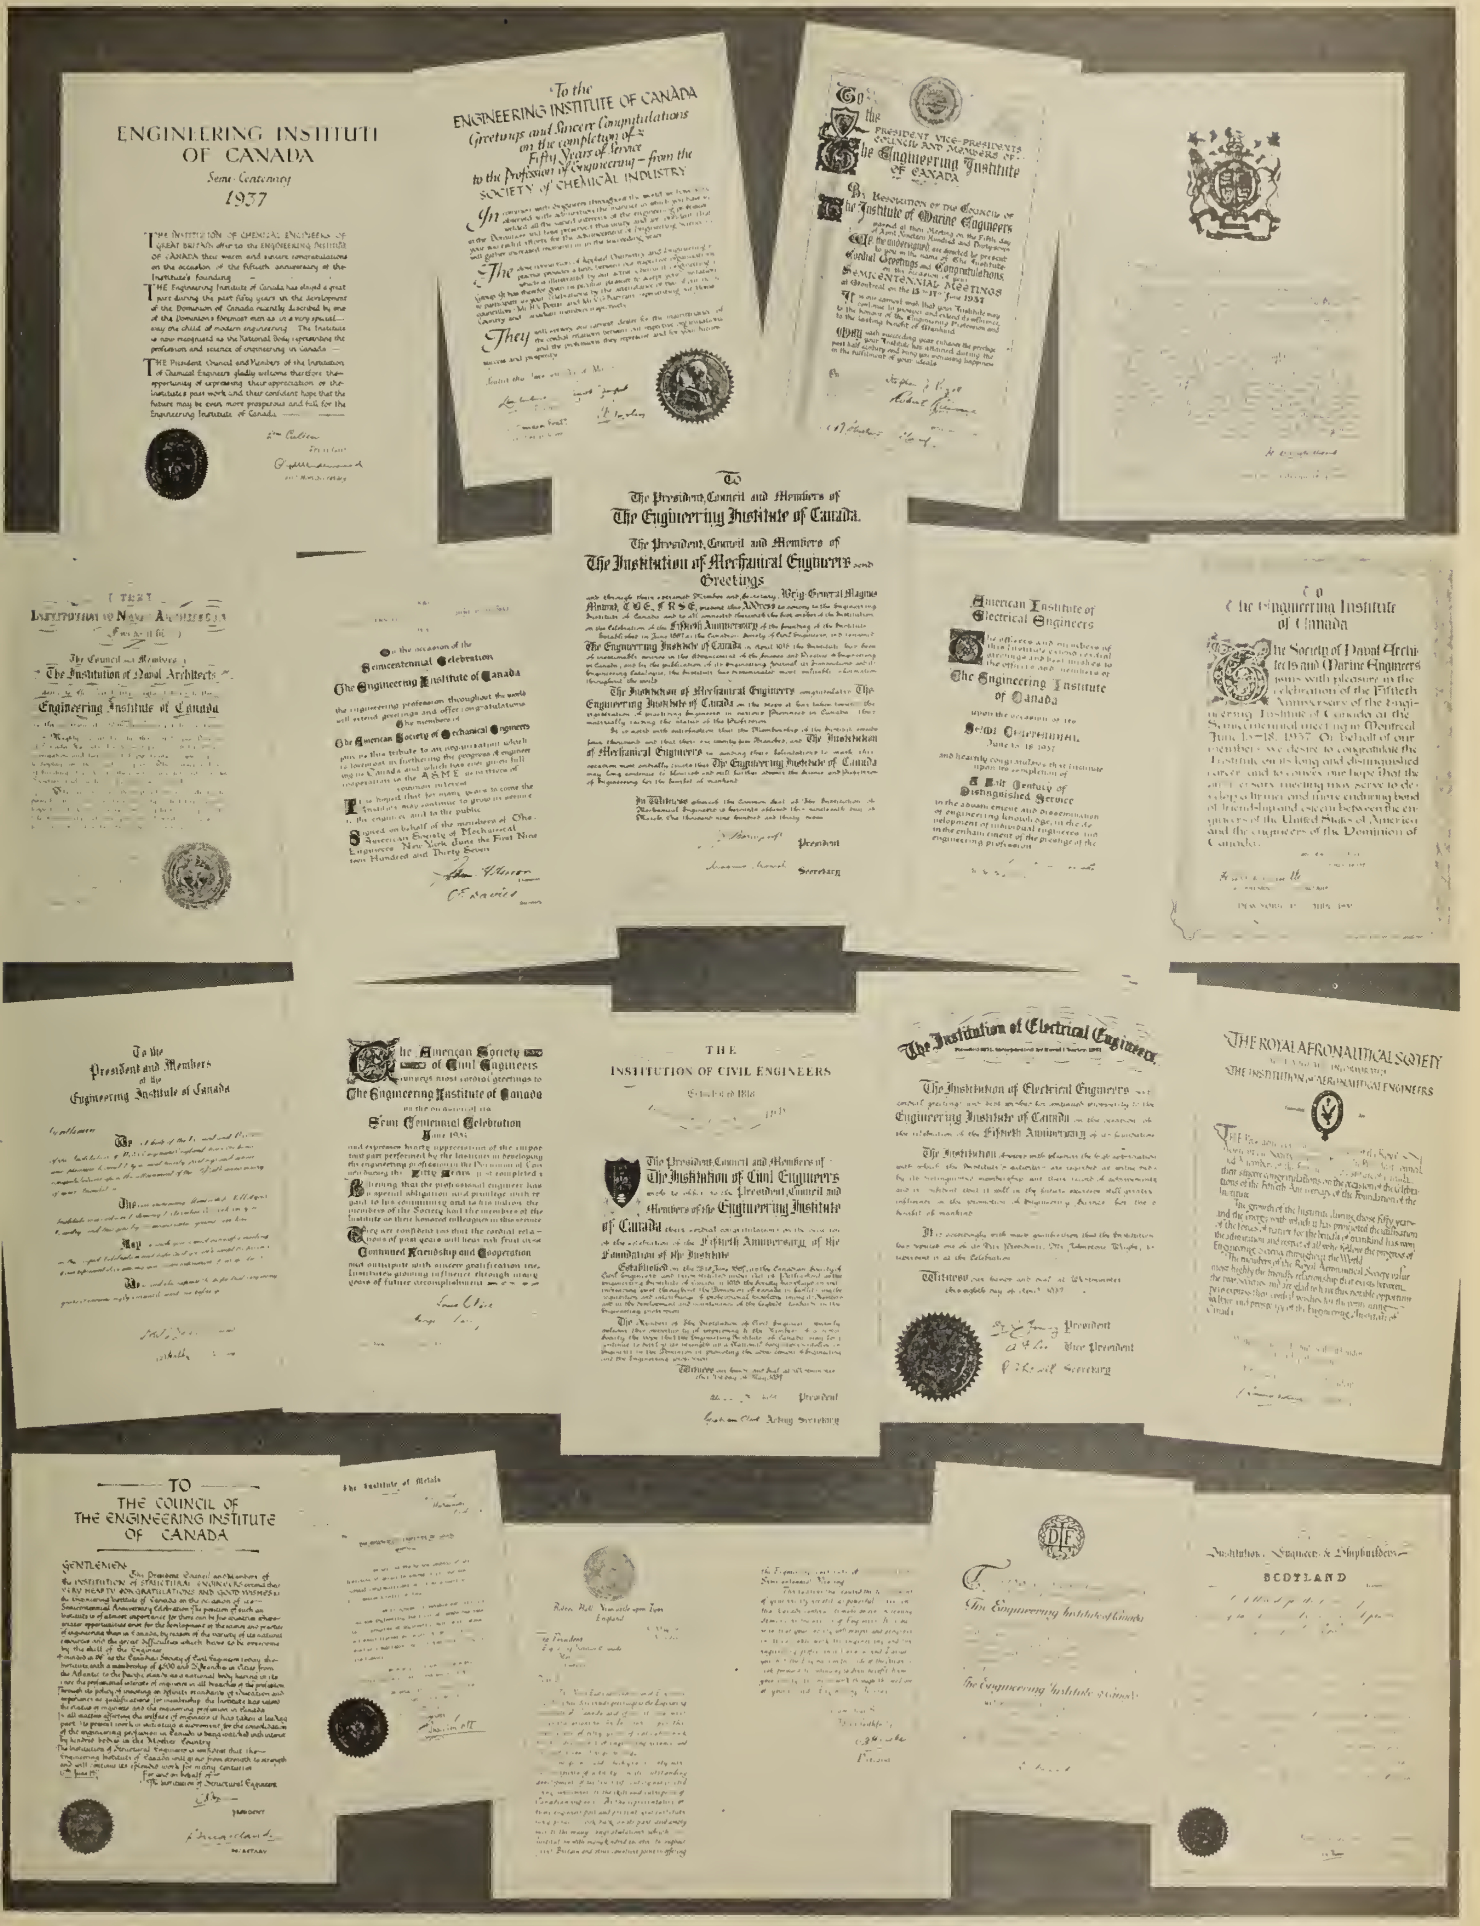
While these preliminary transatlantic crossings are being made, another Imperial Airways flying boat, the *Centurion*, has just flown the 7,200 miles from Southampton to Durban, inaugurating the new airmail services between England and South Africa. These happenings are only a few of the steps which are being taken towards the building up of a chain of air communication which will ultimately be completed by a transpacific air service between Canada and Australia and New Zealand, for which international co-operation is proposed on a basis somewhat similar to that now being arranged for the transatlantic services.

Just three weeks before the *Caledonia* made its fifteen hour flight from the mouth of the Shannon to Botwood, Newfoundland, there was presented at the Semicentennial meeting of The Institute a paper on the North Atlantic Air Service, which we publish in this issue of the Journal. In this monograph the author makes a critical examination of the whole problem of the North Atlantic crossing, and studies the conditions under which it is possible to insure a regular air service on that route for mails and passengers. In doing so Mr. Parkin deals with potential traffic, the weather conditions to be met with, the necessary organization both on the ground and in the air, the types of aircraft available, and other essential points. He gives valuable historical data as to previous achievements. As regards the recent flights it is interesting to note that the eastward and westward journeys of both aircraft gave results closely in accord with those outlined by Mr. Parkin.

Speaking in the discussion on the paper, the President of the Royal Aeronautical Society suggested that for such work in the future a considerable increase in the size of the aircraft was probable; in fact he looked forward to flying boats ten times the weight of the eighteen ton *Caledonia*. Mr. Wimperis, who is on his way to Australia to advise the Australian Government on aeronautical matters, believes that the provision of suitable engine equipment for such large aircraft is the only remaining difficulty which hinders their adoption. He referred to the possibilities of refueling in the air, a scheme which is being explored with very promising results. As an alternative, the use of a carrier machine will be tried, releasing the operating plane at an elevation. Like catapult launching, these methods are intended to avoid the limitation of payload by the large amount of fuel that must be carried on a transatlantic flight. Mr. Wimperis was quite optimistic as to the possible traffic available, particularly as regards first class mail.

In thanking Mr. Parkin for his paper, the Minister of Transport remarked that Canada would be a partner as to 24½ per cent in the commercial enterprise that will follow the experimental North Atlantic flights. In a further address which he delivered at the Semicentennial Dinner at Ottawa, Mr. Howe drew a striking picture of the development of aviation in Canada, pointing out that it presents features of special interest, since its main lines have been decided by the topographical and climatic characteristics of the Dominion and the location of its natural resources, rather than by the distribution of its population. In contrast with countries whose aviation systems have been based on military requirements, or on the need for interurban passenger services, our flying services have to meet the requirements of exploration, the rapid mapping of large areas of sparsely inhabited country, the transport needed by a great mineral industry at points widely scattered over undeveloped territory, and last, but not least, the establishment of a regular trans-Canada mail and passenger service. He gave an impressive account of the progress which has already been made in the provision of landing fields across the continent, their equipment with the necessary aids to navigation, and the training of the large ground staff required. It is not very difficult to obtain suitable aircraft and flying personnel for such a transcontinental service as is contemplated, but it is a huge undertaking to equip and organize a route nearly four thousand miles in length, involving day and night flying, and passing over wilderness and mountains as well as settled lands. In such a case success can only be secured by employing the most modern methods in weather forecasting, radio service, airport lighting, and ground organization.

It is evident that Mr. Howe fully realises the importance to Canada of this newest branch of transport. He is well aware of the magnitude of the task it presents; his personal interest in air travel has done much to awaken public appreciation of what has already been done and what remains to be accomplished in establishing regular transcontinental communication over Canadian territory.



**Official greetings from Sister Societies presented at the Semicentennial Celebrations June, 1937.**

## Joint Meeting of the American Society of Civil Engineers and the Engineering Institute of Canada

**Boston—October 6th, 7th and 8th, 1937**

Three years ago the American Society of Civil Engineers held its Annual Convention in Vancouver, concurrently with a Western Professional Meeting of The Institute. The headquarters of both bodies were in the same hotel; joint sessions and discussions were held; members of both organizations participated in the various social events and excursions; many old acquaintanceships were renewed, and many new friendships formed. The happiest results followed.

The existing cordial relations between the two organizations will be further promoted by the action of the Board of Direction of the American Society of Civil Engineers in inviting the Institute to join with the Society in their Fall meeting in Boston this year. This cordial invitation was gratefully accepted by The Institute Council in the confident expectation that a large contingent of our members, particularly from the east, will take this opportunity of visiting New England and taking part in the joint proceedings.

The outline programme, published elsewhere in this issue, contains many attractions. The list of speakers includes such outstanding men as the Presidents of Harvard University and the Massachusetts Institute of Technology. The professional papers contributed by the members of the Society cover a wide range of topics, among which the rapidly developing science of Soil Mechanics will be a leading feature. The Canadian papers, fewer in number, deal with three major Canadian engineering projects.

Boston and its vicinity afford a delightful setting for the social functions and visits. Many good highways lead to Boston—adequate railway arrangements will be provided—Boston hotels are excellent—and Canadians will be heartily welcomed.

## The Engineering Institute of Canada Prize Awards 1937

Eleven prizes known as "The Engineering Institute of Canada Prizes" are offered annually for competition among the registered students in the year prior to the graduating year in the engineering schools and applied science faculties of universities giving a degree course throughout Canada.

Each prize consists of twenty-five dollars in cash, and having in view that one of the objects of The Institute is to facilitate the acquirement and interchange of professional knowledge among its members, it has been the desire of The Institute that the method of award should be determined by the appropriate authority in each school or university so that the prize may be given to the student who, in the year prior to his graduating year, in any department of engineering has proved himself most deserving as disclosed by the examination results of the year in combination with his activities in the students' engineering organization, or in the local branch of a recognized engineering society.

The following are the prize awards for 1937:—

| | |
|---|---|
| University of British Columbia | Charles H. Davenport |
| University of Alberta | Frederick Johnston Heath |
| University of Saskatchewan | G. N. Moore |
| University of Manitoba | Frank A. P. Athey |
| University of Toronto | Ervine W. Smith |
| Queen's University | R. D. Ramsay |
| Royal Military College | Ernest Roy Hyman, S.E.I.C. |
| McGill University | Pierre A. Duchastel de Montrouge, S.E.I.C. |
| Ecole Polytechnique | Guy Beaudet, S.E.I.C. |
| University of New Brunswick | Gerald A. Campbell, S.E.I.C. |
| Nova Scotia Technical College | R. P. Hudson |

## PERSONALS

Lieut. Colonel E. V. Collier, M.E.I.C., has been appointed general manager of Simplifix Couplings, Limited, manufacturers of compression joints, London, England. Colonel Collier was formerly with the Anglo-Persian Oil Company Limited, at Abadan, Persian Gulf.

Herve A. Gauvin, A.M.E.I.C., for the past three years divisional engineer for the provincial Department of Roads, Quebec, has resigned to accept the position of assistant general superintendent of Belanger Limited, Montmagny, Que.

Major M. Barry Watson, A.M.E.I.C., has been appointed director of the Department of Military Studies in the University of Toronto, vice Brig.-Gen. G. S. Cartwright, retired.

While Major Watson is a well known consulting engineer in Toronto and vicinity, and is continuing in private practice as such, he has been closely connected with military affairs and during recent years has been active in the University of Toronto, Canadian Officers Training Corps.

Keith Dixon, A.M.E.I.C., has recently received an appointment with the Esquimalt and Nanaimo Railway at Victoria, B.C. Prior to securing this position Mr. Dixon was for the past few years with the Ontario Department of Northern Development as divisional and resident engineer in charge of the location and construction of highways. From 1923 until 1931 he was with the construction department of the Canadian Pacific Railway Company.

Commander (E) A. C. M. Davy, R.C.N., A.M.E.I.C., attached to H.M.C.S. *Stadacona* at H.M.C. Dock-yard Halifax, N.S. has recently been promoted from the rank of Lieut.- Commander to that of Commander (E). Commander Davy, is a graduate of the Royal Naval College of Canada and The Royal Engineering College, Devonport, England.

C. D. Schultz, Jr.E.I.C., a graduate from the University of British Columbia, 1931, in Forest Engineering has recently been appointed British Columbia Timber Commissioner to the West Indies with headquarters at Kingston, Jamaicia.

R. E. McMillan, A.M.E.I.C., is now located with the Canadian Industries Ltd., Montreal. Mr. McMillan, who graduated from McGill in 1926 in electrical engineering, was previously plant engineer for the British Rubber Company of Canada, Montreal.

John Clancy, A.M.E.I.C., who graduated from the Nova Scotia Technical College in 1928, is now with the Canadian Pacific Railway Company Communications Engineering Department in connection with Eastern Lines Mr. Clancy was previously with the Northern Electric Company, in their Telephone Systems Engineering Department.

C. E. Frost, A.M.E.I.C., recently received an appointment on the engineering staff of the Bell Telephone Company, Canada, Montreal, Mr. Frost graduated from McGill University in 1931, and was previously assistant engineer with the National Harbours Board, Montreal. He is chairman of the Junior Section of the Montreal Branch of The Institute.

H. A. Thompson, A.M.E.I.C., has been appointed paper mill engineer for the Merritt, Chapman and Scott Corporation of New York City. This firm is at the present time constructing sulphate mills at Savannah, Georgia, Fernandina, and Jacksonville, Florida. Mr. Thompson, graduated from the University of Saskatchewan in 1927 and since that time has had extensive experience in the designing and construction of pulp and paper mills. For the past few years he has been maintenance engineer with the Fraser Companies at Edmondston, N.B.

# The Eighth Plenary Meeting of Council

The Eighth Plenary Meeting of the Council of The Institute was convened at the Windsor Hotel, Montreal, on Monday, June 14th, 1937, at ten o'clock a.m., with President G. J. Desbarats in the chair, and the following members of Council present: Past-Presidents E. A. Cleveland, G. H. Duggan, J. M. R. Fairbairn, F. A. Gaby, O. O. Lefebvre, C. H. Mitchell, F. P. Shearwood, Julian C. Smith, J. G. Sullivan, H. H. Vaughan and George A. Walkem; Vice-Presidents R. L. Dobbin (Province of Ontario), H. S. Carpenter (Western Provinces), J. A. McCrory (Province of Quebec), and H. W. McKiel (Maritime Provinces); Councillors R. J. Askin (Lakehead), W. E. Bonn (Toronto), R. W. Boyle (Ottawa), P. H. Buchan (Vancouver), H. J. A. Chambers (Border Cities), H. Cimon (Quebec), A. B. Crealock (Toronto), J. B. D'Aeth (Montreal), T. H. Dickson (Moncton), R. M. Dingwall (Edmonton), A. Duperron (Montreal), A. B. Gates (Peterborough), B. Grandmont (Three Rivers), A. K. Hay (Ottawa), F. S. B. Heward (Montreal), A. C. Johnston (Saguenay), E. P. Muntz (Hamilton), E. P. Murphy (Niagara Peninsula), F. Newell (Montreal), E. J. Owens (Saint John), E. A. Ryan (Montreal), R. A. Spencer (Saskatchewan), J. A. Vance (London), and Treasurer J. L. Busfield. There were also present by invitation: Mr. C. C. Kirby, Saint John, President of the Dominion Council of Professional Engineers, Mr. H. J. Crudge, Moncton, N.B., President of the Association of Professional Engineers of New Brunswick, and Mr. H. L. Briggs, Secretary-Treasurer of the Winnipeg Branch of The Institute.

After welcoming the members of Council to the meeting, the President remarked that although the recent consolidation proposals had not been approved by the membership, there was no doubt that The Institute members as a whole felt that endeavours should be continued to arrange closer relations with the Professional Associations. The President was glad to welcome so many past-presidents, and also Mr. C. C. Kirby, the President of the Dominion Council of Professional Engineers.

Mr. R. A. Spencer then presented the report of the committee, consisting of himself and Messrs. J. L. Busfield and F. S. B. Heward, which had been appointed on May 28th, 1937, to report on the suggestions put forward by Mr. Spencer at the Council meeting on that date. After sketching the situation in Saskatchewan as a typical case, Mr. Spencer pointed out that the report now submitted recommended the formation of a Committee on Professional Interests, together with a number of provincial subcommittees to deal with salaries and remuneration, professional practice, junior engineers and public education respectively. It was also suggested that a special committee of a temporary nature be set up to investigate and report upon the membership and management of the Institute. The report further recommended the adoption by the Council of a resolution* stating the Council's willingness to negotiate with the Provincial Professional Associations along certain lines.

The report further proposed that steps should be taken leading to closer relations with other engineering organizations operating in Canada, and recommended the appointment of a committee to report on this point.

Past-President Julian C. Smith remarked that while all were agreed as to the desirability of closer relations with Professional Associations, he thought it would be wise to wait for a while before opening up so many important questions. He thought the more pressing matters named in the report should be dealt with first.

*The text of this resolution will be found on page 585 of the July issue of the Journal.

Past-President H. H. Vaughan observed that since 1918, when The Institute promoted the formation of the Provincial Professional Associations during his presidency, his views had changed. A condition had now been reached in which membership in the several Professional Associations endorsed a man's professional competence and therefore gave him a status somewhat similar to that resulting from corporate membership in The Institute, with the added advantage of a legal right to practise. In Mr. Vaughan's opinion recognition of professional standing was not one of the main objects of The Institute, which were the dissemination of professional knowledge, holding meetings to discuss engineering subjects, and bringing together men interested in engineering work so that they could exchange information and become acquainted with one another. Under these circumstances Mr. Vaughan was of opinion that general membership in The Institute should be thrown open to all men engaged in engineering work who desired to participate in The Institute's activities. This would leave to the Provincial Associations all questions relating to qualification to practise, and the activities of The Institute would be greatly strengthened by the admission of many whose co-operation in The Institute's work would be of great value, who hold important and responsible engineering positions but who cannot at present join The Institute as corporate members. This broadening of The Institute's constitution should be accompanied by a reduction in the fee to the general membership, and seniority and eminence in the profession should be recognized by the creation of a class of Fellows. The President thanked Mr. Vaughan for this expression of his views.

Mr. H. J. Crudge, representing the Association of Professional Engineers of New Brunswick, explained the situation existing there, and said that the New Brunswick Association was of the opinion that no benefit would be gained by entering into any specific agreement along the lines suggested at the present time. The Association would, however, co-operate in any further investigation into the subject.

Vice-President H. S. Carpenter said that in Saskatchewan younger members entering the profession tended to join the Professional Association rather than The Institute. He urged that the report of Mr. Spencer's committee should be implemented as soon as possible.

Mr. R. M. Dingwall thought that the Professional Associations needed a Federal organization which would be in contact with all of them. He could not understand the objection so often heard as to the duplication of fees; the total amount payable to an Association and The Institute was not large in relation to the services rendered.

Professor H. W. McKiel did not think any time should be lost in discussing matters with the Nova Scotia group. He hoped that a meeting of the joint committee which had been formed in Nova Scotia to consider the matter would be held very shortly.

Mr. Hector Cimon, in response to a request from the President, stated that in the view of the Corporation of Professional Engineers of Quebec a prime requisite for consolidation was that in the future, admission to corporate membership in The Institute in the province of Quebec should be limited to members of the Corporation. This view was also held by the Quebec Branch of The Institute.

Mr. P. H. Buchan observed that in British Columbia, having regard to the result of the recent ballot of The Institute, it was felt that the B.C. Association should go ahead with the development of their idea of the Dominion Council. Mr. Buchan explained the system in British Columbia, under which the younger men entering the profession were being drawn into the Association, so that in a short time there would be no engineers in British Columbia not registered, and many of them would not be interested in The Institute.

Mr. F. S. B. Heward had been glad to hear the favourable opinions expressed with regard to the report, and *moved* its adoption. His motion was *seconded* by Mr. R. J. Askin.

Past-President George A. Walkem was impressed by the difficulty of obtaining agreement among the Associations, and could not see how a definite amalgamation could take place between The Engineering Institute, a national body, and provincial bodies which had entirely different functions.

Dr. R. W. Boyle had no objection to the report but felt that it opened up a larger number of important questions than had seemed probable when the committee was appointed. He hoped that the decision upon its adoption would not be rushed.

At the President's suggestion, Mr. Kirby spoke. He pointed out that none of the Provincial Associations had suggested consolidation with The Institute, although they had on The Institute's invitation participated in negotiations to find some way in which The Institute could function as the head of the family of engineers in Canada. In view of the result of the recent ballot on the proposals which had followed, Mr. Kirby believed that the Associations were now strongly in favour of the continuance and development of the Dominion Council. Many engineers were surprised to find that The Institute membership had not backed up a measure recommended by The Institute's Committee on Consolidation, approved by a Plenary Meeting of the Council of The Institute last October, and endorsed by The Institute's general meeting last February. He believed that The Institute was now at a parting of the ways, and it was for The Institute to decide whether professional organization was to be carried out by the corporations in co-operation with The Institute, or separately from them.

Mr. H. J. A. Chambers, expressing the ideas of the Border Cities Branch, remarked that they had no objection to admitting members from Provincial Associations whose requirements equalled those of The Institute, but they did object to admitting those of any Association whose requirements did not reach this standard. They hoped some day to see a joint body, membership in which would qualify men to practise in any province of Canada.

At this point Mr. Heward asked permission to interrupt the debate. He pointed out that the Semicentennial Celebrations of The Institute would commence next day, and desired to move that the Council recognize its appreciation of the time and energy which Mr. J. L. Busfield had spent on the organization of these celebrations by authorizing the purchase of a suitable gift for him as a memento of the occasion. Mr. Heward's motion having been *seconded* by Mr. E. P. Muntz, was unanimously *carried*.

Mr. A. B. Crealock noted with regret that in the report under discussion the committees proposed seemed to have some duties which really belonged to the Associations, particularly in respect to questions relating to professional practice. Such matters, in his opinion, concerned the Dominion Council rather than the Engineering Institute. Mr. Crealock desired to urge that no recommendation of any of the committees proposed in the report should become effective unless endorsed by a Plenary Meeting of Council or approved by a majority of the Council on letter ballot. Could Mr. Heward's motion for the adoption of the report be amended to this effect?

It was *agreed* that a statement requiring such endorsation should accompany the report.

Mr. Heward pointed out that if the Provincial Subcommittees named in the report could co-operate with their respective Provincial Associations, the main Committee on Professional Interests could equally well co-operate with the Dominion Council. Failure to mention the Dominion Council in the report indicated no lack of respect for that body. If Mr. Crealock's views could be met by amending the report, Mr. Heward would be glad to see it done.

Professor McKiel inquired whether adoption of the report now under consideration would have any effect on the appointment of Mr. Fowler and himself to act on the committee functioning in Nova Scotia, and the President assured Professor McKiel that the arrangement in Nova Scotia would stand in any case.

The meeting adjourned at twelve fifty p.m. to reconvene at two fifteen p.m.

### Afternoon Session

Mr. H. L. Briggs, the Secretary of the Winnipeg Branch, attended by request, and sketched the situation existing in Winnipeg. The Manitoba Association and the Winnipeg Branch were on very friendly terms; in fact the Association had assisted the Winnipeg Branch financially to help the branch to carry on its technical and social functions. Mr. Briggs felt that the engineers in Manitoba were anxious for some action to be taken now in respect to the proposals for local consolidation which had been put before The Institute Council some two years ago.

Mr. J. A. McCrory remarked that the opinions so far expressed had been so divergent that he wondered how solutions to the various problems could be arrived at by such committees as were now proposed. The investigations contemplated in the committee's report were a heavy task and strong active working committees would be needed to obtain results.

Past-President E. A. Cleveland observed that many of the Professional Associations felt that the membership of The Institute should be confined to Association members. In his opinion there were many possibilities of improvement as to the usefulness of The Engineering Institute, and he hoped that the committees now proposed would be able to devise means by which the younger men in the Associations would form an attachment to a Dominion-wide body such as The Institute.

Mr. Kirby thought it most desirable that at this point The Institute Council should make a definite statement as to its policy. Is it desired to build up an Institute that is highly technical and professional, or is it desired to create a large body including men who may be technicians but who are not practising engineers? This uncertainty contrasted unfavourably with the definite aim of the Associations, namely, that all their members should be men recognized by law as competent engineers.

Mr. Spencer pointed out that this matter would naturally come before the Committee on Management and Membership, and he thought that before making such a pronouncement as that suggested by Mr. Kirby, the report of the Committee on Professional Interests should also be awaited.

After further discussion, the President put Mr. Heward's motion for the adoption of the report, and the motion was *carried* unanimously.

With reference to the personnel of the various committees proposed in the report, Mr. Spencer suggested that a nominating committee be appointed to bring in recommendations on this matter; this Nominating Committee was accordingly appointed as follows:

Dr. E. A. Cleveland, M.E.I.C., Chairman
H. S. Carpenter, M.E.I.C.
H. Cimon, M.E.I.C.
R. L. Dobbin, M.E.I.C.
J. A. McCrory, M.E.I.C.
H. W. McKiel, M.E.I.C.

Mr. Spencer asked whether the Council would think it desirable to appoint a separate committee to act in further negotiations with the Provincial Associations. The Nominating Committee would select the committee of three on Professional Interests; would select the councillor from each province to head the various subcommittees; would select the Committee on Membership and Management, and would select the special committee to report on the feasibility of closer co-operation with other engineering organizations.

After further discussion, the President pointed out to Dr. Cleveland that his committee's duties would also include the nomination of a committee to follow up negotiations with the Associations.

Professor McKiel desired to draw attention to the question of Institute administration at Headquarters. At the President's suggestion the Secretary withdrew from the meeting, and discussion followed on this matter, after which, on the *motion* of Professor McKiel, *seconded* by Mr. Muntz, a resolution of confidence in the Secretary was placed on record.

The Secretary, having returned, presented a report from the scrutineers as to the existence of information regarding the distribution of the recent vote on the amendments to the by-laws. Discussion followed, after which it was *moved* by Mr. Cimon that in future ballots of The Institute the ballots be sorted in such a way that the scrutineers can report how the vote went by provinces. Mr. Cimon's motion was *seconded* by Mr. Muntz. After further discussion, Mr. Cimon having accepted an amendment by Mr. Dingwall, that information as to a vote by provinces should be available only to Council, subject to their decision to publish if thought necessary, Mr. Cimon's motion was put to the meeting and *failed to carry.*

Following further discussion, on the *motion* of Mr. Crealock, *seconded* by Mr. W. E. Bonn, it was *resolved* that the statement of the scrutineers as presented at this meeting be received and published in the next issue of the Journal*.

Mr. Newell drew attention to the very strenuous work of Mr. Pitts and his Committee on Consolidation, which had continued during the past two years. He pointed out that that committee had had the difficult task of trying to devise a scheme which would bring together The Institute and the Professional Associations, and he *moved* that Council accord a very hearty vote of thanks to Mr. Pitts and the members of the recent Committee on Consolidation in recognition of their arduous work. Mr. Vance *seconded* Mr. Newell's motion and desired to add that thanks should be accorded to the Headquarters staff for the large amount of work they had carried on in connection with the work of the Committee on Consolidation.

The President pointed out that although the scheme prepared by Mr. Pitts and his committee had not met with the approval of the membership, their work was by no means lost. A vast amount of information had been gathered; wide interest was awakened in Institute affairs, and the sentiment of all sections of The Institute had been explored, the activities of the committee thus resulting in great benefit to The Institute. The motion was *carried* unanimously.

*This report is printed on page 589 of the July issue of the Journal.

Mr. McCrory *moved* a hearty vote of thanks to the scrutineers for their efficient work in canvassing the vote on the recent ballot on consolidation, and also moved that the ballot papers be now destroyed. Mr. Cimon desired to have the privilege of *seconding* Mr. McCrory's motion. The work of the scrutineers had been unusually heavy. The motion was *carried* unanimously.

In regard to the question of the award of the Sir John Kennedy Medal for the year 1937, it was *resolved*, on the *motion* of Mr. McCrory, *seconded* by Mr. Heward, that the matter be deferred to the next meeting of Council in the hope that other suggestions would come in.

It was noted that since the last meeting of Council a few additional suggestions had been received as to the subject for the Past-Presidents' Prize for the year 1937-1938, and, after discussion, it was decided that the subject should be "Stream Control in Relation to Drought and Floods."

The Secretary presented further correspondence in connection with an inquiry received from a member of the Border Cities Branch as to the ownership of plans prepared by engineers for municipalities. In this connection Mr. Buchan cited a case which had come before the British Columbia Courts some time ago, and kindly furnished information which the Secretary was directed to forward to the enquirer.

Dr. Boyle desired to draw attention to some points in connection with The Institute's organization. In his opinion, the provision in the by-laws for a quorum of five at Council meetings was anomalous, that quorum being only one-eighth of the Council. A quorum of a larger number would, of course, involve the payment of travelling expenses, and Dr. Boyle would suggest that the money now devoted to the holding of a Plenary Meeting each year should be used for the payment of councillors' expenses to ordinary Council meetings, with an increased quorum, preferably twelve. More meetings should be held outside of Montreal, preferably in succession in the various zones, so that the vice-presidents could preside. Dr. Boyle *moved* that this matter of the quorum of Council meetings should be referred to the new Committee on Membership and Management for study and report. The motion having been *seconded* by Mr. A. K. Hay, was put to the meeting and *carried.*

The meeting adjourned at six twenty-five p.m., to reconvene at five thirty p.m. on Tuesday, July 16th, 1937.

At the adjourned meeting on July 16th, Dr. Cleveland presented the report* of his committee, which recommended the appointment of the members of the various committees, and also advised that the main Committee on Professional Interests should be authorized to act in any negotiations with the Professional Associations.

On the *motion* of Dr. Cleveland, *seconded* by Mr. Dobbin, these recommendations were *approved.*

Mr. Chambers desired to draw attention to the work which might be done by the proposed Committee on Professional Interests as regards public education, by which he meant making the public familiar with the value of the engineer and his work. In the past he felt that the resources of radio had been neglected for this purpose, and he thought that this matter should be referred to the Committee on Professional Interests. Mr. Newell undertook to bring this matter to the attention of that committee.

There being no further business, on the *motion* of Mr. Crealock, *seconded* by Professor McKiel, the meeting *adjourned* at six thirty p.m.

*The membership of these committees will be found on page 585 of the July issue of the Journal.

# The Next Fifty Years

*By the late Harrison P. Eddy, Hon. M.E.I.C.**
*Past-President, The American Society of Civil Engineers.*

**This address was prepared by Mr. Eddy for delivery in Montreal, June 16th, 1937, during the Semicentennial Celebrations of The Institute. Owing to his sudden and lamented death just after his arrival in Montreal, the address was sympathetically presented by F. S. B. Heward, A.M.E.I.C. It is published here by the kind permission of Mr. Eddy's family, and is memorable as the last message of an eminent and well beloved American engineer of international renown.**

To present observers the past fifty years appear to constitute a short period in comparison with the fifty years to come. With respect to past and future, the several professions differ materially in their objectives. The clergyman ministers to present spiritual needs; the doctor treats the current illness of his patient; the lawyer deals essentially with the present as based upon the past. He interprets laws which have been passed, not concerning himself with enactments of the future.

The engineer, on the other hand, deals essentially with the future. As the surveyor determines his forward course by first taking an observation on an established point in the rear, so the engineer utilizes the firm foundation of past experience and accumulated knowledge for the basis of his studies for the future. His bridges, his water works, his main highways, his ships, his communication systems, his machines, all are planned not for the past, not alone for the present, but for the future, often for a generation or more in advance.

Engineering as a profession has been said to date from about the seventeenth century, but during the past fifty years it has developed to such an extent that we are now living in an "engineering age." Fifty years ago we depended upon man and beast power, whereas today we depend largely upon mechanical means.

In the fifty year period before us there will be an accelerated advance in the accomplishments of engineering which, broadly speaking, is the application of science. New discoveries in science and their use by means of new inventions, will follow one another with ever-increasing rapidity. Often one discovery will reveal a score or more of new opportunities which speedily will be developed and made useful to man.

This acceleration in the speed of engineering advancement will be due in part to the increase in the number of workers in this field, made available through the competition of engineering colleges to gain students, and especially the growing conviction among parents, whether well-founded or not, that an engineering education carries with it an improved economic and social status. The public has become "engineering-minded."

No one can foretell with accuracy what specific results will ensue from this intensified development along engineering lines; but a few accomplishments are clearly evident:

Space, already so greatly reduced, will, practically speaking, be well nigh eliminated by the conquest of the air.

Mass-production will be extended to far more industries.

Agriculture will yield more and more to combination-control and mechanization. With the aid of new methods of processing and the discovery of synthetic foods, the necessary agricultural products for a unit of population, will be provided with a fraction of the labour and land now used.

Automatic control of production and operation will further greatly reduce the need for manual control.

New scientific discoveries, new sources of power and the development of new processes and inventions, will make necessities and many luxuries more generally available.

Such changes will inevitably shorten the work-time required to satisfy the demands of the public. In Canada and the States it has been reduced one-third during the last fifty years. Is it not probable that an equal reduction will result in the next fifty years? If so, the required work-time will become only one-half what it is at present. Probably twenty hours a week is a conservative estimate.

Whatever this reduction may be, it will result largely from the activities of the engineer. Credit for lightening the human burden, however, will be accompanied by liability for any unfortunate results which may ensue and the public will look to the engineer to provide the means to avoid them.

One of the greatest problems which will be created by such changes and which even now is urgently demanding attention is—

What shall we do with our released time and energy?

Some of the ill effects of a surplus of spare time already have become evident. Among a substantial number of persons there has apparently developed a lack of desire to work for the purpose of bettering their condition. To illustrate, it has recently been found so easy to do a minimum of work for a modicum of compensation, under the guise of relief, that the incentive to produce more for a greater reward has become atrophied. This tends toward a falling, not a rising standard of living.

We are wont to believe that our modern civilization has produced a higher standard of living. Unless this great problem of the application of leisure time is judiciously solved, the undirected forces of human nature may reduce the present standard of living and wreck our civilization.

"For Satan finds some mischief still
For idle hands to do"

will be as true as when stated by Isaac Watts.

The most obvious and popular solution of the problem seems to be the development of recreation, and in the next fifty years games, sports, hunting, fishing, travel and a long list of recreational pursuits will be brought within easy reach of more and more of the people. In providing such means the engineer will take a prominent part. New machines and equipment will be invented and used partly or exclusively for recreation; greater sums will be spent, for the most part under the technical direction of the engineer, on the development of highways, playgrounds, parks, and other recreational facilities. While this movement is valuable, is it to be the sole solution of the problem during the next fifty years? Can recreation take the place of work in providing training and discipline?

It has been said that

"Obedience to law is liberty."

Will the making available of so large a proportion of time for play result in producing a lack of respect for and obedience to law; will it diminish initiative and ambition? There certainly is grave doubt whether the solution can be found in recreation alone.

*Of Metcalf and Eddy, Consulting Engineers, Boston, Mass.

Another promising solution lies in the field of education. To quote Mr. H. G. Wells (*A Year of Prophesying—1925*):
