## Heat Insulation for Buildings

*E. A. Allcut, M.E.I.C.,*
*Professor of Mechanical Engineering, University of Toronto, Toronto.*

**Paper presented before the Hamilton Branch of The Engineering Institute of Canada, November 17th, 1936.**

SUMMARY.—This paper outlines the methods of testing heat-insulating materials and discusses the various factors which affect the accuracy of the results obtained. These include such points as the dimensions of the specimen tested, the mean temperature of the material, its moisture content, its density, thickness, liability to disintegrate and permeability.

The importance of heat insulation, in general, has been known for many years, but its advantages, as applied to industrial and residential buildings, are only just beginning to be appreciated by the public. A pamphlet issued by the Dominion Fuel Board in 1927 indicated that a fuel saving of thirty million dollars per annum was possible if all residential buildings in Canada were properly insulated, and that the savings in Montreal, Toronto, Hamilton and Ottawa alone would be about seven million dollars every year.

Research work on this problem has been proceeding for a number of years at the University of Toronto under the auspices of the School of Engineering Research, to establish the relative values of the materials offered for this purpose.

Various figures, given by salesmen and advertisers, are supposed to indicate the relative merits of such materials, but the principal trouble is that frequently the test results quoted cannot be compared with each other because the methods of testing are different, and the sizes and conditions of the specimens used vary considerably. In many instances, also, the information given is so incomplete that the test figures, while correct in themselves, give very misleading comparisons. For example, the size, thickness, density, moisture content and other similar factors, have considerable influence on the results obtained, and a figure that is correct for a small, thin specimen does not always apply to a large, thick sample. Also, the sample tested might not be a representative one.

The various forms of insulating material may be divided into rigid, filler and blanket types, which derive much of their value from the air spaces contained in them and those which depend largely on the use of bright metallic surfaces. Each of these has its advantages, and there is no one material that gives the best results under all conditions. The best insulating material is that which gives the greatest resistance to the transmission of heat per dollar expended, taking into account the cost of material, the cost of applying it to the structure and the rate of depreciation. Resistance to the action of fire and vermin and to the penetration of air must also be considered.

A survey of some two hundred homes, in 1928, indicated that, on the average, about 16 per cent of the heat was lost through the roof, 27 per cent through the walls, 26 per cent through the windows, 25 per cent by air leakage, and the rest through doors, floors, etc. With various methods of insulation and the addition of weather stripping and storm sashes, the possible reduction of heat loss varied from 13 to 35 per cent, under different conditions, and in one case it was estimated to be as much as 66 per cent, but this was unusually high. This survey indicates that other factors beside insulation enter into the question of fuel economy, and if attention is concentrated on insulation only, the actual saving may be less than it should be.

### PRINCIPLES OF HEAT TRANSMISSION

Heat is transmitted from one fluid to another by conduction, convection, radiation, or by a combination of any two or all three of these. The amount of heat transmitted through an insulating material is generally expressed as the number of British thermal units passing per hour through a square foot with a one degree temperature difference held between the two faces. This is called the conductance "$C$" of the material, and its reciprocal is known as the resistance "$R$." The conductivity is usually calculated by multiplying the conductance "$C$" by the thickness in inches "$x$," but in the author's opinion, this name is badly chosen, as the true conductivity of the material obviously remains constant with different thicknesses, whereas it will be shown later that the conductivity "$k$," when calculated in this manner, varies with different thicknesses. The latter, therefore, is a characteristic of the specimen and not of the material, and so it is preferable to call this property by some other name, such as "apparent conductivity."

In addition to the resistance of the solid wall, there are also, in practice, the resistances of two air films on the inside and outside, respectively. The thicknesses of these depend on the direction and velocity of the air, and for this reason, high air velocities cause the amount of heat transmitted to increase. The total resistance to the transmission of heat is the sum of all the individual resistances and, therefore, there are two ways of determining the resistance to heat transmission, namely, by testing a section of the actual wall, or by adding together the resistances

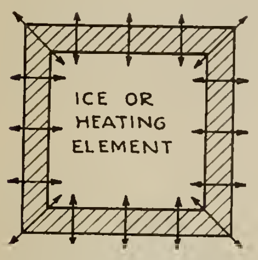

**Fig. 1 —Simple Hot or Cold Box made entirely of Material to be tested.**

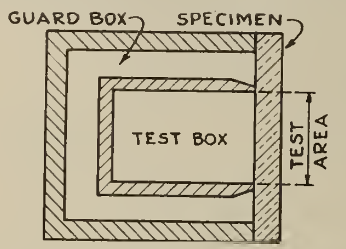

**Fig. 2—Guarded Hot Box. The Guard Box and Test Box are kept at the same temperature by Electric Heaters and Fans.**

of the various materials of which the wall is composed. Thus

$$U = \frac{1}{\frac{1}{f_1} + \frac{x_1}{k_1} + \frac{x_2}{k_2} + \ldots \frac{1}{f_2}}$$

where $U$ is the "air to air" coefficient of heat transfer for the wall,

$f_1$ and $f_2$ are the conductances of the air films,

$\frac{x_1}{k_1}, \frac{x_2}{k_2}, \frac{x_3}{k_3}$ ..... are the resistances of the various sections of the wall.

### Methods of Testing

(1) *Hot Box Method*

The specimen forms one side (or all sides) of a box, the others being composed of highly insulating materials, the heat transmissions of which are known. By using thermometers or thermocouples and heating the inside of the box electrically, it is possible to calculate the amount of heat that passes through the specimen while maintaining either definite air temperatures on each side of the wall or a definite temperature drop between the two surfaces. This method, however, is cumbersome and expensive. It is difficult to obtain even conditions over the whole surface of the specimen, and a long wait is necessary before conditions become sufficiently steady for readings to be obtained. In some cases, two boxes are used, one inside the other, the outside box being kept at the same temperature as the inside so that heat losses are suppressed from all surfaces save that used for testing. (Figs. 1 and 2.) This is still more difficult to control and is a good deal more expensive to construct. In such cases also, if a composite specimen is used, the quality of the workmanship used in constructing the specimen influences profoundly the final result, so that a good deal of uncertainty may be expected. However, tests made in this way are useful for checking purposes. It is usually preferable, wherever possible, to test the materials themselves and to use the figures thus obtained as a basis for calculating the heat transmission from "air to air."

(2) *Hot Plate Method*

In this case, two similar specimens are employed, and these are sandwiched between a central plate that is electrically heated, and two cold plates kept at the required temperature by circulating through them water or cooled brine. (Fig. 3.) The temperatures of the hot and cold faces, respectively, are indicated by thermocouples, and losses from the outside edges of the specimens are avoided by the use of a sufficient thickness of insulation or, alternatively, by using a guard ring; the latter is in the form of a hollow square wound with resistance wire and a current is passed through it sufficient to keep the outside edge of the specimen at the same temperature as the central part which forms the actual test area. (Fig. 4.) The author believes that use of the guard ring, in the case of mean temperatures less than 100 degrees F., is unnecessary and may be undesirable, because if the guard ring is not kept consistently at the same temperature as the centre of the specimen, greater errors may be introduced than when no guard ring is employed. Tests have been made by him with simple plates, adequately protected around the edges by 3½-inch cork board, and in no case has it been found that appreciable errors have resulted from the elimination of the guard ring, even in the case of thick specimens where the errors may be expected to be greatest.

The sizes of these plates vary from 8 inches by 8 inches to 30 inches by 30 inches, and in some cases, even larger plates have been designed, but the larger the plate, the more expensive it is, the more difficult it is to keep conditions constant over the whole area, and the longer is the period required to make a representative test. There is some evidence that the size of the plate used may have an influence on the results obtained, particularly in cases where it is possible for air movement, or convection currents, to be set up within the specimen. When specimens ½ inch thick were tested in hot plates 8 inches and 24 inches square, respectively, the same results were obtained, but when larger and thicker specimens were tested, higher apparent conductivities were obtained with the 24-inch plate as compared with those from specimens one inch thick tested in the 8-inch hot plate, as follows:—

| | |
|---|---|
| Rock wool and glass wool..... | 2 inches thick, increases 40-60 per cent |
| Metal foil, crumpled.......... | 2 inches thick, increases 65 per cent |
| Fibre board.................... | 2 inches thick, increases 24 per cent |
| Packed materials............. | 4 inches thick, increases 70-90 per cent |

It is not clear what part of this increase is due to the larger size of plate, as it was impossible to test the thick specimen in a small plate on account of the large edge losses that would be obtained. It is probable, however, that a good deal of this difference, if not most of it, is due to the increased thickness.

### Thickness of Specimen

With the modern tendency towards the use of thick insulation, there has arisen a demand for tests to be made

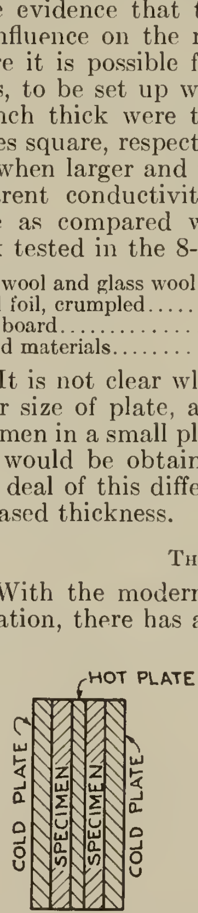

**Fig. 3—Hot Plate Apparatus.**

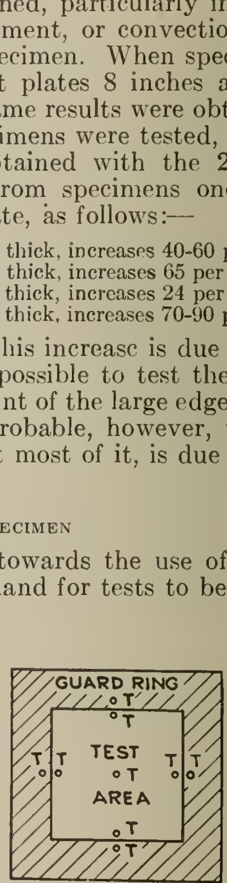

**Fig. 4—Guarded Hot Plate. Thermocouples are Indicated by "T."**

on specimens 2 inches and 4 inches thick, and the apparatus and technique that were apparently suitable for the old conditions do not seem to be readily applicable to the thicker and more highly resistant materials that are now being employed. Experience, both at Toronto and elsewhere, has indicated that the "apparent conductivity" of insulating materials (except in the case of cork board) increases with the thickness, and the form of curve appears to be fairly definite, but the following characteristic figures for fibre boards indicate this effect:—

| Thickness | "k" |
|---|---|
| ½ inch | .38 |
| 1 inch | .41 |
| 2 inches | .44 |
| 3½ inches | .48 |

In the case of rock wool, it has been found that 2-inch and 4-inch thicknesses give apparent conductivities which

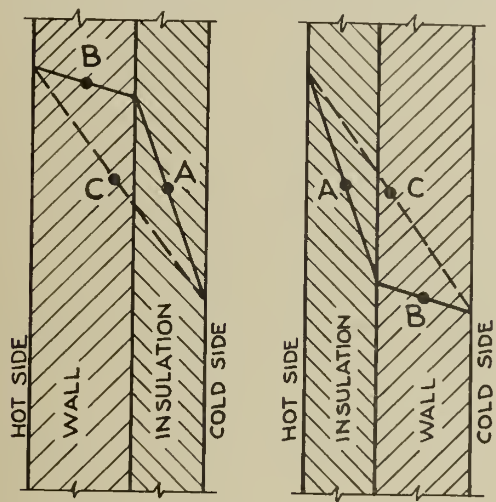

**Fig. 5—Full Line—Actual Temperature Gradient.**
**A—Mean Temp. of Insulating Material.**
**B—Mean Temp. of Building Material.**
**C—Mean Temp. of Structure.**

are 25 and 35 per cent higher, respectively, than those obtained with a thickness of one inch. Similar observations apply also to glass wool and many other substances. In the case of fibre boards and other similar materials, it is probable that surface resistance plays a large part in producing this effect. The author found by embedding thermocouples within cast material, that there was a definite resistance to the passage of heat through the surfaces of the specimen, and other investigators have made similar observations. In the case of packed materials, the situation is somewhat different, but it has been found recently that there is definite evidence of the circulation of air within these materials, and it is quite possible that the amount of heat transmitted in this way may increase materially as the thickness increases. It is possible, also, that radiation may play some part in the operation, but this is not certain.

In some instances, thick materials are being used for the purpose of storing heat and producing a kind of thermal flywheel. This may be very useful in cold weather by evening the heat load and perhaps by storing solar radiation, but sometimes it has been found difficult to control in hot weather when the amount of heat stored was liable to produce undesirable effects.

### Pressure on Sample

Tests have shown that the superficial pressure on the sample of material being tested has no influence on the result, provided that specimen itself is rigid.* Packed or "fill" materials are usually enclosed in a box, so that in this case the question of compressibility does not arise. With soft materials, however, which are tested in the form of a mat or blanket, the pressure must be carefully controlled, as increased pressure both reduces the thickness and increases the density of the material. The calculated value of the apparent conductivity, therefore, may be affected very considerably. A suitable pressure for this purpose would be about 45 pounds per square foot.

*"Heat Insulation as Applied to Buildings and Structures," by the author. Proc.I.Mech.E., December 1934.

### Mean Temperature

The mean temperature of the specimen is usually considered to be the arithmetic mean between the temperatures of the hot and cold faces, but it does not necessarily follow that this will be true in practice, as, with thick walls, and particularly in cases where thick insulation is used, the temperature gradient through the material is seldom a straight line. Further, if different materials are used in series with each other, the slopes of the various lines that represent the temperature gradient will change materially (Fig. 5) and therefore, as far as possible, the apparent conductivity of the material, at the appropriate mean temperature, should be employed in calculations.

If the apparent conductivities of various materials used for insulating purposes are plotted against mean temperatures, it will be found that for temperatures below 100 degrees F. these relationships are not only represented by straight lines, but that the lines themselves are very nearly parallel to each other. (Fig. 6.) The following formula may be used without serious error to indicate the apparent conductivity at a temperature "$t$" when the conductivity at a standard temperature of 50 degrees is known.

$$k_t = k_{50}\,[1 + .0024\,(t - 50)]$$

Similar formulae may be calculated for other standard temperatures. The standard mean temperature of 50 degrees F., which was agreed upon some years ago by a Committee of the National Research Council of Canada, is taken midway between an inside temperature of 70 degrees F. and an outside temperature of 30 degrees F., as these were considered to represent approximately average Canadian conditions. However, this mean temperature is rather awkward to handle, as, if the cold plate employed is at a low temperature, there will either be trouble owing to the formation of ice on the cold side, or, if the temperature is too high for this, the test material may become very wet on the cold side due to condensation of moisture from the atmosphere. On the other hand, if a high mean temperature is standardized, the temperature of the hot side of the specimen may become excessive, and the possibilities of serious heat loss to the atmosphere are increased. The

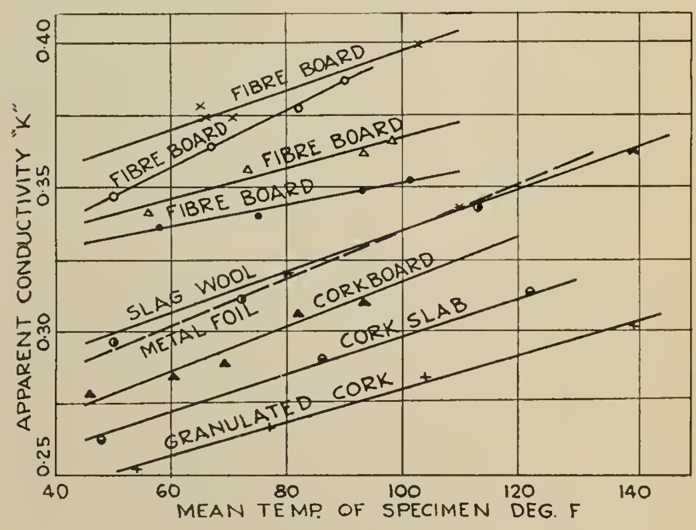

**Fig. 6—Effect of Mean Temperature on Test Results.**

author is of the opinion, therefore, that for general use, a mean temperature of 75 degrees F. represents the best compromise. In this case, the hot plate should be at about 95-100 degrees F., which is not too high for practical use, and the cold plate temperature at approximately 50-55 degrees F., which is usually obtainable without serious difficulty. In some cases, indeed, the water available in the town mains is cold enough for this purpose, and therefore the constant use of a refrigeration machine may be unnecessary, but then, some provision must be made to deal with the question of temperature fluctuation which sometimes gives considerable trouble.

### Temperature Difference

The difference of temperature maintained between the hot and cold sides was formerly considered to be unimportant, provided that a definite mean temperature was used. Tests made by the author confirm this, provided

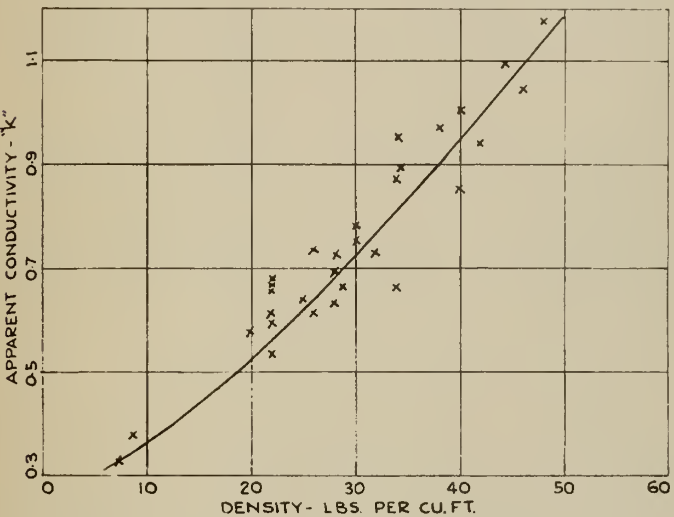

**Fig. 7—Test Results on Dry Timber (Mean Temp. 75 degrees F.)**

that thin specimens are employed, as with specimens of fibre board one-half inch thick and temperature differences varying from 30 to 80 degrees F. no significant differences were obtained in the calculated conductivities. When thicker specimens were employed, however, very considerable differences were noted, and in general, it appears that the apparent conductivity increases with the temperature difference. This may possibly be due to changes in surface resistance, internal convection, radiation, or combinations of these factors. Whatever the causes may be, it is evident that the temperature difference should be standardized as well as the mean temperature. If the temperature difference is small, errors of measurement become comparatively large, and therefore it is suggested that a standard temperature difference of about 40 degrees F., as indicated in the previous paragraph, will give comparable results without involving excessively high or low temperatures.

### Moisture

For research and experimental purposes, it is advisable that tests should be made on specimens that are in a dry condition and the committee referred to above, decided that specimens should be heated to 140 degrees F. and kept at that temperature for twenty-four hours before any tests were made. This temperature was decided on because certain materials underwent structural changes if higher temperatures were employed. In practice, however, the materials actually used sometimes contain considerable amounts of moisture and this may increase the heat transmission through them to a very considerable extent. Of the materials commonly used, glass wool and rock wool contain practically no moisture when received. Cork board contains about ½ to 1 per cent by weight, and fibre boards from 5 to 8 per cent. When exposed to air at 70 degrees F. and 85 per cent relative humidity, no increase in weight took place in the glass wool or rock wool; cork gained by one per cent and fibre board by ten per cent. Thus, in the case of fibre boards, for example, the final moisture content by absorption from atmosphere may be as high as 17 or 18 per cent when estimated on the basis of dry weight. If air infiltration and condensation occur, as when conditioned air is cooled below the dew point, the material may become waterlogged and then will contain many times its own weight of water. The seriousness of this condition is indicated by the fact that the heat conductivity of liquid water is about twenty-four times that of the vapour, and that of ice is about ninety times that of the vapour. The practical disadvantages are obvious.

It is evident, therefore, that the question of the conductivity of those materials which contain various percentages of moisture, deserves further study, but the difficulty is to find a way of distributing the moisture evenly through the specimen and keeping it there while the test is being made. It is a matter of common experience that when a specimen is tested in the hot plate, some of the moisture is evaporated, and even if this does not occur, the moisture tends to leave the hot side and to travel towards the cold side of the specimen. This effect was examined by making a specimen of fibre board 3½ inches thick in two parts which were, respectively, 2 inches and 1½ inches thick. The density of the boards on the hot side decreased during the test from 15 to 14.8 pounds per cubic foot, while that of the boards on the cold side increased from 16.3 to 16.7 pounds per cubic foot. The total density of both boards showed no change, so that in a solid specimen there would be no evidence of loss or gain of moisture, but the condition of the specimen after the test would be different from that before the test. It is possible that some new type of apparatus may have to be devised for making tests of this kind, but in the meantime, tests must be made on specimens containing no moisture, or very little; otherwise, erratic results are likely to be obtained.

### Density

As a general rule, and particularly in cases where solid materials rely for their insulating value on the air cells contained within them, the conductance of materials increases with their density (Fig. 7), but this is not always true. The use of fibrous materials, particularly those that are packed into large air spaces, has introduced materials of very low density. In these cases, it is found that if the density is reduced below a certain value (usually between 2 and 6 pounds per cubic foot) the heat transmitted through the specimen increases. (Fig. 8.) This may possibly be due to the greater facility afforded for the circulation of air within the material; but it is also possible that radiation plays some part in this phenomenon. Recent experiments

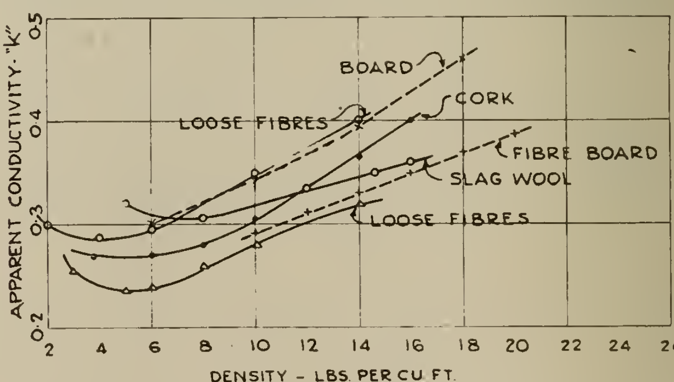

**Fig. 8—Effect of Density on Heat Conductance of Insulating Materials.**

made at the University of Toronto give distinct evidence that movement of air does occur in material packed to a density as high as 10 pounds per cubic foot, and thus some transfer of heat by convection is bound to take place. A specimen 24 inches square and 4 inches thick was tested in the usual way, and was then divided into horizontal layers, each 2 inches wide, by means of paper partitions. It was found that the plain specimen, which gave unrestricted movement of the air, had an apparent conductivity with 40 degrees F. temperature difference, exceeding by 50 per cent the corresponding figure for the divided specimen. Decreased density in such materials reduces the number of contacts between the solid fibres, and therefore decreases the probable transmission of heat by conduction. It appears, therefore, that, in addition to the size and composition of the fibres themselves, their arrangement will have a considerable influence on the results obtained. It is possible that some such studies will have to be undertaken in connection with the structure of heat insulating materials as have been conducted in metallurgical work in connection with the structure of metallic materials. There, it is found that not only the composition, but also the arrangement of the materials has a very considerable influence on the results obtained. It seems probable to the author that similar factors affect the heat transmission of insulating materials, and that some kind of classification may eventually be undertaken that will indicate the most desirable characteristics of such structures. Thus, not only the quantity of solid material present, but also its arrangement, is likely to be important.

### Surface

The fact has been known for many years that the amount of heat transmitted by radiation from a bright surface, and absorbed by it, is very much less than it is in the case of a dull surface. This fact has been utilized in some of the recent materials which rely upon metallic surfaces for the purpose of transmitting, or impeding the transmission, of radiant heat. The effectiveness of these surfaces depends upon their emissivity, which indicates the percentage of radiant heat reaching the surface that is absorbed and transmitted by it; thus, aluminium has an emissivity of 5 per cent, which means that 95 per cent of the radiant heat received by the material is reflected from it. Iron has an emissivity of approximately 10 per cent, and tin of about 20 per cent, so that these materials are less effective in the sense that they transmit more radiant heat than does aluminium.* It is to be noted that the wave length of the heat radiated has an influence on the emissivity, the latter becoming less as the wave length increases. It must also be noted that the value of such materials depends on their surfaces, and therefore that if these are obscured by dust, corrosion, moisture or frost, the amount of heat radiated from them is likely to increase materially. Possibly corrosion may be prevented, either wholly or partly, by the use of some protective covering, but in that case the emissivity may be seriously increased. Dust may be avoided by sealing the insulation against air infiltration, but this procedure is sometimes expensive.

There are three ways of applying these materials: The first is to stretch them across the centre of an air space, thus forming a number of parallel surfaces. This is probably the most effective method from the standpoint of heat insulation. Metal foil is sometimes crumpled and used to fill an air space loosely. This is less effective than the former method, but is cheaper and appears to give good results. The third method is to use it to coat one or both sides of a rigid board, in which case the advantages of both materials are combined. These metallic sheets, in themselves, are not effective barriers to convected heat, and therefore it may be necessary to combine them with some other material that will provide such a barrier.

Such materials, used in thin sheets or as foil, cannot be said to have any conductivity or conductance, as their effect is obtained by combining them, either with the insulating value of one or more air cells, or, alternatively, by using them to coat some other material. Comparisons, therefore, must be made on the basis of the conductance of the structures and not on the conductances of the various materials concerned.

*See "Heat Ray Traps," by Shadgen, "The Iron Age," Feb. 14, 1935. Other figures are given by McAdams in "Heat Transmission" (McGraw Hill).

### Air Spaces

Air is a most efficient insulator provided it can be kept still, and in most of the materials considered above, the air is prevented from moving by entangling it between fibres or enclosing it in small cells. A large air cell can also be used for insulating purposes. As the thickness of the large air cell increases, the amount of heat transmitted through it by conduction decreases on account of the longer path that the heat has to traverse; but that lost by convection is liable to increase because of the lower frictional resistance offered to the circulation of the air. Experiments made by Rowley and Algren at the University of Minnesota, show that the resistance of an air cell 9 inches square increased with its thickness up to about .8 of an inch, but beyond that no further improvement took place. The best results, therefore, are obtained by using air cells that are about three-quarters of an inch thick. In some cases, where metallic insulators are used, it may be advisable to pack more of these materials into a given space, so that the overall dimensions may be reduced.* It is probable that the heat transmitted through an air cell varies with its height as well as its thickness, and therefore it is advisable to keep the height as small as is economically possible. The heat transmission also increases, as might be expected, with the temperature difference across the cell.

In many instances, considerable advantage is obtained by using powdered or granulated materials for the purpose of filling up air spaces and preventing, as far as possible, the formation of convection currents. If the height of the air cell is large, very considerable densities may result, owing to the weight of the material itself, and occasionally vibration causes the material to settle or pack some time after it has been installed, so that the top of the air space is left empty. However, properly applied, such devices can be quite effective.

It has been suggested that a vacuum, such as is employed in thermos flasks, might be useful for insulating purposes, but experiments made many years ago, indicate that, unless extremely high vacua are employed, this method is not effective. If air spaces are used they should be sealed, as far as possible, to prevent air infiltration as, otherwise, moisture is very liable to be deposited in them, causing considerable trouble and loss of insulating value.

### Conclusions

The foregoing arguments may be summarized briefly as follows:—

(A) *Factors that should be Standardized*
- (1) Design of apparatus and testing methods.
- (2) Size of apparatus in relation to the thickness of material tested.
- (3) Mean temperature of material tested.
- (4) Temperature difference to be maintained between hot and cold surfaces.
- (5) Pressure to be applied to specimen when testing (in some cases).

(B) *Factors that should be Listed in the Tables giving the Thermal Conductivities of Insulating Materials.*
- (1) The conditions under which the tests were made, e.g., air to air, or surface to surface. In the former case the velocity, temperature and relative humidity of the air may be important.
- (2) Moisture content of the material when tested.

*Usually about three sheets per inch of thickness are employed.

(3) Density of the material when tested.
(4) Thickness of specimen tested.

(C) *Factors that Affect the Method of Installing Insulating Materials.*
(1) Permeability—particularly when air conditioning is employed.
(2) Possibility of the absorption of moisture or its deposition on a reflecting surface.
(3) Size and shape of air spaces used.
(4) Effect on total heat loss, of other materials used in the structure which have high conductivities.
(5) (Possibly) structural strength or other physical properties of the insulating material, e.g. liability to disintegrate.

# Recent Advances in Electric Welding

*H. Thomasson,*
*Welding Engineer, Canadian Westinghouse Company Limited, Hamilton, Ont.*

**Paper presented before the Montreal Branch of The Engineering Institute of Canada, December 3rd, 1936.**

**SUMMARY.—Discusses the two main types of electric welding, noting first the trend of practice in arc-welding and the adoption of special electrodes for use with alloy steels and sheet steel. Notes follow on the development of various types of resistance welding, particularly as regards electronic control of timing in spot-welding.**

Electric welding comprises two major processes, the arc and the resistance methods; these have only two points in common, first, that metals are fused together, and second, that electricity is the heating agent.

Of the two, arc welding is the better known, and has received more attention than has its less spectacular but equally effective rival. If any proof of the increasing use of arc welding is desired, it is found in the fact that last year some 40,000 tons of electrodes were used, indicating a production of between two and three million tons of weldings.

An outstanding recent development has been the almost complete change to covered electrodes from the older bare rods, and the standardizing of the newer rods into three distinct classes, each with its clearly defined field.

The first class, both in quality of resultant deposit and in time of origin, is the downhand type of electrode, so called because it can only be effectively used in a downhand position placing the metal into a butt weld groove or into a troughed position fillet.

This class of rod produces the highest quality metal, particularly in terms of ductility and density. Generally speaking it is the only type that will pass the tests specified for welds used in the production of high grade pressure vessels or power boilers.

The second type has been developed for the production of high grade, good appearing fillet-welds without the necessity of bringing the weld into a downhand troughed position. These produce extremely good looking fillets; the metal has a somewhat higher ultimate tensile strength and yield point than that from the downhand rods but is inferior in ductility and density averaging 20 to 25 per cent elongation in 2 inches with 25 to 30 per cent reduction in area on all-weld-metal specimens combined with a yield point of 50,000 to 60,000 pounds per square inch and an ultimate strength of 65,000 to 75,000 pounds per square inch.

In the third class of electrodes are the well named all-position rods which differ from the fillet-weld types in that they may be used in any position, including vertical and overhead. The physical properties of the resultant metal are similar to those for fillet-weld rods. This type was the second to be developed and at that time was of great importance in that it covered the field which it now divides with the fillet-weld rods.

Table I
Physical Properties of Arc Weld Metal Deposited from

| | Downhand Rods | Fillet Weld Rods | All Position Rods |
|---|---|---|---|
| Ultimate tensile.......... | 64,890 | 75,705 | 64,630 |
| Yield point.............. | 48,925 | 61,025 | 48,410 |
| Elongation in 2 inches.... | 33.0 per cent | 24.0 per cent | 30.0 per cent |
| Reduction in area........ | 65.8 per cent | 46.4 per cent | 56.0 per cent |

### The Trend of Arc Welding Design

A great many developments go from one extreme to the other and then follow a middle course. The early attempts at designs for arc welding tried to duplicate the appearance of the article as previously built by other methods. Later, designers began to forget casting appearance and design for function. Thus an era was entered upon when weldings were distinguished by square corners and crude box like structures even though utility was, for the most part, well provided for. This phase is rapidly passing, as a result of careful design studies having the triple objective of greater utility, better appearance and lower costs. The most successful means has been a combination of bending and butt welding in preference to corner welds, reducing the amount of welding, which as far as possible is of the superior butt weld form.

Rectangular transformer and circuit breaker tanks are a simple but good illustration, using two shallow "U" sections with butt welding in the sides permitting uniform radii at all corners in preference to the former bend two and weld two corner system.

In the manufacture of small machine parts, it was more difficult for arc welding to replace castings, due to low weights, and the ease of casting with low pattern cost. In the case illustrated, that of bedplates for small motors (see Fig. 1), the advantages of all steel construction combined with good appearance and moderate costs have been attained by a combination of bending and welding. The main member has four slots and four foundation bolt holes punched in it, it is bent into the form of a flanged "U" and the two end straps are welded on to complete the job. An adjustment device and bolt-holding strap may be added if desired.

The same combination is successfully used in bedplates for large machines by combining "U" shaped main members, half mitered at the corners, with a hot formed corner piece, into a nice appearing unit of moderate cost using nothing but stock plate, so that there is no need either to stock or wait for suitable structural shapes. Reinforcing ribs, foundation bolt plates and machine pads may be placed wherever desired.

Another example would be the end treatment of large I or H beams by cutting the web and flanges and welding on a formed plate to continue the upper flange around the end to meet the lower flange.

End bells for a large pump motor form another example of the recent trend (see Fig. 2). In this case each half section was formed cold in four sections under a hydraulic press, butt welded together and the welds ground off to match the customer's previously installed equipment.

The mere mention of grinding welds is likely to provoke discussion. As a general rule, the author is strongly opposed to grinding welds on the ground that there is a danger of hiding inferior work, but in the manufacture of electrical equipment there are cases where it should be done to create

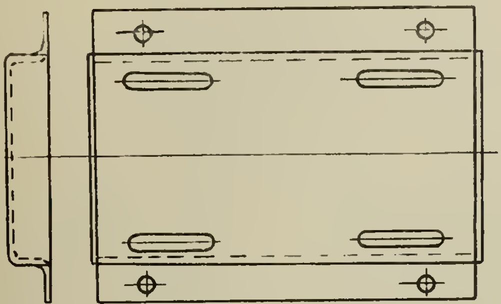

**Fig. 1—Bending and Welding Combined to Produce Substantial Bedplate.**

harmony with the highly finished equipment frequently found in power houses.

A striking recent advance in the field of arc welding has been the development of the so-called high-strength low-alloy steels. These have less than 5 per cent of alloying elements, hence the term "low alloys," but this results in remarkable improvement in their physical properties with tensile strengths of 70,000 to 100,000 pounds per square inch with yield points of 50,000 to 70,000 pounds per square inch compared to the 30,000 to 35,000 yield and 45,000 to 55,000 per square inch ultimates of the ordinary low carbon welding quality steels. These newer steels all possess satisfactory bending and impact strengths and one in particular, a three per cent nickel steel, is useful for low temperature service. In every case these steels were developed with an eye to their weldability, and having a low carbon content, full strength sound welds can readily be made. The effect on welding design is only just beginning to be felt, but results in lighter structures. The material-handling equipment firms are using these steels to advantage; one company in re-designing a drag-line bucket removed 1,000 pounds of dead weight and thus increased pay loads. Another took 1,635 pounds off a coal truck body that previously weighed 5,000 pounds. Therefore the designer can well afford to keep in touch with developments in welding.

The use of stainless steels of the austenitic 18-8 class (18 per cent chromium, 8 per cent nickel) has been greatly facilitated by the ease with which they may be arc welded. The only real problem is to ensure against carbide precipitation adjacent to the welds with the accompanying lessened corrosion resistance. Specifying a carbon content of under .08 will prevent this trouble. In the actual welding of the material to itself a covered electrode of slightly higher alloy content, of about 20 and 9 is used, with 20 per cent less current than for a mild steel rod of the same size. The metal is extremely fluid while passing through the arc, thus requiring somewhat better assembly fits than for mild steel work.

Having an austenitic structure, 18–8 is necessarily non-magnetic, and as such is used in the electrical industry as "no-mag" inserts to break up magnetic circuits. This involves welding it to mild steel. If an 18–8 type rod is used, dilution from the mild steel side produces a brittle martensitic structure and to use a mild steel electrode produces the same results by alloy pick up from the stainless steel. Either procedure causes cracked welds from contractional stresses within the brittle weld metal.

These difficulties are overcome by the use of an electrode having such an excess of alloys that dilution from the mild steel side does not bring the weld below the 18–8 analysis. It has been found that a 25-12 (25 per cent chromium, 8 per cent nickel) electrode will do this and produce excellent results with no other changes in technique from standard stainless welding practice.

### Medium and High Carbon Steels

Until recently medium and high carbon steels presented a difficult problem to the welder, but where the weld can be made from a non-hardenable deposited metal excellent results have been obtained by using a new type of heavily covered rod that deposits metal having a carbon content of .08, nickel .85 and molybdenum .50, and taking care not to unduly heat the base metal. This method has even been used to weld high speed steel to low carbon shanks and to weld together broken broaches and reamers.

### Weld Testing

Many tests have been devised for testing steel in its various forms, including tensile, compression, bending, impact, hardness and fatigue resistance tests. To these must be added those of chemical analysis, microscopic examination, macro etching, and determinations of specific gravity.

All of these methods are used in developing welding processes and applications, but before evaluating these testing methods it is well to analyze some of the reasons for testing welds.

**Fig. 2—End Bells for an Electric Motor.**

(*a*) Test of joint design.
(*b*) Test to determine the quality of the deposited metal resulting from the use of a particular electrode.
(*c*) Test for the efficiency of a given operating technique, i.e., amperage, voltage, etc.
(*d*) Test to ensure that the operator can and is producing sound welds under the given conditions.

The first three of these tests should be completed and definitely specified before any welded articles are produced.

though they are always a subject for study and improvement.

Joint design has been carefully studied and whenever standard types are used there is little need for tests on this account. Where a special design is required the tests should be carefully made, particularly if the joint is subject to shock or fatigue.

In testing for the quality of metal deposited by a given electrode the service requirements will practically specify the tests to be made and the same is true of tests for technique.

Fig. 3—Fillet Weld Testing Fixture with Weld in position for Breaking.

Testing to determine the quality of the work produced by an operator is often handled in a haphazard manner or is not done at all. This attitude is largely the result of too much reliance on one test, that for tensile strength.

In many cases tensile tests have been made on two pieces of plate welded together and pulled, and the usual results were failures of the parent metal at some distance from the joint. This simply indicated that the parent metal had a lower yield point than the weld metal, hence yield started at some point in the parent stock and continued to ultimate failure at that point, though it was quite true that the joint did withstand the quoted strain.

This stressing of tensile values was unquestionably developed in the old bare rod days when that was the only quality worth speaking about and nobody wanted to talk about impact values or ductility.

The test that should be made of an operator's work is one that will reveal the degree of fusion and the presence or absence of slag inclusions and gas pockets. Fortunately, such tests are easily made. In butt welding, it is the nick break in which a section of a joint, one to three inches wide, is nicked with a saw or gas torch at the ends of the weld and then struck a sharp blow with a steam hammer while resting on vee blocks, so that it is broken through the weld. The break is therefore through any defects and lack of fusion, slag or gas pockets are instantly visible.

A similar test for fillet welds consists in two pieces of material placed together in the form of a tee with a weld made on one side of the vertical member only. The weld is then broken by sledge hammer blows.

Figure 3 illustrates a fillet weld testing fixture with a weld in position for breaking. In training welders every fillet weld is broken by the student welder to ensure that he obtains a sound knowledge of the internal conditions within his welds.

Any welder that can pass either of these two simple tests can produce first-class work since he has done all that a welder can do, in that he has deposited metal of the required soundness in the required manner and place.

First class fillet welds are shown in Fig. 4, clean uniform structures with a complete absence of slag and gas inclusions combined with full fusion should be noted.

Figure 5 illustrates the product of untrained operators and the failure to get root fusion or to fuse the upper to the lower layers, and the large number of slag holes and gas pockets should be observed.

The welder has little, if any, control over such factors as ductility, impact or tensile strength except as they are affected by the soundness or otherwise of the metal deposited. If his weld is free from gas pockets, slag inclusions and has full fusion he has done all that he can. The other qualities are up to the management and are functions of electrodes, equipment, procedure and design.

Tests made to evaluate the quality of an electrode or technique are more elaborate and should always begin with one for soundness of the deposited metal and the degree of fusion since failure to pass this test condemns the rod or procedure immediately. The test earlier outlined for testing an operator is a good one to begin with, but always have a first-class operator make such special tests. Should this first test be passed and further information be desired a bend test will be in order, and may consist simply of a bead welded along a bar and bent. An electrode capable of giving 30 to 35 per cent elongation of the outer fibres will bend through 180 degrees on the simple bend test with a radius of bend equal to half the thickness. This test will not give the percentage elongation. If this is desired it may be obtained from all-weld-metal specimens or from a butt weld in which the surfaces are machined, after welding, lightly etched to reveal the edges of the weld, the width of the weld measured and recorded, the specimen bent through the weld, again measured and the percentage elongation calculated.

Whenever an electrode meets the tests for soundness of deposit, shows good bend test values, combined with

Fig. 4—Samples of Tested First Class Welds.

satisfactory appearance and operating characteristics it will be satisfactory for general mild steel applications. If tensile values are designed, tests on an all-weld-metal specimen is the best method.

The simple test in which two pieces of bar or plate are joined together and then tested has little value since the parent stock usually breaks well away from the weld and gives no information at all except the ultimate strength of the bar, or if the weld does break it is almost always due to poor welding which a simpler structure test would reveal. In any case no information is obtained on yield points, reductions in area or percentage elongation, all of which are necessary to determine the quality of a metal.

The all-weld-metal test alone will give this data. Such tests are made by machining the specimen from a butt or fillet weld purposely made large enough to permit of the entire specimen being obtained from weld metal only.

**Fig. 5—Welds Produced by Untrained Operators.**

All physical properties listed in this article were obtained in this manner.

### Arc Welding Light Sheet Steel

An outstanding recent development has been the use of arc welding in the fabrication of parts made from light sheet steel resulting in higher quality and at greater speed than was heretofore thought possible. Most of the applications so far have been on 18 and 20 gauge material with successful welds obtained on 28 gauge.

The major applications so far have been on food compartments for electric refrigerators, range ovens and similar parts, most of which are subsequently vitreous-enamelled. This greatly complicates the welding problem since the presence of any voids or foreign matter in the welds prevents successful enamelling. Nevertheless the experience on white enamelled food compartments is that less than one per cent have any defect over the welds even though the welding is done at speeds of from 22 to 23 inches per minute.

These remarkable results are obtained by the use of a super-imposed high frequency current in a welder using 25- or 60-cycle current stabilized by the super-imposition of a 100,000-cycle carrier or stabilizing current whose only function is to maintain the ionized condition of the arc gap during the period of current reversal. Some means of retaining the ionization is necessary, since it only exists for about twenty-millionths of a second after the currents have dropped below the minimum required to maintain it. At the low current values required to weld these light sheets, the reversal periods of low current flow exceed the twenty micro-second maintenance period and the arc would not be continuous, without the introduction of peak currents every five micro-seconds or four peaks in the period normally required for the loss of ionization. This results in an extremely stable arc despite the low currents of 50 to 80 amperes.

A.c. is used in preference to d.c. to avoid the troubles associated with arc blow due to magnetic effects which are always present with d.c. and never with a.c.

The diagrams in Fig. 6 show graphically how this high frequency stabilization does its work. The upper diagram represents an a.c. sine wave for the low currents desired, showing the large proportion of time during which the current value is too low for arc maintenance. The central diagram indicates the high frequency used to maintain ionization through this period, while the lower diagrams show why the higher currents are stable without high frequency though the lower ones are not.

The light sheet field for arc welding is largely a production proposition in which jigs are used, as for example in the food compartments previously referred to. The inside block has replaceable corners by which the shape of the deposited metal is controlled so that any desired inside contour may be obtained. (See Fig. 7.)

### Resistance Welding

In turning to the general subject of resistance welding, particularly the spot- and seam-welding divisions, it may be noted that this important field has had too little attention as compared with the more spectacular arc-welding process.

The year 1936 marks the fiftieth anniversary of Elihu Thomson's discovery of resistance welding, a process without which modern low cost automobiles, refrigerators, and household appliances would scarcely be possible. Some idea of its importance is indicated by the fact that there are 3,415 welds in a popular four-door sedan, of which 3,154 are spot welds and 44 are other forms of resistance welding. A 6½-cubic foot refrigerator uses 1,509 welds, of which 1,338 are spot welds and 32 of other resistance types. It is interesting to note at the same time that since 1932 each year has seen a greater tonnage of steel ingots go into sheets than into any other form of steel and that in 1935 sheets accounted for over 42 per cent of the steel produced in the United States.

In resistance welding the parts to be welded are heated by passing a heavy single phase low voltage current through the material and pressing the parts together. The electrical resistance at the point where the two or more pieces are in contact results in rapid heating, the pressure forcing

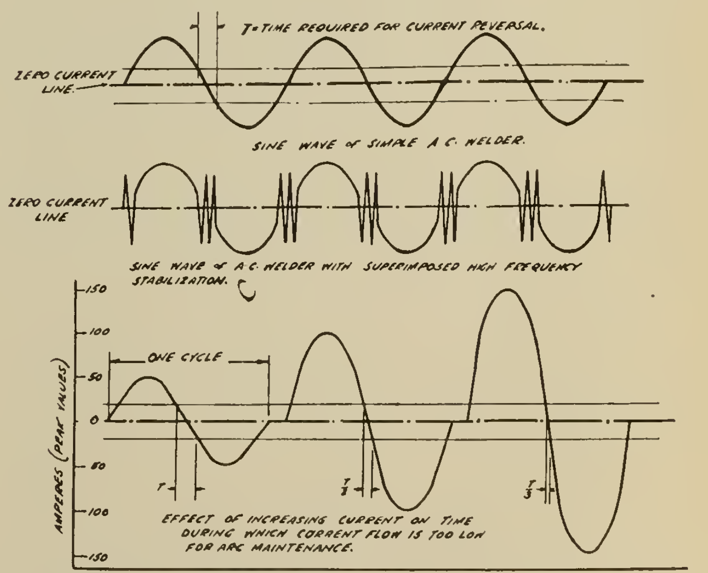

**Fig. 6—Sine Waves for Simple and High Frequency Types of a.c. Welders.**

them together when fusion temperature is reached. The weld may thus be considered as plastic and is distinct from the so-called fusion processes of oxy-acetylene and arc welding which depend for union on the flowing together of liquid metal without the assistance of external pressure.

Alternating current only is used due to the ease with which commercial currents may be transformed into the low voltage-high amperage required; two to eight volts and 300,000 to 800,000 amperes per square inch of contact surface are generally used. Current strength is controlled by means of taps in the primary circuit of the welding transformer. Secondary windings are usually single turn copper forgings or castings, parallel connected by leaf type conductors to the welding arms. The control apparatus is always in the primary circuit and its design requires special attention.

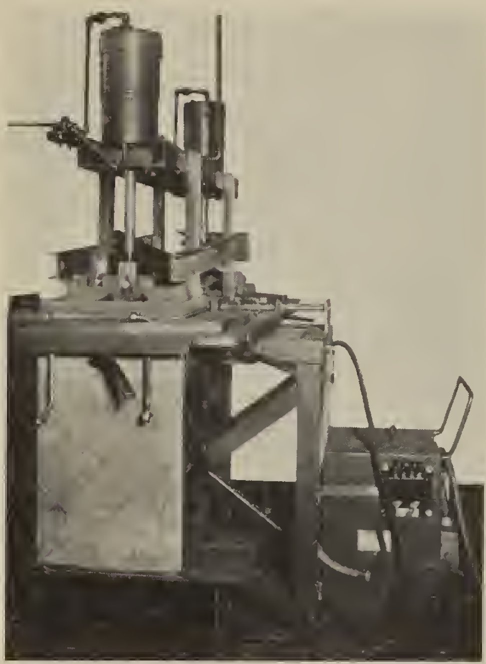

**Fig. 7—Welding Fixture and Equipment for Arc Welding Food Compartments. Welding Speeds 22 to 23 inches per minute.**

Resistance welding is roughly divided into five branches, spot welding, projection welding, seam welding, butt and flash welding. In the first three overlapping flat stock is welded, while in the two latter bar stock is welded end to end, or sheet stock edge to edge.

Spot welding is the best known and most used type and consists of welding a spot through two or more pieces of lapped material, the size and shape of the spot being controlled by the dimensions of the welding tip faces. Its function in joining metals is similar to that of a rivet which it replaces.

The process may be used with any form of ferrous metal sheet or bar and is almost equally successful in the non-ferrous field with mild steel, stainless steel, galvanized iron, aluminum, brass, and the newer copper-silicon manganese alloys welded both to themselves and in various combinations.

Three types of machines are in common use, namely, manual, in which the welding points are brought into contact by man power aided by foot or hand levers; mechanical, acting after the manner of a punch press but with a cam instead of a crank in order to hold the points together for an appreciable period; and pneumatic, in which an air cylinder provides for point motion and pressure.

The important factors in the production of uniform high grade spot welds are current strength, time of current application, pressure of welding points, and the size of the spot to be welded, while the basic principle is that the weld shall be made with as little thermal disturbance of the metal as possible. This involves the shortening of the current period to a minimum, which can only be done by using very high currents, which in turn require extremely accurate time control. It is in the control of welding times that important advances have recently been made, making possible the production of millions of welds without a half cycle variation and resulting in such uniformity and quality as was undreamt of a short time ago.

Before considering the important feature of time control, however, attention should be drawn to other related factors, including the size of the welding points. It is obvious that tip area should be held constant, since any increase or decrease from the predetermined size results in a corresponding but reverse change in unit pressure and current concentration. In the author's work $\frac{9}{32}$ diameter is found best and tips under $\frac{1}{4}$-inch or over $\frac{5}{16}$-inch diameter are not used except on jobs where there is a difference in thickness between the two pieces to be welded. In such cases the tip size used on the lighter stock is in inverse ratio to stock thickness. For example, in welding $\frac{3}{16}$-inch stock to 20 gauge, this is done by a one-inch tip against the light sheet and a $\frac{1}{4}$-inch against the $\frac{3}{16}$-inch plate.

Another exception to the rule of similar tip sizes is when it is undesirable to have indications of a weld in the outside face of one or other of the welded sheets. In this case a copper bar $\frac{1}{4}$ inch by 2 inches of any desired length is placed between the tip and the face which it is not wished to mark.

Uniformity of pressure of the welding points against the material is also important, and modern machines are built with it in mind. Pressures used must be high enough to hold the parts firmly together and low enough to prevent excessive reduction in thickness. Lower pressures will also require less current for a given job than will higher pressures but the higher range gives greater uniformity by reducing the variation in joint resistance due to irregular surface conditions.

It has been found on 20-gauge cold rolled cleaned steel sheets that 200 to 400 pounds total pressure on a $\frac{9}{32}$-inch diameter tip is a good range with an optimum condition at 325 pounds. Higher pressures are required for the high strength non-ferrous alloys and somewhat lower on the softer materials.

The current should always be the maximum that the job will carry consistent with effective control, i.e. if the current can be controlled to a fraction of a cycle, then one cycle welds are practical provided capacity is available to do it in that time.

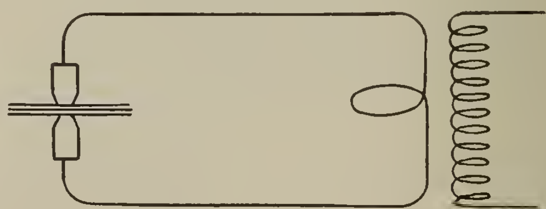

**Fig. 8—Resistance Welding Circuits and Currents.**

This in turn brings up the question of machine sizes. Probably 90 per cent of all machines in use today are too small for the work they are asked to do. This compels the use of excessive times with the resultant defects due to thermal disturbance, large reductions in total joint thickness, accompanied by poor appearance. Another factor worthy of consideration is the length of the welding arms.

It is customary for buyers with an eye on future work to feel that they should get a unit with plenty of throat depth to take care of whatever may come along. This attitude is permissible if a decision on the capacity of the outfit is made with the knowledge that for every 6 inches added to the arm length 25 per cent should be added to the rating. Excessive as this may seem it is in entire accord with electrical laws governing resistance welding conditions. Experience supports this. For example, in one case a particular job on a 60-kv.a. machine was done with 12-inch arms that could not be done on a 100-kv.a. unit of the same make and type with 30-inch arms. A large amount of induction is created by these high amperage low voltage currents. Thus when trying to measure the secondary currents in a large spot welder, it was found that an ammeter 20 feet from the machine and out of circuit registered appreciable currents as a result of the inductive forces released.

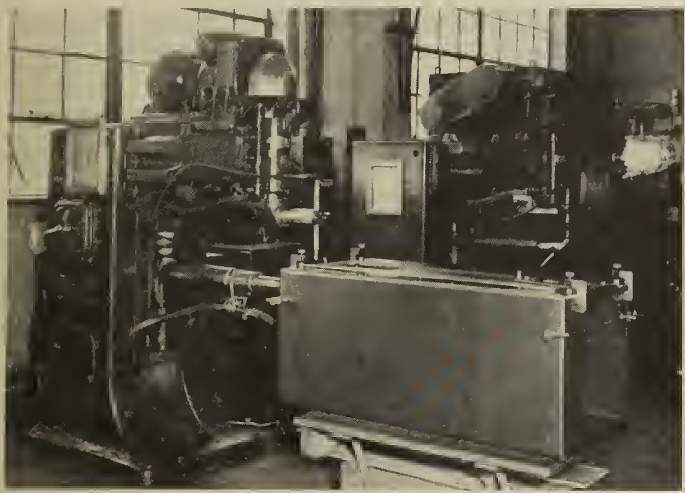

**Fig. 9—Modern Spot Welders used in the Production of All-Steel Refrigerator Cabinets.**

Another simple proof is to hold a steel object close to the arms of a working machine and feel the pull of the inductance, while a noticeable heat is induced in a file held near the arms of a rapid spotting machine for a few moments.

As regards time control, a number of methods are found to be in use. The first method, now entirely obsolete, was by means of a magnetic contactor operated by push button control, in which the time of current flow was determined by the length of time the operator held in the push button. The time of current application was a matter of the operators' judgment on every spot. This resulted in great time-variation, measurements with a cycle counter on an expert workman showing an extreme short time of 3 cycles and a long of 24 on the same job within one hour. His ordinary variation was from 8 to 18 cycles or from one-eighth to one-third of a second. This is remarkably good operating judgment but involved 225 per cent ordinary variation and an extreme difference of 800 per cent in the amount of current passing through the work.

Table II

Time Variations Obtained by Different Methods of Control

| Method | Variations in Cycles |
|---|---|
| Manual | ±10 |
| Mechanical | ± 2 |
| Electronic contactor | ± 1 |
| Ignitron | ± 0 |

In mechanically operated machines, time control is commonly obtained by means of a cam-operated switch to actuate the contactor. The method results in a variation of approximately four cycles from the setting desired, so that times as high as ten cycles may be 20 per cent over or under any spot. Still closer control on any type of machine may be obtained by the use of electronic contactor timers to control the magnetic contactor. With this system of radio-type tube control the closing of the initiating switch by a push button or cam starts a complete cycle of timer operation which closes the main switch and holds it in for the predetermined time, at the close of which it is opened and the entire timing mechanism is in position for the next weld.

This type of control will reduce variation to a maximum of two cycles, one under and over the desired value, and will operate down to about six cycles of 60-cycle current or one tenth second. Thus it will do reasonably good work on low carbon steels but is scarcely practical for work on aluminum, stainless steels, very thin materials requiring short accurate timings, or any high resistance or short plastic range metal.

The use of a magnetic contactor to interrupt the primary current, with inevitable arcing and burning of the contact faces, results in high maintenance costs, loss of production, and—what is of greater importance—a variation in the amount of current passed due to the surface resistance of dirty contact faces, and they are dirty after two or three hundred operations that on a high speed machine are made in something under five minutes.

For more uniform work of higher quality than is possible with a magnetic contactor, a timer is required in which the primary current for the welding transformer passes through and is controlled by electronic tubes. One such timer is known as "Ignitron" control which brings time as a factor in resistance welding under precise control, using no moving current carrying parts. Power current is conducted and interrupted by two Ignitron tubes which function as controlled current rectifiers. The tubes are connected in parallel reverse relation, the combination serving to pass alternating current, and are connected directly between the power source and the welding machine. They are of the mercury pool cathode type. The control feature consists of an Ignitron electrode dipping into the mercury pool. A small ignition current flowing into the pool through this electrode "fires" or causes ionization of the tube for each desired loop of welding current. Once a half cycle of power is initiated in either of the Ignitron tubes it will continue to the end of the loop, at which time the arc is automatically extinguished. Contactors or relays are not depended on, either to interrupt the power current or to control the duration of the weld.

Timing is controlled by electronic circuits whose purpose is to measure out a predetermined number of cycles of welding current during closure of a control switch in the electronic circuit. This switch may be either manual or machine operated. In spot welding, one spot is obtained for each closure of the switch, while in seam welding a succession of spots is obtained as long as the controlling switch is closed. The timing and ignition circuits co-acting with the Ignitron tubes may be likened somewhat to the ignition system of the average automobile. The Ignitron tubes correspond to the cylinders, the ignition electrodes to the spark plugs, and the grid controlled tubes in the Ignitron circuit to the spark coil, while the electronic timing circuit corresponds to the distributor.

The outstanding advantages of this type of timer are extreme precision (even on one cycle welding), low maintenance and adaptability to modern production schedules.

### Testing Spot Welds

It is good policy to provide every spot welder with test material which may be strips, half an inch or more in width and three to four inches long, of the material being used. It can frequently be obtained from trimming die scrap. Regular tests should be made at intervals of not more than fifteen minutes, plus every time the tips are dressed or other adjustments are made. These tests only involve making of two or three spots on a pair of pieces, slipping one end into a vise or holding fixture and tearing them apart with a slotted tee handled bar. A good weld will invariably tear a hole in the parent stock, but some

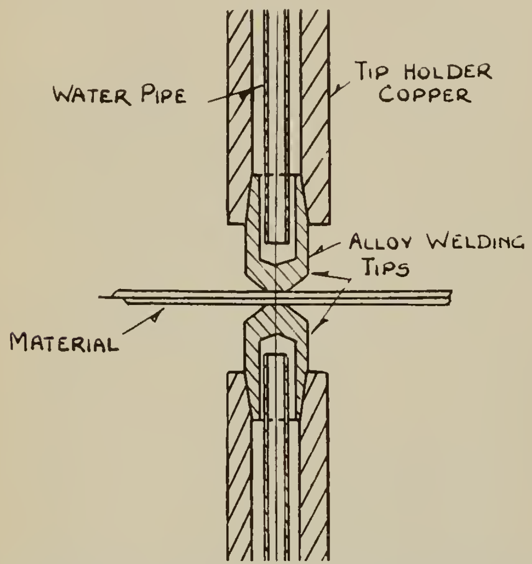

**Fig. 10—Cross-Section of Spot Welder Tips, showing Method of Cooling.**

care is required in interpreting this result since an overwelded spot can be easily torn out, though overwelding tells its own story. Thus if the test spots have good appearance, are not excessively dented and break the parent stock rather than pull apart the weld can be safely used in any well designed product. In making test welds the loaded fixture should be between the welding arms to insure that induction losses during the tests will correspond with those in service.

Machines should be kept clean, especially all contacting surfaces through which current passes, since extremely thin films of grease or oxide will seriously restrict the flow of current. A free flow of cooling water is essential and this must get right into the welding points. Figure 10 illustrates a cross section of a pair of spot welder tips showing the method of cooling. The cooling water pipe should end inside the welding tip which may be of copper-cadmium, copper-chromium or copper-tungsten alloys. Stock should always be clean, and though it is possible to weld low carbon steels without removing mill scale, this introduces serious irregularities and such welds should never be used to carry an appreciable load. Non-ferrous metals, excepting aluminum, should be cleaned within three to four hours of welding to ensure uniform results. Aluminum is the exception that does better with the slight film of oxide on it that it always picks up when exposed. Oil or grease is fatal to good welds with any material.

Projection welding is simply a method of multiple spot welding in which one piece of the material is embossed into a raised point wherever a weld is desired. Dies are used in very powerful machines to weld a number of these points simultaneously.

### Seam Welding

Seam welding consists of spot welding with the welds so close that each one overlaps its neighbour. For gas- or oil-tight joints, ten to fourteen spots are made per inch of seam. Circular revolving discs are used instead of electrode points and Ignitron or other synchronized control is needed since the welding currents must be applied and cut off for each spot with welding speeds as high as twenty spots per second, resulting in up to 10 feet of seam per minute. Attempts have been made to seamweld with the current uninterrupted, but a building up of the heat results either in failure to weld the first few inches or in a burning of the joint if the applied currents are heavy enough to weld from the start. The interrupted method has eliminated this difficulty, producing first class uniform welds along the entire seam.

The synchronous timer which delivers timing impulses to the Ignitron control tubes consists of a synchronous motor, speed reducer, aluminum timing disc and magnetic pick up. The disc has a series of holes drilled around the edge, each hole corresponding to one-half cycle of the power supply. For each half cycle of current conduction desired, a steel pin is inserted in the disc. Thus to put in six pins adjacent to each other would be to pass three cycles of current, to leave out the next six would interrupt three cycles and to continue with six in and six out would be to use a three cycle on and three cycle off welding time. Similarly to put in two pins and leave five out around the disc would be to set it for one cycle on with two and one-half cycles off. Any combination of on and off times is instantly available.

Spot welding may be done on such a seam welder by increasing the off period as three on and twenty-seven off, producing two spots per second, or two on and fifty-eight off for one spot per second or any other desired combination that will work out in the 120 holes in the disc. The distance such spots are apart is controlled by the speed of the disc and will be uniform.

By means of the spot or seam forms of resistance welding all of the following metals may be welded to themselves and to every other one in this group, though combinations of copper to others present the most difficult problems,

Ingot iron
Mild steel
Stainless steel (18–8)
Nickel
Nichrome
Monel metal
Nickel silver
Brass
Bronze
Copper-manganese-silicon alloys
Copper

Aluminum is weldable to itself and to one or two other metals despite the problems due to the short plastic range it possesses.

Any of the plated forms of low carbon steel are readily welded though it is difficult to prevent damage to the coating. Cadmium and zinc are picked up by the electrodes, involving frequent redressing of the wheels or tips.

Aluminum-bronze with up to 10 per cent aluminum and the new copper-beryllium alloys have good resistance welding properties.

So many practical welding combinations have now been produced that a nationally known engineer stated recently that he would like to discover a combination of two metals that could not be welded together under any circumstances, and that such a combination would be extremely valuable.

# Some Debatable Points in the Design of Hydraulic Regulating Gates

*W. B. Scoular, A.M.E.I.C.,*
*Assistant Engineer, Laurentide Division, Consolidated Paper Corporation, Grand'Mere, Que.*

Normally the design of a gate is considerably simplified from the fact that the main load from the water pressure is static and definitely known. However, there are three other fairly common loads which are not so easy to make accurate allowance for. They are the loads from water flowing over the top of the gate, water flowing underneath the gate, and ice loads.

### Water Flowing Over the Top

Sluice gate specifications often call for a gate designed for a normal high water level at the top of the gate, and capable of withstanding perhaps four feet overflow for an emergency case. The top girder in a large gate may be five feet in depth and one foot below the top of the skin plate. See Fig. 1. At "*a*" there is probably very little pressure, or possibly even a vacuum due to the water springing clear from the top of the plate, at "*b*" there may be almost five feet due to some impact, and, at "*c*" perhaps two feet. The distribution and the loading will vary with the depth of the overflow, the depth of the girder and the height of the plate above the girder. In the author's opinion a conservative treatment is to figure on one-half of the overflow distributed over the whole area of the top girder and to provide adequate web stiffeners, and supports for the downstream flange.

### Water Flowing Underneath the Gate

In head gates the skin plate is usually placed on the downstream side to simplify the sealing of the top edge of the gate along the lintel. In gates of this type operating under high heads the bottom girder has to be placed fairly close to the bottom of the gate to take the load from the skin plate. These gates are sometimes called on to close

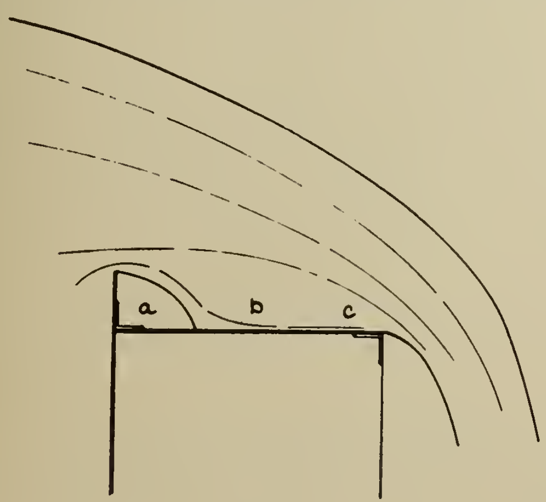

Fig. 1.

openings under free discharge conditions. See Fig. 2. "*A*" shows a flat bottomed gate. As this gate is lowered into the fast moving water, the water springs clear at "*m*." As the gate approaches the sill the water tends to curl up towards "*n*" till a point is reached where it touches the gate at "*n*" and cuts off the air pressure on the bottom of the gate causing a sudden increase in the load on the lowering mechanism.

In order to reduce this vacuum effect it is customary to put a taper bottom on the gate as at "*B*." There will still be a vacuum formed at "*m*," but the area affected will be much smaller and the application will be gradual. The longer the taper and the longer the straight lip the better, but both are limited by strength considerations. Even if the vacuum is eliminated entirely there always will be a big loss in upward water pressure.

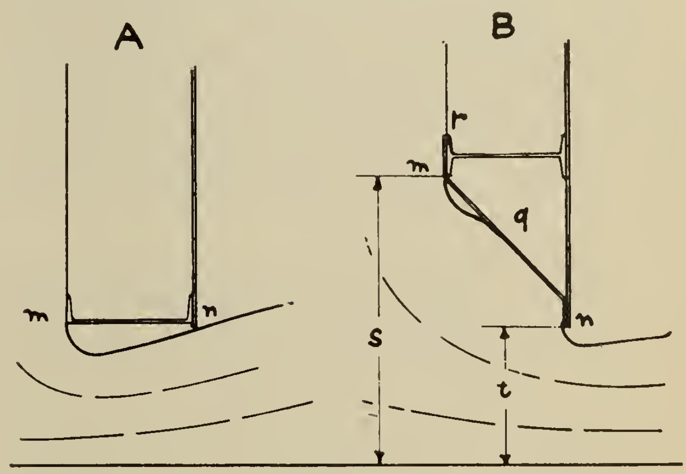

Fig. 2.

Assuming there is no static head left in the water as it leaves the gate at "*n*," then the static head or upward pressure at "*m*" will be the difference in velocity heads at "*n*" and "*m*" and the average pressure on the bottom of the gate will be about one half of this. The velocities at "*n*" and "*m*" will be approximately proportional to the dimensions "*s*" and "*t*." With the gate open a number of feet the difference between "*s*" and "*t*" becomes small giving a small difference in velocity and a small upward pressure. The downward pressure inside the gate at "*q*" is almost that due to the vertical head, being a little less due to the "draw off" from the slight downward velocity at "*r*."

To be safe this downward load on a gate should be figured as the full head at the bottom of the gate by the horizontal area, as while there may be a slight upward balancing pressure, there may also be some vacuum effect. To illustrate the size of this load a 15-foot wide gate with a 24-inch girder under 60-foot head will have a load

$$= 15 \times 60 \times 62.5 = 112{,}000 \text{ pounds or 56 tons.}$$

In lowering a gate this load is partly balanced by the friction of the gate. In raising a head gate in a power house it is good practice to open it a few inches and fill the penstock, then lift it right up in still water. When it is open only a few inches the difference between "*s*" and "*t*" is great so there is considerable upward pressure. But if the gate has to be designed to open up a free discharge this load should be included in figuring the lifting mechanism. This shows the importance in gate design of obtaining full details of operating conditions.

A number of large holes in the bottom plate are helpful, by reducing the area and by causing turbulence and hence increased pressure on the bottom side.

### Ice Loads

Some experimenters have given the possible ice pressure on a gate as 10,000 pounds per linear foot along the water line. As the water line may often vary five feet allowing for this load makes a very heavy top section on the gate. Numerous gates in Canada have been built without any allowance being made and have apparently not sustained any damage through being frozen in all winter. The explanation of this is probably that the gate deflects under the load and allows the ice to expand losing its pressure. Damage from ice during the spring break-up is a different matter. This is caused by large pieces of ice knocking into a partly opened gate before passing through underneath. As these pieces of ice may be very large—for example, 50 feet square by 2 feet thick weighs 150 tons—it is economically impossible to make a gate strong enough to withstand the shock without damage. In the author's experience the ice usually pushes in the skin plate and stiffeners, and the damage done is fairly easily and cheaply repaired with a cutting torch and a welding outfit. If the stiffeners are made stronger there is danger of serious strains in the main girders. The cure seems to be a case of prevention. The gates should not be left partly open with ice in the river. Possibly a balanced gate for quick operation would make the problem easier, as it would permit timing the opening to avoid the larger pieces of ice.

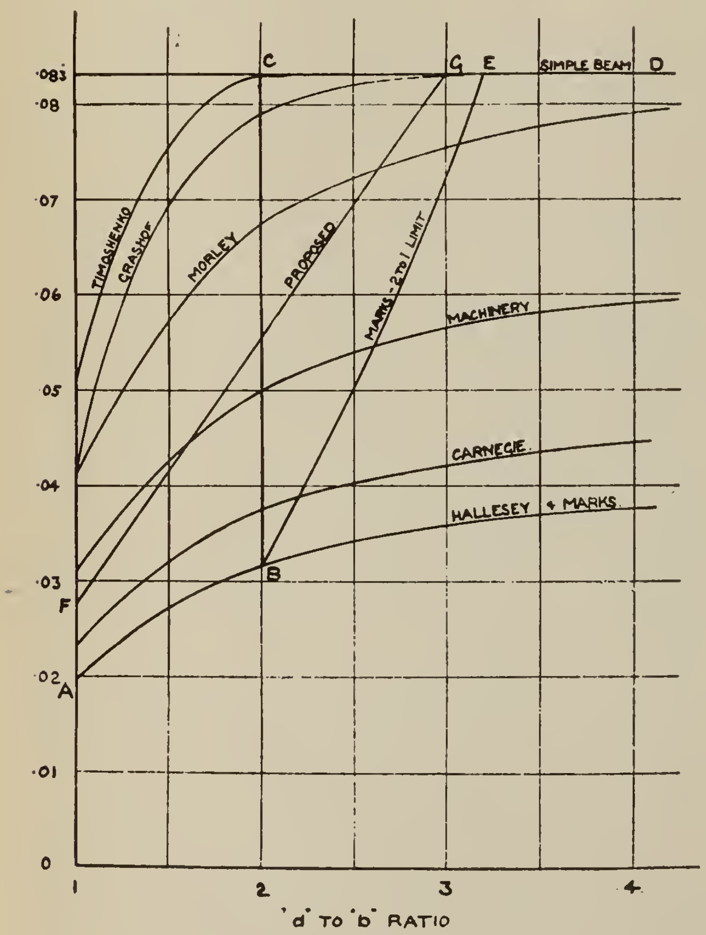

Fig. 3.

### Skin Plates

The usual practice in Canada when building a gate is to have the skin plate stiffeners framed in between the main girders. The skin plate is riveted to the main girders and to the stiffeners. As the main girders are usually very rigid in comparison with the plate, and as the plate is continuous over a number of stiffeners, it seems reasonable to treat the plate at a panel as being supported on four sides with fixed edges. Various authorities give widely different formula for this condition.

Hallesey, and Marks' Handbook both give

$$f = .24 \frac{b^2d^2}{b^2 + d^2} \times \frac{W}{t^2} \text{ or } M = .04 \frac{d^2}{b^2 + d^2} \times b^2w$$

where $f$ = Stress per square inch
$b$ = Breadth of panel
$d$ = Depth of panel
$w$ = Load per square inch
$t$ = Thickness in inches
$M$ = Bending moment

Carnegie's Pocket Companion, Machinery's Handbook and Morley's Strength of Materials, all give the same formula but use 9/32, .375, and .5 for factors instead of .24.

In the Mechanical World Pocket Book the Grashof formula is given as

$$M = \frac{1}{12} \frac{d^4}{b^4 + d^4} b^2w$$

Applied Elasticity by Timoshenko and Lessells gives

$$M = K\, b^2w$$

with a table of values of $K$ for various ratios of $d$ to $b$.

Figure 3 shows the values of $K$ for the various formulae plotted on a basis of $d$ to $b$ ratio. The straight line along the top represents $M = 1/12\, b^2w$ — treating the plate as a simple beam — and it would be expected that all the curves would tend to be tangential to this line when $d/b = \infty$, but this is not the case. The explanation probably is that the stress given in the first formula is the average along the diagonal, though Morley is the only writer to make this point clear. For an infinitely long rectangle the maximum stress along the diagonal will be considerably greater than the average.

It is common practice when using any of the more optimistic formulae to limit their use to a $d$ to $b$ ratio of 2 though none of the authorities quoted give any limit. The curve then becomes $ABCD$. which apart from looking all wrong has another defect. For example with $b = 1$ and $d = 3$.

$$M = .083\, b^2w \text{ or } .083\, w.$$

Now if $b$ is increased to 1.5 the $d$ to $b$ ratio is within the limit

$$\text{and } M = .04 \frac{d^2}{b^2+d^2} \times b^2w = .04 \frac{9}{2.25+9} \times 2.25\, w = .072\, w$$

That is to say that by increasing the spacing of the stiffeners by 50 per cent the stress is actually reduced. This defect can be overcome by putting $c = 1/2\, d$ in place of $b$ in the formula,

$$\text{and} \qquad M = .04 \frac{c^2 \times 4\, c^2}{c^2 + 4\, c^2} w$$

$$= .032\, c^2w$$

and the curve now becomes $ABED$ which looks a little better.

However, it is obvious that the "optimistic" formulae are not rational and the first reaction would be that it is not sound practice to use them. But a great many gates in Canada have been designed to Hallesey's formula with a ratio limit of 2 and a figured stress of 18,000 pounds per square inch and after many years of service have given no indication of overload in the plate. It is sometimes argued that if a skin plate fails when acting as a beam it will deflect enough to take the load as a catenary, but a few figures soon show that before this effect takes place the plate would be stressed far above the elastic limit and would thus show a permanent set.

On looking at the various formulae on the graph, and bearing in mind the satisfactory performance of the most optimistic one in actual service, the reasonable conclusion seems to be to devise some simple formula which will give a curve lying between the extremes.

The straight line *FG* is obtained by using

$$M = 1/36\ bdw$$

or

$$f = \frac{bdw}{6t^2}$$

up to the ratio $d$ to $b = 3$.

To be rational it should be a curve but to obtain this would detract considerably from the simplicity of the formula and would also seem to claim greater accuracy for it than it possesses.

### Side Guide Rollers

The proper function of a side guide roller is to centre the gate between the side guides before it has to take the water pressure. If the gate rollers are not dead in line with the side guides the gate will tend to roll to one side causing it to bear hard against the side guide roller concerned. If the gate is almost closed when this happens the roller will be called on to skid the whole gate under the full water pressure. In a large gate this pressure may be as high as 500 tons and with a coefficient of sliding friction of .1 this means a load of 50 tons on the roller.

To assist the lining up in the field side guide rollers are usually made adjustable. This adjustment often consists of a screw behind the roller bracket. The author has seen many gates with this screw or bracket bent up and the roller pushed in. The probable explanation is that each time the gate goes down the roller is pushed in perhaps only a few thousandths, but as the load is so great something has to yield and the result is a permanent set.

The roller and supports should be made strong enough to take the load, or probably it would be better to use a simple curved guide plate of spring steel which would centre the gate before lowering, and which would always spring back to the same position even if it were deflected a little each time the gate went down.

The views expressed in this paper are the result of the author's experience while employed on gate design by Glenfield and Kennedy Ltd., hydraulic engineers, Kilmarnock, Scotland, for two years and with the Dominion Bridge Company Ltd., for the last seven. Naturally it is through the author's association with these two firms that he has any ideas about gates at all, and he is deeply indebted to them for the experience gained while in their employment. However, it should be understood that the views expressed are not necessarily those held by either of the two firms mentioned.

---

# The Royal Engineers in British Columbia—1858-1863

*His Honour Judge F. W. Howay, LL.D., F.R.S.C.*

**An Address delivered at the Western Professional Meeting of The Engineering Institute of Canada, July 11th, 1934.**

(*Slightly Abridged*)

In the spring of 1858, the world became aware of the existence of gold in the bars of the Fraser River. The mainland of British Columbia was, at that time, merely a vast fur preserve of the Hudson's Bay Company. Its only white inhabitants were less than a score of men scattered amongst the eight or ten widely-separated trading posts of the company. It had no roads, or other civilized means of communication; only the most rudimentary trails, and very few of them. In fact, save for these few forts or trading posts, and save for a little agriculture, that went on around them, it was in a state of nature. There was no government, organized or otherwise. The place was just a "wild, waste land" as Tennyson calls it "where no man comes or hath come, since the making of the world." And it hadn't even a name.

That was the situation when, in April, May, June and July of 1858 a horde of adventurers, seeking the yellow root of all evil, set out from San Francisco. Twenty-five or even thirty thousand people left California, all headed for the Fraser River. They knew nothing of the land or of the climate; all they knew was there was gold, and they were going for it.

Now, at that time, there was a Colony of Vancouver Island, with a Governor, James Douglas, but on the mainland the territory was unorganized. Thus when these people began to arrive from California, the only person who could act at all was Governor Douglas. As Governor of Vancouver Island he had nothing to do with the mainland; but, inasmuch as he was the nearest Crown authority, he naturally wrote to the Home authorities, advising them of what was going on, and was instructed by Sir Edward Bulwer-Lytton, who was then Secretary of State for the Colonies, to act as though he were Governor on the mainland—and do what was, in his judgment, necessary.

As these people came swarming in, Governor Douglas remembered that there were many of them with unsavoury reputations; and California, twice in her history as a gold mining state, had been compelled to form Vigilance Committees to overthrow the weak Courts, and by means of illegal courts, put down illegality! As Governor Douglas was determined to prevent any such condition under the British flag as had occurred in California, he wrote to Sir Edward Bulwer-Lytton, asking him to send a detachment of soldiers, that they might keep order in the country. At that time communication was slow, for the mail had to go by way of Panama, and Governor Douglas' letter, which is dated in July 1858, crossed a letter from Sir Edward Bulwer-Lytton. Governor Douglas had written for soldiers, and Sir Edward Bulwer-Lytton had written to say that he was going to send some. For this purpose Sir Edward had selected the Royal Engineers; and in his letter to Governor Douglas, he indicated just why he had chosen that distinguished corps. In describing the quality of the men he was sending out, he said "The superior discipline and intelligence of this force, which afford ground for expecting that they will be far less likely than ordinary soldiers of the line, to yield to the temptation to desertion offered by the goldfields, and their capacity at once to provide for themselves in a country without habitation, appear to me to render them especially suited for this duty; whilst by their services as pioneers in the work of civilization, in opening up the resources of the country, by the construction of roads and bridges, in laying the foundation of a future city or seaport, and in carrying out the numerous engineering works which in the earlier stages of colonization are so essential to the progress and welfare of the community, they will probably not only be preserved from the idleness which might corrupt the discipline of ordinary soldiers, but establish themselves in the popular goodwill of the emigrants by the civil benefits it will be in the regular nature of their occupation to bestow."

There are his reasons for choosing the Royal Engineers.

Volunteers were called for, and from them 150 non-commissioned officers and men were chosen. That body, under the command of Colonel R. C. Moody, came out in three sections. The first detachment, numbering twenty under Captain Parsons, were mostly surveyors. The second detachment of twelve under Captain Grant, were mostly carpenters. The third section, comprising the main body of 118 non-commissioned officers and men, were accompanied by the women and children. Captain Parsons' and Captain Grant's contingents, totalling thirty-two men, came by way of the Isthmus of Panama, not all together, but they both arrived here about November 1858. Sir

**Present Cariboo Highway, Fraser River Section.**

Edward Bulwer-Lytton is remembered as a novelist and a dramatic author of outstanding ability, but he was also an orator. Moreover, his correspondence, in laying the foundations of British Columbia, shows that he was a statesman—a man of broad outlook and vision.

Sir Edward went down to the ship "La Plata" to say good-by to the Engineers—the first twenty sailing with Captain Parsons; and his address to them on that occasion contains passages which may even stand side by side with Lincoln's celebrated address at Gettysburg. In that address Sir Edward said: "Soldiers, I have come to say to you a few kind words of parting. You are going to a distant country, not, I trust to fight against men, but to conquer nature; not to besiege cities, but to create them; not to overthrow kingdoms, but to assist in establishing new communications under the sceptre of your own Queen. For these noble objects, you soldiers of the Royal Engineers have been especially selected from the ranks of Her Majesty's Armies. Wherever you go, you carry with you, not only English valour and English loyalty, but English intelligence and English skill. Whenever a difficulty is to be encountered which requires not only courage and discipline, but education and science, sappers and miners, the Sovereign of England turns with confidence to you. If this were a service of danger and bloodshed, I know that on every field and against all odds, the honour of the English arms would be safe from a stain in your hands, but in that distant region to which you depart, I hope that our national flag will wave in peaceful triumph on many a Royal birthday from walls and church towers which you will have assisted to raise from the wilderness, and will leave to remote generations as the bloodless trophies of your renown. Soldiers, you will be exposed to temptation, you go where gold is discovered, where avarice influences all the passions, but I know that the voice of duty and the love of honour will keep you true to your officers and worthy of the trust that your Sovereign places in Her Royal Engineers. For my part, as one of the Queen's ministers, I promise that all which can conduce to your comfort and fairly reward your labours shall be thoughtfully considered. You have heard from my distinguished friend, your commanding officer,* that every man amongst you who shall have served six years in British Columbia and received at the end of that time a certificate of good conduct, will be entitled if he desires to become a resident of the Colony, to thirty acres of land,† aye, and of fertile land, in that soil which you will have assisted to bring into settlement and cultivation. In the strange and wild district to which you are bound, you will meet men of all countries, of all characters and kinds. You will aid in preserving peace and order, not by your numbers, not by mere force, but by the respect which is due to the arms of England, and the spectacle of your own discipline and good conduct. You will carefully refrain from quarrel and brawl. You will scorn, I am sure, the vice which degrades God's rational creatures to the level of the brute—I mean the vice of intoxication. I am told that is the vice which most tempts common soldiers. I hope not—but I am sure it is the vice which least tempts thoughtful, intelligent, successful men. You are not common soldiers, you are to be the pioneers of civilization. Nothing more counteracts the taste for drink than the taste for instruction, and Colonel Moody will endeavour to form for your amusement and profit in hours of leisure, a suitable collection of books. I beg to offer my contribution to that object, and I offer it not as a public minister, out of public moneys, but in my private capacity as a lover of literature, myself, and your friend and well-wisher.

"Farewell, Heaven speed and prosper you. The enterprise before you is indeed glorious. Ages hence, industry and commerce will crowd the roads that you will have made; travellers from all nations will halt on the bridges that you will have first flung over solitary rivers, and gaze on gardens and cornfields that you will have first carved from the wilderness; Christian races will dwell in the cities of which you will map the sites and lay the foundations. You go, not as enemies, but as the benefactors of the land you visit, and children yet unborn will, I believe, bless the hour when Queen Victoria sent forth her sappers and miners to found a second England on the shores of the Pacific."

That was Sir Edward Bulwer-Lytton's address; worthy of the occasion, and worthy of being remembered by the people of British Columbia.

The thirty-two men of the Royal Engineers who came by the Isthmus of Panama, arrived in time to take part in the formal launching of the Colony of British Columbia; for in the interval, an Act had been passed creating the Colony of British Columbia, to come into force on its being promulgated in the country; and that promulgation was made at Langley on the 19th of November, 1858. Governor Douglas was then sworn in as the Governor of the Colony of British Columbia, so that there were two separate colonies, Vancouver Island and British Columbia, with one Governor.

The two detachments of Royal Engineers at once began the work of getting ready the buildings for the larger body—the contingent that was coming round the Horn in the "Thames City." They built for a while at Derby; and then their work was interrupted by a "war"—one of the most bloodless wars on record, a war without a shot being fired; the story is complicated, and as it goes along it reminds one of the "House that Jack Built."

*Colonel Moody.

†Later increased to 150 acres.

On Christmas Day of 1858, there were at Hill's Bar, one and a half miles from Yale, two miners who determined to celebrate. Their idea of celebration was to go to Yale and get drunk. Up to Yale they went, and drunk they got. As they were strolling—or rolling—in that condition, on the one street of Yale, they happened to see a negro sitting in the door of his barber's shop. They were in that sort of humour that when they saw this negro they got the idea that the negro ought not to breathe the same atmosphere as theirs; and to impress that upon the negro they beat him up and then strolled back to Hill's Bar to sober up. The negro went to the Magistrate at Yale—a very pompous man—complaining of the assault made upon him, and making charges against the two miners. At once the magistrate issued a warrant for the arrest of these two men for assaulting the negro; and, to make sure he would have the negro when he wanted him at the trial, he locked him up—put him in jail—although he had not got the men who were supposed to have committed the assault. Then he sent his constable to Hill's Bar to get the two miners. But Hill's Bar had a little sailor magistrate, by the name of Perrier, and he did not see why these men who had beaten the negro at Yale, should be tried at Yale. He thought he should try them at Hill's Bar, and when the Yale constable came with the warrant to get the two men the little sailor magistrate regarded it as contempt of his court, to take them to be tried at Yale. He refused to let the two men go, and ordered his own constable to lock them up in the jail at Hill's Bar. So the men who did the mischief were locked up at Hill's Bar, and the poor negro to whom it was done, was locked up at Yale. The magistrate, Perrier, sent his constable up to Yale to ask the magistrate there, "Captain" Whannell, to allow the negro to go to Hill's Bar to give evidence against the men. But when the constable got to Yale and asked for the negro, the Yale Magistrate became very, very angry. He thought it was contempt of his court, that the magistrate from Hill's Bar should send up to get the negro. He refused to let him go, and, what is more, he took the constable from Hill's Bar and locked him up in Yale for coming up to try to get the negro!

When this news reached Hill's Bar, there was great commotion. At that time, there was a man named Ned McGowan at Hill's Bar—a notorious renegade. He was formerly a judge in California, but he had gone downhill, and in the end, being charged as an accessory to a celebrated

Map of Southern British Columbia.

murder in California, he was wanted by the Vigilance Committee. His life was not worth a minute's purchase. One of the Agents of the Vigilance Committee took a shot at him, but unfortunately he was a poor marksman, and the bullet went through the lapel of McGowan's coat; and it caused us a lot of trouble. He came to the magistrate at Hill's Bar, and said "If you will give the authority to me and my friends, we will go up to Yale and release that nigger and bring him down here, and we will release your constable who is locked up there for contempt of court; and, what is more, we will arrest the Yale magistrate and the Yale constable for contempt of your court, and bring them down here." And accordingly it was done. McGowan and his friend went to Yale, and they stamped into Whannell's court room, took possession of the magistrate and his constable—they unlocked the doors of the jail and got the negro, and got the Hill's Bar constable, and the procession came down to Hill's Bar. When they got there, the little magistrate at Hill's Bar sat very solemnly in the matter, and fined Farrell and Burns (the miners who had beaten the negro) seventy-five dollars for committing the assault. Then he had the Yale constable before him for contempt of court in arresting the Hill's Bar constable and locking him up. But the Yale constable said "I did it under order of the Yale magistrate" and the Hill's Bar magistrate said "Well, that is all right; you carried out your instructions." Then he brought his fellow-magistrate before him—tried him for contempt of court for locking up his constable and fined him twenty-five dollars. The magistrate of Yale was as angry as he could be; sent a letter to Captain Grant who was in charge of the Royal Engineers at Langley, telling him that this renegade of renegades had been prison breaking at Yale and was in a deep-rooted conspiracy to overthrow British authority, and hand the country over to the United States. Thus the petty squabble between two magistrates had now expanded to high treason. When the word came to Langley, Captain Grant and his men started up the river, accompanied by Colonel Moody, who had only just arrived on Christmas Day—the day of the trouble. They took with them guns and marines off one of the ships and Judge Begbie, to try the traitors. The river was encumbered with ice, but they succeeded in getting up. They noticed that the nearer they got to Yale and Hill's Bar, the less the trouble seemed, and by the time they got to Hope, they found there was just a miserable squabble between the two magistrates. Finally, the magistrates lost their commissions, the Engineers had an outing, and they did not fire a shot; but it was an instructive affair from one angle. It showed the people from the other side of the line that improper conduct would not be tolerated here.

**Fraser River at Yale, B.C.**

While all this was going on, the main body of the Engineers was coming round the Horn in the "Thames City"—118 non-commissioned officers and men, 31 women and 34 children. To pass away the time, they published a paper every Saturday night, which was read by Captain Luard to the assembled people. It was not printed; it was written on sheets of cardboard—the originals are in the archives at Victoria. The paper contained an account of the events of the voyage—the births and deaths. There were not any marriages. Then there were little gags and jokes; and articles on travel, biography, history, natural history, everything of that kind. And a good deal in the way of original matter—original poetry—or verse at any rate—and original stories.

This gives some idea of the versatility, the varied ability of these men.

Now, owing to the action of Colonel Moody in recommending that the Governor change the capital of the colony of British Columbia from Langley down to New Westminster, the work that the Engineers had done at Langley was all thrown away, and they began to make their permanent camp at Sapperton, now a suburb of New Westminster. The consequence was—the change being made only in February, and the main body being due to arrive on the "Thames City" in April—that when the main body reached Sapperton there was very little done, the advance party having had only a couple of months to work. The site of the camp practically covered the area now taken by the British Columbia Penitentiary.

During the summer of 1859, the Engineers cleared the camp site, between the Fraser River and the crest of the hill. They had probably forty buildings there, including Colonel Moody's residence and the residences of the married officers, the residences of the single officers, quarters for the married men and quarters for the single men; and they had workshops of all kinds for wood and iron-working,—they had main barracks, a theatre, an observatory, and store houses. During the same summer they laid out and surveyed the site of New Westminster, drew the plans, lithographed and printed them. In that year also (1859) they surveyed Hope, Yale, and Douglas, drawing and publishing the plans of those towns; also books were printed in Sapperton by the Royal Engineers' press.

Road construction began, for in 1859 they built a trail leading from the camp out to Burrard Inlet at Port Moody. In the year before, 1858, Governor Douglas had made an arrangement with the miners to build a trail from Douglas through to Lillooet. That had been a rough primitive affair. The Engineers went to work, and they made that in 1859 into a decently passable trail, leading to the Fraser above the canyon. In order to reach the Fraser in the canyon, the Engineers in the same year built a trail from Hope through to Boston Bar, and up to Lytton, keeping to the easterly side of the Fraser. In that year, also, Lieut. Palmer, with another detachment of the Engineers, made a complete exploratory survey of the whole country between Hope and the Columbia River. His report of that work, which is concise and complete, covers some ten closely-printed folio pages. That represented their work for one year, although they had only arrived in April 1859.

The next year, 1860, Governor Douglas made a proclamation in January, permitting pre-emption of land. From 1858 to 1863 on the mainland of British Columbia, Governor Douglas, who had been sworn in at Langley on the 19th of November 1858, was not only Governor, but was also lawmaker. If a law were wanted, and Governor Douglas decided that it was necessary, he sat down and wrote it and handed to the printer, and circulated it; and there was the law. He made this proclamation, and as a result of that, the Engineers—the surveying portion of the Engineers—went to work over the district between Sapperton and Vancouver Harbour or Burrard Inlet, and on the south side of the Fraser River, surveying the land being applied for. They had of course to establish a draughting and record office. In this year, also, they surveyed the towns of Lillooet and Lytton, drew the plans, lithographed and printed them.

The main road to the interior was by way of Douglas and Lillooet. Those familiar with the Harrison River know that there are shoals at certain stages of the water; and so, when a steamer left New Westminster, headed for Douglas, she could only go to the shoals of the Harrison and there discharge her passengers and freight, which had then to be portaged across the shallows. In order to get over that, and make possible a continuous journey by steamer, the Engineers, under Captain Grant, who took eighty men with him, began the construction of large wing dams to control the water on the shoals, so that a steamboat could travel through. However, before the work was finished, the river rose, and being driven from that task, they went to Douglas and began to change the trail of 1859 into a road. The great cry was "Better means of transportation"—thereby, of course, reducing costs; and this trail, which would only accommodate mules, they wanted to turn into a waggon road. In the year 1860, also, the Engineers changed the location of the trail that ran from Yale to Spuzzum. The old trail from Yale—the old Hudson's Bay trail—went by Yale creek in a northwesterly direction, crossed a divide and came down Spuzzum creek in an easterly direction. Governor Douglas determined to build a mule trail along the Fraser from Yale to Spuzzum; it was the first effort to attempt to blast a roadway through those tremendous shoulders of rock. However, the Engineers went to work and did it.

In that year, also, gold was found in the Similkameen country, and the Engineers were called upon to locate a trail so that miners could go from the Fraser River to Similkameen; Sergeant McColl in that summer laid out a trail from Hope to the Similkameen, carrying it over the Cascades 4,000 feet, with no greater single gradient than one foot in twelve. It became known later as the Dewdney trail, because Edgar Dewdney built it in 1860. Next, Governor Douglas was not satisfied with the necessity of using the river to reach Yale and Hope; there was possibility of the river freezing. He wanted to know whether a road could be made from Hope to tidewater. He set the Engineers to work. Captain Parsons in the summer of 1860 explored the whole region between Hope and tidewater, for the purpose of locating a road to serve for occasions when the river might be blocked; and also under Governor Douglas' instructions, he examined into the possibility of utilizing the Chilliwack and Sumas regions (which were then subject to overflow) and protecting them from freshets. At that time, the country being new, when the Governor wanted anything he simply turned to this body of trained men and said "find out the facts for me."

The next year, 1861, was largely a year of preparation. The Engineers were still busy trying to get the road built from Douglas to Lillooet, but people were crying out for still better transportation. They were not satisfied with that road from Douglas to Lillooet. Starting from Douglas, there were twenty-eight miles of land travel. This brought the traveller to Lillooet Lake, where he took a steamer up the lake. There was another land journey to Anderson Lake, and then another steamer to its end. Then a short land trip to Seton Lake. Another steamer on that lake brought him to its end, whence he travelled on to Lillooet by land. It was impossible to speed up traffic under those conditions. So the people said "We want a road that leads into the interior, so that waggons can travel through without any change until the end of the journey, and without waiting for steamers to make connection." Therefore, in 1861 Governor Douglas set the Engineers to work to see whether they could locate a road through the canyon of the Fraser. Now, travellers go through the canyon

**Fraser River Canyon and Old Cariboo Road Bridge, near Spuzzum, B.C.**

in their own (or a friend's) high-powered cars and give no thought to the men who planned the road that was the origin of the present highway. But the Royal Engineers had to hang on as they best could to rocks and trees, striving to get a location where, by means of gunpowder, a road could be built. They went in there first, without any means of transportation at all: just their own hands and feet to make their way with, searching for a practicable route whereby waggons could be brought through that difficult region between Yale and Lytton.

It became plain that the river had to be crossed somewhere and Sergeant McColl was sent out with a party of the Engineers to find the best place—and he found it—the suspension bridge stands there to-day. And that the Royal Engineers made a good choice of a site for a bridge is shown by the fact that when the old Cariboo road went to pieces, after the advent of the C.P.R., and was rebuilt as a scenic highway by the Provincial Government within the last few years, when the Government came to build a suspension bridge (the old one had gone down) they set it at one end, on the very support that the Royal Engineers had chosen! To-day one of the bridge piers rests exactly on the spot that the Engineers chose, and the other is a few feet away only—showing that the work they did was of the substantial kind that stands the test of time.

In this year, also, the Engineers transformed the trail from their camp to Port Moody into a road, which is still in use, the North Road; and Captain Grant with eighty sappers built a road much along the line of McColl's location of 1860, from Hope as far as Skagit Flats about twenty-five miles, on the way to the Similkameen.

Then we come to the next year, 1862. That was the year of the building of the Cariboo waggon road. It has been said that the Engineers built that road. They did not; but they did build two little pieces of it; one, six miles out of Yale, in 1862, and one nine miles out of Spences Bridge in 1863. That is all they built of the whole thing. But at the risk of their own lives they did find out where that road could be put. They made, surveyed and laid out the dangerous and difficult parts, especially along the Fraser and Thompson rivers, and they superintended the construction. During 1862 and 1863, this was a fair portion of their duty—coupled with the work on the Douglas-Lillooet road, because they always kept that going. In 1862, also, the Engineers under Lieut. Palmer explored the whole country between Bentinck Arm and Cariboo, with the idea of finding a shorter route to the Cariboo.

*Courtesy of C.P.R.*

**Coach on the Old Cariboo Trail.**

The last year of the Royal Engineers' work was 1863. In the beginning of that year "The British Columbia Gazette" was established. That was in the charge of Colonel Wolfenden, who has now gone to his reward. But for fifty or sixty years the old colonel was in charge of "The British Columbia Gazette" as The King's Printer. In 1863, the Engineers located the trail from Quesnel through to Barkerville, on Williams Creek, which was then the great gold producing creek. Governor Douglas did not like the existing trail, which was too high, passing over the Bald Mountain, and could be only crossed five or six months in the year. So he wanted a new way; Captain Grant located the trail, and built the whole fifty-nine miles between Quesnel and Barkerville so well that a man could ride it on horseback in a day.

In that year, the Engineers drew the plans, supervised and tested the suspension bridge where it crosses the Fraser twelve or thirteen miles out of Yale. That bridge was built by Mr. Joseph W. Trutch, but it had to be passed by the Engineers. After it was completed, Lieut. Palmer tested it by driving a four-horse team and a loaded waggon, with three tons of goods on it, across the bridge. The bridge stood, and the deflection was less than a quarter of an inch.

In that year also, .the Engineers surveyed, amongst other lands, the original lots that marked the city of Vancouver: lots 184, 185, 186 and 187; George Turner delimited Stanley Park—880 odd acres. It is due to the Royal Engineers that the people of Vancouver, and British Columbia, are blessed with the greatest natural park contiguous to any city in Canada, for the land was reserved by Colonel Moody for military purposes, and was surveyed by his men. A survey was also made of the suburban lots back of New Westminster, and the Council passed a resolution on the 20th of April 1863 as follows:—

"Moved by Councillor A. H. Manson of New Westminster, seconded by John Cooper, that in consequence of the judicious selection of the townsite of New Westminster for the capital of British Columbia by Colonel Moody, R.E., this Council considers it desirable that a space of not less than twenty acres should be reserved in the suburbs now being surveyed, to be called 'Moody Square' in commemoration of the founder of the city, and that the Clerk be instructed to forward a copy of this resolution to the Chief Commissioner of Lands and Works, with a request that the same may be acted upon."

That was done, and is the origin of Moody Square.

But it was not a case of all work and no play with the Engineers. They were out in the summer, in winter they came back to Sapperton, and their camp was then the centre of the social life and activity of the community. They had a social club here. Their theatre was the scene of all kinds of dances and parties and balls, and all that social life which tends, if properly guarded and looked after, to the betterment of a community. The Engineers had a theatrical troupe, and the men of the detachment played comedies and farces and all sorts of dramatic pieces; some of the young fellows took the female parts, and did very well, I understand. One of their plays was "Box and Cox," in which the Surgeon, a big bluff, bewhiskered fellow, played Mrs. Bouncer. That must have been worth seeing.

Summarizing the work of the Engineers, it may be said that they made all the explorations of the country from the time they came here, they surveyed practically all the towns and the country lands; they located and superintended all the trails. They built the North Road, which was originally a trail. They built the Douglas-Lillooet road. They built the Hope and Similkameen road for twenty-five miles; and portions of the Cariboo road. All maps of that time they drew, lithographed and printed in Sapperton. They formed the Lands and Works Department; they established the Government Printing Office. They inaugurated the first Building Society on the mainland; the first social club on the mainland, the first theatre and theatrical society on the mainland. They designed the first public schoolhouse. They designed and built the first Protestant church on the mainland—the Church of St. John the Divine—originally at Langley and now at Maple Ridge. And they designed other churches—the original Holy Trinity, New Westminster, and St. Mary's, Sapperton. They designed the first coat of arms of the Colony. They designed the first postage stamp. They built the first observatory—of course, Captain Cook and Captain Vancouver had temporary observatories, but the first permanent one was built by the Engineers. They fixed its position as 49° 12′ 47″ North latitude, and 122° 53′ 19″ West longitude. They kept the first continuous scientific meteorological observations. They had the first private hospital, and when it was broken up they gave its materials to aid in equipping the Royal Columbian Hospital. The library that they had (which Sir Edward Bulwer-Lytton referred to in his address to them) passed later to the citizens of New Westminster, and it became the nucleus of the library there in the old Mechanics' Institute.

These are the material things. But, apart from that, from the Colonel down, these men were selected men. They were not an ordinary detachment of the Royal Engineers; they were selected men and always took their share in every good work. In everything that went to the upbuilding of the community, as well as in performing their regular duty, Colonel Moody at the head, followed by his officers and men, fully lived up to the motto of their corps "Ubique" and "Quo fas et gloria ducunt."

In October 1863 there came word that the Engineers were to be disbanded. All of the officers and about a dozen of the men returned to England—but the remainder of them settled down here; and through the files of "The British Columbian" of 1863 and 1864, they may be found in civil life as plasterers, plumbers, carpenters, photographers, tailors, shoemakers, undertakers, surveyors, bookkeepers, hotel proprietors—active in every walk of life. In 1863 there were 130 of them here in British Columbia. Thirty years later (1893) there were thirty-four. In 1903 there were twenty-five. In 1909 (that was forty-six years after they were disbanded) there were fourteen. In 1927 the last of them, Philip Jackman, answered his last Roll Call:

In conclusion, looking over the record of the detachment it would seem as if Colonel Moody and his men might have been the soldiers referred to in "Sappers," written fifty years later:—

"I've stated it plain, and my argument's thus,
('It's all one,' says the Sapper)
There's only one Corps which is perfect, that's us,
And they call us Her Majesty's Engineers,
Her Majesty's Royal Engineers,
With the rank and pay of a Sapper!"

The standard that these men strove for in the Colony of British Columbia could not be better described than in another Kipling quotation, from the "Song of the English."

"Keep ye the Law—be swift in all obedience—
Clear the land of evil, drive the road and bridge the ford.
Make ye sure to each his own
That he reap where he hath sown;
By the peace among Our peoples let men know we serve the Lord!"

The descendants of these men are in British Columbia to-day, occupying positions of honour, trust and responsibility in the community, and carrying on in the same sturdy way as their fathers before them.

# THE ANNUAL GENERAL MEETING

WINDSOR HOTEL, MONTREAL

JANUARY 29th and 30th, 1937

## Important Business Discussions

## Montreal Branch Smoker

THE
# ENGINEERING JOURNAL
THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XX JANUARY, 1937 No. 1

## The New Year

The President and Council extend to all members of The Institute cordial good wishes for 1937.

We are pleased to record our belief that the year 1936 marked a very definite milestone in Institute affairs.

The aims and aspirations of The Institute toward a unification of the Engineers of Canada in an effective and all embracing professional organization have crystallized in well defined proposals that should find wide acceptance.

The substantial advance made during the past year in trade and employment, the renewed confidence in the ability of the country to recover from the sustained tension of a long depression and the visible signs of returning prosperity make the New Year one of great hope and promise.

The time seems most appropriate for the exercise of a fine spirit of co-operation among Engineers throughout the length and breadth of the Dominion that will open to all a wider opportunity to share in the interchange of professional experience and the advancement of engineering knowledge.

## The Fifty-first Annual General Meeting

The Annual General Meeting for 1937 will convene, in accordance with the by-laws, at Headquarters at eight o'clock p.m. on Thursday, January 21st, for the appointment of scrutineers to canvass the ballot for the election of officers for 1937. It will then be adjourned to reconvene in the *York Room of the Windsor Hotel, Montreal,* at ten o'clock a.m. on *Friday, January 29th, 1937,* continuing on the following day. At this adjourned meeting the following will be the principal items upon the agenda:

1. Nominating Committee 1937—Announcement of Membership.
2. Prizes and Medals of The Institute—Announcement of the several awards.
3. Report of Council for the Year 1936.
4. Treasurer's Report—Report of Finance Committee—Financial Statement.
5. Reports of Other Committees, including that of the Committee on Consolidation.

The principal item under this head will, of course, be the report of the Committee on Consolidation, discussion on which will centre on the proposals for the amendment of The Institute's by-laws which were printed in the December issue of The Journal, pages 550 to 554. In accordance with Section 75 of the by-laws these proposals will be submitted to the Annual General Meeting for discussion. Amendments to the proposals may be put forward at the Annual General Meeting, and the members present have to decide which of such amendments, if any, shall be included with the original proposals and be printed on the ballot paper which will subsequently be sent out to the membership for vote.

Under Section 75 the chairman at the Annual General Meeting appoints a committee to prepare a statement of the reasons for and against the proposals, which statement will accompany the letter ballot.

At the conclusion of the above important business it will be in order to consider and discuss the remaining committee reports, including those of the Papers Committee, Library and House Committee, Board of Examiners and Education, etc.

6. Reports of Branches.
7. Retiring President's Address.
8. Scrutineers' Report on the election of New Officers.
9. Induction of Newly Elected President.

In view of the Semicentennial Celebrations to be held on June 15th to 18th, 1937, the proceedings of this Annual General Meeting will be confined entirely to Institute affairs, the presentation and discussion of professional papers being postponed until that later date.

### Smoking Concert

Members will please note that the Montreal Branch of The Institute are organizing a *Smoker* to be held in the *Windsor Hotel* at *8.15 p.m.* on the evening of *Friday, January 29th.* Such concerts are a feature of the social life of the Branch; out-of-town members and their guests—to all of whom a special invitation is extended—will enjoy the informal character of the occasion, and the opportunity to meet their fellow members under congenial conditions.

## The Registration of Engineers in the United States

The movement for the consolidation of the engineering profession in Canada has now reached the stage at which a definite scheme for co-operation between The Engineering Institute and the Professional Associations has been drawn up, and is before the members of The Institute for their acceptance. At this point it may be useful to glance at the conditions under which the registration movement is progressing in the United States. The difficulties encountered there in arranging for joint action among the various organizations concerned are in many respects like those on this side of the boundary, but a much larger number of authorities and individuals are involved, so that the scale of the movement is almost as impressive as that of the vast engineering achievements in that country.

In 1930 the Federal Bureau of the Census reported the existence of some 226,000 "engineers and surveyors." It is probable, however, that this figure included a considerable number whose work was not really professional in its nature, and who assumed a status for which they were not qualified by training or experience. In 1935 registration of professional engineers was provided for in twenty-nine states having about 40,000 registered engineers. Presumably in these states there were still many engineers who had not registered. At that time, six other states had laws requiring registration of engineers, and such laws were being promoted in nine other states and in the District of Columbia. In the United States, as with us, legislation of this kind is based on the promotion of the welfare and safety of the public, and is a state, not a Federal, responsibility. Its enforcement is in the hands of the State administration. There would appear to be no organizations having constitutions or powers corresponding to those of our Provincial Associations of Professional Engineers, although in some States voluntary societies of professional engineers have been formed. As regards numbers, New York State heads the list with some 10,000 registrations, followed by California, Pennsylvania, and Ohio, each with from three to five thousand.

The first registration act was passed in Wyoming in 1907, but it was not until 1920 that any considerable number of states had laws governing the practice of engineering. The various acts differ considerably in scope and effectiveness. Some classify applicants as to their respective branches of engineering. Two exempt mining and metallurgical engineers. Almost all the acts have already been amended.

The registration boards, of three to nine members, are in most cases composed of professional engineers, appointed by the Governor of the State or the State Department of Education. Many, but not all, States provide for examinations, and in some cases require these to be taken even by college graduates. Examinations, when required, are conducted by State Boards of Engineering Examiners. Practically all acts have the so-called "grandfather" clauses.

The minimum age for registration varies from 21 to 35; four to ten years professional experience are required for non-graduates, and up to four years for graduates of recognized engineering schools. Fees are moderate, from $15 to $25 on registration, with an annual fee ranging from $1 to $15.

There is thus a marked lack of uniformity as regards the requirements and regulations of the various states, causing difficulties which were recognized as early as 1920, and resulted in the formation of a National Council of State Boards of Engineering Examiners. That Council has now established a National Bureau of Engineering Registration, whose purpose it is to draw up and obtain general recognition for uniform standard requirements for a certificate of qualification and for a uniform interpretation of the term "professional engineer." The Bureau's requirements represent the minimum of education and experience that a man must have to become a professional engineer, and it is hoped that its certificate of qualification will be accepted by the various State Boards of Engineering Examiners as entitling the holders to engage in practice in more than one state of the Union. The work of the National Council and its Bureau is thus of real significance as a foundation for the standardization of registration and as an assistance for the individual applicant.

There seems to be no doubt that the state registration of engineers has come to stay in the United States, and the movement will probably develop more rapidly as time goes on. Its progress has already been such as to raise broad questions affecting the whole profession, such as the relationship between the requirements of the State Boards and the curricula of the engineering schools; the relative importance to be attached to graduation from an engineering school, and to years of professional experience; and the part which the engineering societies of national or local scope, can take in the organization of the profession.

In order to plan for the solution of such problems, six of these national bodies, together with the National Council of State Boards of Engineering Examiners, have now established an Engineers' Council for Professional Development. The general object of this council is the enhancement of the professional status of the engineer. It consists of twenty-one members, three being appointed by each of the following bodies: the American Society of Civil Engineers, the American Institute of Mining and Metallurgical Engineers, the American Society of Mechanical Engineers, the American Institute of Electrical Engineers, the American Institute of Chemical Engineers, the Society for Promotion of Engineering Education, and the National Council of State Boards of Engineering Examiners. It thus represents the professional, technical, educational and legislative aspects of engineering.

There are four standing committees, whose duties are indicated by their names. The Committee on Student Selection and Guidance deals with vocational problems and information concerning engineering as a career. The Committee on Engineering Schools investigates degree-conferring colleges and accredits those whose courses and equipment are found satisfactory. The Committee on Professional Training studies the post graduate technical and cultural development of the young engineer. The Committee on Professional Recognition has as its province the definition of prerequisites for admission to professional status, holding that such qualification should be the equivalent of a professional degree and should be normally obtained by the young engineer between his twenty-fifth and thirtieth years. It will be noted that this legal aspect of engineering is only one of the important features of the work of the Council, whose programme is indeed ambitious. Much of its work is now in the preliminary stage, but its method of operation may already be described as the promotion of a general policy by securing the co-operative support of the national organizations directly representing the professional, technical, educational and legislative phases of an engineer's life.

There is, as yet, no definite scheme in the United States for any formal relation between the hundreds of national and local voluntary technical societies and the state-organized agencies for licensing and registration. The work of the Engineers' Council for Professional Development is in some measure directed towards the co-ordination of all these activities. Its programme for the current year has recently been aided by a grant of $16,000 from the Carnegie Corporation of New York. Financial support is also given by the Engineering Foundation, and by three of the Founder Societies. Its formation is a most important step since it constitutes a central and widely representative body, to which may be referred the many questions which must be thrashed out if the professional advancement of engineering is to proceed.

The present situation in the United States has been ably summarized in a recent report of the Russell Sage Foundation, reviewed elsewhere in this issue.* That report confirms the impression that our neighbours realize the need for team work in connection with professional matters. There must be co-operation between the many authorities concerned, including educationalists; representatives of the associations and institutes—many of them highly specialized—which provide for the interchange of professional knowledge; bodies dealing with questions of professional occupation and employment; and those concerned with the legal aspect of professional qualification and registration. It is hoped and expected that such co-operation will be the result of the growth and activity of the Engineers' Council for Professional Development.

## Centenary of the Swiss Society of Engineers and Architects

It is announced that the Centenary celebrations of this organization, the national engineering society of Switzerland, will take place in Berne on the 4th, 5th and 6th of September, 1937. Invitations to send delegates have been forwarded to engineering and technical societies in foreign countries, for whom a special programme is being arranged for the third day of the meeting, including visits to large industrial plants and important public works characteristic of Swiss engineering practice.

The Council of the Society has extended to The Engineering Institute of Canada a cordial invitation to send representatives to these one hundredth anniversary meetings.

## PERSONALS

John J. Rowan, S.E.I.C., who graduated from the Ecole Polytechnique with the degree of B.Sc. in 1935, is now on the staff of the Montreal East refinery of the Imperial Oil Company.

Major H. L. Sherwood, A.M.E.I.C., formerly District Engineer for Military District No. 10, at Fort Osborne Barracks, Winnipeg, Man., is now District Engineer of Military District No. 11, being stationed at Work Point Barracks, Esquimalt, B.C.

R. C. Robson, Jr.E.I.C., who has been designing draughtsman with the B.C. Sugar Refining Company Limited, at Vancouver, B.C., has joined the staff of the Powell River Company Limited, and will be located at Powell River, B.C.

R. L. Weldon, M.E.I.C., has been appointed president of the Bathurst Power and Paper Company Limited, with offices at Montreal, Que. Mr. Weldon graduated from McGill University in 1918, with the degree of B.Sc., receiving that of M.Sc. in 1920. From 1918 to 1919 Mr. Weldon was assistant in the metallurgical department of Peter Lyall and Company, Montreal, and in 1919-1920 he was engineer with the Laurentide Company at Grand'Mere, Que. In 1920-1923 Mr. Weldon was mechanical engineer with the St. Lawrence Paper Mills Limited, at Three Rivers, and in 1923-1925, designing engineer in charge of the design of the Corner Brook mill of the Newfoundland Power and Paper Company Limited. In 1925 Mr. Weldon became chief engineer and assistant mill manager of the same company, holding that position until 1928 when he joined the staff of the International Power and Paper Company Limited, of Newfoundland, as manager of manufacturing and director of the Newfoundland activities of the International Power and Paper Company at Montreal and Corner Brook, Nfld., and in 1930 he was transferred by the company to New York, as chief engineer.

J. G. Schaeffer, A.M.E.I.C., has been appointed sanitary engineer for the Saskatchewan Department of Public Health, Regina, Sask. Mr. Schaeffer graduated from Queen's University with the degree of B.Sc. in 1923, and was subsequently, until 1928, on the staff of the city engineer of Regina, Sask. From 1928 until 1931 he was on the staff of Underwood and McLellan, consulting engineers, Saskatoon, in charge of the design and construction of water works, sewage disposal plants, and street improvements in Manitoba and Saskatchewan, and in 1932 Mr. Schaeffer was on the staff of the city engineer of Saskatoon. In 1933 he entered private practice, specializing in municipal engineering service, but gave this up in 1935 to join the staff of the Department of Public Works, Canada, in connection with bridge and wharf construction in the provinces of Saskatchewan and Ontario. In July, 1936, Mr. Schaeffer became resident engineer with the Department of Highways of Saskatchewan, but resigned to accept his present appointment.

## Elections and Transfers

At the meeting of Council held on December 18th, 1936, the following elections and transfers were effected:—

*Members*

HALL, Henry Monroe, A.B., (Dartmouth Coll., Hanover, N.H.), mill supt. and wire rope engr., Canada Wire and Cable Co., Toronto, Ont.

McBRIDE, Wilbert George, B.Sc., (McGill Univ.), professor of mining engineering, McGill University, Montreal, Que.

*Associate Members*

LASH, Alfred William, M.Eng., (Univ. of Sheffield), hydraulic engr., Ontario Paper Co. Ltd., Thorold, Ont.

SCOTT, Clarence Whiting Harmer, B.Sc., (Queen's Univ.), dftsman., Canadian Bridge Company, Walkerville, Ont.

*Juniors*

HORTON, Everill Blackwell, B.A.Sc., (Univ. of Toronto), machinist, Link-Belt Ltd., Toronto, Ont.

ROGERS, Joseph Victor, B.A.Sc., (Univ. of B.C.), asst. engr., Churchill River Power Co., Island Falls, Sask.

*Transferred from the class of Associate Member to that of Member*

MACDONALD, Albert Edward, B.Sc., (N.S. Tech. Coll.), M.Sc., (McGill Univ.), professor of civil engrg. and head of the dept. of civil engrg., University of Manitoba, Winnipeg, Man.

REID, John Herbert, B.Sc., (McGill Univ.), gen. supt., Trinidad Electric Co. Ltd., Port-of-Spain, Trinidad, B.W.I.

*Transferred from the class of Junior to that of Associate Member*

HOOPER, William Henry, B.Sc., (McGill Univ.), elect'l. engr., coil dept., Canada Wire and Cable Co. Ltd., Toronto, Ont.

*Transferred from the class of Student to that of Associate Member*

COLEMAN, Sheldon W., F/Lieut., R.C.A.F., B.Sc., (McGill Univ.), Adjutant, No. 8 (G.P.) Squadron, c/o Dept. of National Defence, Ottawa, Ont.

DUNLAP, Clarence Robert, F/Lieut., R.C.A.F., B.Sc., (N.S. Tech. Coll.), Camp Borden, Ont.

FISHER, Charles Boddy, B.A.Sc., (Univ. of Toronto), M.Eng., (McGill Univ.), engr. in charge, radio receiver engrg. dept., Northern Electric Co. Ltd., Montreal, Que.

PHELAN, Michael Alexander Austin, B.Sc., (Queen's Univ.), mgr., Noranda Office, Peacock Bros., Noranda, Que.

*See page 31.

TREBLE, Harold Edison, B.Sc., C.E. (1926), B.E.E. (1927), (Univ. of Man.), Topographical and Air Survey Bureau, Ottawa, Ont.

*Transferred from the class of Student to that of Junior*

BENNY, Walter Robert, B.Eng., (McGill Univ.), transitman, C.P.R., Smiths Falls, Ont.
BERRY, Melville Douglas, B.Sc., (Univ. of Man.), 31 Stanhope Ave., Toronto, Ont.
LEIGHTNER, Donald Benjamin, B.Sc., (Univ. of Man.), engr., Canadian Westinghouse Company, Hamilton, Ont.
SILLITOE, Sydney, B.Sc., M.Sc., (Univ. of Alta.), radio engr., Northern Electric Co. Ltd., Montreal, Que.
STRATTON, Leslie Robertson, B.Sc., (Univ. of N.B.), asst. engr., Saint John Harbour Commission, Saint John, N.B.
WILLOWS, Fred, B.Sc., (Univ. of Man.), mine engr., Rahill Red Lake Mining Co., Red Lake, Ont.
YORK, Frederick Gilbert, B.Eng., (McGill Univ.), asst. to line supt., Ottawa Hydro Electric Commission, Ottawa, Ont.

*Students Admitted*

BUDDEN, John Hastings, (McGill Univ.), 3460 Simpson St., Montreal, Que.
COOK, Kenneth Gilbert, (McGill Univ.), 381 Prince Albert Ave., Westmount, Que.
DAVIS, Eliot Robertson, B.Sc., (Univ. of Man.), 548 Prince Arthur West, Montreal, Que.
DEGUISE, Yvon, (Ecole Polytechnique, Montreal), 58 Church Ave., Verdun, Que.
FERGUSON, Jack Andrew, (Queen's Univ.), 303 University Ave., Kingston, Ont.
HARLEY, Gordon G., (McGill Univ.), 2028 Victoria St., Montreal, Que.
HENSELWOOD, Edward Wilton, (Univ. of Man.), 139 Leila Ave., West Kildonan, Man.
LAMB, Hugh, Jr., (McGill Univ.), 1426 Pierce St., Montreal, Que.
NEUFELD, Cornelius, B.Sc. (C.E.), (Univ. of Sask.), 1328 Elliott St., Saskatoon, Sask.
RICHER, Baxter Dallard, (Ecole Polytechnique, Montreal), 5854 Durocher Ave., Montreal, Que.
SEIFERT, Harold Lorne Bain, (McGill Univ.), 1512 St. Mark St., Montreal, Que.
SENTANCE, Lawrence Crawley, B.Sc. (M.E.), (Univ. of Sask.), 414 Albert Ave., Saskatoon, Sask.
THOMSON, John Alexander, (McGill Univ.), 3653 University St., Montreal, Que.
WESLEY, William Grant, (McGill Univ.), 1445 Van Horne Ave., Outremont, Que.

## FIFTY-FIRST ANNUAL MEETING

### WINDSOR HOTEL, MONTREAL

### JANUARY 29th and 30th, 1937

**Dominion Square, Montreal.**

## SEMICENTENNIAL COMMITTEE

**A. Cousineau, A.M.E.I.C.**
**R. L. Dobbin, M.E.I.C.**
**J. M. Fairbairn, A.M.E.I.C.**
**R. H. Findlay, M.E.I.C.**
**F. S. B. Heward, A.M.E.I.C.**
**J. L. Busfield, M.E.I.C., Chairman**

### CALENDAR

**With this issue of The Journal there is being distributed to all Corporate Members of The Institute a six-month calendar especially featuring the dates of the Semicentennial. It is hoped that this calendar will be prominently displayed by members and used as a reminder that they have a date to keep in June.**

### TECHNICAL PAPERS

**Johnstone Wright, M.I.E.E., Chief Engineer of the Central Electricity Board, London, England, will describe the difficulties confronting the Electricity Industry in Great Britain as a result of piecemeal pre-war development and reviews the steps taken to reorganize the generation side of the Industry in that country on progressive lines to provide for the rapidly expanding demand for electricity. Reorganization is based on the co-ordination of generating resources through a comprehensive network of interconnecting trunk lines, and the paper deals not only with the principles under which the system is operated, controlled and financed, but also some of the general technical aspects of the transmission system popularly known as the "Grid."**

**J. H. Parkin, M.E., M.E.I.C., F.R.Ae.S., of the National Research Council, Ottawa, Ont., will present a paper dealing with the different factors involved in the establishment of an inter-continental service by heavier-than-air aircraft across the North Atlantic. Factors discussed include—nature of service, barriers and methods of surmounting them, possible routes, organization of route and types of aircraft.**

**J. C. Bernier, B.A.Sc., E.E., Assistant Professor of Physics, Ecole Polytechnique, Montreal, who has been engaged for some years in research work on the cathode-ray system of television, and electron optics, will give a demonstration and explanation of the present principal systems of high definition television communication and a discussion of their relative merits.**

### VISITORS

**The Royal Aeronautical Society will be represented by its President, Mr. H. E. Wimperis, who has been in charge of research work for the Air Ministry for many years.**

## Committee on Consolidation

### Report for December, 1936

With the exception of the submission of its official report to the Council of The Institute for presentation to the Annual Meeting, the Committee on Consolidation has finished its work for the year 1936 and the results of its efforts have been placed before the profession.

Since the Annual Meeting of February 5th, 1936, the Committee has held nine regular meetings, one joint meeting with the Dominion Council and representatives of Provincial Associations and Corporation, two joint meetings with the Council of The Institute, and has been represented at the plenary meeting of the Council held on October 16th and 17th to consider its proposals regarding revisions to the By-laws of The Institute.

In accordance with its policy of keeping the members fully informed with regard to the progress being made, reports of these meetings have appeared in The Journal each month and have also been made available to those members of the Provincial Professional Associations who are not at present members of The Institute.

During the year the Committee has carried out the following:—

(*a*) The preparation of the revisions to the By-laws of The Institute considered essential to effect closer co-operation between The Institute and the Provincial Professional Associations.

(*b*) Suggested revisions to certain other clauses of the By-laws not directly related to Consolidation but which it appeared advantageous to introduce at this time.

(*c*) The re-arrangement and re-numbering of the By-laws in a proper and logical sequence for more ready reference by the members. (This re-numbering to take place after the ballot.)

(*d*) The preparation of a standard form of Agreement between The Institute and a Provincial Professional Association, to implement the co-operation provided under the new By-laws.

(*e*) The drawing up of a simplified form of "Application for Admission to The Institute" by a member of a Provincial Professional Association.

The above documents are now before all members of the profession for their consideration.

It will be recalled that at the last Annual Meeting the status of The Institute's Committee on Consolidation was altered by the addition of two representatives from the Dominion Council of Professional Engineers, and that in effect it became a National Committee with the appointment of Mr. C. C. Kirby and Mr. A. B. Crealock to its membership. These representatives of the Associations have made their contribution to the findings of the Committee on behalf of the organizations they represent, and at the same time they have performed the function of keeping the Associations advised of the progress of the deliberations of the Committee.

Under date of December 19th, 1936, Mr. C. C. Kirby, in his capacity as President of the Dominion Council of Professional Engineers, submitted a report on the By-law proposals of the Committee to the various Professional Associations for their consideration and such action as they may find advisable at this time.

With reference to the ballot on the proposed revisions to the By-laws which will come before the membership early in the New Year, we would strongly urge each individual member to carefully investigate the possibilities of these proposals as they apply to himself and to the profession as a whole, and, on the basis of the information which has been made available to him, to express his opinion through his vote. Every member of The Institute, no matter what his opinion, is strongly urged to express it through his ballot.

In connection with Section 7 (*b*) of the Committee's proposed revision of the By-laws, which the Plenary Meeting of the Council proposed to amend by the insertion of the phrase, "who is required by law to be a member of that Component Association," resolutions are being received from a number of Branches of The Institute favouring the Section as originally drawn by the Committee. So far only one Branch favours Council's amendment. Of the Provincial Professional Associations, six support the proposals of the Committee on this Section, and two have expressed no opinion.

The following communication submitted over the signatures of twenty-four members of the Quebec Branch will be of interest, coupled as it is with a resolution by the Executive of the Branch approving this letter and respectfully recommending to Council that it re-consider the decision of the Seventh Plenary Meeting (by a vote of 13 to 8) as regards Section 7 (*b*) of the proposals.

Quebec, P.Q.
December 1st, 1936.

To the Council,
The Engineering Institute of Canada,
2050 Mansfield Street,
Montreal, P.Q.

Gentlemen:—

Under date of September 21st, 1936, we, the undersigned members of The Engineering Institute of Canada (Quebec Branch), formally submitted to you the proposals drafted by the Committee of Consolidation for additions to, amendments of or repeal of existing By-laws of The Institute, in accordance with Section 75 of the By-laws.

By the said letter, we authorized, delegated and directed the Committee on Consolidation, or a majority thereof, to act for us and in our stead, in withdrawing these proposals, accepting any changes suggested *except as to proposed Section 7 (b)* or insisting on the original form, as it may decide.

The proposed Section 7 (*b*) read as follows:—

> "7 (*b*). No person residing in any province in which there is a Component Association shall be admitted as a member of The Engineering Institute of Canada, unless he be a corporate member of such Association."

At the Plenary Meeting of Council, held on October 16th and 17th 1936, the said proposals were discussed and we were duly informed of the opinions and suggestions then approved by resolutions of Council. We have noted that the said Section 7 (*b*) was revised by Council to read:—

> "No person residing in any province in which there is a Component Association *who is required by law to be a member of that Component Association,* shall be admitted as a Member of The Engineering Institute of Canada, unless he be a corporate member of such Association."

Please be advised that we cannot accept this revision of the proposals and that *we hereby insist on the original form.*

We are taking this attitude because we know that Council were divided in reaching their decision as regards the above revision and because the principles involved by the said revision or amendment are not sound, in our opinion, and, therefore, cannot bring anything but detriment to The Institute and the profession.

Since the incorporation of our Society, 50 years ago, the purpose of which was the organization of Canadian engineers from a strictly professional point of view, widely divergent views about the standards of admission have continuously divided the membership in two schools of thought which are properly described by the following quotation which is taken from a paper read by Prof. C. H. McLeod, Secretary of our Society from 1891 to 1916, before the Third Conference, Committee on Engineering Co-operation at Chicago, on March 29th. 1917. Professor McLeod stated:—

"Chief amongst problems of interest to Canadian engineers is the question of legislative protection, in connection with which we have, as elsewhere, those who do not desire any (however remote) suggestion of legal control and those who, on the other hand, would wish to see established the most exclusive protection in the practice of their profession.

"The exponents of the *wide open door* are probably those engineers who occupy the important positions, either as consulting practitioners or as official representatives of large corporations. Those, however, who would limit the practice of engineering by legislative enactments, whether they so express themselves or not, are unquestionably in the majority. This majority desires such protective legislation as is elsewhere accorded to the legal and medical professions . . . That legislative control of engineering practice in Canada is one of the problems which we shall have to face and that in the near future, is, to my mind, beyond peradventure." (See "Canadian Engineer," Vol. 32, April 19, 1917. "How Canadian Engineers Organize.")

Professor McLeod was right.

In 1928, at the Second Plenary Meeting of Council, Mr. F. P. Shearwood, as chairman of a "Committee on Grades of Membership," presented a report which indicated again these two schools of thought, one carrying the suggestion that the scope of the membership of The Institute should be widened so as to admit men who cannot be considered fully and broadly educated engineers, but whose experience in engineering work gives them a valuable technical knowledge, and the other holding for the maintenance of a high standard of educational and practical requirements for admission. (See Report of the Committee on Consolidation, January 1936.)

In 1930, Mr. S. G. Porter, in the very able and elaborate report of the "Committee on Relations" of which he was chairman, recommended "That steps be taken to secure the necessary amendments to the By-laws so that membership or registration in a Professional Association be one of the requirements for admission to Corporate Membership in The Engineering Institute of Canada for all applicants residing in a province where an Engineering Professions Act is in effect." But, on the other hand, in the discussion of this subject, Mr. P. L. Pratley, one of the very few dissenting voices at the meeting, stressed his opinion that educational effort and legislative function should be divorced. He wanted The Institute for men in offices of large companies who have no intention of practising engineering as a profession and did not need licenses to practice. (See "The Journal," March 1930, page 212.)

We claim, and this view has always been held by the Quebec Branch, that The Institute is the National Professional Society of Canadian Engineers and that there is no reason why engineering craftsmen, however valuable may their experience and services be to engineers, should be admitted in The Institute.

Law clerks, who often are specialists in varied branches of law and civil procedure and render most valuable services to the prominent lawyers by whom they are employed, are not admitted in the Canadian Bar Association. Trained nurses, hospital orderlies, dieticians, druggists, etc., although most precious aids to the medical profession, are not admitted in the professional associations inter-linked through the Medical Council of Canada. And, architects do not admit in their Royal Canadian Institute, the draftsmen who work in their offices, the dealers in building materials and the contractors with whom they are in daily contact and who co-operate with them.

However, these opposite views have repeatedly come in conflict throughout the life of our Society. The question of the admission of members has been a never ceasing source of trouble and was the stumbling block which was found in the way of all the most important special Committees of The Institute during the last fifteen years, such as the Committee on Policy, on Relations, on Development. And now, the splendid efforts of the Committee on Consolidation, towards crystallizing a clearly defined engineering profession in this country, are about to be lost if this same obstacle cannot at last be removed.

It is not our intention to deprive The Institute of any of its prerogatives and we hold that The Institute is not abandoning any of its rights in writing in its By-laws that its future members shall comprise registered professional engineers only.

It is a fact that the provincial Associations were incorporated at the instigation and with the support of The Institute for the purpose of fulfilling a function which The Institute, as a Dominion-wide body, could not legally perform according to our Canadian Constitution, namely the legislative control of the practice of the engineering profession.

This function implies the recognition of the engineer professionally and the concept of professional membership must of necessity find acceptance by The Institute. Otherwise The Institute would have caused, through the formation of the provincial Associations, a dismemberment of the profession to its own detriment as well as to that of the profession in the National sense.

We therefore claim that The Institute has willingly entrusted the provincial Association with the duty of admitting, in its stead candidates to professional membership and that, by accepting provincial registration as a prerequisite for admission in its ranks, it is simply enjoying the consequence of its own free act which caused the birth of the Associations.

Furthermore we cannot see our way clear to accept the suggestion that The Institute can go its way and develop along its own lines independently of the provincial Associations because such a course of action would mean nothing less than the repudiation by The Institute of its history for the past half century during which time it has been truly and exclusively representative of the engineering profession within the boundaries of our Dominion and has thus won the respect of the other professional organizations, at home and abroad; such a procedure would mean suicide.

Since the vast majority of professional engineers want to build up a truly integrated profession throughout Canada and unless this be done promptly through The Institute, the Dominion Council of Professional Engineers is bound to become a permanent organization and will then have to assume all the educational and social functions which The Institute has heretofore provided for the profession. In that event, The Institute would no longer be the accredited National body representing the Engineering Profession and could at best be looked upon as a semi-professional organization or service club.

We have endeavoured to express very frankly our viewpoint on a subject which we consider to be the crux of the problem before us and we are convinced that, by insisting on the original draft of Section 7 (*b*) being submitted for ballot to the membership, we are acting in the very best interests of The Institute and the Profession.

Copies of this letter are being sent to the Committee on Consolidation and to all Branches, as a matter of information.

Yours very truly,

(Issued over the signatures of twenty-four members of the Quebec Branch.)

The following resolution was passed at the Seventeenth Annual Meeting of the Association of Professional Engineers of British Columbia on December 5th, 1936:

> "That the earnest efforts of the British Columbia Council on Consolidation during the last two years have caused the partial exclusion or neglect of the usual activities in B.C. and it is essential to return to these activities in the forthcoming year, and further that this meeting wishes the very best of success to The Engineering Institute of Canada and the sister Associations in their endeavour to form a truly national representative body. And further as the B.C. Association Council, to the best of its ability, has put forward its ideas consistently, both in writing and by visits to Hamilton, Toronto and Montreal, that this meeting considers that any further practical effort at consolidation should be sympathetically considered by the incoming Council."

The above indicates the great interest and activity which the Association of Professional Engineers of British Columbia has taken towards Consolidation during the past two years, and their sympathetic support of further practical efforts to that end.

In conclusion, all members of The Institute who can do so, are strongly urged to attend the Annual Meeting in Montreal on January 29th and 30th. when these important matters will be discussed in detail.

GORDON McL. PITTS,
*Chairman*

## Not Guilty

When discussion of the engineering attitude is extended to the point of blaming science and technology for the world's present-day dislocations, it is time for a fitting retort. Such retort was made by Karl T. Compton, head of Massachusetts Institute of Technology, in answering President Roosevelt's recent letter calling on the engineering colleges to equip their students for meeting their social responsibilities. The President charged that the impact of science and engineering upon human life has caused unemployment, bankruptcies and relief; he asserted that engineering in addition to creating tools of production must co-operate in designing "accommodation mechanisms to absorb the shock" of this impact; better balance of college curricula, he said, will enable coming generations of engineers to meet this responsibility. Dr. Compton rejects the indictment; he points to the great social advances that have been made possible by increased productive power and to the improved standards of life which we enjoy—all of them achievements of science and engineering. Moreover, he pointed out that these same arts are continually at work developing new products, new industries, new employment and improved health and welfare. Breadth of knowledge and outlook are no less needed among business leaders, economists and politicians than among engineers, Dr. Compton stated. Finally he urged that the government itself give more support to science and encourage its activities in government, industry and educational institutions. In brief, he restated effectively the known fact that science and technology have helped and not hurt the human race, that they constantly enlarge its productive performance with decrease of toil and open up to all a larger and more effective life.

# Recent Additions to the Library

### Proceedings, Transactions, etc.

Institution of Structural Engineers: Specification for concrete pile-driving, October, 1936.
American Society for Testing Materials: Standards, 1936.

### Reports, etc.

*Canadian Radio Broadcasting Commission:* Annual report for the year ended March 31st, 1936.
*Institution of Engineers, Australia:* Memorandum and Articles of Association.
Rules and By-laws—Melbourne Division.
*Corporation of the County of Wentworth, Ontario, Road System:* Annual Report, 1936.
*Canada, Department of Labour:* Report for the year ending March 31st, 1936.

### Technical Books, etc.

Cyanidation and Concentration of Gold and Silver Ores, by John Van Nostrand Dorr (*McGraw-Hill Book Company, New York*).
Thermodynamic Properties of Steam, by Joseph H. Keenan and Frederick G. Keyes (*John Wiley and Sons, New York*) (*Renouf Publishing Company, Montreal*).

# BULLETINS

*Portable Drills.*—A 12-page bulletin received from the Worthington Pump and Machinery Corporation, Harrison, N.J., describes and illustrates the company's Rockmaster portable drill, especially adapted for down hole drilling, line drilling, hillside drilling, breast hole drilling, side hole drilling and snake holing. It is furnished with pneumatic tires so that the rig may be collapsed for towing behind an automobile, a truck or a tractor.

*Screw-Feed Drifters.*—The Worthington Pump and Machinery Corporation, Harrison, N.J., have issued a 4-page leaflet, describing their screw-feed drifters, which are made in three models, for light, medium and heavy duty.

*Silent Chain.*—A 12-page booklet received from the Hamilton Gear and Machine Company, Montreal and Toronto, contains data regarding their industrial silent chain for power transmission. It gives a simplified method for designing a chain drive with tables to determine outside diameter of sprocket, and the length of chain, and covers the installation and care of silent chain drives.

# BOOK REVIEWS

## Hydraulics

*By Charles W. Harris. John Wiley and Sons, New York. (Renouf Publishing Co. Montreal). 1936. 6¼ by 9¼ inches. 220 pages. $2.75. Cloth.*

Reviewed by Dr. T. H. Hogg, M.E.I.C.*

It is usually considered that hydraulics is not an exact science and that its rational formulas must always be revised to conform with actual results as indicated by experiment and practice. The author of this book takes the view that most of the problems of hydraulics lend themselves to logical treatment. To quote from the preface: "The medium is homogeneous, and the major laws exact... An empirical method under this condition is a subterfuge. It may be tolerated in a specialized field or as a handbook expedient, but... the real student has but passing interest in an unsolved paradox."

The quotation and the length of the volume will suggest that the book is primarily a student's text book. It is a text book of unusual merit, because of its approach to the solution of each problem through fundamental principles. Naturally, many old and valued empirical formulas and generally empirical methods of attack receive short shrift. A course of study in elementary hydraulics, based on the text, would equip the student with a very valuable instrument for use in his professional work.

The book merits study also by the practising engineer, for within its limited scope he will find a considerable amount of valuable data and, above all, a simplification of methods of attack on common problems that will prompt him to discard such empirical debris.

An improvement for practical purposes could be effected by enlarging some of the diagrams, by giving specific references at times, and by extending the space allotted to certain important subjects, even at the expense of cutting down that given to others. For example: under Water-Hammer, the subject of time closure is treated in less than half a page, and backwater and drop-down curves are covered in less than one page. These two problems are of such great practical importance that more space is merited if for no other reason than to impress their importance on the student.

The figures and tables are well prepared and the book is well indexed.

*Chief Hydraulic Engineer, Hydro-Electric Power Commission of Ontario, Toronto, Ontario.

## Design of Reinforced Concrete Structures

*By Dean Peabody Jr. John Wiley and Sons, New York (Renouf Publishing Company, Montreal). 1936. 6 by 9¼ inches. 457 pages. $4.00. Cloth.*

Reviewed by Brian R. Perry, M.E.I.C.*

The author of this book is associate professor of structural design at the Massachusetts Institute of Technology. He states clearly that the volume has been written as a text book to be used in connection with a course of lectures in reinforced concrete design. With the background of M.I.T. we should expect just such a text book as is presented, a complete discussion of the fundamentals of the subject; it fills a need not taken care of in other such books because it is restricted to these fundamentals. Its purpose is not confused by the addition of a mass of information designed to add to its usefulness as a reference book.

It may seem that a few items such as reinforcement for shrinkage conditions, the alternative methods of approach to features such as continuity, etc., might have been given more detailed explanation. In such cases it would appear that the author has rigidly avoided including anything but essentials to basic understanding of the subject. Enthusiasm for detail and developments of special cases has rendered many text books on concrete clumsy, unsuitable and confusing to the reader who most requires them.

The most attractive feature of the book is the author's obvious desire to instil into his students (or readers) the basic idea that concrete design is not a precise procedure but is a matter of opinion based on available information. The various features of such design are merely the accepted rules established by various responsible bodies who determine that very necessary standard known as "best modern practice." He quotes all necessary data and assumptions; refers to various codes and specifically chooses one code for the application in view, often stating the reason for the recommendation but inferring that the choice may be to some extent a matter of personal preference. With this background he develops the application of the formulae of mechanics to reinforced concrete. He repeatedly refers to "commercial design" as being not necessarily a precise procedure and gives the logical reasons for this condition. With the thorough grounding in fundamentals which is given, and the development of this critical attitude toward the data on which the design processes are based, his students and readers should avoid the greatest danger for junior or casual designers who have been taught to accept published texts or codes as being statements of fact from which there can be no departure. When they see the variations that exist in practice there is a possibility that they might discard restrictions somewhat indiscriminately.

Because the text deals with fundamentals it should not be inferred that it is elementary and of use only to students. The theoretical principles for all ordinary building design are developed in a logical sequence and clear illustrative problems are worked out for each phase. It covers all such requirements of structural design including fundamentals of continuity and rigid frames, arches and retaining walls.

A perusal by the seasoned designer is warranted, if only to bring a realization of the aggregate of change and development in the past two decades, and the changes that are still proceeding. There is a great divergence of opinion and no accepted practice for the treatment of such subjects as Moment of Inertia of Concrete Sections; Deflection and Time Flow; Torsion; Two-way Slabs, etc., in this book these subjects are discussed freely in the light of this divergence of opinion and their theoretical development is handled more clearly than in most available references.

The index is somewhat scanty and the bibliography is rather limited for a book of reference. Used for the intended purpose as a text book, this deficiency would not be serious.

*Consulting Engineer, Montreal.

## Mechanical Engineers' Handbook

*Robert T. Kent, Editor in Chief and 28 contributors. John Wiley and Sons, Inc., New York (Renouf Publishing Company, Montreal). 1936. 5⅝ by 8⅝ inches. $5.00. Cloth. 1,254 pages.*

The famous "Kent" handbook has for over forty years been the "bible" for mechanical engineers the world over. Now comes an eleventh edition, designed to meet their specific needs even more fully.

A change has been made in the set-up of the book which is now divided into two volumes, one dealing with power and its applications of interest to the mechanical engineer; the other, methods in design and shop practice. These volumes may be purchased separately or in combination, and the engineer will now find all necessary information in each field conveniently gathered in one compact volume. This review will deal solely with the power volume, since the design and shop practice will not appear until the spring of 1937.

In line with the new plan of design of the Wiley Engineering Handbook Series, of which the power volume Kent is number II, this volume measures 5⅝ by 8⅝ inches. The increased size of the book permits the use of large, clear type, illustrations and diagrams a feature which greatly enhances the practicality of the book.

There are seventeen sections in the power volume, followed by an unusually complete index. Section I, Air, includes a description of the properties of air, a discussion of the flow of air, and a full treatment of air compression, including fans and blowers. Section II, Water, covers the fundamentals of hydraulics including material on flow of water, turbines, pumps and pumping engines. Section III, Heat, offers unusually complete handbook treatments of the measurement of heat, heat transmission, evaporators and evaporation, dryers and drying, heat insulation and thermodynamics, and a section on combustion and fuels follows.

Section V gives the necessary information concerning steam and Section VI applies these principles of the action of steam to the steam boiler, offering thorough descriptions of the various types of steam boilers, their performance, construction and other important data. Section VII follows with a discussion of important data concerning the steam engine, while Section VIII covers the types, performance, etc., of the steam turbine. Section IX deals with condensing and cooling equipment, and Section X with refrigeration and ice making.

Section XI presents a very complete summary of the essential information in the field of heating, ventilating and air conditioning. Section XII devotes space to a discussion of internal-combustion engines, including Diesel, gas and gasoline engines. Gas producers receive full attention in Section XIII. Section XIV is entitled Transportation, and covers railroad engineering, automotive vehicles and aeronautics. Section XV gives a brief summary of the fundamentals of electric power, offering much needed information on purchased power, generated power, conversion equipment, switchboard equipment, batteries, power factor and power distribution. The final section gives a complete and accurate set of mathematical tables of vital importance to the mechanical engineer.

## Electrical Engineers' Handbook

*Harold Pender, Editor-in-chief, William A. DelMar, and Knox McIlwain, Associate Editors-in-Chief. John Wiley and Sons, New York (Renouf Publishing Company, Montreal). 1936. 5⅝ by 8⅝ inches. $5 00. Cloth. 1,300 pages.*

The third revised edition of the famous Pender's Electrical Engineers' Handbook appears in a different form than heretofore. Material fundamental to all engineering (i.e. mathematics, physics and chemistry) has been removed to a separate volume—Eshbach's "Handbook of Engineering Fundamentals" published last September. This edition has also been separated into two volumes, one dealing with electric power and the other with electric communication and electronics, which are listed as Volumes IV and V in the new Wiley Engineering Handbook series.

The electric power volume has been consolidated into nineteen sections, each dealing with a general topic. The treatment accorded to each topic has been handled so that each receives attention in accordance with the importance of the subject in relation to other subjects in the field. Controversial matters have been avoided. The section headings include: mathematics, units and symbols; properties of materials; electric circuits and electric lines; resistors, reactors, magnets; measurements and measuring apparatus; principles of electrochemistry; batteries; direct-current machines; alternating current machines; transformers; converters and rectifiers; switching control and protection; power stations and substations; power transmission and distribution; lighting and heating; industrial applications of motors; transportation; electrochemical and electrothermal industries; electricity on the farm.

The electric communication and electronics volume covers the whole field of communication, including telegraphy, telephony, radio broadcasting, point-to-point radio telephony, facsimile transmission and reception, public address systems, sound motion pictures, aviation radio and television. It gives complete information on electronic control systems, for manufacturing processes, theatre lighting, welding, blind-landing of aeroplanes, etc. Materials are arranged in tabular form, with the mechanical and electrical properties listed with each material so that all information about the material is available at a glance. Complete design information is included on all parts of the system: resistors, inductors, capacitors, microphones, loud-speakers, transformers, wave filters, amplifiers, modulators, detectors, oscillators, antennas and power supply units, as well as articles on complete transmitters and receivers. The first section of the book contains complete mathematical tables, etc., logarithms, trigonometric, exponential and hyperbolic functions, decibels, etc., and in the section dealing with electron tubes exhaustive tables are given, including the new metal tubes, thyratrons, photo-sensitive, cathode ray and x-ray tubes. The book is profusely illustrated.

The volume also includes tables of sound absorptive and insulating properties of building materials; complete descriptions of the new facsimile and television systems; including detailed discussion of the special elements required, and a complete discussion of electricity as used in medical work.

## The Professional Engineer

*By Esther Lucile Brown. The Russell Sage Foundation, New York. 1936. 8 by 5½ inches. Cloth. 75 cents. 86 pp.*

This is one of a series of "studies of social conditions" carried out by the Foundation established in 1907 by Mrs. Russell Sage "for the improvement of social and living conditions in the United States of America." The authors of these Foundation studies are members of its staff, or special workers, who have the benefit of the criticism and advice of their colleagues in the organization.

The author of the report now reviewed has covered a wide field in a few pages. This has been possible largely because her work has been based on sound fundamental ideas. She realizes, for instance what is perhaps the greatest source of difficulty in organizing an "engineering profession" namely that "at one end of the scale engineering merges imperceptibly into pure science, and at the other into business."

The report first discusses engineering education and its development, emphasizing the fact that not all who call themselves engineers have occupations which can be recognized as engineering in a professional sense. It is important to distinguish clearly between technicians and professional engineers as regards the nature of their work and the kind of training necessary to qualify them for it. In the United States some one hundred and sixty engineering schools offer courses of professional character and confer degrees; they have over seventy thousand students, and they send out some seven thousand graduates annually. This imposing array of professional schools may be contrasted with the much smaller number of technical institutes whose training fits "for those vocations lying between the skilled crafts and the kinds of engineering work that require prolonged scientific preparation," schools of a type of which more than one hundred and fifty exist in Britain and more than one hundred in Germany. This disparity seems to indicate a need which should be met.

As regards the advancement of professional standards, recognition is given to the leadership shown by the great number of American engineering societies, headed by the outstanding organizations of national scope, whose work has now resulted in the formation of the Engineers' Council for Professional Development.

A well deserved tribute is paid to the achievements of the Society for the Promotion of Engineering Education, the body which, with the aid of the Carnegie Corporation, was the first to make a systematic study of professional engineering training in the United States.

Passing to a survey of the available statistics regarding the number of engineers, the demand for their services and their earnings in various branches of the profession, Dr. Brown points out their rapid growth in numbers, traces the effect of the depression upon their earnings, and very justly remarks that "engineers and architects are likely to be more at the mercy of economic variations than are the professions that offer their services in the main directly to individuals." It is somewhat surprising to find that in her opinion "information concerning salaries is more extensive and authoritative for engineers than for most of the other professional groups." Engineers as a class are evidently more communicative than some of us have believed.

The figures quoted are analyzed and discussed. Space will not permit even a summary of the interesting results which are given, but the present reviewer feels bound to state his full agreement with the author's opinion that an engineer's chances of earning a high salary are greatly reduced if he cannot combine with his technical skill a generous degree of capacity to deal with men and affairs.

The report concludes with some timely comment on the change of conditions during the past thirty years, which has made the majority of engineers employees of corporations, instead of private practitioners, and in some lines of work has led to the almost complete disappearance of the consulting engineer. It now seems that in future the greatest opportunity of the engineer will lie in planning and administration within the ranks of organized industry, and not in individual practice.

The author has packed a surprising amount of information into the 86 pages of her report. The basic facts are well documented and have been ably analyzed; the conclusions are clearly stated. The brevity and completeness of the book are its best recommendations. It should be in the hands of everyone interested in the progress of engineers and engineering.

## Automatic Control of Colliery Tubs

In a colliery the greater the speed with which the coal can be brought to the surface and passed on to its destination, the greater will be the output, and when handling risks can be greatly reduced the benefits to be derived are incalculable, states the Edgar Allen News for December, edited and published by Edgar Allen and Company Limited, Sheffield, England.

There are many fundamental points of similarity between the working of a railway and the working of a colliery. Each has to deal with the moving of large masses of material, from point to point, over pre-determined routes, and to each, speed of operation with proper regard for safety is an important factor.

Their many years of practical experience in such problems in connection with railway operation enabled the Westinghouse Brake and Signal Company to develop systems and apparatus to handle satisfactorily such problems in colliery working.

# BRANCH NEWS

## Halifax Branch

*R. R. Murray, A.M.E.I.C., Secretary-Treasurer.*
*Chas. Scrymgeour, A.M.E.I.C., Branch News Editor.*

The first fall dinner meeting of the Halifax Branch of The Engineering Institute of Canada was held in the St. Julian room of the Halifax hotel, Thursday, November 19th, 1936, there being about twenty-five members present.

The speaker for the evening was Professor G. Vibert Douglas, Professor of Geology of Dalhousie College, who presented a paper based on his experience in metal mining in various parts of the world which included Africa, Belgian Congo, Northern Rhodesia, Europia and Canada. Professor Douglas also had a large number of unusually interesting slides showing the various formations found in the development of these mines, as well as slides of photographs of the mines, his address being particularly interesting and providing for considerable discussion at the end of the address.

Prior to the talk given by Professor Douglas, the chairman of the Halifax Branch of The Engineering Institute, C. S. Bennett, A.M.E.I.C., made reference to the recent loss the Halifax Branch had suffered through the death of Professor F. R. Faulkner M.E.I.C., and in his memory the members observed a two minutes silence. The chairman, in speaking of the deceased member, made particular reference to the work Professor Faulkner had done in the past for the Halifax Branch of The Engineering Institute and said that the Branch had suffered a deep loss of a valuable member.

## Hamilton Branch

*A. R. Hannaford, A.M.E.I.C., Secretary-Treasurer.*
*A. B. Dove, Jr.E.I.C., Branch News Editor.*

"Heat Insulation Tests and Their Value" was the subject of a lecture delivered by Professor E. A. Allcut, M.E.I.C., of Toronto University, to the Hamilton Branch on Tuesday, November 17th, 1936.

The lecturer explained how he had been asked to investigate this subject by the Tariff Advisory Board who were confronted by the importation of insulation which was not standardized in any way. These materials had with them test sheets which actually meant very little, and the Professor was set the task of showing what was necessary in order to make a test sheet of any real value for purposes of comparison.

Professor Allcut described, with the use of slides, the apparatus used in Toronto University to test samples of insulation, both by the simple hot plate method and the hot box method. The conductance is the amount of heat which will pass through 1 square foot of sample in one hour when there is a temperature difference of one degree and is the unit in use during the tests.

A number of slides were shown giving graphical results of a number of tests. In these, the conductivity, which is relative to the conductance, was plotted and attention was directed to the fact that conductivity varied with different thicknesses of specimen, with different mean temperatures, and with variation in the moisture content of the specimen.

The speaker explained that a film of air on each surface of the specimen had to be considered an insulator, and when the thickness of the specimen varied, the proportion of air film to specimen changed, affecting conductivity values. With regard to moisture content, it was shown from actual tests how the conductivity varied with different percentages of moisture.

In selecting an insulator, the buyer must consider first cost, cost of applying and depreciation. Comparable test conditions must obtain to give one a true value of the material. The buyer should also consider the fire resistance and also vermin resistance of the substance.

Quoting from statistics of the Dominion Fuel Board it was estimated that if all the homes in Canada were properly insulated the saving in a year to the country would be in the neighbourhood of thirty million dollars, while the saving in the four cities Montreal, Toronto, Ottawa and Hamilton would be seven millions.

Interesting figures were given as to heat losses from tests made in two hundred homes. The distribution of the heat loss was

| | |
|---|---|
| Roof | 16.2 per cent |
| Walls | 27. per cent |
| Glass | 25.8 per cent |
| Infiltration | 24.6 per cent |
| Doors | 4.3 per cent |
| Other | 2.1 per cent |

and it was estimated that by the use of insulation, weather stripping and storm sash this could be reduced by 13 to 35 per cent.

W. Hollingworth, M.E.I.C., chairman of the Branch, who occupied the chair for the evening, conveyed to the lecturer the hearty thanks of those present.

At the outset of the meeting, Mr Hollingworth welcomed to the meeting the Hamilton Chapter, Ontario Association of Architects, who were headed by Mr. W. J. Holcombe, who is this year the local President. Mr. Holcombe expressed the thanks of the architects and assured the speaker of the evening that the subject was one which was of great importance to architects.

The meeting adjourned at 9.45 and thereafter refreshments were enjoyed. The attendance was seventy-five.

On Tuesday, December 8th, 1936, the Hamilton Branch of The Engineering Institute met at Hamilton Hall, McMaster University, with W. Hollingworth, M.E.I.C., in the chair. The speaker of the evening, D. G. Geiger, A.M.E.I.C., transmission engineer with the Bell Telephone Company of Canada, Toronto, was ably introduced by J. T. Thwaites, Jr.E.I.C.

### Speech and Music

Mr. Geiger opened his address by an explanation of that elusive and somewhat misunderstood relative power term, the "db." or decibel; this is a measure of gain or loss of amplification and is mathematically referred to as the product of the natural logarithm of the db. multiplied by .006, the reference wattage. Thus a power ratio of 10 is a gain, or plus 10 db.

The speaker discussed those factors important to the transmission engineer and to the telephone subscriber or radio listener. Intelligibility must be preserved, he said, by a knowledge of:

(*a*) The physical nature of speech and music.
(*b*) The reaction of the transmission.

The speaker explained that certain sounds are originated at the larynx, while others depend upon the tongue and roof of the mouth alone. The roof of the mouth and nasal cavity act somewhat as an amplifying chamber, amplifying the throat sounds.

In an explanation of musical notes, Mr. Geiger showed that music has its basis in two classes of instrument, namely vibrating strings or air columns. The fundamental note, he showed by comparative slides of various instruments, usually, but not always, has the lowest frequency present. The pipe organ is one exception to this. Timbre or quality is given by the relative amplitudes of the overtones present. The violin gives the purest tone, and has the simplest wave form largely due to the fact that it exists in almost a single frequency This adds much to the enjoyment of the instrument.

In an extensive study of overtones and frequency permissible in radio reception, it was found that little was lost in filtering out the frequencies below 35 and above 8,500 cycles. The newer types of receivers have this broad reception and naturally the tone of such instruments is much more pleasing than the type which cut out the upper or lower harmonics. Station WLW at Cincinnati is an example of up-to-date broadcasting equipment, and has a noticeable quality reception value over the Canadian stations.

Some frequencies are delayed over wire lines and equipment, delays of even 50 milliseconds are noticeable. Amplifiers and magnetic circuits, moreover, must not set up spurious frequencies. Mr. Geiger stated that one frequent difficulty met in transmission engineering was the possibility of cross talk from radio to telephone lines and vice versa. One did not object to music on the telephone, but the public apparently does not appreciate broadcast of its private conversations over a coast-to-coast hookup.

To persons suitably seated a symphonic orchestra frequently has a range of 10 to 70 db. At the amplification value of 10 db. little can be heard above the audience noise. Experiments conducted at Philadelphia with the Philadelphia Philharmonic Orchestra showed perfect reception in Washington by multispeaker arrangements; so natural was the reproduction that the Washington audience believed the orchestra to be in Washington.

Mr. Geiger then, by means of recordings and amplification apparatus, showed experimentally the effect of cutting out frequencies above and below natural C (256 cycles). These experiments included voice, an instrumental trio—piano, French horn and violin—and orchestral arrangements. It was particularly noticeable that, when playing their natural notes, without overtones, the three instruments of the trio could not be distinguished one from the other. This experiment proved the timbre or quality to be due entirely to the presence of the upper harmonics, without appreciable change in volume. The elimination of the lower frequencies detracted from the volume. Mr. Geiger completed his experiments by showing a comparison of orchestral music on the older phonograph records and the new V.E. (Victor Electro) type, and experiments demonstrating delayed frequencies, distortion, acoustic reflection, and overloading of amplifier systems.

At the close of Mr. Geiger's talk, a vote of thanks was moved by D. W. Callander, A.M.E.I.C., of the Canadian Westinghouse Company. Refreshments were served on adjournment.

## Lakehead Branch

*G. R. McLennan, A.M.E.I.C., Secretary-Treasurer.*

The regular monthly dinner meeting of the Branch was held in the private dining room of the Prince Arthur hotel, Port Arthur, on November 18th, 1936. Seventeen members were present and the chairman, F. C. Graham, A.M.E.I.C., presided.

The meeting was held for the discussion of business and to give G. H. Burbidge, M.E.I.C., councillor, the opportunity of presenting his report of the plenary meeting which he attended last September. Considerable interest in the report was evident and it was suggested that Mr. Burbidge make a further report at a later date when more information in regard to the plenary meeting is in the hands of the members. A vote of thanks to the speaker was moved by J. M. Fleming, A.M.E.I.C., and seconded by B. A. Culpeper, A.M.E.I.C.

A resolution in regard to the status of the engineer was passed and the secretary was instructed to forward the resolution to the secretary of The Institute.

Mr. Burbidge extended an invitation to all university graduates to attend the dinner on the 27th of this month to be given under the auspices of McGill graduates of the Lakehead in honour of Mr. Stephen Leacock.

## Lethbridge Branch

*E. A. Lawrence, S.E.I.C., Secretary-Treasurer.*
*R. F. P. Bowman, A.M.E.I.C., Branch News Editor.*

On the afternoon of Saturday, October 17th, 1936, members of The Institute and friends inspected the surface plant of the new Galt Mine No. 8, of the Lethbridge Collieries, Ltd. The party viewed with interest the modern tipple equipment, and the new electrical hoisting machinery. The boiler plant, workshops and other lesser buildings incidental to a coal mine were visited and explained by mine officials.

In the evening the regular dinner meeting was held at the Marquis hotel. After the usual musical programme the speakers for the evening, two in number, were introduced by J. B. de Hart, M.E.I.C. The first speaker was Wm. Meldrum, A.M.E.I.C., engineer for the Lethbridge Collieries. The guest speaker was Mr. E. J. Carlyle, of Montreal, present General Secretary of the Canadian Institute of Mining and Metallurgy.

### The Galt Mines' Fourth Venture

In introducing the subject, Mr. Meldrum dealt briefly with the economic limitations on the life of a coal mine. From experience, one might estimate the total output for the new No. 8 Galt Mine to be 5 million tons of coal, beyond which the cost of such factors as long main entries, ventilation, haulage, etc., becomes prohibitive. Based on the approximation of 4,000 tons per acre, the workable area is then limited to about 5,000 feet in radius.

The history of the Galt interests in this field began in 1883, and by 1935, the year of closing Galt Mine No. 6, 10,648,000 tons of coal had been produced. Erection of the new mine began in 1934, and the aim is 1,000 tons of coal per day.

The hoisting and air shafts are each 354 feet deep, and from these the main entries radiate in a coal seam 4 feet 10 inches in thickness. The system of underground workings, and also the modern electrical coal cutters were dealt with at length by the speaker.

### One Troy Ounce of Gold

"Civilization follows the miner," to quote Mr. Carlyle, and in Canada this fact is doubly true. The perseverance of the miner has lifted the barrier and pushed civilization back into Canada's wooded northland. In January, 1934, the price of gold sky-rocketed to $35.00 per ounce, thus adding great stimulus to gold mining activity. Canada's share of the world's gold last year was 11 per cent, valued at $100,000,000.

The "Troy Ounce," originating in France, was adopted into England by Edward III for weighing precious stones and jewels. It runs about 10 per cent heavier than the customarily used avoirdupois ounce.

By a number of interesting comparisons, Mr. Carlyle stressed the fact that gold occurs in ores in extremely minute quantities, and winning the precious metal from the gangue material is the problem of "finding a needle in a haystack."

Chemical analyses and microscopic examination are the tools of the successful ore-dresser in extracting the gold, because they show him how the gold is associated with the other minerals. The operation of cyanide extraction of gold was discussed by the speaker, who explained that this is the predominant method used in Canada today.

A simple sketch enlightened the listeners on the underground layout of a typical gold mine, serving to familiarize them with the mining terms used.

Following the talk proper, Mr. Carlyle, upon request, delighted the gathering with a few interesting and humorous reminiscences of his world-wide travels and experiences.

On Saturday, November 21st, 1936, the members of the Lethbridge Branch of The Engineering Institute of Canada with their wives and friends paid a visit to the recently completed beet sugar refinery of the Canadian Sugar Factories Ltd., at Picture Butte. Approximately ninety were in the party, and during the afternoon they were shown through the plant by the members of the technical staff of the company. Following this a dinner was served in the company's dining hall. Community singing and solos were enjoyed.

### The Manufacture of Beet Sugar

Mr. F. H. Ballou, chief engineer of Canadian Sugar Factories Limited, gave an address, in which he gave an historical outline of the beet sugar industry, which had its origin in Germany about 1747, but it was fifty years before a practical process for commercial production of sugar from beets was developed. Napoleon Bonaparte encouraged the industry with the result that by 1812 there were forty factories in France.

In the process followed on this continent the raw beets are brought from the farms and either stored in large piles or delivered directly to the wet hoppers and carried by water to the trash house where sand, leaves, rock, etc., are removed. A large beet wheel raises the beets from the flume, draining off the flume water and discharging them into the beet washer where they are agitated in clean water and passed to the roller table where further dirt is removed. The clean beets are then elevated to the beet hopper being hand picked for rotten beets and are passed over a magnetic pulley. Next the beets go to the slicers and are cut into shreds called cosettes and discharged onto a conveyer belt on which they pass over a weightometer and thence to the diffusion battery, a series of 14 upright cylinders each with a capacity of 4 tons of cosettes, where hot water at 55 degrees Centigrade is circulated to remove the sugar from the beets by osmotic action. The juice thus removed is treated with a milk of lime and carbonic acid gas, which precipitates some of the non-sugars. The juice is then given another carbonation of an alkalinity differing from the first treatment, resulting in the precipitation of more non-sugars, leaving a juice which contains about 17 per cent sugar; which is then treated with sulphur dioxide, neutralizing the alkalinity and having a bleaching action.

The juice next goes to the evaporators where the water content is reduced in a series of tanks operating under varying pressure conditions. Melted sugar is added to the thickened juice and the sulphur treatment repeated, followed by another filtration, after which the juice is boiled under reduced pressure and the first crystalization takes place, the crystals being separated from the mother liquor in high speed centrifugal machines. The mother liquor is twice treated and further sugar extracted till finally only a molasses is left which is used either as a cattle feed or is treated further at the Raymond plant of the company and still more sugar extracted.

The sugar from the centrifugals is dried and elevated to the top of the packing house where it is bagged or is passed to the bulk storage bin.

The average season for a plant of the type at Picture Butte is a seventy-five-day run during which about 100,000 tons of beets are handled and about 298,000 100-pound bags of sugar produced. A staff of two hundred and forty-six is required in and about the factory during the run.

The meeting also heard from Mr. Geo. Wood, district manager of the sugar company, and Mayor D. H. Elton of Lethbridge. A hearty vote of thanks to the speaker and the Sugar Company was proposed by C. S. Donaldson, A.M.E.I.C., and heartily endorsed by those present.

The Lethbridge Branch of The Engineering Institute of Canada met in the Marquis hotel on Saturday evening at a special Ladies night. Major Cross was the speaker. A musical programme followed the dinner, to which solos were contributed by Mrs. Wm. Meldrum and Geo. Brown, Jr. Community singing was also enjoyed.

The speaker of the evening was introduced by G. S. Brown, A.M.E.I.C. He is superintendent on the Eastern irrigation project at Lethbridge, and designed the War Memorial for The Institute now in headquarters.

Major Cross said that in Canada we live in a new country and so are builders. And to build well we must build on the knowledge of past accomplishment, the accomplishments of other peoples and civilizations. For example, the work of the Romans in Britain.

The Romans exhibited wonderful engineering in their works, for example the hot air ducts in the baths are perfect, and the tile of which they are constructed is better than that generally made today. Many of these old arts and crafts are lost.

Major Cross was much impressed, during a recent visit to England, by the railways, which although moderate in price, were both fast and comfortable. He was also impressed by the great port of Manchester, and by the display of naval power at the review of the navy by the late King. Recent industrial developments were large, and there is a great boom in home and apartment building.

The speaker showed a film which illustrated how beauty was related to line, colour, and light and shade, its development and uses, and showed its application in modern industry.

A vote of thanks was moved to the speaker by Mr. F. A. Rudd, after which the members adjourned to the mezzanine for bridge.

## London Branch

*D. S. Scrymgeour, A.M.E.I.C., Secretary-Treasurer.*
*Jno. R. Rostron, A.M.E.I.C., Branch News Editor.*

The regular monthly meeting of the Branch was held on October 20th, 1936, in the City Hall auditorium. Jas. Ferguson, A.M.E.I.C., chairman of the Branch, presided.

The speaker of the evening was Mr. W. O. LeBere of the Canadian National Railways, who is engaged in accident prevention work.

After the reading of the minutes by the secretary, the chairman introduced the speaker.

### Safety in the Erection of Steel

Attention was called to the necessity of the foreman keeping an eye on the condition of his men when reporting for duty. The plan recommended by the speaker, and which he adopts, is to address the men before they start and call their attention to the necessity of care and caution in their work not only for their own safety but that of their fellow-workers. This has the effect of making the men appreciate the effort to safeguard them and stimulates in them a desire to co-operate.

The next point stressed was the necessity of thoroughly overhauling and testing all equipment before use in the field, particularly with regard to cable used in hoisting. In the case of handling heavier loads than usual or in the use of special equipment, the method of operation should be first discussed with the foreman and the strength of the equipment worked out from the engineering angle and not left entirely to the foreman's judgment in the field.

Two prolific sources of accident were named, one being improper and insufficient plank gangways in buildings and hanging scaffolds for riveting both in building and bridge work. Regarding the latter the speaker favoured what is called the ship scaffold, consisting of a plank deck 4 or 5 feet wide and 6 or 8 feet long hung by manilla rope at each corner, as against slinging pipes or beams with loose planks laid on them.

Accidents will happen, and before starting a job of any size full consideration should be given by the contractors and engineers as to what to do when they occur. A first-aid station should be established with a competent man in charge, a survey of the district made and the best doctor for accident work selected and also the nearest suitable hospital. Then, having decided these matters, definite instructions should be given to the foreman and men as to how to act in a case of emergency. Not only were these precautions necessary from a humanitarian point of view, but also from an economic standpoint, in preventing excessive loss from compensation, etc.

The speaker concluded his remarks by making a prophecy of the measures that would be taken during the next fifty years in promoting accident prevention, and the reasons for it.

An interesting discussion followed the speaker's talk and the meeting adjourned after a vote of thanks was proposed by J. R. Rostron, seconded by H. A. McKay, A.M.E.I.C., and unanimously carried.

The regular monthly meeting of the Branch was held on November 25th, 1936, in the board room of the Public Utilities Commission in the city hall.

After the reading of the minutes, the speaker of the evening, J. A. Vance, A.M.E.I.C., was introduced by the chairman, James Ferguson, A.M.E.I.C., who pointed out that Mr. Vance's subject was "Consolidation of the E.I.C. and the Provincial Associations of Professional Engineers" and that as Branch Councillor, Mr. Vance would be able to tell the members of the proceedings up to date on this subject.

Mr. Vance opened by giving a short description of events leading up to the formation of the Dominion Council with C. C. Kirby, M.E.I.C., of New Brunswick, as chairman, and A. B. Crealock, M.E.I.C., of Toronto, as vice-chairman.

He enumerated some of the recommendations of this Committee and went on to the discussion of Council on these matters at its meeting on September 18th, 1936. The most contentious recommendation was that of Section 7 (*b*) which stipulates that in a province whose association becomes Component, a prospective member must be a member of the association before he can be admitted to corporate membership in The Engineering Institute.

The speaker pointed out that the present members of each body would not be affected by this ruling except that all association members would be admitted to The Institute upon application duly made. He read extracts from the minutes referring to this and also copies of correspondence from various engineers both agreeing and disagreeing.

Mr. Vance then took up the question of fees, and stated that it was proposed to abolish the class of Associate Member of The Institute, all present Associate Members becoming Members, and to fix the annual fee for Members at $1.00 more than is now paid by Associate Members. This increase is necessary in order to meet the loss incurred by what would otherwise be a $2.00 reduction of Members' fees.

It was felt by many present that this would mean a loss of new membership to The Institute, for undoubtedly a large number after gaining admission to the Association would not go any further.

Mr. Vance stated the position of affairs exhaustively and quite impartially for the benefit of members present.

A long discussion followed the speaker's remarks; many opinions were expressed but no resolution was passed.

After a hearty vote of thanks to the speaker the meeting adjourned.

## Montreal Branch

### Observations on European Railroad Motive Power

On November 26th, 1936, Mr. A. I. Lipetz, chief consulting engineer in charge of research for the American Locomotive Company, presented a paper before the Montreal Branch of The Institute, describing his European experiences with the Moscow-Kiev-Voronesh Railway. Mr. Lipetz outlined recent European and American railway developments, his address being illustrated with a number of excellent slides.

Previous to the meeting an informal dinner was held at the Windsor hotel, and a special general meeting of the Branch was convened to elect three members on the Branch Nominating Committee.

H. H. Vaughan, M.E.I.C., was in the chair.

### Junior Section

"Patents, their Value and How they are Obtained" was the title of the address given by Mr. Alan Swabey before the Junior Section of the Montreal Branch on November 30th, 1936.

Virgil S. Upton, S.E.I.C., also spoke on the "Design and Manufacture of Aircraft." Mr. Upton, who is chief stress analyst at the Noorduyn Aircraft Limited, St. Laurent, Que., described the steps taken from the time specifications are laid down until the aircraft is test flown. Motion pictures of test flights were shown.

P. E. Savage, S.E.I.C., acted as chairman.

### Recent Advances in Electric Welding

At the meeting of the Montreal Branch held on December 3rd, Mr. H. Thomasson, welding engineer with the Canadian Westinghouse Company, spoke on recent advances in electric welding, describing a newly developed process for arc welding, and on present trends in arc welding design. The paper was illustrated with slides and specimens. This paper appears in full in this issue of The Journal.

Prior to the meeting an informal dinner was held at the Windsor hotel.

D. C. Tennant, M.E.I.C., occupied the chair.

### Town Planning in Montreal

H. A. Terreault, M.E.I.C., addressed the Montreal Branch on December 10th, his talk including a 3-point plan for Greater Montreal under the headings of traffic congestion relief, zoning laws, and parks and playgrounds.

A number of members of the Province of Quebec Association of Architects were present at the meeting, following which light refreshments were served.

The chairman was Leonard Schlemm, M.E.I.C.

### Junior Section

"Steel Rails" was the subject of a talk by Hugh J. Gordon, S.E.I.C., at the meeting of the Junior Section of the Montreal Branch held on December 14th. The speaker reviewed such features as the history, problems arising from service, stresses, defects and their detection, and some of the more recent developments in steel rails.

The second speaker, V. F. Crowley, described the manufacture of high tension porcelain insulators, his talk being illustrated with motion pictures.

R. Warnock, S.E.I.C., acted as chairman.

## Ottawa Branch

*F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.*

### Preservation Treatment of Structural Timbers

At a noon luncheon at the Chateau Laurier on November 5th, 1936, J. F. Harkom, B.Sc., A.M.E.I.C., of the Forest Products Laboratories of Canada, gave an address upon "Preservation Treatment of Structural Timbers."

E. Viens, M.E.I.C., chairman of the Ottawa Branch, presided and in addition head table guests included: Colonel A. E. Dubuc, M.E.I.C., Commander C. P. Edwards, A.M.E.I.C., R. L. Sargent, J. M. Wardle, M.E.I.C., F. H. Peters, M.E.I.C., R. A. Gibson, D. Roy Cameron, M.E.I.C., T. A. McElhanney, A.M.E.I.C., F. G. Smith A.M.E.I.C., and A. K. Hay, A.M.E.I.C.

Mr. Harkom gave the chief causes of deterioration or destruction of timber in service as weathering, insects, marine borers, fire and decay. After dealing rather briefly with the first four he dwelt at length upon the subject of decay and of methods of retarding it, particularly by the use of preservatives. These latter he divided into two classes: oils such as creosote or mixtures containing creosote, and water soluble salts such as zinc chloride.

He also described laboratory methods for the testing of preservatives and indicated the different treating schedules required to obtain best results with different Canadian woods. His complete address will be published in The Engineering Journal.

### The Stone of the Vimy Memorial

At a noon luncheon at the Chateau Laurier on November 19th, 1936, M. F. Goudge, Ottawa, gave an address to the Ottawa Branch on the stone used in the construction of the Vimy Memorial. Mr. Goudge, who is an engineer on the staff of the Department of Mines engaged in investigational work on building stone, marble, and limestone, was present at the unveiling of the Vimy Memorial during the past summer and subsequently obtained much interesting information on the quarrying of the stone and on the details of the construction of the Memorial. His address was illustrated with lantern slides. E. Viens, M.E.I.C., chairman of the Ottawa Branch, presided and in addition head table guests included: A. L. Watson, Col. A. F. Duguid, A.M.E.I.C., G. J. Desbarats, Hon.M.E.I.C., J. M. Wardle, M.E.I.C., F. C. C. Lynch, A.M.E.I.C., John McLeish, M.E.I.C., A. F. Macdonald, P. Sherrin, A.M.E.I.C., B. H. Segre, A.M.E.I.C., Group Captain E. W. Stedman, M.E.I.C., and C. M. Pitts, A.M.E.I.C.

The stone is a beautiful cream colour quite unlike the limestones usually seen in this country. It shows up very plainly in the daylight and when floodlighted at night the Memorial can be seen for miles. It came from a quarry in Dalmatia which had been last used by the Romans under Diocletian in 305 A.D.

The clearing of the site for the Memorial itself was quite an arduous undertaking and the basement was built on a concrete raft two feet thick resting on chalk.

The stone was cut to order at the quarry and each stone was numbered to occupy a certain place in the finished memorial.

Several other large memorials are located in France and Belgium, stated Mr. Goudge, but in his opinion the Vimy Memorial was the finest of them all. In it there was no trace of vindictiveness or of the conquering spirit, but rather of the sadness, sacrifice, and utter futility of war.

Methods of quarrying the stone and engineering problems that had to be met in the construction of the memorial were detailed by the speaker with the aid of the pictures.

#### Changing Over to the Dial System

F. D. Laurie, local manager of the Bell Telephone Company, gave a talk at the noon luncheon at the Chateau Laurier on December 3rd, on "Changing over to the Dial System." He also presented motion pictures illustrative of the recent advances made in trans-oceanic telephony.

The introduction of the dial system in Ottawa, he stated, would be of an evolutionary rather than a revolutionary nature and no hardship would result to the operating staff. The first changes would be made late in 1937 and others would follow until the entire change was made.

He paid tribute to the wonderful work of the scientists and engineers and their dogged persistence in overcoming the many difficult problems met with to perfect a system which so well meets the business and social demands of the day. Since its early days of sixty years ago improvement has been effected to every feature of telephonic communication; lines, switchboard, apparatus; and in this improvement scientific research has played a major part.

With the motion pictures the types of apparatus used on shore and on shipboard to maintain telephonic communication were illustrated. As an indication of advances that have been made the speaker stated that on a recent round the world cruise experimental telephonic communication had been established to New York City from points half-way across the Pacific, from the Indian Ocean and from the Red Sea.

E. Viens, M.E.I.C., chairman of the local Branch, presided and additional head table guests included: Hon. C. D. Howe, M.E.I.C., Mayor Stanley Lewis, Commander C. P. Edwards, A.M.E.I.C., A. H. Fitzsimmons, R. F. Howard, M.E.I.C., John McLeish, M.E.I.C., J. M. Wardle, M.E.I.C., Dr. S. F. Kirkpatrick, T. L. Simmons, M.E.I.C., J. E. St. Laurent, M.E.I.C., Group Captain E. W. Stedman, M.E.I.C., J. G. Macphail, M.E.I.C., V. M. Meek M.E.I.C., and John Murphy, M.E.I.C.

## Peterborough Branch

*W. T. Fanjoy, A.M.E.I.C., Secretary-Treasurer.*
*E. J. Davies, A.M.E.I.C., Branch News Editor.*

#### Annual Dinner

The annual dinner of this Branch was held on Tuesday, November 17th, 1936, at the Empress hotel, with a good attendance of members and guests. H. R. Sills, A.M.E.I.C., Branch chairman, presided. A message from the President was read and responded to by Vice-President R. L. Dobbin, M.E.I.C. A feature of this dinner was a presentation, in absentia, to Mr. B. L. Barnes of an Honorary Affiliated Membership in this Branch in recognition of many years of valuable service to the E.I.C.

The speaker of the evening was Mr. Desmond Killikelly, assistant to the vice-president, Steel Company of Canada, Montreal, who spoke on the subject, "Canada in the Midst of the World's Political Unrest." Mr. Killikelly gave a very vivid and different viewpoint of this question to the gathering. He warned that the issues facing the world to-day are a direct challenge to democracy wherever it exists, and are a threat to the safety of civilization and of Christianity itself.

Pointing out Canada's part in the scheme of current affairs and the responsibility of Canadians as individuals, the speaker declared he was a firm believer in a militant democracy, even as he is a believer in a militant Christianity.

He stated there is no war which threatens the peace of the world in which Canada has no direct concern, all talk of pacifism or neutrality to the contrary.

The speaker described "unity of all the peoples of Canada" as one of the great needs because there are already too many unhealthy symptoms of unrest and dissatisfaction with the status quo.

Mr. Killikelly said, "We should ever be on the alert, ever watchful, ever ready to lend a sympathetic ear, and to try and understand the other fellow's grievances, problems or point of view. Otherwise we fertilize by indifference, neglect or prejudice the soil in which Fascism, Bolshevism or Anarchy flourish.

"We have a heritage to guard. Is it worth saving? Is our civilization a worthy patrimony to leave our children? Let us turn back to God and the humanities of life in a united effort to save our achievements from the plague which threatens; keep our minds free from the prejudices of race, language or religion, and unsoiled by falsehoods one towards the other. This is not a mere hour of politics which attracts our attention—it is an hour of national importance."

#### Concrete Highways

The regular monthly meeting was held on December 10th, at which the speaker was D. O. Robinson, A.M.E.I.C., publicity engineer, Canada Cement Company, Toronto.

Mr. Robinson gave a very interesting and thorough discourse on this subject, in which he emphasized the fact that the main consideration in the construction of concrete highways was a satisfactory, permanent and lasting surface, as this was the greatest factor which would induce the construction of further roads.

Mr. Robinson took as an example the construction of a concrete road to replace a first class gravel road and led his hearers through all the steps from resurveying of the existing road to check for grades and curves, through the location, selection, grading and washing of materials, to the actual laying and finishing of the road. He mentioned in detail the many steps involved both by the contractor and the Department of Highway Engineers to check and test in order to be assured that the finished road was uniform throughout.

## Saskatchewan Branch

*J. J. White, M.E.I.C., Secretary-Treasurer.*

The Papers and Library Committee of the Saskatchewan Branch of The Engineering Institute arranged a summer meeting in the nature of a trip to the Fort Peck dam near Glasgow, Montana, U.S.A. The trip was well organized by R. W. Allen, M.E.I.C., of Regina. Starting from Regina on September 18th, 1936, the party travelled by motor to Glasgow, spending all the day of September 19th at the dam and returning on September 20th.

At Fort Peck the party of twenty-five members of the Branch and their friends were the guests of the United States War Department, which Department had full charge of the construction work under the supervision of the Divisional Engineer, Missouri River District, Kansas City, Mo.

Looking after the pleasure and instruction of the party at the dam was Paul A. Harper. Mr. Harper arranged parties to visit the points of interest, these parties being supervised by competent guides capable of discussing the various phases of construction which were many on work of such magnitude.

The primary engineering purpose of the Fort Peck dam on the Missouri river is the improvement of navigation in the new 8- to 9-foot channel below Sioux City, Iowa, with incidental purposes of flood control and the prevention of bank erosion.

In addition to the strictly engineering purposes, the dam is being constructed at this time to provide work for the unemployed. Employment on July 15th, 1936, was 10,546.

The maximum height of the dam will be 242 feet above the river bed; the length of the main section across the river valley will be about 9,000 feet. The reservoir created by the dam will store 19,412,000 acre-feet of water, and will have a maximum surface area of 245,000 acres.

Four diversion tunnels to carry the Missouri river around the dam and also to control the release of water from the reservoir are being constructed under the right (east) bank. Work commenced on the tunnels in May, 1934. Each will have a finished inside diameter of 24 feet 8 inches, and will vary in length from 7,261 to 5,386 feet.

A flood spillway is being constructed on the east side of the river, approximately three miles from the dam by airline, and is designed to discharge a maximum of 255,000 cubic feet of water per second.

Stripping of overburden from the base of the dam, involving excavation of 4,153,530 cubic yards, was carried on during the summer and fall of 1934.

Construction has been completed on a cut-off wall of steel sheet piling along the axis of the dam. The piling was driven to a maximum depth of 163 feet below the surface to the underlying shale bedrock and extends approximately 20 feet above the original ground surface into the core of the dam. The wall is 10,146 feet long and contains 34,000,000 pounds of steel.

The dam is being constructed of earth by the hydraulic-fill method using four 28-inch, 12,500 h.p. electrically-operated dredge units which were built at the site by the government. On October 13th, 1934, one dredge commenced digging, and up to August 1st, 1936, a grand total of 35,063,250 cubic yards, or over one-third of the total amount required, had been placed.

In order to move the vast quantity of construction materials required for building the various features of the project, a railroad 12.2 miles in length, running from Wiota on the main line of the Great Northern, to the dam, was completed in April, 1934. It is estimated that 12,000,000 tons of material will be transported over this line.

Because of the inaccessibility of the damsite and the sparse population, it was necessary to construct a town, complete in all details, to house the workers on this large project. All heating is by gas, for which purpose an 8-inch line has been constructed from Glasgow to Fort Peck. A 154,000-volt, 50,000-kw. power line, 286 miles in length from Rainbow Falls to the damsite, was completed in September 1934. This line furnishes power for the dredges and all other construction purposes and for business and domestic use in the town of Fort Peck.

At the present time nothing is foreseen which will prevent the orderly completion of the project by the fall of 1939.

The proposed October meeting of the Saskatchewan Branch of The Institute was cancelled in order to join forces in a meeting with the Association of Professional Engineers of Saskatchewan. A number of Institute members were present at the dinner meeting which was preceded by attendance at the final game of Regina vs. Winnipeg in the Western Canadian Rugby Conference.

Some Modern Highway Tunnels and Long Span Bridges

The November meeting of The Institute was held on November 20th at the Champlain hotel, Regina, with thirty members in attendance. This was a dinner meeting, and the guest speaker was Professor R. A. Spencer, A.M.E.I.C., of the faculty of engineering, University of Saskatchewan, Saskatoon. Stewart Young, M.E.I.C., acted as chairman of the meeting.

During the business session R. W. Allen, M.E.I.C., chairman of the Papers and Library Committee, suggested that the Branch hold a meeting of the Kipling Camp at some convenient time during the winter months. Subsequently arrangements were made to hold this Camp, Mr. Allen acting with the Saskatchewan Secretary of the Camp, J. W. D. Farrell.

Mr. Young introduced Professor Spencer, whose topic was "Some Modern Highway Tunnels and Long Span Bridges." The speaker first pointed out that, if it is arbitrarily assumed that a long span bridge of to-day is one of a clear span of 1,000 feet or over, there is only one example in Great Britain, one in continental Europe, one in Australia, two wholly in Canada, and that all the others are in the United States. He then went on to show that the problem of the long crossing for highway traffic really began in about 1914, when there was a sudden upturn in the registration of motor vehicles. In that year, as an example, registration was two millions in the United States and there was a steady increase to over twenty-six millions in the year 1929. The problem began to be acute in certain sections in about the year 1920.

The construction of the Holland tunnels and the George Washington bridge was reviewed in some detail as examples that had far-reaching influence. Further late bridge and tunnel construction work in the New York area was then shown by means of slides. This was followed by brief comments on a number of late similar developments in other parts of the world.

In closing, the speaker compared the relative advantages and disadvantages of bridges and tunnels as regards construction and operating costs, traffic capacity, ease of access, etc. About one hundred and twenty-five lantern slides were shown to illustrate various features of the address.

The paper was followed by much interesting discussion and a hearty vote of thanks was moved by A. P. Linton, M.E.I.C.

## Sault Ste. Marie Branch

*N. C. Cowie, Jr.E.I.C., Secretary-Treasurer.*

The Sault Ste. Marie Branch of the Engineering Institute of Canada held a general meeting for members and guests at the Windsor hotel, Sault Ste. Marie, Ont. on November 30th, 1936.

Dinner was served at 7.00 p.m. to twenty members and guests in the hotel grill room.

Wm. Seymour, M.E.I.C., vice-chairman of the Branch, presided at the meeting, which commenced at 8.00 p.m. A few items of business were speedily attended to. The chairman then introduced O. A. Evans, Jr.E.I.C., of the Algoma Central Railway Mines Department, who spoke on "Gold."

Mr. Evans covered this timely subject in a general way, confining himself, as he stated in his introduction to a short synopsis of the properties, production, distribution and other interesting features of gold.

Mr. Evans' paper was well received by the meeting and was followed by a lively and interesting discussion by the members.

F. Smallwood, M.E.I.C., seconded by C. Stenbol, M.E.I.C., conveyed to Mr. Evans the appreciation of the meeting for his interesting paper.

## Vancouver Branch

*T. V. Berry, A.M.E.I.C., Secretary-Treasurer.*

Annual Meeting

The annual meeting of the Vancouver Branch was held at the Hotel Georgia on the evening of November 23rd, 1936. Thirty-eight sat down to dinner. At the head table with the Branch chairman, James Robertson, M.E.I.C., sat chairman-elect H. N. McPherson, M.E.I.C., vice-chairman elect Colonel J. P. McKenzie, M.E.I.C., President E. A. Cleveland, M.E.I.C., Past President Geo. A. Walkem, M.E.I.C., and the guest speaker of the evening, Mr. Rowe Holland, chairman of the Vancouver Parks Board.

Immediately following dinner, the financial report of the Branch for the year 1936 was presented by the secretary-treasurer, and the election of officers for the year 1937 held.

Dr. Cleveland, President of The Institute, briefly addressed the meeting on the problem of the consolidation of the engineering profession in Canada. He discussed the various controversial points raised by the branches and the Professional Associations. He expressed the opinion that much progress had been made towards the common objective and urged that when the final recommendations of Council are placed before the individual members during 1937, that they examine these recommendations with an open mind and free from sectionalism and partizanship, that the best interests of the profession may be served in Canada.

The guest speaker of the evening, Mr. Rowe Holland, a prominent Vancouver barrister and chairman of the Vancouver Parks Board, was introduced by P. H. Buchan, M.E.I.C.

Mr. Holland gave an inspiring and thoughtful address on his conception of the part played by the scientist and the engineer in the march of civilization. He characterized his early impressions of the engineer as being a "hard fisted realist" but later thought and experience matured his conception of the engineer as a "dreamer whose dreams come true." Behind all planning, labour and effort on the part of the engineer there are years of vision and dreaming. The engineer is a pioneer of thought—one who rends aside the veil that separates our tomorrows from our todays. The speaker expressed his opinion that through the efforts of the scientist and the engineer, civilization will gradually advance until mankind will elevate, and as he termed it "become a race of angels."

Major W. G. Swan, M.E.I.C., tendered the thanks of the meeting to Mr. Holland for his interesting and thought-provoking address.

## Winnipeg Branch

*H. L. Briggs A.M.E.I.C., Secretary-Treasurer.*

Junior Engineers' Association Evening

As a preliminary to the presentation of two papers by members of the Junior Engineers' Association, on December 3rd, 1936, G. E. Cole, A.M.E.I.C., described a number of interesting and humorous experiences relating to his early mining career, in No. 3 of an "I Remember" series being carried out at each meeting of the Branch by the senior members.

Engineering Generalities

A. Sandilands, S.E.I.C., proceeded to discuss the ethics of the engineering profession, and the relation of an engineer to other engineers and to the public. The engineer has no right to think only in terms of the generation of which he is an individual. He must continually scrutinize himself and his outlook—if he does not find things as he would like them, then he should co-operate to secure the changes desired. Regarding remuneration, the real engineer will consider himself well paid when he is able to experience that inner satisfaction of a job well done.

Recent Improvements in Telephone Communication Equipment

T. A. Lindsay described the modern telephone hand-set of the cradle type, scientifically correct in many more respects than the type of instrument it replaces. He told of a highly efficient magnetic type telephone which has been developed which requires no batteries to operate. It can be used over 30 miles of standard cable or 200 miles of open wiring, the voice transmission being remarkably free from distortion and from frying noises. Another development is a static frequency converter, whereby 60-cycle power is converted to 20-cycle pulsations suitable for ringing purposes, by means of a static network except for a starting relay.

Those taking part in the discussion which followed included N. M. Hall, M.E.I.C., E. V. Caton, M.E.I.C., F. G. Goodspeed, M.E.I.C., F. W. Alexander, M.E.I.C., and A. J. Taunton, M.E.I.C. The vote of thanks to Mr. Cole, the Junior Engineers' Association, and to Mr. Sandilands and Mr. Lindsay was proposed by H. M. White, M.E.I.C.

Secession Movements in Canada

On November 19th, 1936, Professor R. O. Macfarlane, Ph.D., of the Department of History, University of Manitoba, presented to the Branch some thoughtful observations upon a number of separatist movements which are present in greater or lesser strength in all provinces in Canada to-day.

The main national east and west boundary is at right angles to the natural economic lines, which are north and south. Canadian Confederation is an economic and political compromise, involving the giving up of certain rights which are often quite real, for other benefits which may not be so apparent. Confederation came just after the American Civil War. It appeared to the framers of the British North America Act that in the United States constitution too much power had been given the individual states and too little to the federal government. The British North America Act represents their efforts, among other things, to build a strong enough central power to overcome the difficulties which had shown up in the American union.

Continuing with individual cases, Professor Macfarlane pointed out that Canadian protectionist policy had been hard on the Maritimes. Also, the other provinces had received immense tracts of Dominion lands in their boundary extensions, whereas the Maritimes had not. They have blamed Confederation for their difficulties. Quebec, the speaker said, has recently developed strong fascist tendencies. Ontario believes that she is paying the piper for the other provinces. The prairie provinces have developed strong localization tendencies. Alberta has isolated herself economically by means of a radical credit structure. British Columbia has strong interests relating her to the south. In judging Confederation, then we must remember that it is a compromise.

Those taking part in the discussion included J. H. Edgar, A.M.E.I.C., and J. W. Porter, M.E.I.C. A vote of thanks to the speaker moved by F. W. Alexander, M.E.I.C., was heartily supported.

Previous to the main paper, Major J. H. Edgar, A.M.E.I.C., presented some humorous excerpts from the book "History of Canadian Railways," of which he is a co-author. He drew attention to the marked effect of the railways upon effective Canadian Confederation and noted that the greater amount of railway construction had occurred since 1867, with a standard gauge. In contrast with this is the case of Australia, federated in 1901, at which time each of the five states had its own railway lines, each of a different gauge.

The chair was occupied by G. E. Cole, A.M.E.I.C.

## The Motorways of Germany

In view of the present road situation in this country, any information about road procedure and practice elsewhere is of value, and considerable interest is likely to be taken in the particulars relating to the new arterial motor roads in Germany which were given by Herr Schmoelder, in a lecture delivered at the College of Technology, Manchester, on Monday, November 16th. Herr Schmoelder, whose lecture was entitled "The Motorways of Germany," dealt first with the programme of construction, which was begun in 1934. It is proposed to construct six motorways, two running roughly from north to south, and the other four from east to west. The total length will be about 4,500 miles, and the rate of construction is expected to reach 650 miles a year; over 750 miles have already been completed. The motorways are designed solely for mechanical transport, and connections to the ordinary road system are made only at large towns.

In general, the roads are divided into two tracks, each 20 feet 6 inches wide, separated by 14-foot strips, with haunches 3 feet wide at the edges. These haunches are laid early, and are used as foundations for the rails carrying the construction plant. The thickness of the concrete slabs is 8 to 10 inches, with steel mesh reinforcement at 4 pounds to the square yard; a camber of 1½ per cent is given to the road surface. The normal cement content of the concrete is 528 pounds per cubic yard. In the earlier work, the concrete was laid in two courses, the upper being of better quality, but single-course construction with uniform concrete is now adopted. The transverse joints are spaced at intervals of 26 to 65 feet, according to the conditions; they are of the standard dowelpin type, with bituminous fillers. The concrete is laid on waterproof paper, and all the subsequent operations are performed by machines spanning the track and running on a rail on each side of it. Full width construction is the general rule. The aggregate and cement are proportioned by weight at a mixing plant, and conveyed to the work by skips drawn by a locomotive running on a temporary track beside the road. The mixer delivers into distributor buckets which deposit the concrete in position. This is followed by a finishing machine, which levels the surface, tamps and vibrates it. Hand finishing is rarely used. The freshly-deposited concrete is protected against the weather by canvas coverings until it has set, and is afterwards kept wet for three to four weeks by wet sand, canvas, etc. Tests are made on all the constituents of the concrete, on samples from the mixers, and on a 6-inch core from every half-mile of road. The surface finish of the road is checked by an irregularity detecting machine, which gives an autographic diagram. The maximum rate of progress attained has been 220 yards of 20-foot 6-inch roadway in an eight-hour day; the average rate is about 130 yards a day.

The elimination of level-crossings has necessitated a large number of bridges and subways. In general, the material used is reinforced concrete, but occasionally steel and masonry are employed. Considerable attention has been paid to aesthetic considerations. In this, and all other aspects of the design of the motorways, architects, landscape gardeners, and others have collaborated with the engineers, with apparently very satisfactory results. Parking and rest places are provided at suitable spots. The Inspector-General of the German road system has absolute power over the work. "As the highest German road officer, he has the last word in all questions of planning, lay-out and technical design, and his decision is final in cases of expropriation or exchange of ground if these procedures should become necessary. As a rule, however, land is acquired by normal purchase." The German Railway is the "holding company" of the Motorway Company. This arrangement was adopted to avoid competition and to take advantage of the railway's long experience in the organization of transport. One of the objects of the scheme was the relief of unemployment, and 35 per cent of the cost is accounted for by the saving on "doles"; a further 25 per cent to 30 per cent of the money invested in the scheme will return as revenue from additional rates and taxes. The remaining 35 per cent to 40 per cent is granted by the Reich by a special agreement between the Reichsbank and the German Railway. The total capital invested up till the end of August, 1936, was £54,000,000. Herr Schmoelder described in some detail the arrangements which are made to ensure the welfare of the workmen, numbering about 120,000, of whom 20,000 live in camps. The services for road users are organized no less thoroughly. Telephones at 1¼-mile intervals, filling stations, and a well-equipped breakdown service are provided. Figures were given to show that the motorways had caused a large reduction in the traffic on the ordinary state highways, though the total volume of motor traffic in the country had increased. Reference was also made to the inauguration of a 'bus service, designed on a speed schedule of 55 m.p.h. to 60 m.p.h.—*Engineering.*

## Association of Professional Engineers of B.C.

The seventeenth annual meeting of the Association of Professional Engineers of the Province of British Columbia was held in Vancouver on December 5th. Colonel H. F. G. Letson, the retiring president, officiated and detailed the negotiations on consolidation during the past year. After discussion the following resolution was submitted and adopted:—

> "That the earnest efforts of the British Columbia Council on consolidation during the last two years has caused the partial exclusion or neglect of the usual activities in B.C. and it is essential to return to these activities in the forthcoming year. And further that this meeting wishes the very best of success to The Engineering Institute of Canada and the sister Associations in their endeavour to form a truly national representative body. And further as the B.C. Association Council, to the best of its ability has put forward its ideas consistently, both in writing and by visits to Hamilton, Toronto and Montreal, that this meeting considers that any further practical effort at consolidation should be sympathetically considered by the incoming Council."

**A. Vilstrup**

As a result of the elections Mr. A. Vilstrup was elected president of the Association for the year 1937. Mr. C. V. Brennan was elected vice-president. The following councillors were elected: James Robertson, M.E.I.C., representing civil engineers; E. Redpath representing mechanical engineers; F. W. MacNeill representing electrical engineers; and A. M. Richmond representing mining engineers.

Colonel H. F. G. Letson becomes a member of the Council as immediate past-president and will represent the mechanical engineers.

The meeting ended with a banquet at which the Hon. Mr. G. S. Pearson, Minister of Mines, Minister of Labour and Commissioner of Fisheries, was the guest of honour and speaker.

In his view, as regards the nature of the work to be done, British Columbia was a paradise for the engineering profession, but he intimated that the financial prospect was perhaps not quite so attractive.

One of the highlights of the evening was the introduction of all the past presidents of the Association presently living in Vancouver, as follows: Professor E. G. Matheson (Provisional president); D. O. Lewis, M.E.I.C.; W. G. Swan, M.E.I.C.; A. E. Foreman, M.E.I.C.; G. A. Walkem, M.E.I.C.; F. Sawford; A. S. Wootton, M.E.I.C.; W. R. Bonnycastle, M.E.I.C.; Major J. C. MacDonald, M.E.I.C.; A. S. Gentles, M.E.I.C.; J. D. Galloway and G. S. Eldridge.

The new president of the Association, Mr. A. Vilstrup, received his early education in Copenhagen, where he graduated in 1902. After some years in England he came to Canada in 1911, entering the service of the B.C. Electric Railway Company. He served successively as assistant engineer and assistant plant manager in the electrical department of the company, of which he is now chief electrical engineer. After serving as a member of the Council of the Association he became vice-president in 1936.

---

*Canadian Wood Pipe and Tanks Ltd.* have been awarded a contract for the largest penstock of its kind ever built. It will be an important unit in the new $8,500,000 development for the Ontario Paper Company on the St. Lawrence river 250 miles below Quebec City. The penstock will measure 18 feet 3½ inches outside diameter and 6,000 feet in length and is for carrying water to their new 75,000 h.p. generating station at Outarde Falls. The electric power will be used in the paper mill at Baie Comeau. In addition to the penstock, the company will supply and erect the 24-inch water supply main and the wood stave flume, four miles in length, to be used as a water and wood conveyor. The material bill for these installations includes 2,500,000 feet b.m. of B.C. Clear fir; 5,000,000 pounds of steel for cradles and bands, and 200,000 pounds of malleable iron fittings.

## The Social Responsibilities of the Engineer

**Extracts from a paper by J. K. Finch, Renwick Professor of Civil Engineering, Columbia University, New York, appearing in the December, 1936, issue of "Civil Engineering."**

The idea has frequently been expressed that engineering activity has made this an engineering age, that it is the engineer who is responsible for the many perplexing economic and social problems we now face, and therefore, *ipso facto,* it is up to the engineer to solve them. Discussion and protest along these lines will probably continue for many years, although a common-sense consideration of the problem will show that the engineer is not responsible for many of the major difficulties of the situation; that it is, in fact, a general problem of Western civilization; and that engineering, powerful and constructive as it is, possesses no magical key which will unlock the gates to a rosy and peaceful future.

* * * *

The public has been led to believe that we are on the verge of a new era in which, in some mysterious way, the engineer can annihilate costs and provide almost free service for all—only "a lack of vision and flexible technical capacity" on the part of the engineering profession holds up the march into Utopia. The abilities of the profession are thus questioned, and the atmosphere should be cleared if sound progress is to be made.

Throughout the ages, the engineer's principal stock-in-trade has been his reputation for absolute honesty and meticulous care in searching out, analyzing, and appraising the basic facts and economic values of those enterprises in the field of his professional activities. When he has recommended a work, he has staked his reputation and standing on its feasibility and soundness. Almost without exception, engineers damned the Passamaquoddy and Florida projects, but no attention was paid to their statements. Similarly, the white elephant at Fort Peck was begun before any economic study worthy of the name had been made, and the engineers were then called in to say that what had been done was wise and good.

* * * *

A bridge may fail physically, through errors in structural design or judgment, or it may fail economically through similar errors of economic analysis or judgment. Either failure is an engineering disaster. There are, thus, many completed works which are technically perfect but which are complete engineering failures. Some of these mistakes are unavoidable and they occur in connection with private as well as public undertakings.

* * * *

At one end of the scale of public undertakings we have works that are capable of reasonably strict engineering-economic analysis. We can say, with some assurance, that we are reasonably near the truth, that such-and-such a project, costing so much, will bring in the funds necessary to maintain and operate it and to amortize its cost, either in direct returns (such as tolls or assessments) or by creating taxable values which can be drawn upon for these purposes. In short, such a work can be definitely expected to add to the national wealth—to the productive earning power of a community, state or nation.

At the other end of the scale is the purely social undertaking, possessing, perhaps, some remote and intangible economic implications but primarily a humanitarian work, constructed for purposes of social uplift, and resting, therefore, on public opinion, on social philosophy, and on humanitarian ideals. Such projects should not be confused with wealth-producing enterprises.

The engineer, however, has no fault to find with such works *per se.* What he objects to is the policy of bringing such projects forward in the false habiliments of economic works, and then expecting him to justify them on the only basis which is humanly possible—namely, tangible economic values. Furthermore, he has had sufficient practice in handling economic matters to know that, in the end, such undertakings must be considered as luxuries, only to be afforded, no matter what one's social philosophy may be, as the surplus, achieved through the creation of actual wealth, permits such practical manifestations of charity.

* * * *

Events of recent years have brought into clearer perspective the necessity of relying on sound engineering advice instead of wishful thinking in the formulation of policies involving the expenditure of public funds on engineering enterprises. In the past, the public works policy of the federal government has been based, or at least has been supposed to be based, on economic considerations. Needless to say, many mistakes have been made, but, with few exceptions, only works that it was thought would aid in the economic development of the nation have been undertaken. On the other hand, the more recent policy is, apparently, not to wait for economic demand to develop, but, in the interests of social as well as economic progress, to anticipate and, presumably, to direct future developments.

* * * *

The engineer, realizing these dangers and difficulties, and jealous of his reputation, would in general advise low speed in an attempt to navigate this new and uncharted sea. Furthermore, he would advise that more effective efforts than ever before be made to separate the soundly economic from the purely social enterprise. He would be the last to deny that if social works are to be built, they should be planned and designed, as far as humanly possible, to furnish the desired service effectively and efficiently.

## List of New and Revised British Standard Specifications

(Issued during August and September, 1936)

B.S.S. No.

216—1936. *Vulcanized Fibre (Natural Colour) for Electrical Purposes.* (Revision.)
This specification states the requirements of vulcanized fibre sheets from 1/16 inch to 1 inch in thickness, intended for electrical purposes. A schedule of abridged tests recommended for material for specific uses is included

394—1936. *Short Link Wrought Iron Crane Chain. (Excluding Pitched or Calibrated Chain.)* (Revision.)
This specification relates only to sizes of chain up to and including 1½ inches and provides for two grades of chain, namely "Standard" quality and "Special" quality. An increased elongation under test load for the "Special" quality is also provided in this revision.

697—1936. *Rubber Gloves for Electrical Purposes.*
Specifies physical, mechanical and electrical tests for rubber gloves intended for electrical purposes in circumstances involving the possibility of direct contact with equipment of which the voltage does not exceed 3,300 volts to earth.

698—1936. *Papers (Unvarnished) for Electrical Purposes, excluding Asbestos Papers and those used in the Manufacture of Cables.*
This specification describes methods of test acceptable both to maker and user, and gives limits for various properties, leaving it to the purchaser to select the paper he requires for a particular purpose.

702—1936. *Silicon Aluminium Alloy Castings for General Engineering Purposes.*

703—1936. *Y-Alloy Castings (as Cast) for General Engineering Purposes.*

704—1936. *Y-Alloy Casting (Heat-Treated) for General Engineering Purposes.*
The above three specifications correspond generally to the British Standard Aircraft Specifications L.33 2 L.24 and L.35 respectively, differing principally in that to meet the requirements of a wider field of construction the aluminium used in the alloy may be of 98 per cent purity as well as 99 per cent and the repair of slight defects not affecting serviceability is specifically permitted, subject to the purchaser's sanction. Provision is also made for a porosity test to be carried out.

705—1936. *Method for the Determination of the Agglutinating Value of Coal.*
A standard method for use in the carbonization industries and in the coal export trade for the grouping of coals according to their agglutinating values.

706—1936. *Sandstone Kerbs, Channels, Quadrants and Setts.*
The specification lays down clauses for the quality of the stone to be used, the finish and dimensions of kerbs, channels, quadrants and setts. Methods for determining the resistance to crushing and the absorption of water are given in appendices.

707—1936. *The Testing of Mine Fans.*
Provides formulae and definitions, together with recommendations in regard to the measurement of pressure, air velocity and power of a mine fan.

708—1936. *Trailing Cables for Mining Purposes.*
Provides for 8 types of trailing cables for use underground with coal cutters. Six constructions are recommended as primary standards and two others are included as secondary standards.

(Issued during November, 1936).

B.S.S. No.

205—1936. *Glossary of Terms used in Electrical Engineering.* (Revision.)
Contains new sections dealing with television, cathode-ray tubes, electric lifts and electric welding, besides bringing up to date the definitions included in the previous edition.

415—1936. *Mains-Operated Apparatus for Radio, Acoustic and Visual Reproduction (Safety Requirements).* (Revision.)
Scope enlarged to cover radio apparatus for A.C. and D.C. mains and also "universal" sets (AC/DC). Includes also provisions for apparatus for visual reproduction.

709—1936. *Methods of Making a Cold Bend Test on Fusion Welded Joints.*
The Specification describes fully the factors which affect a bend test on a weld and lay down four different methods of test—two for determining the ductility of the weld metal and two for testing the joint as a joint.

Copies of the new specifications may be obtained from the Publications Department, British Standards Institution, 28, Victoria Street, London, S.W.1, and from the Canadian Engineering Standards Association, 79, Sussex Street, Ottawa, Ontario.

# Preliminary Notice

## of Applications for Admission and for Transfer

December 28th, 1936

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

**Communications relating to applicants are considered by the Council as strictly confidential.**

The Council will consider the applications herein described in February, 1937.

R. J. DURLEY, Secretary.

---

*The professional requirements are as follows:—

**A Member** shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years inthe case of a candid ate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

**An Associate Member** shall be at least twenty-seven years of,age, and shall have been engaged in some branch of engineering for at least six years which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch ofengineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more year.

**A Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equiva ent standard.

**A Student** beshallat least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

**An Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

**The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.**

### FOR ADMISSION

CARR—NOEL OSMOND, of Ottawa, Ont., Born at Ottawa, Dec. 20th, 1887; Educ., Grad., R.M.C., 1909. With the R.C.A. to date as follows: Lieut., 1909; Capt., 1914; Brevet Major, 1916; Major, 1922; 1929-35, Brevet Lieut.-Col., and at present Colonel. For over six years charged as technical adviser to the Department of National Defence on all matters relating to Artillery equipment, whether concerned with design, production or operation. At present, Director of Mechanization and Artillery, Dept. of National Defence, Ottawa, Ont.
References: A. G. L. McNaughton, E. W. Stedman, G. R. Turner, R. W. Boyle, C. Camsell.

DEY—GORDON A., of 950 William St., London, Ont., Born at Wingham, Ont., April 23rd, 1904; Educ., Three years Technical School; 1923-35, chief dftsman., Dennisteel Ltd.; 1935-36, dftsman., Canada Creosoting Co. Ltd.; At present, production manager, Dennisteel Corporation Ltd., London, Ont.
References: D. S. Scrymgeour, H. A. McKay, H. L. Hayman, H. H. James, F. R. Phillips.

HOGG—ALLAN DOUGLAS, of 9 Temple Ave., Toronto, Ont., Born at Landis, Sask., Aug. 27th, 1913; Educ., B.Sc. (Mech.), Univ. of Sask., 1935; 1935 (2 mos.). asst., Dom. Govt. water survey in Sask.; 1935 (2 mos.), R.C.A.F., Camp Borden; 1935-36, demonstrator, Univ. of Sask.; 1936 (2 mos.), turbine attendant, power plant, Sask.; 1936 (4 mos.), asst., timber mech. divn., Forest Products Labs., Ottawa; Oct. 1936 to date, factory course, Massey Harris Co., Toronto, Ont.
References: C. J. Mackenzie, A. R. Greig, I. M. Fraser, W. E. Lovell, E. K. Phillips, T. A. McElhanney, W. E. Wakefield.

HURTER—ALFRED THEODORE, of Iroquois Falls, Ont., Born at Frankfurt A/M, Germany, July 3rd, 1897; 1915-19, completed four-year civil engrg. course, Ecole Polytechnique Federale, Zurich, Switzerland; R.P.E. of Quebec; 1919 (summer), triangulation work, Swiss Federal Topographical Divn.; 1919-20, designing dftsman., for cement mills, Brown & Pooley Ltd., consltg. engrs., London, England; 1920-23, partner, Huber & Hurter, contractors, Bucharest, Rumania, various constrn. work of industrial nature; 1923-24, designing dftsman., Nfld. Pulp and Paper Co. Ltd., constrn. of new paper mill for Corner Brook; 1924-28, designing engr., George F. Hardy, M.E.I.C., consltg. engr., New York; pulp and paper mill designs for Canada and U.S.A.; 1928-29, res. engr., in charge of extension of paper mill, St. Lawrence Paper Mills Co. Ltd., Three Rivers; 1929 to date, res. engr., Iroquois Falls Divn., Abitibi Power and Paper Co. Ltd., Iroquois Falls. Also consltg. engrg. work for other Abitibi divns. and subsidiaries.
References: J. Stadler, W. I. Bishop, G. F. Hardy, H. S. Taylor, H. L. Trotter, J. A. DeCew, P. A. Trost, D. C. Tennant, F. O. White.

JOMINI—JOHN LOUIS, of Grand'Mere, Que., Born at Grand'Mere, Apr. 28th, 1913; Educ., 1932-35, McGill Univ., completed second year engrg. with exception of two subjects, calculus and physics; Five months work with millwrights, and two years to date, in the dfting office, Consolidated Paper Corporation, Grand'Mere, Que.
References: E. B. Wardle, W. B. Scott, H. G. Timmis, H. O. Keay, W. B. Scoular.

SHAW—FREDERICK W. B., of 167 Birch Ave., St. Lambert, Que., Born at Montreal, May 22nd, 1911; Educ., B.Eng., McGill Univ., 1934; 1934-35 (6 mos.), St. Lawrence Power Co.; 1935 (4 mos.), Canadian Marconi Co.; 1935 to date, junior engr., Steel Co. of Canada, Ltd., Montreal, Que.
References: E. C. Kirkpatrick, J. C. Antliff, H. C. Karn, C. V. Christie, L. O'Sullivan.

### FOR TRANSFER FROM THE CLASS OF JUNIOR

GRIME—LEONARD, of 65 Sanford Ave. So., Hamilton, Ont., Born at Stretford, Lancs., England, May 26th, 1904; Educ., B.A.Sc., Univ. of Toronto, 1926; Summers: 1923, estimator, Duluth-Superior Dredging Co., Detroit; 1924, survey work, City of Royal Oak Engrg. Dept.; 1925, survey work, real estate subdivns. in Detroit; 1926, reinforced concrete dftsman., Truscon Steel Co., Detroit; 1927-1929, struct'l. dftsman., American Bridge Co., Toledo, Ohio; 1929-31, struct'l. dftsman., Standard Steel Constrn. Co., Welland, Ont.; 1931 (July-Oct.), struct'l. dftsman., Hamilton Bridge Co.; 1933-36, mtce. and constrn. work, National Silicates, New Toronto, Ont., estimating, design, erection, field work in connection with new plant; 1936 (Apr.-June), struct'l. dftsman., Canadian Bridge Co.; June 1936 to date, struct'l. dftsman., Hamilton Bridge Co., Hamilton, Ont. (*Jr. 1928.*)
References: R. K. Palmer, J. A. McFarlane, D. T. Alexander, R. E. Smythe, D. D. Whitsun, C. R. Young, C. H. Mitchell.

### FOR TRANSFER FROM THE CLASS OF STUDENT

CHOROLSKY—EUGENE, of Walkerville, Ont., Born at Tsitsihar, Manchuria, Mar. 2nd, 1905; Educ., B.A.Sc., Univ. of Toronto, 1926; Summers 1923-24-25, inspr. on reinforced concrete culverts, arch and beam bridges, testing cement and aggregates for concrete. Dept. of Highways, Sask.; 1926 to date, with the Canadian Bridge Co. Ltd., Walkerville, Ont. Making and checking shop details, layouts, estimates, etc., on all types of bldgs., transmission structures, fixed bridges, moveable bridges, turntables, ferry aprons and mech. parts for same; plant layout; designing and estimating; devising and designing erection methods for all types of bridges and bldgs.; res. engr. on constrn. (*St. 1926.*)
References: A. P. Linton, D. T. Alexander, F. H. Kester, G. V. Davies, A. E. West, F. Stevens, R. C. Leslie.

CAIRNCROSS—ALEXANDER THOMAS, of Chengtu, China, Born at Toronto, Ont., July 31st, 1908; Educ., B.Sc. (Civil), Queen's Univ., 1931; 1926-27, office and field constrn. and equipment, Stirling Appraisal Co. Ltd., Toronto; 1928 (5 mos.), London rural power line constrn., H.E.P.C. of Ont.; 1929 (5 mos.), 1930 (3 mos.), activated sludge plants, storm and domestic systems, Wynne-Roberts Son & McLean, Toronto; 1930 and 1932 (5 mos.), sewers and pavements, Ryan Contracting Co. Ltd.; 1931-32, chief dftsman. of surveys and Minden, Dept. of Northern Development Ontario; 1933-34 (7 mos.), relief camps; April 1935 to date, technical advisor, Dept. of Engrg., Generalissimo Staff, National Government of China. Advising on highway alignment in Prov. of Szechwan. New survey line through areas where motor cars have never been seen. Reports on gasoline usage, transportation and the wood oil industry. (*St. 1928.*)
References: A. Macphail, L. T. Rutledge, W. P. Wilgar, D. S. Ellis.

KOEHLER—JULIUS WILBUR, of Montreal, Que., Born at Stratford, Ont., Apr. 8th, 1908; Educ., (B.Sc. (E.E.), McGill Univ., 1930; Summers: 1927, land surveying S.W. Sask.; 1928, elect'l. helper, C.P.R., Winnipeg; 1929, elect'l. helper, H.E.P.C. of Ontario; 1930-31, elect'l test course, and 1931-32, illuminating engr., Can. Gen. Elec. Co. Ltd.; 1934 (Sept.-Dec.), teaching elect'l. theory and testing, London Technical School; Dec. 1935 to date, lighting service engr., Can. Gen. Elec. Co. Ltd., Montreal, Que. (*St. 1929.*)
References: G. H. Gillett, W. J. Armstrong, C. V. Christie, W. M. Cruthers.

STRATTON—FREDERICK STEPHEN, of 2 Donovan Court, 97 Drayton Gardens, London, S.W.10, England. Born at Birmingham, England, Jan. 24th, 1907; Educ., B.Sc. (E.E.), Univ. of Man., 1930; 1927 (summer), rodman, inspr., Manitoba Power Co.; 1928, rodman, City of Winnipeg Hydro; 1928-29, dftsman., rly. and power house constrn., City of Winnipeg Hydro; 1930 (May-Oct.), field engr., Manitoba Power Co.; 1930-32, field supt., North Western Power Co., trans line constrn.; 1932 (Aug.-Sept.), elect'l. engr. on expedition to study Eclipse of the Sun at Lake Magog, Que., with British Astronomical Party; Apr. 1933 to date, asst. in charge of supervision of various factories in England with Chloride Electrical Storage Co. Ltd., London, England. (*St. 1928.*)

References: E. P. Fetherstonhaugh, E. V. Caton, A. E. Macdonald, G. H. Herriot, L. M. Hovey, H. L. Briggs, W. E. Lovell.

TARR—FRANCIS GILBERT AUBREY, of 387 Reid St., Peterborough, Ont., Born at Salford, nr. Bristol, England, July 26th, 1904; Educ., B.A.Sc., 1926, Ph.D., 1935, Univ. of Toronto. M.S., Cornell Univ., 1932; 1926, students' course, 1927-31 and 1935 to date, switchboard engr. dept., Can. Gen. Elec. Co. Ltd., Peterborough, Ont. (*St. 1926.*)

References: H. R. Sills, E. R. Shirley, T. E. Gilchrist, A. L. Dickieson, B. I. Burgess.

## John Loudon Macadam, 1756-1836

On October 30th, at Ayr, the centenary of the death was commemorated of the famous road-maker, John Loudon Macadam, who was born in Ayr on September 23rd, 1756, and died at Moffat, November 26th, 1836, at the age of eighty. The commemoration included a luncheon at the County Buildings, at which the toast "The Memory of John Loudon Macadam" was proposed by Mr. Hore-Belisha, Minister of Transport, and at which a paper on the life and work of Macadam was read by Mr. G. S. Barry, County Surveyor of Ayrshire. After the luncheon, Mr. Hore-Belisha unveiled a bronze memorial tablet to Macadam, which has been erected in Wellington Square by the Institution of Municipal and County Engineers, as the representative body of highway engineers in Great Britain. When speaking at the luncheon, Mr. Hore-Belisha said that Macadam pleaded consistently that the design and maintenance of roads should be entrusted, not, as was the casual fashion, to amateurs and sinecurists, but to those understanding what he claimed to be a science and having practical experience in its application.

The earlier part of Macadam's career had nothing to do with engineering of any sort, for as a boy of fourteen, his father being dead, he was sent to an uncle, William Macadam, in New York, and it was in his office he learnt those business habits which marked his whole life. That he was successful as a business man is evident from the fact that by 1783 he was able to return to his native country and settle down to the life of a country gentleman. Information as to Macadam's activities, said Mr. Barry, in his paper, is not readily obtainable, but it appears his first incursion into the field in which he was to become famous was the construction of a road to his estate. In 1787, he became one of the Road Trustees in his district, and as such served five years. His interests then apparently became centred in the business of Messrs. The British Coal Tar Company, which the ingenious Lord Dundonald had founded at Muirkirk for the production of tar, lamp-black, paint and other substances. His association with Ayr was a close one and he became a Councillor, a Justice of the Peace, and, when an invasion scare led to the formation of a corps of volunteers, he was recommended for the position of Captain, and by George III was granted a commission as a Major.

In 1798, the year which saw the beginning of the Napoleonic Wars, Macadam, who, in America, had been connected with the sale of war prizes, was appointed an agent for the revictualling of the Navy at the western ports, and took up his headquarters at Falmouth. His hobby of road-making was, however, ever present in his mind, and in 1811 he presented a report to a Committee of the House of Commons on Roads. The war over, Macadam, in 1816, at the age of sixty, began the work he will always be remembered for. He had served for some years as a Trustee of various local Road Trusts, and now, in 1816, he was appointed General Surveyor of Roads to the Bristol Turnpike Trust, and by 1818 was acting as consulting surveyor to no fewer than 34 similar bodies. From this time onwards, he was incessantly writing reports, supervising and advising. His "Remarks on the Present System of Road-making" was published in 1816; his "Practical Essay on the Scientific Repair and Preservation of Roads" in 1819, and his "Observations on the Management of Trusts for the Care of Turnpike Roads" in 1825. From these works, his reports and other documents, Mr. Barry quoted at length, illustrating the methods used by Macadam, and his views on all that appertained to roads. When he had reached the age of sixty-nine he resigned his position at Bristol, only, however, two years later to be appointed by Parliament Surveyor General of Roads, a position he still held at the time of his death. "While it can hardly be said," said Mr. Barry, "that Macadam was the inventor of the system which he practised, it is nevertheless the case that he perfected that system and raised it to its highest standard. . . . His contribution to the advancement of roads was without doubt one of the great features of the early Nineteenth Century."—*Engineering.*

## Fifth International Congress for Applied Mechanics (1938)

The American Committee, to whom responsibility for organizing the Fifth International Congress for Applied Mechanics was delegated by the International Committee at its meeting at Cambridge University, England, in July, 1934, announces that the Fifth Congress will meet in Cambridge, Massachusetts, U.S.A., September 12th-16th, 1938, at Harvard University and the Massachusetts Institute of Technology. As in the past, this Congress is to be a meeting of persons working in the field of Applied Mechanics before whom reports of recent work may be presented for discussion.

The programme will cover three main divisions of Applied Mechanics as follows:

I. Structures, elasticity, plasticity, fatigue, strength theory, crystal structure.

II. Hydro and aerodynamics, gasdynamics, hydraulics, meteorology, water waves, heat transfer.

III. Dynamics of solids, vibration and sound, friction and lubrication, wear and seizure.

Following the meeting at Cambridge, Mass. it is expected that arrangements will be made to visit Washington (National Bureau of Standards), and Langley Field (National Advisory Committee for Aeronautics).

Dormitory and boarding facilities will be made available by Harvard University.

Inquiries should be addressed to the Fifth International Congress for Applied Mechanics, Massachusetts Institute of Technology, Cambridge, Mass., U.S.A.

TH. VON KARMAN, J. C. HUNSAKER } *Secretaries.*

## Steam Heating on Electric Trains

The heating of passenger trains by steam, particularly in these days of large boilers, is a fairly simple matter. A considerable supply of steam at considerably higher pressure than is required is usually available and can be tapped through a reducing valve; but in countries where trains, normally steam hauled, cover long distances behind electric locomotives, the matter is not so easily solved and special arrangements have to be made.

Such operation is frequent in the United States, where a standing Committee on Electric Rolling Stock of the Mechanical Division of the American Railroads Association has, among other matters, had under consideration the steam heating of trains hauled by electrical locomotives. They have had before them replies to a questionnaire giving the summarized experience of four of the leading companies, and it is clear from these replies that the demand made by steam heating is considerable. While definite figures do not appear to be available, the consensus of opinion indicates a consumption of about 250 pounds of steam per car per hour, with a pressure drop of 8 to 10 pounds per car, and, with modern trains of 18 cars or more, this means that the consumption may exceed 4,500 pounds of steam per hour, while an initial pressure of 175 pounds per square inch will be required behind the locomotive.

For this purpose vertical fire tube boilers, burning oil fuel, seem to have been universally adopted. One railway originally tried vertical tube flash boilers, but these proved unsatisfactory in service and prohibitively heavy in maintenance cost. In the earlier boilers a working pressure of 100 to 120 pounds per square inch was used, but for modern requirements 200 to 220 pounds pressure has been found necessary, with a normal output rate of 3,250 to 4,700 pounds of steam per hour, from and at 212 degrees F., and twice this evaporation under forced ratings. Superheaters and feedwater heaters have been installed with satisfactory results. It may be added that the steam consumption of boiler auxiliaries is found to be by no means negligible and has been estimated by one railway, the Chicago, Milwaukee, St. Paul and Pacific, as, for atomizing 300 pounds per hour, feed pump 230 pounds., blower 150 pounds., oil pump 150 pounds., total 890 pounds per hour. The same railway reports that burning heavy crude oil sometimes gives trouble with "gassing," which is particularly undesirable where open observation cars are in use, and for the past three years on their Rocky Mountain section they have been burning a light crude oil, which with careful firing gives no trouble in that respect.

In order to reduce pressure drop a 2-inch pipe line has been standardized and a larger size has been tried, the capacity of the system being governed by the maintenance of a minimum pressure at the last car. One company lays down a minimum at the end of the train of 5 pounds per square inch for steam heating, and adds that if the steam is used alternatively for air conditioning a minimum of 55 pounds pressure at the last car must be maintained. The pressures used having put rubber hose connections out of the question, flexible metallic connectors are universal, and it is stated that if these are well insulated a saving of 10 per cent in loss as compared with uninsulated connectors is obtained. This is an important consideration, affecting not only boiler capacity, but the quantity of feedwater it is necessary to carry, a by no means inconsiderable figure, amounting in one case to 3,000 gallons, as much as is carried in many steam locomotive tenders in this country. It is agreed that the actual steam consumption varies widely in practice, depending on the type of car, weather conditions, speed, difference between internal and external temperatures, and the condition of the equipment. To conserve the steam supply the Committee recommend the fitting of a reducing valve in each coach, as apart from other considerations, the amount of space required in the electric locomotive for the heating equipment is becoming a serious matter.—*Engineering.*

## EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

*All correspondence should be addressed to*

**The Employment Service Bureau, The Engineering Institute of Canada**
**2050 Mansfield Street, Montreal**

## Situations Vacant

ENGINEERING GRADUATE, with mechanical and sales ability. Out of school three or four years, who would like to become associated with a contracting and manufacturing concern in heating, ventilating and air conditioning work. State qualifications and experience to Box No. 1429-V.

YOUNG ELECTRICAL OR MECHANICAL ENGINEER, wanted at once for position of superintendent 2,000 h.p. steam electric generating station. Practical experience similar plant desired. Write full particulars to Box No. 1434-V.

SALES ENGINEER, to organize sales branch in province of Quebec, familiarity with transmission and pulp and paper machinery advantageous. The product has high reputation in all industrial countries of the world, but only recently introduced in Canada. Applicants are asked to give full particulars in first letter stating education, early training, industries most familiar with, and whether bilingual. A per iod of training in Ontario field purposed. Apply to Box No. 1439-V.

### The Civil Service Commission

ASSISTANT MECHANICAL ENGINEER (25864)

25864.—An assistant mechanical engineer, in the Chief Architect's Branch, Department of Public Works, Ottawa, salary rate of $2,220 per annum, subject to a deduction of five per cent during the fiscal year beginning April 1, 1936. Temporary appointment may be made at this time, this examination will qualify for permanent appointment. For such employment the initial salary of $2,220 per annum may be increased upon recommendation for meritorious service and increased usefulness at the rate of $120 per annum until a maximum of $2,700 has been reached.

*Duties.*—To assist in designing and preparing plans and estimates of mechanical equipment and heating, ventilating, power, light, telephone and signal systems; to supervise the construction, installation, maintenance and repair thereof; and to perform other related work as required.

*Qualifications required.*—High school graduation; either graduation in mechanical engineering from a university of recognized standing with three years of practical mechanical engineering experience or eight years of practical engineering training and experience; in either case one year of the experience shall have been in a position of professional responsibility; corporate membership in The Engineering Institute of Canada or membership in a provincial association of professional engineers, or qualifications which would permit of such membership; considerable machine, forging and casting shop experience; tact and ability to handle men. While no definite age limit has been fixed, age may be a determining factor in making a selection.

Application forms properly filled in must be filed with the Civil Service Commission, Ottawa, Ont., **not later than January 21, 1937.**

Application forms may be obtained from the offices of the Employment Service of Canada, from the Postmasters at any City Post Office, The Engineering Institute of Canada, Montreal, or from the Secretary of the Civil Service Commission, Ottawa.

Please quote competition number when filling out application forms.

## Situations Wanted

INDUSTRIAL ENGINEER AND SUPT. Age 31, A.M.E.I.C., with combined electrical, mechanical and steel industry experience. Experience includes design and testing of all types of industrial electrical equipment, supervision of production and cost reduction, heat treating of steel, time study application in several plants. At present supt. of modern factory. Apply to Box No. 132-W.

ELECTRICAL ENGINEER, B.sc., E.E. Age 30. Completed C.G.E. Test Course; five years experience with power company utility work—substation and power house (steam) operation and maintenance, transmission and distribution line operation, maintenance and design. Industrial or utility work desired. Location immaterial. Available on short notice. Apply to Box No. 266-W.

DESIGNING DRAUGHTSMAN, experience in layout of steam power house equipment and piping. Wide experience in mechanical drive and details of machinery, gearing, and hoists. Accustomed to layout of small mill buildings of steel and timber, structural design and details. Good references. Present location Montreal. Apply to Box No. 329-W.

## Situations Wanted

ENGINEER, A.M.E.I.C. Age 30. Single. Employed. Civil and mining experience, capable of designing and superintending construction of timber, concrete and steel structures, rock crushing and ore plante. Would consider position with mining or engineering company designing and building mills. Apply to Box No. 431-W.

MECHANICAL ENGINEER, B.ec. Age 31. Married. Last ten years includes:—Mechanical structural and reinforced concrete design in pulp and paper mills, industrial plants, hydro-electric, mine, sewers and sewage disposal plant construction. My experience also includes shop production, steam plant combustion, fuel analysing, inspecting, supervising and instrument work on industrial construction. Permanent position preferred. Apply to Box No 521-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aero-photographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

### Employment Service Bureau

Enquiries during the past month indicate that the greatest demand for engineers appears to be in the following general classifications:—

- Recent graduates in mechanical engineering.
- Recent graduates in civil engineering.
- Young mechanical engineers
- Sales engineers in all branches of engineering.
- Sales engineers speaking French.
- Engineers with pulp and paper mill experience in design, draughting and maintenance.

If your experience is in any one of the above classifications, why not register with The Institute's Employment Service Bureau. Our list of men available for positions is greatly reduced in number.

ELECTRICAL ENGINEER, B.ec. '28; M. Eng. '35. Two years student apprenticeship at Can. Westinghouse Co., including test and electrical machine design. Also about two years experience in operating dept. of large electrical power organization. Available on short notice. Apply to Box No. 660-W.

MECHANICAL AND STRUCTURAL ENGINEER. Six yeare experience with prominent manufacturer, designing, heating and power boilers, boiler installations, coal and ash handling equipment. Good practical knowledge of steel plate work welding. Also wide experience in designing, estimating and detailing structural steel for buildings and bridges. Good education. Have held position of responsibility. Above can be verified by best of references. Available at once. Apply to Box No. 692-W.

ELECTRICAL AND CIVIL ENGINEER, B.sc. Elec. '29, B.sc. Civil '33. JR.E.I.C. Age 29. Experience includes four months with Can. Gen. Elec. Co., approximately three years in engineering office of large electrical manufacturing company in Montreal, the last six monthe of which was spent as commercial engineer. For the last year and a half employed in electrical repair shop. Best of references. Apply to Box No. 693-W.

ELECTRICAL ENGINEER, B.ec., University of N.B., '31. Experience includes three months field work with Saint John Harbour Reconstruction. Apply to Box No. 722-W.

CIVIL ENGINEER, B.ec. (Alta. '31), E.E.I.C. Experience includes three seasons in charge of survey party. Traneitman on railway maintenance, and concrete bridge designing. Nature of work and location immaterial Apply to Box No. 724-W.

## Situations Wanted

YOUNG CIVIL ENGINEER, B.ec. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.ec., Univ. of B C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as etudent engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

CIVIL ENGINEER, M.ec., A.M.E.I.C., R.P.E. (Ont.), ten years experience in municipal and highway engineering. Read, write and talk French. Married. Served in France. Will go anywhere at any time. Experienced journalist. Apply to Box No. 737-W.

RADIO AND ELECTRICAL ENGINEER, B.Sc., '31, JR.E.I.C. Single. Age 29. One year and a half actual field experience in power and lighting equipment. Extensive work in telephone and radio layouts in switchboard and installation depts. Particularly interested and experienced in sales and traffic work in telephone and radio company. At present supervisor over sales and service of radio and electrical company. Available on short notice. Location immaterial. Apply to Box No. 740-W.

CIVIL ENGINEER, B.sc. '29, A.M.E.I.C. Married. One year building construction. One year hydro-electric construction in South America, eighteen months resident engineer on highway construction, one year on harbour design and construction. Working knowledge of Spanieh. Apply to Box No. 744-W.

PLANT ENGINEER or SUPERINTENDENT, capable of eupervising all phases of industrial plant operation, graduate electrical, eleven years diversified industrial experience including test course, four years on large Quebec industrial development, on construction and operation, also six years with prominent consulting firm supervising electrical and mechanical engineering projects. Age 31, single. Apply to Box No. 795-W.

CIVIL ENGINEER, B.ec. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water eupplies. Position desired ae engineer or superintendent. Available at once. Apply to Box No. 841-W.

STRUCTURAL ENGINEER, B.A.ec., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

CHEMICAL ENGINEER, B.sc. (McGill '21), A.M.E.I.C., age 36, married; three years since graduation with pulp and paper mills; eight years in shops, estimating and sales divisions of well-known gas engineering and construction companies in the United States. Excellent references. Available on short notice. Apply to Box No. 866-W.

ELECTRICAL ENGINEER, graduate 1929, S.E.I.C. Single. Experience includes two years with electrical manufacturing concern and one on highway construction work. Available at once. Will go anywhere. Apply to Box No. 887-W.

CIVIL ENGINEER, B.A.SC., JR.E.I.C., age 32, married. Two years in pulp mills draughting and designing additions, maintenance and plant layout. Three and a half years in the Toronto Building Department, checking and designing for steel, reinforced concrete and ordinary structures. One and a half years as transitman and draughtsman on road location and maintenance work. Available at once. Location immaterial. Apply to Box No. 899-W.

CIVIL ENGINEER, B.ec., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements Available at once. Apply to Box No. 950-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. B.sc. (Man. '23), A.M.E.I.C. Married. Ten years specialized experience in the practical use of magnetic, electrical and mechanical instruments for the prospecting, surveying and mapping of mineral, oil and gas lands. Five years experience with telegraph, telephone and radio equipment. Capable of giving instruction in theory and practice in these lines and in college physics. Available on short notice. Apply to Box No. 1063-W.

ELECTRICAL ENGINEER, B.ec.E.E. (Univ. of N.B. '31). C.G.E. Test Course included industrial control, induction motors and transformers; the transformer test included desk work for two months on computing losses, efficiencies, etc. Available at once. Apply to Box No. 1119-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

ENGINEER, with twenty years experience in industrial, pulp and paper mill, and general engineering and design. Age 41. Last five years chief engineer of paper mill making newsprint specialties and toilet tissues. Apply to Box No. 1246-W.

ELECTRICAL ENGINEER, B.Sc. '34 (Univ. of N.B.), S.E.I.C. Age 21, single. Desires any kind of electrical work. Will consider any location. Apply to Box No 1262-W.

ENGINEER AND DRAUGHTSMAN, Jr.E.I.C., age 33, married. Diplomas from Mtl Tech. Inst. in R.C. and Structural Design. 11½ years experience in civil engineering, draughting and instrument work. This includes 7 years with M.L.H. & P. Cons. as field engineer on construction and maintenance of gas mains. Present location Montreal. Available at once. Apply to Box No. 1326-W.

CIVIL ENGINEER, M.E.I.C. Married. Age 38. Twenty years experience in organization, design and estimating, and cost accounting. Active service in France. Apply to Box No. 1367-W.

ENGINEER SUPERINTENDENT, A.M.E.I.C., R.P.E., Que. and Alta. Age 47. Married. Twenty years experience as engineer and superintendent in charge of hydro-electric, industrial, railroad, and irrigation construction. Specialized in rock excavation and suction dredging. Intimate knowledge of costs, estimating and organizing. Available immediately. Apply to Box No. 1411-W.

CIVIL AND ELECTRICAL ENGINEER, Univ. of Man. '35 and '36. S.E.I.C. Experience in irrigation and mapping. Available at once. Location immaterial. Box No. 1418-W.

CIVIL ENGINEER, B.Sc. 1910, A.M.E.I.C. Married. Twenty-six years experience on heavy construction work, both field and office; rails, roads, power house, hotels, bridges, etc. Location immaterial. Available at once. Apply to Box No. 1470-W.

SALES ENGINEER, M.E.I.C. Age 50. Married. Several years in combustion and general machinery lines. Estimating and layout work (mechanical and electrical). Speaking French fluently. Executive ability. Apply to Box No. 1482-W.

MECHANICAL ENGINEER, 1935 graduate, B.E., (N.S. Tech. Coll.), age 24, single. Experience includes one year's work in a testing laboratory, summer work in foundry, boiler, and machine shops, draughtsman and timekeeper, road inspection on special asphalt. Keenly interested in plant control work, draughting, drying and refrigeration as applied to foods. Available on short notice. Apply to Box No. 1500-W.

ELECTRICAL ENGINEER, B.Eng. (McGill '33). One and a half years experience in plant and production routine, and with considerable training in sales work. Bilingual, single, and available at once for any location. Apply to Box No. 1509-W.

---

## The Wonders of Plastics

Laminated resin products are proving their worth, for instance, for heavy bearings, while in chemical works and factories in which corrosive vapours or liquids have to be handled they have found many special fields. For example, a fan of the material will handle without injury corrosive vapours such as hydrochloric-acid gas, even at a temperature of 100 degrees C. In a recent test one such fan delivered 1,600 cubic feet of this gas per minute at 17 inches w.g., when operating at 2,300 r.p.m. under such conditions. In the matter of piping the material is likewise creating a field for itself and the following figures give some idea of what it is capable of withstanding. A flanged pipe 2 inches i.d. and 2.43 inches o.d., subjected to a hydraulic test at 225 pounds per square inch pressure, showed only slight leakage at the flange threads at the ends; it was not until the pressure reached 1,300 pounds per square inch that leakage appeared at a few pin holes along the pipe. As this piping was intended to be used at pressures of only 50 pounds per square inch, the margin was obviously ample.

As auxiliary materials in the engineering industry the field of plastics is constantly widening. One such field is in the varnish and lacquer industries. In the past few years quite a new manufacturing technique has been developed in these trades, with an accompanying reduction in the cost of raw materials, a simplification of the compounding processes, and an improvement in the finished products. This is due, to a large extent, to the fact that good-quality synthetic resins of uniform composition are now available, while the other half of the varnish—the solvent—has been considerably reduced in cost by the introduction of new hydrogenated solvents from coal. These solvents include hexaline from the hydrogenation of phenol; methyl hexaline from cresol; and tetraline and decaline obtained by hydrogenating naphthalene. All these have great dissolving power for synthetic resins. Coumarone resin varnishes are now made in three distinct types, viz., spirit, oil, and chemically-resistant. Spirit varnish is prepared by simply dissolving the coumarone resin in tetraline or other solvent. The making of oil varnish is simplified by first dissolving the resin in one of the hydrogenated solvents before introducing oil and driers. Due to its resistant properties, coumarone resin is being applied as a coating for ships' bottoms and other structures in contact with sea water. Both coumarone resin and resins of the bakelite type are employed for coating storage tanks and other containers, specifically for the storage of coal-tar derivatives, petrol containing tetra-ethyl lead, and other petroleum products. Small containers, such as barrels and cans, are often lined internally with a coating of synthetic-resin varnish.

British manufacturers have, of late, taken up the production of urea—one of the raw materials for urea-formaldehyde resins—and their factories are now turning out enough to supply all demands of the home market. A considerable fall in price has resulted, and this, in turn, has enabled the laboratory processes for making urea resins to be carried out on a commercial scale. Resins of this class, besides finding application in varnish making, are coming into favour in other directions not usually associated with the plastics industry. For example, the fusible resins are marketed in the form of solutions in water, and are employed in the building trade as a priming coat for plaster and for wood surfaces, and also in the textile industries for waterproofing fabrics and for the preparation of size. The electrical industry also makes use of them, particularly of those produced with an acid catalytic agent, these having, it is said, the greatest insulating value. Besides the coating of paper and fabric insulation with urea resin varnish, the resin itself is used as a binder for finely-divided iron in the manufacture of certain magnet cores.

Perhaps the most interesting outcome of work on urea resins is the new so-called "organic glass," which is a special type of the resin, unfilled, but rendered infusible by heat as in moulding. This substance is superior to glass in some respects, but inferior in others. It weighs only about half as much, which renders it advantageous for aircraft, and it is not splintered by a bullet or shell fragment, but its transparency, while equal, in the new condition, to that of glass, is liable to suffer with use as its surface, being softer, is easily scratched and disfigured. Strong chemicals, like acids, to which glass is generally inert, also gradually attack it. Organic glass is readily machinable and may be treated in the workshop exactly as is done with laminated or bakelite mouldings. Its tensile strength approaches 4 tons per square inch, whilst the compression resistance is about 14 tons per square inch.

—*Engineering.*

## The Dover Dock for the Cross-Channel Train-Ferry Service

An important new departure in cross-channel traffic will be inaugurated on October 14th next, when the first passenger train utilizing the train-ferry service between Dover and Dunkerque will leave Victoria station . . . The service is for both passengers and goods, and the former, if they so desire, can entrain at Victoria station and remain in their compartment until Paris is reached . . . It is proposed to run a service in both directions each night, the Paris train leaving Victoria at 10 p.m. and the London train leaving the Paris Nord station at 9.50 p.m . . . The cars are adapted for running over both the British and French gauges. Specially wide wheel treads are employed, as the two rail gauges differ by half-an-inch.

Before deciding to locate the sea terminus at Dover, every possible alternative location was studied. All likely sites at Dover were then closely examined and the form of construction of the terminal carefully considered. The extreme variation between the highest and lowest water level is 25 feet, and this precluded the adoption of an inclined approach in the form of a bridge, as such an approach would have had to be about 500 feet in length to give a suitable incline over which sleeping cars could pass. In addition, the weather conditions in Dover harbour are frequently severe, so that the mooring of the ship to such a bridge might often have been impossible. It was finally decided to build an enclosed dock, with powerful pumps to regulate the water level to the required height in the shortest possible time.

In addition to the dock, an approach jetty, 400 feet long by 30 feet wide, has been constructed, alongside which the vessels will lie before entering the dock. This jetty was formed of concrete piers enclosed in sheet-steel piling. From the jetty, the vessels will be warped through the open gates into the berth, after which the gates will be closed and the water raised or lowered to the required level by means of the pumps. When the vessel is at the required level, connection to it will be made at the inner end of the dock by means of a bridge 70 feet long. This bridge will normally be approximately level, but as loading and unloading of the trains on to the vessel takes place there will naturally be some tilting both longitudinally and sideways of the vessel. The bridge is a complete articulated structure, being constructed to take up any difference in level caused by the tilting, and it can be raised clear of the vessel when necessary. A large steel pin at the end of the vessel will enter a recess which has been formed in the bridge. Two lines of rail track cross the bridge, so that it will be possible for two lines on the vessel to be dealt with at the same time. The passage of all traffic between the railway lines on the shore and the vessel will be controlled by a complete electric signalling and interlocking installation. Ordinary locomotives will be used for transferring the railway vehicles between the boat and the land. In association with the dock, a customs house is being constructed, and this will also contain the usual railway offices. A transit shed will form part of the terminal station, containing considerable space for bonded stores. Special facilities are provided for the transit of motor-cars, for which a large garage is provided on the upper deck of the ships. In conclusion, it may be mentioned that on the French side, locks were already in existence at Dunkerque, and comparatively little adoption has been required. More than fifteen hundred wagons have been built for the freight service, and it will be possible to send goods direct to any part of the Continent except Russia and Spain, where the gauge is different . . . —*Engineering.*

# Forest Management in Ontario

*C. D. Howe, Ph.D.,*
*Dean of the Faculty of Forestry, University of Toronto, Toronto, Ont.*

**An address delivered before the Toronto Branch of The Engineering Institute of Canada, November 19th, 1936.**

*(Slightly Abridged)*

Engineering and forestry have much in common. They both employ the scientific approach to their problems and they both build for the future as well as for the present. In fact the superstructure of forestry is raised from a triangular foundation in the knowledge of biology, engineering and economics.

The biological foundation of forestry is quite evident because trees, and other plants and the animals which affect their lives, are living things. In fact a forest is a biological community with its members acting and reacting on each other much like a community of human beings.

The engineering base of forestry becomes evident when we consider the fact that a forester may be called upon to establish boundaries and make topographic maps, to construct lookout towers and telephone lines, to make roads and trails, to build chutes and flumes, to understand the mechanics involved in the use of logging and milling equipment and to build dams and improve streams for log driving purposes.

Even without the examples given above, we could maintain legitimately that forestry, considered only as the art of growing successive wood crops, is an engineering profession. Engineering has been defined as the "art of directing the great sources of power in nature for the use and convenience of man." A forest is principally the product of the rainfall, soil, sunshine and temperature of its environment, and forestry the art of controlling the forces of nature in the forest to supply in perpetuity the wood-using needs of man.

For the reasons outlined above, foresters should be accepted as a part of the engineering profession. As a matter of fact, of the four forestry schools in Canada, three grant the degree of Forest Engineer, one as an undergraduate and two as a graduate degree.

Since forestry is concerned primarily in the production, use and maintenance of wealth from forest soils, it must rest on a sound economic foundation. Constructive and intelligent methods of forest management will be employed only if they pay directly in dollars and cents or indirectly in social services such as the regulation of stream flow, the development of recreational facilities in general or the stabilization of community life in forest regions. The purpose of forestry is to obtain from forest lands and their products the greatest economic, industrial and human service.

Over eighty per cent of our forest area is owned by the Crown, that is, it is in public ownership; it belongs to the people of Canada. Are the best interests of Canada being served when three million acres, on the average, are burned each year? This area is equivalent to a strip of land a mile wide from Halifax to Vancouver and one-third of the way back again.

The number of annual fires on a ten-year average is 5,700. Taking the average fire season as one hundred and fifty days, this means that about forty fires are being started each day during the season. Granting the fires start during the day time, a new fire occurs somewhere in Canada each twenty minutes during the daylight hours of the fire season. The cost of fighting fires, the value of timber, young growth and property destroyed amounts in round numbers to ten million dollars a year. In Ontario, on a ten-year average, about half a million acres burn each year. If these were grouped in one block they would cover more than twenty ordinary sized townships.

Are the best economic interests of Ontario being served in the long run by maintaining a system of cutting trees that makes little or no provision for a future crop on the cut over areas? This system has in the past left behind it thousands of square miles of barren and semi-barren lands and depopulated once prosperous saw-milling towns, as for example in the former pine districts of central Ontario.

It is the object of forestry to create forest conditions so that such economic waste would not occur. It is certainly a great problem in this country to prevent such waste by the restoration of normal forest conditions, but it must be resolutely faced and acted upon if the full economic and industrial possibilities of our forest heritage are to be realized.

But the chief purpose of forestry goes beyond the mere restoration of previous forest conditions. What would be the status of agriculture today, if man had continued to be satisfied with the fruits and grains which nature gave him? Nature is satisfied if she covers the ground with trees, whether or not they are of any economic use to man. Thus there are forested areas that are of no direct value to man, although they may have considerable indirect value for watershed protection and cover for game and furbearing animals. The commercial forests themselves are usually uneconomical mixtures. Valueless trees grow side by side with valuable trees. Of the valuable kinds the crooked and decrepit are mixed with the straight and healthy trees. The result is that our forests as nature gives them are low in commercial wood production. For example, the average cut of spruce pulpwood in eastern Canada is about eight cords per acre, based on the area actually worked over for logs leaving out the barren or burned areas. Further, it has taken eighty to one hundred years to produce that eight cords on the average acre. This small yield is not all the wood produced on the average acre during this long period. There may be twice as much wood, or more, but much of it is non-commercial because of kind or quality.

Such low yields on good forest soils near markets are uneconomic.

Just as agriculture has greatly increased the quantity and improved the quality of the crop on farm soils, so also

Sand Dunes Covering Fences.

the science of forestry when given opportunity increases the quantity and improves the quality of the crop on forest soils. An essential difference in the two cases is the time element; it takes longer to bring a crop of trees to commercial maturity than the ordinary farm crop. This then is the chief object and practice of forestry in those countries where it gets a real chance.

### European Methods

There are many European countries where forestry gets a chance to demonstrate what it can do, as for example, in Denmark, Norway, Sweden and Finland. The most impressive thing to a Canadian travelling through those countries is the care and thought put into the propagation and management of the forests. Each stage in their development is the result of careful planning and direction. They leave an impression of well being, tall straight trees with long clean bodies, no crooked trees, no dead or dying trees. There is no devastation by lumbering and no large areas of waste land, at least in the commercial forest regions.

The original charter of a large mining company in a town in central Sweden contains the grant of a large area of forest to furnish charcoal for smelting the copper and iron ore from the mines, and was granted in 1288. When the use of charcoal declined with the introduction of electrical power smelting, the company went into the lumbering and pulp and paper business. The forest holdings of the company have been cut over for the past one hundred and fifty years under the direction of foresters and the land supports more timber per acre today than ever before.

The principle at the base of practically all the forest treatment in the Scandinavian countries is the gradual opening up of the forest. This is accomplished by clean cutting in patches and narrow strips or by a series of thinnings. The latter seems to be in most general use. The thinning begins as soon as the product can be sold and continues at intervals of five years or so over a period of twenty or thirty years. In the later stages the thinnings are heavier, that is, a larger proportion of the trees is removed.

These heavier thinnings let in more light and heat and thus stimulate the food manufacturing processes in the soil. This makes conditions favourable for the natural regeneration of the forest, so a new forest begins to develop under the protection of the older trees. In the last stages of the system there may be only ten or a dozen or even less seed-trees per acre. They do not blow down in their isolated positions, because the protecting trees around them have been removed gradually through a period of twenty or thirty years, sometimes longer. (In our system of cutting pulpwood, if a few scattered seed-trees are left accidentally or otherwise, they are soon overthrown, for there is no attempt to train them gradually to wind resistance.) In time the scattered seed-trees usually cover the ground with young trees, and then the mother trees when no longer needed are removed. In course of time the thinning cycle begins again in the new forest.

In the early stages the thinnings are used for fuelwood and in Sweden particularly for charcoal wood as well; in the later stages for pulpwood and saw logs. The thinnings remove the decrepit and backward trees to give more room for the straight and rapidly growing trees. That is the reason the forests give the impression of vigour and well being. With each thinning the remaining trees have more room for crown expansion and they have fewer competitors for the food materials in the soil; thus they grow faster and, being well pruned when they were growing close together in their earlier stages, they make a better quality of wood.

The result of such treatment is that the well managed pulpwood forests yield much more per acre than our uncared for forests. Scandinavian forests on the best soils yield about a cord of wood per acre for each year of their life, so if the trees are seventy to eighty years old when the final cutting takes place they have yielded since the first cutting seventy or eighty cords per acre. On the medium soils the yield is about one half and on the poorer soils about one fifth this amount. It is a fair statement to say that the commercial forests of Sweden yield forty to fifty cords per acre during the rotation, or in other words five or six times more than our pulpwood forests produce on the average during the same period of time. There are extensive pulpwood areas in eastern Canada that yield no more than five or six cords of commercial wood per acre.

This shows what might be accomplished with our pulpwood forests if regarded not as mines to be exploited as soon as possible but as crops to be continuously reproduced.

In normal times Ontario cuts about a million cords of pulpwood annually. In the lowest of depression years, the production fell to half that amount, but owing to improved business conditions and the energy of the present government it is probable that the amount cut during the present season will equal or surpass the normal of one million cords. Taking the production on the average acre as eight cords, about 125,000 acres are cut over to produce a million cords of pulpwood each year. If these pulpwood forests were as fully stocked and well treated as those in Sweden, 25,000 acres—an area a little larger than that of an ordinary sized township—would furnish an equal amount of pulpwood during the rotation period. Since the rotation in Sweden is eighty years, eighty townships would suffice to furnish perpetually one million cords of pulpwood each year. According to the latest governmental report, the pulpwood concessions in the province aggregated some 53,000 square miles of forest land or the equivalent of more than 1,400 townships in area.

It would of course take a long time to put our forests into such highly productive condition as those of the Scandinavian countries, but would it not be worth while? Other things being equal, it would greatly cheapen the cost of logs at the mill, because one acre during the rotation period would yield an amount of wood equal to five acres of our unmanaged forests. We must keep down the manufacturing costs of wood pulp and newsprint if we are to compete in the world markets. In normal years the tendency has been the other way, that is towards increasing costs, not entirely but largely due to the fact that the wood supplies are receding farther and farther from the mills. Every mile increase in the distance of supplies from the mill, increases our disadvantage in the export markets. Practically the only alternative left to us is to treat our forests in such a way as to greatly increase the production of wood per acre.

**Remains of White Pine Forest with Young Plantation in Background.**

There is another great advantage in the Scandinavian methods, namely the increased efficiency of labour. The woods workers in Sweden, for example, have permanent jobs and live on little farms along the streams in the forest. For the most part, they can return to their homes at night; in fact timber cutting and logging is a trade handed down from father to son. The men make a good living and they are contented. Labour disturbances are very unusual.

Contrast these conditions with those in the pulpwood forests of northern Ontario, where usually three crews are in evidence, one going in, one going out and another actually at work in the woods. A company needing only 500 men for timber cutting may have 1,500 different men on its pay roll during the cutting season. Such a great labour turn-over can only result in inefficiency and high logging costs.

In reply to statements urging us to look to Scandinavian countries for guidance in the management of our forests, it is said that climatic, labour, and market conditions are so different that no just comparisons can be made, but is this true? The climatic conditions of central Sweden, for example, where the commercial pulpwood forests are located, are practically the same as those of northern Ontario. The soils appear to be poorer. It costs the operator about the same amount per cord to get his logs to the mill. The labourers in the mill and in the woods get about the same monthly wage. The tax burden on the industry is certainly as great as in Ontario. The companies pay a property tax to the municipalities in which their timberlands are located; they pay a graded income tax; they contribute towards sickness insurance, old age pensions, and in some cases to unemployment insurance. The employees in the mills in some of the countries draw a two weeks holiday with full pay, or a month's holiday with half pay.

Even with all these charges on the industry, the pulp and paper companies do not feel that they are compelled to cut every available stick of pulpwood on a given area at one time in order to make a reasonable profit. They wish to establish a permanent business, so they handle their forests in such a manner as to make them continuously productive, that is the amount of the annual cut does not exceed the amount of annual growth. It should be noted, however, that this point of view has been brought about gradually under governmental leadership during the past thirty or forty years. The government through the work of its foresters first demonstrated that the forests on Crown lands could be managed on the basis of sustained yield with profit. Then laws were passed which stated in effect that a lumberman or a woodlot owner may cut in any manner he pleases on his own lands, but he must re-establish the crop. There must be no idle forest soils within the commercial forest region. If the owner cuts an area clean he must re-establish the crop by planting seedlings or sowing seeds. If he has not done this within three years, the state does it for him and sends him the bill. If he refuses to pay, the bill is sent to the tax collector. There is no escape from the obligation. As already stated, however, most of the operators get the new crop as a result of their logging operations through periodic thinnings. Here again the state foresters first demonstrated that this method was profitable.

A trade situation follows from the high yield condition of the Scandinavian forests that should be of great concern to every Canadian citizen. The export of chemical pulp from these countries to the United States mills to be converted by them into various paper and cellulose products is steadily increasing from year to year. Thousands of tons of this material pass by Toronto's front door, up the St. Lawrence and over the lakes to mills in Michigan and Wisconsin. Every ton thus going to the United States mills reduces by so much our export market of chemical pulp. The United States mills buy this material because it can be laid down at the United States lake ports and seaports at a smaller price than from our mills only a few hundred miles away. The principal reason for this is that the Scandinavian countries cut five cords where we cut only one on an equal area.

**Pine Seedbeds, showing Protective Shades and Overhead Watering.**

These facts are the basis of the argument that the productiveness of our pulpwood lands must be increased if we are to remain much longer as a competitor in the world markets.

But, we are told, why worry, we have such extensive forested areas that our supplies are inexhaustible. Is this correct, from an economic standpoint? Stands of timber located so far from the mills that they cannot be profitably utilized should not enter into the calculation, so that estimates of our timber supplies should not be accepted without careful analysis. So many modifying influences surround the problem that most predictions as to the limit of pulpwood or sawlog supplies are mere guesses based on insufficient data; only a few are well considered estimates based upon available factual data.

Three-year-old Spruce Beds ready for Planting.

### Forest Depletion

The usual method of procedure is to take the estimate of the total standing merchantable timber in the country and divide it by the annual depletion. The annual depletion by logging is known and the depletion by fire can be fairly well estimated. Using these data, it is found that in the country as a whole we have only about forty years supply of saw-timber and perhaps a little more than one hundred years supply of spruce and balsam pulpwood. More than one-half of the estimated saw-timber is located in British Columbia. This estimate is based on the timber of merchantable size within the territory where logging is profitable under normal economic conditions, but includes within that territory many isolated areas that because of size or geographic location cannot be profitably utilized.

On the debit side of this estimate are other factors of depletion for which data are insufficient. These are insect pests, fungous diseases and wind storms. It is known that the annual depletion from these causes is very great. For example about fifty years ago an infestation of the larch sawfly began on the Atlantic coast and eventually reached the Pacific, killing practically all the larch trees on the way. About twenty years ago an epidemic of spruce budworm is estimated to have killed fifty years supply of pulpwood in Quebec and the maritime provinces. Within the past few years a spruce sawfly, more thorough and destructive in his work than any of the previous pests, started on a rampage in lower Quebec and is spreading rapidly westward. The Federal Government is making heroic attempts to check this latest epidemic by the introduction of parasites from Europe.

The depletion of standing timber values by fungous diseases is much less spectacular than that by insects and usually passes unnoticed except by the trained observer. About a year ago the specialist at Ottawa in charge of the study of forest-tree diseases stated that in his opinion the depletion of timber by fungous diseases each year was at least as great as that by logging.

The attrition by the wind is going on in the forest constantly. Much of this is a normal process but there is no doubt that it has been much increased by the opening up of the forests by lumbering operations and by fire.

Here then are three very important factors of depletion which we have as yet no method of measuring, although no reliable estimate of the duration of forest supplies can be made without taking them into consideration.

On the credit side of the ledger there are other non-assessable factors which are favourable, for instance, the enormous areas of young growth which cover more than four hundred thousand square miles in the Dominion as a whole.

In general there are three classes of these young growth areas. Some of them have been burned over and over again until all the softwood trees have been killed and they are now covered with inferior hardwoods. These areas will probably not enter into the future supply of spruce pulpwood, at least not for a hundred years, unless they are planted. Another class, not so severely burned, contains scattered young softwood trees but probably not enough to make such lands commercially valuable in the future unless they are reinforced by planting. From this type of young growth lands there are all transitions up to well stocked stands of young pine and spruce of great potential value.

Thus about one half of the accessible and productive forest area of the Dominion is covered by young growth stands not yet of commercial size; this is a condition chiefly due to forest fires. When the present commercial stands are cut over, resort must be had to the now young growth areas for future supplies of pulpwood and sawlogs. What can be expected from them? How much cordage are they building up for future use? This must be known before we can make any reliable estimate of the duration of our forest supplies. Before the depression overtook us, the Dominion Government and several provincial governments, including our own, began investigations to determine the growth and yield on second growth areas, but this work was seriously curtailed or wiped out in the name of economy. In Ontario it was completely abandoned. Such investigations should be resumed when budgets are balanced, because there is urgent need for reliable estimates of what is happening on one-half of the accessible forest lands of Canada.

Having pointed out some of the biological factors of depletion and accretion in the forest, and our inability to evaluate them because of insufficient data, we may pass to some of the economic factors of the problem of the duration of supplies. On their present basis, neither the sawmilling industry nor the pulp and paper industry could exist without the export market. Nearly one half of the lumber and more than four-fifths of the pulpwood products are exported. This means that the price of wood pulp, newsprint and lumber is controlled by the foreign markets. Every drop in the price of newsprint contracts the zone around a mill where operations can be profitably carried on. The price of newsprint is about sixty per cent that of ten years ago, and so the available supply of pulpwood has decreased very considerably in the past ten years on areas where not a stick may have been cut or no fire or insect depredation may have occurred.

Railway freight rates are another important factor in the commercial availability of pulpwood supplies for a given mill. There are two mills in this province whose distances from Toronto do not differ by twenty-five miles, yet one pays $6.80 and the other $3.60 per ton on newsprint by rail transportation to this city. This is due to the competition of the cheaper water transport in case of the lower rate. These two companies presumably pay the same amount per cord to the government for their wood. It takes about a cord of wood to make a ton of newsprint, so one company has an advantage of $3.20 per ton of newsprint over the other, on the assumption of equally efficient management. Therefore the company most favourably situated in respect to freight rates can go farther from the mill for its wood, and its commercially available supplies are the larger. The less favourably located company may have twice as much pulpwood on its limits but this is not reflected in the economic duration of its supplies.

There are of course other economic conditions, such as the cost of labour and materials, which enter into the problem of the available supply of timber.

**Plantation of Pine on Blow-sand Area.**

From the above considerations it is evident that any statement as to the length of time our timber supplies will last is entirely meaningless unless the factors of accretion, depletion and economics have been taken into consideration. A statement for example that a province has millions of cords of pulpwood in reserve, without any modification as to their commercial availability, is not only meaningless but misleading if it gives the public, the owners of the forest, a false feeling of security in regard to their property.

### The Fire Hazard

In regard to forest conservation one's first thought is naturally the destruction of the forests by fire and its prevention. Fire is undoubtedly the arch enemy of the forest. The forester's conception of the damage done by forest fires is not the same as that of the public. A newspaper will report that such and such a fire did no particular damage because it killed no standing timber. The forester knows that the most destructive fires are those that burn the young growth areas, from which our future supplies, if we have them, must come. Frequently, the first fire in standing timber does not do much damage, for the commercial trees killed are usually salvaged during the next cutting season and the natural regeneration following the fire is not seriously interfered with. The same holds true of the first fire on cut-over lands. In fact the best stands of young growth pine and spruce are to be found on areas that have been burned once and once only. The hope of the future lies in such stands, but unfortunately most stands of this kind are not allowed to grow up, because they are burned the second time, the third time; some of them are burned over and over again. The public does not realize that each year thousands of acres of potential forest lands are being transferred to the barren and semi-barren class through the agency of repeated forest fires, to remain in this condition for generations of men, unless restocked with commercial species artificially by planting.

Other disastrous effects of repeated forest fires also are not generally realized. They destroy the vegetable binding material of the soil, which with the next heavy rain starts on its way to the sea. Repeated forest fires prevent the accumulation of vegetable matter on the forest floor, which acts as a storage reservoir for rain water. Without this moist blanket, surface drainage is increased, the water flows from the watersheds in a shorter period of time; hence high flood stages of the streams in the spring and after the heavy fall rains, and also low stream stages in the summer. The economic losses resulting from the disrupted regime of our streams would more than pay the cost of a more effective fire protection.

The forest fire problem in its various aspects is so serious in terms of future forest supplies and the disordered condition of streamflow, that it should be given serious thought by all intelligent and patriotic citizens. Is this problem not being attacked at the wrong end? The greater portion of our energy and money is being spent in extinguishing fires after they have started. Would it not be much more logical and businesslike to spend the greater part in forest fire prevention, that is, in educating the people, because eighty or ninety per cent of all forest fires are due to human carelessness.

Most of the forest fires in northern Ontario are caused by tourists, campers, fishermen and the like. Psychologists tell us that it is very difficult to change the attitude of mind of an adult, so it would be well not to spend too much money in the attempt to educate carelessness out of the mind of the average tourist. It would be more effective to compel him to take a licensed guide with him to look after his camp fires and his cigarette stubs. It is probable that most of the tourists would not mind the extra expense and the plan would give at least summer employment to men who need work. There is already a law that gives the government power to close a forest to travel in time of danger, but it is difficult to enforce and in practice has not worked out well. It would be more effective and more profitable to the community to allow the tourist to enter the forest but furnish him with a guardian—at his own expense.

**Red or Norway Pine Plantation, Twenty Years Old. Trees 4 to 8 inches Diameter.**

The tourist-generated fire far in the wilderness is the most difficult to put out and easily gets out of hand, destroying extensive areas of forest. This class of fire should be subjected to more effective measures of prevention than at present exist, this to be accomplished through closer supervision of the deep woods traveller.

The most effective way of educating people into forest fire consciousness is to concentrate on the young people, whose minds are receptive. If the rising generation, the future frequenters of the forest, can be educated into a proper attitude towards forest fires our problem would be practically solved. This method is very successfully employed in the northern European countries and is being used with measurable success in certain states in the country to the south of us. Provision might well be made for giving illustrated lectures on fire protection in every high school in the province. These might be supplemented by simply written pamphlets on the subject to be used as collateral reading in the schools. The boy scout organizations are doing good work along these lines, but a relatively small proportion of the school population becomes boy scouts and we can reach the largest number most effectively by concentrating on the schools.

It seems, then, entirely logical and business-like to spend more money and energy in removing as far as possible the principal cause of forest fires, human carelessness. Until this is done in a well planned thoroughly organized statesmanlike manner, the cost of fire fighting in Ontario will increase until it becomes a serious burden upon the taxpayer. This statement is based upon the well known fact that the hazards are increasing in northern Ontario, due to the increasing tourist traffic and the greater accumulation of slash in the forest with the increasing lumber activities.

### Utilization and Marketing

Next take another problem which has an important bearing on the intelligent treatment of the forests for the purpose of maintaining Ontario's position in the world markets. It has been mentioned that one reason why the Scandinavian countries can keep their forests on a sustained yield basis is because they are able to utilize profitably the smaller trees removed by thinning, this material being used chiefly for fuelwood. These countries are short of coal; they have to import most of it, and their governments make it their business to discourage the sending of money out of the country to buy coal. They set a good example by using wood fuel in all the public buildings outside the few larger coastal cities. They have devised heat conserving furnaces for this purpose. The stoves in the private houses, and there is one in every room downstairs, do their work effectively and are very economical in the use of wood.

We could do a great deal more than at present towards using more of the low grade material for fuel. Good roads and automobile trucks are bringing the supplies constantly nearer the consumer. Cases are already in evidence where fuelwood has been hauled profitably for a distance of fifty miles or more. Greater use of wood for fuel in the country towns and villages would help reduce that twenty-five million dollars sent from Ontario each year, largely to the United States, to purchase coal for domestic heating purposes.

Another closely related problem lies in making possible a greater use of the so-called inferior hardwoods that are quite generally mixed with the more valuable soft woods throughout our forested areas. This could be done by developing minor wood using industries in the smaller towns, manufacturing furniture, tool handles, shoe pegs and perhaps a hundred and one other wood articles in common use now imported, in most part from the United States. The establishment of small woodenware industries would stabilize the working population of the small towns and increase the productivity of the forests.

A serious problem has arisen in marketing our sawmilling products, brought about by the constantly increasing use of substitutes for wood in building. The sawmilling industry, including all the factories that use wood as a whole or in part, produces more wealth annually for this province than the pulp and paper industry. This increasing use of substitutes for wood has been brought about largely by high powered advertising, although as a matter of fact wood is more serviceable in many positions than the substitutes now used.

To maintain our present position in relation to the world markets (to say nothing of improving it), the only way is to produce a better quality of product at the same price or the same quality at a cheaper price than our competitors. The manufacture of pulp and paper products however is so efficiently carried on, that there is probably not much more to be accomplished towards improving the quality of these products. There may however be a wider field for improvement of the quality of the product among many of the sawmilling establishments. The more progressive operators are conscious of this and are making strenuous efforts to remedy the situation.

On the whole then the problem is to put our products into the export markets at a cheaper price than our competitors, even though the cost of logs delivered at the mills is constantly increasing with the increasing distance to the supply, and there is increasing expenditure on higher wages, better housing and improved social services for the labourers in the woods.

The only solution seems to be an increase in the yield per acre. Other countries have done similar things with their forests. It is humiliating to acknowledge that we have less intelligence and less foresight.

The wood nearest the mill is the cheapest to convert into newsprint and pulp and as a general statement the areas nearest the mills have been the most completely wrecked from the standpoint of their continuous wood producing capacity. The first logical step is to restore these areas to productivity. In most cases this would mean planting.

The cheapest pulpwood products today are manufactured where the companies have the advantage of relatively low water transportation cost and this in all probability will be a more pronounced advantage in the future. Therefore the most profitable planting programme would consist in planting pulpwood species on the waste Crown land areas adjacent to the Great Lakes and the St. Lawrence river; there are hundreds of square miles of such lands available now lying practically idle so far as the growing of valuable softwood trees is concerned.

We are compelled to plant because we have abused our forest lands. The planting of large areas is an acknowledgement of our failure to understand nature's recuperative forces in the forest and to make them work for us. It seems illogical and unbusinesslike in our cutting operations to continue to employ methods that only lead to forest sterility so far as the next generation is concerned. Therefore the next step in the process of increasing the productiveness of our forested areas in order to maintain our position in the world markets is gradually to bring about a change in cutting methods, or in other words to treat the forest in such a manner that nature will produce the next crop for us practically free of charge. In this way no cutover lands would lie idle for long periods of time; they would be covered all the time with on-coming crops.

Emphasis has been placed all through this paper on the necessities of the pulp and paper industry if it is to be maintained through a long period of years, but all that has been said applies as well to the sawmilling industry.

The programme outlined is a large one, but the author believes that it must be carried out if our wood using industry, the third largest wealth producer in the province, is to be maintained in the markets of the world.

# Recent Developments in European Railroad Motive Power

*A. I. Lipetz,*

*Chief Consulting Engineer, in charge of research, American Locomotive Company, Schenectady, N.Y.*

**Paper presented before the Montreal Branch of The Engineering Institute of Canada, November 26th, 1936.**

**SUMMARY.—This survey of European practice gives particulars of present-day locomotive performance, discussing the successful modernization of steam locomotives in France, new developments in Great Britain and Germany, and the present situation as regards Diesel railway equipment in European countries.**

## INTRODUCTION

Motive power, and more particularly the steam locomotive, was responsible for the advent of the railway. Iron rails were used in England in the middle of the 18th century (1767), but the railway, as the modern means of mass transportation, had to wait until a successful unit of motive power, Stephenson's "Rocket," came into existence, one hundred and seven years ago. Then the railways sprang up, first in England and in the United States, and shortly afterwards, in every civilized country of the world.

During these one hundred and seven years railroad motive power made tremendous strides in its development and, accordingly, influenced the development of the railroad. The only thing left unchanged, although not without some exceptions, is the standard gauge, or, as it is sometimes called in Europe, the Stephenson gauge. Also, almost unchanged remained the clearance outline of the rolling stock and the bore of the tunnels. Everything else progressed, depending on the development of motive power, and more particularly, on that of the steam locomotive, as its progenitor. The progress in the art of rolling rails, and in rail metallurgy, is the result of the demand of motive power as the weight and speed of the locomotives went up. The same is true for railway signalling, which has made such marvellous progress in the last two or three decades, for automatic brakes, which have kept pace with the increase in weight and speed of our trains, and for every line of railroad engineering—all depending upon the progress which is being made by railroad motive power in general, and by the steam locomotive in particular.

The motive power engineer who is responsible for the up-to-dateness of his locomotive, must watch the progress in stationary power plants, steam boilers and engines, turbines, condensers, Diesel engines, transmissions, etc. Furthermore, he has to be familiar with the progressive ideas and attempts of his fellow engineers in other countries. Practice in Europe, the cradle of the steam locomotive, will repay his careful consideration. The author has been fortunate in being entrusted with the task of making frequent trips to Europe and keeping in touch with European developments by personal contact with railroad motive power and equipment supply engineers, and welcomes the opportunity to share part of his experience and some of his views with the members of this Institute.

## Speed and Power

The present trend in Europe, as also in this country, is towards increased speed. Freight and passenger traffic are being accelerated, not only in England, France and Germany, but also in smaller European countries. There are now in Europe a number of trains with average schedule speeds of 75-80 m.p.h., whereas in 1932 the "Cheltenham Flyer" of the Great Western Railway in England, with an average speed of 71.4 m.p.h., was the only fast train in Europe.

France and England have had a long-established reputation for the fastest trains in Europe; but since 1931 Germany has made enormous strides in this respect. Five years ago Germany had only one train from Breslau to Königszelt, with an average speed of 58.2 m.p.h., over a distance of 30.1 miles, while now there are 157 daily trains at that speed and over, with a total mileage of 11,000, or about thirty-six times as large. Of these trains, ninety-one, covering an aggregate daily mileage of 6,276, are running with speeds of 60 m.p.h. and over; of these latter trains, some are running with speeds over 62 m.p.h. (mileage 5,118); of these again, some with still higher speeds of over 64 m.p.h. (mileage 3,921); still others at speeds over 66 m.p.h. (mileage 3,641); further, with still higher speeds of 68 m.p.h. (3,000 miles), and twenty-nine trains with speeds of 70 m.p.h. and over. These latter trains alone have an aggregate daily mileage of 2,287.*

One of the new flyers, "Der Fliegende Kölner," covers the distance from Berlin to Cologne, 359.5 miles, in four hours and fifty-seven minutes (five stops), with an average speed of 72.6 m.p.h. Another flyer, from Berlin to Beuthen on the eastern border, covers the distance of 322.8 miles in four hours and thirty-four minutes (seven stops), with an average speed of 70.7 m.p.h.

The train "Flying Kölner" referred to above, is of the Diesel-electric type, first introduced in 1932 between Berlin and Hamburg and known as the "Flying Hamburger," with an average speed of 77.4 m.p.h. It makes the trip from Berlin to Hamburg (178.1 miles) in one hundred and thirty-eight minutes. The "Flying Kölner" has five stops between Berlin and Cologne and its average speed is only 72.6 m.p.h. in one direction and 69.8 in the other, but on its way to Cologne it makes a non-stop run from Berlin to Hannover, a distance of 157.8 miles, in one hundred and fifteen minutes, with an average start-to-stop speed of 82.3 m.p.h. This is the highest start-to-stop speed to be found in any railroad timetable, except that of the "Super-Chief" on the Santa Fe, which covers the distance between La Junta and Dodge City, 202.4 miles, in one hundred and forty-five minutes at an average start-to-stop speed of 83.7 m.p.h. There are now in Germany more than a dozen trains of this kind making regular runs daily, sometimes twice daily, between the principal cities of Germany: Berlin, Cologne, Leipzig, Frankfurt, Hamburg, Bremen, Stuttgart, Nuremberg and Munich. The longer distances are usually covered daily by a pair of trains of which one leaves at one end about 6 a.m. and arrives at the other end around noon, while another pair covers the same service from about 6 p.m. until midnight. Thus, a business man can go to a city at a distance of 300-350 miles, spend half a day there, and return home the same day.

Steam power takes care of heavy long-distance trains. There are now in Germany thirty-three daily steam trains with average speeds from 60.0 to 68.9 m.p.h. and thirteen electric trains with speeds in the same range; some of these are high-speed long non-stop runs, the longest high-speed run being from Leipzig to Nuremberg, on which a steam locomotive hauls a heavy train over a distance of 200.1 miles without stop, with an average speed of 58.9 m.p.h.

*These and the following figures, given in this chapter on speed and mileages, including those in Table I, have been taken from Cecil J. Allen's articles on speeds of European trains, which appeared in the Railway Gazette for 1936 (issues of January 31, February 21, March 6, March 27 and June 19). The figures and the table are reproduced here with this periodical's permission, for which the author takes this opportunity to express his sincerest thanks.

High-speed development in France followed a different path. The French railcar, driven by a gasoline engine and called "automotrice," was one of the first to appear in Europe. Now it is called "autorail" and is mostly driven by a Diesel engine. On the 1st of January, 1935, Germany had one hundred and sixty-eight railcars in service and two hundred and twelve under construction, a total of three hundred and eighty railcars compared with four hundred and sixty-three in France. The majority were built with Diesel engines, but the Bugatti and Michelin cars have gasoline motors. Very few have electric transmission. They have either mechanical, or mechanical with hydraulic drive.

The development of the German "Flying Hamburger" had a limited influence on the French high-speed development. Only two three-unit Diesel-electric trains were in service in France early in 1936, although many more trains of this type were under construction. At present at least four high-speed trains are already in operation. The average speed of the first two trains between Amiens and Arras on the Nord Railway is 68.3 m.p.h., but only a slightly lesser speed is being made by steam traction on the non-stop Paris-Brussels express run, covering a distance of 193.1 miles in exactly three hours (average speed 64.4 m.p.h.).

The Bugatti light-weight gasoline cars are used on the Etat, between Paris and Hâvre, on a distance of 141.5 miles, with one stop at Rouen. The average speed is 70.8 m.p.h.· The start-to-stop speed on the two laps of the journey, excluding the stop at Rouen, is 70.2 and 73.2 m.p.h. Bugatti cars are also used on the Est and Paris-Lyon-Méditerranée lines. Their start-to-stop speeds on these roads are about 70 m.p.h. It is interesting to note that the speed limit on French roads, is 87 m.p.h. for the Bugatti cars and only 75 m.p.h. for steam locomotives. Very often the service demands substituting steam locomotives for Bugatti cars. The average speed then drops to only 65 m.p.h.

The Paris-Orléans-Midi line has the distinction of operating the fastest steam trains on the continent of Europe: the distance between Poitiers and Angoulême, 70.2 miles, is covered by the Sud Express in exactly one hour—and this notwithstanding the speed limit of 75 m.p.h. The same road can boast other speed records of steam propulsion, very remarkable ones, considering the limitations imposed by grades, curves and slow-downs; and finally, the P.O.-Midi was, until recently, remarkable as the only French railroad without internal combustion railcars for very high speed; it was able to take care of all its traffic by steam power.

The French roads have quite a number of non-stop runs over 100 miles in length and several of the longest runs on the continent, up to 216.7 miles. The locomotives have no water pick-up, the tenders are not exceptionally large; the engines, therefore, are bound to be economical.

Great Britain is mainly a steam traction country. There are on the British railroads fifty-two daily steam runs with start-to-stop speeds of 60 m.p.h. and over. The mileage of these runs is 5,371. No Diesel or electric train runs belong to this category. In this respect Great Britain differs essentially from both Germany and France, where Diesel railcars and trains are in vogue. A partial explanation of this fact can be found in Sir Nigel Gresley's last presidential address before the Institution of Mechanical Engineers, on October 23rd, 1936, in London. He stated that after a trip in 1934 on the "Flying Hamburger" from Berlin to Hamburg and back, he approached the makers of that train, supplied them with data on the grades, curves and speed restrictions of the London and North Eastern Railway, and got from them a proposition for a Diesel-electric train weighing 115 long tons, to run from King's Cross (London) to Newcastle, 268 miles. They offered to cover the distance in four hours seventeen minutes going up, and four hours fifteen and a half minutes coming down, which the London and North Eastern could easily accomplish with steam power. To prove that, they ran a train on March 5th, 1935, weighing 253 tons and hauled by a regular seven-year old Pacific type steam locomotive at an average speed of 67.05 m.p.h., covering the distance from London to Newcastle in four hours, and thus bettering the time offered by the German Diesel-electric train builders for the London and North Eastern local conditions. The decision to build a steam train, the "Silver Jubilee," was then reached.

This train, which has been running now for over a year between London and Newcastle in four hours, with one stop at Darlington, makes the regular trip from King's Cross to Darlington at an average speed of 70.4 m.p.h. On its down journey the distance between Hatfield and Selby, 156.7 miles, is covered in one hundred and twenty-five and a half minutes at a speed of 74.9, almost 75 m.p.h., from pass to pass, but not from start to stop.

Only one steam train in Great Britain, the "Cheltenham Flyer" on the Great Western, makes slightly better speed than the "Silver Jubilee." It covers 77.3 miles in sixty-five minutes, with an average speed of 71.4 m.p.h. from start to stop. Therefore, the distinction of running the fastest steam trains in Europe still belongs to Great Britain.

The above figures, which should give a brief idea of the present trend in the progress of speed on principal European railroads, as it has established itself in 1936, are summarized in Table I, in which comparative figures are also given for the United States and Canada.

In order to achieve these remarkable results, not only new designs and improvements of the power plants became necessary, but new ideas in the construction of the equipment had to be adopted. This led to the practice of lightening both locomotive and cars, and established a tendency to what may be called "concentration of power." With the increase in speed the power per unit of weight had to

*With electric transmission.

go up. When further the Diesel engine proved its advantage as regards thermal efficiency, there was a great temptation to adopt high-speed Diesel-electric trains. However, the limitation of the Diesel engine, even the high-speed Diesel, with respect to its power-weight ratio, soon became apparent, and, therefore, if the power plant was heavy, the chassis of the vehicle had to be light. Thus, new metals, like aluminum, high tensile or stainless steel, and new methods of construction, like welding, had to be employed. This led to the light-weight Diesel-electric train, introduced first in Germany, and then in the United States and in other European countries. If the Diesel could not meet the power of the steam locomotive, it was necessary to make the vehicle lighter to achieve the same results.

How was the steam locomotive to meet this new challenge? The first of its past rivals had been the electric locomotive, which did not turn out to be so formidable as expected. Then came the switching Diesel-electric locomotive, very modest, with rather limited pretensions; this rival did not prove to be so important either. The latest rival, though, seemed to be serious, and the situation was met by "concentration of power."

### Concentration of Power

This was not new for the steam locomotive, especially in Europe. It was already customary in some countries of Europe to evaluate the perfection of a design of a locomotive by its "quality number." This was arbitrarily expressed by a ratio, the numerator of which was the sum of the water evaporating heating surface of the boiler and 80 per cent of the outside superheating surface, the denominator being the weight of the locomotive in working order (without tender). A more significant figure for our purpose would be the ratio of the actual power, as determined by tests, to the weight of the locomotive with half-loaded tender—this in order to make it comparable to the Diesel locomotive, which has no tender, but carries a supply of fuel and water. For weight calculation, the supply tanks of Diesel locomotives and trains are assumed to be always full. This ratio could be called "power concentration factor," or still better "specific power factor."

Table II gives comparative figures for the specific power factors of some modern steam and Diesel locomotives and trains. The figures are given in rail horse power per ton of weight. The horse power is in British units (660 foot-pounds per second); the weight is in American short tons (2,000 pounds); the weight of the tender is with half supply of water and fuel; the rail power for steam locomotives is taken from test, and when this is not available, is figured from the indicated horse power from test, multiplied by the mechanical efficiency of the engine drive, which is assumed to be 90 per cent. For Diesel-electric locomotives, for which usually the brake horse power of the oil engine is known, the rail horse power is figured on the efficiency of the whole transmission (electric, gear and axle) being 75 per cent. The same applies to power cars of Diesel-electric trains, and for the latter, if the power car has seats for passengers, an adjustment for this part of the weight is made. For trains and locomotives with mechanical transmission the efficiency is assumed to be 92 per cent. For turbine locomotives with direct drive by precision gears the mechanical efficiency is taken equal to 94 per cent; for turbine locomotives with electric transmission, to 75 per cent.

### STEAM LOCOMOTIVES

When multiplied by the ratio of the weight of the locomotive with half loaded tender to the weight of the train, the specific power figure represents the power input per ton of train weight and is a good criterion for the ability of the locomotive to accelerate the train.

Thus, as can be seen from Table II, the greatest concentration of power has been achieved, so far, by the steam locomotive, and in this respect the most remarkable results have been attained by the now famous Pacific locomotives of the Paris-Orléans-Midi Railway of France.

Since 1908 this railway has had a great number of Pacific type locomotives which first had been built as four-cylinder compound locomotives for saturated steam, and later as two-cylinder locomotives for superheated steam. Still later (1912) the railway tried four-cylinder compound locomotives with superheated steam and found them to be very efficient. These locomotives have been in exclusive use on the P.O.-Midi Railway for high-speed passenger trains for more than twenty years.

As the size and weight of locomotives, especially in Europe, were approaching their limit, the increase in power could be achieved only by increasing efficiency. Furthermore, due to conditions of economic depression, it became impossible for the French railways to buy new power. Mr. André Chapelon, mechanical engineer of the P.O.-Midi railway, decided to find out what could be done in order to increase the efficiency and the power of their Pacific locomotives. He realized first that too much wire drawing was taking place in the steam passages of the cylinders. Therefore, it was obvious to him that the passages must be enlarged. The "circulation of steam," as it is called in France, had to be improved. This necessitated changing the cylinder castings, making the steam passages wider.

The valve motion was to be changed too. Poppet valves were, in the opinion of Mr. Chapelon, a better means for steam distribution. He did not go, however, to the new rotary cam poppet valves, as this would require too many alterations in various parts of the locomotive, and furthermore, he did not wish to give up the advantages of the Walschaert gear for railroad operating conditions. He found it sufficient, retaining the Walschaert valve gear, to connect it to Dabeg (Lentz) poppet valves. He considered it important to give the valves, especially those of the exhaust, ample dimensions. They were made: for the high pressure cylinders, $7\frac{7}{8}$ inches, both for admission and exhaust, and for the low pressure cylinders, $8\frac{5}{8}$ inches for admission and $9\frac{7}{16}$ inches for exhaust. At the same time, cylinder dimensions were enlarged, increasing this volume by approximately ten per cent. Thus, the power of the locomotive was increased, in addition to the improvement in efficiency. Figures 1 and 2 show the longitudinal and cross sections of the Pacific locomotives at one stage of the transformation.[1, 2, 3]

The next modification was the adoption of the Kylala, known also as the KC, or Kylchap, smoke box arrangement. In this the exhaust is divided into four jets directed in an intermediate petticoat, from which the steam is further exhausted into an ordinary petticoat before entering the stack. Special tests made on the Paris-Orléans in 1929 proved that with the same back pressure, the vacuum in the smokebox could be almost doubled. By using the duplex arrangement, tried on some American four-cylinder Mallet locomotives—two stacks, two nozzles, two sets of petticoats, alongside one another in the longitudinal centre plane—the back pressure decreased while the vacuum increased considerably. Thus, more power could be obtained from the steam in the cylinders, increasing the evaporation and improving the combustion.

Instead of the Schmidt superheater, a new superheater known as the Houlet was adopted, which is claimed to give about 50 degrees F. more superheat due to the use of better tube proportions and more effective heat exchange. The large flues of the type "A" Schmidt superheater were retained. The principal dimensions of the firebox and boiler remained unchanged, but the firebox was rebuilt and made of steel. The pressure was raised from 230 to 288 pounds per square inch and a Nicholson syphon was intalled.

With these simple means and general refinement in the machinery, like channelling outside rods, improving counterbalancing, etc., several locomotives were first tried out. The results were surprising. The increase in power amounted to 30-40 per cent, due mainly to the improved efficiency of the locomotive. Other locomotives were rebuilt and tried out, giving similar results, not only on the P.O., but also on other roads. On some, like Nord, Est, the modifications were simply duplicated and converted locomotives bought from P.O.-Midi; on others (Etat, P.L.M.), the modifications were further developed. Thus, dozens of the old P.O. locomotives, some twenty-eight years old, but now rejuvenated by Monsieur Chapelon, are doing at present splendid work on the French roads. They are probably the most powerful, and are among the most economical in Europe. The Houlet superheaters, however, have given some trouble when the boilers were forced and the temperatures were high; some parts of the units had to be made of heat resisting steel, a practice which is now being tried by at least one more French railroad.

The steam and coal consumptions per drawbar horse power hour on the latest Chapelon locomotives are given in Table III. The curves are rather flat and when analyzed, bear witness to the remarkable achievement in the efficiency of the locomotive.

Table III
Minimum Water and Coal Consumption per D.B.H.P. hr.

| Speed m.p.h | Water, lbs. | Coal, lbs |
|---|---|---|
| 43.5 | 14.5 | 1.91 |
| 55.9 | 15.6 | 2.02 |
| 68.4 | 16.3 | 2.23 |

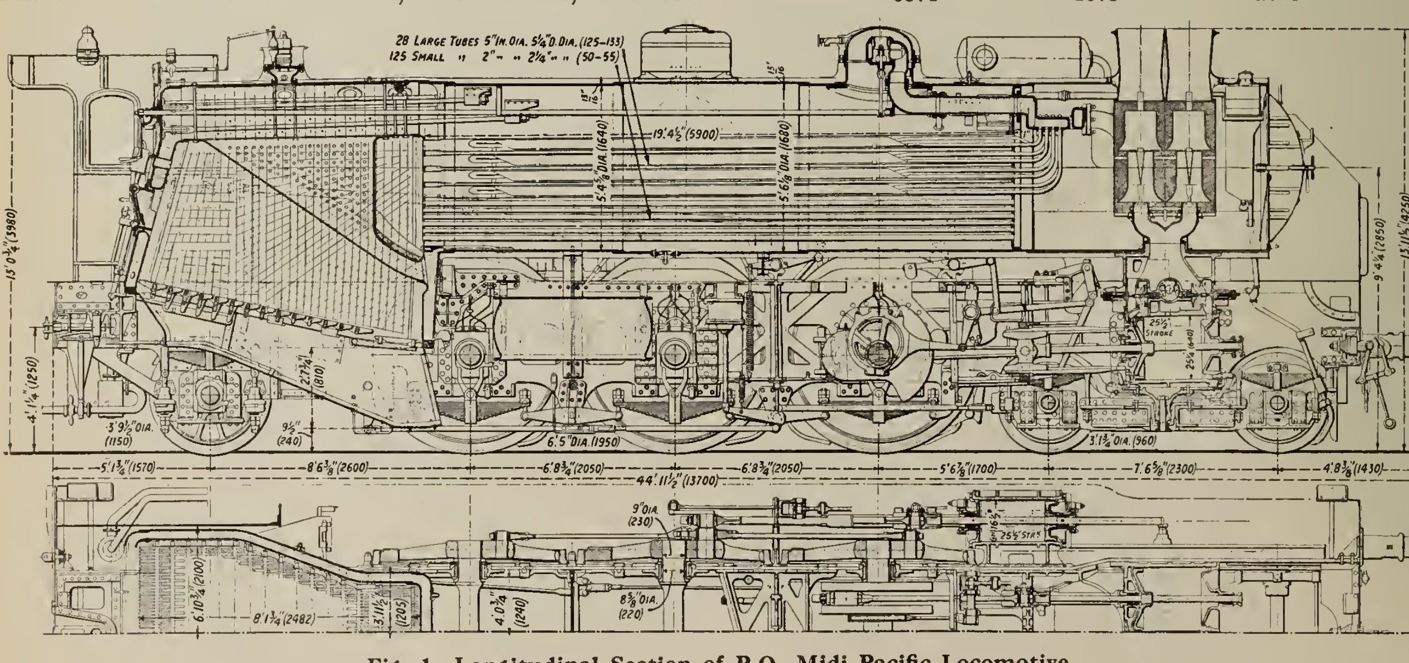

**Fig. 1—Longitudinal Section of P.O.-Midi Pacific Locomotive.**

The author was fortunate in having had the privilege of witnessing the specially made test with train No. 7 from St. Pierre des Corps to Bordeaux on October 3rd 1935, with one of the latest converted Pacific locomotives, No. 231-726 (Fig. 3). At the test, the timing of the Sud Express was followed, but the tonnage was considerably enlarged, namely, instead of a normal 235 metric tonnes, the locomotive pulled 622 tonnes (686 short tons), or a train 2.65 times as heavy. A speed fluctuating around

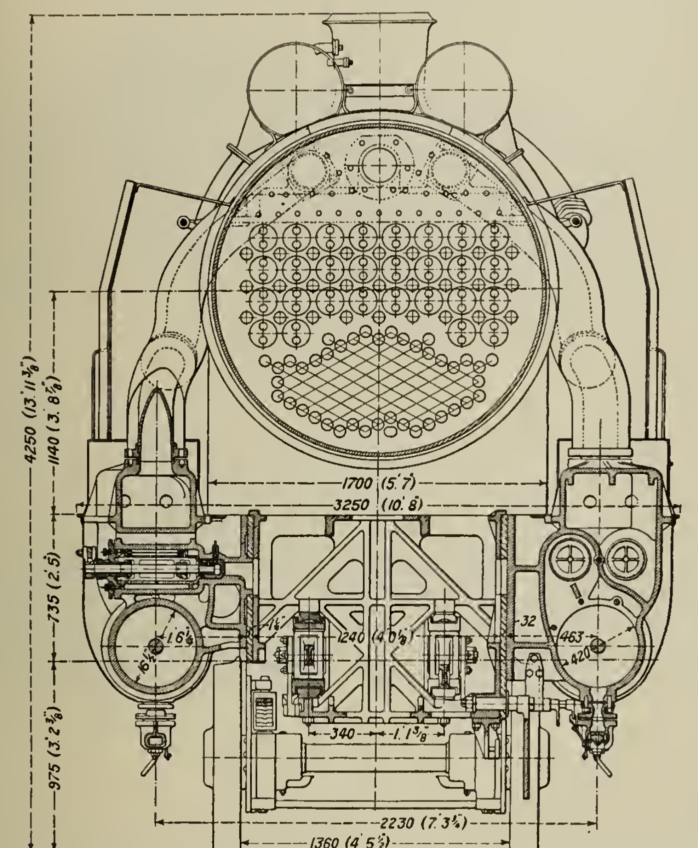

**Fig. 2—Cross Section of P.O.-Midi Rebuilt Pacific Locomotive.**

120 klm. (74.6 m.p.h.) (which is the permissible limit for steam locomotives in France with scheduled trains), was constantly maintained and average speeds of 70 m.p.h. and over were made on the trip between stops—see dynamometer chart between Angouléme and Poitiers (Fig. 4). The power chart for miles, between Angouléme and Charmant, on 0.5 per cent grade, registered 2,100-2,300 d.b.h.p. Adding the locomotive air resistance, friction, and gravity resistance to the drawbar horse power, would give about 3,500 rail horse power.

A number of 4-8-0 locomotives were likewise rebuilt from the same Pacifics. One of them is shown on Fig. 5. This locomotive developed a speed on a level of 150 klm. (93.2 miles) per hour with eight cars weighing 410 tonnes (452.6 short tons).[4, 5]

### Steam Locomotives on Other French Railways

The P.O. locomotives have proved so satisfactory that practically all railways in France adopted their ideas and even bought locomotives from the P.O.-Midi Railway wholly or partly modified in accordance with Chapelon's ideas. This was also due to the fact that French railways during the depression time were dependent upon government subsidies, and as a result, were encouraged to buy converted locomotives from the P.O.-Midi Railway, rather than new ones from builders. However, some new locomotives were also built, with changes to the P.O. recommendations. At present there is a total of 515 locomotives on French railways, converted or new, of the P.O. design. They are distributed as shown in Table IV.

Table IV
Distribution of Chapelon Locomotives on French Railways

| | P.O. | Nord | Est | Etat | A.L. (Alsace-Lorraine) | P.L.M. |
|---|---|---|---|---|---|---|
| Converted Locomotives | | | | | | |
| Type 4-6-0 | .. | .. | 90 | .. | .. | .. |
| Type 4-6-2 | 46 | 20 | 63 | 121 | 40 | 55 |
| Type 4-8-0 | 12 | .. | 40 | .. | .. | .. |
| New Locomotives | | | | | | |
| Type 4-6-2 | .. | 28 | .. | .. | .. | .. |
| Total | 58 | 48 | 193 | 121 | 40 | 55 |

The majority of these locomotives have Dabeg (Lentz) poppet valves, but some railways preferred other valves with which they had experience of their own. Among them was the Trick double ported valve of the piston type recently developed under the name of Willoteaux, with double admission and double exhaust ports. According to the Est Railway, it has given very good results. One hundred and seventy of the converted locomotives were equipped with these valves on the low pressure cylinders. The Etat and P.O. had twenty and fifteen locomotives respectively with Willoteaux valves on the high pressure cylinders. The P.L.M. acquired fifty-five locomotives with new cylinders and old piston valves, both for high and low pressure, with longer travel. The Etat applied six with Renault poppet valves among the converted locomotives.

Similar to the valves, a variety of draft arrangements was also used on the converted locomotives. The majority had either the simple or the duplex (with two stacks) Kylchap arrangements of the P.O. locomotives. However, the P.L.M. and Est Railways retained their simple exhaust nozzles with fingers, similar to the Goodfellow nozzle used in America. (See particulars below, under "Exhaust Arrangements").

### The Machinery of the French Steam Locomotives

The railroads of France, more than those of any other country, have always been in favour of multi-cylinder engines, especially of the four-cylinder compound type. For the last fifty years, since the appearance of the first four-cylinder deGlehn and du Bousquet locomotives, this type has become universal on French railways, because of the higher thermal efficiency and better balancing of the engine. For a while, after the advent of superheated steam, it was thought that superheat would make compounding superfluous and the two-cylinder superheated engine with simple expansion was thus reintroduced, only to be soon replaced by the old four-cylinder compound engine, reinforced, though, by superheat. Since then the four-cylinder compound superheated engine has been very much in vogue.[3]

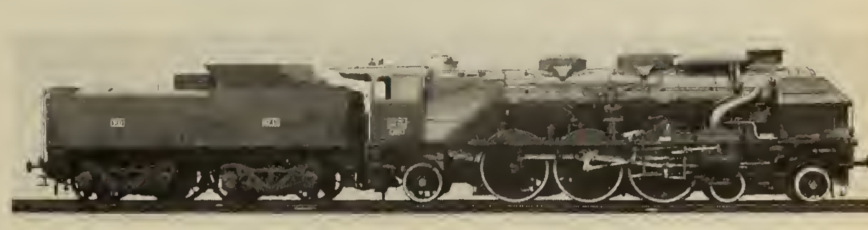

**Fig. 3—Longitudinal View of one of the latest P.O.-Midi Rebuilt Pacific Locomotives.**

However, notwithstanding the universal popularity of the four-cylinder locomotive in France, several hundred three-cylinder locomotives were built and placed in service within the last five or six years on the Est. They were tank engines of the 2-10-2 simple expansion type with superheaters, built by the Société Alsacienne des Constructions Mécaniques. Furthermore, the Northern Railway of France, where the first deGlehn locomotives made their debut about half a century ago, recently built sixty 2-8-2 locomotives of the two-cylinder superheated simple expansion type for heavy suburban traffic. They proved to be very successful. They have 25¼-inch by 27½-inch cylinders, with wide steam passages, 61-inch driving wheels, 261 pounds per square inch boiler pressure, and are able to pull, as a test on August 8th, 1932, has shown, a train of 530 short tons at a speed of slightly over 60 m.p.h. on a 0.5 per cent grade. The locomotives are equipped with cam-operated piston valves of the Cossart type, which are claimed to have very little leakage and permit cut-offs as small as 5 to 7 per cent. During the above referred to test, when the 530-ton train was pulled on a 0.5 per cent grade at 60 m.p.h., the cut-off was 10 per cent. The maximum speed of the locomotive was close to 70 m.p.h., with driving wheels only 61 inches in diameter.[6]

The same Railway (the Nord) has for its freight service 2-10-0 superheated locomotives, also with 261 pounds boiler pressure, but of the four-cylinder compound type. The high-pressure cylinders have a diameter of 19½ inches and a stroke of 26¾ inches, while the low pressure cylinders are 25½ by 27½ inches. The diameter of the driving wheels is also the same—61 inches. These, as practically all French four-cylinder locomotives, have crank axles, two of the cylinders (generally the low pressure) being the inside, and driving the first crank axle, while the outside, smaller cylinders, drive the second main axle. A very bold innovation was introduced in new 2-10-2 locomotives built by the P.L.M., in which also four cylinders, two low and two high pressure, were provided, but all four were placed outside the frame, driving the second and the fourth axles (Fig. 6). As the two rear cylinders had to be placed between the second and third driving axles, side rods could not be placed between them. However, inside side rods were employed in order to keep the outside cranks at a phase of 180 degrees for proper balancing. The inside cranks and side rods are of comparatively small size, as their main function is to keep the main cranks in proper relation and not to transfer power, which is supposed to be equally divided between the two machines. The locomotives, which have already been in service over three years, have given complete satisfaction. The front (low pressure) and the rear (high pressure) engines have Dabeg (Lentz) poppet valves.

Besides the Lentz type poppet valves of the P.O.-Midi and the P.L.M. locomotives and the Cossart cam-operated piston valves, there are one or two locomotives with Caprotti valves and gears on the Nord and several on the Alsatian (Alsace-Lorraine) Railway. A two-cylinder locomotive of the 2-10-2 type, with Caprotti valves, has just been placed in service on the latter Railway. It is the

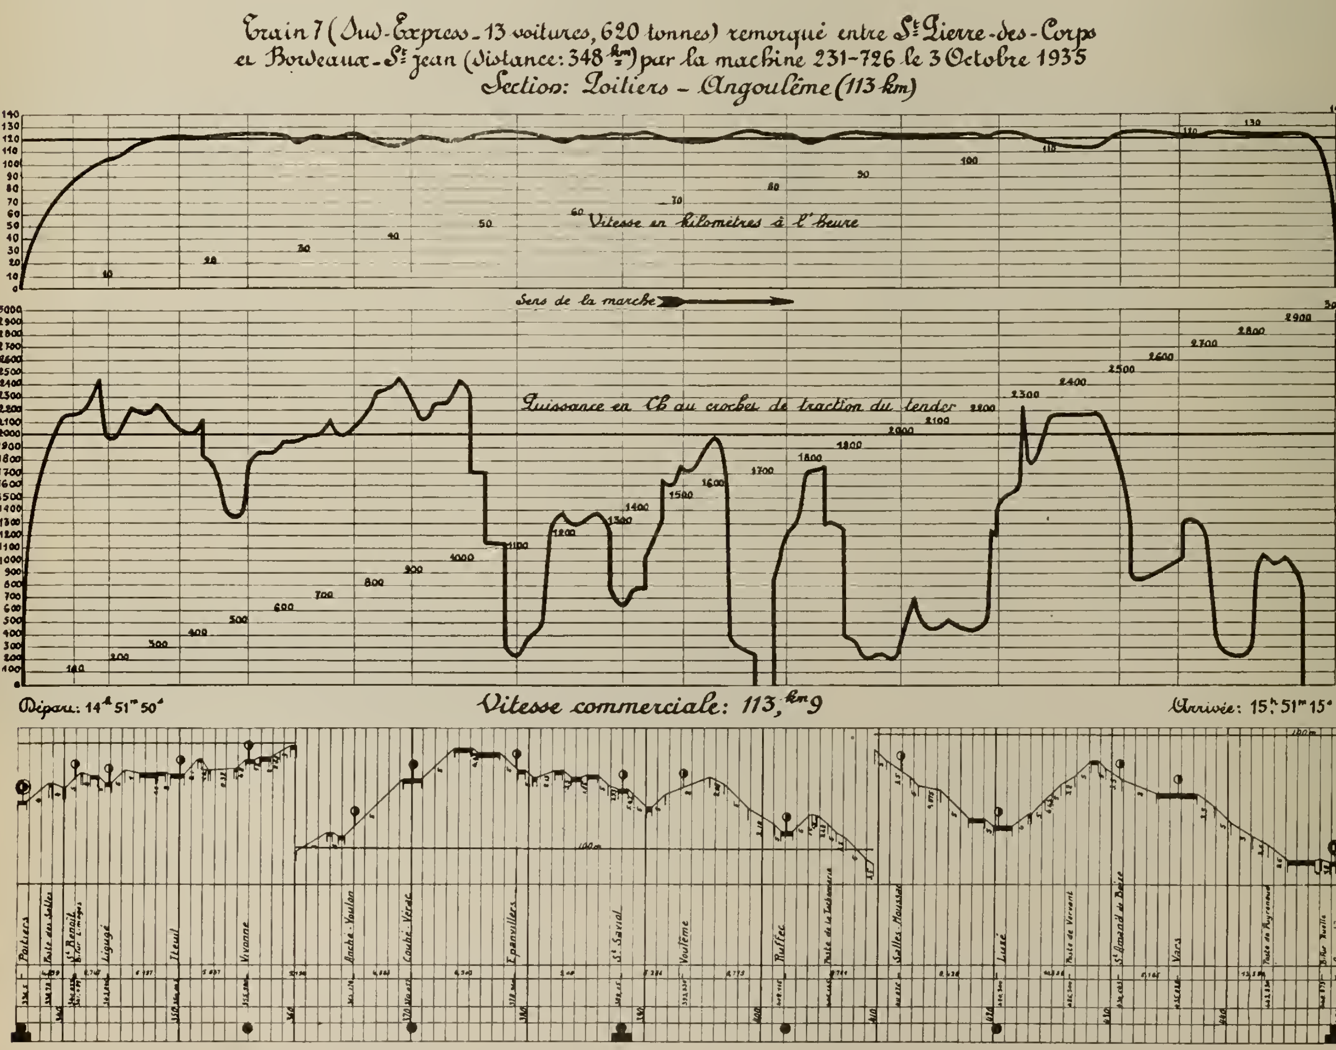

Fig. 4—Chart of Speed, Power and Profile Test with Rebuilt Pacific Locomotive on P.O.-Midi Railway.

first of two, ordered in 1935 from the Société Alsacienne des Constructions Mécaniques. It will probably soon be tested. Two other locomotives of the Pacific type, with Caprotti poppet valves, were also built by the same company and delivered to the railroad.[7]

The P.L.M. Railway, following the P.O. example, rebuilt some of their Pacifics, changing the boiler pressure from 228 to 284 pounds per square inch, increasing the cylinders and steam passages, replacing the valves by

Fig. 5—View of P.O.-Midi Converted 4-8-0 Locomotive.

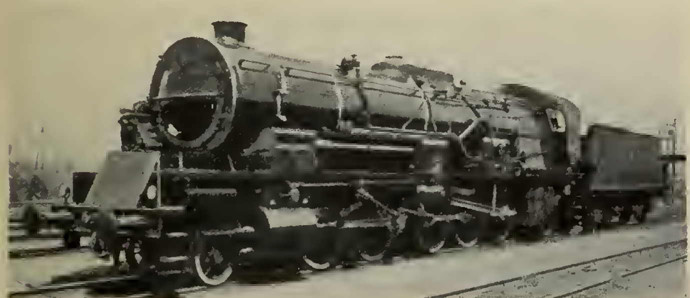

Fig. 6—View of 2-10-2 P.L.M. 4-Cylinder Compound Locomotive with Outside Cylinders.

Dabeg poppet valves, retaining, however, the Walschaert valve motion, and applying the P.L.M. double stack draft arrangement with ordinary nozzles. A regular Schmidt superheater in combination with a Dabeg feed water heater, both situated in the large flues of the superheater, were employed on one locomotive, 231-F-141.[8] It was recently tested at the stationary testing plant at Vitry and, according to information just received, has shown over 3,000 rail horse power.

Likewise, the Nord has just reconditioned a new powerful Pacific locomotive, one of the so-called "Super-Pacifics" (Fig. 7), built in 1931. The locomotive is placed in the recently inaugurated Paris-London Ferryboat train service via Dunkerque-Dover.

### Exhaust Arrangements

We have already seen that Mr. Chapelon adopted the "Kylchap" smokebox arrangement for the P.O.-Midi rejuvenated locomotives. The Nord for years had the variable exhaust with the cone which, by lifting, permitted the variation of the cross-sectional area of the jet. P.L.M. had the ordinary round nozzle with fingers, which was known under the name "trefle," meaning clover. Lately this road adopted the double nozzle arrangement, first introduced in America for some Mallet locomotives in order to separate the exhaust from the low and high pressure cylinders, the phases of which are not related. The "Kylchap" arrangement had been applied both in the single and duplex form, mainly in the latter.

All these diverse arrangements were used with a variety of petticoats and sometimes without them. Several years ago one of the engineers of the Northern Railway of Belgium, which is a subsidiary of the Nord (Northern Railway of France), by name Lemaitre, suggested a draft arrangement in which he used a central nozzle with a cone of the Nord variable exhaust, surrounded by a number of smaller nozzles (Fig. 8), into which the exhaust was directed, as well as in the central nozzle with the cone. All these jets are simultaneously admitted into a regular extension of a 19-inch stack, which, for European conditions, is fairly large.[9]

Very exhaustive tests, made by Lemaitre with a number of combinations of petticoats of different sizes, proved the advantages of reduced back pressure for a given vacuum and found the combination which best increases the output of the locomotive. On a certain test it was found on a thirty-four year old locomotive with the usual "Nord" exhaust with a varying cone, that the output of the locomotive went up, after the Lemaitre arrangement was substituted for the cone, from 1,400 h.p. at a speed of 59 m.p.h., to 1,600 h.p., or 14.3 per cent, and from 800 at a speed of 74.6 m.p.h., to 1,300 h.p., or 62.5 per cent. At this test the back pressure decreased, while the vacuum in the smokebox and the superheat correspondingly increased. Furthermore, forty locomotives equipped with the new Lemaitre arrangements have been tried out for some time past in all kinds of traffic, and the results were most satisfactory.

In view of these results, the Northern Railway of France decided to change the exhaust arrangements of seven hundred and eighty-eight locomotives of different types and classes, about one-half of the total motive power of the Railway, to the new Lemaitre type. These locomotives will include all the "Consolidation" and "Decapod" locomotives for freight, the Mikados with Cossart valves for suburban trains, referred to above, and all the "Pacific" and "Super-Pacific" type engines for the fastest expresses between Paris and Brussels, known as the "Northern Star" and "Blue Bird," and the Channel ferryboat trains between Paris and Dunkerque.

### Streamlining

It is natural that in this great activity in perfecting motive power, as displayed by the French railways within

Fig. 7—Super-Pacific Streamlined Locomotive of the Northern Railway of France.

the last few years, a certain place should have been allotted to streamlining, although it is surprising that the French engineers did it somewhat tardily. The P.O.-Midi Railway, which runs the fastest steam trains in France, until recently had no streamlined locomotives at all, and other French railways in this respect were behind railroads in other countries.

The first French railway to experiment with streamlining was the Etat, which two years ago rebuilt a twenty-seven year old 4-6-2 locomotive and placed it in passenger service. About the same time the P.L.M. streamlined a thirty year old 4-4-2 locomotive, equipping it also with a superheater and a feed water heater. They were first run in with light passenger trains up to 75 m.p.h., and then tested. This railway rendered a great service to the art, as it was the first to make tests with full-size modern equipment, while experimenters in other countries had been making tests with models only. The tests were very scientifically conducted: two locomotives, one streamlined

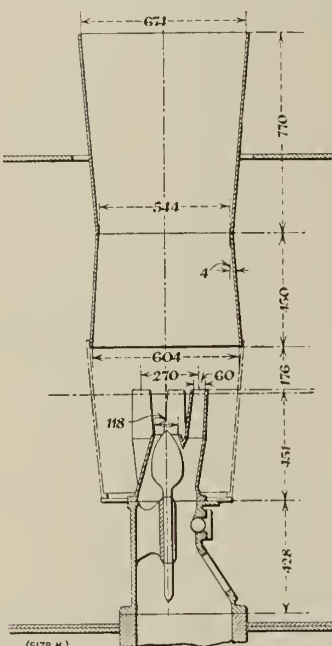

**Fig. 8—General Arrangement of Lemaitre Variable Exhaust Nozzle.**

and another not streamlined, were first tested at the testing plant of Vitry, in order to ascertain accurately the power output under certain conditions of operation (speed, throttle opening, cut-offs), and afterwards on the road with trains composed of streamlined cars and cars without streamlining, duplicating conditions of power output at Vitry. This made it possible to establish the air resistances of the locomotives and cars. It was found, for instance, that for a four-coach train a saving of 450 h.p. is obtained when locomotive and cars are completely streamlined, and only 260 h.p. are saved if locomotive alone is streamlined. Very valuable data were obtained for different conditions, and important conclusions were drawn.[10] After the completion of the tests the locomotives and train were returned to regular service.

The P.L.M. has just completed what it calls a Super-Pacific locomotive referred to above. It is fully streamlined, as can be seen from Fig. 7. The experience of the P.O. Pacific type rebuilt locomotives and of those newly built has been incorporated in the new design.

### New Developments in France

From just after the war until recently, German railways were leading in locomotive research. Turbine locomotives with condensers, high pressure steam locomotives, Diesel locomotives with different transmissions, were not only thoroughly investigated, but actually built. During the last few years, Germany having given up intentionally further construction of research units, except high-speed Diesel-electric trains and a limited number of high-speed locomotives, the French railways have been leading in this research. With the single exception of the ill-fated attempt of the P.L.M. to try the multi-pressure locomotive of the Henschel-Schmidt type, the French attacked the problem in a different way: they first started along practical lines to obtain immediate results from their existing motive power, and later they began investigating ideas disclosed in other nations' research. The P.O.-Midi conversion of old locomotives, the Kylchap and Lemaitre draft arrangements are good examples of the former, while the plans of the "Office Centrale pour les Etudes Materiel des Chemin de Fer" are pointing to the latter. The "Office Centrale" is the French central institution for motive power research, and, together with the stationary plant at Vitry for testing locomotives, became very helpful. Under the sponsorship of the "Office Centrale," which unites the research departments of all railways of the country, the following very important locomotives have been designed and their construction actually started:

1st. The Nord has ordered a 4-6-4 high pressure locomotive of the Winterthur type from the Société Alsacienne des Constructions Mécaniques, which will have a high pressure, 60 atm. (853 pounds per square inch) boiler of a special welded design. A similar boiler was tried out several years ago on a small 2-6-2 locomotive built by the Schweizerische Lokomotiv Fabrik (S.L.M.) of Winterthur, and demonstrated in France and some countries of Central Europe. Three axles of the French locomotive will be driven by three individual six-cylinder, horizontal, uniflow engines, acting on the axles through individual Buchli drives, as in electric locomotives built by the Brown-Boveri Company. The principal dimensions are given in Table V.

Table V

| | |
|---|---|
| Wheel arrangement | 4-6-4 |
| Number of cylinders | 18 |
| Diameter of cylinder, inches | 5.9 |
| Stroke of cylinders, inches | 10 |
| Boiler pressure, pounds per square inch | 853 |
| Diameter of driving wheels, inches | 61 |
| Grate area, square feet | 37.7 |
| Firebox heating surface, square feet | 312 |
| Total heating surface, square feet | 2625 |
| Superheating surface, square feet | 452.1 |
| Total weight, pounds | 253,000 |
| Weight on drivers, pounds | 145,500 |
| Gear ratio from engines to drivers | 1.975:1 |
| Drawbar horse power (at 49.7 m.p.h.) | 2400 |

This locomotive will have the Lemaitre exhaust arrangement.

2nd. A 4-6-0 P.L.M. locomotive is being rebuilt, replacing the old boiler by a new one of the Velox type. The engine remains of the four-cylinder compound type, the cylinders retaining their present dimensions—high pressure 13.4 by 26.7 inches and low pressure 21.3 by 26.7 inches. The chassis of the locomotive remains unchanged; the driving wheels will be 78.8-inch diameter. The Velox boiler is being built in Switzerland, will be placed vertically and will burn oil. This type of boiler is claimed to have an efficiency of 90 per cent and represents the application of an internal combustion turbine, driven by exhaust gases, a compressor and a boiler in which the fuel is burned in an atmosphere of compressed air. The installation will be made by the railway in its own shops.

3rd. A non-condensing turbine locomotive of the 4-6-4 type has been ordered from Schneider, at Creusot, and will probably be tried out on the P.L.M. and some other railroad. The boiler, which will be of the conventional design, will have a diameter of approximately 75 inches and a 39-inch long combustion chamber. The 59-inch driving wheels will be driven by individual turbines. It will thus differ from the turbine locomotive of the London, Midland & Scottish Railway in England by the absence of side rods. The total power of the turbines will be 2,675 metric h.p. at the turbine shafts at a speed of 87 m.p.h., corresponding to 10,000 r.p.m. of the turbine. The gear reduction of the individual drives, which will comprise gears and a flexible drive of the Buchli type, will have a ratio of 21.2: 1. The boiler will carry a pressure of 25 atm. (355.6 pounds). The grate will have an area of 52.7 square feet. The locomotive will weigh 290,000 pounds, of which 129,000 pounds will be the adhesion weight. The tractive effort for starting will be 25,500 pounds.

4th. According to rumour, another high pressure steam locomotive is also being considered now for the P.L.M. It was suggested by Bugatti and will have eight eight-cylinder

**Fig. 9—Streamlined 4-6-2 London and North Eastern Express Locomotive "Silver Link."**

**Fig. 10—Streamlined 4-6-4 German Reichsbahn Locomotive Class 05.**

engines of 250 h.p. each, directly coupled to eight axles on two trucks. Thus, there will be a total of 2,000 h.p. in 64 cylinders. The boiler will carry a pressure of 100 atm. (1,422 pounds per square inch). It is thought that the high speed express trains between Paris and the Riviera will be hauled by this locomotive at a speed of 100 klm. (62.1 miles) per hour.

### British Steam Locomotives

It has been already pointed out that Great Britain has attained a high standard in the performance of its steam locomotives. The London, Midland & Scottish and the Great Western 4-6-0 and 4-6-2 locomotives of the "King" and "Princess" class have shown excellent performance. Although they are conventional locomotives, they have been designed with great care and manufactured with many refinements. One of the L.M.S. 4-6-2 engines was built as a direct-driven 2,500 h.p. turbine non-condensing locomotive with gear transmission. The first axle, which is directly driven from the main turbine through a gear and a flexible connection, is coupled to the second and third axles by means of side rods. Sir Nigel Gresley recently stated that this locomotive has been already placed in regular service, pulling high speed L.M.S. trains.

The London & North Eastern has adhered to the conventional reciprocating steam locomotive, although several years ago it built a Pacific locomotive with 450 pounds boiler pressure. In addition to the three-cylinder 2-8-2 "Cock o' the North" and "Lord President" types, of which one locomotive was built with Dabeg poppet valves and gears, and three others with the conventional piston valves, Walschaert valve motion and Gresley gear, a new three-cylinder type of high pressure Pacifics has been developed for pulling the very high speed "Silver Jubilee" trains (Fig. 9). Three locomotives ("Silver Jubilee," "Silver Link" and "Silver Fox") have already been built and several more are contemplated. The "Silver Jubilee" trains referred to at the beginning, which are now running from London to Newcastle at an average speed of 67 m.p.h., with one stop in Darlington, will be supplemented by new trains, from London to Leeds, at an average speed of 67.5, and to Edinburgh, with an average speed of 65.5 m.p.h. The Edinburgh train will be known as the "Coronation" and will start running next spring.

In Table VI are given the principal dimensions of the "Cock o' the North" (latest edition "Lord President") and the "Silver Jubilee" (locomotive "Silver Link") types:

Table VI

| Locomotive | "Lord President" | "Silver Link" |
|---|---|---|
| Wheel arrangement | 2-8-2 | 4-6-2 |
| Number of cylinders | 3 | 3 |
| Diameter of cylinders, inches | 21 | 18½ |
| Stroke of cylinders, inches | 26 | 26 |
| Diameter of wheels, inches | 74 | 80 |
| Boiler pressure, pounds per square inches | 220 | 250 |
| Heating surface, total, square feet | 2714 | 2576.3 |
| Superheating surface, square feet | 776.5 | 749.9 |
| Grate area, square feet | 50.0 | 41.3 |
| Weight, total, pounds | 240,000 | 230,000 |
| Weight on drivers, pounds | 176,700 | 136,800 |

The boiler of the "Silver Jubilee" locomotive has a combustion chamber, probably for the first time in the history of British locomotive construction, which lengthens the firebox to 10 feet 1¾ inches. The firebox, however, is made of copper. The superheater is of the Robinson type. The locomotive and the whole train are streamlined and the finish of the inside of the train is very luxurious.

### German Steam Locomotives

Shortly after the Diesel-electric high speed, streamlined, articulated trains were inaugurated in Germany, several streamlined locomotives of the 4-6-4 type, with 2,300 mm. (90½-inch) drivers, were built, in order to compare them with Diesel-electric power. So far, locomotives of two types have been built; one comprises tank locomotives, Class 61, built by Henschel, and the others are locomotives with tenders, Class 05, built by Borsig. All have been streamlined, following tests specially made for the determination of the most advantageous shape.

**Fig. 11—View of Streamlined Double-Deck Train, Lübeck-Büchen Railway.**

The Henschel locomotives, Class 61, two of which have been built as two-cylinder simple expansion engines, are pulling light-weight trains between Berlin and Dresden at an average speed of 69.8 m.p.h. one way, and 67.6 m.p.h. on the return way on a distance of 109.3 miles. The cars have been specially built for the train, which is known as the "Henschel-Wegmann" train. The Borsig locomotives, Class 05 (Fig. 10), of which also two have been built of the three-cylinder type, are pulling regular passenger trains weighing 236 short tons between Berlin and Hamburg, on a distance of 178.1 miles, at an average speed of 74 m.p.h., slightly lower than that of the "Flying Hamburger." The third locomotive, also of the 05 Class, is now under construction. It is rumoured that it will be a pulverized coal locomotive with a combustion chamber, the first combustion chamber in Germany. It will run backwards, with the stack behind.[11] The general dimensions of these locomotives are given in Table VII:

Table VII

| Class Designation | 61 | 05 |
|---|---|---|
| Builder | Henschel | Borsig |
| Number of cylinders | 2 | 3 |
| Diameter and stroke of cylinders, inches | $18\frac{1}{8} \times 29\frac{1}{2}$ | $17\frac{11}{16} \times 26$ |

| Weight on drivers, pounds | 119,000 | 123,500 |

Last summer, during a visit of the British Institution of Mechanical Engineers to Germany, a train of 160 short tons, pulled by one of the two Borsig locomotives, made an average speed of 91 m.p.h. over a distance of 250 miles, and during the journey maximum speeds of more than 100 m.p.h., and once a speed of even 115 m.p.h., were reached.*

An interesting new development is the small, streamlined, high speed tank locomotive of the 2-4-2 type built by Henschel & Son in 1935 for the Lübeck-Büchen Railway, and shown (with the train) in Fig. 11. The train, built by Linke-Hoffman, of welded steel sheets, consists of two double deck cars on articulated trucks, with a seating capacity for three hundred persons. In order to provide sufficient room, the floor of the cars between the trucks is lowered and a staircase is made in the aisle to reach either of the two decks.[12] Although it may look crowded to the American eye, the seats are very comfortable and the discharge of passengers is not causing any inconvenience. One of the author's friends, who boarded the car at an intermediate station, wrote that it was amazing to see how many passengers could get into a train of this small size. He found the trip very comfortable, with little vibration, except the swaying in the seats on the second deck on curves. The average speed of the train was about 100 klm. (62.1 miles) per hour; the maximum about 75 m.p.h.

The train does not require turning, the locomotive having one control stand in the engineer's cab in front for one direction, and another stand in the cab in the rear of the second car, for the reverse direction. The control is of the remote type, operated by electro-magnetic valves from either end. When the engineer and fireman are separated, they communicate during the trip by telephone and signals. The cylinders of the tank locomotive are $15\frac{3}{4}$ by 26 inches; the wheels are 78 inches; the boiler, which is of the conventional design, carries a pressure of 227 pounds per square inch. The locomotive is streamlined.

The cars are also streamlined; they have a very agreeable inside finish in lively colours, have a separate baggage compartment, and are air-conditioned. Only second and third class, with comfortable seats, are provided. The weight of the locomotives and cars is about 306,000 pounds. The train is nicknamed "Mickey Mouse."

Two trains were in operation last summer and a third train had been ordered. Each of the first two showed an average mileage of 77,000 miles per year. Water and coal consumption per 1,000 miles were 43.6 and 38.6 per cent respectively less than for comparative passenger traffic with conventional equipment.

A Doble railcar, one of two with a Doble boiler, carrying 1,400 pounds per square inch, and a 300 h.p. engine, is operating on another branch of the same railway. The second Doble car is operating on the Kassel district of the Reichsbahn.†

Besides these locomotives, streamlined, medium power, and small light power, two large size types are going to be developed in Germany, one having a 4-8-4 wheel arrangement with 79-inch drivers for high speed heavy passenger trains, and another of the 2-10-2 type, for heavy freight trains. The type of machinery has not yet been decided. The boilers will be of the conventional design with 20 atm. (284 pounds per square inch) pressure.

### DIESEL RAILWAY EQUIPMENT

The application of Diesel engines to European railroad equipment appeared experimentally about thirty years ago on Swedish, Swiss and Saxon railcars—all with electric transmission. Diesel locomotives are comparatively a recent development, although one of the Swedish 300 h.p. Diesel-electrics was built and used as a locomotive. Shortly after the World War locomotives of greater power (up to 1,000-1,200 h.p.) were built for Russia. Operation of Diesel high-speed trains started, as an experiment, in the autumn of 1932 and regularly in May 1933, also with electric transmission.

In Germany the Diesel locomotive is mostly used in small units up to 150 h.p., sometimes as small as 20 h.p. Several hundred locomotives of this type are now employed in Middle European countries for switching work on small stations, where the work is casual and very light. All these locomotives have, as a rule, mechanical transmission with gear boxes and clutches.[13] For big work in classification yards this type is used very seldom, steam switching locomotives still prevailing.

Recently some experimental applications have been made in Germany and England with hydraulic transmission, and in England with electric transmission. The hydraulic transmission locomotives of a power up to 250-300 h.p., have either a converter for starting, with a hydraulic clutch for running (Voith type transmission), or a hydraulic clutch with a gear box (Vulcan-Sinclair, Daimler fluid flywheel with Wilson gear, etc.). A locomotive of 1,400 h.p. was built last year in Germany with a 920 h.p. M.A.N. engine, supercharged to 1,400 h.p. and Voith transmission, but nothing has been given out about the performance of the locomotive. The electric transmission

**Fig. 12—Renault 1,000 b.h.p. Diesel-Mechanical Train.**

*These speeds, as well as those recently attained on the London and North Eastern (113 m.p.h.), are comparable with the speeds reached in America, the difference, however, being that the tonnage of the American trains is from two to three times greater. The "Hiawatha" train weighs over 480 short tons.

†The German State Railways.

is not very popular in Germany and is not used, but in other European countries it is used for powers above 200-300 h.p.

In England, the London, Midland & Scottish has recently embarked on a rather extensive programme of Diesel locomotives with electric transmission. They will soon have about two dozen 0-6-0 locomotives built by the English Electric Company and Armstrong-Whitworth, of two different types as to engines, arrangement of motors and their coupling to the driving axles.[15, 16]

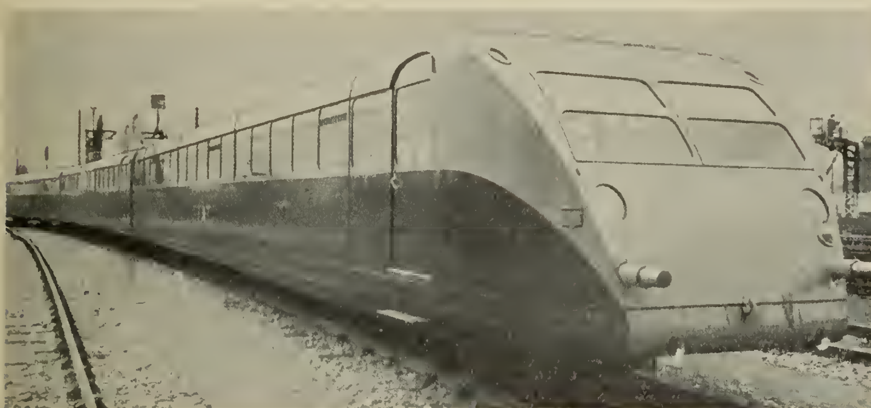

Fig. 13—800-h.p. Bugatti Train.

Ireland and Denmark have made considerable progress in the use of Diesel locomotives. The first is using Burmeister & Wain 260 h.p. Diesel engines of the new two-cycle type, and the second has, in addition to these, four-cycle engines manufactured by Frichs up to 500 h.p.

The P.L.M. and Etat in France have several experimental locomotives, the largest of which is used on the P.L.M. line in Algeria. This locomotive, which is for express trains, has an eight-cylinder M.A.N. engine of 920 h.p., is of the 4-6-4 type, and has six nose-suspended motors.[17]

There are several locomotives of 600 to 900 h.p. in Russia, both with electric and mechanical transmission, with gears and magnetic clutches, and even one or two of larger power, 1,200 to 2,400 h.p., with electric transmission. The design of the Diesel-electric locomotives is conventional and very little is known about their performance, or about the Diesel-gear locomotive which, at the time of its construction (1926), evoked much interest in this country and abroad.[18]

The European railcars, the power of which is about the same as that of the small locomotives, also have, in the majority of cases, mechanical transmission, and sometimes hydraulic transmission with gear boxes. The most interesting developments in Diesel application in recent years have been the growth of railcars in France and the high speed trains in Germany, referred to in the early part of the paper. The first has taken the form of both Diesel and gasoline cars, with mechanical transmission. About half a dozen Diesel engine manufacturers have contributed to this development. The most outstanding are the 500 and 1,000 h.p. cars of the French Etat with one or two Renault engines and mechanical transmission (Fig. 12). The latter car is operating between Paris and Havre on a schedule with 70 m.p.h. average speed. The light gasoline cars sometimes have rubber-tired wheels, due to the efforts of the well-known railcar and automobile builder, Bugatti, and of the tire manufacturer, Michelin. The latest is the new development brought about by the German "Flying Hamburger," for which the Maybach light-weight Diesel engine and the Reichsbahn should get due credit.

### Bugatti Cars

There are now in France about sixty gasoline cars built by Bugatti for the State, P.L.M., Nord and Etat Railways. They are built of two types, 400 and 800 b.h.p., and are able to haul from two to six trailers. Some of them have hydraulic transmission, but all of them have direct drives through shafts, universal joints and bevel gears. The engines are of 200 h.p. each; thus, either two or four engines are used in one car. The control is in the middle unit, in a protruding periscope-like cab, from which the visibility is very good in either direction. The top of the cab is about 13 feet above the rail. The height of the roof of the car is a few feet less. The eight-cylinder Bugatti-Royal gasoline engines develop their full power (200 h.p.) at 2,000 r.p.m., which corresponds to a speed of about 75 miles an hour, but can go up to 2,700 r.p.m., when an overload of 25 per cent is required.

The body of the car is of steel construction of sections bolted together, with rubber fillers between them. Each section is fabricated by welding. Some aluminum is also used for construction. The cars are supported by trucks, of which there are several; the 800 h.p. car consists of three units, each supported on two trucks, with eight steel-tired wheels with rubber in each, a total of 48 wheels. The body is separate from the underframe and is carried direct by the trucks with laminated springs through spherical pivots cushioned with rubber, rubber being used extensively throughout the car. The weight of an 800 h.p. car in working order varies from 40 to 80 tons, depending upon the number of seats.

The large car recently placed in service on the Etat has 152 seats and weighs 80 tons. In this case the horse power per ton of weight of the car is 10.0, including passengers and seats (not to be confused with "specific power factor," which refers to the weight of the power plant alone), but in some cases it is as high as 23 h.p. per ton, which accounts for the rapid acceleration of the cars. Figure 13 shows the latest 800 h.p. Bugatti train on the Etat.[20] The wheels are of special construction, with rubber between the steel tires and steel wheel centres for both radial and lateral cushioning.[21] A maximum speed of 87 m.p.h. is permitted for these cars in France, while 75 m.p.h. is the legal French limit for steam locomotives. Actually, the Bugatti cars reached 120 m.p.h. on several occasions.

Fig. 14—Michelin-Triple-Car Pneumatically-Tired Train.

### Michelin Cars

The French State and other railways have also Michelin cars. Hispano-Suiza, Panhard or other gasoline engines are being used in these cars, which always have mechanical transmission, sometimes through hydraulic or an electro-pneumatic epicyclic gear box (Cotal type), and steel-tired pneumatic and straight pneumatic wheels, both of special design. A 500 h.p. three-unit train built for the Etat is shown in Fig. 14. It is powered by two 250 h.p., 12-cylinder V-type Hispano-Suiza gasoline engines, has a Vulcan-Sinclair fluid fly-wheel and Cotal electro-magnetic gear transmission. The train, which is really an articulated three-unit car, is supported by two carrying and two driving trucks, the latter being in the two articulations of the middle unit. This unit is equipped with a cab, which has a periscope-like window for the driver on one side of the car. All four outside wheels of each truck have steel flanges, the inner wheels having simply pneumatic tires without any flange for guiding. The seating capacity of the three-unit train is 106, and the weight of it is 34.7 tons in working order. The maximum permissible speed of this car is also 87 m.p.h.[22,23]

LIGHT-WEIGHT TRAINS

The improvement of passenger service by placing in operation streamlined, Diesel-engined, light-weight trains was introduced in Germany shortly before the Union Pacific started a similar practice in the United States. The German train, which got the name "Flying Hamburger," began its regular operation in May 1933; before that, it was tried out experimentally for several months. Some reference to this train and its speed has already been made.

The "Flying Hamburger" consists of two articulated units with the articulation placed between the cars; in other words, the train, which weighs, in working order, but without passengers, only 85.3 short tons, is supported by three four-wheel trucks. The bodies and underframe of the cars are of high tensile steel fabricated by welding, resulting in a strong and light structure.[24]

An important feature which contributed to the lightening of the car is the engine developed in Germany by the Maybach Company in Friedrichshafen for the trans-Atlantic Zeppelins. The weight of each of the two 410 metric h.p. (405 b.h.p.) Diesel engines used for the "Flying Hamburger" is only 4,476 pounds, or 11 pounds per b.h.p. Each engine has twelve cylinders of 5⅞ inches diameter by 7⅞ inches stroke and develops its full power at 1,400 r.p.m. It permits a 5 per cent overload for one hour. Each engine with its 300 kw. generator is mounted on the corresponding front and rear power truck, while the middle, articulated, truck carries the two electric motors. The electric transmission has the Gebus differential control. Two controllers, one for each direction, are placed in each of the two end cabs, and the train travels in either direction without turning. The two ends have an identical streamlined form, which is thus a compromise in either direction. The cars have a very luxurious finish inside, carry second class accommodation for 78 to 102 passengers and, when introduced, represented an innovation which became very popular all over Europe.

During the two following years thirteen more two-unit (810 b.h.p.) and four three-unit (1,200 b.h.p.) trains were built; altogether eighteen trains should be now in operation. These trains are known as the "Flying Kölner," "Flying Frankfurter," "Flying Münchener," and so on. The three-unit trains have one hundred and thirty-nine seats and weigh 118 short tons each. They are engined by two supercharged, and thus more powerful, Maybach engines. Each V-type engine has also twelve cylinders, but the diameter was slightly increased, to 6¼ inches instead of 5⅞ inches.

Fig. 16—The Streamlined, High-Speed Train, "Flying Hamburger."

These engines, when used not supercharged on two-unit trains and railcars, retain their rating of 405 b.h.p. per engine. The engines on the three-unit trains are supercharged (on the Buchi principle) to 600 metric b.h.p. and weigh 8.2 pounds per b.h.p. Two of the four 1,200 b.h.p. trains have electric transmission and the engines are mounted with their respective generators on the two extreme trucks in the same way as on the "Flying Hamburger"; the four motors are nose-suspended on the two middle articulated trucks. The remaining two trains have the Voith hydraulic transmission with cardan universal joints and bevel gears.[25]

In addition to the regular automatic air brake and an oil pressure hand brake, used in switching, the "Flying Hamburger" as well as other German highspeed trains of this type, are equipped with electromagnetic track brakes, used only in cases of emergency. The retarding effect of these brakes is independent of the adhesive weight of the trains.

In this connection see Mr. L. K. Sillcox's unfavourable comments in his recent paper before this Institute.[26]

Other countries followed Germany in this development without great delay. France received in 1935 first two three-car, not articulated, trains (with independent trucks) and with two 405 b.h.p. Maybach engines. The average speed of the trains was not supposed to be much higher than 60 m.p.h., with a maximum of 75 miles. Orders for about ten more similar two- and three-car trains followed, both with and without articulated trucks, and the trains were placed in service on French roads. The average speeds of some of the trains are now reaching 68 m.p.h. Likewise, Belgium ordered streamlined light-weight two- and three-car trains of about the same speed, with engines of different

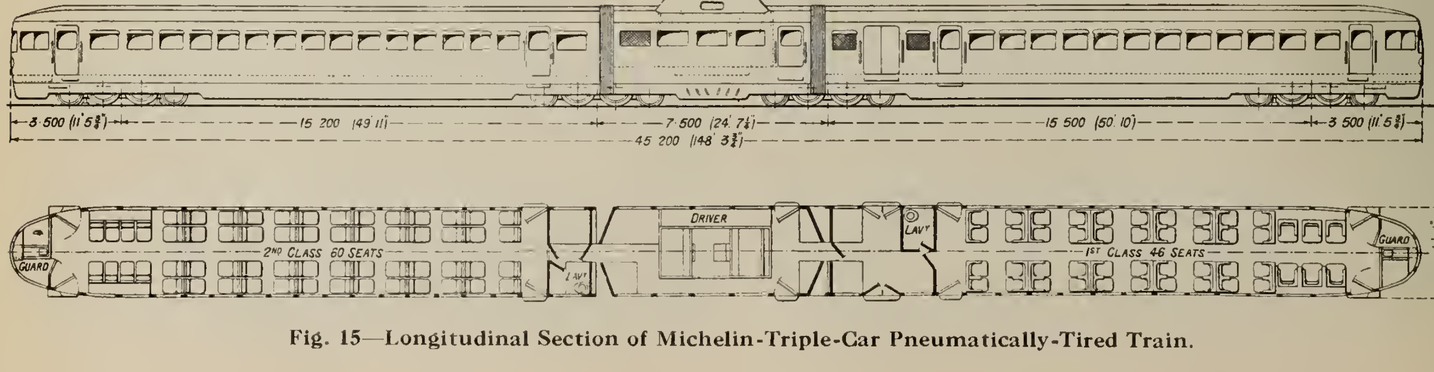

Fig. 15—Longitudinal Section of Michelin-Triple-Car Pneumatically-Tired Train.

make. The trains in Denmark, called "Lyntog," which means "Lightning," revolutionized the passenger service of that country. They have mainly Frich's engines.

The most talked of application, which received wide attention in Europe on account of the accompanying circumstances, was that made to Dutch trains. Forty trains of the three-car type were ordered almost simultaneously. Thirty-five were powered each by two Maybach engines of 405 b.h.p. of the type used on the "Flying Hamburger,"

**Fig. 17—Nord 810 b.h.p. Three-Car Train.**

while five were powered each by two 400 b.h.p. Stork-Ganz-Jendrassik engines. Shortly after the trains were placed in service, the Maybach Diesel engines on all the thirty-five trains started giving trouble, while those on the five continued their service very satisfactorily. The outcome was that the Maybach-engined trains had to be removed from service and replaced by already discarded steam power. The troubles with the Maybach engine trains were due to the unsuitable characteristics of the electric transmission, which resulted in the overloading of the Diesel engines. After some changes were made in both the engines and the transmission, the Diesel-electric trains were reinstalled.

Similar trains and railcars are now being used in Italy (the Litturinas) and Spain. The Italian trains have Fiat engines, while the Spanish have Burmeister and Wain's and Frichs'. In other European countries many light-weight, streamlined, high-speed Diesel trains and railcars are now in operation with engines of the mentioned makes. The service of these trains has proved to be very economical, with 2.7 to 4.6 pounds of fuel oil per train-mile; they are patronized extensively by the public, whose imagination was caught by the speed, comfort and novelty of the trains. They undoubtedly represent a great improvement as compared with the equipment and means of passenger transportation heretofore used on these railways,[27] but the question of ultimate economy of operation, taking into consideration their high first cost, will have to be determined later when more data are available.

This experience is in line with what we already know from the service results of the Union Pacific; Chicago, Burlington & Quincy, and other railroads which introduced light-weight, high-speed service in the United States.

# Report of Council for the Year 1936

The improvement in conditions noted in last year's report has fortunately continued, and has been favourably reflected in The Institute's membership roll, financial situation and branch activities. Employment has been better, particularly as regards the younger members. The Institute's revenue has exceeded the budget by a substantial amount; the increase has, however, been absorbed by unforeseen expenses including those of an additional Institute meeting and a Plenary Meeting of Council.

Throughout the year, the Council has been actively concerned with the movement for the development of co-operation between The Institute and the Provincial Professional Associations, which was discussed so fully at the Annual General Meeting in Hamilton in February 1936. It will be recalled that on that occasion the meeting adopted the 1936 report of the Committee on Consolidation "in principle as a progress report," and added representatives of the Professional Associations to the membership of that committee.

Activity in this matter has continued and has now resulted in a series of definite proposals for the amendment of The Institute By-laws, which have been prepared by the Committee on Consolidation and will be discussed at the Fifty-First Annual General Meeting to be held in Montreal on January 29th and 30th, 1937.

Throughout the committee's deliberations the Council has co-operated with the committee by affording all possible facilities for mimeographing, printing and circulating the different documents and reports, and by meeting the committee for joint discussions. The Council, in committee of the whole, has thus held two sessions jointly with the committee. At the first of these, on May 30th, possible methods of co-operation between the Council and the committee were discussed; there were submitted the preliminary conclusions of a meeting between the committee and representatives of the Professional Associations which had been held in Hamilton on February 7th, and consideration was given to the proposals from Winnipeg for a scheme of local consolidation in Manitoba.

The committee then proceeded with the drafting of its proposed revisions of the by-laws. These received preliminary consideration at a second joint session with the Council on September 18th, when suggestions for a number of changes in the draft proposals were made. The committee having considered these suggestions, finally sent its proposals to the Council on September 21st, and, as required by the By-laws, they were considered at a meeting of Council held on October 16th and 17th. At this Plenary Meeting the Council was assisted by the presence of representatives of the Dominion Council of Professional Engineers, past-presidents of The Institute, the chairman of the Committee on Consolidation, and past chairmen of the various Institute committees which have from time to time dealt with the question. The committee's proposals were discussed item by item during the sessions, which lasted some eighteen hours. With one very important exception, the Council found the proposals acceptable. The Council also suggested certain revisions and a few additional clauses, particularly a provision which would make it possible to meet the wishes of the Professional Association of Manitoba; these suggestions were later accepted by the Committee on Consolidation.

The committee's proposals are now before the membership for discussion, in a form which substantially represents the consensus of opinion of the committee and the Council. The Council desires to point out, however, that there remains the following important proposal of the committee on which there is a difference of opinion, namely, the stipulation that in future in any province whose Association has become "component," no resident who is not a corporate member of the Association can be admitted as a Member of The Institute. It is the opinion of the Council that an engineer who is not required by the law of his province to be a member of such an Association should not be subject to this prohibition.

In the Council's view, it is essential that the ballot paper which will be sent out after the Annual General Meeting shall be so drawn that the difference existing on this one point shall not prevent a clear decision by the membership on the main issue, namely whether the scheme drawn up by the Committee on Consolidation meets with their approval as a whole.

The Council desires to draw attention to the important fact, that a definite scheme for co-operation between the Associations and The Institute has now been drawn up. As in other similar cases, its provisions—a number of which are compromises between opposing views—cannot possibly fulfil the hopes of everyone. But if they are approved by The Institute as a body, they will constitute an offer to the Associations of a workable plan for joint action, which would in fact be the first step towards a unification of the engineering profession in Canada, a plan which may be modified in detail as found necessary in the light of experience gained in operation.

During the year the preparations for the celebration of the Fiftieth Anniversary of the establishment of The Institute have been actively proceeding under a Semicentennial Committee whose chairman is J. L. Busfield, M.E.I.C. The announcements and invitations which have been sent out have been warmly received, and it is anticipated that the meetings commencing on June 15th, 1937, will be largely attended, not only by Canadian engineers, but also by members and delegates from sister societies from various parts of the world.

Among the subjects of public interest which have received the attention of the Council and its committees during the year may be mentioned the Report on Tenders and Contracts for Public Works issued last year, which has given rise to appreciative comment; the work of the Committee on the Deterioration of Concrete Structures, which has now commenced under the chairmanship of R. B. Young, M.E.I.C.; and the work of the Committee on Western Water Problems, under the chairmanship of G. A. Gaherty, M.E.I.C. The Council has also been able to co-operate with the National Construction Council in connection with that body's investigations on low cost housing, and research on construction materials.

Several questions affecting the welfare of engineers as a profession have been suggested and are under consideration by Council. Among these may be mentioned the desirability of studying the supply and demand for technically trained men in Canada with a view to affording vocational guidance for young men desiring to enter the various branches of the profession. Allied with this subject is that of the status and remuneration of engineers, in connection with which it is thought that work similar to that carried out some five years ago by the Institute's Committee on Classification and Remuneration of Engineers could now be undertaken with advantage, so that up-to-date information in line with present day conditions might be available. The Council has felt, however, that other problems of importance to the Institute which are now claiming attention must be decided before it would be proper to initiate these new inquiries.

The policy of holding a number of Council meetings away from Headquarters has been followed during 1936 as far as possible. Well attended meetings of the Council were held in Toronto on May 8th and November 27th, and in Saint John on August 28th; an opportunity for the latter being provided by the Maritime Professional Meeting.

The Council received with appreciation an invitation from the American Society of Mechanical Engineers to have Institute members participate in the meeting of that Society which was held in Niagara Falls, New York, on September 17th to 19th, 1936, an invitation which was largely responded to, particularly by our Ontario members.

The Council has most willingly accepted an invitation from the American Society of Civil Engineers to participate in a joint meeting with that body to be held in Boston during the month of October 1937. Arrangements for this meeting are in the hands of a committee of which Past-President J. M. R. Fairbairn is the convenor.

The Third World Power Conference, held in Washington at the invitation of the President of the United States, from September 7th to 12th, 1936, was the occasion of a brief visit to Canada by a large number of the European and American delegates to the conference. The Institute could not participate officially in the welcome extended to the visitors by the Canadian Provincial and Federal government authorities, but it was gratifying that our branch organizations and individual members were able to take such a prominent part in the proceedings. Local committees, made up largely of Institute members, looked after many of the details of the Canadian visit in an admirable manner, and expressions of gratitude and appreciation have since been received from a number of the visitors, indicating that their experiences in Canada were of a very pleasant and informative character.

The Fiftieth Annual General Meeting convened at Headquarters on January 23rd, 1936, and was adjourned to the Royal Connaught Hotel, Hamilton on Wednesday, February 5th. The whole of that day was devoted to a discussion of the report of the Committee on Consolidation, the result being the adoption of the report, and the addition to the Committee on Consolidation of representatives of the Professional Associations.

On the morning of the following day the regular business of The Institute was transacted; this was followed by the professional sessions on Friday, February 7th, with a symposium of papers on transportation problems as the principal technical feature. Sir Edward Beatty addressed the members, ladies and guests present at the Annual Dinner of The Institute. Although the social features of the meeting were limited, in view of the death of his late Majesty King George V, the meeting was largely attended, and its success reflected credit on the executive committee and members of the Hamilton Branch, on whom so much of the preparatory and organizing work had fallen.

The second important Institute meeting of the year was organized by The Institute branches in the Maritime Provinces, and took place at Saint John on August 27th, 28th and 29th. The meeting was held in co-operation with the New Brunswick and Nova Scotia Associations of Professional Engineers. The professional sessions were characterized by a series of papers on the important road reconstruction work which is being carried out in New Brunswick and Nova Scotia; a paper on modern air conditioning; and one on the extensive reconstruction work in Saint John Harbour, which is now approaching completion, under the supervision of the Saint John Harbour Commissioners. This two million dollar project is of special interest owing to the severe tidal and weather conditions obtaining at Saint John. At the conclusion of the meeting a large number of the members and guests visited Eastport, Maine, and inspected the Passamaquoddy tidal project, a power scheme on the first portion of which substantial progress has been made. The success of these visits and of the whole meeting was the result of the activity and hospitality of the Saint John members and was aided by favourable weather conditions.

### Roll of The Institute

During the year 1936, two hundred and fifty-eight candidates were elected to various grades in The Institute. These were classified as follows:—One Honorary Member, twenty-four Members, fifty-two Associate Members, twenty-eight Juniors, one hundred and forty-six Students, and seven Affiliates. The elections during the year 1935 totalled two hundred and twenty-three.

Transfers from one grade to another were as follows:—Member to Honorary Member, one; Associate Member to Member, sixty-three; Junior to Associate Member, forty-five; Student to Junior, fifty-one; Student to Associate Member, thirty; Junior to Member, one; a total of one hundred and ninety-one.

The names of those elected or transferred are published in The Journal each month immediately following the election.

### Removals from the Roll

There have been removed from the roll during the year 1936, for non-payment of dues and by resignation, seventeen Members, sixty-nine Associate Members, twenty-six Juniors, sixty-four Students, and three Affiliates, a total of one hundred and seventy-eight.

Fifty-two reinstatements were effected, and eighteen Life Memberships were granted.

During the year 1936 twenty-one names were placed on the Non-Active List, which now numbers three hundred and seventy-six.

### Deceased Members

During the year 1936 the deaths of thirty members of The Institute have been reported as follows:—

#### Members

| | |
|---|---|
| Burpee, Moses | Marsh, Karl H. |
| Clark, Farley Granger | Ross, Alexander Bell |
| Douglas, James Atkinson | Ross, Robert Alexander |
| Faulkner, Frederick Richardson | Sykes, Samuel H. |
| Finlayson, Ernest Herbert | Thomson, Frederick |
| Freeman, Philip A. | True, Abbott |
| Hart, Henry Utler | Wallace, Joseph Harrison |
| Hyndman, Walter Eardley | Williamson, F. Stuart |
| Ketchen, William Laird | Zuercher, Max |
| MacKinnon, George Douglas | |

#### Associate Members

| | |
|---|---|
| Boyer, Aurelien | Thornton, Henry Edgar |
| Labelle, Joseph | Walshaw, John Henry |
| Murray, Robert Hutchison | Weekes, Abel Seneca |
| Reakes, George | White, Frank Clinton |

#### Junior

Larrivee, J. Albert Edouard

#### Students

| | |
|---|---|
| Lackey, Wesley James | McIntosh, Douglas Elliott |

### Total Membership

The membership of The Institute as at December 31st, 1936, totals four thousand, two hundred and thirteen. The corresponding number for the year 1935 was four thousand, one hundred and thirty-three. These figures do not include those names which are on the Non-Active List.

| 1935 | | 1936 | |
|---|---|---|---|
| Honorary Members | 7 | Honorary Members | 9 |
| Members | 976 | Members | 1,028 |
| Associate Members | 1,983 | Associate Members | 1,988 |
| Juniors | 320 | Juniors | 326 |

Respectfully submitted on behalf of the Council,

E. A. Cleveland, M.E.I.C., *President.*
R. J. Durley, M.E.I.C., *Secretary.*

### Treasurer's Report

During the past twelve months the course of events has fully justified the confidence expressed by the Treasurer in his report of last February, for The Institute's revenue for 1936 shows a substantial increase over that for 1935, and, what is even more gratifying, practically all items of revenue show an increase over the budgeted amounts. Thus The Institute, in the face of an unforeseen additional expenditure of some $6,000, has been able to close the year's operation with an excess of expenditure over revenue of only $1,100.

As regards the future, the Treasurer would call attention to the financial aspect of the Consolidation Committee's proposals which are now before the membership. If, as we hope, all the Professional Associations agree to co-operate with The Institute as Component Associations, it should be possible to relieve The Institute's Headquarters of some of its present office work in connection with membership records, the admission and transfer of members, and the collection of fees; a moderate reduction in Headquarters expense might then be possible. It is to be noted, however, that Headquarters would still have to look after the publications of The Institute, its professional meetings and papers, the employment service, the library and information bureau, and other service work which at present occupies the major part of the time of the Headquarters staff. But if only a minority of the Associations co-operate, Headquarters would still have to function substantially as at present.

In view of the above, it is evident that in the event of the by-law revisions passing on ballot, no really substantial reduction in The Institute's expenditure can be expected until the new organization has received general acceptance. Therefore, it should not be assumed that if the membership approves the present proposals, the counting of the ballot will be immediately followed by a considerable financial saving.

Respectfully submitted,
J. B. Challies, M.E.I.C., *Treasurer.*

### Finance Committee

The President and Council:

Your Finance Committee in submitting the auditors' report for 1936, wish to add a few supplementary figures in order to present to the membership a clear view of the financial situation as it has been developed throughout the year as well as of the significance of the statement.

After the preparation of the budget early in February at which time revenue and expenditure were estimated to

balance at $63,700, several important questions arose which had to be studied individually by your Committee in order that the Committee might recommend to Council a policy in regard thereto.

In order of occurrence these matters were:

(*a*) The enlargement of the scope of the catalogue (April).
(*b*) The Maritime Professional Meeting (June).
(*c*) The Plenary Meeting of Council (August).
(*d*) The heavy cost of Committee work on Consolidation.

The catalogue was, after due consideration, enlarged to cover additional fields of advertising, namely those concerned with building construction and allied features. It was expected that this policy would result in an increase in the amount of advertising and the revenue therefrom, and that the increased expenditure during the first year would not be such as to destroy the chances of reaping a financial profit on the 1936 issue. These expectations were fulfilled, but the profit as finally established, was very small. However, it is confidently believed that substantial benefits from the enlargement will be realized in future years. The budgeted figures of $15,500 revenue and $14,280 expenditure during the calendar year, have in consequence been replaced by $17,567.82 revenue and $16,990.98 expenditure. It must again be pointed out that as regards the catalogue, the auditors' report exhibits the cost of, and revenue from the "issue" instead of the income and expenditure during the calendar year with which the budget deals, and due solely to the increasing cost of production the carry over from 1935 exceeds the carry forward into 1937 by $498.13 which figures are consequently added by the auditors to the actual operating deficit to produce an apparent deficit of $1,612.39.

The encouraging situation with regard to income from fees in the early part of the year permitted your Committee to agree readily with the proposal to hold a Professional Meeting in Saint John, N.B., during August, which meeting was acknowledged by all participating to be an unqualified success. The total cost to The Institute was in the neighbourhood of $600.

Similarly, at the Council Meeting held in Saint John your Committee was able to tender its advice in response to a request for information, to the effect that the cost of a Plenary Meeting could be substantially met from revenue from all indications then in their possession, so that this very important and valuable meeting was arranged for October. The cost of the Plenary Meeting of Council exceeded the earlier estimates due to the splendid attendance thereat, but your Committee feels that it correctly interprets the attitude of the membership in stating that the meeting was well worth while.

The fourth item where the actual cost during the year has been definitely in excess of the budget allowance,

## STATEMENT OF ASSETS AND LIABILITIES AS AT 31st DECEMBER, 1936

### Assets

| | | |

| | | 98,126.43 |
| | | $126,770.55 |

### AUDIT CERTIFICATE

We have audited the books and vouchers of The Engineering Institute of Canada for the year ending 31st December, 1936. No provision has been made for depreciation of the fixed assets during the year. Subject to the foregoing, we report that the above Statement of Assets and Liabilities and attached Statement of Revenue and Expenditure are properly drawn up so as to exhibit, in our opinion, a true and correct view of The Institute's affairs as at 31st December, 1936, and the result of its operations for the year ending that date, according to the best of our information and the explanations given to us and as shown by the books.

Ritchie, Brown & Co.,
*Chartered Accountants.*

Montreal, 13th January, 1937.

is that involved in the printing, multigraphing, postage, and other expenses incurred by the headquarters office in connection with the work of the Consolidation Committee.

Summing up, it may be stated that the extra expenses above budget expectations are almost entirely confined to these four items and reach the following amounts:—

| | | |
|---|---|---|
| Plenary Council sessions | $2,167.93 | |
| Maritime Professional Meeting | 607.47 | |
| Extra Committee expenses | 771.89 | |
| Catalogue | 2,710.98 | |
| | | $6,258.27 |

This excess cost of operation has been financed to the extent of $5,144.01 from savings in other items and from revenue as follows:—

| | | | |
|---|---|---|---|
| (*a*) Revenue increases: | | | |
| Fees and subscriptions | $ 292.78 | | |
| Journal advertising | 785.41 | | |
| Catalogue | 2,067.82 | | |
| Sundry items | 29.40 | | |
| | | $3,175.41 | |
| (*b*) Savings in expenditure: | | | |
| Production of Journal | $1,803.72 | | |
| Sundry small items | 164.88 | | |
| | | 1,968.60 | |
| | | | $5,144.01 |
| So that the operating deficit for the year is actually | | | $1,114.26 |

The adjustment of the catalogue account in order to cover the "issue" instead of the calendar year, is as follows:—

| | |
|---|---|
| Deferred charge carried forward from 1935 statement | $3,196.36 |
| Deferred charge carried forward into 1937 statement | 2,698.23 |
| | 498.13 |
| Actual operating deficit for the year | 1,114.26 |
| Apparent deficit as shown in Auditors' report | $1,612.39 |

Revenue from fees unfortunately fell away after October and the indications of the monthly statements previous to that date to the effect that $700 or $800, might be looked for, over and above the budgeted estimate, finally gave way to the actual increase above mentioned of $292.78. In this connection the opinion can hardly be avoided that the imminence of a ballot of the consolidation question has given rise to some hesitancy on the part of members whose fees are still outstanding.

Your Committee has given continued and careful consideration during the year to overdue fees and has endeavoured as far as practicable to deal reasonably and even generously with all members whose situation renders it difficult for them to fulfil their obligations promptly. It is felt, however, that the time has arrived when the non-active list should be sensibly reduced from its present length in view of the undoubted improvement in the general conditions among the membership in respect to employment and remuneration.

The Committee in charge of the Semicentennial celebrations has not called upon the regular funds of The Institute for any of its expenses but has established an entirely independent fund which it is obtaining by special means and for which it will account directly to Council.

The Journal, both in respect of revenue and cost, constitutes a matter for gratification and for definite congratulation to the Headquarters staff. The income from advertising exceeded the budget by $785.41, while the cost of production was kept below the estimate to the extent of $1,803.72, a total advantage of $2,589.13.

The general trend of income and expenditure can be well visualized by extending the graphs incorporated in the

## SPECIAL FUNDS AS AT 31st DECEMBER, 1936

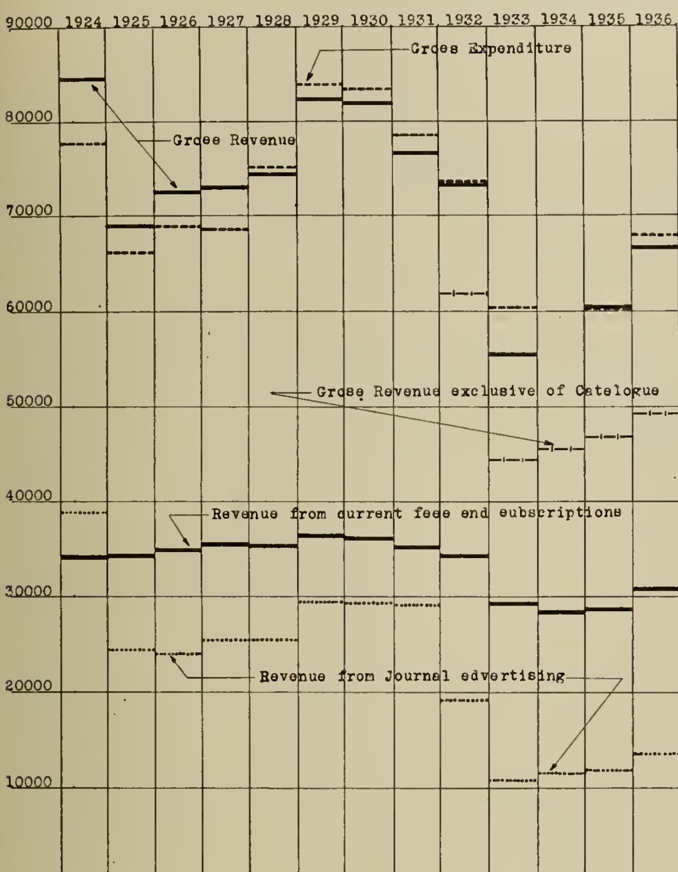
| | 4,758.22 | | | | |
| *Deduct:* Cost of furnishing and erecting Bronze Memorial Tablet | 2,711.89 | | | | |
| | | 2,046.33 | | | 2,046.33 |
| | | $13,665.57 | | | $13,665.57 |

Committee's report for 1933, and published in The Journal of February 1934, page 77, to include the years 1934, 1935, and 1936, which is done in the accompanying diagram. It will here be seen that the gross figures for revenue and expenditure almost duplicate the 1925 situation, but that catalogue advertising replaces the diminution in returns from Journal advertising and current fees.

The investments of The Institute have not changed materially during the year. The market value of the



securities in the regular fund and the special funds has naturally advanced recently in keeping with general conditions and is probably higher at the moment than the cost value listed in the Auditors' statement of assets.

The current liabilities and the special funds have only moved within the normal limits, or as the purpose of the various funds has been fulfilled.

Your Committee again expresses its appreciation of the unstinted labour of the Headquarters staff and its recognition of the special pressure under which they have worked during the past year due to unprecedented activity in connection with the preparation of numerous circulars and reports for committee work. It is to be regretted that only in a partial way has it been possible to implement the hope expressed in your Committee's 1935 report regarding the restoration of salary cuts.

Respectfully submitted,

P. L. Pratley, M.E.I.C., *Chairman.*

| Calgary Branch | J. R. Wood, M.E.I.C. |
| Vancouver Branch | A. S. Gentles, M.E.I.C. |
| Victoria Branch | J. N. Anderson, A.M.E.I.C. |

## Semicentennial Committee

The President and Council:—

Your Semicentennial Committee has been continuously engaged since its appointment in February 1936 upon preparations for the suitable celebration of The Institute's fiftieth birthday.

Arrangements have been completed for the holding of a three day meeting in the Windsor Hotel, Montreal, June 15th to 17th inclusive, followed by a visit to Ottawa on Friday, June 18th. The programme at Montreal will include the presentation of greetings to The Institute by official delegates from many engineering societies, the holding of technical sessions, a reception and dance, banquet, and smoker. One day will be set aside for visits to engineering works, and other places of interest, and possibly a garden party will also be arranged. At Ottawa, there will be a luncheon, visits to the numerous places of interest in and around the Capital, and a dinner dance.

An important feature of the occasion will be the Semicentennial number of The Journal, containing eighteen papers, each dealing with fifty years of engineering development in Canada, by authors who are recognized leaders in the various spheres of activity. Furthermore, there will be an historic review of the Canadian Society of Civil Engineers, and The Engineering Institute of Canada. Interleaved between the papers there will be full page illustrations of notable engineering works in Canada.

One of the technical sessions will be devoted to papers which will be presented in person by engineers of prominence from Great Britain.

A symposium on the burning of Canadian coals will be an important feature of the programme. This symposium will include papers by ten authors covering conditions from Nova Scotia to British Columbia.

In addition there will be papers by twelve authors of particularly high standing in their respective fields dealing with electrical, civil, construction, transportation and general subjects.

We expect to be honoured by the presence of His Excellency the Governor-General at the banquet, and among other prominent visitors, we may mention Sir Alexander Gibb, President of the Institution of Civil Engineers; Mr. Johnstone Wright, Vice-President of the Institution of Electrical Engineers; Mr. H. E. Wimperis, President of the Royal Aeronautical Society; Mr. S. C. Hill, President of the American Society of Civil Engineers, and many others.

Respectfully submitted,

J. L. Busfield, M.E.I.C., *Chairman.*

### Past-Presidents' Prize Committee

The President and Council:—

Only one paper was received, entitled "The Engineer's Contribution to Transportation."

The committee having examined this paper, unanimously agreed that it was not of sufficient merit to be worthy of an award, and therefore recommend that no award be made for the Past-Presidents' Prize for the year 1935-1936.

Respectfully submitted,
C. N. Monsarrat, M.E.I.C., *Chairman.*

### Duggan Medal and Prize Committee

The President and Council:—

The committee ranks the following as the best papers eligible for the Duggan Medal and Prize for the prize year 1935-1936:—

"Modern Arc Welding" by David Boyd, A.M.E.I.C. and

"The Superstructure of the Reconstructed Second Narrows Bridge, Vancouver," by P. L. Pratley, M.E.I.C.

Some difficulty was experienced in selecting one of these two papers for first place, and the committee considers that both are excellent.

Respectfully submitted,
C. M. Goodrich, M.E.I.C., *Chairman.*

Note:—In view of this report and that of the Gzowski Medal Committee, the Council, at its meeting on January 19th, awarded the Duggan Medal and Prize to Mr. Pratley and the Gzowski Medal to Mr. Boyd.

### Gzowski Medal Committee

The President and Council:—

Your Committee, after giving due consideration to the papers submitted, recommend as follows for the 1935-1936 award of the Gzowski Medal:—

First choice:

"Modern Arc Welding" by David Boyd, A.M.E.I.C.

Second Choice:

"Design of Continuous Reinforced Concrete Arches" by E. Nenniger, A.M.E.I.C.

In making the above recommendation your committee was unanimous.

Respectfully submitted,
E. P. Copp, M.E.I.C., *Chairman.*

Note:—In view of this report and that of the Duggan Medal and Prize Committee, the Council, at its meeting on January 19th, awarded the Duggan Medal and Prize to Mr. Pratley, and the Gzowski Medal to Mr. Boyd.

### Plummer Medal Committee

The President and Council:—

The committee has selected from the chemical and metallurgical papers eligible for the award of the Plummer Medal for the year 1935-1936, the following as the most worthy:—

"The Metallurgy of Metallic Arc Welding of Mild Steel" by C. R. Whittemore, A.M.E.I.C.

Mr. Whittemore's paper was considered to be of value as descriptive of his original research work and study on the subject.

The second choice of several of the committee was Mr. D. L. Calkin's excellent paper on "The Soya Bean," and Mr. J. M. Somerville's paper on "The Manufacture of High Voltage Porcelain Insulators" received almost an equal rating.

Respectfully submitted,
A. G. Fleming, M.E.I.C., *Chairman.*

### Leonard Medal Committee

The President and Council:—

The committee, having duly studied the papers eligible for the award of the Leonard Medal for the year 1935-1936, would recommend that the award be made to

L. S. Weldon, M.C.I.M.M., for his paper entitled "Mining Methods and Practices at Lake Shore Mine."

This paper was presented at the Ottawa meeting of the Canadian Institute of Mining and Metallurgy in March 1936.

Respectfully submitted,
A. O. Dufresne, M.E.I.C., *Chairman.*

### Students' and Juniors' Prizes

The reports of the examiners appointed in the various zones to judge the papers submitted for the prizes for Students and Juniors of The Institute were submitted to Council at its meeting on January 19th, 1937, and the following awards were made:

*H. N. Ruttan Prize* (Western Provinces)—No papers received.

*John Galbraith Prize* (Province of Ontario)—To E. C. Hay, Jr.E.I.C., for his paper "Selection of Factors of Photo Electric Cells."

*Phelps Johnson Prize* (Province of Quebec, English)—To Eric G. Adams, Jr.E.I.C., for his paper "Trends in Population and Trade Affecting Transportation."

*Ernest Marceau Prize* (Province of Quebec, English)—To Louis Trudel, S.E.I.C., for his paper "Etude Comparative sur Modèles Réduits."

*Martin Murphy Prize* (Maritime Provinces)—No award.

### Papers Committee

The President and Council:—

The Papers Committee for the year 1936 was composed of the Chairmen of all the Branches. It was thought that in this way the local Branches might be induced to take some interest in the work of the Committee. The main duty of the Committee is to help the smaller branches to secure papers for presentation at their meetings. The larger branches and those situated near large centres of population have very little difficulty in filling their programmes with suitable papers, but the smaller branches in out of the way districts do have trouble.

From time to time certain of our prominent members have arranged to visit some of the smaller branches on their trips throughout the Dominion, and their action in this respect is much appreciated. If more of our members who are similarly placed would make the necessary personal sacrifice, we are sure the operation of the branches concerned would be greatly improved.

The Committee should be able to act as a clearing house for papers and addresses on all subjects. Certain industrial concerns have members on their staffs who can be secured to give papers on their respective processes or business. The same applies to governmental agencies, both Provincial and Dominion.

There are many series of motion picture films available at little or no rental, and these make an entertaining addition to any programme. Lists of these might be kept at Headquarters by the Chairman of the Committee.

The Papers Committee has not been able to do very much for the smaller branches, mainly because so few definite requests were received.

Respectfully submitted,
R. L. Dobbin, M.E.I.C., *Chairman.*

### Library and House Committee

The President and Council:—

Continuing the policy of the past few years of holding down expenses to a minimum, the outlay for maintenance and repairs has been kept approximately within the same range as last year.

It is considered that at the present time, with an acknowledged improvement in business, the services afforded through our library may properly be extended to meet the demands and purpose of the department. A review of the following will justify this view:

*Library and Information Service*

There has been a considerable increase in the use made of this service to members. Requests for information on technical subjects have been twenty-five per cent greater than in the preceding year. Seventy per cent more books have been borrowed, and nearly twice as many bibliographies on technical subjects have been prepared. The utility of the Library and Information Service to our members is greatly limited by the fact that only part time of one member of the staff can be spared for the work.

The small sum available for the purchase of books will only permit us to obtain a very small number of the standard textbooks and handbooks which appear during the year. Were it not for the review copies kindly sent in by publishers, and the kindness of our reviewers in returning these copies for the library, we should have few accessions of technical books.

| | *1935* | *1936* |
|---|---|---|
| Requests for information | 673 | 851 |
| Requests for textbooks, periodicals, etc. | 472 | 577 |
| Technical books borrowed by members | 89 | 153 |
| Bibliographies compiled for members | 21 | 40 |
| Accessions to library (largely reports, etc.) | 589 | 665 |
| Requests for photoprints | 17 | 22 |
| Total pages of photoprints furnished to members | 110 | 119 |
| Books presented for review by publishers | 27 | 32 |

*Building Repairs and Maintenance*

The expenditures on this account have been confined to those essential for meeting ordinary wear and tear on our property and its furnishings. A comparison of the costs for this year and the previous one follows:

| | *1935* | *1936* |
|---|---|---|
| Building maintenance | $520.00 | $526.34 |

In closing, your committee respectfully suggests that in view of the evidence of demand by the membership for increased service from the library, and as present prospects would appear to justify it, the facilities and service that it affords or can be readily made to do, be now extended. This can be accomplished by a moderate allowance in the budget for the purchase of books, periodicals, etc., which has been restricted for the past few years. We believe this policy would meet with general approval, and consider it to be in the interests of the membership at large.

Respectfully submitted,
E. A. Ryan, M.E.I.C., *Chairman.*

### Committee on Relations with National Societies

The President and Council:—

The outstanding feature of the year 1936 was the Third World Power Conference at Washington, held from September 7th to 12th, on the invitation of the President of the United States. It was financed by the United States Government and by the American public utilities organizations. Concurrently with the Conference, the International Commission on Large Dams held its second convention. The gathering was attended by delegates from fifty-two countries.

Canadian participation in the Conference and its activities was looked after by the Canadian National Committee, of which Dr. Charles Camsell, M.E.I.C., is chairman, and Norman Marr, M.E.I.C., Secretary. The arrangements for adequate Canadian representation involved an immense amount of work on the part of these two gentlemen and their committee. Five of the topics for discussion on the official programme of the Conference were the subjects of specially prepared papers by Canadians.

At the Conference the large British delegation took a leading part, and spoke with freedom and vigour in opposition to everything savouring of politics, remarking pointedly that "politics and power will not mix."

President Roosevelt appeared personally at one of the gatherings, and dramatically put into operation electrically from the meeting hall the great Boulder Dam power plant, assuring his nation-wide audience that other undeveloped millions of horse power would soon be made ready for the people if his administration were returned to office.

In almost all their deliberations the delegates from abroad dealt entirely with engineering problems and achievements, but there was a tendency for some of the American delegates to wax eloquent over the financial structures of operating companies.

The Canadian Committee, invited to act as joint host to the delegates from other countries during the post-convention tours which passed through Canada, took an active part in making the necessary arrangements. In the Montreal district, in the Ottawa district and in the Niagara Peninsula, important engineering developments were thrown open and inspected with appreciative interest.

The delegates participating in the tour were entertained by the Federal Government at dinner at Ottawa, the Minister of Transport presiding. They were similarly entertained in Montreal by the Electricity Commission of Quebec, and at Niagara Falls the Hydro-Electric Power Commission of Ontario acted as their hosts. The officers of the Hydro, the Shawinigan Company, the Beauharnois Company, and the Gatineau Power Company were most hospitable, and the delegates were greatly impressed with the industrial developments arising from the utilization of power on Canadian rivers.

After visiting Niagara, the visitors joined in the proceedings of the American Society of Mechanical Engineers, whose Fall Meeting, participated in by The Engineering Institute of Canada, synchronized with the dates of the World Power Conference tours. The Institute was represented at the A.S.M.E. dinner by the undersigned.

At the time of writing, Christmas Eve, a formal resolution of appreciation and gratitude has just arrived; it is signed by fifteen Norwegian delegates to the Third World Power Conference.

Respectfully submitted,
John Murphy, M.E.I.C., *Chairman.*

### Board of Examiners and Education

The President and Council:—

Your Board of Examiners and Education, having been re-appointed from the previous year, beg to report for 1936 as follows:

In accordance with request received from Council your Board prepared several examination papers, namely:

For examination held in May—

*Schedule B*

I. Elementary Physics and Mechanics.
II A. Strength and Elasticity of Materials.

*Schedule C*

II A. Civil Engineering General Paper.
II B2. Hydraulic Engineering.
III A. Electrical Engineering General Paper.

III B3. Utilization of Electric Power.
VII A. Structural Engineering General Paper.
VII B1. Structural Steel Design.

For examination held in November—
*Schedule C*
VII B2. Reinforced Concrete Design.

Your Board received five papers from five candidates for the May examination and from one candidate in November. These papers were marked and returned with reports to Council.

At the request of Council your Board made recommendations as to standing which should be allowed a particular prospective candidate without application and in another instance submitted a report on textbooks suitable for study for The Institute examinations.

The results of the examinations held during 1936 were as follows:—

| *Examined under* | *Number of Candidates* May | Nov. | *Numbers passed* May | Nov. | *Passed in all subjects Completely* |
|---|---|---|---|---|---|
| Schedule B (Junior) | | | | | |
| I Elementary Physics and Mechanics | 1 | .. | 1 | .. | 1 |
| II A Strength and Elasticity of Materials | 1 | .. | 1 | .. | |
| Schedule C (Associate Member) | | | | | |
| I A General Chemical Engineering | .. | 1 | .. | 1 | |
| I B7 Water Softening | .. | 1 | .. | 1 | |
| II A Civil Engineering General Papers | 1 | .. | .. | .. | |
| II B2 Hydraulic Engineering | 1 | .. | .. | .. | |
| III A Electrical Engineering General Paper | 1 | .. | .. | .. | 3 |
| III B3 Utilization of Electric Power | 1 | .. | .. | .. | |
| VII A Structural Engineering General Paper | 2 | .. | 2 | .. | |
| VII B1 Structural Steel Design | 1 | .. | 1 | .. | |
| VII B2 Reinforced Concrete Design | .. | 1 | .. | 1 | |

In conclusion, I wish to express my appreciation to the members of the Board for the ready way in which they have assisted in this work and to thank the secretary for his co-operation.

Respectfully submitted,
H. M. White, A.M.E.I.C., *Chairman.*

### Committee on Western Water Problems

The President and Council:—

The past season was again one of severe drought over a large part of the Western prairies, although the areas affected were not the same as in 1934. Present indications are that 1937 will be a poor crop year, as there is a deficiency of moisture in the soil over a large section of the country.

The Dominion Government has commenced a comprehensive study of soil and precipitation conditions in the area subject to drought, as also a survey of the economic conditions of the individual farmers. In this connection it is interesting to note that several years ago H. J. McLean, A.M.E.I.C., prepared a map based on the Government soil surveys, meteorological and run-off data, classifying the prairie into areas according to crop prospects over a period of years. The map is being used in studying the economic feasibility of transmission line extensions.

It is understood that in 1937-1938 there will necessarily be a substantial increase in expenditure under the Drought Rehabilitation Act, and that it is planned to hold a conference at Regina this spring, at which provincial, municipal, railway, federal and other representatives will be present to map out their programme for the summer. It is intended more particularly to aim at the reorganization of the western drought areas and to assist the farmer in the marketing of farm products and in the promotion of co-operative producing and distributing organizations.

The drought problem is primarily an agricultural one. For relief we must look to the improvement of farming methods and to the development of new types of wheat. The very lands that are subject to drought produce the highest grade of wheat. The engineer can render a service to the farmers on these lands by making them less dependent upon the wheat crop. In this connection a distinction should be made between irrigation for raising a cash crop and water supply to enable the farmer to grow enough vegetables for his own use and feed for his stock. While large scale irrigation is seldom economically feasible, the supply of water for these domestic purposes will support a much higher charge per acre foot.

In this direction, your Committee is able to report progress in the application of electric pumping. The flow of the rivers rising on the eastern slope of the Rockies is high in summer and low in winter and the summer is also the season when the load on the power systems on the Prairie is light. A power rate has been worked out passing on the benefit of this situation to the irrigation user. The Eastern Irrigation District of Alberta in collaboration with Calgary Power Company has recently completed a 10,000 g.p.m. pumping installation operating under a fourteen foot lift for irrigating an extensive tract of land above ditch level. A special type of pump has been developed for this service. While this installation appears to be highly successful, it is early yet to make a full report on the results obtained, or to forecast whether such installations will have any wide application in making the farmers less dependent on the wheat crop in that portion of the drought area having hydro-electric power service.

Respectfully submitted,
G. A. Gaherty, M.E.I.C., *Chairman.*

### Committee on Deterioration of Concrete Structures

The President and Council:—

During the past year the organization of the Committee on Deterioration of Concrete Structures has been completed, the membership of the committee being as follows:—

R. B. Young, M.E.I.C., *Chairman.*
G. P. F. Boese, A.M.E.I.C.
C. L. Cate, A.M.E.I.C.
A. G. Fleming, M.E.I.C.
O. O. Lefebvre, M.E.I.C.
C. J. Mackenzie, M.E.I.C.
J. A. McCrory, M.E.I.C.
J. H. McKinney, A.M.E.I.C.
R. M. Smith, A.M.E.I.C.
E. Viens, M.E.I.C.
C. N. Simpson.

The work of the Committee has commenced; its members are now preparing reports on different structures, which will later be assembled for study.

Respectfully submitted,
R. B. Young, M.E.I.C., *Chairman.*

### Honour Roll and War Trophies Committee

The President and Council:—

During the year the large bronze Record Tablet, containing the names of 949 members who served overseas with the Allied Forces during 1914 to 1918, has been cast and erected at a total cost of $2,711.89. It replaces the temporary record which was put up just after the War, and is believed to be accurate and complete. Adequate lighting has been provided, as well as for the smaller Memorial

Tablet, and the Record Tablet is ready for unveiling. It is hoped that arrangements may be made for this ceremony to take place during the Semicentennial in June next.

There remains an unexpended balance of $2,046.33 to the credit of the fund, and your committee would suggest that this amount might form the nucleus of a fund for a suitably named prize or scholarship.

Respectfully submitted,
A. E. Dubuc, M.E.I.C., *Chairman.*

## Employment Service Bureau

The President and Council:—

The Employment Service Bureau of The Institute is now able to report an improvement in employment conditions for the fourth consecutive year. The following figures show the placements effected during the past five years:—

| *1932* | *1933* | *1934* | *1935* | *1936* |
|---|---|---|---|---|
| 58 | 50 | 70 | 77 | 110 |

The following figures show the extent of the Bureau's work for 1936 as compared with 1935:—

| | *1936* | *1935* |
|---|---|---|
| Number of registrations during the year—members.... | 103 | 96 |
| Number of registrations during the year—non-members | 45 | 38 |
| Number of members advertising for positions......... | 77 | 86 |
| Replies received from employers..................... | 42 | 59 |
| Vacant positions registered......................... | 195 | 145 |
| Vacancies advertised in Journal..................... | 25 | 27 |
| Replies received to advertised positions............ | 66 | 124 |
| Men notified of vacancies........................... | 259 | 209 |
| Men's records forwarded to prospective employers..... | 746 | 518 |
| Placements definitely known......................... | 110 | 77 |

At the present time 225 members are registered with the Employment Service Bureau (which compares with 224 a year ago), 117 of whom have advised us that they are temporarily employed, or desire to change their present positions.

Over one thousand interviews were given in connection with employment during the past year.

As The Journal is published monthly, it has been found impossible to include many of the "Situations Vacant" advertisements, and latterly a mimeographed bulletin has been issued to those registered with the Bureau. It is proposed to continue the issuing of this bulletin each month during 1937, and if possible to increase its scope to include "Situations Wanted" advertisements, and the mailing list covering prospective employers.

Enquiries during the past few months indicate that the present demand for engineers appears mainly to be in the following general classifications:—

- Recent graduates in mechanical engineering.
- Young mechanical engineers with two or three years experience.
- Recent graduates in civil engineering.
- Sales engineers in all branches of engineering.
- Sales engineers speaking French.
- Engineers with pulp and paper mill experience in design, draughting and maintenance.

Employment conditions for engineers have so improved that within a few months it seems likely that the demand will exceed the supply in most parts of Canada; this has already happened in a number of specialized lines.

There are few totally unemployed engineers at the present time. There are, however, some who are temporarily out of work for the winter months, particularly in the Maritime and Western Provinces. There are still a considerable number of experienced construction engineers in unsatisfactory positions.

Reports from various Branches on the Unemployment Situation were received in December 1936, as follows:—

*Saint John Branch*

Although there are a few unemployed, especially among Students and Juniors, the employment situation shows considerable improvement.

*Moncton Branch*

None of the Corporate Members of the Branch are unemployed. There is one Student who is trying to find work.

*Peterborough Branch*

Employment conditions for engineers in this district are practically on a level with those of pre-depression years.

*London Branch*

To our knowledge only one engineer is unemployed at the present time.

*Lakehead Branch*

As far as is known, all engineers of the Branch have been employed for the greater part of the past year. Some of the work has been temporary but little difficulty has been had in placing engineers. Several engineers were brought in from outside districts. Remuneration has not yet reached a satisfactory level. This Branch has had only one case in which financial aid was necessary. This was the case of an aged transient engineer who was provided for until work was obtained for him in the mining area.

*Sault Ste Marie Branch*

The unemployment committee which functioned during 1935 has been discontinued, the Executive feeling that the need for this committee was over due to the betterment of business conditions in this territory.

*Victoria Branch*

There have been no calls during the year for financial assistance and the Executive has no knowledge of any members in need of such assistance. It would appear that general conditions are improved as at least three members of the Branch are known to have bettered their positions during the year.

*Vancouver Branch*

Employment conditions amongst engineers have improved greatly during 1936. Briefly, all engineers in geological, mining and metallurgical engineering are employed. There is much improvement in conditions affecting civil, mechanical and structural engineers. There is still, however, some distress amongst electrical engineers. Indications for 1937 are that all engineers will probably be employed.

*Calgary Branch*

The situation regarding the employment of engineers in this district has improved only slightly in the year 1936. This slight improvement is due to employment of engineers on government projects and to increased activity in the Turner Valley oil fields. Several engineers of this Branch, including experienced engineers as well as recent graduates, are unemployed, and the present prospects do not indicate any material betterment of this condition in the immediate future.

*Lethbridge Branch*

To date there is no unemployment amongst the members of the Lethbridge Branch, according to data from the local committee on unemployment.

*Saskatchewan Branch*

It is safe to say that virtually all engineers in Saskatchewan were gainfully employed for at least some period during 1936. Some engineers are now unemployed by reason of seasonal conditions and a very small percentage have nothing in view at all. However, we look to 1937 with the prospect of having every engineer engaged in some kind of work even though it be only temporary employment.

Respectfully submitted,
R. J. Durley, M.E.I.C., *General Secretary.*

## Committee on Consolidation

The President and Council:—

At the Annual Meeting of The Institute held in Hamilton on February 5th, 1936, the report of the Committee on Consolidation for the year 1935 was presented, discussed, and the following resolution was unanimously passed by the meeting:—

"That the Report of the Committee on Consolidation be adopted in principle as a progress report; also that the Committee on Consolidation be continued with instructions to add to their number two members of the Dominion Council of the Associations, and be empowered to add further to their number, providing such additional members be approved by Council, and that Council and the Committee shall co-operate for the speedy consummation of consolidation, co-ordination or confederation throughout the Dominion."

The report contained the following recommendations:—

(1) That in view of the general approval which has been given the broad principle of consolidation by the profession in Canada, The Engineering Institute of Canada take immediate steps to put the same into effect with those Provincial Professional Associations with whom satisfactory arrangements can be made.

(2) That The Engineering Institute agree to accept as qualification for admission to membership in The Institute the standard of membership requirement of the Provincial Professional Associations or Corporation and that when the engineers of a Province come into Consolidation, only members of the Provincial Professional Association or Corporation of such Province shall, thereafter, be accepted into membership in The Institute from that Province.

(3) That The Engineering Institute agree to accept into membership of a certain class, upon payment of a determined nominal fee, those members of the Provincial Professional Associations coming into consolidation, who are not and may not become full members of the national body.

(4) That The Engineering Institute of Canada make representation to the several Provincial Professional Associations for the acceptance of corporate membership in The Institute as qualification for admission to the Professional Association when permissible under the law of the province. This to apply only to those who are corporate members of The Institute at the time of consolidation with such Provincial Professional Association.

(5) That The Engineering Institute apply the principle of Provincial Divisions and that the same shall include the present branches of The Institute and the membership of the Provincial Professional Associations on a system of organization and administration to be determined by a properly representative committee of the Associations and The Institute.

(6) In the event of consolidation being effected as between The Institute and any Provincial Professional Association, The Institute agree to the establishment of a properly constituted authority in such province for the collection and distribution of membership fees within the province and to the national body, in accordance with a mutually approved contract.

(7) That The Institute agree to act as the national body in the event of consolidation being consummated with any or all of the Provincial Professional Associations.

(8) That The Institute undertake to constitute the members of The Institute within any province into a Provincial Division of The Institute in that province should the Provincial Professional Association not be prepared to proceed to consolidation at this time.

(9) That The Institute continue the present Committee on Consolidation with the commission to represent The Institute in discussions with the Provincial Professional Associations and for the purpose of achieving consolidation on the general basis above outlined.

The Committee regrets that it has not been possible to submit to Council for action at this Annual Meeting, certain specific recommendations involving basic changes in the By-laws of The Institute as outlined in paragraph No. 2 of the above recommendations, which would materially facilitate the early consummation of consolidation.

---

Since the Annual Meeting of February 5th, 1936, the Committee has held nine regular meetings, one Joint Conference with the Dominion Council and other representatives of the Provincial Professional Associations and Corporation, two joint meetings with the Council of The Institute, and was represented at the Seventh Plenary Meeting of Council held in Montreal on October 16th and 17th, to consider the Committee's proposals for revisions to the By-laws of The Institute designed to effect closer co-operation between The Institute and the various Professional Associations and Corporation.

At a meeting of the Committee held on February 6th, and with the subsequent approval of the Council, Dr. F. A. Gaby was added to the membership of the Committee.

At a meeting of the Dominion Council and other representatives of the Professional Associations and Corporation, held in Hamilton on February 6th, 1936, Mr. C. C. Kirby of Saint John, N.B., and Mr. Archie B. Crealock of Toronto, President and Vice-President respectively of the Dominion Council of Professional Engineers, were appointed as its representatives on the Committee on Consolidation, and the Committee assumed a national significance.

On Friday, February 7th, an informal conference was held of the Dominion Council, the representatives of the Provincial Professional Associations, and the representatives of The Engineering Institute.

Those present at this meeting were:—

Members of the Dominion Council of Professional Engineers:—

| | |
|---|---|
| C. C. Kirby, (President). | Saint John, N.B. |
| Archie B. Crealock, (Vice-President). | Toronto, Ont. |
| Colonel F. H. G. Letson, | Vancouver, B.C. |
| P. M. Sauder, | Lethbridge, Alta. |
| D. A. R. McCannel, | Regina, Sask. |
| Professor F. R. Faulkner, | Halifax, N.S. |

Other Representatives of the Provincial Professional Associations:—

| | |
|---|---|
| E. A. Wheatley, | Vancouver, B.C. |
| T. C. Main, | Winnipeg, Man. |
| J. M. H. Cimon, | Quebec, P.Q. |
| A. B. Normandin, | Quebec, P.Q. |
| G. Stead, | Saint John, N.B. |

Members of the Committee on Consolidation, representing The Engineering Institute of Canada:—

Dr. O. O. Lefebvre,
J. B. Challies,
Dr. F. A. Gaby,
Professor R. E. Jamieson,
Gordon McL. Pitts
(Chairman).

This was a most momentous day in the history of the engineering profession in Canada, as it provided the long-sought opportunity for a round table discussion of the many details and varying points of view involved in the uniting of the engineering organizations of the Dominion into one coherent, expressive, national body. Those present appreciated the significance of the occasion and the deliberations and discussions were carried on in the spirit of the fullest co-operation and compromise.

Mr. C. C. Kirby acted as Chairman of the meeting and Mr. E. A. Wheatley as Secretary. The conference lasted throughout the day and the results of its discussions are represented in the following Memorandum.

*Memorandum of Informal Conference*

Between Representatives of the Provincial Professional Associations in Canada and of The Engineering Institute, prepared for the purpose of discussion only and without prejudice to the action by any member present at this meeting, held at Hamilton, February 7th, 1936.

We record with satisfaction and appreciation the opportunity afforded in Hamilton, this day for the first time for accredited representatives of all Provincial Professional Associations in Canada (The Associations' Dominion Council) and also The Engineering Institute (The Committee on Consolidation), to confer for the common good of the engineering profession.

We feel the opportunity thus afforded to be of such great moment to the engineering profession in Canada that it must be taken full advantage of. Therefore, we desire to place on record the following preliminary conclusions as a basis for definite progress.

1. General principles only should now be asserted. Constitutional details and precise methods of procedure to accomplish the general principles could be left in abeyance for the time being.

2. The Provincial Professional Associations must continue to function in their present capacities and for the purpose set out in their respective acts, and the E.I.C. should continue to function.

3. There should be a national engineering body for Canada, comprising within its membership all the qualified engineers of Canada.

4. The Engineering Institute of Canada can be the basis for such a national engineering body, and it is desirable that it should be.

5. To accomplish the purpose set out herein, we suggest for the consideration of the Provincial Professional Associations and of The Engineering Institute the following specific recommendations:—

(*a*) That The Engineering Institute agree to consolidate its two classes of corporate membership into one class.

(*b*) That The Engineering Institute agree to admit to corporate membership only those applicants who are members of a Provincial Professional Association.

(*c*) That The Engineering Institute agree to grant a special non-voting membership, without payment of either entrance fee or annual dues and without right to hold office, to those members of the Provincial Professional Associations who may not for the time being desire to apply for corporate membership in The Engineering Institute.

(*d*) That The Engineering Institute agree to enlarge its Council to permit each Provincial Professional Association to be represented directly by an accredited representative.

(*e*) That the Provincial Professional Associations continue their Dominion Council until such time as the purposes of the negotiations connoted by this memorandum are accomplished.

(*f*) That the Provincial Professional Associations con sider an acceptable plan by which the non-voting members referred to in paragraph "*c*" shall be encouraged to become corporate members of the national body.

In conclusion, it is the opinion of all assembled that the Provincial Professional Associations should encourage all their members to become corporate members of The Engineering Institute to the end that as soon as practicable there will be a real and a complete common membership as between the Provincial Professional Associations and the national engineering body.

---

At its meeting of March 21st, the Committee considered the recommendations of the Joint Conference, item by item, and it was unanimously agreed that they should form the basis for further progress in the development of a plan for closer co-operation mutually acceptable to the whole profession. It was further agreed that the plan should be drafted in a manner generally acceptable to the Associations, and should provide the opportunity for each Provincial Association and Corporation to avail itself of the advantages of the co-operation afforded thereby at such time as the Association might decide. It was not considered an essential principle of the plan to require that all the Associations come in simultaneously.

On April 18th, Mr. C. C. Kirby, President of the Dominion Council, met the Chairman of the Committee on Consolidation in an informal conference to study certain tentative revisions to the By-laws of The Institute prepared by Mr. Kirby in accordance with the principles approved by the Annual Meeting, the Memorandum of the Joint Conference, and the general discussions of the Committee. Mr. Kirby's proposals were circulated to the Corresponding Members of the Committee and of Council.

At its meeting of May 30th, the Committee again discussed and approved the Memorandum of the Joint Conference at Hamilton. It also considered the resolution of the Joint Consolidation Committee of the Province of Manitoba of April 29th, 1936, urging immediate action by The Institute to permit Consolidation to go into effect in that province at an early date. The Committee expressed its sympathy with this desire for early Consolidation within the Province, coupled with the hope that the engineers of Manitoba would co-operate with the Committee to the extent of delaying action until such time as the proposed revisions to the By-laws had been approved and forwarded to them.

The Committee also considered representations from British Columbia regarding simplified forms of admission to The Institute, and the tentative revisions to the By-laws as prepared by Mr. Kirby were reviewed. It further recommended to Council that the Committee be authorized to contact various engineering organizations in Ontario relative to the organization of the profession in that Province and the definition of the aims of the Committee.

Immediately following this meeting the Committee met in a Joint Meeting with the Council of The Institute, at which the "Memorandum" of the Joint Conference in Hamilton was considered item by item and duly recommended for approval by Council with the addition of the phrase, "who shall be a corporate member of The Institute," to Section 5 (*d*) of the "Memorandum." The Joint Meeting also discussed the resolution of the Manitoba Joint Consolidation Committee, and Mr. Kirby's suggested revisions to the By-laws. At a subsequent meeting of the Council the "Memorandum," as revised by the Joint Meeting, was approved.

At its meetings of July 21st, August 4th, August 21st and 22nd, the Committee gave detailed study to proposals for the revision of the By-laws of The Institute and it was decided to request a joint meeting with the Council to consider these on September 18th. This joint meeting discussed the proposals section by section and made many constructive suggestions to the Committee regarding some of the more important clauses. It was decided that a Plenary

Meeting of the Council should be held on October 16th and 17th.

On September 19th the Committee again reviewed the By-laws and the suggestions of the Joint Meeting relative thereto, and arrangements were made for the presentation of the proposals to the Council over the signatures of twenty or more members of The Institute in accordance with the provisions of the present By-laws.

The Chairman, by special invitation, represented the Committee at the Seventh Plenary Meeting of the Council, at which the By-laws were again carefully reviewed and certain modifications and additions were suggested. The results of the Plenary Meeting were reviewed by the Committee at its meeting of November 14th, and subject to minor modifications suggested by the legal adviser, all the suggestions of the Council were accepted and incorporated by the Committee into its By-law proposals with the one exception that Sub-Section 7 (*b*), which appeared in the Committee's proposals as:—

> "No person residing in any province in which there is a Component Association shall be admitted as a Member of The Engineering Institute of Canada unless he be a corporate member of such Association."

Council recommended this Sub-Section should be revised to read:—

> "No person residing in any province in which there is a Component Association, *who is required by law to be a member of that Component Association*, shall be admitted as a Member of The Engineering Institute of Canada unless he be a corporate member of such Component Association."

The Committee very carefully considered the amendment of this Section proposed by the Council, having in mind the views expressed by certain of the Associations with reference to this clause and its direct effect on the possibilities of achieving closer co-operation with the Associations, and finally came to the conclusion that it had no alternative but to adhere to the Section as originally drafted by the Committee.

In arriving at this decision, the Committee has taken the following into consideration:—

(1) Paragraph 7 of the Report of the "Committee on Relations of The Institute with the various Provincial Associations," which was accepted at the Annual Meeting of The Institute of February 12th, 1930, with one member dissenting. (See page 3, Report of the Committee on Consolidation of January 1936.)

> "That steps be taken to secure the necessary amendments to the By-laws so that membership or registration in a Professional Association be one of the requirements for admission to Corporate Membership in The Engineering Institute of Canada for all applicants residing in a province where an Engineering Professions Act is in effect."

(2) The overwhelming majority of the profession which gave an affirmative answer to question No. 2 of the Questionnaire of the Committee on Consolidation issued in June, 1935.

> "In your opinion, should the corporate membership of the Provincial Professional Associations and of the National organization be identical?"

The replies to Question No. 2 were:—

Yes, 3,868 (91.6 per cent); No, 353 (8.4 per cent).

(3) Section 2 of the Report of the Committee on Consolidation to the Annual Meeting of February 5th, 1936, which was unanimously "adopted in principle as a progress report" by that meeting.

> "That The Engineering Institute agree to accept as qualification for admission to membership in The Institute the standard of membership requirement of the Provincial Professional Associations or Corporations and that when the Engineers of a Province come into Consolidation, only members of the Provincial Professional Association or Corporation of such Province shall, thereafter, be accepted into membership in The Institute from that Province."

(4) Paragraph 5 (*b*) of the Memorandum drawn at the Joint Conference of members of the Dominion Council, representatives of Provincial Professional Associations, and the members of the Committee on Consolidation as representing The Institute, in Hamilton, on February 7th (see page 303 of The Journal for June 1936), which Memorandum was subsequently approved by the Committee on Consolidation, the joint meeting of Council and the Committee of May 30th, and further approved by Council at its meeting of June 12th, 1936. (See Journal, August 1936, page 385.)

> "5 (*b*) That The Engineering Institute agree to admit to corporate membership only those applicants who are members of a Provincial Professional Association."

(5) The Resolution of the Annual Meeting of the Corporation of Professional Engineers of the Province of Quebec, held on March 27th, 1936. (See page 13, Report of Committee on Consolidation, January 1936.) The above Resolution was further confirmed at the Annual Meeting of the Corporation in 1936.

> "That The Engineering Institute of Canada should, after the date of such change, admit no person to corporate membership who is not at the time of application a member of his own local provincial body."

(6) In addition, this By-law and the policy it embraces, has been approved by many Branches of The Institute, Joint Committees on Consolidation and Professional Associations.

Sub-Section 7 (*b*) as proposed by the Committee on Consolidation in no way affects the standing of any of the present members of The Institute and, in view of the fact that it represents a principle of co-operation which has been accepted by The Institute and recognized by the Provincial Professional Associations over a period of years, it is felt that a complete reversal of policy by The Institute at this time may be prejudicial to its efforts for closer co-operation with these Associations.

The phrase, "who is required by law to be a member of that Component Association," as proposed by the Council, is not legally practical, as it provides no authority within the profession to determine the legal qualification of the candidate and in many cases this might require an expensive court action.

---

The revisions of the By-laws of The Institute as proposed by the Committee on Consolidation were officially issued to the membership in accordance with the provisions of By-law No. 75 on pages 550 to 553 of The Journal for December 1936, and a copy thereof is attached as an Appendix "A" to this report.

In connection with the present proposals for the revisions to the By-laws of The Institute, our legal adviser and the Committee on Consolidation recommended to the Council of The Institute that the occasion for such revision should be made the opportunity for re-arranging and re-numbering the By-laws of The Institute in a proper sequence that they may be presented in logical order and easily accessible form for the use of the members. The proposed sequence of re-numbering is attached to this report as an

Appendix "B" and the Committee has been advised that the Council has decided that the re-numbering and re-arrangement of the By-laws should not take place until after the ballot.

At its meeting of November 14th, and with the assistance of our legal adviser, the Committee prepared and approved a proposed form of Agreement between a Component Association and The Institute. Copy of this Agreement appears as an Appendix "C" to this report.

At this meeting the Committee also prepared and approved a proposed Form "C," being the form of Application for Admission to The Institute by a member of a Professional Association. This form appears as an Appendix "D" to this report.

At this meeting the Committee also considered the form of the ballot by which the proposed revisions to the By-laws should be presented to the membership for ratification, and it was generally agreed that Council should be requested to consult with the Committee on this matter and that the ballot should if possible take the general form as appearing as an Appendix "E" to this report.

---

The proposals of the Committee may be briefly summarized as follows:—

The status of an engineer who is registered as entitled to practise by any one of the Associations, is acknowledged by The Institute as sufficient evidence of eligibility to become a member of The Institute, with merely the formality of a signed application to complete the admission, provided proper credentials are submitted. No entrance fee will be required of such an applicant.

The Associations are to signify their willingness to co-operate with The Institute by entering into individual agreements with The Institute in accordance with the terms of these By-laws to carry out their several parts of the undertaking. The Associations so agreeing shall be styled "Component Associations" for purposes of reference.

An Association may become a Component Association by registering at one time its total corporate membership as Members of The Institute and the payment of a per capita fee to be determined by the Council.

Again, an Association may become a Component Association by entering into an agreement with The Institute to that effect with the provision that Membership in The Institute will remain optional on the part of each member of an Association. Those who do not wish to join The Institute will be styled "Associates" of The Institute for purposes of reference and can, if they wish, participate in Institute Branch meetings and receive The Journal of The Institute at the same rate as other members.

The detail work of furthering co-operation between the various Provincial Associations on inter-provincial matters and of endeavouring to obtain more uniformity in their Provincial requirements, will be delegated to a Standing Committee of The Institute to be known as "The Committee on Association Affairs." This Committee shall report to the Council and to their respective Associations.

Component Associations may appoint or elect one member each, who is a member of The Institute, to the Council of The Institute, who may act as ordinary Councillors on the affairs of The Institute and who shall constitute the "Standing Committee on Association Affairs."

In order that this "Committee on Association Affairs" shall have the opportunity to do effective work by meeting together, provision is made that such a meeting shall be held annually with expenses of the members paid by The Institute. The Institute to be recompensed for this expense by a payment or grant from each Association on the basis of fifty cents per capita for each of its members entitled to practise.

The Council of The Institute may arrange with a Component Association for the collection of fees of joint members. A Component Association paying a per capita fee will collect these fees and forward the same to The Institute in accordance with the provisions of their Agreement.

The present grade of "Associate Member" of The Institute will be abolished and all such present members shall be styled "Members." The fees for the new grade of "Members" shall be reduced two dollars a year from the fees of the present grade of "Member."

"Engineers in training" and "Pupils" of any of the Associations may be admitted to classifications of "Juniors" or "Students" of The Institute with similar nominal formality to that for corporate members.

The Institute will confine itself for future members in a province where there is a "Component Association" to members of such Association.

In considering the revisions to the By-laws proposed by the Committee, the attention of the membership is drawn to the following:—

The proposals are so designed that the present status, function, operation and administration of The Institute undergo no fundamental change in the event of none, one or all of the Professional Associations taking advantage of the co-operation for which these proposals make provision.

The proposals make possible a very material reduction in the fees of those engineers who are members of both a Professional Association and the National body.

The fees of Members are reduced.

Present Associate Members are raised to the grade of "Member" without having to pay a transfer fee ($10.00), without the complications of application, recommendation and acceptance, and without having to pay the present fee for the grade of "member." All this more than compensates the present "Associate Member" for the small additional annual fee (one dollar) he will pay as a "Member."

The financial position of The Institute is not jeopardized by these proposals. On the other hand possibilities are provided for increased revenue through greatly increased membership. Economies in administration should also be possible.

The qualifications for admission to membership are more clearly defined and the procedure for admission has been greatly simplified.

The gap between the legal and technical functions within the profession has been effectively bridged and provision is made for the elimination of those divergences in ideal and action which impede the progress and development of the profession and are bound to spring up and develop through a multiplicity of unrelated engineering organizations.

The principle of united action for the common good of the profession, individually and collectively, can now be effectively applied.

Since its inception the Committee has maintained its policy of keeping the general membership informed as to its progress through periodic reports in The Journal of The Institute. These reports have also been made available to all members of Provincial Professional Associations and the Corporation who are not at the present time members of The Institute. It is hoped that this effort toward publicity on the part of the Committee has achieved the desired result and that all members of the profession have taken the opportunity of making themselves familiar with the many aspects of this problem as it developed.

---

In conclusion, your Committee on Consolidation recommends:—

(1) That the Council of The Institute and the Committee on Consolidation being in agreement on all the proposed revisions to the By-laws of The Institute as appearing in Appendix "A" of this report, with the exception of Sub-Section 7 (*b*), these revisions be accepted by the Annual Meeting and be sent forward to ballot by the general membership without further amendment.

(2) That in view of the attitude of the majority of the Professional Associations on Sub-Section 7 (*b*) and in the interests of achieving Consolidation, every effort be made to accept the Committee's proposal on this Sub-Section without modification or amendment for submission by ballot to the general membership.

(3) That the Annual Meeting approve the form of the "Memorandum of Agreement" between The Institute and a Component Association, as submitted in Appendix "C" of this report, subject to such modification within the terms of the By-laws as may be agreeable to the Council of The Institute and the Associations and Corporation.

(4) That the Annual Meeting approve Form "C" as proposed by the Committee in Appendix "D" of this report, being the form of Application for Admission to The Institute by a member of a Provincial Professional Association or Corporation.

(5) That the ballot on the By-law proposals be drawn in the general form as appearing in Appendix "E" of this report and that the Committee on Consolidation be authorized to take part in the drafting of the form of the ballot.

(6) That subject and subsequent to the approval of the By-law proposals by a ballot of the membership, the By-laws be re-arranged and re-numbered before being printed and issued to the membership in accordance with the Index appearing as Appendix "B" of this report.

(7) That the Committee on Consolidation be continued as presently constituted to function in connection with the preparation of the ballot, and otherwise for the purposes of Consolidation, until after the results of the ballot have been announced, and that thereafter a special committee be appointed by Council to actively promote Consolidation.

Respectfully submitted.

GORDON McL. PITTS, A.M.E.I.C., *Chairman.*

# Branch Reports

## Border Cities Branch

The President and Council:—

The Executive committee of the Border Cities Branch submits the following report for the calendar year 1936.

The Executive committee met six times during the year for the transaction of Branch business.

Including the annual meeting eight regular meetings and one special meeting were held.

The following is a list of the meetings held together with a note on the subject, speaker, and attendance:—

1936

Jan. 17.—**Welding High Pressure Piping** by S. Crocker and D. H. Corey, engineers for the Detroit Edison Company, Detroit. Attendance 27.

Feb. 14.—**Impressions of Portugal** by C. M. Goodrich, M.E.I.C., chief engineer for Canadian Bridge Company, Walkerville, Ontario. Attendance 24.

Mar. 20.—**Modern Problems in Railroad Engineering** by T. H. Jenkens, A.M.E.I.C., of the Grand Trunk Western R.R. Co., Detroit. Attendance 20.

April 24.—**Mining Development in Canada** by A. D. R. Fraser, of the Windsor Vocational School. Attendance 22.

May 26.—**Performance Limits of the Four Cycle Engine** by R. Janeway, of the Chrysler Motor Corporation, Detroit. Attendance. 30.

Sept. 21.—**Consolidation of the Engineering Profession in Canada** by J. F. Plow, A.M.E.I.C., Assistant to the Secretary of The Engineering Institute of Canada. Attendance 24.

Oct. 17.—Joint Meeting with the Border Cities Chapter, Ontario Association of Architects on the occasion of the Annual Meeting of the President and Council of the Association of Architects. Attendance 20.

Nov. 27.—**Drop Forgings** by R. E. Waldron, chief engineer for The Dominion Forge and Stamping Co., Walkerville, Ontario. Attendance 25.

Dec. 11.—Annual Meeting and Election of Officers. **Reminiscences in Engineering** by W. H. Baltzell, M.E.I.C., chief engineer for the Canadian Steel Corporation, Ojibway, Ont. Attendance 30.

The average attendance at the regular meetings was 25.

MEMBERSHIP

The membership of the Branch is made up as follows:—

| | *Resident* | *Non-Resident* | *Total* |
|---|---|---|---|
| Members | 12 | 3 | 15 |
| Associate Members | 32 | 6 | 38 |
| Juniors | 4 | 2 | 6 |
| Students | 8 | 6 | 14 |
| Affiliates | 1 | .. | 1 |
| | 57 | 17 | 74 |

A comparison of our present membership with that of other year is shown in the following table:—

| | *1932* | *1933* | *1934* | *1935* | *1936* |
|---|---|---|---|---|---|
| Members | 21 | 17 | 14 | 10 | 15 |
| Associate Members | 42 | 34 | 32 | 35 | 38 |
| Juniors | 8 | 5 | 3 | 3 | 6 |
| Students | 11 | 11 | 13 | 11 | 14 |
| Affiliates | 1 | 1 | 1 | 1 | 1 |
| | 83 | 68 | 63 | 60 | 74 |

FINANCIAL STATEMENT

*Receipts*

| | | |
|---|---|---|
| Balance on hand, January 1st, 1936 — This includes $24.32 unemployment fund. | $163.63 | |
| Rebates on dues for October, November and December, 1935 | 8.10 | |
| Rebates on dues for January, February, March and April, 1936 | 99.00 | |
| Rebates on dues for May, June, July, August and September, 1936 | 10.80 | |
| Rebates on dues for October, November and December, 1936 | 10.80 | |
| Dinner receipts | 62.40 | |
| | | $354.73 |

*Expenditures*

| | | |
|---|---|---|
| Printing and stamps | $ 35.40 | |
| Meals | 87.55 | |
| Speakers | 5.43 | |
| Miscellaneous | 30.53 | |
| Balance on hand in bank — This includes $24.32 unemployment fund. | 185.02 | |
| Accounts receivable, rebates, October, November, and December, 1936 | 10.80 | |
| | | $354.73 |

Respectfully submitted,

THOS. H. JENKINS, A.M.E.I.C., *Chairman.*
BOYD CANDLISH, A.M.E.I.C., *Secretary-Treasurer.*

## Calgary Branch

The President and Council:—

On behalf of the Executive committee of the Calgary Branch we have the honour to submit this report covering the activities of the Calgary Branch for the year 1936:—

MEMBERSHIP

| | *Branch Resident* | | *Branch District* | | *Total* | |
|---|---|---|---|---|---|---|
| | *1935* | *1936* | *1935* | *1936* | *1935* | *1936* |
| Members | 17 | 17 | 3 | 5 | 20 | 22 |
| Associate Members | 43 | 48 | 10 | 10 | 53 | 58 |
| Juniors | 6 | 6 | 1 | 1 | 7 | 7 |
| Students | 9 | 13 | 1 | 4 | 10 | 17 |
| Affiliates | 8 | 6 | .. | .. | 8 | 6 |
| Total | 83 | 90 | 15 | 20 | 98 | 110 |

We regret to report the death of J. H. Walshaw, A.M.E.I.C., which occurred on September 16th, 1936. We also regret the resignation of M. P. Bridgland, M.E.I.C., and E. F. Pullen, A.M.E.I.C., who have both been associated with the Calgary Branch for several years.

MEETINGS

During the year the Branch Executive committee held nine meetings for the purpose of conducting the business of the Branch. The various sub-committees held meetings as required for the carrying on of their work.

Twelve general and special meetings of the Branch were held during the year. Pertinent data of these meetings is shown by the following summary:—

1936

Jan. 16.—Branch General Meeting, T. Lees, M.E.I.C., on Steel Rails. Attendance 38.

Jan. 30.—Branch General Meeting, Mr. A. Calhoun, Librarian, Calgary Public Library, on The Engineer and Society. Attendance 29.

Feb. 13.—Branch General Meeting, Mr. R. J. Stringer, Branch Affiliate, on **Diesel Engines.** Attendance 38.

Feb. 27.—Branch General Meeting. The speaker was Mr. W. Pratt, District Manager, Otis-Fensom Elevator Co., Ltd., and films also were shown. Attendance 55.

Mar. 14.—Branch Annual Meeting, A. Griffin, A.M.E.I.C., spoke on the **Annual Meeting of The Institute**, Hamilton, February 5th, 6th and 7th, 1936. Attendance 31.

Mar. 21.—Joint Dinner with Association of Professional Engineers of Alberta and Rocky Mountain Branch Canadian Institute of Mining and Metallurgy. Total attendance 109.

June 11.—Branch Special Meeting, Mr. P. E. Biggar on **Diesel Engines.** Attendance 65.

Aug. 29.—Annual Golf Tournament held at Strathmore Golf Course. Attendance 30.

Sept. 25.—Branch Special Meeting, Dr. E. A. Cleveland, M.E.I.C., President of The Institute spoke on **Problems of The Institute.** Attendance 30.

Oct. 20.—Branch General Meeting, Mr. J. E. A. Macleod, K.C., gave a talk on **Early Western Travel and Travel Ways.** Attendance 34.

Nov. 5.—Branch General Meeting at which a number of films were shown. Attendance 126.

Nov. 27.—Annual Dance held at Renfrew Club. Attendance 60.

Dec. 8.—Branch General Meeting, Mr. C. A. Choate, instructor, Provincial Institute of Technology and Art, Calgary, spoke on **The Evolution of the Motor Car.** Attendance 28.

The average attendance at Branch General Meetings was 50.

### Supplementary Report Regarding Employment Conditions in Calgary Branch Territory

The situation regarding employment of engineers in this district has improved only slightly in the year 1936. This slight improvement is due to employment of engineers on government projects and to increased activity in the Turner Valley oil fields. Several members of this Branch, including experienced engineers as well as recent graduates, are unemployed and the present prospects do not indicate any material betterment of this condition in the immediate future.

### Financial Statement

*Revenue*

| | | |
|---|---|---|
| Rebates from membership fees:— | | |

## Cape Breton Branch

The President and Council:—

The Cape Breton Branch held four meetings during the year as under:—

1936

Feb. 18.—Annual Meeting and Banquet.

Mar. 3.—Talk by E. L. Ganter of Canadian General Electric Co., on **Development of Electricity in Canada and Applications of Electricity in the Home.** Illustrated.

Mar. 18.—Paper by R. S. Eadie, M.E.I.C., of Dominion Bridge Co., on **Steel-Concrete Composite Construction.** Illustrated.

Nov. 7.—Discussions by Vice-President H. W. McKiel, M.E.I.C., on **Consolidation of Engineering Organizations** and on **Engineering Education.**

The average attendance at these meetings was 32.

The financial statement is as below:—

*Receipts*

| | | |
|---|---|---|
| Brought forward | $219.84 | |
| Rebates from Headquarters | 102.30 | |
| Annual Meeting | 36.00 | |
| | | $358.14 |

*Expenditures*

| | | |
|---|---|---|
| Meetings | $126.79 | |
| Telegrams | 1.89 | |
| Wreath | 10.00 | |
| Secretarial expenses | 13.20 | |
| Balance on hand | 206.26 | |
| | | $358.14 |

Respectfully submitted,
Sydney C. Mifflen, M.E.I.C., *Secretary-Treasurer.*

## Edmonton Branch

The President and Council:—

On behalf of the Executive committee of the Edmonton Branch we wish to submit the following report for the year 1936:—

### Membership

Our present membership is as follows:—

| | *Resident* | *Non-Resident* | *Total* |
|---|---|---|---|
| Members | 18 | 2 | 20 |
| Associate Members | 25 | 6 | 31 |
| Juniors | 6 | 2 | 8 |
| Students | 28 | .. | 28 |
| | 77 | 10 | 87 |

This shows an increase of 14 members over the 1935 membership.

### Meetings

The Executive committee held four meetings during the year to transact the business of the Branch.

The Branch held six general meetings through the year. The following is a summary:—

1936

Feb. 4.—Dinner and Meeting at Macdonald hotel, addressed on **Treatment of Water** by Alex Ritchie, A.M.E.I.C., acting superintendent of City of Edmonton Power Plant.

Feb. 27.—Dinner and Meeting at Macdonald hotel, addressed by Julian Garrett, M.E.I.C., on **The Use of Temperature Statistics in the Gas Business.**

Mar. 25.—Dinner and Meeting at the University of Alberta. Election of officers for 1936-37 Session, and inspection of the Civil Engineering Laboratories and University Power Plant.

April 24.—Dinner and Meeting at the Corona hotel. This was the annual mixed meeting of the Branch when the members entertained their wives and friends. Mr. John Blue, Secretary, Edmonton Chamber of Commerce, gave an address on **The Odyssey of the North.**

Nov. 10.—Inspection of Canada Packers Plant, followed by dinner and meeting at Corona hotel, addressed by Mr. C. J. Long, plant superintendent, on **Processing and Equipment.**

Dec. 15.—Dinner, followed by debate, at Macdonald hotel, on **"Resolved that the Railways are a Moribund Form of Transportation."** R. J. Gibb, M.E.I.C., was leader for the affirmative, with R. W. Ross, A.M.E.I.C., leader for the negative.

## Halifax Branch

The President and Council:—

The year 1936 was a fairly active one in the Halifax Branch. For the first time in many years the Branch sent an official representative to the Annual Meeting of The Institute. H. S. Johnston, M.E.I.C., was the delegate and his report on the proceedings was circularized to all members of the Halifax and Sydney Branches, and as a result interest in Institute affairs was greatly stimulated in this territory.

The usual number of meetings were held as follows:—

1936

Jan.— The Annual Banquet in co-operation with the Nova Scotia Society of Professional Engineers was held at the Nova Scotian hotel and the attendance was greater than any previous banquet.

Feb.— The February meeting was addressed by Lt.-Col. J. B. Dunbar, A.M.E.I.C., A.A. and Q.M.G., Military District No. 6 Halifax, N.S., on **Some Road Construction Work in Connection with the Unemployment Relief Project at Valcartier Camp.** This paper was interesting as it dealt with the making of modern roads with primitive equipment as under the terms of the Unemployment Relief Project no machinery could be used on this work.

April.—In contrast with Col. Dunbar's paper was the one delivered by Mr. R. W. McColough, the chief engineer of the Department, of Highways, in April. Mr. McColough spoke on **The Rebuilding of the Main Trunk Highways in the Province of Nova Scotia,** describing the construction from beginning to end.

Sept.— In September, Dr. E. A. Clevcland, M.E.I.C., the President of The Institute, gave a very interesting speech dealing with the activities of The Institute.

Nov.— The November meeting was addressed by Professor G. Vibert Douglas, head of the Department of Geology at Dalhousie University, who spoke on **Geology with Respect to Metal Mining.**

The attendance and interest shown by members during the past year has shown a decided improvement and it is hoped that this will be further improved during the coming year.

During the year the Saint John Branch assisted in sponsoring a Maritime Professional Meeting at Saint John in August and the Halifax Branch was well represented, seventeen members of the Branch being present at the meeting.

EMPLOYMENT

There has been a definite improvement in employment of engineers in the province during the past year. While the work available may not be as remunerative as one would desire, still there was no reason for any trained engineer to be idle. The works programme of the Department of Highways and the development work undertaken by the power companies, especially the Nova Scotia Light and Power Co., and the increased activity of the Dominion Coal Co. absorbed all available engineers, and present indications show that there will be a scarcity of trained men during the coming year.

FINANCES

For the first time in a number of years the financial statement shows a deficit for the year's operation but there is still a substantial cash balance available. A copy of the financial statement follows:—

FINANCIAL STATEMENT

*Income*

| | | | |
|---|---|---|---|
| Rebates—January, 1936 | $ 36.42 | | |
| June, 1936 | 163.20 | | |

| Juniors | 11 | .. | 11 |
| Students | 30 | 6 | 36 |
| Affiliates | 2 | .. | 2 |
| Branch Affiliates | 16 | .. | 16 |
| | 129 | 22 | 151 |

Also 4 Members, 3 Associate Members, and 4 Students on the non-active list.

MEETINGS AND PAPERS

1936

Jan. 14.—Annual Business Meeting. Professional Meeting—**Air Conditioning** by J. W. Bishop of the Canadian General Electric Co. Local Chapter, Ontario Association of Architects were guests on this occasion. Attendance 100.

Mar. 26.—**Aircraft Development in Europe** by Professor T. R. Loudon, M.E.I.C., of Toronto University. Hamilton Aero Club invited to attend this meeting. Attendance 80.

April 3.—Joint Meeting with the Toronto Section, American Institute of Electrical Engineers, with the Canadian Westinghouse Co. as hosts. **Recent Electrical Developments in the Steel Industry** by R. H. Wright of the Westinghouse Electric and Manufacturing Co., Pittsburgh. Attendance 200.

May 15.—**Description of the Grand River Conservation Scheme** by E. T. Sterne of Brantford. Attendance 45.

Oct. 2.—**The Lumber Industry in British Columbia** by Archie Moore, manager, "B.C. Lumberman." Attendance 60.

Oct. 20.—**The Life and Inventions of James Watt** by Professor R. W. Angus, M.E.I.C., of Toronto University. Attendance 55.

Nov. 17.—**Heat Insulation Tests and their Value** by Professor E. A. Allcut, M.E.I.C., of Toronto University. Architects and builders' supply firms invited to hear this lecture. Attendance 80.

Dec. 8.—**Speech and Music and their Relation to Transmission Problems** by D. G. Geiger, A.M.E.I.C., of the Bell Telephone Co. of Canada, Toronto. Attendance 70.

W. J. W. Reid, A.M.E.I.C., chairman of the Meetings and Papers committee, has once again discharged his duties efficiently and acceptably and is to be congratulated on the speakers he has secured. The attendance at meetings is ample evidence of the interest aroused.

An appeal was made for Students and Juniors to submit papers for competition, but the response was so disappointing that it was decided to withdraw the contest for 1936.

With the exception of one meeting held in the Canadian Westinghouse Co. auditorium, all the meetings were held in the Chemistry Lecture Room at McMaster University and the Executive would, once again, place on record their indebtedness to the authorities of McMaster University for their kindness in extending to the Branch the privilege of meeting there.

INSTITUTE ANNUAL GENERAL AND PROFESSIONAL MEETING

Sponsored by the Hamilton Branch, the Annual Meeting of The Institute was held in the Royal Connaught hotel, February 5th, 6th and 7th, with a total registration of 335 men and 77 ladies. In addition to the usual business, professional and social functions, which were all well attended, February 5th saw three business sessions in connection with the work of The Institute Committee on Consolidation.

PUBLICITY

The Executive committee acknowledge the courtesies extended by the "Hamilton Spectator," particularly in connection with The Institute Annual Meeting.

OBITUARY

During the year, the Branch lost a very valued supporter in the passing of H. U. Hart, M.E.I.C., a Past-Chairman of the Branch. Mr. Hart devoted much time and energy to Branch affairs and as recently as The Institute Annual Meeting rendered outstanding service.

FINANCIAL STATEMENT

*Income*

ALEX. LOVE, M.E.I.C., *Secretary-Treasurer.*

## Kingston Branch

The President and Council:—

During the year 1935-1936 the Kingston Branch met six times as follows:—

1935

Oct. 31.—Annual Meeting, for the presentation of reports and election of officers.

Dec. 4.—J. L. Busfield, M.E.I.C., gave a talk on **The Development of the High Speed Diesel Engine with Special Reference to Automotive Work.** Nineteen were present at the meeting and seventeen at the preceding dinner. Mr. Busfield gave a very interesting discussion of the present stage of Diesel development, and illustrated his remarks with a number of excellent slides.

1936

Jan. 17.—Commander A. D. M. Curry, M.E.I.C., presented his paper entitled **From Sail to Steam in the Royal Navy.** Twenty-one were present at the dinner and meeting, and the paper was very much appreciated.

Jan. 30.—Professor J. K. Robertson, Queen's University, gave a lecture on **Some Modern Concepts of Physics.** The lecture, which was well illustrated, dealt with recent discoveries and theories as to the structure of the atom. Eighteen were present.

Feb. 27.—Professor L. T. Rutledge, M.E.I.C., presented a paper entitled **Film Lubrication.** A discussion of the principles of lubrication and the factors affecting it. Well illustrated with slides and with samples of lubricating oils. Dealt with the results of the most recent research. Eighteen present.

Sept. 29.—A dinner and general meeting of the Branch was held for the report of Dr. L. F. Goodwin, M.E.I.C., Branch Councillor, on the progress of the Committee on Consolidation, and to consider certain other business.

EMPLOYMENT

The Branch was able to assist one member in finding suitable employment during the past year.

CHAMBER OF COMMERCE

No meetings of the Chamber of Commerce have dealt with questions in which the Branch, as such, is concerned.

MEMBERSHIP

The membership for the past five years is given below:—

| | Honorary Members | Members | Associate Members | Juniors | Students |
|---|---|---|---|---|---|
| 1931-32 | 1 | 12 | 17 | 6 | 7 |

## Lakehead Branch

The President and Council:—

On behalf of the Executive committee of the Lakehead Branch we beg to submit the following report for the year 1936:—

During the year ten regular meetings and five Executive meetings were held. Of the regular meetings five were held in Port Arthur, four in Fort William and one at Kakabeka Falls.

The list of monthly meetings are as follows:—

1936

Jan. 22.—Dinner meeting at which R. F. Legget, A.M.E.I.C., gave an address on **Steel Piling.**

Feb. 18.—Meeting at the mill of The Provincial Paper Co. Dinner was held in the restaurant of the mill, and after a brief description of the plant the members were taken through the mill in small groups headed by members of the staff.

Mar. 18.—Dinner meeting. Illustrated lecture by Mr. J. M. Murie on **Electric Arc Welding.**

April 23.—Annual Meeting at which officers for the year were elected. The guest speaker was Mr. F. V. Siebert. Representatives of other professions were guests.

May 13.—Dinner meeting at which P. L. Pratley, M.E.I.C., gave an illustrated lecture on **The Isle D'Orleans Bridge.**

Sept. 16.—Dinner meeting at Kakabeka Falls at which Mr. W. L. Bird gave a short sketch of the history of the plant of the Kaministiquia Power Co., after which the members were conducted through the plant.

Sept. 23.—Meeting at which J. L. Rannie, M.E.I.C., gave an interesting lecture on **Geodetic Surveying.**

Oct. 21.—Dinner meeting at which Mr. Erle Smith gave a talk on roads in the district.

Nov. 18.—Dinner meeting devoted to business.

Dec. 10.—Dinner meeting at which members and guests heard an interesting lecture on building construction by W. H. Greene, A.M.E.I.C. Guests of the evening were lumber merchants, architects and those interested in the use of lumber.

### Employment of Engineers

Regarding employment at the Head of the Lakes we might say that we have been extremely fortunate.

As far as we know all the engineers of the Branch have been employed for the greater part of the year. Some of this work was only temporary but little difficulty was had in placing engineers. Several engineers were brought in from outside districts. Remuneration has not yet reached a satisfactory level.

This Branch had only one case in which financial aid was necessary. This was the case of an aged transient engineer who was provided for until work was obtained for him in the mining area.

## Lethbridge Branch

The President and Council:—

The following is a report of the operations of the Lethbridge Branch, Engineering Institute of Canada, for the year 1936.

Since January 1st, 1936, nine regular meetings with an average attendance of 44, two corporate members meetings, average attendance 12, and seven executive meetings, average attendance 7, were held.

The Entertainment committee have worked very hard and as a result the social side of our programmes have been excellent. All regular meetings have been held in the Marquis hotel, preceded by a dinner during which numbers were rendered by Geo. Brown's instrumental quartette, followed by vocal solos and community singing.

The list of speakers and subjects chosen follows:—

1936

Jan. 25.—Motion picture films. **Building the 8000 Locomotive,** Mr. E. J. Lemieux, division master mechanic, Canadian Pacific Railway, Lethbridge. Attendance 40.

Feb. 8.—Thomas Lees, M.E.I.C., District Engineer, Canadian Pacific Railway, Calgary, on **Some Observations of Railway Rails.** Attendance 28.

Mar. 7.—Joint meeting of the Lethbridge Branch, Engineering Institute of Canada, with the Professional Engineers of Alberta. Attendance 45.

Mar. 14.—Motion pictures and lantern slides. Speaker: P. F. Peele, A.M.E.I.C., Canadian General Electric Co., Calgary who talked on **Electron Tubes.** Attendance 30.

Sept. 25.—Dr. E. A. Cleveland, M.E.I.C., President of The Engineering Institute of Canada, on **Institute Affairs.** Attendance 25.

Oct. 10.—Air Commodore H. Hollick-Kenyon who gave an address on **The Ellsworth Antarctic Expedition.** Ladies as guests. Attendance 53.

Oct. 17.—Inspection trip to Lethbridge Collieries Ltd. Galt Mine No. 8. Wm. Meldrum, A.M.E.I.C., mines engineer, Lethbridge Collieries Ltd., Lethbridge, who spoke on **Galt Mines Fourth Venture.**
Mr. E. J. Carlyle, General Secretary, Institute of Mining and Metallurgy, Montreal, on **One Troy Ounce of Gold.** Attendance 32.

Nov. 21.—Inspection trip to the Canadian Sugar Factories Ltd. plant at Picture Butte. Mr. F. H. Ballou, chief engineer, Canadian Sugar Factories Ltd., on **The Manufacture of Beet Sugar.** Attendance 90.

Dec. 5.—Ladies Night, Musical Programme, Bridge. Major F. G. Cross, M.E.I.C., Superintendent Operation and Maintenance, C.P.R., D.N.R., Lethbridge, who spoke on **The Artist and the Engineer.** Attendance 52.

The annual meeting of the Branch was held on March 14th, 1936, the officers being elected for the 1936-1937 season.

At December 31st, 1936, the membership of the Branch stood as follows:—

| | *Resident* | *Non-Resident* | *Total* |
|---|---|---|---|
| Members | 4 | .. | 4 |
| Associate Members | 15 | 7 | 22 |
| Juniors | .. | 5 | 5 |
| Students | 4 | 5 | 9 |
| Affiliates | 27 | .. | 27 |
| | 50 | 17 | 67 |

There is no unemployment among the members of the Lethbridg Branch, Engineering Institute of Canada, according to data obtaine from the local Committee on Unemployment.

*Liabilities*

Nil.

We have examined the books, papers, vouchers and the foregoing statement prepared by the Secretary-Treasurer and find the same to be a true and correct account of the standing of the Branch.

C. S. Donaldson, A.M.E.I.C. }
G. S. Brown, A.M.E.I.C. } Auditors.

Respectfully submitted,

E. A. Lawrence, S.E.I.C., *Secretary-Treasurer.*

## London Branch

The President and Council:—

During the year 1936 the following meetings were held:—

1936

Jan. 29.—Annual Meeting with Capt. T. F. Williams, instructor at the London Flying Club, as guest speaker. Attendance 26.

Feb. 20.—Illustrated lecture by R. C. Manning, engineer of the Canadian Institute of Steel Construction, on **Steel Industry in Canada.** Attendance 21.

Mar. 26.—Talk by J. S. Milligan on **The New Canadian Home,** illustrated by slides showing new type of house construction introduced by Pigott Construction Co. of Hamilton. Attendance 66.

April 22.—Social evening at home of Councillor J. A. Vance, A.M.E.I.C., of Woodstock; speaker, W. G. Ure on **Calendar Reform.** Attendance 25.

May 28.—Address by E. C. Neville, Bridge and Building Master, C.N. Railways, on **Underwater Inspection of Bridge Structures.** Attendance 16.

July 25.—Tour of inspection through New Dominion Public Building, London, and J. Labatt's Brewery. Attendance 40.

Sept. 19.—Tour of inspection through Kellogg Co. plant, London. Attendance 35.

Sept. 22.—Dinner Meeting to meet J. F. Plow, A.M.E.I.C., of the Headquarters Staff of The Institute. Attendance 13.

Oct. 3.—Tour of inspection through Silverwood's Ltd. plant, London. Attendance 14.

Oct. 20.—Lecture by W. O. LeBere of C.N. Railways on **Safety in the Erection of Steel.** Attendance 15.

Nov. 25.—Talk by Councillor J. A. Vance on points raised and discussed at Plenary Meeting in Montreal. Attendance 10

Average attendance of all meetings 25.

In addition to above, five Executive meetings were held with an average attendance of 6.6.

Financial Statement

*Receipts*

| Rebates due from Headquarters for October to December, 1936 | 3.90 | |
| | | $281.60 |

Respectfully submitted,

James Ferguson, A.M.E.I.C., *Chairman.*

D. Stuart Scrymgeour, A.M.E.I.C., *Secretary-Treasurer.*

## Moncton Branch

The President and Council:—

On behalf of the Executive committee we beg to submit the seventeenth annual report of Moncton Branch.

The Executive committee held seven meetings. Six meetings of the Branch were held, at which addresses were given and business transacted as follows:—

1936

Feb. 28.—A meeting was held in the City Hall. Professor H. W. McKiel, M.E.I.C., delivered an illustrated address on **Domestic Air Conditioning.**

Mar. 13.—A meeting was held in the City Hall. R. S. Eadie, A.M.E.I.C., of Dominion Bridge Company, Montreal, gave an illustrated address on **Steel-Concrete Composite Construction.**

Mar. 20.—A meeting was held in the City Hall. Dr. H. E. Bigelow, Professor of Chemistry, Mount Allison University, read a paper on **National Problems for Research in Canada.**

May 8.—A meeting was held for the purpose of nominating Branch officers for 1936-37.

May 29.—The annual meeting of the Branch was held on this date.

Aug. 31.—A luncheon meeting was held at the Riverdale Golf Club. Dr. E. A. Cleveland, M.E.I.C., President of The Engineering Institute of Canada, addressed the meeting on **Institute Affairs.**

Membership

Our membership at present consists of sixty members, as follows:—

| | *Resident* | *Non-Resident* |
|---|---|---|
| Members | 5 | 1 |
| Associate Members | 19 | 7 |
| Juniors | 3 | 2 |
| Students | 6 | 9 |
| Affiliates | 8 | .. |
| | 41 | 19 |

Financial Statement

*Receipts*

| | | |
|---|---|---|
| Balance in bank, January 1st, 1936 | $111.02 | |
| Cash on hand, January 1st, 1936 | 6.22 | |
| Rebates on dues | 78.90 | |
| Affiliate dues | 35.00 | |
| Tickets sold for luncheon meeting | 9.00 | |
| Bank interest | .85 | |
| Rebates due from Headquarters | 6.00 | |
| | | $246.99 |

*Expenditures*

| | | |

| Honorarium to Secretary | 25.00 | |
| Miscellaneous | 31.35 | |
| Balance in bank | 134.27 | |
| Cash on hand | 1.85 | |
| Rebates due from Headquarters | 6.00 | |
| | | $246.99 |

*Assets*

| | | |
|---|---|---|
| Balloptican lantern | $ 30.00 | |
| Motion picture equipment | 85.00 | |
| Attache case | 5.00 | |
| Unpaid Affiliate dues | 5.00 | |
| Cash in bank | 134.27 | |
| Cash on hand | 1.85 | |
| Rebates due from Headquarters | 6.00 | |
| | | $267.12 |

*Liabilities*

None.

Audited and found correct,
James Pullar, A.M.E.I.C. }
R. H. Emmerson, A.M.E.I.C. } Auditors.

Respectfully submitted,

G. L. Dickson, A.M.E.I.C., *Chairman.*

V. C. Blackett, A.M.E.I.C., *Secretary-Treasurer.*

## Montreal Branch

On behalf of the Executive Committee we have the honour to submit the annual report for the year 1936, the nineteenth session.

The Executive Committee consists of the following members:—

Officers

Chairman .......... J. B. D'Aeth, M.E.I.C.
Vice-Chairman .......... H. Massue, A.M.E.I.C.
Secretary-Treasurer .......... C. K. McLeod, A.M.E.I.C.

Committee

Past Chairman .......... F. S. B. Heward, A.M.E.I.C.

*Elected Members of Committee*

| | |
|---|---|
| R. H. Findlay, M.E.I.C. | J. A. E. Gohier, M.E.I.C. |
| J. A. Lalonde, A.M.E.I.C. | C. C. Lindsay, A.M.E.I.C. |
| B. R. Perry, M.E.I.C. | T. C. Thompson, A.M.E.I.C. |

*Ex-Officio Members of the Committee*

| | |
|---|---|
| O. O. Lefebvre, M.E.I.C. | A. Cousineau, A.M.E.I.C. |
| F. P. Shearwood, M.E.I.C. | A. Frigon, M.E.I.C. |
| C. B. Brown, M.E.I.C. | F. Newell, M.E.I.C. |
| E. A. Ryan, M.E.I.C. | P. L. Pratley, M.E.I.C. |

Officers of Committees

| *Committee* | *Chairman* | *Vice-Chairman* |
|---|---|---|
| Papers and Meetings | B. R. Perry, M.E.I.C. | K. O. Whyte, A.M.E.I.C. |
| Membership | T. C. Thompson, A.M.E.I.C. | |
| Admission | C. C. Lindsay, A.M.E.I.C. | E. Gohier, M.E.I.C. |
| Reception and Entertainment | R. H. Findlay, M.E.I.C. | |
| Nomination | J. A. Lalonde, A.M.E.I.C. | |
| Publicity | J. M. Fairbairn, A.M.E.I.C. | |
| Unemployment | J. A. McCrory, M.E.I.C. | E. A. Ryan, M.E.I.C. |
| Town Planning | Leonard Schlemm, M.E.I.C. | J. A. Lalonde, A.M.E.I.C. |
| Finance | J. B. D'Aeth, M.E.I.C. | C. K. McLeod, A.M.E.I.C. |

### Membership Committee

During the year the Membership Committee has done valuable work in listing the Members of the branch according to various fields of Engineering in which they are engaged, also, a list has been made showing the non-active Members, and another of persons removed from membership. These lists, we believe, will be of great value to future Membership Committees.

A committee consisting of eight members under the leadership of the Chairman are endeavouring to again interest many of the ex-members and qualified Engineers to join The Institute. The practical result of their labours is indicated by the membership roll which follows:

| *Montreal Branch Active List* | *Number* | *Increase or Decrease over 1935* |
|---|---|---|
| Honorary Members | 1 | 0 |
| Members | 216 | − 5 |
| Associate Members | 498 | +12 |
| Juniors | 66 | −15 |
| Students | 258 | +52 |
| Affiliates | 15 | − 1 |
| | 1,054 | +43 |
| *Montreal Branch District Active List* | | |
| Members | 4 | −4 |
| Associate Members | 34 | +1 |
| Juniors | 7 | −4 |
| Students | 8 | −5 |
| | 53 | −12 |
| *Non-Active List* | | |
| Members | 3 | −2 |
| Associate Members | 48 | −6 |
| Juniors | 14 | −3 |
| Students | 8 | 0 |
| Affiliates | 1 | 0 |
| | 74 | −11 |

*Summary*

| | |
|---|---|
| Total Active Members | 1,107 |
| Total Non-Aetive | 74 |
| Total Membership | 1,181 |

Increase over 1935 = 20

### Members Deceased

The Committee deeply regrets to record the loss by death of the following members:

*Members:*

George Douglas MacKinnon
Robert Alexander Ross (Past President E.I.C.)
Frederick Thomson
Abbott True
F. Stuart Williamson.
Max Zuercher

*Associate Members:*

Aurelien Boyer
Jos. Labelle.
George Reakes
Frank Clinton White

*Junior:*

J. A. E. Larrivee.

### Applications

The Committee on applications dealt with a total of 43 applications for membership of which the following is a summary:

| | |
|---|---|
| Applications for admission: | |
| Member | 1 |
| Associate Members | 7 |
| Juniors | 4 |
| Branch Affiliates | 1 |
| Institute Affiliates | 1 |
| Total | 14 |
| Transfers: | |
| To Member | Nil |
| To Associate Member | 25 |
| To Junior | 4 |
| Total | 29 |

In addition to the above there were 85 Students admitted to The Institute but their applications do not pass through the Executive Committee.

### Town Planning

During the earlier part of the year there was considerable discussion regarding the necessity for improving the traffic conditions leading into Montreal, from the ends of the Island. Your executive felt that there was real need for this improvement, and accordingly passed a resolution which was sent to the Federal Government, Provincial Government, City of Montreal and various civic associations recommending that means be taken to alleviate the present congested traffic conditions.

Care had to be taken in drawing up this resolution, so as not to become involved in the political aspect of the situation, and for this reason, we refrained from mentioning any particular route.

### Reception and Entertainment Committee

This committee has sponsored all the entertainment undertaken by the Branch.

On February 11tb, an impromptu luncheon was given for the newly elected President of The Institute, E. A. Cleveland, M.E.I.C. Colonel H. F. G. Letson, M.E.I.C., President of the Association of Professional Engineers of British Columbia, and E. A. Wheatley, M.E.I.C., Registrar and Secretary Treasurer of the Association of Professional Engineers of British Columbia, were also present. As it was only known the day before of the intended visit, it was impossible to issue a general luncheon notice; however, sixty members were in attendance.

An interesting series of movie films were provided for the Branch Annual Meeting on January 9th.

To wind up the spring session a smoker was held at the Windsor Hall on April 24th. The occasion was greatly enjoyed by the three hundred or more guests and members present.

To open the fall session your committee had arranged for an evening's entertainment on one of the C.P.R. boats. Unfortunately, at the last minute the C.P.R. found it necessary to cancel these arrangements.

In view of the request for a smoking concert at the Annual Meeting of The Institute on January 29th, plans for another social event for this fall were abandoned.

The committee have always had members present at meetings of the branch for the purpose of welcoming and introducing new members, etc. They have also greatly helped the Secretary in regard to the complimentary dinners to out of town speakers.

### Papers and Meetings Committee

The report of the Chairman of the Papers and Meetings Committee is as follows:—

"The personnel of the Committee was appointed by the Executive Committees. The list of these members is given below. In addition to these members the Mechanical and Electrical Sections had the co-operation of several other Branch members who did not participate in the Committee meetings except R. C. Flitton, A.M.E.I.C., who rendered considerable assistance and attended several meetings.

"The programme of meetings for the fall and spring sessions was submitted to the Executive Committee and approved by them; these schedules are also listed below.

"Other arrangements of a general character which involved this Committee such as courtesy dinners for out-of-town speakers, invitations to sister societies to attend our meetings, etc., have been carried out as in the past.

"Early in the year it was recommended by the members of the Junior Section that it seemed inadvisable to continue the past practice of devoting two Thursday evenings in the year to Junior Nights. This recommendation was submitted to the Executive and approved. Since this time the members of the Junior Section took little part in the proceedings of the Committee and it is probable that this section need not be formally represented on the Papers Committee.

"Your Committee spent considerable time in trying to determine the proper method of approach to a programme of meetings such as ours and were strongly of the opinion that our general scheme of papers and meetings is far from ideal and is probably basically wrong. This discussion was carried on primarily to arrange our own work and a recommendation was presented to the Executive Committee early in the year. The most obvious evidence pertaining to this question is the formation of so many branch technical societies in the City all of wbicb overlap on the functions presumably taken care of in the E.I.C. If the E.I.C. cannot provide all of the technical information and the associations desired by every member or prospective member, then strenuous efforts should be made to arrange for close co-operation for mutual benefit. The alternative will tend to disintegration to some extent. In any event a close study of the whole subject would at least give the Branch valuable information as to our own condition of health.

"Further to this discussion it was the opinion of the majority of your Committee that the continuance of 'Special Technical Meetings' was not particularly desirable. In this sense, what is a technical paper? What part should any non-technical paper play in our programme? (except, of course, in a few instances). The attendance at our meetings is the accepted criterion of the success of the paper and the tendency has been that authors have through instructions or inference been somewhat general in the treatment of their papers in order to be attractive to as many of our miscellaneous membership as possible. As a result many members who should be most interested in a subject are not enthusiastic because the paper is general where it should be specific and technical, and those who could benefit most by contact with the speaker, who is presumably an expert in his subject, do not have the proper opportunity to make use of his visit or of his paper. The above applies especially to out-of-town speakers.

"It is also the opinion of several of your Committee members, although not a recommendation of the Committee as a whole, that the sections should be made much larger and should carry on as separate units, and probably to arrange for many more meetings than one per week. While the recommendation of a Sectional Committee is usually acceded to, nevertheless the Committee as a whole makes the final choice and inherently is therefore influenced by the general appeal of the subject to our miscellaneous membership. The Committee, as at present constituted, has the right to increase its numbers but it is extremely doubtful if this can be effective unless the arrangement is definitely established by the Executive.

"Your Committee is of the opinion that the present method of arranging for publication of papers and articles is not satisfactory. This matter is not a function of either the Papers Committee or of the Montreal Branch and yet both are involved in the existing set up. The Papers Committee is constantly reminded (and rightly so) to keep the requirements of the Journal in mind. On the other hand there is no consideration given to the arrangements that the Papers Committee must make, and the individuals who conclude all arrangements with the authors can make no statement whatever regarding the publication of a paper, which by the general ethics, if not by law, becomes the exclusive property of The Institute; this member cannot even say that his opinion or the opinion of the Committee will be sought or considered. The feature that your Committee feels to be unattractive is the hesitant and negative position of this contacting member in discussing with the author this matter of publication which must come up in practically all cases; not primarily because the author desires publicity but because it involves the way in which he will prepare his paper. There are other features that must be kept in mind. The Journal is the only technical publication of The Institute. Many papers are not suitable for publication, but there are many subjects that should be made available for publication that are not suitable for presentation as papers because they are narrowly technical or because they are too short to occupy a full meeting. Similar American Societies have many subjects that are published without having been presented at a meeting. There is no thought on the part of the Committee that future Committee Members should be given the right to commit The Institute to publish any article or to determine in any way the commercial procedure of the Journal which is probably the best technical magazine in Canada. But in so far as this same magazine is the only technical publication of a technical society, they recommend that consideration be given to some procedure for the guidance of those arranging for papers that will be somewhat similar to the procedure in similar societies. In connection with this matter of publication in either magazine or transactions it may be pointed out that the idea of making a paper general or popular as discussed previously renders it unattractive for publication.

"Your Committee recommends also that some definite system of continuity in the Committee membership be established that will enable the Committee in one year to conclude arrangements for papers which may have to be given in the succeeding year. They have found in three or four cases that particularly attractive papers have not been available because of the element of time; in some cases re-opening the subject in the future will not necessarily improve the point. There is at present a tacit arrangement by which a part of the Committee representation does continue, but because it is only tacit it increases rather than diminishes the reticence of one group in making commitments which will involve the freedom of choice of their successors. If half of each Committee were definitely appointed for two years there would be no such embarrassment. It is felt that the approach to an author is more representative of the desires and prestige of the E.I.C. when it is carried to a definite conclusion even if there is to be some considerable delay in the actual presentation.

"The above suggestions are made in the hope that they are constructive and it is realized that they involve functions which are not entirely the allotted work of the Papers and Meetings Committee.

"Your Committee is appreciative of the assistance given them by several members and particularly that of our Branch Secretary. With the exception of one section, the members appointed to the Committee carried out their duties sincerely and whole-heartedly and attended the many Committee meetings very faithfully."

1936 PROGRAMME OF MEETINGS

Oct. 8.—**Air Conditioning**, D. W. McLenegan.
Oct. 15.—**The Induction Motor of To-day**, E. W. Henderson.
Oct. 22.—**The 200-inch Diameter Telescope Disc**, Dr. A. O. Gage.
Oct. 29.—**Diesel Locomotives**, R. Tom Sawyer.
Nov. 5.—**Depreciation of Industrial Plants in Valuation Studies**, Herbert H. Cantwell, A.M.E.I.C.
Nov. 12.—**Fan Design and Calibration**, H. F. Hagen.
Nov. 19.—**Acoustic Networks in Radio Receivers**, Hugh S. Knowles.
Nov. 26.—**Observations of European Railroad Motive Power**, A. I. Lipetz.
Dec. 3.—**Recent Advances in Electric Welding**, H. Thomasson.
Dec. 10.—**Town Planning in Montreal**, H. A. Terreault.

1937

Jan. 14.—**Petroleum Products and the Automobile**, R. S. Weir, A.M.E.I.C.
**Gasoline for To-day's Automobile**, Gordon Connor.
Jan. 21.—**Modern Trends in Illumination**, A. L. Powell.
Jan. 29.—, Jan. 30.— Annual General Meeting.
Feb. 4.—**Recent Developments in Steam Heating**, H. F. Marshal.
Feb. 11.—**Some Phase of Radio Research**, W. Wilson.
Feb. 18.—**Modern Highway Construction**, Hon. F. J. Leduc.
Feb. 25.—**Non Ferrous Alloys**, H. J. Roast, M.E.I.C.
Mar. 4.—**Schorer Method of Analysis applied to Pipe Line Design**, A. W. F. McQueen, A.M.E.I.C., and E. M. C. Molke, A.M.E.I.C.
Mar. 11.—**Telemetering**, Perry Borden.
Mar. 18.—**Flash Butt Welding of Rails**, H. G. Drake.
Mar. 25.—**Construction of the Bridge at St. Anne de la Parade**, P. G. A. Brault, A.M.E.I.C.
April 1.—**Negative Regeneration in Communication Circuits**, C. B. Fisher, S.E.I.C.
April 8.—**Ocean Soundings by Sound Wave Reflection**, Dr. L. V. King.
April 15.—**Ship Design**, H. H. German.
April 22.—**Indeterminate Roof Trusses**, E. R. Jacobsen, S.E.I.C.
April 29.—**The Problem of Economic Stability** (As seen by an Engineer), P. A. Akerman.

PAPERS AND MEETINGS COMMITTEE

*Chairman* Brian R. Perry, M.E.I.C.
*Vice-Chairman* K. O. Whyte, A.M.E.I.C.

| | | |
|---|---|---|
| Mechanical Section.... | Kenneth G. Cameron, A.M.E.I.C. | *Chairman* |
| | R. A. Gurnham, A.M.E.I.C. | *Vice-Chairman.* |
| Electrical Section...... | D. A. Ross, A.M.E.I.C. | *Chairman* |
| | I. S. Patterson, Jr.E.I.C. | *Vice-Chairman.* |
| Civil Section.......... | Allen Bone, A.M.E.I.C. | *Chairman* |
| | R. E. Heartz, M.E.I.C. | *Vice-Chairman.* |
| Railway Section....... | G. G. Ommanney, M.E.I.C. | *Chairman* |
| | W. F. Drysdale, M.E.I.C. | *Vice-Chairman.* |
| Junior Section......... | L. A. Duchastel, Jr.E.I.C. | *Chairman* |
| | C. E. Frost, A.M.E.I.C. | *Vice-Chairman.* |
| Municipal Section..... | P. G. Delgado, A.M.E.I.C. | *Chairman* |
| | Eugene Roy, A.M.E.I.C. | *Vice-Chairman.* |
| Radio Section......... | S. T. Fisher, Jr.E.I.C. | *Chairman* |
| | D. J. McDonald, Jr.E.I.C. | *Vice-Chairman.* |

JUNIOR SECTION

*Special Committee*

Following a discussion on the "Engineer's Place in Industry" a Special Committee was formed under the Chairmanship of Mr. E. R. Smallhorn to investigate new fields of work. The object being to further the employment of engineers in industrial plants.

*University Students*

This year a special effort has been put forward in an endeavour to interest the students of L'Ecole Polytechnique to join The Institute. The Chairman, Léon A. Duchastel, Jr.E.I.C., addressed the students and pointed out the advantages to be derived by attending the meetings and becoming a Student Member. Considerable encouragement was given by the Dean, Dr. A. Mailhiot, M.E.I.C., in his introductory remarks.

At McGill a steady effort is being made to induce the students to join.

The following figures show the Student Members from Montreal admitted to The Institute.

| *Year* | *1934* | *1935* | *1936* |
|---|---|---|---|
| Ecole Polytechnique.......... | 11 | 10 | 43 |
| McGill University............ | 28 | 41 | 42 |
| Totals.............. | 39 | 51 | 85 |

*Papers and Meetings*

During the past year twelve regular meetings were held, at which fifteen papers either in French or English were read. The average attendance at the meetings was forty-nine, which is an increase over last year of eleven percent.

The papers are usually well delivered, interesting, of a high standard and bring out considerable discussion. It is felt that this section is filling a long needed want for the young engineer.

A list of the meetings and papers follows:

1936

Jan. 20.—Annual Meeting. Talk by J. B. D'Aeth, M.E.I.C., Chairman Montreal Branch.

Feb. 6.—Junior Section Night, Montreal.
**La Détermination des Cœfficients de Débit des Barrages Déversoirs à L'Aide de Modèles Réduits** by Raymond Boucher, Jr.E.I.C.
**Economical Quantity Inventory Control** by R. F. Brosseau.

Feb. 17.—**Various Types of Anti-Friction Bearings** by H. Little, S.E.I.C.
**Petroleum Products with Particular Reference to their Use in Modern Automobiles** by R. S. Weir, A.M.E.I.C.

Mar. 2.—Discussion on the recent trend towards employing engineers in connection with plant operation, supervision and maintenance and the possibility of increasing the demand for this type of engineering service. Leaders of the discussion were: R. J. Durley, M.E.I.C., on "Experience of The Institute and Employment Service," Dean Ernest Brown, M.E.I.C., on "The University Viewpoint," J. B. D'Aeth, M.E.I.C., on "Viewpoint of Engineers Generally," and Mr. T. Moran, on "Comments on Actual Experience in Employment of Engineers in a Manufacturing Plant," followed by a general discussion.

Mar. 23.—**Shop Procedure with Relation to Distortion Control** by Gordon Cape.

April 6.—**Home Air Conditioning** by Leo Roy, S.E.I.C.

April 20.—**The So-Called Problem of Public Speaking** by J. Alex Edmison.

Fall Session

Oct. 21.—Opening Meeting. Remarks by the Chairman, L. A. Duchastel, Jr.E.I.C., and E. R. Smallhorn, A.M.E.I.C.
**Incorporating your Business** by W. H. Laidley, B.C.L.

Nov. 2.—**The Interdependence of Architecture and Engineering** by Sidney S. Bunting, B. Arch., M.R.A.I.C.

Nov. 16.—**Le Haut-Fourneau Electrique** by C. Herbert, S.E.I.C.
**Development of Radio Communication in the Bush** by Mr. D. R. Taylor.

Nov. 30.—**Patents—their Value and How they are Obtained,** by Alan Swabey.
**Design and Manufacture of Aircraft** by V. S. Upton, S.E.I.C.

Dec. 14.—**Steel Rails** by Hugh J. Gordon, S.E.I.C.
**The Manufacture of Insulators** by V. F. Crowley.
Moving pictures on **Long Distance Communications** kindly supplied by the Bell Telephone Co. of Canada.

### Unemployment

With the advent of better times it was felt that there was no longer any need to call for further contributions and that the most pressing cases had been taken care of.

From the balance of $98.44 left over from last year we continued to distribute to those in most urgent need. There is a balance remaining of $12.87 which the Executive Committee decided had best be placed to the credit of the General Branch Account.

### Publicity

The Committee on Publicity has succeeded quite satisfactorily in maintaining the interest of the public through the press. The press have consistently given us advance notice of meetings and in the majority of cases given a good condensed account of the papers presented.

### Sister Societies

Among other things we have had to consider during the year is the formation of other technical society branches in Montreal and their effect on The Institute.

Perhaps as an outstanding example of these the "Montreal Branch of the Institution of Radio Engineers" might be mentioned.

This body has been recently formed and a committee of your Executive has met with some of their officers both here and in New York. The purpose of these meetings was to offer our co-operation and see if these two bodies could not be brought closer together.

As an immediate result of these conferences joint technical meetings will probably be held and it is hoped that the two bodies will eventually work closely together.

Similar conditions exist with regard to other bodies.

### Financial Statement

### Executive Committee Meetings

During the past year the executive committee have held 10 meetings with an average attendance of 12 members per meeting.

Your secretary, after twelve years of service, finds that due to pressure of business he is unable to carry on, and has asked to be relieved of his duties.

In presenting this report your committee desires to acknowledge the assistance from members during the year, and trusts that the activities undertaken by your executive have been such as to meet with your approval.

Respectfully submitted,

J. B. D'Aeth, M.E.I.C., *Chairman.*
C. K. McLeod, A.M.E.I.C., *Secretary-Treasurer.*

## Niagara Peninsula Branch

The President and Council:—

The Executive committee of the Niagara Peninsula Branch presents herein the report for the year 1936.

The Executive held 5 regular meetings and one electoral meeting with an average attendance of eleven.

The Branch meetings are listed as follows:—

1936

Jan. 15.—Dinner meeting, Hotel Leonard, St. Catharines. Mr. J. W. Bishop, Canadian General Electric Co., on **Air Conditioning.**

Feb. 3.—Special meeting held at Council Chambers, Thorold, to discuss the report of the Committee on Consolidation and appoint delegates to the Annual Meeting.

Feb. 24.—Dinner meeting, King Edward hotel, Niagara Falls. Dr. T. Kennard Thomson, New York City, on **Some Problems of a Consulting Engineer.**

Mar. 25.—Meeting scheduled cancelled on account of weather conditions.

April 15.—Dinner meeting, Welland House, St. Catharines. Mr. C. A. Cline, Hamilton, Ont., on **Proposed Establishment of a "Free Port Area" within the Niagara Peninsula.**

May 7.—Annual Meeting, Hotel General Brock, Niagara Falls. Professor T. R. Loudon, M.E.I.C., University of Toronto, on **Aircraft Development in Europe.**

Sept. 11.—Inspection trip to the Guarantee Dye and Silk Co. plant, St. Catharines, followed by a dinner meeting at the Welland House. Mr. G. R. Wyer, Canadian Fairbanks Morse, gave a talk on **Recent Developments in Diesel Engines.**

Oct. 14.—Dinner meeting, Foxhead Inn, Niagara Falls. Mr. G. C. Grubb, Canadian Industries Ltd., Montreal, on **Uses of Explosives.**

Nov. 18.—Dinner meeting, Hotel Leonard, St. Catharines. R. A. Crysler, A.M.E.I.C., Canada Cement Co., on **Development of Cement and Concrete.**

Dec. 16.—Dinner meeting, Foxhead Inn, Niagara Falls. Mr. J. W. Bateman, Canadian General Electric Co., on **A New Viewpoint in Lighting.** Members of the A.I.E.E. joined in this meeting.

## Ottawa Branch

The President and Council:—

On behalf of the Managing committee of the Ottawa Branch we beg to submit the following report for the calendar year 1936.

During the year the Managing committee held eleven meetings for the transaction of general business. In addition the Branch held eighteen meetings. These meetings were well attended and excellent addresses were enjoyed at the Branch meetings.

It is with deep regret that we report the loss through death of one of our members—Mr. W. T. Cuffe-Quinn, Branch Affiliate.

As in previous years the Branch donated two sets of draughting instruments to the Ottawa Technical School for presentation as prizes for proficiency in draughting. A copy of "Standard Handbook for Electrical Engineers" was presented to the Hull Technical School to be awarded to one of its students.

PROCEEDINGS AND PUBLICITY

During the year eighteen luncheon meetings were held. The dates of the meetings and speakers are as follows:—

1936

Jan. 23.—Dr. T. E. Warren, **The Hydrogenation of Coal.** Attendance 81.

Feb. 13.—Dr. C. D. Niven, **The Insulation of Houses and Allied Problems.** Attendance 129.

Feb. 27.—Dr. D. de Waal Meyer, **Communications in South Africa.** Attendance 88.

Mar. 12.—Dr. E. S. Archibald, **Soil Drifting.** Attendance 87.

Mar. 26.—Norman Jaques, M.P., **Social Credit as it relates to the Engineering Profession.** Attendance 81.

April 2.—F. W. Bridges, **Fifty Years of Ship-building—A Retrospect.** Attendance 82.

April 16.—Sir Francis Floud, **Housing in Great Britain.** Attendance 108.

April 30.—Lt.-Col. E. L. M. Burns, **New Air Survey Methods.** Attendance 112.

May 14.—R. F. Leggett, A.M.E.I.C., **Steel Piling.** Attendance 58.

May 28.—R. C. Manning, **Steel Construction.** Attendance 99.

Aug. 20.—B. J. Meighan, **Civil Engineering and Contracting in Great Britain.** Attendance 74.

Sept. 4.—Dr. F. C. Breckenridge, **Trends in Aviation Lighting.** Attendance 70.

Sept. 16.—Dr. E. A. Cleveland, M.E.I.C., President of The Engineering Institute of Canada, **Institute Affairs.** Attendance 76.

Oct. 22.—Dr. G. C. Laurence, **Radium, its Production and Use.** Attendance 80.

Nov. 5.—J. F. Harkom, A.M.E.I.C., **Preservative Treatment of Structural Timbers.** Attendance 65.

Nov. 19.—M. F. Goudge, **The Construction of the Vimy Memorial.** Attendance 95.

Dec. 3.—F. D. Laurie, **Changing Over to the Dial System.** Attendance 106.

Dec. 17.—Dr. J. M. Swaine, **The Greatest Menace to Canadian Forests.** Attendance 70.

MEMBERSHIP

With several adjustments during the year the membership roll now shows a decrease of 5 during the year.

The following table shows in detail the comparative figures for the years 1935 and 1936:—

| | *1935* | *1936* |
|---|---|---|
| Honorary Members | 1 | 2 |
| Members | 83 | 82 |
| Associate Members | 170 | 170 |
| Affiliates of Institute | 3 | 3 |
| Juniors | 14 | 17 |
| Students | 32 | 30 |
| Branch Affiliates | 31 | 28 |
| Resident Members | 334 | 332 |
| District Members | 74 | 70 |
| Total | 408 | 402 |

FINANCES

The attached financial statements show that the Branch had an excess of $27.40 in expenditures over revenue at the end of the year. The year closed with a balance of $648.94 in the bank, $10.13 cash on hand, and $1,000 in Government Bonds. In addition the Branch had assets of $26.60 in rebates due from the Main Institute, $33.15 due from the Proceedings committee, and $21.00 in equipment, etc.

AERONAUTICAL SECTION

Seven evening meetings were held, when technical papers dealing with aeronautical or related subjects were read and discussions held. The average attendance was 28, an increase of 10 over the previous year.

OFFICERS FOR 1937

The annual meeting of the Branch will be held on the 14th of January when the officers and members of the Managing committee for 1937 will be elected.

FINANCIAL STATEMENT

*Receipts*

### Aeronautical Section

OFFICERS

The officers for the year were:—

*Chairman.*—Dr. J. J. Green
Wind Tunnel,
National Research Council,
Ottawa, Ontario.

*Secretary*—J. T. Dyment, S.E.I.C.,
Assistant Engineer,
Aeronautical Engineering Division,
Department of National Defence,
Ottawa, Ontario.

PROCEEDINGS

The following technical papers were given at evening meetings of the Aeronautical Section:—

1936

Jan. 24.—Mr. E. J. Mulligan, Chief Test Engineer of Canadian Wright Ltd. Subject: **The Cyclone Engine and Test Visit.** Attendance 10.

Feb. 4.—Mr. R. J. Moffet, Manager of the Aircraft Department of Canadian Vickers. Subject: **Metal Aircraft Construction as Exemplified by Northrop.** Attendance 15.

Feb. 20.—Group Captain E. W. Stedman, O.B.E., F.R.Ae.S., M.E.I.C., etc., Chief Aeronautical Engineer for the Department

of National Defence. Subject: **Stratosphere Flying.** Attendance 40.
Mar. 12.—Capt. M. Windsor, Canadian representative of the Armstrong Siddeley Motors of England. Subject: **Tour of Aeroplane and Engine Shops.** Attendance 50.
Mar. 19.—Mr. K. F. Tupper, B.A.Sc., A.F.R.Ae.S., etc., of the National Research Council. Subject: **Fatigue of Metals.** Attendance 15.
April 16.—Mr. E. M. Lester, B.S., M.S., Assistant Executive Engineer for Pratt and Whitney Aircraft Corp. Subject: **Controllable Pitch Propellers.** Attendance 32.
April 30.—Mr. R. J. Anderson, B.A.Sc., District Service Engineer for the Dominion Oxygen Company. Subject: **Welding of Light Walled Tubing.** Attendance 34.

The average attendance was 28, an increase of 10 over the previous year.

Almost all the consistent attendants were members of The Engineering Institute of Canada or the Royal Aeronautical Society. No charge was levied on casual visitors as they usually came by invitation of the Secretary.

## Peterborough Branch

The President and Council:—

I have the honour to submit on behalf of the Executive committee, Peterborough Branch, Engineering Institute of Canada, the following report covering the activities of the Branch during the year 1936:—

MEETINGS

1936
Jan. 9.—**Mechanized Warfare** by Lt.-Col. N. C. Sherman, M.E.I.C., Military District No. 3, Kingston, Ont. Attendance 67.
Feb. 20.—**Nickel Alloys** by Mr. Hugh G. Watson, foundry engineer, Peckovers Ltd., Toronto, Ont. Attendance 26.
Mar. 12.—**The Mining Industry** by Mr. G. C. Monture, editor in chief of publication "Mines Branch," Ottawa. Attendance 29.
April 15.—Annual Students and Junior Night. **The Engineer in Social Life** by A. R. Jones, Jr.E.I.C.; **Metal Radio Tubes** by Mr. G. Levy; **Panic** by R. S. Hull, Jr.E.I.C.; **A Mathematical Problem** by A. J. Girdwood, Jr.E.I.C.; **The Modern Pipe Organ** by Mr. W. S. McMullen. Attendance 34.
May 7.—Annual Meeting, reports and election of officers. Attendance 31.
Sept. 19.—Annual Outing to R.C.A.F. Station, Trenton, Ont. Attendance 50.
Oct. 8.—**Metalizing and Metal Spraying** by Mr. C. E. Simpson, consulting engineer, Toronto. Attendance 30.
Nov. 17.—Annual Dinner. Mr. Desmond Killikelly, Assistant to the Vice-President, Steel Company of Canada. Subject, **Canada in the Midst of the World's Political Unrest.** Attendance 63.
Dec. 10.—**Concrete Highways** by D. O. Robinson, A.M.E.I.C., publicity engineer, Canada Cement Company, Toronto. Attendance 25.

Number of Executive meetings held during the year was seven. Special sub-committees were as follows:

| | |
|---|---|
| Meetings and Papers Committee | V. R. Currie, A.M.E.I.C. |
| | E. J. Davies, A.M.E.I.C. |
| | B. Ottewell, A.M.E.I.C. |
| Branch News Editor | E. J. Davies, A.M.E.I.C. |
| Membership and Attendance Committee | A. L. Dickieson, A.M.E.I.C. |
| | D. J. Emery, Jr.E.I.C. |
| | A. L. Killaly, A.M.E.I.C. |
| Social and Entertainment Committee | W. M. Cruthers, A.M.E.I.C. |
| | A. L. Killaly, A.M.E.I.C. |
| | A. B. Gates, A.M.E.I.C. |
| By-laws and Development | A. B. Gates, A.M.E.I.C. |
| | R. L. Dobbin, M.E.I.C. |
| Auditor | E. R. Shirley, M.E.I.C. |

Employment conditions of engineers in our district are practically on a level with those of pre-depression years.

Respectfully submitted,
W. T. FANJOY, A.M.E.I.C., *Secretary-Treasurer.*

## Quebec Branch

The President and Council:—

On behalf of the Executive committee of the Quebec Branch, we beg to submit the annual report for the calendar year 1936:—

MEMBERSHIP

| | *Resident* | *Non-Resident* | *Total* |
|---|---|---|---|
| Branch Honorary Member | 1 | 0 | 1 |
| Members | 19 | 0 | 19 |
| Associate Members | 66 | 9 | 75 |
| Juniors | 2 | 3 | 5 |
| Students | 9 | 2 | 11 |
| Affiliates | 1 | 0 | 1 |
| | 98 | 14 | 112 |

It is with deep regret that we report the death of F. T. Cole, M.E.I.C., and D. Lemieux, S.E.I.C.; both passed away during the course of the year.

MEETINGS

Four meetings of the Branch Executive committee were held during the year and seven Branch meetings, as follows:—

1936
Jan. 11.—Luncheon meeting at Chateau Frontenac. Our guest of honour, Dr. F. A. Gaby, M.E.I.C., President of The Institute, addressed the meeting on Institute's affairs and delivered a lecture on **Transportation Problems.**
Feb. 17.—Luncheon meeting at Chateau Frontenac. Speaker, P. S. Gregory, M.E.I.C., assistant general manager, Shawinigan Water and Power Co., Montreal. Subject: **Utilization of Secondary Electric Energy for the Production of Steam.**
Mar. 30.—Evening meeting at Chateau Frontenac. Speakers and subjects: J. H. A. Laplante, S.E.I.C., (Quebec Roads Department), **Le revêtement économique des chaussées**; Maurice Archambault, C.E. (Bureau of Mines, Quebec), **Engineering and the Mining Industry of Quebec**; J. H. Theriault, C.E. (Quebec Roads Department), **Construction des pavages en béton.**

May 4.—Luncheon meeting at Chateau Frontenac. Speaker: Alfred Marois, C.E., Chairman of the Quebec Board of Trade. Subject: **Le rôle de l'ingénieur dans l'industrie.**

June 5.—Annual Meeting and election of officers at Montcalm Palace.

Sept. 17.—Luncheon meeting at Chateau Frontenac. Guest of honour, E. A. Cleveland, M.E.I.C., President of The Institute, who addressed the meeting on Institute's problems.

Dec. 7.—Evening meeting at Chateau Frontenac. Speaker: G. Lorne Wiggs, A.M.E.I.C., consulting engineer, Montreal. Subject: **Fundamentals of Air Conditioning.**

Committees

Special Branch committees are as follows:—

| | |
|---|---|
| Nominating | L. P. Methe, A.M.E.I.C. |

## Saint John Branch

The President and Council:—

On behalf of the Executive committee, we beg to submit the annual report for the calendar year 1936:—

Membership

| | Resident | Non-Resident | Total |
|---|---|---|---|
| Members | 10 | 6 | 16 |
| Associate Members | 18 | 15 | 33 |
| Juniors | 6 | 4 | 10 |
| Students | 17 | 27 | 44 |
| Affiliates | 1 | .. | 1 |
| | 52 | 52 | 104 |

Meetings

Ten meetings of the Branch Executive committee were held during the year and six Branch meetings as follows:—

1936

Jan. 30.—The annual joint dinner meeting with the Association of Professional Engineers of the Province of New Brunswick. T. C. Macnabb, M.E.I.C., General Superintendent of the New Brunswick Division of the C.P.R., gave an illustrated talk on **Arctic Flying.**

Feb. 20.—A dinner dance was held by the Branch in the Admiral Beatty hotel with an attendance of 159.

Mar. 5.—D. O. Turnbull, Jr.E.I.C., of the Foundation Co., read a paper, illustrated by slides, on **The Foundation Scarboro,** one of the largest floating derricks in Canada.

Mar. 26.—D. O. Robinson, A.M.E.I.C., read a paper on **Modern Cement Concrete Highways.**

May 7.—Annual dinner and meeting of the Branch at the Riverside Golf and Country Club. The present officers were elected at this meeting. Lt.-Col. P. B. Fleming of the U.S. Army Corps of Engineers addressed the meeting on **The Passamaquoddy Tidal Power Project.** The address was illustrated by slides and moving pictures.

Aug. 27., 28., 29.—A Maritime Professional meeting was held in Saint John with a total registration of 114. The technical papers read were as follows: **Stabilization, Realignment and Surfacing of New Brunswick Roads** by D. R. Smith of the New Brunswick Highway Department; **The Fundamentals of Air Conditioning** by G. L. Wiggs, A.M.E.I.C., of Montreal; and **The Reconstruction of Berths 1, 2, 3 and 4 in Saint John Harbour** by V. S. Chesnut, A.M.E.I.C.

Inspection trips included a visit to the above Berths; a boat trip around the Harbour in a tugboat supplied by the Saint John Drydock and Shipbuilding Co.; and a car trip to the Passamaquoddy Tidal Power Project.

Entertainment included a dinner dance, on the evening of the 27th; luncheon as guests of the Foundation Co. and the Saint John Drydock and Shipbuilding Co. at noon on the 28th; and luncheon as guests of the Saint John Branch at Eastport. The ladies were guests of the Saint John Branch at a luncheon at the Westfield Golf Club on the afternoon of the 28th. The Hon. Michael Dwyer, Minister of Mines in Nova Scotia addressed the Branch on the evening of the 28th.

Employment

Although there are quite a few unemployed, especially among the Students and Juniors, the employment situation shows considerable improvement at present.

Financial Statement

*Receipts*

| | | |
|---|---|---|
| Balance, December 31st, 1935 | $293.52 | |
| Headquarters rebates—January to April | 103.20 | |

| | | $1,014.32 |

Respectfully submitted,

J. R. Freeman, m.e.i.c., *Chairman.*
F. A. Patriquen, Jr.e.i.c., *Secretary-Treasurer.*

## St. Maurice Valley Branch

The President and Council:—

There was very little, if anything, done by this Branch during the year just ended. There was one general meeting, two meetings of the Executive committee, and one technical meeting, at which A. C. Abbott, a.m.e.i.c., distribution engineer, Shawinigan Water and Power Company, Three Rivers, was the speaker.

Financial Statement

*Receipts*

| | | $153.66 |

Respectfully submitted,

J. Albert Hamel, a.m.e.i.c., *Secretary-Treasurer.*

## Saskatchewan Branch

The President and Council:—

On behalf of the Executive we submit the following report of the activities of the Saskatchewan Branch for the year 1936:—

Membership

The membership of the Branch shows an increase of five over last year, being as follows:—

| | Resident | Non-Resident | Total |
|---|---|---|---|
| Members | 20 | 10 | 30 |
| Associate Members | 17 | 24 | 41 |
| Juniors | 7 | 6 | 13 |
| Students | 3 | 12 | 15 |
| Branch Affiliates | 2 | 1 | 3 |
| | 49 | 53 | 102 |

Committees

The Executive committee was elected on March 20th, 1936 and held five meetings during the year (including trip to Fort Peck).

The standing committees are:—

Papers and Library............R. W. Allen, m.e.i.c., Convenor.
Nominating..................D. A. R. McCannel, m.e.i.c., Convenor.
Membership..................J. J. White, m.e.i.c., Convenor.

Meetings

There were four regular meetings of the Branch, each being preceded by a dinner at which the average attendance and general interest was good. In addition, a general meeting was held during the month of October under the auspices of the Association of Professional Engineers.

The trip to Fort Peck dam proved to be of great educational and instructive value, so much so that those who attended contemplate another trip in 1937.

The programme for the year was as follows:—

1936

Jan. 24.—Address by Dr. E. W. Stapleford on **Blazing New Trails.**

Mar. 20.—Address by Stewart Young, m.e.i.c., on **Reminiscences of Mountain Climbing in British Columbia,** illustrated by maps and charts.

Sept. 19.—Members of the Branch visited Fort Peck Dam, Montana, U.S.A.

Nov. 20.—Address by Professor R. A. Spencer, a.m.e.i.c., on **Some Modern Highway Tunnels and Long Span Bridges,** illustrated by lantern slides.

Dec. 18.—Address by W. H. Ross, r.p.e. Saskatchewan, on **Diesel Engines.**

Finances

The financial standing of the Branch is as follows:—

*Receipts*

| | | |
|---|---|---|
| Bank balance, December 31st, 1935 | $ 53.39 | |
| Rebate from Headquarters | 178.65 | |
| Branch dues | 8.00 | |
| Miscellaneous | 8.00 | |
| | | $248.04 |

*Expenditures*

| | | |
|---|---|---|
| Postage | $ 8.61 | |
| Meetings (notices, printing, etc.) | 66.43 | |
| Secretarial | 50.00 | |
| Miscellaneous | 26.53 | |
| Bank balance, December 31st, 1936 | 96.47 | |
| | | $248.04 |

Respectfully submitted,

W. E. Lovell, m.e.i.c., *Chairman.*
J. J. White, m.e.i.c., *Secretary-Treasurer.*

## Sault Ste. Marie Branch

The President and Council:—

On behalf of the Executive committee we submit the following report of the Sault Ste. Marie Branch for the calendar year 1936:—

The Executive committee met January 27th and appointed standing committees as follows:—

Papers and Publicity..................Wm. Seymour, m.e.i.c.
Legislation and Remuneration.........F. Smallwood, m.e.i.c.
Entertainment........................C. W. Holman, a.m.e.i.c.
Membership...........................E. M. MacQuarrie, a.m.e.i.c.

The unemployment committee which functioned during the year 1935 was discontinued, the Executive feeling that the need for this committee was over due to the betterment of business conditions in this territory.

The Executive committee met seven times during the year to discuss and promote Branch activities.

Seven dinner meetings were held during the year. No regular meeting date was adhered to rigidly as the Executive found that it was necessary to fit the date of the meeting to suit the convenience of the speakers.

Programmes of the meetings were as follows:—

1936

Jan. 3.—Annual Meeting for 1935—followed by a social evening.

Feb. 6.—**Aluminum Cables, Steel Reinforced, for Electrical Conductors** by Mr. Theodore Varney, consulting engineer, Aluminum Company of Canada.
**Some Aspects of Aluminum and its Alloys** by Mr. W. M. Gifford, Vice-President, Aluminum Company of Canada.

Mar. 6.—**Aeronautical Development and Design** by Mr. George Ponsford, Director of Province of Ontario Air Service. This meeting was followed by an interesting tour of the local aerodrome.

April 8.—**Informal Talk** by His Honour Judge Frederick Stone. A social evening followed this enjoyable address.

May 20.—**Alloy Irons** by Mr. Hugh Watson, chief engineer, Peckovers Limited.

Oct. 30.—**Human Relations and the Engineer** by R. S. McCormick, m.e.i.c., chief engineer and general superintendent, Algoma Central and Hudson Bay Railway.

Nov. 30.—**Gold** by O. A. Evans, Jr.e.i.c., Mines Department, Algoma Central & Hudson Bay Railway.

The membership record of the Branch at the close of 1936 is as follows:—

| | Resident | | Non-Resident | | Total | |
|---|---|---|---|---|---|---|
| Regular | 1935 | 1936 | 1935 | 1936 | 1935 | 1936 |
| Members | 9 | 9 | 11 | 8 | 20 | 17 |
| Associate Members | 10 | 10 | 25 | 27 | 35 | 37 |
| Juniors | 4 | 3 | 10 | 12 | 14 | 15 |
| Students | 1 | .. | 12 | 14 | 13 | 14 |
| Branch Affiliates | 8 | 9 | .. | .. | 8 | 9 |
| | 32 | 31 | 58 | 61 | 90 | 92 |
| Associate Members | 1 | 1 | 2 | 1 | .. | .. |
| Junior Members | .. | .. | 1 | 1 | .. | .. |
| Non-Active | .. | .. | .. | .. | .. | .. |

The movement of members during 1936 is summarized as follows:—

| | In | Out | Transfer |
|---|---|---|---|
| Elected to Membership | 6 | .. | .. |
| Moved out of Branch | .. | 13 | .. |
| Moved into Branch | 15 | .. | .. |
| Resignations and Non-Actives | .. | 6 | .. |
| Transfer to higher grade | .. | .. | 3 |
| | 21 | 19 | 3 |

Net gain ............ 2 Regular Members
Net loss ............ 1 Non-Active Member

FINANCIAL STATEMENT

## Toronto Branch

The President and Council:—

On behalf of the Executive committee we submit the annual report of the Toronto Branch for 1936.

The annual meeting of the Branch was held at the Canadian Military Institute on April 16, 1936, and was preceded by a dinner.

The chairmen of standing committees are:

Papers ............ O. Holden, A.M.E.I.C.
Finance ............ C. E. Sisson, M.E.I.C.
Publicity ............ A. U. Sanderson, A.M.E.I.C.
Meetings ............ Nicol MacNicol, M.E.I.C.
Membership ............ W. E. P. Duncan, M.E.I.C.
Student Relations ............ A. M. Reid, A.M.E.I.C.
Branch Editor ............ D. D. Whitson, A.M.E.I.C.
Social ............ W. E. Bonn, M.E.I.C.

During the past year the Executive committee has held 13 meetings for the transaction of Branch business, with an average attendance of about nine at each meeting.

The following regular meetings were held during 1936:

1936

Jan. 16.—**The Economic Value of the Steel Industry to Canada**, Mr. A. G. Wright, Dominion Foundries and Steel, Ltd., Hamilton. Attendance 75.

Jan. 29.—Two Hundredth Anniversary of the Birth of James Watt. Meeting arranged by the University with the co-operation of The Engineering Institute of Canada, the American Society of Mechanical Engineers, the Institution of Mechanical Engineers, and the American Institute of Electrical Engineers. Speakers, Brig.-General C. H. Mitchell, M.E.I.C., Professor Robt. W. Angus, M.E.I.C., and Professor E. A. Allcut, M.E.I.C. Attendance 425.

Feb. 20.—**Radium**, Mr. F. B. Friend, Eldorado Gold Mines, Ltd. Attendance 60.

Mar. 5.—**Sheet Piling**, Robt. F. Leggett, A.M.E.I.C., Canadian Sheet Piling Company. Attendance 60.

Mar. 17.—**Acoustics**, Mr. C. W. Meyer, Johns Manville Co., New York. Attendance 150.

Mar. 27.—**Fifty Years of Ship Building—A Retrospect**, Fred Bridges, M.E.I.C., Sorel, Que. Attendance 25.

April 16.—Annual Meeting. Dinner at the Canadian Institute following which Professor L. Joslyn Rogers spoke on **Technical Methods in the Detection of Crime.** Attendance 55.

Oct. 2.—**Musical Sounds and their Engineering**, Dr. W. B. White, American Steel and Wire Co., Chicago. A joint meeting with the American Society of Metals and the American Society of Mechanical Engineers. Attendance 150.

Oct. 15.—**The Geology of Northern Ontario**, Mr. H. C. Rickaby, Ontario Provincial Geologist. Attendance 80.

Nov. 5.—**Metal Mining and Milling**, C. G. Williams, B.A.Sc., consulting mining engineer. Attendance 85.

Nov. 18.—**Forestry**, Dean C. D. Howe, Faculty of Forestry, University of Toronto. Attendance 30.

Dec. 3.—**Pulp and Paper**, E. W. McBride, A.M.E.I.C., Abitibi Power and Paper Company. Attendance 70.

In addition to the regular meetings, two social evenings have been held, one in April and one in December, for members and their wives, at which about eighty were present on each occasion. These were held at the Engineers Club, where dinner was served and the evening spent with music, billiards, bridge and other entertainment.

It will again be noted that a number of meetings have been held with other engineering societies, and these have proved most successful and enjoyable. Dinner is frequently arranged before the regular Branch meetings and this affords an opportunity for the members to meet in a social way.

The Toronto Branch E.I.C. Loan Fund, established four years ago for the assistance of members, is in a satisfactory condition and during the past two years no applications for help have been received. At the present time there is a balance of $298.01 in the Fund.

The membership of the Branch, as at December 31st, 1936. is as follows:

| | Resident | Non-Resident | Non-Active | Total |
|---|---|---|---|---|
| Members | 124 | 7 | 4 | 135 |
| Associate Members | 195 | 7 | 30 | 232 |
| Juniors | 40 | 4 | 9 | 53 |
| Students | 68 | 13 | 5 | 86 |
| Affiliates | 5 | .. | .. | 5 |
| | 432 | 31 | 48 | 511 |

It is with regret that we record the death of the following members during the year: Colonel C. J. Ingles, M.E.I.C., and Thos. Taylor, M.E.I.C.

FINANCIAL STATEMENT

*Receipts*

| | | | $1,188.80 |

The Branch also holds a Dominion of Canada $100.00 Bond.

Respectfully submitted,
O. HOLDEN, A.M.E.I.C., *Chairman.*
W. S. WILSON, M.E.I.C., *Secretary-Treasurer.*

## Vancouver Branch

The President and Council:—

On behalf of the Executive committee of the Vancouver Branch we beg to submit the following report of the activities of the Branch during the year 1936:—

### Meetings

Nine meetings of the Branch were held during the year and two inspection trips made as follows:—

1936

Jan. 29.—Annual Meeting(1935) held at the Grosvenor hotel. Speaker: J. P. Forde, M.E.I.C. District Engineer, Department of Public Works. New Westminster, B.C. Subject: **A Trip to Glacier Bay, Alaska, B.C.**

Feb. 3.—Joint meeting with the American Institute of Electrical Engineers, Vancouver Section. Held at the Medical Dental Auditorium. Speaker: Prof. E. G. Cullwick, Jr.E.I.C., Department of Electrical Engineering, University of B.C. Subject: **Hydro-Electric Development in Scotland.** (Illustrated.)

Feb. 27.—Dinner in honour of the President, Dr. Ernest A. Cleveland, M.E.I.C., at the Terminal City Club.

April 15.—Dinner meeting at the Grosvenor hotel. Speaker: Mr. W. D. McLaren, consulting engineer. Subject: **San Francisco Bridge.** (Illustrated.)

April 27.—Dinner meeting at the Grosvenor hotel. Speaker: D. O. Lewis, M.E.I.C. Subject: **A Study of the Physical and Operating Conditions of the Pacific Great Eastern Railway.** (This paper was published in the September Journal.)

May 5.—Meeting at the Medical-Dental Auditorium. Speaker: P. L. Pratley, M.E.I.C. Subject: **The Isle of Orleans Bridge.** (Illustrated.)

Sept. 21.—Meeting of the American Society of Electrical Engineers, Vancouver Section, to which the E.I.C. Vancouver Branch were specially invited, a large number availing themselves of the invitation. Speaker: Mr. L. W. Chubb, Director of Research, Westinghouse Electric Co., Pittsburgh. (Illustrated.)

Oct. 18.—Joint luncheon with the Canadian Institute of Mining and Metallurgy, B.C. Section. Luncheon held at the Spanish Grill, Hotel Vancouver. Speaker: Dr. E. A. Cleveland.

Nov. 23.—Annual Meeting (1936). Dinner at the Hotel Georgia. Guest speaker: R. Rowe Holland, Chairman of the Vancouver Parks Board.

### Inspection Trips

May 12.—Inspection trip to the British Pacific Properties West Vancouver, B.C., by courtesy of the British Pacific Properties Co.

Dec. 12.—Inspection trip to the Pattullo Bridge under construction across the Fraser River at New Westminster, B.C., by courtesy of Major W. G. Swan, M.E.I.C., consulting engineer on the project, and the Dominion Bridge Co. and the Northern Construction Co., general contractors.

All meetings and inspection trips were well attended.

The Executive committee held nine meetings during the year.

### Relations of the Branch with the B.C. Association of Professional Engineers

We are happy to report that there has been, as heretofore, a measure of close co-operation between the B.C. Association of Professional Engineers and the Vancouver Branch. As has been the custom for several years past, the President and the Registrar of the Association were appointed ex-officio members of the Executive committee and it has been found an excellent arrangement, particularly during the year 1936 when "Consolidation" matters affecting the interests of both groups were constantly under discussion. Mr. James Robertson, M.E.I.C., the Branch chairman, was also a member of the Association's Board during the year.

### Dr. E. A. Cleveland, President

The Vancouver Branch felt signally honored when it learned that one of its members, Dr. E. A. Cleveland, had been elected President of The Institute for the year 1936. Dr. Cleveland as an ex-officio member of the Vancouver Branch Executive committee has on a number of occasions made valuable contributions to the Committee's deliberations, on "Consolidation" matters particularly. These have been of great assistance and have been much appreciated by the Committee.

### Membership

The Resident and Non-Resident membership of the Branch shows an increase of nine members during the year. The membership of the Branch now stands as follows:—

| | Resident | Non-Resident | Total |
|---|---|---|---|
| Members | 64 | 16 | 80 |
| Associate Members | 44 | 31 | 75 |
| Juniors | 2 | 6 | 8 |
| Students | 12 | 9 | 21 |
| Affiliates | 1 | .. | 1 |
| | 123 | 62 | 185 |

### Walter Moberly Memorial Book Prize

The Walter Moberly Book Prize Award (value $25.00) for the year 1936 was awarded to Mr. Victor A. Zanadvoroff, a metallurgical student in the graduating year at the University of British Columbia.

### Consolidation Affairs

The Vancouver Executive committee have from time to time given much thought and study to Consolidation affairs. The Annual Meeting held at Hamilton in February was attended by Dr. Cleveland, E. A. Wheatley, M.E.I.C. (Registrar of the B.C. Association), Dr. Harry Letson, M.E.I.C. (President of the B.C. Association), and A. S. Wootton, M.E.I.C., Branch Councillor. Plenary meetings were also attended by Dr. Cleveland, Mr. Wootton and James Robertson, M.E.I.C., the Branch chairman.

From time to time these members returned with first hand information as to the progress of the Consolidation project.

Much correspondence, too, has passed between the Executive and the Committee on Consolidation during the year.

The Vancouver Executive feel that much excellent progress has been made towards the solution of this problem and are confident that in the near future the common objective will be reached that will be satisfactory to all the interested groups and in the best interests of the Profession in Canada.

### Employment

Employment conditions amongst engineers in the Vancouver District have improved greatly during 1936.

Briefly all registered engineers in geological, mining and metallurgical engineering are employed. There is much improvement in conditions affecting civil, mechanical and structural engineers. There is still, however, some distress amongst electrical engineers. Indications for 1937 are that all engineers will probahly be employed.

### Financial Statement

The financial statements of the Vancouver Branch for the period indicated are appended hereto.

#### General Account

## Victoria Branch

The President and Council:—

On behalf of the Executive committee we beg to submit the following report on the activities of the Victoria Branch of The Institute during the year 1936.

Meetings

Five general meetings of the Branch were held during the year, one of which was a luncheon meeting and one a dinner meeting, the average attendance being 27. Technical papers presented before the meetings were as follows:—

1936

Feb. 7.—**Air Mail Routes Through B.C.** by Major E. C. G. Chambers, A.M.E.I.C.

Nov. 4.—**The Island of Orleans Suspension Bridge Construction** by P. L. Pratley, M.E.I.C., Vice-President of The Institute.

On June 26th, the Branch was honoured by having as its dinner guest Dr. E. A. Cleveland, M.E.I.C., President of The Institute for 1936. Dr. Cleveland addressed the Branch on the proceedings of the last Annual General Meeting with respect to Consolidation.

Four meetings of the Executive committee were held during the year with an average attendance of 60 per cent. The only outstanding business coming before the executive was that pertaining to the proposed Consolidation of the Engineering Profession, in consideration of which this executive has endeavoured to work earnestly and diligently.

The annual meeting, which took the form of a dinner, was held on the 10th of December, at which the election of officers for 1937 took place. The meeting was followed by an illustrated address.

Membership

The membership of the Branch stands at sixty-four, a net gain of four members for the year. Two new Members and one new Associate Member were enrolled during the year; three Associate Members and one Student transferred to other Branches, two Members, one Associate Member, two Juniors and one Student were transferred to the Victoria Branch from other parts of Canada.

Employment

With regard to the employment situation there have been no calls during the year for financial assistance and the Executive has no knowledge of any members in need of such assistance. It would appear that general conditions are improving as at least three members of the Branch are known to have improved their position during the year.

In conclusion the Executive committee wishes to extend its sincere thanks and appreciation to the Secretary and Assistant Secretary at Headquarters for their unfailing assistance and courtesy during the year.

## Winnipeg Branch

The President and Council:—

The following report of the Winnipeg Branch for the year ending December 31st, 1936, is respectfully submitted.

Membership

The membership of the Branch is as follows:—

| | *Resident* | *Non-Resident* | *Total* |
|---|---|---|---|
| Members | 36 | 3 | 39 |
| Associate Members | 73 | 15 | 88 |
| Juniors | 13 | 4 | 17 |
| Students | 35 | 8 | 43 |
| Affiliates | 2 | .. | 2 |
| Branch Affiliates | 2 | .. | 2 |
| | 161 | 30 | 191 |

Meetings

There were fifteen general meetings of the Branch throughout the year, the attendance at the regular meetings averaging 73.

1936

Jan. 23.—Professor J. W. Dorsey, University of Manitoba, **High Voltage Low Current D.C. Transmission.** Attendance 62.

Feb. 6.—Meeting taken by the Student's Engineering Society of the University of Manitoba.
Mr. F. P. Findlay, **Bituminous Materials in Highway Construction.**
Mr. J. D. McKenzie, **Atmospheric Phenomena during Dust Storms, and their Effect on High Tension Wires.**
Attendance 39.

Feb. 10.—Annual supper dance, Winnipeg Branch E.I.C. and the Association of Professional Engineers of the Province of Manitoba, at the Royal Alexandria hotel.

Feb. 20.—Annual Meeting of the Branch. Mr. Frank Simmons, M.A.S.S.E., **Sewer and Water Lines in the Frozen North.** Attendance 61.

Mar. 9.—Dr. A. D. Blackhurst, **Scalebuoys, and Scale Removal from Boilers.** Attendance 77.

Mar. 19.—Meeting taken by Junior Engineer's Association.
Mr. Frank Dempsey, **Hard Surfacing of Highways.**
Mr. D. C. Brazier, **Creosoting.**
Attendance 51.

April 2.—Mr. Hew M. Scott, M.E.I.C., superintendent, Nelson River Construction Co., **Sewers in Tunnels.** Attendance 102.

April 16.—Prof. A. E. Macdonald, M.E.I.C., Professor of Civil Engineering, University of Manitoba, **Foundations on Unstable Soils.** Attendance 62.

May 11.—P. L. Pratley, M.E.I.C., **Island of Orleans Bridge.** Attendance 55.

Aug. 24.—Farewell dinner to Prof. J. N. Finlayson, M.E.I.C., at the Fort Garry hotel, in conjunction with the Association of Professional Engineers and the Engineer's Alumni Association.

Sept. 23.—Luncheon meeting to meet and hear President E. A. Cleveland, M.E.I.C., held at the Carleton Club.

Oct. 15.—Film **Noranda,** with introduction and comments by G. E. Cole, A.M.E.I.C., Director of Mines, Province of Manitoba. Attendance 160.

Nov. 5.—Film **Boulder Dam,** with introduction and comments by Mr. J. McMahon. Attendance 139.

Nov. 19.—Prof. R. O. Macfarlane, Ph.D., Department of History, University of Manitoba, **Secession Movements in Canada.** Attendance 38.

Dec. 3.—Meeting taken by Junior Engineer's Association.
A. Sandilands, Jr.E.I.C., **Engineering Generalities.**
Mr. T. A. Lindsay, **Recent Improvements in Telephone Communication Equipment.**
Attendance 26.

The Executive committee of the Branch held eleven meetings throughout the year.

Consolidation

Close co-operation continues between the Association of Professional Engineers of the Province of Manitoba, and the local Branch. The general strong desire for effective and prompt consolidation continues; members of the Association are mailed notices of all general meetings of the Branch. As will be noted by the financial statement. the Association has generously assisted the Branch to carry out this mailing and to provide light refreshments at the meetings.

Major A. J. Taunton, M.E.I.C., Chairman of the local Joint Committee on Consolidation, carried the Manitoba proposals on the subject to the Plenary Meeting of Council in October. The Manitoba proposals have been crystallized for more than a year. By continuing the previous good work of Councillor T. C. Main, A.M.E.I.C., Major Taunton was able to persuade Council of the reasonableness of these, to the extent that enabling clauses designed to allow the proposals to be put in effect, have been placed in the suggested revisions to Institute by-laws.

# ENGINEERING JOURNAL

THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XX FEBRUARY, 1937 No. 2

## The Steam Locomotive of To-day

Readers of technical journals must have noted many recent references to the innovations and improvements in railway motive power which are being made by the railway administrations in Europe as well as in North America. Many of these are experiments on a large and expensive scale, their principal aims being reduction in operating costs and, what is even more important, an increase in the attractiveness of the passenger and freight services offered by the railways. Both these objects must be attained in substantial measure if the railways are to succeed in retaining, if not the lion's share of land transportation, at least a considerable slice of the business which offers or can be developed.

A number of these experimental changes in the character of railway motive power and equipment have now been in operation for a sufficient length of time to enable a judgment to be formed as to their results. For example, in England, the chief mechanical engineer of the London and North Eastern Railway, in a recent address, announced that as a result of the popularity of their high speed train services during the past twelve months a number of additional trains of this character will be put on during the coming summer, all timed at average speeds of from 65 to 67 miles per hour. A new train from London to Leeds will cover the distance of 186 miles in one hundred and sixty-five minutes. From the experience already gained Sir Nigel Gresley is convinced that these trains have very largely created their own traffic and have not drawn their passengers from existing services. They have proved profitable in operation; they demonstrate the possibilities of the steam locomotive and modern equipment if designers take advantage of the new materials now available and the advances made possible by present day technical knowledge. In France, Germany and the United States the experience has generally been similar, both in the case of steam-driven and internal-combustion-engined high speed trains. Trains of the former type running between Chicago and Minneapolis and St. Paul are operated by three roads and the public response as regards traffic results is understood to have been satisfactory in all three cases.

It is somewhat surprising to find that no very radical change in the conventional type of steam locomotive has yet proved its desirability in practice. The steam turbine and the water tube boiler have not yet come into their own for locomotive work. The successful locomotive boiler of today is built on the same general lines as the boiler of Stephenson's "Rocket," although it may be required in some cases to furnish steam for an engine developing 2,000 to 3,000 h.p. Among innovations in locomotive design which have proved acceptable are the superheater; in some cases the addition of a combustion chamber to the boiler, and the employment of modern valve gear in place of the old Stephenson link motion.

The designer of a modern steam locomotive has no easy task, particularly in Europe, where the permissible overall dimensions are so limited by tunnels, platforms and other permanent structures along the line. Not only must he provide for greatly improved performance, both as to capacity and economy, but this must be obtained without sacrificing any advantages due to the inherent simplicity and reliability of the machine. These are the qualities which, as Mr. Sillcox has pointed out, have enabled the steam locomotive, in spite of its lower thermal efficiency, to compete successfully with other more efficient but more complex types. Its lower first cost, maintenance and fixed charges, compensate in many cases for the higher fuel economy of its competitor.

In a paper published in this issue of The Journal and dealing with European railway motive power, attention is drawn to the remarkable results which have been obtained in France by the modernization of existing steam locomotives. Rebuilt locomotives, some of them twenty years old, have shown results comparable with those of new engines of the most modern type, both as regards increased speed of passenger service and greater fuel economy. These results have been obtained under the most severe conditions as regards limitation of first cost. Marked progress in locomotive design along similar lines has also been made in the United States, particularly as regards high speed, the record for the fastest steam train in regular service having now passed from the "Cheltenham Flyer" of the Great Western Railway in England, to the "Hiawatha" of the Chicago, Milwaukee and St. Paul road.

In Germany, France and other European countries, as well as in the United States, the problem of high speed passenger transportation has also been attacked in another way, namely, by the introduction of the light weight Diesel-electric train, designed so as to take advantage of the particular characteristics of the internal combustion engine. As regards the Diesel-electric trains of this type, it seems too soon to judge as to their economy in operation, but they have undoubtedly proved very popular in passenger service. In Germany, one of these trains, the "Fliegende Kölner," makes the run from Berlin to Hannover, 157.8 miles, in one hundred and fifteen minutes, a start-to-stop average of 82.3 miles per hour.

Comparison of the performances of such widely different types of motive power is not easy. For this purpose Mr. Lipetz proposes to use a figure which he calls "specific power factor," the ratio of horse power at the rail as determined on test, to the weight of the steam locomotive with half-loaded tender, or to the weight of the Diesel locomotive with full tanks, as the case may be. This ratio works out at from 8 to 12 in the latter case, and reaches nearly 20 in some of the modern steam locomotives.

There is no doubt as to the stimulating effect which the introduction of the Diesel locomotive has had on steam locomotive development. The resulting improvement in performance is only one example of the betterment which is now taking place in almost every branch of railway activity. The extent to which this is going on in North America is well shown in the exhaustive report* on railway equipment prepared for the Federal Co-ordinator of Transport, Washington, by his Mechanical Advisory Committee. The railways are determined to improve their services in every possible way to meet the new conditions. But while ready to consider any proposal for new equipment which promises the desired results, their past experience makes them cautious in departing widely from established trends of design.

## Committee on Consolidation

**Report for January 1937**

The report of the Committee for the year 1936, which appears elsewhere in this issue of The Journal, was presented and discussed at the Annual Meeting held in Montreal on January 29th. The meeting received and adopted the report and the seven recommendations of the Committee attached thereto, with the addition to recommendation No. 6 on the re-numbering of the By-laws, of the following phrase—"all such modifications thereof as Council may determine."

As was to be anticipated, the greater part of the discussion centred around Sub-section 7 (*b*), and the amendment thereto proposed by the Council. The Annual Meeting approved the clause as originally recommended by the Committee and in addition resolutions were received from the following Branches approving the Committee's 7 (*b*):—Victoria, Vancouver, Calgary, Lethbridge, Saskatchewan, Winnipeg, Lakehead, Niagara Peninsula, Hamilton, Toronto, Ottawa, Quebec, Saint John and Halifax. No definite decision was received from Montreal or Edmonton. No replies were received from Cape Breton, Moncton, Sault Ste. Marie, St. Maurice Valley, Peterborough, London or Border Cities. Kingston favoured the omission of Ontario from the provisions of this clause, and Saguenay favoured the Council's amendment.

A summary of the discussions of the Annual Meeting and of the resolutions received from the Branches of The Institute and from various Professional Associations, will appear in the March issue of The Journal.

The success which has marked this movement for closer co-operation between The Institute and the Professional Associations is in itself a demonstration of that spirit of co-operation which it is the aim of the profession to maintain and develop in the highest possible degree. Only the splendid support which your Committee has received from Branches of The Institute and from Provincial Professional Associations and the Corporation has made this achievement possible. The Committee expresses to these organizations and to the individual members of The Institute, its deepest appreciation and thanks for their encouragement and fine co-operation.

When, as a member of The Institute, the opportunity comes to you to express your wishes in this important matter, you may add your personal co-operation through the sending in of your ballot. Every member should VOTE.

Gordon McL. Pitts,
*Chairman.*

## PROGRAMME

(Subject to Revision)

**TUESDAY, JUNE 15th, 1937**

Registration, at Windsor Hotel, Reception, Presentation of Addresses, Greetings and Honorary Memberships.

Opening Luncheon.

Presentation of Technical Papers and Discussions.

Reception and Supper Dance.

**WEDNESDAY, JUNE 16th, 1937**

Presentation of Technical Papers and Discussions, continued.

Luncheon.

Presentation of Technical Papers and Discussions, continued.

Banquet—His Excellency the Governor-General of Canada, Lord Tweedsmuir, guest of honour. This function will probably be connected by telephone circuits with the twenty-five branches of The Institute. It is also hoped that greetings will be heard direct from England, India, Australia, South Africa and New Zealand.

**THURSDAY, JUNE 17th, 1937**

Visits to points of technical and general interest in and around Montreal. Arrangements will also be made for those who wish to play golf. Garden Party.

Smoking Concert. Ladies' Bridge Party.

**FRIDAY, JUNE 18th, 1937**

Transportation to Ottawa, Ont.

Luncheon at Ottawa.

Visits to points of technical and general interest in and around Ottawa.

Dinner Dance. Conclusion of main programme.

The Ladies' Committee will arrange special entertainment for visiting ladies.

# The Engineer in Business

## Address of the Retiring President

*E. A. Cleveland, M.E.I.C.*

Delivered before the Fifty-First Annual General Meeting of the Engineering Institute of Canada, Montreal, January 29th, 1937.

You have had before you the reports of Council and of the Finance Committee for the year 1936. Considering the times through which we have been passing you will doubtless all agree that the position of The Institute has been well maintained. An increase in membership and in revenues even though the latter has been accompanied by increased expenditures is a significant sign of progress.

The reports of the various Committees, together with those of the Branches, attest the lively interest taken in Institute affairs, as well as the activities of the Branch organizations in matters affecting the public welfare and the work of The Institute in promoting the interchange of professional knowledge.

Inasmuch as the labours of the Committee on Consolidation have dealt with a problem that has a vital bearing on the whole future of The Institute that Committee's report will be received with more than usual interest. It is confidently hoped that every member of The Institute will give to the report and to such action as may be taken thereon at this meeting his most careful and conscientious consideration.

I take this opportunity of extending to all the Committees and the officers of the Branches, the thanks of the membership at large for splendid services freely given. Few realize fully the extent of the time and ability voluntarily bestowed, particularly at Headquarters, on the work of The Institute. To the General Secretary and his able staff I extend the thanks of every member of The Institute for their undivided attention and loyalty to its interests.

May I say a personal word of appreciation of the privilege I have enjoyed in serving for the year as your President. The conquest of science and engineering over time and space has hardly been complete enough to permit a man from the farthest West to be at Headquarters sufficiently long and often to do full justice to his responsibilities. To the Vice-Presidents and members of Council who have so kindly acted as proxies and ably filled the gaps my most grateful thanks are tendered.

It is customary for the retiring President to make an address upon or some allusion to recent progress in engineering. As that subject will be so fully dealt with at the forthcoming Semicentennial of The Institute in June I am furnished with an adequate excuse, though perhaps not full justification, for addressing you briefly upon another subject: that of the Engineer in Business.

The call of business upon the engineer has always been more or less insistent, particularly to those whose intellectual qualities include an aptitude for acquisition, a regard for material values and what may be termed the trader's instinct. During the period of depression, which is now making a leisurely retreat, the urge of engineers to engage in business has probably embraced many whose dominating interests have been deflected and redirected by circumstances, from applied science to the solution of more personal problems.

Business is spoken of here in the general sense not only of the trading in commodities for gain and in the transformation of one kind of commodity into another as in industry, with the same motive, but also as including occupations involving constant public contacts and relations of a non-professional nature.

The general assertion that engineers are poor business men has been often made and leads one to enquire as to whether it has a foundation in fact. The statistical basis for such an enquiry is probably not available. The ratio of the number of engineers in business to the number of all other classes of men so engaged may for a community or a country be obtainable but could not in any event take account of the peculiar relation of the engineer, as a professional man, to business. His position in many cases as professional adviser makes it quite impossible to break down his advice into those elements that are distinguishable as engineering and those that may be classed as business. The considerations that enter into a certain recommendation may involve a complete knowledge on the part of the engineer of the methods of operation and costs of machinery and equipment to fabricate or produce a certain commodity and alternatively the practicability of the production of modified, enlarged or entirely new types of machines to accomplish a specified end. Since the purpose of business is to make profit, the specified end almost invariably is to produce a better commodity at the same cost or the same commodity at a lower cost than hitherto. The creative mind that produces a new and novel mechanical device or devices, or a new technical process, may be quite capable of comparable originality in the field of business.

The startlingly original engineering advice given to owners of early gold mines on the Rand to sell their properties on the outcrop of the reef and to acquire land on the dip was founded on a thorough engineering appreciation of the difficulties of deep mining and the methods to be employed to effectively overcome them. It grew, however, out of the belief, born of experience and good judgment, that to sell developed ground and to buy virgin ground in which few had any confidence would be profitable business.

The great enterprises that have been built upon the production of cheap power from hydro-electric or fuel sources and the vast business of power production, transmission and distribution, have been correlated on the foundation of engineering advice wise in its awareness of the business aspects of these complicated inter-relations.

A review of some of the major enterprises in these categories will disclose instances where a succession of undertakings had its inception in the mind of an engineer. The investigations not only compassed the engineering possibilities of a power site or series of sites capable of economic development, but embraced a whole congeries of more or less unrelated projects. Engineering knowledge coupled with business discernment indicated the combination as a profitable market for power and profitable alike to the industries to be established. Thus have flourishing communities, towns and young cities been created. What higher type of business ability can be found than that displayed by engineers who not only initiate such enterprises, but as managing heads carry them through over a long period of years in progressive stages of development as market demand grows or is created?

The amazing development of the automobile business is displayed not only in the technical perfection of the machine and its growing usefulness and appeal, but also in the mass production methods that have by the use of improved materials and equipment increasingly permitted the production of better cars at lower prices. This has been based not alone on technical achievement but also upon the sagacity of engineers whose business ability permitted them, in their wide survey of aims and perfections still unaccomplished, to choose for each year's progress those things that were practically well enough advanced to serve the market. What keener type of business sense could be evoked? Indeed in this great industry engineering has given to business some of its brightest minds.

This is not less true of the transportation business, where some of the great railways are headed by engineers of recognized capability and of proven business judgment and ability. The recent large improvement in railway passenger traffic has been an engineering achievement. Streamlined engines and trains, the steady approach toward a higher degree of perfection of the internal-combustion locomotive and air-conditioned cars could scarcely have arrived save as the engineer visualized them as an answer to the drooping curve of railway passenger business. His share in the operation of these means of locomotion in the great business of transportation is not confined solely to a care for the precision and certainty of their operation, but as well to their reactions on the travelling public and their adequacy for the intended purpose. He would seem to be doubly a business man who discerns the need for the resuscitation of a failing business and at the same time commands the technique for the creation, development and improvement of the means to achieve that end.

It is appropriate to allude to one of the newer businesses, that of motor-bus transportation, a factor of considerable importance in the drop in railway passenger revenues just referred to. Here the engineer through his knowledge of the major technical factors involved may be discovered directing or assisting in management.

One needs but to observe some of the other important businesses of the world to note that the engineer is playing his part in them. The great chemical, metallurgical and oil industries where not only plant but intricate processes of manufacture are a predominant care and interest of the business administration find engineers emerging into management.

In the realm of the relations between employer and employee instances may be found of engineers of great ability and scientific attainments, combining in a marked degree qualities of humanitarianism and business acumen, who have shown to belligerents both in the fields of capital and labour that the best business for all results when some of the profits of industry are shared with labour according to pre-arranged and specified plans.

The construction of great public works, running into many millions and occasionally hundreds of millions of dollars, will generally be found entrusted to men who combine engineering skill and business ability. They are noteworthy men in whose judgment governments and other public bodies deem it wise to leave the management of construction and frequently the direction and operation of the completed works. The actual construction of this class of large undertakings demands the exercise of the highest talents. A scale of operations in size and speed of hitherto unequalled dimensions frequently requires new and untried equipment and fresh methods of attack. The correlation of many large sized and divergent operations limited by strict time schedules, the purchase of machinery, equipment and supplies in large quantities, the housing and feeding of thousands of men, the preservation of good relations with the public and their representatives through whom funds are supplied and with the staff, trained men of many kinds and labour generally, the cost-keeping and accounting, all imply the skilled use of the methods and appliances of big business.

Engineers are frequently to be found at the head of great electrical and other public utilities where intimate knowledge of engineering matters is a pre-requisite. A sound knowledge of business gained generally through gradual emergence from strictly engineering departments to management is a not unusual characteristic of such leaders in business.

Public utility commissions, where the determination of what is fair demands rational analyses of both tangible and intangible elements as factors in costs in rate-making and other problems, constitute a fertile field for engineers. Public confidence in the protection afforded through this necessary sort of over-lordship is not alien to its recognition of the value of sane combinations of engineering and business ability often observable in these highly responsible positions.

And in the profitable and highly organized business of dealing in money and credit the engineer has left his impress. In the highest positions in banking and on the directorates of banks and other large financial institutions are to be found men whose knowledge of and respect for detail as well as of and for broad principles alike in engineering and in business has made them important figures in business life.

City managership has provided engineers with opportunities of demonstrating that administrative and executive positions may be acceptably filled by engineers. An understanding of the mechanisms of the public works and utilities of a city, with the ability to dissect and interpret a balance sheet and other forms of financial records and operations, is a stepping stone to useful public service. Experience in the handling of men in engineering work may be soundly applied to the sometimes slower moving forces of a city.

Toward the important business of government engineers have not displayed notable ambition. Our great neighbour to the South has twice filled her highest elective office from their ranks: in the days when military engineering was still the mother engineering art and again when the choice fell upon a man of international reputation as a mining engineer and executive. In our own country the engineer appears to be generally disinclined to offer his services in the arena of politics. Possibly his mental habit of getting things done is irked by the contemplation of the interminable aspect of the affairs of government. There have been, however, of late years two well-known engineers at the heads of important departments of Federal Government and a similarly small representation in provincial cabinets. It is to be hoped that these may be looked upon as successful precedents in a career where enrichment of the public service should override the unalluring aspects of a political campaign.

As permanent heads and in less conspicuous positions in government departments are to be found splendid examples of efficient engineers as public officers. The duties of such positions are not more difficult nor the services rendered less effective because the incumbent happens to blend talents for administration with knowledge of engineering. Precedents such as these should act as a spur to those whose inclinations are in the direction of public service.

Moreover there is the multitude of small businesses, in the conduct of which engineering training, even where not essential, is an added advantage. In them, equally with those of larger amplitude, the training in and appreciation of the principles which underlie economic judgment afford their possessor a certainty in decision that may often be denied the less fortunate.

For a world where technologic advance has outstripped social progress special facilities should be developed to train engineers for social and business leadership. In the education of engineering students some methods of selection might be evolved that would set apart for special training in human relations those whose aptitudes for leadership are well marked. This formal training should be the foundation upon which to rear a knowledge and understanding of men and the ability to appraise their qualities. These are among the prime elements of success in business and are to be gained only by wide personal contacts with many sorts and conditions of men.

This brief recital of some of the avenues of business along which engineers have progressed may help younger members of The Institute to dispel an inferiority complex in respect of the fitness generally of engineers to engage therein.

They too may share in the spirit of the Happy Warrior of Wordsworth:

"It is the generous spirit, who, when brought
Among the tasks of real life, hath wrought
Upon the plans that pleased his childish thought;
Whose high endeavours are an inward light
That makes the path before him always bright;
Who with a natural instinct to discern
What knowledge can perform, is diligent to learn."

## OBITUARIES

### Francis Thornton Cole, M.E.I.C.

The membership of The Institute will learn with regret of the death on August 28th, 1936, at Quebec, of Francis Thornton Cole, M.E.I.C.

Mr. Cole was born at St. Catharines, Ontario on July 8th, 1884, and graduated from McGill University in 1910, with the degree of B.Sc.

Following graduation, Mr. Cole joined the staff of the Dominion Bridge Company, and in 1910-1911 was engaged on draughting, designing and estimating various structures and in 1912 he was resident engineer for the company in Toronto. In 1913 Mr. Cole was appointed chief engineer of the Eastern Canada Steel Company, being in charge of all structural steel contracts for the company, among which were St. Anne's College at St. Anne de la Pocatière, and structures in Quebec city such as the exhibition grand stand, the steel trestle for the Terrace, sheds for the Harbour Commission, etc., and also many highway bridges for the Provincial government. Mr. Cole held this position until the time of his death.

He joined The Institute (then the Canadian Society of Civil Engineers) as a Student on October 8th, 1908, became a Junior on October 14th, 1913, an Associate Member on January 18th, 1917, and a Member on April 22nd, 1919.

### Joseph Labelle, A.M.E.I.C.

It is with deep regret that we place on record the death by drowning in St. Mary's Current, on December 17th, 1936, of Joseph Labelle, A.M.E.I.C., of Montreal.

Mr. Labelle was born at Montreal on November 24th, 1879, and graduated from the Ecole Polytechnique in 1903 with the degree of B.A.Sc. Following graduation Mr. Labelle was until 1905 with the Buoy Service of the River St. Lawrence Ship Channel, when he became connected with the Locomotive and Machine Company. In 1907 Mr. Labelle was with the Standard Construction Company, subsequently working on the staffs of the Structural Steel Company and the Dominion Bridge Company. In 1925 he entered private practice as a consulting engineer, and in 1933 joined the staff of the Montreal Water Board.

Mr. Labelle joined The Institute (then the Canadian Society of Civil Engineers) as a Student on April 23rd, 1903, and became an Associate Member on April 17th, 1909.

### Denis Lemieux, S.E.I.C.

It is with great regret that we record the untimely death by electrocution on July 30th, 1936, of Denis Lemieux, S.E.I.C.

Mr. Lemieux was born at Quebec, Que., on November 2nd, 1909, and having obtained the degree of B.A. cum laude from the Seminaire de Quebec in 1931, graduated from the Ecole Polytechnique in 1936 with the degree of B.A.Sc.

In the summer of 1933 Mr. Lemieux was a roads inspector for the city of Montreal, and in those of 1934 and 1935 he was with the Road Department of the Province of Quebec. At the time of his death, Mr. Lemieux was on the staff of the Canadian General Electric Company at Toronto, Ontario.

He became a Student of The Institute on March 6th, 1936.

### James John Humphreys, M.E.I.C.

It is with regret that we place on record the death at Montreal on January 24th, 1937, of James John Humphreys, M.E.I.C.

Mr. Humphreys was born at Bayonne, N.J., on March 22nd, 1871. In 1886-1889 he was assistant to the superintendent of the Bayonne and Greenville Gas Company, and then was a cadet engineer on electric plant and gas works construction with the United Gas Imp. Company at Kansas City, Mo. From 1891 to 1893 he was assistant superintendent on gas works construction and operation for the same company at Waterbury, Conn. In 1893 Mr. Humphreys came to Canada as secretary-treasurer and general manager of the Ottawa Gas Company, but in the same year he was appointed general manager of the Westchester Gas Company, in Pennsylvania, and remained with that company until 1897, when he became superintendent of the Worcester Gas Company at Worcester, Mass. In 1902 Mr. Humphreys was appointed general manager of the Brooklyn Borough Gas Company at Coney Island, N.Y., and in 1910 he became general manager of the Louisville Gas Company at Louisville, Ky. In 1914 Mr. Humphreys was general manager of the Augusta Gas Company at Augusta, Georgia. From 1915 until 1917 he was superintendent of shell shops for the Linderman Machinery Company in Michigan, and with the McKinnon Dash Company at St. Catherines, Ontario. He then joined the 7th Regiment, New York, and was transferred to the Ordnance Department serving as liaison officer between the United States, France and Great Britain in 1917 and 1918. On his return he joined the staff of the Montreal Light, Heat and Power Company as gas engineer. Mr. Humphreys was later appointed gas engineer with the gas department, which position he held at the time of his death.

Mr. Humphreys joined The Institute as a Member on April 2nd, 1929.

### John Wilbert Purcell, A.M.E.I.C.

Regret is expressed in placing on record the death at Toronto, Ontario, on January 6th, 1937, of John Wilbert Purcell, A.M.E.I.C.

Mr. Purcell was born at Listowel, Perth county, Ontario, on February 29th, 1872. From 1892 to 1896 Mr. Purcell was with the Detroit Electric Light and Power Company, and from 1896 until 1912 he was engaged on superintending the installation and the operation of the electrical plant of Hiram Walker and Sons. In 1912 Mr. Purcell joined the staff of the Hydro-Electric Power Commission of Ontario, first as assistant engineer, and then as electrical engineer, which position he held at the time of his death.

Mr. Purcell became an Associate Member of The Institute on September 20th, 1921.

## PERSONALS

F. G. Rutley, A.M.E.I.C., vice-president of the Foundation Company of Canada Limited, Montreal, was elected for a second term as president of the Canadian Construction Association at the annual convention of the Association held recently in Ottawa, Ont.

Mr. Rutley graduated from the University of Toronto in 1912 with the degree of B.A.Sc. and following graduation was for a time instrumentman on a field survey for the Alberta Interurban Railway Company, Calgary, Alta. In 1913 he became designer and field engineer on a water power development at Kananaskis Falls, Alberta, for the Calgary Power Company Limited, and in 1914 he joined the staff of The Foundation Company as resident engineer, which position he held for some years, acting for the company on the construction of the Magnetewan River bridge, and the Shaws Creek bridge on the Canadian Pacific Railway, the steam power house for the Dominion Iron and Steel Company at Sydney, N.S., a man shaft for the Dominion Coal Company at Glace Bay, and many other important works. Mr. Rutley next became secretary of the company and assistant to the general manager, subsequently becoming purchasing agent, assistant general manager, and in 1931 vice-president of the company.

J. Colin Kemp, A.M.E.I.C., has been appointed to assist in the organization of the Home Improvement Plan in the Province of Quebec. Mr. Kemp, who is a former executive of the National City Company at Montreal, was also for some time in private practice as a consulting engineer. More recently he has been assistant to the president of Dominion Stores Limited.

A. Ritchie, A.M.E.I.C., is now associated with the Whiting Corporation (Canada) Limited, at Toronto, Ontario. Mr. Ritchie, who was formerly chief engineer of construction with the city of Edmonton Power Plant, at Edmonton, Alta., was at one time Service and Research engineer with the Riley Engineering and Supply Company, Limited, Toronto, Ontario.

**C Kirkland McLeod, A.M.E.I.C., Becomes Alderman**

C. K. McLeod, A.M.E.I.C., was recently elected by acclamation as alderman for the City of Westmount, Que. Mr. McLeod graduated from McGill University with the degree of B.Sc. in chemical engineering in 1913, and immediately following graduation became plant chemist with the Canada Cement Company Limited, remaining with that organization for the next three years. From 1916 to 1919 he was engaged on the inspection of explosives with the Imperial Ministry of Munitions. In May 1919 Mr. McLeod was appointed chief chemist for the Dominion Glass Company, and a year later became superintendent

C. K. McLeod, A.M.E.I.C.

with the Consumers Glass Company. In May 1921 Mr. McLeod was with the Phoenix Bridge and Iron Works on design and sales of structural steel work. When this firm was taken over in October, 1923, by Canadian Vickers Limited, he occupied a similar position with the new organization. Since 1925 Mr. McLeod has represented the Permutit Company, Walter Kidde and Company and the American Hard Rubber Company in Eastern Canada, first as manager of the Chemical Engineering Equipment Company, then as a principal of Busfield McLeod Limited, and in 1934 he entered into business under his own name representing the same interests.

Mr. McLeod is very well known to the membership of The Institute as Secretary-Treasurer of the Montreal Branch. He has held this onerous office for ten years, and his resignation was accepted with great regret at the last meeting of the Executive Committee of the Branch. Mr. McLeod felt obliged to relinquish this secretarial work in consequence of the civic duties which he has now undertaken.

C. E. Frost, A.M.E.I.C.

Clifford E. Frost, A.M.E.I.C., was elected chairman of the Junior Section of the Montreal Branch of The Institute at the Annual Meeting of the Section held on January 18th, 1937. Mr. Frost graduated from McGill University in 1931 with the degree of B.Sc., and since that time has been an assistant engineer on the staff of the Harbour Commissioners of Montreal.

H. Massue, A.M.E.I.C., was elected chairman of the Montreal Branch of The Institute for the coming year, at the Annual Meeting of the Branch held on January 7th, 1937. Mr. Massue graduated from Laval University in 1913 with the degree of B.A.S., and following this was for eight months in 1914 at the Massachusetts Institute of Technology. Returning to Montreal Mr. Massue became connected with the Quebec Streams Commission, remaining with that organization until 1928, when he joined the staff of the Shawinigan Water and Power Company, Montreal, as assistant engineer.

## ELECTIONS AND TRANSFERS

At the meeting of Council held on January 19th, 1937, the following elections and transfers were effected:

*Member*

NARIMAN, Rustum Kaikhushro, A.C.H., (Royal Indian Engrg. College), consltg. engr., Sapper Lines, Secunderabad, India.

*Associate Members*

DEWAR, Charles Leonard, B.Sc., M.Sc., (McGill Univ.), outside plant and transmission engr., Bell Telephone Company of Canada, Montreal, Que.

GORDON, Harry J., B.Sc., (McGill Univ.), sales engr., Fred Thomson Co. Ltd., Montreal, Que.

KELLY, William Henry, B.Sc., (McGill Univ.), supt. in charge of logging operations, Buckingham, Que.

*Juniors*

HENRIKSON, Gunnthor John, B.Sc., (Univ. of Man.), Selkirk, Man.

JARRELL, Gordon James, B.A.Sc., (Univ. of Toronto), inspr., Beatty Bros., Fergus, Ont.

LAUGHTON, James Alexander, B.Sc., (Univ. of Man.), engr., Canadian Brown Steel Tank Co. Ltd., Brandon, Man.

*Transferred from the class of Associate Member to that of Member*

ASKIN, Robert J., B.Sc., (Queen's Univ.), mgr., Thunder Bay Paper Co., Port Arthur, Ont.
HOWRIGAN, Clyde Paige, mgr., Aranka Gold Mines, British Guiana. (Home) Bakersfield, Vt.

*Transferred from the class of Junior to that of Associate Member*

McILQUHAM, Walter Scott, B.Sc., (Queen's Univ.), engr., Dominion Engineering Works Ltd., Montreal, Que.

*Transferred from the class of Student to that of Associate Member*

JEHU, Llewelyn, Jr., B.Sc., M.Eng., (McGill Univ.), designer, Dominion Bridge Co. Ltd., Montreal, Que.
KING, Peter Campbell, B.Sc., (Queen's Univ.), laboratory instructor, Queen's University, Kingston, Ont.

*Transferred from the class of Student to that of Junior*

ANDERSON, Roderick Victor, B.A.Sc., (Univ. of B.C.), asst. refinery engr., Tropical Oil Co., Barranca, Bermeja, Colombia, South America.
FRANCIS, John Barten, B.Sc., (McGill Univ.), engr., Canadian Industries Ltd., Montreal, Que.
FRASER, Ralph Percy, B.Sc., (Univ. of Man.), junior voltage tester, Winnipeg Electric Company, Winnipeg, Man.
MacPHERSON, John Miles, B.Sc., (Univ. of N.B.), instr'man., N.B. Highway Dept., North Devon, N.B.

*Students Admitted*

BRICELAND, Emmett Vincent, (Queen's Univ.), Kingston Junction, Ont.
BROWN, Donald Whidden, (Queen's Univ.), 196 Stuart St., Kingston, Ont.
CLAIRMONT, Adolphe, B.A.Sc., C.E., (Ecole Polytechnique, Montreal), 198 St. Charles St., St. Johns, Que.
CUNNINGHAM, Donald David MacCoubrey, B.Sc. (E.E.), (Univ. of N.B.), 21 Lowell St., West Saint John, N.B.
DESJARDINS, Roger, (Ecole Polytechnique, Montreal), 1621 St. Hubert St., Montreal, Que.
DURANCEAU, Charles Arthur, (McGill Univ.), 3480 Harvard Ave., Montreal, Que.
HOPKINS, Alfred, B.E. (E.E.), (N.S. Tech. Coll.), Canadian Westinghouse Company, Hamilton, Ont.
MOTHERWELL, Charles Gordon, (McGill Univ.), 574 Cote St. Antoine Road, Westmount, Que.
McMILLAN, Thomas Stewart, (Univ. of N.B.), University of New Brunswick, Fredericton, N.B.
SCHEEN, Marcel, (Ecole Polytechnique, Montreal), 1230 St. Hubert St., Montreal, Que.
SCOTT, James Munroe, (Univ. of N.B.), University of New Brunswick, Fredericton, N.B.

## CORRESPONDENCE

Vancouver, B.C., January 26, 1937

The Editor,
The Engineering Journal.

Dear Sir,

Having been associated with The Engineering Institute of Canada and its predecessor for nearly thirty years I am one of the oldest members in British Columbia. I should like to claim the privilege of expressing my views on consolidation and ask for them the same publicity as has been given to contrary opinions. That I was also an active worker in favour of the B.C. Engineering Act, a Member of the B.C. Association Council in 1920 and in 1931, should indicate that I am unprejudiced as between the two bodies. As I am not in favour of anonymous publications I ask that my name be attached.

The Dominion of Canada has nine provinces, in each of which, with the exception of Prince Edward Island, there is an Assoeiation of Professional Engineers. As under the Dominion constitution the control of any professional body is solely a provincial affair, these associations can never be amalgamated or consolidated into a single unit. But why should not the requirements for registration be the same in all the provinces?

The answer is, first, that within each province the engineers themselves have not been unanimous; second, legislatures look on professional Acts, especially engineering, as class legislation, and insofar as a dissatisfied voter is more potential dynamite than a dozen complacent non-voluble engineers, they will pay more attention to that class of citizen than they will to any claim based on the "protection of the public." As long then as the Professional Associations remain individual with entirely different legal requirements for membership, entirely different educational requirements, entirely different professional training requirements, so long will professional engineers remain in the morass. Engineers early recognized this fact and in 1919 The Engineering Institute of Canada, at its own expense, called together representative engineers from all the provinces and formulated the "Model Act" with the hope that each province would adopt the principle. Expediency required divergence here and there, so that few of the eight provincial Acts are an exact copy of the model.

The Act in British Columbia, due to its legislatures both Liberal and Conservative being more progressive than in the other provinces, has probably surpassed other acts in stringency. British Columbia has also probably placed more stress on entrance requirements than have the others. Obviously it is desirable that there should be reciprocity between the provinces, i.e. an engineer registered in one province should be acceptable without proof of education or professional standing in any other province.

If all standards of education and professional experience were the same, British Columbia's Council would not then have to admit, because of diplomatic reasons, men of qualifications inferior to its own requirements. To accomplish this ideal spasmodic efforts have been made. In 1926 Mr. Geo. Walkem, President of The Engineering Institute and also President of the Professional Association, did a prodigious amount of work on the subject. On his retirement the matter lapsed. It was resurrected to some extent in 1931 when I was a member of the Board. Finally there was set up a Council of Four, then a Council of Eight, composed of members of the various Provincial Associations. But in all the years of their existence they did not evolve a single constructive suggestion which could be put before the various Provincial Associations even as a Report of Progress.

The Engineering Institute of Canada at its meeting in January, 1935, observed the stagnation and appointed a committee on Consolidation. In 1936 at Hamilton this committee reported. Two members of the Council of Eight were added to the committee on consolidation. A plenary meeting of The Institute Council in conjunction with the Committee on Consolidation met in Montreal in October, 1936, and set up a proposed set of by-laws which, if accepted, will completely change the constitution of The Institute, so that it will become the consolidation factor in the Provincial Associations around which could be developed uniformity of laws and professional requirements. Discussion at the E.I.C. General Meeting in Montreal on January 29th and 30th will be followed by a ballot of the whole corporate membership of The Institute.

Now a small body of engineers has taken exception and violent objection to the proposed consolidation. That is to be expected, as in my experience never at any time has there been complete unanimity on the Engineering Act or its amendments.

In 1920 the passage of the B.C. Engineering Act was disapproved by many of the same group. In 1924, 1925, 1926, 1929 and 1930 the Committee on Amendments had to compromise or withdraw much needed reforms in the Act, and in 1933 this same opposition was so virile that the whole amendment scheme was dropped and has not since been brought up. All disadvantages of the proposed consolidation scheme will be advanced by that body of objectors and so I will set forth what to me seems the evident advantage of the new setup. I quote the aims and objectives of The Engineering Institute of Canada "To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public." The highest professional consideration is the basis of its objectives—no thought of petty bickering of one branch of engineering with another, no thought of exploitation by its members of the public. Can we suggest higher ideals? To achieve them depends entirely upon the ethical standards of the members. After reading the list of the Presidents, Vice-Presidents, Councillors and Members of The Institute since its formation in 1887 no person need worry over a let-down of professional standing by The Engineering Institute of Canada.

The Registered Engineers in the various provinces are in the main not different from the members of The Engineering Institute of Canada. We would therefore not expect to find any deterioration in professional standing because of adherence to one organization or the other. It is felt that the years will remedy any substandard condition that may exist and that minimum professional requirements and a well observed code of ethics will convince the public that Canadian Engineers are all properly qualified.

The scheme of consolidation proposed by The Institute is at least a scheme. No other body has proposed seriously any alternative. If there is not complete satisfaction amendments can be made in accordance with the will of the majority. That perfection is not always reached on the first effort is evidenced by the fact that since 1920 there have been five changes in the B.C. Engineering Act. More are needed. But we must all admit that this Act of 1920 was infinitely better than no Act at all, and so is the consolidation scheme outlined by The Institute. Accept it, amend its inconsistencies from time to time, but get something started.

The Institute has been developed to include all branches of engineering. Mining, electrical, mechanical, chemical and other branches of engineering have their own associations dealing with their own problems and some of these engineers advance the argument that an all-including Institute is not necessary and that The Engineering Institute should confine itself to civil engineering only. May I point out that civil engineering is divided into many subdivisions each of which is probably as large in the number of its members as the usually named more general branches of engineering. An engineer under any one of these subdivisions must unite with others to disseminate the literature and knowledge of that particular calling. But that does not preclude him from sympathetically assisting the other broader field covered by The Institute.

For fifty years The Institute has been looked upon as a leader in the engineering profession. When new legislation or amending legislation is required the prestige of these years is something that cannot be overlooked in the provincial fields. To many members of legislatures it is the hall mark of perfection. Do not discard this winning card for the sake of holding a joker whose unmasked features can only disclose the face of prejudice. In other provinces The Institute is not held in the Holy Horror that some of our registered men in British Columbia seem to have for it.

Notwithstanding some members' claim that The Institute has never accomplished much (which view can only be held by one who has accomplished nothing for The Institute) The Engineering Institute for fifty years has catered to the professional welfare of Canadian engineers from coast to coast. The amount of time and money it has spent on efforts to better the engineering profession cannot be defined in dollars.

Another and more widespread contention, that the component associations' representatives of one councillor from each association would be swamped by the branch councillors is entirely a misconception, for in the past ten years probably ninety per cent of the councillors have been registered in the provinces they represented. Can you imagine Wootten, Swan Buchan, Walkem and hundreds of others as selling the Associations 'down the river'?

And finally, The Engineering Institute of Canada is Canadian. Whether native born or immigrant, our living in engineering is made in Canada and if we cannot support an all-Canadian organization we should at least keep quiet on the subject.

At a Pittsburgh dinner a few days ago Myron Taylor, Board Chairman of the United States Steel Company, spoke the following words, except those in italics which I have paraphrased:

> "I have faith that if patience is invoked, if all prejudice and ill feeling are discarded, if honest intention to co-operate predominates, if self-interest is subordinated to the common good, we can and must, through common effort... accomplish that equitable relationship between the *Provincial Associations, The Engineering Institute of Canada and other technical or scientific organizations* which will solve our existing *professional* discord."

Let us accept that thought and get along with our professional improvement.

W. H. Powell, M.E.I.C.

L'Assomption,
January 13th, 1937.

The Editor,
The Engineering Journal.

Dear Sir:—

I join with all engineers in rejoicing over the recent election of C. K. McLeod, A.M.E.I.C., to the Council of the City of Westmount. Surely, any municipal administration is to be congratulated on having that fine type of citizen at the helm.

Besides being a level-headed and public-spirited citizen, Mr. McLeod is also a very prominent member of our profession. Was any mention made of that in any of our newspapers? Both the "Montreal Star" and "Le Canada" published photos and a short write-up, but neither mentioned the fact that he is an engineer. Where was our publicity committee?

We, as engineers, are often accused of not taking a sufficient part in the legislative domain. But when some member of the profession storms the bulkwarks the public isn't even told he's an engineer. I am not in the least suggesting that this should be introduced into the campaign; but I, for one, should have liked to have seen an A.M.E.I.C. after his name wherever published. Those who are fellow members can profit by the reflected glory, and Mr. Public who doesn't know what the letters mean may be moved to find out—which wouldn't be such a bad thing for The Institute.

The medical practitioner never forgets the M.D. and nobody that I know of has ever accused him of conceit for carrying it around.

Very truly yours,

Herve A. Gauvin, Jr.E.I.C.

## Planning and Housing Officials

A conference of planning and housing officials is to be held in conjunction with the annual meeting of the Canadian Union of Municipalities at Ottawa, commencing on March 16th, 1937.

All those interested, including members of Town Planning Commissions and Home Improvement Associations, are cordially invited to attend.

## Recent Additions to the Library

### Proceedings, Transactions, etc.

Institution of Mechanical Engineers: Proceedings, vol. 132, 1936.

### Reports, etc.

*Governor of the Panama Canal:* Annual Report for the year ended June 30th, 1936.

*Canada, Bureau of Statistics:* Statistics of Steam Railways of Canada, 1935.

*American Institute of Mining and Metallurgical Engineers:* Year Book, January, 1937.

*Canada:* Report of the Minister of Public Works for the year ended March 31st, 1936.

*American Society for Testing Materials:* Tentative Standards 1936.

*Edison Electric Institute:* Report of the Hydraulic Power Committee on Penstocks, December 1936.

*Federal Co-ordinator of Transportation, United States:* Report of Mechanical Advisory Committee to December, 1935.

*City of Hamilton, Ontario:* Annual Report of the City Engineer for the years 1934 and 1935.

*Canada, Dept. of Mines and Resources:* Memorandum Series No. 65. Analyses of some Fuel Oils Sold in Canada.

*Montreal Light, Heat and Power Cons.:* 20th Annual Report, 1936.

*Association of Appraisal Executives:* Basic Standards of Appraisal Practice and Procedure.

### Technical Books, etc.

Canadian Almanac, 1937 (*Copp Clark Co. Ltd., Toronto*).
Federation of British Industries: Fuel Economy Review, 1936.
S.A.E. Handbook 1936.

## BULLETINS

*Nickel Products.*—A 50-page booklet has been received from Canadian Nickel Products Limited, Toronto, which contains information regarding the use of high grade nickel alloys in modern engineering developments such as hydroelectric plants, steam generation, highways, pumps, aircraft, automobiles, etc. Technical facts and data are included.

*Diesel Engines.*—Dominion Engineering Company, Montreal, has issued a 4-page leaflet containing specifications and a description of Dominion-Crossley, Types BW1 and BW2 vertical four-stroke cycle Diesel engines.

*Unit Air Conditioners.*—An 8-page bulletin issued by the Carbondale Division of the Worthington Pump and Machinery Corporation announces a new line of air conditioning units which are made in 5 models in both vertical floor and horizontal suspended types. Particulars of four models of shower condensers are also given.

*Lathes.*—Brown and Sharpe Mfg. Company, Providence, R.I., has issued a 4-page folder containing particulars and specifications of their Universal hand lathes and polishing and finishing machinery.

*Magnetic Switches.*—Two 4-page leaflets received from the Canadian General Electric Company Ltd., Toronto, describe their CR-7006 and 7008 magnetic switches full-voltage starters for induction motors.

*Glassware.*—A 4-page bulletin received from Canadian General Electric Company Ltd. describes the company's rippled street-lighting glassware.

*Cable.*—An 8-page booklet issued by the Canadian General Electric Company Ltd. contains particulars of technical installations and specifications of rubber insulated service cable from pole to and into buildings.

*Switchboard Instruments.*—The Canadian General Electric Company Ltd. have published a 12-page booklet which describes a complete line of rectangular switchboard instruments, including ammeters, voltmeters, power-factor meters, etc.

*Unit Heater.*—A 4-page folder published by the Canadian General Electric Company gives particulars of an electric unit heater for circuits of 550 volts and below; sizes of 10 kw. to 20 kw.

## Report of Mechanical Advisory Committee to the Federal Co-ordinator of Transportation

### December 27th, 1935

Two years ago the United States Federal Co-ordinator of Transportation appointed a committee of six members to advise regarding mechanical problems affecting the railroads. Under the chairmanship of L. K. Sillcox, M.E.I.C., vice-president of the New York Air Brake Company, this committee has prepared a comprehensive report which has just been issued by the Association of American Railroads, Mechanical Division.

The committee's attention was devoted to eight major topics as follows:

1. Steam locomotives.
2. Internal combustion engine locomotives.
3. Electric locomotives and electrification of steam railroads.
4. Freight train cars.
5. Rail-highway vehicles.
6. Passenger train cars.
7. Rail motor cars.
8. Streamlined trains.

The committee received and considered a great amount of documentary evidence based upon the practical experience of railroad organizations and manufacturers. Its report makes available a mass of engineering, historical and mechanical material hitherto inaccessible. To mention only a few examples, the committee has reviewed the designs of sixty-one types of steam locomotives. It has collected and discussed pertinent data regarding the present status of internal combustion locomotives. It gives up to date information regarding the various alternative methods for refrigerating freight cars. It has made a study of container service and transfer methods, and deals with the many problems involved in the adaptation of existing passenger equipment to the high speeds and new standards of comfort required in present day service.

The report is, in effect, a survey of the modern art in the construction of railroad train equipment, and throws light on the practicability of many suggested innovations and developments.

## Acoustical Terminology

A standard Acoustical Terminology for "sound" engineers which will eliminate confusion in movie, radio and building fields has just been completed, according to an announcement of the American Standards Association.

The committee gives a broader meaning to the word "noise" now defined in terms of the listener as an "unwanted" sound, rather than in terms of the sound itself. Another section of the standard deals with architectural acoustics. Other parts dealing with the conversion of sound to electrical energy, and with acoustic transmission systems, will be of particular value to the movie and radio professions.

A separate section for music brings engineers and acoustical experts into agreement with musicians on a basic standard pitch, the importance of which can be judged by the fact that an increase of only 4.14 per cent in pitch carried out through the entire keyboard of a piano would throw an additional strain of something like half a ton on the framework of the instrument.

The Association has already approved two other standards in the "sound" field. One of these, completed eight months ago, establishes "reference" and "intensity" levels for sound measurement. The other specifies the characteristics of "noise meters" used by builders, radio engineers and music teachers.

## Basic Standards of Appraisal Practice and Procedure

The reports of the Association of Appraisal Executives' Committee have been embodied in a recently issued pamphlet entitled "Basic Standards of Appraisal Practice and Procedure." This statement of principles and definitions should prove of much value to those using or relying upon appraisal reports.

The need for more generally accepted standards of appraisal practice and for greater uniformity in terminology used by appraisers has been long-recognized, and there is a demand upon the appraiser, both from business men and from regulatory bodies, for clearer definitions of the appraiser's responsibility and procedure.

Under the heading "Principles of Valuation" the pamphlet describes concepts and bases of value, and sets forth that the main goal of an appraisal is the determination of "Value for Use."

There are included about one hundred definitions of terms frequently found in appraisal reports.

The publication discusses the elements of original and historical cost, trended cost, cost of reproduction new; considers depreciation problems, and sets forth approved methods of valuation and conclusions which the members of the Association have reached through experience in appraising industries, public utilities, commercial properties and real estate.

## Erratum

In publishing a review of the Electrical Engineers' Handbook, published by John Wiley and Sons, in the January issue of The Journal, it was not made clear that the cost of these two volumes is as follows: The one on Electric Communications and Electronics $5.00, and that on Electric Power, $6.00.

# BRANCH NEWS

## Border Cities Branch

*J. F. Bridges, A.M.E.I.C., Secretary-Treasurer.*
*F. J. Ryder, Jr.E.I.C., Branch News Editor.*

After the regular monthly dinner meeting held at the Prince Edward hotel on Friday evening, December 11th, 1936, a meeting for the election of officers was held. With sixteen members present the meeting was called to order by T. H. Jenkins, A.M.E.I.C., the retiring chairman, who gave a short summary of the activities and discussions throughout the past year. The committees which had assisted him were praised for their co-operation which has made the year a very successful one.

Boyd Candlish, A.M.E.I.C., presented the Secretary-Treasurer's report, noting the improvement in the financial status of the Branch.

C. G. Armstrong, A.M.E.I.C., Branch Councillor, then gave a short synopsis of his activities at the Plenary Meeting. The points stressed were: the question of Consolidation of The Engineering Institute with the various Provincial Professional Associations, and the coming Semi-centennial of The Institute in June.

D. T. Alexander, M.E.I.C., spoke for the papers committee and was highly commended for his labours.

Owing to the absence of members there were no reports from the Membership Committee or the Educational Committee.

J. B. Clark Keith, A.M.E.I.C., and F. J. Ryder, Jr.E.I.C., were appointed scrutineers and nominations were called for the various Branch officers.

C. F. Davison, A.M.E.I.C., was elected chairman by acclamation. E. M. Krebser, A.M.E.I.C., was elected vice-chairman and J. F. Bridges, A.M.E.I.C., secretary-treasurer.

It was moved by H. J. A. Chambers, A.M.E.I.C., and seconded by F. Stevens, A.M.E.I.C., that the Councillor should bring to the attention of Headquarters the radio broadcasting that is being undertaken by the legal and medical professions and to see if something of a similar nature could not be arranged in order to inform the public of the work that is carried on by engineers. Carried unanimously.

W. H. Baltzell, M.E.I.C., who has been a member of the Branch for a long period, was presented with a gold membership badge for his services and received a hearty ovation from those present.

In the remaining time, Mr. Baltzell reviewed some of the peculiar problems which had confronted him in the past and his method of approaching the solution of them. Among the most outstanding was the manufacture of a cotton press, the design of a peculiar type cannon, furnaces built in waterproof tanks in areas subjected to floods, blast furnaces and many others. Mr. Baltzell believes that he made the first electric flash-light and battery in the United States. However it was not an invention as he merely improved on one borrowed from an English friend.

R. C. Leslie, A.M.E.I.C., who was amazed at Mr. Baltzell's memory for details as far back as 1867, moved a hearty vote of thanks with which everyone unanimously agreed.

### Drop Forgings

The Border Cities Branch held their monthly dinner meeting in the Prince Edward hotel, with twenty-three persons present. After the dinner, T. H. Jenkins, A.M.E.I.C., the chairman, introduced Mr. R. E. Waldron, chief engineer of the Dominion Forge and Stamping Company Limited, Walkerville, who delivered a paper on "Drop Forgings."

A brief historical sketch of the development of drop forging was given. Very little information is obtainable on this subject for in the early days the art of forging was kept in the family with great secrecy, and was passed on from father to son. The first known method was the use of the hand hammer to work brass and iron that had been heated. The art of smelting iron was unknown at that time. The product obtained in those days was far superior to present day attempts. Later the hand hammer was replaced by the pedal-operated hammer and then by horse-motivated power followed by the use of water and steam power. Naismith's hammer is the ancestor of the modern steam-hammer of which there are several types.

On this continent, the New England states was at first the centre of the drop-forging industry. However, with the coming of the automobile the centre of the industry moved west to the vicinity of Detroit. At present 80 per cent of all drop forgings are used by the automobile factories.

Mr. Waldron then gave examples of the operations required to forge a connecting rod and a crank shaft for an automobile, showing the form of the material after each operation with samples taken from actual production.

During each operation scaling, cleaning and oiling of the metal takes place. Usually all operations are finished with the material being given only one heat. After the piece is finished it is heat-treated, quenched and drawn.

With the aid of plaster of paris dies of the crank shaft, the speaker explained how the dies would wear down and would have to be recut. A very careful check of the finished pieces gave warning when it would be necessary to recut the dies.

Mr. Waldron received a hearty vote of thanks which was moved by Boyd Candlish, A.M.E.I.C., and endorsed by everyone.

## Halifax Branch

*R. R. Murray, A.M.E.I.C., Secretary-Treasurer.*
*C. Scrymgeour, A.M.E.I.C., Branch News Editor.*

The annual meeting of the Halifax Branch of the E.I.C. took place at the Halifax hotel on Thursday, December 17th, 1936, when there were about thirty members present.

After the election of officers, the Chairman, C. S. Bennett, A.M.E.I.C., introduced Professor H. W. McKiel M.E.I.C., of Mount Allison University and a member of the Plenary Council, who gave a particularly interesting and instructive address on the subject of the proposed consolidation or amalgamation between The Engineering Institute of Canada and the various professional Provincial bodies, as well as with other engineering societies. Professor McKiel pointed out in his opening remarks that he found a general feeling prevailed that the Council did not feel consolidation was necessary, but this impression was incorrect, as the Plenary Council did feel that consolidation was both necessary and would in time be made possible, but that the many difficulties of putting consolidation into effect, due to the varied ideas on this subject in the respective provinces, made it necessary for slow and deliberate action before a definite proposition could be submitted which would be acceptable to the engineers in Canada as a whole.

The particular drawback of the situation at present apparently, according to Professor McKiel's address, is the difficulty surrounded by Clause 7 *b* of the recommendations made by the Committee on Consolidation.

At the conclusion of the speaker's address, Harold Johnston, M.E.I.C., spoke at length outlining the expressions of opinion as generally agreed upon by the Halifax Branch, and in addition, several other speakers were heard on the same subject.

## Hamilton Branch

*A. R. Hannaford, A.M.E.I.C., Secretary-Treasurer.*
*W. W. Preston, S.E.I.C., Branch News Editor.*

### Annual Meeting

When the Hamilton Branch of The Institute held its annual dinner meeting on January 6th, 1937, in the Wentworth Arms hotel, seventy members saw how an annual meeting is made unusually interesting. The highlight of the evening was a burlesque address by Geo. E. Patton of Toronto, but other features also contributed much to the members' enjoyment. The business session which followed the dinner was as brief as possible. With W. Hollingworth, M.E.I.C., the retiring chairman, as presiding officer, A. Love, M.E.I.C., the retiring secretary-treasurer, presented his annual report, which showed a healthy financial condition and an excellent attendance at the general meetings of 1936. Mr. Hollingworth commended the retiring secretary-treasurer for the enthusiastic service which he has rendered the Branch, and pointed out that credit for the largely attended meetings was due in no small measure to the outstanding succession of speakers secured by W. J. W. Reid, A.M.E.I.C., retiring chairman of the Papers Committee. The election of officers was a simple matter, as the report of the Nominating Committee was accepted without amendment. Chairman-elect Col. E. G. MacKay, A.M.E.I.C., then took the chair. In a few well chosen words he expressed his thanks for the honour bestowed on him, and added a word of congratulation to Mr. Reid who had not only arranged a fine series of meetings for 1936 and the present meeting, but had also an announcement to make concerning the next five meetings. Two of the prominent visitors, R. L. Dobbin, M.E.I.C., of Peterborough, and Mr. Jos. Culley of the Construction Association, brought words of greeting. The guest speaker of the evening, the Toronto entertainer, Geo. E. Patton, was introduced by W. Patterson, of Brantford. Mr. Patton had as his subject "The Tropical Valley of Alaska." In a unique address with lantern slides he uncovered south sea scenery on an Alaskan sea shore in the middle of Australia. He kept his hearers in continual tears of laughter as he kept pointing out formations of bare rock which were likely to be overlooked. The lecture added to (or subtracted from) the members' knowledge of geography, geology and streamlining. Mr. Patton later gave two humorous readings. The vote of thanks was moved by E. P. Muntz, M.E.I.C.

### Acoustical Engineering

On January 14th, 1937, Mr. W. J. Hodge, acoustical engineer with Johns-Manville of New York, addressed the Hamilton Branch at McMaster University on the subject of "Acoustics and Sound Control." The attendance of 122 included several members of the Hamilton Chapter, Ontario Association of Architects, and representatives of the Hamilton Construction Association.

Sound, Mr. Hodge stated, is the father of vibration, and vibrat io the father of sound. When sound is recorded on a phonographic disc lines of vibration are inscribed thereon, and when the disc is run in a phonograph the lines of vibration produce the original sound. By means of a sound film the speaker reviewed the important principles underlying vibrations and sounds. The unit of sound measurement is the decibel which was defined as the slightest change in loudness that can be perceived by the human ear. The range of hearing is bounded by zero decibels on the sound scale and 120 decibels. Zero is the level which is just inaudible and on reaching the 100 decibel level the ear experiences lasting pain. Mr. Hodge demonstrated various sound levels using an instrument called the noise meter. He expressed the opinion that when the decibel scale is more widely known, it will be just as informative as our temperature scale.

The problems which the acoustical engineer faces are of two types. The first, which may be termed the acoustics of room interiors, deals principally with air-borne sounds. It may be a question of improving audition in a public hall, that is eliminating echoes and reverberations, and at the same time preserving clarity of tone with its many harmonics, or it may be a question of reducing a noise level as in an office. The second type of problem, which may be classed as sound isolation, treats with vibrations through materials. The engineer attempts to prevent sounds and vibrations generated in one place from reaching another through interposing material such as walls and floors. In this division comes the isolation of machine-vibrations from the building which houses the machine. Frequently both problems must be considered simultaneously.

Although the architectural design of a room has a considerable effect on sound control, the sound absorbing properties of the building materials must be carefully considered. When sound waves strike a hard surface they are readily reflected, but when they strike a porous material they become entangled in the pores and are dissipated (rather than absorbed) as heat. The thicker the material the better the absorption. However, excessive thickness will make the room too dull. Thin flexible materials also absorb sound well. Even though hard surfaces reflect sound, a perforated sheet of metal placed over a porous material is just as effective as the sound absorbing material by itself. The truth of this statement Mr. Hodge verified by demonstration.

To prevent the transfer of vibrations between adjacent bodies, all solid connections must be separated and some isolating material such as hair felt interposed. The speaker demonstrated the amount of this absorption by comparing amplified noises which resulted when he placed a small running motor on a thin concrete slab (whose vibration noises were amplified) with the noise generated when he placed the motor on an isolated platform resting on the slab.

In conclusion Mr. Hodge described a modern acoustical laboratory and answered a number of questions.

Following a vote of thanks the meeting adjourned for refreshments.

### The Oil Industry

At a joint meeting of the Hamilton Branch of The Institute and the Hamilton Chemical Association at McMaster University on January 20th, 1937, F. A. Gaby, D.Sc., M.E.I.C., Executive Vice-President of the British American Oil Company, Limited, gave an address entitled "The Engineer and Chemist in the Oil Industry." Dr. Gaby, who was introduced by J. B. Carswell, M.E.I.C., discussed the magnitude of the oil industry on this continent, its importance to the people of the world, and the place held by the engineer and chemist in bringing it to its enormous and valuable position.

The oil industry began about eighty-five years ago, though the use of oil was known for centuries; the Egyptians preserved mummies with it and built asphalt streets. In 1850 an Englishman eliminated coal oil from coal, and a few years later oil was obtained from wells in Pennsylvania. The first oil well in Canada was operated in 1858. The production from our industries reached a peak in 1924 and has since declined. Canada has had no fields of any magnitude, but it is hoped that a recent discovery on the west flank of the Turner Valley in Alberta will be exceptionally productive. The oil industry, now advanced to the place where its derivatives are counted by thousands, employs a million people and represents an investment of fourteen billion dollars.

In outlining the various problems that confront the engineer and the chemist in the oil industry, Dr. Gaby referred to the methods of finding deposits, drilling, pumping, transportation, refining and marketing. It is the engineer's task to locate pockets of oil and gas. The chief difficulty is to find suitable rock formations. When the geology of a district cannot be interpreted, the indirect methods of prospecting, such as by seismograph, are useless, and bore holes must be drilled. Drilling is an expensive operation and requires a great deal of skill. In the rotary method, which is the most popular, the problem is to direct the path of the drill at various angles through different rocks. The speaker praised the mechanical engineers for designing drills which can penetrate 13,000 feet underground without breaking under the tremendous torsional strains developed. When a drill strikes an oil pocket there may be sufficient gas pressure to drive out the oil, but frequently it must be pumped. A turbine pump, Dr. Gaby stated, on a well from 6,500 to 7,500 feet deep and having a five-inch discharge pipe, will deliver about 2,500 barrels per day. The magnitude of the transportation problem is apparent from the fact that one tenth of the total tonnage carried by the railways is for the oil industry. The early methods of refining depended largely on physical rather than chemical considerations, but it is now realized that pressure, temperature and catalytic actions are of supreme importance. The practice of oil cracking during the past twenty-three years has provided a great boom to the industry in U.S.A. Oil being lost in gas is separated by a squeezing process, but 95 per cent of the waste gas is burned because of high transportation costs. As the trend of the automotive industry is to increase speed there is an ever enlarging market for products of the oil industry. Diesel engines in ships, heavy trucks and busses, and agricultural implements also provide a field for the oil industry.

In closing, Dr. Gaby told his hearers that the oil industry had suffered long from lack of technical research, but now that engineers and chemists are adopting scientific methods to replace empirical methods, conditions are much better. He expressed the opinion that if the technical man took a greater interest in political economy and its problems, world conditions would also improve.

L. W. Glegg proposed a vote of thanks which was heartily supported.

## Montreal Branch

### Annual Meeting

The annual general meeting of the Montreal Branch of The Institute was held on January 7th, 1937, with J. B. D'Aeth, M.E.I.C., in the chair.

H. Massue, A.M.E.I.C., was elected chairman of the Branch for the year 1937, and Brian R. Perry, M.E.I.C., vice-chairman.

Business included the reception of the following reports: The Executive Committee; the Financial Statement, showing a cash surplus of $1,349.00; The Membership Committee, the total membership of the Branch is 1,181, being an increase for the year of 20 members; and the Papers and Meetings Committee.

The meeting received with sincere regret the resignation of C. K. McLeod, A.M.E.I.C., which terminates a period of twelve years of able service as Secretary-Treasurer of the Branch.

Following the meeting, moving pictures were shown and refreshments served.

### Petroleum Products

At the meeting of the Branch held on January 14th, two papers were presented: one entitled "Petroleum Products and the Automobile," by R. S. Weir, A.M.E.I.C., of Imperial Oil Limited, Montreal, and one on "Gasoline for To-day's Automobile," by Mr. G. M. Connor, of the Ethyl Gasoline Corporation, Toronto, Ontario.

### Modern Trends in Lighting

Mr. A. L. Powell, supervising engineer of the Incandescent Lamp Department, General Electric Company, New York, addressed the Branch on January 21st, his subject being "Modern Trends in Lighting."

Mr. Powell has had much to do with many outstanding lighting developments in the past two decades, and gave an exceptionally interesting talk illustrated with numerous coloured slides.

Prior to the meeting an informal dinner was held at the Windsor hotel.

R. N. Coke, A.M.E.I.C., was in the chair.

### Junior Section

At the annual meeting of the Junior Section of the Branch held on January 18th, C. E. Frost, A.M.E.I.C., was elected chairman of the Section, P. E. Savage, S.E.I.C., was elected vice-chairman, and Messrs. L. Trudel, S.E.I.C., and V. S. Upton, S.E.I.C., were elected to the Executive Committee.

At this meeting H. Massue, A.M.E.I.C., chairman of the Montreal Branch, gave a very interesting talk on "Economic Trends and Their Effect on the Employment of Engineers," in which the speaker analyzed economic trends and their lesson to the engineer.

## Niagara Peninsula Branch

*P. A. Dewey, A.M.E.I.C., Secretary-Treasurer.*
*C. G. Moon, A.M.E.I.C., Branch News Editor.*

With Chairman George H. Wood, A.M.E.I.C., presiding, the fourth dinner-meeting of the season was held at the Fox-head Inn on December 16th, 1936.

Mr. J. W. Bateman, manager of the lighting service department, Canadian General Electric Company, Toronto, had prepared a paper dealing with "A New View-point in Lighting." The subject covered newer developments in the lighting field brought out by recent research into the relationship between vision and lighting. Previous technical progress dealt largely with light sources, reflectors and the control and distribution of light, but it is now realized that seeing is a partnership of vision and lighting.

Mr. Bateman was unavoidably prevented from attending the meeting and Mr. H. C. Jones, of the same department, dealt most capably with the subject, explained the slides and answered the many questions which followed.

Mr. Graham of the A.I.E.E. spoke briefly in appreciation of the courtesies of the Branch meetings being extended to local members and Messrs Gisbourne, Buss, McKenzie and Griffiths took a prominent part in the discussion which followed the speaker's address. Councillor E. P. Murphy, A.M.E.I.C., it is understood, was attending another meeting in Montreal.

### Transmission of Speech and Music

A joint dinner meeting with the Niagara District Chemical and Industrial Association was held on January 14th, at the Leonard hotel in St. Catharines.

D. G. Geiger, A.M.E.I.C., transmission engineer with the Bell Telephone Company, was the principal speaker. His address dealt with the transmission of speech and music and, aided by a loud-speaker phonograph attachment, he was able to demonstrate effectively the variation in tone caused by the elimination of upper or lower harmonics.

An attendance of 106 filled the large dining room of the hotel, giving promise of a healthy up-swing and encouraging the officers in their endeavour to make the Niagara Peninsula noted for good meetings.

W. D. Bracken, A.M.E.I.C., introduced the speaker as an old school friend and Mr. Harold Fair, of the Chemical Association, seconded by E. P. Murphy, A.M.E.I.C., proposed the vote of thanks.

At the close of the meeting an Executive session was held to deal with various routine matters and some questions concerning "Consolidation." Clause 7 *b* was discussed and, in an endeavour to smooth out differences which threaten to wreck the whole scheme, a unanimous resolution was passed asking Council to reconsider the stand taken at the Plenary Meeting.

## Ottawa Branch

*F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.*

The 27th annual meeting of the Ottawa Branch of The Engineering Institute of Canada was held at the Auditorium of the National Research Laboratories, Sussex Street, on the evening of January 14th, 1937. About 75 members were present, the retiring chairman, E. Viens, M.E.I.C., presiding.

The chairman's address presented a brief summary of the activities of the Branch for the year and also touched upon certain steps that had so far been taken in connection with the proposed consolidation of the profession in Canada through the facilities of The Institute in co-operation with the provincial engineering associations.

The secretary-treasurer's report revealed that the finances of the Branch were in good condition with a cash balance (including bank balance, cash on hand and government bonds) of $1,659.07, and total assets of $1,739.82. The total membership is 332 resident and 70 non-resident members. The death was recorded with deep regret of Mr. W. T. Cuffe-Quinn, Branch Affiliate.

In accordance with the motion passed at the last annual meeting the Branch donated two sets of draughting instruments to the Ottawa Technical School for presentation as prizes for proficiency in draughting. A copy of "Standard Handbook for Electrical Engineers" was sent to the Hull Technical School to be awarded to one of the students.

During the year the Managing Committee held eleven meetings for the transaction of general business. The Branch itself held eighteen luncheon meetings at which addresses were heard on engineering and allied topics. Attendance at these luncheon meetings varied from 59 to 129.

Reports of Committees presented, after the Chairman's address and the Secretary-Treasurer's report, included: Proceedings Committee by E. M. Dennis, A.M.E.I.C., Membership Committee by N. B. MacRostie, A.M.E.I.C., Advertising Committee by G. R. Turner, A.M.E.I.C., and By-laws and Reception Committee by T. A. McElhanney, A.M.E.I.C.

The report of the Aeronautical Section stated that this section held seven evening meetings at which technical papers relating to aeronautical engineering were given. The average attendance at these meetings was 28. During the year the chairman was Dr. J. J. Green, of the National Research Laboratories, and the Secretary was J. T. Dyment, S.E.I.C., of the Aeronautical Engineering Division, Department of National Defence. A small cash grant by the Ottawa Branch of The Institute is given over to this Section each year.

A vote of $25 was also passed by the Branch to take care of further awards during the forthcoming year to the Ottawa and Hull Technical Schools.

There was a lengthy discussion on certain proposals on the question of consolidation after which the branch adopted a resolution which recommended to the E.I.C. Council that steps be taken to change the name of The Institute to The Royal Engineering Institute of Canada if, as and when the consolidation of the engineering profession takes place.

After the reading and discussion of reports, together with business arising therefrom, the election of officers for the new year was announced.

The retiring chairman, E. Viens, M.E.I.C., then called upon the new chairman, J. G. Macphail, M.E.I.C., to take the chair.

G. J. Desbarats, Hon.M.E.I.C., and Dr. R. W. Boyle, M.E.I.C., moved the vote of thanks to the retiring officers. Dr. Boyle made special reference to the retirement of F. C. C. Lynch, A.M.E.I.C., who had served the Branch for more than fifteen years as secretary-treasurer.

After the business portion of the meeting was concluded, W. L. Saunders, A.M.E.I.C., of the Department of Highways, Ontario, who took part in the Vimy Pilgrimage and later visited Germany, gave an illustrated address on construction work in Germany, with particular reference to highways construction. Following his address, refreshments were served, the meeting lasting until midnight.

### Some Observations on Highway Construction in Germany

Road building machines in use in Canada and the United States are toys by comparison with the machinery being used in Germany for the construction of super-highways, stated Mr. Saunders. The work was all let on contract and conditions, he said, were an eye-opener to him. The specifications demanded were extremely high.

The men working on road construction lived in camps and had accommodation as good as in a hotel. There were even bedspreads on the cots. They were well paid and married men, working on road jobs, received extra pay as separation allowance.

Formerly there was no co-ordination in road building in Germany, Mr. Saunders said. Each province built its own roads with the result that there were roads of all kinds and widths, with numerous intersections and grade crossings. Now there is a system of super-highways under way and the entire country is under a minister of highways. Thousands of pieces of heavy machinery are being used in building these roads which are in parallel sections each 29 feet wide, each section being a one-way road

The road building programme in Germany has been going on for about three years and up to May 1936 some $350,000,000 had been spent, which provided 40,000,000 hours of work to 118,000 men. The programme provides for between 4,000 and 5,000 miles of highway and all has been located and improved, the speaker said.

The new super-highways, he added, by-pass municipalities; there are no grade crossings, and all are in new locations. All crossings are under or over and it is estimated that 10,000 bridges will be required. Pedestrians must also use bridges to cross the highways.

There is no speed limit on the one-way super-highways which were being designed for a half-century hence. In answer to those who said Germany was building the roads for purposes of war, Mr. Saunders said the country was doing a very thorough job and if the roads were to be used for war, such war was a long time off as there was still a great deal of construction ahead of the nation.

### The Greatest Menace to Canadian Forests

At the last noon luncheon of the 1936 calendar year, held at the Chateau Laurier on December 17th, the members of the Ottawa branch listened to a most interesting address upon the subject "The Greatest Menace to Canadian Forests." Dr. J. M. Swaine, director of Research of the Dominion Department of Agriculture, and former Associate Dominion Entomologist, was the speaker.

E. Viens, M.E.I.C., chairman of the Ottawa Branch, presided and in addition head table guests included: Major General A. G. L. MacNaughton, M.E.I.C., Dr. G. S. H. Barton, C. J. Booth, Dr. A. Gibson, F. C. Askwith, A.M.E.I.C., D. Roy Cameron, M.E.I.C., L. L. Bolton, M.E.I.C., T. A. McElhanney, A.M.E.I.C., T. S. Mills, M.E.I.C., F. E. Lathe, and J. McLeish, M.E.I.C.

"The total mortality caused by insect ravages in our forests is many times greater than that caused by fires," stated Dr. Swaine, "yet only a few thousand dollars a year are spent on the investigation and control of forest insect pests, whereas very large sums are spent every year towards the control of forest fires. The time has come in this country, indeed it is long since past, when the control of forest insect and fungus pests should receive the same sort of attention that is devoted to the prevention and control of fires.

"During the last thirty years or more, fires have destroyed some 70 million cords of balsam fir and spruce pulpwood," he remarked. "But during one great insect outbreak alone, more than 200 million cords of balsam fir and spruce pulpwood were killed."

Dr. Swaine referred to a few of the more important forest insect epidemics: the small four-winged larch sawfly that first came over from across the Atlantic about a hundred years ago and that did inestimable damage across the country before efforts were undertaken to fight it by the introduction of parasites, the spruce budworm which caused appalling losses in Eastern Canada in the last quarter of a century, small bark beetles of various kinds, and others.

Another sawfly, called by entomologists the European Spruce Sawfly, was noted in 1930 doing extensive injury to the spruce in the Gaspe peninsula. The Dominion Entomological Branch of the Department of Agriculture concentrated its efforts upon fighting it through the liberation of imported parasites since it appeared to be immune from attack from native parasites.

This sawfly has subsequently spread eastward across New Brunswick and into Nova Scotia, and westward across the St. Lawrence river and past lake Timiskaming into Ontario. The heavy infestation and actual mortality of the timber is still confined to the centre of the Gaspe peninsula, where the injury has been very heavy, but how rapidly the light infestations will develop into the destructive stage no one can yet foretell, remarked Dr. Swaine.

With regard to the most valuable stands aeroplane dusting with poisonous dusts may sometimes be used, but this costs money. With the spruce pest the cost is from $3 to $6 an acre, and the operation, due to the life habits of the sawfly, would need to be repeated for at least several successive seasons. No other direct method of control could be effective.

The entomologists therefore hope to control this epidemic with the importation of the sawfly's native parasites from their original home in Europe. Over there, parasites have succeeded in keeping it well under control.

Millions of these parasites have been collected in Europe and shipped to the Parasite Laboratory of the Entomological Branch at Belleville, Ontario, from which place, after being multiplied to enormous numbers, they are eventually liberated in many parts of the infested forest.

Dr. Swaine closed his address with the statement that only through co-operative effort on the part of all those interested could a task be accomplished so great as policing the forests of eastern Canada and reporting and investigating infestations in their initial stages, when effective control measures can be applied with any hope of success. "We are hopeful that," he concluded, "before much longer, forest protection in Canada will include protection from insect pests and fungus diseases as well as protection from fires."

## Saskatchewan Branch

*J. J. White, M.E.I.C., Secretary-Treasurer.*

The regular monthly meeting of the Saskatchewan Branch of The Engineering Institute was held in the LaSalle hotel, Regina, on December 18th, 1936, with an attendance of thirty-one members and guests. Stewart Young, M.E.I.C., vice-chairman of the Branch, was in the chair.

Mr. Young requested Mr. Junius Jonsson, city engineer of Prince Albert, to say a few words on behalf of the visitors present.

At the conclusion of the business portion of the meeting, the members enjoyed a very interesting and instructive address by Mr. W. H. Ross, superintendent for Dominion Electric Power Limited, on "Diesel Engines and Their Operation," particularly with respect to cylinder heads and common causes of failure in standard type heads. Mr. Ross went on to describe a new type 2-cycle Diesel cylinder head of his own design which he has recently had patented and of which he now has five operating in a very successful manner and with considerable saving in fuel.

The meeting closed with a lengthy and animated question period during which Mr. Ross answered a great number of questions very much to the interest and satisfaction of his questioners, after which a hearty vote of thanks to the speaker was moved by H. S. Carpenter, M.E.I.C., and seconded by J. W. D. Farrell, M.E.I.C., with the hearty applause of those present.

## Winnipeg Branch

*H. L. Briggs, A.M.E.I.C., Secretary-Treasurer.*

### Shelling of Tires

At the meeting of the Branch held on January 7th, 1937, the speaker was Mr. James Gilchrist, chief inspector of materials, Canadian National Railways Western Region. The shelling of tires is the flaking and flatting of steel tires in railway service, and takes place most frequently during severely cold weather such as is experienced at times in Western Canada. After the beginning of the Great War, when Krupp tires could no longer be purchased, the shelling out of tires on locomotives, coaches and other rolling stock became very serious. The shelled tire nicks the rails, and the wheels which follow break the rails. As many as 20 miles of rails have been broken in one night by a shelled tire.

The difficulty can be overcome by the proper heat treatment of the tire before it is placed. If a very fine crystalline structure is produced in the metal of the tire, it will not shell out. The cause of the shelling out is a pulling apart of the metal itself, under the condition of the surface of the tire being heated due to rolling on the rail, while the main body of the tire is very cold due to the low temperature.

D. L. McLean, A.M.E.I.C., moved a hearty vote of thanks to the speaker.

Prior to the main paper, A. J. Taunton, M.E.I.C., presented number 4 of the "I Remember" series, speaking on his early experiences in engineering work in Western Canada.

The chair was occupied by G. E. Cole, A.M.E.I.C.

## The Leipzig Fair

A recent announcement emanating from the President of the Leipzig Fair Administration states that the Engineering Exhibition next Spring will be four times as extensive as that of the year 1932, and is expected to exceed that of 1936 by about 15 per cent. The new arrangements, which will be followed in future, provide for the removal of the International Trade Exhibition into the town, and the concentration of the various branches will require separate halls for the Office Requisites Industry and for the Textile, Laundry and Sewing Machines Industry. In order to provide the required accommodation, it will be necessary to build new halls, and as these will not be ready in time for the next Spring Fair a large marquee is being erected as a temporary measure.

The Samples Fair in the inner town has also been considerably enlarged, mainly as a result of the exhibitions of raw materials. Transportation arrangements for overseas visitors to the Fair will be greatly improved and airship traffic will materially reduce the time taken in travelling.

In connection with this Fair, a tour of Canadian and American business men is being arranged, which will start on February 20th via the liner *Bremen* and provide for the return on the *Hansa*, arriving in New York on March 26th. The trip will also include visits to several industrial centres in Germany, and an opportunity to inspect a number of large industrial plants. Information in this connection may be secured from Mr. L. Mueller-Hickler, honorary representative, Leipzig Trade Fairs, 1178 Phillips Place, Montreal.

## Hydro-electric Progress in Canada in 1936

The annual review of hydro-electric progress in Canada prepared by the Dominion Water and Power Bureau, Department of Mines and Resources discloses that, although a comparatively small addition was made to the total developed water-power capacity in the Dominion during 1936, there are a number of developments actively under construction which will add materially to the total in the next year or more. New installations during 1936 aggregated 36,475 h.p., bringing the total for the Dominion at the end of the year to a figure of 7,945,590 h.p.

The programme of hydro-electric development throughout Canada during the past few years has been largely influenced by conditions brought about by the recession period 1930 to 1933. In the month of May of that year the demand again turned upward and has continued to do so month by month to the present time. Notwithstanding conditions in the years of recession much construction, being well started, had to be proceeded with and gradually brought to completion, thus providing a generating capacity in excess of existing power demand and rendering unnecessary for the time being the initiation of new projects. The spread between installed capacity and power output has been rapidly narrowing in the past three years.

In this connection the monthly figures of output of central electric stations compiled and published by the Dominion Bureau of Statistics are of special significance.

The principal activities in hydro-electric development in the various provinces are described hereunder.

### British Columbia

New water-power installations in British Columbia were four in number. Quesnel Light and Power Company completed a 200-h.p. hydro-electric plant on Baker creek near Quesnel. Hope Utilities Limited installed a 50-h.p. plant on Schkam creek near Hope which is now supplying power to that village. The Canadian National Railways installed a 100-h.p. plant on Stoyoma creek to supply electrical energy to the railway shops and premises at Boston Bar. The Ashloo Gold Mining Company has installed a 75-h.p. Pelton wheel for the purpose of supplying compressed air for mining purposes.

A number of other installations are under consideration. The Vancouver Island Power Company proposes to supplement its power supply by a 1,953-h.p. installation on Loss creek. The Consolidated Mining and Smelting Company is, through its subsidiary the Buena Vista Mining Company, installing two 1,500-h.p. wheels on Cascade creek for the purpose of supplying Big Missouri Mine.

### Alberta, Saskatchewan and Manitoba

No new power development was undertaken in Alberta during the year but in Saskatchewan the Churchill River Power Company is installing an additional 19,500-h.p. unit at its Island Falls plant for which concrete work and the power house extension is about completed. It is expected that the new unit will be placed in operation about midway through 1937. In Manitoba the city of Winnipeg has commenced the installation of a third unit, 12,500 h.p., at its Slave Falls development on the Winnipeg river which, it is expected, will be ready for operation next autumn.

The Manitoba Power Commission added 133 miles to its transmission system and erected a number of new substations during 1936.

### Ontario

In Ontario, development was confined to the northwestern section of the province. The Hydro-Electric Power Commission of Ontario which completed the construction of and operates the Canyon (Abitibi river), and constructed and operates Ear Falls (English river) and Rat Rapids (Albany river) stations as trustee for the Provincial Government brought a new unit of 1,750 h.p. into operation in the Rat Rapids station early in October and is proceeding with construction to provide for the installation of a second unit of 5,000 h.p. in the Ear Falls station during the coming year.

The Commission acquired by purchase during the year three plants on the Trent Canal System at and near Lakefield. These three plants have a combined capacity of 4,200 h.p. and will be operated to augment the power supply of the Commission's Eastern Ontario System.

Consideration was also given by the Commission to the development of a 10,000-h.p. site at Ragged Rapids on the Musquash river to augment the supply of power to its Georgian Bay System and also to further development on the Madawaska river for its Eastern Ontario System.

The Great Lakes Power Company has constructed a dam and power house on the Montreal river which will be interconnected with its other plants at Sault Ste. Marie and Michipicoten Falls. The initial installation is 10,000 h.p. and is expected to be in operation early in 1937.

### Quebec

The only additional installation in the province was that of a fourth 30,000-h.p. unit at the Maclaren-Quebec Power Company's hydro-electric plant on Lievre river at High Falls, bringing this development up to its full capacity of 120,000 h.p.

Power developments now under construction include the Ontario Paper Company's 66,000-h.p. hydro-electric plant on Outardes river at Outardes Falls where the dams and intake have been practically completed; the penstock and pipe line foundations have been well advanced; the power house substructure and the super-structure steel as well as the tailrace are almost completed, while work has been started on the transmission line to Baie Comeau, 10 miles distant.

The city of Sherbrooke has started preliminary work on a 7,000-h.p. development at Two-Mile Falls on the St. Francis river.

The Beauharnois Light, Heat and Power Company has not increased its installed capacity of eight 50,000-h.p. units but made the necessary changes to operate another of its units at 60 cycles so that it has now four units furnishing 60-cycle and four units 25-cycle power.

The Mont Laurier Electric Company has started work on replacing its present 200-h.p. installation with a 500-h.p. unit.

The town of Magog contemplates a $400,000 hydro-electric development on Salmon river near Kingsbury.

Short additions have been made to transmission lines in various parts of the province while substantial extensions of distribution systems are also to be noted.

### New Brunswick

No new hydro-electric installations were undertaken in New Brunswick during the year but the New Brunswick Electric Power Commission completed the new 6,250-kilowatt turbo-generator additions to its fuel-power station at Newcastle creek.

In addition to the above the Commission has completed and placed in operation about 190 miles of 6,600-volt transmission lines.

### Nova Scotia

In Nova Scotia, the Nova Scotia Power Commission has completed the 4,300-h.p. addition to its Ruth Falls plant on East River Sheet Harbour, installed a new 24-h.p Diesel plant at St. Peters, Cape Breton.

There are now under construction a 2,500-h.p. development at Salmon Hole on the St. Croix river by the Minas Basin Pulp and Power Company and a 3,750-h.p. development on Paradise Brook by the Annapolis Power and Paper Company, whilst a 5,200-h.p. development is projected by the Nova Scotia Power Commission at Lower Great Brook on the Mersey river to supply increasing power demands of the Mersey Paper Company.

There has been a considerable amount of transmission line extension during the year; those of the Nova Scotia Power Commission aggregated about 6 miles whilst those of the Nova Scotia Light and Power Company and its subsidiaries total between 60 and 65 miles.

## List of New and Revised British Standard Specifications

(Issued during December, 1936)

B.S.S. No.

417—1936. *Galvanized Mild Steel Cisterns, Tanks and Cylinders.* (Revision.)
The revised specification provides for an increased range of sizes for cisterns, tanks and cylinders. Requirements are included for the methods by which the larger sizes should be stayed. A further modification in the revision is the permission to use welded construction.

688—1936. *Bituminous Filling Compounds for Electrical Apparatus (excluding those used for Cable Boxes)*
Applies to fluid, plastic and hard bituminous compounds suitable for use as filling compounds which are subjected to electrical stress in service in electrical apparatus other than cable boxes.

699—1936. *Copper Cylinders for Domestic Purposes (Grades 1, 2 and 3).*
Specifies the quality of the material, the method of workmanship and the sizes of cylinders. It provides for three grades differentiated by the thickness of the copper sheet used in the construction, which in consequence limits the working head with which they can be used.

717—1936. *"Combustion Testing" of Domestic Gas Appliances.*
Describes standard methods for the "combustion testing" of gas fired cooking appliances for water heaters and fires.

718—1936. *Density Hydrometers.*
A specification for Hydrometers to indicate density—mass per unit volume—in grammes per ml. at 20 degrees C.

Copies of these specifications may be obtained from the Publications Department, British Standards Institution, 28 Victoria Street, London, S.W.1, and from the Canadian Engineering Standards Association, 79 Sussex Street, Ottawa, Ont.

## Empire Exhibition, 1938

The Guarantee Fund in connection with the Empire Exhibition which is to be held in Glasgow, Scotland, in the spring of 1938, is rapidly approaching the £600,000 mark. Preliminary plans regarding the layout of the site have been drawn up and work is expected to begin early this year.

Applications for space have already been received from many firms, not only in the United Kingdom, but in various parts of the Empire.—*Industrial Britain.*

# Preliminary Notice

## of Applications for Admission and for Transfer

January 25th, 1937

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

**Communications relating to applicants are considered by the Council as strictly confidential.**

---

The Council will consider the applications herein described in March, 1937.

R. J. Durley, Secretary.

---

•The professional requirements are as follows:—

**A Member** shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years inthe case of a candid ate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

**An Associate Member** shall be at least twenty-seven years of,age, and shall have been engaged in some branch of engineering for at least six years which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch ofengineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more year.

**A Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equiva ent standard.

**A Student** beshall at least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

**An Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

**The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.**

### FOR ADMISSION

ANVIK—HERLAUG, of Temiskaming, Que., Born at Telemark, Norway, Oct. 5th, 1892; Educ., 1911-15, Kristiana Technical College. Diploma in mech. engrg.; 1915-17, dftsman., Kvaerner Brug, Oslo, Norway; 1917-18, dftsman., Union Co., Oslo, Norway; 1918-20, mill engr., Bosnische Electricitaets A.G., Innsbruck, Austria; 1920 to date, efficiency engr., Canadian International Paper Co., Kipawa and Hawkesbury, Ont.

References: C. B. Thorne, J. G. Hall, W. S. Kipp, J. L. E Price, W. G. C. Gliddon.

ASKWITH—WINSTON M., of 222 Powell Ave., Ottawa, Ont., Born at Ottawa, May 28th, 1911; Educ., B.Eng., McGill Univ., 1936; Summer work: 1928, rodman, Gatineau Power Co.; 1929-30, engr's. asst., N. B. MacRostie, A.M.E.I.C.; 1932, water service location, City of Ottawa; 1931, rodman, Ottawa Suburban Roads Commn.; 1934, engr's asst., Ont. Dept. of Highways; 1934-35, chemical analysis asst., to Dr. J. S. G. Shotwell; 1936 to date, instr'man. and asst. engr. with Federal District Commission, Ottawa, Ont.

References: A. K. Hay, F. C. Askwith, L. M. Hunter, W. M. Johnstone, N. B. MacRostie, H. R. Cram, C. D. Wight.

BRADFORD—GEORGE ALLEN McCLEAN, of 114 Cameron St., Sarnia, Ont., Born at Brockville, Ont., May 29th, 1908; Educ., B.Sc. (Mech.), Univ. of Sask., 1932; 1927-30 (summers), with constrn. party, Geodetic Survey of Canada, last two years in charge of party; Jan. 1933 to date, dftsman., Imperial Oil Ltd., Sarnia, Ont.

References: W. M. Dennis, C. J. Mackenzie, A. R. Greig, I. M. Fraser, E. K. Phillips.

CROSSE—CLAUDE ST. CYR, of Niagara Falls South, Ont., Born at London, England, Feb. 22nd, 1894; Educ., 1913-16, Calgary and Edmonton Technical Schools. Private study of engrg. subjects during the past 18 years; 1917-18, with Royal Air Force, overhauling, tuning and inspection of aero engines, and School of Aerial Gunnery; 1918-26, meter and testing lab., H.E.P.C. of Ont., Niagara Falls, Ont., gen. elect'l. tests, meter and relay calibrations; 1926 to date, Toronto power generating and transformer stations, H.E.P.C. of Ontario, gen. engrg. pertaining to plant operation and mtce., elect'l. tests and dfting.

References: A. W. F. McQueen, W. Jackson, L. L. Gisborne, B. Candlish, H. L. Bucke, H. M. King, G. E. Griffiths, G. C. Mountford, G. H. Wood, M. F. Ker.

DORAIS—GABRIEL, of 3659 Northcliffe Ave., Montreal, Que., Born at Sherbrooke, Que., Oct. 11th, 1913; Educ., B.A.Sc., C.E., Ecole Polytechnique, Montreal, 1935; 1931-32 (summers), road dept., Prov. of Quebec; 1933-34 (summers), Quebec Streams Commission; 1935-36, res. engr., road dept., on Mont Laurier-Senneterre highway; 1936-37, computor and asst. office engr., at Baie Comeau for the Ontario Paper Co. townsite office; at present, chief of a surveying party for E. Gohier, M.E.I.C., Consltg. Engr., Montreal, Que.

References: A. Mailhiot, A. Frigon, E. Gohier, A. Paradis, P. G. Gauthier.

ENGLER—CHARLES ROY, of 145 Powell Avenue, Ottawa, Ont., Born at Ottawa, July 1st, 1907; Educ., B.Sc., Queen's Univ., 1934; 1935 (Jan.-Dec.), press operator, and from July, on staff of standards dept., Beatty Bros.; Dec. 1935 to date, designer and dftsman, J. H. Connor & Son Ltd., Ottawa, Ont.

References: R. A. Low, L. T. Rutledge, L. M. Arkley, G. B. Dodge, S. D. Fawcett.

FRY—FREDERICK GEORGE, of 780 Quebec St., London, Ont., Born at London, England, Nov. 16th, 1908; Educ., B.A.Sc., Univ. of Toronto, 1933; 1927-31, shop asst. and clerk, Toronto Hydro Electric System; 1935 to date, asst. divnl. engr., Shell Oil Co. of Canada Ltd., London, Ont.

References: T. R. Loudon, W. J. Smither, J. R. Cockburn, C. R. Young, D. S. Scrymgeour.

GRAHAM—GEORGE, of 193 Waverly St., Ottawa, Ont., Born at Winnipeg, Man., Feb. 7th, 1907; Educ., B.Sc. (Civil), Univ. of Sask., 1933; 1924-26 (summers), chainman and rodman on municipal work; Summers 1927 to 1931, worked for city engr. of Saskatoon, inspr. in chief of semi-Macadam pavement constrn., also concrete sidewalk and paving and sedimentation basins; i/c concrete lane paving, also earthwork on river bank; inspr. on sewer and water constrn.; 1935 (June-Nov.), i/c field party, Dept. of Mines, investigating ground water resources of the Prairie Provinces; June 1936 to date, writing reports by municipalities on ground water resources of the same area.

### FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

DINGWALL—ROBERT MACFARLANE, of 10224-131st St., Edmonton, Alta., Born at Glasgow, Scotland, Mar. 16th, 1890; Educ., Associate, Royal Technical College, 1914, R.P.E. Alta.; 1906-11, ap'ticeship as mech. engr., A. & J. Inglis Ltd., and London and Glasgow Shipbldg. and Engrg. Co. Ltd., Glasgow; 1911 and 1913 (vacations), asst. foreman with latter company; 1914-19, overseas service. 1915, Comm'd. Officer, British Army. 1917, transferred to Royal Engrs., District Technical Office, Eawy District, France, until 1919; 1919, master mechanic, Drumheller; 1919-20, master mechanic, Mountain Park; 1921-26, head of mech. engrg. dept., Provincial Technical Institute, Calgary; 1926-28, engrg. sales mgr., Riverside Iron Works Ltd., Calgary; 1929 to date, manager and director, Standard Iron Works Ltd., Edmonton, Alta. (*A.M. 1923.*)

References: W. J. Dick, R. J. Gibb, R. W. Ross, C. E. Garnett, J. Garrett.

KEAN—DAVID JACQUES, of Whitby, Ont., Born at Cambridge, Ont., April 1st, 1884; Educ., Diploma course, S.P.S., Univ. of Toronto, 1906-1909; 1906, Ontario land survey; 1909, Ontario survey and mining claims, Nor. Ontario; 1909-10, location and constrn., C.N.R. and C.P.R.; 1911-13, Dom. Land Survey, Foothills, Alta.; 1912-13, res. engr., C.N.R.; 1913, Dom. Land survey, Peace River; 1919 to date, county road supt. and county engr., County of Ontario, including bridge design and road constrn. (*A.M. 1920.*)

References: A. E. Jupp, H. T. Routly, J. A. P. Marshall, H. A. Lumsden.

TALMAN—STEPHEN GOLDWYER, of 88 Delaware Ave., Toronto, Ont., Born at Broadstairs, Kent, England, Dec. 20th, 1875; I.C.S. Engrg. Diploma, 1910. Toronto Tech. School Surveying Diploma, 1915; 1890-92, pupil, Clay Inman Forge Co., Birkenhead; 1892-95, ap'tice, W. H. Ross & Co., Liverpool, "Scottish Isles"; 1895-97, 3rd Mate, "Scottish Isles"; 1897-98, 3rd and 2nd Officer, S.S. "Pondo"; 1898-1899, Auxiliary 2nd Officer, S.S. "Fort Salisbury"; 1900-01, South African War. Brabants' Horse; 1901-02, laying out forest reservation and road making, Cape Colony; 1902-04, asst. to Kidley & Barrie, contractors, Beira; 1904-05, river control work, Cape Colony; 1905-06, renewal of pier and tracks, Laurenco Marques Wharf Co., S.E. Africa; 1907-12, engrg. staff, DeBeers Cons Mines; 1913-17, instr'man., Dept. of Works, Toronto; 1918-19, designing, Imperial Munitions Board; 1919-20, design of plant for Salts and Potash Co. of Canada Ltd.; 1920-21, designing, Dominion Tire Co., Kitchener, Ont.; 1921 to date, with the City of Toronto as follows: 1921-22, alterations to asphalt plant; 1922-24, rly and bridge section, inspr. in charge of boring, field engr. and dftsman.; 1924-33, sewer section, dftsman.; 1933 to date, in charge of design and dfting. at water distribution machine shop. (*A.M. 1914.*)

## EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

*All correspondence should be addressed to*

**The Employment Service Bureau, The Engineering Institute of Canada**
**2050 Mansfield Street, Montreal**

## Situation Vacant

SALES ENGINEER. Manufacturer of heavy electrical apparatus has vacancy for a man who should preferably have established connection with public utilities and Industry. Reply should give detailed particulars in first instant, including age, education, engineering and sales experience and details of sales territories acquainted with. Apply to Box No. 1461-V.

EXPERIENCED SALESMAN required for province of Quebec by a manufacturer of electric motors, transmission and switchgear. Apply to Box No. 1470-V.

JUNIOR ENGINEER, required at Montreal for estimating and specification work by manufacturer of electric motors, transmission and switchgear. Should have commercial ambitions and electrical education. Good prospects for keen young man. Apply to Box No. 1471-V.

SERVICE ENGINEER, required for Montreal and district by electrical machinery manufacturer. Should have aptitude for soliciting orders for electric repairs and rewinds. Apply to Box No. 1472-V.

CIVIL OR MECHANICAL ENGINEER preferably with two or three years experience for a pulp and paper mill in Ontario. Apply to Box No. 1473-V.

NATIONAL RESEARCH COUNCIL

The Associate Committee on Radio Research invites applications for a temporary assistant in the Radio Section of the National Research Council. Appointment is to be made for a period of one year commencing April 1st; salary about $1,800 per annum.

*Qualifications:* University graduate in electrical engineering, radio engineering or engineering physics, or honours graduate in physics with special radio training.

*Experience:* At least two years, preferably with test and maintenance of receiving type equipment. License (Commercial or Amateur) to operate in Continental code. Experience in operation of transmitters. Some experience with direction finders and also with aircraft and aeronautical work is desirable.

Applications should be in the hands of the Secretary-Treasurer, National Research Council, not later than February 27th. Particulars of the candidate to include age, race, nationality, training, experience and references.

## Situations Wanted

ELECTRICAL ENGINEER, B.Sc., E.E. Age 30. Completed C.G.E. Test Course; five years experience with power company utility work—substation and power house (steam) operation and maintenance, transmission and distribution line operation, maintenance and design. Industrial or utility work desired. Location immaterial. Available on short notice. Apply to Box No. 266-W.

MECHANICAL ENGINEER, B.Sc. Age 31. Married. Last ten years includes:—Mechanical structural and reinforced concrete design in pulp and paper mills, industrial plants, hydro-electric, mine, sewers and sewage disposal plant construction. My experience also includes shop production, steam plant combustion, fuel analysing, inspecting, supervising and instrument work on industrial construction. Permanent position preferred. Apply to Box No. 521-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aero-photographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

ELECTRICAL ENGINEER, B.Sc. '28; M.Eng. '35. Two years student apprenticeship at Can. Westinghouse Co., including test and electrical machine design. Also about two years experience in operating dept. of large electrical power organization. Available on short notice. Apply to Box No. 660-W.

## Situations Wanted

ELECTRICAL AND CIVIL ENGINEER, B.Sc. Elec. '29, B.Sc. Civil '33. Jr.E.I.C. Age 29. Experience includes four months with Can. Gen. Elec. Co., approximately three years in engineering office of large electrical manufacturing company in Montreal, the last six months of which was spent as commercial engineer. For the last year and a half employed in electrical repair shop. Best of references. Apply to Box No. 693-W.

CIVIL ENGINEER, B.Sc. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing. Nature of work and location immaterial. Apply to Box No. 724-W.

YOUNG CIVIL ENGINEER, B.Sc. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

### Employment Service Bureau

Enquiries continue to be received for young engineers, particularly with mechanical training or experience, engineers with pulp and paper mill experience, and sales engineers speaking French.

In the months of December and January employment bulletins were sent to members whose names are on the active list of the Employment Service Bureau, listing all positions vacant at the time that could be advertised.

Unfortunately, many of these positions were of a transitory nature or could be filled on short notice and therefore did not warrant insertion in the Journal, as from ten days to two weeks and even longer might elapse before the date of mailing and receipt of replies.

Your attention is called to the annual report of the Employment Service Bureau appearing on page 73 of this issue of the Journal.

RADIO AND ELECTRICAL ENGINEER, B.Sc., '31, Jr.E.I.C. Single. Age 29. One year and a half actual field experience in power and lighting equipment. Extensive work in telephone and radio layouts in switchboard and installation depts. Particularly interested and experienced in sales and traffic work in telephone and radio company. At present supervisor over sales and service of radio and electrical company. Available on short notice. Location immaterial. Apply to Box No. 740-W.

PLANT ENGINEER or SUPERINTENDENT, capable of supervising all phases of industrial plant operation, graduate electrical, eleven years diversified industrial experience including test course, four years on large Quebec industrial development, on construction and operation, also six years with prominent consulting firm supervising electrical and mechanical engineering projects. Age 31, single. Apply to Box No. 795-W.

CIVIL ENGINEER, B.Sc. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W.

## Situations Wanted

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C., age 32, married. Two years in pulp mills draughting and designing additions, maintenance and plant layout. Three and a half years in the Toronto Building Department, checking and designing for steel, reinforced concrete and ordinary structures. One and a half years as transitman and draughtsman on road location and maintenance work. Available at once. Location immaterial. Apply to Box No. 899-W.

CIVIL ENGINEER, B.Sc., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. B.Sc. (Man. '23), A.M.E.I.C. Married. Ten years specialized experience in the practical use of magnetic, electrical and mechanical instruments for the prospecting, surveying and mapping of mineral, oil and gas lands. Five years experience with telegraph, telephone and radio equipment. Capable of giving instruction in theory and practice in these lines and in college physics. Available on short notice. Apply to Box No. 1063-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

ELECTRICAL ENGINEER, B.Sc. '34 (Univ. of N.B.), S.E.I.C. Age 21, single. Desires any kind of electrical work. Will consider any location. Apply to Box No. 1262-W

ENGINEER AND DRAUGHTSMAN, Jr.E.I.C., age 33, married. Diplomas from Mtl. Tech. Inst. in R.C. and Structural Design. 11½ years experience in civil engineering, draughting and instrument work. This includes 7 years with M.L.H. & P. Cons. as field engineer on construction and maintenance of gas mains. Present location Montreal. Available at once. Apply to Box No. 1326-W.

CIVIL ENGINEER, M.E.I.C. Married. Age 38. Twenty years experience in organization, design and estimating, and cost accounting. Active service in France. Apply to Box No. 1367-W.

ENGINEER SUPERINTENDENT, A.M.E.I.C., R.P.E., Que. and Alta. Age 47. Married. Twenty years experience as engineer and superintendent in charge of hydro-electric, industrial, railroad, and irrigation construction. Specialized in rock excavation and suction dredging. Intimate knowledge of costs, estimating and organizing. Available immediately. Apply to Box No. 1411-W.

CIVIL AND ELECTRICAL ENGINEER, Univ. of Man. '35 and '36. S.E.I.C. Experience in irrigation and mapping. Available at once. Location immaterial. Box No. 1418-W.

CIVIL ENGINEER, B.Sc. 1910, A.M.E.I.C. Married. Twenty-six years experience on heavy construction work, both field and office; rails, roads, power house, hotels, bridges, etc. Location immaterial. Available at once. Apply to Box No. 1470-W.

SALES ENGINEER, M.E.I.C. Age 50. Married. Several years in combustion and general machinery lines. Estimating and layout work (mechanical and electrical). Speaking French fluently. Executive ability. Apply to Box No. 1482-W.

ELECTRICAL ENGINEER, B.Eng. (McGill '33). One and a half years experience in plant and production routine, and with considerable training in sales work Bilingual, single, and available at once for any location. Apply to Box No. 1509-W.

ELECTRICAL ENGINEER, B.Sc. '31 (Univ. of Alta.), Jr.E.I.C. Age 28. Married. One year students' test course with C.G.E.Co. including testing and operation of transformers, meters, industrial control and switchgear apparatus. Two years as instrumentman on highway construction. Desires electrical utility, commercial lighting or air conditioning work, location immaterial and available at once. Apply to Box No. 1522-W

## Transport Legislation in Argentina

A National Co-ordination of Transport Bill has now passed the Argentine Senate, and only awaits promulgation in order to become law. This measure is a valuable example of the "benevolent treatment" which has been promised to British capital by the Argentine Government. It provides for the appointment of a National Commission for Co-ordinating Transport, which will consist of seven members and will be the authority from which all public motor-transport services carrying passengers or goods, except those operating within the bounds of a single province, must obtain licences. In considering applications for licences the Commission will take into account public necessity in the district to be served, and will arrange to avoid duplication and to ensure that preference is given to carriers who provide a continuous service under the best conditions as to price and time. A road maintenance fund is to be created by a tax varying from £6 to £25 for each vehicle. Tariffs must be approved by the Commission, and routes, schedules, wages and general working conditions will also come under strict control. The advancement of the Bill to its present stage has only been effected in face of energetic and continuous opposition. This has mainly taken two forms: One that the measure is directed against the working classes in the interests of foreign capital; and the other that the railways have now largely served their purpose and must make room for other forms of transport. It is pointed out, however, that the interests of the small man are adequately safeguarded, and that the railways are still essential for the transport of bulky goods in large quantities. In railway circles in London, in fact, the Bill is regarded as an important step towards the elimination of wasteful road competition. As it is, the complete freedom under which road transport has operated in Argentina in recent years has led to the creation of a multitude of small mushroom companies whose services have often been run without regard to ultimate commercial results. Thus, no allowance has been made for depreciation, and there has been much fare cutting and picking and choosing of freights. Fortunately, there has been an increasing recognition of the fact that in spite of the foreign capital involved, the railways actually carry 90 per cent of both the exports and imports of Argentina, and that they still have a great part to play in the development of the national resources of the country.—*Engineering.*

## Canadian Chemical Association

The annual convention of the Canadian Chemical Association and the Canadian Institute of Chemistry is to be held in Vancouver on June 17th, 18th and 19th, 1937.

Plans are being made for a special train to leave Toronto and Montreal on Friday evening, June 11th, spending a few hours in Winnipeg on Sunday morning, then on to Kimberly where the Sullivan Mine, the greatest silver-bar mine in the world, will be visited. The following day the Consolidated Mining and Smelting Company's plant at Trail, B.C., will be visited and the special train will arrive in Vancouver on Wednesday evening. The all-inclusive expense of this trip is estimated at $200.

More complete information as to the programme will be released later, and in the meantime, those seeking more detailed information as to itinerary and cost should address their enquiries to Dr. R. I. Elworthy, Secretary, Canadian Chemical Association, 366 Adelaide Street West, Toronto, Ontario.

## Changes in Employment

Some striking changes in the distribution of employment in Britain during the last thirteen years are shown in statistics recently issued by the Ministry of Labour. The biggest proportionate increase in employment since 1923, 70.1 per cent, has been in miscellaneous services. These include professional services, entertainments and sports, hotel, public-house, restaurant, boarding house, club, etc. service and laundries, dyeing and dry-cleaning.

Next comes building and contracting, with a gain of 62.7 per cent compared with July, 1923. Then comes transport, communication, storage and distribution up 47.4 per cent. Fishing shows an advance of 44.1 per cent, gas, water and electricity supply 27.2 per cent, national and local government 25.6 per cent, and commerce, banking, insurance and finance 16.3 per cent. Manufacturing accounts for half the insured work people in the country, 6,188,690 out of a total of 13,338,700. This group shows the smallest proportionate increase, 8.3 per cent, but in this group, of course, are included industries which have greatly expanded and others which have greatly contracted. The only decrease is shown by mining and quarrying, where there is a fall of 23.6 per cent. The total number of insured work people increased by 19.5 per cent over the period.—*Industrial Britain.*

## Young College Graduates and Steel Companies

Nearly one thousand college trained men are expected to find jobs open to them in the steel industry in the United States when they graduate this spring, according to estimates made by the American Iron and Steel Institute.

The number of such youths going into the steel industry this year will be larger than ever before, reflecting the expanding operations and increased employment in the industry. Most of them will be from technical and engineering schools.

A number of steel companies have organized plans for recruiting college trained men, close contacts being maintained with various institutions for that purpose. Likely candidates for jobs are selected from among the graduating classes. Some companies also are planning to offer opportunities for summer training in the mills to undergraduates.

More than 70 per cent of the college men hired by one leading steel company in the past thirteen years have held degrees in engineering. About 13 per cent of them were bachelors of arts or of science. Included in the remainder were specialists in economics, marketing, architecture, journalism and law. The men were graduated from some 102 colleges, universities and technical schools.

The degree most commonly held was that of mechanical engineer, received by 149 of the men. Other degrees were in chemistry and chemical engineering, 97; civil engineering, 95; metallurgical engineering, 70; mining, 57; bachelor of arts, 45; electrical engineering, 42; and bachelor of science, 38. More than 100 had specialized in or had received degrees in business administration, industrial engineering, or affiliated subjects.—*Steel Facts.*

# THE ENGINEERING JOURNAL

## THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

VOLUME XX | MONTREAL, MARCH, 1937 | NUMBER 3

## Some Features of Mining Geology

*G. Vibert Douglas, A.M.E.I.C.,*
*Professor of Geology, Dalhousie University, Halifax, N.S.*

**An Address delivered before the Halifax Branch of The Engineering Institute of Canada, November 19th, 1936.**

SUMMARY.—After naming various classes of ore-bodies, the author gives notes based on his visits to the pyrite deposits of Rio Tinto and Sulitelma, briefly discusses the mining regions of Northern Rhodesia and the Belgian Congo, and mentions some of the important factors to be borne in mind in estimating the worth of a mining venture.

The problem that confronts every mining engineer or mining geologist sometime during his career involves the question of finding new ore-bodies which will prolong the life of his mine.

To answer this question it is necessary to know how ore-bodies are formed. What processes have resulted in the formation of ore? To gain some knowledge of that problem it is necessary to study the conditions in various types of deposits and then attempt some classification which is based on genesis. The author has adopted the following classification, which he presents with the hope that it may be helpful:—

A.—Surface deposits. The result of mechanical forces such as stream action but not excluding some chemical action.
1. Alluvial—e.g. Placers. The valuable minerals have been washed from their parent rock and concentrated by conditions resulting from slackening currents and differences of specific gravity.
2. Residual—The host rock has been washed away leaving a concentration of the minerals of economic value.

B.—Deposits resulting from supergene action, chiefly chemical.
1. Syngenetic—e.g. Wabana iron ores of Newfoundland, gypsum and salt deposits of Nova Scotia.
2. Epigenetic—The only genuine example of this type studied by the author is a deposit of barytes near Glencar, County Sligo, Ireland. It is a comparatively rare type.

*Note*—Supergene action is equivalent to surface effects; it is to be contrasted with hypogene action which suggests effects produced from depth.

Syngenetic means contemporaneous and epigenetic means later than.

C.—Deposits resulting from hypogene action—chiefly chemical.
1. Syngenetic—
   (*a*) In lavas—Some copper and zeolite deposits.
   (*b*) In dykes—Pegmatite and other dykes frequently carry minerals of economic importance.
   (*c*) In plutonic or deep seated igneous rocks. Examples are Sudbury (in Canada), Kiruna (Sweden), Bushveld igneous complex (Transvaal).
2. Epigenetic—Hydrothermal and gaseous agents.
   (*a*) In veins—Very common.
   (*b*) In zones—Some of the largest ore-bodies such as Rio Tinto and the great Northern Rhodesian copper mines.
   (*c*) In stockworks, i.e. intersecting veinlets cutting the country rock. Some of the Rio Tinto deposits.
   (*d*) Volcanic emanations. Sulphur in Sicily.

*Note*—(*a*), (*b*) and (*c*) chiefly formed by hydrothermal solutions, (*d*) chiefly gaseous.

The problem of finding ore resolves itself into first classifying the deposit and then trying to imagine the passages which the ore carriers followed to their final destination. Having set up a working hypothesis the next step is to test its validity by directed exploration.

**Fig. 1—Rio Tinto. Atalaya Opencast. Porphyry on the Right, Slate on the Left, with Ore Between.**

In connection with all the epigenetic hydrothermal deposits a complication enters into the general picture. This complication is the observed fact that the values in a vein are not co-extensive with the vein. The values form shoots whose boundaries are often only determinable by chemical analysis. What do these shoots represent? It has been suggested by Douglas, Howse and Sheppard*

*Concerning Ore-Shoots—Bull. C.I.M.M. 1934.
Further Notes on Ore-Shoots—Bull. C.I.M.M. 1935.

that these shoots are the loci of channel ways which were open at the time when the solutions were charged with the ore minerals. This conception involves the idea that the solutions were differently charged at different times. There is justification for this idea in the observed zoning of many mineral deposits, notably those in Cornwall, England. Closest to the parent igneous rock are to be found such minerals as tinstone and wolframite, further out chalcopyrite and still further out galena. These minerals as

**Fig. 2—Rio Tinto. View of Smelter Stacks.**

arranged are also in decreasing order of hardness and it would appear that this same order is that in which they were given off from the parent rock and travelled through the possible openings available at the time. The last sentence shows the importance of structure, for as soon as the solutions leave the source rock the structure of the host rocks to a great extent governs the permeability and locus of deposition. Examples of some of these types will now be cited.

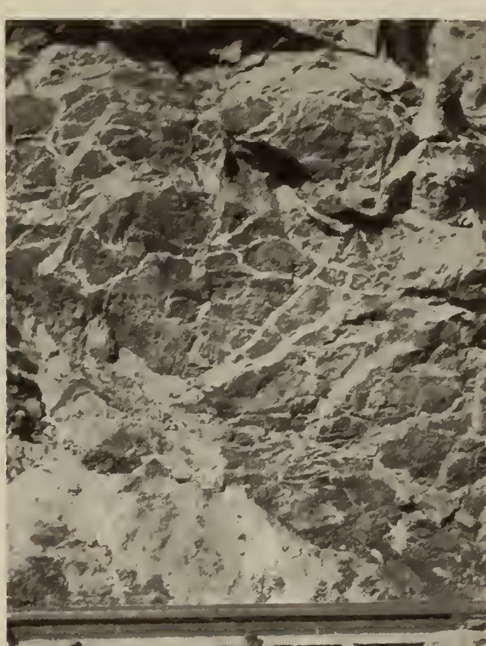

**Fig. 3—Stockwork Porphyry on Footwall of San Dionisio Orebody. The White Veins are Massive Pyrites.**

## Rio Tinto

These ancient mines which have been worked off and on for over two thousand years are situated in the province of Huelva in south-western Spain. Iberians, Phoenicians, Romans, Swedes and British have worked these mines which have yielded pyrites, copper, gold and silver. (Figs. 1 and 2.) The ore-bodies may be grouped into the following classes:—

(*a*) Massive sulphides with slate walls, as lenses and veins.
(*b*) Contact bodies between porphyry and slate.
(*c*) Stockwork and disseminated sulphides entirely in porphyry.

These three classes are not to be thought of as isolated but rather as forming one large scheme.

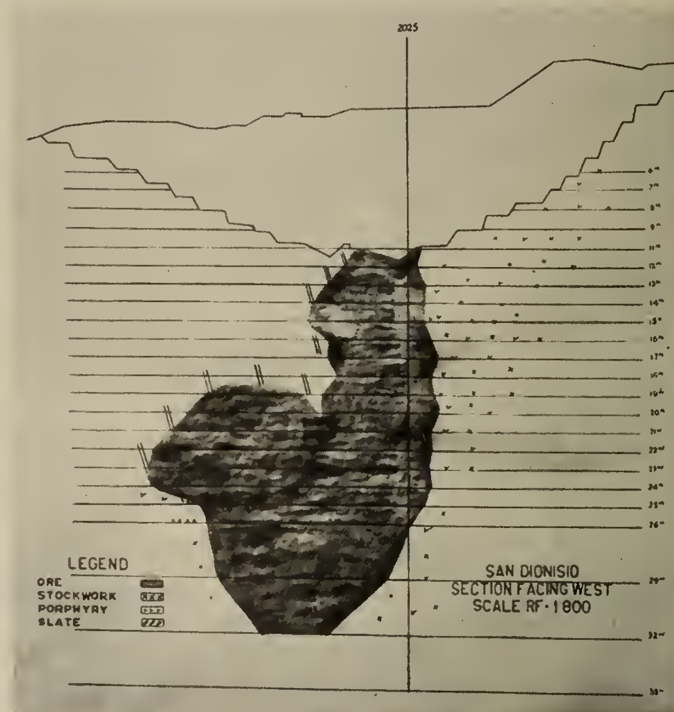

**Fig. 4—San Dionisio Orebody. Footwall to Hanging Wall approximately 200 Metres.**

An idealized section would show a stockwork porphyry passing upwards into massive sulphides at the contact and above this zone, entirely in slate veins and lenticles of sulphides. (Figs. 3, 4 and 5.)

The important point to be noted with regard to the location of the ore-bodies is that the slaty cleavage was developed before the porphyry or ore solutions were introduced.

The porphyry was injected as sills and as wedge dykes. In the latter case one flank of the dyke undercuts the slaty cleavage which dips north and the other flank lies parallel to the cleavage. As a matter of observed fact the ore lies at the undercut contact. The other contact is barren. Stated another way, the slates are permeable edge on but are impermeable normal to their dip. A realization of this structural control facilitates the finding of new ore-bodies.

Both opencast and underground methods are employed in the mining of these enormous masses. It is found that opencast mining is much cheaper than underground methods for lodes of this type. The ratio of overburden to ore that makes opencast methods feasible is dependent on a number of factors.

The ratio is a function of:—

1. Depth of cover
2. Toughness of rock
3. Angle of repose
4. Cost of transport
5. Amount of ore to be won.

The following table is from data obtained at the mine.

| Nature of Rock | Tons of Rock to | Tons of Ore |
|---|---|---|
| Porphyry and hard slate............... | 3.8 | 1.0 |
| Soft slate........................... | 5.5 | 1.0 |

The largest of the Rio Tinto ore-bodies is San Dionisio. The cross-section of this mass is shown in Fig. 4 and its size may be realized when it is stated that from footwall to hanging wall at its widest point the ore-body is nearly 200 metres in width, the whole of that distance being massive ore.

Rio Tinto was one of the first, if not the first place where leaching was practised. Some of the ore is spread out over the surrounding country and is sprayed with mine waters. These waters carry sulphates of iron and copper and also sulphuric acid. The copper in the ore, if it be in the form of bornite, chalcocite, covellite or as oxide copper is leachable. The liquors are caught in reservoirs and are then passed over iron scrap. The sulphate solutions deposit copper at the expense of iron (Fig. 6). The iron sulphate is rejected and flows into the river together with considerable zinc sulphate. The colour of the river is at first green, due to the ferrous state of the iron, but after passing over some small rapids it is oxidized and hence the river enters the sea a brilliant red colour.

Under the management of W. A. Carlyle and W. J. Browning, Rio Tinto set the price of sulphur on the Atlantic seaboard and also was one of the world's cheapest producers of copper.

At the present time, due to political difficulties in Spain, the cheapness of Gulf sulphur and the discoveries of the large copper deposits in Africa and South America, the mine is not in such a favourable position. However its long history, present reserves and accessibility still make it one of the great potential mines of the world.

A partial bibliography of Rio Tinto references is given at the end of this paper.

### Norway

There are some extremely interesting pyritic mines in the Scandinavian peninsula; Orkla near Trondhjem and Sulitelma which is north of the Arctic Circle and can be

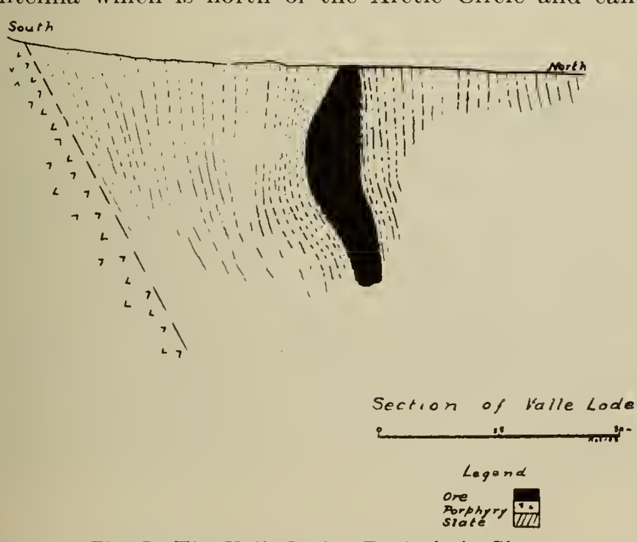

Fig. 5—The Valle Lode. Entirely in Slate.

reached from the port of Bôda. Both of these mines have considerable reserves of good ore and are worked by very capable engineers.

Sulitelma is a broad mineralized anticline. Figure 7 shows its cross-section. The crest of the anticline has been eroded and the ore is being won from the flanks. The country rock is a schist which has been invaded by sheets of gabbro. The ore is in schist which it replaces and frequently there is a gabbro sheet above the ore-body. Sometimes this sheet lies below the ore.

The sections of the ore-body at Sulitelma give some useful criteria for replacement. There are numerous inclusions of schist in ore. These inclusions have the same orientation as the walls. In the walls there are veins and lenticular pods of ore up to two or three metres in length, detached from the massive ore. The massive ore has no

Fig. 6—Cementation Launders where Copper Liquors pass over Scrap Iron.

chilled margins, which would be expected if the ore had been intruded as a magma or molten mass from below.

The ore at Sulitelma is brought down to the rail level from the hillsides by buckets on rope conveyors operated by gravity.

At Orkla one of the mining features which impressed the author was the bifurcating shoot leading from the haulage level to the shrinkage stopes. This double arrangement prevents a holdup in the drawing of the ore, for if one shoot jams the ore runs through the other until it is possible to remove the obstruction.

### Africa

In Northern Rhodesia and the Belgian Congo there lies one of the greatest copper deposits known in the world. In the Congo there are mines occurring at intervals over approximately four hundred miles. These bodies are chiefly composed of oxide copper—malachite, azurite chryscolla, cuprite and tenorite. Associated with these copper minerals there are cobalt minerals and in some of the deposits radioactive ores.

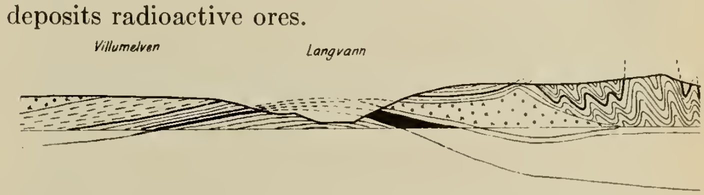

Fig. 7—Section Sulitelma. The Ore lies below the Black Bands.

These deposits, which are enormously rich, represent the concentration of oxide minerals by surface waters. The original minerals are believed to have been sulphides of hypogene origin which by exposure were oxidized and later concentrated by solution and reprecipitation.

This mineralization occurs in a remarkably uniform series of rocks, Precambrian in age. These rocks are sediments which include arenaceous, argillaceous and calcareous types. Robert's column of the beds forming the Série des Mines with the thickness in metres follows:—

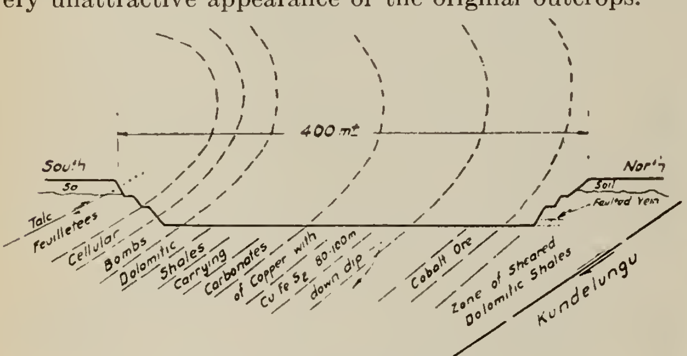
| | |
|---|---|
| Dolomite.................. | 200 to 400 metres |
| Dolomitic shales.............. | |
| Cellular quartzite............ | |
| Banded quartzite............. | |
| Inferior shales............... | |

This column gives the key to the structural interpretation of the Congo mines, because the cellular quartzite is a very easily distinguished rock, being white and porous. Below it is the dense banded quartzite or feuilletées. These two rocks are markers and if they are found inverted it can be taken that the beds have been overturned. Figures 8, 9, 10 and 11 give some idea of the structure and size of these large bodies.

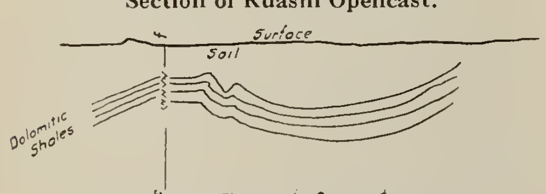
Fig. 8—The Ruashi Mine, Belgian Congo.

Turning now to the Northern Rhodesian mines we have to deal with a predominantly sulphide mineralization.

The minerals are chalcopyrite and bornite with chalcocite and covellite. The first mineral to be deposited was linnaeite which is a cobalt sulphide. The ores are hypogene and are disseminated in the country rock which is principally shale. The appearance of the ore in some of the mines is decidedly non-spectacular; it often requires a very careful scrutiny or use of a hand lens to see the sulphides. It will always be to the credit of the original finders of these deposits that they did recognize possibilities in the very unattractive appearance of the original outcrops.



Section of Ruashi Opencast.



Section of West End Ruashi.
Fig. 9

The mineralization occurs where these sedimentary beds have been cut by granite. The ore does not occur very close to the contact nor does it form an aureole around the intrusion but rather certain beds which offered passages for the solutions given out from the granite are mineralized for considerable lengths in their vicinity. The sediments had been folded prior to mineralization and subsequently eroded, so that the crests of the anticlines have disappeared. The mineralized beds have therefore only been preserved in the limbs and troughs of the synclines. It is interesting to speculate about the enormous tonnage which must have been lost due to erosion of the anticlinal crests.

The chief Northern Rhodesian mines are as follows:—

| Mine | Owner | Tonnage | Tenor |
|---|---|---|---|
| N'Kana, Mindola | Rhokana | $127 \times 10^6$ | 4%± |
| *N'Changa | Rhokana | $144 \times 10^6$ | 7%± |
| Roan Antelope | Selection Trust | $104 \times 10^6$ | 3.4% |
| Mufulira | Selection Trust | $116 \times 10^6$ | 4.4% |
| Chambishi | Selection Trust | $25 \times 10^6$ | 3.4% |
| Baluba | Selection Trust | $21 \times 10^6$ | 3.4% |

*Some of the N'Changa ore must be considered as oxide copper ore.

For those who wish to delve further into the geology of these areas the bibliography at the end of this paper may be helpful.

It is obviously impossible in a paper of this character to do more than touch on some points here and there which appear to be relevant to the subject. Regarding Canada the author does not intend to describe any specific mines but to confine himself to some opinions.

The first opinion is that Canadian mines are not paying dividends at a sufficiently high rate. The result of this low rate is for the investing public to buy mining stock hoping that it will rise and thus pay for the venture. There are of course exceptions to this statement but in general the statement is true.

A well known mining engineer in London told the author that in his opinion, considering the risks involved, an investor should receive ten per cent on his money. Hoover's figures are approximately the same.

Secondly, it is the practice in Canada, also with exceptions, not to state the general reserves. This omission also leads to speculation and not to sound investment. It is impossible to calculate the real value of any mining shares unless the following data are given:—

(*a*) Total reserves.
(*b*) Tonnage mined per annum.
(*c*) Net profit per ton.
(*d*) Number of shares issued.

Fig. 10—The Chituru Mine, Belgian Congo.

Given these data the calculation is as follows:—

$$\frac{(a)}{(b)} = \text{"}n\text{" years or life of mine.}$$

$$(b) \times (c) = \$ \text{ "}A\text{" which is the yearly profit.}$$

The present worth of \$ "*A*" for "*n*" years expecting 10 per cent return and 4 per cent redemption can be obtained from the formula

$$\text{Present worth} = \frac{A}{\dfrac{(0.04)}{(1 + 0.04)^n} + 0.10}$$

or from tables given in Hoover's Principles of Mining or Baxter and Parks Mine Valuation.

The present worth divided by the number of shares issued (*d*) gives the real value of the shares.

If the investing public would only demand these data and take the trouble to do a little arithmetic the Canadian mining industry would be on a much sounder and healthier basis than it is at present.

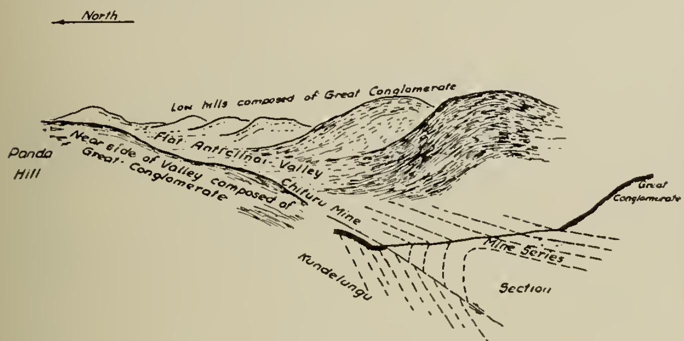


**Fig. 11—Sketch of Chituru Mine.**

In Nova Scotia there are numerous cases of well meaning persons embarking on mining ventures where there is no real hope for success. The glitter of gold dazzles their judgment. The veins on the average are narrow and it requires very careful planning to make these ventures pay. Too much attention cannot be paid to the question of tenor.

As a rough guide in deciding on which veins are possible and which are doubtful the author has plotted the following curves. They can be used in a number of ways (see Figs. 12, 13 and 14).

For example a vein is found with a certain width and by careful sampling the tenor has been obtained. (Tenors of 0.25, 0.50, 0.75 and 1.0 oz. per ton have been used.) Each of the three sets of curves has these four tenors. Find the point on the curve which corresponds to the width of the vein and the known tenor. If the point is above the abscissa on all three sets it is possible that the vein may be of commercial value. If the point is below on one set and above on another it means that the cost of mining will have to be considered very carefully for it will lie between $3 and $4 or $4 and $5 per ton.

These curves show the minimum widths of veins of various gold tenors with assumed total mining costs of 3, 4 and 5 dollars per ton.

The value of an ounce of gold is taken as $35.

One ton is taken as equivalent to 12 cubic feet.

Example—A vein carrying 0.50 ounce gold per ton would require to have a width of at least 0.75 feet (or 9 inches) to be considered economic with mining costs at $5 per ton.

Milling costs are not included but if known may be applied to the curves by raising the abscissa (or line through 0, 1, 2, 3) for as many dollars as the cost of milling.

A further point which might be mentioned is that mining costs as reported are often very misleading. Cost per ton, cost per ton mined, cost per ton milled, etc., are common phrases in mining and financial reports. The really informative statement would be cost per ounce of gold produced, cost per pound of copper and so forth.

Anything which will tend to convince the world that we are proud of our mines, as we have a right to be, and are prepared to open all facts regarding the mines to the sunlight will be to be the good of the mining industry and to the good of Canada.

# Organized Labour and the Rationalization of Industry and Transport in England

*W. L. Waters, M.E.I.C.,*
*Consulting Engineer, New York.*

**An address delivered before the Ottawa Branch of The Engineering Institute of Canada, January 21st, 1937.**

**NOTE:—On a recent visit to England Mr. Waters was privileged to discuss organized labour with a number of labour leaders, business executives and politicians; and this paper is a summary of the views and facts which they kindly placed at his disposal. In this the author merely acts as a commentator, his own views not being introduced in any way.**

Organized labour in England has always considered that from a political economy standpoint it has developed further than labour in North America. In Canada and the United States we have regarded this claim with complacency in view of the lower standard of living in England. But at the present time there is little doubt but that this superior feeling of organized labour in England is justified; and we find labour leaders in that country taking a broad long range view of industry which is in contrast to the continual agitation for minor concessions that is so prevalent in certain other countries.

Several things have contributed to this; principally

(1) The public reaction to the general strike of 1926.

(2) The fact that a Labour Ministry had the responsibility of governing the country for several years, which had a sobering effect on labour leaders.

(3) The post war depression in foreign trade made labour realize that it is fighting foreign competition rather than capital.

When the necessity of rationalizing British industries to meet external competition first became evident, it was opposed by labour as resulting in unemployment due to the shutting down of obsolete plants and the introduction of labour saving machinery. But they soon realized that it is better to have a hundred men employed at good wages than a hundred and fifty at sweat shop rates; and that once an industry becomes prosperous it will expand, so that ultimately the additional fifty men who had to go on the dole, will be re-employed at living wages. Thus we now find organized labour in England favouring the rationalization of industries, consolidations, and the introduction of modern machinery. The "man-in-the-street" at times declaims against such developments. But the labour leaders know from experience that it is easier to negotiate with a single strong company that is prosperous, and to obtain concessions, than it is to fight a number of small concerns which are subject to demoralizing competition. They point to the cotton textile industry as typical of one which has only been able to pay low wages because of obsolete equipment in a number of independent plants, and antiquated trade practices. And they mention the chemical industries' trust as an example of a well managed prosperous enterprise which has virtually become a national institution, and which has treated labour well, while at the same time handling its market in a broad gauge manner; the only criticism being that its profits go to stockholders, and high private profits irritate labour.

Generally speaking, in the belief that it will ultimately permit of a shorter work week and higher wages without the necessity of raising prices, organized labour in England now encourages the modernization of plants and the introduction of labour saving machinery. It also favours unions covering a whole industry, as they permit dealing with conditions as a whole, while craft unions do not. There is a solidarity between labour unions, when labour considers it is fighting capital, but none when one industry is fighting another; a typical example of this being the sentiment of bus employees against cheap workmen's bus fares, based on the belief that such would lower profits and so prevent the payment of high wages to bus labour.

Apart from the rationalization of industries, the mental progress of labour leaders in England has been most evident in the way in which they have influenced new legislation in the transportation field.

The Labour Party in Great Britain is frequently considered to be the political branch of the labour unions. This is only true to a limited extent, as the Labour Party, though affiliated in a general way with the unions, is strictly a political party like the Conservative or the

Liberal; and the labour leaders are wise enough to keep themselves in a position where they are able to demand concessions from any party that happens to be in power. The members of the unions are conservative or radical according to their individual opinions; and only on rare occasions does labour vote as a solid political party. This desire of the labour unions for freedom of action was evident when it was proposed in the Railways Act of 1921 that labour should be represented on the boards of directors of the amalgamated railway companies. The labour leaders saw that the responsibilities which would result from being represented on the directorates would restrict their independence of action; so they permitted this feature to be withdrawn when it was opposed by the railways. They were thus able to obtain equal representation with the railways on the wages boards, a continuation of the war time wages which were at about two and a half times the pre-war level, and the condition that no employee of five years standing should be dismissed as a result of the amalgamations without adequate financial compensation.

At that time the labour unions were strongly advocating the nationalization of the railways. But they soon saw the country was not ready for it, so they contented themselves with the thought that the amalgamation of the one hundred and twenty railways into four consolidated properties would tend to simplify nationalization at some future date, and that the Railways Act of 1844 permitted the State to acquire the railways at any time.

The negotiations connected with the Railways Act of 1921 were the first trial of the wings of the labour unions after the war-time responsibilities had caused them to break out of their pre-war rut; and in the fifteen years since 1921 they have learned much.

When the 1921 Railways Act was under discussion there was some vague talk that labour should share in the profits of the railways. The Act instructs the Rates Tribunal to set rates that would insure to the railways a standard return based on the 1913 earnings; and when any permanent annual net earnings in excess of this standard return became evident, 80 per cent of the excess was to be allotted to a reduction of rates and 20 per cent was to be retained by the railways as an increase in the standard return they were permitted to earn. Labour assumed that a considerable part of this 20 per cent would be captured by them as increased wages, and that this would be the labour share of the profits which had been mentioned. But severe highway competition developed, so that the railways no longer had a monopoly; and this, with the depressed condition of trade, resulted in low net earnings for the railways, and there never were any profits for labour. So labour supported the railways when in 1927-8 they applied for powers to enter the road transport field, and has since been active in forcing the regulation of road transport as to wages and operating conditions, and even in an indirect way in regard to rates; so that it is now an organized industry, and the early evils of cutthroat competition are disappearing. Further, labour began to consider that a complete monopoly of all public transport, (i.e. all freight and passenger transport for hire), was the only solution for the transportation problem in England.

Because of the development of the suburbs, requiring extensions to the underground railways which were not in condition to finance such, and the numerous independent pirate buses which were demoralizing the profitable short haul traffic, and the complaints of labour as to the erratic wage scales wherein some of the unprofitable enterprises were paying wages much lower than the prosperous bus lines, the problem of passenger transportation in the London Metropolitan area had gradually become a sore spot. Accordingly the Labour Government in 1930 introduced a Bill which consolidated under the London Passenger Transport Board all underground railways, buses and tramways, and pooled their receipts with those of the suburban traffic of the main line railway systems; and this Bill was passed by the new National Government through a predominantly Conservative House in 1933. The Bill covered all passenger transportation for hire in the metropolitan area, both municipal and privately owned, except taxi cabs; and as the taxi cabs are now suffering from the efficient competition of the Transport Board, and are beginning to complain, they may also be ultimately absorbed. Though the public was from experience quite satisfied as to the ability of a municipality to manage a simple undertaking such as an electric light plant or a local tramways, it was sceptical as to any politically controlled body operating such an important enterprise as the London Transport Board, which controls the entire passenger transportation for hire, except taxi cabs, of the London area of 2,000 square miles with a population of nearly ten million. And though the labour unions were still theoretically in favour of the nationalization of all transport facilities, the leaders were beginning to think that labour might be worse off under government operation, e.g. under a bureaucracy or a civil service such as the Post Office, than it had been under the Railways Act of 1921, and in the rationalized industries. Accordingly there was little opposition to the Bill which made the Board free from political control, and specified that its seven members should be elected by the Chairman of the London County Council, a representative of the London and Home Counties Traffic Advisory Committee, the Chairman of the Committee of the London Clearing Bankers, the President of the Law Society, and the President of the Institute of Chartered Accountants, acting as Appointing Trustees. So that the principal labour criticism of the Bill was directed against the prices paid for the absorbed properties, on the grounds that paying dividends on excessive capitalization takes money that should go for higher wages. But the labour leaders realized that debentures and loans could not be disturbed without injury to the whole financial system of trust funds, insurance investments, charitable endowments, etc., and so concentrated their disapproval on the "C" stock of the Transport Board (limited to 6 per cent dividends if earned), which was given in exchange for the equity or goodwill of the absorbed properties. The government has since recognized the justice of this labour criticism as to the burden of high capital charges, by loaning the Board funds for extensions and improvements; thus offering it one of the most important advantages claimed for State ownership, viz., cheap money.

The clause in the Railways Act of 1921 which ruled that no employee of five years standing at the date of passage of the Act could be dismissed as a result of the amalgamations without financial compensation had worked well. The railways had taken particular care to safeguard human relations and had relied on the natural loss by retirement and death to render possible the gradual development of the economies made possible by the Act, so that less than one-quarter of the decrease in employees had been due to men losing their jobs because of the amalgamations; though since 1930 a number have been laid off because of the depression. But in the London Transport Board Act labour obtained the concession that no employee of *two* years standing at the date of passage of the Act should be dismissed, instead of *five* years standing as in the Railways Act. Actually, however, the number of employees of the Transport Board has increased about three per cent in its three years of operation, due to extensions to the system. However, some incompetent employees who were penalizing earnings have been dismissed; it is interesting to note that labour sentiment endorsed this action, and that it also favours high fares so that the property will be prosperous and able to pay good wages.

The London Transport Board plan was regarded as an experiment to give mass passenger transportation at reasonable prices and avoid the dangers of government ownership. Apparently it has been successful. Labour has obtained a number of wage increases for low paid employees and better working conditions, because the Board was better able to give them than many of the constituent properties which were subject to severe competition. The public has benefited through numerous fare reductions and better services and facilities. And the Board is functioning in an efficient business like manner, free from political or local interference.

The next experimental trial of the idea of labour that all transport should be a regulated monopoly was the passage in 1935 of the North Ireland Road and Rail Transport Act which consolidated under a government appointed Board all passenger and freight highway transportation for hire in Northern Ireland (other than the Belfast municipal and a few minor properties), and pooled the receipts with the railways. The Act specifies that the commercial functions of the Board, i.e. services, fares, rates and charges, new facilities, pooling arrangements, etc., shall be under the Joint Committee consisting of three members appointed by the Board and three appointed by the railways. So that it is apparently the purpose of the Act that the management shall be partially in the nature of a public trust in which the important of the existing enterprises are represented.

Under the Motor Vehicles Acts of 1926-1934 the conditions of operation (excluding wages and rates) of all highway transport in Northern Ireland were already regulated by the Ministry of Home Affairs, and bus fares controlled by the Road Transport Tribunal. And under the 1935 Act the wages and rates of any local carriers that are authorized by the Act to operate and of any independent public carriers that the Board permits to operate, are apparently made subject to the jurisdiction of the same appeal tribunals which ultimately control the wages and rates under the Board operations.

A government-selected board, rather than one appointed by independent interests like the London Transport Board, was possibly decided upon because of the ten weeks rail strike in 1933, which indicated that the joint railways and labour councils were not working as smoothly in Northern Ireland as they had in England; and because some of the labour unions were still nominally advocating the nationalization of all forms of transport.

Like the London Transport Board Act, the 1935 Road Transport Act of Northern Ireland safeguarded against dismissal all employees of two years standing.

The Board is authorized to issue "A" stock to pay for the physical assets of the absorbed properties, and "B" stock (limited to 6 per cent dividends if earned), for equities or goodwill. But to meet the opposition of labour to taking over properties at high prices, practically all have been acquired at their appraised physical value; and though the first annual report (1936) has not yet been issued, it is understood that only a very minor amount of "B" stock has been authorized.

The idea of labour was that the plan would probably result in the abandonment of some of the weak railways; but that dismissed employees would be absorbed by the highway transport as it developed. And though the fact that six of the nine railways in Northern Ireland extend also into the Irish Free State had influenced the government decision not to consolidate the railways with the highway transport under the Board at this time, labour expects that ultimately a way will be found for the Board to take over all the railways; thus enabling the experiment of a complete monopoly of all passenger and freight transport for hire to be tried in a small section of the country where a failure would not have serious consequences.

We have accordingly three experiments in the monopoly of public transport which have resulted from the pressure of organized labour.

(1) The amalgamation of the English railways into four territorial systems under private ownership and management, which through the pooling of freight and passenger traffic between common points has practically eliminated rail competition; but which is still subject to independent highway competition.

(2) The London Passenger Transport Board, with its securities privately owned and its properties under a management which is virtually a public trust free from political interference, and operating a monopoly of passenger transportation for hire in the London area, with receipts pooled with the suburban railway traffic.

(3) The government appointed Northern Ireland Road Transport Board, with its securities privately owned and its receipts pooled with the railways, operating all highway passenger and freight transport for hire in Northern Ireland under a management which apparently will be partly in the nature of a public trust in which the important existing enterprises are represented; and which labour expects will ultimately absorb the railways, and so become a monopoly of transport in the territory.

However, none of these three is an absolute monopoly, as they are all subject to the competition of privately owned automobiles and trucks which are used exclusively in the owner's business or pleasure.

All three of these transport monopolies are privately owned. But to conciliate those who consider that capital charges penalize wages, the stocks of the London Transport and the Northern Ireland Road Transport boards are made redeemable at par after twenty to thirty years.

Organized labour in England is not afraid of monopoly, either in industry or transport, as it realizes from experience the economies it makes possible, and the benefits to labour which result from strongly organized prosperous consolidated properties; and it is satisfied that no monopoly, especially a public utility monopoly, can abuse its power; as if it attempts to do so, the public always develops an effective way to control conditions. The "man-in-the-street," however, still talks at times in favour of State ownership and operation of all public utilities; and the miners are advocating the nationalization of the coal mines. But labour leaders are satisfied that labour will fare better with the rationalization of industries under private ownership and management, than under the State; and though some of the labour unions are still nominally in favour of nationalization of all forms of transportation, the leaders believe that a transport monopoly of any size, at least in England, would be more likely to satisfy public needs and be able to pay good wages to labour, if it were conservatively capitalized and managed as a public trust, free from political interference and bureaucratic control, like the London Passenger Transport Board.

Socialists, radicals and communists would be satisfied only with State ownership and operation of both industry and transport. But though this sentiment is strong in some districts such as Glasgow and South Wales, its influence in the national labour councils, other than the miners, is small. As one labour leader said, "We are willing to have the communists with us, as they keep us 'pepped up' and do not disturb our policies." Delegates to labour conferences have occasionally endorsed communist or socialist motions. But they have done so on their own emotional impulse, without instruction from their membership. So that such spontaneous actions are without significance.

The labour leaders in England are level headed and have learned much in the last fifteen years. So that though they at times talk radically for the benefit of some of their fire-eating constituents, they are following a conservative far sighted policy, and they are able to keep their membership in line. So long as this condition continues, organized labour cannot fail to be a powerful constructive force in English national life, and to be considered with the middle classes as the backbone of the country.

* * * *

The following is of interest in connection with the paper as it is an extract from an address by John Marchbank, the General Secretary of the National Union of Railwaymen, the most important of the English railway labour unions, before the Wandsworth Technical Institute, London, October 23rd, 1936.

> "In the view of the trade unions, transport should be brought under one control on a national basis, and the experiment in the case of the London Passenger Transport Board tends to support the view that the complete organization of transport is a necessity which must materialize at some future date.
>
> Viewed broadly, it may now be stated that the State, by the march of events, has been compelled in the national interest to act as co-ordinator of transport. In this capacity, as evidenced by the Railways Act of 1921 and the London Passenger Transport Act of 1933, legal compulsion has been put upon private interests or statutory bodies in order to secure amalgamations, a step which has had the effect of diminishing the disadvantages which existed during the time uneconomic competition reigned supreme."

The following is from a letter to the author, dated December 29th, 1936, also from Mr. Marchbank, to whom the paper was submitted for comments.

> "Whilst it is true that the Trade Union Congress makes representations to the Government of the day, no matter whether it is Liberal, Labour or Conservative, it must not be overlooked that trade unions are affiliated direct to the Labour Party and use the machinery of the Labour Party to give expression to their political ideas."

A letter dated February 16th, 1937, received from Mr. Allan Meikle, President of the Winnipeg National Labour Council, and member of the Executive Board of the All Canadian Congress of Labour, reads in part:

> "I congratulate you upon having observed from a standpoint outside the labour movement what many have failed to discern owing to their subjective position. Some of us in Canada have been trying for a long time past to induce organized workers to make a more practical approach to their problems than that which is suggested by the theoreticians. Sooner or later I am convinced they will come around to our view."

The following is an extract from an undated memorandum from Mr. W. T. Burford, Secretary of the Canadian Federation of Labour, Ottawa:

> "Labour movements the world over owe so much to the workers organizations of Great Britain that the recent tendency of labour in that country to revert to its original empiricism is of profound significance. In his paper Mr. Waters comments on the change he has observed in British labour's attitude towards industrial rationalization. This and other changes indicate an abandonment of traditional doctrines, and, above all, an emergence from the habit of letting political theory dictate economic policy."

# Power Development in Northern Ontario

*T. H. Hogg, C.E., D.Eng., M.E.I.C.,*
*Chief Hydraulic Engineer, Hydro-Electric Power Commission of Ontario, Toronto, Ontario.*

**Paper presented before the Toronto Branch of The Engineering Institute of Canada on January 21st, 1937, and before the Kingston Branch on January 26th, 1937.**

SUMMARY.—The demand for power for mining and for the pulp and paper industry in Northern Ontario since 1916 has led to the development of many power sites on the rivers draining into Lake Winnipeg, James Bay, Lake Superior and Lake Huron. The various plants of the Hydro-Electric Power Commission in this area generated some 325,000 h.p. last December; they are described and the conditions of sale and utilization of their power are discussed.

The vast portion of Ontario lying north of the forty-sixth parallel of latitude, which skirts the northerly shore of Georgian bay, produces a considerable share of the world's supply of newsprint and metallic minerals, particularly gold and nickel, and this would not be possible without the provision of large amounts of low cost power, which is as vitally important to these industries of the north as it is to the commercial, manufacturing and domestic consumers in southern Ontario. With only a small percentage of the total population, northern Ontario has developed water power sites with installations totalling over 1,000,000 h.p., as against southern Ontario's installations totalling approximately 1,350,000 h.p., which latter figure includes 950,000 h.p. installed on the Niagara river. Of the 1,000,000 h.p. of developed sites in the north, in round figures about 800,000 h.p. is at present being absorbed, 400,000 h.p. by the pulp and paper industry, 300,000 h.p. by the mining and metallurgical industries, and 100,000 h.p. by municipal and manufacturing concerns.

In capacity of undeveloped sites, northern Ontario leads southern Ontario by 2,500,000 h.p. as against 1,800,000 h.p. This figure of 1,800,000 h.p. includes Ontario's share of the power available in the international section of the St. Lawrence river, estimated at 1,100,000 h.p., but does not include power from any further diversion of water in the Niagara river through a revision of the Boundary Waters Treaty. Ontario's share of the undeveloped resources of the Ottawa river is about 630,000 h.p., of which 250,000 h.p. is located north of the forty-sixth parallel.

## POWER RESOURCES OF NORTHERN ONTARIO

Before proceeding with some comments on the more interesting phases of power development in the north, and in order to provide a background for the subject, it is desirable to describe briefly some of the more important power rivers in this area, and to mention the principal operating plants, the uses to which the power from them is put, and the undeveloped resources of these rivers. Many of these are shown on the map in Fig. 1.

### Lake Winnipeg Drainage

*English River*—The English river is a tributary of the Winnipeg river with headwaters at Lac Seul, and has a drainage area of 20,000 square miles at its junction with the Winnipeg. The only power development constructed on this river is the plant at Ear Falls, at the outlet of Lac Seul, where one 5,000-h.p. unit is at present installed. The installation of a second 5,000-h.p. unit is now under way, the ultimate capacity of this site being 25,000 h.p. Below Ear Falls there are three undeveloped sites aggregating approximately 120,000 h.p.

*Wabigoon River*—The Wabigoon is a tributary of the English river on which three small developments with capacities totalling 6,000 h.p., owned by the Dryden Pulp and Paper Company, are installed.

*Winnipeg River*—The Winnipeg river flows from Lake of the Woods into lake Winnipeg, being joined by the English river a short distance east of the Manitoba boundary line. There are two developed sites, totalling 30,000 h.p., owned by the Keewatin Power Company, supplying power to pulp and paper mills at Kenora, and two others of 6,000 h.p. capacity owned by the Lake of the Woods Milling Company located at the outlets of the Lake of the Woods. Two undeveloped sites with a capacity of 80,000 h.p. are located between Lake of the Woods and the Manitoba boundary.

*Rainy River*—The Rainy river flows from Rainy lake into Lake of the Woods and on it is one development at Fort Frances, owned by the Ontario and Minnesota Power Company, supplying power to the paper mills in the vicinity.

*Seine River*—The Seine river empties into Rainy lake from the east and there are three developments on it, with a total capacity of 36,000 h.p., also owned by the Ontario and Minnesota Power Company, whose output is fed principally to the paper mills in the Fort Frances district.

### James Bay Drainage

There are several large rivers north of the Albany, of which the Severn, Winisk and Attawapiskat are the principal ones, with undeveloped power resources, from our present knowledge, in the neighbourhood of 200,000 h.p.

*Albany River*—The Albany river is at present our Northern frontier, the mines in the Pickle Crow area in this vicinity representing the farthest north producing mines in Ontario. With headwaters at lake St. Joseph, the river has a drainage area of 50,000 square miles at its mouth, and is exceeded in size in Ontario only by the Ottawa, Niagara and St. Lawrence rivers. The only existing development on the Albany is at Rat Rapids, at the outlet of lake St. Joseph, which supplies power to the mines in the Pickle Crow area some twenty-five miles to the north. The undeveloped sites on the Albany are capable of producing up to 300,000 h.p., while its principal tributaries, the Ogoki, Kenogami, and the Kabinakagami, have undeveloped sites with a potential capacity of 200,000 h.p.

*Missinaibi River*—The Missinaibi river joins the Moose river near sea level. There are no developments constructed on this river, but there are undeveloped sites with a potential capacity of 100,000 h.p.

*Mattagami River*—On the Mattagami river there are three hydro-electric developments owned by the Canada Northern Power Company, having a total capacity of 25,000 h.p., supplying power to the mines in the Porcupine area. A 9,000-h.p. plant at Smooth Rock Falls is owned by the Abitibi Power and Paper Company, and one of 55,000 h.p. capacity at Smoky Falls supplies power to the Spruce Falls Pulp and Paper Company's mills at Kapuskasing. With its tributary, the Kapuskasing, there are undeveloped sites aggregating 275,000 h.p. on the Mattagami river.

*Abitibi River*—The Abitibi Power and Paper Company own three plants on this river, Twin Falls with a capacity of 30,000 h.p., Iroquois Falls with 28,000 h.p., and Island Falls with 48,000 h.p., which supply power to the Abitibi Company's mill at Iroquois Falls. The Canyon plant, about twenty-four miles downstream from Island Falls, owned by the province and operated by the Commission, has an installation of 275,000 h.p. This plant supplies primary power to the mines in the Porcupine, Kirkland lake, and Sudbury districts, and surplus power for steam production to the Abitibi Company's mills at Iroquois Falls and Smooth Rock Falls.

### Lake Superior Drainage

*Kamanistiquia River*—There is a development of 35,000 h.p. on this river at Kakabeka Falls, owned by the Kamanistiquia Power Company, the output of which is absorbed in Fort William and vicinity, also an undeveloped site of 25,000 h.p. capacity.

*Nipigon River*—Two hydro-electric developments owned by the Commission are located on the Nipigon river at Cameron Falls and Alexander, with installations of 75,000 h.p. and 54,000 h.p., respectively. The output from these plants supplies power to the pulp and paper mills located at Port Arthur and Fort William, to these municipalities, and to the Little Long Lac and Sturgeon river mining areas to the northeast. There is an undeveloped site of 100,000 h.p. capacity available a short distance upstream from Cameron Falls.

*White River*—The White river has undeveloped sites of 40,000 h.p. capacity, but no developed sites.

*Michipicoten River*—On the Michipicoten river is a development of 22,000 h.p. capacity, owned by the Great Lakes Power Company, which supplies power to Sault Ste. Marie and vicinity, and undeveloped sites of 30,000-h.p. capacity.

*Montreal River*—On the Montreal river the Great Lakes Power Company are constructing a development and installing one 10,000-h.p. unit, the ultimate capacity of this site being 20,000 h.p. They have a lease on another site of equal capacity farther downstream.

### Lake Huron Drainage

*St. Mary's River*—The St. Mary's river connects lakes Superior and Huron, through a drop of 18 feet. Two developments owned by the Great Lakes Power Company of 42,000-h.p. capacity supply power to municipal and industrial customers in Sault Ste. Marie.

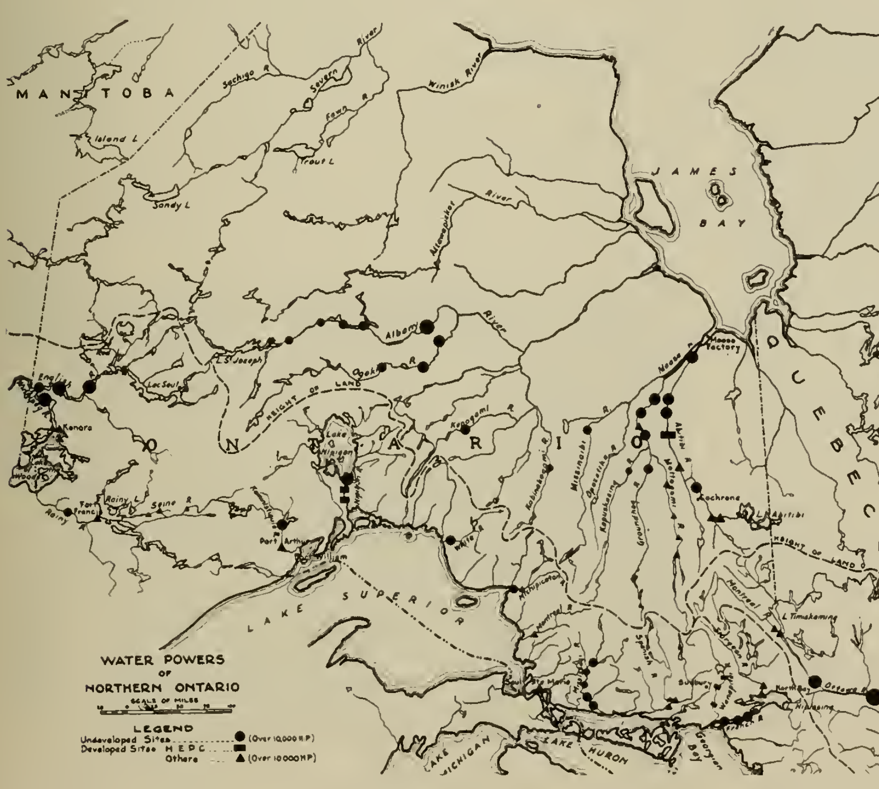

**Fig. 1—Map of Northern Ontario showing Location of Developed and Undeveloped Water Power Sites.**

*Mississagi River*—There are no developments constructed on the Mississagi river, but the potential capacity of this river is 140,000 h.p. which may be developed at reasonable cost in eight sites.

*Spanish River*—There are four developments on the Spanish river with a total capacity of 86,000 h.p., 56,000 h.p. in three plants at Big Eddy, High Falls and Nairn owned by the International Nickel Company, and one at Espanola owned by the Abitibi Power and Paper Company which formerly supplied power to the Espanola mills.

*Wanapitei River*—On the Wanapitei river, a tributary of the French river, there are three developments, operated by the Commission, which supply 60-cycle power to the Sudbury district.

*French River*—The French river flows from lake Nipissing into Georgian Bay and has a potential capacity in three undeveloped sites of 40,000 h.p.

*Sturgeon River*—The Sturgeon river, which flows into lake Nipissing from the north, has two developments at Crystal Falls and Sturgeon Falls, owned by the Abitibi Power and Paper Company, which formerly supplied power to the Sturgeon Falls mills.

### Ottawa River Drainage

No developments have been constructed on the interprovincial section of the Ottawa river between Pembroke and lake Timiskaming, but Ontario's share of the undeveloped power available in this section is 250,000 h.p. A fall of 200 feet exists on this reach, of which 70 feet is above Mattawa, and 130 feet below.

*Montreal River*—The Montreal river flows into lake Timiskaming from the west, and five developments with a total capacity of 32,000 h.p., owned by the Canada Northern Power Company, supply power to the mining areas to the west. There is also a development of 13,000 h.p. on the Matabitchewan, which joins the Montreal near its mouth, also owned by the Canada Northern Power Company. Undeveloped sites totalling 30,000 h.p. are available on the Montreal river.

## HYDRO-ELECTRIC POWER COMMISSION DEVELOPMENTS

### Cameron Falls

The Commission's first venture in Northern Ontario was the construction of a plant on the Nipigon river at Cameron Falls to supply a demand for power in the municipality of Port Arthur, and for pulp and paper mills in the vicinity. Because of the small potential market, consideration was first given to a site on the Kamanistiquia river with a potential capacity of 25,000 h.p., which was a considerably shorter distance from the market. Looking to a major growth in load in the near future, however, it was decided to proceed with the initial stage of the development at Cameron Falls, which site had an ultimate capacity of 75,000 h.p. with regulation of the outflow from Lake Nipigon. Two 12,500-h.p. units were installed in the first stage. Construction of this plant was begun in 1919, and the initial installation went into service in 1921.

The growth in load on the system necessitated the installation of two additional units by 1924, which brought the capacity of the plant up to 50,000 h.p. Almost immediately after the third and fourth units were installed, it was necessary to proceed with the fifth and sixth units, which went into service in 1925. At this time the construction of the Virgin Falls dam at the outlet of Lake Nipigon was completed, which provided practically complete regulation of the flow of the river.

Starting from January 1921 with an initial load of 10,000 h.p., by the end of 1923 the load was approaching the capacity of the first two units. By the end of 1925 the load had reached 50,000 h.p., or the capacity of four units, and by 1929 the load was in excess of the rated capacity of the plant. This phenomenal growth in load was due primarily to the absorption of large blocks of power by the four pulp and paper mills operating in this district.

The development consists essentially of a reinforced concrete headworks and power house on the right bank, and a stop-log sluiceway dam across the river at the crest of Cameron Falls, where formerly a natural drop of 30

Fig. 2—Cameron Falls Development, Nipigon River.

feet occurred. The dam raises the water 45 feet, flooding upstream for a distance of twelve miles, and provides a head of 75 feet. Six auxiliary dams were required to close off low areas in the headwater reach. A short tailrace channel carries the water from the power house to the lower river below the rapids.

A complete reinforced concrete superstructure was constructed over the generator room, headworks and interconnecting supply pipes, and the transformers are installed indoors above the supply pipes, as it was thought advisable at that time to provide complete protection for all operating equipment.

Access to the site was obtained by means of a short railway spur from the Canadian National Railways, which passed close to the river at this point on the opposite bank. The provision of the large headpond with very low velocities permits the formation of an ice cover early in the winter, and no operating difficulties due to ice trouble have been experienced during the fifteen years this plant has been operating.

High tension lines transmit the power to Nipigon on the north shore of lake Superior, and then southwesterly to Port Arthur and Fort William. A recent development has been the construction of a 44-kilovolt transmission line northeast to the Little Long Lac and Sturgeon river mining areas, the present load on this line being approximately 4,000 h.p. A new 110-kilovolt line is now under construction from Cameron Falls to Little Long Lac to meet the growth in load in this district, and to provide better service to the operating mines.

### Alexander

Preliminary construction in connection with the Alexander Development was commenced in 1927, but it was not until 1929 that operations were speeded up to keep pace with the load growth, the plant going into service in 1930. The head at this site is 60 feet, and three 18,000-h.p. units are installed, provision being made for the addition of a fourth unit by the construction of the headworks portion. An earth fill dam, constructed by the semi-hydraulic fill method, was built across the river channel at a turn in the river, and a low concrete spillway section connects the end of the earth dam with the power house which is located on the right bank at tailwater level.

During the construction of the main dam the water was diverted through a channel excavated in rock immediately adjacent to the power house. This diversion channel now carries the water to the power house, and the lower end is blocked off with a concrete plug. There are no regulating sluices installed at this plant, the free spillway being of sufficient length to discharge the flood flow of the river within a range in elevation of five feet.

The generator room superstructure is of brick, the headworks, with the exception of a small area housing the headgate hoists, being left open. An outdoor transformer station is located adjacent to the power house. This is a departure from the layout at Cameron Falls, where the headworks and transformers are housed in.

The Alexander plant is tied into the transmission lines feeding the Port Arthur and Fort William districts. On account of the small area of headpond between Alexander and Cameron Falls, these two plants are required to operate in step, the Alexander plant thus obtaining full advantage of the large headpond at Cameron Falls. The firm power demand on these two plants is now approximately 80,000 h.p., the remaining energy being used for the generation of steam for use in the pulp and paper mills in the Port Arthur district.

### Ogoki Diversion

The diversion of the run-off from 6,000 square miles of the Ogoki river, to the north of Lake Nipigon, which now joins the Albany river and flows into James Bay, has been studied by the Commission for some time. This scheme proposes the construction of a dam on the Ogoki at Waboose Rapids and the diversion of the flow above this point through an artificial channel across the height of land, thence following the valleys of the Little Jackfish river, or Seymour creek, into Lake Nipigon. This diversion would provide an additional flow of 4,000 cubic feet per second to the Great Lakes system, and would increase the dependable capacity of the two plants on the Nipigon by 35,000 h.p. An undeveloped head of 105 feet still remains between Lake Nipigon and Cameron Falls head-

Fig. 3—Alexander Development, Nipigon River. Interior View of Power House.

water, the capacity of this site being 100,000 h.p. with present river flow, and 130,000 h.p. if the Ogoki diversion scheme is consummated.

### Ear Falls Development

The Lac Seul conservation dam, at the outlet of the lake, was constructed in 1928-1929 by joint agreement between the Province of Ontario and the Dominion Government (acting on behalf of the Province of Manitoba) to regulate the flow of the English river for the benefit of the power plants on the Winnipeg river in Manitoba, and to increase the dependable capacity of the undeveloped sites on the English river in Ontario. The area of Lac Seul is 420 square miles, and a 14-foot variation between the maximum and minimum regulated levels gives very nearly complete regulation of the total outflow.

The Howey mine at Red lake was planning the construction of a large mill at this time and required a considerable block of power for their operations. Accordingly, the Ear Falls development was constructed by the Commission at the site of the conservation dam, and a transmission line, about forty miles long, built by the Mining Company into Red lake. The power house is located immediately downstream from the dam, on the north bank of the river, two short 12-foot diameter wood-stave pipes carrying the water from the two end sluices of the dam. One vertical unit, rated at 5,000 h.p. under 36-foot head, was installed, which went into operation early in 1930. This unit has now been operating continuously for over seven years, except for three shutdowns of short duration for inspection purposes, which is believed to establish a record in Canada for continuous operation of one unit.

The plant operates under a head varying from 30 feet to 44 feet, dependent on the levels of Lac Seul and the tail-water, the latter also having an extreme range of 14 feet. An outdoor transformer station is located immediately adjacent to the power house, and the transmission line delivers power to the Howey mine at Red lake, from which point it is distributed to Mackenzie Red Lake and Red Lake Gold Shore mining properties. Contracts have also been executed with several other mines in the district, and negotiations are being carried on with mining companies in the Woman lake district to the east.

For the installation of the first unit the winter freight rate from rail head to Ear Falls was $65 per ton, and the summer rate by water route $12 per ton. The development of the mines in the Red lake district has resulted in a tremendous increase in freight movement from Hudson to and beyond Ear Falls, and these rates have dropped, for the installation of the second unit, to $30 and $7 per ton, respectively.

### Rat Rapids Development

In 1934 the Central Patricia and Pickle Crow mining companies had been carrying along development work in the Pickle Crow area aided by power derived from steam plants using wood for fuel, to the point where the installation of mills was justified, and these companies approached the Commission with a view to obtaining a supply of electric power for their mining and milling requirements at a price which would make the development of their properties attractive. The power from their wood-burning plants was costing approximately $200 per horsepower per annum, and the source of fuel supply was getting farther and farther from the mines. The cost of power from Diesel plants was estimated by the mining companies to be $120 per horsepower, and, in spite of the fact that good power sites were not available within economical transmission distance from the mines, contracts were made with these two companies to supply them with power at an initial figure of $65 per horsepower.

Near the height of land, as in this district, it is unusual to find economical sites for power development as concentrations of head and volume of flow are low. Several sites on the Albany river below Lake St. Joseph were investigated and found to be favourable for larger blocks of power than these two mines appeared to be able to use, as the initial requirement for which the mines were prepared to contract was in the neighbourhood of 1,000 h.p. Accordingly, the site at the outlet of Lake St. Joseph, where a head of from 10 to 16 feet was available, with an ultimate potential capacity of about 3,000 h.p., was selected. One unit was installed with a capacity of from 1,000 to 1,500 h.p.

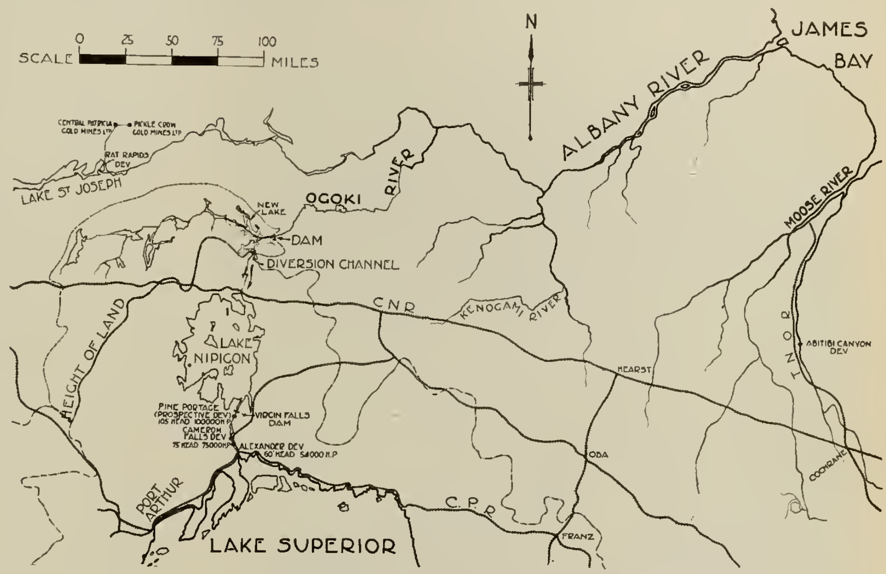

**Fig. 4—Map showing proposed Diversion of Portion of Ogoki River into Lake Superior.**

In order to keep the initial cost of the development as low as possible, timber crib dams were constructed at the northerly, or Rat channel, outlet, and also at the southerly, or Cedars channel, outlet, some five miles south of the Rat channel. The power house was built at the northerly outlet and contains one horizontal turbine with four runners, direct-connected to a horizontal type generator. This unit complete — turbine and generator — was available in storage at the Commission's Calabogie plant on the Madawaska river, and because of its size, being rated at 3,000 h.p. under 27-foot head, it was thought to be particularly suited to supply a mining load of the type expected. New runners were required to adapt the unit to the reduced head under which it would operate. This plant was built in 1934-1935, and went into operation in March 1935, a transmission line, twenty-five miles long, having been built from the power house to the Central Patricia mine and then on to the Pickle Crow.

Transportation costs from rail head to the site played an important part in the design of the structures and the materials used. In the construction of the first stage of the development, the total transportation costs from rail head to the site on all items amounted to 20 per cent of the total cost of the work, in spite of the fact that timber was adopted for the construction of the dams and other structures wherever possible, and that the minimum amount of concrete was used in the power house. The freight rate by winter road amounted to $60 per ton, and practically all of the material was taken in in this manner, the transportation cost on cement alone amounting to about $18 per cubic yard.

Unlike Ear Falls, where a considerable amount of local timber suitable for construction was found, at Rat Rapids the local timber was of smaller diameter, and it was necessary to scour the district to find a sufficient amount for the construction of the timber crib dams. A good stand of red pine was discovered about forty miles up the lake, and arrangements were made with the provincial authorities to obtain sufficient of this for the structural timber requirements. If B.C. fir had been used, the transportation costs alone from rail head would have been $100 per thousand. Because of these high transportation costs, the construction of rock fill crib dams using local timber was decided upon, as the rock fill was readily obtainable. While timber crib dams in such localities cost considerably less than concrete dams, their life is only from ten to fifteen years, but, considering the probable life of the mines, their construction is amply justified.

**Fig. 5—Ear Falls Development. Showing Lac Seul Conservation Dam, Power House and Transmission Line to Red Lake.**

The load on the Rat Rapids plant increased rapidly to the point where an additional unit was required, and a second unit, rated at 1,750 h.p., was installed, which went into operation in October 1936. At the present time the load on this plant is 2,100 h.p.

For the installation of the second unit, the Root river transportation route had been constructed, and practically all the material for the installation of this unit was taken over the water route, the rate from rail head to Rat Rapids being $25 per ton, as compared with $60 per ton by winter haul for the initial development.

The synchronization of mining hoist and compressor motor loads results in load swings at the power house equal to 50 per cent of the total load at times, these swings being at the rate of 15 to 25 per minute, and it will be realized this is a very severe operating requirement for a hydro-electric plant, particularly with only one unit installed. This difficulty has been remedied somewhat by the installation of the second unit, which furnishes additional flywheel effect.

### Wanapitei River Plants

In 1929 the provincial government acquired three plants on the Wanapitei river, formerly owned by the Wahnapitae Power Company, which were supplying 60-cycle power in the Sudbury district. These three plants have a normal capacity of 16,500 h.p. A regulating dam at the outlet of Wanapitei lake had been partially constructed by the Company when these plants were acquired, and this dam was completed by the Commission in 1930. This dam gives nearly complete regulation of the flow of the river and enables the full rated output of the plants to be obtained. The present load on these plants is over 15,000 h.p., approximately one-third going to the Falconbridge Nickel Company, one-third to the International Nickel Company, and one-third to the City of Sudbury. The International Nickel Company and the Falconbridge Nickel Company are also taking a considerable amount of 25-cycle power from the Abitibi Canyon plant.

### Abitibi Canyon

Construction of a large hydro-electric power development on the Abitibi river at the Canyon was undertaken in 1930 by the Ontario Power Service Corporation, a subsidiary of the Abitibi Power and Paper Company. The work was well on the way to completion when the company met with financial difficulties, and went into liquidation. The Ontario Power Service Corporation had contracts with the Commission and with the Abitibi Company for large blocks of power. In 1932 the provincial government decided to buy out the assets of the Ontario Power Service Corporation and complete the development, in order to obtain an ample supply of power for the mines in northern Ontario.

A concrete, gravity-type dam having a maximum height of 290 feet, was constructed across the gorge of the river, flooding back twenty-four miles to the Abitibi Company's Island Falls plant, and making available at this site a head of 240 feet. The power house, housing five 25-cycle units rated at 55,000 h.p. each, is located immediately downstream from the dam in the middle of the river channel, the water supply being obtained through a headworks structure at the top of the dam and steel penstocks eighteen feet in diameter. A tailrace was excavated in the river bed 1,800 feet long to the slack water reach downstream. Five 45-foot sluice gates capable of discharging a maximum flow of 150,000 cubic feet per second were installed on the right, or east, bank adjacent to the power house, and a training wall 3,000 feet long was built between this high water channel and the river, in order to protect the power house and tailrace channel. Complete unwatering of the site during construction of the dam and power house was obtained by the provision of two diversion tunnels on the west side of the river.

The transformers are located on the power house roof, and the high tension switches behind the headworks at the upper level. Steel headgates are provided for unwatering the units and a specially constructed unloading crane was installed on the west bank to handle equipment from the railway spur at this point into the power house.

Two steel tower transmission lines were built to Hunta, just west of Cochrane on the Canadian National Railway, and one from Hunta to Sudbury to supply 25-cycle power to the Falconbridge and International Nickel Companies. Lines were also built from Hunta to Smooth Rock Falls and from Hunta to Iroquois Falls to supply power to the Abitibi Company's mills at these points. From Iroquois Falls a line was built to Kirkland lake to supply the mines in this vicinity, the line from Hunta to Sudbury passing through Timmins supplies the mines in the Porcupine area. A contract was made with the Canada Northern Power Company wherein the Company agreed to take from the Commission power for all their growth in load for a ten-year period.

The Canyon plant started operation in May 1933 with an initial load of 15,000 h.p. The growth in load since that time has been very rapid, and at the present time the primary load on this system is 75,000 h.p. It is estimated that within the present year the primary load will have reached 100,000 h.p., all of which will be absorbed by the mines in the three mining districts served. At present the surplus capacity is being disposed of to the Abitibi Company for steam production at its mills, but this service will be reduced as the primary load increases.

The outflow from Abitibi lake is controlled by the Abitibi Company's power plant at Twin Falls and the six-foot range available on this lake provides sufficient water for the full rated output of the large mill at Iroquois Falls (which is capable of producing 600 tons of newsprint per day), the necessary power being obtained from the plants at Twin Falls, Iroquois Falls and Island Falls.

The capacity of the Canyon site may be increased by approximately 40,000 h.p. with more complete regulation of the flow of the river by the construction of a storage dam on the Frederick House river with 300,000 acre feet capacity. This river joins the Abitibi just upstream from the Island Falls plant. The installation of this storage was a part of the general scheme of the development of the Canyon site proposed by the Ontario Power Service Corporation, and consideration is being given to it by the Commission and the Government at the present time.

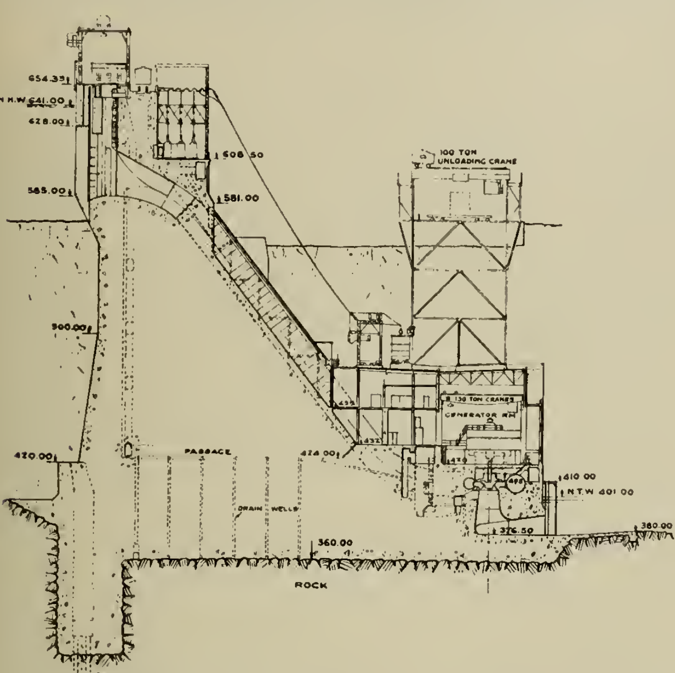

**Fig. 6—Abitibi Canyon. Cross Section through Main Dam and Power House.**

## DISTRIBUTION OF POWER

### The Pulp and Paper Industry

Reviewing the foregoing, there are power plants on the Winnipeg river supplying power to the mills at Kenora, and plants on the Seine and Rainy rivers supplying power to the mills at Fort Frances. The two Nipigon river plants and the Kamanistiquia river plant supply power to the mills in the Port Arthur and Fort William districts. The Smoky Falls plant on the Mattagami river supplies power to the Kapuskasing mills, and the three plants on the Abitibi river supply power to the Abitibi Company's mill at Iroquois Falls. These are the five large producing areas in northern Ontario.

The modern pulp and paper mill requires about 100 h.p. per ton of daily output. Large power reserves in undeveloped sites in proximity to the mills are available, and the capacity of these undeveloped sites is sufficiently large to at least double the present output of the companies now operating in Ontario.

### The Mining Industry

For mining and milling a producing mine requires from 2½ to 5 h.p. per ton of daily output. The present requirements of the mines in the Red lake district are being taken care of by the development at Ear Falls, with one 5,000-h.p. unit installed, and an additional 5,000-h.p. unit being added at the present time, the ultimate capacity of this site being 25,000 h.p. Other sites of large capacity are available farther down the river should the mines require more power than the Ear Falls site could provide.

The Rat Rapids development, with the present installation of 3,000 h.p., provides for the present requirements of the producing mines in the Pickle Crow area, and additional sites are available on the Albany river downstream from Rat Rapids, within economical transmission distance of these mines.

There are a number of promising mining properties operating in the region midway between the Pickle Crow and the Red lake areas, in the vicinity of Woman lake and the Cat river. If these mines require hydro-electric power, a transmission line from Ear Falls could be constructed. This area is near the height of land between the northerly and the southerly drainage, and also is the divide between the easterly and westerly drainage. The country is flat and no power sites of any appreciable capacity exist in the immediate vicinity.

The mines in the Little Long Lac and Sturgeon river areas are at present supplied from the Cameron Falls plant on the Nipigon river, and ample power is available from this river for any possible expansion for years to come.

The Porcupine and Kirkland lake mining areas are the major gold producers in Ontario, and receive their power supply from the Canada Northern Power Company, with plants on the Montreal and Mattagami rivers, and from the Commission's Canyon plant on the Abitibi. There is a considerable reserve of power still available from the Canyon plant to supply growth in load in these areas, and there are additional undeveloped sites of large capacity in the vicinity.

The Canyon plant also supplies 25-cycle power to the International Nickel Company and the Falconbridge Nickel Company in the Sudbury district. These companies, which are understood to be the largest producers of nickel in the world, also obtain 60-cycle power from the three Wanapitei river plants. The International Nickel Company also owns and operates three plants on the Spanish river which supply power to their smelters. Future power supply for this district, in smaller amounts, is available from three sources within short transmission distance, the Spanish, Sturgeon and French rivers. Larger blocks of power would be available from developments on the Mississagi or the Upper Ottawa river, as well as from the Canyon plant.

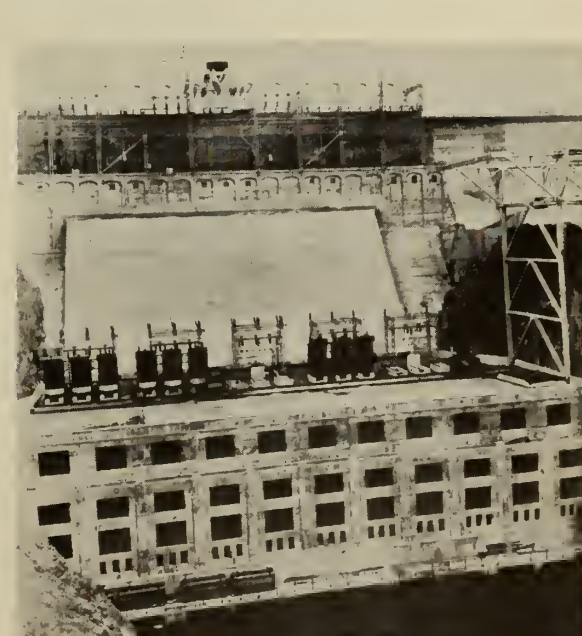

**Fig. 7—Abitibi Canyon. General View of Dam and Power House.**

MINING CONTRACTS

The rapid expansion of the mining industry in northern Ontario has been briefly outlined, and present indications are that this rapid growth will continue. The rates at which power can be sold, and the terms of the contract under which delivery is made, are of prime importance in the development of the mining industry. Two essentials must be observed—safeguarding of the investment of public funds, and the adoption of a rate schedule enabling the purchase of power to be made at reasonable cost to operating companies, particularly in the early stages of their development. The Commission's mining contracts fulfil these two conditions. The standard contract requires the customer to provide a bond sufficient to cover the immediate investment in transmission costs to serve their property, and to cover three months' power bills. In new mining districts largely in the development stage, such as the Red lake and Pickle Crow areas, the customers may be required to bear the entire cost of the transmission line.

Fig. 8—Abitibi Canyon. Interior View of Power House.

An initial rate for power is set in some instances, for isolated properties, sufficient to write off the major portion of the cost of the development in from five to ten years' time, at the end of which period the rate per horsepower would be reduced if the mine were still operating. The term of these contracts is for ten years, or the mining life of the property, whichever is the shorter.

If at any time during the continuance of the contract a fault in the customer's ore bodies makes necessary extensive exploration work to locate future working ore bodies, and thereby makes necessary a substantial or complete shutdown of the customer's mill, the customer is entitled to special consideration and may be relieved of payment for 75 per cent of the contract amount of power during the continuation of this fault period. If within three years of the commencement date of the contract the customer abandons all mining operations, the minimum bill called for in the contract is paid for two months and the contract may then be cancelled without further penalty. Abandonment after three years of operation may be made without any penalty whatsoever.

Power is paid for on the basis of the highest ten-minute average or integrated peak created during each month at 85 per cent load factor and 85 per cent power factor. Penalties are required for loads established below 85 per cent power factor and above 85 per cent load factor. Prevailing rates in the Abitibi district for high tension power are $32.50 per horsepower for demands up to 5,000 h.p., $22.50 for demands between 5,000 and 10,000 h.p., and $17.50 for demands between 10,000 and 20,000 h.p. In the Little Long Lac, Sturgeon river and Red lake areas prevailing rates are $35 per horsepower per annum. In districts where special developments are required to serve specific mining properties, such as the Pickle Crow and Central Patricia mines, special rates are adopted.

The entire rate schedule of the Commission for all mining districts has been built up on the basis of providing an amortization fund to retire all capital investment in connection with mining properties within a reasonable time, considering the probable mining life of the various properties to which power is being supplied. The rate is also based on the collection of sufficient revenue to meet all operating and administration costs, as well as all fixed charges, including interest and the amortization fund mentioned above.

The Commission, with the generation of over 325,000 h.p. last December, is now the largest producer of power in northern Ontario. Its plants on the Nipigon river have operated since 1921 primarily on pulp and paper mill load. At the present time it is supplying power to mining properties to a total of 95,000 h.p., and this load has been built up from zero in the last six years. In supplying power for mining purposes in northern Ontario, the endeavour of the Commission has been to give a high standard of service commensurate with the load to be served, keeping in mind the advisability of giving power at as low a cost as possible in initial stages of development. With the exception of the Nipigon river plants, all of the Commission's developments in northern Ontario are in connection with the mining industry, and the generating plants are owned by the Provincial Government and operated for them by the Commission.

The rapid growth in the pulp and paper industry between 1915 and 1930 was made possible, to a large extent, by the availability of large amounts of low cost power. The output of the mills was curtailed somewhat during the ensuing four years, but the 1936 output exceeded that of any preceding year. At the present time all of the larger mills are operating at or near capacity, with ample power reserves, and if future markets demand the construction of additions to these mills, suitable undeveloped power sites are available to supply additional power.

Mining in Ontario assumed major proportions in 1908 when the silver mines in the Cobalt area came into production. Then about 1916 the big gold producers at Porcupine and Kirkland lake became active, and from that time until 1930 the mining industry in Ontario, particularly gold and nickel producers, expanded rapidly and became a major industry. The availability of ample supplies of power materially assisted in this development. In the last two years, due primarily to the higher price of gold and base metals, output was speeded up, new mines came into production, and large amounts of power were absorbed. Moreover, it is the opinion of mining authorities that this speeding up will continue for a number of years, and, if so, there are large undeveloped sources of power which can be made available for the industry as required. Thirty years ago most people thought of northern Ontario as a vast unproductive wilderness. Present knowledge indicates that it is destined to play a very important part in the future prosperity of our province.

# Speech and Music and Their Relation to Transmission Problems

*D. C. Geiger, A.M.E.I.C.*

*Transmission Engineer, Western Area, Bell Telephone Company of Canada, Toronto, Ontario.*

**Paper presented before the Hamilton Branch of The Engineering Institute of Canada, December 8th, 1936, and before a joint meeting of the Niagara Section of the Canadian Chemical Association and the Niagara Peninsula Branch of The Engineering Institute of Canada, January 14th, 1737.**

The development and growth of radio broadcasting has aroused a widespread interest in the transmission of speech and music over long distances, both as radio waves and over communication lines. Although before radio broadcasting had become general, nearly everyone was familiar with the telephone and its transmission of speech, and in a few cases music, it was looked upon as an ordinary feature of daily life with very little thought being given to its performance. On the other hand, in the case of radio broadcasting, in which the quality and volume of the received speech and music are somewhat within the control of the person at the receiving end, the problems incident to the transmission of speech and music have become of interest to many persons.

Because of this general interest, it seems timely to present some of the factors underlying the proper transmission of speech and music.

In the telephone business the proper transmission of speech is the primary function, as the subscriber wishes to communicate with others easily and understandably. For such a transmission service, the main requirement is intelligibility, although in recent years improvements in the art have gone beyond just the provision of intelligibility. However, in the transmission of speech or music for broadcasting purposes the entertainment requirements are such that it is important that their naturalness be preserved.

The telephone engineer has become vitally interested in the problems associated with providing such a high grade service because except under special and unusual conditions all connections between studios or sources of broadcasting material and transmitter stations are by means of land lines rather than radio channels. Thus the telephone engineer has had a problem which has required solution somewhat as follows:—

(1) The determination of the physical nature of the sounds to be transmitted from one place to another; or in other words the obtaining of an understanding of the physical nature of speech and music.

(2) The determination of the reactions of any transmission system upon the electrical waves produced by these sounds.

The solution of this problem makes it possible to predict the characteristics of the thing which is delivered to the receiver, be it a telephone set or radio system. To this information, however, must be added a knowledge of the effects of any such distortions as may occur upon the interpretation given by the ear.

It is the purpose of this paper to discuss the two phases of the problem outlined above.

First, then, consider the mechanism of the production of speech. The lungs, by their bellows-like action, supply streams of air which pass through the vocal passages, the vocal chords, the mouth, the lips and the cavities of the nose and throat. These by variations in their adjustments impress on the air streams from the lungs variations which are heard as speech sounds. The diagram in Fig. 1 shows a longitudinal section of a human head giving the relative positions of these various organs. The vocal chords, which are a pair of muscular ledges on either side of the larynx forming a straight slit, are set in vibration by streams of air from the lungs, and thus create sound waves which are conducted through and modified by the vocal passages. The passages impress upon the air vibrations resonant characteristics which determine the character of the resulting speech. The so-called voiced sounds, including all the vowel and consonant sounds except p, t, ch, k, f, s, th (thin) and sh are produced in this manner. The production of the last mentioned speech sounds does not involve the vocal chords but is a matter of the setting up of vibrations by the mouth itself.

The voiced sounds may be divided into two classes according to their method of production. The continuants are produced by a continuous flow of air past the vocal chords, as for example, the vowel sounds. The stops are produced by a sudden stoppage in the air passage by the lips, or tongue, as for example, b, d.

It will also be noticed from Fig. 1 that there are two variable resounding cavities through which the air vibrations from the vocal chords pass, the throat and the mouth. These two resounding cavities, then, cause the continuants to have magnified frequencies in two principal regions. For example as is shown in Fig. 2, the sound ah sung d, has the two principal frequency ranges at about 200 and 1,000 cycles and it is largely these particular regions of resonance that distinguish it from other sounds.

Use of this knowledge has been made in aiding those unfortunates who have had to undergo the surgical operation

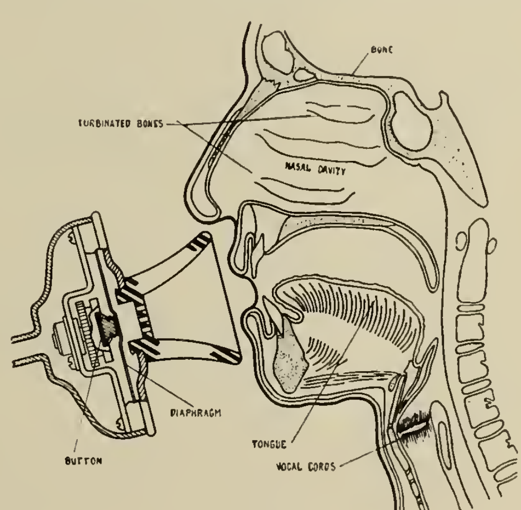

**Fig. 1**

known as tracheotomy, which operation leaves no connection between the lungs and the mouth. When a patient recovers from such an operation, the process of breathing is carried on by drawing the air in and out through a small opening in the neck, consequently, the patient can make no vocal sounds. If an attachment is made to the opening of the windpipe so that the patient can blow a whistle such as is used in toy balloons and the sound is directed into the corner of the mouth, the patient can learn to talk again. Such a device, now known as the artificial larynx, has been developed and is being used by a number of such patients. The quality at present, is, of course, somewhat different from that of the human voice but the speech is understandable and it is hoped that through refinement and further investigation the naturalness of the speech sound thus produced will be improved.

The sung sounds are produced in much the same manner as the spoken sounds. One difference of course lies in the greater emphasis placed on the continuants.

Musical sounds are characterized by being sustained at definite pitches for comparatively long times and by having the changes in pitch take place in definite steps known as musical intervals—thirds, fifths, octaves, etc. Musical tones are produced mainly by two physical mechanisms besides the voice: vibrating strings as with the violin, harp, piano, etc., and vibrating air columns as by the pipe organ, flute, horns, etc.

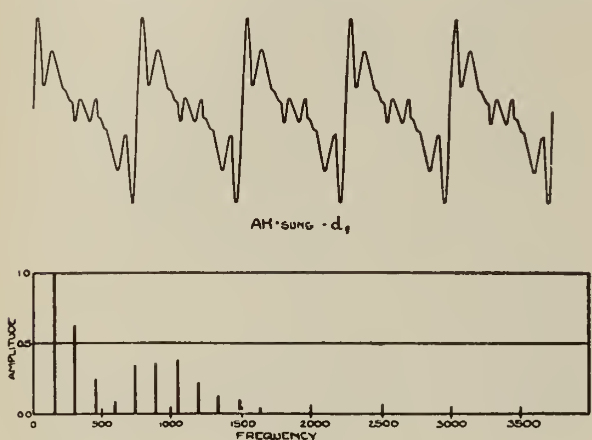

Fig. 2

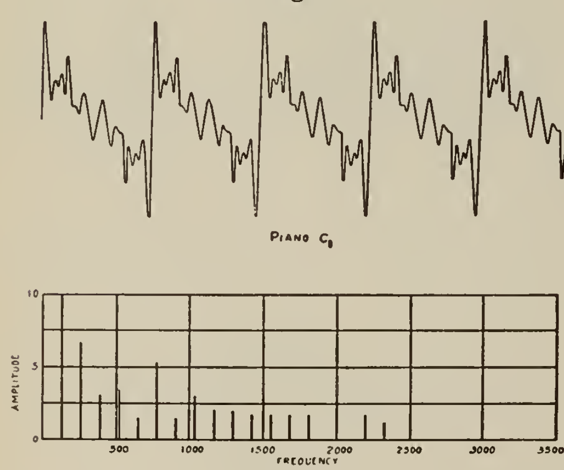

Fig. 3

A single musical note contains more than one frequency of vibration and is therefore a complex tone. For most musical tones the component frequencies are multiples of a fundamental which is the lowest frequency present in the tone, and which is the frequency determining the pitch of the tone, which in turn is that subjective characteristic by means of which the listener is enabled to locate the position of the tone on a musical scale. The richness and quality of musical tones are due to the abundance and relative amplitudes or energies of the harmonic components and, in general, a listener is enabled to recognize the kind of musical instrument producing the sound because of the differences in the numbers and relative amplitudes of the harmonics. This characteristic is usually referred to as the timbre of the musical tone.

In Figs. 2, 3, 4, 5 and 6 are shown some wave forms of musical sounds produced by the voice, piano, violin, and cello organ pipe and also the relative amplitudes of the fundamental and harmonics. For each of the examples shown except for the cello organ pipe it will be noted that the fundamental frequency corresponds to the assigned pitch and that this frequency has the greatest amplitude. In the case of the cello organ pipe, however, the frequency of greatest amplitude is the third harmonic and this corresponds to the assigned pitch. It is also interesting to note that the voice, the cello organ pipe and the piano in its lower registers have numbers of relatively intense harmonics while the violin and the piano in its upper ranges have few harmonics of relatively weak intensity. These differences explain the purer and sweeter tones of the violin and upper registers of the piano.

In the case of pipe organ music, the principal charm is contained in the strong bass notes whose pitches lie in the range below about 100 cycles. Although the older types of circuits used in radio broadcast transmission were somewhat inefficient at these low frequencies the principal offender was usually the loud speaking receiver of the radio set. Latterly both the circuits and receivers have been improved within this range.

From what has been reviewed it will be realized that a great deal is required of any transmitting medium between concert hall or studio and receiver to assure of satisfactory reception at the receiver of the transmitted sounds.

One of these requirements is that the system must be capable of transmitting a wide range of frequencies without changing their relative intensities. Figure 7 gives some data relative to the frequency ranges required for musical instruments and the voice. This figure indicates that there should be transmitted a range of from near 35 cycles to near 15,000 cycles. Tests have shown, however, that if within the range of from 35 to 8,000 cycles the relative intensities are maintained the results obtained are very pleasing.

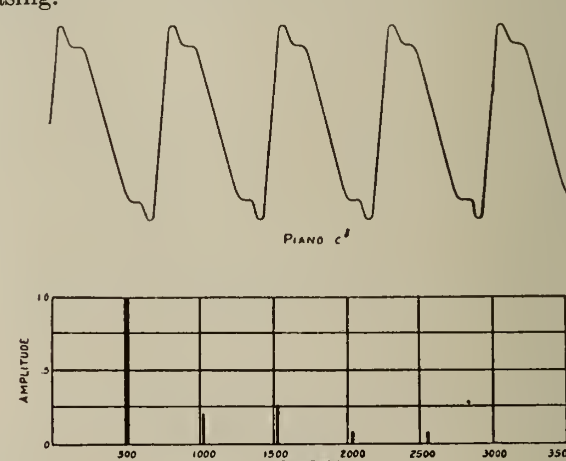

Fig. 4

Over wire lines and through amplifying equipment the time of transmission differs for the various frequencies being transmitted. Tests have indicated that in the range of from 5,000 to 8,000 cycles the time of transmission should not differ from that at 1,000 cycles by more than 5 to 10 milliseconds and that as between 50 and 1,000 cycles this difference should not be more than 75 milliseconds. These maximum differences require that amplifying equipment be very carefully designed for very small differences and that the differences inherent in transmission facilities be corrected by delay equalizing networks.

There must be within the transmission system no production of spurious frequencies except in minute quantities. Consequently, amplifiers must have extremely small modulation effects and in any magnetic circuits the ratio of flux density to ampere turns must be substantially constant.

The human ear can hear volume ranges as shown in Fig. 8, in which the ordinates indicate decibels* relative to a reference energy of $10^{-16}$ watts per square centimeter and the abscissae indicate frequency. At 1,000 cycles the lowest intensity that the average ear can hear is 0 db. or $10^{-16}$ watts per sq. cm. and on the other hand the intensity at which the average ear begins to have a sensation of

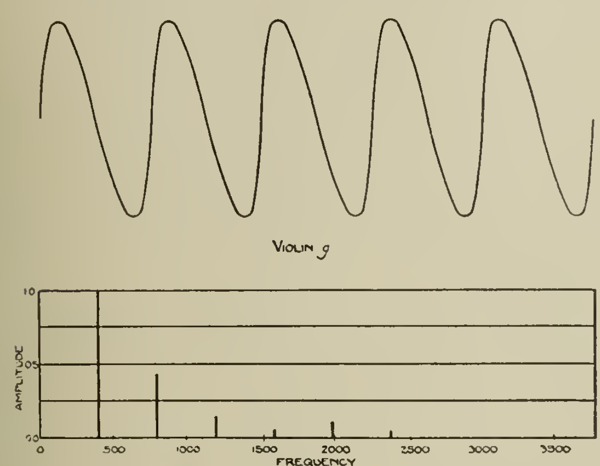

**Fig. 5**

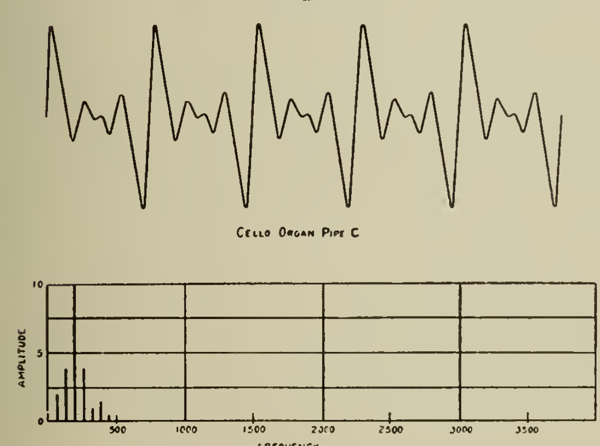

**Fig. 6**

feeling rather than hearing is 120 db. greater or $10^{-4}$ watts per sq. cm. There is produced at the ear of a favourably positioned listener to a symphonic orchestra an intensity range of about 70 db. which is located in the hearing range as shown in Fig. 8. Allowing for a 10 db. range at the lower intensities for the masking effects in a concert hall of audience and similar noises there remains an intensity range that could be appreciated by an audience of about 100 db. which is 30 db. greater than that available at present from a large symphony orchestra. For rooms in residences, due largely to room noise masking the quieter passages or undesirably great intensities during loud passages it has been found that it is not desirable to exceed a maximum range of about 40 db. In addition in radio reception the presence of static noise may raise the lower level of the range, thus narrowing it. Any system for the transmission of radio programme material should therefore be capable of transmitting a range of volumes of about 40 db. without introducing appreciable amounts of noise during the intervals of transmission of low volume or causing distortion during intervals of high volume.

From the above somewhat sketchily presented information it therefore will be realized that any system for the high grade transmission of speech and music must be carefully designed, constructed and maintained.

*See Appendix I.

## Appendix I

*Definition of the Decibel*

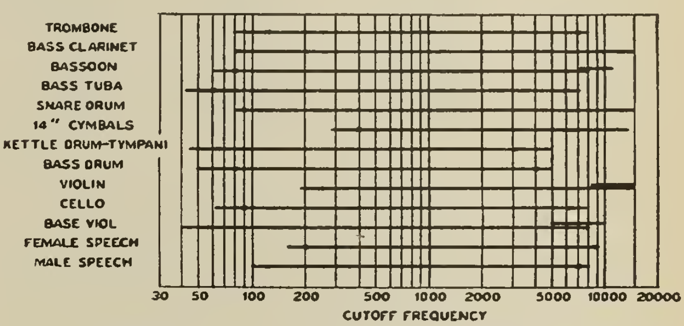
The international unit of measurement of communication transmission is the bel, and one derived practical unit much used on the North American continent, is the decibel, or db., which is one tenth of a bel. This unit relates two quantities of power through the common logarithm of their ratio. For example a power ratio of 10 or 1/10 represents 10 db, gain or loss, a power ratio of 100 or 1/100 represents 20 db., etc. For a power ratio of 45 the gain is:

$$10 \log 45 = 10 \times 1.653 = 16.53 \text{ db.}$$

For the same power ratio the loss is:

$$10 \log 1/45 = 10 \log 0.0222 = 10 (\bar{2}.347) = -10 \times 1.653 = -16.53$$

By the use of decibels rather than power ratios the calculation of transmission losses or gains becomes one of addition and subtraction rather than multiplication and division.



-Summary of important ranges required for different instruments.

**Fig. 7**

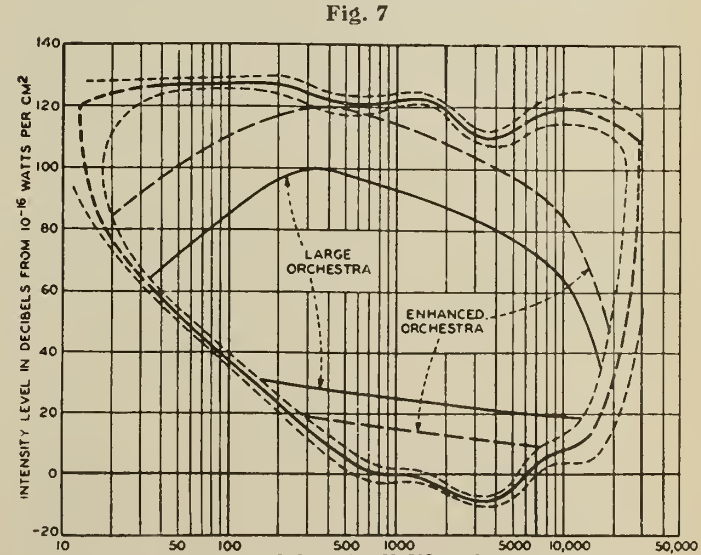


**Fig. 8**

Since decibels refer to relative powers, zero db. is only a power ratio of unity and for the designation of absolute powers a reference power must be used. The reference power level referred to in this paper is a power of 0.006 watts. Then, for example, −45 db. volume level is 45 db. level below 6 milliwatts.

$$\text{Then power ratio} = \text{antilog } 45/10 = 31630$$

$$\text{Therefore—45 db volume level is a power of } 0.006/31630 = 1.9 \times 10^{-7} = 0.00000019 \text{ watts}$$

THE
# ENGINEERING JOURNAL
THE JOURNAL OF
THE ENGINEERING INSTITUTE
OF CANADA

VOLUME XX MARCH, 1937 No. 3

## The Vote on By-law Revisions

The proposals for the revision of The Institute's By-laws which will shortly be put before the corporate membership for approval by ballot are not mere verbal amendments affecting minor points of procedure. They contemplate an important change in The Institute's course, a broadening of the road along which it is progressing, and the establishment of closer relations with the Provincial Associations of Professional Engineers. For this purpose they invite the members of all these associations to join with The Institute membership so as to constitute a Dominion-wide organization.

The report of the annual general meeting at which these matters were debated, is published in this issue of The Journal. It indicates that the proposals of the Committee on Consolidation were approved by the members present. The Plenary Meeting of Council had previously approved them, with some suggested modifications, and they have been endorsed by a large number of the Branch Executive Committees. It appears, however, that the proposed revisions are not in accord with the views of some members, who feel that the emphasis laid on the legal organization of the profession tends to divert attention from the original objects with which The Engineering Institute of Canada are formed, based on the interchange and dissemination of professional knowledge. To these members the control and organization of the profession under legal enactments does not seem so important as the technical and service activities of a voluntary engineering society. In this column it would not be proper to state the arguments advanced by the two schools of thought, or even to attempt to summarize them. That is the duty of the committees appointed by the chairman of the annual general meeting to prepare brief statements of the arguments for and against the proposals, which will be placed in the hands of each corporate member with his ballot paper.

An assembly like the annual general meeting affords an excellent opportunity for debate, but the majority opinion on any question expressed at a meeting of one or two hundred members is not necessarily that of the three thousand corporate members who have the right to record their votes on ballot. The result of the ballot which is now in preparation, can only reflect the real majority opinion of the membership *if all will take the trouble to vote.*

The proceedings of the Committee on Consolidation have been clearly placed before the membership by monthly reports in The Journal. The views of councillors, as given during the debates of the Plenary Meeting of Council, have also been reported at length, and the arguments advanced at the annual general meeting are given in this issue of The Journal. In the case of proposals so vitally affecting the future of The Institute it is the duty of every member who has the interests of his Institute at heart to study these reports and papers, particularly the summaries of pro and con arguments which will accompany the ballot. He must then record his vote if the result of the ballot is really to represent the voice of the corporate membership of The Institute.

## Coming Meetings with Sister Societies

The Council of The Institute has received with great appreciation, and has gladly accepted, invitations to participate this year in the activities of two of the Founder Societies of the United States, namely, the American Society of Mechanical Engineers, and the American Society of Civil Engineers. Our members are asked to note the dates and places of the following meetings and to make arrangements to attend them.

During the week of May 17th, 1937, the American Society of Mechanical Engineers is holding its Semi-Annual Meeting at the Hotel Statler, Detroit, Michigan, and its Council has invited the members of The Institute to take part in the technical and social events of the meeting. It will be remembered that last year the Society was good enough to extend the same invitation in respect to its Fall Meeting at Niagara Falls, N.Y. Many of our Ontario members attended and received a most hearty welcome.

The Detroit meeting will include a series of six general sessions, which will be held on the mornings and evenings of Tuesday, Wednesday and Thursday, May 18th, 19th and 20th. The first of these sessions deals with the contribution of automotive engineering to other fields. Mr. C. F. Hirshfeld's address on this subject should awaken engineers to the possibility of adopting in their own work the successful features of the technique of the automotive industry. The key note for the next general session will be improved methods of fabrication and Mr. William S. Knudsen of the General Motors Corp. will be one of the speakers; the third will have as its topic "Lightweight Highspeed Trains" and will be sponsored by the Railroad Division. E. G. Budd, of the company which built the "Zephyr," will speak on this subject. The fourth general session, sponsored jointly by the A.S.M.E. Management Division and the Society of Automotive Engineers, will deal with management and mass production methods. Mr. K. T. Keller, president of Chrysler Corp., and W. J. Cameron of the Ford Motor Co. will address the meeting. The fifth general session, on steel and its application, will be sponsored by the A.S.M.E. Iron and Steel Division, and the concluding summary of the implications of the week's programme will be delivered by Willard T. Chevalier, vice-president of Engineering News-Record.

In addition to the programme outlined above, technical sessions and tours will be held on Tuesday, Wednesday and Thursday afternoons, for which papers will be contributed by the A.S.M.E. Professional Divisions.

There will be excursion trips to the many points in and near Detroit which are of interest to engineers, and during the proceedings the Calvin W. Rice Memorial Lecture will be delivered. Detailed programmes of this meeting are not yet available, but the above outline will sufficiently indicate the interest and importance of the meeting.

At the invitation of the Board of Direction of the American Society of Civil Engineers a joint meeting of The Engineering Institute of Canada and the Society will be held in Boston, Massachusetts, on Wednesday, Thursday and Friday, October 6th, 7th and 8th, 1937. The Institute Council, on receiving the invitation from the American Society of Civil Engineers, appointed Past-Presidents Fairbairn, Shearwood and Cleveland to act as a committee to confer with a like committee of the Society, and the plans for the meeting are being worked out jointly in this way.

It is proposed to devote one of the technical sessions entirely to papers contributed by members of The Engineering Institute of Canada on Canadian engineering matters. The other sessions will be arranged by the technical divisions of the American Society of Civil Engineers, and a particularly interesting feature will be the work of the new division on Soil Mechanics and Foundations.

As regards entertainment and visits to engineering works, those members who have had the privilege of attending A.S.C.E. meetings need no assurance as to the excellence of the arrangements that will be made. The Boston meeting will be particularly attractive to E.I.C. members as offering an opportunity for the renewal of the happy relations developed in July 1934 when our Western Professional Meeting was held in Vancouver concurrently with the Annual Convention of The American Society of Civil Engineers. The joint meeting planned for October will, it is hoped, be largely attended by Institute members, particularly from the east. The time selected is favourable for travelling by road or rail, and the attractions of Boston as a meeting place are undeniable.

Detailed programmes of the meetings will be published in The Journal as soon as available.

## Past-Presidents' Prize 1936-1937

The subject prescribed by Council for this competition for the prize year July 1st, 1936 to June 30th, 1937, is **"The Need of the Engineer's Participation in Public Affairs."**

The rules governing the award of the prize are as follows:—

The prize shall consist of a cash donation of the amount of one hundred dollars, or the winner may select books or instruments of not more than that value when suitably bound and printed, or engraved as the case may be.

The prize shall be awarded for the best contribution submitted to the Council of The Institute by a member of The Institute of any grade on a subject to be selected and announced by Council at the beginning of the prize year, which shall be July 1st to June thirtieth.

The papers entered for the competition shall be judged by a committee of five, to be called the Past-Presidents' Prize Committee, which shall be appointed by the Council as soon after the Annual Meeting of The Institute as practicable. Members and Honorary Members only shall be eligible to act on this Committee.

It shall be within the discretion of the Committee to refuse an award if they consider no paper of sufficient merit.

All papers eligible for the competition must be the bona fide work of the contributors and must not have been made public before submission to The Institute.

All papers to be entered for the competition must be received **not later than June 30th, 1937,** by the General Secretary of The Institute, either direct from the author or through a local Branch.

SEMICENTENNIAL 1887 THE ENGINEERING INSTITUTE OF CANADA FOUNDED 1887 1937 JUNE 15-18 1937

## Semicentennial Committee

TORONTO BRANCH
C. E. Sisson, M.E.I.C.

### VISITORS

Recent advices are to the effect that the following names may be added to the list of "prominent visitors"—

Brigadier General Magnus Mowat, C.B.E., F.R.S.E., etc., representing The Institution of Mechanical Engineers.

James H. Herron, M.Am.Soc.M.E., representing the American Society of Mechanical Engineers.

H. V. Potter, representing the Society of Chemical Industry.

A. C. Gardner, F.R.S.E., representing the Institution of Engineers and Shipbuilders in Scotland.

### SMOKING CONCERT

This function will be one of the features of the meeting. It had been hoped to make an announcement regarding the programme, but Mr. R. H. Findlay, Chairman of the Smoker Committee, who has so successfully organized previous functions of this character in Montreal, insists upon keeping his plans a profound secret.

### RECEPTION COMMITTEE

F. S. B. Heward, Member of Council, is undertaking the duty of Chairman of the Reception Committee. Mr. Heward says that he and his associates on this Committee will do everything in their power to insure that every visitor to the Semicentennial receives a warm and cordial welcome.

### VISITS

Plans are well under way for members to visit such points of interest in and around Montreal as the Harbour of Montreal; Beauharnois Power Development; Dominion Engineering Works; Montreal Water Board; Dominion Bridge Company; Canadian Car and Foundry Company; Canadian Steel Foundries; C.N.R. Shops.

## Committee on Consolidation

**Report for February 1937**

Since the inception of the Provincial Professional Associations, there has been a growing demand for closer co-operation between the engineering organizations in Canada through a truly representative national body.

The reports of Special Committees, Plenary Meetings of Council and Annual General Meetings during the past ten years, provide conclusive evidence of the strong desire that the gap between the legal and technical functions of the profession be effectively bridged and provision made for the elimination of those divergencies in ideal and action which, due to a multiplicity of unrelated engineering organizations, undermine the unity and impede the progress of the profession.

The Committee on Consolidation, including representatives appointed by the Dominion Council of the Professional Associations, has completed two years of concentrated study of this problem, during which they have carefully considered all suggestions and recommendations for its solution. The conclusions of the Committee are expressed in the proposed revisions to the By-laws of The Institute now submitted for your approval in the form of a ballot.

These By-law revisions were approved by the Seventh Plenary Meeting of Council on October 16th, 1936, but with an amendment to Sub-section 7 (*b*). A majority of the Branches of The Institute, six of the Professional Associations and the Corporation are not in favour of this amendment and, in addition, it has been pronounced impracticable and would involve serious contention with the Associations. *In order that Consolidation might be a possibility, the Committee had to decline to accept the Council's amendment to Sub-section 7 (b).*

On January 28th, 1937, the Fifty-first Annual General Meeting approved these By-law revisions without amendment and with specific acceptance of the Committee's Sub-section 7 (*b*).

Discussions at this and other meetings indicate a strong and widely-held opinion that unless The Institute is prepared to take its proper place as the national organization of the profession as provided for under these By-laws, it will forfeit its position as the major engineering organization in Canada. Outside the appointment of a Councillor from each Component Association, there is no change in the administration or function of The Institute or the election of its officers. As to the handing over of The Institute and its autonomy to any outside organization, The Institute will continue to be administered and its policies determined only by members of The Institute.

It has been claimed that the Committee's Sub-Section 7 (*b*) will exclude a certain type of engineer from becoming a member of The Institute. This is not a fact, as any engineer in any province, who so desires and is properly qualified, may become a member of The Institute on exactly the same conditions as any other engineer in that province.

The proposals of the Committee represent an earnest endeavour to harmonize the expressed requirements of the profession with established conditions in a workable and generally acceptable plan which will make possible that close and effective co-operation between all groups and grades of engineers in Canada essential to a strong, united, national, professional body.

In order that the proposals of the Committee on Consolidation may become effective, it is essential that the membership of The Institute endorse *all* the Committee's revisions, *including its Sub-section 7 (b)*.

Gordon McL. Pitts,
*Chairman.*

## ELECTIONS AND TRANSFERS

At the meeting of Council held on February 19th, 1937, the following elections and transfers were effected:

*Members*

CARR, Noel Osmond, Colonel, R.C.A., (Grad. R.M.C.), Director of Mechanization and Artillery, Department of National Defence, Ottawa, Ont.

HURTER, Alfred Theodore, (Ecole Polytechnique Federale, Zurich), Abitibi Power and Paper Co. Ltd., Iroquois Falls, Ont.

*Associate Member*

SCHERMERHORN, Henry Lewis, (Queen's Univ ), district engineer of municipal roads, Dept. of Highways of Ontario, Napanee, Ont

*Juniors*

HEROUX Georges, B.A.Sc., C.E. (Ecole Polytech., Montreal), asst. city engr., Three Rivers, Que.

HOGG, Allan Douglas, B.Sc., (Univ. of Sask.), student, factory course, Massey Harris Co. Ltd., Toronto, Ont.

SHAW, Frederick W. B., B.Eng., (McGill Univ.), junior engr. Steel Company of Canada, St. Lambert, Que.

*Transferred from the class of Junior to that of Associate Member*

COBBOLD, Robert James, A.C.G.I., (City and Guilds Engrg. Coll.), asst. engr., outside erecting dept., English Electric Company, Rugby, England.

GRIME, Leonard, B.A.Sc., (Univ. of Toronto), struct'l. dftsman., Hamilton Bridge Company, Hamilton, Ont.

*Transferred from the class of Student to that of Associate Member*

CHOROLSKY, Eugene, B.A.Sc., (Univ. of Toronto), designing and estimating, Canadian Bridge Co. Ltd., Walkerville, Ont.

STRATTON, Frederick Stephen, B.Sc., (Univ. of Man.), asst. in charge of supervn. of various factories, Chloride Electrical Storage Co. Ltd., London, England.

TARR, Francis Gilbert Aubrey, B.A.Sc., (Univ. of B.C.), M.S. (Cornell Univ.), Ph.D. (Univ. of Toronto), switchboard engrg. dept., Can. Gen. Elec. Co. Ltd., Peterborough, Ont.

*Transferred from the class of Student to that of Junior*

DUFF, Duncan Clemens Verr, B.Sc., (N.S. Tech. Coll.), supervisory operator on processing and refining equipment, Tropical Oil Company, Barranca-Bermergha, Colombia, South America.

KOEHLER, Julius Wilbur, B.Sc., (McGill Univ.), lighting service engr., Can. Gen. Elec. Co. Ltd., Montreal, Que.

*Students Admitted*

ARNASON, Einar, (Univ. of Man.), 628 Victor St., Winnipeg, Man.

DRYDEN, Laurence Elliott, B.Sc., (Univ. of N.B.), 298 Aberdeen St., Fredericton, N.B.

JACOBS, David Sinclair, (McGill Univ.), 146 Wolseley Ave., Montreal West, Que.

LACOMBE, Jean L., (McGill Univ.), 301 St. Louis Square, Montreal, Que.

MacLEOD, Gordon Ross, (McGill Univ.), 4585 Harvard Ave., Montreal, Que.

MACNUTT, Ernest Gerrard, (McGill Univ.), 4308 Montrose Ave., Westmount, Que.

MILLER, John Jackson, (Univ. of Man.), 632 Jessie Ave., Winnipeg, Man.

SADLER, Wilfred Robertson, (Univ. of Man.), 211 Belvidere St., Winnipeg, Man.

SMITH, Allan Garfield, (McGill Univ.), 7446 Wiseman Ave., Montreal, Que.

SWINGLER, Russell Henry, (Queen's Univ.), 250 Alfred St., Kingston, Ont.

WILSON, Bertram H. J., (Univ. of Man.), 149 Monck Ave., Norwood, Man.

# George Joseph Desbarats, C.M.G., Hon.M.E.I.C.

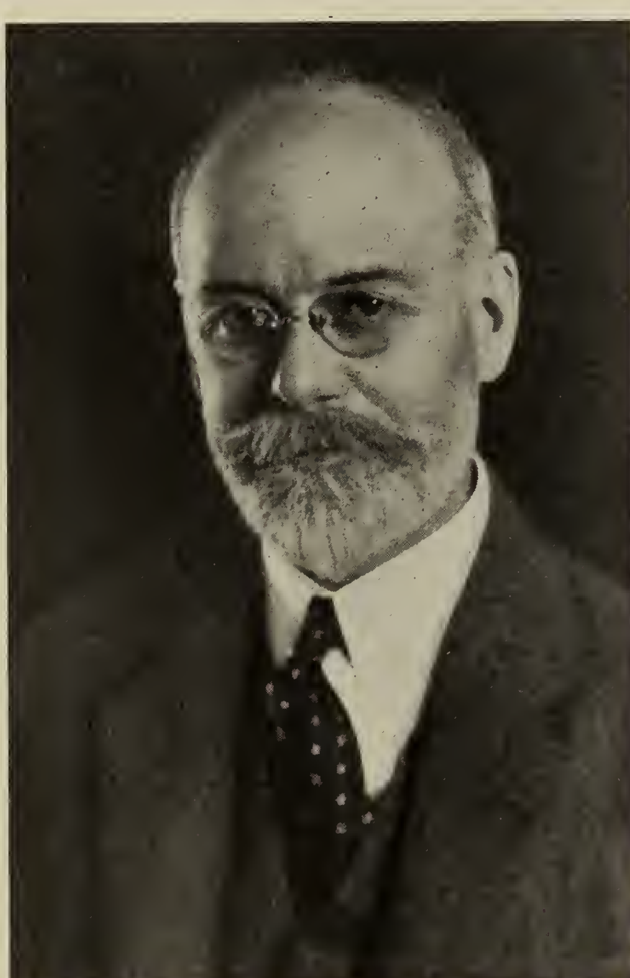
Ten years ago the presidential chair of The Engineering Institute of Canada was occupied by a distinguished French Canadian, Dr. A. R. Decary, a member of the Dominion Civil Service. Since then two other eminent Civil Servants have passed the chair, Dr. Charles Camsell and Mr. A. J. Grant. For the year 1937 the choice for President has fallen upon one of Dr. Decary's compatriots, whose professional life has also been spent in the Government Service.

The early engineering work of Mr. Desbarats was along lines typical of the varied activities of several departments of the Federal Government. During his later career as an administrative officer he was the executive head of one of that government's most important departments. Mr. Desbarats has achieved well-merited success as a public servant in both these fields of work.

Born in 1861 in the province of Quebec, he was educated at the college at Terrebonne, and at the Ecole Polytechnique, Montreal, where he graduated with honours at the age of eighteen. Entering the service of the Dominion Government in 1879 as assistant engineer in the Department of Railways and Canals, he began his professional work at the time when some of the most important sections of our canal system were being built. He was engaged on the design and construction of the Carillon Canal, the locks at Ste. Anne de Bellevue, and later the Canadian locks at Sault Ste. Marie, the Welland Canal and the Soulanges Canal.

In 1892 he was appointed Inspector of Railways in British Columbia for the Dominion Government, serving there for four years.

He then severed his connection with the Government service, and for the next three years was engineer for Messrs. Larkin and Sangster, the contractors for the construction of the Galops Canal.



G. J. Desbarats, C.M.G., Hon.M.E.I.C.

Later, returning to the Government Service, he was in charge of a hydrographic survey on the St. Lawrence from 1899 to 1901.

He was then appointed director of the Government shipyard at Sorel, and was responsible for the reconstruction of that establishment and its subsequent operation under the then Department of Marine and Fisheries. Promotion soon followed. In 1909 Mr. Desbarats was appointed Deputy Minister of the Department, and in the following year, on its organization, became Deputy Minister of the Department of Naval Service, a position to which heavy responsibility attached during the war. His service in this capacity were recognized in 1915, when he was made a Companion of the Order of St. Michael and St. George.

During the war his Department undertook many duties in addition to its regular war-time activities in connection with the naval defence of Halifax, Sydney and the St. Lawrence. Among these may be mentioned the construction of a fleet of one hundred and fifty mine-sweepers for the Admiralty, and a smaller fleet of torpedo motor launches, as well as the supply of their crews. In fact, during the war, the Department acted generally as agent in Canada for the British Admiralty.

The Department also organized the Royal Canadian Naval Air [Service (the precursor of the present R.C.A.F.), constructed air stations at Halifax and Sydney for the defence of those ports, and enrolled a large number of pilots for the Royal Naval Air Service.

In 1923 the Government decided to establish a Department of National Defence, and to merge in it the existing Departments of Militia and of Naval Service, together with the Air Board. The three military services were thus brought under one administration, and Mr. Desbarats became the Deputy Minister of the new Department. He held that appointment with distinction until his retirement from the Service nine years' later.

During this period his ability as an administrator found full scope, not only in the strenuous days of 1914 to 1919, but also in the succeeding years during which there were so many changes in organization and in the development of new technical branches of Government work. In Canada, for example, this period saw the rise of modern aerial navigation, with its profound influence on transportation problems of all kinds. Mr. Desbarats early perceived the commanding position which air transportation must take in Canada, a country of such vast distances and with such immense and sparsely populated areas. Accordingly under him there grew up an active civil aviation branch in addition to the Royal Canadian Air Force.

During the next few years the Department surveyed the Trans-Canada Airway, contructing and operating the links between Montreal and Windsor, and from Winnipeg to Calgary and Edmonton. These routes were provided with beacons, directional radio-beams, teletype communication and meteorological service. They functioned until the depression came, when they had to be discontinued; they are now being revived under the new Department of Transport.

At this time, under the Department of National Defence, there were also constructed and operated a chain of radio-stations extending from Edmonton north to Dawson and Herschel Island, providing communication with these far northern regions and thus facilitating the mining developments which have since taken place.

Apart from these activities, the department of which Mr. Desbarats was the chief executive had to administer the armed forces of Canada, and at the same time to keep abreast of many new technical problems arising in connection with all arms of the service, a notable example being the mechanization of army equipment both for fighting and transport, under Canadian conditions.

During his period of public service Mr. Desbarats held a number of important appointments additional to his departmental work, having served as plenipotentiary delegate from Canada to the Wireless Conference in London in 1912, and as Canadian Government representative to the Seamen's Conference, League of Nations, in Genoa, in 1920.

During Mr. Desbarats' long connection with The Institute, which he joined as a Member in 1897, he has taken an active part in its affairs. He served on Council in 1900, 1907, 1933 and 1934; was a vice-president in 1909, and was elected an Honorary Member in 1936. He has now been distinguished by election as President. He has always been active in the affairs of the Ottawa Branch, of which he was chairman in 1931. His wise counsel and knowledge of public affairs has been of the greatest benefit in connection with any difficult questions which have arisen, concerning either The Institute or the branch to which he belongs.

# The Fifty-First Annual General Meeting

**Convened at Headquarters, Montreal, on January 21st, 1937, and adjourned to the Windsor Hotel, Montreal, on January 29th, 1937.**

The Fifty-First Annual General Meeting of The Engineering Institute of Canada commenced at Headquarters on Thursday, January twenty-first, nineteen hundred and thirty-seven, at eight o'clock p.m., with Past-President F. P. Shearwood, M.E.I.C., in the chair.

The Secretary having read the notice convening the meeting, the minutes of the Fiftieth Annual General Meeting were submitted, and on the motion of C. K. McLeod, A.M.E.I.C., seconded by J. L. Busfield, M.E.I.C., were taken as read and *confirmed.*

### Appointment of Scrutineers

On the motion of R. H. Findlay, M.E.I.C., seconded by I. S. Patterson, Jr.E.I.C., Messrs. B. R. Perry, M.E.I.C., and J. A. Lalonde, A.M.E.I.C., were appointed scrutineers to canvass the Officers' Ballot and report the result.

There being no other formal business, it was *resolved,* on the motion of J. L. Shearer, A.M.E.I.C., seconded by P. E. Jarman, M.E.I.C., that the meeting do adjourn to reconvene at the Windsor Hotel, Montreal, at ten o'clock a.m., on the twenty-ninth day of January, nineteen hundred and thirty-seven.

## Adjourned General Meeting at the Windsor Hotel, Montreal

The adjourned meeting convened at ten fifteen a.m., on Friday, January 29th, 1937, with President Cleveland in the chair.

The Secretary announced the membership of the Nominating Committee to nominate the officers of The Institute for 1938 as follows:

### Nominating Committee—1937

*Chairman:* W. H. Munro, M.E.I.C.

| *Branch* | *Representative* |
|---|---|
| Halifax Branch | H. Fellows, A.M.E.I.C. |
| Cape Breton Branch | F. W. Gray, M.E.I.C. |
| Saint John Branch | F. P. Vaughan, M.E.I.C. |
| Moncton Branch | H. B. Titus, A.M.E.I.C. |
| Saguenay Branch | N. F. McCaghey, A.M.E.I.C. |
| Quebec Branch | L. P. Méthé, A.M.E.I.C. |
| St. Maurice Valley Branch | J. F. Wickenden, A.M.E.I.C. |
| Montreal Branch | P. E. Bourbonnais, A.M.E.I.C. |
| Ottawa Branch | C. M. Pitts, A.M.E.I.C. |
| Peterborough Branch | W. M. Cruthers, A.M.E.I.C. |
| Kingston Branch | A. Jackson, A.M.E.I.C. |
| Toronto Branch | J. J. Traill, M.E.I.C. |
| Hamilton Branch | H. B. Stuart, M.E.I.C. |
| London Branch | D. S. Scrymgeour, A.M.E.I.C. |
| Niagara Peninsula Branch | C. G. Moon, A.M.E.I.C. |
| Border Cities Branch | J. Clark Keith, A.M.E.I.C. |
| Sault Ste. Marie Branch | A. E. Pickering, M.E.I.C. |
| Lakehead Branch | H. G. O'Leary, A.M.E.I.C. |
| Winnipeg Branch | F. V. Seibert, M.E.I.C. |
| Saskatchewan Branch | A. P. Linton, M.E.I.C. |
| Lethbridge Branch | P. M. Sauder, M.E.I.C. |
| Edmonton Branch | H. R. Webb, A.M.E.I.C. |
| Calgary Branch | J. R. Wood, M.E.I.C. |
| Vancouver Branch | A. S. Gentles, M.E.I.C. |
| Victoria Branch | J. N. Anderson, A.M.E.I.C. |

### Awards of Medals and Prizes

The Secretary then announced the award of the various prizes and medals of The Institute, and stated that it is intended to make the actual presentations at the dinner which will be held in Montreal in June at the time of the Semicentennial Celebrations.

*The Sir John Kennedy Medal* to J. G. Sullivan, M.E.I.C., Winnipeg, Man., Past-President of The Institute.

*The Duggan Medal and Prize* to P. L. Pratley, M.E.I.C., Montreal, for his paper "The Superstructure of the Reconstructed Second Narrows Bridge, Vancouver."

*The Gzowski Medal* to David Boyd, A.M.E.I.C., Lachine, Que., for his paper "Modern Arc Welding."

*The Plummer Medal* to C. R. Whittemore, A.M.E.I.C., Montreal, for his paper "The Metallurgy of Metallic Arc Welding of Fine Steel."

*The Leonard Medal* to L. S. Weldon, M.C.I.M.M., Kenya, E. Africa, for his paper "Mining Methods and Practice at Lake Shore Mine."

### Students' and Juniors' Prizes

*John Galbraith Prize* (Province of Ontario) to E. C. Hay, Jr.E.I.C., Toronto Ont., for his paper "Selection of Factors of Photo Electric Cells."

*Phelps Johnson Prize* (Quebec—English) to Eric G. Adams, Jr.E.I.C., New York (formerly Montreal), for his paper "Trends in Population and Trade Affecting Transportation."

*Ernest Marceau Prize* (Quebec—French) to Louis Trudel, S.E.I.C., Montreal, for his paper "Etude Comparative sur Modèles Reduits."

### Report of Council and Treasurer's Report

The Secretary read the report of Council for 1936, and J. B. Challies, M.E.I.C., presented the Treasurer's report, after which, on the motion of Mr. Challies, seconded by Past-President Shearwood, the report of Council and the Treasurer's report were *adopted.*

### Report of Finance Committee

P. L. Pratley, M.E.I.C., chairman of the Finance Committee, presented that committee's report, together with the financial statement, which, on the motion of Mr. Pratley, seconded by W. McG. Gardner, A.M.E.I.C., was *adopted.*

### Reports of Committees

The Secretary then indicated some points of interest in the reports of the various committees, and they were presented for approval, after which, on the motion of

P. L. Pratley, M.E.I.C., seconded by G. A. Gaherty, M.E.I.C., it was *resolved* to adopt the following reports: Library and House Committee, Papers Committee, Board of Examiners and Education, Honour Roll and War Trophies Committee, Committee on Relations with National Societies, Committee on Western Water Problems, Committee on Deterioration of Concrete Structures, and the Employment Service Bureau.

J. L. Busfield, M.E.I.C., then presented the report of the Semicentennial Committee, which, on the motion of G. Stead, M.E.I.C., seconded by E. Viens, M.E.I.C., was *adopted.*

Report of the Committee on Consolidation

Following the presentation of the above committee reports, that of the Committee on Consolidation was submitted to the meeting. W. McG. Gardner, A.M.E.I.C (Montreal), *moved* the following resolution, which was *seconded* by E. Viens, M.E.I.C. (Ottawa):

> That the chairman of the Committee on Consolidation read the report of his committee or such portions thereof as he may consider necessary to provide a proper background for the discussion of the report. This presentation of the report to be followed by a period not exceeding thirty minutes, during which questions relative to the report may be asked of the chairman of the committee. Following this question period the recommendations of the committee attached to the report to be considered separately and consecutively, and so passed upon by the Annual Meeting; all resolutions from branches and Associations relative to Subsection 7 (*b*) to be presented to the meeting before the discussion of the committee's recommendation Number 2.

Mr. Gardner explained that the intent of his motion was that the chairman of the Committee on Consolidation might have an opportunity to speak to the report and answer any questions, following which the recommendations of the committee would be considered item by item, and dealt with in an orderly fashion.

Mr. Pratley did not like the resolution, as he feared that if adopted it might tend to limit the discussion only to the recommendations. He thought that it should be possible at this meeting to discuss the consolidation question from all points of view.

Mr. Challies remarked that the purpose of this meeting was to give every latitude in discussion. He hoped that Mr. Pitts would have a free hand in presenting his report.

G. Mc.L Pitts, M.E.I.C., stated that he had himself drawn up the resolution with no thought of limiting the discussion on any point that might be raised. His reason in suggesting a thirty-minute question period was because at the last annual meeting at Hamilton a similar motion had worked very satisfactorily.

Mr. Pratley said that everyone wished to give Mr. Pitts all the liberty he required, but the resolution appeared to limit the discussion to the questions which might be asked or to the recommendations, and would thus prevent a general discussion, which, in his opinion, was very desirable.

Mr. Pitts said that the only reason for the motion was to indicate a regular system of procedure and he was sorry that Mr. Pratley felt that there was anything which was calculated to limit discussion.

The President remarked that if the resolution passed, as chairman of the meeting he would have to be bound by the wording of the resolution.

Mr. Pitts then expressed his willingness to strike out the words "not exceeding thirty minutes" and *moved* an amendment to that effect.

Mr. Pitts' amendment, having been *seconded* by W. Chase Thomson, M.E.I.C. (Montreal), was put to the meeting and *carried,* after which the original motion, omitting the deleted phrase "not exceeding thirty minutes," was put and *carried.*

Mr. Pitts, in presenting the report of his committee, remarked that this meeting, with the ballot, would close the first phase of the effort to get closer co-operation between the professional bodies in Canada. He could assure the meeting that his committee had worked at this problem most diligently for the past two years, particularly in the last year. He wished to express his personal thanks to his committee members for their efforts. The committee's work had cost a good deal more money than he had ever thought likely, the explanation being the amount of printing and the distribution of the printed matter necessary to keep all interested parties informed.

Having read the principal paragraphs of his report, Mr. Pitts remarked, with reference to the questionnaire which his committee had issued in June 1935, that some Institute members had questioned the reliability of the figures which he had based on the replies to that questionnaire. He could only say that the questionnaire had been sent out in such a way as to give every member of The Institute an opportunity of expressing a personal opinion, either individually or through his branch executive committee. Thus, the committee had done their best to ascertain the opinion of The Institute membership, particularly as to whether the corporate membership of the Provincial Professional Associations and the national organization should be identical.

Mr. Pitts drew attention to the appendices to the report, giving respectively the committee's proposals for amendment of The Institute by-laws; an index suggesting a desirable way of renumbering the by-laws; a suggested form of agreement between a professional association and The Institute; a suggested form of application for admission to The Institute by a member of a Professional Association, and finally a suggested form of ballot. With regard to the latter, Mr. Pitts explained that the form suggested called for a single vote on all the by-laws submitted by the Committee on Consolidation exclusive of Subsection 7 (*b*), this subsection being voted on separately. He sincerely hoped that at the present meeting no amendment would be added to those proposals on which the committee and the Council had come to an agreement.

In closing, Mr. Pitts urged that every member of The Institute should register his vote, because the future of The Institute was now in the hands of its members, and depended on the result of the ballot.

The President thanked Mr. Pitts for his presentation, and stated that there was now an opportunity for questions.

J. A. McCrory, M.E.I.C. (Montreal), desired to ask two questions. First, assuming the adoption of the proposals so that The Institute could only accept into corporate membership members of the Professional Associations, had the Committee on Consolidation any idea of the number of associations which would reciprocate by accepting into their membership members of The Institute, particularly in view of the fact that there would possibly be an increase in the fees of the associations. Secondly, he would like to ask whether the Committee on Consolidation had made any estimate of the revenue which The Institute would receive under the new set-up.

In reply, Mr. Pitts stated that with regard to the admission of Institute members to the associations, certain of the associations were taking steps to make this possible, but in Mr. Pitts' opinion, if a man had the qualifications for admission to The Institute the examining boards of the associations could be trusted to reciprocate. He had, however, no authority to speak on this point, and it could only be answered by the Councils of the Associations themselves. With regard to finance, a statement as to the probable financial situation after consolidation had been presented at the Plenary Meeting of Council. It had been drawn up by The Institute's Finance Committee and indicated that, with the Committee on Consolidation's original proposals, a deficit of around $2,000 might be expected, this being probably because the proposals included that of abolishing the class of Associate Member and reducing the Members' fee to that now paid by Associate Members. This point had, however, been taken care of in revising the committee's proposals by proposing that the Associate Members' fees would be increased $1 above their present level.

Mr. McCrory understood from Mr. Pitts that there had been no commitment by the Dominion Council or the Provincial Associations as to their becoming component associations. Mr. Pitts replied that several provincial associations were taking definite steps to come in under the provisions of the new by-laws providing that they are approved by The Institute membership. Mr. Pitts had letters and resolutions indicating the definite position of some of the associations, but Mr. Kirby, the President of the Dominion Council, would no doubt be able to speak on this point.

Vice-President E. V. Caton, M.E.I.C., stated that as regards the Manitoba Professional Association they were definitely committed, in the event of consolidation going through, to accept automatically, without entrance fee, all corporate members of The Institute then in good standing in the province of Manitoba. He thought that this indicated, as far as Manitoba was concerned, a very co-operative spirit.

C. C. Kirby, M.E.I.C. (Saint John), said that if this were the proper time to answer questions as to the attitude of the various Provincial Associations he would like to make a statement on the matter.

A telegram had been received from the registrar of the Nova Scotia Association stating that the annual meeting of that Association supported the proposals of the Committee on Consolidation.

In New Brunswick the Association, at its recent annual meeting, had resolved that the Association would become a component association of The Engineering Institute at as early a date as possible, without loss of the identity of the Association or its functions under the Provincial Act.

The registrar of the Association of Saskatchewan had written that the proposals of the Committee on Consolidation had met with entire approval, and were acceptable to that Association.

Mr. Caton had reported as regards Manitoba.

In respect to the Province of Quebec, Mr. Kirby had not received any official communication, but there were representatives of the Corporation present who would no doubt make a statement.

As regards Alberta, Mr. Kirby was not able to give any definite information.

In British Columbia the annual meeting of the Association of Professional Engineers in December had passed a resolution sympathetic to the proposals for consolidation.

One definite statement had been received declining to enter consolidation, namely, that from the Association of Professional Engineers of the Province of Ontario, contained in a letter dated January 23rd, 1937, which Mr. Kirby read.

In response to a question, Mr. Kirby stated that the approximate numbers of members of the various Provincial Associations were, in 1936:—Nova Scotia—200; New Brunswick—125; Ontario—1,146; Saskatchewan—88; Alberta—256; British Columbia—815; Quebec—927, a total of 3,557, exclusive of Manitoba.

S. R. Banks, A.M.E.I.C. (Montreal), desired to draw attention to the concessions which would be made by The Institute to the Professional Associations if the present proposals carried. He felt that the abolition of the class of Associate Member and the transfer of present Associate Members to the class of Member would not raise the status of The Institute's corporate members in any way. The present Associate Members were nearly twice as numerous as the Members, so that the resulting grade as to general professional experience would on the average be nearer the present Associate Members' status than that of the present Members. All Associate Members' fees would be slightly higher, a hardship on the younger men, whereas the senior members, better able to pay higher annual fees, would have a reduction. Mr. Banks further pointed out that while there was a provision in the proposals for the automatic expulsion from The Institute of a member expelled from a component association, there was no corresponding provision calling for the expulsion from a component association if expelled from The Institute. It would therefore appear that a person expelled from The Institute still remaining a member of a Provincial Association could at once apply again and rejoin The Institute.

H. S. Johnston, M.E.I.C. (Halifax), asked for an interpretation with regard to Subsection 7 (*b*). He thought that the wording did not indicate clearly whether corporate membership in a Professional Association would be the sole requirement for admission to The Institute, or whether it would be only one of a number of requirements. He thought the wording of this subsection should be clarified on this point.

W. Chase Thomson, M.E.I.C. (Montreal), asked whether he was correct in assuming that corporate membership in an Association would be full and sufficient evidence of eligibility for admission to The Institute, and Mr. Pitts replied that any full member of an Association accredited by his Association would be admitted to The Institute as a Member.

F. S. B. Heward, A.M.E.I.C. (Montreal), understood that Mr. Pitts had stated that The Institute supported Subsection 7 (*b*) as proposed by the Committee on Consolidation, but Mr. Heward desired to point out that at the Plenary Meeting of Council held in October The Institute Council was not in agreement with the proposed Subsection 7 (*b*) as put forward by the Committee on Consolidation, the reasons being, first, that the committee's version involved the surrendering of the autonomy of The Institute, and, secondly, that it would exclude from The Institute a great many fully qualified engineers not now members of a Professional Association, nor required by law to be members. In Mr. Heward's opinion Subsection 7 (*b*) was the crux of the situation. There were some who believed that the whole consolidation movement would be wrecked unless the committee's proposal for Subsection 7 (*b*) was adopted, because in this event some of the Professional Associations would no longer be interested in the proposals. Mr. Heward desired to point out that on the other hand there were many members of The Institute who felt that unless the Council's proposal was agreed upon the consolidation movement would not be advanced.

In reply Mr. Pitts stated that The Institute Council itself, up to the time of the Plenary Meeting in October, had accepted the principle of Subsection 7 (*b*) as proposed by the committee. He did not know the Council's reasons for the reversal of opinion which took place at that time, or whether the general membership would support that reversal of opinion. Mr. Pitts suggested that questions of this kind regarding Subsection 7 (*b*) would be more properly discussed when recommendation number two of his committee was under consideration.

Mr. H. S. Johnston remarked that Nova Scotia believed that autonomy should rest in the provinces, and that considerations with regard to membership and qualifications for membership should be decided by the provinces.

Clarence M. Pitts, A.M.E.I.C. (Ottawa), thought that members of The Institute should have additional information as regards the position of the Ontario Association, of which he was a member. He had received a copy of a Christmas message from the President of the Association in which it was stated that the Ontario Association desires to co-operate with other Associations of Professional Engineers, but could not consolidate the members of the various branches in a general Canadian Engineering Institute. "Institute consolidation," said the President, "is for The Institute representing the various branches." From this Mr. Pitts gathered that the Ontario Association is definitely opposed to any scheme such as that now before The Institute. He judged that the Ontario Association did not desire to have one national body representing engineering in Canada, but would like to have separate associations directing civil engineering, mechanical engineering, mining engineering, and so on. If this view was prevalent in the Ontario Association the co-operation of that body would not be possible.

H. R. Sills, A.M.E.I.C. (Peterborough), desired to draw attention to the provisions of Sections 9 and 10 in the proposals, regarding the qualifications for Juniors and Students, in whose cases age limits of 33 and 27 respectively had been specified. This arrangement had existed in The Institute by-laws for some time, and he believed that the younger members had taken undue advantage of it. In his opinion, Students and Juniors, as soon as they attain the age limit should become liable for the fee of the next grade of membership, whether they apply for it or not. This would be helpful in the way of finance, and would bring these men out of the lethargy to which some of them were liable. Mr. Sills hoped that this point would receive consideration.

Mr. Pitts remarked that Mr. Sills had raised a point not definitely related to consolidation, therefore one which his committee had not taken up. It would, of course, be impossible to put such a suggestion in the ballot at this time.

Mr. Pratley inquired whether in closing the question period it would be permissible to discuss such general features as were now being brought up. Would this be possible when dealing with the recommendations seriatim?

The President explained that the intention was that the meeting have every opportunity to consider every phase of the subject, but he hoped that the direct questions could be dealt with first, so that the recommendations could be proceeded with.

Frederick Bridges, M.E.I.C. (Sorel), drew attention to the proposed provision by which members of Professional Associations might become Associates of The Engineering Institute. They would then presumably be able to attend meetings and have all the privileges except that of voting. He did not think that this offered any inducement to a member of a Professional Association to join The Institute as a corporate member.

Mr. Pitts explained that the arrangement of which Mr. Bridges had spoken was intended to be applicable in the case of those of the associations amongst whose members there were some who did not desire to become active members of The Institute. Its intention was to bring every engineer in some way in contact with The Institute in order to encourage his relationship with it. In the case of an Association becoming a Component Association under Subsection 7 (*a*)1 the question would not arise, but it might arise in a case where an Association was not yet ready to bring in all its members at once and therefore could not take advantage of the fee advantage which total membership would bring. He felt that if the present proposals went through it would be realized that The Institute had taken a broad liberal view, and from the information which he had received he believed that that feeling would be reciprocated in the Associations.

At this point the President extended a welcome to Mr. C. E. Davies, Secretary of the American Society of Mechanical Engineers, who was present; his visit had been a source of great pleasure to the meeting.

Mr. Davies, in a few words of greeting, expressed his pleasure at being able to attend, and complimented The Institute members on the way in which their very complicated problem was being approached. He might say, however, that the complexity of the situation in Canada, although sufficiently great, was small in comparison with the difficulties of the similar problem in the United States.

The meeting adjourned at twelve forty-five p.m. to reconvene at 2.15 p.m.

---

The meeting reconvened at 2.15 p.m. with the President in the chair.

The President having asked whether any member desired to ask any further direct questions, the meeting proceeded to the consideration of the seven recommendations with which the report of the Committee on Consolidation concludes.

*Recommendation No. 1.*

> That the Council of The Institute and the Committee on Consolidation being in agreement on all the proposed revisions to the By-laws of The Institute as appearing in Appendix "A" of this report, with the exception of Sub-Section 7 (*b*), these revisions be accepted by the Annual Meeting and be sent forward to ballot by the general membership without further amendment.

Recommendation No. 1 having been read, E. P. Muntz, M.E.I.C. (Hamilton), *moved* the acceptance of the recommendation and this motion was *seconded* by Geoffrey Stead, M.E.I.C. (Saint John).

Mr. McCrory did not agree with this proposal and was of the opinion that the whole of Section 7 should come under discussion; he then *moved* that the recommendation be amended by changing the words "Subsection 7 (*b*)" to "Section 7."

Mr. McCrory's amendment having been *seconded* by G. P. Hawley, M.E.I.C. (Montreal), Mr. Pitts desired to point out that if the amendment were carried the consideration of the whole question would be thrown into confusion, the reason being that Subsection 7 (*b*) was the only paragraph on which Council and his Committee were not in agreement. Recommendation No. 2 had to do with Subsection 7 (*b*) only, but any other portion of Section 7 could be properly considered under the heading of Recommendation No. 1.

Mr. McCrory was still unable to agree with Mr. Pitts. As he understood it, if the meeting voted for Recommendation No. 1 that would practically shut out further discussion of everything except Subsection 7 (*b*).

Mr. Pitts replied that discussion of everything except Subsection 7 (*b*) was now in order, and this was confirmed by the President.

Mr. McCrory was of opinion that quite a number of important proposals were included in Section 7, and he felt that there was some inconsistency in its various provisions. For instance, Subsection 7 (*a*) provided that the Council shall admit any corporate member of an Association upon application duly made and upon presentation of the credentials requested under the by-laws. On the other hand, Subsection 7 (*d*) said that every candidate who has not graduated from a school of engineering would be required to pass an examination. There seemed to him to be some inconsistency here, and he thought these clauses should be clarified.

Mr. McCrory having *withdrawn* his amendment, with the agreement of his seconder, Mr. Pitts explained that the difficulty really arose because the two concluding paragraphs of Section 7, namely, Subsections 7 (*c*) and 7 (*d*), should really be taken together. Both paragraphs should, in fact, be combined as Subsection 7 (*c*). Subsection 7 (*a*) provides for the admission of corporate members of an Association; Subsection 7 (*a*)1 for the admission of all members of an Association by registration of its total membership; Subsections 7 (*c*) (including 7 (*d*)) for the admission of those members who do not reside in a province where there is a Component Association. These three subsections, therefore, provide for the admission of Members to The Institute in three different ways.

G. J. Desbarats, HON.M.E.I.C. (Ottawa), asked whether the meeting could have put before it a definition of its powers under the by-laws.

The Secretary having read the second half of Section 75 of the By-laws, pointed out that the question had been considered at the Plenary Meeting of Council, at which time it was decided that the intent of the clause was that the decision as to what amendments, if any, are to go to ballot in addition to the printed proposals, should be the decision of a majority of the members present at the Annual General Meeting. Under the by-laws, the proposals of the Committee on Consolidation and the proposals put forward by Council, having been duly published and put before the membership, must go to ballot, but they might be accompanied by such amendments to the proposals as this Annual General Meeting might decide to put forward in addition.

R. H. Findlay, M.E.I.C. (Montreal), inquired whether difficulty would not arise in case all of the by-laws were approved on ballot with the exception of Subsection 7 (*b*).

Mr. Pitts pointed out that if the Council had been agreeable to all the amendments of the Committee on Consolidation there would only have been one vote to place upon the ballot paper. Possibly the meeting would rather discuss Subsection 7 (*b*) first, and then pass on the balance of the by-laws.

Mr. Kirby thought that Mr. Findlay was under a misapprehension in suggesting that if all the other recommendations were passed and Subsection 7 (*b*) did not, serious difficulty would arise. That was not the case. As far as consolidation was concerned, all of the machinery was provided in other sections, and would work independently of Subsection 7 (*b*). Members would note that Subsection 7 (*b*) is merely a prohibition, preventing The Institute from admitting members under certain circumstances. He would also point out that Council had not recommended that Subsection 7 (*b*) be thrown out entirely, but had wished to see the prohibition qualified. Mr. Kirby understood that the Quebec Corporation might be prevented from becoming a Component Association if Subsection 7 (*b*) was not passed. That, however, was merely their choice, and the total omission of Subsection 7 (*b*) would not place any obstacle in their way.

Mr. Heward remarked that the whole question of the revision of the by-laws had been based on the hope that there would be consolidation. It would be very unfortunate if The Institute should be left in the position of changing its by-laws and then finding that the Professional Associations did not want the proposed arrangement. Why change the by-laws if consolidation was not going to carry?

Mr. Pitts pointed out that if none of the Associations agreed to co-operate under the scheme the present method of functioning of The Institute would not change at all. The only effect of the proposed changes in the by-laws in that case would be the abolition of the class of Associate Member, a principle which had been accepted for many years, and with this exception there would be no change in The Institute's organization.

Mr. Pitts desired to state that the committee and the Council had now studied this matter over a period of two years. These bodies had had before them all the correspondence and expressions of opinions from individuals, from branches, and from the Associations. The result had been the scheme which was now before the meeting. Possibly members in studying the proposals might see some points which they thought might present difficulty. He could assure members, however, that his committee and Council were satisfied that the scheme was workable, and he believed the meeting would be quite safe in taking Recommendation No. 1 as Council and the Committee had approved it.

Mr. Heward remarked that a number of members did not believe that the present scheme is exactly the form of consolidation desired by the majority. If the proposals fail to carry on ballot then that should terminate the matter, and the Council of The Institute should be left free to make progress with regard to consolidation along other lines.

Mr. Pitts desired to ask Mr. Heward, in view of the remarks just made, whether he had in mind a scheme for professional consolidation which he honestly thought was better than the one now put forward by the committee, and which has been under discussion for two years. If so, why had Mr. Heward not communicated his scheme to Council and to the committee?

Mr. Heward said that in his opinion the present movement was not one for consolidation but one for absorption of The Institute by the Professional Associations. If there were a genuine desire on the part of the Associations to enter into closer relations with The Institute that might be accomplished without having to surrender the autonomy of The Institute or shutting the door in the face of a great many engineers who are fully qualified for Institute membership, but who are not required to be members of Professional Associations. Mr. Heward believed that a much simpler revision of the by-laws of The Institute could be arranged, providing for closer working arrangements with the Professional Associations without running the danger of surrendering to them the autonomy of The Institute.

Mr. Pitts considered that in that case Mr. Heward, as a councillor of The Institute, had failed in his duty in not putting his scheme before The Institute before this.

Mr. Heward replied that he had addressed a communication to the Committee on Consolidation in which he strongly urged a compromise with regard to Subsection 7 (*b*).

Mr. Pitts remarked that the communication to which Mr. Heward had referred was a letter to the committee sent after the Plenary Meeting of Council, and Mr. Heward's recommendation had been, not that the scheme of consolidation should be changed, but that the committee should adopt the Council's version of Subsection 7 (*b*).

Mr. Findlay said that if he understood Mr. Heward correctly, the thought was that a certain section of The Institute was going to be seriously penalized by the proposed by-laws. Mr. Findlay would call Mr. Pitts' attention to the report of his committee which had been published in The Journal for February 1936 and which had been presented at the 1936 Annual Meeting. In that report it was stated that there are three classifications of engineers in each province, namely, (A) those who are members of The Engineering Institute and also of a Professional Association; (B) those who are members of The Institute but who do not belong to a Professional Association, and (C) those who are members of Professional Associations and not of The Institute. In the proposals now before the meeting, as published in the December 1936 Journal, Mr. Findlay had found that classes (A) and (C) had been provided for, but no provision had been made for class (B). In fact, in Mr. Pitts' reports it was stated that this class would tend to disappear. The proposed amendments to the by-laws would now make that tendency into a definite fact.

Mr. Findlay desired to point out the large proportion of The Institute membership who are in class (B). In the province of Quebec this class amounted to more than forty-five per cent of the membership of The Institute in that province. It included large numbers of engineers employed by manufacturing and industrial companies; it was the class which produced the largest number of papers read before The Institute, and was the most valuable and active in the dissemination of professional knowledge. It was this class which, under the amended by-laws, would disappear.

Mr. Findlay agreed with Mr. Heward that the committee had planned only for an Institute composed of Association members. He felt that the committee had been so busy discussing details that they had not dealt with the principles on which these details should have been based. Why had not the chairman of the committee adhered to his original suggestion as a method of approach to the problem, namely, that a group of Institute representatives in each province should meet with a group of Association representatives, and, after coming to an agreement, should report to the Committee on Consolidation? This would have been a common-sense method. The committee had had a heavy task, but Mr. Findlay believed that the personnel of the committee had made it impossible for them to handle the matter in the manner just referred to. There was not on the Committee on Consolidation a real representative of the large class of engineers to whom Mr. Findlay had referred, namely, those employed by large manufacturing and industrial companies. He thought that most members of The Institute would agree that the committee had been more association-minded than Institute-minded. Mr. Findlay urged the acceptance of Council's revision of Subsection 7 (*b*), in which case, while there was nothing to prevent the Associations coming in, this large group of valuable members of The Institute would be preserved. If, after a few years, conditions changed, there would be nothing to prevent the revision of Subsection 7 (*b*) at that time if thought wise to do so.

The President pointed out that while Mr. Findlay's review was interesting, and possibly mistakes had been made, it was his duty to point out that the meeting should confine itself directly to the questions that arise out of the recommendation which was under consideration.

It seemed to Mr. Pratley that the consideration of Recommendation No. 1, which was now proceeding, would give the only opportunity for general discussion. The succeeding recommendations were all definitely directed to some particular point. He suggested that discussion on general features must be held now or not at all. Questions should now be opened up which would lead to considerations regarding the proposal of amendments, if any. The object of this meeting was not to accept everything given to it, but to discuss with a view of proposing such amendments as might be acceptable.

The President remarked that the meeting was open at this point to any discussion that would be crystallized in the form of an amendment.

W. Chase Thomson, M.E.I.C., pointed out that members might possibly be inclined to agree with Recommendation No. 1 if one of the two forms in Recommendation No. 2 were agreed to, whereas they might not agree at all to Recommendation No. 1 if the alternate form of Recommendation No. 2 were adopted. In Mr. Thomson's opinion the whole of the proposals including Subsection 7 (*b*) should be discussed in detail as Mr. Pratley had said.

Mr. Pitts wished to reply to Mr. Findlay's suggestions, which were, first, that members of The Institute, not members of the Professional Associations, were not affected by the proposals, which was not the case, and secondly, that the committee had been association-minded. The committee had been engineering-minded, that is, socially-minded as far as the engineering profession was concerned. He thought Mr. Findlay's presentation had been a little unfair to the committee whose purpose had been to do the best job it could for all engineers in Canada. In regard to its guiding principles, his committee had supposed, up to the 16th of October, that The Institute was in favour of the principle of accepting only Association members into the organization after consolidation had carried, and it was only at the eleventh hour that a change of opinion by the Council had brought in the difference expressed in the two proposals for Subsection 7 (*b*).

Mr. Pratley did not think Mr. Pitts' reply had disposed of what Mr. Findlay had stated. The fact that those members who belong only to The Institute (class B) had been generously treated by the committee and had been left in The Institute, did not remove the necessity for considering the future. A large percentage of the younger Institute members belonged to this class, which there was no reason to suppose was about to disappear. Mr. Pitts was willing at the moment to let those members stay in The Institute who did not belong to the Associations. During the next ten years many people would come along who are not in the Associations, but who should belong to The Institute. Under the proposals they would be kept out.

A. R. Ketterson, A.M.E.I.C. (Montreal), suggested that time would be saved if the discussion were confined at present to Subsection 7 (*b*). If so, he would propose to take with it the consideration of a portion of Section 11 providing for the disappearance of the class of Affiliates. In Mr. Ketterson's opinion this change was undesirable.

Mr. Pitts stated that his committee had proposed the dropping of the class of Affiliates of The Institute because every useful purpose served by that class would continue to be served by the class of Branch Affiliates, which had been retained. Any engineer who could enter The Institute now would be able to enter if the proposals were passed.

Mr. Heward did not agree with Mr. Pitts. The matter was a question of principle. Men who are not required by law to be members of a Provincial Professional Association should not be obliged, in future, if they desire entrance to The Institute, to register with a provincial body.

Mr. H. S. Johnston remarked that up to the Plenary Meeting in October, Nova Scotia had not been satisfied with the progress made by the Committee on Consolidation. After the Plenary Meeting they felt more hopeful, as the co-ordination proposed by the Committee on Consolidation appeared to be likely to develop into real consolidation, which was what the Nova Scotia members desired. Subsection 7 (*a*)1, providing for a Provincial Association to come in as a body into The Institute, had given Nova Scotia what it wanted to a large degree, and if put into effect there would mean that all the engineers in that province would voluntarily enter the consolidated profession.

With regard to the class to which Mr. Findlay had referred, Mr. Johnston thought that they should join the Professional Associations for the sake of the profession at large. Why should they insist on standing outside in a class by themselves? In Nova Scotia, however, it was believed that the present proposals showed real progress as a result of two years of earnest work. The committee had made an earnest effort. Its report had been practically accepted by the Plenary Meeting of Council, a large assembly at which all the provinces were represented. He hoped that the proposals would be accepted by the membership at large, and that the progress of the last two years would not be put aside so that a new beginning would have to be made.

Mr. Findlay desired to point out to Mr. Johnston, on behalf of himself and forty-five per cent of The Institute members in the province of Quebec who are not members of the Quebec Corporation, that they did not join that body, as its work meant nothing to them, and for that reason they did not see why the Corporation should be the only door by which they could get into The Engineering Institute.

J. L. Rannie, M.E.I.C. (Ottawa), remarked that as a Dominion Civil Servant, he was another Institute member who did not have to join the Professional Association. In this he was one of a large percentage of the Ottawa Branch of The Institute, who had nevertheless realized that to get into The Institute, after the passage of the proposals, they would have to join the Provincial Association. They had accepted this condition at the Annual Meeting of the Branch without a single dissenting voice. The Ottawa members had enough interest in consolidation to say that if in order to get somewhere it was necessary to give something up they were prepared to do so.

Mr. Muntz supported Mr. Rannie's view, and stated that he wished to convey to the meeting the opinion of the Hamilton Branch, which was to exactly the same effect. That Branch was made up almost entirely of members who are employed engineers and are not interested in the Professional Association from the legal standpoint. Nevertheless they are backing the Committee on Consolidation and are prepared to join the Association if that is necessary for consolidation.

Mr. Busfield recalled that at the Plenary Meeting of Council he had requested a clear explanation of the necessity for these drastic changes in the by-laws, and the reply he had received was that he should read the reports of the Committee on Consolidation. This he had done, and he had found that one of the objects of the Committee on Consolidation was to take care of the group of engineers who do not belong to the Professional Associations, a group to which Mr. Findlay had already referred. All he found in the by-laws, however, was that this group would be compelled to belong to the Professional Associations. He found also in the proposals that without any guarantee of consolidation whatsoever, the privilege of membership in The Institute was to be given away to any Association desiring to take advantage of it. He also noted that one recommendation of the Committee's report of last year was that the Provincial Professional Associations should be approached to give reciprocal privileges to The Engineering Institute as regards recognition of membership. In the proposals now before the meeting he found nothing of this kind, although a report from Manitoba had stated that if the proposals go into effect Manitoba will recognize Institute membership. On the other hand, it had been stated that other Associations had definitely gone on record that they did not propose to give any recognition to Institute membership. Mr. Busfield felt, therefore, that many of the recommendations of last year had not been implemented in the proposals now submitted.

In these proposals Mr. Busfield had failed to find anything which could really be called consolidation. The Institute itself, under these proposals, would operate under entirely different conditions in the eight provinces. That was not consolidation, but in his opinion, as far as The Institute was concerned, was a breaking down rather than a building up.

He found nothing in the picture indicating any consolidation of the Professional Associations themselves. There was nothing in the proposals which would have any effect of this kind, except the provision for a Standing Committee, which neither the Associations nor The Institute needed. He had heard that some associations are ready to become component. This was understandable since they had everything to gain and nothing to lose. Mr. Busfield had, therefore, come to the conclusion that the effect of the proposed changes would be to hand over the control of the national body and The Institute's privileges to the Professional Associations. Our grades of membership were to be changed so as to have one grade of corporate member to fit the ideas of the Professional Associations. The Institute's qualifications would be entirely changed so as to admit members of the Professional Associations. Then a group of Associates would be set up for the benefit of those members of the Association who do not want to belong to The Institute, taking these men in without any fee whatever.

None of these proposals were really based on a determination of what is really needed in the profession, but had been made to fit the conditions found to exist in the different provinces. Mr. Busfield questioned the desirability of eliminating the class of Affiliates simply because they did not fit in with the provincial arrangements. Other national engineering societies had had such a grade for many years. He had noted further that the method of application for transfer was to be greatly simplified and made automatic in the case of Association members, but The Institute would retain its present standards of admission in provinces where there were no component associations. All the changes proposed in methods of election and transfer were entirely to the advantage of the Associations.

It seemed to him inevitable that the Provincial Associations would in a short time have the absolute control of The Institute. This arrangement of a national body directed by eight Provincial Associations would possibly be workable, although he could see some very definite disadvantages. In the first place the membership of the national engineering body, heretofore built up of men selected for technical and professional engineering qualifications, would be on a different basis from the selection of Association members. He believed that there were cases where persons had been admitted to the Provincial Associations for reasons quite apart from their technical qualifications.

The ultimate control of The Institute by the Provincial Associations had been definitely visualized by the President of the Dominion Council of Professional Engineers in reviewing the proposals now before the meeting. In a memorandum on the Manitoba proposals, which Mr. Busfield understood had been distributed in British Columbia and elsewhere, Mr. Kirby had stated that the Association members, as nominators and electors of The Institute Council, would in time control the personnel of that Council, so that ultimately the by-laws of The Institute could be made to comply fully with the requirements of the Associations. Mr. Busfield would suggest that the real question to be discussed to-day by the meeting would be, is it advisable for the Provincial Associations to control The Institute?

Mr. Pitts desired to point out that The Institute would always be run by the members of The Institute.

Mr. H. S. Johnston desired to add that Mr. Busfield should have included Nova Scotia with Manitoba as an Association which would grant reciprocal privileges.

Mr. Kirby remarked that Mr. Busfield had criticized him for pointing out to the professional engineers in Canada that they are not being absorbed by The Institute but are being brought into The Institute. The proposal which Mr. Busfield disliked came from the Plenary Meeting of Council itself, when The Institute Council adopted the Manitoba proposals as to group membership, and said to the Associations "we are glad to have you come in as a body." Mr. Kirby would urge that if there were going to be a real national engineering body in this country, all engineers must be in it or it would not be a real national society. When everybody had joined, the majority would rule;

The Institute had already committed itself to the principle that engineers should be registered. In Mr. Kirby's opinion it was right and proper that the provincial engineers of Canada should have the majority vote in the affairs of The Institute. Why should The Institute's policies be dominated by a group residing close to headquarters who are not sympathetic to the principle of registration for engineers? Such domination was not in accordance with the view of The Institute itself, which had gone on record as approving the desirability of registration for engineers in Canada.

Brian R. Perry, M.E.I.C. (Montreal), pointed out that although Mr. Findlay had suggested that forty-five per cent of The Institute members in the province of Quebec were not interested in registration, nevertheless in replying to the questionnaire sent out by the committee asking for an expression of opinion, approximately eighty per cent of the Montreal members had turned in ballots in favour of the proposals now before the meeting. Mr. Perry did not agree with Mr. Kirby that a group of members of the Council representing the Montreal Branch were opposed to consolidation. In Mr. Perry's opinion rejection of the present proposals by the membership could only result in increased activity on the part of the Professional Associations along lines which are at present the functions of The Engineering Institute. There would not be room in any locality for two organizations whose objects would clash in this manner.

Mr. Perry then drew attention to the increased activity noticeable in Montreal and in Toronto on the part of American and other engineering associations of a specialized character, and pointed out that young engineers joining them did not see much point in paying a double fee, so that these bodies were gaining membership to a large extent at the cost of the membership in The Engineering Institute. In many cases the members of these associations were not qualified engineers, but they called themselves engineering societies. This would lead the Professional Associations to take an interest in their activities, in doing which the Associations would tend to overlap the functions of The Engineering Institute.

F. P. Shearwood, M.E.I.C. (Montreal), desired to point out that the question at issue was apparently whether at this time licensing should be made compulsory for every future member of The Engineering Institute. Actually, the possibility of the complete application of licensing had not been demonstrated, especially in the provinces of Ontario and Quebec. The voluminous reports published from time to time by the Committee on Consolidation had dealt largely with the background of the subject and had not answered questions such as the following: (1) What must be classed as and be licensed for professional practice in engineering, especially as it is carried on in industry? (2) Will the present proposals improve our personal incomes or our reputations as members of the profession? (3) Will they define more honestly and more convincingly the responsibility of engineers to the public? (4) Will they bring into The Institute those highly experienced employees of industries who contribute so much to engineering progress, but who do not belong to The Institute, and give their allegiance to foreign societies? (5) Will the proposals of the committee encourage the interchange of experience which is at the root of engineering development? These questions should be investigated and reported on.

The Committee on Consolidation had claimed justification for many of their proposals because of large majority votes at Annual Meetings and favourable answers to questionnaires, but in Mr. Shearwood's opinion these votes had nearly always been given in general approval of the movement for co-operation and should not be taken as an endorsement of the particular proposals contained in the committee's reports. Mr. Shearwood himself, in voting for the committee's report of last year did not thereby necessarily endorse all its proposals. Undue significance should not be given to majority votes at Annual Meetings. He had repeatedly pointed out to the committee that their members were not sufficiently conversant with the requirements of engineers employed by industries, no member of the committee having had responsible charge of large industrial departments. Thus he feared that the committee had not appreciated the difference between the requirements desirable for an engineering licence and those required for service in the industries. Further, the committee had not realized the unprofessional character of the work of the sales-engineer.

Mr. Shearwood's experience in industrial work had made him realize the need for an efficient licensing system giving protection to those aspiring to consultant service and serving as a guarantee to the public. While the committee was insisting on the inclusion of Subsection 7 (*b*) restricting membership in The Institute to members of the Provincial Associations, they had failed to state what engineering work can be and is restricted to licensed engineers. This being so, why were some forty-five per cent of The Institute members in the province of Quebec not registered? These men, many of whom are prominent members, are not forced to pay $7 per annum to the Corporation for the right to earn a living by engineering, and it did not seem fair to compel all future members to pay this amount for a licence which most of them do not require. The raising of the standard of engineers' professional qualifications had been given as the reason for Subsection 7 (*b*), particularly in the Province of Quebec, and yet the standard for admission to the Quebec Corporation was actually lower than that required for corporate membership in The Engineering Institute.

Mr. Shearwood felt that the present proposals of the Committee, except Subsection 7 (*b*), could be accepted by both The Institute and the Associations to their mutual benefit, but that subsection should be approved in the form recommended by Council, so that the complete control of all future membership in The Institute would not be given over to the provincial bodies, at least not until the scope and benefits of licensing had been clearly defined.

Mr. Pitts noted Mr. Shearwood's remarks, in which he had criticized the Committee on Consolidation for not elaborating the ideals which he had laid out. It would have been impossible to bring forward proposals along Mr. Shearwood's lines, as these would require a complete change in the existing Acts of the various provinces, a practical impossibility. Mr. Pitts' committee had made every effort to find out the opinions of people in all parts of the country. In regard to Subsection 7 (*b*), Mr. Pitts would point out that the version proposed by his committee had been supported by the branches in Victoria, Vancouver, Edmonton, Calgary, Saskatchewan, Winnipeg, Lakehead, Niagara Peninsula, Hamilton and Ottawa. The Montreal Branch Executive could not make up its mind. The branches at Quebec, Saint John and Halifax had approved the committee's version of Subsection 7 (*b*). Their version had also been approved by the following Associations: British Columbia; Alberta; Saskatchewan; Manitoba; Quebec; New Brunswick and Nova Scotia. Ontario had not done so. These expressions were what the committee had to go by in making their decisions, and they should be contrasted with the action of the Plenary Meeting of Council, which had approved a different version by a vote of 13 to 8. Mr. Pitts did not see how the expressions of branch opinion to which he had referred could be overlooked.

Mr. Crealock desired to make a personal explanation. Mr. Kirby had already read to the meeting a letter from the President of the Ontario Association of Professional Engineers, which stated the view of the Council of that Association as not being in favour of the scheme of consolidation put forward by The Institute's Committee on Consolidation. He had been on that committee as one of the two representatives appointed by the Dominion Council of Professional Engineers. Mr. Crealock was also a member of the Council of the Professional Association in Ontario, and in view of the attitude taken by that Council he now found it necessary to submit his resignation as a member of the Committee on Consolidation. That he had done, and he desired the meeting to be made aware of the fact.

Speaking next as a member of The Institute Council representing the Toronto Branch of The Institute, Mr. Crealock reported that the executive committee of that branch, on October 7th, 1936, had passed a resolution supporting Council's version of Subsection 7 (*b*). On January 21st, 1937, following the announcement of the attitude of the Ontario Association, that executive committee had passed the following resolution "that the previous motion of the executive committee passed on October 7th, 1936, recommending an amendment to Subsection 7 (*b*) of the report of the Committee on Consolidation, be rescinded." At the same meeting it was also resolved "that the branch councillors be instructed to support at the Annual Meeting Subsection 7 (*b*) as contained in the report of the Committee on Consolidation."

Mr. E. V. Caton desired to point out that the Winnipeg Branch appreciated the generous gesture made by The Institute in the proposals now before the meeting. With these amended by-laws, the Manitoba members believed they could get what they regarded as essential, namely, one body representing the engineering profession in Manitoba. Under the new by-laws it would be possible to register practically the whole body of engineers in Manitoba, who would pay one fee, which he believed would possibly be less than the one fee now paid, and certainly less than the two fees now paid by some. The Institute would thus be strengthened in Manitoba. Mr. Caton believed that if each province were given an opportunity to consolidate under the auspices of The Institute there would soon be a national engineering body with The Institute as a head. In the west it was felt that if The Institute is to become the national body it should have all members of the profession within it.

Mr. W. McG. Gardner felt that if Recommendation No. 1 of the committee were adopted, and the proposals carried on ballot, there would be a national body, but there would not be The Institute. He believed the impossible was being attempted, namely, a unification scheme which not everybody would join.

G. H. Wood, A.M.E.I.C. (Niagara Falls), pointed out that two views had been expressed, one, that The Institute would be dominated by the Professional Associations, and another, that the Professional Associations would be dominated by The Institute. He did not think that either would be the case. Some members seemed to have the idea that there was some stigma attached to voluntary registration, and that a man who does so is not quite as good as the man who refuses to register unless compelled to do so. Mr. Wood could not understand such a view.

Geoffrey Stead, M.E.I.C. (Saint John), believed that the feeling was strong for consolidation in New Brunswick, and that if consolidation did not go through he feared The Institute would suffer rather than the Professional Association. In New Brunswick they believed the present proposals to be a good working set of by-laws, and in fact the New Brunswick Association had resolved to become a component association as soon as possible.

Mr. Shearwood inquired whether a provincial act could cover all engineering work. Mr. Wheatley had admitted that such acts could not do so.

In reply Mr. Stead read from the New Brunswick Act the description of a professional engineer.

Mr. Shearwood observed that the Committee on Consolidation, and also the Quebec Branch, had referred to a report made by a committee of which he had been chairman. It would have been better if they had read the last paragraph of the report to which he referred, in which he had suggested that a committee be appointed to investigate and report on (*a*) the conditions existing in the engineering shop and field departments of large engineering works and contracting and manufacturing corporations, (*b*) the class of work and type of training necessary for the various engineering employees of these corporations, and (*c*) the policy of The Institute in regard thereto.

Mr. Kirby suggested that the time to appoint such a committee would be after consolidation when there would be one big body of engineers representing everybody.

Mr. Pratley remarked that Mr. Kirby's reference to one big body would serve him as a text. In regard to the committee's proposals, numerically small bodies would have a very easy task as, for example, in Saskatchewan with 88 members; New Brunswick with 121, and in Manitoba, but in the larger Associations such as Ontario, Quebec and British Columbia the problem was not so simple. Mr. Pratley had before him a letter from the Council of the Association in British Columbia, of which he was a member, containing the statement that the Committee on Consolidation is moving too quickly in this matter. Mr. Pratley agreed with this, particularly because there was no assurance from the three large provinces, without whose co-operation consolidation would be a farce, that they are prepared to co-operate. It was definitely known that Ontario would not do so. The Quebec Corporation would only do so with a very one-sided interpretation of qualifications. Mr. Pratley did not see why the Corporations and The Institute should not mutually agree to let each other function and to help each other without trying to join together an unequal bunch of quite different bodies.

In British Columbia Mr. Pratley understood that on January 19th a meeting had been called by the Council of the Professional Association to discuss or protest against the proposals now before The Institute. At that meeting Mr. Vilstrup, the President of the Association, had said, "Here, in British Columbia, the view has been consistently held for many years that the logical procedure in the matter of consolidation would be for the Provincial Associations to establish a permanent Dominion body with which then consolidation with The Engineering Institute of Canada and perhaps other bodies could be subsequently arranged." . . . "While those of us not members of The Engineering Institute of Canada may feel we are not interested or concerned with by-law revisions, we cannot, nevertheless, escape important consequences if they pass and result in consolidation." . . . "Those of us not members of The Engineering Institute of Canada cannot vote for or against the proposed by-laws, although the result of the by-laws may greatly affect the destiny of our Association, but we are free to discuss them."

These extracts from Mr. Vilstrup's speech would show that in British Columbia they are not prepared to accept the proposals of the Committee on Consolidation. During the meeting of the B.C. Association the opinion was expressed that those proposals were dangerous, and instead of uniting engineers across Canada the result would be quite the opposite. Mr. Pratley agreed with this opinion. At the same meeting the Vice-President of the British Columbia Association, not a member of The Engineering Institute, had advocated a federation of the Provincial

Associations joined together and equal, and the claim was made that the proposals emanating from The Engineering Institute of Canada did not contemplate such an arrangement, "some members of The Engineering Institute of Canada having appointed themselves to the task of making The Engineering Institute of Canada the Dominion body." These views, expressed by people prominent in the British Columbia Association, were considered so important that the Association had published them. It did not seem likely that the British Columbia Association would be willing to enter into consolidation on the present proposals. Thus, if those proposals carried, the three major provinces would still operate as they are now quite independently of The Institute. This would result in difficulty. Why would it not be better to take the thought expressed by the British Columbia Council that we are going too fast?

Colonel H. F. G. Letson, M.E.I.C., the Past-President of the British Columbia Association, had suggested in his presidential address that, following the procedure initiated in the United States, a National Engineering Council should be formed in Canada, representing such bodies as The Engineering Institute of Canada, the Canadian Institute of Mining and Metallurgy, the Provincial Associations, and the members of the various foreign engineering societies having branches in Canada. Mr. Pratley did not think such a proposal had yet been explored; such exploration should be a task for The Institute.

Speaking as one of the Montreal councillors, Mr. Pratley said that the representatives of the Montreal Branch on Council had agreed to the committee's proposals involving the surrender of The Institute's autonomy, but had felt they were wrong in doing so. They had not opposed the approval of those proposals by Council, because they were not opposed to the principle of co-operation or federation; further, in doing so they had not misrepresented the branch on the question of Subsection 7 (*b*) as Mr. Perry had suggested. Actually, the Montreal Branch had never discussed Subsection 7 (*b*), though the branch had recorded its approval of consolidation as a principle.

Mr. Pratley would like to make one last plea—that members should think very seriously before giving consent to the present proposals, which were dangerous, because if they carried, membership of The Institute would become merely a matter of registration. There would then be little value in putting M.E.I.C. after one's name, since, if the proposals carried, members would have to accept as their equals, as corporate members of The Institute, graduates of our various schools of engineering without any engineering experience whatever. For fifty years membership in The Engineering Institute of Canada had been a certificate of standing. If the by-laws were amended as now proposed this would no longer be the case.

Mr. Pitts remarked that Mr. Pratley was evidently against the form of consolidation now proposed, which, for the time being at least, was equivalent to opposing consolidation. With regard to Mr. Pratley's quotations from speakers in British Columbia, Mr. Pitts pointed out that these opinions were personal and did not necessarily represent the opinion of the total membership of the British Columbia Association, in regard to which there was on record a resolution passed by the British Columbia Council indicating a point of view very sympathetic to the present proposals. There was undoubtedly a group in British Columbia definitely in opposition to The Institute, but Mr. Pitts was satisfied that these people did not represent the opinion of the majority of the members of the British Columbia Association.

Mr. Pitts did not think that Mr. Pratley was justified in saying that Quebec would not come in. There was no evidence of such a course in any communication he had had, and the Quebec Corporation was undoubtedly ready to support the movement. In regard to the Ontario Association their situation should be regarded sympathetically. They had not an effective Act, and he hoped that The Institute, as a national body, would get behind the Ontario Association and support them in getting a satisfactory enactment, so that every engineer in Ontario would be glad to enter the organization.

Mr. Pitts could not report enthusiastically that British Columbia was coming into consolidation, at all events for the time being.

The question having been called, the Secretary read the resolution with regard to Recommendation No. 1, as proposed by Mr. Muntz, seconded by Mr. Stead, that the meeting accept Recommendation No. 1 as follows:—

> "That the Council of The Institute and the Committee on Consolidation being in agreement on all the proposed revisions to the By-laws of The Institute as appearing in Appendix "A" of this report, with the exception of Subsection 7 (*b*), these revisions be accepted by the Annual Meeting and be sent forward to ballot by the general membership without further amendment."

The resolution having been put to the meeting was *carried* with applause.

*Recommendation No. 2.*

> That in view of the attitude of the majority of the Professional Associations on Subsection 7 (*b*) and in the interests of achieving Consolidation, every effort be made to accept the Committee's proposal on this Subsection without modification or amendment for submission by ballot to the general membership.

E. P. Muntz, M.E.I.C., then *moved* that Recommendation No. 2 be approved, his motion being *seconded* by G. Lorne Wiggs, A.M.E.I.C. (Montreal).

The President pointed out that under the By-laws, Subsection 7 (*b*), as proposed by the Committee, and the alternative version of Subsection 7 (*b*), as proposed by the Council, must both go to the general membership for ballot.

Mr. Findlay desired to *move* that in view of the large number of Institute members who are not members of the Professional Associations, this meeting go on record as approving the Council's revision of Subsection 7 (*b*). Mr. Findlay's motion having been *seconded* by J. L. Busfield, M.E.I.C., the President pointed out that the motion being equivalent to a direct negative of the main motion must be disallowed. The same result would be obtained if the recommendation of the committee were disapproved.

Mr. Gordon Pitts pointed out that Recommendation No. 2 was equivalent to a request to this meeting to express its opinion as to which version of Subsection 7 (*b*) was preferable.

Mr. Pratley was unable to accept this view, and Mr. Pitts pointed out that while both proposals must go to ballot, his committee hoped that this meeting would approve Subsection 7 (*b*) and direct that it go forward without any further amendment.

Mr. Clarence Pitts did not agree with Mr. Pratley as to the meaning of the committee's recommendation. That committee was asking for the meeting's approval of their version of that subsection. Council's proposals seemed to Mr. Pitts to be almost inexplicable. By the use of the words "required by law" they would place the matter in the hands of the Courts so that the engineering profession would have to go to the legal profession in order to find out who an engineer is. Council thought this was simplifying the problem, but it actually made more complication. The resolution asked the Annual Meeting to endorse the position of the Committee on Consolidation, Mr. Pratley hoped that it was quite clear that Council's amendment to Subsection 7 (*b*) would go to ballot. Mr. Clarence Pitts had referred to the difficulty of deciding who is "required by law" to be a member. In Mr. Pratley's view this was a simple matter, since in a province having an effective Act, the mere fact that an engineer is not a member of the Professional Association implies that the law does not require him to be so, the Professional Association not having taken action in his case.

The resolution for the approval of Recommendation No. 2, proposed by Mr. Muntz and seconded by Mr. Wiggs, was then put to the meeting and *carried* by a vote of 39 to 17.

*Recommendation No. 3.*

That the Annual Meeting approve the form of the "Memorandum of Agreement" between The Institute and a Component Association, as submitted in Appendix "C" of this report, subject to such modification within the terms of the By-laws as may be agreeable to the Council of The Institute and the Associations and Corporation.

The Secretary having read Recommendation No. 3 as above, Mr. Muntz *moved* its approval, and his motion was *seconded* by Mr. G. H. Wood. There being no discussion, the motion was put to the meeting and *carried.*

At this point Mr. Pratley, *seconded* by T. C. Thompson, A.M.E.I.C. (Montreal), *moved* that the meeting adjourn, but on being put the motion was *lost.*

*Recommendation No. 4.*

That the Annual Meeting approve Form "C" as proposed by the Committee in Appendix "D" of this report, being the form of Application for Admission to The Institute by a member of a Provincial Professional Association or Corporation.

*Recommendation No. 5.*

That the ballot on the By-law proposals be drawn in the general form as appearing in Appendix "E" of this report and that the Committee on Consolidation be authorized to take part in the drafting of the form of the ballot.

*Recommendation No. 6.*

That subject and subsequent to the approval of the By-law proposals by a ballot of the membership, the By-laws be re-arranged and re-numbered before being printed and issued to the membership in accordance with the Index appearing as Appendix "B" of this report.

*Recommendation No. 7.*

That the Committee on Consolidation be continued as presently constituted to function in connection with the preparation of the ballot, and otherwise for the purposes of Consolidation, until after the results of the ballot have been announced, and that thereafter a special committee be appointed by Council to actively promote Consolidation.

The approval of Recommendations Nos. 4, 5, 6 and 7 was then *moved* by Mr. C. C. Kirby, *seconded* by Mr. G. H. Wood, on which Mr. Findlay *moved* as an amendment that Recommendation No. 5 be changed to say that the ballot on the by-law proposals be prepared by Council with the co-operation of the Committee on Consolidation. The amendment having been *seconded* by Mr. T. C. Thompson, was put to the meeting and *lost.*

Mr. Challies desired to ask Mr. Pitts with regard to Recommendation No. 6, the renumbering and rewording of the by-laws, whether Council would be precluded from making minor changes in wording. Mr. Challies would like to see this point covered in the recommendation, and, with the agreement of Mr. Gordon Pitts, *moved* as an amendment the addition to Recommendation No. 6 of the words "or such modification thereto as Council may determine." The amendment having been *seconded* by Mr. Gordon Pitts was put and *carried.*

The main motion for the adoption of Recommendations 4, 5, 6 as amended, and 7 was then put and *carried.*

Mr. Gordon Pitts desired to *move* that the meeting adopt the report of the Committee on Consolidation with the revisions as they have been approved and with the amendments suggested under the various clauses. The resolution having been *seconded* by Mr. Challies was put to the meeting and *carried.*

### Amendments to the By-laws Proposed by the Council

The meeting next considered the amendments to The Institute by-laws proposed by the Council, of which copies had been distributed to the members present.

Mr. H. S. Johnston *moved* that the amendments proposed by Council be approved for ballot, the motion being *seconded* by Professor McKiel.

Mr. Clarence Pitts pointed out a difficulty with regard to Subsection 7 (*b*), the meeting having already approved of the committee's version of that Subsection. He accordingly *moved* an amendment that the proposals of Council be approved with the exception of that referring to Subsection 7 (*b*). The amendment was *seconded* by J. A. Lalonde, A.M.E.I.C. (Montreal), and on being put to the meeting was *carried.*

### Branch Reports

The meeting next considered the branch reports. The President suggested that unless representatives from any of the branches desired to draw special attention to some particular point these reports might be taken as read and accepted. Mr. McCrory, having *moved* that the branch reports be accepted, his motion was *seconded* by E. Viens, M.E.I.C., put to the meeting and *carried.*

Mr. Gordon Pitts drew attention to the many letters and resolutions which had been received from The Institute branches with regard to the committee's proposals, more particularly as to Subsection 7 (*b*). He asked that this correspondence should be printed in the record of the Annual Meeting for the general information of the membership of The Institute.

The Secretary having pointed out that if all the letters were included the material would be somewhat voluminous, Mr. Pitts agreed that a list of the resolutions and letters, with a brief statement of their contents would be sufficient. Mr. Pitts then *moved* that a summary of the communications from the branches with reference to consolidation should be printed with the record of the Annual Meeting. His motion having been *seconded* by Hector Cimon, M.E.I.C. (Quebec), was put to the meeting and *carried.*

This summary list of communications follows:—

| From: | Received: 1936 | Remarks |
|---|---|---|
| Saskatchewan Branch | Nov. 26th | Favours Committee's Subsection 7 (*b*). Urges that ballot be submitted to membership in such a form as to permit of a single vote on major question of consolidation. |
| Quebec Branch | Dec. 8th | Resolution and letter signed by 24 corporate members of Quebec Branch favouring Committee's Subsection 7 (*b*). |
| Winnipeg Branch | Dec. 18th | Endorsing Saskatchewan resolution. |
| | 1937 | |
| Calgary Branch | Jan. 2nd | Favouring Committee's Subsection 7 (*b*). |
| Lakehead Branch | Jan. 2nd | Endorsing Saskatchewan resolution. |
| Saint John Branch | Jan. 12th | Endorsing Saskatchewan resolution. |

| | | |
|---|---|---|
| Kingston Branch | Jan. 16th | Suggesting that Council's amendment to Subsection 7 (*b*) should apply to Ontario only, or that words "except in the case of the Province of Ontario" should be added to original Subsection 7 (*b*). |
| Niagara Peninsula Branch | Jan. 19th | Recommending Council to reconsider decision of Plenary Meeting re Subsection 7 (*b*). |
| Saguenay Branch | Jan. 19th | Favouring Council's amendment to Subsection 7 (*b*). |
| Ottawa Branch | Jan. 19th | Favouring Committee's Subsection 7 (*b*) and urging that ballot be submitted in such a form as to permit of a single vote on major question of consolidation. |
| Lethbridge Branch | Jan. 20th | Favouring Committee's Subsection 7 (*b*). |
| Vancouver Branch | Jan. 23rd | Favours Committee's Subsection 7 (*b*). Urges that ballot be submitted without alternative choice for Subsection 7 (*b*). |
| Winnipeg Branch | Jan. 25th | Favouring Committee's Subsection 7 (*b*). Urges that separate ballot be taken on Subsection 7 (*b*) if alternative proposals are sent out. |
| Victoria Branch | Jan. 25th | Favouring Committee's Subsection 7 (*b*). Requests that Council withdraw their proposed amendment. |
| Toronto Branch | Jan. 27th | Favours Committee's proposal for Subsection 7 (*b*). |
| Hamilton Branch | Jan. 28th | Supporting Committee's Subsection 7 (*b*). |
| Halifax Branch | Jan. 28th | Choice of two alternatives for Subsection 7 (*b*) not a serious one, particularly if Subsection 7 (*a*)1 carries. But if decision will have detrimental effect on report of Committee on Consolidation will support report of Committee on Consolidation. |

Mr. Gordon Pitts desired to draw attention to the facts that the result of the ballot would be known during the month of May; the wishes of the membership thereby expressed would affect the future policy of The Institute; and many members will be present at the Semicentennial in Montreal in June. Mr. Pitts *moved* that the Council arrange for a special general meeting of The Institute in Montreal at a convenient time during the Semicentennial Celebrations, for the reception and discussion of the results of the ballot.

The motion having been *seconded* by Robert F. Legget, A.M.E.I.C. (Kingston), Mr. Pitts explained that at that meeting there would be an opportunity for representatives of the Professional Associations to indicate their attitude towards consolidation.

Mr. Busfield, as chairman of the Semicentennial Committee, said that his committee, and the Council, felt it inadvisable to hold meetings at that time dealing with general business of The Institute, the only exception being the Plenary Meeting of Council which was to form part of the Semicentennial proceedings. It was possible, he thought, that the Dominion Council of Professional Engineers might see fit to hold a meeting at that time, but Mr. Busfield did not think that a business meeting of The Institute should then be held.

Mr. Pitts, in reply, said that the meeting would be a special general meeting which would deal with no other business than that stated in the resolution.

The resolution having been put to the meeting was *carried.*

Mr. Gordon Pitts desired to make another proposal, and *moved* that the ballot on the revisions to the by-laws be issued to the membership on or before the first day of March 1937, and be returnable to the Secretary not later than the twentieth day of April 1937, and that the Council announce the result of the ballot on or before May 1st, 1937.

The Secretary pointed out that the date on which the ballot could be sent out would depend upon the time taken by the *pro* and *con* committee in preparing their statements.

S. G. Porter, M.E.I.C. (Calgary), *moved* as an amendment that the matter be referred to the incoming Council. The amendment having been *seconded* by W. McG. Gardner, A.M.E.I.C., was put to the meeting and *carried*, the resolution therefore being *lost.*

The President reminded the meeting that under the by-laws it was his duty to nominate a committee composed of an equal number of members favouring and opposing the proposals, who would prepare a statement of reasons for and against which would accompany the letter ballot. He proposed to make those appointments at the opening of the next session of the annual meeting.

At this point, six five p.m., on the motion of Mr. Clarence Pitts, *seconded* by Professor H. W. McKiel, it was *resolved* to adjourn and reconvene at ten o'clock on Saturday morning.

---

The meeting reconvened at ten fifteen a.m. on Saturday, January 30th, 1937, with President Cleveland in the chair.

The Secretary presented a telegram from The Institute membership and the Professional Association in Saskatchewan, signed by D. A. R. McCannel, M.E.I.C., the President of the Association, and Councillor Stewart Young, M.E.I.C., conveying greetings, and urging the Annual Meeting to present a clear cut proposal on consolidation to The Institute membership.

The President made the following nominations as members of a committee to be appointed under Section 75 of the By-laws to edit the reasons advanced for and against the proposals: Committee on reasons for—Gordon McL. Pitts, A.M.E.I.C., J. B. Challies, M.E.I.C., O. O. Lefebvre, M.E.I.C.; Committee on reasons against: P. L. Pratley, M.E.I.C., F. S. B. Heward, A.M.E.I.C., R. H. Findlay, M.E.I.C.

In making these appointments, the President urged the desirability of limiting the length of the presentations which must accompany the ballot and suggested a memorandum not exceeding 200 words in each case.

### Address of Retiring President

Dr. Cleveland then delivered his presidential address, the subject being "The Engineer in Business." (This is published *in extenso* on pages 98 and 99 of the issue of The Journal for February 1937.)

### Election of Officers

The Secretary presented the report of the scrutineers appointed to canvass the officers' ballot for 1937, as follows, and the President declared the various nominees duly elected to their respective offices:—

| | |
|---|---|
| President | G. J. Desbarats |
| Vice-Presidents: | |
| Zone A | H. S. Carpenter |
| Zone C | J. A. McCrory |
| Councillors: | |
| Halifax Branch | H. S. Johnston |
| Saint John Branch | E. J. Owens |
| Saguenay Branch | A. C. Johnston |
| St. Maurice Valley Branch | B. Grandmont |
| Montreal Branch | J. B. D'Aeth |
| | A. Duperron |
| Ottawa Branch | R. W. Boyle |
| Kingston Branch | J. E. Goodman |
| Toronto Branch | W. E. Bonn |
| London Branch | J. A. Vance |
| Border Cities Branch | H. J. A. Chambers |
| Lakehead Branch | R. J. Askin |
| Saskatchewan Branch | R. A. Spencer |
| Edmonton Branch | R. M. Dingwall |
| Vancouver Branch | P. H. Buchan |

The newly-elected President, Mr. G. J. Desbarats, was then escorted to the chair by Past-Presidents F. P. Shearwood and S. G. Porter, who presented him to the meeting amid hearty applause.

Dr. Cleveland briefly extended a welcome to Mr. Desbarats, and expressed the hope that he would have the highest satisfaction in the discharge of his duty.

President Desbarats, on taking the chair, expressed his thanks to the members for the honour of being elected President of The Engineering Institute of Canada, particularly as this distinction came in a year which was such an important one for The Institute, as including the Semi-centennial Celebrations. He knew that in carrying out his duties he would have the full support of members of Council and of The Institute members.

The Secretary then presented the following resolution from the Ottawa Branch regarding a change in the title of The Institute:

> "That the Ottawa Branch, Engineering Institute of Canada, in Annual Meeting assembled, request the Council of The Institute to take the necessary steps to obtain assent to change the name of The Engineering Institute of Canada to The Royal Engineering Institute of Canada and that corporate members of The Institute may thereafter be designated by the abbreviation R.E.I.C., as and when consolidation proposed is effected.
>
> "Be it further resolved that a copy of this resolution be sent to the branches of The Institute and to Council to be presented at the next Annual Meeting in Montreal."

Mr. Clarence Pitts *moved* that the Annual General Meeting adopt this resolution which had been unanimously passed by the Ottawa Branch and was intended to suggest that when The Institute became truly representative of the engineers throughout Canada it might properly aspire to the honour of the title of "Royal." He hoped that the meeting would go on record as being in favour of that step when consolidation had become effective.

Mr. Challies was not only opposed to the idea on its merits, but also felt that the method proposed to secure the change of name was incorrect. Such a change could only be made as a result of the same procedure as that required for a change in The Institute by-laws.

Mr. Clarence Pitts did not agree with Mr. Challies on this point. The resolution merely asked the Council to take the necessary steps, but did not force any issue.

Mr. Challies inquired whether Mr. Clarence Pitts would be satisfied to have the whole matter referred to the Council. Further, Mr. Challies pointed out that some twenty years ago, when the name of the Canadian Society of Civil Engineers was changed, the same proposal had been brought up and had given rise to strong opposition. The suggestion was then abandoned, one of the principal reasons being that The Institution of Civil Engineers, the senior engineering society in Great Britain, had been satisfied to proceed without this honour. In Mr. Challies' opinion The Institute was in no way comparable to any of the organizations in Canada which had sought and had been granted the privilege. Further, he believed that any change in the name of The Institute at the present time would be unwise.

Mr. Clarence Pitts observed that his motion had not been seconded. He had moved that the resolution of the Ottawa Branch be adopted by the Annual Meeting. Mr. Pitts' motion was then *seconded* by Mr. Legget.

Mr. Gordon Pitts remarked that the subject should not be a very controversial one, and was not of importance in relation to the by-laws. The change suggested, however, would designate The Institute as an important national body, and distinguish it from a number of organizations which are springing up and which are making a very free use of the term "engineering." Mr. Pitts further pointed out that quite a number of The Institute branches had sent in recommendations to the Plenary Meeting of Council, but at that meeting the Council had not had time to give the matter proper consideration. Now it should be settled by The Institute. Mr. Pitts thought it would perhaps be possible to get a larger expression of opinion than was possible at a regular annual meeting as to whether the use of the title would be of sufficient significance to go to Parliament and ask for the privilege.

Vice-President Caton agreed with Mr. Challies that the present time was not opportune to introduce any additional contentious subjects. In the Manitoba Branch it was the general opinion that at the present time it was not even opportune to discuss whether or not the change was desired.

Mr. G. H. Wood stated that at a meeting of the Niagara Peninsula Branch held last fall, a motion was passed recommending that no action be taken on the matter.

Mr. Rannie desired to propose an amendment to the resolution and *moved* that the matter be presented to the Council to be taken up as the Council might find advisable. In that way the Council could take any action they desired and sound out the members of The Institute at the proper time. The amendment was *seconded* by R. L. Dobbin, M.E.I.C. (Peterborough).

President Desbarats observed that the effect of the amendment would be to refer the resolution of the Ottawa Branch to the Council for such action as they might deem advisable and possible. It would, however, hardly be a task for the 1937 Council, as consolidation could not possibly be completed during the present year.

After further discussion Mr. Crealock suggested that the mover and seconder of the resolution might with propriety defer action for a year, and Mr. Clarence Pitts, with the consent of his seconder, having *withdrawn* his motion, Mr. Rannie, with the consent of his seconder, *withdrew* his amendment.

Mr. Clarence Pitts then *moved* that the Ottawa Branch resolution be laid on the table. The motion having been *seconded* by Mr. Legget, was put and *carried.*

The Secretary presented the following resolution from the Vancouver Branch, which had been submitted to the Council at its meeting on December 18th, 1936:—

> "That the secretary be instructed to write Headquarters asking that consideration be given by Council to an amendment to The Institute's by-laws giving full proxy powers to substitutes appointed by branches to Plenary Meetings when the duly appointed councillors are unable to attend."

The Secretary reported that while the Council had felt that this suggestion deserved serious consideration, it was impossible and inadvisable, to put forth a proposal for such an amendment to The Institute by-laws at the present time. The Council had been of the opinion, however, that it would be well to get an expression of opinion from the Annual General Meeting for the guidance of the Council as to future action.

Vice-President Caton favoured such a resolution. Having served on the Council he realized the difficulty of always getting councillors from distant branches to appear at a Plenary Meeting of Council, and thought there was a real necessity for the arrangement suggested. He then *moved* that the matter be referred to the Council to be taken up at the proper time, with a recommendation for favourable action.

In *seconding* Mr. Caton's motion, P. E. Doncaster, M.E.I.C. (Fort William), observed that such a change would be a great help to a branch such as the one he represented. In the Lakehead Branch it had often been impossible, for private reasons, for their councillor to attend Council meetings, even although matters of import to the branch were to be decided. With the suggested change it would be possible, for instance, for the Manitoba representative, on his way to attend a Council meeting, to be authorized to act for the Lakehead Branch, with instructions as to his vote on any question, and in that way the Lakehead Branch would have a voice on any resolution presented to the Council at Headquarters or elsewhere.

The sense of the meeting appeared to be favourable to Mr. Caton's suggestion, but the motion was not formally put, since at this point the proceedings were interrupted, owing to the sudden illness of the President.

When the meeting was resumed the chair was taken by Vice-President R. L. Dobbin.

Mr. E. P. Muntz then *moved* that a vote of thanks be tendered to the scrutineers for their services in preparing the report on the election of officers, and that the ballot papers be destroyed. The motion having been *seconded* by Mr. G. H. Wood, was put to the meeting and *carried.*

On the *motion* of Professor H. W. McKiel, *seconded* by R. W. Boyle, M.E.I.C., it was unanimously *resolved* that the thanks of The Institute be conveyed to the Montreal Branch in recognition of their hospitality and activity in connection with the holding of the Fifty-First Annual General Meeting.

It was then *moved* by Past-President S. G. Porter that a hearty vote of thanks be accorded to the retiring President and members of Council in appreciation of the work they have done for The Institute during the past year.

Past-President Shearwood, in *seconding* this vote of thanks, said that a special acknowledgment was due to the retiring President. Any one who had been on the Council during the past year would realize the services rendered by Dr. Cleveland; and especially the sacrifice of his time in travelling to and from the Pacific, not only to Montreal but also to the Maritime Provinces. The Institute owed him a great debt of gratitude for the trouble, time and effort he had given. The resolution was *carried* by acclamation.

Mr. Viens desired to *move* a vote of thanks to the members of the Committee on Consolidation for their effective work during the past year. The motion having been *seconded* by A. Duperron, M.E.I.C., was *carried* unanimously.

Professor McKiel did not think that the meeting should adjourn without some expression of thanks to Mr. P. L. Pratley, ending his term as senior vice-president and chairman of the Finance Committee. Mr. Pratley had given a great deal of time and thought to the finances of The Institute, and his guidance had been invaluable during a very difficult period.

Professor McKiel's motion was *seconded* by Dr. Cleveland, who drew attention to the amount of work which, in his absence, had unavoidably fallen to Mr. Pratley, in presiding at Council meetings and dealing with Institute affairs from day to day.

Mr. Rannie had known Mr. Pratley for many years and desired to express admiration for his devotion to the interests of The Institute.

Vice-President Dobbin did not think there was any need of putting Professor McKiel's resolution to the meeting, the feeling of the assembly having been indicated by such vigorous applause.

Mr. Heward, before the meeting terminated, desired to voice the deep regret of the meeting at the unfortunate indisposition of the new President, and asked that at the first opportunity the Secretary would convey to Mr. Desbarats the sympathy of the meeting, and the best wishes of everyone for his speedy recovery.

Vice-President Dobbin was sure that all present greatly regretted the distressing illness of the President. The Secretary was directed to convey these expressions to Mr. Desbarats.

The meeting terminated at eleven forty a.m.

## The San Francisco - Oakland Bay Bridge

The illustration shown above is an interesting view of the San Francisco-Oakland Bay bridge, which was opened to traffic on November 12th, 1936. The bridge was built as a result of the ever-increasing demand for transportation. A ferry system handled more than four million vehicles and fifty million passengers in 1930. Plans and specifications for the bridge proper were completed late in 1932, and bids were invited early in 1933. In the same year the State Legislature passed all the bills necessary for financing the construction and maintenance.

The total length of the bridge is 8¼ miles, 4½ miles of which are over water; it has fifty-one piers, and the cost was $77,000,000. The bridge includes the only large twin suspension bridge ever built, and the longest and heaviest cantilever bridge in the United States, and third longest in the world. It is a doubledeck structure providing for six lanes of pleasure automobiles on the upper roadway and three lanes of trucks and a double track rapid transit railway on the lower roadway.

## Annual Fees

Members are reminded that a reduction of One Dollar is allowed on their annual fees if paid on or before March 31st of the current year. The date of mailing, as shown by the postmark on the envelope, is taken as the date of payment. This gives equal opportunity to members residing in all parts of the country.

# Sir John Kennedy Medal Awarded to John G. Sullivan, M.E.I.C., Past-President of The Institute

John G. Sullivan, M.E.I.C., a Past-President of The Institute, is the recipient of the Sir John Kennedy Medal of The Engineering Institute for the year 1936.

Previous recipients of this award have been the late Colonel R. W. Leonard, M.E.I.C., G. H. Duggan, M.E.I.C., A. J. Grant, M.E.I.C., R. A. Ross, M.E.I.C., and A. H. Harkness, M.E.I.C.

This gold medal was established in commemoration of the great services rendered to the development of Canada, to engineering science, and to the profession by the late Sir John Kennedy, Past-President of The Institute. It is the highest honour which The Institute can bestow, and is given only when the occasion warrants, as a recognition of outstanding merit in the profession or of noteworthy contribution to the science of engineering or to the benefit of The Institute.

John G. Sullivan, M.E.I.C.

Mr. Sullivan was born at Bushnell's Basin, Munroe county, New York, U.S.A., on January 11th, 1863, and graduated from Cornell University with the degree of C.E. in June 1888. He commenced his engineering work with the great Northern Railway as rodman, shortly after graduating, going to Washington Territory in the spring of 1889, where he was engaged as instrumentman and assistant engineer, for the Spokane Falls and Northern Railway, until the fall of 1890 when he went to Seattle and was assistant engineer on the Pacific Extension of the Great Northern Railway, until June 1893.

Mr. Sullivan first came to Canada as assistant engineer on the Alberta Railway and Coal Company in July 1893, and in 1894 he was engaged as locating engineer on the Butte Anaconda and Pacific Railway.

In the spring of 1895 he commenced work as principal assistant engineer on the Kaslo and Slocan Railway and in 1896 he became reconnaissance engineer for the Columbia and Western Railway.

From 1898 to 1900 Mr. Sullivan was principal assistant engineer on the construction of the Columbia and Western Railway, and from 1900 to 1905 was division engineer of construction on the Canadian Pacific Railway; during this time he had entire charge of all surveys and construction on new lines built by the Canadian Pacific Railway, West of Fort William.

From 1905 to 1907 Mr. Sullivan was assistant chief engineer of the Panama Canal; his principal assignment being the excavation and disposition of waste from the Culebra Cut; but for three months while Mr. Stevens was in Washington, he was acting chief engineer in charge of all works. In the course of his duties on the Panama Canal, Mr. Sullivan designed details for the Lidgerwood Side Plough, which made the plough workable when operating flat cars with one solid side. As originally designed the plough would not work on a solid-side car in rock or boulders. His improvements increased the capacity of flat cars to 25 or 30 cubic yards, so that by reason of the long hauls involved, it was much more economical to use the plough and flat cars, than to use dump cars. This saved millions of dollars in the cost of canal excavation.

From the spring of 1907 to the fall of 1908 Mr. Sullivan was manager of construction for the Eastern Lines of the Canadian Pacific Railway, and then was promoted to the position of assistant chief engineer for the Eastern Lines, with offices at Montreal. There being no Chief Engineer, he was in charge of the Engineering Department.

In the spring of 1911 he was transferred to the Western Lines of the Canadian Pacific Railway, as assistant chief engineer, with offices at Winnipeg; and in October 1911, was made chief engineer of Western Lines. In 1915 he was appointed chief engineer of the Canadian Pacific Railway; which position he resigned in July 1918, being retained as consulting engineer up to December 31st, 1927.

Beginning with the year 1911, there was a rapid growth of railways in the West; and during some of the years of Mr. Sullivan's tenure of office, as much as fifty million dollars per annum was spent for betterments and new lines under his direction. In the construction of the Connaught Tunnel the plan of driving a centre heading was adopted. This was devised by Mr. Sullivan. With reference to this feature, the Engineering News of January 11th, 1917, made the following editorial comment:—

> "A few months back, the completion of the Rogers Pass (Connaught) Tunnel, a sound-rock tunnel, signalized the brilliant success of a radically novel method of attack in rock. The system of blasting in rings from a central pilot tunnel, a bold innovation, was the key to success. Though centuries of prior art in rock tunnelling were available, sound engineering in this case lay, in abandonment of precedent."

In 1916, the Canadian Pacific Railway Company permitted Mr. Sullivan to act as a member of the Special Board of Consulting Engineers Reporting on the design of the Aqueduct for the Greater Winnipeg Water District.

After his retirement from the Canadian Pacific Railway in 1918, Mr. Sullivan engaged in consulting work in Winnipeg, alone and later in partnership. For some years he was President of the firm of Sullivan, Kipp and Chace in that city.

Since July 1918, he has had varied experience, acting as arbitrator in labour disputes, as arbitrator between railways, and in an advisory capacity on engineering projects. Notes on some of this work are given below:—

From 1919 to 1922 he was Chairman of the Manitoba Drainage Commission, whose report was finally adopted by a Committee of the local Legislature, although not all of its recommendations were adopted by the government.

In 1919 Mr. Sullivan reported to the Minister of Public Works of Manitoba on the Economics of the proposed government Electric Power Distribution System.

During 1920 and 1921 he was retained by the Dominion Government as consulting engineer in the arbitration between the Government and the Grand Trunk Railway Company.

In 1922 he reported to the Premier of British Columbia on the physical and economic features of the Pacific Great Eastern Railway.

In 1923 Mr. Sullivan was a member of the Commission appointed by the Government of Manitoba to study and report as to the policy the Government should adopt with regard to the Provincial Hydro System.

In 1924 he reported to the Southern Railway Company on the economics and revision of that company's line between Cincinnati and Chattanooga. The result of this report was a radical change of the policy of the Southern Railway in connection with the proposed plans for this line.

In the same year he reported to Price Bros. Company on the method to be adopted in protecting their paper mill plant at Kenogami from slides which threatened the plant. Sir William Price lost his life in one of these slides. The protection works for the plant were carried out in accordance with the plans suggested by Mr. Sullivan.

In 1925 Mr. Sullivan was appointed a member of a Board of Engineers to make a joint report to the Presidents of the Canadian Pacific and Canadian National Railways, on the railway situation in the Peace river country. The result of this report has undoubtedly saved the expenditure of several millions of dollars before the development of the country would justify such expenditure.

In 1925 he was retained by a firm of consulting engineers in London, England, who had charge of a private bill proposing a vehicular tunnel between Liverpool and Birkenhead, under the Mersey river; to give testimony before a Parliamentary Committee. The applicants were successful and the tunnel has been constructed.

In 1926 he was retained by the Denver and Salt Lake Railway Company to report and advise on the practicability of ventilating the Moffat Tunnel, to permit of the operation of steam locomotives. The tunnel having been ventilated in accordance with the plans proposed by Mr. Sullivan, steam locomotives are now being successfully operated through it.

Mr. Sullivan joined The Institute, then the Canadian Society of Civil Engineers, as a Member in 1900. He served on Council in 1910 and 1918; was a Vice-President in 1911-12-13, and was President of The Institute in 1922. His interest in and services to the Winnipeg Branch have been continuous. He is a Member of the American Society of Civil Engineers, and of the American Railway Engineering Association, having been President of that body in 1918.

## Award of Medals and Prizes

### Duggan Medal and Prize

P. L. Pratley, M.E.I.C., is the first recipient of the Duggan Medal and Prize, which was established in 1935, to be presented each year from the proceeds of a donation by Past-President G. H. Duggan, D.Sc., LL.D., M.E.I.C., for the purpose of encouraging the development of the branches of engineering in which he practised. Mr. Pratley receives

**P. L. Pratley, M.E.I.C.**
*Duggan Medal and Prize*

this award for his paper entitled "The Superstructure of the Reconstructed Second Narrows Bridge, Vancouver," which was presented before the General Professional Meeting of The Institute at Hamilton, Ontario, in February 1936, and was published in the January, 1936, issue of The Engineering Journal.

Mr. Pratley was born at Liverpool, England, and received his education in that country, receiving the degree of B.Eng. with first class honours from the University of Liverpool in 1905, and the Master's degree in 1908.

Coming to Canada in 1906, Mr. Pratley was with the Locomotive and Machine Company, Montreal, as designer and draughtsman, and from 1906 until 1909 held a similar position with the Dominion Bridge Company, Montreal. In 1909-1910 he was with the Quebec Bridge Board as mathematician, designer and checker; from April to September of the latter year he was engaged with the St. Lawrence Bridge Company as designing engineer in charge of designs for the Quebec bridge, later returning to the Quebec Bridge Board during the official investigation of submitted designs. From 1910 until 1920 Mr. Pratley was designing engineer with the Dominion Bridge Company in charge of the estimating and designing office. In 1920 he served on the G.T.R. Arbitration Board, with the Department of Railways and Canals. In 1921 he became a member of the firm of Monsarrat and Pratley, consulting engineers, Montreal.

Mr. Pratley received the Gzowski Medal for the year 1934-1935 for his paper entitled "The Sub-structure of the Reconstructed Second Narrows Bridge, Vancouver."

He has long taken an active interest in Institute affairs having served as a Councillor for many years, and as a Vice-President.

### Gzowski Medal

David Boyd, A.M.E.I.C., has been awarded the Gzowski Medal for the year 1935-1936 for his paper entitled "Modern Arc Welding" which appeared in the November, 1935, issue of The Journal.

Mr. Boyd, who is assistant works manager with the Dominion Bridge Company, Montreal, has been with that firm since his graduation from McGill University in 1928 with the degree of B.Sc., first as draughtsman and checker, than as maintenance superintendent, and finally in his present position.

### Leonard Medal

The Leonard Medal (for which members of The Institute or of the Canadian Institute of Mining and Metallurgy are eligible) has been awarded this year to

**David Boyd, A.M.E.I.C.**
*Gzowski Medallist*

**L. S. Weldon**
*Leonard Medallist*

Mr. L. S. Weldon, who is resident general manager with the Geita Gold Mining Company Limited, Geita, Taneanwika, Kenya, East Africa, for his paper entitled "Mining Methods and Practice at Lake Shore Mine" which was presented before the Annual General Meeting of the Canadian Institute of Mining and Metallurgy in March, 1936, and appeared in the March 1936 issue of the Bulletin of that Institute.

Mr. Weldon graduated from McGill University in 1921 with the degree of B.Sc. in mining, and following graduation was employed with the engineering department of the Hollinger Consolidated Gold Mines Limited. In 1922-1923 he was engineer in charge of development and construction with the Nighthawk Peninsular Gold Mines Limited, and from 1924 until 1929 he was with the British Metal Corporation (Canada) Limited, as follows: 1924-1925, mine superintendent and manager, Tetreault Mine, Montauban, Que.; 1926-1927, engaged on the examination and development of properties in Canada and Newfoundland; 1928-1929, manager, Zurak Silver Lead, in Northern Nigeria, B.W. Africa; 1929, manager, Tetreault Mine, Montauban, Que. In 1930 Mr. Weldon was a member of the Empire Mining Congress to South Africa, and in the same year he became connected with Lake Shore Gold Mines Limited, being mine captain on development for two years, and on production for two years. In 1934 he was for a short time manager of St. Anthony Gold Mines Limited, returning in that year to Lake Shore Gold Mines Limited at Kirkland Lake as underground superintendent In October 1936 he accepted his present appointment.

### Plummer Medal

C. R. Whittemore, A.M.E.I.C., is the recipient of the Plummer Medal for the year 1935-1936 for his paper entitled "The Metallurgy of Metallic Arc Welding of Mild Steel" which appeared in the December 1935 issue of The Engineering Journal.

**C. R. Whittemore, A.M.E.I.C.**
*Plummer Medallist*

**Eric G. Adams, Jr.E.I.C.**
*Phelps Johnson Prizeman*

Mr. Whittemore graduated from McGill University in 1924 with the degree of M.Sc. in metallurgy, and was subsequently research chemist with the McArthur Irwin Paint Company. In 1925 he joined the staff of the Consolidated Mining and Smelting Company, at Trail, B.C., and was engaged in 1925 on experimental work in ore dressing; in 1926 he was placed in charge of the technical service department; and in 1927 he became technical librarian for the company. In 1929 he was again connected with the McArthur Irwin Paint Company, Montreal, and in 1931 was appointed metallurgist for the Dominion Bridge Company Limited, Montreal, which position he still holds.

### Students' and Juniors' Prizes

Three of these prizes were awarded this year as follows:

The John Galbraith Prize (Province of Ontario) to E. C. Hay, Jr.E.I.C., who is with the Canadian Westinghouse Company Limited, Toronto, for his paper on the "Selection of Factors of Photo Electric Cells."

**E. C. Hay, Jr.E.I.C.**
*John Galbraith Prizeman*

**Louis Trudel, S.E.I.C.**
*Ernest Marceau Prizeman*

The Phelps Johnson Prize (Province of Quebec, English) to Eric G. Adams, Jr.E.I.C., of Coverdale and Colpitts, consulting engineers, New York, N.Y., for his paper entitled "Trends in Population and Trade Affecting Transportation."

This is the third time that Mr. Adams has been the recipient of an Institute award, having received the Phelps Johnson Prize once before in 1930-1931 for his paper on "Some Economic Problems Confronting the Wider Application of Railroad Electrification in America" and the Past-Presidents' Prize for the year 1932-1933 when the subject was "The Relation of Economics to Engineering."

The Ernest Marceau Prize (Province of Quebec, French) to Louis Trudel, S.E.I.C., of the Quebec Electricity Commission, Montreal, for his "Etude Comparative sur Modèles Réduits."

### Periodicals in Institute Library

Over two hundred periodicals are received regularly by The Institute Library in Montreal, and are available for reference purposes in the reading room. Back numbers are also on file. Out-of-town members may obtain photostat copies of any articles appearing therein at a cost of thirty cents a page, plus postage, etc.

For the convenience of members we are listing these periodicals in this and in the April issue of The Journal.

Aero Digest.
Agricultural and Industrial Progress in Canada.
Air Commerce Bulletin.
The American Engineer.
American Midland Naturalist.
Anales de la Sociedad Cientifica Argentina.
Arts et Métiers.
The Beaver.
Bell Laboratories Record.
Bell Telephone Quarterly.
Boletim do Instituto de Engenharia Sao Paulo.
Building in Canada and Building Reporter.
Building Science Abstracts.
Bulletin, American Society for Testing Materials.
Bulletin de la Société des Ingénieurs Civils de France.
Bulletin, American Railway Engineering Association.
Bulletin of the Brooklyn Engineers Club.
Bulletin of Canadian Airways Limited.
Bulletin of the Canadian Engineering Standards Association.
Bulletin, Canadian Institute of Mining and Metallurgy.
Bulletin de la Société Belge des Ingénieurs.
Bulletin de la Société Française des Electriciens.
Bulletin, Edison Electric Institute.
Bulletin, The Electrochemical Society.
Bulletin, Hamburg World Economic Archives.
Bulletin, Hydro-Electric Power Commission of Ontario.
Bulletin, New Zealand Society of Civil Engineers.
Bulletin Mensuel de l'Association des Ingénieurs Electriciens Montefiore.
Bulletin Mensuel de la Société Industrielle de Nord de la France.
Bulletin of Hygiene.
Bulletin, Western Society of Engineers.
The Business Week.
Canadian Aviation.
Canadian Business.
Canadian Chemistry and Metallurgy.
Canadian Defence Quarterly.
Canadian Engineer.
Canadian Journal of Research.
Canadian Machinery and Manufacturing News.
Canadian Magazine.
Canadian Mining Journal.
Canadian Patent Office Record.
Canadian Surveyor.
Canadian Transportation.
Chemical and Metallurgical Engineering.
Chimie et Industrie.
Civil Engineering (American).
Civil Engineering and Public Works Review.
Cleveland Engineering.
Colliery Engineering—with supplement, Coal Carbonization.
Colorado Engineer.
Commercial Intelligence Journal.
Compressed Air Magazine.
Concrete.
Concrete and Quarry.
Contractors and Engineers Monthly.
Dependable Highways.
The Dominion Engineer.
Edinburgh Journal.
Electric Journal, The.
Electric Welding.
Electrical Digest.
Electrical Engineering.
Electrical News and Engineering.
Electrical Review, The.
Electrical Times.
Electrical World—and News Issue.
Electronics.
The Engineer.
Engineering.
Engineering—Notes and Extracts from.
Engineering and Boiler House Review.
Engineering and Contract Record.
Engineering and Mining Journal.
Engineering Experiment Station Bulletin.
Engineering Inspection.
Engineering News-Record.

*(To be continued in April Journal.)*

# OBITUARIES

## Henri Dessaulles, M.E.I.C.

Regret is expressed in placing on record the death in Montreal on February 21st, 1937, of Henri Dessaulles, M.E.I.C., of Shawinigan Falls, Que.

Mr. Dessaulles was born at St. Hyacinthe, Que. on December 1st, 1879, and graduated from the Ecole Polytechnique, Montreal, in 1903, with the degrees of B.A. and B.Sc.

For several years following graduation Mr. Dessaulles was engaged on the construction of the transcontinental line for the Canadian National Railways. In 1909 he joined the engineering staff of the Shawinigan Water and Power Company. From 1911 until 1913 he was employed on the construction of the Manouan river storage dams and in charge of surveys for the Gouin dam; from the latter year until his retirement from active work a few years ago due to ill health, Mr. Dessaulles was local agent and resident engineer for the Shawinigan Water and Power Company at Shawinigan Falls, Que., being in charge of real estate, house construction and general supervision.

Mr. Dessaulles joined The Institute (then the Canadian Society of Civil Engineers) as a Student on April 23rd, 1903. On January 14th, 1909, he became an Associate Member, and on May 6th, 1930, was elected a Member.

## John William Seens, A.M.E.I.C.

It is with much regret that we place on record the death at Detroit, Mich., on January 25th, 1937, of John William Seens, A.M.E.I.C.

Mr. Seens was born at Cincinnati, Ohio, on November 8th, 1881, and graduated from the University of Michigan in 1904 with the degree of B.S. (C.E.). Following graduation Mr. Seens was until 1905 a draughtsman on the staff of the Canadian Bridge Company, and then joined the staff of the city engineer of Grand Rapids, Mich. In February 1906 Mr. Seens again became connected with the Canadian Bridge Company, and remained with that firm until 1911 when he was appointed manager of the Structural Steel Company Ltd., Montreal, at that time a subsidiary of the Canadian Bridge Company. Mr. Seens became sales manager of the Canadian Bridge Company in 1918, and remained in Montreal until 1927 when he was transferred to Walkerville, Ont. He was elected a director in 1922, and vice-president in 1926. In 1927 Mr. Seens became President and general manager of the Canadian Bridge Company, and received a similar appointment from the Essex Terminal Railway. He was made president of the Canadian Steel Corporation in 1932.

J. W. Seens, A.M.E.I.C.

Mr. Seens joined The Institute (then the Canadian Society of Civil Engineers) as an Associate Member on March 12th, 1908.

## Thomas Lockwood Simmons, M.E.I.C.

Regret is expressed in placing on record the death at his home in Ottawa, Ontario, on January 19th, 1937, of Thomas Lockwood Simmons, M.E.I.C.

Mr. Simmons was born at Sheffield, N.B., on January 17th, 1872, and graduated from the University of New Brunswick with the degree of B.A. and a diploma in civil engineering in 1893. Following graduation he was engaged on bridge construction for the Bangor and Aroostook Railway, and a re-location survey north of Houlton. In 1895 he became assistant engineer on a preliminary survey of the line from Minto to Fredericton, and in 1896 he was on a location survey of the Woodstock and Centerville Railway. From 1898 to 1901 Mr. Simmons was in charge of the deepening of river reaches of Lake St. Francis; from 1901 to 1904 he was inspecting engineer with the Department of Railways and Canals. In 1904 Mr. Simmons joined the staff of the Board of Railway Commissioners as assistant engineer, becoming assistant chief engineer in 1909. On the death of George A. Mountain, M.E.I.C., in 1927, Mr. Simmons succeeded him as chief engineer of the Board of Railway Commissioners, which office he has held since that time.

T. L. Simmons, M.E.I.C.

Mr. Simmons joined The Institute (then the Canadian Society of Civil Engineers) as an Associate Member on December 21st, 1899, and became a full Member on April 24th, 1923.

## Roderick Will McKinnon, M.E.I.C.

The membership of The Institute will learn with regret of the death at Winnipeg, Man., on January 27th, 1937, of Roderick Will McKinnon, M.E.I.C.

Mr. McKinnon was born at Battleford, Sask., on November 25th, 1885. Battleford was then in the North West Territories, and Mr. McKinnon, who was the son of a Hudson's Bay Company factor, was the first white child born in that city. Mr. McKinnon studied at Dalhousie University from 1905 until 1908, and from 1908 until 1910 was an assistant on location with the Canadian National Railways. In 1910-1912 he was location engineer with the same Railway.

In 1912 Mr. McKinnon joined the staff of the Manitoba Public Works Department, and was assistant engineer in charge of the construction of the sewers and water supplies for the new agricultural college then being constructed in Manitoba. In 1913 he joined the staff of the Reclamation Branch as district engineer. In 1924 Mr. McKinnon became right-of-way agent and assistant chief engineer, and later in the year was made Commissioner of Northern Manitoba, which position he occupied until August 1925. From that date until 1930 he again acted as right-of-way agent and assistant chief engineer for the Reclamation Branch of the Department of Public Works, and on June 15th, 1930, following the death of H. A. Bowman, M.E.I.C., was appointed Chief Engineer of the Reclamation Branch, which position he occupied continuously until his death.

For the past two years, Mr. McKinnon was on the engineering committee in charge of the sewage disposal plant of the Greater Winnipeg Sewerage System.

Mr. McKinnon joined The Institute as an Associate Member on November 27th, 1917, and became a Member on March 6th, 1936.

### Robert Wood, A.M.E.I.C.

It is with deep regret that we place on record the death at Montreal on February 7th, 1937, following a short illness, of Robert Wood, A.M.E.I.C., of Quebec.

Mr. Wood was born at Kilmarnock, Scotland, on May 12th, 1902, and was educated in this country, graduating from the Montreal High School in 1919 and from McGill University in 1924 with the degree of B.Sc.

Following graduation, Mr. Wood was a student engineer with the Shawinigan Water and Power Company until 1925, when he became assistant chief engineer of the Quebec Power Company and the Quebec Railway Light and Power Company. In 1927 Mr. Wood was appointed superintendent of the Power Division of the Quebec Power Company, being in full charge of generation, transmission and distribution in the company's territory. In 1929 his ability was recognized by his selection as executive assistant of the president of the Quebec Power Company, his duties including the analysis of engineering and economic problems affecting all divisions of the company. He held that office up to the time of his death.

Mr. Wood was actively associated with the Junior Board of Trade of Quebec, and was past-president of that organization. He was an active member of the McGill Graduates Society (Quebec Branch), the Kent Golf Club and the Winter Club of Quebec.

Mr. Wood joined The Institute as a Student on March 22nd, 1921, and transferred to the class of Associate Member on May 18th, 1934.

## PERSONALS

### J. A. McCrory Vice-President of The Institute

J. A. McCrory, M.E.I.C., vice-president and chief engineer of the Shawinigan Engineering Company Limited, was elected vice-president of The Institute for 1937-1938 at the Annual General Meeting held in Montreal on January 29th, 1937.

Mr. McCrory graduated from Pennsylvania State College in 1907 with the degree of B.Sc. in mechanical engineering, and, coming to Canada in 1910, located in Toronto, where he was engaged on the design and construction of the London Hydro sub-station and in general building work. In 1912 he moved to Montreal, and for four years was employed on the design and supervision of reinforced concrete construction. Mr. McCrory joined the staff of the Shawinigan Water and Power Company in 1916 as designer, and on the formatation of the Shawinigan Engineering Company Limited in 1918, was appointed office engineer. He was subsequently engaged on the investigation and design of a large number of hydro-electric developments for the Shawinigan Water and Power Company and others, and in 1935 he received his present appointment.

Mr. McCrory has taken an active interest in the affairs of The Institute since he became an Associate Member in 1921 and a Member in 1926, having been chairman of the Montreal Branch in 1929. He represented that Branch on the Council of The Institute during the years 1930-1935.

J. A. McCrory, M.E.I.C.

Mr. McCrory is a member of the Corporation of Professional Engineers of Quebec, the Canadian Engineering Standards Association, the Canadian Electrical Association and the American Society for Testing Materials.

A. O. Wolff, M.E.I.C., Divisional Engineer, with the Canadian Pacific Railway Company, at London, Ontario, was elected chairman of the London Branch of The Institute for the current year, at the annual meeting of the Branch held recently.

Professor A. E. Macdonald, M.E.I.C., is now chairman of the Winnipeg Branch of The Institute. Professor Macdonald is professor and head of the department of civil engineering at the University of Manitoba, Winnipeg, Man.

N. W. Kershaw, S.E.I.C., is now assistant manager of the Drummondville, Que., plant of the Eagle Pencil Company. Mr. Kershaw graduated from the University of Saskatchewan in 1933 with the degree of B.Sc., and from October of the same year until May, 1934, he was instructor in the mechanical engineering laboratory of the same university. Mr. Kershaw was subsequently with the Dominion Oilcloth and Linoleum Company Ltd., at Montreal, and in 1935 joined the staff of the Eagle Pencil Company as mechanical engineer.

Horace L. Seymour, M.E.I.C., has again been retained as consultant for the Town Planning Commission of the City of Saint John, New Brunswick. Saint John is now taking advantage of the provisions of the Town Planning Act of New Brunswick drafted by Mr. Seymour which was passed by the provincial legislature last year. Information has been collected, traffic counts taken, numerous studies have been made, and maps on a large scale prepared showing the information in a graphical form easily understood by the public as well as Commission and Council members. A Major Street By-law and Map have been prepared, and the public will be consulted shortly about these proposals.

R. G. Watson, A.M.E.I.C., has been appointed by Edmonton, Alberta, City Council as superintendent of the municipally-owned power plant.

Mr. Watson came to this country from Scotland in 1912, and from that time until 1924 was mechanical superintendent and chief engineer of power with the Nova Scotia Steel and Coal Company and the British Empire Steel Corporation. In 1924-1929 he was chief engineer with the St. John Dry Dock and Shipbuilding Company. In 1929 Mr. Watson was chief draughtsman with R. A. Ross and Company, engaged on the design and supervision of installation of tube generator and auxiliaries, and from 1929 until 1932 he was mechanical engineer supervising all mechanical work on the building of the Beauharnois canal and power house. From 1932 to 1933 he was designing engineer with R. A. Ross and Company. In 1933 Mr. Watson entered private practice as a consulting engineer in Toronto as a member of the firm of Watson and Ferguson.

#### H. S. Carpenter, M.E.I.C., New Vice-President of The Institute

At the Annual General Meeting of The Institute held in Montreal on January 29th, 1937, H. S. Carpenter, M.E.I.C., Deputy Minister, Department of Highways of the Saskatchewan Government, Regina, Sask., was elected a Vice-President for the years 1937-1938.

Mr. Carpenter graduated from the University of Toronto with the degree of B.A.Sc. in 1898, and was subsequently in charge of an assay office at Sudbury, Ontario. In 1899 he practised as an Ontario Land Surveyor at Collingwood, Ontario, and in 1900 became assistant engineer for the Department of Railways and Canals on the Yukon Railway exploration. From 1901 until 1905 Mr. Carpenter was an assistant engineer with the same Department on the construction of the Trent Canal. In 1905 he entered the service of the Government of the Province of Saskatchewan, and since that time has filled the following offices: 1905-1906, district engineer and surveyor, Department of Public Works; 1907-1908, Director of Surveys; 1909-1910, Superintendent of Highways; 1911-1912, Acting Deputy Minister and Chief Engineer, Department of Public Works; 1913-1914, Superintendent of Highways with Board of Highway Commissioners; 1915-1917, Acting Chairman, Board of Highway Commissioners and in the latter year, Mr. Carpenter received the appointment which he still holds.

H. S. Carpenter, M.E.I.C.

Mr. Carpenter became an Associate Member of The Institute in 1904, a Member in 1922, and a Life Member in December, 1934. He has taken an active interest in Institute affairs, and represented the Saskatchewan Branch on the Council during the years 1921-1922 and 1923.

## Recent Additions to the Library

### Proceedings, Transactions, etc.

Institution of Mechanical Engineers: Proceedings, 1936.
American Institute of Electrical Engineers: Transactions, 1936.
Junior Institution of Engineers Inc.: Transactions, 1935-1936.

### Reports, etc.

*Canada, Dept. of Mines, Mines Branch:* Investigations in Ore Dressing and Metallurgy, January to June, 1935.
*American Association of Railways:* American Railway Signaling and Practices, Chapter XXII.
*Toronto Harbour Commissioners:* Annual Report, 1935.
*McGill University:* Annual Report, 1935-36.
*Canada, Bureau of Statistics:* The Highway and Motor Vehicle in Canada, 1935.

### Technical Books, etc.

Procedure Handbook of Arc Welding Design and Practice, Lincoln Electric Company, Cleveland, Ohio.
Road Curves for Safe Modern Traffic, by F. G. Royal-Dawson. (*E. and F. N. Spon Ltd., London.*)
Timber Design and Construction, by Jacoby and Davis. (*John Wiley and Sons, New York.*) (*Renouf Publishing Company, Montreal.*)

## BOOK REVIEWS

### Procedure Handbook of Arc Welding Design and Practice

*The Lincoln Electric Company, Cleveland, Ohio, U.S.A. 1936. 4th edition. 5¾ by 8¾ inches. $2.00. Leather.*

This volume is divided into nine parts, Part 1 covering welding methods and equipment, including forge welding, thermit welding, resistance welding, arc welding, etc. Part 2 is on the technique of welding, and includes weld dimensions, strength of welded joints, study of stress distribution in welded joints, contraction, distortion and residual stress and so forth. Procedures, speeds and costs for welding mild steel are dealt with in Part 3, with Part 4 covering the structure and properties of weld metal. Part 5 covers the weldability of metals, including factors affecting weldability, high tensile steels, chrome-molybdenum steel, chrome-nickel steels, high carbon steel, etc. Part 6 deals with designing for arc welded steel construction of machinery and gives a comparison of rolled steel and cast iron and their limitations as applied to machine design, design of levers, clevices, pins, crankshafts, bases and so on. Designing for arc welded structures is covered in Part 7, and some of the advantages of arc welded design over riveted design are given. Reinforcement of columns, beam connections, welds and calculations for continuous beam action, reinforcement of columns, etc., are also dealt with. Part 8, which contains 201 pages and 353 illustrations, shows some typical applications of arc welding in manufacturing construction and maintenance.

### Thermodynamic Properties of Steam

*By Joseph H. Keenan and Frederick G. Keyes. John Wiley and Sons Inc. New York (Renouf Publishing Company, Montreal). 1936. 7½ by 10¼ inches. $2.75. 89 pages. Cloth.*

Reviewed by Professor C. A. Robb, M.E.I.C.*

This new book has been prepared by a mechanical engineer with experience of turbine design and a physical chemist having a fine background of research on steam properties. The combination augurs well for this type of literature in the future. With its enlarged pressure and temperature range, improved accuracy, its table extending continuously from vapour to liquid states above the critical point, an international table, and the addition of auxiliary data and charts, it can hardly be considered as merely another edition of an earlier work.

These tables constitute an indispensable tool for the mechanical engineer and others who aspire to accurate heat balance calculations, particularly in the field of thermal power.

The range of pressure to 5,500 lbs./in.$^2$ and of temperature to 1,600 degrees F. has been extended beyond that of the Keenan tables of 1930, publication of which served to stimulate researchers to find common ground and reduce tolerances assigned to the skeleton table resulting from the international conference on steam properties of 1934.

A comparison of the 1936 tables and Mollier chart shows deviations in the 1936 chart, from the values in the corresponding tables, somewhat greater than for the 1930 (Keenan) chart in the case of the enthalpy, and considerably less for the entropy, over the pressure range 400-3,000 lbs./in.$^2$ with temperatures of 700-1,000 degrees F. Discrepancies in enthalpy values in the 1936 chart for the above conditions are of the order of +0.1 to +0.9 B.t.u. per pound. The corresponding differences in the 1930 chart are from −0.3 to +0.2 B.t.u. per pound. Entropy values show differences of −.0001 to +.0005 B.t.u. per degree F. per pound in the 1936 chart as against −.0004 to +0010 for the 1930 chart.

A comparison of the new and more accurate tables of 1936 with the older tables in the above pressure-temperature area shows the important modifications which have resulted from the later studies. Enthalpy values have been reduced by as much as 0.4 to 4.4 B.t.u. per pound and entropy values have been changed by amounts varying from −.0249 to +.0033 B.t.u. per degree F. per pound.

The preface contains a fine example of international co-operation in this important field and the review of fundamental thermodynamics preceding the tables will be appreciated by those who have been unable to keep in close touch with the various researches. This, with the bibliography, will go far in establishing the integrity of the whole effort which, in the opinion of the reviewer, is timely, worth doing and well done. It is unfortunate that in so representative a bibliography the name of Professor H. L. Callendar is omitted, although reference to his work is included in the text.

A Mollier chart for mercury vapour might be included with advantage in a later edition.

The book is an important contribution to engineering literature and the authors and publishers are to be congratulated on its production.

*Professor of Mechanical Engineering, University of Alberta, Edmonton, Alberta.*

## A Survey of the Present Organization of Standardization—National and International

A survey of the Present Organization of Standardization—National and International, published by the Central Office of the World Power Conference, 36 Kingsway, London, W.C.2, at a cost of 3/6 net, plus 2d postage, contains the first authoritative compilation of facts regarding national organization of standardization in thirty-two countries: Argentine Republic, Australia, Austria, Belgium, Canada, China, Czechoslovakia, Danzig Free City, Denmark, Egypt, Estonia, Finland, France, Germany, Great Britain, Hungary, Indian Empire, Irish Free State, Italy, Japan, Jugoslavia, Netherlands, New Zealand, Norway, Poland, Roumania, Spain, Sweden, Switzerland, Union of Socialist Soviet Republics, Union of South Africa, United States of America.

In the section on International Standardization, the organization, constitution, procedure and field of work of the two international standardizing bodies, The International Electrotechnical Commission (I.E.C.) and The International Federation of the National Standardizing Associations (I.S.A.) are described in detail. There are also notes on the International Association for Testing Materials (I.A.T.M.) and the International Commission for Testing Electrical Installation and Wiring Equipment (I.F.K.).

Five appendices list respectively the Advisory Committees of the I.E.C. publications issued by the I.E.C. and Technical Committees of the I.S.A., summarize the present organization of National Standardization and give a list of the abbreviated designations of International and National Organizations described in the Survey.

## Lafarge Aluminous-Cement Refractory Concrete

The aluminous cement, known as Ciment Fondu, was first produced in France in 1908, was perfected commercially in 1918, and was introduced into England in 1923. Since 1926, the material has been manufactured at the Fondu Works, West Thurrock, Essex, and has acquired a deservedly high reputation among contractors, engineers and builders. One of the newer applications of the material is its use, in conjunction with refractory aggregates, for the production of refractory concrete. Briefly, this concrete is produced by the bonding of pieces and particles of a refractory material with Ciment Fondu, which cement, it is pointed out, is itself refractory. The concrete, when it has set and hardened, is claimed to possess the physical properties of strength and hardness of ordinary aluminous-cement concrete and also the property of immunity from attack by sulphur-containing gases. The degree of refractoriness of the concrete and its strength under load at high temperatures, it is, however, emphasized, are functions of the properties of the refractory materials used in making the concrete and of the amount of cement incorporated in the mix. While the proportions of the ingredients will vary with the nature of the work involved, a 3:2:1 mix is suggested for refractory concrete for general purposes. The three parts of coarse aggregate consist of ¾-inch to ⅛-inch pieces of firebrick, and the two parts of fine aggregate of grog particles from ⅛ inch down. For refractory mortar the proportions of fine grog to one part of the cement, may range from 2½ parts to 4 parts. For higher refractoriness such products as sillimanite, chrome or chrome-magnesia materials are employed.

Speaking generally, the concrete is stable under load at temperatures up to 1,300 degrees C. and has a melting point of about 1,450 degrees C. The material, however, can be used at temperatures up to 1,600 degrees C. when chrome or chrome-magnesia aggregate are employed. Among other advantages, the material is claimed to be ready for use twenty-four hours after placing into position, to require no prefiring, to have no appreciable drying shrinkage or after-contraction, and to be approximately of the same size at working temperatures as when originally moulded. It is also interesting to note that the thermal conductivity of the concrete is stated to be less than that of the firebrick employed for its production and hence that the material possesses a certain insulating value. The refractory concrete is non-spalling, and it will withstand wide and sudden fluctuation of temperature in service.

The properties of the material and some account of the research work carried out upon it during the past five years are contained in a handbook recently issued by Messrs. Lafarge Aluminous Cement Co. Ltd.—*Engineering.*

# CORRESPONDENCE

THE EDITOR,
THE ENGINEERING JOURNAL.

DEAR SIR,

At the recent Annual Meeting all the Proposals of the Committee on Consolidation were approved. This result is not necessarily the opinion of the membership of The Institute at large, though it may have an influence on the voting of members when they cast their ballots. The question of approval of these proposals by the members is of such vital consequence to The Institute that a simple exposure of the present situation upon which each member will be called on to vote in the near future seems not only warranted but essential.

By reason of the form of the ballot paper, the fundamental question as to how Consolidation should be effected is liable to be masked by alternatives in respect to detail. Therefore, Mr. Editor, I beg space in The Journal as the best medium of expression to the membership body to present a brief analysis of some of the fundamental changes in the character of our Institute which would follow the adoption of the recommendations of the Committee on Consolidation.

1. *Admission to Corporate Membership.*

| (a) As Proposed by Committee on Consolidation. | (b) As at Present. |
|---|---|
| In future in any province where the Provincial Association becomes "component," to become a corporate member of The Institute, one must first be, or become, a member of a Provincial Professional Association. | Admission to The Institute is by application and depends upon the professional qualifications and experience and personal character of the applicant. |

According to 1 (*a*) above, membership in The Institute requires *only* that the applicant be a member of a Provincial Professional Association. The qualifications for membership in these associations is admittedly low; in Quebec Province graduation from an engineering college without any other qualification is sufficient.

Being created by Provincial legislation there must be the possibility of admission to membership in the Provincial Associations for reasons of politics.

Per contra, (*b*) above, membership in The Institute as at present is based solely on academic, professional and personal qualifications of a much higher standard than that required by the Provincial Associations, and is not, nor ever has been, influenced by political considerations.

The proposal in (*a*) requires that those engineers not required by law to become registered in Provincial Associations will have to be so registered in order to join The Institute as corporate members. Registration in any Provincial Association is a technical requirement only—there are in general no educational or engineering service features furnished by the Provincial Associations to their members. There is no conclusive reason why the obligation of registration should be imposed on that type of engineer not legally required to register. The only reason why such engineers should join a Provincial Association is, strangely enough, that by so doing, and only by so doing, may they become corporate members in The Institute. This would establish a peculiar anomaly; to become a member of The Institute one must first become a member of an organization whose standards of admission are lower than those of The Institute, and no other qualifications for membership in The Institute are then required.

2. *Grade of Membership.*

| (a) As Proposed by Committee on Consolidation. | (b) As at Present. |
|---|---|
| In future there is to be but one grade of corporate member | Associate Members and Members, etc. |

The proposal in 2 (*a*) above establishes all corporate members of The Institute as of equal rank, whether they be prominent, responsible and experienced, or merely a graduate product of an engineering college.

The present classification of membership in The Institute (2 (*b*)) establishes that an Associate Member has some engineering status and that a Member has senior qualifications and responsibilities in the engineering world.

3. *Institute Revenue.*

(Actual operating deficit in 1936 was $1,114)

| (a) Estimated as resulting from Proposals of Committee on Consolidation. | (b) Estimated under present Constitution. |
|---|---|
| At the Annual Meeting the Chairman of the Committee on Consolidation quoted an estimated deficit under these proposals from the table shown on page 546 of the December Journal. This estimate shown in the table varies from $2,291 to $2,515, depending upon the assumptions. | The Finance Committee of The Institute is as usual preparing a balanced budget for 1937. |

The Committee on Consolidation have undoubtedly worked hard and have gone to great lengths to produce the present proposals. Their work has exposed, however, that the Engineering Profession in Canada, as represented by The Engineering Institute and by the Provincial Associations, is divided into two groups having distinctly different points of view respecting the manner of Consolidation. Practically the whole representation favoured consolidation as a principle. One group, however, favours the manner proposed in detail by the Committee, the other favours a consolidation that does not destroy The Institute in its present form and with its present ideals. Within the first group there appear to be those who favour the Provincial Associations regardless of any effects on The Institute. Hence there is another alternative as follows:—

4. *Constitution of The Institute.*

| | |
|---|---|
| (*a*) As Proposed by the Committee on Consolidation. | (*b*) As Desired if Present Autonomy of The Institute is to be preserved. |

The organization as proposed in 4 (*a*) can quite easily result in The Institute being controlled and managed by those that favour the interests of the Provincial Associations regardless of the present ideals and objectives of The Institute. This point of view has actually been expressed in writing by the President of the Dominion Council of Professional Engineers in a letter dated from Saint John, N.B., November 11th, 1936, addressed to E. A. Wheatley, Vancouver, B.C. In this letter Mr. Kirby says, " . . . I believe we have the door already opened a way and all we have to do is to place our foot in the opening and keep it there until we can swing it wide open. This is because the Associations, if they accept the present proposals and *make use of them* can dominate The Institute . . . " "Future By-law changes for The Institute would be voted on by ALL Association Members, vastly outnumbering non-Association Members, and the whole set-up of The Institute depends on its By-laws." And in a memorandum attached to that letter he writes further—" . . . the Association Members (would) control the personnel of the Council and can require it to do what they desire... the By-laws of The Institute can be made to conform fully to the requirements of the Association Members." And again, "With (the proposed) representation on Council of The Institute a nucleus is set up that is strongly favourable to the Association. If the present Council of The Institute is not willing to grant favourable terms... it may be necessary to await the next Plenary Meeting (where) there is an assured majority, plus the eight Association representatives."

Thus, the deliberate desire of this group is to gain control of The Institute, not to further its present ideals but apparently to proceed along lines not hitherto exposed by the Committee on Consolidation in their portrayal of the objectives of the Consolidation movement. The proposals 4 (*a*) "have already opened the door" for the complete absorption of The Institute and the dictation of its constitution and policy by this group which cannot with consistency claim to value the present ideals of The Institute. With the policies of such a group dominating Council, indiscriminate revision of The Institute's By-Laws to an unlimited extent is possible in the future.

On the other hand, (under 4 (*b*)) there are members with the true interest of The Institute at heart, who desire a consolidation without these hazards. These persons believe that use can be made of the valuable work of the Committee, together with further efforts towards a consolidation which will not affect The Institute adversely nor jeopardize its standing, ideals and traditions.

Mr. Editor, in view of the grave decision that must be made by the membership body by ballot, I need not apologize for the length of this letter nor for the valuable space in The Journal it will occupy. I have tried to confine my remarks to facts. I am not attempting to express a personal viewpoint though this cannot but be apparent. I am on the other hand making an impersonal effort to define clearly the possible results accruing from the decision of the membership body. If the proposals of the Committee on Consolidation are approved I can see the dangers outlined above. If these proposals are rejected then consolidation will be delayed. In the first case I fear The Institute as such will be jeopardized. In the second case we will not have committed ourselves to a possibly intolerable and irrevocable situation, and will still be able to pursue the principle of consolidation—a principle which, if applied as it can be applied, is not inconsistent with the ideals of The Institute as quoted on the title page of every issue of The Journal.

Yours faithfully,

T. C. Thompson, A.M.E.I.C.

4870 Cote des Neiges Road,
Montreal.
6th February, 1937.

## The James Watt International Medal

The first award of the James Watt International Medal by the Institution of Mechanical Engineers (Great Britain) has been made to Sir John A. F. Aspinall, well known railway engineer and administrator.

The Medal was established by the Council of the Institution at the time of the celebration in 1936 of the Bicentenary of the birth of James Watt. It is to be awarded biennially with the co-operation of mechanical societies in leading industrial countries throughout the world for outstanding achievements in mechanical engineering.

# BRANCH NEWS

## Border Cities Branch

*J. F. Bridge, A.M.E.I.C., Secretary-Treasurer.*
*F. J. Ryder, Jr.E.I.C., Branch News Editor.*

After the regular dinner meeting held at the Prince Edward hotel, on Friday evening, January 22nd, 1937, the twenty-three persons present listened to a talk by one of its own members, S. E. McGorman M.E.I.C.

### The Vagaries of Population

By means of a large graph, Mr. McGorman showed how the world's population had remained fairly constant from the time of Julius Caesar (54 B.C.) to the time of Henry VIII, a period of about seventeen hundred years. Then the curve of the graph became more vertical. The ravages of cholera, the black death and smallpox had kept the curve level, but with the beginning of medical science these diseases were controlled and gradually the population increased. Wars have not been such a big deterrent in checking population increases as people imagine. For Europe at the present time has 25,000,000 more people than at the outbreak of the Great War of 1914.

Mr. McGorman sees little difference in the Communistic and Fascist controlled countries such as Japan, Russia, Germany and Italy. They are similar in that a small group controls the country. All these countries are endeavouring to increase their population, but Russia is the only one that has sufficient territory on which to support an increase in population. The labour systems in these countries are similar in that they are under government control, the difference being that Russia has a "good" Communist in charge at each plant resulting in poor production. The other countries allow the industries to remain in the hands of private management, generally resulting in good production.

However, the democracies are voluntarily reducing their population. Most of the births are occurring in the lower classes which either cannot work or are already state charges. The labour policies seem to be to try to place the minimum wage above the best average wage, and no country can afford to do this.

The present tendency of a good number of Canadians is to shut their eyes to any future wars in which England may become engaged. However, with Canada's population just about at a standstill, England's protection is needed as it is all which stands between Canada and the rest of the world.

O. Rolfson, A.M.E.I.C., and A. J. M. Bowman, A.M.E.I.C., moved a very hearty vote of thanks to Mr. McGorman for his enlightening talk.

## Halifax Branch

*R. R. Murray, A.M.E.I.C., Secretary-Treasurer.*
*C. Scrymgeour, A.M.E.I.C., Branch News Editor.*

The regular monthly meeting of the Halifax Branch of The Engineering Institute of Canada took place on Thursday, February 18th, 1937, at the Halifax hotel, with John R. Kaye, A.M.E.I.C., chairman of the Branch, presiding.

As a means of stimulating increased interest in these meetings the council provided a splendid musical entertainment which was presented during the dinner at the first part of the evening's programme and following which, the chairman introduced the speaker for the evening, Major John S. Roper, Member of the Nova Scotia Public Utilities Commission, who gave a very interesting and particularly amusing address on "The Engineering Profession as Viewed by the Legal Profession."

Following the address a general discussion took place with a number of the members expressing their views in rebuttal to the speakers' remarks and all of which provided continued interest and much amusement.

## Lethbridge Branch

*E. A. Lawrence, S.E.I.C., Secretary-Treasurer.*

### Electric Power Engineering

The Lethbridge Branch of The Engineering Institute of Canada held their regular dinner meeting in the Marquis hotel on Saturday night, January 16th, 1936, with P. M. Sauder, M.E.I.C., chairman. Mr. H. Randle of the Calgary Power Company, Calgary, was the speaker, taking for his subject, "Electric Power Engineering, Achievements, and Operating Facts."

The first part of the meeting after recess was taken up with business and correspondence on the Semicentennial Year and Consolidation, after which Mr. Randle began to speak.

He said that there are two kinds of engineering achievement: that, resulting from imaginative or analytical thinking, and that, resulting from new and improved materials or methods of manufacture. Both types may be seen in the development of alternating current for transmission. Although alternating current and the transformer were known to Faraday and others of his time, direct current was used almost exclusively, until George Westinghouse in 1886 became impressed with its possibilities and pushed its development. The invention of the induction motor for alternating current by Telsa in 1888 gave greater impetus to the movement and alternating current is practically universal today. And again for example, the incandescent lamp. Edison had trouble getting patents for his first lamps since others had had the same idea. However since their inception lamps have improved continuously, and in the last decade alone the efficiency has increased 25 per cent while the cost has decreased 60 per cent.

Mr. Randle then spoke of the transmission of power. It is interesting to note that the first proposals to draw power from Niagara Falls were to use compressed air for the distribution of that power. Finally, however, alternating current was decided on, at a frequency of 25 cycles per second. This is still in use but is not so satisfactory as the 60-cycle current used in most other places. As the generation of power became centralized at large stations and distribution systems became larger, many problems arose. Costs of lines had to go down, and today we find ten to fifteen structures to the mile as compared to fifty to sixty formerly used. Aluminum has replaced copper as the conductor. These increased spans however, meant higher wire tensions, which in turn caused vibrational stresses at the point of support, in countries much affected by wind. These stresses were overcome by the use of armour rods at the point of support and by the use of springs and rods as dampers.

These large generating plants and distribution systems must deliver current as continuously as possible, and at the correct voltage, that is, they must be stable. The problem is acute, and Mr. Randle described apparatus and methods in detail used to overcome such difficulties as inter-connection of plants, remote control of sub-stations, remote metering, interchange of load, flicker on long lines, and protection against lightning. A few remarks about electronics, photo-electric cells, and their many uses, concluded Mr. Randle's talk.

Two films were then shown which were very much enjoyed. A vote of thanks was moved to the speaker by J. M. Campbell, A.M.E.I.C., and the meeting closed with "God Save the King."

## London Branch

*D. S. Scrymgeour, A.M.E.I.C., Secretary-Treasurer.*
*Jno. R. Rostron, A.M.E.I.C., Branch News Editor.*

The annual dinner meeting and election of officers of the London Branch of The Institute was held on January 20th, 1937, at the Richmond Street Armouries as guests of the Military Engineers Association.

The speakers of the evening were P. L. Pratley, M.E.I.C., of the firm of Monserrat and Pratley, Montreal, and R. L. Dobbin, M.E.I.C., General Manager, Public Utilities Commission, Peterborough, Ontario.

About sixty-four members and guests sat down to a substantial dinner provided by the Branch, and showed their appreciation by doing full justice to it.

As the Branch members were the guests of the Military Engineers Association, Colonel Ross, former commander of the First Divisional Engineers' Corps, took the chair for the opening of the meeting, and welcomed the members of the Branch to the Officers' Mess, reminding them that they might join the Military Engineers Association for a small fee. He then called upon Brigadier General Stewart, Officer Commanding Military District No. 1, who addressed the meeting, and extended a welcome to all present.

Mayor Kingsmill then expressed his pleasure at being invited to attend the gathering, and in the course of his remarks referred to the difficulty often experienced by public works officials, whether engineers or otherwise, in carrying out their work properly and adequately when interfered with by others who, although in authority, were unskilled in the nature of the work on hand and also in many cases the funds necessary for the job were curtailed. These influences were not desirable and were likely to impair the efficiency of the work.

Colonel Ross then vacated the chair, which was taken by Jas. Ferguson, A.M.E.I.C., chairman of the Branch. After a short address in which he thanked the officers for their courtesy, he called upon the first speaker of the evening.

Mr. Pratley opened by observing the happy union of the Military Engineers Association and that of the London Branch and referred to the similar association of the Royal Engineers with the Institution of Civil Engineers in London, England.

He quite agreed with the remarks made by Mayor Kingsmill and enlarged upon them. In several cases in his experience such interference had given considerable trouble. He pointed out the system largely adopted in Canada, of getting the fabricating firms to design as well as tender for the job instead of employing a competent engineer to design the work and then call for tenders as was the practice in England. Many steel fabricating firms in Canada were objecting to this as, in the case of unsuccessful tenderers, they were put to a lot of trouble and expense for which they received no recompense.

The speaker then gave short descriptions of various works on which his firm had been engaged as designers or consultants. The suspension bridge over the St. Lawrence at Ile d'Orleans was first mentioned, also the new bridge over the Fraser river in British Columbia at which a severe washout occurred to the foundations. These were restored by driving steel sheet piling around the piles, excavating to solid ground and filling up with gravel to the underside of the substructure.

A few facts concerning the suspension of the First Narrows at Vancouver were then given. This structure is being erected by private capital at a cost of four and a half million dollars, the revenue to be earned by "toll" charges. The roadway is 29 feet wide and there are two 6-foot sidewalks. The suspension span is 1,500 feet, and slung by wire cables.

The Thousand Islands bridge is of the suspension type with a 700-foot span, 20-foot roadway and a narrow sidewalk. The proposed international bridge at Sarnia is to be of steel construction with cantilever arms supporting the large trusses of the centre span. There is to be a road 20 feet wide, with two sidewalks 3 feet wide each.

J. A. Vance, A.M.E.I.C., in moving a vote of thanks to Mr. Pratley for his address, expressed appreciation of his services to The Engineering Institute of Canada. The vote was unanimously carried. He also introduced Mr. Dobbin, as one of the vice-presidents of The Institute, and manager of the Public Utilities Commission of Petersborough for the past fifteen years.

Mr. Dobbin said he felt it was an honour to be invited to address this meeting as a representative of the president of The Institute. He reminded the members of the annual meeting of The Institute which was to be held shortly at Montreal and would be glad to meet the members of the Branch there. This also applied to the Semicentennial Celebrations of The Institute next June. He had intended to outline the present situation as to the proposed consolidation of The Institute and the Provincial Professional Associations but as time was getting short he would leave any talk on that matter to the business meeting which was to take place later in the evening.

E. V. Buchanan, M.E.I.C., general manager of the Public Utilities Commission, London, Ontario, being, so to speak, a business rival of Mr. Dobbin, proposed a vote of thanks to the speaker in a humorous speech which caused much merriment.

The chairman then asked the guests to retire to the entertaining room, where cards, games and refreshments were provided, while the business of the meeting was conducted.

The first business was the reading of the minutes and the auditors' report which were unanimously adopted. During and after the ballot for the election of officers for the ensuing year, a thorough discussion of the matter of consolidation was carried on; Mr. Dobbin, Mr. Pratley and Mr. Vance (Branch Councillor) giving much helpful information.

The election of officers then followed.

Mr. Ferguson, before vacating the chair, thanked the members for their co-operation during his year of office, and welcomed the newly elected chairman, A. O. Wolff, A.M.E.I.C., who said he hoped to enjoy the continued co-operation of the members, and promised to do all he could to promote the interests of the Branch.

Votes of thanks were given to the retiring chairman and to Major W. M. Veitch, A.M.E.I.C., for successfully organizing the meeting in the military quarters.

The members then joined the guests and a social evening was thoroughly enjoyed.

## Montreal Branch

*E. R. Smallhorn, A.M.E.I.C., Secretary-Treasurer*

### Junior Section Plant Visit

On the afternoon of Saturday, January 30th, 1937, the Junior Section of the Montreal Branch had an opportunity of visiting the plant of the Consumers Glass Company Limited at Ville St. Pierre.

Arrangements were made through the courtesy of officials of the company, and a most interesting inspection trip was the result. Those attending inspected the plant and equipment, including the furnaces, machine shop, bottle blowing plant and inspection room. Technical information was provided by Messrs. Morrison, DiBenga and Anglin.

### Recent Developments in Steam Heating

At the meeting of the Montreal Branch held on February 4th, H. F. Marshall, advertising manager and assistant sales manager of Warren, Webster and Company of Camden, N.J., gave an address in which he reviewed the developments of the modern steam heating system for dealing particularly with modernization and improved control of steam circulation.

J. G. Hall, M.E.I.C., was in the chair.

### Transmission Over Electric Wave Guides

Dr. G. C. Southworth, of the Bell Telephone Laboratories, New York, gave a most interesting talk before the Branch on February 11th, covering some of the newest developments in the art of radio transmission.

Prior to the meeting an informal dinner was held at the Windsor hotel.

Professor G. A. Wallace, A.M.E.I.C., was chairman.

### Junior Section

At the meeting of the Junior Section held on February 15th, two papers were presented: One by J. M. Fairbairn, A.M.E.I.C., general manager of Chas. Warnock and Company, on "Some Interesting Features of Inspection and Testing Work" and the other entitled "The Photo-Elastic Method of Stress Analysis" by Carleton Craig, S.E.I.C., lecturer, Department of Civil Engineering and Applied Mechanics, McGill University.

### Modern Highway Construction

At the meeting of the Montreal Branch held on February 18th, the Honourable Francois Leduc, Minister of Roads of the Province of Quebec, spoke on "Modern Highway Construction." Mr. Leduc referred to highway construction in general and to the special road programme of the province of Quebec.

Prior to the meeting a dinner was held at the Windsor hotel which was attended by seventy members and friends.

The chairman was J. A. McCrory, M.E.I.C.

## Ottawa Branch

*F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.*

### Recent Progress of Organized Labour in England

At the first noon luncheon of the new year, held at the Chateau Laurier on January 21st, 1937, the speaker was W. L. Waters, C.E., M.E.I.C., consulting engineer of New York City. Mr. Waters, who has been engaged principally in transportation activities in the United States, Canada, Central America and England, spent several months recently in the Old Country studying labour conditions. His address was on "Recent Progress of Organized Labour in England" and comprised, as he explained, a summary of ideas obtained from labour leaders, business executives, and others.

J. G. Macphail, M.E.I.C., newly elected chairman, presided, and in addition head table guests included: G. J. Desbarats, C.M.G., Hon.M.E.I.C., P. M. Draper, president of the Trades and Labour Congress, G. A. Stone, of the Board of Railway Commissioners of Canada, F. A. McGregor, registrar for the Combines Investigation Act, C. W. Bolton, chief statistician of the Department of Labour, Squadron Leader A. Ferrier, A.M.E.I.C., P. Sherrin, A.M.E.I.C., R. K. Odell, B. F. Haanel, M.E.I.C., E. Viens, M.E.I.C., and Dr. R. W. Boyle, M.E.I.C.

Labour leaders in England have learned much in the past fifteen years, stated Mr. Waters. Even though at times they may talk radically for the benefit of some of their fire-eating constituents, they are following a conservative and far-sighted policy; and they are able to keep their membership in line. So long as this condition continues, organized labour cannot fail to be a powerful constructive force in English national life, and to be considered with the middle classes as the backbone of the country.

The speaker traced the history of organized labour in the Old Country since the War, with particular emphasis upon its part in transportation. Over there, he stated, labour leaders are taking a broad long-ranged view of industry in marked contrast to the continual agitation for minor concessions so prevalent in North America. The public reaction to the general strike of 1926, the sobering effect on the labour leaders of the fact that a labour ministry had the responsibility of governing the country for many years, and the realization during the depression that labour was really fighting foreign competition rather than capital, are among the more important of the reasons for this attitude.

At first labour was fearful lest the rationalization of British industries to meet external competition would result in unemployment through the shutting down of obsolete plants and the introduction of labour-saving machinery. "But they soon realized," stated Mr. Waters, "that it is better to have 100 men employed at good wages than 150 at sweat shop rates; and that once an industry becomes prosperous it will expand, so that ultimately the additional 50 men who had to go on the dole, will be re-employed at living wages. Thus we now find organized labour in England favouring rationalization of industries, consolidations and the introduction of modern machinery."

Generally speaking labour believes that such a course will ultimately permit of a shorter week and higher wages without the necessity of raising prices. It also favours unions covering a whole industry, as such permit dealing with conditions as a whole, while craft unions do not.

The Labour Party in Great Britain must not be considered as a political branch of the labour unions, remarked the speaker. "The Labour Party is strictly a political party like the Conservative or Liberal," he said, "and the labour unions are wise enough to keep themselves free from political entanglements, so that they can be in a position to demand concessions from any party."

The speaker then referred to three examples of monopoly or quasi-monopoly in the field of transportation resulting from the pressure of organized labour. The first of these was the amalgamation of the English railways into four territorial groups under private ownership and management. Through the pooling of traffic between common points this has practically eliminated rail competition though it is still subject to independent highway competition.

The second is the London Passenger Transport Board, operating a monopoly of passenger transportation for hire in the London area, with receipts pooled with the suburban railway traffic. The securities of the Board are privately owned and the properties are under a management virtually a public trust free from political interference.

The third is the government-appointed North Ireland Road Transport Board, with its securities privately owned, operating all highway passenger and freight transportation for hire, with receipts pooled with the railways. This will first be tried as a public trust selected by the existing enterprises and labour expects that ultimately the railways will be absorbed resulting in a monopoly of public transport in the territory.

Actually, pointed out the speaker, none of these is an absolute monopoly, as they are all subject to the competition of privately owned automobiles and trucks used exclusively in the owner's business or pleasure.

Organized labour in England, however, is not afraid of monopoly, either in industry or transport, as it realizes from experience the economies and the benefits to labour which result from strongly organized and prosperous consolidated properties. It is also satisfied that no monopoly, especially a public utility monopoly, can abuse its power; as if it attempts to do so, the public always develops an effective way to control conditions.

*Note.*—This paper is published in full elsewhere in this issue of The Journal.

### New Developments in Refrigeration

At the noon luncheon at the Chateau Laurier on February 11th, 1937, W. H. Cook, D.Phil., of the National Research Laboratories, gave an address on "Some New Developments in Refrigeration and Cold Storage." Dr. Cook for the past six years has been conducting investigations at the laboratories into the transport and storage of perishable foodstuffs. In June of last year he attended the Seventh International Congress on Refrigeration held at The Hague, Holland, and spent part of the summer at the Low Temperature Research Station, Cambridge University, England.

J. G. Macphail, M.E.I.C., chairman, presided and additional head table guests included: G. J. Desbarats, C.M.G., Hon.M.E.I.C., president of The Institute; Dr. H. Barton, Deputy Minister of the Department of Agriculture; Dr. R. Newton, Dr. J. B. Dabbitt, and Dr. C. A. Winkler, of the National Research Council; Col. H. O. Lawson and Major C. S. Jones, of the Department of National Defence; E. Viens, M.E.I.C., Col. R. L. Wheeler, John Murphy, M.E.I.C., and B. F. Haanel, M.E.I.C.

Dr. Cook, after mentioning that certain principles of refrigeration were known for many centuries, stated that one of the first reasonably successful shipments of meat was made on the steamship "Frigorifique" from Buenos Aires to Rouen in 1877. He then outlined modern methods of refrigeration both for stationary storage of perishables and for transport, and indicated methods for meeting some of the problems that arose.

The need for extending the storage life of commodities held in the chilled condition has recently resulted in several new methods of preservation, he stated. Among these—for those foods which can be frozen—is quick freezing and storage at low temperatures, a procedure which is not so destructive to tissues as slow freezing or temperatures just below the freezing point. The reason for this is that much smaller ice crystals are formed in the quick freezing process and maintained at the very low temperatures.

Dr. Cook elaborated upon the methods in use for obtaining and maintaining these low temperatures. He also dealt with the use of gases, particularly carbon dioxide gas, as an aid in the preservation of foodstuffs along with humidity control as well.

## Winnipeg Branch

*H. L. Briggs, A.M.E.I.C., Secretary-Treasurer.*

### The Cathode Ray Oscillograph

On February 4th, 1937, Dean E. P. Fetherstonhaugh, M.C., B.Sc., M.E.I.C., Professor of Electrical Engineering, University of Manitoba, delivered an interesting paper on the subject "The Cathode Ray Oscillograph."

After touching on the "point by point" method of analyzing electric waves, and pointing out the limitations of the Duddles type oscillographs, Dean Fetherstonhaugh went on to describe the recent types of cathode ray oscillographs or oscilloscopes, using inertialess beams of cathode rays or electrons. The beam is in each case produced by attracting electrons from a hot cathode toward an anode. The anode has a small hole in its centre; certain of the electrons carry on through this hole; these are concentrated by being passed concentrically through a hollow cylinder maintained at proper voltage; they are then deflected in one plane by being passed between parallel plates whose potential difference corresponds to the electric quantity being examined; the electrons are then deflected in a second plane at right angles to the first by being passed between parallel plates which give a time base to a trace which appears on the fluorescent screen at the end of the tube.

The speaker explained adjustments, advantages and disadvantages of the instruments, and gave several demonstrations of their use.

J. W. Sanger, M.E.I.C., expressed the feeling of the meeting in moving a hearty vote of thanks.

The meeting then proceeded with the business of the annual meeting of the Branch, reports being presented as synopsized in the February issue of The Journal.

G. E. Cole, A.M.E.I.C., 1936 Chairman of the Branch, handed the meeting over to the incoming Chairman, Professor A. E. Macdonald, M.E.I.C., who, after a few appropriate remarks, declared the meeting adjourned for refreshments.

## Competition for Scientific Papers on Arc Welding

To encourage scientific interest in the thousands of uses to which arc welding may be put, the James F. Lincoln Arc Welding Foundation has set aside $200,000, which will be awarded to persons who prepare satisfactory papers upon this subject.

To participate in this contest, it is necessary only that the papers submitted describe either the re-design of an existing machine, structure, building, etc., so that arc welding may be applied to its manufacture; or present a design (either in whole or in part) of a machine, structure, building, etc. not previously made—the description to show how a useful result, which was impractical with other methods of construction or could better be done by arc welding, is obtained.

Owners and operators of established companies specializing in welding may be entered in the competition through papers which describe the details for successfully conducting such an establishment.

Enquiries regarding this competition should be addressed to the Secretary, the James F. Lincoln Arc Welding Foundation, P.O. Box 5728, Cleveland, Ohio.

# Preliminary Notice

## of Applications for Admission and for Transfer

February 27th, 1937

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

**Communications relating to applicants are considered by the Council as strictly confidential.**

---

The Council will consider the applications herein described in April, 1937.

R. J. Durley, Secretary.

---

*The professional requirements are as follows:—

**A Member** shall be at least thirty-five years of age, and shall have been engaged in soms branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at ths discretion of the Council, be reduced to ten years inthe case of a candid ate for election who has graduated from a school of engineering recognized by the Council. In every case ths candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

**An Associate Member** shall be at least twenty-seven years of,age, and shall have been engaged in some branch of engineering for at least six years which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch ofengineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more year.

**A Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by ths Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

**A Student** beshallat least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by ths Council.

Hs shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which hs has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

**An Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

> The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

### FOR ADMISSION

DUGAS—JOSEPH ESDRAS ARMAND, of Montreal, Que., Born at Joliette, Que., Jan. 5th, 1907; Educ., B.A.Sc., C.E., Ecole Polytechnique, Montreal, 1932; 1928-29 (summers), and 1932-33, inspr. on gen. underground conduit systems, Electrical Commission, City of Montreal; 1933-35, sales engr., Superior Automatic Heating Co.; 1935-36, with Arthel Ltd., in charge of sales, preliminary design and complete installns. of Arthel Sunlight Apparatus; Dec. 1936 to Jan. 1937, in charge of work inspection, Imperial Oil Wharf, Montreal East, for Montreal Harbour Commissioners; At present, with Montreal Light, Heat and Power Cons., in Industrial Lighting Divn., New Business Dept.

### FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

WIGHTMAN—JOHN FREDRICK CARMAN, of Kentville, N.S., Born at Lawrencetown, N.S., Oct. 25th, 1893; 1913-15, 2 years engrg. course, Mt. Allison Univ.; Home study and corres. courses; 1915-18, overseas service, Capt.; 1920, supt. of highways, Cumberland and Colchester Counties, N.S.; 1921-22, town engr., Amherst, N.S.; 1923-24, private practice; 1924-25, constrn. engr., 1927-30, county engr., N.S. Highways Dept.; 1930 to date, town manager and engineer, Kentville, N.S. (*A.M. 1920.*)
References: H. W. McKiel, A. R. Chambers, C. A. Fowler, K. L. Dawson, W. P. Copp, H. F. Laurence.

### FOR TRANSFER FROM THE CLASS OF JUNIOR

ANDREWS, WILLIAM EDWARD, Capt., R.C.E., of London, Ont., Born at Beamsville, Ont., Oct. 28th, 1902; Educ., Grad., R.M.C., 1924. B.Sc. (Civil), McGill Univ., 1927; 1927-29, courses at School of Military Engrg., Chatham, England; 1929-33, instructing at Royal Canadian School of Military Engrg., Halifax, N.S. Employed on engr. services and works (bldg. mtce., military camps, rifle ranges, etc.); 1933, Acting District Engr. Officer, Mil. Dist. No. 3, Kingston, Ont.; 1934-35, Acting District Engr. Officer, Mil. Dist. No. 2, Toronto; 1935 to date, District Engr. Officer, Military Dist. No. 1, London, Ont. (*Jr. 1930.*)
References: W. M. Veitch, H. L. Hayman, S. W. Archibald, C. S. Bennett, I. Leonard.

BLACKMORE—CYRIL LESLIE, of 3515 Durocher St., Montreal, Que., Born at Tilt Cove, Nfld., June 14th, 1898; Educ., B.Sc. (E.E.), McGill Univ., 1927; 1919-20, line distribution work; 1920-22, electrn., paper mill work; 1927-29, students course, and 1929-30, elect'l. engr. in charge of power house installn. at Deer Lake, for International Paper Company; 1930-31, elect'l. engr., Gatineau, in charge of elect'l. equipment; 1933 to date, president, C. L. Blackmore & Co. Ltd., electrical contractor, Montreal, Que. (*St. 1925, Jr. 1930.*)
References: C. V. Christie, C. M. McKergow, G. L. Wiggs, W. G. Hunt, J. H. Trimingham.

FOULKES—THOMAS, of Kapuskasing, Ont., Born at Liverpool, England, July 26th, 1904; Educ., B.Sc., (E.E.), Univ. of N.B., 1926; 1922 (Sept.-Dec.), compassman, N.B. Forestry Survey; Summers 1924-25, rodman and instr'man., N.B. Elec. Power Commn.; 1926-27, test dept., 1927-28, induction motor design dept., Can. Gen. Elec. Co., Peterborough; 1928-29, substation mtce. man., and 1929 to date, mtce. materials engr., Spruce Falls Power and Paper Co., Kapuskasing, Ont. (*St. 1925, Jr. 1929.*)
References: C. W. Boast, C. R. Murdoch, V. S. Foster, A. B. Gates, W. M. Cruthers.

MOSLEY—HAROLD GORDON, of 760 Mechanic St., Glace Bay, N.S., Born at Glace Bay, N.S., Mar. 16th, 1904; Educ., Passed E.I.C. Exam. under Schedule "B" for admission as Junior, Nov. 1935. I.C.S. Courses; 1920-21, mine survey dept., 1921-23, dfting. office, and 1923-28, surveyor, Dominion Coal Company, Glace Bay; 1929-30, struct'l. dfting. office, Dominion Bridge Company, Lachine, Que.; 1930-34, asst. to town engr., Glace Bay, N.S.; 1934 to date, mining engrg. dept., Dominion Coal Company, Glace Bay, N.S. (*Jr. 1935.*)
References: A. L. Hay, J. R. Morrison, M. F. Cossitt, C. M. Anson, S. C. Mifflen.

PAULSEN—RUDOLPH O., of Toronto, Ont., Born at Erickson, Man., July 13th, 1906; Educ., B.Sc. (C.E.), Univ. of Man., 1929; 1927, leveller on drainage with Manitoba Govt., Dept. of Public Works; 1928, reinforced concrete inspr. with C. D. Howe & Co. on constrn. Pool Terminal No. 7 at Port Arthur; 1929-30, detailing reinforced concrete and struct'l. steel and reinforced steel inspection on constrn. Slave Falls Development, Winnipeg Hydro-Electric; 1931, asst. to res. engr. on constrn.. Winnipeg River Bridge at Lac du Bonnet, Winnipeg Hydro-Electric; 1932 36, res. engr. on constrn. of Trans-Canada Highway, with Dept. of Northern Development of Ontario; At present struct'l. dftsman., Toronto Iron Works, Toronto, Ont. (*Jr. 1930.*)
References: J. W. Sanger, E. A. Kelly, A. E. Macdonald, G. H. Herriot, T. F. Francis, C. T. Barnes.

### FOR TRANSFER FROM THE CLASS OF STUDENT

CAREFOOT—HERBERT REGINALD, of Ottawa, Ont., Born at Floradale, Ont., Oct. 17th, 1905; Educ., B.Sc. (C.E.), Univ. of Sask., 1929. Imperial College of Science and Technology, London, England, 1935-36; 1926-27 (summers), drainage surveys and highway location; 1929 to date, General List Officer, Royal Canadian Air Forces. Variously employed technically as commanding an advanced overhaul base, and now employed as asst. in the Aircraft Development Section. (*St. 1929.*)
References: E. W. Stedman, A. Ferrier, C. J. Mackenzie, R. A. Spencer, G. R. Turner.

COLGAN—PATRICK JOSEPH, of Yarmouth North, N.S., Born at Halifax, N.S., Nov. 16th, 1908; Educ., B.Sc. (E.E.), N.S. Tech. Coll., 1934; 1934-36 (18 mos.), shop experience in various depts. of the Massey-Harris Co. Ltd., Toronto works; 1936 (5 mos.), road inspr., Milton Hersey Inspection Co. Ltd.; At present, asst. in roll repair shop and stockroom, Cosmos Imperial Mills, Yarmouth, N.S. (*St. 1930.*)
References: S. Ball, C. W. McCarthy.

DALE—JOHN CLAPHAM, of Calgary, Alta., Born at Lloydminster, Sask., Sept. 18th, 1909; Educ., B.Sc. (E.E.), Univ. of Alta., 1932; 1932-35, engrg. dept., Northwestern Utilities Ltd., Edmonton, Alta.; 1935 to date. rates, franchise, design, dfting, estimating, with the Canadian Utilities Ltd., Calgary, Alta. (*St. 1930.*)
References: J. Garrett, E. Nelson, E. W. Bowness, J. Haddin, R. S. Trowsdale.

DORE—RICHARD FRANCIS, of 16 Aylmer Ave., Ottawa, Ont., Born at Ottawa, Oct. 20th, 1908; Educ., B.Sc. (Civil), Queen's Univ., 1932; 1928, leveller, topog. survey, Dept. Interior, Ottawa; 1929-30 (summers), chainman, Man.-Ont. Boundary Survey; 1932 and 1934 (summers), student asst., geol. survey, Dept. of Mines; 1934-35, junior instructor, dept. of civil engrg., Queen's University; 1935 to date, junior topog'l. engr., Bureau of Economic Geology, Dept. of Mines and Resources, Ottawa, Ont. (*St. 1932.*)
References: J. V. Butterworth, E. M. Dennis, W. G. H. Flay, N. B. MacRostie, S. M. Steeves, W. P. Wilgar.

KELLAM—GEORGE DOUGLAS, of Calgary, Alta., Born at Montreal, Que., Feb. 23rd, 1911; Educ., B.Sc. (E.E.), Univ. of Man., 1933. One year post-graduate study in economics, extramurally; 1933-34, demonstrator, Univ. of Man., elect'l. dept.; 1934-35, asst. engr., running survey of diamond drilling, Canadian Mining Projects, Herb Lake, Man.; 1935-36, shop asst., 1936 to date, asst. engr., Canadian Western Natural Gas, Light, Heat and Power Co. Ltd., Calgary, Alta. (*St. 1933.*)
References: F. J. Heuperman, E. W. Bowness, E. P. Fetherstonhaugh, N. M. Hall, J. F. Cunningham, W. F. Riddell.

SAVAGE—PALMER ERNEST, of Montreal, Que., Born at Brandon, Man., July 20th, 1909; Educ., B.Sc., 1931, M.Eng., 1934, McGill Univ.; Studied transportation at Yale Univ., 1933-34, on Strathcona Memorial Fellowship; 1928 (summer), rly. constrn. in Alta.; 1929-30 (summers), dftsman., and 1931 (autumn), dftsman. and designer, Dominion Bridge Co.; 1932 (Feb.-Sept.), inspr. on constrn., C.P.R.; June 1934 to date, struct'l. designer, Dominion Bridge Co. Ltd., Lachine, Que. (*St. 1930.*)
References: F. P. Shearwood, E. Brown, R. E. Jamieson, F. Newell, R. S. Eadie.

WESELAKE—EDWARD JOSEPH, of 503½ Selkirk Ave., Winnipeg, Man., Born at Winnipeg, Man., June 20th, 1907; Educ., B.Sc. (E.E.), Univ. of Man., 1930; 1928 (5 mos.), topog'l. survey, Island Falls, Sask.; 1929 (5 mos.), inspr., rock ballasting, C.P.R., Kenora; 1930-31 (16 mos.), dftsman., preparation of plans, central steam heating system, Northern Public Service Corpn. At present not employed in engrg. work. (*St. 1927.*)
References: E. P. Fetherstonhaugh, W. G. Chace, N. M. Hall, C. A. Clendening, G. H. Herriot.

## New Industrial Developments in Toronto

Reflecting the general trend of improved business during 1936, the establishment of new industries in the Toronto area last year exceeded the records of both 1934 and 1935 in all three major particulars—floor space occupied, capital invested and employment created. This was the salient feature of the report of the Toronto Industrial Commission presented at its annual meeting recently by John A. Tory, president. The report showed that the Commission not only co-operated with eleven outside concerns in commencing factory operations in Toronto last year, but also assisted eight existing Toronto firms in connection with expanding their plant facilities, adding new lines of manufacture and other problems.

An outstanding feature of the report was the statistical summary of the Commission's activities since it began operations nearly eight years ago. It showed that one hundred and twenty-six new industries had been established and twenty-four manufacturing arrangements effected in the Toronto area with the assistance of the Commission. At December 31st, 1936, these one hundred and fifty industrial developments represented capital investment in plant and equipment of over $6,904,000, a gain of over $1,300,000 compared with the total a year ago; direct employment of four thousand and fifteen persons, seven hundred and forty-three more than a year ago; an annual payroll in excess of $4,000,000, an increase of $831,000 over the 1935 figure; and 1,919,390 square feet of floor space occupied, a gain for the year of over 270,000 square feet.

Directors elected to the Board included Mayor D. D. Robbins, representing the city council; the following six representing the Board of Trade—R. C. Berkinshaw, general manager of the Goodyear Tire and Rubber Company Ltd.; A. E. K. Bunnell, M.E.I.C., consulting engineer, Wilson and Bunnell; C. L. Burton, president, The Robert Simpson Company Ltd.; Ivor R. Lewis, staff superintendent, the T. Eaton Company, Ltd.; F. D. Tolchard, general manager, Board of Trade, and John A. Tory, supervisor, Sun Life Assurance Company of Canada; three representing the Toronto Branch of the Canadian Manufacturers' Association—A. B. Cooper, M.E.I.C., general manager, Ferranti Electric Limited; A. Ross Robertson, A.M.E.I.C., manager, Dominion Bridge Company Ltd., and F. E. Waterman, general manager, Toronto Brick Company Ltd.; and the following four representing public bodies of the city of Toronto—E. M. Ashworth, general manager, Toronto Hydro-Electric System; J. E. Ganong chairman, Toronto Harbour Commissioners; D. W. Harvey, general manager, Toronto Transportation Commission, and Elwood A. Hughes, general manager, Canadian National Exhibition Association. C. L. Burton was elected honorary president of the Commission; John A. Tory, president, and A. B. Cooper, F. E. Waterman, and E. M. Ashworth, vice-presidents.

## EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

*All correspondence should be addressed to*

**The Employment Service Bureau, The Engineering Institute of Canada**

**2050 Mansfield Street, Montreal**

### Situations Vacant

MECHANICAL ENGINEER, about 30 years of age, with mechanical and combustion training. Will be used in technical or sales work. Apply to Box No. 1481-V.

MECHANICAL ENGINEER, under 30 years of age, to act as assistant to the Assistant Manager. The work comprises the design, construction and maintenance of general chemical plant and plant buildings. The position holds good prospects. Apply to Box No. 1489-V.

MECHANICAL DESIGNER DRAUGHTSMAN, familiar with pulp and paper mill equipment. Apply to Box No. 1490-V.

TECHNICAL ADVISER TO SALES department of manufacturing firm selling to pulp and paper mill industry. Must be familiar with mechanical design of pulp and paper mill equipment. Preferably one who has also had actual mill operation experience. Apply to Box No. 1491-V.

YOUNG ENGINEER, with electrical and civil experience or training to act as engineer for a small town in the province of Quebec. Apply to Box No. 1493-V.

ASSISTANT MASTER MECHANIC, for 10,000 E.H.P. plant in the province of Quebec. Young man required. Electrical and mechanical work. Good living conditions. Apply to Box No. 1494-V.

DRAUGHTSMAN, with at least ten years experience on general construction and machinery layouts, preferably in large mines. For the right man this position will have a degree of permanency. Apply to Box No. 1497-V.

### Situations Wanted

ELECTRICAL ENGINEER, B.Sc., E.E. Age 30. Completed C.G.E. Test Course; five years experience with power company utility work—substation and power house (steam) operation and maintenance, transmission and distribution line operation, maintenance and design. Industrial or utility work desired. Location immaterial. Available on short notice. Apply to Box No. 266-W.

MECHANICAL ENGINEER, B.Sc. Age 31. Married. Last ten years includes:—Mechanical structural and reinforced concrete design in pulp and paper mills, industrial plants, hydro-electric, mine, sewers and sewage disposal plant construction. My experience also includes shop production, steam plant combustion, fuel analysing, inspecting, supervising and instrument work on industrial construction. Permanent position preferred. Apply to Box No. 521-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aerophotographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.

ELECTRICAL ENGINEER, B.Sc. '28; M. Eng. '35. Two years student apprenticeship at Can. Westinghouse Co., including test and electrical machine design. Also about two years experience in operating dept. of large electrical power organization. Available on short notice. Apply to Box No. 660-W.

ELECTRICAL AND CIVIL ENGINEER, B.Sc. Elec. '29, B.Sc. Civil '33. Jr.E.I.C. Age 29. Experience includes four months with Can. Gen. Elec. Co., approximately three years in engineering office of large electrical manufacturing company in Montreal, the last six months of which was spent as commercial engineer. For the last year and a half employed in electrical repair shop. Best of references. Apply to Box No. 693-W.

CIVIL ENGINEER, B.Sc. (Alta. '31), S.E.I.C. Experience includes three seasons in charge of survey party. Transitman on railway maintenance, and concrete bridge designing. Nature of work and location immaterial. Apply to Box No. 724-W.

### Situations Wanted

YOUNG CIVIL ENGINEER, B.Sc. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

RADIO AND ELECTRICAL ENGINEER, B.Sc., '31, Jr.E.I.C. Single. Age 29. One year and a half actual field experience in power and lighting equipment. Extensive work in telephone and radio layouts in switchboard and installation depts. Particularly interested and experienced in sales and traffic work in telephone and radio company. At present supervisor over sales and service of radio and electrical company. Available on short notice. Location immaterial. Apply to Box No. 740-W.

#### Employment Service Bureau

Members are again reminded that we are receiving an increasing number of enquiries for engineers.

Why not register with the Employment Service Bureau of the Institute, or if you are already registered bring your record up-to-date?

You may be missing an opportunity to make a satisfactory connection.

PLANT ENGINEER or SUPERINTENDENT, capable of supervising all phases of industrial plant operation, graduate electrical, eleven years diversified industrial experience including test course, four years on large Quebec industrial development, on construction and operation, also six years with prominent consulting firm supervising electrical and mechanical engineering projects. Age 31, single. Apply to Box No. 795-W.

CIVIL ENGINEER, S.E.I.C., B.Sc. in C.E. (Sask. '32). Single. Age 27. Three years experience includes—instrumentman, compiling reports and draughting with a National Park; in charge of construction of water supply and sanitary sewer systems; assistant on city surveys. Excellent draughtsman. Available at once. Location immaterial. References. Apply to Box No. 818-W.

CIVIL ENGINEER, B.Sc. '15, A.M.E.I.C., married, extensive experience in responsible position on railway construction, also highways, bridges and water supplies. Position desired as engineer or superintendent. Available at once. Apply to Box No. 841-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C., age 32, married. Two years in pulp mills draughting and designing additions, maintenance and plant layout. Three and a half years in the Toronto Building Department, checking and designing for steel, reinforced concrete and ordinary structures. One and a half years as transitman and draughtsman on road location and maintenance work. Available at once. Location immaterial. Apply to Box No. 899-W.

### Situations Wanted

CIVIL ENGINEER, B.Sc., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

ELECTRICAL ENGINEER AND GEOPHYSICIST. B.Sc. (Man. '23), A.M.E.I.C. Married. Ten years specialized experience in the practical use of magnetic, electrical and mechanical instruments for the prospecting, surveying and mapping of mineral, oil and gas lands. Five years experience with telegraph, telephone and radio equipment. Capable of giving instruction in theory and practice in these lines and in college physics. Available on short notice. Apply to Box No. 1063-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

ELECTRICAL ENGINEER, B.Sc. '34 (Univ. of N.B.), S.E.I.C. Age 21, single. Desires any kind of electrical work. Will consider any location. Apply to Box No. 1262-W.

CIVIL ENGINEER, B.A.Sc. (Toronto '33), S.E.I.C. Married. One year as instrumentman and draughtsman with provincial Highways Dept. One year on grading and reinforced concrete construction with Dept. of National Defence. One year in charge of contractor's branch office on highway paving job. Desire permanent position with opportunity for advancement. Apply to Box No. 1265-W.

ENGINEER AND DRAUGHTSMAN, Jr.E.I.C., age 33, married. Diplomas from Mtl. Tech. Inst. in R.C. and Structural Design. 11½ years experience in civil engineering, draughting and instrument work. This includes 7 years with M.L.H. & P. Cons. as field engineer on construction and maintenance of gas mains. Present location Montreal. Available at once. Apply to Box No. 1326-W.

CIVIL ENGINEER, M.E.I.C. Married. Age 38. Twenty years experience in organization, design and estimating, and cost accounting. Active service in France. Apply to Box No. 1367-W.

ENGINEER SUPERINTENDENT, A.M.E.I.C., R.P.E., Que. and Alta. Age 47. Married. Twenty years experience as engineer and superintendent in charge of hydro-electric, industrial, railroad, and irrigation construction. Specialized in rock excavation and suction dredging. Intimate knowledge of costs, estimating and organizing. Available immediately. Apply to Box No. 1411-W.

CIVIL AND ELECTRICAL ENGINEER, Univ. of Man. '35 and '36. S.E.I.C. Experience in irrigation and mapping. Available at once. Location immaterial. Box No. 1418-W.

CIVIL ENGINEER, B.Sc. 1910, A.M.E.I.C. Married. Twenty-six years experience on heavy construction work, both field and office; rails, roads, power house, hotels, bridges, etc. Location immaterial. Available at once. Apply to Box No. 1470-W.

SALES ENGINEER, M.E.I.C. Age 50. Married. Several years in combustion and general machinery lines. Estimating and layout work (mechanical and electrical). Speaking French fluently. Executive ability. Apply to Box No. 1482-W.

ELECTRICAL ENGINEER, B.Eng. (McGill '33). One and a half years experience in plant and production routine, and with considerable training in sales work. Bilingual, single, and available at once for any location. Apply to Box No. 1509-W.

ELECTRICAL ENGINEER, B.Sc. '31 (Univ. of Alta.), Jr.E.I.C. Age 28. Married. One year students' test course with C.G.E.Co. including testing and operation of transformers, meters, industrial control and switchgear apparatus. Two years as instrumentman on highway construction. Desires electrical utility, commercial lighting or air conditioning work, location immaterial and available at once. Apply to Box No. 1522-W.

CIVIL ENGINEER, B.Sc. '32, S.E.I.C., P.E.N.B., Dy.L.S.N.B., age 32. Experience in mining, both coal and metals, private and legal surveys, railroad construction, geology and building construction. At present in private practice in coal mining district. Desirous of changing location for position either in mining field or construction in Canada, or abroad. Apply to Box No. 1562-W.

# Recent Developments in Alaskan Aviation

**Extracts from a paper by Hugh Brewster, Supervising Aeronautical Inspector, Bureau of Air Commerce, Anchorage, Alaska, appearing in the January 15th, 1937, issue of the Air Commerce Bulletin.**

Alaska was not many years behind the States in the advent of commercial aviation following the war. However, the wild, rugged terrain, and the extremely variable climatic conditions of both the seasons and the various localities presented obstacles not easily overcome. Not until the late 1920's had the pioneers of Alaskan aviation sufficiently worked out the problems incident to flying in the Territory to demonstrate that it was to become the foremost means of travel if given the opportunity.

* * * *

In the early 1930's the industry "made haste slowly" building up volume of business painstakingly, lowering rates to the point where it was not only faster and more comfortable, but actually far cheaper for the large transient mining population of the interior mining camps to travel by airplane to railheads or seaports than to go "by hand" or by dog team. To sustain a profitable volume of business over the long winter months when mining operations were at a standstill, it was necessary to demonstrate to the permanent residents of the isolated villages that it was feasible for them to procure fresh eggs, meats, fruit and greenstuffs.

* * * *

Then came the momentous increase in the price of gold and with it a great new surge in mining activity throughout the Territory.

* * * *

Where it was necessary before for an airplane organization to base in a large railroad or seacoast town in order to obtain a profitable volume of business it now became possible for an individual operator to locate with one or two planes in any one of the key interior settlements and build up a nice little business "right in his own back yard." . . . At the present time there are twenty-one operators actively engaged in aviation in the Territory.

In the six months from January to June 1936, Alaskan aircraft operators flew 953,487 miles and carried 8,733 passengers. Statistics, by years, from 1930 to 1935 follow:—

Aircraft Operations in Alaska

| Year | Passengers Carried | Miles Flown |
|---|---|---|
| 1930 | 3,654 | 338,422 |
| 1931 | 5,292 | 454,312 |
| 1932 | 6,637 | 742,854 |
| 1933 | 6,237 | 1,019,891 |
| 1934 | 6,628 | 845,897 |
| 1935 | 16,441 | 1,931,736 |

The advent of the individual operator has opened a new field of aviation industry in the Territory. Since it is impossible for each operator of one or two planes to maintain complete shop facilities, demand has arisen for maintenance and repair agencies in the larger cities.

* * * *

The added number of planes and operators has given employment to a number of new pilots and mechanics in the territory.

* * * *

The labour turnover is necessarily very low, as the majority of the flying and mechanical work is of a far different nature than any experienced anywhere but in Alaska. It is safe to say that at least two years are required for either a pilot or a mechanic to become sufficiently acquainted with all of the unusual conditions encountered to make him an asset to his employer.

* * * *

Pilots must be able to service their own planes for long periods when away from their base.

* * * *

In winter it takes a pilot, working alone, never less than an hour to put a ship away for the night, and never less than two hours to get it ready to go in the morning. . . . More ingenuity, knowledge and persistence are required in flying float airplanes than in any of the other types of flying. This is principally true because an airplane on the water cannot be definitely controlled to the extent that it can on land on either wheels or skis.

* * * *

The pilot is solely responsible for his plane, many times is without aid from any source, and in localities without communication, where the loss of the plane would not be known without an expensive and time-taking search by other planes.

Aside from the ingenuity required of an Alaskan pilot in his principal work of flying, he must always be prepared to care not only for himself, but also for his passengers in the event of a forced landing. He must be a cook, hunter, trapper, and all-round woodsman. . . . Emergency rations carried are the result of years of experience and are surprisingly adequate for the weight represented.

A compilation showing the increase in number of pilots, aircraft and airports since 1930 follows:—

Pilots, Aircraft and Airports in Alaska

| Year | Licensed Pilots | | | | | Aircraft | | | Airports |
|---|---|---|---|---|---|---|---|---|---|
| | Transport | Industrial | Limited Commercial | Private | Total | Licensed | Identified | Total | |
| 1929* | 5 | 0 | 1 | 1 | 7 | 8 | 4 | 12 | 53 |
| 1930* | 5 | 0 | 4 | 6 | 15 | 14 | 5 | 19 | 66 |
| 1931* | 22 | 1 | 2 | 1 | 26 | 29 | 5 | 34 | 69 |
| 1932* | 28 | 1 | 2 | 16 | 47 | 28 | 8 | 36 | 75 |
| 1933* | 28 | 0 | 3 | 3 | 35 | 36 | 5 | 41 | 78 |
| 1934* | 37 | 0 | 4 | 4 | 45 | 29 | 1 | 30 | 76 |
| 1935* | 53 | 0 | 2 | 7 | 62 | 69 | 1 | 70 | 82 |
| 1936† | 56 | 0 | 3 | 10 | 69 | 74 | 2 | 67 | 83 |

*As of December 31.
†As of September 30.

Scheduled air-transport operation as it is known in the States is non-existent in the Territory. The small continuous volume of passenger travel caused by the seasonal nature of the work in the Territory and the lack of landing fields and weather reporting stations have prevented its development. The nearest approach to scheduled operation is carried on by the Pacific Alaska Airways of Fairbanks, division of the Pan American Airways system. Their operation consists of a weekly schedule from Juneau to Nome, with a side mail run during the winter weekly from Fairbanks down the Kuskokwim river to Bethel.

The Juneau-Fairbanks division is operated on wheels the year around, as the lack of snow in Juneau prevents the use of skis at that point. The snow on the Fairbanks field and on the intermediate fields is rolled to make it hard enough to support a wheel plane. Modern twin-engine ships are used on the main line, with single-engine transports operating on the Kuskokwim mail run. All ships are equipped with two-way radio and the company maintains a chain of ground stations situated at strategic points along each of its routes. Numerous landing fields have also been privately constructed. It remains for organizations of this type to determine whether scheduled operation is feasible in the territory and if not, to lead the way in making the already common charter service safer and more reliable by the addition of emergency fields, and weather reporting facilities.

Almost all of the government fields that have been built so far are situated at towns and settlements where there is a considerable volume of airplane traffic. This is also true of both government and private radio stations available for weather-reporting service. Practically all of the emergency landing fields and weather stations maintained along the principal air routes are maintained by the principal operators using such routes. . . . The effectiveness of the weather reports is lost to a great extent by the lack of information from intermediate points along the routes. . . . Alaskan aviation's prime present need is for weather stations and intermediate landing fields at such places. The inherent safety of ski and float operation has retarded this development to some extent, but it is only a matter of time until the big volume of flying will fall to the wheel planes. The larger mining districts are in localities inaccessible to float aircraft. Also, floats are expensive in both first cost and maintenance, and they detract from a plane's performance.

* * * *

This summarizes the difficulties that aviation in Alaska has surmounted to become a successful bidder for its place in the transportation system of the Territory.

## Cylinder-Bore Wear

To the Los Angeles Railway Corp., operating a fleet consisting of two hundred and thirty-three coaches, forty-five automobiles and fifty-nine trucks and tractors, the subject of cylinder-bore wear is one of considerable importance.

The first indication of wear in an engine is usually reported by the fuel clerk who notices a drop in the miles per gallon of fuel and miles per quart of oil, and if after the usual tests for leaking valves and so on, it appears necessary to take the engine down, the cylinders are calipered and, provided the wear does not exceed 0.010 to 0.012 inches new piston rings are installed. In the older types of engine this is usually necessary around 50,000 miles. After a total of from 0.015 to 0.020 inches has been reached, cylinders are reground and new piston rings fitted. This operation can usually be performed three times before it is necessary to discard the engine block, provided, of course, the walls have not been scored heavily or otherwise damaged. When this damage occurs, and the cost of a new block is considerably in excess of a repair job, sleeves are installed.

In the more modern engines a different picture is presented. Cylinders of engines inspected, which have operated from 200 to 300 miles per day over a period of one year, show little or no appreciable wear. A fleet of twenty engines equipped with the above type of engine has run an aggregate total of 2,500,000 miles without regrinding, although piston rings were replaced at approximately 57,000 miles on account of increased oil consumption.—*S.A.E. Journal.*

# THE ENGINEERING JOURNAL

## THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

Published monthly at 2050 Mansfield Street, Montreal, by The Engineering Institute of Canada, Incorporated in 1887 as The Canadian Society of Civil Engineers.

Entered at the Post Office, Montreal, as Second Class Matter.

*"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."*

**April, 1937** **Volume XX, No. 4**

## CONTENTS

Price 50 cents a copy, $3.00 a year, in Canada, British Possessions, United States and Mexico. $4.50 a year in Foreign Countries. To Members and Affiliates, 25 cents a copy, $2.00 a year.

# The Engineer and Non-Ferrous Alloys

*Harold J. Roast, M.E.I.C.,*
*Vice-President, The Canadian Bronze Company Limited, Montreal.*

**Paper presented before the Montreal Branch of The Engineering Institute of Canada, February 25th, 1937.**

**SUMMARY.—The paper deals with such points in the metallurgy of non-ferrous alloys as concern the engineer, including composition diagrams, the characteristics of different phases of alloys, considerations governing the design of castings, the choice and standardization of alloys, and recent developments in the non-ferrous alloy field.**

Mechanical engineers are used to the outward performance in structural combinations rather than the inner life and activity of metals and alloys. In watching a tensile test to destruction, their main interest is in the force, as measured by the weight applied, that the specimen will withstand, rather than imagining the inner activities going on in the test bar causing some bars to have obvious and irregular plate-like formations after elongation, as compared with others that have a fine grained surface, both tests being on the same alloy.

Similarly in heat treatment the interest of the mechanical engineer is in the strength of the resulting product rather than the internal molecular changes that have occurred. If this be true, it may be of interest to view these and other phenomena through the eye of the metallurgist.

**Fig. 1—Wrought Iron, Magnification 100.**

First it must be noted that all metals and alloys are composed of an aggregate of crystals of varying form and shape held together by a non-crystalline or amorphous material which is another phase of the same metal or alloy. The terms alloy, solid solution, precipitation hardening, eutectic, intercrystalline shrinkage, crystal growth, dendrite, and also the use of the Greek letter descriptions such as Alpha Brass, Beta Brass, etc., were defined by the author in a paper in 1927,* but a number are now repeated.

*Bearing Metal Bronzes, by H. J. Roast, M.E.I.C., and Fred Newell, M.E.I.C., The Engineering Journal, April, 1927, p. 213.

**Fig. 2—P.M.G. Silicon Bronze.**

An "alloy" is a material having metallic properties and consisting of two or more elements, of which at least one is a metal.

By the term "solid solution" is meant the absorption, without changing the solid phase of the alloy, of two or more so-called compounds that exist as definite units capable of being seen under the microscope. They are then no longer visible in the microscopic field and are said to have gone into solid solution. A solid solution alloy has the characteristics of a pure metal.

"Precipitation hardening" is the increasing of certain physical properties by means of the following procedure. This procedure depends on the fact that certain alloys contain a constituent that by suitable heat treatment in the solid phase may be put into "solid solution" and may, by a further "precipitation heat treatment," be thrown out of solution in a finely dispersed sub-microscopic form. Or, as discussed by Merica in 1932, this hardening constituent may harden the alloy by distortion of the lattice structure without itself being precipitated.

"Eutectic" means the lowest melting point alloy of a given series; for example, the alloy of 63 per cent tin and 37 per cent lead (see Fig. 5), is the lowest melting point alloy of the tin-lead series. It is characteristic of eutectics that their melting point is lower than that of the lowest melting point constituent. They consist of two components frequently in a finely laminated form, though not always so.

"Intercrystalline shrinkage" is a separation of the bond between the crystals present in the inside of the metal due to the contraction of the same on cooling.

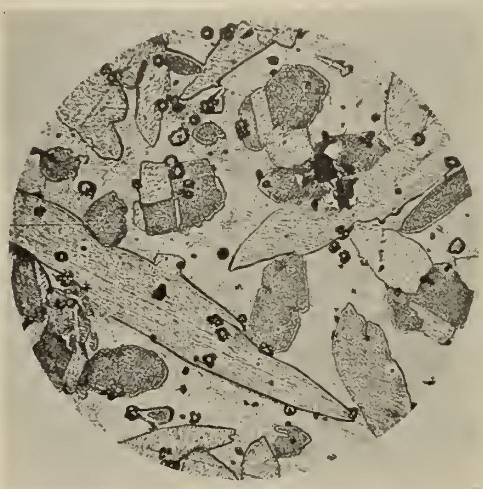

**Fig. 3—Manganese Bronze Casting, Magnification 100. Cooled in Sand.**

**Fig. 4—Manganese Bronze Casting, Magnification 100. Quenched from 1,000 degrees F. in water.**

"Crystal growth" is the simple increase of size of some crystals at the expense of others, such growth going on while the metal is in the solid phase.

A "dendrite" is a crystal formed during solidification having many branches and a tree-like pattern, the word comes from the Greek dendron—a tree.

The use of Greek letters to describe various compounds or phases is merely for the sake of nomenclature; numbers 1, 2, 3, etc., or the Roman alphabet A, B, C, would do equally well, except perhaps for the thought that the use of the Greek symbols gives a touch of erudition.

### Manganese Bronze

Consider as an example of the non-ferrous alloys a piece of manganese bronze, as it is generally called. Is this just a lump of metal? No, it is an aggregation of polyhedral crystals themselves of duplex structure. This duplex structure is capable of being enlarged or reduced, or resolved into one homogeneous mass of crystals by heat treatment. Accompanying these structural changes are increases or decreases in hardness, elasticity, tensile strength, yield points, etc. Therefore, this lump of metal is really very complex in nature. If this metal is heated to 1,500 degrees F., still a solid, quenched in cold water and again examined under the microscope, it will be found that all the duplex structure has gone into solid solution, or, rather, the Alpha Beta of the original has been changed by the Beta dissolving all the Alpha, leaving the whole of the metal in the Beta condition (see Figs. 6 and 7). If something is known of the physical constants of the Alpha and Beta, one may be guided as to what to expect in the way of physical changes due to the treatment. When it is known that strengths of from 55,000 to 110,000 pounds per square inch can be produced in manganese bronze, mainly by altering the ratio of copper to zinc in this alloy together with roughly 1 per cent of tin, aluminum, manganeze and iron, it will be realized that non-ferrous alloys have just as many complications as their ferrous cousins.

The best tool for studying the inside structure and activity of a piece of metal is the microscope. The procedure is as follows: A piece of the metal is obtained of about the same dimensions as a piece of cube sugar. One face is ground to a plane or flat surface by means of emery paper of increasing fineness. Finally it is polished and mounted so as to bring the plane surface at right angles to the vertical axis of the microscope. It should be mentioned that polishing differs essentially from grinding, no matter to what degree of fineness the latter may be carried. Polishing causes the metal, even the hardest, to flow, and an amorphous surface layer of extreme thinness is left by this operation. If the inside structure of the metal is to be viewed this amorphous layer must in general be removed. This is accomplished by etching the layer of metal with a suitable solvent. Certain structures, such as particles of slag, holes and unalloyed metal may be examined before the amorphous layer is removed, as these have resisted the flow effect and stand out in relief. In the case of the manganese bronze under discussion, a good etching medium is a 10 per cent solution of ammonium persulphate in water followed by an instantaneous dip in a weak solution of ferric chloride in hydrochloric acid, washing with cold water and drying rapidly.

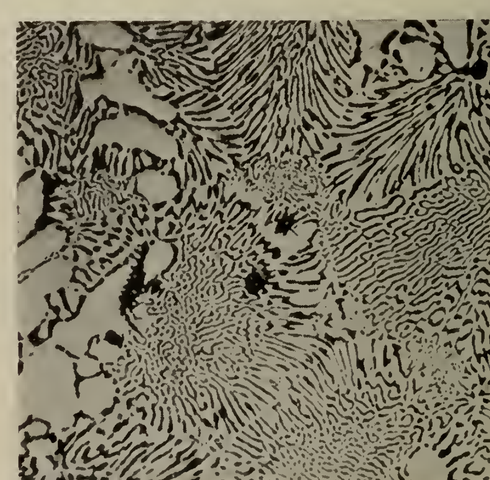

**Fig. 5—Eutectic Solder, Magnification 100. Tin 63 per cent. Lead 37 per cent.**

### Brass and Bronze Alloys

It might be well at this point to define the terms brass and bronze. Brass is an alloy of copper in which zinc is the dominating alloy element. Bronze is an alloy of copper in which zinc is not the dominating alloy element. It used to be stated that bronze was essentially an alloy of copper and tin but there are now bronzes that contain no tin at all.

As a further study consider briefly the constitution diagram of the copper-zinc series. The constitution diagram of any given series of alloys sums up the knowledge of the reactions of this series to alteration of ratio between the two components and of these ratios to varying temperatures. It is the result of the combined efforts of the foundryman, the metallurgist, the chemist, the physicist, the metallographist and the X-ray specialist. The data are obtained by:—

**Fig. 6—Manganese Bronze Casting, Magnification 100. Cooled in Sand.**

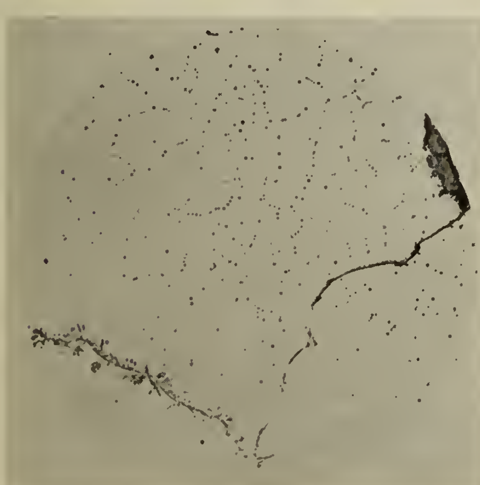

**Fig. 7—Manganese Bronze Casting, Magnification 100. Quenched in water from 1,000 degrees F.**

1. Melting a number of alloys of the two components from 0 to 100 per cent of each.
2. By making a thermal analysis of the various alloys, that is, recording the varying rates of cooling of the alloys and the peculiarities of the rate of cooling in each individual alloy.
3. By quenching samples at varying temperatures and examining them for their anatomical structure under the microscope.
4. By making X-ray examination of particles of these various alloys at the different stages.
5. By making chemical analyses of the various heats to check up the ratio of one component to the other and in rarer cases to ascertain the composition of compounds collected by means of centrifugal separation from the liquid phase.

Thus it will be seen that the final constitution diagram of this copper-zinc alloy series as in Fig. 8, or any other, is the result of collecting together the work of many investigators.

This constitution diagram shows that all the area above the curved line 1083, 905, 833, and 800 represents liquid metal, that is that any alloy of copper and zinc of given composition is entirely melted when raised to a temperature within this area. If any given spot be chosen on the diagram its physical condition as to liquid or solid, or both, is indicated, also its composition as to copper-zinc ratio and also as to its being in a state of solid solution or otherwise. Another important piece of information is the spread in temperature during which the metal is partly solid and partly liquid. This is indicated on the diagram by the liquidus-solidus area at any given point of composition. This will be referred to again later.

It is clear that any alloy of copper and zinc having under 33 per cent of zinc is in a state of Alpha solid solution at any temperature at which the alloy is solid. When 35 per cent of zinc is reached the alloy may be either a mixture of Alpha and Beta if quenched at any temperature higher than 1,300 degrees F.; or again entirely Alpha solid solution if below this temperature. It must be remembered, of course, that the constitution diagram is based on the alloy having time to reach its equilibrium at any given temperature. This is not always the case when an alloy is cast in sand, and never so if cast in a chill.

In general solid solution alloys are the most resistant to corrosion. This is especially so in the copper-zinc series. The 20 per cent zinc alloy is resistant to many corrosive liquids despite the corrodability of ordinary zinc in such liquid media. The well known Muntz metal is the 40 per cent zinc alloy of this series. This is not a solid solution but an Alpha Beta structure at any temperature below 1,410 degrees F. The area of the diagram made of Alpha and Beta Prime and Gamma is still under discussion and as Beta Prime is, if anything, a variety of Beta not distinguishable from Beta by microscopic examination, the matter need not be considered just now. An alloy of 45 per cent zinc will be practically a solid solution of Beta at any temperature at which it is in the solid phase. From 58 to 67 per cent zinc the alloy will be a solid solution of the Gamma phase.

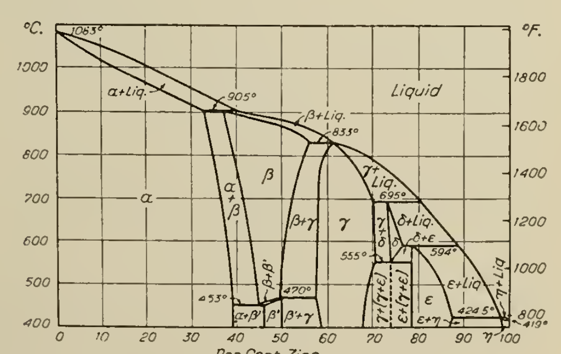

**Fig. 8—Constitution of Copper-Zinc Alloys.**

The engineer naturally asks what are the outstanding characteristics of these various constituents. Speaking for this series, the Alpha is a soft, comparatively weak constituent. The Beta is harder and stronger but less ductile. The Gamma is weak, hard and brittle. It is possible to so proportion the ratio of Alpha and Beta as to get within limits a required ductility with suitable strength and hardness.

Ordinary yellow brass is 30 per cent zinc and has the following physical constants as cast:—

Tensile strength....... 23,000 pounds per square inch

| | |
|---|---|
| Yield point | 7,000 pounds per square inch |
| Elongation | 35 per cent |
| Brinell hardness | 39 |

Muntz metal is 40 per cent zinc and has these constants:—

| | |
|---|---|
| Tensile strength | 40,000 pounds per square inch |
| Yield point | 14,000 pounds per square inch |
| Elongation | 40 per cent |
| Brinell hardness | 60 |

Brazing metal having 50 per cent of zinc must be carefully made as if the zinc be 52 per cent there is danger,

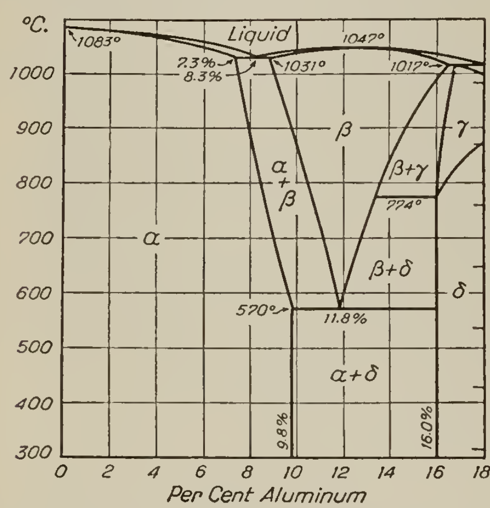

**Fig. 9—Copper-Aluminum Constitution Diagram. (Stockdale.)**

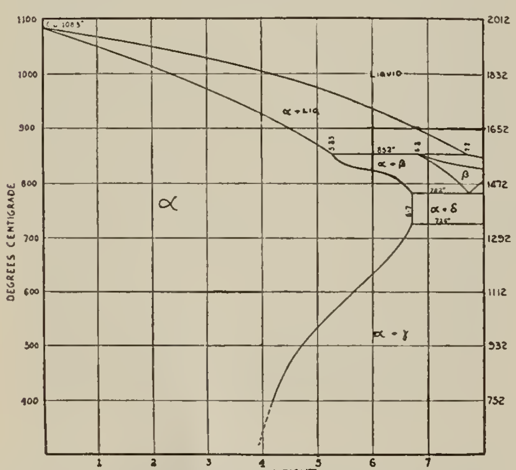

**Fig. 10—Copper-Silicon Constitution Diagram. (0-8% Silicon.) (Smith.)**

despite the chill effect of brazing, of getting some of the brittle Gamma constituent which greatly weakens the joint. The Gamma constituent of the copper-zinc alloys is not suited to mechanical uses, the same applies to the Delta, Epsilon and Eta modifications, until over 96 per cent of zinc content is reached.

The copper-zinc constitution diagram has been covered in some detail as it gives a good example of the complexities of non-ferrous alloys and the need of study of such aspects in the non-ferrous field.

### Solidifying Temperature Range

Certain alloys give trouble in the foundry and subsequently in the worked state due to segregation or solid solution concentration of the alloy components. The possibilities of this segregation or solid solution concentration are greatest with those alloys having the steepest temperature gradient in the solidus-liquidus area. If a comparison is made of the constitution diagrams of the series copper-aluminum, 9 per cent aluminum; copper-zinc, 10 per cent zinc; copper-zinc, 20 per cent zinc; copper-silicon, 4 per cent silicon; and copper-tin, 10 per cent tin, it will be seen that the solidus-liquidus temperature spread runs from practically nothing in the case of copper-aluminum to 54, 70, 130 and 270 degrees F. respectively for the remaining alloys (see Figs. 9, 8, 10 and 11). This means that the copper-aluminum alloy is in a class by itself as it passes directly from the liquid to the solid phase. This fact is a desirable quality from the point of view of the foundryman and the engineer and is a recommendation for the use of aluminum-bronze. At the same time aluminum-bronze has its own difficulties in connection with castings but as this is not a dissertation on a foundry subject, it is not necessary to go further into that matter at this time.

Of the remaining alloys the copper-zinc series lack the strength frequently needed, also corrosion resistance. The copper-tin alloy is the best known bronze but has the greatest temperature spread. The copper-silicon alloys have a reasonable temperature spread and have even greater strength than the tin-bronze and especially good anti-corrosion properties. It is this high temperature solidus-liquidus spread of the tin-bronzes that gives so much trouble in regard to segregation of high tin compounds and uneven crystals which carries with it varying solid solution concentrations, all of which tend to make for uneven corrosion attack.

### Choice of Alloy

The choice of a brass or bronze alloy for any given job is not always easy. Not only is strength a desirable feature but so is the property of being an easily cast alloy. After all a somewhat poorer alloy that can readily be cast by the ordinary jobbing foundry, at a comparatively low cost, may give a more reliable product than one requiring special moulding and melting experience that many foundries have not had occasion to acquire.

In making his decision it is well that the engineer should be acquainted with the outstanding features of

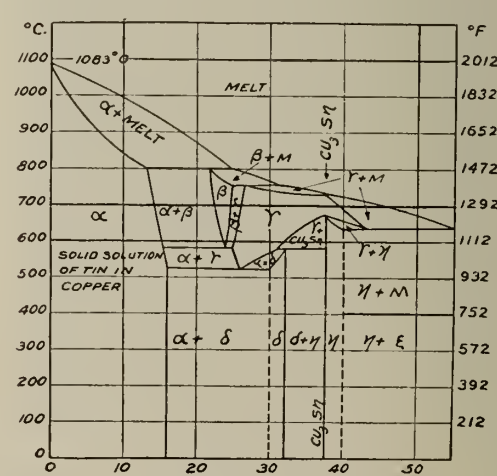

**Fig. 11—Copper-rich portion of the Copper-Tin Diagram.**

representative brasses and bronzes. High liquid to solid shrinkage generally goes hand in hand with great strength and shock resistance. The very shrinkage of the alloys results in the consolidation of the molecular and crystalline structure. The superior quality of steel over cast iron is in part due to the enormously greater shrinkage of the former. So it is that aluminum-bronze and manganese-bronze (or rather manganese-brass as it should be called) which have shrinkages nearly equal to steel, are the outstanding strong cast non-ferrous alloys. While manganese-brass, an alloy based on Muntz metal with certain 1 per cent additions, can have a tensile strength as cast of 110,000 pounds per square inch, aluminum-bronze has in addition to its strength of 70,000 pounds per square inch a greater fatigue resistance than manganese-brass. Unfortunately a high shrinkage constant gives a great deal of trouble in the foundry. Much greater care has to be taken to have as uniform a cross-section as possible, if not there is a strong tendency to develop surface and internal shrinkage at changes of cross-section, because the molten metal does not readily feed the heavier section on account of the fact that it is isolated by thin sections that solidify before the heavier ones. It is true, of course, that chills can be introduced and risers provided to offset these difficulties.

Another difficulty in the cases of aluminum and manganese-bronze is the readiness with which they form dross when they are agitated, the dross being composed of the oxide of the metal. If such dross remains in the casting it means weakness and porosity. Many mechanically ingenious methods have been worked out by the foundryman to offset this drawback. Naturally the special methods required increase the price of the castings from this type of alloy as compared with alloys less difficult to handle. The benefits of these super-strength brasses and bronzes are obvious and where the work is of sufficient importance to justify it they should, of course, be specified. Similarly special provisions have to be made in the production of castings of pure aluminum and to a less extent for the aluminum light alloys, while those of magnesium make still greater demands.

This is not a paper for foundrymen and the details of casting methods do not call for discussion. It is thought, however, that an understanding of the general founding characteristics of alloys is of benefit to the engineer.

On account of these difficulties of high shrinkage and drossing proclivities, alloys giving less trouble are to be preferred for ordinary purposes. The well known alloy copper 85, tin 5, lead 5, zinc 5 has comparatively small shrinkage and no drossing tendency, nor is segregation of the components a problem, the tin and zinc forming solid solution alloys with the copper, only the lead retaining its identity.

The alloy 88 copper, tin 10, zinc 2, is also free from drossing proclivity and undue mass shrinkage but it is sensitive in regard to intercrystalline shrinkage, particularly in the presence of traces of silicon or aluminum. By traces is meant percentages of the order of 0.005 per cent. Both these alloys are sensitive to chill effect, that is when cast into a sand mould in the form of a bar, say, 1¼ inch square and 6 inches long, the metal on fracturing will have a close fine texture for a depth of 1/16 inch to ⅛ inch, while the inner portion will be comparatively coarse. The more uniform and the finer the grain of a metal the better its properties as to pressure and corrosion resistance. It is for this reason that the recent silicon-bronzes such as P.M.G. have found favour.

These silicon-copper alloys have slight drossing characteristics but much less so than manganese or aluminum-bronze, their shrinkage is also less while their general constants are in between these and the tin-bronzes. The solidus-liquidus range at 4 per cent silicon is about 130 degrees F., about half that of a 10 per cent tin-bronze, and the alloy is in the solid solution group. Silicon-copper alloys have little if any chill effect when cast into sand, which means that the close grain structure extends throughout a heavy cross-section even up to 3 inches, which in its turn explains to some extent at least their pressure and corrosion resistance properties.

### Forgeability

Forgeability is often a desirable attribute. Brasses containing less than 35 per cent of zinc are not readily forgeable. This is borne out by the fact that castings of these metals are commonly heated to a red heat and broken up by a sledge hammer. Manganese-bronze, aluminum-bronze and silicon-bronze may be readily forged at a bright red heat and tin-bronze also but to a less extent and between narrower temperature limits (further reference to these bronzes is made under section "Heat Treatment"). In fact in the case of aluminum-bronze a gate of, say, ½ inch cross-section attached to a casting may be twisted a complete turn and back again while at a bright red heat without detaching it from the casting. Muntz metal, the copper-zinc alloy of 40 per cent zinc, forges well at a red heat due to the Beta associated with the Alpha, while in the cases of aluminum-bronze and silicon-bronze the Alpha is itself forgeable.

### Precipitation Hardening and Heat Treatment

In the field of the aluminum and magnesium light alloys considerable advance has been made in precipitation hardening and heat treatment. As already stated the mechanics of precipitation hardening is that there is a constituent in the alloy (generally in small proportions) that can be put into solid solution at one temperature and reprecipitated in a fine state of division at another temperature. Frequently the reprecipitation takes place slowly at room temperatures but can be made to complete itself in a few hours under the correct heat treatment temperature. At its best the precipitated substance is too fine to be seen microscopically but its effect is shown in the improvement of the physical properties. The new copper-beryllium alloys give an outstanding example of precipitation hardening. The constitution diagram (see Fig. 12) indicates that there is a solid solution area of Alpha possible up to 2.4 per cent beryllium, that there is an Alpha Beta and Beta area and an Alpha and Gamma area.

In this alloy Alpha is ductile, Alpha Beta hard and brittle and Alpha Gamma hard and not brittle. With this to work on it is found that if an alloy of 2.15 per cent beryllium be cast and quenched at a temperature within the Alpha area, say 1,472 degrees F., it can be retained in the soft Alpha condition. If this metal be then reheated to

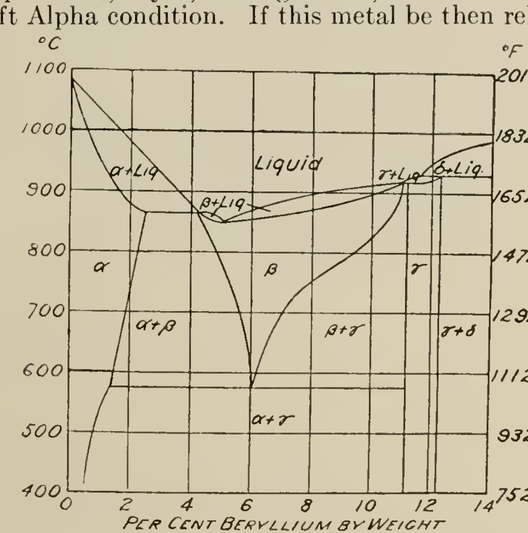

**Fig. 12—Copper-Beryllium Constitution Diagram.**

572 degrees F. for two hours the Gamma phase will be precipitated in a very fine state of division with the following astonishing results:

| | Quenched from 1,472 degrees F. | Quenched from 1,472 degrees F. and reheated to 572 degrees F. |
|---|---|---|
| Tensile strength.................. | 70,000 | 175,000 p.s.i. |
| Yield point....................... | 31,000 | 134,000 p.s.i. |
| Elongation........................ | 45 per cent | 6.3 per cent |
| Brinell hardness.................. | 110 | 340 |

### Heat Treatment

In the case of aluminum and manganese-bronze heat treatment is used to hold the alloy in the required condition, Beta or Alpha form (at other times the Alpha Beta mixtures are obtained by altering the composition). Copper-tin bronzes afford an opportunity of heat treatment and, in fact, the Chinese thousands of years ago were well aware of this possibility, although probably not knowing the underlying scientific reason. For example, when they wanted to

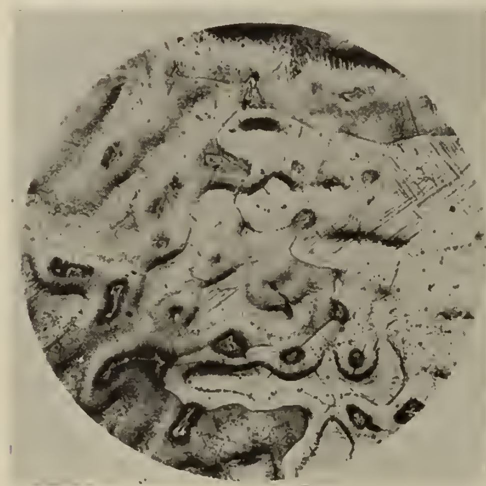

**Fig. 13—10 per cent Tin-Bronze, Magnification 100, as Sand Cast. (Note Dendritic structure and tin-copper compound.)**

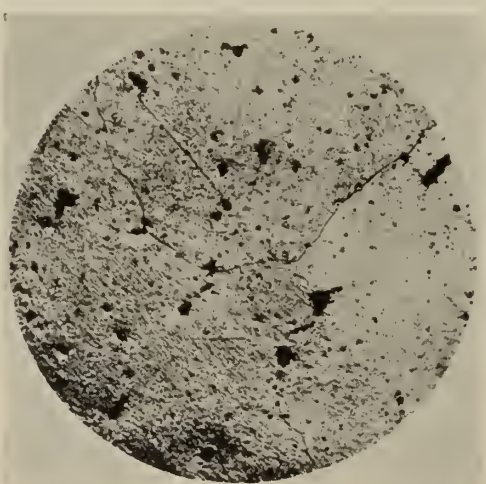

**Fig. 14—10 per cent Tin-Bronze, Magnification 100, as Annealed at 1,000 degrees F. (Note that Dendritic structure and tin-copper compound have gone into solid solution.)**

hammer out bronze gongs they heated the bronze to a dull red heat because they found that until this temperature was reached the bronze was brittle. They also found that if they heated it to a bright red heat it again became brittle, with the result that they forged or hammered out their gongs within this temperature range.

Assuming that the bronze was of a composition 17 to 20 per cent tin, then the explanation is as follows: The Alpha constituent is soft and ductile, the Beta constituent is stronger and less ductile, the Gamma and Delta constituents are hard and brittle. A mixture of Alpha and Beta is forgeable at the right temperature. A mixture of Alpha and Delta is not forgeable. In addition the change from Alpha and Delta at room temperatures to Alpha and Beta occurs at about 1,000 degrees F. (a just visible red heat) and is complete at 1,472 degrees F. (a bright red heat) above which part of the interior of the alloy is liquid, which is a scientific explanation of the Chinese modus operandi. (See Fig. 11.) The forgeability of Alpha Beta depends on the fact that both constituents are forgeable, whereas in the case of Alpha Gamma, although the Alpha condition is forgeable, the Gamma is not. In the case of the low tin-bronzes, the Alpha condition can itself be forged.

The characteristic dendritic structure of 10 per cent tin alloys can be removed by annealing at 1,000 degrees F. (see Figs. 13 and 14).

### Importance of Homogeneity

The importance of homogeneity in brass and bronze as to density and crystal size is a point often overlooked by the engineer and as a result pressure and corrosion characteristics are not what they should be. Not only should the engineer want good metal to go into the casting but also that the casting be of a nearly equal strength as the absolutely necessary changes in the cross-section will permit. If the casting is to be subsequently machined and then used for pressure work or corrosion resistance the uniformity of the crystals and also the actual size of the same become of major importance.

Take a bushing of, say, ¾-inch wall as cast, with a heavy collar near one end of, say, 1½-inch cross-section. The sand cast bushing in, say, 88 copper, 10 tin, 2 zinc will have a narrow width of chill, in which area the crystals are small and of uniform size, the centre portion of the metal having larger crystals. In the inside of the heavy cross-section these crystals will reach their maximum and unless special provision has been made they will be very dendritic. The cohesion of large dendritic crystals is likely to be weak and moreover microscopic channels may exist and finally reaching the surface, the casting leaks. Safety lies in providing ample feeding of hot metal to such a heavy cross-section of the casting so that even if the crystals are large they will be dense and well knit together. Such a casting will not leak under hydrostatic pressure. Another protection is to chill the metal at this point.

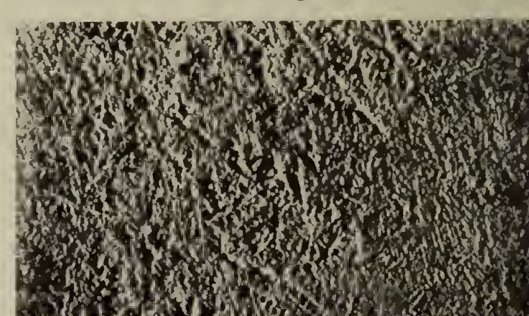

**Fig. 15—Three-inch Diameter Bronze Stick Composition. 85 per cent copper—5 tin—5 lead—5 zinc. Unevenly Fed.**

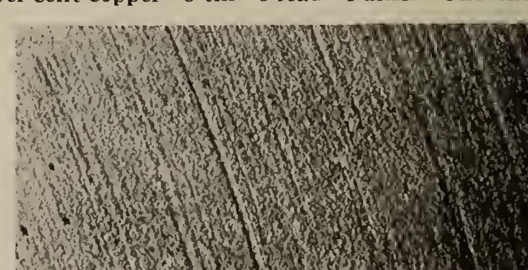

**Fig. 16—As Fig. 15. Evenly Fed. (Scratches are saw marks.)**

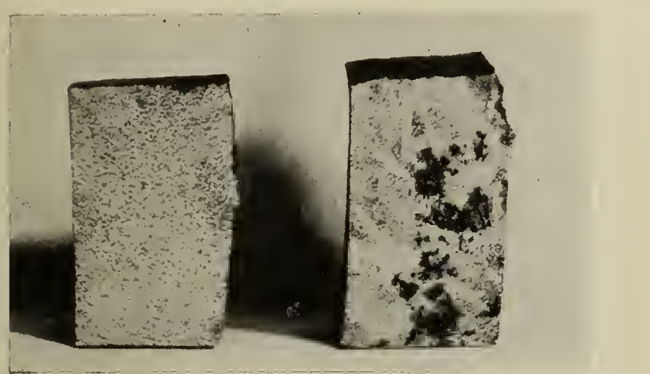
If the problem is one of corrosion resistance it is not enough to have the crystals well knit but they must also be of the smallest size that is compatible with maximum cohesion. Stick bronze of composition 85 copper, 5 tin, 5 lead, 5 zinc, gives a good example of homogeneity. In general stick bronze is not homogeneous as to crystal size and for this reason does not resist corrosive attack uniformly. This can be shown by sawing a 3 inch stick of brass in two, grinding one half to a flat surface and "deep etching it." By deep etching is meant putting the casting into a dish containing a solution of three parts of nitric acid, one of hydrochloric and one of water, all acids being commercial, and leaving it there for ten minutes. It is then removed and plunged immediately into cold water, finally washed under the tap, dried and painted with clear white shellac. After such a treatment the stick brass will have a



A B

**Fig. 17—P.M.G. Bronze. A—properly made, B—coarse crystals.**

surface that shows that it is not uniformly attacked. The chilled outside edge will be found to have eaten away uniformly but fissures will be seen between the crystals in the inside area. (See Figs. 15 and 16.)

If the metal be allowed to enter the mould in a manner to permit it to feed itself uniformly and the same test be applied, it will be found to be attacked equally over the whole area by the etching solution, there being no crevices opened up between the crystals. Apart from the composition or nature of the alloy it will be found that this fineness of grain and maximum provision for shrinkage must be provided if the best results are to be forthcoming. Another example is that shown in Fig. 17 of P.M.G. alloy, one with small uniform crystals and the other with un-uniform crystals.

### Relation of Design, Pattern and Final Casting

The engineer generally wants strength primarily, that is strength in the whole of any given casting. It is reasonable to assume that the useful strength is that point at which the relation between the actual strength of the casting and the maximum force it has to withstand bear the lowest ratio to each other. There may be parts in the casting that are actually weaker than such a point but which under the conditions have less strain put upon them. In order that the engineer may attain his objective he must consider in his design the characteristics of the metal to be used and the practicability of producing a satisfactory casting in the foundry. This entails either a knowledge of such matters or consultation with those who have such knowledge. In the matter of shrinkage, this characteristic of the alloy does not mean the shrinkage indicated on the patternmaker's rule, but the performance of the alloy where a heavy cross-section joins a light. Other considerations such as the need of elimination from the casting of sharp angles and undercut projections, and the limitations of the founding art concerning small diameter cores of considerable length, etc., etc., must receive attention if trouble is to be avoided. The more consultations between the designing engineer, the patternmaker and the foundrymen, the better. It is not uncommon for the patternmaker to be instructed to keep the machining allowance low in order to reduce the weight of the casting and therefore the intrinsic value thereof. In such manner is the door opened to false economy. It is true that the foundry replaces free of charge, that is free of direct charge, a faulty casting, but the engineer is put to the expense and loss of time that the machining has required. A more generous machining allowance is in the end an economy of both time and money. A custom that has nothing to recommend it is that of producing a pattern of improper foundry design and as the first foundry to which it is sent turns out a bad job, shopping around from foundry to foundry until some unlucky wight succeeds, more by good luck than good management, in obtaining one satisfactory casting. This immediately strengthens the purchasing agent's hand and he says to all the other foundries—"We got a good casting from A, therefore the pattern is all right." The fact of the matter is the pattern design was fundamentally wrong and although under a fortuitous combination of circumstances one good casting was obtained, it is no argument that the pattern was right. Had the pattern been right all reasonably good foundries would have been able to handle it.

Suppose that the casting has been properly designed, properly "patterned" and cast, it may still be spoiled by poor machining, either due to sharp angles or rough finish. Engineers of all people should appreciate the result of these errors in connection with their stress concentration effect, a frequent cause of subsequent progressive fracture. Much has been said and doubtless much has been learned in this connection but every day brings examples of the continuation of these fundamental mistakes.

### Test Bars

No discussion of this nature should omit the vexed question of test bars. The requirement often made is that the test bar form an integral part of the casting. The reason for this is that it was intended to protect the purchaser from the reprehensible custom of submitting as representative of the given casting a test bar from another melt altogether. However test bars have been welded onto steel castings after they were cast but before the inspector arrived. The answer to this sort of malpractice is to confine one's dealings to firms of recognized and established probity. There is, of course, a reason for the statement that it is unsatisfactory to insist on the test bar being integral with the casting, and the answer is found when it is agreed as to what is the purpose of the test bar. It is neither to indicate the strength of the casting at all points nor to inform one of the strength of the casting at any

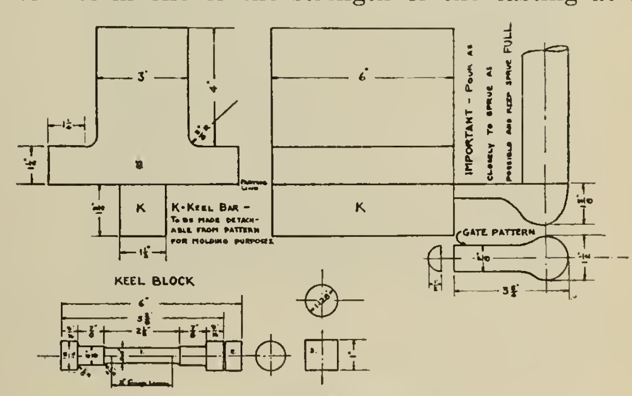


**Fig. 18—Standard Keel Block.**

particular point nor to show the elasticity or rigidity of the casting; the function is simply to show the quality of the metal used to make the casting—nothing more. This can only be done if the test bar is cast at the optimum temperature for the pattern from which it is made, the pattern itself being such as to bring out the reasonable constants of that particular metal. The nearer the cross-section of the test bar is to the average cross-section of the casting, the better. For example, it is fairer and better for all concerned to cast a reasonably heavy bar rather than a small cast to size bar. When the test bar is machined out of the larger bar the element of skin strength is eliminated and although some of the constants obtained may be lowered, they give a good average as compared with the small bar and its higher constants due to skin or chill effect.

One of the most important considerations is the complete feeding of the test bar.

Let us look at the keel block form of test bar, described, though not originated, some years ago in the Roast-Newell

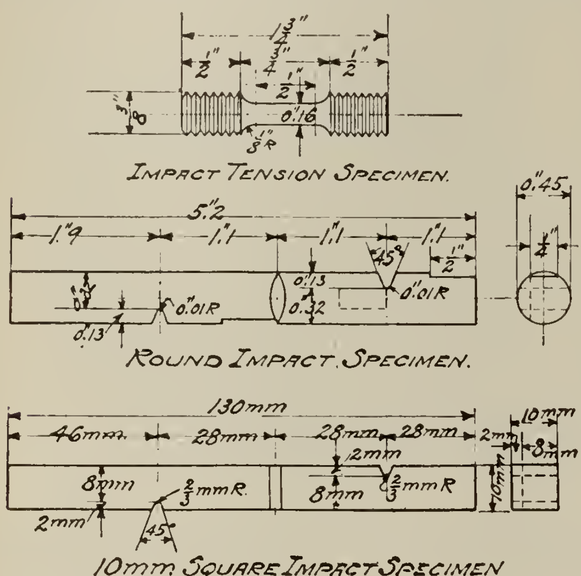

Fig. 19

paper to which reference has already been made. This pattern ensures perfect feeding, gives a fairly heavy cross-section from which to machine the bar, has a reasonably slow cooling rate (made as it is in a dry sand mould), gives three bars of closely agreeing physical constants and will, in the hands of different operators, give closely agreeing results (see Fig. 18). If desired, one side bar can be used for tensile test, the other for Izod test, as per Fig. 19, and the keel bar for compression specimen and Brinell. The shock or impact test as also indicated in Fig. 19 will be found useful.

If the test bar be attached to the casting it may draw metal from the casting and thus weaken it or may be drawn upon by the casting, thus weakening the test bar. Further, the temperature of the metal at the time of its entry into the test bar may not be the optimum temperature required. When it is borne in mind how sensitive is the question of feeding molten metal as it passes from the liquid to the solid state, then one can appreciate the differences in physical constants between one part of a casting and another. This is a problem of design and foundry practice and is a thing apart from the quality of the metal. If, however, the metal poured is not of good quality, then the whole of the casting will be inferior. This question of quality of metal is what the test bar controls.

If the importance of the casting justifies it, the casting may be cut up or fractured, the fracture examined and test bars taken from areas of different cross-section. After this the engineer and foundryman in consultation will be able to modify the design and pattern to correct any weaknesses that have been discovered.

### Specifications

Nine-tenths of the non-ferrous alloy specifications should be eliminated. Practical scientific bodies, such as The Canadian Engineering Standards Association, The American Society for Testing Materials, The American Foundrymen's Association, The American Institute of Mining and Metallurgical Engineers, The American Society of Mechanical Engineers and the British Standards Institution have stamped with their considered approval enough non-ferrous alloys to cover all but the most unusual requirements. Why then are over 8,000 alloys listed in so recent a book as "Engineering Alloys"?* Largely because individual consulting engineers, plant engineers and supply engineers have from time to time found a certain piece of metal to give long and satisfactory service. This they proceed to have analyzed (as though composition were the main criterion of longevity) and the result of this analysis is recorded and becomes alloy 8001. The more scientific way is to study existing standard alloys and see which one is most suited. It is a pity that so little information is to be had regarding the proved uses for alloys and this is a field that needs considerable extension.

In any case some alloy has to be specified and composition is the easiest starting point. Certain metals and metalloids shall and others shall not be present. There are admitted limitations to chemical analysis, all percentages therefore should be expressed as maximum and minimum and desired figures, and in the case of small amounts of impurities a note as to how much should be taken for analysis, the absence of which impurity under these conditions should constitute "none."

The question as to whether virgin metal or other is to be used will be covered in part by the price the engineer purchaser wishes to pay. It is no use specifying virgin metal and then shopping around until the lowest price submitted is less than the cost of the component virgin metals, to say nothing of manufacturing cost and profit. It has been abundantly proved that in many instances good scrap metal is at least equal to virgin, particularly if to the usual additions there be added a modicum of metallurgical brains. The most direct check on metal quality is the test bar under the conditions already described. It is legitimate and desirable to add that the casting shall be clean and free from shrinkage, either inside or out. It is unfair to insist on anything in a specification that is not actually checked by the purchaser. Neglect to do so reacts unfairly on those who charge a fair but higher price for fulfilling all the requirements stated as compared with those whose price is lower because they do not intend to fulfil all the conditions.

It would be a great help to the foundry if purchasing agents wanting a special alloy would state the name of the specification as well as the designating letter or number. If these designations were prefixed by such letters as S.A.E. and C.E.S.A., etc., the information could readily be obtained.

### Wear

The question of wear is of interest to engineers and there are many anomalies in this connection. For instance the hardened steel razor blade is sharpened on a soft leather strap, the hardness of the rubber eraser on your desk is shown by the scleroscope to be greater than the hardest steel, augers are sharpened on a soft lead banded wheel. Similarly the softer, less dense bronze will outwear a harder, denser bronze under such conditions as bearings for locomotives.

In a series of tests recently made on bronze, two pieces of identical size and shape were put in a suitable machine, ample lubrication provided and the specimens pressed against a revolving steel axle. The two sets were made of the same chemical composition, actually out of the same melt, the one cast so as to be dense metal, the other to be more porous metal. After cleaning the specimens the weight was taken at each one million revolutions. The softer, weaker, and less dense bronze showed the least wear. This led to an investigation as to the oil absorbing properties of the two classes.

It was found quite feasible to get constant results, by washing the specimens, weighing about an ounce, in ether,

*Published by the American Society for Metals.

placing them in a desiccator, drying them, and after allowing them to reach the same temperature as the balance room, weighing them to within one tenth of a milligramme. They were then warmed to 200 degrees F., and put into the lubricant used for the test. After an interval they were removed, wiped and weighed till the weight remained constant. The increase in weight was taken as representing the oil absorbed. The better wearing bronze showed a definite increase over the other in the amount of oil absorbed.

### Aluminum and Magnesium Alloys

Aluminum and magnesium base alloys include outstanding examples of the rapidity with which scientific discoveries are turned into commercial accomplishment and not by hit and miss rule of thumb methods but by definite logical scientific reasoning. Duralumin, with the general composition copper 4 per cent, magnesium 0.5 per cent, manganese 0.5 per cent, balance aluminum, is a good example. Starting with aluminum, a metal of high shrinkage constant, difficult to cast, low in strength, incapable as all really pure metals are of improvement by heat treatment, the addition of such metals as copper and silicon suggested themselves. While this gave higher tensile factors, the strength and the hardness were still low. Attention was turned to the possibilities of precipitation hardening, so thoroughly investigated by Merica, it having been found that the copper-aluminum compound $CuAl_2$ could be put into solid solution by heating to 932 degrees F. and quenching in water. The alloy would then age-harden at room temperature until the strength was double.

As magnesium is only some two-thirds the weight of aluminum, and as the demand was growing for still lighter fabricating alloys, the magnesium base alloys have developed along the same general lines, till today there is the Dow Company's alloy of magnesium having, after heat treatment, a tensile strength of 39,000 pounds per square inch.

In England a company has developed an aluminum-magnesium-cerium alloy for use in aeroplane parts. This alloy indicates the complicated nature of some of these light alloys. It contains copper, nickel, magnesium, silicon, iron, cerium about 1 per cent, balance aluminum. It is capable of heat treatment based on precipitation hardening and before heat treatment the chill cast material has a Brinell hardness of 67 to 77. After heat treatment the Brinell hardness is between 130 to 140. At the same time the yield point and tensile strength are increased.

### Co-operation of Engineers

Two influences have been at work all these years. The steady logical research of trained metallurgists and physicists, undertaken purely as research, and the demands of the engineer for ever stronger and lighter alloys to meet the new call for heavier than air transportation and lightweight trains. The co-operation of both has been necessary to bring the light alloys to their present development.

### Tin-Lead Alloys

Another division of non-ferrous alloys is that of white metals exclusive of aluminum and magnesium, namely tin, antimony and lead. In general the uses of solder and babbitt are well known, but even here much progress has been made since definite scientific methods have been invoked. This is especially true concerning the ill-effects of the presence of such metals and elements as copper, zinc, antimony, lead, silicon and occluded gases. Also of the importance of the condition of the surface of metal before tinning or babbitting, the definite effect of rate of pouring, temperature of metal and temperature of mould, etc.

Considering impurities first, the presence of zinc is apparent by the surface of the molten metal or the appearance of the exposed surface of the cast metal. Its effect is to make the alloy sluggish and difficult to pour, and to interfere with the proper adhesion of the two metal surfaces. The presence of copper causes the metal to act in a similar manner, a compound with antimony, $Cu_2Sb$, is very brittle and this has to be borne in mind. The unique violet colour of this copper antimony compound is a help in its detection (see Fig. 20).

In the presence of a sufficient quantity of tin the preference of copper for tin eliminates the possibility of the $Cu_2Sb$ existing under ordinary conditions and the preference of antimony for tin over its preference for lead gives rise to the compound SnSb.

In babbitting engineers are primarily interested in the adhesion of the babbitt to the bearing whether it be steel

**Fig. 20—Copper Antimony Eutectic, Magnification 100. Dark bars are violet $Cu_2Sb$ and dark background is also $Cu_2Sb$.**

**Fig. 21—Babbitt, Magnification 100. Composition. Tin 83⅓ per cent; Antimony, 8⅓ per cent; Copper, 8⅓ per cent; The squares are SnSb; the Stars are Tin-Copper compound.**

or bronze. It may be of interest to outline briefly the pitfalls in this connection. To take a bronze bearing as an example, tin is the best medium to use as a bond between the bronze and the babbitt. To list the pitfalls categorically:—

1. No proper adhesion is possible between tin and a cast metal surface due to the film of oxidized metal on the latter.

2. No mechanical bond, such as is attempted by the insertion of undercut V slots, is as good as the bond provided by the interpenetration of tin into the clean surface of metal and of the babbitt into the tin.

These figures are all the average results of actual tests on commercial quantities by Harold J. Roast M.E.I.C. and Lecturer in Metallurgy McGill University - May 1935

Drawing No. 30

Fig. 22—Physical Constants and Analyses of Non-Ferrous Alloys.

3. Cleaning of the metal surface includes not only the machining of the cast or fabricated surface, but also the prevention or the removal of any grease even such as is left by finger prints if the machined surface is handled. It is no exaggeration to say that even grease left by handling is sufficient to prevent proper tin penetration and subsequently babbitt adhesion.

4. Delay between the machining of the surface and tinning may result in the formation of a fine oxidized film hardly discernible, but which prevents adhesion. In this connection the condition of the atmosphere has a distinct bearing. In one plant bearings can be left for two or three days after machining with safety, while in a different location one must not allow allow an interval of more than twenty-four hours, less being desirable.

5. The use of sand blasting is not satisfactory as a cleaning medium. The treatment leaves a fine sand film on, or rather in, the metal that is inimical to proper adhesion.

6. The right application of zinc chloride flux.

7. There is an optimum temperature for all of the following that should be maintained if the best babbitting results are to be secured:

*a.* That of the solder.
*b.* That of the bronze back.
*c.* That of the babbitt.
*d.* That of the mould or mandril.

in addition attention must be paid to the cooling rate of the babbitt and mandril unit and the rate of pouring.

The same precautions apply to the babbitting of a steel shell.

The presence of sulphur and other occluded gases is another feature to be guarded against as it may be the cause of gas holes in the babbitt which may or may not be detrimental under the conditions of use. Methods have been devised to eliminate this gas condition. It will be seen from the foregoing that the apparently straight forward process of babbitting a bearing is not quite so simple as it may have been thought to be.

### Special Features

A few moments might perhaps be given to some special feature alloys. The engineer called for greater accuracy in measure. The linen tape varied in length according to the humidity, the incorporation of brass wire still left the alteration due to the expansion or contraction of the metallic wire, so the metallurgist provided Invar, an alloy that neither contracts or expands within a quite considerable range of atmospheric temperatures, this by alloying 36 pounds of nickel with 64 pounds of iron. The fire protection engineer called for metal that would melt below the temperature of boiling water, the metallurgist provided Woods metal, an alloy of 12½ per cent cadmium, 50 per cent bismuth, 25 per cent lead and 12.5 per cent tin, that melts at 160 degrees F., which is used to plug the water line in automatic sprinklers. The explosive engineer called for hammers and chisels that would not spark when struck. The metallurgist replied by exploding the Egyptian myth of the hardening of copper which was actually due to an unconscious alloying of tin to copper plus cold working. Such maximum hardness must have been somewhere between 70 and 135 Brinell. In its place the metallurgist offered the heat treated beryllium-copper alloy at 340 Brinell.

It is regrettable that some of the really startling optical effects in alloying cannot be shown. For instance, 200 pounds of molten manganese-bronze with all the metals in except 1 pound of aluminum will be a dirty brown colour if ingot is poured. Now add 1 pound of aluminum and the metal on ingoting is a bright golden colour, hardly believable in view of the small quantity of aluminum added.

Again, take 200 pounds of leaded-bronze, zinc 3 per cent, lead 15 per cent, tin 7 per cent, copper balance, and cast an ingot in the sand in a closed mould and the surface will be smooth and greenish brown. Add to the pot 1½ ounces of aluminum and then cast an ingot and it will be silvery white. Only about five hundredths of a percent of aluminum has been added. Repeat the experiment and add 1½ ounces of silicon, the surface of the ingot will be all worm eaten to a depth of one sixteenth of an inch and the colour will be chalk white.

Melt 1,000 pounds of battery lead, containing 5 per cent of antimony, and raise to 1,000 degrees F., the surface will be covered with an orange red liquid scum of molten oxides. Add 1 pound of tin and the orange red becomes silver colour and the molten oxide a dry powder. Only one-tenth of a percent of tin has been added.

Another example is that of the preferential attack on yellow brass by the "white water" of a pulp and paper mill. The "white water" with its various acids dissolves the zinc progressively and the alloy suffers dezincification. Only a fine wire of the original yellow brass is left surrounded by a copper rich material. The metallurgist provides a silicon-bronze wire screen for this purpose, that has no zinc content.

The engineer and the metallurgist hand in hand produce tungsten wire drawn so fine that 10 miles of it only weigh one ounce, or copper-nickel-chromium-nickel sheet so thin that it takes 500 sheets to make the thickness of an ordinary sheet of note paper. The sheets are only six millionths of an inch thick. The telephone desk set we all use has the following metals in its assembly, fourteen in all —aluminum, zinc, tin, iron, nickel, copper, silver, lead, gold, cobalt, chromium, magnesium, cadmium and palladium.

### Powder Metallurgy

Recently "powder metallurgy" has come to the fore. This is an instance of the engineer being the prime mover and the metallurgist the assistant, for while the metallurgist is necessary in order to prepare the metals used in the right form, the principle of "powder metallurgy" depends on the union of metal surfaces under conditions of extremely high compression and this compression is made possible by the ingenuity of the mechanical engineer. Various metals are prepared by reducing their oxides, casting, followed by mechanical pulverizing, or by electrolytic precipitation. The finely comminuted metals are then mixed and fed into a suitable press and given the desired form. This is generally followed by a heating process at a temperature below the melting point of any of the components and a final metallic product results strong enough to take the place of the usual cast bronze bearing of the modern locomotive, the product having a crushing strength of more than 75,000 pounds per square inch. This process has opened up the field of alloying, as it were, metals and graphite, and even metals and porcelain. The pressures required are considerable, running from 2 to 100 tons per square inch or, say, the pressure exerted by placing two of the largest loaded coal cars on each other and supporting the whole on a cube 1 inch square. The pressure required is a function of the area of cross-section and at present 6 inches diameter and 6 inches deep are the maximum possibilities.

In this paper an attempt has been made to show not only some of the relations between the engineer and non-ferrous alloys, but also to give some idea that complex problems in metallurgy are not confined by any means to the ferrous group of iron and steel.

The Roast-Newell paper contained a data sheet based on work done in a Montreal foundry by the author, to which several alloy constants have recently been added. This is now presented as a part of the present paper in Fig. 22.

# Modern Highway Construction in the Light of Past and Present Experience

*The Honourable Francois Leduc,*
*Minister of Roads of the Province of Quebec, Quebec, Que.*

**Paper presented before the Montreal Branch of The EngineeringInstitute of Canada, February 18th, 1937.**

**SUMMARY.—After sketching the development of motor traffic in North America, the author discusses the various factors which should now govern highway design, having regard to the interests of the taxpayer and the motor vehicle operator.**

The relationship between human existence and transportation is such that the economic and social welfare of the people of any country, or any region, depends to a large extent on the facilities of communications available there. These facilities appraised at any period are a fair indication of the existing state of society.

The rise of the Roman Empire saw a great advance in the art of road making. Twenty-nine highways radiated from Rome into various parts of Europe, Asia and Africa, thousands of miles of improved roads reveal the degree of civilization reached at that period and, ever since, Roman roads have been symbolical of Roman culture and domination.

The succeeding period known as the Dark Ages saw these roads abandoned and, in many instances, even deliberately destroyed. Transportation reverted to pack horses. Civilization and religion declined and many kings and princes could neither read nor write. The art of road building mastered by the Romans was lost to mankind and it was not until the middle of the eighteenth century that systematic road building was again undertaken with the construction of the King's Highway in France after the appointment by Louis XIV in 1764 of Pierre Marie Jerome Tresaguet, of Limoges, to the post of assistant inspector general of public works, in charge of all roads and bridges.

The revolution interrupted the development of the national roads of France, but later Napoleon gave it new impetus by extending the main highways and building crossroads. He organized a maintenance service with a patrolman for every 5 to 6 miles of road and maintenance materials stored along the road-sides, thus inaugurating the systematic maintenance of roads.

For centuries roads and vehicles improved slowly. At first, man used his own back and arms in carrying loads as is still done today in places where civilization has not yet penetrated. Later he learned to tame wild animals and turn them into beasts of burden and, in time, he found that a cluster of branches placed under a heavy load helped when dragging it along. Gradually the wheel and then the cart came into use.

Each succeeding improvement in load carrying devices necessitated corresponding improvements in ways of communication, and finally the original trails were transformed into roads of a definite width, free of trees, stumps and boulders. However, in spite of the slow though still gradual improvement in ways of communication and means of transport, locomotion remained practically the same for ages with the horse finally emerging as the favourite among the beasts of burden.

Then about the year 1769, Nicholas Joseph Cugnot designed the first motor vehicle to be operated by steam; and in 1827 Goldsworthy Gurney of England built a steam coach capable of carrying twenty-one passengers at a speed of 15 miles per hour on level ground. Sir Charles Vance, in 1831, organized the first public conveyance system, between Cheltenham and Gloucester, and five years later, in 1836, a law was passed in England obliging all mechanically propelled vehicles to be preceded, at a distance of one hundred feet, by a man on foot or horseback carrying a red flag, and limiting the speed to four miles per hour. This law was repealed in 1896 because no law, even that limiting the speed of automobiles to 30 miles per hour, can stop the march of progress.

About the year 1830, Carter, of Newark, New Jersey, invented the buggy which later was to be manufactured by millions in the United States. R. W. Thompson, an Englishman, invented the pneumatic rubber tire in 1876, which was not accepted favourably, because a silently moving vehicle was then looked upon as a public danger. Etienne Lenoir is said to have built the first gas-motor in 1859. Gottlieb Daimler, in 1884, patented a small gas-explosion engine and Karl Benz, in 1883, built the first motor vehicle to be operated successfully. In 1880, Amédée Bollée, of Le Mans, built a steam car "La Nouvelle" which, in 1895, covered 745 miles between Paris and Bordeaux in ninety hours, an average speed of approximately 8 miles per hour.

In the United States, Charles E. Duryea built his first gas-motor horseless carriage in 1892. R. E. Olds began experimenting with the internal combustion motor in 1892 and in 1895 built his first Oldsmobile. Barnum and Bailey exhibited an automobile in their circus in 1896. A man named Winton made the first authentic auto sale in the United States, on April 1st, 1898, and this feat was considered the best joke of the time. Henry Ford began experimenting in 1890, and in 1899 started to build autos commercially. And thus, forty years ago, there began a new era in highway locomotion which, although entirely unsuspected, was to see the motor vehicle quickly replacing the centuries-old horse-drawn vehicle.

**Fig. 1—Route No. 17, between Rigaud and Ste. Anne de Bellevue, Que.**

The advent of the motor car and the first years of its development found a great difference in condition between the roads of Europe and those of North America. While many of the European countries, and France particularly, had been endeavouring for many years to improve their road communications, the United States and Canada had been primarily concerned with the development of their railway systems. In spite of this disadvantageous condition, it was nevertheless in North America that motor vehicle transport was to expand most rapidly.

The good roads movement in North America first began in New Jersey in 1891 and in Massachusetts in 1894, Connecticut in 1897, and New York in 1898. The advent of the motor vehicle, in 1896, therefore coincided with the commencement of road improvement in North America, but the motor vehicle at that time, and for some years after, did not exert any influence on this movement, whose main object was the improvement of conditions for horse-drawn vehicle traffic and was for the benefit of the farmers in particular.

In order that bigger loads might be carried on these improved roads, they followed the line of least resistance by going around hills and all obstacles that were too expensive to overcome. A highway text-book printed in 1896, states that the reason Roman roads were built straight over hills was because the movement of armies, at the time, was more important than the movement of products and merchandise, but it adds that all arguments such as the saving of time, greater loads carried or economy of maintenance, justify a somewhat longer but nearly level line. In conclusion it states that the straight line is only an abstract idea of no practical utility.

Ten years later, the number of cars had increased from 4 cars in 1896 to 107,000 in 1906. Possession of a car then was looked upon as a luxury restricted to a few wealthy city residents. When travelling by auto on the surrounding country roads one was looked upon as a tourist. Horse-drawn vehicle traffic was still the major consideration in road improvement and the idea continued to prevail that road location should be around hills rather than over them so as to follow, as much as possible, the line of least resistance. In a book entitled "Economics of Road Construction" published in 1906, reference is again made to the Roman roads and their lack of regard to topography and recommends that roads be located so that the profile will average ½ per cent grades, with a maximum of 3 per cent and, if necessary and possible, the road location be shifted so as to secure better material for both sub-grade and surfacing.

Nine years later, in 1915, the number of motor-vehicles had reached a total of 2,500,000, including 136,000 motor-trucks, and still the horse-drawn vehicle was the chief consideration in rural road improvement. In Farmers' bulletin No. 505 of the United States Department of Agriculture, the statement is again made that it is advisable to go around hills rather than over them and so obtain better grades, and it also states that "on any grade in addition to the tractive force due to surface condition, the force of gravity must be overcome. The horse must also raise his own weight and because of the manner in which his strength is applied, it becomes less and less available as the grade increases." The same bulletin, however, mentions that each year the roads were being used by a larger number of automobiles and that the motorist had done a great deal to secure the improvement of roads.

As can be seen, most of the improvements on rural roads performed up to 1915, had in view the improvement of horse-drawn traffic conditions. Curves were of short radius, and 50 feet was usually fixed as a minimum except on roads with a certain amount of motor-vehicle traffic, where the minimum was in most instances 150 feet. But the situation was soon to change, with the motor-vehicle becoming a factor of important consideration in the design and construction of roads. The increase in this mode of transportation was such that those interested in road construction began to think of its future development. Few indeed had visions of what was really to come, as shown by the statement of a well-known authority on road construction who, as a foreword to his text-book "Practical Road Construction" published in 1917, made the following forecast: "With 3,500,000 automobiles (1916) in use in the United States, it is natural that there should be the widest interest among motorists in the improvement, construction and maintenance of public highways. It is altogether probable that the ultimate number will be double those now in use." This author estimated 7,000,000 as the ultimate number of automobiles in the United States but

Fig. 2—Isle of Orleans, Typical Gravel Road.

three years later, in 1920, motor-vehicles totalled 9,300,000 including 1,066,000 trucks.

By 1920, the horse-drawn vehicle was no longer a factor of importance in the design and construction of roads, but most of the improvements of the previous twenty-five years had been introduced mainly to meet the requirements of that kind of traffic, with the result that any increase in motor-vehicle traffic made these roads less adequate for a mode of transportation for which they were not intended. From 9,300,000 in 1920, the number of motor-vehicles in North America increased to 20,600,000 in 1925 and to 27,785,000, including 3,800,000 trucks, in 1930, the first of the economic depression years.

This constant and rapid increase in motor-vehicles, and heavy trucks particularly, then equipped with solid or high-pressure pneumatic tires, was playing havoc with road surfaces which had not as yet been improved to take care of this new type of traffic. So, from 1920, the rebuilding of such surfaces absorbed much of the effort made towards the improvement of roads. Moreover, many of the old pavements had to be rebuilt in order to satisfy the new load requirement. At first many of the pavements were built only 16 feet wide, but later the 18- and 20-foot width had to be adopted on main roads.

Thirty and thirty-five miles an hour were the speed limits generally fixed by law and at first the average speed of cars did not exceed these limits. Alignments, curves and visibility for such speeds were provided in new constructions.

Year after year, however, motor-vehicles were being perfected and rendered capable of faster movement, together with better control. Speed limits began to be ignored generally without much interference by the authorities and, by 1930, the average speed of cars had reached 40 miles per hour.

From 1930 to 1934, motor-vehicle registration decreased by about 3,000,000 in North America, but still the traffic on roads continued to increase as shown by a much greater gas consumption. In 1935, registration was on the increase again and, in 1936, it had almost reached the 30,000,000 mark.

At almost any time during its development, the motor-vehicle has been ahead of the road in technical perfection, but never has this been more evident than at present. The result is that, today, vehicles capable of high speed are being driven at sixty miles an hour on 30-mile-an-hour roads. This increase in speed capacity of motor-vehicles, coupled with the large increase, not only in the total number of vehicles but also in the number of miles covered yearly, has rendered inadequate for safe and economical driving at least 90 per cent of the main highways of most countries in the world and especially those where motor-vehicle traffic has increased most rapidly.

**Fig. 3—Highway No. 6 near Matapedia, Gaspe Peninsula.**

This situation is responsible for the intensive movements taking place in so many countries for better and safer roads, roads of a standard suitable for present day traffic and that which is expected in the near future.

Canada is one of those countries where motor-vehicle traffic has developed most rapidly.

Table I

Registered Motor Vehicles in

| | |
|---|---|
| United States | 25,163,000 |
| France | 1,914,000 |
| United Kingdom | 1,814,000 |
| Canada | 1,114,000 |
| Germany | 968,000 |
| Australia | 595,000 |
| Italy | 377,000 |
| Argentina | 255,000 |
| Belgium | 198,000 |
| Russia | 180,000 |
| Spain | 177,000 |
| Province of Quebec | 171,000 |
| Sweden | 149,000 |
| Denmark | 126,000 |
| Brazil | 125,000 |
| Japan | 120,000 |
| Czechoslovakia | 116,000 |
| Mexico | 90,000 |
| Ireland | 85,000 |
| Norway | 58,000 |
| China | 49,000 |
| Portugal | 34,000 |
| Poland | 26,000 |

In the number of cars per mile of road, the Province of Quebec occupied a still higher place compared to nations having the greatest number of vehicles.

Table II

| | |
|---|---|
| Belgium | 10.5 cars per mile of road |
| United States | 8.2 cars per mile of road |
| France | 4.9 cars per mile of road |
| Quebec | 4.2 cars per mile of road |
| Italy | 3.6 cars per mile of road |
| Spain | 2.5 cars per mile of road |
| Canada | 2.0 cars per mile of road |
| Argentina | 1.6 cars per mile of road |
| Russia | 0.2 cars per mile of road |

But neither the total number of vehicles, nor the number of vehicles per mile of road, give a true picture of the intensity of traffic on the roads of a country or locality.

This is especially true of Canada as a whole and of the Province of Quebec in particular. With a neighbouring country possessing, in 1936, approximately 28,000,000 motor-vehicles, or 70 per cent of the world's total number, and with a neighbouring province, Ontario, possessing nearly 600,000 vehicles, or one vehicle to every six persons, the Province of Quebec is in an exceedingly advantageous position as regard tourist traffic. In such circumstances it is obvious that cars of outside registration form a great part of the total road traffic.

The consumption of gasoline is a much better indication of traffic intensity than the total number of vehicles registered. For example, there were 149,000 vehicles registered in this province in 1928, and 171,000 in 1936, an increase of only 15 per cent in eight years. During the same period, the gas consumption rose from 66,729,000 gallons in 1928 to 106,540,000 gallons in 1936, an increase of 60 per cent.

Considering that motor-vehicles operating on Quebec roads in 1936 averaged, as a whole, more miles to the gallon than those of 1928, it is safe to say that the intensity of traffic increased by more than 60 per cent during that period, in spite of the fact that motor-vehicle registration showed only a 15 per cent increase.

This increased traffic is due to more tourists and to a larger yearly mileage covered by Quebec vehicles.

Great intensity of traffic on inadequate roads means unsafe and uneconomical operation of motor-vehicles. The situation of the Province of Quebec, in this respect, is unfortunately no better than that of countries with higher intensity of traffic.

The latest statistics available for the United States give 827,000 accidents with 37,000 killed, 105,000 permanently injured, 1,000,000 injured and a loss estimated by economists at $1,600,000,000 for the year 1935.

The total number of accidents, persons killed and injured is evidently less in Quebec but as high, if not higher, in proportion to number of vehicles as the following comparison will show:—

United States—1 person killed for every 700 motor-vehicles
Quebec —1 person killed for every 570 motor-vehicles

There is however this difference that whereas in the United States the majority of fatal accidents occur on highways, in the Province of Quebec they occur on city streets. Unless necessary steps are taken, the situation is likely to become worse, as in the former country there is one car to every 5 persons and in Quebec the ratio is one car to every 18 persons and, consequently, is more susceptible to increase.

The Province of Ontario, with a population not greatly in excess of that of Quebec, has approximately 600,000 motor-vehicles. On the same population-registration basis, Quebec should have 500,000 motor-vehicles instead of 171,000.

Toronto, in 1935, with a population smaller than that of Montreal had 124,754 motor-vehicles. In the same proportion greater Montreal should have had 150,000 motor-vehicles instead of 71,793.

Of course there are factors which will continue to prevent motor traffic developing as rapidly in the Province of Quebec as in Ontario, one of the most important being the heavy snowfall which closes most of the highways throughout the winter. There are only some hundred miles of roads kept open in winter at present but there may be a few thousand miles before very many years.

Everything considered, it is evident that there is room for a large increase in traffic on the roads of this province. With further increases also in the number of vehicles in the United States and the provinces of Canada, tourist traffic is bound to grow. For these reasons there seems to be no exaggeration in saying that ten years from now there should be 300,000 motor-vehicles in this province, and that traffic on roads should be two to three times what it is at present.

Inadequate roads are not only costly in the number of persons killed, permanently injured, wounded and in property damages, but also in the operating expenses of motor-vehicles. With the large increase in transportation of persons by automobile and of goods and products by motor-truck, cost of operation and time of displacement, which affect the cost of transportation, have become factors of economic importance. An average saving of one cent a mile in operation on vehicles averaging 8,000 miles a year, represents an annual saving of $80 per vehicle. Shortening the Trans-Canada highway between Montreal and Quebec by ten miles would result in an average economy for passenger cars and trucks of $0.75 per single trip or $1.50 a round trip.

As already stated, the advent of the motor-vehicle and its rapid development have made the majority of the most important roads in North America obsolete as far as safe and economical driving are concerned. In the past, efforts have been directed mostly towards improving the technique of pavement construction. Expensive but durable pavements with an expected life of twenty or forty years have been laid, with the best of supervision and care, only to be either reconstructed or abandoned ten to fifteen years later because of faulty location, alignment, or subgrade.

In modern highway construction, many of the factors that were formerly either ignored or neglected must now be given first consideration. The problem of road design and construction is a complicated and difficult one, which, to be solved adequately, must be the object of thorough study by the most experienced highway technicians.

It is not only necessary that roads be designed and constructed to meet present and near-future requirements, but in order that every dollar invested may be used to best advantage they should be built in such manner that the bulk of the work performed may serve in later improvements, when such are warranted by greatly changed conditions of speed, volume and type of traffic.

Rational road planning and construction now requires, first of all, a survey of existing traffic facilities on the important highways. This survey should include consideration of the width of right-of-way, pavement, shoulders and structures; distance between and depth of ditches; nature of pavement; degree of curves and sight distances; parking facilities, sidewalks, as well as a list and description of all obstructions and hazards that may affect the speed, volume and safety of traffic.

Next, a survey of road utilization should be made for the purpose of forming a picture of traffic conditions. The maximum daily number of automobiles, trucks, autobusses and horse-drawn vehicles should be noted together with hourly, daily and seasonal fluctuations. The origin and destination of such traffic according to class of vehicle, as well as the registration by cities, villages and counties should also form part of such survey. By use of the short-traffic-count method of traffic census, the survey may be made at less cost than by methods previously employed and should be just as efficient. This survey should include the collection of all data which may serve to evaluate the probable increase, or perhaps decrease, of traffic according to type. The improvement of a road often attracts traffic that hitherto used another road, and this fact must also be taken into account. Increase in population, industrial development, tourists and the potential capacity of the people to own vehicles are other factors to be considered in the design of each highway, or section.

A survey of road accidents must also be made with the location, cause, nature and time of each accident and covering as long a period as possible must be recorded. A study of the accident survey in relation to road facilities and use will help in determining the real causes of accidents and provide for their elimination when rebuilding.

Finally, a survey should be made of all the financial resources that are presently available, or which may later become available, to carry out a reconstruction programme. It is important that those entrusted with making any programme should be informed as to the money available in order that it may be planned and carried out in a rational manner. This survey would help in determining on which roads the proposed improvements may be undertaken, and carried through immediately; the improvements that may be undertaken, but carried out in stages; and finally any improvement which must, for financial reasons, be delayed two, three or more years. It would also be useful in carrying out a maintenance programme on the roads affected, and prevent any unnecessary expenditures.

From the surveys thus made, maps may be prepared to show, in a simple way, the existing road and traffic conditions for each highway, and section of highway, and the schedule of improvements decided upon.

In highway construction, the principal elements that must be considered are: (1) speed and volume of traffic and safety of the public; (2) the comfort of the travelling public and roadside residents; (3) the aesthetics of the road. All these elements affect the design of the road and for this reason must be fully considered, each according to its importance.

In highway design, the first detail to be considered is the location of the road. The existing location should be followed wherever possible, and, if a relocation is contemplated, both the advantages and the disadvantages of the actual and proposed location must be studied and weighed. Relocation, when the existing road is not to be closed to traffic, will increase the total mileage of roads

**Fig. 4—View along Route No. 17 at Vaudreuil Hill, showing Joseph Lalonde's house built in 1827.**

and therefore the maintenance cost. However, if the advantages gained by a relocation outweigh all other considerations it should be carried out as planned for the benefit of the public.

Perhaps the most important point in road design is alignment. Many roads built in the last twenty-five years have faulty alignment, and will have to be reconstructed with the total or partial loss of still serviceable structures, foundations and pavements, which could have been made use of if the road had been better designed in the first place.

Straight sections need not be miles long, but no break should occur in a tangent unless it is justified by some serious topographical or other obstruction, or by some unfavourable condition of the subsoil that cannot be remedied. The importance of the road, and the terrain through which it runs will, of course, dictate the alignment. On heavily travelled roads, perfect alignment is a primary necessity as any slight defect in the design will reduce the traffic capacity of the road as well as its safety.

Curves should be designed so as not to interfere with the normal flow of traffic, and so as to provide sufficient sight distances. In a country with variable climatic conditions the coefficient of friction between tires and pavement is subject to sudden change, and therefore the speed at which a curve can be negotiated with safety will vary. Frequent rains, sleet and icy conditions, render dangerous curves that can be travelled safely in dry weather. The banking of curves does not remedy the situation properly, and should be avoided wherever possible by providing easier curves.

On important roads, the degree of curvature should be such that no banking is necessary for speeds up to 60 miles an hour. Curves up to 1° 30′ will fulfil this requirement and should be adopted whenever possible. On the less travelled roads, or sections of roads, curves should be as easy as possible, and in open country should never exceed 6 degrees.

In future, transition curves between tangents and the curve proper should be adopted at least on the more important roads, as they are an improvement on ordinary curves.

Width of right-of-way is another detail of road planning which should be given the best of attention. The procedure of first fixing the width of the right-of-way and then crowding in the other components of the road is not rational. The right-of-way should be sufficiently large to take care of all design requirements, such as width of pavement and shoulders, and ditches should be placed as far away from the shoulders as possible with an easy slope in between. The right-of-way, above all, should be sufficient to take care of future increases in width and design of pavement. Ribbon development or the building of residences, garages, stores and restaurants along the roadside will often take place after an important road has been improved. If sufficient space is not provided when bordering properties may be bought at a reasonable cost, it will be found extremely expensive to acquire it later on.

Grades influence the average speed of heavy motor-vehicles such as trucks and autobusses, and should be well designed. On short grades the momentum of a heavy vehicle is sufficient to carry it along without changing gear, but on long grades this vehicle may have to slow down to a speed that will interfere with the normal flow of traffic on important roads. Therefore, on highways with a large amount of heavy traffic, grades should be kept as low as possible, and should not exceed 3 per cent on long slopes. On other roads the grade may be increased, but not more than absolutely necessary. Where the flow of loaded heavy vehicles is mainly in one direction, efforts should be made to obtain easier ascending grades in that direction.

On vertical curves a sight distance of not less than 700 feet on heavily travelled roads, and 500 feet on other roads, should be provided. On three-lane pavements the sight distance should not be less than 1,000 feet. On highways where opposite lanes of traffic are divided by a central neutral zone, the sight distance may be reduced to 500 feet.

The design of the travelled roadway must be given the best of attention because the traffic capacity of a road is one of the most important factors of highway economics. Intensive observations and studies are at present being made in an effort to determine the working capacity of roadways of various width and design, and their relative safety, the working capacity of a road being the limit at which congestion of traffic becomes apparent.

Opinions differ on certain aspects of the question of roadway design, but all seem to agree that, whenever a road is important enough to be redesigned and reconstructed, the minimum number of lanes should be two, one for each direction, and the minimum width of each lane 10 feet.

What is much more difficult to determine is the maximum capacity of such a road without congestion of traffic. Many factors influence this working capacity, as for example the uniformity of speed of motor-vehicles; the percentage of traffic in one direction; the percentage of each type of vehicle, automobiles, trucks, autobusses and horse-drawn vehicles, as also the number of pedestrians and cyclists.

The working capacity of a two-lane road, twenty feet wide, may vary from four thousand to eight thousand vehicles a day. The type of vehicle and rate of flow of traffic cannot be easily controlled, but if a twenty-foot road is well located and designed its working capacity will be much greater than otherwise. On a heavily travelled road with earth shoulders, the working capacity will be increased if the width of each lane is 11 feet instead of 10 feet, giving a total width of 22 feet.

The working capacity of a three-lane highway is larger. From observations it is estimated to be about double that of a two-lane road, under similar conditions. Also, its capacity will be greater when the flow of traffic is about 70 per cent in one direction. The capacity of such roads is estimated at between ten thousand and seventeen thousand cars per day, depending on the conditions mentioned above for two-lane roads. Because of the higher average speed and volume of traffic on these three-lane roads, they should be more perfect in design and have higher standards than two-lane roads. Due to a lack of practical experience, many of the existing three-lane roads have not been properly designed for higher speeds and greater volume of traffic and many accidents have occurred that could have been avoided.

Mr. R. E. Toms, Chief of Design of the Bureau of Public Roads of the United States, made the following interesting statement at the 1936 annual highway conference of the University of Illinois: "Opinion is sharply divided as to the wisdom of three-lane construction. In the vicinity of cities, where the predominating flow of traffic is in one direction at different periods during the day, and ample sight distance is available, three-lane construction undoubtedly adds to the flexibility of movement and traffic capacity of the road. It is extremely questionable whether this is the case where approximately equal volumes of traffic flow in opposite directions at the same time. Certainly the three-lane highway is not a safe highway, and its evolution and use has been due more to the stress of economic necessity than anything else."

Mr. Toms states that the three-lane highway is not a safe highway, which is true. But neither the two-lane nor the four-lane highway are safe highways. According to Mr. A. H. Vey, state traffic engineer for New Jersey, from studies of accidents on New Jersey highways, the two-lane pavement is safer than the three-lane and the three-lane safer than the four-lane pavement. Evidently, as speed and volume of traffic increase so also does the danger of accidents. For this reason three-lane roads must be designed to better standards than two-lane roads if, for economic reasons, a much more expensive type of highway, with divided roadways, cannot be built.

Four-lane roadways have a working capacity at least three times as great as that of two-lane roads. Over the Boston Post Road, on certain peak days, the flow has reached 40,000 vehicles a day. Four-lane roads are especially dangerous at intersections with other important roads, because of the wide space that has to be crossed through a large flow of traffic. These intersections account for 19 per cent of the accidents and worst traffic jams.

Divided-lane roadways are now advocated as the best solution to the problem of reducing the ever increasing accident rate on highways. Of course accidents will always happen, whatever the perfection in the design of a road,

**Fig. 5—Highway No. 3, near Sorel. Concrete Pavement completed late in 1936.**

since so much depends on the capacity of each individual to drive a high-powered vehicle at high speed.

The flow of traffic, on a highway, has been compared to a river. Intersectional friction takes place at cross roads and accounts for 19 per cent of all accidents. Medial friction takes place in the central part of the road where the traffic flows in opposite directions. About 17 per cent of all accidents occur there. Internal stream friction is produced by traffic flowing in the same direction, close together, at different speeds. It accounts for perhaps 44 per cent of the accidents. Marginal friction occurs at the shoulder between flows of traffic and parked vehicles, trees, guard rails, telephone poles and other objects, and causes about 20 per cent of the accidents.

With divided lanes of traffic, medial friction would disappear and intersectional friction would be reduced because of the safety zone provided at the central neutral strip. To be really effective in reducing intersectional friction, the central neutral zone must not be less than 15 feet wide. These roads, however, are expensive to build, and for the present at least, cannot be built on a large scale except perhaps in states such as New York, which collects annually over $95,000,000 in license fees and gasoline tax, but which, through highway fund diversion in the last few years, has not spent more than half of this revenue on the improvement of its roads. They are more costly of maintenance, both in summer and winter, and their illumination is more expensive.

The technique of pavement construction is far ahead of other details of road design, but even expensive pavements that were laid with the best of care have soon lost their good quality, due to a faulty and unstable subgrade. A pavement is as good as the base that supports it and no better.

Intensive research and experimentation on subgrade soils have led to important discoveries regarding their characteristics and reactions and the means of eliminating or reducing unfavourable reactions. Soil science is still in its infancy, and although a lot is known much more remains to be learned.

Highway illumination is another detail that will soon find its place in the design of heavily travelled roads within a certain radius of large centres of population. Night driving has increased considerably and motor-vehicles now travel at a speed beyond the range and capacity of their lighting equipment, which explains the large increase in night accidents. Good illumination requires surfaces that will diffuse the light and not reflect it. The design of such road surfaces, for this reason, is most important.

A discussion of modern road construction would be quite incomplete if a few words, at least, were not said about the economic value of road improvement. For many years, it appeared that the chief function of highway organization was to build and maintain roads at the lowest cost possible, as long as motor vehicles were, at first, kept out of the mud and, later, out of the dust. Little consideration, if any, was given to the cost of operation of motor-vehicles and to cost of transportation. Today the situation has changed; highway transportation is now one of the most important of all human activities and cost of transportation one of the most important of economic factors.

The people of the Province of Quebec spend annually about $95,000,000 in owning and operating motor-vehicles. At least 40 per cent of this money finds its way out of the province in the purchase of motor cars, tires, repair parts, etc., a sum as large as the total revenue of the government of the province. In ten years from now this annual expenditure will be much larger. On the other hand, the average annual expenditure, in the last five years, for road improvement and maintenance in the Province of Quebec, has been approximately $12,000,000, of which not over a million a year has been spent outside of the province. It is evident therefore that the saving in cost of operation of motor-vehicles is much more important to the public in general, than the economy that could be realized in more restrained improvements and maintenance of roads.

By building adequate roads, suited to present and near-future needs of traffic, much needless reconstruction will be avoided later on, and much money will be saved. Furthermore, and most important of all, if by the rational designing of roads that have to be rebuilt, an economy of say only 10 per cent is made in the cost of operation of motor-vehicles and time saved, the annual cost of highway transportation will be reduced by that amount and an annual economy of $15,000,000 will be made possible in a few years when the total yearly expenditure will have reached $150,000,000. As a great part of this money would otherwise find its way out of the province, this economy is important.

In conclusion, it is hoped that this paper has succeeded in demonstrating that firstly, because of the continued predominance of the ages-old horse-drawn vehicle through the first twenty years of this century, and secondly, because of the tremendous and unexpected development of the motor-vehicle, too much effort has perhaps been directed towards the design of pavements, certainly not enough towards the design of other details of the road such as location, alignment, grades and widths, and too little towards such important factors as safety and cost of transportation. Highway transportation is today like an overgrown child. Up to now we have been trying to fit him with his grandfather's clothes by letting out the seams and patching here and there. It is high time that an up-to-date suit was made for him, to his measure, so that he may go about at ease and in safety.

# Some New Forms of Electrical Transmission

*G. C. Southworth, Ph.D.,*
*Research Engineer, Bell Telephone Laboratories, New York, N.Y.*

**Paper presented before the Montreal Branch of The Engineering Institute of Canada, February 11th, 1937.**

SUMMARY.—Treats of a promising method of transmitting energy by very high frequency electromagnetic waves along a column of dielectric known as a wave guide. The waves are generated by an oscillator.

The forms of electrical transmission commonly used in radio and wire line practice are not the only ones possible. Actually there are many such forms and they belong to a general class which for convenience has been called wave guide transmission. A wave guide differs from an ordinary wire line in that there is no return conductor, at least of the usual kind. In some cases the guide takes the form of a hollow metal pipe and in others a cylinder of dielectric, either with or without a metal sheath.

Transmission through wave guides is possible only when the wavelength is comparable with the diameter of the guiding structure. These extremely high frequency electric waves are guided along such structures roughly as sound waves are propagated inside of a speaking tube. There are many kinds of these waves each corresponding to a particular orientation of the electric and magnetic forces in the wave front. One of these waves has a calculated attenuation characteristic that decreases as the frequency is indefinitely increased.

With an ordinary concentric conductor, such as is used for feeding a radio antenna, the outer tube forms one side of the circuit and the central conductor the other. If, however, instead of operating such a structure at a frequency of about a million cycles, approximately the average frequency for broadcasting, a frequency of two billion cycles were employed, it would be found that the central conductor could then be completely withdrawn and still the structure would be able to transmit power. It would be necessary, of course, to provide a suitable means for launching the waves, and the form of transmission would be radically different.

In this example the pipe would have had to be at least 4½ inches in diameter, but if the pipe had been filled with an insulating material having a dielectric constant of 4, a 2¼-inch pipe could have been used, while if the dielectric constant had been 9, a 1½-inch pipe could have been used. As a matter of fact, the outer pipe itself may also be done away with, and the transmission will take place along a wire or rod of insulating material, and the attenuation will be least when the resistivity of the insulator, acting as a guide, is the greatest.

Incredible as these phenomena may seem at first sight, they are readily explicable on mathematical principles that have been known for many years. As early as 1897 Lord Rayleigh obtained solutions for certain differential equations occurring in electrical theory which indicated that wave power could be propagated through either hollow metal pipes or through dielectric rods. So far as is now known, no experimental work was attempted at that early date. As often happens in science these principles were independently discovered by others. In particular, a group of workers in Germany studied this problem, and published several papers. They were Hondros and Debye in 1910, Zahn in 1916 and Schriever in 1920. Both Zahn and Schriever did a small amount of experimental work but it related mainly to the form of wave guide consisting of insulation alone, and dealt with just one of the many types of waves that may be propagated. The published literature indicates that their work was dropped at that point.

In 1931 the author resumed some experimental work on this subject, which he had started in 1920. Some of the earlier results have already been given in the April, 1936, issue of the Bell System Technical Journal.

### Nature and Properties of Wave Guides

Analysis has shown that there are many kinds of waves that may be propagated through cylindrical guides. However, four of them are of unusual interest and are such as merit special consideration at this time. All four have been experimented with in our laboratory and their more important characteristics have been determined. This experimental work has been paralleled by a mathematical analysis to which it conforms most satisfactorily.

A good mental picture of the nature of the waves propagated through guides can probably best be had by abandoning the ordinary concept of current electricity flowing in a "go and return" circuit in favour of that of lines of electric and magnetic force. This latter concept has, of course, always been applicable, even for low-frequency

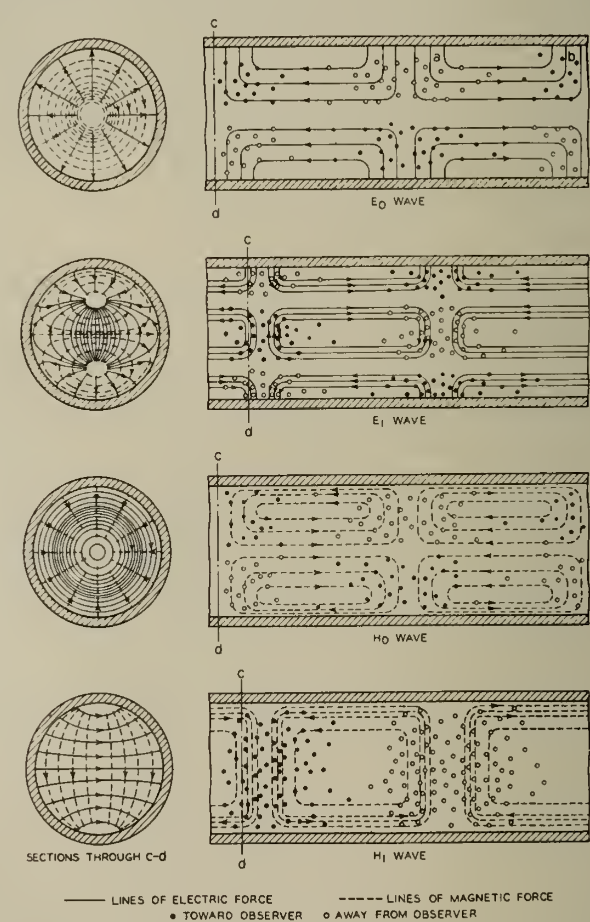

**Fig. 1—Some of the Possible Configurations of Lines of Electric and Magnetic Force that may be transmitted through a Wave Guide. Propagation is assumed to be directed to the right and away from the Observer.**

transmission over parallel wires or coaxial conductors, but due to its complexity in pictorial representation it has usually been avoided. In the form of transmission with which we are now concerned, the field point of view is almost necessary.

Figure 1 is a pictorial representation, based on this point of view, of the four types of waves mentioned above as found in a guide surrounded by a metallic conductor. In these models the lines of electric force have been represented by solid lines and the lines of magnetic force have been shown by dotted lines. In the longitudinal sections, the small closed circles represent lines of force directed toward the observer. The open circles represent lines directed away from the observer. The designations $E_0$, $E_1$, $H_0$ and $H_1$ are convenient reminders of certain characteristics of these waves.

The first two waves have been designated as electric because there is a component of electric force in the direc-

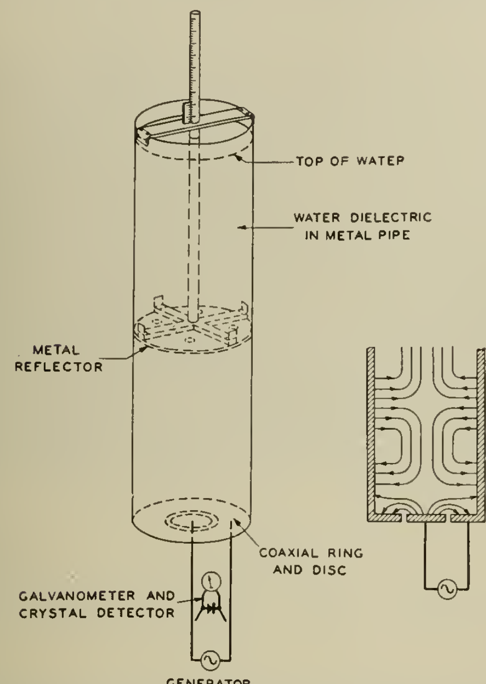

**Fig. 2—Apparatus used in Determining Fundamental properties of Wave Guides.**

tion of propagation. For similar reasons the latter have been known as magnetic waves. Such a designation is, of course, rather arbitrary and should not be construed to mean that either component resides alone. It is true here as in other forms of electromagnetic waves with which we are generally familiar, that both the electric and magnetic components are essential to the very existence of the wave

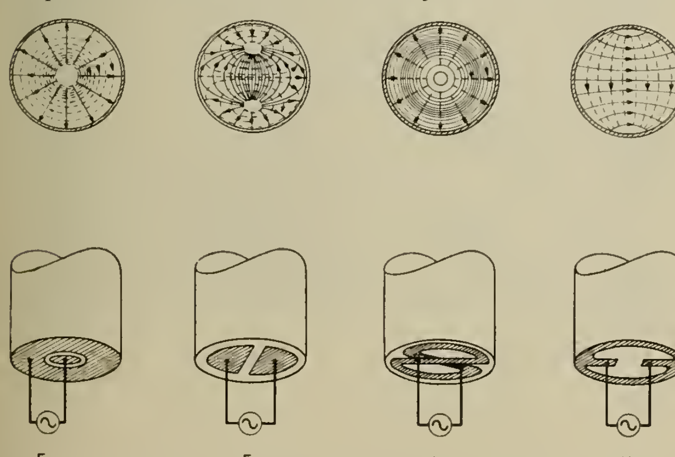

**Fig. 3—Methods of launching various types of Waves in a Guide.**

and that they may conveniently be considered as different aspects of the same thing.

Natural questions that might be asked are: (1) How do we know when these peculiar waves are present? (2) How are they launched and received? and (3) How do we know that they assume the neat configurations shown in Fig. 1? Like many other questions arising in physical science there are two answers. One is mathematical and the other is experimental. The first has already been mentioned. Some of the more crucial experiments are given below.

### Experimental Verification

The verification of the above mentioned properties of waves and their guides has involved two rather different ranges of frequencies. In the earlier work which is the particular object of this paper, frequencies between 100 and

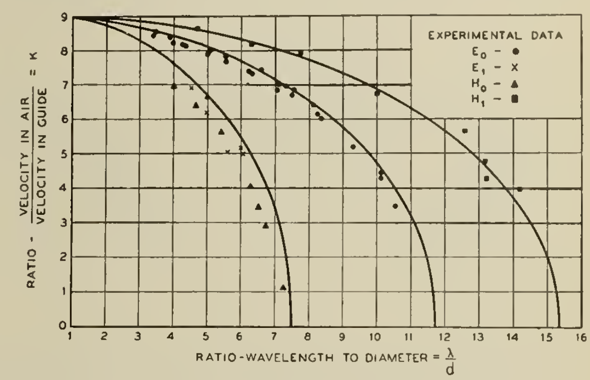

**Fig. 4—Comparisons between calculated and measured Velocities of Propagation.**

400 megacycles were used. These were obtained from a vacuum tube generator of a conventional type. The waves were propagated through cylinders of water which served as the experimental guides. More recently it has been feasible to use air core guides. However, this has called for much higher frequencies. The latter are of the order of 1,000 mc. ($\lambda$ = 30 cm.) and 4,000 mc. ($\lambda$ = 7.5 cm.). The results obtained by the two methods are, however, very similar so that the more recent work can be said to be largely confirmatory.

The apparatus used in this preliminary study is shown in very simple schematic form in Fig. 2. As already explained the dielectric guide under observation consisted of a cylinder of water. It was contained in a column about four feet long. In the course of the experiments four such columns were used. Two were enclosed in copper tubes 10 inches and 6 inches in diameter respectively, and two were within bakelite tubes of these same diameters. The bakelite was considered sufficiently thin and its dielectric constant so low compared with water that the whole could be regarded as a cylinder of water only. On account of the dielectric losses present, water would not ordinarily be considered a good medium for a wave guide but because of its high dielectric constant it was excellent for the simple experiment at hand.

The shape of the conductors on the launching mechanism determined the type of wave produced. When the $E_0$ type of wave was desired this pad, as it was called, took the form of a metal disc surrounded by a metal ring. The two wires leading from the vacuum tube generator were connected to the disc and outside ring, respectively. If other types were wanted pads were used made up of other electrode arrangements as illustrated in Fig. 3 below.

Loosely coupled to the lead wires from the generator to the pad was a crystal rectifier and a d.c. microammeter. This indicated in a rough way the relative power passing into the wave guide. It was sufficiently sensitive that any reactions from the wave guide back onto the generator were accompanied by rather marked changes in the meter deflections. By suitable reflections in the wave guide standing waves could be set up which gave rise to maxima and minima readings in the meter.

Standing waves were produced in the water column by three rather different methods. Substantially the same results were obtained by all. In one case water was admitted slowly to the column. As the level of the water rose the deflection of the meter varied periodically through rather wide limits, indicating points of resonance in the column with a corresponding absorption of power from the generator. When the coupling between the column and the parallel wire circuit could be made small, the reaction between the two was also small except at points close to where absorption took place. This method is very similar

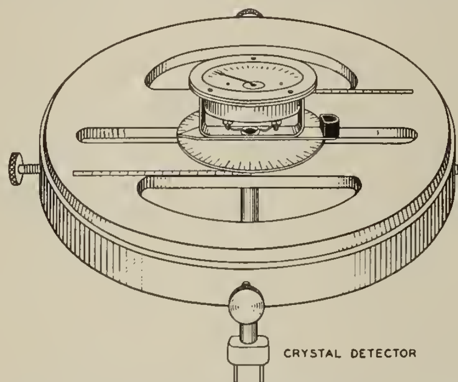

**Fig. 5—Apparatus used in Verifying the various Configurations of the Lines of Force shown in Fig. 1.**

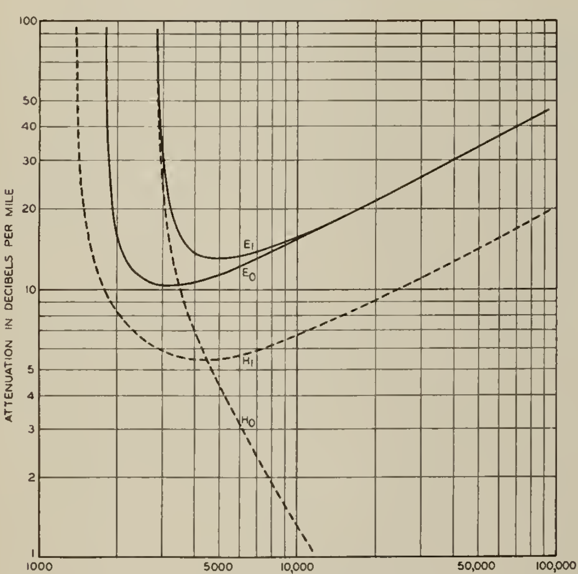

**Fig. 6—Calculated Attenuation Characteristics of a 5-inch Hollow Copper Pipe.**

to the scheme that is sometimes used in radio measurements whereby resonance in a secondary circuit is indicated by absorption in a primary. In this experiment the distance between successive absorption points was taken as one-half of the wavelength as measured in the medium.

These simple experiments not only showed the existence of electric waves but they also gave data relating to their velocity of propagation. The difference in water level between alternate maxima and minima gave the wavelength as measured in the guide. Previous determinations of a slightly different sort had given the frequency of the generator. Velocity could then be calculated in the usual way by multiplying wavelength by frequency.

Measurements of this kind were made on all four types of waves. The resulting data for the case of the shielded guide are plotted as points in Fig. 4. The solid curves were calculated from the mathematical theory. It assumed that the correct dielectric constant of water is eighty-one. In order to include on the same sheet data for different diameters of guide there has been plotted as abscissae the ratio of wavelength to diameter. Also it has seemed desirable to plot instead of velocity in the guide, its ratio to velocity in free space. The approximation between measured and calculated results is evident.

The configurations of the lines of force in a wave guide were verified by means of probe measurements similar in principle to those sometimes used in verifying the magnitude and direction of the magnetic flux near the poles of magnets. Figure 5 shows the details of both the probe and its bakelite mounting. The latter was clamped to the top of the water column and adjusted so that the probe wires just reached the water. The probe could rotate about its axis as well as be moved laterally along the slot shown. The part carrying the slot was also free to rotate with respect to the column so that the entire surface of the water could be investigated. The two rotating parts were laid off in degrees and the slot carried a centimeter scale.

In exploring the field of a pure $H_1$ wave it was readily verified that the lines of force were chords generally parallel to the plane of the lead wires from the generator (shown schematically in Fig. 3). When the probe was carried across the diameter along which the electromotive intensity was applied, the deflection was optimum only when the line connecting the probe wires was kept parallel to this diameter and was zero or very small when oriented at right angles thereto. When the probe was carried along the diameter perpendicular to that in which the electromotive intensity was applied again the deflection was optimum only when it was parallel with the electromotive intensity. At points near the wall there was a definite tendency for the optimum position to be radial. This is of course in keeping with the idea that small areas of conductors may be regarded as equipotentials.

**Fig 7—Experimental Wave Guides shown in testing the Mathematical Theory of Guided Waves.**

For the $E_0$ type of wave the probe meter read a maximum when the line connecting the two probe wires was radial and a minimum (usually zero) when it was tangential. Similar measurements on the $H_0$ type of wave gave nearly opposite results for it was only when the line of the probe wires was kept tangential that the readings were a maximum. No great effort was made to verify the shape of the $E_1$ wave. However, it was not difficult to establish the two null points that are evident from the configuration shown in Fig. 1.

### Attenuation

Wave guides behave somewhat like wire lines in that they have a definite characteristic impedance and a definite attenuation. The calculated attenuations of the four principal waves are of particular interest. They are shown in Fig. 6 for the special case of a five-inch hollow copper pipe.

It will be noted that all waves suffer infinite attenuation at or below certain critical frequencies, and that with an increase in frequency this attenuation decreases very rapidly. For three of the types of waves it approaches a minimum, and then increases for higher frequencies. For the wave that has been designated as $H_0$ this attenuation appears to decrease indefinitely with increase of frequency.

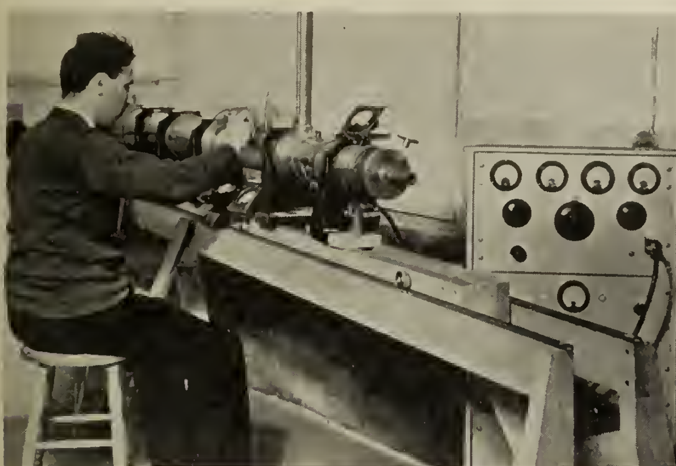

Fig. 8—Transmitting end of Experimental Wave Guide.

Not all of the calculated characteristics of wave guides have yet been verified experimentally. In particular, relatively little information is yet available on the very interesting $H_0$ wave except near cutoff. At present, work is being done at the Holmdel (New Jersey) Radio Laboratory directed at measuring these attenuations. For this purpose two hollow copper pipes are used, which are four inches and six inches in diameter and 1,250 feet long. These pipes are shown in Fig. 7.

The experimental results to date indicate that the attenuations may be calculated with reasonable accuracy and that they are not in general as great as for ordinary wire lines operated at these frequencies. Figures 8 and 9 show respectively the transmitting and receiving apparatus used in the attenuation measurements. Details of this apparatus are outside the scope of this paper. However, certain of its features will be evident from some of the fundamental principles that are mentioned below.

### Wave Guide Apparatus

An interesting technique is being built around these new forms of transmission. In much the same way that a pair of wires may resonate to waves travelling along their length, or an air column may resonate to certain sound waves, so may a short section of wave guide be made to resonate electrically to the frequencies which it is able to propagate. In its role as a resonator it behaves as if it were a coil and condenser, sometimes in series with an electromotive force, and sometimes in parallel. These resonance effects are very pronounced and may be simply demonstrated by a cylindrical chamber such as that shown in Fig. 7. This figure shows the author holding one of the resonant chambers used for tests of wave-guide transmission. Behind him are the two experimental transmission lines.

In its role as a tuned circuit, the resonant chamber is sometimes used as a wave-meter, sometimes in connection with a generator of short waves (thereby enabling a vacuum tube to work more effectively) and sometimes as an element in a receiver (thereby impressing on a detector a maximum of the received wave power).

The open end of a guide may be made to radiate wave power much the same as sound waves issue from a pipe. To enhance this effect the pipe may be expanded into a cone, thus producing an electrical horn. Tests show that it may function much the same as an acoustical horn, and accordingly may be used as an efficient radiating load for the generator to which it is connected.

### Generators

One arrangement for generating the $H_1$ type of wave consists of connecting the primary source of waves between diametrically opposite points on the inside of a hollow cylindrical conductor as shown by Fig. 10 (a). This primary source may consist of a positive grid (Barkhausen) tube or a magnetron.* Both have been used successfully to give frequencies up to about 3,330 mc. ($\lambda = 9$ cm.).

A typical arrangement of such an oscillator is shown in Fig. 10 (b). The terminals of the spiral grid of the Barkhausen tube are connected to diametrically opposite points through a suitable by-pass condenser. The filament and plate leads enter along a plane perpendicular to that of the grid. Since the grid leads correspond to lines of electric force in the generated wave, the diametral plane perpendicular thereto corresponds to an equipotential. By locating the plate and filament leads in such an equipotential, their presence will not materially affect the normal field prevailing in the chamber. In the design shown the filament connectors constitute the outside plates of a three-plate-by-pass condenser. The third or central plate is a rigid member grounded on the main guide. It connects to the plate of the Barkhausen tube. Connections to the exterior are had through five insulated binding posts. The oscillator unit shown carries on its exterior a plug connector leading by cable to a nearby d.c. power supply unit.

Fig. 9—Receiving End of Experimental Wave Guide.

If an oscillator similar to that described above were connected into the middle of a long hollow pipe, waves would, of course, be propagated in both directions. Those that would ordinarily be propagated to the left may be reflected by a suitably located reflecting wall or piston so as to reinforce those being propagated to the right. Also

*"Vacuum Tubes as High-Frequency Oscillators," M. J. Kelly and A. L Samuel, B.S.T.J., Vol. 14, p. 97, January 1935.

an iris of suitable proportions may be so located in front of the generator as to further enhance oscillations. As has been pointed out above the section of pipe bounded by the piston and iris together approximate in behaviour a tuned circuit. It is convenient to regard the chamber as a load impedance characteristic of the tube itself or perhaps it should more properly be regarded as a transformer by which the oscillator is matched to the line.

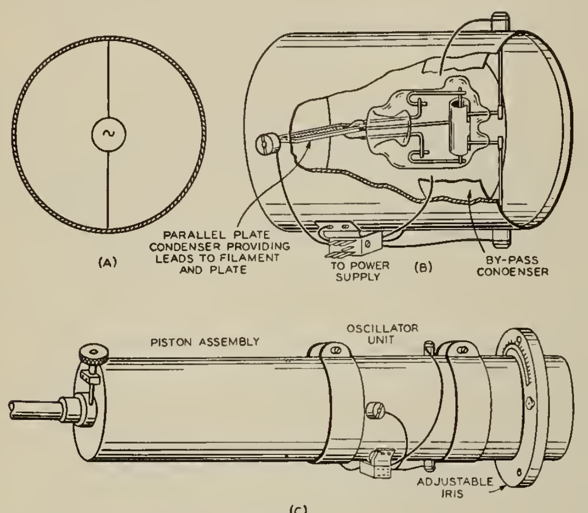

**Fig. 10.—Various Component Parts of a Wave Guide Generator. (a) Schematic representation of Connections. (b) The Oscillator Unit. (c) Complete Generator including Oscillator, Iris and Piston.**

### Possible Applications

The question naturally arises as to what use wave guides may be put. This is a difficult question at this early day. Wave guides have definite limitations. The diameter of the hollow pipe that may be used is directly proportional to the wavelength. For a pipe that is at all convenient in size, the frequencies are the highest that have yet been tried out for radio. It is true that the diameter of pipe might be reduced if it could be filled with a suitable insulator. However, at this point we are met with a conflicting difficulty of producing at reasonable cost the necessary medium that will incorporate high dielectric constant with sufficiently low losses. It is true too that low attenuation could probably be had with much smaller pipes by the use of $H_0$ waves, but this calls for an even higher range of frequencies. For long-distance transmission, the situation is that the art at these extreme frequencies is not yet at a point which permits a satisfactory evaluation of practical use. For transmission over very short distances, however, or for use as projectors of electric waves, or as selective elements under certain conditions, the use of wave guides has definite possibilities.

# Air Conditioning in a Northern Climate

*D. W. McLenegan,*

*Assistant Engineer, Air Conditioning Department, General Electric Company, Bloomfield, N.J.*

**Paper presented before the Montreal Branch of The Engineering Institute of Canada, on October 8th, 1936.**

**SUMMARY.—The paper deals with the advantages and limitations of air conditioning in summer and winter in Canada, and gives some typical results as regards operating conditions, comfort and power required.**

In these days one is likely to hear many people speak of air conditioning as "the coming thing" or "the next big industry." Although these statements are often made casually and without study, they do indicate a general belief that this new industry offers something of real value. Since the permanent growth of an industry is basically related to the benefits which it produces, it is well to examine more specifically the contribution to our well-being which air conditioning offers, and something of the technique by which the results are obtained. What does one seek to gain by conditioning the air of homes, stores, offices and trains?

Probably foremost is the control of temperature, utilizing heating or cooling to avoid extremes. However, this control need not produce a dead level of constant temperature, which would probably be monotonous. There is good evidence that the frequent variations of a northern climate produce a stimulating effect, although the extremes also cause much physical wear and tear. Hence the method of control should remove the extremes of heat and cold and yet allow some latitude in the choice of temperatures to suit activity and bodily condition.

Control of humidity is also becoming recognized as important. The humid days of summer depress one as badly as the extreme heat in the prairie states, which is not accompanied by high humidity. In winter the dryness of the winter air, when heated in the home, does not represent a normal condition; and the extreme dryness is not healthful. Here again, air conditioning enables one to avoid the extremes.

Still another factor is that of normal air circulation to prevent the air from settling into hot and cold strata. In houses or offices where there is no forced circulation of air, or where the circulation is not properly directed, it is not uncommon to find ten degrees temperature difference between air at the floor and air at the breathing height.

Circulation of air also helps to dissipate odours, particularly if enough new air is constantly being brought in. Of course, in many of the older houses, adequate ventilation is more than assured by the steady in-leakage of air around windows, doors, and even through the walls. In the newer construction, insulated, weather-stripped, sealed, this leakage is greatly reduced, and mechanical ventilation may actually be needed to prevent staleness. In either case, it is desirable to be able to bring in most of the ventilation air at one point, distributing it as needed rather than allowing it to leak in irregularly and disturb the control of temperature.

Some means for cleaning air should be a part of any air conditioning system. The various types of filters available are classified as to capacity—which determines the frequency of cleaning or replacement—and as to dirt-catching efficiency, which may vary from 60 to 95 per cent for various sizes of dust particles commonly encountered. In applying air conditioning to homes already clean and well-kept, it has been found that immediately after installation the filters become filled with dirt in two or three weeks. This represents the accumulation not only in the air but on walls, furniture, and draperies which is not easily removed by ordinary methods. After this initial "house cleaning" by an air conditioning system, six months may elapse before the filters again require attention.

Then there are certain collateral advantages of air conditioning which, in the opinion of the author, have not adequately been recognized. A well-planned system can do much to shut out noise and odours—both of which are irritant and tend to reduce working efficiency. Equipment and the installation technique have now reached a point where little or no sound reaches the occupants from the air conditioning plant itself. Many a building manager can recite the difficulty of renting the lower floors of an apartment or an office building facing a busy street. If the windows are opened, the occupants must put up with the street noise, but with closed windows, and a separate source of fresh air, most of this outside noise can be kept out. Furthermore, the gasoline fumes and dirt from the street may be eliminated, since the fresh air for ventilation may be drawn in at the other side of the building, or from a shaft extending above the roof, or any location most free from contamination.

The relative importance to be given to all these phases of air conditioning depends, therefore, not only on the climate but also on the immediate surroundings of a building and on the conditions of occupancy within the structure itself.

In this climate, there is no question of the need for winter air conditioning, that is, the proper control of temperature and humidity, and the cleaning and circulation of air. In heated buildings, a relative humidity of 40 per cent is desirable. For hospital operating rooms, even higher humidities of 50-60 per cent are sometimes called for, to reduce the possible hazards from sparks of "static" and to improve conditions for patients who may be in a weakened state. Actually, however, the degree of moisture which may safely be added to the air is often determined by the building construction. A tightly-constructed building, particularly with double glass windows, can usually be maintained at 40 per cent relative humidity even in severe weather without danger of condensation. In poorer construction, it is often necessary to restrict the humidity on cold days to 30 or even 25 per cent, not only to avoid the formation of frost on the windows, but also to insure against condensation where cold air pours in through cracks, or circulates through thinly built walls.

Of the various types of humidifiers available, some simply discharge fine water particles in a moving stream of air, leaving the real evaporation to be completed as these particles are discharged into a room. In other devices, heat is applied to convert the water to water vapour in the air before it is discharged. Humidifiers of the latter type are safer, since the evaporation is assured, and local condensation does not occur unless the warm humidified air is discharged close to a cold wall or window. In the author's experience, it has been found desirable to go a step farther, and actually heat the humidified air above room temperature before discharging it. A stream of air at 70 degrees feels cold to most people. Hence a humidifier should preferably discharge air at 85-90 degrees, to avoid the criticism of producing a cold draft. Figure 1 illustrates the application of a humidifier of this type. Air withdrawn

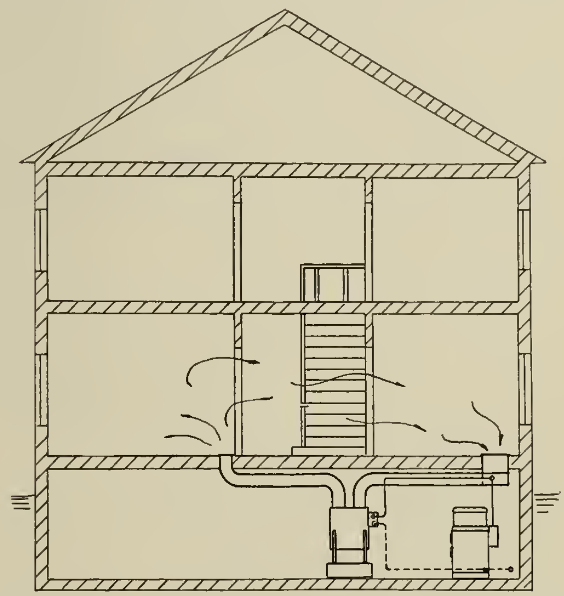

**Fig. 1—Typical Installation of Winter Air-Conditioning for House with Radiator Heating, illustrating Heating Connections and Method of Air Distribution.**

through a duct at one side of a house is brought to the device, heated, filtered, humidified, and then discharged through a duct to some adjacent room. Thus the humidifier cleans and circulates the air as well. For rooms not in the direct air circuit, the vapour pressure assures even distribution of moisture, and this spreading takes place quite independently of the circulation of air.

Where summer air conditioning (i.e. cooling, drying, cleaning, ventilating and circulating) is in question, the need is determined more than ever by the immediate locality and by conditions of occupancy. Some examples may emphasize this statement.

Here is the summary of the cooling load of a restaurant which was recently air conditioned in a nearby city. Although higher temperatures sometimes occur, the load was calculated for outdoor conditions of 90 degrees dry bulb and 74 degrees wet bulb. These same conditions incidentally are frequently used as a basis for design in Montreal.

| | B.t.u. per hour | |
|---|---|---|
| *Removal of Sensible Heat* | | |
| Conduction through walls, windows, etc. | 6,000 | |
| Sun effect | 0 | |
| Ventilation air | 12,500 | |
| From 100 occupants | 22,000 | |
| From appliances | 30,600 | |
| | | 71,100 |
| *Removal of Latent Heat* | | |
| From ventilation air | 8,600 | |
| From 100 occupants | 18,000 | |
| Estimated evaporation from food, coffee, etc. | 3,000 | |
| | | 29,600 |
| Total | | 100,700 B.t.u./hr. |

Here, only a small part of the heat load or the moisture load results from the outdoor condition, in fact only 25 per cent; by far the greater part is generated within the restaurant. There is no question but that such a condition justifies the installation of equipment to reduce both the temperature and the humidity, even in fairly mild weather. Without air conditioning, the temperature in this restaurant would (and did) frequently exceed 100 degrees F.; and this temperature, combined with a high humidity, would make it difficult for anyone to enjoy even the best of food. Ventilation alone might have been supplied to give some

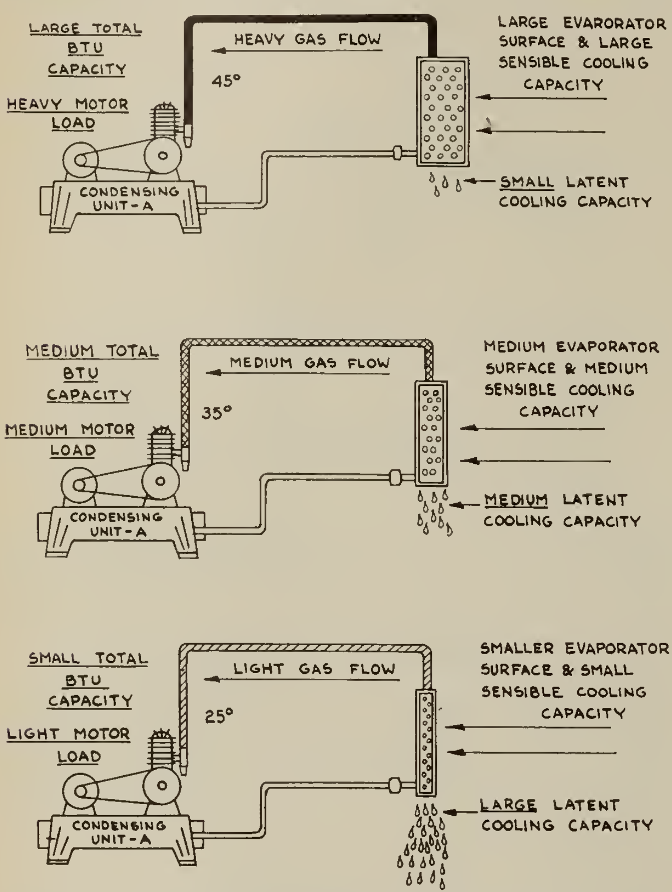

**Fig. 2—Selection of Equipment for Central Plant Air Conditioning Systems.**

relief. But calculations indicate that even if a temperature 5 degrees higher than outdoors was accepted, an excessive air flow would be needed to carry away the heat, producing drafts and still leaving the humidity uncomfortably high. Therefore, complete summer air conditioning became a necessity if the restaurant was to be attractive to its patrons and profitable to its owners during the summer months.

Another example may be worth mentioning, since it is typical of a situation which all have seen. In a northern city studies were recently made of an office building which houses the central office of a national concern. The building is rather long and narrow, and relies on windows at front and rear for air and for natural light. Even with windows open, the ventilation in summer has been inadequate. On windy days, those nearest the windows must tolerate the scattering of papers, if the others are to get any fresh air. Close work with ledgers and records has required the addition of a large amount of artificial light, which produces a considerable amount of heat. On the top floor, skylights eliminate much of the use of artificial lighting, but the direct rays of the sun produce even more intense heat. Even though this city does not experience many sweltering days, the owners of this building have recently made a substantial investment for a year-round air conditioning plant. They anticipate that the more uniform and comfortable conditions and the absence of drafts will reduce the time lost through sickness, enable more work to be done with fewer errors, and prolong the useful life of their building; and by no means least important, they expect from their employees a favourable mental reaction for this gift which enables them to work under more comfortable and healthful conditions.

Many more cases could be mentioned where the need for cooling goes far beyond the occasional hot day—crowded theatres, which really need cooling until the outdoor temperature drops to 50 degrees; beauty shops, where the many curling and drying appliances produce nearly half the heat needed in winter; hospital operating rooms, where the sterilizing equipment, the intense light, and the quick activity of the several doctors and nurses produce a degree of heat and humidity both uncomfortable and sometimes unfavourable to both the patient and to the efforts of the surgeon. It is significant that many hospitals are conditioning the air of their operating rooms, and that this activity is not restricted to the southern cities with their longer summer seasons.

In the design and installation of air conditioning systems many problems arise, particularly in older buildings for which air conditioning was not planned at the outset. A large proportion of the cost arises from attempting to work the system into the building in such a way as to avoid disfiguration and to avoid injuring the structure. In a department store, all equipment might be placed in a central machinery room, and ducts run to the various floors. This is sometimes done, although the tearing up and redecorating involves considerable interruption of business. But the arrangement and use of successive floors may not be suited to a simple repeated pattern of risers and return ducts. So one must consider the alternative of having the heat-generating and the cooling equipment in a central plant, and connected by pipes to several smaller air conditioning units serving limited areas. Not only the space arrangement, but also exposure, internal heat load, sources of odours, or differences in noise level can then be considered for the individual spaces, and designs made accordingly.

In an office building, space is often conditioned for one tenant, occupying part or all of a single floor. If on an upper floor, it may be necessary to reserve a space for equipment adjacent to the conditioned space. Here the choice and location of equipment must take into account the location and size of power feeders, water and drain lines. The distribution of air must be planned with an eye to the possible rearrangement of partitions and offices, to make the system as flexible as possible.

A problem most carefully studied is the distribution of the heating or cooling effect to spaces having unlike exposures or variable loads. A west room may require little cooling until afternoon, and then develop a heavy load; for an east room, just the opposite; the tap room or tavern of a hotel may become crowded in the evening, when other parts of the system are only slightly in need of cooling. Rooms with a north exposure may require the least summer cooling but the greatest amount of winter heating. Of course, these requirements can usually be anticipated. They must be dealt with not only as to the provision of maximum cooling or heating capacity, but also as to suitable control. As far as practicable, spaces having similar requirements are combined into one zone or division of the plant. The rate of air flow may be controlled by dampers, although too great reduction impairs both ventilation and air distribution. With separate heat transfer surfaces, continuous air flow may be maintained, and the degree of cooling or heating modulated to meet varying requirements; or part of the air may be passed through the heat transfer surface, and the rest deflected around. All of these methods and others may be utilized in meeting widely different requirements in parts of the same system.

The design of an air cooling system should always be calculated to produce adequate air drying. Too many systems, improperly proportioned in this respect, produce a cold, clammy sensation, as of entering a cave. The moisture to be removed is not only that which enters with the ventilation air, but also that generated by people and processes in the space. The degree of moisture removal obtainable is governed by the coldness of the cooling surface. Figure 2 attempts to illustrate the relationships involved. With a relatively high temperature of refrigerant (and with adequate cooling coil surface) a given system develops its greatest capacity, but with only a small air-drying effect; conversely, a low refrigerant temperature reduces the total capacity, but permits more condensation of moisture, with a smaller coil surface. Usually, for comfort cooling installations, the average case is about right, using a refrigerant temperature of 35 to 40 degrees F., with the result that 25 to 35 per cent of the total plant capacity is used for dehumidification.

These relationships are easily shown on a psychrometric chart (Fig. 3). Let us assume a case where the indoor condition is to be 80 degrees with 50 per cent relative humidity and the outdoor is 91 degrees with 74 degrees wet bulb temperature; also that one-third of the total circulation represents ventilation air drawn from out of doors. If this air is mixed with the recirculated air before entering the conditioner, the temperature and moisture content of the mixed air will be indicated by a point on a straight line between the indoor and outdoor points—in this case, at 83.7 degrees, since the greater part of the air is recirculated. In order to be able to absorb both the heat and the moisture generated within the room, the air leaving the conditioner must be colder and drier than the nominal room condition. In the case of the restaurant described above, with a total air circulation of 3,500 c.f.m., air would have to leave the conditioner at 65 degrees and with moisture content of 67 grains per pound. Connect by a straight line the points representing "air entering" and "air leaving" the conditioner, this line extended to its intersection with the saturation curve will indicate the temperature of the cooling surface which must be used to produce the respective proportions of air cooling and air

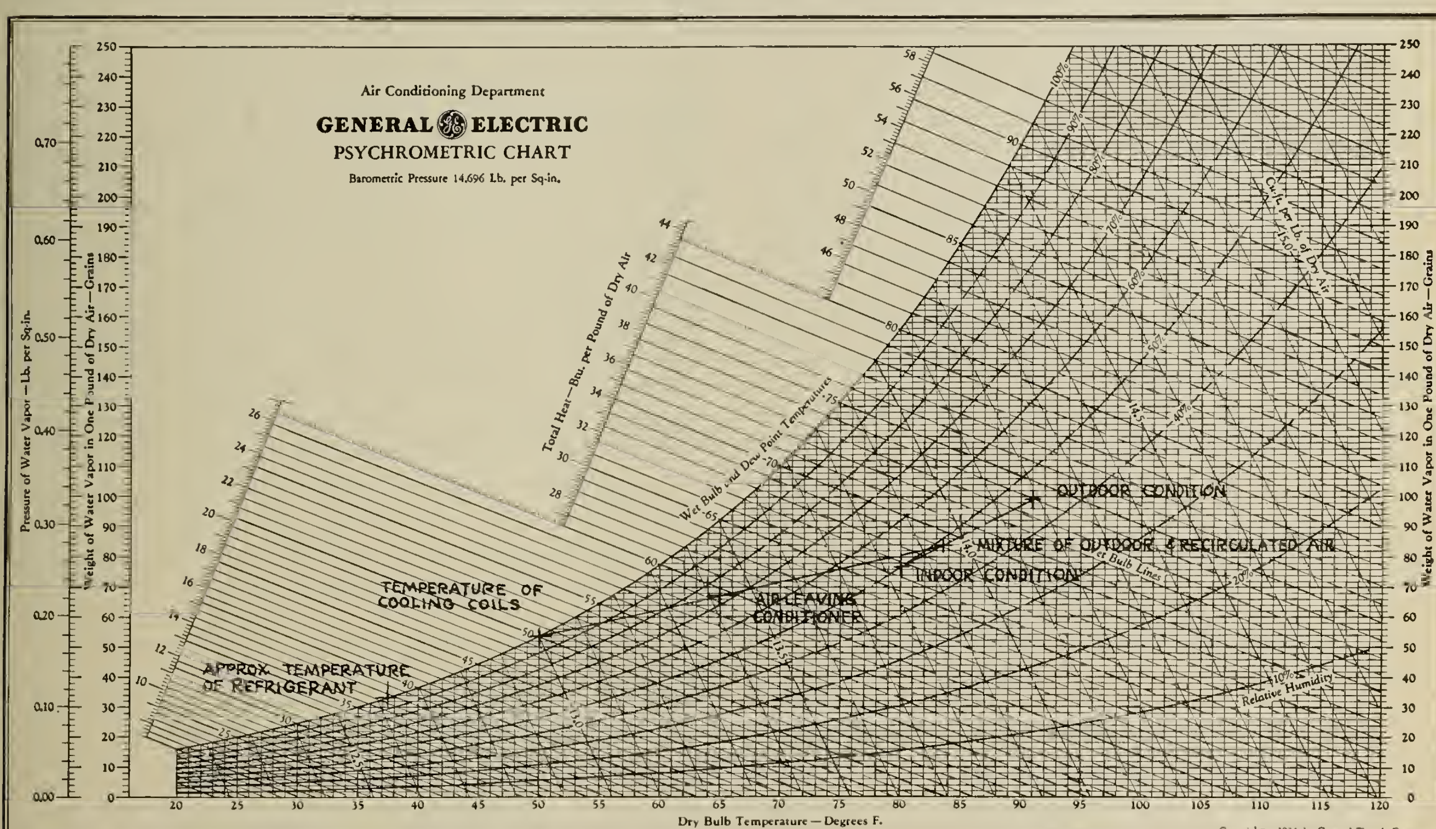

**Fig. 3—Psychometric Chart.**

Note.—If two properties of air are known, all properties may be found as follows:

Dry Bulb Temperature is read directly by following vertically down to the bottom scale.

Wet Bulb Temperature is read directly at the intersection of the wet-bulb line with the 100 per cent relative humidity line (saturation curve). The scale is marked along the 100 per cent line.

Relative Humidity is read directly from the curved lines marked Relative Humidity. For a point between the lines, estimate by distance.

Moisture Content, or Absolute Humidity, is read directly from horizontal lines with scales to the right and left of the chart, and is the weight of water vapour contained in a quantity of air and water-vapour mixture which would weigh one pound if all water vapour were extracted.

Dew Point Temperature is read at the intersection of a horizontal line of given moisture content with the 100 per cent relative humidity line.

Total Heat is read directly by following the wet bulb line to the scale marked Total Heat. Total heat refers to a quantity of air and water-vapour mixture which would weigh one pound if all water vapour were extracted, and includes the heat of the water vapour.

Specific Volume is read directly from the lines marked Cu-ft. per lb. of Dry Air. For points between lines, estimate by distance. Specific volume is the volume occupied by a quantity of air and water-vapour mixture which would weigh one pound if all water vapour were extracted.

Vapour Pressure corresponding to a given moisture content is read directly from the left-hand scale marked Pressure of Water Vapour.

drying required; in this case, a surface temperature of 50 degrees, corresponding to a refrigerant temperature of about 38 to 40 degrees within the coils. This straight line relationship, which should be a part of every cooling calculation, but which is so frequently neglected, furnishes an easy basis for making sure of adequate air drying along with the cooling process.

The electric load aspects of air conditioning have been carefully studied by many of the electric utilities, as well as by the manufacturers. For winter air conditioning, the electrical demand is small, in keeping with the existing load of lights and small appliances. Its load factor is good, since an automatic heating system may operate more than two thousand hours during the heating season, and the operation of air circulating equipment is at least as much, if not actually continuous.

For summer cooling, the operation of motor-driven compressors involves a larger demand—approximately 3 to 5 kw. for complete cooling of an 8-room house—and the number of hours of operation is smaller. Fortunately, however, this load occurs in a season when the load of a power system is likely to be lowest; and from an hourly standpoint, it occurs mainly during the day and drops off before the evening lighting peak begins. As it becomes possible to study the combined electric load of many installations, it is reasonable to anticipate a considerable diversity in the time of peak demand, due to both occupancy and building construction. For the cooling of homes, the peak demand occurs in the late afternoon; for theatres, generally in the evening, when the attendance is greatest. Even among homes, the electrical diversity factor will be marked, since some houses of light construction follow rapidly the outdoor temperature changes, whereas heavily built or insulated houses respond after a time lag of several hours. Therefore, although some individual distribution lines will have to be enlarged, the overall effect of a large residential and commercial air conditioning load appears to be a favourable one.

Looking broadly at this subject of air conditioning which has lately engaged so much attention, one can draw a few conclusions as to its future effects, as it becomes more widely applied. The effects of air conditioning are not spectacular and, in fact, the operation is most successful when it permits us to be unconscious of our atmospheric surroundings, rather than acutely aware of them. Although not a panacea, and even though the name "air conditioning" is still being applied to many devices of the "gold brick" type, air conditioning equipment properly applied has a wide field of usefulness. In its various phases, air conditioning offers improvements towards comfort and health, substantial relief in many cases to hay fever sufferers, and is a sound investment for many types of business which serve the public by direct contact.

The cost of air conditioning will be lowered somewhat as the designs of new buildings are modified to aid the installation, and as those engaged in planning new structures become more accustomed to considering air conditioning as an integral part of a building, rather than as an appendage. In return, the advance of air conditioning is helping the architect and the builder to secure public realization of the advantages of better building materials. The author has seen many cases where insulation, better window frames, better wiring, and even structural improvements have been adopted after their advantages had been seen from the particular standpoint of air conditioning.

A considerable amount of statistical evidence is becoming available, showing that, where one can work and live in greater comfort and avoid the mental and physical annoyance of noise, dirt, drafts, and sudden changes of temperature and humidity, the output of productive work is increased. And such measurements, most easily obtained among groups performing routine work, might logically be assumed to apply also to those engaged in more creative types of work which require the greatest mental energy and concentration.

Probably the best index of the widespread future use of air conditioning lies in the extent to which it has already been adopted as a sound investment by many industries, not only to facilitate manufacturing processes and improve products, but also to improve working conditions for employees in shops and offices alike.

## A.S.M.E Semi-Annual Meeting—Detroit, May 17-21, 1937

As announced last month, the general programme of the American Society of Mechanical Engineers meeting at Detroit will be based on a series of six sessions at which authorities from engineering and industrial fields in the Detroit area will develop a broad survey of modern techniques employed by mass production industries, typified by the building of automobiles. In addition, simultaneous sessions of the professional divisions of the Society will provide opportunity for the presentation and discussion of papers along the lines of their special interest.

*The members of The Engineering Institute of Canada have been invited to participate in these activities, and will be made welcome at any of the technical sessions or functions which they wish to attend.*

Monday, May 17th—Registration, business meetings and inspection tours.

Tuesday, May 18th—

9.00 a.m. The Scope and Purpose of the Planned Programme, C. F. Hirshfeld.
Historical Sketch Contrasting the Practice of Automotive Design and Production with Methods in Older Engineering Fields, C. F. Hirshfeld and E. H. Piron.
Modern Locomotive and Axle Testing Equipment, Tracy V. Buckwalter O. J. Horger, and W. C. Sanders.

2.00 p.m. A Year of the New Apprenticeship in the Detroit Industries, Chester W. Culver.
Organization and Growth of the Future Craftsmen of America, J. Lee Barrett.
Design, Construction and Operation of Springwells Station of the Detroit Dept. of Water Supply, W. C. Rudd and B. J. Mullen.
The Separation and Removal of Cinder and Fly Ash, Arthur C. Stern.
Incinerators—Municipal, Industrial and Domestic, H. F. Hersey.
Industrial Power Plants, E. Boomhaur.
Industrial Heating and Process Furnaces, E. F. Holser.
The Contribution of Broaching to the Automotive Industry, Sol Einstein and Millard Romaine.
Industrial Bearing Design as Influenced by Automotive Practice, A. B. Willi.

8.00 p.m. Recent Developments in the Basic Processes of Fabrication, viz., Casting, Forging, Welding, Machining, Pressing and Rolling, with Social and Economic Implications, William S. Knudsen.
Contribution of Machine Tool Builders to Mass Production in the Automotive Industry, by Fred W. Cederleaf.

Wednesday, May 19th—

9.00 a.m. The Aspects of Automotive Engineering which have been Applicable to Railroading, Ed. G. Budd.
The Economics of Power for Light-Weight Trains, Dr. Rupen Eksergian.

2.00 p.m. Welded Fabrication of Large Frames, by Everett Chapman.
Hydromatic Welding of Frames, C. L. Eksergian.
The Prevention of Surface Condenser Tube Failures, Robert, E. Dillon, George C. Eaton, and H. Peters.

2.00 p.m. (Cont.) The Condensation of Flowing Steam, John I. Yellott and C. Kenneth Holland.
Panel Discussion on Spreader Type Stokers, led by J. F. Barkley.
The Automobile Industry and Young Engineers, C. J. Freund.
Apparatus and Test Results on Dry Friction. Various Materials and Comparisons with Other Data, by W. E. Campbell.
Oil Film Thickness at Transition from Semi-Fluid to Viscous Lubrication, by G. B. Kayelitz and J. N. Kenyon.
Descriptive Lectures and Tours to Plymouth Assembly Line and Forge Shop of Chevrolet Gear and Axle Plant.
The Petroleum Industry in Michigan, by C. R. Miller.

8.00 p.m. The Decentralization of Industry, by W. J. Cameron.

Thursday, May 20th—

9.00 a.m. Modern Methods of Production and Quality Control of Sheets for Automobile Fabrication, T. F. Olt.
Proper Grain Structure Required for Deep Draw and Discussion of other Problems involved in Application of Wide Sheets, J. E. Angle and W. F. McGarrity.

2.00 p.m. Properties of Steel when Subjected to High-Velocity Loading, Col. Glen F. Jenks.
Economic Characteristics of Typical Business Enterprises, Walter Rautenstrauch.
A Study of the Lip Clearance on Twist Drills, Charles J. Starr.
The Grinding of Cemented Carbide Milling Cutters, Hans Ernst.
Report of Subcommittee on Metal Cutting Data on Reducing Production Costs by more Effective Use of Metal Cutting Tools, R. C. Deale.
The Pooling of Power Sources in a Large Industrial Centre, J. W. Parker and R. E. Greene.
Analysis and Tests on the Hydraulic Circuits of Surface Condensers, G. H. Van Hengel.
Notes on High Speed Diesel Engine Maintenance Practice in the Canadian National Railways, I. I. Sylvester.
New Urban Transportation Equipment and New Steam Railroad Equipment, H. L. Andrews.

6.30 p.m. Dinner Meeting.
President James H. Herron to speak on
1. Summary of Week's Programme and its implications.
2. Society Affairs.
Principal Speaker—Col. Willard T. Chevalier.
Followed by informal reception and dance.

Friday, May 21st—

9.00 a.m. Operating Experiences in the Steam and Power Department of the South's First Alkali Plant, G. P. Avery.
Formulas for Stresses in Bolted Flanged Connections, Everett O. Waters, D. B. Rossheim, D. B. Wesstrom, and F. S. G. Williams.
Railroad Streamlining, Dr. A. I. Lipetz.

An important feature of the meeting will be the sightseeing and technical inspection tours, arranged for both visiting engineers and ladies, a number of these being held each day throughout the meeting.

## The Plastics Industry

The discovery of a whole class of materials of a new type is an important event. That is what has happened within the last few years in the invention of the substances known as synthetic resins or resinoids. Many of these possess qualities which have enabled them to fill requirements for which no suitable material was previously available.

The synthetic resins belong to the class of plastics, substances which can be placed in moulds and then hardened in their finished form. Thirty years ago celluloid and vulcanite were the only plastics in common use. Their utility was limited, since after being moulded they soften at a moderate temperature and are subject to other disadvantages. In 1906, however, L. H. Baekcland discovered that on heating a mixture of phenol (carbolic acid) and formaldehyde (formalin) with a little ammonia, a substance was produced which resembled natural resin, and when warmed could be squeezed into a mould. He found that if the mould was then heated to about 300 degrees F. the material hardened, and thereafter did not soften at a reasonable temperature. The resulting material was hard, amber-like, an electrical insulator, had considerable mechanical strength, absorbed little or no moisture and was acid resistant. Under the name of bakelite it soon found wide acceptance, particularly in the electrical industry. Later it was found advantageous to mix the resinous mass with a filler, such as wood flour or paper pulp, and grind the mixture to a coarse powder, known as moulding powder. The powder, which becomes plastic under heat and pressure, is then pressed in the mould and is heated for a few minutes until the hardening reaction takes place. The use of a suitable filler led to a considerable saving in cost, and in many cases an increase in mechanical strength. If a long fibrous filler in woven or loose state is used, the finished product possesses much greater resistance to shock. In fact, laminated bakelite of this type can be used for gear wheels and for parts of electrical machinery or aeroplane equipment which require toughness and strength. Resinoids with a breaking strength of from 10,000 to 20,000 pounds per square inch are now available.

For some purposes, the brownish colour of bakelite was found to be a disadvantage. About 1920 it was discovered that urea, a substance formed synthetically from carbon dioxide and ammonia, would combine with formaldehyde to give a colourless, translucent resinoid which can be dyed or filled with coloured pigment. Some recent plastics are so clear and transparent that they can be used as a substitute for glass. Others are valuable as bases for paints and varnishes, for which purpose their superior resistance to weather enables them to replace natural resins to a considerable extent, thus leading to marked improvement in the protective power and durability of paints and varnishes for both wood and metal surfaces.

In addition to the phenolic and urea types of plastics there are others of more recent discovery. The alkyd resinoid, formed by chemical action between glycerine and phthalic acid, for instance, is a water-white material which cuts like horn, and can be used as a substitute for shellac in electrical insulation. Still other classes are produced from acetylene or from acetone, the latter being the basis of the material which shows most promise as a light-weight substitute for glass for aeroplane screens and windows. In fact, patents for new types of synthetic resins are constantly appearing.

When a resinoid is hardened by heat, interesting molecular changes occur, due to a process which chemists call polymerization. It is now known that the linking of atoms into rings and chains by interchanging their chemical bonds may produce larger units less easily moved by the atomic vibrations which we call heat. This happens when bakelite is heated to about 300 degrees F., when the short chains of perhaps a half dozen minute links of phenol and formaldehyde join each other and form comparatively long chains of molecules. The hardened bakelite is thus an irregular tangle of minute thread-like chains of molecules, which further heat will not disentangle, although at a much higher temperature the material will ultimately char and decompose. Actually, vegetable and animal fibres are all composed of chain-molecules of this type, held together by electrical attraction.

The development of the plastics industry has been favoured by the cheapness of its raw materials. Fortunately coal, air and water are plentiful. For example, nitrogen, from air, and hydrogen, from water, are made to combine under high pressure to form ammonia, which in turn will react with carbon dioxide, also under high pressure, to form urea. Formaldehyde is made from air and methyl alcohol, which itself is made from carbon monoxide and hydrogen, both these gases being produced by blowing steam over white hot coke. The resulting urea and formaldehyde give us one important class of plastics.

It seems unlikely that plastics will replace metals for most engineering purposes, or that research will be able to produce resinoids approaching steel in tensile strength, hardness or resistance to wear, but they are replacing metals for many articles not requiring great strength or hardness, particularly for household use. They are now indispensable in the electrical industry, where they supply a long felt want. They will probably replace pottery for many purposes. A list of their present uses would fill pages of this Journal.

The plastics industry has now passed through the troubles of infancy, and has taken its place as an important source of supply for electrical, aircraft and automobile manufacture, and for innumerable personal and domestic requirements. It forms an effective auxiliary in many lines of manufacture and increases the demand for a wide range of basic products. The creation of an entirely new industry of such wide scope is likely to have many favourable economic results. There is a recent suggestion, for example, that unemployment conditions, which are still so difficult in certain "depressed areas" in Britain, could be materially improved by the local development of factories for plastic products.

## Semicentennial Committee

A. Cousineau, A.M.E.I.C.
R. L. Dobbin, M.E.I.C.
J. M. Fairbairn, A.M.E.I.C.
R. H. Findlay, M.E.I.C.
F. S. B. Heward, A.M.E.I.C.
J. L. Busfield, M.E.I.C., Chairman

**OTTAWA BRANCH**
Alan K. Hay, A.M.E.I.C.

**QUEBEC BRANCH**
H. Cimon, M.E.I.C.

**TORONTO BRANCH**
C. E. Sisson, M.E.I.C.

### TRANSPORTATION

The Canadian Passenger Association has granted reduced fares—namely, one and one third plus 25 cents, for the Semicentennial, good going June 11th to June 17th, return limit 30 days. All members will be supplied with the necessary identification certificate very shortly.

More complete particulars will appear in our next announcement.

### OTTAWA MEETING

Committees under the general chairmanship of Mr. A. K. Hay, A.M.E.I.C., are actively engaged in preparation for the Semicentennial activities on Friday, June 18th. A luncheon and dinner dance are being arranged, at both of which there will be guest speakers of prominence.

In addition, arrangements are being made for visits to such notable engineering works as the power plants of the Gatineau Power Company, the Gatineau Mill of the Canadian International Paper Company, and the laboratories of the National Research Council.

### VISITORS

The Society of Naval Architects and Marine Engineers (New York) is being represented at the Semicentennial by seven members of its Council, including Mr. H. Gerrish Smith, Vice-President and Secretary-Treasurer, and a number of notables in the marine engineering world.

### TECHNICAL PAPERS

The papers for presentation at the Semicentennial, and also those dealing with the historical review of engineering in Canada, for the Semicentennial issue of the Journal are now rolling into headquarters. In due course they will be made available in preprint form.

The Symposium on the burning of Canadian coals by eleven authors is going to be a notable contribution to the meeting, and to the literature of engineering.

### PLENARY MEETING OF COUNCIL

A plenary meeting of the Council of The Institute has been called for Monday, June 14th.

## OBITUARIES

### Frederick William Angel, A.M.E.I.C.

It is with deep regret that we place on record the death at St. John's, Newfoundland, on March 4th, 1937, of Frederick William Angel, A.M.E.I.C.

Mr. Angel was born at St. John's on December 15th, 1874, and graduated in engineering with first class honours from McGill University in 1898. He returned to St. John's as mechanical draughtsman with the Reid Newfoundland Company, and in 1899 became acting superintendent of the locomotive shops of the same company. In 1900 Mr. Angel joined the staff of the Dominion Iron and Steel Company, and was located at Bell island until 1902. He subsequently became secretary and manager of the Angel Engineering and Supply Company, and within ten years became one of Newfoundland's leading consulting engineers. At the time of his death Mr. Angel was president of William Heap and Company, and William Noseworthy Limited; vice-president and managing director of the St. John's Nail Manufacturing Company; managing director of the Bell Island Transportation Company; secretary of the Consolidated Foundry Limited, and a director of the Newfoundland Power and Paper Utilities Corporation.

Mr. Angel joined The Institute (then the Canadian Society of Civil Engineers) as an Associate Member on October 12th, 1905.

### Joseph William Heckman, A.M.E.I.C.

It is with regret that we place on record the death at Montreal on March 20th, 1937, of Joseph William Heckman, A.M.E.I.C., a member of The Institute of many years standing.

Mr. Heckman was born in October 1854, and was a graduate of the University of King's College, Nova Scotia, from which institution he received the degree of Bachelor of Engineering in 1876. He was subsequently engaged in the location and construction of railways, and from 1880 until 1887 he was on the staff of the Federal Department of Railways and Canals. In 1888 Mr. Heckman entered the service of the Canadian Pacific Railway Company, as assistant engineer. In 1898 he was appointed photographer in the engineering department, and in 1902 he became inspector, and was located at Fort William, Ontario. In 1903 Mr. Heckman was transferred back to Montreal, and was engaged in various capacities until April 1921 when he retired from the service.

Mr. Heckman joined The Institute (then the Canadian Society of Civil Engineers) as an Associate Member on February 24th, 1887, and was made a Life Member on May 27th, 1924.

### Alphonse Lafleche, M.E.I.C

We regret to have to record the death at Montreal on March 8th, 1937, of Alphonse Lafleche, M.E.I.C.

Mr. Lafleche was born at St. Martin, Laval County, Quebec, on December 5th, 1884, and graduated from the Ecole Polytechnique, Montreal, in 1909, with the degree of C.E. After two years of general engineering work, he entered the service of the Dominion Department of Marine as assistant engineer in 1911. In 1917 Mr. Lafleche became senior assistant engineer, and in 1929 was appointed assistant chief engineer, the River St. Lawrence Ship Channel, which office he held until his death. Mr. Lafleche's knowledge of the St. Lawrence river from Montreal to the sea was wide and thorough, and this was recognized by the Federal Government in 1934 when he was appointed a member of the Interdepartmental Water Levels Board, appointed to study and report on the cause of recurring low water levels in the St. Lawrence and at Montreal.

Mr. Lafleche became a Student of The Institute on January 14th, 1909, an Associate Member on June 27th, 1916, and a full Member on May 21st, 1935.

### Thomas Taylor, M.E.I.C.

Members of The Institute will learn with much regret of the death at Toronto, Ontario, on December 21st, 1936, of Thomas Taylor, M.E.I.C.

Mr. Taylor was born at Cheltenham, Ontario, on January 1st, 1876, and graduated from the School of Practical Science, University of Toronto, in 1902. Following graduation Mr. Taylor was employed in detailing and checking structural work with various construction companies in the United States and Canada, and from 1909 until 1911 worked with the Canada Foundry Company, designing and estimating steelwork for buildings. In 1912 Mr. Taylor entered the service of the Department of Works of the City of Toronto as assistant to the engineer of railways and bridges, and was engaged on bridge maintenance and construction. He designed and superintended the construction of the Bloor Street viaduct, and later was appointed engineer of railways and bridges for the city. During his service in this capacity, Mr. Taylor supervised the designing of the St. Clair Avenue East bridge, the North Glen Road bridge, and the Eastern Avenue bridge. He held the appointment up to the time of his death.

Mr. Taylor became a Member of The Institute on April 18th, 1916, and took an active interest in the affairs of the Toronto Branch, having been chairman of the Branch in 1929.

### Samuel Fraser Workman, M.E.I.C.

Deep regret is expressed in placing on record the accidental death at Goldstream, B.C., on March 19th, 1937, of Samuel Fraser Workman, M.E.I.C.

Mr. Workman was born at Montreal, Que., on November 2nd, 1884, and from 1906 until 1910 was chainman and transitman with the Canadian Northern Railway. In 1910 he joined the staff of the Canadian Northern Pacific Railway as transitman; from 1912 until 1914 he was resident engineer for the railway in charge of construction on Vancouver Island. Proceeding overseas with the Canadian Railways Troops, Mr. Workman was lieutenant in charge of construction and operation of light railways, with the Canadian Corps. From November 1916 until February 1919 he was officer commanding the Light Railway Company with the Canadian Expeditionary Force in France, with the rank of Major. Mr. Workman was twice mentioned in despatches and was awarded the Military Cross.

Returning to Canada in 1919, Mr. Workman became resident engineer in charge of construction of the Okanagan Branch of the Canadian National Railways. In 1922 he was with the Black Mountain Irrigation District at Rutland, B.C., and in 1923 he was attached to the Department of Public Works of the Province of British Columbia. In 1930 Mr. Workman was superintendent with the Fraser Valley Tie and Timber Company at Kamloops, B.C., and at the time of his death he was road engineer for the Associated Engineering Company.

Mr. Workman became an Associate Member of The Engineering Institute of Canada on March 23rd, 1920.

## PERSONALS

A. Clairmont, S.E.I.C., who has been connected with the Singer Sewing Machine Company at St. Johns, Que., has been appointed plant engineer for the same company at Thurso, Que. Mr. Clairmont graduated from the Ecole Polytechnique in 1936, with the degree of B.A.Sc.

O. N. Mann, S.E.I.C., is now on the staff of the Eagle Pencil Company at Drummondville, Que. Mr. Mann, who graduated from the Nova Scotia Technical College in 1935 with the degree of B.Sc., was formerly with the Imperial Oil Limited, at Halifax, N.S.

Charles L. Bates, M.E.I.C., has recently been appointed chief engineer of the Pacific Great Eastern Railway, Vancouver, B.C. Mr. Bates graduated from the Massachusetts Institute of Technology in 1903 with the degree of B.Sc. and in 1904 joined the Canadian Pacific Railway Company as resident engineer on construction. He also served in that organization as assistant division engineer in the construction department and in the engineering department on maintenance of way until 1915. From 1915 until 1920 Mr.

Charles L. Bates, M.E.I.C.

Bates was engaged in private municipal engineering practice. In 1921, after being on the construction of Pier B.C. in Vancouver for the Canadian Pacific Railway, he joined the Northwest Dredging Company of Vancouver, as chief engineer and superintendent, remaining with that company until 1926. Since 1927 Mr. Bates has been with the Pacific Great Eastern Railway as maintenance of way engineer.

M. F. Cossitt, A.M.E.I.C., has been appointed city engineer of the City of Sydney, N.S. Mr. Cossitt, who has been engaged in private practice in Sydney, was at one time with the International Paper Company Limited, at Corner Brook, Nfld.

A. J. E. Smith, S.E.I.C., who graduated from the University of Toronto in 1935 with the degree of B.A.Sc., and is sales engineer with Canadian Allis-Chalmers Limited, has been transferred by that company from Toronto to Winnipeg, Man.

B. P. Rapley, A.M.E.I.C., has returned to Talara, Peru, as chief engineer for the International Petroleum Company there. Mr. Rapley was acting chief engineer for the company at Talara in 1935, but during 1936 was with the Imperial Oil Company at Sarnia, Ontario.

G. H. E. Dennison, A.M.E.I.C., has recently returned from a trip to Europe, where he visited Great Britain, Norway, Sweden, Finland and Russia, spending about two months in a number of paper mills in the U.S.S.R. Mr. Dennison, who is with the Canadian Carborundum Company Limited, at Niagara Falls, Ontario, has made a number of similar trips to Europe during the past few years, making a special study of groundwood and grinding problems. Following graduation from the Royal Military College in 1920, Mr. Dennison was connected with the Lake Superior Paper Company, and the Spanish River Pulp and Paper Mills Limited, at Sault Ste. Marie, Ontario. From 1928 until 1930 he was engineer at the Sault Ste. Marie mill of the Abitibi Power and Paper Company, and from 1931 until 1934 was with the Algoma Steel Corporation. In 1934 Mr. Dennison accepted the position with the Canadian Carborundum Company which he now holds.

A. Duperron, M.E.I.C., formerly chief engineer of the Montreal Tramways Commission, has been appointed chief engineer of the Montreal Tramways Company. Mr. Duperron is a graduate of the Ecole Polytechnique, Montreal, from which he received the degree of B.A.Sc. in 1911. During his college course he was engaged on various survey works, and immediately following graduation he was associated with Mr. E. Laignon on hydro-electric and building construction. In September of the same year he was engaged on railway location with the Central Railway of Canada between Hawkesbury and Ottawa, and in January 1912 Mr. Duperron accepted a position with W. I. Bishop, M.E.I.C., on hydro-electric surveys on the St. Francis river and on construction work at Drummondville, Que. From September 1912 until May 1913 he was employed in the office of the construction department of the Canadian Pacific Railway at Montreal, subsequently being transferred to the bridge department on the design and preparation of bridge plans. In August 1915 he joined the staff of the Quebec Streams Commission, first as chief of a survey party in the Lake St. John district, and later in charge of construction of the superstructure of a bridge over the Sauvage river in connection with the Lake St. Francis reservoir. Following this he was on the staff of the Commission at Montreal. In 1927 Mr. Duperron was appointed chief engineer of the Montreal Tramways Commission.

Mr. Duperron takes an active interest in Institute affairs, having been chairman of the Montreal Branch in 1931, and at the present time represents that Branch on the Council.

E. C. Kirkpatrick, M.E.I.C., is now works manager of the Montreal Division of the Steel Company of Canada, Limited. Mr. Kirkpatrick has been connected with that company since graduating from McGill University in 1906 with the degree of B.Sc., first as a draughtsman, later as superintendent of construction, and then as mechanical engineer, which position he has held for a number of years.

**F. H. Kester, M.E.I.C.**

F. H. Kester, M.E.I.C., has been elected President of the Canadian Bridge Company Limited, Walkerville, Ontario. With this office he combines the general managership. Mr. Kester, who studied structural and mechanical engineering at the University of Wisconsin, joined the staff of the Canadian Bridge Company in 1907 as draughtsman, becoming successively, assistant engineer from 1912 until 1919, contracting engineer from 1919 until 1927, and vice-president and director from 1927 until the present time.

R. A. Spencer, M.E.I.C., was recently appointed vice-president of the Canadian Bridge Company Limited, Walkerville, Ont. Mr. Spencer graduated from the University of Vermont in 1908 with the degree of B.Sc. and in 1909 was field superintendent for the Peterson Lake Mining Company, located at the Nova Scotia Mining Company, Cobalt, Ontario. During the years 1910-1912 he was with

**R. A. Spencer, M.E.I.C.**

the Nova Scotia Mining Company as cost keeper and assistant to the superintendent during the construction of cyanide mills. In 1912 Mr. Spencer joined the staff of the Canadian Bridge Company Limited as a draughtsman, and continued with that company in various capacities until 1927 when he was appointed contracting engineer, which position he has held up to the present time.

Colonel J. L. H. Bogart, R.C.E., D.S.O., A.M.E.I.C., has been appointed Officer Commanding Military District 13, at Calgary, Alta. Colonel Bogart, who was formerly stationed at Petawawa, Ontario, was at one time Director of Engineer Services, Department of National Defence, Ottawa, Ont.

V. W. Dick, A.M.E.I.C., is now in the engineering office of the Winnipeg Electric Company in Winnipeg, as junior engineer. Mr. Dick graduated from the University of Manitoba in 1921 with the degree of B.Sc., and subsequently took the students course of the Canadian Westinghouse Company Limited. From 1923 until 1926 he was with the same company as sales engineer, and from 1926 until 1929 he was draughtsman with the Manitoba Power Company Limited. In 1929 Mr. Dick became electrical designer for the Northwestern Power Company Limited, and remained in that position until 1931 when he was electrical inspector for the Northern Power Company at Seven Sisters, Man. He was later operator for the Northwestern Power Company Limited.

A. Holland, A.M.E.I.C., has been appointed as Colonial Engineer and Surveyor General, with the Public Works Department, Roseau, Dominica, Leeward Islands. Mr. Holland's previous colonial service was as an executive engineer, with the Public Works Department, Gold Coast Colony, West Africa. More recently Mr. Holland has been located in Chester, England.

S. McCune, Jr. E.I.C., is now on the staff of the General Engineering Company (Canada) Limited, and is at present engaged in the design of the mill extension of the Aldermac Copper Corporation at Arntfield, Que. Mr. McCune, who graduated from the University of Illinois in 1930 with the degree of B.Sc., was formerly with the Ontario Department of Northern Development at Sudbury, Ontario.

## Elections and Transfers

At the meeting of Council held on March 23rd, 1937, the following elections and transfers were effected:

*Members*

ANVIK, Herlaug, M.E., (Kristiania Tech. Coll.), efficiency engr., Canadian International Paper Co. Ltd., Temiskaming, Que.

WATSON, Alexander, (Robt. Gordon's Coll.), chief engr., marine dept., Canadian Vickers Ltd., Montreal, Que.

*Associate Member*

FRY, Frederick George, B.A.Sc., (Univ. of Toronto), asst. divnl. engr., Shell Oil Co. of Canada Ltd., London, Ont.

SHAW, William Ulric, B.A.Sc., (Univ. of Toronto), asst. engr., Fairchild Aircraft Ltd., Longueuil, Que.

WILSON, William Bowman, B.Sc., (McGill Univ.), res. engr., R.C.A.F. Station, Trenton, Ont.

*Juniors*

ASKWITH, Winston M., B.Eng., (McGill Univ.), instr'man. and asst. engr., Federal District Commission, Ottawa, Ont.

BRADFORD, George Allen McClean, B.Sc., (Univ. of Sask.), dftsman., Imperial Oil, Ltd., Sarnia, Ont.

DORAIS, Gabriel, B.A.Sc., C.E., (Ecole Polytech., Montreal), with E. Gohier, M.E.I.C., consltg. engr., Montreal, Que.

ENGLER, Charles Roy, B.Sc., (Queen's Univ.), dftsman., J. H. Connor & Son Ltd., Ottawa, Ont.

FOTHERINGHAM, William Webster, B.Sc., (Univ. of Man.), engr., Standard Iron Works Ltd., Edmonton, Alta.

GRAHAM, George, B.Sc., (Univ. of Sask.), bureau of economic geology, Dept. of Mines, Ottawa, Ont.

SOMMERVILLE, Donald Barton, B.A.Sc., (Univ. of Toronto), struct'l. engr., Canadian Comstock Company, Toronto, Ont.

STEIN, Marcus, B.Eng., (McGill Univ.), 3849 St. Urbain St., Montreal, Que.

*Affiliate*

CROSSE, Claude St. Cyr, plant operation and mtce., Hydro-Electric Power Commission of Ontario, Niagara Falls South, Ont.

*Transferred from the class of Associate Member to that of Member*

DINGWALL, Robert Macfarlane, A.R.T.C. (Mech.), (Royal Technical College), mgr. and director, Standard Iron Works Ltd., Edmonton, Alta.

KEAN, David Jacques, (Univ. of Toronto), county engr. and road supt., P..O. Box 579, Whitby, Ont.

TALMAN, Stephen Goldwyer, dftsman., dept. of works, water distribution section, City of Toronto, Toronto, Ont.

TURNER, Earle O., S.B. (Civil), (Mass. Inst. Tech.), professor of civil engrg., University of New Brunswick, Fredericton, N.B.

*Transferred from the class of Junior to that of Associate Member*

ELLIOT, Donald George, B.Sc., (Univ. of Edinburgh), asst. mill engr., Anglo-Newfoundland Development Co. Ltd., Grand Falls, Nfld.

GAUVIN, Herve Alfred, B.Sc. (Civil), (McGill Univ.), divn. engr., Dept. of Highways, L'Assomption, Que.

WARDLEWORTH, Theophilus Hatton, B.Sc., (McGill Univ.), designer, Aerocrete Construction Co. Ltd., Montreal, Que.

*Transferred from the class of Student to that of Associate Member*

CAMERON, John, B.Sc., (N.S. Tech. Coll.), asst. engr., Can. Gen. Elec. Co. Ltd., Peterborough, Ont.

DYMENT, John Talbot, B.A.Sc., (Univ. of Toronto), asst. engr., aeronautical engrg. divn., Dept. of National Defence, Ottawa, Ont.

EMERY, Donald Joseph, B.A.Sc., (Univ. of B.C.), asst. engr., Can. Gen. Elec. Co. Ltd., Peterborough, Ont.

*Transferred from the class of Student to that of Junior*

DAVIDSON, Arthur Campbell, B.Sc. (C.E. and E.E.), (Univ. of Man.), 1732-11th St. West, Calgary. Alta.

DOUGLAS, Arnold Howard, B.Eng. (Civil), (Univ. of Sask.), junior engr., Dept. Public Works, Canada, Langham, Sask.

TOLLINGTON, Gordon C., B.Sc., (Univ. of Alta.), induction motor engrg. dept., Can. Gen. Elec. Co. Ltd., Peterborough, Ont.

*Students Admitted*

ANDRE, Kenneth Bailey, (Queen's Univ.), 324 Johnson St, Kingston, Ont.

BAKER, William Gordon, (McGill Univ.), 821 McEachran Ave., Outremont, Que.

BECKER, Sidney John, (McGill Univ.), 282 Villeneuve St. W., Montreal, Que.

BOONE, Harold Percival, (Univ. of N.B.), 470 Charlotte St., Fredericton, N.B.

BOURNE, James Douglas, (McGill Univ.), 32 Holton Ave., Westmount, Que.

CARSON, Robert John, (Grad. R.M.C.), (Queen's Univ.), 72 Barrie St., Kingston, Ont.

DICK, William Arthur, (McGill Univ.), 1512, St. Mark St., Montreal, Que.

DOUCETT, Rolphe Leigh, B.Eng., (N.S. Tech. Coll.), Shediac, N.B.

DRAKE, Thomas Stuart, (McGill Univ.), 3298 Cedar Ave., Westmount, Que.

DUCHASTEL, Pierre Arthur, (McGill Univ.), 640 Dunlop Ave., Outremont, Que.

EDWARDS, Milton Chalmers, (Univ. of Alta.), P.O. Box 193, University of Alberta, Edmonton, Alta.

ELFORD, Wesley Fred, (Univ. of Alta.), Foremost, Alta.

EXELROD, Bert, (McGill Univ.), 260 Laurier Ave. W., Montreal, Que.

FISH, Abe, (McGill Univ.), 2012 Ontario St. East, Montreal, Que.

HALL, Gordon Hudson, (R.M.C.), 88 London St., Peterborough, Ont.

HERTEL, Alfred Frederick, B.Sc., (Queen's Univ.), 155 Central Ave., London Ont.

HIBBARD, Ashley Gardner, (McGill Univ.), 4712 Western Ave., Westmount, Que.

HORWOOD, William Osmund, (McGill Univ.), 5806 Notre Dame de Grace Ave., Montreal, Que.

HURST, Charles Kenneth, (Univ. of Alta.), St. Stephen's College, Edmonton, Alta.

KENNEDY, Harold E., (Queen's Univ.), 48 Highview Crescent, Toronto, Ont.

KIRKPATRICK, Robert Evans, (McGill Univ.), 47 Ainslie Rd., Montreal West, Que.

KOSNAR, Vincent George, (McGill Univ.), 3591 Jeanne Mance St., Montreal, Que.

LANGSTON, John Francis, (Univ. of Alta.), Edmonton, Alta.

LEGER, Joseph Arthur Kennedy, (Univ. of N.B.), P.O. Box 245, Newcastle, N.B.

LEWIS, Crompton Emerson, B.A.Sc., (Univ. of Toronto), 334 Reid St., Peterborough, Ont.

LOISELLE, Harold John, (McGill Univ.), 65 Duverger Ave., Outremont, Que.

MacGIBBON, James Alexander, (McGill Univ.), 3723 Jeanne Mance St., Montreal, Que.

MARSHALL, Welsford Allen, (Queen's Univ.), 184 University Ave., Kingston, Ont.

McLEAN, Murray Douglas, (McGill Univ.), 2325 St. Luke St., Montreal, Que.

NOWLAN, Brete Cassius, (McGill Univ.), 5510 Queen Mary Rd., Montreal, Que.

PARKER, Edmund Norval, (McGill Univ.), 505 Argyle Ave., Westmount, Que.

PARSONS, Ronald Albert, (Univ. of Alta.), 8909-112th St., Edmonton, Alta.

PEACOCK, Robert Frederick, (Univ. of N.B.), Lady Beaverbrook Residence, University of New Brunswick, Fredericton, N.B.

POOLE, John Edward, (Univ. of Alta.), 11716-100th Ave., Edmonton, Alta.

SCHWARTZ, Harry H., (McGill Univ.), 5230 Clarke St., Montreal, Que.

SHECTOR, Lindley, (McGill Univ.), 2241 Maplewood Ave., Montreal, Que.

SPRINGFORD, William R. H., (Univ. of N.B.), 29 Allen St., Fredericton, N.B.

THOMPSON, Arthur McCall, (Univ. of Alta.), P.O. Box 194, University of Alberta, Edmonton, Alta.

WILSON, Murray Edgar, (Univ. of N.B.), 34 Enterprise St. Moncton, N.B.

## Erratum

In publishing Professor G. Vibert Douglas' paper entitled "Some Features of Mining Geology" in the March, 1937, issue of The Engineering Journal, the formula shown at the foot of the right-hand column on page 118 should have read as follows:—

$$\text{Present Worth} = \frac{A}{\dfrac{0.04}{(1+0.04)^n - 1} + 0.10}$$

## CORRESPONDENCE

The Editor,
The Engineering Journal,
Montreal.
Dear Sir:—

I have just recently returned from Europe, and thought that you might be interested to hear something of my trip. I visited Great Britain, Norway, Sweden, Finland and Russia, spending about two months in a number of paper mills in the U.S.S.R. The Russian cities, particularly Moscow, reflect the increasing prosperity of the country, and I found the appearance of the streets, the shops and the dress of the people themselves considerably improved in the last year. The new constitution adopted last November guarantees citizens peaceful possession of personal belongings, and jewels, furs, etc. long concealed appear in public once more. Money appears plentiful in certain quarters, particularly among writers, musicians and artists attached to the theatre, and there is plenty of feasting, drinking and dancing in the Moscow restaurants, although the prices are still exorbitant. Whether this last phase of existence will be lasting or not remains to be seen. Russia has passed through many phases since the revolution.

Industrial development continues in Russia to absorb most of the national income. Capital construction goes about 75 per cent into new plants, equipment and transport; 25 per cent into dwellings, schools, theatres, etc. The output of industry has been considerably increased by the adoption of piece-work as a basis of payment, known in Russia as the Stahkanov movement. The unit output per worker is still however only a fraction of that obtained here and their living conditions vastly inferior to that of workmen in Canada.

Although there are said to be 10,000 newspapers in Russia, only two of them, Pravda and Izvestia, are widely read or widely circulated within the country. The circulation of these papers has to be restrained due to the scarcity of paper, for although there are many newsprint mills in Russia, their output is used for a wide variety of purposes for which finer papers are used here.

The output of paper in Russia this year will be increased by nine new machines of their own manufacture, and is expected to approximate one million tons. The new machines are similar to the Bagley-Sewell machines operating at Balahkna, but incorporate features of other makes and original designs of the Russian engineers.

Everything considered, the paper industry in Russia has lagged in development behind other industries, but steps are now being taken to bring it up in line. Interest in machine improvements, in pre-heating cooking acid for digesters and in vitrified abrasives for pulp grinding is strongly evidenced on all sides.

In Norway, Sweden and Finland, rapid progress is being made towards industrial recovery. Many Norwegian paper mills have been shut down or operating at reduced output, but now with rising prices an active programme of rehabilitation is going forward while Finland's rapidly growing export trade has already made its influence felt on world markets.

Yours very truly,
Geo. H. Dennison, A.M.E.I.C.

Niagara Falls, Ontario,
March 21st, 1937.

## BULLETINS

*Construction Machinery.*—A 20-page booklet received from the London Concrete Machinery Co. Ltd., London, Ontario, contains particulars of their concrete mixers and general line of construction machinery, including hoses, pumps, engines, etc.

*Grinding Machine.*—Brown and Sharpe Mfg. Company, Providence, R.I., have issued an 8-page leaflet describing their new No. 10 cutter and tool and grinding machine. This is a new design and the complete equipment can cover a wide variety of grinding. Particulars of attachments are included.

*Proportioning Equipment.*—A 24-page catalogue issued by D. W. Haering and Company, Inc., Chicago, Ill., describes the operation and application of proportioning equipment, and explains the use of the Haering fluid piston principle, including detailed descriptions of the new model twin feeders. The use of pitot tubes, fluid pistons and proportioning of various chemicals is discussed in detail.

*Water Meter.*—The Worthington-Gamon Meter Company, Harrison, N.J., has issued an 8-page bulletin describing their Watch Dog disc water meter of heavy duty type, which comes in 3- and 4-inch sizes, having respectively a safe maximum delivery capacity of 315 and 500 gallons p.m.

*Milling Machinery.*—An 8-page folder received from Brown and Sharpe Mfg. Co., Providence, R.I., contains a description of their No. 22 plain milling machine, for which they claim quick setups, unusual rigidity, etc.

*Turret Lathes.*—A 4-page leaflet received from The Bullard Company, Bridgeport, Conn., contains particulars of their vertical turret lathes, manufactured in 24, 36, 42, 54 and 64 inch sizes.

*Diesel Engines.*—The English Electric Company of Canada Limited, St. Catharines, Ont., in a 22-page bulletin, give specifications of design and construction of their 2-stroke cycle engines, of medium speed, in sizes of 150 to 1,000 B.h.p.

## BOOK REVIEW

### Rayon and Synthetic Yarn Handbook

*By Dr. E. W. K. Schwarz and Herbert R. Mauersberger. Rayon Publishing Corporation, New York. 1936. 5¼ by 7¾ inches. 558 pages. 230 illustrations, tables, charts. Second enlarged edition. $4.50. Cloth.*

This handbook, which is described as a practical reference book for the producer, manufacturer, processor, distributor, dry-cleaner, launderer, economist and student, contains twenty chapters, the first of which deals with the historical background of the European and the American rayon industry. The economic and statistical background of the industry, and raw materials and their preparation are dealt with in the opening chapters. Chapter four includes a description of the following four yarn manufacturing processes: viscose, cellulose acetate, the cuprammonium process, and the nitro-cellulose process. The winding, soaking and throwing, warping and warp sizing, and weaving of rayon goods, are described in the ensuing chapters, as is the construction of commercial grey goods and the manufacture of rayon knit goods. The next chapters deal with the dyeing of rayon yarns and goods, the printing of rayon and synthetic fabrics, and dry finishing and special processes. Chapters dealing with physical and chemical tests and identification follow, and the dry cleaning of rayon and acetate materials, the laundering of washable synthetic fabrics have not been neglected.

A bibliography of American and foreign literature is included.

# Developments in the Art of Surveying

**Extracts from an address before the Canadian Institute of Surveying on February 3rd, 1937, by Major-General A. G. L. McNaughton, C.M.G., D.S.O., LL.D., M.E.I.C. President, the National Research Council, Ottawa.**

Eleven years ago I had the privilege of addressing your organization, then the Association of Dominion Land Surveyors.

In the interim, it has been my fortune to hold a position from which I could watch the many developments in the art of survey in Canada, particularly those which have come about in the Geographical Section.

During this period, the most notable advance has been the application of air photographs to survey purposes and their development from the rudimentary uses in the Great War until today they form an essential component in the mechanism of map-making in all its various divisions. From elementary qualitative results, today, the air photograph is depended upon for precise measurements, both in plan and in elevation, and for much of the topographical and other information which requires to be depicted on the modern map, and which otherwise could only be acquired by the painful and slow process of traversing the ground on foot.

Canada was in a specially favourable position to take advantage of the air photograph for survey. We had available all the wealth of practical experience which had come from the work of Bridgland and Wheeler in the photogrammetric survey of the mountain areas of British Columbia and Alberta; we had the experience which our survey officers brought back from Europe where, under the strong incentive of war, developments had taken place which, otherwise, might have required decades; and, perhaps most importantly, we had in front of us an urgent task to make available maps of vast areas which could not be met by any of the methods previously available. Further, much of the area to be mapped was interspersed with large lakes which provided automatically a horizontal plane of reference and thus enabled the use of a simplification of the oblique perspective method appropriate to the then state of the art.

It was recognized from the earliest days of the formation of the Department of National Defence that the pilots of the Air Force would need extensive training and practice in air photography, as this is one of their important duties in war, and it was the preoccupation of all concerned to see that this work served also a useful economic purpose.

Much the same is true of the maps made by the Geographical Section. The personnel had to be trained and there is no training so useful as a job of practical work.

On the formation of the Department of National Defence in 1923, one of the first things done was to establish an Interdepartmental Committee so that requests for air photos could be co-ordinated and the best possible use made of the limited flying time available from the R.C.A.F.

In 1926, reorganization and consolidation of survey services were very much under discussion. We have had to wait for more than ten years for this objective to be realized, but it has been realized at last and I join in sincere congratulations to the Hon. T. A. Crerar, and to his Deputy, Dr. Camsell, who have now brought about this much desired consummation. All of us who are interested in the progress of survey in Canada can look forward to a period of great progress.

We are now in a position, for the first time, to really plan our mapping and charting programmes on a broad and comprehensive basis, and the organization which has been set up makes possible a concentration of effort on those sections of the work which are, for the time being, of predominant importance.

The Interdepartmental Committee on Air Photographs was reorganized in 1929 to provide wider representation of the services concerned. In 1933 the whole situation was re-examined and as a result it seemed that requirements in connection with air photographs could best be met by dividing the task into several parts: first, the control of actual photographic operations was entrusted to a reorganized Interdepartmental Committee under the chairmanship of Dr. Camsell; second, the investigation of new methods of turning the advantages of the air photograph to account was remitted to a Survey Research Committee organized under the Research Council; and, third, the general responsibility for finding new and advantageous uses for air photographs, not only for mapping but for other purposes as well, was entrusted to a separate division of the Topographical Surveys under the charge of Mr. A. M. Narraway. Mr. Narraway became the secretary both of Dr. Camsell's committee and of the Research Council committee, thus providing a very necessary link between the several organizations concerned.

As regards Dr. Camsell's committee, and its predecessor, in the intervening years since 1922, 700,000 photographs, covering nearly as many square miles of our territory, have been taken by the R.C.A.F., or acquired from other sources, and these photographs have been classified and indexed as a national collection available for any purpose required.

Today, I am to speak primarily from the point of view of the National Research Council, and, particularly, of our Committee on Survey Research, and to endeavour to give you some account of the facilities which we can place at your disposal to assist you in the development of new and still further improved methods so that the maps required to plan and execute the development of our vast territories may be made available at less cost, in less time, and to the end that they will possess that high degree of precision in the representation of relevant detail and topographical features which are now such essential characteristics if they are to serve a useful purpose.

The Committee on Survey Research is now in process of reorganization to fit in with the consolidation which has taken place in the Department of Mines and Resources. At present the committee has sections devoted to:

- Infra-red and Colour Photography;
- Contouring from Air Photographs and Instruments for Plotting;
- Photographic Aircraft;
- Aerial Camera Auxiliaries and Testing of Film and Photographic Material.

The membership of these subcommittees comprises not only the technical officers of the various branches of survey but also representatives of the user and operating services as well, and they provide a forum where difficulties, present and prospective, can be discussed and solutions suggested.

From the Council's staff, technical experts in almost every line can be brought in for consultation and advice; expert chemists to advise on plate emulsions and developers, inks for printing and paper to meet the special needs of maps; physicists on lenses and other optical devices; engineers on mechanical problems, such as are presented in the axis bearings of precise theodolites; skilled designers who can take the general ideas suggested for new devices and work them into apparatus which is practically realizable, and last, but not least, a very competent workshop in which these new instruments can be constructed to a degree of precision and finish which compares favourably with the best that Europe can turn out.

This committee has behind it a long record of useful accomplishments, and, by way of example, I mention one item of the work of the Subcommittee on Contouring from Air Photographs and Instruments for Plotting. I refer to the radial line plotter which has now been completed and put into use. This machine has cut the time required for the measurement of detail on vertical photographs in half, so that there is no doubt that our investment in time and money will be well repaid. The instrument cost us $2,842 to build, and this went largely to Canadian workmen. Alternatively, we estimate that at least $21,000 would have been required if the contract for the machine had been let abroad and then we would have failed to acquire that knowledge and experience which only goes to those who essay to launch out and pioneer a new development.

The experience gained in this venture alone is more than worth the whole cost because it gives confidence in undertaking to find, ourselves, the answer to the many special problems that face us in the mapping of the vast spaces of Canada—problems which differ both in degree and in kind from those of any other country on earth. If we waited for others to produce the answers we require, we would wait in vain. Therefore, I say to you that research is not the least important of the duties that fall to the attention of those who are responsible for survey in Canada.

Another example is a very useful improvement developed by the Subcommittee on Photographic Aircraft, the multi camera mount. This, in addition to tripling the number of photographs from a given flying time, has resulted in giving us co-ordinated sets taken from the same point in space from which the required measurements can be determined with great facility. I would say, conservatively, that in operations where oblique photography is required this improvement alone has reduced air survey costs by at least one half.

In the foregoing remarks, I have been thinking of the air photographs in terms principally for supplying topographical information for maps. But the air photograph is useful for many other purposes as well. We think that now we should be able to carry forward a traverse for considerable distances without even having to go on the intervening ground at all. To help in the investigation of this problem, a special instrument, known as a stereogoniometer, was designed by Mr. Fourcade, a South African. In collaboration with our own technical officers the design of this instrument has recently been modified to suit our special requirements and, thanks to the generosity of the Imperial Oil Company, funds have been provided for its construction, and an order has been placed with Messrs Barr and Stroud in England.

In the other fields as well the closest attention has been given to the development of new methods and instruments, and some important improvements have been made. However, it is clear that the greater share of the credit for the remarkable increase in the rate of production, as well as in the quality of our maps, undoubtedly belongs to air survey, and is reflected in the fact that in the whole history of Canada up to 1922 only some 240,000 square miles of our territory, mostly in the settled portions, had been mapped. Since 1922, and the arrival of the air photograph, 481,000 square miles have been mapped and this area lies mostly in the more difficult unsettled regions, where, previous to the development of the air, it was impossible to do any detailed survey at all. For this north country, the air has wiped out a frontier and opened new lands for economic development. In 1935, the freight carried by air into these parts exceeded 26 million pounds, a figure which represents six-sevenths of all the freight carried by air in the whole British Empire; this year it is estimated that an increase of over one-third will be realized.

If time had permitted, I would have liked to refer to the uses being found for air photographs in forest inventory work; in the study of road, railway and transmission line location; in the geological field for ascertaining the position of faults in the earth's surface so that prospectors may be guided to the most likely areas of mineralization; in water power development; in city planning—to mention only a few of the wide variety of services which now make use of air photographs.

To give point to the economic value of this work, I would mention that some of the photographs in the national collection have been put to over twenty separate uses in a single year. The average is estimated at over ten uses for each photograph. In one case in Manitoba, as a result of information obtained, an important new road to a mining area was shortened by 31 miles at a saving of $5,000 to $7,000 per mile—the saving on this one project alone exceeding the total cost of all photographic flying in Canada for the year.

The wide diversity in the application of air photographs means that the costs chargeable to any one service are proportionately reduced, thereby extending the possibilities for economic use.

I think I have said enough to indicate in a general way the value, the economic importance and the economy which comes from the use of air photographs. For all this benefit to Canada, we are primarily indebted to the officers and other ranks of the Royal Canadian Air Force, who have carried out the difficult and, ofttimes, dangerous flying involved, who have borne cheerfully and without complaint the hardships inseparable from prolonged operations far away from civilization, and who have contributed from their great experience to the technical developments which have taken place, and to the training of all concerned in their use.

In conclusion, I would observe that, through the various sub-committees of the Survey Research Committee, we are closely in touch with similar work being carried out in Great Britain, in the United States, and on the continent of Europe, and that the committee is alert to seize upon and turn to our own advantage any new development which may take place.

I assure you that this committee and the National Research Council are anxious to assist you in any and every way which may be possible.

## The Great Flood of 1936 in New England

Following the floods of July, 1935, in the New York State, floods rising to unprecedented heights inundated the river valleys of the North-Eastern States of the United States of America. Between March 18th and March 21st, 1936, nearly every river, large and small, in the 200,000 square miles of country from the Canadian boundary to Virginia and Ohio created new records of flood heights and peak-flow volume, submerging the lower districts of the valley cities and carrying havoc and destruction on their way.

The rainfall was due to a series of cyclones which traversed this area, causing heavy rain and snow. There was a heavy snowfall during the winter months and such rains as fell were held by the snow cover. During the first fortnight of March there was a succession of warm days, which loosened the snow cover. Heavy rain in the second week of March caused floods in several smaller rivers, the larger rivers began to rise almost to "bank-full stage," and the thick ice on the rivers began to break up. On the afternoon of March 17th, heavy rain fell in the nothern area of New England, followed by a general downpour throughout the eastern states.

Pinkham Notch, New Hampshire, in the White Mountains, registered nearly 8 inches of rainfall on March 12th and 13th, with a maximum daily temperature of 44 degrees. During the next week, from March 17th to 19th, the same station registered nearly 10 inches of rainfall and a daily temperature of 47 degrees.

The major streams affected were the Potomac in Maryland, the Ohio from Pittsburgh to Cincinnati, the Allegheny and Monongahela in Pennsylvania, the Susquehanna in New York and Pennsylvania, the Connecticut, the Merrimac, the Androscoggin, the Kennebec and the Penobscot in New England, and the St. Johns River in Canada. The unprecedented heights reached, the magnitude of the area and the number of populous cities affected by submersion, ranks the inundation as one of the major catastrophies of the United States.

The Potomac River, at Harpers Ferry, on March 18th, rose to a height of 36.6 on the river gauge, the previous highest level recorded being 36.0 in 1889. At Hancock, higher up the river, the water reached a level of 47.5 on the gauge, nearly 8 feet above the level reached in 1889.

Pittsburgh, Pennsylvania, at the junction of the Alleghany and the Monongahela rivers, has always been subject to floods. Because of the immense losses so sustained, the Pittsburgh Flood Committee was formed to study methods of preventing the recurrence of such disasters, particularly that of 1907. The Committee submitted its report in 1911, and predicted a future flood stage of 43.0, based on a probable flow of 634,000 cusecs from the two rivers.

On Monday, March 16th, 1936, at 8.0 a.m., the river gauge stood at 19.8, with a rising river; by 8.0 a.m. of the 17th, the water had risen to 24.7; on the 18th, 8.0 a.m., it had risen to 42.0; and by 7.0 p.m. a maximum stage of 46.0 was reached, and stood at this height for four hours, the crests of the floods in the two rivers arriving simultaneously at Pittsburgh. By 6.0 p.m., March 20th, the river stage had fallen to 25.0. The estimated flood discharge of the river at stage 46.0 was 640,000 cusecs, which slightly exceeded the predicted maximum flood discharge. The high stage of 46.0 might have been due to obstructions and encroachments on the stream and to navigation dams, or to a reduced flood slope.—*Engineering.*

# BRANCH NEWS

## Border Cities Branch

*J. F. Bridge, A.M.E.I.C., Secretary-Treasurer.*
*F. J. Ryder, Jr.E.I.C., Branch News Editor.*

After the regular dinner meeting of the Border Cities Branch, Professor Geo. J. Higgins, Ae.A., of the University of Detroit, spoke on "Archery."

The container for holding arrows usually holds ten to twelve arrows. In medieval days the quiver held twenty-four arrows, and each archer had two quivers.

Arrows are made of all kinds of material, depending on personal ideas and theories. The broadhead type, so-called because of the shape of the arrowhead, predominates. These may be of two types, the barbed or the barbless, both types being used for hunting. The blunt head arrow is used for practice and target arrows have special heads. Long distance or flight arrows have small vanes and are usually longer and lighter than the ordinary arrow.

Bows vary in shape and size. The long-bow equals the height of the owner, the strength depending on the length of arm and the strength of the individual. The old English archers drew their bowstrings to their ear, but present day archers draw to their chin and line the string with the target, their sight thus giving them the plane of flight. The short-bow is coming more and more into prominence as it is more easily handled, especially for hunting purposes.

An archer's equipment consists of a quiver with arrows, a variety of bows, a bracer which is worn on the wrist to protect it from the vibrations of the bowstring after release, and finger protectors for the hand that holds the bowstring.

A hunter using a bow and arrow must stalk his game as well as shoot it. Indians were good hunters not because of their skill with a bow and arrow but because of their cleverness in stalking game.

Most distance shooting is done with a very strong bow, the bow being held by the feet while the archer lies on his back, elevates his bow to the correct angle and draws the bowstring back with his hands. All old records for long distance shooting have been surpassed by this style of shooting.

Scientists and physicists are now at work studying archery and trying to design bows that give a maximum performance with a minimum amount of effort.

Roy C. Leslie, A.M.E.I.C., moved a hearty vote of thanks to Professor Higgins, which was seconded by E. M. Krebser, A.M.E.I.C., and unanimously approved by all present.

## Calgary Branch

*James McMillan, A.M.E.I.C., Secretary-Treasurer.*

### Overhead Conductor Vibration

The first meeting of the Calgary Branch in 1937 was held on January 14th. At this meeting, W. J. Gold, Jr.E.I.C., spoke on "Overhead Conductor Vibrations" discussing in detail the causes of vibration, particularly in the case of steel reinforced aluminum conductor, and the methods used to combat vibration. By means of illustrations and samples Mr. Gold showed the application of the "festoon" method, Stockbridge dampeners and armour rods and their effectiveness in reducing conductor vibration. At the conclusion of the talk a number of members contributed to an interesting discussion of the use of dampening devices, especially armour rods.

### Annual Joint Dinner

On January 23rd the Renfrew Club, Calgary, was the scene of the annual joint dinner of The Calgary Branch of The Engineering Institute of Canada, the Association of Professional Engineers of Alberta, and the Rocky Mountains Branch of the Canadian Institute of Mining and Metallurgy. This event is arranged each year by a committee of members of each organization and contributions towards the expenses are made by each organization. At this year's dinner, P. Turner-Bone, M.E.I.C., one of the oldest engineers in Alberta both in years and in service, was chosen as chairman, and Mr. A. E. Ottewell, Registrar, University of Alberta, was selected as guest-speaker. Mr. Ottewell took as his subject "Nothing Remains to be Done," and in his talk he covered briefly the advances made by the various professions, advances so marvellous and so, relatively, progressive that it would seem as if nothing further needed to be done while actually so much still remains to be done in engineering and other professions. About one hundred engineers attended this enjoyable function.

### Sound Natural and Unnatural

The Branch general meeting on February 11th was addressed by A. T. McCormick, A.M.E.I.C., who took as his subject "Sound, Natural and Unnatural." This talk was supplemented by diagrams and curves projected on a screen and also by a special gramophone which was used to bring out the effect of sound suppression above and below certain frequencies. Mr. McCormick's talk was followed by a very interesting discussion.

Beet Sugar Refining

On March 4th a joint meeting of the Calgary Branch and the Junior Section of the Calgary Board of Trade was addressed by Mr. F. H. Ballou, chief engineer, Canadian Sugar Factories, Ltd. and B.C. Sugar Refining Co., Ltd., Vancouver, on "Beet Sugar Refining" and "Construction of the Picture Butte Sugar Factory." Mr. Ballou commenced his address by enumerating the factors to be considered in selecting a site for a beet sugar factory and explained how the site chosen at Picture Butte fulfilled these conditions. The speaker described the methods of construction used and the equipment installed in the various parts of the sugar factory. The total investment made is about $1,500,000. In concluding his talk Mr. Ballou made a strong plea to those present to aid the beet sugar industry in Southern Alberta by using beet sugar. After the talk a number of pictures illustrating the construction of the Picture Butte factory were shown and various points were explained by Mr. Ballou.

The talk and showing of pictures were followed by an interesting discussion in which several members took part. One of the points brought out in the discussion was that, contrary to popular opinion in some quarters, there is absolutely no difference between beet sugar and cane sugar. R. S. Trowsdale, A.M.E.I.C., in moving the vote of thanks to Mr. Ballou, pointed out the importance of the beet sugar industry in the economic situation of Southern Alberta and advocated the support of this industry.

## Edmonton Branch

*M. L. Gale, A.M.E.I.C., Secretary-Treasurer.*
*F. A. Brownie, Jr.E.I.C., Branch News Editor.*

The annual mixed meeting of the Branch was held on February 16th, 1937, when members entertained their wives and friends at dinner in the Corona hotel.

Branch Chairman E. Stansfield, M.E.I.C., presided, and after a very short business meeting introduced the guest speaker, Captain E. R. Gibson of the Alpine Club of Canada. Captain Gibson chose as his subject "Climbing on the Great Divide." His talk was illustrated with many excellent slides, and he drew from a wealth of personal experience for the material of his address.

The speaker described the climbing of many well-known peaks in the Jasper area, including the great Mount Robson. Several of the climbs were "first ascents." Particularly difficult was the ascent of Mount Clemenceau on account of its isolated position. The two previous ascents of this peak had been accomplished by fairly large parties, well equipped and using horses. Captain Gibson's party was small, unassisted by horses, and carried only what was possible by back-packing. The Athabasca river formed one of the worst hazards of the expedition, but was crossed by the ingenious use of a raft and the climb completed without serious mishap.

Of particular local interest was the detailed account of the accident on Mount Geikie, when an Edmonton doctor broke his leg. He was forced to spend a very cold night on the mountain-side, and his subsequent rescue down steep rock and snow slopes proved both difficult and hazardous.

The address was much enjoyed by the audience, and J. D. Baker, M.E.I.C., moved a vote of thanks to the speaker.

## Hamilton Branch

*A. R. Hannaford, A.M.E.I.C., Secretary-Treasurer.*
*W. W. Preston, S.E.I.C., Branch News Editor.*

Vancouver Jubilee Fountain

The new policy of the Papers committee of the Hamilton Branch was well received at the general meeting held at McMaster University on February 19th, 1937. The speaker at most previous meetings has come from outside the city, but on this occasion two local engineers addressed the Branch, G. F. Mudgett, manager of the illuminating division of the Canadian Westinghouse Company, an outstanding authority on illumination, and J. T. Thwaites, Jr.E.I.C., who has had wide experience in thermionic control, spoke on the design and operation of the Jubilee fountain designed by Mr. McKenzie, and recently erected in Stanley Park, Vancouver. The popularity of the meeting was apparent from the fact that the attendance of ninety-five included several ladies.

Mr. Mudgett, who was introduced by the chairman, E. G. MacKay, A.M.E.I.C., described the appearance of the fountain. It is a monument of classical architecture, set in the middle of a lagoon with rustic background. The structure is built of concrete on a foundation of long piles. There is a lower basin of 40-foot diameter, and an upper basin of 14-foot diameter. From these two levels, five individual water effects are produced. A stream of water varying in height from nil to 135 feet issues from a 28 mm. nozzle in the centre of the upper pool. Around the edge of this pool there is a ring 13 feet in diameter, with a hundred and thirty-two 10 mm. nozzles. The water rising therefrom gives the appearance of a vertical cylinder with a height up to 35 feet. Around the lower pool there are eight rings, each 4 feet in diameter, and each has a 10 mm. nozzle at its centre. These central jets rise to a maximum height of 35 feet and the water cylinders surrounding them to a height of 20 feet. The remaining individual water effect is a parabolic dome which is formed by streams from three hundred and ten nozzles inclined 15 degrees to the vertical in a ring 35 feet in diameter around the lower pool. All streams are floodlighted in varying colours. The lights are under water in hermetically sealed, aluminum cases, each with a single coloured lense. By changing the intensity of illumination of the various coloured floodlights, and by varying the heights of the different water streams, it is estimated that there are about two and a half million different effects being produced continually.

Mr. Thwaites explained why the $32,000 fountain performed in the manner described by his colleague. This speaker discussed the method employed to control the gradual variations in water pressure on the nozzles and then outlined the difficulties of choosing a lighting control that would give smooth changes in illumination. Flashing, he stated, was an undesirable control because of its abruptness. Dimming by the familiar resistance method was also objectionable, due to high power losses and to the large number of costly resistance steps required. Reactance dimming, in which d.c. flows around the iron core of the reactance as a.c. passes through it, gives a wide range of control with little power loss, but cannot be employed unless d.c. is available. When the only source is a.c. thermionic tubes are used as rectifiers. It is this last control that is used on the Jubilee fountain. The complex cycle on which variations in water pressure and coloured lighting operate was described. Although the cycle is automatic it is possible to insert a manual control unit. The power consumption for all controlling devices totals only 40 watts. Peak load is 38.6 kw.

Throughout the lecture lantern slides were shown, and at the close a demonstration on the mixing of coloured lights was given. Unfortunately, colour filming will not give a satisfactory picture of this fascinating fountain in Stanley Park, Vancouver.

The vote of thanks to the speakers was moved by H. A. Lumsden, M.E.I.C., and the meeting adjourned for refreshments.

The Manufacture of Cold Drawn Wire

A meeting of the Hamilton Branch was held at McMaster University on March 10th, 1937.

The speaker was A. B. Dove, A.M.E.I.C., a member of the Branch, whose subject was "The Manufacture of Cold Drawn Wire and Some Factors Affecting its Physical Properties."

Mr. Dove, who is a chemical engineer engaged with the Canada Works of the Steel Company of Canada in Hamilton, was introduced by the chairman, Col. E. G. Mackay, A.M.E.I.C.

Wire has become a highly specialized product and to illustrate the scope of the wire industry the speaker said that one of his firm's customers calls for two hundred and eighty-one different sizes and grades of wire.

Specifications for such special products demand accurate tests of the material in all its processes from the open hearth furnace to the finished wire.

The McQuaid-Ehn test which was developed in 1922 was explained with the help of a series of lantern slides. After the material is carburized the outer layers are examined under a microscope to determine the size of the grains; the material is then classified by a number which indicates one of eight standard grain sizes. This test is of major importance because the properties of the metal are definitely related to the grain structure.

The rod coming from the rolling mill has a mill scale that must be removed before the rod can be drawn through the die; this is removed by pickling but this process exposes the rod to hydrogen embrittlement. This condition is overcome by the rod passing through a further process of liming and baking.

The rod then goes to the drawing blocks and next passes through the dies, which are of special design, and so is finally reduced to the required size. The throat of the nozzle shaped die must be of a definite angle for each particular grade of material so that the wire will not break in the die.

Before the drawing operation the grains have a cubical shape but as the wire passes through successive reduction dies the grains assume a needle like shape, lying in the direction of flow of the metal.

A further operation of annealing or patenting, depending on the carbon content of the material, may be employed to relieve a grain stress and permit further working of the material to bring it to the required size.

Finally the wire is tested for such qualities as tension, elongation, hardness, torsion, crimping and bending, depending, of course, on the purpose for which the wire will serve.

The speaker stated that under a continuous load or strain a wire would undergo a change of grain structure, thus its physical properties would change. For this reason, particularly, the greatest care should be exercised in the choice or selection of wire for each particular purpose.

A hearty vote of thanks was accorded Mr. Dove for the interesting manner in which he had presented his subject to an audience of fifty-five members and visitors.

The meeting adjourned for refreshments and this usual feature of the Branch was enjoyed until a late hour.

## London Branch

*D. S. Scrymgeour, A.M.E.I.C., Secretary-Treasurer.*
*Jno. R. Rostron, A.M.E.I.C., Branch News Editor.*

The regular monthly meeting of the Branch was held on February 25th, 1937, in the Public Utilities Commission Board Room at the City Hall, the speaker being G. Harold Reavely, M.A., D.I.C. (London), Assistant Professor of Geology at the University of Western Ontario, London.

The chairman of the Branch, A. O. Wolff, M.E.I.C., presided and after the reading of the minutes which were unanimously adopted he called on H. F. Bennett, M.E.I.C., chairman of the newly formed Papers Committee, to report progress. Mr. Bennett explained the aims and objects of the Committee and said so far they had met with success and already had one or two favourable responses from prospective speakers and they hoped soon to have a complete programme for the entire year. He also urged members to contribute papers.

SOME GEOLOGICAL PRINCIPLES AFFECTING THE ENGINEER

Professor Reavely pointed out that chemistry and physics were fundamental to geology as also to engineering and that often the trained engineer was not conversant with geology. Among the important questions which the engineer has to consider are the character of rocks for building and road material; for tunnelling operations; dam and reservoir foundations; landslides, etc.; the geological conditions affecting and controlling underground water supplies and the relation of soils to sewage disposal and water purification. Some familiarity with materials on fuels, clays, cements is necessary.

In considering rocks from the standpoint of road construction it is necessary to study the character of the rock and its structure. Clays are likely to give much trouble owing to expansion if wet and shrinkage if dry.

All rocks contain joint and other types of planes and may slide along any of these if unsupported. If water is present frost causes a great tendency towards slipping.

Local sources of supply are usually drawn upon for road construction and broken stone may be any kind of rock included in the igneous, sedimentary or metamorphic groups but the minerals which make up these may be divided into two classes, viz., primary and secondary. The former include quartz, feldspar, pyroxens, amphibolite, biotite, muscovite, calcite, dolomite, garnet, olivene, etc. The latter chlorite, kaolinite, sericite, limonite, serpentine, epidote and sometimes calcite and quartz. The weathering properties are important and depend upon the mineral composition and not the hardness. Granites have several features mitigating against their best use alone as road metals. They are of low toughness and low cementing value, their texture is granular rather than interlocking and contain platy mica; thus they are liable to fall apart. They should not be exposed to the traffic but placed in the foundation.

Regarding building stone the selection of material is wide, but the properties governing this selection are different. One of the most important features is texture. This is the result of the physical aggregation and size of the mineral crystals and particles which compose the stone. It may be coarse, fine, even grained, porphyritic or dense or porous. Coarse grained rocks disintegrate more rapidly than fine grained and porphyritic more than even grained. This is due to the different expansion of the individual minerals. Rocks containing more pyritic minerals should never be selected for building stone, chemical products of oxidation ($H_2SO_4$) dissolve the rock material.

In addition, the speaker described the three main divisions of rocks, the structures in rocks and something about underground waters.

An interesting discussion followed the speaker's remarks, and a vote of thanks was proposed to Professor Reavely by E. V. Buchanan, M.E.I.C., seconded by H. F. Bennett, M.E.I.C., and unanimously carried.

## Montreal Branch

*E. R. Smallhorn, A.M.E.I.C., Secretary-Treasurer.*

THE ENGINEER AND NON-FERROUS ALLOYS

At the meeting of the Montreal Branch held on February 25th, 1937, H. J. Roast, F.C.S., F.C.I.C., M.E.I.C., vice-president in charge of technical operations for the Canadian Bronze Company and its subsidiaries, presented an interesting paper which dealt particularly with the necessary relations between design, pattern making and casting of non-ferrous alloys. Useful general information was also given concerning these alloys, and an explanation as to their use. The paper was illustrated with slides.

H. W. B. Swabey, M.E.I.C., was in the chair.

JUNIOR SECTION

At the meeting of the Junior Section held on March 1st, two papers were presented, one by Yvon Deguise, S.E.I.C., a student in his final year at the Ecole Polytechnique, Montreal, entitled "L'Application des relais pour la protection des lignes des transmissions," and one by M. J. Lupton, S.E.I.C., who is on the staff of the Dominion Bridge Company, Limited, Lachine, on "Further Research on the Residual Stresses Set up by Welding."

Mr. W. Horwood acted as chairman.

LARGE PIPE LINES WITH SUPPORTING RING GIRDERS

E. C. Molke, A.M.E.I.C., and A. W. F. McQueen, A.M.E.I.C., who are both with H. G. Acres and Company Limited, Niagara Falls, Ont., addressed the Montreal Branch on March 4th, their subject being the design problems of an 18-foot diameter steel penstock, which is at present being constructed in connection with the Comeau Bay development of the Ontario Paper Company.

Previous to the meeting an informal dinner was held at the Windsor hotel.

The chairman was M. V. Sauer, M.E.I.C.

TELEMETERING

On March 11th, Mr. P. A. Borden, development engineer for the Bristol Company of Waterbury, Conn., addressed the Branch, his subject being "Telemetering." The speaker described metering by the current, voltage, frequency and position systems. The talk was illustrated by lantern slides.

An informal dinner was held at the Windsor hotel prior to the meeting.

Graham Kearney, M.E.I.C., was in the chair.

JUNIOR SECTION

At the meeting of the Junior Section held on March 15th, J. M. Cape, S.E.I.C., a member of the engineering staff of E. G. M. Cape and Company, presented a paper on "The Theory and Application of Sliding Forms in Concrete Structures having Thin Walls," and W. E. Griffiths, Jr.E.I.C., presented one which dealt with "The Handling of Concrete in the Field."

Hugh Gordon, S.E.I.C., was chairman.

APPLICATION OF NEGATIVE REGENERATION IN COMMUNICATION

On March 18th, C. B. Fisher, A.M.E.I.C., radio receiver engineer for the Northern Electric Company Ltd., in Montreal, spoke on the principle of negative regeneration, which is one of the most important technical advances in electrical communication in recent years. The paper was illustrated and demonstrations were made of some of the phenomena involved.

J. H. Thompson, A.M.E.I.C., was in the chair.

ALL WELDED STEEL HIGHWAY BRIDGE

At the meeting of the Montreal Branch held on March 25th, P. Brault, A.M.E.I.C., of the Dominion Bridge Company Limited, presented a paper dealing with the design, fabrication and erection of the new all welded steel highway bridge over the Ste. Anne river at Ste. Anne de la Perade. This bridge is a six-span continuous deck plate girder type.

Huet Massue, A.M.E.I.C., acted as chairman.

## Niagara Peninsula Branch

*P. A. Dewey, A.M.E.I.C., Secretary-Treasurer.*
*C. G. Moon, A.M.E.I.C., Branch News Editor.*

AIR COMPRESSORS—SELECTION AND DESIGN

The February meeting of the Niagara Peninsula Branch was held on the 18th at the Fox-head Inn, Niagara Falls.

G. H. Wood, A.M.E.I.C., graced the chair, while vice-chairman L. C. McMurtry, A.M.E.I.C., was on hand to introduce the speaker.

Councillor E. P. Murphy, A.M.E.I.C., and the chairman reported upon their trip to the Annual Meeting in Montreal.

E. T. Harbert, A.M.E.I.C., of the Canadian Ingersoll-Rand Company, presented a paper dealing with the selection and design of air compressors. Illustrated by means of lantern slides, this paper discussed reciprocating compressors and their relation to modern industry, giving examples of varying types with figures of their energy losses and regulation. The subject of valves, and valve actions, was given special consideration.

R. A. Bradley, A.M.E.I.C., expressed the thanks of the meeting to the speaker for his able handling of a complex subject.

At the close of the meeting, a session of the Executive was held to discuss general business and to make arrangements for subsequent meetings.

## Ottawa Branch

*F. C. C. Lynch, A.M.E.I.C., Secretary-Treasurer.*

ADDRESS BY PRESIDENT

An event of outstanding interest to the Ottawa Branch was the noon luncheon on February 25th, 1937, at which G. J. Desbarats, C.M.G., Hon.M.E.I.C., president of The Institute, addressed the members upon Institute affairs. Mr. Desbarats, a resident of Ottawa, has long been a member of The Institute, his period of membership ante-dating by a dozen years the formation of the Ottawa Branch in 1909.

J. G. Macphail, M.E.I.C., chairman of the Branch, in his introduction, referred to the career of Mr. Desbarats both as an engineer and as a public servant up to the time of his retirement a few years ago from the position of Deputy Minister of the Department of National Defence. Mr. Desbarats, in acknowledging the introduction, stated that he felt the office of president for the 1937 year was one of particular responsibility in that The Institute was celebrating the Semicentennial anniversary of its formation during the summer.

The speaker then briefly traced the history of the organization since its formation dealing with its growth from a mere 288 members at first to its present status with headquarters at Montreal and 25 branch organizations extending from Sydney, Nova Scotia, to Victoria, British Columbia. A point brought out in this history was the fact that at the time of the commencement of the Great War in 1914 the membership was about 2,800 of which 950 or more than one-third enrolled for overseas service. Of these 119 never returned.

A considerable portion of the president's address was taken up in reviewing the various steps that had been taken to date toward arranging for the consolidation of The Institute with the various provincial engineering associations.

Fifty years is a short period in the life of an organization of this kind, stated Mr. Desbarats at the conclusion of his address, but during that time engineering has completely revolutionized our manner of living. "Progress has indeed been great," he concluded, "and it is to the members of this Institute, and particularly to the younger members, one looks to see that the progress of the future measures up to that of the past. It is our lot to contribute a very vital part to the advance of civilization, the improvement of social security, and the happiness of mankind."

The luncheon was well attended both by members of The Institute and others who wished to pay tribute to the distinguished speaker. At the head table in addition to the chairman and the speaker there were: Major General A. G. L. McNaughton, M.E.I.C., president of the National Research Council; F. C. Green, M.E.I.C., Surveyor General of British Columbia, Victoria, B.C.; Hon. Michael Dwyer, A.M.E.I.C., Minister of Mines of Nova Scotia; George H. Desbarats, A.M.E.I.C., Low, P.Q.; K. M. Cameron, M.E.I.C., Commander C. P. Edwards, A.M.E.I.C., Noel Ogilvie, M.E.I.C., Dr. R. W. Boyle, M.E.I.C., Major General T. V. Anderson, A.M.E.I.C., Lieut. Col. G. R. Turner, A.M.E.I.C., Group Captain E. W. Stedman, M.E.I.C., and John McLeish, M.E.I.C.

Engineering in Agriculture

"Engineering in Agriculture" was the subject of the noon luncheon address on March 11th at the Chateau Laurier, the speaker being E. S. Hopkins of Ottawa, Dominion Field Husbandman of the Dominion Experimental Farms.

Dr. Hopkins, at the commencement of his address, enumerated various ways wherein engineering knowledge was called into use in connection with farming operations. Drainage, irrigation, the design of farm buildings, farm machinery, the utilization of farm power, studies in relation to electrification, water erosion, soil drifting control and flood control were some of the ways listed.

In times of depression, a solution commonly advocated for the employment of those who have lost their positions in the cities and towns is to place them out on farm lands. Those who propose such measures lose sight of the fact that farming is becoming a more highly specialized occupation, requiring capital, assurance of revenue, a knowledge of machinery, education, good physical condition, and many other things. Furthermore with the increased use of machinery and mechanization generally there has been a marked decrease for years in the proportion of those engaged in rural occupations.

According to the last census figures, there was one tractor for every seven farms in Canada. In the Prairie Provinces the figures were one tractor for every three farms. With the increased mechanization there is a tendency to increase the size of the farms themselves.

Showing the effect of the size of farm holdings, Dr. Hopkins stated that it had been determined in investigations carried on in Western Canada in 1930 that when a quarter-section of 160 acres was devoted to the production of wheat the cost of production was about $1.02 per bushel. When larger acreages were farmed for the same purpose costs were respectively: 80 cents per bushel for a half section, from 63 to 77 cents per bushel for a full section, and from 51 to 55 cents per bushel for two to three sections, depending upon the nature of the equipment used. Some might deplore carrying on farming operations in a large way, but it must be considered in the light of what the farmer himself can make out of it.

Although agriculture on first sight does not seem to be a very competitive line of business, yet looked at in a broad national and international way it is very much so. In the future farming will tend to become more specialized, and will more and more require the aid of specialized knowledge. The engineer will accordingly occupy a greater part than he already has, and his services will be called upon to a greater extent in connection with the many engineering aspects of agriculture.

J. G. Macphail, M.E.I.C., chairman, presided at the luncheon and in addition head table guests included: G. J. Desbarats, Hon. M.E.I.C., Murray Clark, M.P., Dr. H. T. Gussow, Dr. A. Gibson, L. L. Bolton, M.E.I.C., E. Viens, M.E.I.C., T. A. McElhanney, A.M.E.I.C., Robert Brindley, P. Sherrin, A.M.E.I.C., Maxwell Tobey, M.E.I.C., C. L. O'Brien and Alan K Hay, A.M.E.I.C.

## Peterborough Branch

*W. T. Fanjoy, A.M.E.I.C., Secretary-Treasurer.*
*E. J. Davies, A.M.E.I.C., Branch News Editor.*

The first meeting of the Peterborough Branch for this year was a supper meeting held at the Kawartha Club House on January 14th. Members brought as guests young engineers who were prospects for membership in The Institute. The meeting was under the chairmanship of H. R. Sills, A.M.E.I.C., who called on R. L. Dobbin, M.E.I.C., vice-president of The Institute. Mr. Dobbin outlined aims and objectives of The Institute and explained to the prospective members reasons why they should become affiliated with this organization.

Nepheline Cyanite

Mr. H. R. Deeth, manager of the Canadian Nepheline Cyanite Co. of Lakefield, gave a short address on "Nepheline Cyanite" which is now being manufactured at Lakefield. Nepheline cyanite is a natural rock formation found on Blue Mountain, Methune Township, Peterborough County. It looks like granite and is used in the glass industry after it has been finely ground. The grinding is done in part of the old Canada Cement plant at Lakefield. The producers of this powder claim that it greatly clarifies the manufactured glass.

After the address the student and junior section of this branch was reorganized and then the members and guests spent the balance of the evening at bridge or ping pong.

Electric Welding

On Thursday, January 28th, the members of this Branch were addressed by Mr. H. Thomasson, engineer on electric arc welding, Canadian Westinghouse Co., Hamilton. Mr. Thomasson has been actively engaged in electric arc welding for many years and has followed its development from the crudest possible methods to its present status. He told of great recent improvements in methods and of the advance effected in the substitution of composition-coated welding rods for the older type of straight metal welding rods. He spoke of the new use of alternating current in seam welding. As alternating current of the lower cycles in common use is of no use, 100,000 cycle current is superimposed.

Referring to a popular make of 4-door sedan cars, Mr. Thomasson said the completed job contains 3,415 separate welds. A typical six and one-half cubic foot refrigerator has 1,509 welds in its construction.

The operation of a great automatic seam-welding machine which will fasten two large sheets of metal together much as a sewing machine fastens together two pieces of cloth, was explained. The two edges of metal to be welded pass between two power rollers. Intermittent arcs weld a solid seam as the rollers pull the metal through.

Electric welding played an important part in the construction of a great liner for the first time in history as welding was employed almost throughout in the construction of the great *Queen Mary*.

General Electric House of Magic

The General Electric "House of Magic" visited Peterborough on February 17th and 18th, under the joint auspices of The Engineering Institute, Kiwanis Club, and Social and Athletic Club of the Canadian General Electric. The demonstration was in charge of Mr. Wm. A. Gluesing. The term "House of Magic" was applied to the General Electric Laboratories at Schenectady, N.Y., in 1928 and these laboratories employ nine hundred workers including three hundred scientists, technicians and physicists.

Responding to general public demand the company built a miniature "House of Magic" on wheels. A similar unit to the one in Peterborough was a feature of the Century of Progress Exposition at Chicago, where Mr. Gluesing exhibited it for two years. It was also at the Canadian National Exhibition and in New York City.

Among a whole series of amazing demonstrations that were presented by Mr. Gluesing in rapid succession, and which held his audience enthralled, polaroid, the new material that enables light to travel only in one plane was demonstrated publicly for the first time, and one cannot but be impressed with the apparent number of commercial possibilities which it offers.

When two sections of this glass-like material are placed against each other it is possible by changing the relative positions of the two pieces of polaroid to either pass light or stop it.

Using the phototube or what has come to be known as the "electric eye," Mr. Gluesing picked up the music of a phonograph from a light beam and converted the light back into sound through a loud speaker.

The current from the phonograph pick-up was so arranged that it travelled to a lamp on a tripod, the sound waves being transformed into light. The lamp having the ability to go on and off hundreds of thousands of times to the second transmitted an ever-changing beam of light equivalent to the notes of the phonograph record. Focussed on the receiving end of a phototube pick-up at the other end of the stage, however, the light was turned back to music. Mr. Gluesing played many uncanny tricks with the light beam, cutting off the music at will, or diminishing the sound.

In another experiment which demonstrated the versatility of the phototube, Mr. Gluesing used it to turn the light of an incandescent tube into sound—flickering on and off one hundred and twenty times a second, too fast for the human eye to observe, but slow enough for the ear to hear.

The voice-controlled electric train which Mr. Gluesing operated by such words as "come ahead again old man," "back-up" and "stop" was among some of the more uncanny demonstrations. The demonstrator explained that he did not rely on the use of any particular word in the control of his train, but the use of certain syllables properly timed.

Other experiments performed by Mr. Gluesing included high frequency radiations, lighting an electric lamp with a match, the cathode-ray oscillograph, and "invisible" light.

This demonstration was very popular and filled the house, accommodating eight hundred and fifty people, at four performances.

## Sault Ste. Marie Branch

*N. C. Cowie, Jr.E.I.C., Secretary-Treasurer.*

The Sault Ste. Marie Branch of The Engineering Institute of Canada held a general meeting at the Windsor hotel, Sault Ste. Marie, Ontario, on Friday, February 19th, 1937.

An enjoyable dinner was served by the hotel staff to twelve members and five guests at 7.15 p.m.

C. W. Holman, A.M.E.I.C., chairman of the Branch, called the meeting to order at 3.00 p.m. The minutes of the previous meeting, a few items of business, which included the auditors' report by H. O.

Brown, A.M.E.I.C., and a short talk by the chairman of the Membership Committee, A. H. Russell, A.M.E.I.C., were dealt with by the meeting.

W. A. Dawson, A.M.E.I.C., chairman of the Papers and Publicity Committee, then introduced the speaker of the evening, W. M. Reynolds, A.M.E.I.C.

Mr. Reynolds, who was with the God's Lakes Mines in charge of construction during the erection of the Kanuchuan power development, then told the members of this project.

Mr. Reynolds dealt chiefly with the unusual difficulties that had to be overcome during the construction of a power development north of latitude 53. Mr. Reynolds' paper was of great interest to the members present and was followed by an interesting discussion which brought up other interesting features of this development.

The members, through E. M. MacQuarrie, M.E.I.C., and A. H. Russell, A.M.E.I.C., thanked Mr. Reynolds for his very entertaining and interesting paper.

## Toronto Branch

*W. S. Wilson, M.E.I.C., Secretary-Treasurer.*
*D. D. Whitson, A.M.E.I.C., Branch News Editor.*

### Transportation Methods in Use in Northern Ontario

At the meeting of the Toronto Branch held on January 7th, 1937, at Hart House, the members of the Branch had the pleasure of hearing two addresses on "Transportation Methods in Use in Northern Ontario." D. Forgan, A.M.E.I.C., of the Ontario Hydro-Electric Power Commission, dealt mainly with the transportation problems encountered in the construction of northern hydro power developments, stating that the transportation costs had, for some plants, amounted to 40 per cent of the total cost of construction. Diesel tractors pulling trains of sleighs and cabooses under very difficult operating conditions was a favourite method after freeze-up had occurred, and water transportation by scow and tug previous to freeze-up, with the assistance of marine railways to get the scows over the many portages was the other main method used for the transport of heavy material or large quantities of supplies.

Mr. W. A. Scott, of Canadian Airways, on the same evening opened the eyes of most of those present to the enormous strides that air transport is making in the heretofore "inaccessible" northland. A load of many hundred pounds of mail, supplies, food or accessories to be carried to destinations two or three hundred miles distant is everyday performance for our airways, either in winter or in summer. In certain cases, boilers weighing many hundred pounds and cows have been transported by air. The Canadian Airways maintain several radio stations, keep in touch with the planes, and give extremely valuable broadcasts on weather conditions. Both Mr. Forgan and Mr. Scott had many fine slides to illustrate their talks and a point stressed by both speakers was that over 70 per cent of the entire country has no rapid means of travel available except by the use of the airplane.

### Power Development in Northern Ontario

On January 21st, the Toronto Branch met at Hart House with O. Holden, A.M.E.I.C., in the chair, and had the pleasure of hearing a paper by Dr. T. H. Hogg, M.E.I.C., Chief Hydraulic Engineer of the Hydro-Electric Power Commission of Ontario on "Power Development in Northern Ontario." The address was fully illustrated by slides and was read by Mr. Holden in the unavoidable absence of Dr. Hogg. All varieties of power plants were discussed, including their location, length of transmission line, costs, ice difficulties, etc. This paper appeared in full in the March, 1937, issue of The Engineering Journal.

### Arc Welding, Its Testing and Inspection

At the meeting of the Toronto Branch held at Hart House on February 4th, a most interesting address on "Arc Welding, Its Testing and Inspection" was given by W. D. Walcott, A.M.E.I.C., Inspecting Engineer with the Hydro-Electric Power Commission of Ontario. Mr. Walcott covered the subject most fully, and had some fine slides to illustrate his talk. Messrs. Bonn and Hamilton took an active part in the lively discussion which followed the address.

### Electrical Equipment for the Abitibi Canyon Development

On February 18th, the Toronto Branch met at Hart House with O. Holden, A.M.E.I.C., in the chair. W. E. Ross, A.M.E.I.C., of the Canadian General Electric Company, presented a paper on the "Fabrication and Installation of the Electrical Equipment for the Abitibi Canyon Development." Illness prevented the author from being present, and his paper was read by Mr. F. C. Barnes of the same company.

Emphasis was placed on the great influence of transportation limitations on the design and shop fabrication of such large generators and transformers as are installed at Abitibi, particularly when one considers that this development is approximately 600 miles north of Toronto in virgin country. How successfully these limitations were overcome was clearly shown by the author, as the equipment was installed and placed in commercial operation without any difficulties, except of a very minor nature.

The paper was illustrated by slides showing scenes at the site, with views of the canyon before any construction was started, followed by pictures of progressive stages during installation, and final views of the plant as it went into operation.

A series of views of the hydraulic equipment was also shown, having been loaned by the turbine manufacturer.

The paper also included a complete description of the high and low voltage switching equipments, station service facilities, and the control and relay protective systems.

## Vancouver Branch

*T. F. Berry, A.M.E.I.C., Secretary-Treasurer.*
*J. B. Barclay, A.M.E.I.C., Branch News Editor.*

### Joint Meeting with A.I.E.E.

A joint meeting of the Vancouver Branch of The Institute and the Vancouver Section of the American Institute of Electrical Engineers was held on Tuesday, January 26th, 1937. About a hundred and twenty members of the two organizations and visitors were in attendance. The speaker was Mr. J. F. Lincoln, President of the Lincoln Electric Co. of Cleveland, Ohio.

Mr. Lincoln addressed the meeting on "Modern Developments in Electric Arc Welding." He described the early difficulties in arc welding practice due to oxidation and how these difficulties had been overcome by the use of the shielded arc rod by which method it was now possible to obtain welds as strong and stronger than the parent metal with consistent performance.

Mr. Lincoln showed some interesting lantern slides describing the application of arc welding to the manufacture of electric motor frames, bases and end rings, and compensator boxes etc., together with the comparative costs of manufacturing these machine parts both by cast metal and welded construction. The cost of fabrication in each case was in favour of welded construction, sometimes by wide margins. At the conclusion of the lecture Mr. Lincoln replied to many questions from his audience concerning the welding of stainless steels, aluminum, mild steel to cast iron and other problems of practice and design that present themselves to engineers. A vote of thanks was proposed by H. N. Macpherson, M.E.I.C., chairman of the Vancouver Branch E.I.C., and seconded by Mr. Bartholomew, of the Vancouver Section A.I.E.E.

### Vancouver's Traffic Problems

Twenty-six members and guests of the Vancouver Branch sat down to dinner at the Hotel Grosvenor on the evening of February, 11th. Following dinner, the members were addressed by Inspector Harold Mortimer, Superintendent of Vancouver Police Traffic Department, on "Vancouver's Traffic Problems."

Inspector Mortimer stressed the need of the education of the public to an appreciation of the fact that traffic laws and regulations are for their convenience and safety, and that only by the wholehearted co-operation of the public will traffic codes be effective in this regard. Vancouver's toll from traffic accidents in 1936 was 35 fatal and 1,749 hospital cases and it was the speaker's contention that the majority of there accidents were avoidable had intelligence and necessary vigilance been employed by the motoring public. The speaker dealt with the many phases of traffic control in a large city—parking regulations, control of pedestrian traffic, the several types of traffic signals, the relation of the street car to auto and pedestrian traffic, "through streets" and uniform highway and street signs. Following the lecture, Mr. Randolph Martin, traffic engineer of the City of Vancouver Engineering Department, briefly addressed the meeting on the functions of the traffic engineer. The balance of the evening was given over to the discussion of this most vital problem of the modern city.

## Winnipeg Branch

*H. L. Briggs, A.M.E.I.C., Secretary-Treasurer.*

### Colour Photography

At the meeting of the Winnipeg Branch held on February 18th, 1937, the chair was occupied by A. E. Macdonald, M.E.I.C.

Approximately one hundred and seventy-five members heard Dr. Alexander Gibson present the paper "Colour Photography."

Historically, Clerk-Maxwell superimposed three photographs, each of which recorded one of the three photographic primary colours—red, green and blue. Then Lumiere combined the process into one picture-taking operation by covering the film surface with a large number of small starch particles which had been dyed the different colours. Dufay further improved the method by using coloured lines ruled across the surface of the film, 20 to the millimeter, in two sets at right angles to each other.

The kodachrome process uses three colour sensitive layers, separated by neutral layers, all on the same film base. Each layer is responsive to light rays of one colour. In developing, the metallic silver obtained proportionally to the light intensity on a given area is dissolved out, and its place taken by dye of the appropriate colour and in proportional amount.

A large number of colour slides were shown of English, American and Canadian scenes, slides illustrating the process described, also two kodachrome films taken locally by Dr. C. H. Goulden.

E. V. Caton, M.E.I.C., expressed the appreciation of the audience to the speaker.

### Students' Prize Papers

At the meeting of the Winnipeg Branch held on March 4th, 1937, S. V. Antenbring, S.E.I.C., presented a paper entitled "Locating the

Control for a Detailed Geological Survey," which dealt with the methods used last summer in the Rice lake area of Manitoba. The whole area worked over was staked with mining claims. The claim posts as shown by the surveys of the claims were used as preliminary control points for the work, which was done mainly by plane table although the chain and compass method had to be used in certain places. Traverses were set up radiating from the claim posts, from which a grid system two hundred feet to a side was laid out and marked on the ground. Geologists then used this grid for plotting their information.

"Air Conditioning in Railway Cars" by J. J. Miller, S.E.I.C., dealt with equipment which was placed in a number of cars at the Transcona shops of the Canadian National Railways last summer. An electric fan picked up the stale air from suitable locations, forcing it through cooling coils or heating coils as desired, then through air filters, and through two main duct systems, one to the main part of the car and the other connecting with the individual berths. Three ice boxes, each holding 2,700 pounds of ice, were used for cooling.

Those taking part in the discussion included Messrs. A. I. Bereskin, Jr.E.I.C., D. M. Stephens, A.M.E.I.C., G. H. Herriot, M.E.I.C., E. P. Fetherstonhaugh, M.E.I.C., and N. M. Hall, M.E.I.C. G. E. Cole, A.M.E.I.C., moved the vote of thanks.

Before the presentation of the main papers, Professor G. H. Herriot thoroughly entertained the Branch by recalling a number of his early surveying experiences in the Peace river country of Alberta, and in Manitoba.

## Periodicals in Institute Library

(Continued from March Journal).

Listed below is the balance of periodicals which are received regularly by The Institute Library, and which are available for reference purposes in the reading room. The first part of this list appeared on page 155 of the March issue of The Journal.

Engineering Progress.
English Electric Journal.
Experiment Station Record—U.S. Dept. of Agriculture.
Factory Management and Maintenance.
Financial Post, The.
The Foundation-Engineering Society of Detroit.
G.E.C. Journal.
General Electric Review.
General Manager's Bulletin, Kenya and Uganda Railways and Harbours.
Génie Civil, Le.
Heating and Ventilating.
Heating, Piping and Air Conditioning.
Highway Magazine, The.
Houille Blanche, La.
Highway Research Abstracts—Highway Research Board.
Indian Engineering.
Industrial and Engineering Chemistry.
Industrial Britain.
Industrial Canada.
Industrial Standardization.
De Ingenieur.
International Conciliation.
Iron Age, The.
Iron and Steel of Canada.
Journal of the Aeronautical Sciences.
Journal of the American Concrete Institute.
Journal of the American Water Works Association.
Journal of the American Welding Society.
Journal, Boston Society of Civil Engineers.
Journal of Engineering Education.
The Canadian Banker.
Journal of the Franklin Institute.
Journal of the Institution of Civil Engineers.
Journal, Institution of Electrical Engineers.
Journal of the Institution of Engineers Australia.
Journal, Institution of Municipal and County Engineers.
Journal of Research—U.S. Bureau of Standards.
Journal of the Royal Aeronautical Society.
Journal, Royal Architectural Institute of Canada.
Journal of the Royal Artillery.
Journal of the Royal Society of Arts.
Journal, Society for the Advancement of Management.
Journal of the Society of Automotive Engineers.
Journal, South African Institution of Engineers.
Journal of the Western Society of Engineers.
Junior Institution of Engineers—Proceedings.
Library Bulletin of Abstracts.
Lubrication.
MacLeans Magazine.
Marketing.
McGill News, The.
Mechanical Engineering.
Mémoires et Compte Rendu des Travaux.
Mining and Metallurgy.
Modern Power and Engineering.
Monthly Bulletin (Canadian Chamber of Commerce).
Monthly Bulletin (Maritime Teleg. and Teleph. Co.).

## American-Operated Air Lines Carry 1,147,969 Passengers in 1936

Air lines operated by American companies (domestic and foreign extensions) carried 1,147,969 passengers and 8,350,010 pounds of express during the calendar year 1936.

Of the total number of passengers carried in 1936 there were 1,020,931 who travelled on the domestic air lines and 127,038 who flew on extensions to foreign countries.

In 1935 the American-operated air lines carried 860,761 passengers and 5,511,737 pounds of express.

Miles flown by all scheduled operators in 1936 were 73,303,836 as compared with 63,540,233 flown in 1935. Passenger-miles flown in 1936 were 491,744,053 and for 1935 this figure was 360,569,431. A passenger-mile is the equivalent of one passenger flown one mile.

There were 380 airplanes in operation on the scheduled air lines at the end of the year. The air lines furnished employment for 9,972 persons (as of December 31st) classified as follows: 690 pilots, 543 co-pilots, 2,864 mechanics and ground crew men, 1,764 other hangar and field personnel, 3,721 operations and office personnel, 287 hostesses, and 103 stewards.

The domestic lines had 106,774 flights scheduled of which 100,335 were started. There were 4,702 extra sections flown and the total number of trips completed was 100,420. Of all trips started the air lines completed 95.6 per cent.

The average speed for all domestic air lines at the end of the year was 151 miles per hour, and the average length of a passengers trip was 427 miles. Of seats which were available, 64 per cent were used.

# Preliminary Notice

### of Applications for Admission and for Transfer

March 27th, 1937

**The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.**

**It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.**

**In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.**

**If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.**

**Communications relating to applicants are considered by the Council as strictly confidential.**

The Council will consider the applications herein described in May, 1937.

R. J. Durley, Secretary.

---

*The professional requirements are as follows:—

**A Member** shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years inthe case of a candid ate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

**An Associate Member** shall be at least twenty-seven years of,age, and shall have been engaged in some branch of engineering for at least six years which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch ofengineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more year.

**A Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

**A Student** beshallat least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

**An Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

FOR ADMISSION

BOUCHARD—JEAN, of St. Hyacinthe, Que., Born at St. Hyacinthe, Sept. 28th, 1904; Educ., B.A.Sc., C.E., Ecole Polytechnique, Montreal, 1931; 1926, 28, 29 (summers), student engr., River St. Lawrence Ship Channel; 1931, 3 mos. with Quebec Streams Commission, and 3 mos. with Quebec Roads Dept.; 1932 to date, city engineer, St. Hyacinthe, Que.
References: A. Frigon, O. O. Lefebvre, N. B. McLean, T. J. Lafreniere, A. Duperron, C. K. McLeod.

CANTIN—L. ARTHUR, of 1106 Sherbrooke St. East, Montreal, Que., Born at St. Romuald, Que., April 17th, 1900; Educ., B.Sc. (E.E.), Tri-State College of Engrg., Angola, Indiana, 1932; 1925 (Jan.-Aug.), Coyne Electr'l School, Chicago; 1925-26, electrn. on constrn. and mtce., International Harvester Co., Chicago; 1926-29, elect'l. constrn. and mtce. (mtce. foreman for last 18 mos.) Aluminum Co. of Canada, Arvida, Que.; 1929 (Sept.-Dec.), control and high tension work, Shawinigan Engrg. Co., Grand Mere, Que.; 1929-30, elect'l. constrn. and mtce., Dominion Rubber Co., St. Jerome, Que.; 1930, installn. of electric elevators, Otis Fensom Elevator Co. and Turnbull Elevator Co., Montreal; 1933, electr'l constrn. and motor repairs (private business); 1933-34, power house constrn., Shawinigan Engrg. Co., Rapide Blanc, Que.; 1934 (June-Nov.), electr'l. constrn. and mtce., Aldermac Mines Ltd., Arntfield, Que.; Nov. 1934 to date, i/c electr'l. mtce. for Canadian Lastex Ltd., Montreal, Que.

#### FOR TRANSFER FROM THE CLASS OF ASSOCIATE MEMBER TO THAT OF MEMBER

BURNS—CHARLES HENRY McLEOD, of 105 Dorothy St., Welland, Ont., Born at Amherst, N.S., Oct. 21st, 1889; Educ., 1909-11, Mt. Allison Univ.; 1911-12, asst. to mech. engr. on power plant and concentrator constrn.; 1912-20, res. engr. with Maritime Coal Railway & Power Co. Ltd., Nova Scotia; 1920-24, designing engr. on mine plant and equipment, and mech'l. handling equipment, Link-Belt Co., Philadelphia; 1924-28, with same company in charge of plant changes, design and constrn. of new plants, and changes in mfg. methods in steel shops, mach. shops, grey iron and steel foundries; 1928-29, designing engr., International Nickel Co. of Canada, Copper Cliff, Ont.; 1929-31, chief engr., Dodge Mfg. Co. Ltd., Toronto; 1931-32, inspr. for Ontario Power Service Corpn. on power development project at Abitibi Canyon, Ont.; 1932-34, consltg. mech'l. engr.; 1935 to date, asst. mgr. in charge of operation and mtce. of drop forging and heavy forging plants of Canada Foundries and Forgings Ltd., Welland, and also direction of all technical research and control. (*A.M. 1920.*)

References: W. J. Ripley, P. C. Kirkpatrick, H. T. Kirkpatrick, R. E. Smythe.

NICHOLSON—JOHN BILLINGTON, of Scarsdale, N.Y., Born at Hamilton, Ont., Dec. 5th, 1890; Educ., B.A.Sc., Univ. of Toronto, 1914; 1913, constrn. of bldgs., Oliver Chilled Plow Works; 1913, Toronto Hamilton and Buffalo Rly. City of Hamilton, Hydro-Dept., bldg. electric transmission lines; 1915-26, vice-president in charge of design and constrn., J. B. Nicholson Ltd. and The Nicholson Company, New York; 1926 to date, president, The Nicholson Company, New York. Sole owner and entire charge of engrg. constrn., grain elevators, coal pockets, elevator storage constrn., etc. Also president, J. B. Nicholson Ltd., Toronto, and president, Fairmont Constrn. Co., New York. (*Jr. 1914, A.M. 1917.*)

References: R. L. Latham, F. W. Paulin, J. J. MacKay, H. M. Campbell, N. E. D. Sheppard.

#### FOR TRANSFER FROM THE CLASS OF JUNIOR

LLEWELLYN—LEOPOLD WILLIAM, of 2848 Retallack St., Regina, Sask., Born at Kilkenny, Ireland, May 19th, 1902; Educ., B.Sc. (Mech.), Univ. of Sask., 1927; 1924-26 (summers), rodman, dept. of highways, Regina, Sask.; 1927-28, dftsman., Canadian Westinghouse Company, Hamilton, Ont.; 1928-29, surveyor and inspr., Montreal Engineering Co., Regina; 1929-30, dftsman., Vancouver Engrg. Co., Vancouver; 1930, dftsman., B.C. Electric Rly., Vancouver; 1931, asst. engr., city engr's. dept., Moose Jaw, Sask.; 1932, pipeline inspr., waterworks dept., Regina; 1933, elec. supt. and asst. to supt., World's Grain Show, Regina; 1934 to date, designer with Northwestern Iron Works Ltd., on design and production of of the "Ross Diesel Cylinder Head." (*Jr. 1929.*)

References: H. C. Ritchie, J. W. D. Farrell, D. A. R. McCannel, A. P. Linton, R. W. Allen, A. R. Greig.

#### FOR TRANSFER FROM THE CLASS OF STUDENT

CHARLEWOOD—CHARLES BENJAMIN, of 10 McKenzie St., Galt, Ont., Born at Toronto, Ont., Aug. 10th, 1908; Educ., B.Sc. (Mech.), McGill Univ., 1931; 1929 (summer), rodman and instr'man., constrn. survey, C.P.R.; 1930 (summer), student, Laurentide Divn., Canada Power and Paper Corpn., Grand Mere, Que.; 1931 (June-Nov.), production foreman, radio manufacture, Victor Talking Machine Co., Montreal; 1931-32, service engr., Canadian Diesel Engine Corpn., Montreal; 1932-34, surface labour, underground pumpman and mechanic, Noranda Mines Ltd., Noranda; 1934 (Feb.-Oct.), steam and power clerk, Cons. Paper Corpn., Shawinigan Falls; 1934-36, lubrication foreman, boiler operator, Noranda Mines Ltd.; At present, engr., Babcock-Wilcox & Goldie-McCulloch Ltd., Galt, Ont. (*St. 1931.*)

References: E. A. Allcut, J. R. Bradfield, L. F. Grant, A. R. Roberts, D. B. Simpkin.

KERSHAW—NORMAN WILLIAM, of Drummondville, Que., Born at Saskatoon, Sask., Mar. 14th, 1913; Educ., B.Sc. (Mech.), Univ. of Sask., 1933; 1932 (summer), ap'tice electrn., J. M. Taylor, Saskatoon; 1933-34, instructor in mech. engrg. lab., Univ. of Sask.; 1934-35, asst. to asst. factory mgr., oilcloth divn., Dominion Oilcloth and Linoleum Ltd.; 1935-1937, mech. engr., and Jan. 1937 to date, asst. factory mgr., Eagle Pencil Co., Drummondville, Que. (*St. 1935.*)

References: C. J. Mackenzie, R. A. Spencer, W. G. Worcester, A. R. Greig, W. E. Lovell, I. M. Fraser.

LAING—DAVID ALEXANDER SHEARER, of 5865 Notre Dame de Grace Ave., Montreal, Que., Born at Dundee, Scotland, Mar. 22nd, 1906; Educ., B.Sc. (Mech.), McGill Univ., 1930; 1923-24, foundry and tool making, Lunkenheimer Valve Co., Cincinnati; 1924-25, gen. machinist, Curtiss Aero and Motor Corpn., Long Island, N.Y.; 1925-26, installn. and service, Socony Oil Burner Corpn., New York; 1930-31, tool and gauge design, and 1934 to date, cable engrg. and development, Northern Electric Co. Ltd., Montreal. (1931, Pilot Officer, R.C.A.F., Camp Borden, Ont.). (*St. 1930.*)

References: R. E. Jamieson, C. M. McKergow, N. L. Dann, W. H. Eastlake, A. J. Lawrence, S. R. McDougall, N. L. Morgan.

MANN—OSWALD NELSON, of Drummondville, Que., Born at Sydney, N.S., Sept. 8th, 1912; Educ., B. Eng. (Mech.), N. S. Tech. Coll., 1935; 1934 (summer), helper in shops, Dom. Steel and Coal Corpn., Sydney, N.S.; 1935 (summer), dftsman. and timekpr., Sydney Foundry and Machine Works Ltd.; 1935-37, asst. chemist and asst. meter engr., Imperial Oil Refinery, Dartmouth, N.S.; At present, asst. plant engr., Eagle Pencil Co. of Canada, Drummondville, Que. (*St. 1936.*)

References: R. L. Dunsmore, W. E. Clarke, M. Dwyer, I. P. MacNab, S. Ball.

McKENZIE—RALPH BAYNTON, of 1230-5th Ave. South, Lethbridge, Alta., Born at Lethbridge, Apr. 23rd, 1908; Educ., B.Sc. (Chem.), Univ. of Alberta, 1932; 1929-30 (summers), ditch surveyor, Lethbridge Northern Irrig. Dist.; 1931 (summer), and 1933-35, asst. chemist, Maple Leaf Petroleum Ltd., Coutts, Alta.; At present, elect'l. contracting, estimating, salesman, etc., McKenzie Electric Ltd., Lethbridge, Alta. (*St. 1932.*)

References: P. M. Sauder, J. T. Watson, W. L. McKenzie, N. H. Bradley, J. Haimes, W. Meldrum.

ROMBOUGH—JOSEPH HAROLD MELVILLE, of 231 Arthur St., Oshawa, Ont., Born at Smiths Falls, Ont., July 28th, 1908; Educ., B.Sc. (Civil), Queen's Univ., 1931; 1929 (summer), assting. O.L.S. in Aultsville, Ont.; 1930-32, asst. city engr., Sudbury, Ont., in charge of field and office work relating to all municipal local improvements; design, plans, layout and inspection of reinforced concrete bridges, culverts and retaining walls; At present, labourer in tapping dept., Fittings Limited, Oshawa, Ont. (*St. 1928.*)

References: D. S. Ellis, W. L. Malcolm, W. P. Wilgar. G. J. Smith, J. E. Goodman.

STANLEY—THOMAS DOUGLAS, of Calgary, Alta., Born at High River, Alta., July 10th, 1908; Educ., B.Sc. (Arts), 1929, B.Sc. (E.E.), 1932, Univ. of Alta. M.Eng. (Elec.), McGill Univ., 1933. 1933-34, extra post-graduate year at Univ. of Alta., selected courses in civil and elect'l. engrg.; 1928-34, sessional demonstrator in physics, Univ. of Alta.; With the Calgary Power Co. Ltd., Calgary, Alta., as follows: 1935 (summer), and 1936 (2 mos) hydrometric survey and collection of stream flow data; Sept, 1935-Mar. 1936, floorman and mtce. man., Ghost River plant; 1936 (2 mos), constrn. dept.; July 1936 to date, compilation and computation of stream flow data. (*St. 1932.*)

## List of New and Revised British Standard Specifications

(Issued during January, 1937)

530—1937. *Graphical Symbols for Telephony, Telegraphy and Radio Communication.* (*Revision.*)
Revision bringing 1934 edition into line with the International Electrotechnical Commission publication (I.E.C. No. 42-1936).

720—1937. *Standard Method for the Calibration of Carburettor Jets for Petrol Engines (all types) (for Flows not exceeding 2,000 ML. per minute).*
Supersedes B.S.S. No. 5030-1925, gives particulars of the standard reference jet calibrator and jets deposited at the National Physical Laboratory and information as to construction, installation, use and maintenance of the commercial carburettor jet calibrator.

722—1937—*Borehole and Well Pump Tests.*
One of a series covering the determination of the performance and efficiency of borehole pumps and well pumps when handling water at temperatures up to 85 degrees F.

723—1937. *Sewage Pump Tests.*
One of a series covering the determination of the performance and efficiency of sewage pumps (i.e. pumps handling liquids having appreciable amounts of solid matter in suspension) when handling liquid at temperatures up to 85 degrees F.

724—1937. *Vaporising Liquid Pump Tests.*
One of a series covering the determination of the performance and efficiency of condensate extraction pumps, hot water boilers for pump feed and other purposes and pumps for petrol and other similar volatile liquids but not air lift pumps and those for foaming liquid such as beer.

725—1937. *Hot Rolled Mild Steel Strip (or Hoop) not exceeding 10 inches wide for General Engineering Purposes.*
Covers a commercial quality of hot rolled mild steel strip (or hoop).

Copies of the new specifications may be obtained from the Publications Department, British Standards Institution, 28, Victoria Street, London, S.W.1, England, and from the Canadian Engineering Standards Association, 79 Sussex Street, Ottawa.

## EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

*All correspondence should be addressed to*

**The Employment Service Bureau, The Engineering Institute of Canada**

**2050 Mansfield Street, Montreal**

## Situations Vacant

DRAUGHTSMAN, general draughtsman with some experience in pulp and paper mill work. Apply to Box No. 1520-V.

INSTRUMENTMAN, with experience in layout and construction of roads and streets. Location province of Quebec. Apply to Box No. 1521-V.

DESIGNERS AND DRAUGHTSMEN, on pulp and paper mill plant extensions. Location province of Quebec. Apply to Box No. 1523-V.

DESIGNER, experience in the design of transformers, to act as assistant in design department. Location Ontario. Apply to Box No. 1527-V.

ELECTRICAL ENGINEER, experience in the erection of switchboards, panels, and electrical equipment generally. Location Ontario. Apply to Box No. 1528-V.

---

THE NATIONAL RESEARCH COUNCIL has under consideration the establishment of a position in the Radio Section of the Laboratories under the auspices of the Associate Committee on Radio Research. The Salary will be $1,800 per annum, and the appointment will be made for one year.

The duties of the position will be to assist with research and test work undertaken by the National Research Council.

Candidates must be University Graduates, either in Electrical (Radio) Engineering, or Physics, with special training in radio, and preferably with some research experience.

Applications should be addressed to the Secretary-Treasurer, National Research Council, Ottawa, stating age, race, nationality and giving full details of training and experience.

## Situations Wanted

CHIEF ENGINEER-CONSTRUCTION MANAGER, nineteen years construction maintenance operating, industriel plants, steam and hydro power, canals, water supply, etc., estimates, plans, specifications, supervision of construction. Apply to Box No. 36-W.

**MECHANICAL ENGINEER, B.Sc. Age 31. Married. Last ten years includes:—Mechanical structural and reinforced concrete design in pulp and paper mills, industrial plants, hydro-electric, mine, sewers and sewage disposal plant construction. My experience also includes shop production, steam plant combustion, fuel analysing, inspecting, supervising and instrument work on industrial construction. Permanent position preferred. Apply to Box No. 521-W.**

**DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aero-photographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.**

**DESIGNING ENGINEER AND ESTIMATOR, grad. Univ. of Toronto in C.E., A.M.E.I.C., twenty years experience in structural steel, construction and municipal work. Available at once. Apply to Box No. 613-W.**

ELECTRICAL ENGINEER, B.Sc., E.E., age 38. Married. Ten years electrical experience; including, one year operation, one year maintenance, and four years on construction of hydro-electric plants and sub-stations. Four years electric maintenance and construction in pulp and paper mill Also experience on highway construction and Geological Survey Available at once. Apply to Box No 636-W.

**ELECTRICAL AND CIVIL ENGINEER, B.Sc. Elec. '29, B.Sc. Civil '33. Jr.E.I.C. Age 29. Experience includes four months with Can. Gen. Elec. Co., approximately three years in engineering office of large electrical manufacturing company in Montreal, the last six months of which was spent as commercial engineer. For the last year and a half employed in electrical repair shop. Best of references. Apply to Box No. 693-W.**

## Situations Wanted

**YOUNG CIVIL ENGINEER, B.Sc. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.**

**MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.**

**RADIO AND ELECTRICAL ENGINEER, B.Sc., '31, Jr.E.I.C. Single. Age 29. One year and a half actual field experience in power and lighting equipment. Extensive work in telephone and radio layouts in switchboard and installation depts. Particularly interested and experienced in sales and traffic work in telephone and radio company. At present supervisor over sales and service of radio and electrical company. Available on short notice. Location immaterial. Apply to Box No. 740-W.**

### Employment Service Bureau

Members are again reminded that we are receiving an increasing number of enquiries for engineers.

If you are registered with the Employment Service Bureau please bring your record up-to-date.

The more information you give us, the more intelligently and effectively we can place your record for consideration with prospective employers.

**PLANT ENGINEER or SUPERINTENDENT, capable of supervising all phases of industrial plant operation, graduate electrical, eleven years diversified industrial experience including test course, four years on large Quebec industrial development, on construction and operation, also six years with prominent consulting firm supervising electrical and mechanical engineering projects. Age 31, single. Apply to Box No. 795-W.**

CIVIL ENGINEER, S.E.I.C., B.Sc. in C.E. (Sask. '32). Single. Age 27. Three years experience includes—instrumentman, compiling reports and draughting with a National Park; in charge of construction of water supply and sanitary sewer systems; assistant on city surveys. Excellent draughtsman. Available at once. Location immaterial. References. Apply to Box No. 818-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C., age 32, married. Two years in pulp mills draughting and designing additions, maintenance and plant layout. Three and a half years in the Toronto Building Department, checking and designing for steel, reinforced concrete and ordinary structures. One and a half years as transitman and draughtsman on road location and maintenance work. Available at once. Location immaterial. Apply to Box No. 899-W.

CIVIL ENGINEER, B.A.Sc. (Univ. of Toronto '27). Age 34. Familiar with house building cost, experience combines structural engineering, construction and house building and improvement, interested in obtaining a connection with firms investigating housing problems, making building loans or with a company engaged in construction or building costs. Apply to Box No. 910-W.

**CIVIL ENGINEER, B.Sc., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.**

## Situations Wanted

**ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.**

ELECTRICAL ENGINEER AND GEOPHYSICIST. B.Sc. (Man. '23), A.M.E.I.C. Married. Ten years specialized experience in the practical use of magnetic, electrical and mechanical instruments for the prospecting, surveying and mapping of mineral, oil and gas lands. Five years experience with telegraph, telephone and radio equipment. Capable of giving instruction in theory and practice in these lines and in college physics. Available on short notice. Apply to Box No. 1063-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

ELECTRICAL ENGINEER, B.Sc. '34 (Univ. of N.B.), S.E.I.C. Age 21, single. Desires any kind of electrical work. Will consider any location. Apply to Box No. 1262-W.

CIVIL ENGINEER, B.A.Sc. (Toronto '33), S.E.I.C. Married. One year as instrumentman and draughtsman with provincial Highways Dept. One year on grading and reinforced concrete construction with Dept. of National Defence. One year in charge of contractor's branch office on highway paving job. Desire permanent position with opportunity for advancement. Apply to Box No. 1265-W.

CIVIL ENGINEER, M.E.I.C. Married. Age 38. Twenty years experience in organization, design and estimating, and cost accounting. Active service in France. Apply to Box No. 1367-W.

ENGINEER SUPERINTENDENT, A.M.E.I.C., R.P.E., Que. and Alta. Age 47. Married. Twenty years experience as engineer and superintendent in charge of hydro-electric, industrial, railroad, and irrigation construction. Specialized in rock excavation and suction dredging. Intimate knowledge of costs, estimating and organizing. Available immediately. Apply to Box No. 1411-W.

CIVIL AND ELECTRICAL ENGINEER, Univ. of Man. '35 and '36. S.E.I.C. Experience in irrigation and mapping. Available at once. Location immaterial. Box No. 1418-W.

CIVIL ENGINEER, B.Sc. 1910, A.M.E.I.C. Married. Twenty-six years experience on heavy construction work, both field and office; rails, roads, power house, hotels, bridges, etc. Location immaterial. Available at once. Apply to Box No. 1470-W.

SALES ENGINEER, M.E.I.C. Age 50. Married. Several years in combustion and general machinery lines. Estimating and layout work (mechanical and electrical). Speaking French fluently. Executive ability. Apply to Box No. 1482-W.

ELECTRICAL ENGINEER, B.Eng. (McGill '33). One and a half years experience in plant and production routine, and with considerable training in sales work. Bilingual, single, and available at once for any location. Apply to Box No. 1509-W.

ELECTRICAL ENGINEER, B.Sc. '31 (Univ. of Alta.), Jr.E.I.C. Age 28. Married. One year students' test course with C.G.E.Co. including testing and operation of transformers, meters, industrial control and switchgear apparatus. Two years as instrumentman on highway construction. Desires electrical utility, commercial lighting or air conditioning work, location immaterial and available at once. Apply to Box No. 1522-W.

CIVIL ENGINEER, B.Sc. '32, S.E.I.C., P.E.N.B., D.L.S.N.B., age 32. Experience in mining, both coal and metals, private and legal surveys, railroad construction, geology and building construction. At present in private practice in coal mining district. Desirous of changing location for position either in mining field or construction in Canada. or abroad. Apply to Box No. 1562-W.

RESIDENT ENGINEER, familiar with all types of surveys and construction work including, railway, roads, irrigation, drainage, buildings and air ports. Executive ability. Had charge of several large projects. Intimate knowledge of reports and estimates. Available immediately. Any location. Apply to Box No. 1567-W.

CIVIL ENGINEER, B.Sc. '17, O.P.E. Married. Executive and administrative experience. Extensive office and field experience in harbour works, dredging; both steam and electric railways in location, construction and maintenance; telephone works in design, construction and maintenance of pole lines, wire, cable and conduit; highways in location, construction and paving; municipal works in roads, sidewalks, sewers and water mains. Intimate knowledge of estimating, unit costs, cost accounting and analysis. Some knowledge of air conditioning. Willing to locate anywhere. Available at once. Apply to Box No. 1587-W.

# Highlights of Research

### A Brief Review of the Work of the National Research Council in 1936.

In the National Research Laboratories at Ottawa the investigations under way have for their main object the promotion of the process of absorption whereby industry and commerce may be improved and expanded through the adoption of the latest and best methods.

The laboratories, employing about one hundred and ninety persons, including scientific, clerical and shop staffs, are organized in five main divisions: agriculture and biology; chemistry; physics and electrical engineering; mechanical engineering including aeronautics; and research information, with which is associated a national scientific library service.

Through its associate committees the Council has continued as in previous years to receive the advice and active support of some hundreds of research workers and technologists in government departments, the universities, and industries. Researches carried out under this system have been productive of good results at a minimum cost to the Council.

Scholarships are granted annually by the National Research Council and in 1936 thirty students, selected from thirteen Canadian universities, benefited under this scheme.

Service to industry is increasing. This consists of the investigation of special problems or the making of tests that cannot be readily carried out in Canadian commercial laboratories. It should be noted, however, that the National Research Laboratories seek to avoid in any way competing with consulting or commercial laboratories in the Dominion. Many problems are brought to the Council from time to time, either by individual companies or by associations that are willing to defray the total cost of the proposed investigations. This is an increasing source of revenue to the Council.

#### Biology and Agriculture

Most of the work now being carried on in the Division of Biology and Agriculture forms part of large co-operative research projects, mainly in collaboration with the Department of Agriculture, but also with the universities and other such organizations.

Food storage and transport depends to a large extent for its success on the proper design and operation of cold storage rooms. A low temperature laboratory, operating at 32 degrees F. and upwards with all the usual laboratory services, has been fitted up. Provision has also been made for quick freezing, using temperatures as low as −40 degrees F. Studies have been initiated to determine the temperature and humidity necessary in the cold store to prevent "freezer burn" or "pock-marking" and encouraging results have been obtained.

Research on malting barley is being carried on and as maltsters ordinarily pay a premium ranging at the present time up to 25 cents a bushel for barley of malting quality, the advantages of this research to producers of barley are obvious.

A most exhaustive survey on peeling of barley kernels during cleaning and handling was completed and reported during the year. It was found that improper threshing was the most important cause of damage.

A co-operative research with the Department of Agriculture is being carried on in crossing wheat and wheat grasses to get large-seeded drought-resistant grass for the dry prairie areas. Partially fertile lines of considerable economic promise have already been produced.

A comprehensive review of the literature on chemical weed killers is being published as a guide to experimental research in this field.

#### Chemistry

At present the Division of Chemistry has an organized relationship for research with the laundering and dry cleaning industry, the asbestos industry, the manufacture of basic refractories, and to a slighter extent the wool manufacturing and sugar industries.

In recent years Canada's buffalo herds have increased very considerably in numbers and it has been necessary to slaughter large numbers of the animals each year. About fifteen hundred buffalo hides are now available annually from them. As the ordinary methods of treating the buffalo skins were not satisfactory, experimental work was undertaken both in the tanning and later in the dyeing of buffalo hides. Preliminary studies have also been undertaken on the treatment of reindeer hides and on Canadian sources of tannin.

In an investigation undertaken with the object of promoting the utilization of Canadian deposits of magnesian rock, success has been attained in the production of a stable refractory from dolomite and other cheap and widely available raw materials. This investigation has also resulted during the year in (1) the perfection of a method of manufacturing a strong unburned basic brick; (2) major improvements in the quality of refractories bonded with sodium silicate; (3) development of a method of increasing the plasticity and workability of refractory cements; and (4) production of a greatly improved refractory with hydraulic bond.

Success has been attained in modifying potato starch so as to obtain from it results in culinary products similar to those given by standard corn starch.

Paints, varnishes and enamels are under study in the laboratories to determine their behaviour under Canadian climatic conditions and on various Canadian woods.

Fundamental work has been undertaken on the composition of the soya bean to determine the distribution of oil, proteins, phosphatides, etc., in the commercial products prepared from this material. Soya beans are now being produced in Canada on a small but increasing scale.

An extremely efficient distillation column was built in the laboratories during the year and may also be applicable in the production of gasoline with such superlative anti-knock qualities as to enable aeroplanes to make longer journeys on a given load of gasoline.

#### Mechanical Engineering

The Division of Mechanical Engineering includes the aeronautical laboratories, and during the year the snow resistance of aircraft skis was thoroughly investigated. It was found that most of this resistance is due to solid rubbing friction and that the shape of the ski is of secondary importance. By treating the surface of a wooden ski with a suitable wax preparation the resistance to friction was greatly reduced, and a much better performance could be obtained from wooden skis so treated than from any metal surface.

At the request of the Department of National Defence a study is being made of the stalling of heavily tapered wings as used on modern aircraft.

As part of a study of stressed skin construction, as used in modern aircraft, strength tests are being made of full scale aircraft floats under the two conditions of loading corresponding to the so-called two-wave condition and the bow-landing condition.

Work is proceeding on the design of a windmill that will operate in light winds and thus be suitable for use in the development of electric power on farms.

In the model-testing basin work was completed during the year on models for two 120-foot. twin Diesel patrol boats for the Royal Canadian Mounted Police.

#### Physics and Engineering

In co-operation with the Canadian National Railways the Council has developed a new heating system for refrigerator-type cars in which perishable goods are shipped during winter months.

Aerial photography holds an important place in map making. In converting the photographed information into a map, it is necessary to correlate the series of photographs, and this is done by taking advantage of the principles of perspective projection. The usual practice has been to employ a hand graphical method, but now a machine has been developed under the auspices of the Surveys Research Committee and constructed in the National Research Laboratories whereby the operation can be carried out mechanically, with greater accuracy and speed.

It has been found that the results obtained by research laboratories in testing the sound absorption values of wallboards vary considerably, and an investigation has been undertaken to determine the best methods of making these measurements.

The accuracy now attained in practical gauges used in engineering is such that the primary standards of length from which these gauges are derived must frequently be known to one-millionth of an inch. Apparatus has now been installed in the laboratories that permits limited measurements to be made in terms of light waves.

Radio methods in weather forecasting are being investigated. For this purpose a cathode ray direction finder, constructed in the laboratories, was installed at Forrest, Manitoba, with the co-operation and assistance of the Civil Aviation Branch of the Department of Transport. A similar station has been installed in Ottawa with the help of the Canadian Broadcasting Corporation. Sources of static appear to be intimately related to weather conditions.

Apparatus was set up recently for X-ray crystal analysis for the purpose of making many investigations in the laboratories.

It has been found in Germany and England that the electrical stunning of hogs before killing reduces the difficulty of handling. It was suggested by the Department of Agriculture that this principle might be applied to poultry with a view to obtaining better feather release and improved bleeding.

Demands from within the laboratories for precisely regulated voltage in connection with work on X-rays, heat conductivity tests, light tests on incandescent lamps, etc., prompted the development fo a precise voltage regulator. The significance is seen in that a change of one per cent in the applied voltage will affect the life of a lamp by 14 per cent. The principle employed in this regulator has also been adapted to the speed control of electric motors.

Assistance has been given the colour and printing trade in the development of a daylight recorder whereby the grading of colours for fastness can be placed on a scientific basis. Another development was the installation of a very fine three-meter concave grating with 30,000 lines to the inch for spectroscopic work in the analysis of minerals, alloys and the detection of small quantities of impurities in substances.

#### Division of Research Information

This division serves the laboratory workers by searching the scientific literature for references to previous work on any projected research. A library service is maintained; translations within certain limits are made as required; secretarial and other necessary services are provided for the associate committees, and, in general, a liaison is maintained between the laboratories and the public.

# THE ENGINEERING JOURNAL

## THE JOURNAL OF THE ENGINEERING INSTITUTE OF CANADA

**Published monthly at 2050 Mansfield Street, Montreal, by The Engineering Institute of Canada, Incorporated in 1887 as The Canadian Society of Civil Engineers.**

ENTERED AT THE POST OFFICE, MONTREAL, AS SECOND CLASS MATTER.

*"To facilitate the acquirement and interchange of professional knowledge among its members, to promote their professional interests, to encourage original research, to develop and maintain high standards in the engineering profession and to enhance the usefulness of the profession to the public."*

**May, 1937** **Volume XX, No. 5**

## CONTENTS

Price 50 cents a copy, $3.00 a year, in Canada, British Possessions, United States and Mexico. $4.50 a year in Foreign Countries. To Members and Affiliates, 25 cents a copy, $2.00 a year.

# The British Grid System

*Johnstone Wright, M.Inst.C.E., M.I.E.E.,*
*Chief Engineer of the Central Electricity Board, London, England.*

**Paper to be presented before the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

SUMMARY.—The author describes the way in which the Central Electricity Board has co-ordinated the operations of the many local supply systems in Great Britain, establishing a national system of high-voltage transmission lines, controlling the generating stations feeding the network, and supplying energy in bulk to the various distributing authorities.

The Semicentennial of The Engineering Institute of Canada is an event of particular interest to engineers. Your Society, while not so old as the British Institution of Civil Engineers (which, founded in 1818, is the doyen of our professional institutions), is in one sense older than the British Institution of Electrical Engineers, for though the Society of Telegraph Engineers was founded in 1871, it did not become the Institution of Electrical Engineers until 1888.

Faraday's fundamental discovery of induction goes back more than a century, but the whole technique of modern large-scale electricity distribution is dependent on alternating current practice—and alternating current technology was only in its infancy when your Institute was established. It is difficult to imagine that electricity supply could have reached its present position without high-pressure alternating current transmission. The history of your Institute therefore covers the whole period during which, in all the principal countries of the world, the distribution of electricity has grown to the dimensions of an industry of primary national importance—a public service as vital as water supply or sanitation.

The problems of power supply differ widely from country to country, but the differences are more in detail than in the central objective of the supply industry, which is the same everywhere—to meet the ever-growing need of the community for economical and reliable electrical service.

This paper is presented in the hope that some account of the problems confronting the supply industry in the Mother Country, and of the methods adopted in their solution, will be of interest and service to those who have similar problems on the much wider geographical scale of the great Dominion of Canada. The paper is particularly appropriate on this occasion, for 1937, the fiftieth anniversary of your Institute, is ten years after the date when the Central Electricity Board of Great Britain was first established.

### Public Supply in Great Britain Prior to the Grid

Any problem needs to be viewed in perspective against its natural background—in this case the environment and development of the supply industry. To do this we must go back a long way, for like most British institutions the Grid has its roots in history.

The basic unit in British local administration is the Parish, which was the zone of influence of a single place of worship when religion dominated community life in the Middle Ages. Rural districts, urban districts and boroughs have been built up by the aggregation of parishes, and national parliamentary representation is still organized on that fundamental unit. As a consequence, in spite of at least a century of reforms, revisions and amalgamations, there are still over two thousand separate authorities responsible for local community organization.

Up to the middle of the 18th century, the population of Great Britain was fairly evenly distributed over the country in farming villages surrounding small market towns, each village and town having its own parish church. In these conditions administration on a parochial basis was natural and logical. But the coming of the Industrial Revolution and the opening up of the great grain-producing areas of the Dominions brought a vital change. Farming communities dwindled at the calls of emigration and industry. Steam brought the industrial age, and steam meant coal to be won and used. Developing world trade meant the building of docks and harbours on the estuaries which are Britain's natural arteries of commerce, and the construction of an intricate network of roads and railways. Population followed these developments, huddling into the coalfields and along the larger estuaries and creating huge urban agglomerations.

Crowded urban centres brought in their train new problems in public health, and the various types of local authority were the natural media for the work of providing essentially local services such as drainage, sanitation, and road maintenance. Legal powers obtained for these purposes gave local authorities a commanding position when public water and gas supply came into question, and although these services were in some instances first provided by private enterprise, they are largely in the hands of local authorities.

None the less, the participation of private enterprise in connection with water and gas was substantial, and the conflict of interest between the bodies concerned in road maintenance, drainage, sewage disposal, water and gas supply became so acute that Parliament was obliged to devote a great deal of its time to elaborating various forms of regulative legislation.

It was into this atmosphere that the electricity supply industry was born.

The first public supply of electricity in Great Britain was given in 1881. All the essential basic discoveries had of course been made many years earlier. Electricity had been transmitted by wire nearly one hundred and eighty years before. In 1812 Davy's arc lamp had shown the applicability of the new force to lighting, and 1881 was the semi-centenary of Faraday's fundamental discovery of induction.

The first parliamentary enactment dealing with public electricity supply—the Electric Lighting Act of 1882—while providing for both local authority and company ownership, contained provision for the compulsory purchase of company systems by the local authority after a period of twenty-one years, at the then market value of the physical assets without regard to goodwill or profits. This limitation on tenure, coupled with purchase terms which would obviously militate against expansion, was a deterrent to private enterprise, and in 1888 a further Act doubled the period of tenure.

Early legislation thus clearly favoured supply by a local council—and there were over two thousand such bodies. The more powerful, wealthy and progressive of these were of course to be found in the rapidly-growing urban centres, and not in the shrinking rural communities. The earlier act had given power to local councils to contract with private concerns to provide and maintain electricity works, and this type of business absorbed the attention of most of the pioneer companies; where a company desired to obtain powers itself, it was obviously easier to negotiate with a single local authority than to apply for powers over a wider area. On the technical side, private lighting had started with 110-volt direct-current belt-driven dynamos and batteries. The earlier public distribution systems were merely enlargements of this prototype, and therefore had a very limited range of operation.

All factors therefore favoured the setting up of a large number of small generating stations, designed to supply only in their immediate vicinity, towns alone being served, to the almost complete neglect of country districts. Further, with electrical science still in its infancy, the inventive skill of the pioneers produced a wide variety of systems. The alternator had actually been invented in 1878, but direct current started with an initial advantage in practical application. Although the work of Ferranti demonstrated the potentialities of alternating current transmission, the small distribution areas resulting from the early legislation, the abundant supply and wide geographical distribution of coal and the absence of substantial waterpower resources, gave at that stage no such incentive in favour of alternating current as existed in other countries.

When alternating current began to make headway, lighting was still the chief load to be considered, and one and two phase systems were at first adopted, with a variety of frequencies. With small scale independent systems mainly supplying local lighting loads, such variations were perhaps not of major importance. But industry began to turn to the new source of power, so much more flexible than reciprocating engines and mechanical drives, and small scale public generation offered no attractions to the industrialist accustomed by the steam age to regard provision of his power requirements as an integral part of his manufacturing process. Experience in the Dominions and elsewhere was already showing the advantages of large scale production coupled with high voltage transmission, but in Great Britain the early legislation had made the logical corollary of larger supply areas impracticable, first by the limited tenure system, which would have rendered small sections of any comprehensive distribution network liable to purchase by local councils at various differing dates, and secondly by the prohibition of amalgamation and coordination.

It was clear that the supply industry was outgrowing its early legislative clothing. In 1898 a number of special Bills were promoted in Parliament, so far-reaching in their proposals that a Parliamentary Joint Committee presided over by Lord Cross was appointed to deal with them. As a result of that committee's recommendations, ensuing years saw the establishment of a number of "power companies" differing from the earlier distributing companies in that they operate under special individual acts giving perpetual franchise, and the right to supply over wide areas, mainly for industrial power and traction purposes and for bulk sale to distributing authorities. In areas covered by such "power" acts, however, the interests of existing local authority distributors were safeguarded by rights of veto on supply by the power companies within their borders, and since the existing local authority areas naturally consisted of those parts most ripe for development complete co-ordination was impracticable.

The power company legislation tacitly conceded the principle that the economic unit for electricity purposes was much larger than the local administrative boundaries. In 1909 a further general act made it possible for neighbouring distributors to give and take bulk supplies and establish transmission lines for that purpose, but up to the outbreak of the Great War in 1914, development was mainly along the lines of isolated systems with individual small scale generation and relatively little interconnection. As will be seen from Table I, supply powers were very largely confined to the urban centres.

Table I

Percentages of Total Area and Population of Great Britain Covered by General Supply Powers

| Year | Area | | Population | |
|---|---|---|---|---|
| | Urban | Rural | Urban | Rural |
| 1891 | 8.0 | 0.1 | 22.6 | 0.1 |
| 1901 | 31.9 | .5 | 67.5 | 1.6 |
| 1911 | 46.3 | 5.0 | 80.1 | 16.7 |
| 1921 | 57.6 | 7.0 | 88.1 | 22.4 |
| 1926 | Passing of Electricity (Supply) Act, 1926. | | | |
| 1931 | 96.8 | 63.3 | 99.0 | 84.1 |
| 1937 | 99.8 | 85.8 | 99.9 | 94.8 |

Manufacturing industry continued to rely mainly on its highly-developed individual steam-power equipment, and public supply development was hampered by the bewildering variety of voltages, frequencies, generation and distribution systems, and methods of charge, which had gradually accumulated. In Greater London, for example, even in 1921 there were some eighty separate supply authorities, seventy generating stations, fifty different systems of supply, twenty-four different voltages and ten different frequencies. The multiplicity of technical systems had involved manufacturers in duplication of patterns, types and stocks, and thus deprived them of the advantages, both in home and foreign markets, which would have derived from concentration of production on a few standard types.

The War at last focussed attention to the long felt need for reform. The demand for war material brought with it an unprecedented change in the direction of industrial effort, at a time of acute strain on manpower resources. Steam power industrial equipment proved to be relatively inflexible, and in four years the load on public electricity supply systems was more than doubled. It came to be recognized that lack of co-ordination in public supply had re-acted adversely on the application of electricity to industrial power purposes and had resulted in unnecessary expenditure of capital, unduly high fuel consumption and consequently higher charges to the consumer than those which would have ruled with larger supply areas, larger generating units, and more economically situated generating stations.

The need for re-organization was so obvious that even during the War three successive governmental Committees were set up to consider various aspects of the situation. In 1919 the first step in the development of a comprehensive system of generation, transmission and distribution was taken. An act was passed which further facilitated interconnection, transferred the supervisory powers previously vested in other government departments to the newly-formed Ministry of Transport, and established under that Ministry a new administrative body, the Electricity Commissioners. This body was charged with control over the erection and extension of generating stations and transmission lines, and given the duty of initiating schemes for the voluntary establishment of regional co-ordinating authorities with the object of interlinking the existing systems and unifying both production and distribution over the whole region. The act, however, did not make the establishment of such authorities compulsory, and although the Electricity Commissioners duly initiated a number of such schemes, the divergence of interest between local authority and company distributors was too great to be bridged by voluntary schemes, and only three Joint Authorities were actually established.

By 1925 it had become clear that more drastic measures were necessary, and a further Government Committee, under the chairmanship of Lord Weir, was set up to reconsider the whole situation. That Committee's recommendations constituted the basis upon which the reorganization of generation and main transmission in Great Britain has been carried out, and it is interesting to see the state of the industry at the time of their deliberations.

The area of England, Scotland and Wales is 88,141 square miles, and at the 1921 census it had a population of 42,769,000, of which 33,346,000 were in urban areas and only 9,423,000 in rural districts. As will be seen from Table I, 88 per cent of the urban and only 22 per cent of the rural population were then covered by supply powers. Only minor extensions took place between then and 1925, and yet, in the latter year, there were 338 public authorities and 225 companies holding supply powers, and a total of 539 separate systems actually giving supplies. No less than 301 of these systems relied entirely on their own individual generating stations, a further 119 supplemented local generation by a partial bulk supply, and only the remaining 119 depended entirely on bulk supply. Table II summarizes the position as it existed when the Weir Committee was appointed:—

Table II
State of British Supply Industry in 1924-5

Population Served

| Total Population of Supply Area | No. of Systems |
|---|---|
| 500,000 and over | 17 |
| 100,000 and under 500,000 | 84 |
| 50,000 and under 100,000 | 71 |
| 10,000 and under 50,000 | 229 |
| Under 10.000 | 123 |
| | 524 |

Electricity Sold

| Millions of Units Sold to Consumers | No. of Systems |
|---|---|
| 100 and over | 9 |
| 50 and under 100 | 17 |
| 10 and under 50 | 84 |
| 1 and under 10 | 172 |
| Under 1 | 246 |
| | 528 |

Size of Generating Stations

| Total Installed Capacity (Megawatts) | No. of Stations |
|---|---|
| 100 and over | 1 |
| 50 and under 100 | 12 |
| 10 and under 50 | 96 |
| 1 and under 10 | 178 |
| Under 1 | 207 |
| | 494* |

*Average capacity = 7.54 megawatts (mw.)

Average Fuel Consumption at Steam Stations

| Lb. of Fuel per Unit Generated | No. of Stations |
|---|---|
| Under 2 | 8 |
| 2 and under 3 | 87 |
| 3 and under 5 | 112 |
| 5 and under 10 | 63 |
| 10 and over | 20 |
| | 280 |

Combined returns in certain cases affect the comparability of the totals given in this table; this applies particularly to the numbers of steam stations. The figures are striking evidence of the relatively small scale of operation which characterized the industry at that time. The medley of systems then employed is amply demonstrated by the figures in Table III:—

Table III
Supply Systems in Use in Great Britain in 1924-5

Types of Supply Afforded

| Current | No. of Systems |
|---|---|
| A.c. only | 145 |
| Both a.c. and d.c. | 203 |
| D.c. only | 191 |
| | 539 |

A.C. Frequencies Employed

| Cycles | No. of Systems |
|---|---|
| 25 per sec. | 26 |
| 40 per sec. | 21 |
| 50 per sec. | 288* |
| 60 per sec. | 7 |
| 100 per sec. | 11 |
| All others | 15 |
| | 368† |

*Includes 252 employing 3-phase and 36 using 1 or 2 phase only.
†Systems employing more than one frequency have been counted under each frequency.

The retarding influence of these factors on the electrification of British manufacturing industry can be judged from Table IV:—

Table IV
Power Equipment of British Industries in 1924

| Type | Horsepower | Per cent of total power |
|---|---|---|
| Mechanically applied | 7,203,900 | 48.3 |
| Electric motors driven by generators at works | 3,516,400 | 23.6 |
| Electric motors driven by purchased electricity | 4,197,100 | 28.1 |
| Totals | 14,917,400 | 100.0 |

### Reasons for Adoption of Grid Policy

Although these figures rather present a picture of chaos, it is not suggested that the supply industry was inefficient. In the five years from 1920 to 1925, the national average fuel consumption at all steam-driven public generating stations was brought down from over 3.3 lb. of coal per unit generated to 2.4 lb. In the same period, many of the larger generating stations which are now linked up with the Grid were built by the more important supply authorities, while there was a steady lowering of price to the consumer, expansion of supply areas, and extension of distribution systems.

But experience was indicating that nation-wide interconnection was not only practicable but was necessary to an effective solution of our problems. Even if the voluntary co-ordination proposals had not broken down, they would have been only a palliative. To give but one reason, important areas of the country had been developed at 25

Fig. 1—Main "Grid" Transmission Lines.

and 40 cycles, and a system of co-ordination by regions would almost certainly have perpetuated those two frequencies. Standardization was essentially a national problem.

The problem set before the Weir Committee, therefore, was to review the whole national problem of the supply of electrical energy. Its task was not an enviable one. Voluntary schemes of co-ordination had broken down, and some measure of compulsion was inevitable.

After hearing a wide variety of evidence, from both British and overseas witnesses, the committee came to the conclusion that there was a natural line of cleavage between production and distribution, and that retail distribution was a local matter, which might well be suitable for decentralization. On the production side, however, they considered it necessary to treat the whole country as one unit, the experience of other countries being conclusive evidence in favour of concentrating production into a relatively small number of large and efficient stations, interconnected by a national system of main transmission lines. Such a plan would entail standardization of frequency, and the rapidity with which industrial demand was growing made the re-organization of production and main transmission a matter of urgency. They recommended that a central authority should be set up with compulsory powers to construct and operate a national system of trunk mains and to control the generating stations feeding into it.

The findings of the Weir Committee were the basis of the Electricity (Supply) Act of 1926.

### Main Features of the 1926 Act

That act started out by creating a new type of administrative organization. The Central Electricity Board consists of an executive chairman and seven members, all of whom are appointed by the Ministry of Transport after consultation with the bodies concerned with local government, electricity, commerce, industry, transport, agriculture and labour, but are not formally representative of or appointed by such interests. They are appointed for not less then five or more than ten years, and are eligible for re-appointment at the end of their term of service. Although appointed by the Minister of Transport, and presenting annual reports and accounts to him, the Board is in no sense a government department. So far as such matters as the raising of capital, the standards of construction, and the routes of transmission lines are concerned, the Board is subject to the same regulation and control by the Minister of Transport and the Electricity Commissioners as any other body holding statutory powers for the supply of electricity. Otherwise the Board has complete freedom from political control, and no Member of Parliament is allowed to serve thereon. It is in short a business corporation, given a maximum measure of independence in its policy and administration; it is required to be financially self-supporting, but is not allowed to make any profits.

The Central Electricity Board was given power to decide what standardization of frequency was necessary to the re-organization, and to require the non-standard systems concerned to be converted by their owners to the 50-cycle basis adopted as the British standard. The capital for the purpose was to be advanced by the Board, who should be recouped for the interest and sinking fund charges on the money so advanced by a levy on all distributing authorities proportionate to their revenue from the sale of electricity. The adoption of a forty-year basis for the sinking fund ensures the spreading of the cost of standardization over a period reasonably related to the benefits, which will only accrue gradually and must to some extent be dependent on the growth of output.

The act next provided that the Grid itself should be constructed and operated by the Central Electricity Board, the capital required both for that purpose and for standardization of frequency being raised by public issues of fixed interest bearing redeemable stock.

The existing efficient stations to be used in conjunction with the Grid remain in their original ownership, but their operation is directed by, and their whole output sold to, the Central Electricity Board at the actual cost of production, the items of expenditure in that cost being specified. Capital charges include, in the case of local authorities (which normally raise capital by fixed interest bearing stock) the actual interest and sinking fund charges attributable to the capital expenditure on generation account. In the case of companies, interest is included at a minimum of 5 and a maximum of 6½ per cent on the money expended as generation capital, while depreciation is allowed on a prescribed scale.

The Board is to direct the operations of the stations connected to the system in such a manner as to produce the best results for the system as a whole and is to sell electricity in bulk to the distributing authorities. The act provides that the Board's tariffs shall contain a fixed kilowatt charge and a running charge, these charges being calculated to cover the estimated revenue expenditure, including interest and sinking fund charges, with such margin as the Electricity Commissioners may allow, the whole being equated over a period of years. This equating of charges makes some of the benefits of the scheme available from the outset, since the demand for electricity may be anticipated to grow fairly rapidly and therefore the fixed charges will be spread over a larger volume of sales in the later years. To the same end, the Central Electricity Board is empowered to charge interest to capital account in the preliminary period and to suspend sinking fund payments for a limited number of years.

The general recommendation of the Weir Committee was that production of electricity should be concentrated into the more efficient stations (designated "Selected" stations) and that the less efficient stations should be closed down, but the 1926 Act contains safeguards designed to ensure that no distributing authority is placed in a worse position by the establishment of the "Grid." It provides that no non-selected generating station can be closed down compulsorily unless the Board shows that the cost of supply on their standard terms will for a period of not less than seven years be lower than the existing cost of local generation excluding such capital charges as would continue if the station were closed down.

A somewhat similar safeguard is given to the owners of selected stations. The act contemplates in general that selected station owners will purchase so much of their requirements as is produced at their own station or stations at the actual cost of production adjusted to the load factor of their own supply, with the addition of a due proportion of the charges associated with the Grid, or at the Board's

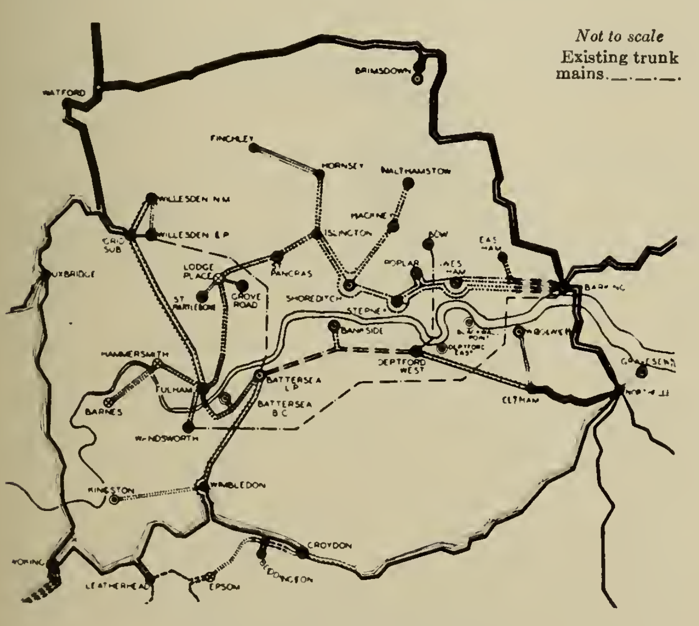

**Fig. 1a—London Cable Grid.**

general tariff if that proves more favourable, with an over-riding protection that in any event they shall not be charged more for their supply than the costs they would have had to face under conditions of completely independent operation.

### The Establishment of the Central Electricity Board

Following the passing of the 1926 Act, which received the Royal Assent in December of that year, the Central Electricity Board was set up in March, 1927, its first chairman being Sir Andrew Duncan, who will be remembered by Canadians for his chairmanship of the Nova Scotia Coal Mines Commissions of 1925 and 1932 and the Maritime Claims Commission of 1926. Sir Andrew is still a member of the Board, but on his appointment as Executive Chairman of the British Iron and Steel Federation, Sir Archibald Page was appointed Chairman of the Board.

To facilitate the work of the Board, the act provided that Great Britain should be divided into a number of regional scheme areas, which the Electricity Commissioners were to define and for each of which they were to prepare a technical scheme setting out the stations to be selected, the sections of the national transmission network to be built and the standardization of frequency to be effected. Each of the schemes when received by the Board was published and opinions thereon invited from all interested parties. The Board, after making such changes as were deemed desirable, proceeded to adopt the schemes, to work out in detail the technical arrangements necessary and to arrange for the constructional work and the standardization of frequency involved. The act further laid down a period, after the adoption of each scheme, within which any supply authority upon whom obligations were laid, and who felt prejudiced thereby, might appeal to arbitration. It says much for the soundness of the initial plans, and for the conciliatory policy of the Board, that in no instance was recourse to arbitration found necessary.

Nine schemes (Central Scotland, South East England, North West England and North Wales, Central England, Mid-East England, East England, North East England, South West England and South Wales, and South Scotland) were adopted between 1927 and 1932, covering the whole of Great Britain except North Scotland, which consists mainly of sparsely-populated mountainous country (the whole area of over 20,500 square miles contains under 2 per cent of the national population) and for which no scheme is in immediate contemplation. The general geographical layout of the system is shown in the accompanying map (Fig. 1).

### Technical Features of the Grid

High voltage transmission is now long established practice, but in countries other than Great Britain is mainly used for transmitting large quantities of power from sources of energy remote from population centres to principal consuming points. In Great Britain, where the sources of energy are comparatively close to each other and where generating stations are mainly located at or in close proximity to consuming centres, the function of the high voltage system is not the one-way transmission of large blocks of power, but the interconnection of power plants so as

(*a*) to raise plant utilization factors by reducing the amount of reserve generating plant required in individual stations, and
(*b*) to secure the highest practicable load factor on the most efficient plant in the system.

The system may be likened to a magnified set of sectionalized bus-bars to which all the generating plant is connected and from which all the main feeders are run. Interconnection of power stations for such purposes had, of course, already been carried out in other countries on a comparatively large scale, and, indeed, had been used to a limited extent by the power companies in Great Britain.

The novelty of the Grid scheme lies in the application of these principles on a national scale, involving the construction of a high-voltage system of considerable magnitude and the parallel operation of a large number of individual power plants.

The physical layout of the British system was of course largely determined by the geographical location of the efficient generating stations existing at the time it was established. Since those stations were situated at or near the principal centres of demand, the interconnection of the stations automatically provided a plan adjusted to existing load conditions, while the connecting lines could in future be tapped if new centres of load grew up. For example, in planning the system due regard was had to the potential demand which might arise if extensive main-line railway electrification were undertaken.

The general principle followed in the layout of the Grid is that all important load centres should be served by two separate Grid links. The system therefore consists of a number of rings, connected by tie lines to neighbouring rings, and is designed for 3-phase operation at 132 kv. between phases, this voltage being chosen as the most economical for the load requirements and transmission distances encountered in Great Britain. It was also the highest voltage for which the design of underground cables was then reasonably well developed.

The main 132 kv. Grid system serves as a feeder for extensive lower voltage (mainly 66 and 33 kv.) systems supplying undertakings whose load requirements are insufficient to justify direct connection to the main Grid.

The 132 kv. system is designed for operation with all neutral points directly earthed, for the following reasons:—

First, multiple earthing would be the least objectionable from the standpoint of inductive interference with communication systems.

Secondly, considerable economies would be effected by the use of transformers with graded insulation.

Thirdly, discriminative protective equipment could be simplified.

Fourthly, maximum phase potential to earth would be limited.

There are now 2,898 route miles of 132 kv. lines, 1,227 route miles of 66 kv. and lower voltage lines, and 289 transforming and switching stations, with an aggregate transforming capacity of 9,475 mva. (megavolt-amperes).

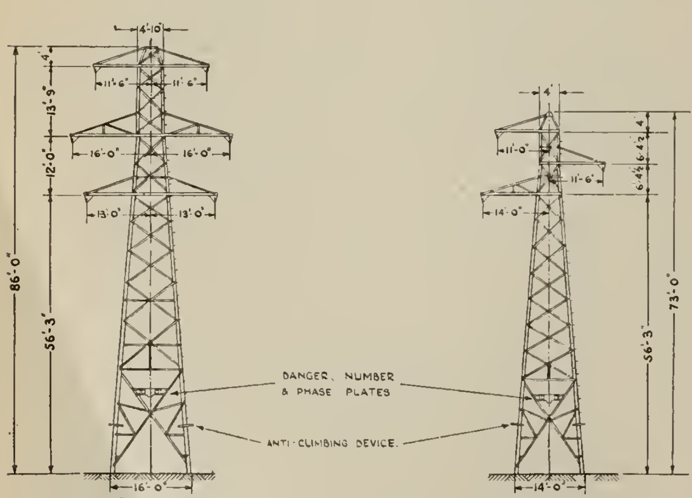

Fig. 2—Typical 132-kv. Towers.

*Overhead Lines*

The lines comply with the regulations of the Electricity Commissioners, but factors of safety were adopted somewhat in excess of those strictly required. Steel-cored aluminium conductors were chosen for practically all the Grid lines, a major reason for this choice being the difficulty, in a densely-populated country such as Great Britain, of obtaining wayleaves for tower positions, which made imperative the use of long spans.

The standard 132 kv. conductor consists of a central core of 7 strands of galvanized steel wire each 0.11 in. diameter, surrounded by 30 strands of aluminium wire of the same diameter in two layers. Conductivity is equivalent to that of a copper conductor of 0.175 sq. in. cross sectional wire. The overall diameter is 0.77 in. The nominal capacity per 132 kv. circuit is 50 mva.

A continuous earth conductor is attached to the apex of all towers. The earth conductor consists of a 7-strand

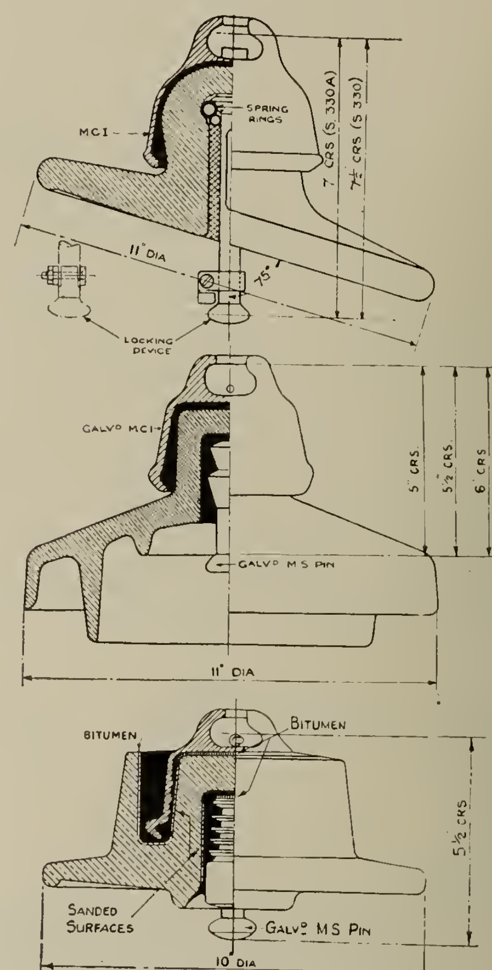

Fig. 3—Anti-Fog Type Insulators.

steel core covered by 12 strands of aluminium in a single layer. All strands are 0.11 in. diameter. The steel core is protected against corrosion by bitumenizing.

*Towers*

The standard Grid towers are all of the broad base lattice steel type with phase conductors in triangular formation on single circuit lines and hexagonal formation on double circuit lines. The broad base type was chosen mainly for economic reasons, but aesthetic considerations played a considerable part in the choice. A horizontal arrangement of conductors has much to commend it from the engineering point of view, but was ruled out by economic considerations.

Mild steel is normally used for the towers, protected against corrosion by galvanizing. In the Central England Area, however, ungalvanized painted copper-bearing steel was adopted. Foundations of the excavated earth, concrete block and concrete ball type have been used, the particular type chosen depending on the nature of the subsoil. Figure 2 shows the general design adopted for standard single and double circuit towers.

*Insulators*

Suspension insulators of the cap and pin type with ball and socket fittings have been standardized. Ninety per cent of the units are of the general form used in Canada and elsewhere, but the remaining 10 per cent. are special anti-fog types. Certain areas of Great Britain are notorious for the prevalence of fog and industrial atmospheric pollution. In these areas the anti-fog insulators have been effective in improving the degree of immunity of the lines from fog flashover. Figure 3 shows the three types which have been used.

*Switching Stations*

The majority of the transforming stations have two incoming lines and two transformers, controlled by three 132 kv. circuit breakers. Figure 4 shows that one circuit-breaker acts as a section switch between the two incoming Grid lines, while the two others are in the transformer primary connections. In cases where more than two lines or two transformers have to be controlled, the switching arrangements are of the busbar or mesh types. An example of the mesh type station is illustrated in Fig. 5. In cases where extreme economy was necessary, the switching arrangements were simplified and the circuit-breakers were omitted from the transformer primary circuits. In one case all supplies are delivered to the Grid from a large selected generating station through transformer feeders without the intervention of higher voltage switchgear. The outstanding feature of the Grid switching arrangements has been the keeping of the number of circuit-breakers to the absolute minimum necessary for safe operation, which has effected great economies in construction as compared with similar high power and high voltage interconnected networks elsewhere.

The physical layout of the switching equipment naturally varies in accordance with the site facilities available. Where the requisite ground area has been available low type switching stations are used, high type stations being adopted only where ground area is restricted.

*Transformers*

With the exception of a few banks of single-phase units, all transformers are of the 3-phase type, provided with on-load ratio-changing equipment fitted to the high voltage windings. The lower voltage is in accordance with the requirements of the individual undertakings, and varies from 3.3 to 66 kv. The capacities of the 132 kv. units range from 3 to 75 mva., an example of the latter being shown in Fig. 6. All transformers were designed for transport over the British railway systems, which have a somewhat restricted loading gauge. Transformers of 10 mva. and below have natural cooling, but in exceptional cases natural cooling has been used on 20 mva. units. Large transformers have natural cooling up to approximately half load, and at higher loads have forced air-blast cooling and forced oil circulation. It was a primary requirement that all transformers should operate as silently as possible.

132 and 66 kv. windings are star-connected, and the lower voltage windings delta-connected. All 132 kv. transformers have a voltage regulating range of ± 10 per cent. The lower voltage transformers are of the same general type as the 132 kv. but the phase arrangements and voltage regulation range are varied to meet local requirements.

Probably the most noteworthy feature in the Grid transformers is the wholesale adoption of on-load ratio-changing equipment. This step, which was a somewhat bold one, in view of the small amount of development of such gear prior to the construction of the Grid, has proved to be eminently satisfactory.

*Protective Gear—Selective Protection*

British power systems prior to the Grid were on a comparatively small scale. Where exact selective protection equipment was essential, this was provided by balanced pilot wire equipment. Owing to the prohibitive cost which would have been involved in providing highly insulated pilot wires for the whole of the Grid system, it was necessary to design a protective scheme of a less costly nature but giving similar performance.

Underground cables and line sections less than 10 miles long have pilot protection either of the balanced type using normal pilots or of the interlock type using pilots

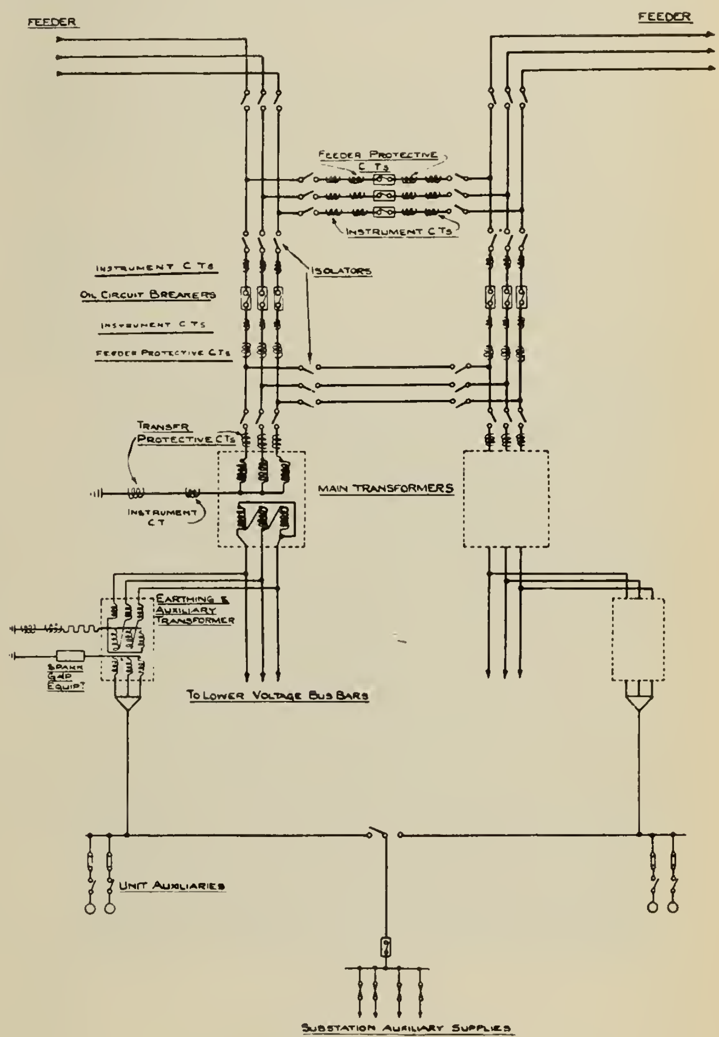

**Fig. 4—Typical Three-Switch Substation.**

hired from the communication authorities. Longer sections have distance protection of the ratio balance or impedance type. Certain sections connected to the system through transformers only are protected by earth leakage and overload gear. All main transformers have balanced discriminative earth leakage protection.

*Metering*

The provisions of the 1926 Act entail metering equipment of a special nature. At each selected station, it is necessary to make the following measurements of both kilowatts and kilowatt hours:—

(1) The output of the generators.
(2) The export from the station to the Grid.
(3) The import from the Grid to the station.
(4) The consumption of the local undertaking.

To make this last mentioned measurement, it is necessary with both power and energy to add imports to generation and subtract exports. To reduce clerical computations to a minimum, special high accuracy summating systems were evolved to do this. Special long-scale indicators were introduced to measure the maximum demand with high accuracy, and printometers were developed to give a permanent half-hourly record of the principal maximum demands, namely, the undertaking's requirements, the generators and the import. Reactive component metering had also to be installed to provide the power factor measurements required by the act.

An example of a typical selected-station metering equipment is illustrated in Fig. 7.

*Special Constructions*

More detailed technical information than can be given in this necessarily brief outline is contained in the papers mentioned in the bibliography. Of the special constructional features of the Grid, space only permits the mention of two, but many of them, although only details in the general plan, are in themselves major engineering works.

In the overhead lines the river crossings are all of considerable interest. The Thames crossing at Dagenham—the highest river crossing in the world—is shown in Fig. 8. It is now a landmark which is familiar to all approaching England by way of the Thames. In switchgear the most striking example of a pioneering all British development is the 132-kv. metalclad installation at Tongland which is shown in Fig. 9.

*Cables*

The great extent of the Grid overhead line system tends to overshadow the cable sections. It is however important to note that in Central London and in the connections between the Central London System and the Outer Grid, underground cables had to be used. The London Grid cable system is shown in Fig. 1a. It comprises 42.5 route miles of 66 kv. cable and 23.6 route miles of 132 kv. cable. The oil-filled cable so far holds the field for voltages of the order of 132 kv. and above, but the Board has also assisted in the development of other types of cable which promise to eliminate the disadvantages associated with oil-filled cable. A 2½ mile section of 3-phase 66 kv. cable of the external nitrogen pressure type has been in commercial service between Hackney and Walthamstow since 1932, and an experimental one-mile length of 132 kv. internal pressure nitrogen cable will shortly be installed at Wimbledon.

*Control*

For control purposes the Grid is directed from seven control centres situated at Glasgow, Newcastle, Leeds, Manchester, Birmingham, Bristol and London. General particulars of the systems are set out in Table V—the largest of these systems is that controlled from London,

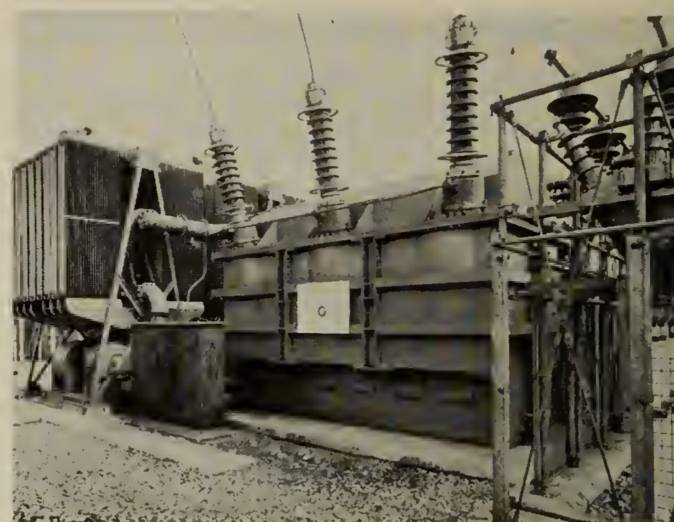

**Fig. 6—75 mva. Three-Phase Transformer compared with Faraday's Induction Ring.**

the present capacity of the generating plant directed from that centre being about 2,000 mw.

The communication circuits are hired from the British Post Office, the majority being in underground cables.

With the exception of a few omnibus circuits serving two stations where traffic is light, separate circuits are provided between the control centre and each main grid point. Stations on the lower voltage secondary lines are served by extension omnibus circuits from the parent grid point concerned.

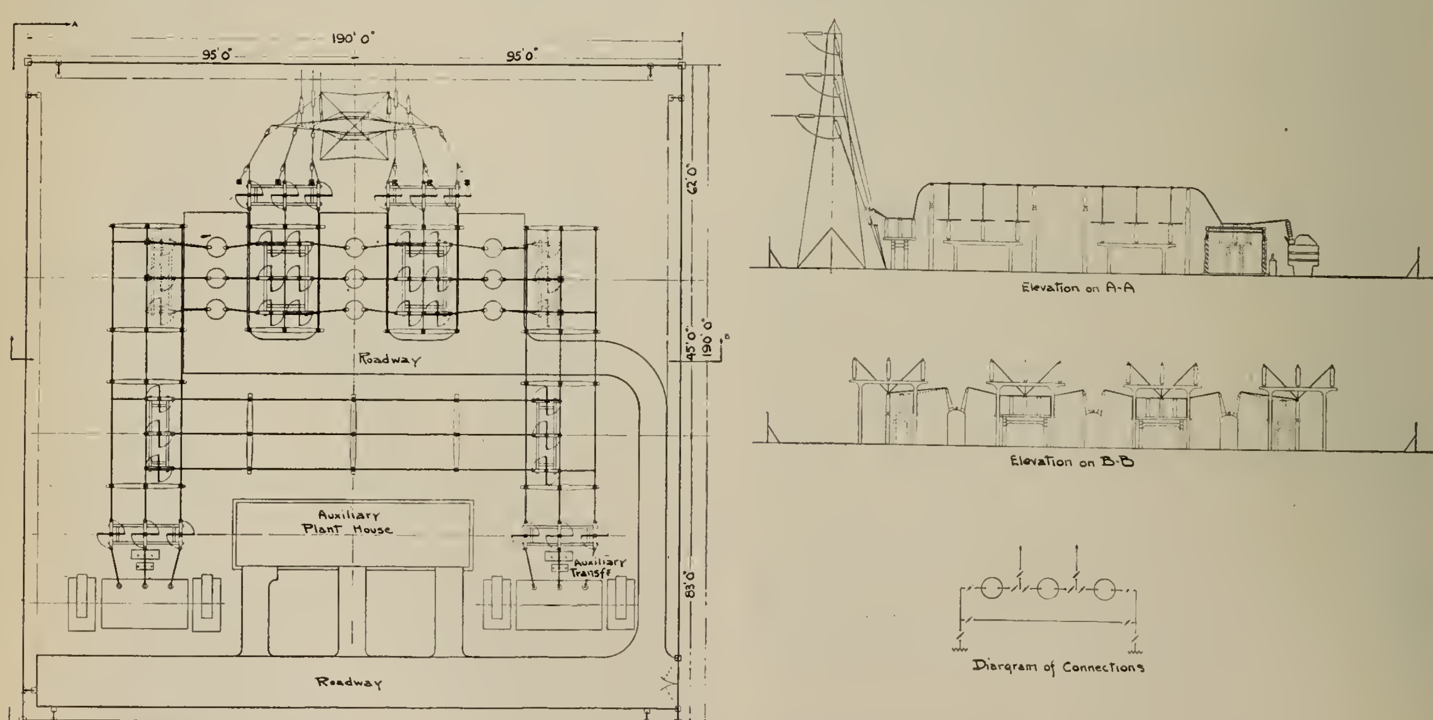

**Fig. 5—Typical Mesh-Type Substation.**

TABLE V
POSITION AT 31ST DECEMBER, 1936

| Scheme | Location of control centre | Area | Population 1935 | Electricity generated by public stations 1936* | Number of selected stations | Lengths of lines and cables under control | | | Number of switching and transforming stations | | | Length of communication channels |
|---|---|---|---|---|---|---|---|---|---|---|---|---|
| | | | | | | 132 kv. | Lower voltage | Total | 132 kv. | Lower voltage | Total | |

| Totals | | 67,632 | 44,787,544 | 19801.7 | 137 | 2,898 | 1,227 | 4,125 | 133 | 156 | 289 | 4,974 |

*Provisional

Each control room is equipped with:—

(*a*) Combined telephone and automatic indicating equipment giving, over the single channel to each main grid point, direct telephone communication between the control centre and all main and important secondary grid points. Automatic indication is given of circuit breaker position and transformer ratio, of load transfers between grip sections and systems, and of important station outputs. Indication on demand is also given of less important station and transformer loads, and of system voltage at various points. Seven-point telegraphs are provided for routine signals to stations.

(*b*) A specially designed control desk or desks.

(*c*) A complete system diagram showing all lines, oil switches, isolating and earthing switches, and transformers, under the control of the Board.

(*d*) Frequency and time-control equipment.

Most of the equipments have been designed on automatic telephone principles. Remote metering indications are mostly provided on demand by impulse systems, and where continuous, by a photo-electric system.

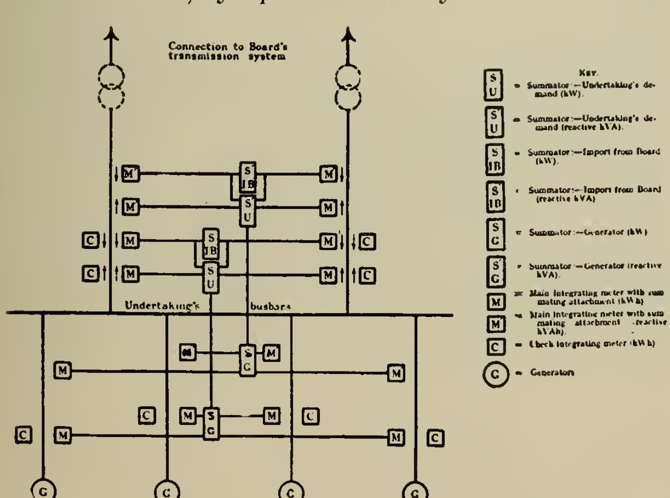

**Fig. 7—Metering Scheme for Stations with Generating Plant.**

The use of automatic telephone apparatus makes possible a convenient concentration of receiving devices. In the arrangement shown in Fig. 10, the circuit breaker ratio change and meter indicators are carried in a well in the front of a special desk.

**Fig. 8—Thames Crossing at Dagenham. Towers 497 ft. high, Span 3.060 ft.**

STANDARDIZATION OF FREQUENCY

The areas which had to be changed to the standard 50-cycle basis before the Grid system could be brought into full operation are shown in the map (Fig. 11). The magnitude of the work involved can be judged from the fact that it has entailed the rewinding or replacement of over 900 mw. of generating plant and 300 mw. of converting plant in addition to a huge amount of apparatus on consumers' premises.

It is worthy of note that motors having a total capacity of over 1,800,000 h.p. have been changed over to standard frequency without dislocation of industrial production.

But for the fact that growth of industrial equipment has been retarded by the trade depression from 1930 to 1934, the amount of apparatus to be dealt with would have been even larger. The work, which began towards the end of the year 1927, has been estimated to cost some £19 millions. While the actual cost will probably be less than that figure, it is safe to say that if the change had been delayed until the present time, the cost would have been in the neighbourhood of £30 millions.

THE GRID IN OPERATION

The introduction of a high voltage system of the magnitude of the Grid, in a highly developed and densely populated country such as Great Britain, involved administrative problems at least as great as those on the technical side.

The act gave the Board power to acquire wayleaves for its lines compulsorily, on reference to the Minister of Transport, but in spite of the magnitude of the task, involving negotiations with some twenty-two thousand separate landowners and tenants, and in spite of the fact that the establishment of a comprehensive national network of overhead lines was viewed with a natural concern by all those interested in the preservation of amenities, no serious delay was occasioned by wayleave negotiations, and resort to compulsion was only necessary in some 2½ per cent of the cases dealt with.

**Fig. 9—Metal Clad 132-kv. Switchgear at Tongland.**

Figure 12 gives a comprehensive summary of the progress from the time of the passing of the 1926 Act to full operation of all the schemes except North East England, where general trading is still deferred pending the completion of frequency standardization.

On the establishment of the Grid, the Board's operations fall naturally into two divisions:—

(i) those associated with the production and transmission of energy, and

(ii) those relating to the sale of electricity.

(i) *Production and Transmission.*

The 137 selected stations and 37 other stations under the directions of the Board vary widely in size and economy of production. Proximity to a coal field or to cheap sea transport facilities gives certain stations the advantage of a low coal price. A high thermal efficiency is obtainable with stations situated on the sea coast or on rivers with ample condensing water. Large and economical stations had been built to meet heavy electrical loads in the main population centres, but at other load centres the existing stations were less efficient.

By using only the best stations continuously and relegating the others to restricted operation, it is possible to produce the energy requirements of the system as a whole at a reduced over-all running cost.

The operating programmes aim at reducing the running costs of generation in each area to the minimum compatible with reliability of supply, on which considerable stress is laid in Great Britain.

Each of the seven systems into which the grid is divided is normally operated independently, and no attempt is made to transfer large blocks of energy from one area to another except in the case of the hydro-electric stations in South Scotland, which export most of their output to Central Scotland and North West England.

As a result of the concentration of production at the most economical stations, out of the 155 stations operating under the Board's directions in 1936 in the areas in which general trading was in force, only 26 ran the full 8,784 hours in the year, 27 others ran between 8,783 and 6,600 hours, 50 others between 6,600 and 2,400 hours, 47 less than 2,400 hours, while five were not in operation at any time during the year. Sixteen of the most economical of these stations produced over 50 per cent of the energy generated for the Board in those areas.

Figure 13 shows the growth of winter load between 1925 and 1935, and the magnitude of the normal daily variations for Great Britain except North Scotland.

Since the advent of the Grid the responsibility of arranging for generating plant extensions has devolved on the Board. The programmes of plant extensions are based on surveys of probable load development for the four ensuing years and after approval has been obtained from the Electricity Commission the Board issue formal directions to the station owners to carry out the extensions. In planning extensions of generating plant and of the Grid equipment each of the seven systems is considered separately. The interconnecting lines between these systems provide, however, an additional safeguard facilitating mutual assistance should occasion arise.

For the five years 1935-1939 inclusive, the Board have arranged for new plant at average annual rates of about 550 mw. for generators and about 6,700,000 lb. per hour for boilers together with the necessary reinforcing of the Grid system. The most usual sizes of machine are 30 mw. at 3,000 r.p.m. and 50 mw. at 1,500 r.p.m. with boiler pressures ranging from 400 to 600 lb. per sq. in. and superheat up to 850 deg. F. 40 mw. sets at 3,000 r.p.m. are, however, under construction, and 60, 75 and 100 mw. sets at 1,500 r.p.m. are in operation. In addition, a 50 mw. installation designed for operation at 1,900 lb. per sq. in. and 930 deg. F. is approaching completion.

**Fig. 10—Southwest England and South Wales Control Room, Bristol.**

(ii) *Sale of Electricity.*

Reference has already been made to the financial arrangements between the Board and selected stations, including the repurchase by the latter of the energy required for their own purposes.

As soon as general trading has begun in a Scheme Area, the Board is under obligation to furnish supplies to all distributing authorities in that Area who may demand supplies from the Grid, but the Board may decide whether a supply shall be given directly or indirectly through the system of some neighbouring authority. The interests of the indirectly supplied authorities are, however, safeguarded by a provision in the 1926 Act that they are to receive supplies on the same terms as the authority through which their supply is drawn, with the addition only of the actual costs and charges involved in transmission.

**Fig. 11—Areas Changed from Non-Standard a.c. Frequency.**

The first point of interest in the Board's tariffs is the fact that budgeting on a ten-year basis involves estimating the probable growth in the demand for electricity for that period, and assessing the costs of generation and transmission likely to be entailed in catering for the projected demand. Forecasting over such an extended period may at first sight seem rather hazardous, but it is after all no more so than that involved in the construction of any capital works of magnitude having an extensive period of life. Much of the expenditure, particularly that on plant extensions, can be regulated within the period if there are changes from the assumed rate of growth. Up to the present the growth assumed in the initial tariff calculations has been somewhat exceeded. The most inflexible element in the calculations is the cost associated with the initial Grid construction, which of necessity was planned to meet the future conditions envisaged at the time of the 1926 Act. The Weir Committee based their recommendations upon the assumption that public sales of electricity in Great Britain would amount to 21,385 million units by about the year 1940. Unlike other countries, the production of electricity in Great Britain did not register an actual decline even at the worst of the depression (the lowest annual increase being 4½ per cent in the year 1931). The total output of public stations in 1936 was 20,220 million units, corresponding to sales of about 17,000 millions; sales are now increasing by over 1,500 millions per annum, and there is thus little doubt that the general scale of electrical development will be such as to justify the estimates on which the Weir Committee's recommendations were founded.

The next point of interest is that although the principle of a small ultimate margin made it necessary to approximate as closely as possible to a true cost basis, so as to secure low initial prices, it was found possible to introduce promotional elements into the tariffs, to encourage load development.

In the first place, the fixed charge per kilowatt is related to the "basic" demand of the authority taking the supply, defined as the demand upon that authority by its consumers in 1932, subject to a minimum of 2,000 kw. Any demand in excess of that "basic" level is supplied at three lower grades of kilowatt charge, the steps being related to "standard increments" of demand which vary inversely with the amount of the basic demand.

Secondly, the period during which the chargeable maximum demand is measured is restricted to the four months of January, February, November and December in each year, and it is thus possible for a distributing authority supplied at the tariff to develop new loads during the eight summer months without incurring additional kilowatt charges, thereby encouraging improvement of load factors.

Apart from these two features, the tariffs follow normal practice by incorporating a fuel clause, designed to cover changes in wage levels and general prices as well as alterations in the calorific value and price of fuel, a power factor clause penalizing authorities whose power factor of supply is below 0.85 lagging, and a rates clause reflecting variations in the level of local taxation. All demands are measured on a half-hourly basis.

The principal features of the Grid tariffs so far in force are summarized in Table VI.

It was realized that certain non-selected stations could with advantage be utilized during the remainder of their economic life. Arrangements were accordingly made for them to be operated for the time being under the directions of the Board for peak load and standby purposes, the

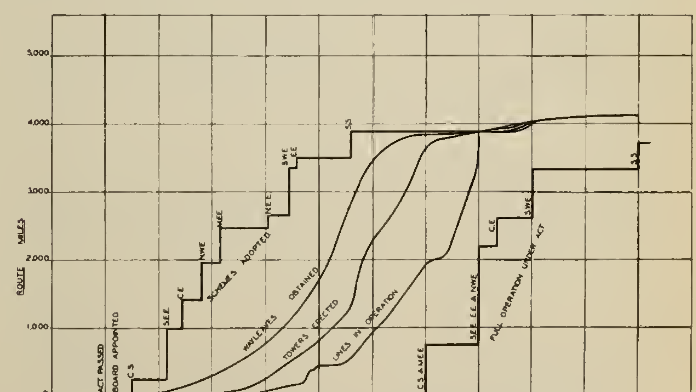

**Fig. 12—Progress of Grid Schemes.**

Board supplying the whole requirements of the owners and paying appropriate rentals for the use of the stations. As the outstanding capital expenditure on the stations is amortized, the rentals can be gradually reduced until ultimately the stations are closed down, the owners continuing to purchase the whole of their requirements from the Grid. Such arrangements have mainly been made with distributing authorities in respect of their own generating stations, but in a few cases somewhat similar arrangements have been made in regard to generating plants owned by large industrial consumers, which are operated on behalf of the Board through the local distributing authority.

Sanction for such arrangements was conveyed by a further act in 1935, which also improved the flexibility of the Board's trading in two important respects. First, it empowered the Board (subject to the approval of the Electricity Commissioners) to give a special supply to a distributing authority, at a rate different from the Grid tariff, for the purposes of an industrial consumer whose circumstances were so special as to justify an exceptionally low rate. Secondly, it permits the Board (again after approval by the Electricity Commissioners) to give direct traction supplies to railway companies, subject to a limited veto by selected-station owners on the use of such supplies within the areas controlled by them.

### Effects and Results of the Grid

While the Grid will not be seen in its true perspective at least until the first ten-year period of normal operation has elapsed, some of the more salient results have already become visible.

In the first place, the policy which was planned in the comparative prosperity of 1924-1929 was largely executed in the following years of depression and contributed in no small measure to the alleviation of conditions during that period. For the Grid as originally designed and constructed, 150,000 tons of steel were required for more than 26,000 lattice-work towers and for the steel cores for conductors on 4,000 route miles of transmission line. 12,000 tons of aluminium were also required for the overhead lines and some 200,000 strings of insulators and porcelain bushes. Coal mining, iron and steel manufacture, cable making, electrical engineering, cement, pottery, building and contracting industries all made their contribution to the Grid scheme. The cost, approximately £27,000,000, was within 2½ per cent of the original estimates.

Not only did the construction of the Grid have a beneficial effect upon national employment, at a time of acute depression, but the experience in high voltage construction which it entailed has placed British manufacturers once more in the forefront of technical progress.

The first effect to be looked for from the establishment of the Grid is the reduction in the plant capacity needed to satisfy a given demand. During the years immediately prior to the establishment of the Grid, the amount of spare plant which it was necessary to maintain as an insurance against breakdown was steadily rising, due mainly to the large sets then coming into use, which entailed the retention of commensurate standby capacity. While the Grid was

| Exceeding 12,000 but not exceeding 13,000 kw.... | 2,000 kw. | | |

(*c*) Increase of kw. charge per 0.1 in P.F. below 0.85 lagging.

(*d*) Average local taxation for the year in respect of all the selected stations in the area, per kilowatt of the generating plant in those stations at the beginning of the year.

under construction, the proportion of standby plant remained approximately constant in spite of further increases in demand, as sections of the Grid were coming into operation, and thus uneconomical plant extensions were being avoided. It will be seen from Fig. 14 that since 1933, when general trading began, reserve plant has been absorbed very rapidly until today, with the Grid not yet in full operation, it represents not much more than the minimum which will be required under conditions of completely

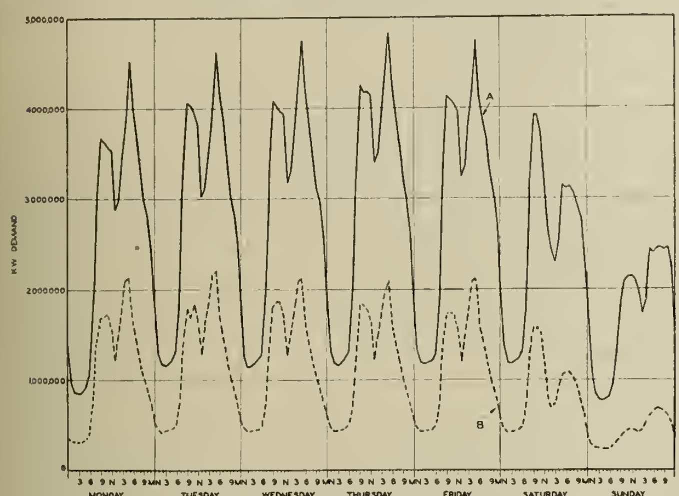

**Fig. 13—Aggregated Load Curves Winter Week.**

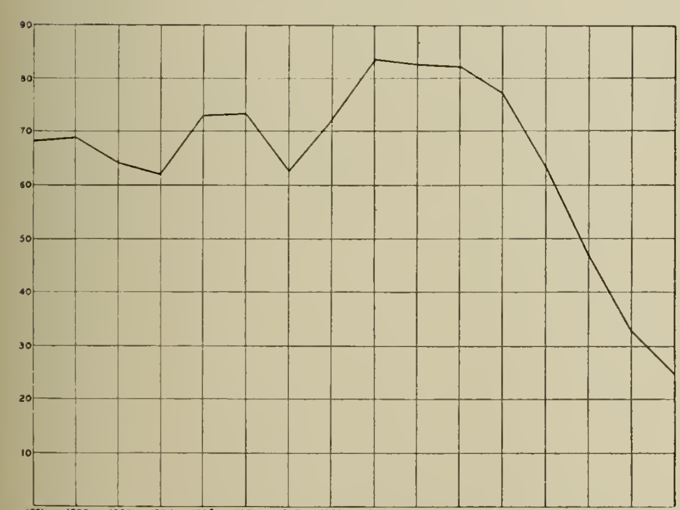

**Fig. 14—Reserve Plant in British Public Stations as Percentage of Aggregate Demands thereon.**

interconnected working. Future plant extensions will, therefore, be proportionate to the actual growth in demand upon the system, which can, however, be met by the installation of a relatively smaller amount of additional plant. The net savings in reserve plant, which at the end of 1936 were already estimated to amount to some £14,000,000 will, therefore, continue to grow.

Apart from the reduction in reserve plant brought about by the Grid, the concentration of production into the most efficient stations has resulted in a very considerable increase in the aggregate thermal efficiency of the system and a corresponding decrease in fuel consumption. The extent of these economies can be judged from Fig. 15, in which the performance of the stations now associated with the system is compared with the performance of such of those stations as were in full operation independently in 1932. It will be seen from this diagram that thermal efficiency has increased by no less than 14 per cent of the 1932 figure, while the average fuel consumption per unit sent out from the stations has decreased proportionately. Part of this increase in efficiency, of course, arises from the better performance of the new plant installed in the selected stations since 1932, but this better performance is in itself partly attributable to the Grid, since larger individual sets are possible with interconnected working. In 1936 the average size of generator arranged by the Board to be installed was some 35 mw. which, as will be seen from Table II, is over four times the average capacity of a complete station in 1924-25. The magnitude of the saving on fuel can be judged by the fact that the overall fuel consumption of the system in 1936 was nearly two million tons less than it would have been at the 1932 average fuel consumption per unit. At the coal price ruling in 1935 this would have meant a saving in the fuel bill for the year of over £1,400,000, but as is well known, coal prices in Great Britain hardened in 1936 and at the average price actually paid in 1936, the saving amounted to nearly £1,600,000.

The full benefit cannot be felt by the consumers until the national demand for electricity has increased sufficiently to spread the charges incidental to the Grid over the market for which it was designed to cater. None the less, it is already clear that the Grid is having a marked effect upon the average costs of energy to the distributing authorities in general and this after all is the real criterion of whether the policy is sound. In recent years there was a marked

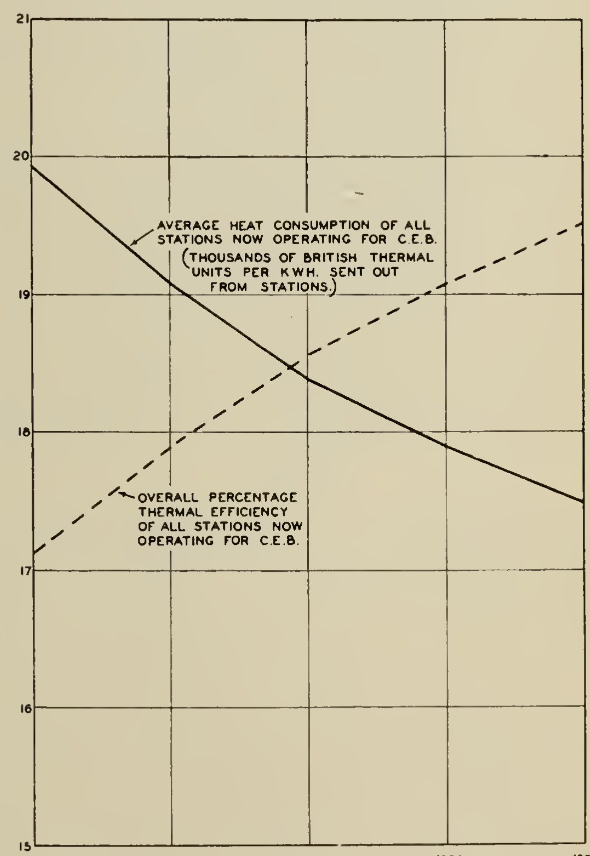

**Fig. 15—Fuel Reduction with Grid Operation.**

downward trend in average production costs even before the establishment of the Grid, due partly to the efforts of the supply authorities, but mostly to the general decline in national price levels after the War. To obtain some real measure of the contribution of the Grid to the economy of the supply industry, it is necessary first of all to eliminate this latter factor. In Fig. 16 are shown the total costs from 1921-22 to 1935-36 to the supply authorities of the country of the electricity required to serve their consumers, the costs having been adjusted for all price changes outside the control of the industry and also for the increase in load factor which has been a feature of electrical development in Great Britain in the last fifteen years. (Corrected to Load-Factor 33.24 per cent and price levels in 1934-35.) Since the costs in the later years include the amounts which have been paid by distributing authorities in respect of Grid supplies, the marked change in the curve since 1932 is effective evidence of the value of the Grid system.

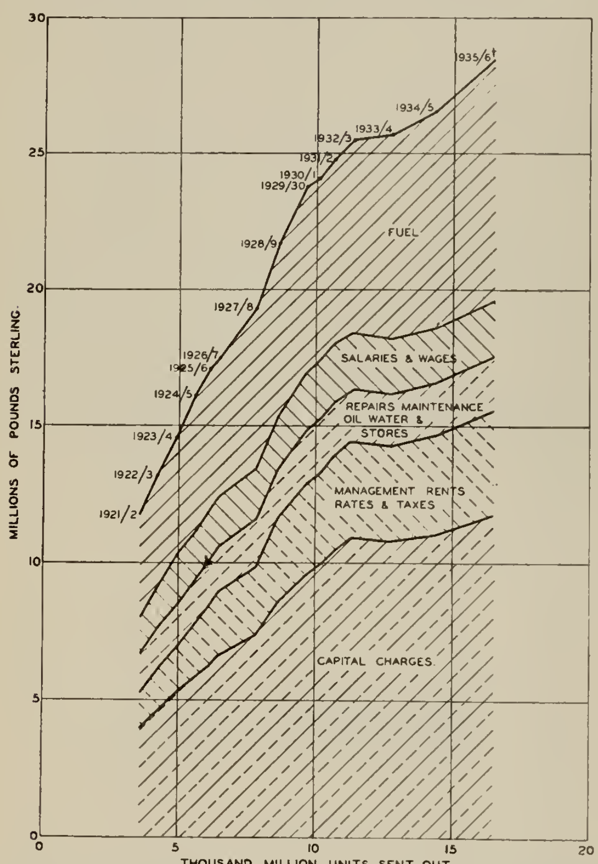

**Fig. 16—Total Costs of Energy sent out on local Distribution Systems.**
†Provisional.

The direct financial effects of the Grid policy are not the only measure of its value to the community. It can be claimed with confidence—and the figures in Table I adequately support the claim—that the existence of the Grid has brought about the development of supplies in rural areas far more rapidly than would have otherwise been the case, with a consequent increase of the amenities of country life. It has undoubtedly assisted in the decentralization of industry and has thus made possible more rational planning of national life. Railway electrification has also received an impetus and one of the principal railway systems of the country—the Southern Railway, which serves the majority of South East England—is now in an advanced stage of main line electrification. Incidentally, the Grid has caught the popular imagination and has undoubtedly advertised electricity in the public mind with a consequential increase in the pace of domestic electrification.

Although inaugurated by an act of Parliament, such a system could not have been superimposed on the electricity supply industry without the co-operation of all parties. From the outset, the Board has endeavoured to be not a separate entity, but an integral part of the public electricity supply industry. To that end, technical consultative committees, representative of the principal supply interests, have been set up in each scheme area, with whom the Board consult on such questions as local trading arrangements, operating programmes and plant extensions, while questions of general principle are discussed with a National Consultative Committee, representative of the whole supply industry. The existence of these committees and the establishment of central control rooms for each area permit of extremely rapid dissemination of important information, while the adoption of a unified system of costing in the production side of the industry has resulted in data being quickly available on a comparable basis for all the stations associated with the Grid.

### Problems Still Awaiting Solution

It will have been seen from the foregoing that the Grid system is now well established and is in a fair way to performing the functions for which it was set up. The problems on the production and main transmission side may reasonably claim to be nearing solution. It is not desired to imply, however, that the whole of the problems of the electricity supply industry in Great Britain have been resolved thereby. Much still remains to be done before the legacy of over fifty years of piecemeal development are overcome. The 1926 Act provided for the standardization of the alternating current frequencies employed, but did not deal with the multiplicity of voltages in use in the low tension distribution networks. Furthermore, considerable portions of these networks are still operated on direct current, while the multitude of separate authorities has naturally led to an enormous variety of tariffs, some of which are promotional in character and encourage development, while others unfortunately have a retarding effect. The whole field of the distribution side of the industry has recently been the subject of a Governmental enquiry, presided over by Sir Harry (now Lord) McGowan. The report of that committee was published last year and is now under consideration by the Government. With that report still *sub judice*, it is too early to make any definite statement on distribution matters, but no doubt the problems will be energetically tackled and the industry will be able to face with confidence a future in which electricity is destined to be of supreme national importance.

To sum up, the rapidity of the growth of the supply industry in Great Britain since the Grid was established, and during a period of world-wide depression, shows that the Grid, which is the first step in the national reorganization of electricity supply, has been established without dislocation to industry and is being of material assistance to it. The policy is undoubtedly sound—indeed it is difficult to see any practicable alternative—and there is every prospect that it will be a financial success. It has made exceptional demands upon the British manufacturers of high voltage electrical apparatus, who have met all the demands made upon them in the best British tradition of design and craftsmanship. The energy hitherto expended in overcoming the retarding influence of small scale individual production is now released for the more important function of load building. There is, therefore, good ground for believing that with the handicaps of the past overcome, electrification in the Mother Country, which is now proceeding apace both industrially and on the domestic side, will soon approach the high level which has been achieved in these fields in the great Dominion of Canada.

**Paper to be presented at the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

SUMMARY.—This paper covers the design and construction of a reinforced concrete highway bridge with three tied-arch spans, the longest being 213 ft. The substructure work was done under very severe winter conditions. Maximum concrete stresses in the arch rings were reduced by using temporary reinforced concrete hinges at the crowns. Records of concrete temperature are given, also figures as to quantities and costs.

The Borden bridge, a reinforced concrete structure approximately 851 ft. long, was built in 1935-36 to replace the "Ceepee" ferry where the Jasper highway crosses the North Saskatchewan river about forty miles northwest of Saskatoon. The existing location and elevation of the highway at this crossing demanded that the bridge floor line should be no higher than necessary to clear flood waters, and a through type of bridge was clearly indicated. A reinforced concrete structure was favoured by the local authorities, not only on account of appearance and economies in maintenance, but also due to the larger percentage of local labour that would be thereby provided. The nature of the river bottom on the west bank made the consideration of fixed elastic arch spans unattractive, and, as the bridge had to be of the through type in any case, bow-string or tied arches were adopted for the major spans, as such structures are unaffected by slight pier settlements or rotations, and would not require an expensive thrust pier on the west bank. A study of different span lengths and arrangements indicated that the most economical and pleasing combination consisted of three bow-string arches flanked by girder spans as shown in Figs. 1 and 2.

Compared to European practice, there are few very long span concrete bridges on this continent, although arches up to 460 ft. have been built in the United States.[1] In Europe there are several arch bridges approximating 600 ft. in span.[2] These are deck structures built in cellular construction and with the aid of hinges, either temporary or permanent, two valuable design features that might with advantage be made more use of on this continent. A through arch bridge, claimed in 1935 to be the largest of its kind, was built at La Roche-Guyon, France, with a clear span of 528 ft.[3]

Bow-string spans, however, have never approached the above dimensions and, as far as the authors have been able to learn, the largest span of this type in America was built during 1935-36 by McCullough in Oregon[4] with a span of 210 ft. centre to centre of piers. Elsewhere such bridges have been built at least up to spans of about 300 ft. as in Tunisia.[5] In Canada many small highway bridges of this type have been built, but few, if any, with a span greater than 150 ft. The Borden bridge has a centre span of 213 ft. and thus in Canadian practice can be considered a long span of this type. It is proposed, therefore, to discuss in detail certain aspects of design and construction that become controlling factors in such cases but are not so important in shorter spans, and which, it is hoped, will be of value to engineers interested in highway bridge construction.

This paper is divided into three sections. Part I deals with design features, Part II with experimental data obtained during construction, together with calculations and conclusions arising out of these observations, while in Part III construction experiences and aspects are described and a brief statement of quantities and costs presented.

### I. DESIGN

From the aesthetic standpoint an attempt was made to obtain a pleasing effect by careful proportioning only, as it was considered that, on such a rural highway bridge, panelling or other decorative features would be inappropriate. The roadway line from abutment to abutment was constructed on a flat parabolic curve obtained by making the middle piers five inches higher than the other two. The centre span was made slightly longer than the adjacent ones and the crowns of the arches are therefore points on a parabola of sharper curvature but in keeping with the deck line; a camber of three inches was provided in the floor system of individual spans and the resultant elevation of these members together with the arch outline, which is also parabolic, is pleasing. The handrailing on the girder spans, made of a substantial concrete section, gives a sense of security on these short deck spans, and harmonizes

well with the heavy arch ribs and terminal blocks over the end piers. On the arch spans a steel fence, painted a dark green, not only lightens the dead weight, but with the slender verticals and shallow fascia beams emphasizes the functional aspects of the main members. The overhead sway bracing, potentially unattractive, was designed and constructed so that each member lies on a warped surface, the upper and lower surfaces forming part of an imaginary plane following the curvature of the arch rings, and, while the form work was thus complicated somewhat, the result was well worth the effort; Fig. 3 is a photograph illustrating the effects obtained.

### Specifications—Loading and Stresses

In general the specifications of the Canadian Engineering Standards Association for Highway Bridges and Reinforced Concrete were followed and the following loads and stresses assumed:

Live Loads:—Slab, floor beams, girders, hangers; two 15-ton trucks abreast plus 30 per cent impact.
Foundations, arch rings, horizontal ties; uniform load 80 lb. per sq. ft.
Wind:—30 lb. per sq. ft. on vertical projection of spans.
Temperature:—General range, 130 deg. F.
Differential lag between arch rib and horizontal tie temperature 20 deg. F.
Concrete Class "A"—arch rings, sway bracing . . 3,500 lb. per sq. in.
Concrete Class "B"—substructure above elevation 1445, superstructure except in "A" . . . . . . . . . 3,000 lb. per sq. in.
Concrete Class "C"—substructure below elevation 1445 . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . . 2,500 lb. per sq. in.
Concrete flexure stresses were limited to 1,000 lb. per sq. in. in arch rings and 1200 lb. per sq. in. in floor system and girders. Steel stresses in the horizontal tie and vertical hangers were limited to 18,000 lb. per sq. in., while 20,000 lb. per sq. in. was allowed in other members.

### Foundations

The general foundation conditions are shown in Fig. 1. Wash borings indicated that the river bed varied greatly over its width. On the east bank yellow clay outcropped at the surface and pier 4 was located on a hard glacial clay into which it was unnecessary and impractical to drive bearing piles. The clay stratum dipped continuously towards the west end where it was overlain with 60 ft. of fine river sand. The top of the clay stratum, which appeared from the wash borings to be firm boulder clay, as is usually found below the boulder line in this region, was found during construction to be far from firm or uniform and was interspersed with lenses and pockets of soft material, sand and boulders, which created many unforeseen difficulties; the dotted line on Fig. 1 shows the hard firm clay line as found, which was overlain by softer clay, three to ten feet thick.

All foundations were designed carefully to avoid excessive and differential settlements. Records of settlement taken by the authors on another bridge on the South Saskatchewan river[6] showed that a differential settlement between upstream and downstream ends of one-half inch had occurred on all river piers due to the unsymmetrical base plan caused by the ice breaker provisions on the upstream end of piers, an almost uniform practice on Saskatchewan river bridges. Consequently, a corresponding base extension, as shown in Fig. 4, was provided on the downstream end of piers, in order to make pier bases perfectly symmetrical, and settlement records to date indicate that no measurable differential settlement has taken place. Table I shows the foundation loading used and the settlements recorded.

[6]Broadway Bridge; Engineering Journal, January, 1934.

Fig. 2—General View of Bridge.

Fig. 3—Sway Bracing and Other Details.

On the Saskatchewan rivers erosion of the bed around piers is a serious matter, both during construction and at subsequent flood periods. After careful studies it was decided that the river piers should be carried down 17 feet below the stream bed as it existed when borings were taken. Subsequent experience during construction proved that this allowance was not too liberal, as during a temporary ice jam in October, 1936, quite extensive areas around pier 2 were eroded down to within a few feet of the pier base. As a further precaution, a rock fill mat was placed over this area and around all other piers and foundations, and it is felt that after all falsework piles and cofferdams are removed there will be little danger of further excessive erosion around the piers.

### Girder Spans

Figure 1 shows the general arrangement and Fig. 5 the design details of the girders, columns and abutments. Expansions for spans 1, 2, and 3 were taken care of by hinged rockers at the western abutment and split hinged columns at bent 2. All of these hinges are of the Mesnager type designed according to the recommendation of Moreel, Parsons and Stang.[7] This semi-articulated method was chosen primarily because the sand bar on which the columns are located may be subjected to combined flood and severe ice conditions and a rugged, well-integrated structure was desired.

The expansion for span 7 was taken care of by steel rollers and bearing plates. This design was selected in order to obtain comparative costs and operating characteristics of reinforced concrete rockers and rollers. Cost data subsequently proved the former to be much cheaper than rollers, and the limited observations obtainable to date suggest the former are equally satisfactory in operation.

Records of actual expansions, during the past ten months, indicate that the movement of the hinged rocker end of the west girder span has been only about two-thirds of the theoretical. It is felt that there is an appreciable restraint in the rocker and that it would have been better had either the concrete covering at the hinges been reduced to one-quarter inch or horizontal mastic layers of one inch been used to separate the concrete at these sections.

The girder spans are of ordinary design and were proportioned to care for stresses due to a 1-in. differential settlement of supports as well as the specified loading. Rigid frame analyses of the fixed end girders and column bents suggested the advisability of placing hinges in the split columns in order to relieve bending stresses. Table II gives a summary of the calculated column stresses under hinged and fixed conditions.

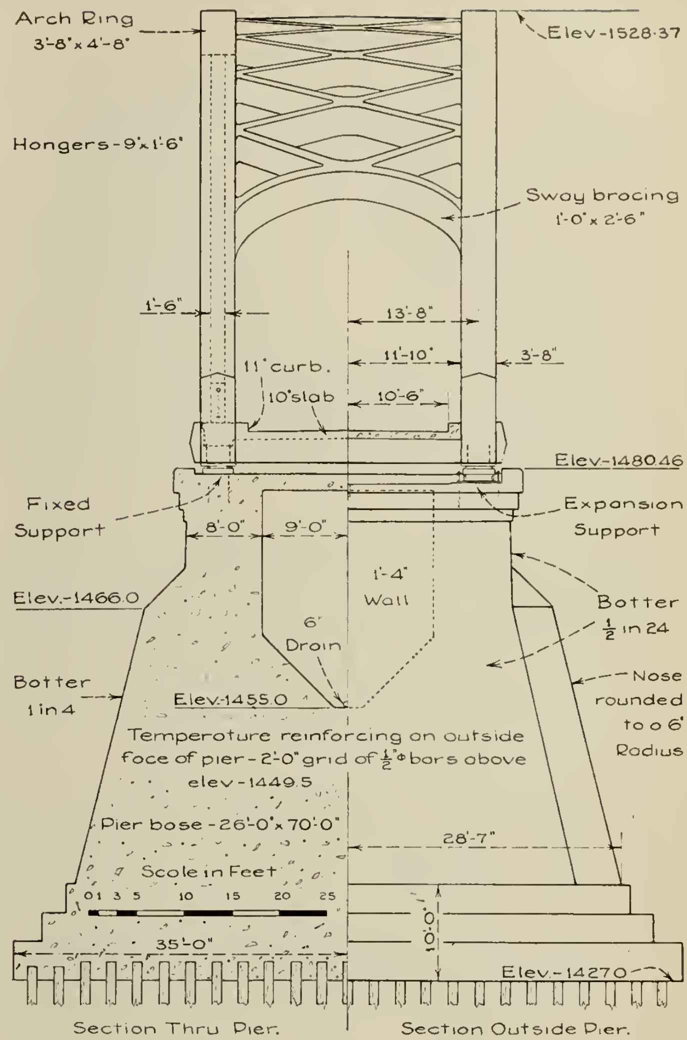

**Fig. 4—Side Elevation of Pier with Superstructure.**

### Table I

#### Foundation Loads and Settlements

| Foundation | Type | Dead load of bridge plus pier surcharge (1) | Sub-structure completed | Super-structure completed | Initial settlement reading | Total settlement at Nov. 23rd, 1936 (2) |
|---|---|---|---|---|---|---|
| Pier 1 | Pile foundation in sand. 171—35 ft. piles. | 18 tons per pile | July 28/36 | Oct. 30/36 | July 28/36 | 0.041 ft. |
| Pier 2 | Pile foundation in firm clay. Moisture content 24 per cent. 225—24 ft. piles. | 18 tons per pile | April 1/36 | Oct. 30/36 | Aug. 13/36 | 0.043 ft. |
| Pier 3 | Pile foundation on shale, plastic clay and quick sand. Clay moisture content 27 per cent. 225—14 to 30 ft. piles. | 18 tons per pile | Mar. 12/36 | Oct. 10/36 | June 23/36 | 0.048 ft. |
| Pier 4 | Foundation on hard clay interspersed with gravel. Moisture content 12 to 14 per cent. | 2.9 tons per sq. ft. | Nov. 22/35 | Sept. 19/36 | Nov. 22/35 | 0.041 ft. |
| Abut. 2 | Piles in clay containing sand pockets. 48—16 ft. piles. | 10 tons per pile | Dec. 4/35 | June 11/36 | Mar. 13/36 | 0.038 ft. |

(1) Surcharge was about 15 per cent of total

(2) Levels taken on March 3rd, 1937, showed that no further settlements had occurred.

Table II
Moments at Column Top—Bent 2
Length = 28.0 ft.

| | Column without hinge | Column hinged as shown |
|---|---|---|
| Dead load = | 200,000 ft.-lb. | 158,000 ft.-lb. |
| Live load = | 58,000 ft.-lb. | 46,000 ft.-lb. |
| Impact = | 17,400 ft.-lb. | 13,800 ft.-lb. |
| Temperature = | 91,000 ft.-lb. | 47,500 ft.-lb. |
| Total = | 366,400 ft.-lb. | 265,300 ft.-lb. |
| Max. $f_c$ = | 1,650 lb. per sq. in. | $f_c$ = 1,192 lb. per sq. in. |
| $f_s$ = | 31,500 lb. per sq. in. | $f_s$ = 19,450 lb. per sq. in. |

*Bow-String Spans*

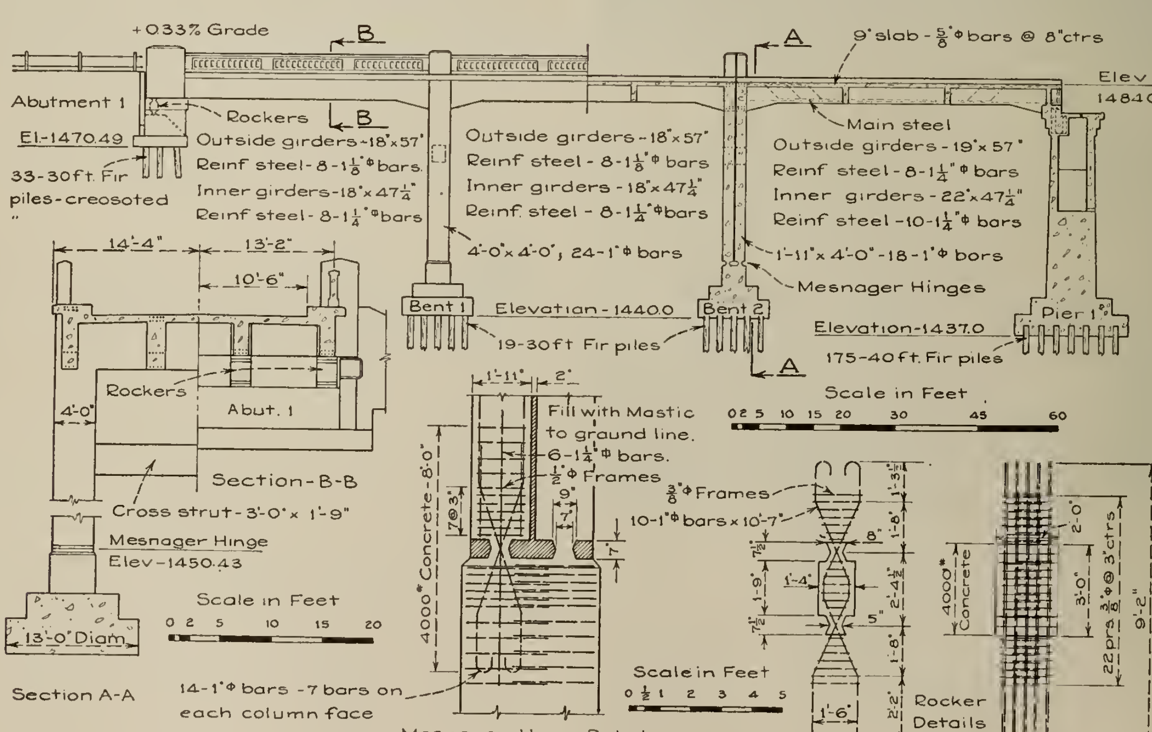
These spans constitute the most interesting elements of the bridge and the design will be discussed in some detail together with test data on the behaviour of the structure during and after construction. Figure 6 shows clearly the general dimensions, reinforcement and other design features of span 5.

Bow-string, like other arches, are subject to stresses caused by dead and live loads, arch shortening and concrete shrinkage, but the large temperature stresses found in fixed elastic arches, exposed to wide temperature variations, are theoretically absent. There are, however, other potentially large stresses brought about during construction, due to the elastic elongation of the horizontal tie when the falsework is struck, and the resultant horizontal movement of the supports which causes bending moments in the arch ring.

It has been general practice in this country to design bow-string spans as two-hinged arches, to construct the arch rib and horizontal tie together, and permit the moments, due to elastic elongation of the horizontal tie, arch shortening, concrete shrinkage, and temperature differentials to be taken by arch rib stresses. In longer spans such stresses become comparatively large and the resultant arch sections uneconomical. In the design under review, it was decided to provide temporary hinges at the crown and to obtain practical articulation at the springing by using a spherical bearing support and temporarily omitting the concrete in the end panels of the horizontal tie, in order that the structure might act substantially as a three-hinged arch during construction and thus relieve most of the potential arch ring stresses due to tie elongation, arch shortening, concrete shrinkage and arch temperature drop during construction. That well over eighty per cent of the potential moment was relieved by the hinges will be shown later when the results of experimental measurements taken in the field are discussed. Suffice it to say, for the present, that had temporary hinges not been employed it would have been impossible to keep the stresses down to the maximum used with a solid rectangular section of any size and the best possible section would have been considerably deeper in which maximum stresses would have been 125 lb. per. sq. in. greater than in the design adopted.

When designing it was assumed that the arch rib, horizontal tie and floor beams would be poured first and that after the falsework had been struck under these members, the floor system would be poured and when the arch was carrying this full dead load, the vertical hangers and end panels of the ties would then be concreted, and the temporary crown hinge filled in, making the arch continuous. It was assumed that thereafter the structure would act as a two-hinged arch, subject to live loads and small temperature stresses, due to the fact that the heavy arch section will have a temperature lag in relation to the smaller heavily reinforced tie; it was assumed that this lag would be 20 deg. F. on both rising and falling temperatures, but readings obtained during the past six months indicate that the differential will probably never be greater than 15 deg. F. Accordingly, the structure was designed as a two-hinged arch subject to dead and live loads, partial concrete shrinkage and a small temperature effect.

The arch rings, reinforced with 0.08 per cent of steel, are rectangular in section and of the same size throughout. The dimensions were determined by considerations of stress, stiffness and width required for the crown hinges. In calculating stresses a dead load eccentricity of 0.1 ft. was assumed in the direction to give maximum stress.



Half Elevation in sections of Girder Spans.

**Fig. 5—Details of Girder Spans.**

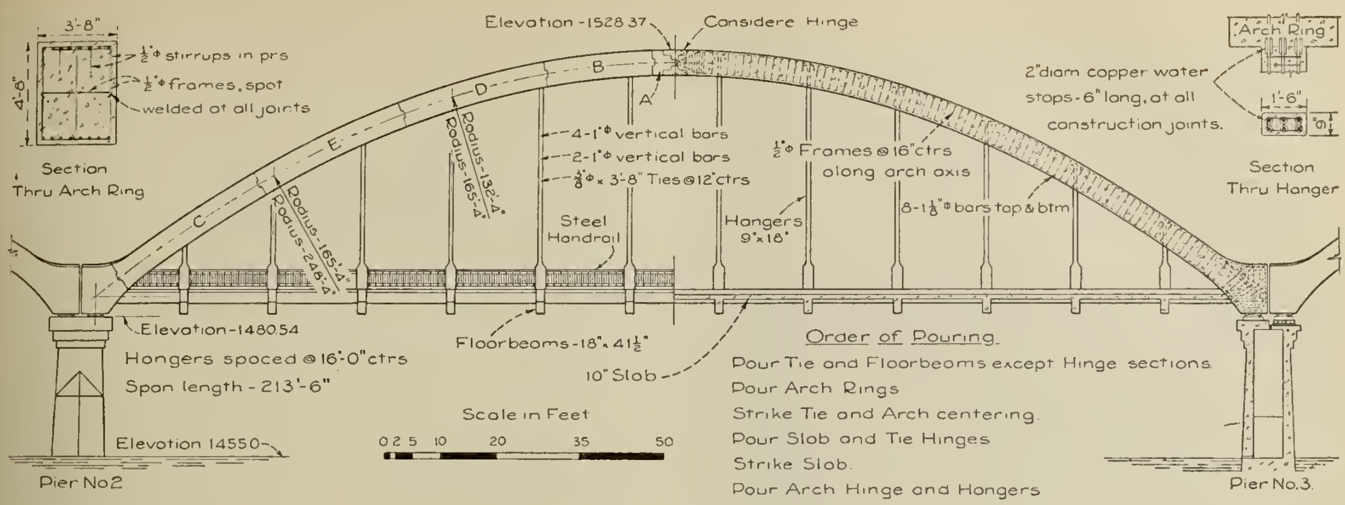


**Fig. 6—Elevation of Span 5.**

Table III shows calculated stresses at the quarter point of span 5 and indicates that the theoretical stress reductions obtained by using a crown hinge amount to over 200 lb. per. sq. in. or about 20 per cent.

TABLE III
CALCULATED STRESSES AT QUARTER POINT—SPAN 5

| | With Temporary Crown Hinge as Constructed | | | Without Temporary Crown Hinge | | |
|---|---|---|---|---|---|---|
| | Stresses—lb. per sq. in. | | | Stresses—lb. per sq. in. | | |
| | Direct | Bending | Total | Direct | Bending | Total |

HORIZONTAL TIE

The horizontal tie is a tension member consisting of forty $1\frac{1}{4}$ in. sq. bars encased in concrete as shown in Fig. 7. The bars were spliced by lapping forty diameters and hooking the ends; welding was considered but the expense of obtaining reliable welding at this location and the difficulty of welding and placing so many and such long bars made simple lapping more attractive.

Bar lengths varied from 40 to 67 ft. and the splices were carefully staggered so that no more than two-fifths of the total number of bars were spliced in any one panel. As shown, the member was well tied transversely and laboratory tests indicated that with the ratio of concrete volume to spliced bars at any vertical transverse section and with the ample transverse ties the factor of safety for splices was high; the total longitudinal steel being 7.5 per cent and the transverse ties 0.3 per cent by volume of the core.

The horizontal tie was designed to carry a total direct tension of 1,078,000 lb., equivalent to a unit stress of 17,300 lb. per. sq. in. with bending stresses due to dead load between hangers of about 700 lb. per. sq. in. Wind stresses will be only a few hundred lb. per. sq. in.

The manner in which the horizontal tie elongated, due to direct tension, was interesting. Careful measurements, to the nearest 1/100 of an inch, were made of the movement of the free ends of ties and it was found that in all cases the concrete of the tie section took a very large proportion of the total tension when first stressed, but within a few months most of this was transferred to the steel. To illustrate, on span 5 the first day after the arch rings and ties were decentred the elastic elongation of the tie was only 0.55 in. compared with a theoretical extension of 0.96 in. on the assumption that all tension was carried by the steel alone: this means that the concrete was carrying then over 42 per cent of the total tension and was stressed to about 285 lb. per. sq. in. At the end of thirty-five days, when the floor system had been poured, the total elastic elongation was 1.08 in. with a theoretical indicated value of 1.27 in. for action of steel only. After five months there was little further elastic elongation, which shows that the initial tension of the concrete was transferred gradually to the steel, and apparently after the floor slab was poured some of the tension was carried by this member. It is possible that the delayed extension of the tie was due to the plastic flow of the concrete but it was also observed that very fine transverse hair cracks appeared in the tie concrete section at intervals of about 18 inches.

That a percentage of the extension of the horizontal tie was deferred until after the crown hinge was closed means that the arch stresses were increased perhaps 40 lb. per. sq. in. at the quarter point over the design assumptions.

The connection between the arch rib and horizontal tie was designed to transfer the forces with as little moment as possible and approximate calculations for shear and moment conditions indicate that the joint as designed was of ample strength. Figures 7 and 8 show plan and photograph of this detail, and while the density of reinforcement is apparent, concrete was placed readily and satisfactorily with the aid of a vibrator.

HANGER STEEL

Probably the most unsatisfactory results were obtained with the vertical hangers due to the fact that they were anchored in the tie when the arch rib concrete was being placed, and, as the arch falsework deflected with respect to the tie, deflections of the steel occurred in an irregular manner. Strain gauge readings indicated that, while the average stress in all bars was within 50 lb. per. sq. in. of the calculated stress, there was considerable variation between individual bars, which must cause some error in arch ring moments and stress calculations. It is felt that some modification in design or construction methods to avoid this uncertainty is worthy of attention for future design.

### Floor System

The floor system is of usual design, but over the arch spans, due to the fact that the floor beams were poured some time before the slab, and also as it was advisable to have T-beam action, horizontal shear keys 3½ in. by 8 in. by 8 in. were provided at 16-in. centres between the stem of the floor beam and the slab to take care of horizontal shear.

One-quarter of the total negative steel was run continuously through the top of the slab to care for tension

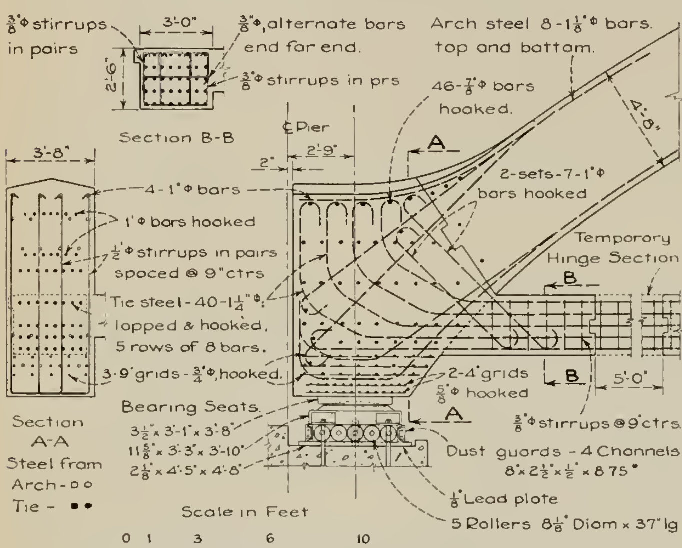

Fig. 7—Detail of Terminal Block.

which might be developed due to elastic extension of the ties under live loads. Actually, due to the deferred tie elongation mentioned above, much greater tension developed and transverse hair cracks appeared in the slab at the panel third points where the top steel was bent down. It is felt that as time will not normally permit a delay in pouring the slab until tie elongation has reached equilibrium, further provision should be made to take care of longitudinal tension in the slab.

## II. MEASUREMENTS AND EXPERIMENTAL DATA ON ACTUAL BEHAVIOUR OF THE STRUCTURE

As little experimental data on the actual behaviour of temporary hinges under such conditions could be found

Fig. 8—Terminal Block Reinforcement.

in engineering literature, it was decided to take strain gauge readings to determine rotations at the hinges, and, by recording temperatures and crown deflections, to determine approximately what percentage of the potential moment due to tie elongation, concrete shrinkage, arch

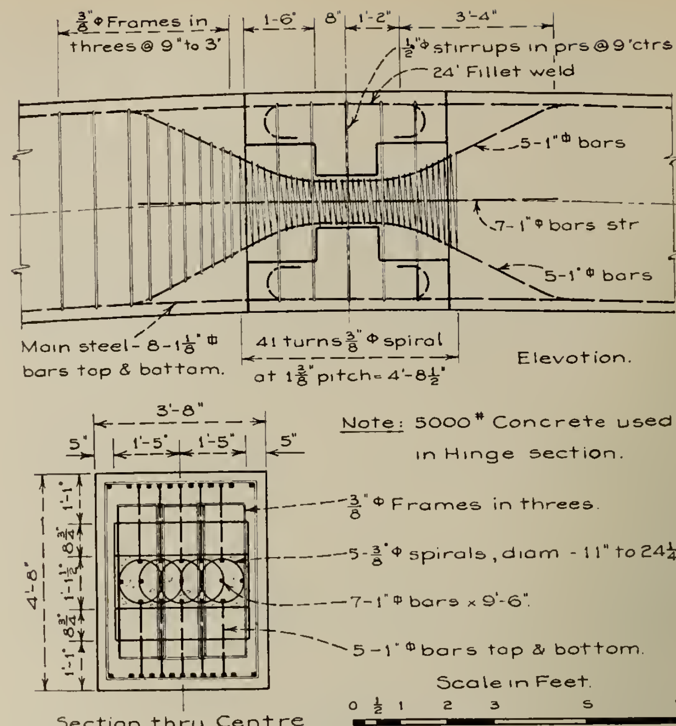

Fig. 9—Details of Crown Hinge.

shortening and temperature drop was eliminated and what maximum stresses were reached in the hinge. Unfortunately due to lack of previous experience with such structures and the need for haste in completing all concrete work in the face of the rapidly approaching low fall temperatures, the readings were neither as complete or extensive as desirable, but several hundred readings were taken and it is felt they do throw sufficient light on the behaviour of such hinges to warrant presentation in detail.

The hinge design is shown in detail in Fig. 9 and the reinforcement and hinge as constructed are illustrated in photographs in Figs. 10, 11 and 12. The hinge is of the modified Considere type with the main arch steel discontinuous until made continuous by welding just before the hinge was concreted in. This type has been used extensively in Europe and in several structures by McCullough[4] in America, and consists essentially of short, closely spiralled and interlocked columns, which when subjected to high direct stresses are supposed to be comparatively flexible and capable of relieving most of the moments in the heavier arch rib sections. It is evident that such a hinge cannot remove all moments and it is equally evident that a theoretical analysis of the percentage removed is uncertain and involved, and experimental work on this problem seems desirable.

To obtain crown rotations and hinge moments and stresses, five gauge lines were established by setting steel plugs 20 inches apart in the concrete as indicated in Fig. 13; the measurements on gauge lines 1 and 5 were used to determine crown rotations, while the hinge moments and stresses were calculated from measurements on lines 2, 3 and 4. All measurements were read by means of a strain gauge reading to 1/5000 of an inch.

The rotations at the terminal blocks were determined by measuring the distance between two points, one on the top movable plate of the spherical bearing, the other on the bed plate. Measurements were made by means of an inside micrometer gauge reading to 1/1000 of an inch.

Vertical deflections of the crown were read by means of an accurate level reading to the nearest 1/100 of an inch.

Temperature measurements were made by resistance thermometers buried in the concrete when poured. These thermometers were made of 500 ohm telephone coils inserted in a ¾ in. steel tube 7 in. long and well sealed with a hot solution of paraffin and rosin in equal parts. Short leads of rubber-covered mine cable were attached and readings taken with a portable Wheatstone bridge. All coils were carefully calibrated before placing and an accuracy of ½ deg. F. was obtained. Such thermometers were placed at the third points in all arch rings, in the horizontal ties and road slabs, and the leads from all thermometers in span 6 were wired to a permanent location, so that temperature records might be taken during the following year; later in this paper a graph of the temperature variations in this series through the winter of 1936-37 will be shown. In addition, careful readings were kept of the temperatures in the crown hinges by means of mercury thermometers inserted into holes in the hinges, these records were used in correcting the strain gauge measurements.

### Behaviour of Span as a Three-hinged Arch

The question of fundamental interest in connection with the temporary crown hinge is: To what extent does this element permit the behaviour of the arch ring during construction to approach that of an ideal three-hinged arch? Three different methods of approach to the solution are presented, of which the last is the most dependable. First, the observed vertical deflection of the crown can be compared with the theoretically calculated value for a perfect three-hinged arch. Secondly, the calculated rotations that would occur at the crown for a three-hinged arch can be compared with the observed rotations. Thirdly, the residual moment carried by the hinge can be measured and thus an estimate obtained of the percentage reduction in the potential arch ring moment. The first two methods will be discussed briefly and the third, which is more illuminating, examined in detail.

The measured deflection of the arch crown on decentring was 1.15 in. which would correspond to an effective change in span length of 0.93 in. The calculated change found by adding the measured horizontal tie elongation of 0.55 in. to the calculated elongations due to arch shortening, concrete shrinkage and temperature drop in the rib amounts to 1.21 in. The difference of 0.28 in. is probably due to the uncertainties surrounding the assumptions of shrinkage and temperature effects during the early curing period. The thermal coefficient of green concrete is probably lower than 0.000006, which was used in the calculations, and, as the temperature drop during the period from September 29th to October 8th was 26 deg., an error of relatively large magnitude is possible in this factor. Again the assumed coefficient of shrinkage, 0.00004, during the first ten days is subject to question. In any event, the above method indicates that the deflection is at least 80 per cent of that indicated for a perfect three-hinged arch at the end of ten days, and other data point quite clearly to the fact that the correspondence became closer with time.

Fig. 10—Hinge Reinforcement.

In applying the second test, it should be noted that the total crown rotations should be twice those at the springing. Actual observations showed that rotations occurred as expected but at the springing they were more irregular and lagged several days behind those at the crown. The maximum crown rotation of 0.002 radians occurred immediately after the arch ring was decentred. When the floor system was struck the rotation was reduced to 0.0013 radians, which was due to decrease in dead load eccentricity at the crown and probably some stress adjustment in the hinge. The theoretical rotation for perfect articulation for this later condition is 0.0018 radians. The rotation at the springing, which immediately after the arch ring was decentred measured only 0.0004 radians, increased later on to 0.001 radians. Part of this increase is probably due to further extension of the elastic tie after the closure of the crown hinge. The observed rotations at the crown suggest that the structure was behaving substantially as a three-hinged arch.

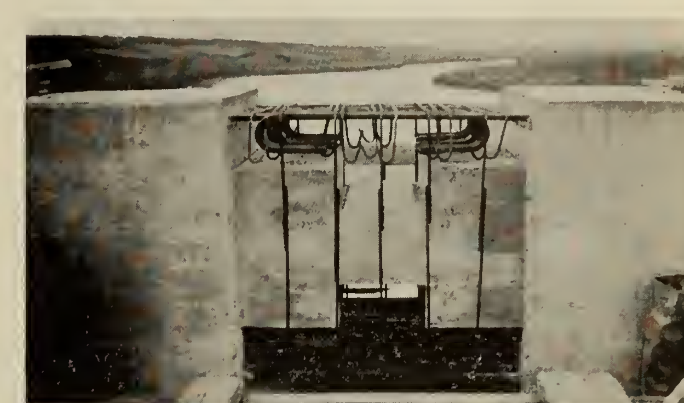

Fig. 11—Hinge, showing Main Rib Reinforcement.

Fig. 12—Arch Ring with Hinge in Place.

A very interesting observation was made on the effect of leaving the last panels of the horizontal tie unconcreted until final closure. At one end of span 4, in order to make the supports more rigid over the long spliced falsework piles, the end panels were concreted before the arch ring was poured. The resultant rotations at this end were only about 70 per cent of those at the other end. Calculations on the basis that both ends had been so concreted show that the arch rib stresses would have been increased thereby only 30 lb. per. sq. in. and one might question the value of providing this extra flexibility at a joint which functions quite well without it. The assumption that after final closure the structure will act approximately as a two-hinged arch was incidentally also verified.

### Actual Moments and Stresses in Crown Hinge

The third and most dependable test was based on strain gauge measurements at the crown hinge. In determining stresses from strain measurements, particularly if these be large, knowledge of the exact elastic behaviour of concrete of that particular strength and age is essential. Consequently, cylinders of similar strength of concrete to that used in the hinge were made and stress strain curves obtained for an age and strength comparable to those of the hinge concrete when strain measurements were being made, and these curves were used for all determinations of stresses from measured strains.

As concrete shrinkage deformations also enter into stress calculations an attempt was made to determine the shrinkage coefficient by strain gauge measurements at the extrados, intrados and axis lines of the arch rib at the quarter point before decentring the rib. Considerable difficulty and uncertainty were experienced in interpreting the results obtained due to the large variation and changes of temperature in the ring and to the fact that shrinkage along the extrados appeared to be about twice as great as that at the intrados. However, it is felt that an average value of 0.00004 for the coefficient for the first ten days after pouring can be taken as reasonably correct.

The first strain gauge measurements were taken on the hinge of span 6 and the experience so gained suggested certain beneficial modifications which were adopted for the other two spans. While data are available for all spans the following discussion, for the sake of brevity, will be restricted to observations on span 5.

The strain gauge points were placed in the hinge of span 5 two days after the arch ring pour had been completed. At this time three vertical tension hair cracks were noticed at the ends and centre of the top half of the reduced hinge section, and these cracks made difficult the interpretation of strain gauge readings on gauge line 2. It was believed at first that these cracks which appeared on all hinges, were developed by negative bending moments

Table IV
Temporary Arch Crown Hinge Rotations, Deformations and Stresses

(3) Tension cracks not closed, readings meaningless.

caused by the settlement of the falsework under the ring sections adjacent to the hinge, but subsequent observations pointed to shrinkage as the cause.

The gauge readings on the third day after pouring of the arch showed that the hinge section had elongated appreciably in twenty-four hours. The apparent concrete stresses varied from 100 to 200 lb. per. sq. in.; unfortunately these records do not indicate how much extra elongation was developed during the first two days, but there is little doubt that the entire arch ring was in tension caused by concrete shrinkage. The fact that at the quarter points the shrinkage at the extrados was twice as great as at the intrados suggests that the cracks referred to above were caused by shrinkage. At the end of six days extensometer readings on the top layer of the exposed bars of the horizontal tie showed these bars to be in compression to the extent of 2,700 lb. per. sq. in., but unfortunately arrangements had not been made to obtain measurements on the lower layers. It was at first thought that this compression was uniform throughout the tie section and was caused by the horizontal component of the tension in the rib due to shrinkage. Subsequent study, however, led to the belief that the above-mentioned stresses were caused in the main by a bending moment arising out of an upward vertical force at the supports and a downward deflection of the central falsework, both of which were due to the shrinkage tension in the rib. Possibly there was also direct compression of a small magnitude in the tie but without the necessary records it is unfortunately impossible to proportion or evaluate these factors. It is also believed that the tension of appreciable magnitude which, it is known, developed at the crown hinge was much greater in the central than in the springing sections of the arch rib.

During the following eight days from September 29th to October 7th the settlement of the falsework developed a positive moment in the hinge as indicated in Table IV and Fig. 13.

Until the extrados of the hinge was under sufficient compression to close the tension cracks, the measured deformations were not due to concrete stresses but to stresses and adjustments in the top longitudinal steel. Observations and calculations indicated that these tension cracks opened up a maximum total distance of 0.0002 in. and strain gauge readings were corrected by this amount before using them in moment and stress calculations. Table IV gives the observed hinge deformations corrected for temperature, shrinkage and cracks, together with the stresses as obtained from the appropriate stress-strain curve. Figure 13 shows in graphical form the same data and Table V gives a convenient summary of the data and stresses calculated therefrom.

On October 8th, when the arch ring falsework was struck, the largest rotation, 0.002 radians, was observed: That the rotation should have been a maximum at this time, before the dead load of the floor system was being carried, is indicated theoretically. As the function of the hinge is to remove the moment that would have existed had the hinge not been used, that moment for the above conditions was calculated and found to be + 500,000 ft. lb., due to dead load eccentricity, tie extension, drop in arch temperature and concrete shrinkage. The calculated moment in the hinge at this time was + 200,000 ft. lb., the thrust eccentricity having been reduced from 1.25 to 0.50 ft. by the hinge. The theoretical direct stress was 710 lb. per. sq. in., as compared with an apparent value of 680 lb. per. sq. in., and the stress distribution across the hinge section for this condition was nearly planar. It seems that the hinge removed only about 60 per cent of the potential moment at this time.

When the floor system was decentred, the hinge rotation decreased to a value of 0.0013 radians and its

Table V
Extensions, Rotations, Stresses
Summary

moment to + 100,000 ft. lb., with an apparent direct stress of 1,580 lb. per. sq. in., compared with a calculated value of 1,300 lb. per sq. in., the distribution of the stress appearing to be approximately planar. The above decrease in rotation and apparent moment was caused by the diminishing dead

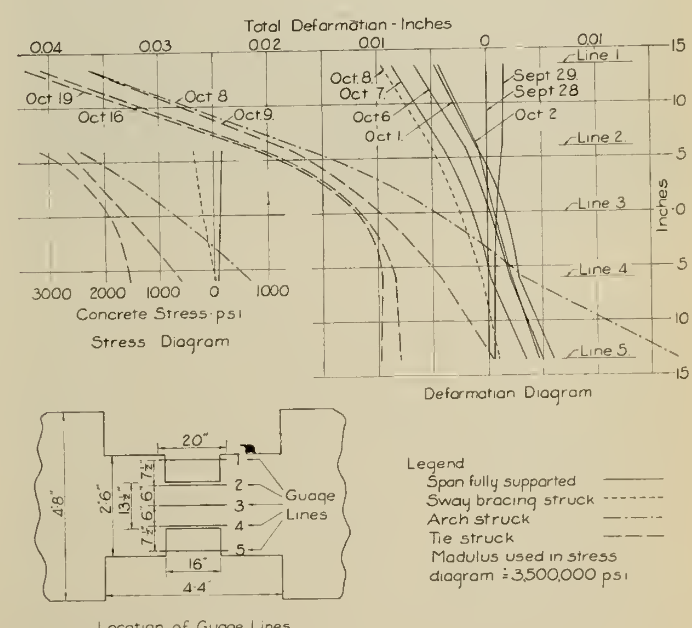

**Fig. 13—Hinge Deformations and Stresses.**

load eccentricity with the application of the floor load. One week later, under the same load conditions, the rotation had decreased again slightly to 0.0012 radians, but an appreciable stress adjustment appeared to have taken place with a parabolic distribution evident, this adjustment tended to equalize the stresses over the hinge section.

It is believed that the largest concrete stresses in the hinge did not occur with maximum deformations, but that greatest stress at the extrados was about 2,550 lb.

per sq. in., approximately double the calculated average direct stress. The maximum stress determined by later strain deformations is 3,160 lb. per sq. in., but it seems certain that these were never realized and that plastic flow produced the additional deformations. The calculated average plastic flow between the 9th and 16th of October is 0.0030 in. in the 20-in. gauge length. This corresponds to a unit flow of 0.00015 in. under a direct load of 1,350 lb. per sq. in., sustained for seven days and is in harmony with the findings of Davis and Davis.[8]

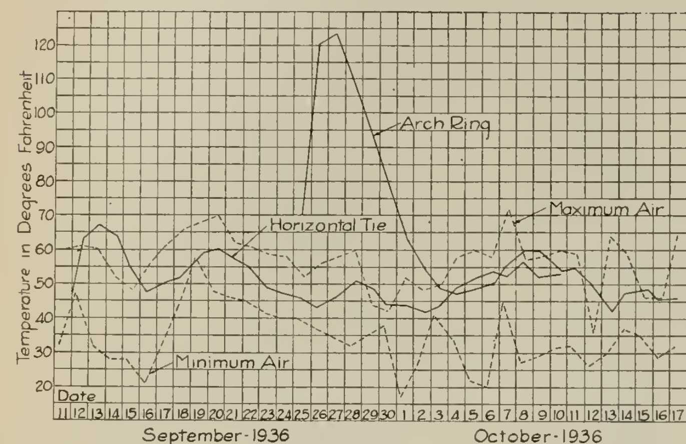

**Fig. 14—Temperatures in Main Members during Construction.**

In view of the large stress adjustment or plastic flow which seems to have taken place, it would appear that the longitudinal steel near the intrados and extrados must have taken additional stress and therefore be responsible for a major portion of the residual moment in the hinge as the steel could not suffer any appreciable bond failure. For this reason it is felt that it might be better design to concentrate most of the steel near the axis in hinges of this type.

Probably the matter of greatest interest and importance is the magnitude of the residual moment in the hinge at closure. The maximum possible value of this moment as calculated from the stress diagram without any allowance for plastic deformation is 87,000 ft. lb. When corrections for such deformations are made the moment is reduced to 44,000 ft. lb. with a thrust eccentricity of 0.66 in. Under similar load conditions the moment at the crown for a two-hinged arch would have been 370,000 ft. lb., so it is seen that the temporary crown hinge actually relieved about 88 per cent of the potential moment and that until closure the structure acted substantially as a three-hinged arch. The moment relieved would have been even greater had it been feasible to delay closure for a longer time, but it is estimated that under the existing circumstances the hinge decreased the concrete stresses 160 lb. per sq. in. at the quarter points and 170 lb. per sq. in. at the crown of the arch rings, a very considerable reduction amounting to about 20 per cent of the maximum stresses.

The residual moment in the hinge causes a stress of only 20 lb. per sq. in. in the arch rib and this could have been theoretically eliminated by placing the hinge axis 0.66 in. below the arch axis, but this eccentricity is not of much significance in a ring of such depth.

*Temperature Records*

As has been stated, temperature records in the various members were obtained immediately after pouring and during the subsequent winter. Figure 14 shows the temperature variations that occurred in the arch ring and horizontal tie for the first few days after completion and indicates clearly the difference in rib and tie temperatures at decentring, which must be taken into consideration in the calculations previously mentioned. Figure 15 is a graph of the temperature variations during a particularly cold period in the winter of 1936-37 and suggest that, if summer temperatures do not go above 100 deg. F., which is unlikely, the assumed design figure of 130 deg. F. for the general temperature range was reasonable.

## III. CONSTRUCTION

The construction programme covered approximately one calendar year. While the contract was signed in October, 1935, it was November before the work was in full swing, as the contractor had to erect boarding accommodation for the men, carpenter and blacksmith shops and engineers' quarters before active operations could commence due to the fact that the bridge site is seven miles from the nearest small town and forty miles from the nearest city. In November, 1936, the bridge was opened for traffic.

The yearly climatic cycle made it imperative to construct the river piers and most of the other sub-structure during the winter months in order that the main superstructure could be completed during the four months intervening between the high water stages in June and the freeze-up in October. Fortunately, the river levels are at their lowest during January and February, which helped to offset the additional costs incurred due to the low temperatures experienced during these months. The work naturally fell into three periods. During the six months that the river was frozen over, October to April, the river and east shore piers were completed. During the period between spring break-up and high-water in June the west pier, column foundations, abutment and girder spans were constructed, while in the remaining four months the three long river spans were built in their entirety.

### Sub-structure

The difficult river piers were constructed during one of the coldest winters on record for this locality, when for fifty-eight days the minimum daily temperatures were below zero F. continually, and for twenty-seven days below −25 deg. F., with ten days below −40 deg. F. When it is

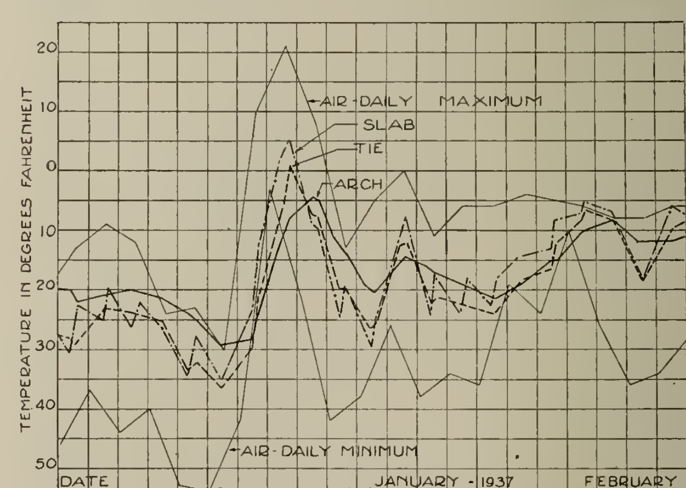

**Fig. 15—Temperatures in Members during Winter 1936-1937.**

realized that during all this time work was carried on continuously during twenty-four hours each day with no rest for Sundays or holidays, and that excavation, pile driving and concrete work had to be done under these conditions, the severity of the working conditions will be appreciated.

During the fall months of 1935, pier 4 and abutment 2 on the east shore were constructed without difficulty. Concreting of pier 4 was finished in November and, while air temperatures varied from 20 deg. above to 10 deg.

[8]Journal American Concrete Institute, March, 1931.

below zero F., no protection was used other than heating the mixing water and aggregate. Thermometers located just inside the forms indicated that the temperatures remained above 40 deg. for ten days, and in the centre of the piers temperatures were over 60 deg. for twenty days.

The concrete mixing plant for all the units, excepting those on the west shore, was located on the east bank at the bridge floor level. The mixers were housed in, as also was the coarse aggregate stock pile, which was placed over a steam pipe grid consisting of 1¼ in. pipes on 24-in. centres with the maximum depth of pile about six feet; a steam tractor was used for heating. The sand was heated in the open by means of several movable steam jets placed in the stock pile; this method proved the best of several tried. An ingenious method, both satisfactory and economical, of heating the mixing water was used. A small steam pump delivered water under pressure to a vertical boiler which raised the water temperature up to 100 deg. or more. An air compressor maintained air, in the upper portion of the boiler, in sufficient volume and pressure to supply hot water at a uniform rate to the mixers.

In the extreme cold weather it was difficult to obtain uniform temperatures in the coarse aggregate pile and steam jets were used as an aid. The sand, although unprotected, heated more uniformly and retained its heat longer, and jets operated for two days before pouring kept the sand pile at temperatures between 100 deg. and 150 deg. F. Temperatures of the resulting concrete coming out of the mixers were watched very carefully and were maintained at from 70 deg. to 90 deg. F.

The concrete was wheeled to the river piers on a trestle built to the pier top level; men wheeled the buggies up to a maximum distance of 500 ft. on this unprotected runway 35 ft. above a wind-swept river for twenty-four hours a day with the thermometer approaching 50 deg. below zero. Figure 16 is a view taken during the concreting of pier 3, the men and buggies are clearly seen on the runway; the picture was taken February 8th, 1936, the official temperature reading at the time being 45 deg. below zero. The buggies were dumped into steel chutes which discharged into the pier and when things went well the concrete reached its destination with very little loss in temperature, but when, as sometimes happened, a temporary clogging of the chute occurred, if it could not be cleared by hammers immediately, the concrete in the chute and in the waiting buggies would freeze solidly and concreting would have to be suspended until the chutes and buggies were cleared with steam jets. Even during the periods of extreme cold weather no outside protection of the concrete in the piers, other than the forms, was used, but as soon as a pour was finished the surface was covered with tarpaulins and shiplap and steam jets used under the covering until the next pour started, just before which the covering was removed and the surface of the concrete picked, wire brushed and cleaned. Temperatures were taken in the piers continuously, and generally after dropping to about 60 deg. the heat of setting would force the temperature up to 140 deg. in two or three days, after which it would fall gradually down to 32 deg. in ten to fifteen days. Thermometers placed directly inside the forms showed that even at the surface the concrete temperatures stayed well above freezing for ten days. The resulting concrete in all piers was excellent, as shown in Fig. 17.

While the concreting of the two river piers during the extremely cold weather of January and February demanded constant care, the construction of the cofferdams, the excavating and driving of bearing piles, were by far the most difficult and strenuous of all the operations. Work was carried on in three shifts day and night, and at many times workmen would be standing in 18 in. of water, shovelling sand, with air temperatures around 40 below, and everything covered with ice. Again, excavation would be proceeding at one end of the cofferdam while bearing piles were being driven at the other end, the steam from the hammer would fill the air with mist and during the night, even with numerous lights, the danger and exposure of such work were extreme and great credit is due to the courage and tenacity of the local farmers, inexperienced in such work, who cheerfully took this opportunity of avoiding the alternative "relief."

**Fig. 16—Cold Weather Concreting.**

**Fig. 17—Pier 3 and Ice "break up."**

On pier 3 the contractor decided to use a double row of wooden sheet piling with clay puddle wall for the cofferdam, and as the depth of the pier base was 27 ft. below the ice level in the river, the pressures made the problem a difficult one under the best conditions. A stratum of large boulders at the river level accentuated the difficulty and many of the piles could not be driven until the dam was unwatered, the excavation carried down, and the boulders removed. When the excavation was within six feet of grade, a stratum of quicksand was struck in the clay and a serious blow-in filled the dam, washing in several hundred cubic yards of material and carrying away one-third of the puddle wall. A large depression 8 ft. deep was created in the river bed and a third row of longer sheet piling had to be driven along one side. One of the expensive items was clay puddle, as all spoil banks and natural soil beds were frozen to depths of 4 to 8 ft. and had to be laboriously thawed by steam jets before removing. When the bottom was within 4 ft. of grade, three distinctly different types of material showed over the foundation base; at one end there was a hard shale-like material, at the other end, a soft plastic blue clay, while in one corner there was a large pocket of quicksand which caused endless worry and expense due to the constant threat of "blowing." While the excavation was still 4 ft. from grade, the bearing piles were driven to lessen the danger of blow-ins and to reduce the pressure on the cofferdam during pile driving. The remaining excavation was removed in sections and the concrete mat poured. Drains had to be constructed through the concrete mat to a central sump to care for numerous leaks that threatened to leach the freshly deposited concrete.

The cofferdam at pier 2 where the water was 13 ft. deep consisted of a single row of 38-ft. Algoma steel sheet piling, driven into the clay to a distance of 6 ft. below the pier base. As this dam was not started until February 11th, time was a pressing factor and every effort was made to avoid delays. The piles were all set in place resting on the river bottom and supported by two frames, one on the ice and the other 15 ft. above it, and each pile was carefully plumbed in two directions, with the result that closure was made without any difficulty whatsoever. After the piles were driven, when the leakage at interlocking joints made it impossible to lower the water level when pumping at a rate of 2,000 gallons per minute, the contractor adopted a novel and inexpensive method. Large panels of shiplap were dropped around the outside of the piling and the spaces formed by the inset portion of the steel piling and the panels filled with straw manure. When pumping was again started the filling material sealed the leaks and the dam was readily dewatered, the pressure difference then tightened the joints and little further trouble was experienced.

No special difficulties were found in excavating through the 14 ft. of sand and clay to the pier base, but during driving of the bearing piles great pressures were developed on the cantilevered portion of the steel piles below the lowest wale, due to vibration and unbalanced earth pressures. The bottom wales were made of new 14 in. by 16 in. fir and the struts, which were 10 ft. by 10 in., were on 8 ft. 3 in. centres; the great pressures caused indentations of struts into wales of over 1 in. and it was thought advisable to put in a second system of wales and struts before completing the driving.

The cofferdam bracing was designed with sufficient strength to permit the removal of the timber work as concreting proceeded without restrutting the cofferdam to the pier concrete, thus eliminating a delay that could be ill afforded. A point worth mentioning is the fact that in all cofferdams the timber bracing is subject to the greatest stresses when the lower systems are being removed as the pier forms are built up.

The foundation piles in the river piers were driven by a 5,500-lb. Union steam hammer operated in swinging leads, the piles were 30 ft. in length and driving finished at from four to twenty blows to the inch. In pier 2, 225 piles were driven in five and a half days of continuous work. Concreting on that pier was finished on April 1st and the ice in the river broke up on April 19th. Although the break up was unusually violent and the flow of ice heavy, no abrasion was evident on the noses of the ice breakers, although these were not protected by steel of any kind, the concrete merely being made richer in these portions by puddling extra cement into the concrete, as placed. Figure 17 gives an idea of the nature of the ice flow at "break-up" and the thickness of the ice which in the winter measured 46 in.

The foundations for pier 1 and the bents on the sand bar at the west end were constructed during the spring months after the ice went out, although some preliminary work was done on the pier cofferdam in November, 1935. These foundations were all in fine river sand and the piers rested on bearing piles driven to the clay stratum about 50 ft. below water level. In such cases, it has generally been assumed that it is important to drive the sheeting a sufficient distance below the foundation base in order to prevent blow-ups inside the cofferdam as the excavation approaches the design levels. For the bent footings, circular cribs, 17 ft. in diameter, were constructed of 6-in. by 12-ft. tongue and grooved fir sheet piling. The cribs were driven 11 to 12 ft. below the base of the foundation, but even then considerable difficulty was encountered as the sand gave definite evidences of approaching instability when the excavation approached the final elevations. Preliminary calculations were made to determine the probable rate of flow into the cribs of bent 2 on the assumption that the ordinary principles of the hydraulics of shallow wells would be applicable. The sand was found to have an effective size of 0.12 m.m. and a porosity of about 35 per cent, the sand stratum was assumed to be 50 ft. in depth and it was assumed that water would flow to the crib well from all sides and the radius of the circle of influence would be 100 ft., the approximate distance to the river line. On this basis and with the water level in the crib drawn down 20 ft. it was calculated that there would be a flow of approximately 20,000 gallons per hour. Actually the measured flow was about 25,000 gallons per hour and while this appears to be a good check it should be realized that the many assumptions necessary in such calculations subject the method to potentially large errors. It will also be noted that the theoretical flow is not influenced at all by the distance the sheeting extends below the foundation base. It would seem, therefore, that, provided the sheeting has watertight walls and extends far enough below the foundation base to prevent the sand being forced directly into the excavation zone in a horizontal direction, there is no great benefit to be derived from further depths. What the proper depth is cannot be determined theoretically but experience would suggest that for such conditions as were found on this job a maximum distance of 9 to 10 ft. below the excavation level is sufficient. Providing that the cribbing has been driven properly, it would seem that the conditions for success would be that the upward vertical velocity of the water in the casing should not exceed the hydraulic subsiding value of the fine particles of the sand, but here again theoretical calculations are not reliable because the flow is not uniform and "boils" occur over the area; this was particularly evident in the larger excavation for pier 1. However, the empirical data obtained on bent 2 are valuable, where it was found that with an average upward velocity of 2.5 ft. per min. calculated on the gross cross sectional area, sands of 0.12 m.m. effective size are approaching the limit of stability. It will be further realized that had these small bent footings been carried much deeper, other methods of construction would have been necessary. An interesting and practically useful observation was made in connection with "boils" in all sand excavations; it was found that such boils seemed to depend on the gradual and progressive opening up of small channels in the sand and that, if the excavation were allowed to fill up with water when stability was threatened, these channels were blocked again and after dewatering excavation could be carried on for a time with no signs of dangerous "boils."

The foundation for pier 1 was taken to a depth 23 ft. below the water level, or 3 ft. lower than that for the bents. The cofferdam, 26 ft. by 70 ft. in plan, was constructed of wooden sheet piling driven 9 ft. below the pier base, and while the total inflow was much greater, the rate of flow per unit area was much less and the sand consequently more stable.

If the excavation within the cofferdam of pier 1 be considered as a gallery with water flowing in from both sides under a head of 23 ft. and if the distance "$R$," from the edge of the gallery to the line where the ground water level can be considered as unaffected by the flow, is taken as 10 ft, then hydraulic calculations will indicate that the rate of flow into the excavation when it is dewatered should be 4 to 5 times that for the column crib and, as the area of the former is about 8 times the latter, less trouble from unstable sand would be anticipated and this, as stated above, proved to be the case. The interesting conclusion, which of course is apparent on reflection but frequently overlooked, is that in such cofferdams in sand, if taken to the same depth, the smaller the area the more trouble will be experienced.

All of the sheet and bearing piles on these units were driven easily with the aid of a water jet consisting of a 1½-in. jet on the end of a 2½-in. pipe, supplied with water from a steam pump at the rate of 250 gallons per minute, under a pressure of 60 lb. per sq. in. at the nozzle. A steam hammer was used, but light driving only was necessary until the piles were within 8 ft. of their final location, when the jet was removed and the hammer used alone.

### Superstructure

During construction, the bow-string spans demanded constant attention and careful inspection, but were finished without mishap. Driving of falsework piling was started about the middle of July and within four months the bridge was opened for traffic; the first concrete was poured on August 17th and the slab of the last arch of the three was finished October 29th. Due to the cold weather at that time, the concreting of the vertical hangers was deferred until the spring of 1937.

The falsework piles in the river were driven with a 2,600-lb. drop hammer operated on a scow which was held by a cable suspended right across the river. A small gasoline hoisting engine operated the hammer and the entire layout proved flexible and efficient and more convenient and economical than the steam hammer. The piles were driven readily 15 to 25 ft. into the river bed without the use of jets. The driving was constantly watched by an engineer inspector and all piles driven to a penetration corresponding to a safe bearing value of 10 tons by the Engineering News formula. Where erosion had occurred around pier 2, piles were driven through 28 ft. of water, 50-ft. piles were used spliced by pipe sleeves 12 in. in diameter and 24 in. long. The average load per pile

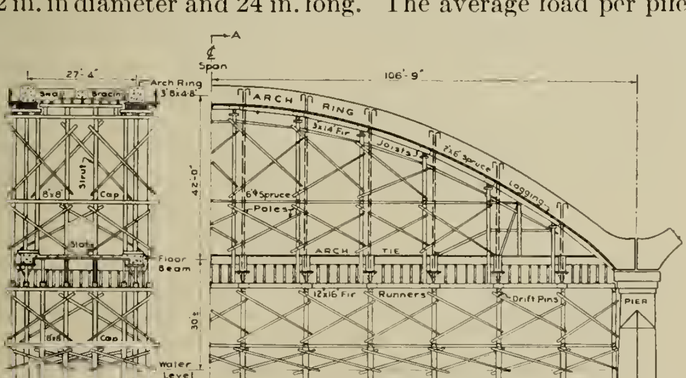

Fig. 18—Falsework for Bowstring Spans.

in each bent was 14 tons, and, while some individual piles carried 18 tons, careful levels kept on the piles during concreting operations showed that no settlement over 1/8 in. occurred anywhere.

The piles were Saskatchewan spruce, 40 ft. in length with an average butt diameter of 14 in. The piling and falsework were braced with 3 in. spruce poles. Figure 18 shows clearly the arrangement of falsework. Under each floor beam a bent of eight piles was driven and capped. Above this a second system of bents was erected, which supported directly the floor system and horizontal tie forms. A third and fourth system of bents were erected above, but offset 2 ft. to clear the floor beam forms. These latter bents after capping carried directly the 3 in. by 14 in. joists which were sawed to the proper curves, allowing ½ in. for deflection, to support the arch and sway bracing forms. The forms for the horizontal ties and floor beams were then finished and the concrete poured, after the roadway slab forms had been constructed to serve as a working platform. A section in the end panels of the horizontal tie was left

Fig. 19—Falsework and Forms during Concreting.

unconcreted but the terminal connection between the tie and arch rib was finished with the ties.

After the ties had been poured, the arch ring and sway bracing falsework was finished and, as shown, two of the bent posts supporting the arch rib rested directly on the horizontal tie, thus giving greater uniformity of loading on the pile bents below.

The arch ring joists were lagged with 2-in. by 6-ft. planks spaced on 12-in. centres and the form bottoms consisted of 1-in. by 4-in. matched spruce flooring laid longitudinally and bent to a smooth curve which gave a perfectly curved surface that was easily rubbed.

Before the ribs were poured, the floor beam supports were struck in order to relieve any possible negative moments in these members due to slight settlement of the arch falsework. The arch ribs and sway bracing were poured together, the rib in sections as shown in Fig. 6 and the central panel of the sway bracing was not poured until the arch ring and tie falsework had been struck and the crown deflection realized, otherwise the forces set up during deflection would have caused serious damage to the bracing.

The arch ring, sway bracing and horizontal tie falsework was struck about ten days after the pour was completed, the falsework was then removed over the roadway and this slab completed. After the floor system supports were struck, the main arch reinforcement laps at the crown hinge were welded, and the concreting of the hinge and sway bracing completed.

### Concrete

The coarse aggregate and sand were both of excellent quality, the latter was obtained locally but the former had to be brought in 100 miles by train. The aggregates were measured by volume and careful check was kept on the mixing, allowances being made for bulking of sand and water content in the aggregates. A test cylinder was taken for every 25 cu. yd. poured and unusually uniform and high strengths obtained. Table VI gives a resumé of the proportioning used and the average strengths from over 300 test cylinders.

### Vibration

On all of the superstructure and on part of the substructure concrete vibrators were used. The equipment consisted of two 4-in. diameter electric vibro-spades operated by a portable 1½ kv.a. generator driven by a gasoline engine, manufactured by the Electric Tamper and Equip-

Table VI
Concrete Mixes and Strengths

| Location | Mix by volume | Slump Inches | Water/cement ratio | | Ave. 28-day strength lb. per sq. in. | |
|---|---|---|---|---|---|---|
| | | | Imp. gal. per bag of cement | Bags cement per yd. | Obtained | Designed |
| Piers below elev. 1445 | 1 : 2.6 : 3.8 | 1 | 6 | 5.2 | 3,000 | 2,500 |
| Piers above elev. 1445 | 1 : 2.2 : 3.6 | 1½ | 5¾ | 5.5 | 3,200 | 3,000 |
| Girder spans | 1 : 1.9 : 3.4 | 2 | 5 | 6.2 | 3,600 | 3,000 |
| Arch rings | 1 : 1.7 : 3.0 | 2 | 5 | 6.6 | 3,800 | 3,500 |
| Horizontal ties | 1 : 1.8 : 3.2 | 3 | 5¼ | 6.2 | 3,300 | 3,000 |
| Hinges | 1 : 1.4 : 2.0 | 6 | 4½ | 8.0 | 5,000 | .... |

ment Company. Excellent results were obtained, particularly in the heavily reinforced section where vibration of the reinforcing rods made it possible to use a dry mix that could not otherwise have been placed. Figure 20 shows such concrete being placed in one of the horizontal ties and the manner in which the concrete flowed around the bars can be observed.

The road slab was vibrated by means of a vibro-spade which was dismantled and fastened to a 2-in. by 12-in. plank three feet long. The device was provided with handles and two men operated it easily and satisfactorily.

Vibrators were very useful in placing the foundation mats on the sand foundations where the upward velocity of the water tended to leach the cement out of the concrete. The concrete mix for these mats was harsh and dry and the vibrators compacted it sufficiently to prevent the forming of channels by the rising water. Batches of concrete mixed without any water and vibrated into the placed concrete were found to assist in preventing leaching.

Fig. 20—Concrete Vibrator.

It was found that in mass concrete work the best surface results were obtained by keeping the vibrators a short distance from the forms, as, if operated too closely, grout was driven through the forms and surface pockets formed.

It is believed that vibration effected a saving of about 8 per cent in cement, reduced the cost of placing concrete by 20 cents per yard and eliminated a great deal of expense in patching, provided a strong and homogeneous concrete and gave a uniform and fine appearing concrete surface.

Cold weather was experienced during the pouring of the last arch span. The arch ribs, being of considerable cross section, were protected easily by covering the exposed top surfaces with tar paper and boards, but more difficulty was experienced with the thinner road slab. Two days after the road slab was poured the air temperature had dropped to zero and to 13 deg. below in a week. The temperature in the slab dropped rapidly even though a covering of shavings and boards was used. The slab was then cleared and covered with tarpaulins and steamed for five to six days. Concrete temperatures read by resistance thermometers buried in the concrete, as mentioned in Part II of this paper, enabled an estimate to be made of the curing conditions and when it was determined that 50 per cent of the twenty-eight day strength had been obtained the falsework was struck.

### Settlements

Careful levels were taken during construction to determine settlements of the structure. The calculations and allowances made for falsework settlements checked well with those actually read for all spans. It was found that an average settlement of 1/16 in. per horizontal joint in the falsework was obtained. The following table gives the data recorded for span 5, which are typical of the other spans as well.

Table VII
Settlements of Structure During Construction

| | As recorded |
|---|---|
| Settlement of horizontal tie immediately after concreting | 0.54 in. |
| Further settlement of horizontal tie after arch ring was concreted | 0.58 in. |
| Settlement of falsework between the tie and ring after concreting | 1.00 to 1.50 in. |
| Deflection of arch crown immediately after decentring | 1.15 in. |
| Deflection of horizontal tie at centre after decentring | 1.28 in. |
| Total settlement and deflection of arch crown | 3.23 in. |
| Further deflection of arch crown thirty days after decentring | 0.42 in. |

### Cost Data

The total cost of the bridge was $291,500 of which the substructure accounted for $155,100 and the superstructure $136,400. There were 9,640 barrels of cement, 680 tons of steel and 19,200 ft. of piles used in the job. The excavation totalled 4,500 cu. yd. and the concrete placed 6,500 cu. yd., of which 3,800 cu. yd. were in the substructure and 2,700 in the superstructure.

The following table gives data on unit costs and quantities:

Table VIII
Unit Costs and Quantities

| | |
|---|---|
| Girder Spans:— | |
| Total length | 221.08 ft. |
| Cost per lineal foot | $ 84.41 |
| Cost per square foot (road and sidewalks) | $ 3.33 |
| Concrete per lineal foot | 2.09 cu. yd. |
| Concrete per square foot | 0.08 cu. yd. |
| Reinforcing steel per cubic yard concrete | 205 lb. |
| Arch Spans:— | |
| Length | 623 ft. |
| Cost per lineal foot | $187.20 |
| Cost per square foot (road and sidewalks) | 7.24 |
| Cost per square foot (clear width) | 7.91 |
| Concrete per lineal foot | 3.54 cu. yd. |
| Concrete per square foot | 0.137 cu. yd. |
| Reinforcing steel per cubic yard concrete | 351 lb. |

This project, undertaken as part of the 1935 public work programme of the Federal Government, was under the direction of K. M. Cameron, M.E.I.C., chief engineer, and F. G. Goodspeed, M.E.I.C., district engineer of the Department of Public Works of Canada. The senior author was consulting engineer, responsible for the design and general supervision; the junior author acted as designing engineer and afterwards was engaged by the Department as senior assistant engineer in charge of construction.

# The Characteristics and Application of Modern Electrical Relaying

*E. M. Wood,*
*Electrical Engineer, Hydro-Electric Power Commission of Ontario, Toronto, Ontario.*

**Paper to be presented at the Semicentennial Meeting of The Engineering Institute of Canada, in Montreal, June, 1937.**

SUMMARY.—A discussion of various types of high speed protective relay equipment for power systems, some problems in design, certain difficulties in operation, and some of the benefits obtained.

A relay, in electrical practice, has been defined as "a device which is operative by the variations in one electric circuit to effect the operation of other devices in the same or another electric circuit." The owner of an early water-wheel driven generator for lighting his property who devised a push button arrangement so that he could shut down the water-wheel when he was ready to go to sleep, made use of a relay circuit to his great convenience. From such early beginnings, the application of relay devices to the control and protection of electrical and other systems has been extended until practically every branch of industry depends for control and safety on varied forms of these devices.

The peculiar susceptibility of electrical energy to control in this way has resulted in many relay and control devices being electrical in character even when not actually applied to electrical circuits. In a paper such as this it will not be possible to discuss all these applications. Attention will, therefore, be devoted chiefly to the field of protective relaying in power supply systems. A brief survey of some of the other fields is included as a matter of interest.

Relays of the control type find a widespread application in industry. More recently older types of relays are being supplemented by various classes of devices of the electron tube type. Equipment of these types in the proper combination can be used for the starting and stopping of motors and other devices, for automatic speed control, for control of sequences in various manufacturing processes and in numerous other ways to promote increased output of and accuracy in the product which cannot be obtained by other means. Examples are to be found in the modern paper and steel industries. In electric welding the rapid fabrication of structures is made possible by accurate control by means of relays and electronic devices; while applications of the photo-electric tube (the "electric eye") are becoming commonplace.

In the field of communication the setting-up of signalling and talking circuits is an important function of relay devices. Such relays are typically compact, reliable, inexpensive and of low energy requirement, so that they can be operated at distances of several miles over light wire pairs in the ordinary telephone cable. Relays of a very similar type are used with such conductors for the remote control of apparatus in electrical supply stations, enabling several such stations to be controlled from a central point.

In cases where the stations are beyond the practical operating range of control over telephone wires, the functions may be performed by high frequency "carrier" currents transmitted over the power wires, so that the range of control is greatly extended. For example in the case of the transmission lines from the Boulder dam to the City of Los Angeles, an installation of control by "carrier" current applied to four conductors of the two main 287 kv. transmission circuits enables the operator at the generating station to control and obtain various indications from the receiving-end station some 270 miles distant, as well as from two intermediate line switching stations.

However, probably the most important form of relay application in the field of electric power generation and supply is that selected as the principal subject of this paper. "Protective relays," as they may be termed, perform the function of automatically ridding the system of any element which has developed an abnormal condition, usually an electrical fault or short circuit, as in the failure of insulation. The feature which characterizes modern practice in protective relaying is the development and growing adoption of methods for very rapid clearance of such faults. This has involved the development of high speed equipment in both relays and circuit breakers, because the total clearance time is the sum of the operating times of these two pieces of equipment.

It is of interest to note that use of most of the characteristic methods of high speed relaying is not new in this part of Canada. Such protective equipment has been advocated and quite extensively applied in Quebec province and to some extent in Ontario in the decade 1920 to 1930 though in conjunction with the standard oil circuit breakers of that period. A number of these installations have been described in papers presented to this Institute. Insofar as this author is aware, however, no other such installations were made up to about 1929.

The earlier standard types of relaying were based on the use of the induction disc relay similar in construction to the familiar watthour meter. The device is basically an inverse time or inverse definite time overcurrent relay, but with special adaptations may be made to function as a directional, current balance or differential relay and as a discriminating relay for voltage, power, frequency or other electrical quantity. It is rugged, accurate and reliable over long periods of hard usage and can be successfully applied in the following cases:—

> Where the relay is required to carry a normal load current into the circuit protected not in excess of one-fourth the minimum sustained current that results from a fault in that section.
>
> Where the relay is not normally affected by load current, that is in differential or balanced connections, or when directionally controlled as at the receiver end of a line; also as a residual current relay for ground fault protection.

In the main high voltage network of most high capacity systems, or in any system where the capacity and loading of the circuits is high in comparison with the generating capacity connected, this type of relaying is clearly inadequate. It is too slow to hold stability between power sources or to prevent damage, and too dependent on connected generation for reliability. In such systems the increasing tendency at present is to adopt high speed methods of fault clearance.

Standard equipment now being offered in relays and oil circuit breakers for circuits of any voltage will clear faulty sections selectively in less than 0.2 sec. as compared to 0.5 to 5 sec. which may be required for selective clearance with the older type. In many cases, the older types of circuit breakers may be rebuilt to this standard at a moderate cost. Special oil circuit breakers are available at extra cost which with standard high speed relays will clear a circuit in less than 0.1 sec.

## CHARACTERISTIC METHODS IN HIGH SPEED PROTECTIVE RELAYING

The usual electrical supply system includes generators, transformer banks, busses, transmission circuits and feeders, each of which is referred to herein as an "element." A fault on any element of the system is detected by the protective relays which automatically open the switching devices to segregate the faulty element from the system. It is characteristic of modern relaying that the relays are arranged so that they are not affected by disturbances occurring anywhere in the system outside the element or elements which they protect.

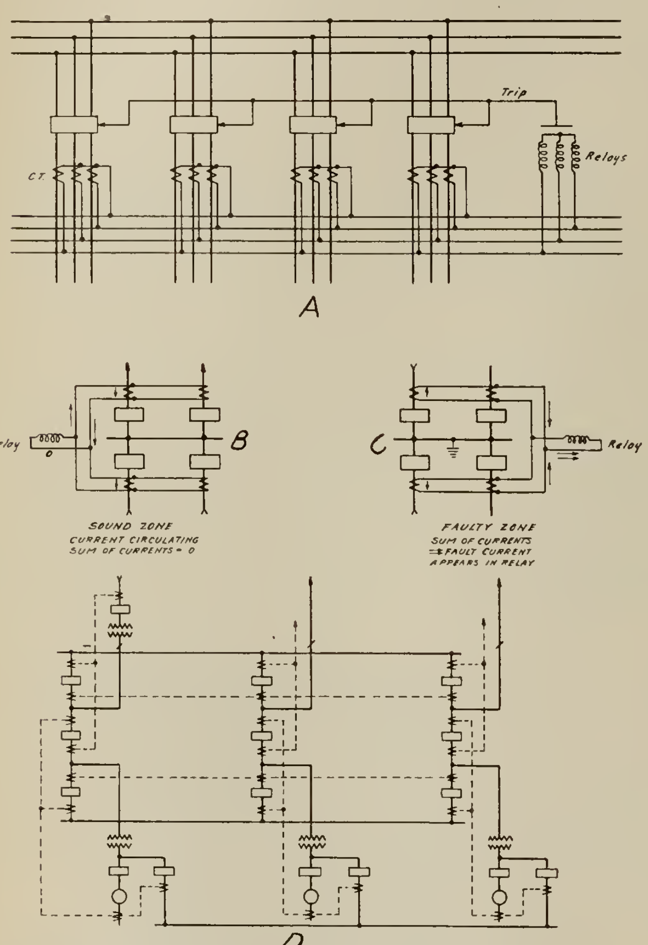

**Fig. 1—Essentials of Zone Differential Protection.**

### Zone Differential Type of Protection

In a generating or distributing station, the busses, station circuits and equipment are usually grouped in a small area, the boundaries of each group being established by oil circuit breakers so that current differential protection can be applied to each group or zone. The essential features of such a protective scheme appear in Fig. 1. This shows *A*, a typical differential connection scheme; *B* and *C*, the principle of operation for sound and faulty zones respectively, and *D*, the wiring diagram of a station with complete zone protection.

While faults on busses are not frequent, they are usually accompanied by heavy fault currents which may cause serious damage and prolonged outage if not quickly cleared. If the failure is in an oil circuit breaker, delayed clearance may result in an oil fire.

### Distance Type of Protection for Transmission Circuits

In the case of transmission circuits, the termini are usually too remote from each other to permit of the use of a simple current differential scheme. For protection of such circuits, stepped-range distance relaying of the impedance or reactance measuring type, with directional characteristic where needed, is widely used. The principles on which this type of relaying is based and the manner in which it is applied are shown in Fig. 2. In this figure, *A* indicates the principles of impedance distance relaying; *B*, the connections of directional impedance relays for phase-to-phase faults; *C*, the application of the stepped ranges of distance relays to line sections of a system, and *D*, the time characteristic of a high-speed distance relay. An instantaneous impedance relay set for a balance point just short of the end of the section to be protected will not be affected by faults beyond its setting and will, therefore, be selective for external faults.

Due to limitations in the accuracy of the equipment, the highest speed of clearance is obtained for faults in about 80 to 90 per cent of the line adjacent to the relaying point. Beyond that point, protection is given by a second relay of similar type which overlaps the other elements of the system but which is delayed in action so as to be time-selective with the instantaneous protections of those sections, providing a back-up effect for faults on a terminal bus or other elements. For more extended back-up effect, a third impedance element of still longer range and longer time delay may be provided.

The time characteristic of a typical high speed element of an impedance relay is shown in Fig. 2D. These relays will operate accurately on values of fault current which, when flowing to a fault at the "remote end" of the line section will produce a voltage at the relaying point of 3 to 5 per cent of the normal value. The minimum effective value of fault current will depend on the impedance of the circuit, but in the case of overhead lines is usually well below normal load except in the case of very short sections. Because of this requirement, however, and because the impedance which may exist in an open arc will be added to the impedance of the line, creating an indeterminate factor for which allowance cannot be made in the relay setting, this type is not applicable to lines of very low impedance.

The impedance relay requires a continuous source of potential representing accurately the primary voltage at the relaying point. Safeguards must be provided against tripping in case of failure of this source.

Impedance relays are not suitable for "tapped" or "branched" lines where there is generation on the branches or where there are high capacity step-down stations; they will, however, function properly with small step-down stations tapped to the line section.

In the impedance form, they may fail to operate on high resistance faults such as those caused by trees over the line, until the resistance has been gradually reduced by charring. As ground relays, they are not very reliable on wood pole lines unless the hardware is grounded.

However, for flashovers, as from lightning or sleet, where the arc strikes cleanly, the impedance type relay is reliable and fast within its range.

They are subject to undesirable tripping when applied to sections of line interconnecting systems and power sources in cases of instability or of wide angular swings approaching instability. In such cases there will be a node of low voltage and high current in one of the tie sections, its location depending on the distribution of the impedance between the power sources. In such cases the impedance relays will operate as though there were a three-phase short circuit at the node and may open the interconnection at an undesirable location.

### Pilot Type Protection for Transmission Circuits

In this type of protection the relay installations at the termini of the circuit are interconnected by a secondary or control circuit so as to give results similar to those obtainable on station zones—namely high speed clearance of any fault in the circuit without danger of tripping for any external condition. This type is theoretically the ideal.

Forms of it have been in use for many years, especially in England and to a much less extent in America. Its development has recently received much attention, so that equipment is now offered which will give very high speeds of complete fault clearance.

Pilot protective schemes differ greatly in details among various installations. For short feeders, the secondary current may be circulated over the pilot between the termini as in the zone differential in a station. In other cases the relays at the termini may be interconnected by a control circuit by which the behaviours of directional elements are compared to determine whether the fault is internal so that tripping should be allowed, or external, in which case the circuit breakers are prevented from tripping. For circuits up to 10 to 12 miles in length this pilot circuit is often a pair of telephone wires, but where the line is much longer, it is usually more economical to utilize a high frequency carrier current system coupled to a conductor of the overhead transmission line. With the carrier system the length of the line protected may be of any length from one mile to 300 miles at about the same cost.

The highest speed carrier pilot schemes offered, while differing in details, have the following in common:—

The carrier equipments at the termini of the protected section are each coupled to the same conductor of the transmission line, which is suitably "trapped" to retain the carrier current on the section. The sending sets, each consisting of an ordinary oscillator tube with amplifiers, are tuned to the same frequency, in the range of 50 to 150 kc. per sec. The filaments are continuously heated, but sets are prevented from generating by a negative grid bias on the oscillator tube.

In the relay equipment at each terminus is a set of sensitive non-directional relays of the impedance type for phase faults and operating on residual current for ground faults.

In case a fault anywhere on the system creates sufficient disturbance to operate any of these sensitive relays, it removes the grid bias from the respective carrier set and puts a carrier current of the correct frequency on the line which functions through receiver relays to open the trip circuit of the breakers at the terminals of the section. Carrier from one terminal of a section will lock out all the breakers of that section in a fraction of a cycle.

The generation of carrier at any terminal is stopped if fault current is flowing into the section at that point as shown by the contacting of directional relays. So long, however, as any one terminal shows fault current outflowing, indicating that the fault is external, the carrier will maintain the lock-out at all terminals and retain the section in service.

In the case of a fault in the section the directional elements at the points where the fault detectors have operated will point toward the section, removing the carrier and allowing the same or other relays to trip the circuit breakers. The relays are all of the high speed type, and the overall relay-operating time for internal faults is of the order of one to two cycles of system frequency.

In case instability or severe swing should occur on the system following the clearance of a fault so that a pilot-protected section is likely to be tripped due to the surge, it is possible to add a device which will indicate such a condition and prevent the trip-out of the line.

This type of pilot protection is the only type of high speed relaying of general application which gives simultaneous high speed clearance at all terminals for a fault anywhere in the protected section and in which provision is available to prevent trip-out of the line section on wide swings between power sources.

It may be applied to any line section of any practicable length without reference to the relaying on the remainder of the system.

The relays are sensitive and where necessary are operative on fault currents below normal load.

The application of these relays can be made effective to a much larger extent than other types on branched or tapped lines, thus allowing greater freedom in the line arrangement and often permitting important economies in line construction and switching. This should not, however, be taken as permitting unrestricted application to all such lines without careful investigation of each case.

### Current Balance Relaying

Where two or more equal parallel circuits without taps exist between common terminal busses, high speed equipment operating on the principle that under fault

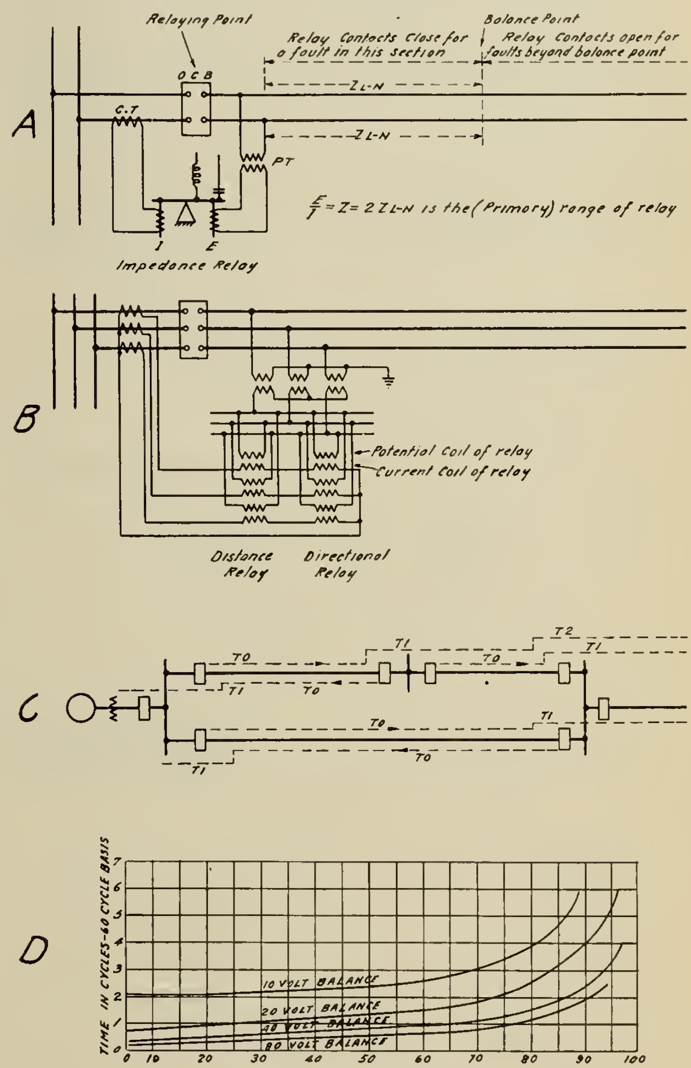

**Fig. 2—Essentials of Distance Relaying for Transmission Circuits.**

conditions their currents will be unbalanced, is available. Such equipment has the advantage of simplicity. Over 60 to 70 per cent in the central section of a line it will give the fastest relay time available, of the order of one one-hundredth of a second. Being inexpensive, it is a useful supplement to other types of protection where it is applicable though the number of possible applications is limited. It is not usually subject to incorrect operation on system surges.

INSTANTANEOUS OVERCURRENT RELAYING

In some systems where the expenditure to install impedance or pilot protective schemes is not considered warranted, or where the induction overcurrent equipment has been installed and is giving reasonably reliable service, but is considered too slow in operation, an important improvement can be made at a nominal cost by adding instantaneous over-current relays. For phase-to-phase these are not of universal application but may often be of assistance if set above the maximum fault current that can pass through a long line section. When used in the residual connection for single-wire or two-wire ground faults on line sections which had dead-grounded transformer neutrals at or near either terminal, they give results in many cases practically equivalent to those obtained from more expensive types.

## SOME DESIGN PROBLEMS IN THE APPLICATION OF HIGH SPEED RELAYING

The successful application of relay equipment which is often so sensitive that it will operate at currents below ordinary load values in one cycle or less of system frequency

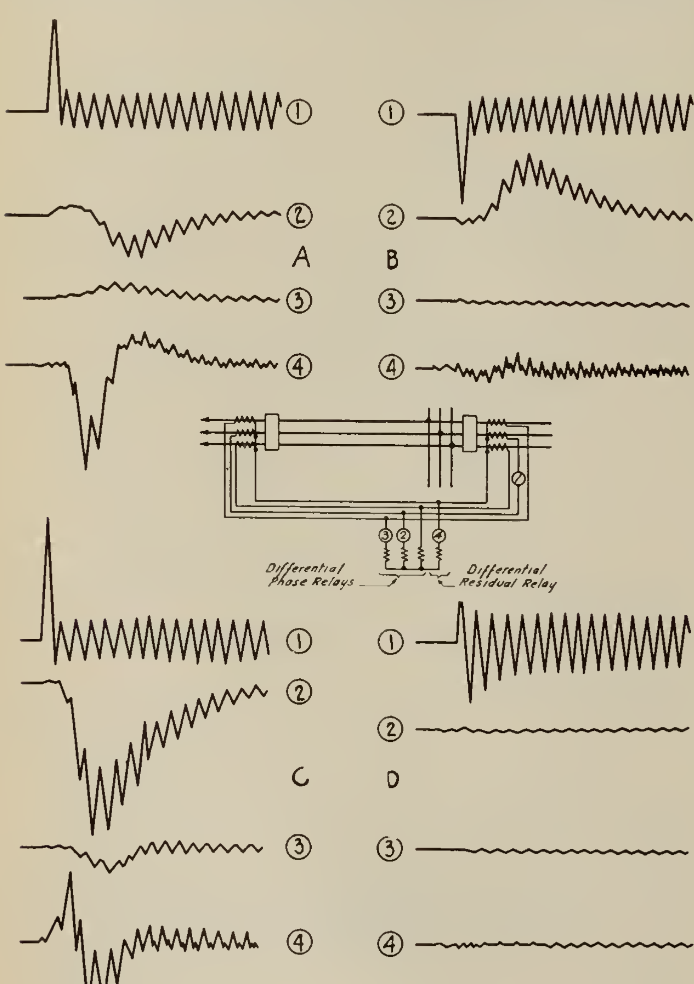

**Fig. 3—Transient Differential Relay Occurrence.**

requires care and judgment in the co-ordination of the relays to the conditions of the system to a greater extent than in the case of slower types of protection. The application for the best results must be based on sound data including the following items:—

1. A fund of information on the nature and manner of occurrence of faults on the power system and of the behaviour of the system and of various types of relaying under fault conditions is essential and may be accumulated in the course of time from the following or other sources:—

By means of automatic recording devices which are instantly put into operation by the disturbance due to the fault and may record the transient conditions of voltage, current, power flow, sequence of circuit clearances and the like. The most useful of these is the automatic oscillograph whose records in the course of time give a very fine insight into the nature of accidental faults on a power system and the consequent behaviour of the system.

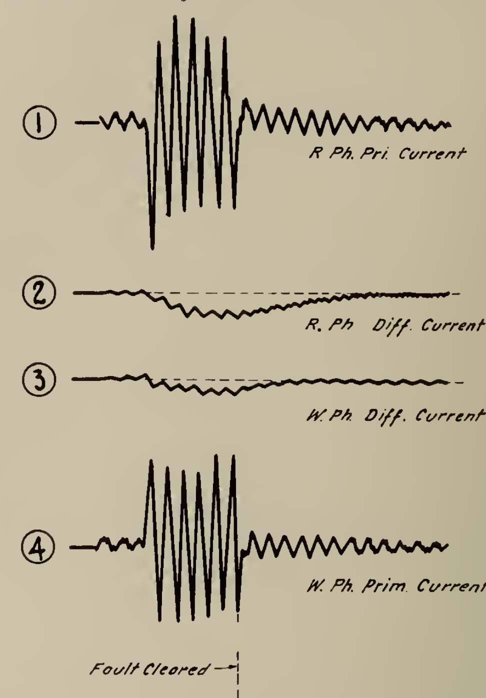

**Fig. 4—Transient Differential Relay Occurrence.**

By means of "staged" tests in which pre-arranged faults are placed on the system in the way to give the maximum of information, allowing observations of system quantities and behaviour to be made and recorded by automatic devices. Such tests should be made after any important relaying installation has been completed, especially if new types are involved, as they will furnish a valuable check on the correctness of the design and adjustments and will often prevent incorrect operation in service.

By means of well designed operation indicators on the relays. High speed relays are usually made of simple elements, each of which performs a single definite function in a sequence. Proper provision of indicators for each function, including timing, will furnish much valuable information.

2. The range of values of fault current and in some cases of voltage and phase angle for each of the relaying points should be available. The most satisfactory way to calculate unbalanced faults is by the method of symmetrical components. For the more complicated networks a calculating board is useful, preferably of the a.c. type; however, solutions from the d.c. board will be sufficiently accurate for most relay applications.

3. Information should be available as to the characteristics and limitations of the relays which it is proposed to use including their speed and the behaviour of the contacts over the range of currents and voltages which may be encountered in service. Freedom from chattering or rebounding of relay contacts is always important in high speed applications and is essential in some lock-out pilot

schemes. The burdens imposed by the relay coils in their relation to current and potential devices on which they are to be used should be known so the overall sensitivity of the equipment can be predicted.

With data of this sort available the power system engineer and the relay designer are prepared to co-operate closely to install equipment which may be expected to give the desired results.

In dealing with sensitive high speed equipment used in differential or other balanced protective schemes where secondary currents from various current transformers are compared and expected to be zero in the relay circuit for faults outside the protected element, there is a certain possibility of improper tripping of the relays on heavy currents "through" the zone.

Figures 3 and 4 have been prepared from oscillograms taken during staged tests on a low voltage and a high voltage system respectively. They indicate that one cause of incorrect relay operation lies in the different response made by current transformers to the transient d.c. component in the primary current wave. In a large number of sensitive equipment and bus zone differential protections which have been under the observation of the author for a number of years, a few incorrect operations of zones at voltages below 15 kv. have been experienced, all for disturbances at that voltage. The author knows of only one case of incorrect operation of a bus differential for a fault on a high voltage line and in that case the fault was a metallic short circuit at the terminals of the station. Presumably the tendency of high voltage faults to strike at the peak of the voltage wave keeps the d.c. component and the transient differential current at a minimum.

In Fig. 3, *A*, *B*, *C*, *D*, are taken from a series of oscillograms of four transitions in the starting sequence of a large synchronous condenser. A number of incorrect differential relay operations had occurred at times of transition from starting to running.

Oscillograph elements 1, 2, 3, 4, are connected in the respective locations shown in the diagram. The following points are of interest:

The exaggerated unidirectional value of the first cycle, element 1, in *A*, *B*, and *C*. This is more severe than would occur on an accidental short-circuit.

The unidirectional nature of the differential current (element 2) for the same phase as 1. The small alternating component is probably due to slight differences in the current transformers.

The irregularity of the differential residual current in element 4.

The very small differential currents in start *D* where the asymmetry of the primary current is not so pronounced.

Figure 4 is from an oscillogram for a metallic short-circuit, wire-to-wire just outside a differentially protected station zone of a high voltage system.

Element 1—current "through" the zone in phase "*R*."

Element 2—current in the differential circuit in phase "*R*."

Element 3—current in the differential circuit in phase "*W*."

Element 4—current "through" the zone in phase "*W*."

It should be noted that the differential current in 2 does not go to zero when the fault is cleared but dies away slowly.

In designing differential schemes which must be sensitive, and at the same time be stable on heavy "through" currents, the following precautions are of assistance:—

The current transformers should be identical in characteristics over a wide range to minimize the unbalanced alternating current. They should be liberal in design with large cores and low resistance in the secondary circulating current path so that the flux and induced voltage will be low under the maximum "through" fault condition.

Tendency to trip on unbalanced a.c. components can sometimes be met by use of the percentage differential principle whereby the relay setting is a percentage of the "through" current and is automatically raised for external faults; this device does not help in case of d.c. differential components as may be seen from Fig. 4. Such components can be bypassed from the relay operating coil by a transient shunt designed to admit the direct current while forcing the alternating component through the operating coil.

For cases where these are not effective as for the irregular transient, one apparent remedy is to use the sensitive relay with slight time delay supplemented by a high speed device set above the transient unbalance.

## BENEFITS FROM THE USE OF HIGH SPEED PROTECTION

The criterion for the value of any relay application is the results obtained in operation. On those power systems where relays of the high speed type have been in service for a number of years the following very definite advantages have been realized:—

Damage to equipment and to structures in stations where the fault has been cleared rapidly has been negligible even with a heavy concentration of current at the point of fault. Oil fires very seldom develop.

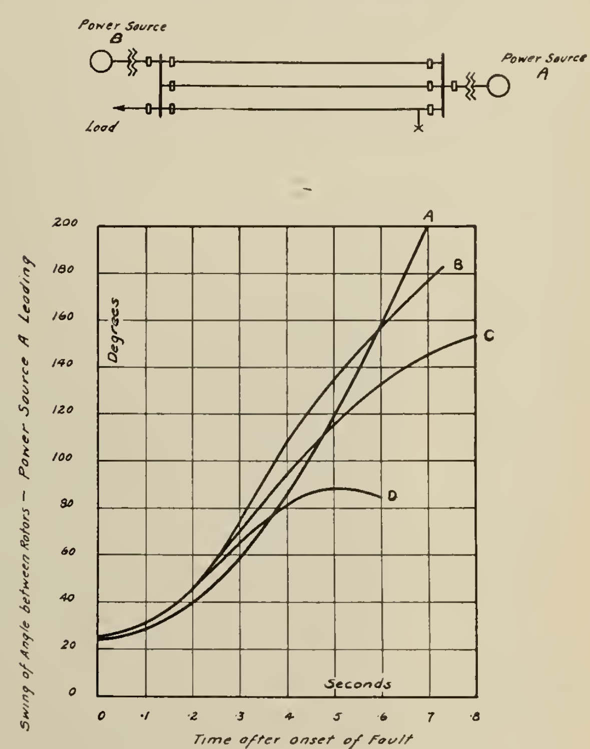

**Fig. 5—Effect of Fault Clearance Time on Transient Stability of a System.**
**Fault Location at X.—Phase to Phase to Phase.**

Burning of the heavier conductors of transmission lines has been greatly reduced so that faults are often difficult to locate. There is seldom any shattering of insulators. So far as arc damage is concerned the circuit is, in a high percentage of cases, in condition to be reclosed immediately.

The operation of interconnected power sources and transmission networks is greatly improved by rapid clearance of faults. Figure 5 is drawn from a study of the effect of fault clearance times on the transient stability of a system.

*A*—Clearance time in 0.3 sec. at end adjacent to the fault; in 0.8 sec. at the remote end.

*B*—Clearance simultaneous in 0.3 sec. as by "carrier" pilot scheme.

*C*—Clearance in 0.2 sec. at the adjacent end and 0.5 sec. at the remote end.

*D*—Clearance simultaneous in 0.2 sec.

System conditions, loads and fault location are approximately constant for all.

It is to be noted that for the particular conditions of test, the system is stable if the fault is completely cleared in 0.2 sec. but not if it lasts for 0.3 sec. The gain for clearance in 0.1 sec. is also apparent.

Comparison of curves *C* and *D* shows the disadvantage in this particular set of conditions of delayed clearance at the end remote from the fault as in the stepped range impedance relaying of *C*. The requirement in this case is for simultaneous clearance at both ends as in *D*.

The increased stability permits heavier loading of interconnections.

When high speed relaying has been applied to systems arranged to take the fullest advantage of it, service outages will be very few no matter how many accidental faults occur. In any case interruptions will usually be short because the circuit can quickly be restored to service.

If faults on a system are cleared rapidly so that voltage dips are short, industrial customers can readily arrange their control equipment to enable their motors to ride through, which will go far to eliminate delays and loss of production in manufacturing operations.

### High Speed Relaying and Automatic Reclosure of Circuits

There is much interest at the present time in automatic reclosure of overhead circuits immediately after a trip-out. With high speed relaying this can be done successfully in as high as 90 per cent of all cases. The equipment to control the reclosure is very simple and inexpensive. With ordinary oil circuit breakers on voltages up to 130 kv. reclosure can be made in one-half to one second after the onset of the fault if the line is completely cleared at high speed.

Standard control equipment is available which will carry induction motors through this period and in the case of synchronous motors will, if it is desirable to do so, remove the field and resynchronize the motor after pulling it into step.

It is of interest to note that while high speed relaying permits automatic reclosure with a high degree of success, the adoption of the latter permits greater freedom and simplicity in the application of high speed relaying by removing to some extent the requirements on the relays for selectivity.

The development of this combination will in the opinion of the author bring forth a major advance both in economy in system construction and in quality of service which can be rendered.

Montreal from Mount Royal.

# Programme for the Semicentennial Meeting

*(All times are Eastern Daylight Saving Time and will be strictly adhered to.)*

MONDAY—JUNE 14th—

Plenary Meeting of Council, and Round Table Conference of Branch Delegates. (Note: these meetings are not open to the general membership.)

TUESDAY—JUNE 15th—

**9.00 a.m.** OPENING OF REGISTRATION, Windsor Hotel, Montreal. (See enclosed attendance form for particulars re advance registration, reservation of rooms, and so forth.)

**10.00 a.m.** OFFICIAL OPENING OF THE SEMICENTENNIAL (Rose Room).
*Chairman*—G. J. DESBARATS, Hon.M.E.I.C., President, The Engineering Institute of Canada.

**Presentation of greetings and reception of official representatives.**

The Institution of Civil Engineers,
The Institution of Mechanical Engineers,
The Institution of Electrical Engineers,
The Royal Aeronautical Society,
Society of Chemical Industry,
The Institution of Engineers and Shipbuilders in Scotland,
The Institution of Structural Engineers,
The Institution of Water Engineers,
The Institute of Marine Engineers,
Institution of Naval Architects,
The Institution of Royal Engineers,
The American Society of Civil Engineers,
The American Society of Mechanical Engineers,
The American Society of Electrical Engineers,
The Society of Naval Architects and Marine Engineers,
Société Française des Electriciens,
Provincial Associations of Professional Engineers,
Canadian Universities and Societies.

**Presentation of Honorary Membership—**

Honorary Membership will be conferred upon the following:

Robert W. Angus, M.E.I.C., Toronto,
G. H. Duggan, M.E.I.C., Montreal,
E. P. Eddy, M.E.I.C., Boston,
Sir Alexander Gibb, M.E.I.C., London, England,
Hon. C. D. Howe, M.E.I.C., Ottawa,
S. J. Hungerford, M.E.I.C., Montreal,
Jacques Rabut, Paris, France,
Hon. Grote Stirling, M.E.I.C., Kelowna.

**Presentation of Prizes—**

SIR JOHN KENNEDY MEDAL—J. G. Sullivan, M.E.I.C., Winnipeg, Man., Past-President of The Institute.

DUGGAN MEDAL AND PRIZE—P. L. Pratley, M.E.I.C., Montreal, Que., "The Superstructure of the Reconstructed Second Narrows Bridge, Vancouver."

GZOWSKI MEDAL —David Boyd, A.M.E.I.C., Lachine, Que., "Modern Arc Welding."

PLUMMER MEDAL —C. R. Whittemore, A.M.E.I.C, Montreal, Que., "The Metallurgy of Metallic Arc Welding of Fine Steel."

LEONARD MEDAL —Mr. L. S. Weldon, Geita, Tanganyika, East Africa, "Mining Methods and Practice at Lake Shore Mine." (Already presented.)

STUDENTS' AND JUNIORS' PRIZES—

JOHN GALBRAITH PRIZE *(Province of Ontario)* —E. C. Hay, Jr.E.I.C., Toronto, Ont., "Selection of Factors of Photo Electric Cells."

PHELPS JOHNSON PRIZE *(Province of Quebec—English)* —Eric G. Adams, Jr.E.I.C., New York (formerly of Montreal), "Trends in Population and Trade Affecting Transportation."

ERNEST MARCEAU PRIZE *(Province of Quebec—French)* —Louis Trudel, S.E.I.C., Montreal, Que., "Etude Comparative sur Modèles Réduits."

**12.45 p.m.** LUNCHEON—(Windsor Hall).
Welcome from His Worship the Mayor of Montreal.
Guest speakers—H. V. Potter, of London, England, representing the Society of Chemical Industry.
J. H. Herron, of Cleveland, Ohio, representing the American Society of Mechanical Engineers.

**2.40 p.m.** "OVERSEAS" SESSION—(Rose Room).
*Chairman*—MAJOR-GENERAL A. G. L. MCNAUGHTON, C.M.G., D.S.O., M.E.I.C.

**The British Grid System** by Johnstone Wright, M.I.E.E., Chief Engineer of the Central Electricity Board, London, England.
This paper will deal with the re-organization of the generation side of the electrical industry in Great Britain subsequent to the piecemeal pre-war development, with the co-ordination of resources through a comprehensive network of interconnecting trunk lines, taking care of the rapidly expanding demand for electricity.

**3.50 p.m.** **Industrial Zoning** by Hugh Beaver, M.I.E.Chem., Partner, Sir Alexander Gibb and Partners, London, England.
This paper will deal with the improvement and cheapening of primary services, such as transport, electricity supply, postal and telephone services, etc., the re-organization of the larger industries, such as shipbuilding, iron and steel, coal, etc., planning new industries and new industrial areas.

**4.50 p.m.** **British Engineering Societies and Their Aims** by Brigadier-General Magnus Mowat, C.B.E., F.R.S.E., Secretary, The Institution of Mechanical Engineers, London, England.
The mediaeval Guilds were the forerunners of engineering institutions, and then came scientific societies of wide scope, such as The Royal Society of London. Amongst the purely engineering bodies, the activities and objects of the Institution of Civil Engineers and The Institution of Mechanical Engineers will be described in some detail, and brief particulars will be furnished of many other national and local associations in the British Isles, the purposes of which are very similar.

**9.00 p.m.** RECEPTION AND SUPPER-DANCE—(Windsor Hall and Rose Room).
Guests will be received by President and Mrs. G. J. Desbarats, and by Past-President and Mrs. F. P. Shearwood.

NOTE:—*Advance Proofs of the majority of the Technical Papers will be available. Copies may be obtained on application to The Secretary, The Engineering Institute of Canada, 2050 Mansfield Street, Montreal.*

**WEDNESDAY—JUNE 16th—**

**9.45 a.m.** Technical Session—(Prince of Wales Salon).

**Symposium on the Burning of Canadian Coals.**

*Chairman*—Dr. R. W. Boyle, m.e.i.c.

B. F. C. Haanel, b.sc., m.e.i.c., and R. E. Gilmore, m.e.i.c., Department of Mines and Resources, Ottawa, will discuss the physical and chemical characteristics of Canadian coals, classifying them according to the new methods adopted by the International Committee on Coal Classification. Investigations relating to boiler heating, carbonization, hydrogenation, and other research work will also be discussed.

F. H. Sexton, ll.d., President, Nova Scotia Technical College, Halifax, N.S. The basic characteristics of Nova Scotia coals.

John Stephens, d.sc., m.e.i.c., Professor of Mechanical Engineering, University of New Brunswick, Fredericton, N.B. Performance at the Grand Lake plant of the New Brunswick Electric Power Commission at Minto, N.B.

R. L. Sutherland, Combustion Engineer, Truax-Traer Coal Company, Winnipeg, Man. The economics of mining and marketing Saskatchewan lignite and its use in domestic and industrial plants.

E. W. Bull, Superintendent, Light and Power Department, City of Regina, Sask. Operating results at the Regina plant with various coals and types of stokers.

Edgar Stansfield, m.sc., m.e.i.c., Chief Chemical Engineer, Research Council of Alberta. The burning of low rank Alberta coal—combustion and control.

C. A. Robb, b.sc., m.e.i.c., Professor of Mechanical Engineering, University of Alberta, Edmonton, Alta. The burning of low rank Alberta coals—the steam generating plant.

R. R. MacNaughton, b.sc., Metallurgist, Consolidated Mining and Smelting Company, of Canada Limited, Trail, B.C. Some phases of the use of British Columbia coal.

J. Roberts, Chief of Motive Power, Canadian National Railways, Montreal. The use of Canadian coals in steam locomotives.

D. G. Munro, Vice-President and General Manager, Montreal Coke and Manufacturing Co. Ltd., Montreal. The use of Canadian coals in the coking and by-product industry.

**9.45 a.m.** Technical Session—(York Room).

*Chairman*—Dr. A. Frigon, m.e.i.c.

A. G. Dickinson, b.sc., Electrical Engineer, Consolidated Mining and Smelting Co., of Canada Limited, Trail, B.C. **Utilization of Electric Power at Trail's Metal and Fertilizer Plant.** The use of electric power plays an important part in the various processes for the production of metal, chemicals and fertilizer. This paper will deal mainly with layout and operation problems.

National Research Council, Ottawa.

J. C. Bernier, b.a.sc., c.e., e.e., Assistant Professor Ecole Polytechnique, Montreal, Que. **Mechanical and Cathode-ray Systems of Television.** An explanation of the principal system of high definition television, discussing their relative merits, with a demonstration of television and electron optics.

E. M. Wood, b.a.sc., Electrical Engineer, Hydro Electric Power Commission of Ontario, Toronto, Ont. **The Characteristics and Application of Modern Relaying.** The importance of protective relay equipment on transmission systems and on various types of stations connected thereto.

A. S. Wall, m.e.i.c., Dominion Bridge Company Limited, Montreal, Que. **Modern Technique in Welding Processes.**

**12.45 p.m.** Luncheon—(Windsor Hall).

Welcome from the Prime Minister of the Province of Quebec.

Guest speakers—A. C. Gardner, Glasgow, Scotland, representing the Institution of Engineers and Shipbuilders in Scotland.
Harrison P. Eddy, m.e.i.c., Boston, Mass., Past-President, The American Society of Civil Engineers.

**2.40 p.m.** Technical Session—(Prince of Wales Salon).

*Chairman*—H. F. McKiel, m.e.i.c.

R. E. Chadwick, b.sc., m.e.i.c., President, The Foundation Co. of Canada Limited, Montreal, Que. **Precast Concrete Units in Engineering Construction**, especially developing the idea that such units can be built better and more economically at a suitable construction yard rather than *in situ*.

C. J. Mackenzie, b.e., m.e.i.c., Dean of Engineering, University of Saskatchewan, and

B. A. Evans, m.sc., Senior Assistant Engineer, Department of Public Works of Canada, Ceepee, Sask. **The Ceepee Bridge**, covering the design and construction of a highway bridge across the North Saskatchewan River at Ceepee, Sask., which consists of approach girders and three bow-string arches of long span, involving unusual design features. Results of extensometer tests. Construction methods in low temperatures.

J. B. D'Aeth, b.sc., m.e.i.c., Engineer, Fraser Brace & Company Limited, Montreal, Que. **Freight Hauling in Undeveloped Territories**, especially as related to the construction, mining and forestry industries in Canada. Methods and cost of transporting heavy machinery, equipment and supplies to remote places.

**2.40 p.m.** Technical Session—(York Room).

*Chairman*—Brigadier J. Lindsay Gordon, d.f.c., a.m.e.i.c.

H. J. McLean, m.e.i.c., Production Superintendent, Calgary Power Company Limited, and

O. H. Hoover, b.a.sc., m.e.i.c., Engineer-in-Charge, Dominion Water Power and Hydrometric Bureau, Calgary, Alta. **A Study of Standard and Increment Methods of Measuring Stream Flow**, describing methods used for the efficient apportionment of load to machines in each hydro-electric plant of a system, and the hourly calculation of water available.

J. H. Parkin, m.e., m.e.i.c., f.r.ae.s., National Research Council, Ottawa, Ont. **North Atlantic Air Service London-Montreal.** Different factors involved in the establishment of an intercontinental air service by heavier-than-air aircraft across the North Atlantic—such as nature of service, barriers and methods of surmounting them, possible routes, organization of route and types of aircraft.

H. B. Bowen, m.e.i.c., Chief of Motive Power, Canadian Pacific Railway, Montreal, Que. **Modern Motive Power.**

**7.30 p.m.** Banquet—(Rose Room).

Guest of Honour and Principal Speaker—His Excellency the Governor General, Lord Tweedsmuir.

Other Speakers—Sir Alexander Gibb, London, President, The Institution of Civil Engineers; L. C. Hill, Los Angeles, President, The American Society of Civil Engineers; Arthur Surveyer, Past President, The Engineering Institute of Canada; E. A. Cleveland, Past President, The Engineering Institute of Canada.

This function will be broadcast between the hours of 9 and 9.30 p.m., Eastern daylight saving time (which will include the address of His Excellency the Governor General), over the national network of the Canadian Broadcasting Corporation, comprising the following stations—

CJCB—Sydney; CHNS—Halifax; CFCY—Charlottetown; CKCW—Moncton; CFNB—Fredericton; CHSJ—Saint John; CHNC—New Carlisle; CRCS—Chicoutimi; CRCK—Quebec; CRCM—Montreal; CRCO—Ottawa; CRCT—Toronto; CRCW—Windsor; CKSO—Sudbury; CKPR—Fort William; CKY—Winnipeg; CKCK—Regina; CFQC—Saskatoon; CFAC—Calgary; CJCA—Edmonton; CJOC—Lethbridge; CRCV—Vancouver.

It is probable that other stations will be added to the network in due course.

THURSDAY—JUNE 17th—

VISITS TO PLACES OF INTEREST

*(Subject to Revision)*

Tour 1—Leave Windsor Hotel 8.45 a.m., board "Sir Hugh Allan" at foot of McGill Street 9 a.m., general tour of the Harbour; debark Imperial Oil Company's wharf 12 noon. Lunch, courtesy Imperial Oil Company, inspection Imperial Oil Company's refinery at Montreal East, return by bus to Montreal at 4 p.m.

Tour 2—Leave Windsor Hotel 9.10 a.m. for Shell Oil Company's Montreal East Refinery and Canadian Vickers Limited; lunch at the latter plant. Return to Montreal 3.45 p.m.

Tour 3—Leave Windsor Hotel 9.15 a.m. for Montreal East, Canadian Copper Refineries, Canada Wire and Cable Company, Canadian Steel Foundries, return to Montreal 1.30 p.m.

Tour 4—Leave Windsor Hotel 9.20 a.m. for Canadian Pacific Angus Shops, Montreal Locomotive Works, Canadian National Shops, Point St. Charles, lunch, courtesy Montreal Locomotive Works.

Tour 5—Leave Windsor Hotel 9.25 a.m., bus to Cartierville and Pont Viau, thence to Pie IX Blvd. bridge (under construction), across Jacques Cartier bridge to South Shore, thence to Caughnawaga bridge and to plant of Dominion Bridge Company, who will provide lunch. Inspection of Bridge Company's plant and return to Montreal 4 p.m. This tour will include 4 steel bridges and 1 concrete bridge.

Tour 6—Leave Windsor Hotel 9.30 a.m. for Beauharnois, inspection of Beauharnois Hydro-Electric plant and works, lunch at plant, return to Montreal 4 p.m.

Tour 7—Leave Windsor Hotel, 9.35 a.m. for Canadian Car and Foundry Company, Turcot and Dominion plants; Dominion Engineering Works Limited at Rockfield, who will provide a buffet lunch, return to Montreal 4 p.m.

Tour 8—Leave Windsor Hotel 9.40 a.m. for Steel Co. of Canada, Notre Dame and St. Henry plants, and Canadian Tube and Steel Products Company at Ville Emard, return to city at 3.45 p.m.

Tour 9—Leave Windsor Hotel at 9.45 a.m. for Northern Electric Company's works; thence to Bell Telephone Company's toll building, who will provide a buffet lunch. Then to Canadian Marconi Company's works in the Town of Mount Royal, return to Montreal at 3.45 p.m.

Tour 10—Leave Windsor Hotel 9.50 a.m. for the plants of the Dominion Textile Co. Limited, and Belding Corticelli Company.

Tour 11—Leave Windsor Hotel at 10 a.m. for the Montreal Water Board pumping station, filtration plant and McTavish upper level pumping station, returning at 12.45 p.m.

Golf—For those who wish to play Golf, arrangements can be made at one or more of the clubs in the vicinity of Montreal.

**4.00 p.m.** GARDEN PARTY—(McGill University Campus).
Through the courtesy of McGill University, arrangements have been made to hold a Garden Party on the Campus. With the kind permission of the Commanding Officer, Colonel A. T. Howard, V.D., the band of The Black Watch (Royal Highland Regiment) of Canada will be in attendance.

**8.00 p.m.** SMOKING CONCERT—(Windsor Hall).

FRIDAY—JUNE 18th—OTTAWA—

**8.50 a.m.** Leave Windsor Street Station, Canadian Pacific Railway, 8.50 a.m. (7.50 a.m. Eastern Standard Time), arrive Ottawa 12 noon (11.00 a.m. Eastern Standard Time).
(Members returning to the West of Ottawa on convention tickets will be able to stop over on their return ticket. Others will travel on a group rate, which will depend on number of tickets.)

**12.45 p.m.** LUNCHEON—(Chateau Laurier, Ottawa).
Welcome by His Worship the Mayor.
Guest Speaker—To be announced.

VISITS TO PLACES OF INTEREST

Tour 1—Leave Chateau Laurier 2.30 p.m. for inspection of Chelsea and Farmers Power plants of the Gatineau Power Company on the Gatineau river, return to Ottawa 6 p.m.

Tour 2—Leave Chateau Laurier 2.35 p.m. for inspection of Gatineau mill of Canadian International Paper Company at East Templeton, return to Ottawa 5.30 p.m.

Tour 3—Leave Chateau Laurier 2.40 p.m. for inspection of laboratories of the National Research Council.

Tour 4—Leave Chateau Laurier 2.45 p.m. for "circular tour" taking in the Central Experimental Farm, Parliament Buildings, Memorial Chamber, Peace Tower, and the Driveway, return 5.30 p.m.

**7.30 p.m.** DINNER—(Chateau Laurier, Ottawa).
Guest Speaker—(to be announced).

**9.30 p.m.** DANCE—(Chateau Laurier, Ottawa).

C.N.R. Locomotive 6400 Series.

SATURDAY—JUNE 19th—

The heads of a number of Government engineering departments will be "at home" to receive visitors. Announcement will be made later as to the details.

## Ladies Programme

With the exception of the Smoking Concert on Thursday evening, ladies will be welcome at all the social functions and at the technical sessions if they so desire. The following additional arrangements have been made for the ladies.

TUESDAY, JUNE 15th—
**4.00 p.m.** TEA—(Prince of Wales Salon, Windsor Hotel).

WEDNESDAY, JUNE 16th—
**3.00 p.m.** LAKESHORE DRIVE AND TEA—(Royal St. Lawrence Yacht Club, Dorval).

THURSDAY, JUNE 17th—
**8.00 p.m.** BRIDGE—(Prince of Wales Salon, Windsor Hotel).

## TRAVEL ARRANGEMENTS

Through the courtesy of the Canadian Passenger Association all members of The Institute together with their dependents may obtain special fare concession for round trip equivalent to 1⅓ times single fare plus 25 cents, on presentation of the identification certificate enclosed herewith. Alternatively one-way tickets may be purchased at ⅔ single fare in either direction.

Tickets will be issued on the following dates (inclusive in each case):—British Columbia—June 8 to 14; Alberta—June 9 to 15; Saskatchewan, Manitoba and Ontario, Port Arthur and West—June 10 to 16; Ontario, East of Port Arthur, Quebec and Maritime Provinces—June 11 to 17.

### DO NOT MISLAY IDENTIFICATION CERTIFICATE

**For full information regarding travel arrangements, issuing of tickets, parties travelling together—members should get in touch with their local Branch representative as under— (or local Railway Agent)**

**Halifax—**
R. R. Murray, A.M.E.I.C.,
c/o Wm. Stairs, Son & Morrow Ltd.,
Halifax, N.S.

**Cape Breton—**
S. C. Mifflen, M.E.I.C.,
60 Whitney Avenue,
Sydney, N.S.

**Saint John—**

### HOTEL ACCOMMODATION

Reservations of rooms will be made by the Committee at both the Windsor Hotel, Montreal, and the Chateau Laurier, Ottawa. (See Advance Registration Form for detail of rates.) As the Registration will be unusually heavy it will be appreciated if you will return the Advance Registration Form as early as possible.

A cordial welcome is assured all visiting members. Guests will also be welcome at the various functions upon introduction by a member.

### Prices of Tickets

**MONTREAL**

| | | |
|---|---|---|
| Tuesday, June 15th, | Luncheon | $1.50 |
| | Complimentary to visiting ladies. | |
| | Ladies Tea | $0.50 |
| | Complimentary to visiting ladies. | |
| | Supper Dance, Couple | $5.00 |
| | Single | $3.00 |
| Wednesday, June 16th, | Luncheon | $1.50 |
| | Lakeshore Drive, Ladies only | $1.00 |
| | Banquet | $3.00 |
| Thursday, June 17th, | Garden Party | $1.00 |
| | Complimentary to visitors. | |
| | Smoking Concert | $1.25 |
| | Ladies Bridge | $0.50 |

**OTTAWA**

| | | |
|---|---|---|
| Friday, June 18th, | Luncheon | $1.00 |
| | Dinner and Dance | $2.50 |
| | Dance only | $1.25 |

It will be appreciated if members would care to send in their cheque for tickets with their advance registration form, in which event tickets and badge will be prepared in advance and found at the "Advance Registration Desk." Adjustments can be made after arrival for tickets not required, or additional tickets obtained.

### COMMITTEES

**Ladies Committee—**
Mrs. F. P. Shearwood,
Convenor.

**Ottawa Committee—**
Allan K. Hay, A.M.E.I.C.,
Chairman.

**Reception Committee—**
F. S. B. Heward, A.M.E.I.C.,
Chairman.

**Semicentennial Committee—**
J. L. Busfield, M.E.I.C.,
Chairman.

## DESCRIPTION OF PLACES TO BE VISITED

MONTREAL AND VICINITY—JUNE 17TH—

**The Harbour of Montreal,** situated at the junction of ocean and inland navigation on the River St. Lawrence, approximately 1,000 miles from the sea—an outstanding example of modern seaport organization and recognized as one of the great harbours of the world. (*Tour 1*)

**The Beauharnois Power Development,** a modern hydro-electric plant with an installed capacity of 450,000 hp. (nine turbine units), 15 miles of canal, and control dams on the River St. Lawrence. (*Tour 6*)

**Dominion Engineering Works, Limited,** manufacturers of heavy commercial machinery in Canada, containing the largest vertical boring mill in the Dominion. It is possible that a large modern paper machine will be assembled and available for inspection. Special gear cutting machines will also be set up for demonstration. (*Tour 7*)

**Montreal Water Board,** the largest single municipal pumping station in the world, supplying the whole of the City of Montreal; together with a modern filtration plant with continuously automatic chlorinator regulated by photo-electric cell contact, designed by the Board's own engineering staff. (*Tour 11*)

**Dominion Bridge Co. Limited.** Fabricators and erectors of all types of structural steel work, boilers, coal pulverizers, cranes, etc. This Company has built many of the most important bridges in Canada. They are pioneers in welded construction, and their shop is equipped with the largest stress relieving furnace in Canada, X-ray apparatus and other modern equipment.

During the visit the fabrication of both welded and riveted steel work, pressure vessels, and heavy machinery will be in progress, including the construction of the Pie IX Boulevard Bridge.

In the course of Tour 5, the following bridges will be visited:—

Pont Viau is a five-span, three-hinge, arch bridge of reinforced concrete and provides for six lines of traffic. It is 1,050 ft. in length, the spans, varying from 202 to 222 ft. in length, are 56 ft. in width.

The Jacques Cartier Bridge is approximately 9,150 ft in length, with the main span a symmetrical cantilever, providing a clear navigation channel of over 1,000 ft. and a clearance of 155 ft. The north and south approaches to the central span consists of a series of short deck truss spans carried on masonry, concrete and steel piers. The central roadway is 36 ft. wide.

The Honoré Mercier Bridge is approximately 4,470 ft. in length, with a steel superstructure 2,918 ft. consisting of thirteen spans; ten of these being 235 ft. and the main span 400 ft. In all there is a clearance of 120 ft.

Cartierville Bridge is a modern three-span steel highway bridge.

The Pie IX Boulevard Bridge, which is now under construction, will comprise five-span arches supporting a composite superstructure.

**Canadian Car and Foundry Company, Limited,** with freight and passenger cars in all stages of construction from the wheel foundry and the spring shop, through the fabricating shop to the delivery track. (*Tour 7*)

**Canadian Steel Foundries, Limited,** a completely equipped modern plant for the manufacture of steel castings. (*Tour 3*)

**Canadian National Railways** Locomotive Shops, Montreal, one of the most modern locomotive shops on the continent—its power plant, machine shop and assembly tracks are under one roof. The Railway will make arrangements for a new streamlined locomotive to be at the shop for detailed inspection. (*Tour 4*)

**Belding-Corticelli Limited**—A modern plant for manufacturing silk goods from the raw product to the finished article, such as silk hosiery and ribbons. The processes involve taking the raw silk and manufacturing it into the necessary threads which are then put through various processes plus the dyeing, pairing and boxing. In the Ribbon Mill both silk and rayon ribbons are woven and dyed. (*Tour 10*)

**Shell Oil Co. of Canada Limited**—The Montreal East Refinery consists of a modern combination topping, cracking and stabilizing system producing gasoline and fuel oil direct from crude oil. A vapour phase clay treating system is built integral with the cracking plant, and an absorption system is employed to strip process gas. Steam required for refinery operations is generated in the company's boiler plant, and there is a well equipped laboratory for making standard petroleum tests. (*Tour 2*)

**Imperial Oil Limited**—The Montreal Refinery at Montreal East has a capacity of 20,000 barrels daily, with a full range of over one hundred products, gasoline, lubricants, kerosene, distillates and asphalts (the largest asphalt refinery in Canada). Gasoline is produced by the tube and tank cracking process, and of special interest is the combined atmospheric vacuum and cracking unit. (*Tour 1*)

**Canadian Copper Refiners Limited**—The Montreal East plant is a modern refinery which refines blister by the electrolytic process, and produces refined copper shapes, gold and silver bullion, also refined selenium and tellurium. The plant has a capacity of 7,500 tons of copper per annum. (*Tour 3*)

**Canadian Tube and Steel Products Limited**—Manufacturers of bolts, nuts and rivets of all descriptions, wire and wire products, wire nails, screws, the rolling of merchant bars, structural shapes, angles, etc. The plant also includes a pipe mill for the manufacture of various forms of pipe, and electric furnace for the melting of steel. (*Tour 8*)

**Montreal Locomotive Works Limited**—This plant covers sixty acres and consists of foundry, forge, boiler, wheel, cylinder, tank, machine, and erecting shops. Thirty Hudson type locomotives are under construction for the Canadian Pacific Railway Company. (*Tour 4*)

**Northern Electric Co. Limited**—At this plant everything in the nature of manual and automatic telephone apparatus and equipment is manufactured, together with a complete line of telephone wires and cables, in addition to which rubber covered wire and paper insulated lead covered power cables are made to meet all commercial low and high tension requirements. Here, too, are manufactured special products such as broadcasting transmitters, radio receiver sets, fire alarm and police signal equipment, theatre and speech input equipment. (*Tour 9*)

**Bell Telephone Company**—Long distance building housing switchboards, test desks, power apparatus, repeater units, etc., taking care of all long distance traffic. Also equipment for overseas messages between Canada and the world in general. This plant also contains apparatus through which radio programmes from the United States for distribution to Eastern Canadian radio stations are handled. An opportunity will also be provided for a visit to the Historic Museum in the head office building. (*Tour 9*)

**Steel Co. of Canada Limited**—At Notre Dame Works there are 9, 12 and 18 in. merchant mills, rolling bars for concrete reinforcing, etc., and also bars to be further processed in the horse shoe and bolt works. There is also a wire mill, which draws wire for the trade, for the bolt works and for the wire nail department. All kinds of wire nails are manufactured, including cut nails, staples, tacks, etc. The bolt and nut works manufactures bolts and nuts, washers, pole line hardware, rivets, spikes, etc.

At St. Henry Works, located about one mile west of Notre Dame Works. buttweld pipe is manufactured up to and including 4 in. diameter, also couplings, nipples and gate valves. (*Tour 8*)

**Canadian Pacific Railway Company,** Angus Shops, situated in the north end of the City. These are the largest locomotive shops on the Continent where all heavy maintenance and overhaul work is carried out. The shops also include passenger coach and freight car departments, iron foundries, paint shops, and at the present time there is considerable work being done in the installation of air conditioning equipment in passenger coaches. (*Tour 4*)

**Canada Wire and Cable Co. Limited,** Montreal East Plant, adjacent to Canadian Copper Refineries. At this plant copper wire bar is received from the Copper Refineries and put through various rolling and annealing processes to produce rods and wire. The bars are first heated in oil fired billet heating furnaces, then delivered to a roughing mill, and finally passed through intermediate and finishing mills to the pickling room. (*Tour 3*)

**Canadian Vickers Limited**—The following activities of interest will be available for inspection:—Industrial Department: mining machinery, Ontario Paper penstock, boilers and possibly hydraulic turbines; Structural Steel Department: steel for Beattie Mines building and roaster; Marine Department: besides drydock activities, shipyard will be completing a barking drum barge; Aircraft Department: all-metal planes at various stages of construction. (*Tour 2*)

OTTAWA AND VICINITY—JUNE 18TH—

**Canadian International Paper Company**—Gatineau Newsprint Mill, at East Templeton, on the Ottawa river, about 5 miles from the City of Ottawa, has a capacity of 750 tons of paper per day, and covers an area of over 10 acres, while the entire mill site covers 27 acres. The mill is of modern design, electrically operated throughout, with power from Farmers, Chelsea and Paugan plants of the Gatineau Power Company.

**Gatineau Power Company**—Plants at Chelsea and Farmers on the Gatineau river are about 8 miles from Ottawa. These two plants form part of a comprehensive development of 100 miles of river, which has a minimum regulated flow of about 10,000 c.f.s. Chelsea and Farmers operate under heads of 97 and 67 ft. respectively. The former is equipped with 34,000 and the latter four 24,000 hp. units.

**National Research Council, Ottawa**—A modern building situated on the bank of the Ottawa river houses administrative offices, and biological, chemical, physical and electrical engineering laboratories. In the Annex are the mechanical and aeronautical engineering laboratories having a 9-ft. wind tunnel, and a water channel 400 ft. long, laboratories for engine and fire hazard testing, and extensive model and instrument shops.

**Central Experimental Farm**—Comprising over 800 acres, is the headquarters of the Dominion system of experimental farms and stations, and is operated under such divisions as Animal Husbandry, Agricultural Bacteriology, Bees, Botany, Plant Pathology, Cereals, Chemistry, Economic Fibre Production, Field Husbandry, Forage Crops, Horticulture, Illustration Stations, Poultry and Tobacco. Beautiful, well kept grounds is the keynote of the farm, and points of special interest include the Arboretum, The Flower Garden, The Macoun Memorial Garden, Greenhouses, Live Stock, Farm Buildings and Machinery, Experimental Fields and Plots.

**The Ottawa Driveway**—The City of Ottawa is almost entirely circled by a beautiful driveway following the Rideau canal, Dow's lake, and the Ottawa river. On the Driveway are located many of Ottawa's finest homes.

**The Parliament Buildings**—Are the centre of governmental interest and are well worth a visit. The Peace Tower and Memorial Chamber are striking centres of public interest, especially when the carillon is in operation.

## Electricity Supply in Great Britain

The effective co-ordination of the policies of a number of independent local authorities is always difficult and sometimes almost impossible. The existence of vested interests, the divergent views of various advisers, insistence on local view points, and the wet blanket of the pessimists oft n combine to hinder progress. The conditions under which the electrical supply industry developed in Great Britain in the eighties and nineties resulted in a state of affairs which was far from ideal, which seriously delayed the general adoption of electrical equipment, and even hampered the country's industrial efforts during the war. It is to be noted that in Britain there are few sites at which any substantial amount of water power can be developed, but coal is abundant and cheap, so that electrical energy was generated by coal-fired, steam-driven stations. In general, manufacturing establishments were served by their own individual steam plants, with a resulting inflexibility which made rapid industrial expansion very difficult.

Under these circumstances, there sprang up a multitude of small separate electricity-distributing authorities, mainly supplying the towns, paying little attention to the rural areas, and served by a correspondingly large number of small generating stations. There was an extraordinary multiplicity of voltages, frequencies, and systems of distribution. There could be little or no standardization of equipment, the capital expenditure was excessive due to the high proportion of reserve plant which had to be provided, and the fuel consumption was great owing to the small average scale of production.

During the reconstruction period after the war, it became increasingly evident that British industry was being handicapped by the lack of cheap and widely distributed electrical power, while practically nothing had been done towards popularizing the use of electricity in country districts. Attempts at voluntary reorganization of the industry were not successful and would, at best, have perpetuated local differences leading to the continuation of the existing anomalous arrangements. As a result Parliament took action in 1926 by the creation of a Central Electricity Board, with powers to construct and operate a national network of high voltage transmission lines, to control the generating stations connected with it, to standardise frequency, and to supply electricity in bulk to the various local distributing authorities. The Board members are chosen as representative of a number of the principal business and community interests of the country; no member of Parliament is eligible. It is not a government department and is free from political control. The capital required has been raised by the public issue of long term, fixed interest stock, and beyond earning this interest, the Board is not allowed to make any profits. The general type of organization of which the Central Electricity Board is thus an example is one which has proved successful in England in another branch of public utility service, namely, the co-ordination and control of passenger transport in London.

Serving a population of more than forty millions in a highly industrialized country, the Central Electricity Board's operations are on a large scale. The capital expenditure on the 'Grid,' its main network of high voltage lines, is nearly one hundred and fifty million dollars. This network provides for the interconnection of over one hundred and fifty generating stations so as to reduce reserve plant in individual stations to a minimum. It enables the best plants to be run continuously; the less efficient to be restricted in operation, and the inefficient closed down. With these ends in view, the Board directs the operation of the various stations connected with the Grid, and purchases their entire output at the actual cost of production. It then supplies the various local distributing authorities at its standard tariff rates.

In a paper published in this issue of the Journal, the Board's chief engineer describes its operations. He is able to point out that although now only in its tenth year of operation, the Bc ard's activities have already had a marked effect on costs. They have assisted rural development; helped industrial decentralization and railway electrification; have promoted the use of electricity in the home and in fact have made the country electricity-minded. These results must be a matter of justifiable pride to all who have been connected with the development of the scheme, and have taken part in putting it into effect.

In their work the Board's technical officers have taken full advantage of the latest developments in transmission, switching, and protective apparatus, and have completed a modern and effective installation. On the financial side, the cost of installing the system was substantially less than the original Estimate, and as regards results, the total fuel consumption of the stations connected to the Grid is nearly two million tons less than it would have been had the formerly existing system, (or lack of system) continued, the corresponding annual monetary saving being some eight million dollars.

The Grid is thus an example of a great public utility established under government initiative, but effectively divorced from politics; paying reasonable return on the capital invested; operated in the interest of the country as a whole, and interfering as little as possible with the business of the local authorities, railways or industrial concerns which it supplies. We have not many organizations in Canada to which all of these statements would apply.

Hail to the crown by freedom shaped---to gird
An English sovereign's brow! and to the throne
Whereon he sits! whose deep foundations lie
In veneration and the people's love.

## The Ballot on the Consolidation Proposals

The interest taken by the Corporate membership of the Institute in the question of "Consolidation" is shown by the heavy vote which was cast, practically fifty per cent of the membership having sent in their ballots, a proportion of votes to voters which is unusually high. The results of this ballot, which are announced on this page, indicate clearly that the proposals of the Committee on Consolidation have not been approved by the Corporate membership but do not mean that the majority of The Institute members are opposed to Consolidation as a live policy of The Institute. On the contrary, there is abundant evidence that a large body of the Corporate membership believe that joint action with the Professional associations, leading to the ultimate formation of a national body, is highly desirable. While the present vote shows that the particular scheme put forward by the Committee on Consolidation is not acceptable to our corporate membership, it must not be taken as ruling out further action nor the exploration of other possibilities.

The negative decision thus reached, after two years of effort by the Committee on Consolidation, will come as a disappointment to those who anticipated rapid and comparatively easy progress towards the desired end, but will meet the views of the presumably larger number, who hold that a different line of advance should have been adopted. Actually, there are many features of the Committee's proposals which may well be considered in any discussions into which the Council may enter, either with the Dominion Council, if that body decides to confer with the Council of The Institute, or with those Professional associations which have signified their desire for co-operation with The Institute.

At this point it seems proper to recall the views expressed by speakers at the Seventh Plenary Meeting of Council, who clearly indicated the wish of the engineers in Manitoba for prompt action. The hope was expressed that this would be along the lines of a proposal from a joint committee of the Winnipeg Branch of The Institute and the Association of Professional Engineers of Manitoba, which had been submitted to The Institute Council in November 1934. This proposal was then approved by Council, subject to further consideration, but its presentation took place just before the formation of the Committee on Consolidation by the Annual General Meeting, in February 1935, and action upon it has remained in suspense since that time.

Following suggestions made at the Plenary Meeting of Council, some of the features of the Manitoba scheme were later included in the proposals of the Committee on Consolidation. Similar joint committees have also functioned in Saskatchewan and Alberta, although their projects did not reach such a definite stage of development as in Manitoba.

There has also been a movement in the Maritime Provinces. During the fall of 1934 a scheme of local co-operation was drafted for Nova Scotia in sufficient detail to be submitted to The Institute branches there, and to the Nova Scotia Professional Association, with some prospect of eventual agreement. In this case also activity had to be suspended while the Committee on Consolidation was developing its proposals.

When the result of the ballot was reported to Council on April 30th last, attention was naturally drawn to the desirability of ascertaining and, if possible, meeting the present views of the provinces named above. It was suggested that as a preliminary step it might be possible for members of Council to visit the Maritime or Prairie Provinces and confer informally with engineers there. As a result of such conferences it was hoped that at the Plenary Meeting of Council, which is to be held on June 14th, an idea could be formed of the views now held in those provinces, particularly as to the possibility of using the existing provisions in The Institute by-laws for the formation of Provincial Divisions as a basis for co-operation with the several Professional Associations.

It is encouraging to be able to announce that as a result of that discussion in Council President Desbarats has kindly undertaken to journey to Winnipeg within the next two or three weeks, while Mr. Busfield has been good enough to arrange for a visit to Halifax and Saint John. In these cities The Institute councillors are being asked to arrange for informal round table conferences with the officers of the Professional Associations in the hope that a clear mutual understanding may result.

Thus it will be evident that the result of the recent ballot does not close the "consolidation" chapter in the Institute's history, but clarifies the situation, and, it is hoped, opens the way for the development of a more acceptable programme for joint action between The Institute and the Professional Associations.

## Ballot on Amendments to By-laws 1937

The report of the scrutineers appointed by Council to canvass this ballot, was submitted and accepted at the Council meeting on April 30th.

The scrutineers certify the following results:—

*Vote I.* (Proposals submitted by the Committee on Consolidation, less subsection 7(*b*))
In favour .......... 677
Against .......... 780
Total valid ballots cast .......... 1,457
Affirmative votes required under Section 75 of the By-laws (2/3 of 1,457), 972.
This item therefore *fails* of adoption, lacking 295 affirmative votes.

*Vote II.* (Council's proposed version of Subsection 7(*b*))
In favour .......... 398
Against .......... 866
Total valid ballots cast .......... 1,264
Affirmative votes required (2/3 of 1,264), 843.
This item therefore *fails* of adoption lacking 445 affirmative votes.

*Vote III.* (Committee's version of Subsection 7 (*b*))
In favour .......... 540
Against .......... 758
Total valid ballots cast .......... 1,298
Affirmative votes required (2/3 of 1,298), 866.
This item therefore *fails* of adoption lacking 326 affirmative votes.

*Vote IV.* (Proposals not directly related to Consolidation, and affecting Sections 28 and 75 of the existing By-laws)
In favour .......... 1,150
Against .......... 227
Total valid ballots cast .......... 1,377
Affirmative votes required (2/3 of 1377), 918.
This item therefore *carries* by 232 votes.

As a result of these votes the proposals of the Committee on Consolidation fail to carry, and Sections 28 and 75 of the By-laws are amended to read as follows.

*Election and Transfer*

*Section 28.*—The council shall consider all the information with reference to each application, making further inquiries if deemed expedient, and shall then decide whether the application shall be accepted, and if so, to what class of membership the applicant shall be admitted. Before reaching this decision, however, not less than twenty-five of the forms referred to in section 27 must have been returned to the secretary, and the recommendations contained in these forms must be placed before council.

If five or more members of council oppose the admission or transfer of an applicant, he shall not be elected, otherwise **the affirmative** vote of three-quarters or more of those present **and** voting at a council meeting shall determine the classification of the applicant, with or without examination, and thereby constitute his election, subject to examination if so required.

A rejected candidate shall be notified promptly that his application has not been accepted, and he may renew his application for admission or transfer at any time after the expiration of one year from the date of his notification.

Application for membership in the class of Student shall be passed upon by council without the formality of notification to all councillors.

Amendments

*Section 75.*—(*a*) Proposals to introduce new by-laws or to amend or repeal existing by-laws shall be presented in writing to the council, signed by at least twenty corporate members, and shall reach the secretary not later than the first day of October. The council shall consider the proposals and the proposers shall be notified of the opinion of the council in regard thereto not later than the seventh day of November. The proposers may then withdraw their proposals, accept any changes suggested, or insist on the original form, sending their decision to the secretary not later than the fifteenth day of December. The proposals, as accepted by the proposers, shall be mailed to corporate members not less than twenty-one days before the annual general meeting. Proposals to introduce new by-laws or to amend or repeal existing by-laws, may also be made by the council and shall be mailed to corporate members not less than twenty-one days before the annual general meeting.

All proposals shall be submitted for discussion at the annual general meeting; the members there present may propose an amendment or amedments thereto, and all proposals together with such amendment or amendments **as are approved by the annual general meeting** shall be printed on a letter ballot to be submitted to the corporate membership of The Institute. The secretary shall issue the letter ballot not later than two months after the annual general meeting. The reasons advanced for and against the proposals edited by a committee appointed by the chairman consisting of an equal number of members favouring and members opposing the proposals shall accompany the letter ballot. The letter ballot shall be returnable to the secretary not later than three months after the annual general meeting. Scrutineers appointed by the council shall immediately thereafter count the ballots and report the result to the council.

An affirmative vote of two-thirds of all valid ballots shall be necessary for the amendment or repeal of existing by-laws, or for the adoption of new by-laws.

The by-laws as revised shall take effect forthwith, except that changes affecting the tenure of office of an officer of The Institute shall not take effect until the next annual election.

**(*b*) Notwithstanding anything to the contrary in this Section, the council may, at intervals of three years, strictly for purposes of clarification and simplification, reword any by-law or rearrange the by-laws. Such re-wording and/or re-arrangement shall become effective if and when it has been (*a*) approved by a majority of members of the council upon letter-ballot, (*b*) approved by the resolutions of the executive committees of a majority of The Institute Branches, (*c*) published in The Journal, and (*d*) finally approved, upon a formal motion to that effect, at a regular business session of an annual general meeting of The Institute.**

## International Conference on High Tension Electric Systems

The ninth biennial session of the International Conference on High Tension Electric Systems (C.I.G.R.E.) will take place in Paris from June 24th to July 2nd, 1937. This permanent organization was created in 1921 under the auspices of the International Electrotechnical Commission and its sessions are attended by delegates from different countries for the discussion of problems relating to the design, construction and operation of high tension electric systems. In 1935 there was an attendance of more than 1,200 representatives, largely from government departments and engineering and scientific organizations. At the forthcoming session in Paris over 100 technical papers will be presented from twenty different countries. Information regarding the conference may be obtained from Mr. F. Attwood, 50 Church Street, New York City, the President of the U.S. National Committee of the C.I.G.R.E.

## Special General Meeting of The Institute Monday, June 21st, 1937

The Council hereby gives notice that in accordance with Section 42 of the By-laws a *Special General Meeting of The Institute will be held at Headquarters at 10 a.m. on Monday, June 21st, 1937.*

The request for this meeting is dated April 30th, 1937, and reads as follows:—

> "We, the undersigned corporate members of The Engineering Institute of Canada, hereby request that a Special General Meeting of The Institute be called on Wednesday, June 16th, 1937, at 9.15 a.m., in a suitable room in the Windsor Hotel, Montreal, *for the purpose of receiving and discussing the results of the ballot on the By-laws of The Institute returnable on April 20th, 1937, and for the consideration of the general policy and administration of The Institute and for the taking of such action relative to the above matters as the meeting may consider to be in the best interests of The Institute,* all in accordance with Section No. 42 of the By-laws."

It is signed by the following sixty-one corporate members in good standing:—

| | | |
|---|---|---|
| P. E. Doncaster | M. H. Jones | James Weir |
| Geo. H. Burbidge | W. R. Hughson | Chas. M. McKergow |
| Hartvik Os | Dan Anderson | G. J. Dodd |

The above request was received and considered by Council at its meeting on Friday, April 30th, 1937. It was noted that on June 16th, the date suggested in the request, members would be in attendance at the sessions of the Semicentennial Meeting. For this reason, in the opinion of Council, the purpose of the special meeting would be better served by holding it on the first date available after the close of the Semicentennial Celebrations, namely June 21st, and this date was accordingly selected.

R. J. Durley,
*Secretary.*

Montreal,
May 1st, 1937.

## The Eighth Plenary Meeting of Council

The result of the ballot on Consolidation and the future policy of The Institute in connection with that important question, will be the principal item on the agenda for the Plenary Meeting of Council which has been called for Monday, June 14th, the day before the commencement of the Semicentennial Celebrations. This date was chosen to take advantage of the presence of many members of Council, and thus secure a fully representative gathering.

# OBITUARIES

## Robert Neale Blackburn, M.E.I.C.

It is with regret that we place on record the death of Robert Neale Blackburn, M.E.I.C., which took place at Ross-on-Wye, England, on March 31st, 1937.

Mr. Blackburn was born at Sefton, Lancashire, England, on September 1st, 1866, and was educated at the Liverpool School of Science, obtaining a Whitworth Scholarship in 1887. He took first class honours in mechanical engineering at the City and Guilds of London Institute

Robert Neale Blackburn, M.E.I.C.

in 1888. Mr. Blackburn served a six years' apprenticeship in the works of George Forrester and Company, Liverpool, and was for seven years with Thornewill and Warham, at Burton on Trent, becoming chief draughtsman in 1901. He was subsequently for five years engaged in private practice as a consulting engineer in Liverpool. Coming to Canada, Mr. Blackburn entered the service of the provincial government of Saskatchewan in 1908, as boiler inspector, and three years later was appointed Chief Inspector of Steam Boilers. In 1924 Mr. Blackburn became Chief Mechanical Superintendent, Department of Public Works, Saskatchewan, holding that office until he retired in 1931. During his official career at Regina, Mr. Blackburn's technical advice was sought on many important engineering questions affecting the welfare of the province, more particularly as regards the utilization of local fuel resources, the generation and distribution of electric power and the problem of water supply.

Mr. Blackburn joined The Institute as a Member on April 27th, 1920, and became a Life Member on December 15th, 1931. He took a keen interest in Institute affairs, having served as chairman of the Saskatchewan Branch, and as representative of that Branch on the Council of The Institute during the years 1923 to 1925.

## John Vickers Angus, A.M.E.I.C.

It is with deep regret that we place on record the sudden death in Montreal, on April 8th, 1937, of John Vickers Angus, A.M.E.I.C.

Mr. Angus was born at Stocksfield-on-Tyne, England, on March 29th, 1889, and was educated at Sheffield University, Rutherford College, Newcastle, and Armstrong College, Durham University. He was apprenticed to the Wallsend Slipway and Engineering Company Limited, shipbuilders and engineers, from 1907 to 1911, and from 1911 until 1914 was assistant superintending engineer with Ellerman Lines Limited. From 1914 to 1919 Mr. Angus was engineer officer in charge of machinery afloat in the Naval Reserve and Merchant services, and saw much active service, his experiences including that of being torpedoed. After the war Mr. Angus was for a year efficiency engineer with the Manchester Steam Users Association, and in 1921 became associated with the Armstrong Whitworth Company, coming to Canada in the same year as assistant general manager of their Canadian Company. In 1923 Mr. Angus returned to England and was assistant to the manager of the Disposal Corporation, the British Government organization that was responsible for the disposal of surplus war machinery, being in charge of the sale, removal and installation of power plant and other equipment until 1927. In that year he joined the staff of the Montreal Engineering Company, acting as their purchasing agent in London until 1929. He then returned to Canada as chief mechanical engineer, which position he held until his untimely death.

Mr. Angus joined The Institute as an Associate Member on March 21st, 1922.

## Frank D. Anthony, M.E.I.C.

It is with deep regret that we place on record the death at West Chicago, Ill., on March 16th, 1937, of Frank D. Anthony, M.E.I.C., a member of The Institute of many years' standing.

Mr. Anthony was born at Hamilton Mine, Michigan, on December 30th, 1860, and commenced his career with the Chicago and Northwestern and the Minneapolis, Sault Ste. Marie and Atlantic Railways, filling positions ranging from chainman to construction engineer. From 1888 until 1890 he was principal assistant engineer with the Duluth South Shore and Atlantic Railway, and in 1891 was engineer in charge of ore docks in Cuba for the Sigua Iron Company. In 1892 Mr. Anthony was in Guatemala as chief engineer with the Ferro Carril del Norte, and during the following three years was in charge of construction with the Duluth Mesal a and Northern, and other railways, at Duluth. Mr. Anthony was next, in 1896-1899, chief engineer with the New York and Ottawa Railway, and then became special engineer in charge of construction of a large ore dock at Superior, Wisconsin, for the Great Northern Railway. In 1900-1901 he was bridge engineer with the Algoma Central Railway, and for the next year was division engineer with the Cape Breton Railway. In 1902 Mr. Anthony became chief engineer for the Quebec Southern Railway. Later he joined the staff of the Delaware and Hudson Railway Company, being construction engineer and later general fire inspector with that organization. He retired in 1928.

Mr. Anthony joined The Institute (then the Canadian Society of Civil Engineers) as a Member on December 18th, 1902, and was subsequently placed on the Life Membership List.

## Geoffrey Robertson Milne, S.E.I.C.

It is with deep regret that we place on record the death by drowning at Sorel, Que., on April 23rd, 1937, of Geoffrey Robertson Milne, S.E.I.C. Mr. Milne jumped to the rescue of a deck-hand who fell overboard, and both were drowned.

Mr. Milne was born at Newcastle-on-Tyne, England, on October 30th, 1901, and was educated in that country. He was for several years structural draughtsman with the Welland Ship canal at St. Catharines, Ontario, and later joined the staff of Lambert and German, naval architects, Montreal. In 1930 Mr. Milne became connected with the Manseau Shipyards Limited, and remained with that company until his untimely death, having been made assistant superintendent of the company in 1935.

Mr. Milne became a Student of The Institute on December 21st, 1921.

### John Thomas Morkill, M.E.I.C.

It is with regret that we place on record the death at Sherbrooke, Que., on April 14th, 1937, of John Thomas Morkill, M.E.I.C., a member of The Institute of many years standing.

Mr. Morkill was born at Sherbrooke, Que., on June 10th, 1856, and in the spring of 1874 began his engineering career as a rodman with the Quebec Central Railway. Later he acted as leveller and transitman on construction, and subsequently became an assistant engineer on construction. In 1881 he went to Brazil and was an assistant on the construction of the Imperial Brazilian Natal and Nova Cruz Railway; in 1883 and 1884 he was engaged on railway work in Nova Scotia. In the latter year he again joined the staff of the Quebec Central Railway, becoming chief engineer of that organization in 1905. Mr. Morkill's work took him to many parts of the continent, and he was at various times located in Nevada, Idaho, California, British Columbia, New Brunswick, Ontario and Quebec. In later years, Mr. Morkill was engaged in private practice in Sherbrooke.

Mr. Morkill joined The Institute (then the Canadian Society of Civil Engineers) as a Member on March 22nd, 1888, and became a life member on January 18th, 1928.

### Arthur Langley Mudge, M.E.I.C.

The membership of The Institute will learn with regret of the death at Toronto on April 29th, 1937, of Arthur Langley Mudge, M.E.I.C.

Mr. Mudge was born at Montreal on October 17th, 1873, and was educated at the Montreal High School and McGill University, graduating from the latter institution in mechanical engineering in 1894 and in electrical engineering in 1895. He spent some years in Canada and the United States in electrical testing, construction, estimating etc., and from 1899 to 1901 was electrical engineer to the Grand Trunk Railway, with headquarters at Montreal. In 1908 Mr. Mudge joined the staff of the consulting engineering firm of Smith, Kerry and Chace, of Toronto. For fifteen years he devoted his attention mainly to water power development and industrial electrical engineering, during which time he acted as chief electrical engineer on such works as the series of water power developments on the Trent river, the Calgary Power Company development at Horseshoe Falls, the Matabitchouan plant in northern Ontario, and the Calabogie Light and Power Company project on the Madawaska river. In 1925 Mr. Mudge was appointed power plant engineer on the staff of the Canadian section of the Joint Engineering Board of the St. Lawrence Deep Waterways Project, and in the same year joined the service of the Department of Railways and Canals at Ottawa. He subsequently became senior electrical engineer for the Welland Ship Canal at St. Catharines, Ontario, retiring from that office about three years ago to settle near Toronto.

Mr. Mudge, who was the first president of the Canadian Electrical Association, and a past-chairman of the Toronto section of the American Institute of Electrical Engineers, was also very active in Institute affairs.

He was a member of The Institute of many years standing, having joined as a Student on March 29th, 1894. He became an Associate Member on March 15th, 1899, and a Member on September 15th, 1925.

## PERSONALS

R. Weir, A.M.E.I.C., has recently been appointed industrial sales engineer for the province of Quebec by Imperial Oil Limited. Mr. Weir has been with that company for the past four years.

H. W. Tooker, A.M.E.I.C., was recently elected chairman of the Calgary Branch of The Institute. Mr. Tooker is in the Divisional Engineer's Office of the Canadian National Railways at Calgary, Alta.

A. U. Sanderson, A.M.E.I.C., chief engineer, Water Supply Section, Department of Works of the City of Toronto, has been elected chairman of the Toronto Branch of The Institute for the current year.

J. G. Chenevert, M.E.I.C., and E. Nenniger, A.M.E.I.C., have recently become partners in the firm of Arthur Surveyer and Company, consulting engineers, Montreal.

Mr. Chenevert graduated from the Ecole Polytechnique, Montreal, with the degree of B.A.Sc. in 1923, and has been associated with the organization of which he now becomes a partner, since that time.

Mr. Nenniger graduated from the Technical School at Burgdorf in 1921, and following graduation was for several years designing engineer in the office of W. Schreck, Dipl.

J. G. Chenevert, M.E.I.C.

E. Nenniger, A.M.E.I.C.

Ing. in Switzerland. He came to Canada in 1923, and joined Dr. Surveyer's staff in the same year.

Arthur Piché, Jr.E.I.C., who is on the staff of the Department of Public Works of Canada, has been transferred from Terrebonne to Quebec, Que. Mr. Piché graduated from the Ecole Polytechnique, Montreal, in 1930, and later was combustion engineer with Anthracite Coal Service, Montreal. In 1935 he was an engineer with the Department of Agriculture at Victoriaville, Que.

Alexander Rose, s.e.i.c., is now employed as assistant in the leather laboratories of the Division of Chemistry, National Research Council, Ottawa. He was previously connected with Donald-Hunt Limited, and Canadian Copper Refiners, Limited.

E. V. Buchanan, m.e.i.c., general manager of the Public Utilities Commission, London, Ontario, was elected chairman of the Canadian Section of the American Water Works Association, at the meeting of that organization held recently in Montreal.

Virgil S. Upton, s.e.i.c., has joined the staff of Bennett Aircraft Incorporated at San Fernando, Calif. Mr. Upton, who was formerly with the Noorduyn Aircraft Company at St. Laurent, Que., graduated from the University of Saskatchewan in 1935, with the degree of B.Sc.

Bernard Collitt, m.e.i.c., metallurgist for Jenkins Brothers Limited, Montreal, was elected chairman of the Montreal Chapter of the American Society for Metals at the Annual Meeting of the Chapter held on May 3rd.

C. E. Garnett, m.e.i.c., vice-president of Gorman's Limited, Edmonton, Alta., was elected President of the Association of Professional Engineers of Alberta, at the annual meeting of the Association which was held on March 20th, 1937.

G. J. Jarrell, jr.e.i.c., has become connected with the Willard Storage Battery Company of Canada Limited, at Toronto, Ontario. Mr. Jarrell, who graduated from the University of Toronto in 1935 with the degree of B.A.Sc., was formerly with Beatty Brothers, at Fergus, Ontario.

E. G. Eggertson, a.m.e.i.c., has joined the staff of the American Gas and Electric Company, New York, N.Y., as assistant electrical engineer. Mr. Eggertson, who is a graduate of the University of Manitoba, was for a time with the Aluminum Company of America at Pittsburgh, Pa., and subsequently with the Safe Harbour Water Power Corporation, at Baltimore, Md.

F. Irvine, a.m.e.i.c., who was formerly assistant engineer with F. S. B. Heward and Company Limited, has become associated with Peacock Brothers Limited, Montreal. Mr. Irvine was at one time combustion engineer with the Cleaton Company (Canada) Limited, and then sales and service engineer with Affiliated Engineering Companies Limited.

T. Foulkes, jr.e.i.c., who recently became connected with Canadian Cottons Limited, at Valleyfield, Que., graduated from the University of New Brunswick in 1926 with the degree of B.Sc. Following graduation Mr. Foulkes took the students' test course with the Canadian General Electric Company and in 1927-1928 was in the induction motor engineering department of the same company. In 1928 he joined the staff of the Spruce Falls Power and Paper Company at Kapuskasing, Ont., and was engaged on general electrical maintenance and installation and in 1929 he became engineer on maintenance, which position he has held up to the present time.

R. Eric Crawford, a.m.e.i.c., has resigned from the advertising department of Dominion Engineering Company Limited to become assistant superintendent of the Bagley and Sewall Company, Watertown, N.Y. Mr. Crawford, after graduating from McGill University in 1922, joined the Dominion Engineering Company in the production department, from which he was transferred in turn to the estimating department and sales department, entering the advertising department in 1928.

Don B. Sommerville, jr.e.i.c., has joined the staff of the International Petroleum Company, and will be located at Talara, Peru. Mr. Sommerville graduated from the University of Toronto in 1935 with the degree of B.A.Sc. and in the same year was an instrumentman with the Geological Survey of Canada. In 1936 he was a draughtsman with the Department of National Defence, and subsequently was structural engineer with the Canadian Comstock Company.

F. H. Cothran, m.e.i.c., consulting engineer, Charlotte, N.C., has been elected President of the Piedmont and Northern Railway and the Durham and Southern Railway, with offices at Charlotte, North Carolina. Mr. Cothran was at one time vice-president of the Quebec Development Company, in charge of construction on the Saguenay river projects, and in 1929 was connected with the Beauharnois Construction Company, Beauharnois, Que.

At the Annual Meeting of the Canadian Institute of Mining and Metallurgy held in Montreal recently, Professor H. E. T. Haultain, m.e.i.c., professor of mining engineering at the University of Toronto, was the recipient of the Bruce Gold Medal for the year 1936. This medal, which was instituted by the Honourable Randolph Bruce, is awarded at the discretion of the Council of the Canadian Institute of Mining and Metallurgy to those who have made outstanding contributions to the arts of mining and milling.

W. E. Lovell, m.e.i.c., Professor of Electrical Engineering at the University of Saskatchewan, Saskatoon, Sask., was elected President of the Association of Professional Engineers of the Province of Saskatchewan, at the annual meeting of the Association which was held recently. Professor Lovell graduated from the University of Manitoba in 1921 with the degree of B.Sc., and was subsequently with the Manitoba Power Company. In 1923 he became assistant professor of electrical engineering at the University of Saskatchewan, and in 1928 received the appointment which he still holds.

Hugh J. Leitch, a.m.e.i.c., who was formerly manager of the warehouse department of the Dominion Bridge Company, Lachine, Que., is now manager of the Sault Structural Steel Company Limited, at Sault Ste. Marie, Ontario. Mr. Leitch graduated from McGill University in 1926 with the degree of B.Sc., and was subsequently resident engineer for the Steel Gates Company Limited, on the erection of the lock gates of the Welland Ship Canal. In 1929 he joined the staff of the Dominion Bridge Company as assistant engineer in the designing department, and in 1933 received the appointment from which he has now resigned.

W. S. Wilson, m.e.i.c., who has been Secretary-Treasurer of the Toronto Branch of The Institute since 1931, is now retiring from that office.

Mr. Wilson graduated from the University of Toronto in 1921 with the degree of B.A.Sc., having been overseas with the Canadian Expeditionary Force from 1915 to 1919, holding the ranks of lieutenant and captain. In 1921-1922 Mr. Wilson was engaged on estimating and supervising construction work with Wilson and Falconer, and in 1922-1923 was estimator with Dowling-Williams Limited. From 1923 until 1926 he was demonstrator in the Department of Engineering Drawing, University of Toronto, and in the following year was with R. W. H. Binnie, general contractor, as estimator. In 1927 Mr. Wilson was appointed secretary of the Faculty of Applied Science and Engineering of the University of Toronto, which position he still holds.

## Elections and Transfers

At the meeting of Council held on April 30th, 1937, the following elections and transfers were effected:

*Members*

OGILVIE, Gordon, Lt.-Col., C.M.G., Director (Civilian) of Munitions, Department of National Defence, Ottawa, Ont.

REID, Wilfrid Thomas, President, Crude Oil Engine and Engineering Co. Ltd., Montreal, Que.

*Associate Members*

DUGAS, Joseph Esdras Armand, B.A.Sc., C.E., (Ecole Polytech.), industrial lighting divn., Montreal Light, Heat and Power Cons., Montreal, Que.

MARCHAND, Raymond, B.A.Sc., C.E., (Ecole Polytech.), res. engr., Dept. of Roads, Province of Quebec, Quebec, Que.

MILLETT, Ralph Strathie, B.Sc., (Mech.), (N.S. Tech. Coll.), forest products engr., Forest Products Labs. of Canada, Ottawa, Ont.

SNAPE, John Ball, res. engr., Jasper National Park, Jasper, Alta.

WHITE, Arthur Floyd, transitman, Toronto, Hamilton & Buffalo Rly., Hamilton, Ont.

*Juniors*

DUNNE, Charles Vincent, B.Eng. (McGill Univ.), constrn. engr., E. B. Eddy Co., Hull, Que.

MARTIN, Gerald, B.A.Sc., C.E., (Ecole Polytech.), boiler designer, Dominion Bridge Co. Ltd., Montreal, Que.

MORENCY, John, B.A.Sc., C.E., (Ecole Polytech.), engr., Parkhill Gold Mines Ltd., Gold Par P.O., Wawa, Ont.

*Transferred from the class of Associate Member to that of Member*

WIGHTMAN, John Fredrick Carman, (Mt. Allison Univ.), town manager and engr., Kentville, N.S.

*Transferred from the class of Junior to that of Associate Member*

ANDREWES, William Edward, Capt., R.C.E., (Grad., R.M.C.), B.Sc., (McGill Univ.), District Engineer Officer, Mil. Dist. No. 1, London, Ont.

BLACKMORE, Cyril Leslie, B.Sc., (McGill Univ.), President, C. L. Blackmore & Co., 1118 St. Catherine St. West, Montreal, Que.

FOULKES, Thomas, B.Sc., (Univ. of N.B.), Canadian Cottons Ltd., Valleyfield, Que.

PAULSEN, Rudolph O., B.Sc., (Univ. of Man.), struct'l. dftsman., Toronto Iron Works, Eastern Ave., Toronto, Ont.

*Transferred from the class of Student to that of Associate Member*

CAREFOOT, Herbert Reginald, Fl.-Lieut., R.C.A.F., B.Sc., (Univ. of Sask.), R.C.A.F., Headquarters, Ottawa, Ont.

DORE, Richard Francis, B.Sc., (Queen's Univ.), junior topog'l. engr., Bureau of Economic Geology, Dept. of Mines and Resources, Ottawa, Ont.

SAVAGE, Palmer Ernest, B.Sc., M.Eng., (McGill Univ.), struct'l. designer, Dominion Bridge Co. Ltd., Montreal, Que.

*Transferred from the class of Student to that of Junior*

COLGAN, Patrick Joseph, B.Sc., (N.S. Tech. Coll.), Cosmos Imperial Mills, Yarmouth North, N.S.

DALE, John Clapham, B.Sc., (Univ. of Alta.), Canadian Utilities Ltd., Calgary, Alta.

WESELAKE, Edward Joseph, B.Sc., (Univ. of Man.), Ste. 1, 503½ Selkirk Ave., Winnipeg, Man.

*Students Admitted*

**Students at McGill University**

ALEXANDER, John Andrew, 209 Strathearn Ave., Montreal West, Que.
ARCHAMBAULT, George, 288 McDougall Ave., Outremont, Que.
BUBBIS, Morris Israel, 3471 Hutchison St., Montreal, Que.

WALLER, Jack Jason, B.Eng., (McGill Univ.), 3797 Decarie Blvd., Montreal, Que.

## The Late Dr. Elihu Thomson

Members of The Engineering Institute of Canada will learn with regret of the death at Swampscott, Mass. on March 13th, 1937, of Dr. Elihu Thomson, who was a brother of the late Frederick Thomson, M.E.I.C., of Montreal, who died on August 8th, 1936.

By the death of Dr. Thomson, world electrical engineering has lost one of its greatest and most widely-esteemed leaders, a man who for very many years through his scientific inventiveness, research and industry, contributed to the electrical advance which has been spread over the last fifty to sixty years.

Dr. Thomson was born in Manchester, England, in March 1853, and was brought to the United States at the age of five, in 1858. In 1880, Elihu Thomson and Dr. Houston, both of them teachers, began a collaboration which was destined to have far-reaching results. Dr. Thomson was the founder of the original Thomson-Houston Company, from which the B.T.H. Company developed. The manufacturing and associated operations of Thomson and Houston became so extensive by 1892 that it was decided to merge the organization with the Edison General Electric Company, the two businesses being combined under the title of the American company now so well known as the General Electric Company.

As is well known, honours fell to Dr. Thomson from all directions, the Royal Society awarded him the Hughes Medal, the Institution of Electrical Engineers the Faraday Medal, American Science the John Fritz Medal, and German engineers the Grashof Medal. He was an honorary member of the Institution of Electrical Engineers, the Institution of Civil Engineers and the Royal Institution; a past-president of the American Institute of Electrical Engineers, of the International Electrical Congress at St. Louis, and the International Electrotechnical Commission at Turin. He was also an officer of the Legion of Honour.

## CORRESPONDENCE

The Editor, March 31st, 1937.
The Engineering Journal,
Montreal.

Dear Sir:—

The paper published in the January issue of The Journal under the title "Heat Insulation for Buildings" by Professor E. A. Allcut is very interesting. We hope that everyone in Canada will eventually become acquainted with the importance of thermal insulation and the fuel savings possible through it.

There is one statement which seems to call for comment, namely, that the thermal conductivity varies with the thickness or size of the sample. If this is true, it will be very disturbing to engineers and architects who must use these figures in computing heating loads. Professor Allcut shows that he obtained different results on samples of different thicknesses. This can be due to either an actual change in the "$k$" value or to uncertainty in the measurements. In regard to the former, it is very difficult to understand in a material consisting of minute cells why the first inch should be different than the second or the succeeding inches of thickness. In respect to the latter explanation, it should be pointed out that with increasing thickness smaller heat transfers are involved and more difficulty is experienced in maintaining the parallel line of flow, or in other words, to prevent losses to or gains from the room. This, in other words, means a higher percentage error in the measurements. Professor Allcut recognizes this point as per his statement that "it was impossible to test a thick specimen in a small plate on account of the large edge losses that would be obtained." In this connection also, he points out "That the size of the apparatus in relation to the thickness of material should be standardized."

It is our belief that because of the two possible explanations of the differences it has not been shown that the "$k$" value varies with the thickness, and in as much as this conclusion is very disturbing, we should like to protest the point and consider it a matter requiring further investigation. We will appreciate having this note published.

Very sincerely yours,

H. C. Bates,
Chief, Fibre Products Laboratory

Corning Glass Works,
Corning, New York.

---

The Editor, April 6th, 1937.
The Engineering Journal,
Montreal.

Dear Sir:—

In reply to Mr. Bates' letter dated March 31st, 1937, commenting on one aspect of my paper "Heat Insulation for Buildings," I may say that some years ago my attention was directed to the influence of thickness on the apparent heat conductivity of insulating materials, when I compared the results obtained by different laboratories on fibre boards of similar composition and density, but of different thicknesses. In all cases, higher values were obtained with increasing thickness. Similar tests made at the University of Toronto produced the same results, which are difficult to account for other than by the hypothesis of surface resistance. When the investigation was extended to include packed fibrous materials, we were surprised to find that in these cases also, the value of "$k$" increased with thickness. It was at once assumed that the results were wrong and several months were spent in checking the apparatus and technique, but no appreciable source of error was discovered. Since that time, numerous tests have been made on packed materials of different kinds and all of these have confirmed the original results.

I fully appreciate the force of Mr. Bates' arguments, but these results have been obtained repeatedly and a reasonable explanation must be found for them. The suggestion that edge losses are contributory factors does not apply in this case, as the edges of the large specimens were shielded from the atmosphere by thick insulation, and the mean temperature, in most cases, was very close to that of the atmosphere. There is some evidence, however, to indicate the presence of convection inside the specimens.

I agree with Mr. Bates that more experimental work is desirable and propose to continue this investigation during the summer of 1937. The detailed evidence obtained up to this date will be available in published form during May 1937.

The principal object of the paper, however, was not to compare one class of insulating material with another, as their relative merits are mostly unaffected, but to call attention to the need for proper standardization of the methods and apparatus for testing heat insulating materials so that the results obtained may be more valuable both for purposes of comparison and application.

Yours faithfully,

E. A. Allcut, m.e.i.c.

Department of Mechanical Engineering,
University of Toronto,
Toronto 5, Canada.

## Recent Additions to the Library

### Proceedings, Transactions, etc.

Institution of Water Engineers: Transactions, 1936.
Punjab Engineering Congress: Proceedings, 1936.
American Society of Civil Engineers: Transactions, 1936.

### Reports, etc.

*Dominion Bureau of Statistics:* Preliminary report on the Mineral Production of Canada, 1936.
*Port of New York Authority:* 16th Annual Report, December, 1936.
*National Parks of Canada:* Annual Report 1935-1936.
*American Institute of Consulting Engineers:* Constitution, By-laws and List of Members, 1937.
*New Brunswick Electric Power Commission:* 17th Annual Report, for the year ending October 31st, 1936.
*Quebec Bureau of Mines:* Annual Report 1935, Part A.
*Ontario, Dept. of Mines:* Preliminary Report on the Mineral Production of Ontario in 1936.
*National Harbours Board:* Annual Report, 1936.
*Nova Scotia Power Commission:* 17th Annual Report for the year ending November 30th, 1936.
*Montreal Board of Trade:* Report of Special Committee appointed to study the basis of motor truck registration and regulations governing highway transportation in the province of Quebec.

Standard Specifications for Arc Welding Metal Bridge Structures, 1935.

### Technical Books, etc.

History of Munitions Supply in Canada, 1914-1918, by D. Carnegie (*Longmans, Green and Company.*)
Metallic Corrosion Passivity and Protection, by Ulick R. Evans (*Edward Arnold and Company, London.*) (*Longmans, Green and Company, Toronto.*)

## BULLETINS

*Water Tube Boilers.*—An 8-page pamphlet issued from Canadian Vickers Limited, Montreal, gives details of their Vickers-Keeler water tube boilers. Seven different types of furnace arrangement are illustrated. It is stated that these can be modified to meet the requirements of any type of combustion equipment.

*Motor Truck Scales.*—Canadian Fairbanks Morse Company Ltd., Sherbrooke, Que., have issued a 6-page folder describing their type S motor-truck beam scales. These are made in capacities of 10 to 20 tons, with varying sizes of platforms.

*Motors.*—A 6-page bulletin, No. 42, received from Bepco Canada Ltd., Montreal, illustrates their Corcooled motor. This is manufactured by the Lancashire Dynamo and Crypto Ltd. and is a totally enclosed motor produced for both a.c. and d.c. types, available in either squirrel cage or slip ring type from 30 h.p. upwards.

*Pumps.*—The Worthington Pump and Machinery Corporation, Harrison, N.J., have issued a 4-page leaflet describing their balanced multi-stage volute centrifugal pumps for boiler feed service in three sizes with capacities from 200 to 1,500 r.p.m., pressures up to 1,200 lb. per sq. in.

*Motors.*—A 4-page circular received from the Canadian General Electric Company Limited describes their high-speed synchronous motors, 7,000 series, manufactured in a large range of sizes from 25 to 200 h.p. with varying r.p.m.s.

*Caterpillar Diesels.*—A 12-page booklet received from the Caterpillar Tractor Company, Peoria, Ill., illustrates the various uses of Caterpillar Diesels in connection with the construction of roads.

---

The March number of the Royal Engineers' Journal contains an interesting and complete article on "Coast Protection on the North Sea Coasts of Holland, France, Belgium and Germany." The author, Mr. van der Burgt, is engineer of the Netherlands State Waterways Administration, and the article has been translated and printed by permission from "De Ingenieur." The problem of coast protection is a vital one in Holland, and the paper, which is fully illustrated, forms a remarkable record of the achievements of Dutch engineers in this class of work. Reprints of the paper may be had from the Editor, Royal Engineers Journal, Chatham, Kent, England, at the cost of 2s. 6d. post free.

## BOOK REVIEWS

### Cyanidation and Concentration of Gold and Silver Ores

*By John Van Nostrand Dorr. McGraw-Hill Book Company, New York. 1936. 6 by 9¼ inches. $5.00. Cloth. 485 pages.*

Mr. Dorr's achievements in the development of the art of cyanidation and concentration are so outstanding as to win for him the admiration and respect of all interested in the industry. It is indeed fortunate that he has been able to find time to write a book which, as was to be expected, is excellent.

Following an introductory historical chapter, is a discussion of the examination and testing of ores. Four chapters follow in which the preparation of ore for cyanidation is covered by a description of coarse crushing, sorting, fine grinding and classification. Sand and slime treatment are fully considered and in this is included a description of types of equipment and examples of practice. Concentration of ores and treatment of concentrates, bullion recovery and plant control are covered in three rather extensive chapters. Of interest is the section on the treatment of simple and complex ores which includes descriptions of plant equipment and numerous flow sheets, in which particulars are given for some fifty mills in all parts of the world, handling a large variety of ores. Treatment of old residues is covered in a further chapter and costs and power consumption receive considerable attention details being given for a large number of mills. Chapter 15 contains useful reference information and includes a table of elements, general conversion factors, a list of metals and minerals based on information from Dana's text book of mineralogy, tables on slime density relations, and finally a list of books on cyanidation.

### Engineering Geology

*By H. Ries and the late Thos. L. Watson. John Wiley and Sons Inc., New York (Renouf Publishing Company, Montreal). 1936. 6¼ by 9¼ in. $5.00. 750 pages. Cloth.*

Engineering Geology was first published in 1914, and a fourth edition appeared in 1931. The present, the fifth edition, comprises nineteen chapters, and has been considerably revised, with new bibliographical references added. This volume contains an excellent presentation of the fundamental principles of geology relating to engineering problems.

The opening chapter covers rock forming minerals, and is followed by one dealing with rocks, their general characters, mode of occurrence and origin. Chapters on the structural features of rock will be of particular interest to engineers as well as those on rock weathering and soils. Surface and sub-surface waters, landslides and land subsidence, wave action and shore occurrence, the origin and structure of lakes and glacial deposits are comprehensively covered. Chapter II, on the geology of reservoirs and dam sites is new, the author stating that "the geologic examination of reservoirs and dam sites has within the last few years become a matter of recognized importance, its necessity having been well emphasized by the leakage from a number of reservoirs or the failure of dam sites due to unfavourable geologic conditions."

Building stone, lime, cement and plaster, and clay and clay products are covered in three chapters of some one hundred pages and chapters on coal series, the micro-constituents of coal, types of coal and effect of constituents, petroleum, natural gas and other hydro carbons follow.

The closing chapters cover road foundations and materials, ore deposits and historical geology.

The book is printed on good quality paper and the type is easy to read. The contents are well indexed.

Practising engineers who have problems related to geology might well add this volume to their library.

## Symposium on the Burning of Canadian Coal at Semicentennial Meeting

### Summaries of Papers to be Presented

#### British Columbia Coals in Metallurgy

*R. R. McNaughton*

This paper sketches the distribution and character of British Columbia coal fields in which the coals range from lignite to high carbon bituminous, many of the latter coals being suitable for coking. Factors influencing the selection of coals are covered in some detail, also the application of coal in metallurgy. Factors involved in the design of a powdered coal plant are described, and the advantages and disadvantages of types of equipment are discussed.

#### The Burning of Low Rank Alberta Coals, The Steam Generating Plant

*Professor C. A. Robb, M.E.I.C.*

The author deals with the development of the steam generating plant in central electric stations burning low rank Alberta coals. He discusses plants and their equipment with performance data and trends in design. At the end of 1934 the installed capacity of fuel burning stations was 166,959 kv.a. and the kilowatt hours generated, 185,865,000. One of the largest steam generators in Canada is in operation at a Regina plant, and consists of a bent tube boiler, combination superheater and a tubular air preheater. The furnace has one steam-cooled and three water-cooled walls, and may be fired by pulverized fuel or gas or both. Bituminous coal or lignite is prepared by a unit system.

#### The Burning of Low Rank Alberta Coals, Combustion and Control

*Edgar Stansfield, M.E.I.C.*

This paper presents recent developments in the methods and conception of coal analysis, and with their significance in combustion problems, and provides data relative to combustion. Coals taken as samples are all from Alberta, but the discussion is applicable to the combustion of any coal. The low rank coals are studied by comparison with those of high rank.

#### Experience in Burning Western Canadian Coals

*E. W. Bull*

This paper covers experiences in burning coal lignites and bituminous coal with stokers and pulverized fuel equipment installed in the Regina power plant. This plant started originally with underfeed stoker fired boilers operating at 200 lb. pressure, but is now equipped with modern pulverized fuel equipment.

#### The Saskatchewan Lignite Industry

*R. L. Sutherland*

The author describes recent developments in the Saskatchewan lignite industry and the effect of production methods on employment and the earnings of labour. This industry owes its existence to its geographical position and proximity to the most densely populated area of the Prairie Provinces, and its future development will depend on the extent to which production methods are adopted which require minimum capital investment in relation to the production value, and which at the same time reduces the present seasonal fluctuation in employment to a minimum. The annual production has increased from about 500,000 tons to more than a million tons since 1929, which has been effected in competition with coal from other western provinces and imported from western lake ports. The author gives reasons for the increased use of lignite in industrial plants, and outlines the expansion of mining plants to produce increased tonnage. In the author's opinion the experience of the past seven years indicates that stabilization of the industry to ensure fair wages, a fair return to the operator and value to the customer can best be effected if certain definite policies which he outlines are followed.

#### Characteristics and Qualities of Nova Scotian Coals

*F. H. Sexton*

The excellent bituminous coals in Nova Scotia are the basis of a large industry which supports some 60,000 people, and due to the fact that the St. Lawrence river offers a means of cheap transportation, Nova Scotian producers are able to supply most of the soft coal requirements from the Maritime Provinces to Montreal. There has been a dearth of technical and scientific data concerning Nova Scotia coals, as while an extensive investigation was made some twenty years ago, conditions to-day are somewhat different. Recent investigations, however, conducted at the Nova Scotia Technical College cover tests and trials of four different kinds, and include chemical analyses, standard boiler trials, a series of efficiency trials in hot-water boilers for domestic heating, and weathering tests of stored coal. The results of these extensive tests are given in detail by the author.

#### The Economic Use of New Brunswick Coal

*John Stephens, D.Sc., M.E.I.C.*

The workings of the New Brunswick coal field are the oldest in North America, but the output has so far not exceeded 900,000 tons a year. The coal, while in general local use for railway and industrial purposes, has been described previously as a difficult coal to handle continuously at high ratings. The author gives operation results, complete with cost data, on this coal used at the Grand Lake plant of the New Brunswick Hydro-Electric Power Commission, and proves that there is no physical difficulty in connection with its combustion. The average energy content of the coal used is 12,000 B.t.u. per lb. with an ash content of 16 per cent. With reasonable capital and maintenance costs a kilowatt can be produced with less than 1.6 lb. of fuel.

#### Some Observations on the Use of Bituminous Coal as Locomotive Fuel

*John Roberts*

The purchasing, distribution and economical consumption of coal on any large railway system presents a complex problem as may be gauged by the fact that the total coal bill for the Canadian National system for 1936 amounted to over $18,000,000. The quality of the coal obtained from the many different seams varies widely, and the resulting problems of the mechanical and fuel departments of the railway are discussed in the paper. The author gives an explanation of the modern locomotive boiler and describes its evolution over the past one hundred years. Combustion conditions and locomotive services are entirely different from those in any other type of steam generator, for in addition to providing for efficient generation of steam, other difficulties have to be faced, such as fire hazard and smoke nuisance. The fuel consumption of the Canadian National Railways per 1,000 gross ton miles from 1923 to 1936 amounted to over 22 per cent, notwithstanding the adverse effect of high operating expenditure. During this period the average freight train speed increased by over 39 per cent.

# BRANCH NEWS

## Border Cities Branch

*J. F. Bridge, A.M.E.I.C., Secretary-Treasurer.*
*F. J. Ryder, Jr.E.I.C., Branch News Editor.*

### The Future of Private Aviation

The March monthly meeting of the Border Cities Branch of The Institute was held in the Prince Edward hotel, Friday, March 19th, 1937, at 6.30 p.m.

Dinner was served to fourteen people, three of whom were visitors. Twenty-one attended the lecture immediately afterwards.

Minutes of the February meeting were read and adopted. C. F. Davison, A.M.E.I.C., chairman, presided.

Dr. H. F. Gerhardt, Professor of Aero Engineering, Wayne University, Detroit, was introduced by Boyd Candlish, A.M.E.I.C., as the speaker of the evening, and had as his subject, "The Future of Private Aviation." He traced the history of aviation from the time man first tried to fly by imitating the action of birds on the wing to the present day planes. He pointed out that it was hopeless for man to ever expect to fly by his own power, as his weight per horse power developed was in the range of 2,400 to one, whereas it has been found that with most recent planes, this bears the ratio of 1½ lb. per hp.

Dr. Gerhardt pointed out that the future private plane must be an automobile with aerodynamic accessories, so that it could be used for land transportation and go into the air occasionally. It must be capable of vertical ascent and descent, and have folding or removable wings which could be stored at the hangar. He was firmly of the opinion that the miniature plane was not the answer to private aviation. The lecture was illustrated by slides.

A hearty vote of thanks was moved by Mr. Porter and tendered to the speaker by the chairman.

Meeting adjourned at 10.30 p.m.

The regular monthly dinner meeting of the Border Cities Branch was held in the Prince Edward hotel, on Friday evening, April 16th, 1937, with nineteen persons present.

O. M. Perry, M.E.I.C., introduced the speaker for the evening, Professor Levy of Toronto, who is well known for his lectures and practise in psychology. Professor Levy's subject was "The Human Map Speaks for Itself."

As a psychologist, Professor Levy has been practising for thirty-eight years. He does not claim infallibility for his profession, but does claim that it is the best method of determining the characteristics of a man and how to judge that man from them.

Modern psychologists have three methods of judging man:

1. The Imperial method is mainly guess work as it depends upon the ability of the psychologist to judge a person from outward physical signs only. This is not used much as there is too much guess work.
2. The anthropathological method is the science of determining man's characteristics biologically and ethnographically.
3. The Psychological method considers the first two methods along with certain definite tests and measurements.

If any of the laws of God or man are broken by a person it has its effect on their characteristics, to the psychologist, the posture, walk, tone of voice, laughter, cleanliness of body and any outward peculiarities all mean something. (However, they must be considered in relation with other tests.)

The most important part of the psychologists work is the corelating of the tests and observations so as to deduce the correct result.

Professor Levy has been employed by a good number of firms to study the characteristics of their employees in order to ascertain their best qualities and to place them where they are best fitted.

C. M. Goodrich, M.E.I.C., moved a hearty vote of thanks which was seconded by W. H. Baltzell, M.E.I.C., and heartily approved by all.

## Hamilton Branch

*A. R. Hannaford, A.M.E.I.C., Secretary-Treasurer.*
*W. W. Preston, S.E.I.C., Branch News Editor.*

The annual joint meeting of the Hamilton Branch of The Institute and the Toronto Section of the American Institute of Electrical Engineers was held on April 9th, 1937, in the Westinghouse auditorium.

On this evening the engineers were the guests of the Canadian Westinghouse Company and the speaker was Dr. L. W. Chubb, Director of Research, Westinghouse Electric and Manufacturing Company, Pittsburg. His subject was entitled Industrial Progress Through Science and Research and was illustrated.

The attendance at this meeting was 293.

The opening remarks of Dr. Chubb pointed out that there is no "last word" in achievement and the time will not likely come when the engineer finds there is nothing for him to improve. Ideas are continually ripening from what has gone before and hindsight is better than foresight. Through improvements developed in the laboratories of our universities and industries by science and research, we are ever pushing back the frontiers of industry.

Frequently the problem of the research engineer is to develop a new material or process. If there is not a suitable metal for the job on the market, the metallurgist is given the desired properties and asked to make a new alloy. Indeed, metallurgy has developed from an art to a science.

In the car industry, Dr. Chubb stated that a heat treatment used to take half an hour but has been reduced to eight minutes as a result of a scientific investigation.

Another field of research is found in the study of the fundamentals of science. It is a long term work; there is no immediate application of such knowledge to industry, and the only justification for undertaking it, is the hope that continual study will reveal its usefulness. Just as Neon rose from a laboratory curiosity to a commercial product, so it is hoped that present investigations on the breaking of atoms will some day have commercial value.

Dr. Chubb concluded his address with a number of illustrations and demonstrations showing the results of research. He referred to the Streule lamp used in the operating room to prevent infection and after operation fever. Several experiments with polarized light proved very interesting. Particular stress was given to the application of polarized light to automobiles, as a means of eliminating head light glare. The speaker said that when light falls on a polar screen, that part of the light which lies in one certain plane passes through and the rest is absorbed or dissipated as heat. If these screens were placed on the head lights of all cars so that the emitted light left in a plane of forty five degrees to the vertical; rising from the left wheels to the right; and if the driver looked through another screen similarly oriented, then, the lights from his own headlights would be visible to him. The two screens are placed to pass light in a given plane.

Though the headlights of both cars emit light in the same plane the light of the approaching car is absorbed in the screen before the driver's eyes.

The safety feature of this scheme is very desirable but it has the disadvantage that one half of the candle power of the lamps is not used.

A good discussion completed the work of the lecturer.

Colonel E. G. Mackay, A.M.E.I.C., chairman of the Hamilton Branch introduced Professor Smith, chairman of the A.I.E.E., and he in turn introduced the speaker.

W. B. Dunbar, A.M.E.I.C., moved a very hearty vote of thanks to Dr. Chubb for a most interesting evening which was then completed by a very delightful array of refreshments that had been prepared for all present by the kindness of our hosts.

## London Branch

*D. S. Scrymgeour, A.M.E.I.C., Secretary-Treasurer.*
*Jno. R. Rostron, A.M.E.I.C., Branch News Editor.*

The regular monthly meeting of the Branch was held on March 18th, 1937, in the Officers' Mess Room at the Armouries, Dundas Street, and the speaker was Mr. C. A. Cline, B.Sc. (O.A.C.), of Burlington Steel Company, Hamilton. The title of his address was "A Niagara Free Port."

The chairman of the Branch, A. O. Wolff, M.E.I.C., presided and after the reading of the minutes he introduced the speaker.

Mr. Cline commenced by defining a free port as a "Segregated area on which goods not otherwise prohibited may be unloaded and stored, subject to varying restrictions as to storing, grading, repacking, manipulation and manufacturing, and in which such goods or authorized manufactures therefrom may be reloaded and shipped to foreign destinations, all without the imposition of the customs formalities and duties applicable to similar goods entering customs territory."

In the speaker's opinion, the area between the Welland Ship canal and the United States border would form an ideal situation for such a port. It is centrally located with respect to the largest manufacturing districts in both Canada and the United States. Imported goods could be brought in from the Atlantic ports by rail during the winter and directly from the country of origin by vessel during the navigation season. Manufacturers would have an easily accessible place to visit for the inspection, selection and purchase of such commodities as they might want and no duty would be paid until such goods moved out of the area or were consumed by the local industries.

Shipping on the upper lakes should benefit from the location of a free port at such a point because West-bound cargoes would be available. Importers could bring in cargo lots at a minimum shipping charge because the tramp steamers would have a good prospect of a turn-around cargo of grain or flour to be picked up either at Niagara or further down the St. Lawrence. The load factor is the important point in this connection and will have to be given careful study but on prior investigations have indicated that it would prove favourable and that return cargoes would be available in the great majority of cases, particularly if the grain trade improves.

There is no question of such an area not remaining a part of Canada as national, provincial and municipal jurisdiction remain at present. The customs frontier only is affected. Immigration and all other dispositions are unchanged. Existing manufacturers and business of all kinds within the area enjoy their present facilities unimpaired. They benefit to the extent of a larger market and lower transportation charges—such a port has recently been established in New York Harbour.

Free ports are in operation at Hamburg (Germany), London (England), Hong Kong and at other places.

Essentially a free port is a legal device to permit a more free interchange of commodities, without lowering tariffs.

The establishment of a free port on the Niagara Peninsula would create employment by stimulating—

(a) The constructing industry.
(b) Increase in high classification business (package goods) for the lake freighters and the railways.
(c) Lower costs of raw materials to manufacturers.
(d) Enlargement of our export markets by giving ocean shipping facilities at our doors.

Taking the Port of Hamburg, Germany, as a successful free port, the factors contributing to the success are as follows—

(a) Few customs formalities.
(b) Favourable load factor.
(c) Traffic cross lane.
(d) Rich hinterland.
(e) Adjacent to and contiguous with customs frontier.
(f) Speed and capacity in handling cargo.
(g) Private capital finances and manager.

It was then shown that these factors were already present, or only needed adequate regulations and proper facilities to bring them into operation in the Niagara Peninsula.

Senate Bill E. 2 permits only one free port in each province, the claims of the Niagara Peninsula as the site of the Ontario free port merit every consideration. This bill also provides for the proper establishment, control, layout and management of such a port.

After an animated discussion, a vote of thanks was proposed to the speaker by S. W. Archibald, A.M.E.I.C., seconded by Murray Dillon, and unanimously carried.

About twenty members and guests were present.

## Montreal Branch

*E. R. Smallhorn, A.M.E.I.C., Secretary-Treasurer.*

### Special Meeting

On Thursday, April 1st, 1937, a special meeting of the Montreal Branch took place, called at the request of thirty corporate members, for the purpose of discussing the question of the consolidation of the Engineering Profession in Canada. The meeting was well attended, and an interesting and enlightening discussion took place.

Huet Massue, A.M.E.I.C., chairman of the Branch, was in the chair.

### Junior Section

H. E. Cunningham, S.E.I.C., who is with the Dominion Engineering Company, presented a paper on "Gears," and Louis Trudel, S.E.I.C., who is with the Quebec Electricity Commission, presented one on "An Actual Case of Research Work on Reduced Models of Spillways," at the meeting of the Junior Section of the Montreal Branch held on April 5th. Both papers proved to be extremely informative and interesting, and were illustrated by slides and motion pictures. Prior to the meeting an election took place, to fill the vacancy on the Executive Committee caused by the resignation of V. S. Upton, S.E.I.C., who has left Montreal. R. N. Warnock, Jr.E.I.C., was elected.

Jacques Hurtubise, S.E.I.C., was in the chair.

### The Production of Radio Active Substances

On Thursday, April 8th, Dr. J. S. Foster, F.R.S., Macdonald Professor of Physics at McGill University, presented a paper on "The Production of Radio Active Substances." Dr. Foster's address covered the difficulties confronting scientists studying radium and other radio active materials, recent achievements in the large scale production of neutrons, and the commercial development of radio active forms of common substances.

Professor R. E. Jamieson, M.E.I.C., was in the chair.

### The Problem of Economic Stability as Seen by an Engineer

At the meeting of the Montreal Branch held on April 15th, P. Ackerman, A.M.E.I.C., consulting engineer, Montreal, spoke on "The Problem of Economic Stability as Seen by an Engineer." Mr. Ackerman's talk covered an analysis of our economic system presented in engineering language by the use of simple mathematics and graphs, and indicated how the analytical tools of practical science could serve in obtaining a clearer understanding of this perplexing problem.

Professor C. V. Christie, M.E.I.C., acted as chairman.

### Junior Section

"Highway Development in Alberta" was the subject of an address by J. L. Pidoux, Jr.E.I.C., and "Elements of Modern Combustion Design" that of Mr. G. Martin, at the meeting of the Junior Section held on April 19th. Both of these talks, while brief, were most interesting and well illustrated.

The chairman was C. J. Pimenoff, S.E.I.C.

### The Adaptation of Rigid Structural Frames to Modern Construction

"The Adaptation of Rigid Structural Frames to Modern Construction" was the subject of a paper presented by E. R. Jacobsen, A.M.E.I.C., at the meeting of the Montreal Branch held on April 22nd. This paper was based on the construction of four churches, recently completed, in which all welded frames of rigid design were used, and included a description of the general construction and of the design and analysis of the steel frames. The author is on the staff of the Dominion Bridge Company Limited.

Gordon McL. Pitts, A.M.E.I.C., acted as chairman.

## Niagara Peninsula Branch

*P. A. Dewey, A.M.E.I.C., Secretary-Treasurer.*
*C. G. Moon, A.M.E.I.C., Branch News Editor.*

A joint meeting of the Branch with the Niagara Chemical and Industrial Association was held on March 18th, 1937, at the Hotel Leonard in St. Catharines.

Chairman George Wood A.M.E.I.C., presided and about seventy members assembled to hear Mr. Gordon McIntyre explain the process of refining gasoline.

Mr. McIntyre was introduced by Sydney Hairsine, A.M.E.I.C., as the chief chemist for the Imperial Oil at Sarnia. His talk was illustrated by lantern slides showing diagrammatic sections of the treating towers and processing machinery.

### Gasoline Refining

Most of the gasoline used in Canada and the United States as a motor fuel, explained Mr. McIntyre, is obtained from crude oil. It contains molecules of various sizes or properties and in the combining of these molecules rests the surety of a fuel which is adequate and economical for the modern automobile. As the car is improved so must the relative constituents of the fuel be varied and the two must progress simultaneously.

Quick starting, rapid acceleration and high compression call for an entirely different gasoline from that used in the earlier cars. Climatic variations also necessitate other changes in the molecular grading of the gasoline which is therefore regulated from time to time in the refinery.

By means of heat and pressure the crude oil is separated into the constituent parts containing roughly 20 per cent gasoline, 14 per cent kerosine, 24 per cent lubricating oil and the balance distillate, fuel oil and asphalt.

The "cracking coil" is the most important part in the process. Motor cars could not function properly without cracked gasoline which, combined with straight gasoline and absorption gasoline, produces the article of commercial use. Volatility and detonation are the important tests of a gasoline; the former being varied from as low as 5 lb. per. sq. in. for very hot climates, about 9 lb. for our temperate summer, to 10 or 12 lb. for winter use.

In replying to questions which were raised during a lengthy discussion, Mr. McIntyre made the following points.

Lubricating oil added to the gasoline is recommended, particularly for a new car. About ¼ per cent or a pint to 10 gallons of gasoline, does not change the octane value. A special "break-in" oil is also made to be used in the crank case.

The modern automobile engine has a thermal efficiency of some 25 per cent while the most efficient engines, those used in the Schneider cup races and burning a blend of gasoline, ethyl fluid, benzene and alcohol, attain 40 per cent efficiency.

Rapid acceleration, which is highly developed in the newer cars, is the principal cause of high fuel consumption.

Great Britain and Germany distil some of their gasoline from coal but this is not done in Canada.

A synthetic fuel of 100 octane value will increase the horse power of an engine 30 per cent or more, over a standard 87 octane gasoline, when used in a properly designed aircraft engine.

M. F. Ker, A.M.E.I.C., of Stamford, proposed the vote of thanks.

On April 15th, 1937 the Branch held an afternoon and evening meeting at Port Colbourne. Through the kindness of the International Nickel Company, members and their friends were shown something of the mysteries pertaining to refining.

The huge plant, with the recent extensions, was thrown open for inspection and qualified guides explained the various processes from the initial grinding and sulphide leaching to the electrolytic separation of the pure metal.

After a pause for refreshments at the well-appointed Company clubhouse, dinner was served in the new hall of the First Presbyterian Church.

Mr. Herbert Walter, manager of the refinery, spoke briefly after dinner and introduced Mr. F. L. LaQue, of the New York office, who then explained many of the properties and applications of nickel and the non-ferrous alloys.

The three principal sources of nickel are as follows: Copper-nickel bearing pyrohlite in which the chief nickel-bearing mineral is pentlandite. This is the most important source and is found chiefly in the Sudbury district, also to some extent in Norway; the Sudbury deposits comprising the largest known supplies of nickel in the world. These deposits are sufficient for possibly a hundred years at the present rate of consumption.

Silicates or oxidized ores in which garnierite is the principal nickel-bearing mineral; found in New Caledonia, an island in the Pacific ocean east of Australia and formerly a French penal colony.

The arsenical ores of nickel and cobalt, found in northern Ontario and, to some extent, on the continent in Saxony and elsewhere. A recent source for a small amount of Nickel is a by-product of the electrolytic copper refineries. Many copper ores carry minute quantities of nickel which accumulate in the electrolyte and have to be periodically removed; the nickel usually finding its way to the market as nickel salts used in electro-plating.

Mr. LaQue's talk on the non-ferrous metals was illustrated with slides and motion pictures depicting the development of the nickel industry. Several other films of local interest were also shown which filled in an enjoyable evening.

C. G. Cline, A.M.E.I.C., expressed the thanks of the meeting to the speaker, to Mr. Walter and to the International Nickel Company for their kindness and hospitality. Councillor E. P. Murphy, A.M.E.I.C., and Norman Geale, A.M.E.I.C., did the spade work for the meeting and are to be congratulated. An attendance of eighty-three made this one of the notable gatherings of a good season.

*E. J. Davies, A.M.E.I.C., Branch News Editor.*

### Weather Forecasting

On March 11th, 1937, Dr. J. Patterson, Controller, Meteorological Service of Canada, addressed this Branch on the subject of weather forecasting. Dr. Patterson stated that despite frequent claims by amateur experimenters on behalf of methods of long range weather forecasting scientific meteorolgists are not yet able to forecast weather with any guarantee of accuracy more than twenty-four to thirty-six hours in advance. He held little hope for development of long range prediction in the near future.

At wide variance from the old amateur stand-bys of weather observation were the scientific methods of the present-day weatherman described by Dr. Patterson. It seemed that the scientific weatherman puts little stock in such household slogans as "Rain before seven, clear before eleven," and pays little attention to the thickness of rabbits' fur in the fall, or the matter of the bear seeing his shadow in the spring. The science of weather prediction has progressed in great strides in recent years.

The army general studying his outspread battlefield maps showing troop position and movements would feel almost at home in the modern meteorological headquarters, it appeared as Dr. Patterson described roughly the methods of prediction. Just as the military man anticipates likely results by observing the progress of various human forces on his maps, the weatherman predicts weather by observing the progress of elemental forces. By charting and graphing hundreds of thrice-daily reports from weather stations throughout the Dominion, meteorologists make for themselves a composite picture of the air mass movements under way in Canada.

Certainty of weather forecasting has been advanced in recent years through concentration on study of the movements of the dry, cold air masses from the polar areas and the warm, moist masses from the Tropical areas. Formerly, principal attention was paid not to the actual air movements but to air pressures at various points. Interpretation of air pressure data left too much to guesswork.

Dr. Patterson exhibited slides which traced the development of the meteorological science from 1872 to the present. The release of the balloons by means of which temperatures at heights from 10 to 20 miles are taken was depicted. Unexpectedly, the lowest stratosphere temperatures are encountered in the stratosphere over the equator and warmest stratosphere temperatures are encountered over the poles.

### Annual Students' and Juniors' Night

April 8th was the annual meeting which is in charge of students and juniors of this Branch and at which A. L. Malby, Jr.E.I.C., was chairman. Papers were given by four student members who are employed at the Canadian General Electric Company's Test Course.

W. Bergman, S.E.I.C., gave a talk on the "Features of the Petroleum Industry with special reference to the Turner Valley Oil Fields." Supporting his statement that the oil industry is a silent competitor of electricity he mentioned that in 1929 there were 450 men employed in the field of development and in 1937 there are over 900 thus employed. Mr. Bergman explained in detail the two general methods of sinking oil bore holes, i.e., the percussion method and the hydraulic rotary method. He also mentioned the fact that occasionally it was necessary to combine the two methods on the one hole as the nature of the substrata encountered varied from hard rock which requires the percussion method to sandy, soft soil which requires the rotary method.

E. L. Toy, S.E.I.C., gave a very interesting description of the "Sardine Industry," mentioning in particular the New Brunswick Sardine Plant. He explained the process from the catching of the small herring which are used for sardines, through the different operations of salting, flaking, drying, packing, oiling, cooking and packing for shipment. In this industry there is very little waste as the heads, tails and unsuitable herrings are used for fertilizer and the oil extracted from this waste is used for soap making. One point which is considered in the favour of Canadian sardines over European sardines is the fact that Canadian sardines are not smoked and are therefore considered more easily digested.

C. E. Lewis, S.E.I.C., gave a very thorough and informative paper on "Cylinder Wear in Gasoline Engines." Mr. Lewis stressed particularly the three main causes of cylinder wear, i.e., abrasion, erosion and corrosion, going into complete detail as to the action that occurs in each case with the consequent result. Mr. Lewis mentioned that the manufacturers are exerting every effort to incorporate features which will keep down or reduce cylinder wear and for the private owner he mentioned the following points:—

1. Use a good type of air cleaner and keep it clean.
2. Frequent changes of oil, using a good quality oil.
3. Keep the operating temperature of the engine well up, using a thermostat to control this.
4. Steady engine operation with proper gasoline mixture.

Mr. Lewis mentioned the fact that high engine speed did not necessarily cause cylinder wear, provided proper lubrication was available.

D. C. McCrady, S.E.I.C., discussed "Sanitary Analysis of Drinking Water." Mr. McCrady explained in detail the method of testing samples of drinking water for palatability and possible pollution. He went through the various steps as carried out in a modern laboratory to detect the possible presence of sewage particles in their chemical components. The most important part of this test was the personal inspection of the source of supply and its surroundings, as very frequently, although the water does not show any sign of pollution, the surroundings may be such that pollution may soon occur due to the breakdown of the soil through which the water filters to the well.

## Saskatchewan Branch

*J. J. White, M.E.I.C., Secretary-Treasurer.*
*R. J. Fyfe, A.M.E.I.C., Branch News Editor.*

### Annual Meeting

The annual meeting of the Saskatchewan Branch of The Institute was held in the LaSalle hotel, Regina, on April 2nd, 1937. Thirty-one members and friends were in attendance.

Stewart Young, M.E.I.C., the vice-chairman, conducted the business of the meeting. The speaker was Dr. J. W. Hedley, Regina, his subject being "Heredity and Environment." This subject, although greatly removed from any engineering activity, was very much appreciated by the members present, and a hearty vote of thanks was moved by Messrs. A. P. Linton, M.E.I.C., and H. C. Ritchie, M.E.I.C.

The election of officers of the Branch for the ensuing year resulted in Stewart Young, M.E.I.C., being elected chairman, with Messrs. R. W. Allen, M.E.I.C., H. S. Carpenter, M.E.I.C., and J. W. D. Farrell, M.E.I.C., being elected to the Executive committee.

## Vancouver Branch

*T. V. Berry, A.M.E.I.C., Secretary-Treasurer.*
*J. B. Barclay, A.M.E.I.C., Branch News Editor.*

At an evening meeting of the Vancouver Branch, on February, 26th, 1937. Mr. R. Weir, local manager of the Pressure Pipe Company of Canada, gave an address, illustrated with lantern slides, of the 14,000 ft. concrete pipe line installed at Capilano Canyon for Vancouver's water supply.

The pipe has an internal diameter of 63 in. with a head of water of water of 500 ft. giving a pressure of 218 lb. per sq. in.

The process of manufacture was to build a light cylindrical shell of No. 7 to No. 10. gauge steel. This was wrapped with a continuous steel spiral, kept 1 in. from the shell. An inner lining of reinforcing rods was then manufactured and inserted, special methods being adopted to keep the steel the necessary distance from the shell. This completed the fabrication of the reinforcing. The company's plant was equipped to rotate the pipe while in a horizontal position at a rapid speed, the inner concrete lining was then poured and spinning continued until the concrete was dense. Steam curing was then continued for four hours. The outer lining was then poured by setting the pipe in a vertical position and placing steel forms around it. Vibrators were used during the pouring. Steam curing was then continued for twenty hours.

Joints were made by welding a socket to the inner lining and the joints made on the field as in a socket and spiggot pipe, using oakum and lead. At each field joint the inner lining was plastered, and the outer by placing forms around the pipe and concreting.

This pipe has proved highly satisfactory, both during the laboratory tests for structural strength and leakage, and in the field for ease of erection and serviceability.

A vote of thanks was proposed by C. Brakenridge, M.E.I.C., for Mr. Weir's very interesting paper on this subject of manufacture of concrete pipes.

At the meeting of the Vancouver Branch of The Institute held on March 9th, Mr. A. G. Zima, research metallurgist of the International Nickel Company, gave an address illustrated with lantern slides, his subject being "The Role of Nickel in the Development of Cast Iron."

During the war, nickel was thought of only as a war-time material, and at the close of the war the price dropped to practically nothing. This caused the research department of International Nickel to try to find new uses for this metal, with the result that its uses in the field of armaments takes second place now. Cast iron, which was once replaced by cast steel, is now finding the uses of the former again relinquished to it.

Alloys of cast iron and nickel, with additions of chromium, copper, zinc, aluminum, etc, can be made to produce materials which have amazing properties. These alloys can be cast amazingly thin, they can be hardened to an unbelievable extent, they can be made non-corrosive, and if conditions warrant it, they can have a coefficient of expansion of zero. It is even possible to have a crucible product of cast iron which can be bent cold.

Ordinary cast iron contains particles of graphite throughout its mass. These particles are comparatively large, especially if the casting has cooled slowly, and these irregular pieces of graphite account for the weakness and non-uniformity of this material. The introduction of nickel acts as a graphitizer, that is, it causes the graphite to be distributed in very minute pieces uniformly so that they do not weaken the mass. At the same time the nickel toughens it and gives it uniform density and uniform strength. The nickel dissolves 100 per cent in the iron giving a tough material which can be machined. The further addition of chromium hardens the alloy and is especially useful where there is abrasive action. An alloy, for example, of 4½ per cent nickel with 1½ per cent chromium gives the toughest commercial cast iron alloy. In chill hardened cast iron, chromium acts as a chill deepener and nickel as a chill intensifier. This type of alloy with varying proportions of the nickel and chromium is largely used for dies in automobile manufacture for stamping fenders, and has three times the life of ordinary cast iron. It can be further heat treated thereby increasing the life another four times. This alloy is so strong that it has been used to replace manganese steel and effectively replaces the latter, except where there is excessive impact.

It is interesting to note that ordinary steel and alloys of steel have a modulus of elasticity of between 29 and 31 million, this modulus varies very slightly within these limits regardless of the steel alloy considered. Ordinary cast iron which has a modulus of from 8 to 12 million, can be made to have a modulus as high as 28 million with additions of nickel, chromium, and other elements. This increase in stiffness has made it possible to use cast iron in machine parts, such as paper mill rolls where stiffness is essential and if they were made of steel would be very costly.

Some of the uses for this new field of alloys are for rock crushers; pipes and tanks for chemical works, where the new Ni-resist has great non-corrosive properties; dies; grate bars, these are not subject to "grain growth" which was the disadvantage of using ordinary cast iron; abrasive surfaces; bearings, where the graphite in the iron acts as a natural lubrication, and many other places.

This address contained an unusual amount of information and Mr. Zima received a very sincere vote of thanks for his excellent paper.

The Vancouver Branch held its monthly dinner meeting on the evening of March 22nd, 1937. Twenty members sat down to dinner. After dinner the members were addressed by Mr. F. Vernon Jones, chief surveyor of the Fire Branch of the B.C. Underwriters Association.

Mr. Jones spoke on the subject "How Construction Affects Fire Insurance Rates." He discussed at length various factors in the construction of buildings and their relations to fire risks and insurance rates. Types of walls, floors, roofs, skylights, fire doors, openings in floors, window trim, etc, are all factors in fire hazard and the determination of fire rates. Other contributing factors influencing the rates are relative efficiencies of fire fighting systems, quantity and pressure of water available for fire fighting, proximity of other buildings, the nature of their construction and occupancy, nature of occupancy and nature of process hazards. All these factors have received a great amount of study and research and architects and engineers in designing structures should study these factors carefully in their design.

Following the address, a number of questions were answered by Mr. Jones.

Before adjournment the meeting was thrown open for a discussion on the proposed amendments to The Institute's by-laws.

## Winnipeg Branch

*H. L. Briggs, A.M.E.I.C., Secretary-Treasurer.*

THE BRITISH PROGRAMME OF PROTECTION AGAINST AERIAL GAS ATTACK

On March 25th, 1937, approximately one hundred and fifty members of the Winnipeg Branch and visitors heard Dr. F. W. White, of the faculty of medicine, University of Manitoba, deliver a paper on the above subject. Dr. White served for four years with the Royal Engineers.

One method of classifying gases is according to their effects. There are the lung irritants, such as chlorine, the sneezing gases, the tear gases, and the blister gases. The most powerful of the present day gases, mustard gas and lewisite, come within the last classification.

Three parts of lewisite mixed with 100,000,000 parts of air, make necessary the use of a gas mask. The blister gases attack all body surfaces, particularly if any perspiratory dampness is present. A complete outfit, consisting of respirator headpiece, oilskin clothing, and gum rubber boots, is necessary for complete protection.

Slides were shown of different types of gas masks which are being manufactured. An Air Raids Precautions Department has been operating for a year, and a large school has been established, giving instruction in the protection from gas. Householders are advised to make their cellars gasproof. Encouragement is being given to the construction of types of buildings which can readily be converted into first aid posts and decontamination centres.

The appreciation of those present was voiced to Dr. White by W. M. Scott, M.E.I.C.

An extended discussion took place on the consolidation by-law revisions, the ballots having been received shortly before the meeting.

Professor A. E. Macdonald, M.E.I.C., was chairman of the meeting.

THE TECHNIQUE OF MODERN FLYING

The address on April 1st by Flight-Lieutenant D. Edwards, of No. 12 Squadron, Royal Canadian Air Force, on the above subject, was received with much interest by sixty members and visitors present.

Flight-Lieutenant Edwards described how the horizon is used as the reference for level, and a distant cloud, a railway line, or some such feature as the reference for direction when an air pilot is flying by 'feel' or 'sense.' When scheduled flights must be made under practically all conditions of weather and light or darkness, these references are not available, moreover, the sense of balance of a human being when fast turns or banks are being made is not reliable.

Instrument flying is based primarily on the bank and turn indicator, while other instruments almost as indispensable are the air speed indicator, the altimeter, and the compass. The speaker clearly explained the comparative ease with which a pilot flying blind without the use of instruments could get into a spin.

The radio beam system as commonly used involves the directional transmission of short wave radio signals, the Morse signal for "a" (dot dash) being transmitted in two opposite quadrants, and the signal for "n" (dash dot) being transmitted in the other two quadrants. Neighbouring quadrants overlapped about three degrees, and any receiving set in this area when tuned in would pick up a continuous signal, which constitutes the so-called "beam." Every thirty seconds the "a" and "n" transmission is interrupted to give station identification.

The speaker was introduced by G. E. Cole, A.M.E.I.C., and the vote of thanks moved by D. A. Ross, M.E.I.C.

The chair was occupied by Professor A. E. Macdonald, M.E.I.C.

ELEVENTH ANNUAL SUPPER DANCE OF THE ASSOCIATION OF PROFESSIONAL ENGINEERS OF THE PROVINCE OF MANITOBA, AND THE WINNIPEG BRANCH OF THE ENGINEERING INSTITUTE OF CANADA.

April 2nd, about 370 members of the two engineering bodies and their guests attended this habitually successful annual event, held in the main dining room of the Royal Alexandra hotel at Winnipeg. The arrangements were carried out by Mr. J. A. Meindl, with the assistance of a committee composed of Messrs. C. S. Landon, A. W. Smith, D. M. Stephens, A.M.E.I.C., and W. Youngman.

## List of New and Revised British Standards

(Issued during February and March, 1937)

B.S. No.

721—1937. *Machine Cut Gears. C. Worm Gearing.*
Applies to worm gearing comprising correctly generated worm wheels and profile-ground worms, connecting shafts at right angles, and having a normal pressure angle of worm thread of 20° of the following classes:—
Class A. Precision Gears for wheel pitch line speeds above 1000 feet per minute.
Class B. High Class Gears for wheel pitch line speeds below 1500 feet per minute.
Class C. Commercial Gears for wheel pitch line speeds below 300 feet per minute.

727—1937. *Standard Method for the Characteristics and Performance of Apparatus for the Measurement of Radio Interference.*
This Standard defines the characteristics and performance of apparatus suitable for the measurement of radio interference, these characteristics having been internationally agreed. Also, describes in detail the design of an instrument complying with the Standard as developed by the General Post Office.

Copies of the new specifications may be obtained from the Publications Department, British Standards Institution, 28, Victoria Street, London, S.W.1., and from the Canadian Engineering Standards Association, 79, Sussex Street, Ottawa.

# Preliminary Notice

## of Applications for Admission and for Transfer

April 30th, 1937

The By-laws provide that the Council of The Institute shall approve, classify and elect candidates to membership and transfer from one grade of membership to a higher.

It is also provided that there shall be issued to all corporate members a list of the new applicants for admission and for transfer, containing a concise statement of the record of each applicant and the names of his references.

In order that the Council may determine justly the eligibility of each candidate, every member is asked to read carefully the list submitted herewith and to report promptly to the Secretary any facts which may affect the classification and selection of any of the candidates. In cases where the professional career of an applicant is known to any member, such member is specially invited to make a definite recommendation as to the proper classification of the candidate.

If to your knowledge facts exist which are derogatory to the personal reputation of any applicant, they should be promptly communicated.

**Communications relating to applicants are considered by the Council as strictly confidential.**

The Council will consider the applications herein described in June, 1937.

R. J. Durley, Secretary.

*The professional requirements are as follows:—

**A Member** shall be at least thirty-five years of age, and shall have been engaged in some branch of engineering for at least twelve years, which period may include apprenticeship or pupilage in a qualified engineer's office, or a term of instruction in a school of engineering recognized by the Council. The term of twelve years may, at the discretion of the Council, be reduced to ten years inthe case of a candid ate for election who has graduated from a school of engineering recognized by the Council. In every case the candidate shall have held a position in which he had responsible charge for at least five years as an engineer qualified to design, direct or report on engineering projects. The occupancy of a chair as a professor in a faculty of applied science of engineering, after the candidate has attained the age of thirty years, shall be considered as responsible charge.

**An Associate Member** shall be at least twenty-seven years of,age, and shall have been engaged in some branch of engineering for at least six years which period may include apprenticeship or pupilage in a qualified engineer's office or a term of instruction in a school of engineering recognized by the Council. In every case a candidate for election shall have held a position of professional responsibility, in charge of work as principal or assistant, for at least two years. The occupancy of a chair as an assistant professor or associate professor in a faculty of applied science of engineering, after the candidate has attained the age of twenty-seven years, shall be considered as professional responsibility.

Every candidate who has not graduated from a school of engineering recognized by the Council shall be required to pass an examination before a board of examiners appointed by the Council. The candidate shall be examined on the theory and practice of engineering, with special reference to the branch ofengineering in which he has been engaged, as set forth in Schedule C of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Sections 9 and 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard. Any or all of these examinations may be waived at the discretion of the Council if the candidate has held a position of professional responsibility for five or more year.

**A Junior** shall be at least twenty-one years of age, and shall have been engaged in some branch of engineering for at least four years. This period may be reduced to one year at the discretion of the Council if the candidate for election has graduated from a school of engineering recognized by the Council. He shall not remain in the class of Junior after he has attained the age of thirty-three years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

Every candidate who has not graduated from a school of engineering recognized by the Council, or has not passed the examinations of the third year in such a course, shall be required to pass an examination in engineering science as set forth in Schedule B of the Rules and Regulations relating to Examinations for Admission. He must also pass the examinations specified in Section 10, if not already passed, or else present evidence satisfactory to the examiners that he has attained an equivalent standard.

**A Student** beshallat least seventeen years of age, and shall present a certificate of having passed an examination equivalent to the final examination of a high school, or the matriculation of an arts or science course in a school of engineering recognized by the Council.

He shall either be pursuing a course of instruction in a school of engineering recognized by the Council, in which case he shall not remain in the class of Student for more than two years after graduation; or he shall be receiving a practical training in the profession, in which case he shall pass an examination in such of the subjects set forth in Schedule A of the Rules and Regulations relating to Examinations for Admission as were not included in the high school or matriculation examination which he has already passed; he shall not remain in the class of Student after he has attained the age of twenty-seven years, unless in the opinion of Council special circumstances warrant the extension of this age limit.

**An Affiliate** shall be one who is not an engineer by profession but whose pursuits, scientific attainments or practical experience qualify him to co-operate with engineers in the advancement of professional knowledge.

The fact that candidates give the names of certain members as reference does not necessarily mean that their applications are endorsed by such members.

### FOR ADMISSION

ALLEN—ARCHIE MENZO, of Edmonton, Alta., Born at Cameron, N.Y., July 17th, 1883; Educ., Private study; 1901-04, lineman and inspr., Century Telephone Constrn. Co.; 1909-10, inspr. and combination man, N.W. Telephone and Telegraph Co.; 1910 to date, with the Alberta Government Telephones, Edmonton, Alta., as follows: 1910-13, inspr., dist. foreman, and chief inspr.; 1914-19, local agent and wire chief; 1920-29, plant chief; 1929 to date, constrn. engr.

### FOR TRANSFER FROM THE CLASS OF STUDENT

LILLEY—LEDFORD GEORGE, of 57 Havelock St., West Saint John, N.B., Born at West Saint John, June 11th, 1913; Educ., B.Sc. (E.E.), Univ. of N.B., 1935; 1935-36, dftsman., 1936-37, inspr. of constrn. on reconstrn. of wharves at Saint John, National Harbour Board; at present, dftsman., Dept. of Public Works of Canada, Saint John, N.B. (*St. 1935.*)

References: F. C. Jewett, V. S. Chesnut, G. Stead, J. R. Freeman, G. H. Thurber.

MATHIESON—JOHN RICHARD, of Port Arthur, Ont., Born at Winnipeg, Man., June 26th, 1909; Educ., B.Sc. (C.E.), Univ. of Man., 1936; 1927-29, chainman, rodman, C.P.R. constrn. dept.; 1929-31, instr'man., C.P.R.; 1936 to date, designer dftsman., C. D. Howe Co. Ltd., Port Arthur, Ont. (*St. 1935.*)

References: B. L. Reid, E. A. Kelly, T. F. Francis, A. E. Macdonald, J. M. Fleming.

PASK—ARTHUR HENRY, of Drummondville, Que., Born at Zeneta, Sask., July 2nd, 1911; Educ., B.Sc. (E.E.), Univ. of Man., 1935; 1936 (2 mos.), dfting and assimilation of paper mill operational data, Howard Smith Paper Mills; 1936-37, dftsman., pump and Diesel engine installns., Canadian Fairbanks Morse Co. Ltd.; at present, asst. plant engr., Eagle Pencil Co., Drummondville, Que. (*St. 1935.*)

References: M. Gerin, W. G. Scott, J. F. Plow, N. M. Hall, E. P. Fetherstonhaugh.

## EMPLOYMENT SERVICE BUREAU

The Service is operated for the benefit of members of The Engineering Institute of Canada, and for industrial and other organizations employing technically trained men—without charge to either party.

*All correspondence should be addressed to*

**The Employment Service Bureau, The Engineering Institute of Canada**

**2050 Mansfield Street, Montreal**

## Situations Vacant

YOUNG MECHANICAL ENGINEER, interested in sale of mechanical equipment. Location Montreal. Salary. Apply to Box No. 1537-V.

DRAUGHTSMAN, experienced with knowledge of light structural steel detailing and mechanical details for general conveyor work. Opportunity to work into chief draughtsman. Apply to 1558-V.

DESIGNING ENGINEER, or draughtsman, preferably with paper mill experience. Location Eastern Ontario. Apply to Box No. 1560-V.

YOUNG GRADUATE ENGINEER, preferably mechanical or chemical for operating department of a pulp and paper mill. Location Eastern Ontario. Apply to Box No. 1560-A-V.

GRADUATE ENGINEER, experience railway or highway construction, selling experience if possible. French and English. Good prospects. Apply to Box No. 1561-V.

CHIEF ENGINEER, familiar with water tube boiler design. In replying state past experience, age, and salary required to Box No. 1566-V.

## Situations Wanted

CHIEF ENGINEER-CONSTRUCTION MANAGER, nineteen years construction maintenance operating, industriel plants, steam and hydro power, canals, water supply, etc., estimates, plans, specifications, supervision of construction. Apply to Box No. 36-W.

STEAM AND MECHANICAL ENGINEER. Married. Wants position with industrial company within 100 mile radius of Montreal. Would prefer position in charge of maintenance. Can undertake plant layout work, handling steam lines, look after alterations or extensions, make installations on construction work. Previously in charge of similar work and can prepare own drawings. Have good all round knowledge of all trades. 35 years experience. Apply to Box No. 441-W.

DOMINION LAND SURVEYOR, and graduate engineer with extensive experience on legal, topographic and plane-table surveys and field and office use of aero-photographs, desires employment either in Canada or abroad. Available at once. Apply to Box No. 589-W.

ELECTRICAL ENGINEER, B.Sc., E.E., age 38. Married. Ten years electrical experience; including, one year operation, one year maintenance, and four years on construction of hydro-electric plants and sub-stations. Four years electric maintenance and construction in pulp and paper mill. Also experience on highway construction and Geological Survey Available at once. Apply to Box No. 636-W.

ELECTRICAL AND CIVIL ENGINEER, B.Sc. Elec. '29, B.Sc. Civil '33. Jr.E.I.C. Age 29. Experience includes four months with Can. Gen. Elec. Co., approximately three years in engineering office of large electrical manufacturing company in Montreal, the last six months of which was spent as commercial engineer. For the last year and a half employed in electrical repair shop. Best of references. Apply to Box No. 693-W.

YOUNG CIVIL ENGINEER, B.Sc. (Univ. of N.B. '31), with experience as rodman and checker on railroad construction, is open for a position. Apply to Box No. 728-W.

MECHANICAL ENGINEER, S.E.I.C., B.A.Sc., Univ. of B.C. '30. Single, age 24. Sixteen months with the Allis-Chalmers Mfg. Co. as student engineer. Experience includes foundry production, erection and operation of steam turbines, erection of hydraulic machinery, and testing texropes and centrifugal pumps. Location immaterial. Available at once. Apply to Box No. 735-W.

## Situations Wanted

CIVIL ENGINEER, B.Sc., M.Sc., R.P.E.; Lieut. C.E., R.O. 16 years municipal, highway and construction, 5 years overseas. Married. Read, write and talk French. Will go anywhere. Apply to Box No. 737-W.

RADIO AND ELECTRICAL ENGINEER, B.Sc., '31, Jr.E.I.C. Single. Age 29. One year and a half actual field experience in power and lighting equipment. Extensive work in telephone and radio layouts in switchboard and installation depts. Particularly interested and experienced in sales and traffic work in telephone and radio company. At present supervisor over sales and service of radio and electrical company. Available on short notice. Location immaterial. Apply to Box No. 740-W.

PLANT ENGINEER or SUPERINTENDENT, capable of supervising all phases of industrial plant operation, graduate electrical, eleven years diversified industrial experience including test course, four years on large Quebec industrial development, on construction and operation, also six years with prominent consulting firm supervising electrical and mechanical engineering projects. Age 31, single. Apply to Box No. 795-W.

### Employment Service Bureau

Members are again reminded that we are receiving an increasing number of enquiries for engineers.

If you are registered with the Employment Service Bureau please bring your record up-to-date.

The more information you give us, the more intelligently and effectively we can place your record for consideration with prospective employers.

CIVIL ENGINEER, S.E.I.C., B.Sc. in C.E. (Sask. '32). Single. Age 27. Three years experience includes—instrumentman, compiling reports and draughting with a National Park; in charge of construction of water supply and sanitary sewer systems; assistant on city surveys. Excellent draughtsman. Available at once. Location immaterial. References. Apply to Box No. 818-W.

STRUCTURAL ENGINEER, B.A.Sc., A.M.E.I.C. Twenty-two years experience in design of bridges and all types of buildings in structural steel and reinforced concrete. Three years experience in railway construction and land surveying. Apply to Box No. 856-W.

CIVIL ENGINEER, B.A.Sc., Jr.E.I.C., age 32, married. Two years in pulp mills draughting and designing additions, maintenance and plant layout. Three and a half years in the Toronto Building Department, checking and designing for steel, reinforced concrete and ordinary structures. One and a half years as transitman and draughtsman on road location and maintenance work. Available at once. Location immaterial. Apply to Box No. 899-W.

CIVIL ENGINEER, B.A.Sc. (Univ. of Toronto '27). Age 34. Familiar with house building cost, experience combines structural engineering, construction and house building and improvement, interested in obtaining a connection with firms investigating housing problems, making building loans or with a company engaged in construction or building costs. Apply to Box No. 910-W.

CIVIL ENGINEER, B.Sc., O.P.E. Experience includes several years on municipal work-design and construction of sewers, steel and concrete bridges, watermains and pavements. Available at once. Apply to Box No. 950-W.

ENGINEER SUPERINTENDENT, age 44. Engineering and business training, executive ability, tactful, energetic. Had charge of several large projects. Intimate knowledge of costs and prices, reports and estimates. Available immediately. Any location. Apply to Box No. 1021-W.

## Situations Wanted

ELECTRICAL ENGINEER AND GEOPHYSICIST. B.Sc. (Man. '23), A.M.E.I.C. Married. Ten years specialized experience in the practical use of magnetic, electrical and mechanical instruments for the prospecting, surveying and mapping of mineral, oil and gas lands. Five years experience with telegraph, telephone and radio equipment. Capable of giving instruction in theory and practice in these lines and in college physics. Available on short notice. Apply to Box No. 1063-W.

CIVIL ENGINEER, A.M.E.I.C., with over twenty years experience in field and office on construction, maintenance, surveying, location, etc., desires position preferably of a permanent nature. At present near Montreal, but willing to locate anywhere. Apply to Box No. 1168-W.

ELECTRICAL ENGINEER, B.Sc. '34 (Univ. of N.B.), S.E.I.C. Age 21, single. Desires any kind of electrical work. Will consider any location. Apply to Box No. 1262-W.

CIVIL ENGINEER, M.E.I.C. Married. Age 38. Twenty years experience in organization, design and estimating, and cost accounting. Active service in France. Apply to Box No. 1367-W.

ENGINEER SUPERINTENDENT, A.M.E.I.C., R.P.E., Que. and Alta. Age 47. Married. Twenty years experience as engineer and superintendent in charge of hydro-electric, industrial, railroad, and irrigation construction. Specialized in rock excavation and suction dredging. Intimate knowledge of costs, estimating and organizing. Available immediately. Apply to Box No. 1411-W.

CIVIL AND ELECTRICAL ENGINEER, Univ. of Man. '35 and '36. S.E.I.C. Experience in irrigation and mapping. Available at once. Location immaterial. Box No. 1418-W.

CIVIL ENGINEER, B.Sc. 1910, A.M.E.I.C. Married. Twenty-six years experience on heavy construction work, both field and office; rails, roads, power house, hotels, bridges, etc. Location immaterial. Available at once. Apply to Box No. 1470-W.

CONSTRUCTION SUPERINTENDENT, M.E.I.C. Age 49. Married. Twenty-two years experience as engineer, superintendent and manager in charge of hydro-electric, mechanical production, structural steel erection, also considerable experience in steam plants, combustion, transmission lines, millwright work, complete mine installations, rock work, rock crushers and conveyors. Executive ability. Speaking French fluently. Location immaterial. Apply to Box No. 1482-W.

ELECTRICAL ENGINEER, B.Eng. (McGill '33). One and a half years experience in plant and production routine, and with considerable training in sales work. Bilingual, single, and available at once for any location. Apply to Box No. 1509-W.

ELECTRICAL ENGINEER, B.Sc. '31 (Univ. of Alta.), Jr.E.I.C. Age 28. Married. One year students' test course with C.G.E.Co. including testing and operation of transformers, meters, industrial control and switchgear apparatus. Two years as instrumentman on highway construction. Desires electrical utility, commercial lighting or air conditioning work, location immaterial and available at once. Apply to Box No. 1522-W.

CIVIL ENGINEER, B.Sc. '32, S.E.I.C., P.E.N.B., Dy.L.S.N.B., age 32. Experience in mining, both coal and metals, private and legal surveys, railroad construction, geology and building construction. At present in private practice in coal mining district. Desirous of changing location for position either in mining field or construction in Canada. or abroad. Apply to Box No. 1562-W.

RESIDENT ENGINEER, familiar with all types of surveys and construction work including, railway, roads, irrigation, drainage, buildings and air ports. Executive ability. Had charge of several large projects. Intimate knowledge of reports and estimates. Available immediately. Any location. Apply to Box No. 1567-W.

CIVIL ENGINEER, B.Sc. '17, O.P.E. Married. Executive and administrative experience. Extensive office and field experience in harbour works, dredging; both steam and electric railways in location, construction and maintenance; telephone works in design, construction and maintenance of pole lines, wire, cable and conduit; highways in location, construction and paving; municipal works in roads, sidewalks, sewers and water mains. Intimate knowledge of estimating, unit costs, cost accounting and analysis. Some knowledge of air conditioning. Willing to locate anywhere. Available at once. Apply to Box No. 1587-W.

ELECTRICAL ENGINEER, B.Sc. '27 (McGill), A.M.E.I.C. Age 36. Married. Bilingual. Three years experience in telephone work (installation of manual and automatic exchanges). One year electrical prospecting. Nine years experience with electrical power company. Apply to Box No. 1601-W.

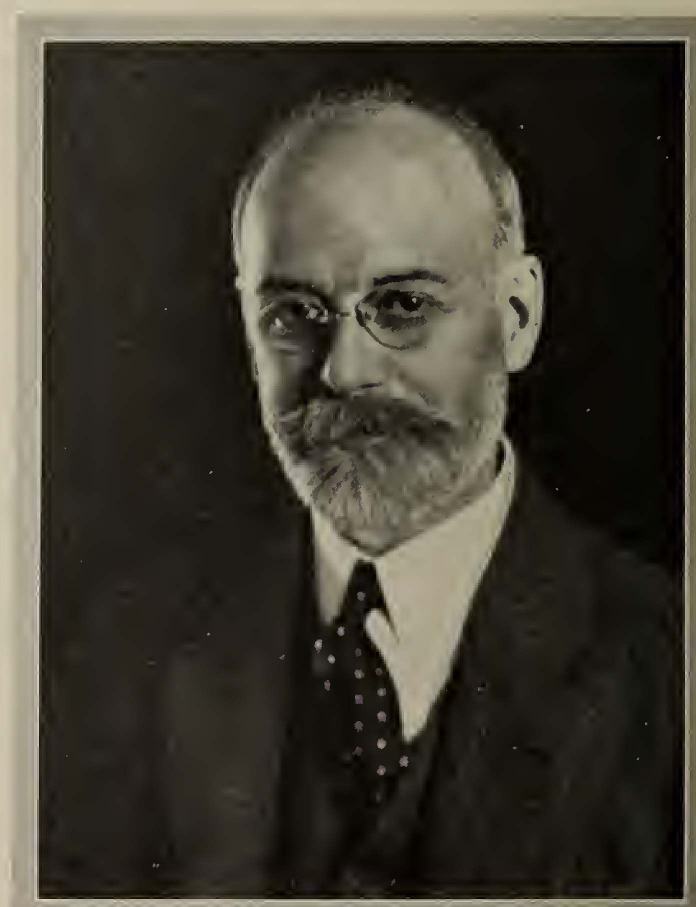
THOMAS COLTRIN KEEFER
President, 1887



GEORGE JOSEPH DESBARATS
President, 1937

# Foreword by the President

In writing the life of an eminent Canadian engineer, a boy from a Scottish country school who became chief engineer of two great Canadian railways and Chancellor of a great university, his biographer began with these words:

> "How often has it been said that while the engineer as a technologist may be capable, he is not usually a citizen in the enlarged sense of the word! His structures may be safe; his work may display an ingenuity that compels admiration; his integrity may be above question, but outside of his professional work his influence is not felt. Those engineers who have received recognition are the exceptions, and they have won it largely through widening their contact with the pulsating life of their time."

In this paragraph Peter Gillespie pointed directly to the main reason for the formation of such societies as The Engineering Institute of Canada, whose Semicentennial we are celebrating this month. To do his best work the engineer must not lead a cloistered life apart from his fellow workers and unrecognized by the public. He needs to exchange professional information and experience with others who belong to the "calling of an engineer," and he should have a recognized standing in the community as a member of an honourable profession. These two things he gets by belonging to a professional society with a high standard of membership, which also gives him the opportunity to join in contributing to the constructive thought of his time. Such benefits are of special importance to the younger men, who, at the outset of their careers, must take advantage of them if their professional development is to be complete and well balanced.

The promotion of its members' interests in this manner has been an important, if not the main, object of The Engineering Institute of Canada dating from the day in January 1887 when its forerunner, the Canadian Society of Civil Engineers, came into being. The extent to which first the Society and then the Institute have succeeded in the aims so clearly expressed in their organization Charter may be judged by their growth in influence and in number of members, and by the degree of public esteem accorded to membership in them.

In the opinion of many the day is at hand when the engineer will be increasingly concerned in the humanitarian and economic questions of our time. Many of these problems have arisen as a direct result of the engineers' work in developing communication and transportation, providing ample supplies of power, and replacing costly handicraft work by the product of machine tools.

The engineer has thus a responsibility to the public which he can best discharge through the collective action of national engineering societies. Membership in these enables him to make his voice heard on matters of general interest to the community.

During the period covered by The Institute's existence, our country has changed from a mainly agricultural land, of which only a small part had adequate means of communication, to one in which industry and transportation by rail and water have developed to a remarkable degree. A considerable proportion of our population has become urban rather than rural, with all that this involves in the provision of the many amenities made possible by modern technical developments. It has seemed desirable to mark these changes by the publication at this time of a series of monographs, forming a feature of this Semicentennial number of The Engineering Journal, in which the progress of some twenty different branches of engineering and industry in Canada since 1887 has been recorded by some of the men who have themselves been largely responsible for the work accomplished.

This series of papers has been prepared in the hope that the picture they present will give at least a general idea of our progress in Canada during that period, and the contribution of the engineer thereto.

At this fiftieth anniversary of the establishment of The Engineering Institute of Canada, the President desires to express The Institute's most cordial welcome to the delegates, officers and members of sister societies, who are bringing their greetings and are gracing the celebrations with their presence. These visits, and also the many messages of friendship which are being received, are evidence—if any were needed—of the fellow-feeling which ties together engineers of all branches of the profession, wherever they may be carrying on their work.

# The Story of The Engineering Institute of Canada

## 1887 — 1937

As time passes, events seem to recede gradually in perspective, so that at length it becomes possible to form an estimate of their importance and their effect upon the life of an individual or the development of a society.

In the hurry of modern industrial life few engineers have the inclination and still fewer the leisure to make a survey of past conditions. But the fiftieth milestone in a journey seems a natural point at which to pause and look back, remembering, however, that retrospection in itself is worth little; it is only when the story of the past is used as a guide for the future that its real value is appreciated.

The occurrence of an anniversary such as that which The Institute is now celebrating gives us an opportunity to review the happenings of the past fifty years. It will be timely to place on record some account of the persons and circumstances concerned in The Institute's formation, note the conditions under which they worked, and observe how the methods and organization they adopted have had to be modified to meet the changes which have since occurred.

As far as technical achievements are concerned, the series of papers presented in this number of the Engineering Journal trace the development of some principal branches of Canadian engineering and industry. Such articles, however, necessarily feature the works themselves rather than the engineers who designed, constructed or operated them. The great majority of these men took an active part in the formation of The Canadian Society of Civil Engineers and in the various movements which resulted in its change into the present Engineering Institute of Canada.

Those of us who are now middle aged—to say nothing of those of riper years—have seen remarkable changes in living conditions in Canada. There has been a rapid development in industry, manufactures, and commerce. The telephone, the motor car, the radio, the aeroplane, the growth of existing, and the use of new, methods of communication and transport, are among the influences which have quickened the tempo of life, and so greatly increased its demands on everyone—engineers included.

* * *

Engineering work in Canada dates back to the seventeenth and early eighteenth centuries, when the activities of the French military engineers were naturally directed principally to the construction of the fortifications necessary to defend their infant cities against the incursions of the Indians and the British colonists from the south. Enough of their handiwork remains at such places as Quebec and Louisburg to attest the ability and skill of these pioneers.

In the course of time, the French were succeeded by the British military engineers, who not only erected fortifications, but also built roads and commenced the construction of canals and other public works.

The first road was opened from Quebec to Montreal in 1734, being gradually completed with the growth of the French settlements, and the St. Lawrence canal system was commenced in 1779. A highway from York to Simcoe was constructed in 1794. The canal system was under active development during the beginning of the nineteenth century, the present Lachine canal, (along the line of a smaller channel constructed by the French), having been commenced in 1821, and the Welland canal in 1824, while the Rideau canal was completed in 1832. Many of these works were designed originally for military purposes, but were essential to the development of communications in Upper Canada. With the development of transportation facilities came the civil engineer.

Railway construction commenced in Canada about 1830, the first line, that from Laprairie to St. Johns, Que., having been opened in 1836, but railway development was not at its height until the 'fifties, at which period there was a considerable influx of civil engineers into Canada, many of whom were brought out from Britain, while others came from the United States.

After the Union of Upper and Lower Canada, there arose further demand for efficient and rapid means of communication between the two provinces, and for access to the Atlantic during the winter when navigation is closed on the St. Lawrence. One result of this movement was the construction of the railway from Montreal to Toronto in 1856, so that by 1860, on the completion of the Victoria bridge at Montreal, there were eight hundred miles of direct railway communication from Portland to Sarnia.

In 1867, the Confederation agreement called for the construction of the Intercolonial Railway to connect the Upper and Lower provinces, and this and other projects led again to increased engineering activity.

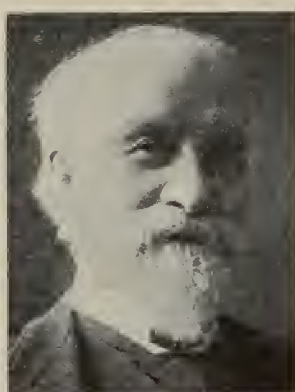
From this time on, small groups of engineers were to be found scattered throughout the Dominion, most of whom, as might be expected, were engaged in work in connection with the construction of the railways, roads, harbours, waterways, and municipal engineering works, the need of which was so pressing at that stage of the country's development. Many of them gained international reputation. Those doing pioneer work often had adventurous careers, and many of their projects had to be carried out with little or no help from experience in older countries where entirely different conditions prevailed. They had to blaze their trails, in some cases literally as well as figuratively.

* * *

What types of men were responsible for this engineering work in Canada during the closing years of the nineteenth, and the opening years of the twentieth century? Space only permits of one or two examples. We may recall, for instance, the romantic career of a young Polish engineer, who after serving in his country's war of independence in 1830 was wounded and made prisoner by the Russians, and who ultimately succeeded in reaching America, landing in New York at the age of twenty-three practically without resources. At first young Gzowski supported himself by teaching music and fencing, but finding engineering employment at length, he came to Canada, where he entered the Government service and was soon put in charge of "roads, harbours, lighthouses and bridges." The location, laying out and supervision of these scattered works, with very limited assistance from men who, though willing, had little engineering knowledge or experience, was no easy task. Communication was difficult, and travel arduous, whether in the saddle, by canoe, or on foot.

In 1850 we find him engaged in harbour work in Montreal, and reporting on the deepening of the St. Lawrence Ship Channel. Turning then to railway work, Gzowski had much to do with the original construction of the Grand Trunk Railway. Years later, he entered the contracting field, and in 1873 his firm built the international bridge across the Niagara River near Buffalo. He proved to be an excellent business man as well as an outstanding engineer, and his wide interests, civil and military, brought him into contact with people in all ranks of life. He was knighted in 1890. From Confederation till his death in 1898 there was no Premier or Governor General who did not avail himself of the advice of Sir Casimir Gzowski.

Sandford Fleming was another pioneer, but of very different type. Educated in a Scottish parish school, he started his career as an apprentice to an engineer and surveyor in Kirkcaldy. On his arrival in Canada, at the age of eighteen, he found employment as a surveyor in Peterborough, then a town of two thousand people.



**Sandford Fleming**

His first construction work was on one of the early railways of Ontario, the Northern Railway, running north from Toronto into then unsettled regions. In 1863 he was chosen by the people of the Red River Settlement, now part of Manitoba, to go to England to urge upon the Imperial authorities the necessity of establishing railway communication between the east and west of Canada. Later, appointed chief engineer of the Intercolonial Railway, he located its route, and displayed some characteristic traits in a strenuous fight with his commissioners for the adoption of iron instead of wood as the material for the railway's bridges. After carrying the matter to the then Prime Minister, Sir John A. Macdonald, he ultimately gained his point.

His greatest engineering undertaking began in 1871, when as engineer-in-chief of the Canadian Pacific Railway he was required to carry out the surveys for the railway across Canada to the Pacific. He determined to undertake the conduct of the expedition himself. His party reached Winnipeg from Lake Superior, travelling by canoe and wagon, via Rainy Lake and Lake of the Woods. Thence to Edmonton the journey was made by pony and Red River cart, and it took two weeks to cover the distance from Edmonton to the Yellowhead Pass. This was the railway route finally advised by Fleming, reaching the Pacific down the North Thompson and the Fraser Rivers, but his recommendations were not accepted. He resigned in 1880 owing to political exigencies; by that time two thousand miles of the Canadian Pacific were under construction.

He was an active advocate for a Pacific cable, and submitted a plan for such a project in 1879, thus beginning an agitation which he led persistently for twenty-three years, until at last his efforts were successful.

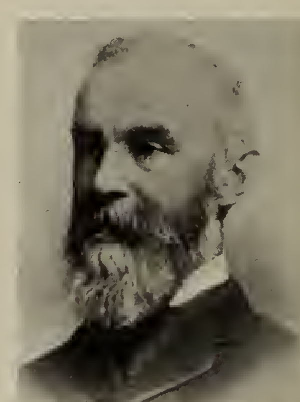
After his appointment as Chancellor of Queen's University in 1880, his continued activity in various public questions, and his writings and speeches in various branches of science and literature, gave him a life of constant usefulness. He received the honour of knighthood in 1897, and closed his long and active life in 1915.

There were of course many other men of high calibre, sketches of whose careers would equally well illustrate the conditions under which engineers performed their work in those days. Not a few of them had records of service to the public and to their country which it would indeed be difficult for their successors to surpass today.

* * *

The first movement towards the organization of an engineering society in Canada appears to have been set on foot before Confederation by Sandford Fleming, who, with some other prominent men, endeavoured to interest members of the profession in the advantages of such an association. Difficulties at that time, however, proved insuperable, and it was not until after the entry of British Columbia into confederation had led to the construction of the Canadian Pacific Railway, and considerable engineering development had taken place in the west, that conditions ripened sufficiently to enable a society to be organized with success.

In May 1880, Mr. E. W. Plunkett, a well known engineer of Irish extraction, circularized his fellow engineers in Canada, setting forth the necessity and advantages of organization. Possibly as a result of the circular, an attempt at the legal regulation of civil engineers in Ontario was made in February 1881, when "an act respecting civil engineers" was introduced in the Legislative Assembly of that province. However, the bill did not commend itself to the Legislature, or, indeed, to all of the engineers named in it, and it never became law.



**Alan MacDougall**

About this time, the authorities of Toronto and McGill Universities realized the importance of having educational facilities for training engineers, and the advantages of having an association with which to co-operate, if such could be formed. Further, Montreal, Toronto and Ottawa were the cities most frequented by the profession, and conditions suitable for the formation of a society were gradually developing at these places.

The idea of a Canadian engineering society was apparently present during this period in the minds of many members of the profession, and during the construction period of the Canadian Pacific Railway the scheme was very thoroughly canvassed by a number of men both in Ontario and Quebec who later became officers or prominent members of the Society they were proposing to form. Their number included Alan MacDougall, C. E. W. Dodwell, T. C. Keefer, Sandford Fleming, J. L. P. O'Hanly, S. Keefer, Frank Shanly, Kivas Tully and others. At length, in February 1886, Alan MacDougall of Toronto issued a circular over his own signature advocating the formation of an association, and as a result a number of meetings were held in Toronto, Ottawa and Montreal. Of these meetings perhaps the most important was that of the fourth of March, held in Montreal at the Harbour Commissioners' office, of which the manuscript minutes have been preserved. Alan MacDougall was in the chair, and P. W. St. George acted as secretary. At this meeting it was moved by H. D. Lumsden, seconded by P. A. Peterson, and resolved

> "That a society of engineers in Canada be formed comprising all branches of engineers, and that a committee be appointed to meet the other committees of engineers from other cities, and then to arrange and form a preliminary constitution, which form of constitution shall be sent around to those gentlemen who send in their names as being willing to form such a society; and that each gentleman present be requested to forward the names of engineers and their addresses to the local secretary."

A Montreal local committee was then appointed, and its meeting resulted in a draft constitution for the proposed society.

On the 30th of March, 1886, as the result of conversations between Mr. R. A. Davy and Lieut.-Colonel W. P. Anderson, a meeting took place in the City Hall, Ottawa, and was addressed by Alan MacDougall. The Montreal draft constitution was considered and afterwards amended by the Ottawa local committee.

Meanwhile a similar local committee had been acting in Toronto, and had appointed delegates to confer with those from Ottawa and Montreal.

The Montreal committee held another meeting on November 11th, 1886, and considered a printed constitution which in the interval had been prepared and amended by correspondence between the local committees at Montreal, Toronto and Ottawa. A provisional committee was then formed, first to revise and complete the constitution and second to establish the association. This provisional committee consisted of:—Colonel C. S. Gzowski, Kivas Tully, W. T. Jennings, A. MacDougall, T. C. Keefer, H. F. Perley, W. P. Anderson, R. Surtees, H. T. Bovey, J. Kennedy, P. A. Peterson and P. W. St. George. Mr. MacDougall was appointed provisional secretary.

On December 9th, 1886, the provisional committee held a meeting at the St. Lawrence Hall, at which it was decided to call the proposed society the "Canadian Society of Civil Engineers." At this meeting it was further resolved that the provisional committee should hold a meeting on the second Tuesday in January for the election of members and to decide on a date for a general meeting of the Society.

Accordingly, on January 19th, 1887, the provisional committee met again in Montreal, to consider the list of applicants for membership, and continued their session on the following day. One hundred and sixty-two elections to membership were effected.

Again, on the 21st of January and the 3rd of February, 1887, further meetings of the provisional committee were held, and, on the latter date, the membership was further augmented. Elections were made in this way up to February 24th, on which date 288 members of all classes had been elected.

The first officers were elected by letter ballot, which was sent to members who joined previous to February 24th, and was canvassed at the first general meeting. This was held on Thursday, February 24th, 1887, in the board room of the Harbour Commissioners' building, Montreal. The result of the ballot was announced and the reports and actions of the provisional committee were adopted and approved.

The minutes of this gathering can be found in the first annual report of the transactions of the Canadian Society of Civil Engineers, together with a list of those present. Representatives had come from Toronto, Ottawa and other places, and it was decided to apply to the Dominion Government for a charter.

* * *

The charter was carried through Parliament by one of the vice-presidents, Walter Shanly, M.P., and received Royal sanction on June 23rd, 1887. It incorporated the

**Walter Shanly**

Society, defined its objects and powers, and enabled it to pass regulations and by-laws for the direction and management of its affairs.

The following were named as its first members:—Thomas C. Keefer, Ottawa; Casimir S. Gzowski, Toronto; John Kennedy, Montreal; Henry T. Bovey, Montreal; Frederick N. Gisborne, Ottawa; Edmund P. Hannaford, Montreal; William T. Jennings, London; Samuel Keefer, Brockville; Louis Lesage, Montreal; Hugh D. Lumsden, Toronto; Alan Macdougall, Toronto; Henry F. Perley, Ottawa; Hurd Peters, Saint John, New Brunswick; Peter A. Peterson, Montreal; Henry S. Poole, Stellarton, Nova Scotia; Henry N. Ruttan, Winnipeg; Collingwood Schreiber, Ottawa; Percival W. St. George, Montreal; and Herbert Wallis, Montreal, "and all other persons who may hereafter be associated with them."

Twelve of these men afterwards served as Presidents of the Society.

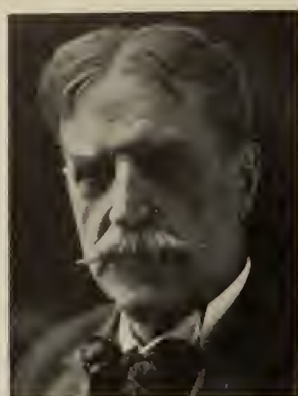
The objects of the Society, as set forth in its Act of Incorporation were "to facilitate the acquirement and interchange of professional knowledge among its members, and more particularly to promote the acquisition of that species of knowledge which has special reference to the profession of civil engineering, and further, to encourage investigation in connection with all branches and departments of knowledge connected with the profession." The Society was also given power to make regulations and by-laws "including all rules that may be deemed necessary for the maintenance of the honour and dignity of the profession." These aims, as more particularly defined and expanded in the by-laws, have remained unchanged to the present day.

The By-laws of the Society made it clear that the term 'civil' engineering, used in the Act, had reference to all types of engineering activity other than military.

It should be remembered that in 1887 mechanical, chemical, mining, electrical and other specialized branches of engineering as we now know them, were only in process of development in Canada. It was therefore inevitable that most of the early members of the new organization should be men engaged in railway surveys or construction, in contracting for public works, or in municipal or government service. The founders of the new body could not possibly foresee the extent of future development of all branches of engineering work in Canada, but they realized the trend, and accordingly the by-laws of the Society provided that its membership should include every branch of the profession.

* * *

Space will not permit more than a brief mention here of the men who were actively engaged in the formation of the Canadian Society of Civil Engineers. Sketches



C. E. W. Dodwell

of the careers of those among them who afterwards served as presidents will be found in the pages following this article. Some notes regarding a few of the other founders may, however, be added at this point as further picturing the kind of men who worked so effectively for the establishment of the new body.

One of the most active among them was Alan MacDougall, a Scotsman who had received his engineering training with the North British Railway, and on coming to Canada entered the service of the Canadian Pacific Railway, then in its early stages. Later he became a consulting engineer in Toronto. He was greatly interested in the status of the engineer and in the training of young engineers. During the 90's it became evident that the English pupilage system for the training of engineers was not altogether suitable for Canadian conditions. The engineering schools at the Canadian universities were just then beginning their development, and MacDougall took the matter up, commenting on the apathy of his professional brethren as regards questions of engineering education. He retained his interest in the Society and its work until his death in 1897.

One of MacDougall's colleagues in the Canadian Pacific service in Toronto was a fellow member of the Institution of Civil Engineers, C. E. W. Dodwell, with whom he used to discuss the various organization problems of the profession. Mr. Dodwell, on his transfer to Montreal in 1885, continued the discussions there, and found that his ideas as to the formation of an engineering society were favourably received. After leaving the Canadian Pacific in 1891, he entered the Government service, ultimately becoming superintendent district engineer for the Public Works Department in Halifax. He was a man of broad views, liberal education, and great intellectual activity, and had the question of professional status very greatly at heart. It was under his chairmanship that a committee of the newly transformed Engineering Institute of Canada drew up the draft by-law in 1919 which formed the basis of the present provincial legislation establishing the various provincial Associations of Professional Engineers. Dodwell may, in fact, be regarded as the father of engineering legislation in Canada. He became the first president of the Association of Professional Engineers of Nova Scotia, and his services to the profession were fitly recognized in 1922 by his election as an Honorary Member of The Institute.

In Ottawa, discussions appear to have been initiated by R. A. Davy, an older engineer of wide experience in railway location and construction. Davy was able to interest Lieut.-Colonel W. P. Anderson, chief engineer of the then Department of Marine and Fisheries, and their combined energy launched the scheme there. We are indebted to Mr. Davy for a collection of reminiscences which gives the most complete historical record of the formation days which is now available.

Though he never became president, Collingwood Schreiber, then chief engineer of the western end of the Canadian Pacific Railway, served several terms on the Society's Council, and aided in much of the early development work. This distinguished engineer later became chief engineer and deputy minister of the Department of Railways and Canals, and in 1905 was appointed general consulting engineer to the Dominion Government. After leaving the Canadian Pacific Railway service he was largely concerned with the developments which led to the building of the transcontinental railways which were afterwards taken over by the Dominion Government.

Among the founders of the Society who did not become President there may also be named Hurd Peters, city engineer of Saint John; H. F. Perley, chief engineer of the Department of Public Works, Ottawa; Louis Lesage, the man who developed the waterworks system of Montreal, and F. N. Gisborne, general superintendent of Government telegraphs, Ottawa, one of the prime movers in trans-Atlantic telegraphy.

It was decided to locate the Society's headquarters in Montreal, where accommodation for its meetings was at first provided by the kindness of McGill University. As the Society developed and funds became available, it was found possible to lease suitable rooms, so that in 1890 the Secretary's office and the library were moved to the upper floor of the Bank of Montreal building at the corner of Mansfield and St. Catherine streets. The need for extension was soon felt, and was met in 1899, when a house at 877 Dorchester street was bought and adapted for the Headquarters of the Society. There Headquarters remained until 1913, when a building at 2050 Mansfield street was purchased and enlarged so that better facilities for the office staff, library and meeting rooms could be provided.

From the outset the young Society showed healthy growth, indicated by the fact that its original membership of about three hundred doubled itself in the first ten years of its existence; in thirty years the membership had reached the three thousand mark.

Its real beginning, however, was at the meetings in January and February 1887, at which its earliest members joined and planned its structure and organization. Twenty-four of these pioneers are still with us,* although their ranks are gradually thinning out.

It must be with a feeling of real satisfaction that these senior members witness the fiftieth anniversary of the establishment of the Society whose success is so largely due to their loyal support during its early years.

In drawing up the original by-laws of the Society it was realized that the membership of such a Dominion-wide body would necessarily be scattered geographically, and that as far as possible a decentralized type of organization should be adopted. For this purpose the formation of local branches was authorized; later, geographical districts and provincial zones were provided for. The first branch was formed in Toronto in 1890; the second in Cape

*The list is headed by T. H. White, of Vancouver, now eighty-nine years of age, who joined as a Member at the meeting of January 20th, 1887.

Breton in 1905.* By 1912 branches had been formed in Quebec, Winnipeg, Ottawa, Vancouver, Kingston, and Victoria, and others followed as opportunity occurred, until to-day there are twenty-five, located in the principal cities of the Dominion from Sydney, Cape Breton, to Victoria, Vancouver Island. These branch organizations perform an indispensable function, giving The Institute a local habitation in every important centre, and stimulating there an appreciation of the engineer and his work, both in a personal and a professional sense.

The growth of the membership in numbers was accompanied by a corresponding increase in the diversity of the branches of engineering followed by the members. This soon resulted in the formation of four sections, general, electrical, mechanical and mining. After about ten years of the Society's existence it was felt by some members that the term 'civil' engineering had come to be generally used in a much more restricted sense than that in which it had been employed at the time of the Society's foundation; this feeling was later to be one of the motives leading to the change in the Society's name and the wider extension of its activities.

* * *

Following the outbreak of the War in August 1914, many of the Society's members joined the Canadian forces and proceeded overseas. Under war conditions the maintenance of the Society's activities became a difficult task. Finance was a problem which had to be solved by determined retrenchment. The Council nevertheless remitted the annual fees of members serving overseas and established a modest fund for their families. Representations were made to the Dominion Government respecting the training of engineer officers, in view of the fact that many engineers were serving in units where their professional knowledge could not be utilized; the Council further expressed the Society's desire to co-operate with the Government in this matter.

*This branch appears to have been discontinued later, and reformed in 1921.

A bronze Memorial Tablet in the Headquarters building in Montreal records the names, ranks and honours of 119 members of the Society who were killed in action or died of injuries received while on active service, from 1914 to 1919.

The total number of members who served overseas was 949; their names and honours will be found on a bronze Record Tablet now erected near the Memorial. Of the total membership at the outbreak of the War over thirty-two per cent served in the Allied Forces.

* * *

Among the members of the Society there were always many who felt that in addition to promoting the dissemination of professional knowledge the new body should take steps to enable the public to distinguish between qualified and unqualified engineers. At the Annual Meeting of 1896 a committee was appointed to consider the question of professional status, the chairman being Mr. Alan MacDougall. In consultation with provincial subcommittees a draft act of provincial incorporation was prepared, which, with some modifications, became law in Manitoba in 1896, and in Quebec in 1898, limiting the practice of 'civil' engineering to members of the Society. These enactments, however, did not prove satisfactory in operation, and further provincial legislation was not attempted at that time.

It was not until 1917 that renewed interest was awakened in the subject, in connection with the report of a Committee on Society Affairs, whose chairman was Professor H. E. T. Haultain. That committee was appointed "for the purpose of studying and reporting upon the policy

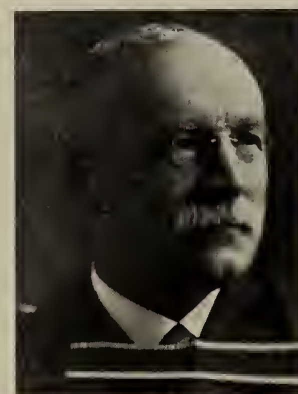
**Group taken at the Annual Meeting of the Canadian Society of Civil Engineers at the Montreal Headquarters—1897.**

for increasing the prestige and influence of the Society" including a consideration of the organization and by-laws. Its report suggested a number of important changes, including the appointment of a whole time secretary, the establishment of a monthly journal, and a change in the Society's name. Meetings in Alberta and in Ottawa during 1917 had also urged the desirability of action regarding professional status, and this question received a further impetus in 1918 after the name of the Society had been changed and its organization extended. The action which followed at that time will be briefly reviewed later.

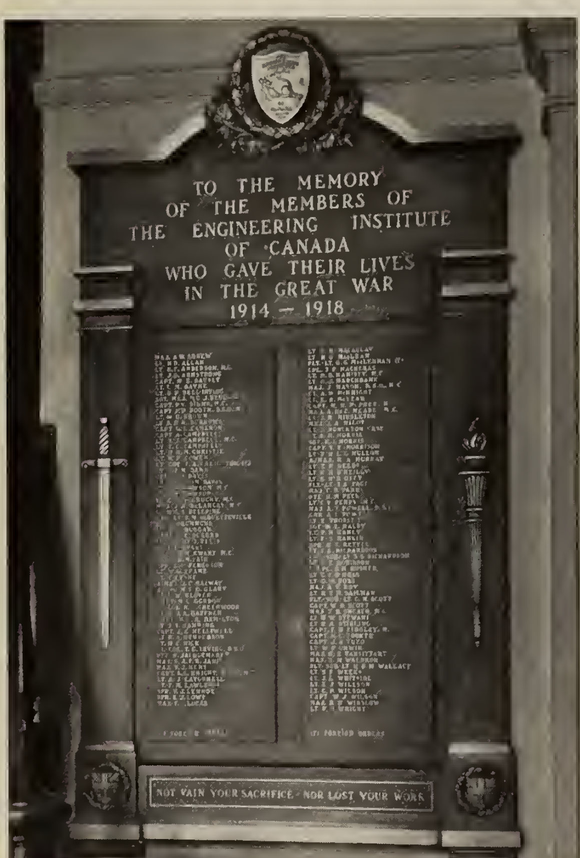
As a result of the work of the Committee on Society Affairs appropriate steps were taken, and an Act of the Dominion Parliament was obtained, which became effective on April 15th, 1918, changing the Society's name to The Engineering Institute of Canada, a title which was thought more expressive of its aims and functions. New by-laws were prepared, providing for more comp'ete branch organization and representation, the formation of provincial divisions, and other desirable changes; the Engineering Journal was established as the organ of The Institute; a whole time secretary was appointed, and as a result growth in membership was resumed and the activities of the Institute and its branches showed renewed enthusiasm. At the first General Professional Meeting of the Engineering Institute of Canada, held in Toronto in March 1918, President H. H. Vaughan pointed out that one of the motives underlying the change in name and organization was the desire "to unite all engineers in Canada, to whatever branch of the profession they may belong, in one society."

During the next three years eleven more branches were formed, and the membership increased from over three thousand to nearly five thousand.

The secretary during the first five years of the Society's existence was Professor H. T. Bovey of McGill University. He was followed in 1891 by Professor C. H. McLeod, who watched over the growth of the organization during the succeeding twenty-five years, and saw it reach maturity. When he died in 1917 the duties had become so onerous that at the beginning of the new regime a full time secretary was found necessary; Mr. Fraser S. Keith was then appointed as General Secretary and as the first editor of the Engineering Journal. On his resignation in 1925 he was succeeded by Mr. R. J. Durley.



**Professor C. H. McLeod**
Secretary, 1891-1916



**Memorial Tablet**

The reorganization was barely completed when the question of legislation regarding professional status was again brought up, this time in August 1918, at the Second Professional Meeting of The Institute at Saskatoon, when the subject was ably discussed in a paper by Mr. F. H. Peters, then of Calgary. At that time provincial legislation was being suggested in Manitoba, Saskatchewan and Alberta. The expressions of opinion at that meeting were in favour of action by The Institute in order to promote uniform legislation in all the provinces.

At the following Annual General Meeting in Ottawa in February 1919 a committee was appointed, under the chairmanship of Mr. C. E. W. Dodwell, to draw up a model act for consideration in the proposal of provincial enactments. This was done, and when submitted to the corporate membership for ballot in July 1919 met with general approval. The Institute Council accordingly endorsed the model act, and passed it to the branches and provincial divisions for suitable action in their respective provinces. During 1920 provincial acts based on this model were obtained in British Columbia, Quebec, Manitoba, Alberta, New Brunswick and Nova Scotia. By 1923 similar legislation had been obtained in all the provinces except Prince Edward Island and Saskatchewan. An act was obtained in the latter province in 1930.

It is perhaps unfortunate that the relations of The Institute (a voluntary body) with the new Associations (provincially constituted bodies having compulsory membership), could not be clearly defined from the outset, for it soon became evident that such questions as the duplication of fees and the diversity of standards for admission as between the associations and The Institute, and also between the associations themselves, would have to receive consideration. On the invitation of The Institute Council in December 1925, a conference of delegates of the provincial Professional Associations was held in Montreal in February 1926. The principal item on the agenda of this meeting was co-operation with The Engineering Institute of Canada. The seven associations then existing were represented, and the delegates left with a resolution recording the sense of close association developed by the conference and their appreciation of the courtesy extended to them by The Institute.

**The Members of The Institute who Served Overseas 1914-1918**
(Record on Bronze Tablet 12 ft. 8 in. by 5 ft. 9 in.)

In the following year an endeavour was made by the Council of The Institute to interest the governing bodies of the various provincial associations in a movement to bring about substantial uniformity in the requirements for admission by examination to the several professional associations and to the Institute. The desirability of such joint action was one of the topics considered at the first Plenary Meeting of the Council of The Institute held in October 1927, at which a standing committee was set up to study this and other problems involved in co-ordinating the activities of The Institute and the several associations of Professional Engineers. This committee continued to function until 1931 in an effort to obtain joint action with the associations. It was then found desirable for The Institute representatives to stand aside, following representations that the associations should first come to an agreement among themselves. At this stage the matter rested for a time, awaiting further action by the associations. Meanwhile the Council of The Institute again expressed its desire to co-operate with the associations in furthering the best interests of the profession throughout Canada.

During 1934 the Council received communications from the Winnipeg, Halifax and other branches, making suggestions for co-operation with their local provincial associations. Before definite action could be taken, however, the subject became the chief matter of debate at the Annual General Meeting of The Institute in February 1935, with the result that a Committee on Consolidation was formed under the chairmanship of Mr. Gordon McL. Pitts. That committee, after two years of strenuous work, prepared a series of proposals for the amendment of The Institute by-laws, defining the lines along which, in the committee's opinion, The Institute could best co-operate with the associations. These amendments, however, did not carry when submitted to ballot, and it would seem that a solution acceptable to The Institute membership as a whole has yet to be found.

* * *

With its twenty-five branches, scattered over seventy degrees of longitude, the problem of effective representation of the branches on The Institute's Council is not an easy one. Much can be done to keep the branches informed of Institute problems and conditions by the personal visitations, which many of the presidents and vice-presidents are able to make from time to time. The Journal is an effective means of communication and reaches the membership individually. An important step towards effective branch representation on matters of Institute policy was taken in 1927, when the First Plenary Meeting of Council was held, attended by twenty-nine out of its forty-two members, for the purpose of discussing Institute affairs. Since then, similar meetings have been held each year except 1932, 1934 and 1935, their number having been limited by considerations of expense. It is generally agreed that these Plenary Meetings have proved of inestimable value, enabling councillors from all parts of the Dominion to know each other, exchanging ideas and reconciling divergent viewpoints.

**Fraser S. Keith**
General Secretary, 1917-1925

Reference should be made to the work accomplished by many of The Institute committees, particularly those dealing with problems of organization. Following the Committee on Society Affairs in 1916, and the committee which drew up the model act in 1919, a committee on Policy was appointed in 1920 under the chairmanship of Mr. J. B. Challies. Its report, presented in 1923, resulted in a new expression of many lines of policy, later embodied in important changes in the by-laws. The work of the Committee on Relations with Professional Associations, 1927-1931, has already been mentioned. A new Committee on Policy, whose chairman was Dr. O. O. Lefebvre, was appointed in 1929, and presented its report in the following year. In 1931 a Committee on Development, under the chairmanship of Mr. J. L. Busfield, commenced a comprehensive review of the constitution and aims of The Institute. It reported in 1933; its proposals for further changes in the by-laws, however, failed to carry on ballot.

In addition to these and other committees dealing with purely Institute affairs, committee work has been done on many subjects of public, professional or technical interest. Among them may be mentioned Fuel, the Deterioration of Concrete in Alkali Soil, the Western Water Problem, Standard Construction Contract Forms, Members Unemployment and Low Cost Housing. The Institute has co-operated actively with the National Construction Council and the Canadian Chamber of Commerce in regard to questions studied by them which affect engineering work. These notes indicate some of the activities directed by Council, which have as their object the well-being of the membership of The Institute and the progress of the engineering profession in Canada.

Among the many prizes and medals awarded annually by Council, some are marks of professional distinction, like the Sir John Kennedy Medal, and others, like the Duggan Prize and the Past-Presidents' Prize, are given to encourage the preparation of professional papers of a high order of merit, or as a recognition of good work by Students or Juniors of The Institute.

Mention may also be made of various services for members. There are, for instance, facilities at Headquarters for furnishing, on request, bibliographies or lists of references to current technical publications for the benefit of members of The Institute, and to supply photostat copies of these.

The Institute's Employment Service Bureau maintains a file of the qualifications and engineering experience of the members registered, and is thus enabled to render a valuable service, without charge, both to members seeking employment and to firms employing engineers.

Like many other public organizations, The Engineering Institute of Canada was seriously affected by the depression years; there was a drop both in membership and revenue. A substantial proportion of the members were indeed without employment, a condition which the Council recognized by the establishment of a Non-Active List containing, at one time, nearly seven hundred names. During these difficult times a number of the branches took steps to assist those of their members who were in financial stress by collecting and distributing local funds. This course did much to help many deserving members, and restore their normal outlook on life. Recent figures show marked improvement and indicate that The Institute membership is again resuming its normal rate of growth.

* * *

What of the future? This brief story of the origin and progress of The Engineering Institute of Canada pictures an organization aiming to advance the scientific and engineering knowledge of its members; to set for them a high standard of professional competence and ethics; to advance their professional, social and economic welfare, and to aid them in fulfilling the engineer's obligation to the public. As in the case of all human institutions, actual performance has fallen short of the ideal; there have been many lines along which advance has been desirable but has not been found possible. Nevertheless, the story shows that worth while results have been obtained, and that the benefits derived from membership have been due entirely to the active and unselfish labour of individual members of the organization.

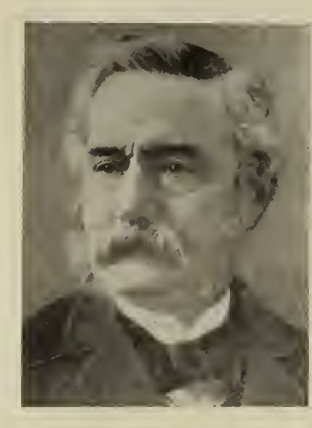
The Institute's influence has made for unity and solidarity among engineers of all branches of the profession in Canada, and has done much to give them a Dominion-wide viewpoint, in contrast to that sectional outlook which, if carried too far, blocks progress instead of promoting it.

May we not expect that in the future this influence will grow, and that the members of the engineering profession in Canada, whether practising independently or working in the service of a government or industrial corporation, will realize to an increasing extent the fact that advance can only result from united effort?

# Notable Figures in The Institute's Past

## Past-Presidents

THOMAS COLTRIN KEEFER (1821-1915), author and eminent engineer, was born at Thorold, Ont. and educated at Upper Canada College. His first engineering work was on the Erie canal, and later the Welland canal. In 1849 one of his most important publications "The Philosophy of Railways" appeared and in the same year he won Lord Elgin's prize for his book "The Influence of the Canals of Canada on Her Agriculture." Mr. Keefer was appointed Commissioner for Canada to the First International Exposition in London in 1851, in 1878 he was Executive Commissioner at the Paris Exposition, was made a C.M.G. by Her Majesty, and elected an Officer of the Legion of Honour (France.) After making an investigation of the St. Lawrence channel, he engaged in preliminary surveys for the Grand Trunk Railway for the line between Montreal and Toronto and prepared plans for bridging the St. Lawrence at Point St. Charles, resulting in the building of the Victoria bridge. He designed and built Montreal's first aqueduct, in 1874-75 was chief engineer of the Ottawa Waterworks Commission and was afterwards engineer to the Montreal Harbour Commission. A Fellow of the Royal Society of Canada, he was President of the American Society of Civil Engineers in 1888. Mr. Keefer was one of the founders of the Canadian Society of Civil Engineers, and became an Honorary Member in 1903.



THOMAS COLTRIN KEEFER, C.M.G., LL.D.
President, 1887 and 1897

SAMUEL KEEFER (1811-1890), railway and canal engineer, was a descendent of United Empire Loyalists who came to Ontario from New Jersey. His early education was at the country schools, and his first insight into engineering work was upon the Welland canal, operated by a company of which his father was the president. After two years at Upper Canada College, Samuel Keefer in 1833 was appointed secretary to the Board of Commissioners for the Improvement of the River St. Lawrence. On the establishment of a Board of Works for the United Provinces, (resulting from the union of Upper and Lower Canada) he became engineer to that Board in 1841. For a man of thirty, the responsibilities of this position were not light. Besides the reconstruction and enlargement of the Welland canal, he had to deal with the canals upon the St. Lawrence and Richelieu rivers, and with the demands for highway communication over a territory extending from Gaspé to Lake Huron. He constructed many bridges, including the first suspension bridge in Canada at the Chaudiere Falls, Ottawa. When the railway era began, like many other engineers, he turned his attention to railway work, becoming inspector of railways in 1857. Retiring from the public service in 1864, he continued the practice of his profession until his death.

SAMUEL KEEFER
President, 1888

CASIMIR STANISLAUS GZOWSKI (1813-1898), railway consulting engineer and contractor, was born at St. Petersburg, Russia, attended the Military College at Kremenetz, and in 1830 obtained a commission in the Imperial Russian Engineers. However, owing to the part which he took in the Polish insurrection of 1830-1831, he was, after being confined in a military prison, shipped to the United States, landing in New York in 1833. In order to perfect himself in the English language, he articled himself as a student in law in Pittsfield, Mass., and in 1837, was admitted to the bar, and practised in Pennsylvania until 1841. In that year he moved to Toronto, obtained a position in the Department of Public Works, and became superintending engineer of roads and harbours in western Ontario. In 1846 he became a naturalized British subject, and from 1850 to 1853 was engineer of the harbour works at Montreal, and consulting engineer on channel improvements between Montreal and Quebec. Casimir Gzowski next became chief engineer of the main line of the Grand Trunk Railway between Montreal and Island Pond, and later, resigning, entered into partnership with Sir Alexander Galt, the Hon. H. Holton and Sir David Macpherson for the construction of the Grand Trunk main line from Toronto to Sarnia. He was also interested in military matters, acted as President of the Dominion Rifle Association and in 1879 was gazetted a Colonel and an honorary A.D.C. to the Queen. He was created K.C.M.G. in 1890. Sir Casimir was one of the founders of the Canadian Society of Civil Engineers.

SIR CASIMIR GZOWSKI, K.C.M.G., A.D.C.
President, 1889, 1890, 1891

Sir John Kennedy, LL.D., D.C.L., Hon.M.E.I.C.
President, 1892

P. Alex. Peterson
President, 1894

John Kennedy (1838-1921), railway and harbour engineer, was born at Spencerville, Ont., and educated at McGill University. While still a young man he had risen to the position of chief engineer of the Great Western Railway System and in 1875 when the deepening of the St. Lawrence River ship channel was determined upon, the management of the work as well as harbour enlargement was put into his hands as chief engineer. On the revival of trade in 1888 the Commissioners instructed Mr. Kennedy to prepare a scheme for the enlargement of the Port of Montreal; this work was commenced in 1890, under his supervision. In 1899 Mr. Kennedy's eyes became affected by an incurable ailment, so that by 1907 his sight was so far gone that he resigned his position as chief engineer, the Commissioners appointing him their consulting engineer. He served on many Royal Commissions; in 1916 his services were recognized by a knighthood; in 1917 the degree of LL.D. was conferred on him by McGill University and in 1921 that of D.C.L. by McMaster University.

Edmund Phillips Hannaford (1834-1902), railway engineer, was born at Stoke Gabriel, Devon, England, coming to Canada in 1856, and joining the staff of the Grand Trunk Railway Company. For nine years he acted as assistant engineer and then engineer of the western division, and in addition was chief engineer on the construction of a bridge over the Niagara river, which was completed during 1873. Mr. Hannaford was at this time made chief engineer of the Grand Trunk System, and among the many works undertaken during his tenure of office were the construction of the Montreal and Champlain Junction Railway, the United States and Canada Railway, the erection of general offices at Point St. Charles, the original Union Station at Toronto and the passenger station at Montreal. He was a charter member of the Canadian Society of Civil Engineers.

P. Alex. Peterson (1839-1913), railway engineer, was born at Niagara Falls, Ont. and in 1859 was articled to Thomas C. Keefer. From 1863 to 1867 he was engaged on various engineering works, and in 1867 was appointed resident engineer of the Northern Division of the New York and Oswego Midland Railway. In 1872 he was made chief engineer of the Toronto Water Works, then about to be constructed. Commencing in 1875 he became in turn chief engineer of a section of the Quebec, Montreal, Ottawa and Occidental Railway, the Atlantic and North West Railway and in 1890 the Canadian Pacific Railway, holding this position until 1902, when, owing to ill health, he was appointed consulting engineer, retiring in 1908. Mr. Peterson was a charter member of the Society and was a vice-president in 1889, 1892 and 1893.

Thomas Monro (1831-1903), railway and waterways engineer, was born at Londonderry, Ireland, and coming to Canada in 1850 was employed under T. C. Keefer. From 1854 he was on the construction of the Grand Trunk Railway near Prescott, the Hamilton and Port Dover Railway and the Hamilton waterworks. From 1860 until his death Mr. Monro was in the service of the Canadian Government filling many responsible positions, including an appointment as inspector of railways. In 1871 he located the new Welland canal and in 1889 a 14-foot canal between Lakes St. Louis and St. Francis. This work, including all structures, was designed by Mr. Monro, and carried out under his supervision. He designed the waterworks for the city of St. Catharines, and in 1895 was chairman of a board reporting on the harbour of Montreal. A charter member of the Society, he served on Council and as a vice-president.

Herbert L. Wallis (1844-1922), mechanical engineer and designer, one of the outstanding figures in the early history of the engineering development of Canadian railways, was born at Derby, England, and educated at Ockbrook, serving his apprenticeship with Matthew Kirtley, locomotive superintendent of the Midland Railway. In 1871 he came to Canada as assistant mechanical superintendent of the Grand Trunk Railway at Montreal, and two years after became chief mechanical superintendent. He retired in 1896. The first compound locomotive upon the Grand Trunk Railway was built by Mr. Wallis, who was instrumental in improving the shops of the company so as to construct practically all the new locomotives for its service. He joined the Society on January 20th, 1887, served on the Council from 1887 to 1893, was Treasurer, and in 1894 became a vice-president.

Edmund Phillips Hannaford
President, 1893

Thomas Monro
President, 1895

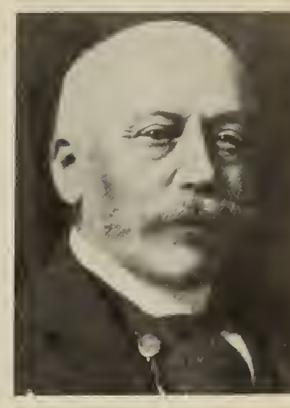
Herbert L. Wallis
President, 1896

William George MacNeill Thompson (1832-1903), railway and canal engineer, was born at Saltford, Lancashire, England, and from 1852 to 1856 was engaged on the construction of the Grand Trunk Railway from Toronto westward. He was subsequently, until 1859, resident engineer on the Welland Railway, then contractors' engineer on the Rivière du Loup section of the Grand Trunk Railway, and the reconstruction of the Northern Railway. In 1863 Mr. Thompson was engineer and manager for Dyphwys Cassen Mining Company in North Wales, and in 1864 went to Ceylon. Returning to Canada in 1868 he was resident engineer on the construction of the Intercolonial Railway, from 1872 to 1889 on the southern division of the Welland canal enlargement, and later the Sault Ste. Marie canal. He was a member of Council of the Canadian Society of Civil Engineers in 1895, and a vice-president in 1896 and 1897.

William Tyndale Jennings (1846-1906), railway, municipal and consulting engineer, was born in Toronto and receiving his education at Upper Canada College, began his professional career in 1869 under T. N. Molesworth. In 1870 he entered the service of the Great Western Railway and on its completion in 1875 was appointed locating engineer on the British Columbia section of the Canadian Pacific Railway. In 1890 he became city engineer of Toronto, resigning in 1891 to enter private practice as a consulting engineer. From 1892 to 1895 he was chief engineer of the British Columbia Southern Railway. He reported in 1897 on a route from Fort Wrangel on the Pacific coast to Teslin Lake, also among others on the country between Lake Nipissing and James Bay, and on the dry docks at Halifax and Esquimalt. He was a charter member of the Canadian Society of Civil Engineers, a councillor and a vice-president.

William Tyndale Jennings
President, 1899

Henry T. Bovey (1852-1912), first dean of the Faculty of Applied Science of McGill University, was born in Devonshire, England, and educated at Queen's College, Cambridge, coming to Canada in 1878 as professor of civil engineering and applied mechanics at McGill University. He was one of the founders of the Canadian Society of Civil Engineers, held office as secretary-treasurer or member of Council for many years, and was vice-president of the Society in 1896-97. Following his resignation from McGill University in 1908, he was appointed rector of the Imperial College of Science and Technology, London. Dr. Bovey received many distinctions in the academic world, including the Fellowship of the Royal Society of London, an honorary LL.D. from McGill and Queen's Universities, the degree of D.C.L. from Bishop's College, and an Honorary Fellowship of his old College at Cambridge.

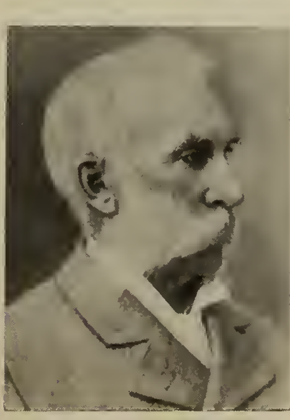


Edward Henry Keating
President, 1901

Edward Henry Keating (1844-1912), railway, municipal and consulting engineer was born at Halifax, N.S. and educated at Dalhousie College. He studied engineering under George Whiteman, in Nova Scotia, and was with the Truro and Pictou, the Windsor and Annapolis, and the Intercolonial Railways. From 1873-1890 he was city engineer of Halifax, and also designed waterworks for Truro, Windsor, Dartmouth and Moncton. He was later city engineer of Duluth, Minn. and then chief engineer of Toronto, Ont. In 1898 Mr. Keating became general manager of the Toronto Street Railway, and in 1904 went to Mexico as engineer and manager of construction with the Monterey Railway Light and Power Company. Latterly he acted as consulting engineer and arbitrator in valuation disputes. He served as a member of Council for three years, and as a vice-president for two years.

Martin Murphy (1832–1926), railway, highway and bridge engineer, was born at Cooleycarny, Wexford, Ireland, and educated at Ballindagin National School. He occupied several positions before coming to Canada to become city engineer of Halifax in 1868. After two years he became engaged in railway survey work in Nova Scotia, and then as a contractor on the construction of bridges on the Intercolonial Railway. In 1875 he was appointed provincial chief engineer for the government of Nova Scotia, which position he occupied for many years. Subsequent to his retirement he acted as inspection engineer on the construction of the western division of the Transcontinental Railway. Dr. Murphy was noted for his work on railway bridges and received the degree of D.Sc. from King's College, Windsor, N.S. He was a member of Council of the Society in 1888, 1889 and 1897, and a vice-president in 1895.

William George MacNeill Thompson
President, 1898



Henry T. Bovey, D.C.L., LL.D., F.R.S.
President, 1900

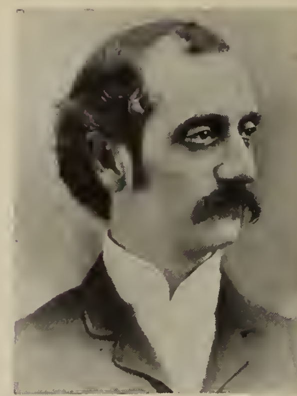
Martin Murphy, D.Sc.
President, 1902

Kennet William Blackwell
President, 1903

Kennet William Blackwell (1850-1920), mechanical engineer and manufacturer, was born in Wiltshire, England, and came to Canada as a youth. He was educated at Bishop's College, Lennoxville, and apprenticed as a mechanical engineer in the shops of the Grand Trunk Railway, later becoming mechanical superintendent for that railway and subsequently joining the Canadian Pacific Railway in the same capacity. In 1882 he went into the manufacturing business, the firm eventually becoming Montreal Steel Works Limited, of which he was president and managing director. This company was later absorbed by the Canadian Car and Foundry Company under the name of Canadian Steel Foundries Limited, with Mr. Blackwell as vice-president. He was a vice-president of the Merchants Bank of Canada and a director of other prominent business concerns. He served on the Council of the Society for five years, and was a vice-president in 1898 and 1899.

William Patrick Anderson (1851-1927), chief engineer and superintendent of lighthouses, was born at Levis, Que., and educated at Bishops College, Lennoxville, and Manitoba College, Winnipeg. In 1874 he entered the civil service as a draughtsman in the Department of Marine and Fisheries, Ottawa, soon becoming assistant engineer, and in 1880 was appointed to the post which he held until his retirement in 1919. Colonel Anderson took an active interest in military matters, serving in the Canadian Militia during the Fenian Raids, and later commanding the 43rd Regiment. He was one of the first members of the Canadian Society of Civil Engineers and assisted in its organization, being appointed to Council in 1890, 1891 and 1901, and a vice-president in 1902. He was created a C.M.G. in 1913.

Colonel William Patrick Anderson, C.M.G.
President, 1904



Ernest Marceau, B.A.Sc.
President, 1905

Ernest Marceau (1852-1919), professor and canal engineer, was born at Danville, Que., and graduated from the Ecole Polytechnique, Montreal, in 1877. During his entire engineering career he was associated with the canals of eastern Canada, and for many years was Superintending Engineer of Canals in the province of Quebec. In 1904 he was appointed head of the Ecole Polytechnique of Montreal, and in 1909 went to Europe on behalf of that institution. Mr. Marceau served on the Council of the Canadian Society of Civil Engineers in 1897, 1898 and 1899; in 1901 was elected vice-president for three years, and in 1909 was appointed Treasurer. He was the recipient of the Gzowski Medal in 1909 for his paper on the Carillon Canal, Dam and Slide.

Hugh David Lumsden (1844-1928), land surveyor and railway engineer, was born at Belhelvie Lodge, Aberdeenshire, and received his early education in Aberdeen and at Wimbledon, coming to Canada in 1861. He served his time as provincial land surveyor at Woodville, Ont., and was admitted to practice in 1866. In 1871 Mr. Lumsden was engaged on the location of the Toronto and Nipissing Railway, and from that time was almost continuously employed in the location or construction of railways. On the commencement of the National Transcontinental Railway in 1904 Mr. Lumsden was appointed chief engineer, and held that position until 1910. He then carried on a consulting practice until 1914. He joined the Canadian Society of Civil Engineers in 1887, and after serving on Council for some years, became a vice-president in 1898.

Hugh David Lumsden
President, 1906

W. McLea Walbank (1856-1909), architect, land surveyor and hydro-electric engineer, attended the engineering course of Queen's University, Ireland, and subsequently that of McGill University, graduating in 1877. He practised as an architect and land surveyor in Montreal for some years, during which time he designed and carried out sewerage works and constructed several factories. One of his most important surveying commissions was the subdivision of the Caughnawaga reserve. He was, however, chiefly known to the engineering world in connection with the construction of the Lachine Land and Hydraulic Power Works, of which he was general manager. When this company sold out its interests to the Montreal Light, Heat and Power Company, he became vice-president and chief engineer of the latter company. One of the original members of the Canadian Society of Civil Engineers, Mr. Walbank served on Council in 1903 and 1904, being elected a vice-president in 1906.

W. McLea Walbank, B.A.Sc.
President, 1907

John Galbraith (1846-1914), educationalist and engineer, was born in Montreal, and graduated from the University of Toronto in 1868. It was through Dr. Galbraith's efforts that the Legislative Assembly sanctioned the establishment of the well-known School of Practical Science at Toronto, and upon its establishment he assumed the responsibility of instruction in engineering. In 1906 this School became the Faculty of Applied Science and Engineering of the University of Toronto, of which Dr. Galbraith was appointed dean. In recognition of his work both Toronto and Queen's Universities conferred upon him the honorary degree of LL.D. He had also a notable career as an engineer, having been engaged on the construction of the Intercolonial Railway and the Midland Railway extension to Sudbury. His extensive knowledge of the geographical and geological nature of the country was acquired by canoe and trail years before other white men had penetrated into the Indian's domain.

George Alphonso Mountain (1860-1927), noted railway engineer, was born at Quebec City, and studied for his profession with the city engineer of Quebec. His early engineering work was with survey parties of the Quebec and Lake St. John Railway, on work at the Quebec graving docks and on the Newfoundland Railway. In 1881 he joined the staff of the Canada Atlantic Railway, as assistant engineer, being appointed chief engineer in 1887, and holding that position until 1904 when he became chief engineer with the Board of Railway Commissioners. For twenty years he held the latter important post, resigning in 1924 on account of ill health. Mr. Mountain was one of the first members of the Canadian Society of Civil Engineers, and served on Council in 1893, 1899, 1900 and 1901. He was a vice-president in 1903 and 1905.

Henry Norlande Ruttan (1848-1925), soldier, railway and municipal engineer, was born at Cobourg, Ont. and during his active engineering career held many important positions with the Grand Trunk, Intercolonial and Canadian Pacific Railways. In 1874 he was engaged on the first surveys for the Canadian Pacific Railway along the north shore of Lake Superior, and during the following two years had charge of the first survey party through the Yellowhead Pass. For a period of twenty-nine years, 1886-1915, he was city engineer for Winnipeg, Man. At the age of sixteen years General Ruttan joined the Cobourg Rifles, was a veteran of the Fenian Raids and the Northwest Rebellion, in 1915 was appointed O.C. at Winnipeg, retiring in 1918. General Ruttan was one of the signatories of the Charter of the Canadian Society of Civil Engineers, a councillor for twelve years, 1887-1906, and in 1909 a vice-president.

Charles Henry Rust (1852-1927), municipal engineer, was born at Great Waltham, Essex, England, and received his education at Brentwood Grammar School, coming to Canada in 1872. He was first engaged on a preliminary survey of the Ontario and Quebec Railway, later entering the service of the city of Toronto. In 1892 Mr. Rust was appointed acting city engineer, then deputy city engineer, and later city engineer and manager of water works at Toronto. In 1912 he resigned to become city engineer of Victoria, B.C., but returned to Toronto six years later to accept a position with the Toronto Street Railways and Toronto Electric Light Company, subsequently the Toronto Hydro-Electric System. His services were frequently in demand as a consultant and expert among the municipalities near Toronto. He served as a councillor of the Society during 1899, 1900, 1905 and 1907, and as a vice-president in 1901 and 1910.

William Francis Tye (1861-1932), railway and consulting engineer, was born at Haysville, Ont., and educated at Ottawa College and the University of Toronto, graduating in 1881. In 1882 he joined the Canadian Pacific Railway, in 1886-1887 was on the location of the St. Paul, Minneapolis and Manitoba Railway, and then spent several years on railway and mining work in Mexico. From 1890-1896 he was with several railways in Western Canada and in 1897 joined the Canadian Pacific Railway as personal engineering assistant to Lord Shaughnessy, becoming chief engineer in 1904, but retiring two years later to engage in consulting work. Mr. Tye was awarded the Gzowski Medal in 1917 for his paper on "Canada's Railway Problem and its Solution." He served on Council and as a vice-president from 1905 to 1910.

Phelps Johnson (1849-1926), bridge designer and industrialist, was born at Warwick, N.Y., and began his engineering career at Springfield, where from 1867 until 1878 he was with the R. F. Hawkins Iron Works. He was subsequently with the Wrought Iron Bridge Company at Canton, Ohio, and in 1882 joined the Toronto Bridge Company at Toronto. In 1883 Mr. Johnson was appointed manager and engineer in charge of the Toronto works of the Dominion Bridge Company, succeeding in 1888 to the post of chief engineer at Montreal, becoming managing director, and from 1913-1919 president of the company. From 1911-1920 and during the construction of the Quebec bridge he was also president and general manager of the St. Lawrence Bridge Company. In 1921 the honorary degree of LL.D. was conferred upon him by McGill University. He served on the Council of The Institute on several occasions and as a vice-president in 1907.

Matthew Joseph Butler (1856-1933), railway and consulting engineer, began the study of engineering at the University of Toronto in 1874, and was successively assistant and chief engineer for the Kingston and Pembroke Railway, chief engineer of the Napanee, Tamworth and Quebec Railway, and assistant engineer with the National Transcontinental Railway. In 1885 he conducted a number of surveys for the Ontario government and in 1905 was appointed Deputy Minister of Railways and Canals, becoming chairman of the Board of Management of the Canadian Government Railways in 1909. From 1910 until 1913 he was general manager of the Dominion Iron and Steel Corporation, and later took charge of the Longueuil plant of the Armstrong Whitworth Corporation. He entered private practice as a consulting engineer in 1919. Mr. Butler was a member of Council in 1896, 1897, 1904 and 1905, and a vice-president in 1906 and 1907.

Francis Clarke Gamble (1848-1926), railway and public works engineer, was born in Toronto and attended Upper Canada College, and Rensselaer Polytechnic, Troy, N.Y. He entered the employ of the Intercolonial Railway in 1869, and subsequently the Great Western Railway, the Prince Edward Island Railway, becoming assistant engineer on the Intercolonial Railway in 1876, and in 1880 first assistant engineer with the Canadian Pacific Railway. In 1881 he entered the service of the Department of Public Works, British Columbia, and in 1898 was appointed public works engineer, becoming chief engineer of the Department of Railways for the province in 1910. Mr. Gamble was elected a member of Council in 1892 and again in 1898, and in 1913 and 1914 was a vice-president.

George Herrick Duggan (1862), Chairman of the Board of the Dominion Bridge Company, Limited, and Vice-President of the Royal Bank of Canada, was born in Toronto, and graduated from the University of Toronto in 1883. He was appointed chief engineer of the Dominion Bridge Company in 1891, and subsequently joining the Dominion Coal Company, was promoted to second vice-president and general manager in 1904. In 1910 he returned to the Dominion Bridge Company as chief engineer, being appointed president in 1918, and president and managing director of the Dominion Engineering Works in 1920. In 1920 he received the degree of D.Sc. from the University of Toronto; the honorary degrees of LL.D. from Queen's University in 1919 and from McGill University in 1921. Dr. Duggan served on the Council of The Institute for nine years, was a vice-president for five years, and was the recipient of the Sir John Kennedy Medal in 1931.

John Stoughton Dennis (1856), surveyor, irrigation engineer, and soldier, was born at Weston, Ont., and after securing the degrees of Dominion Land Surveyor and Dominion Topographical Surveyor played an important part in the development of the prairie provinces, rising to the position of Deputy Minister of Public Works, and chief engineer of the Northwest Territories. As land commissioner for the Hudson Bay Company he assisted in developing irrigation in the west; in 1903 he joined the Canadian Pacific Railway and in 1912 became assistant to the president. He was appointed Chief Commissioner of Colonization and Development of that Company in 1917, retiring in 1930. From 1915 to 1917 Colonel Dennis was head of the Canadian Mission in the United States; served on the British-Canadian Mission; in 1918 was chairman of the Siberian Trade Commission and was awarded the C.M.G. and also foreign decorations. He was a member of Council of the Society in 1906 and 1911, and a vice-president in 1907.

Matthew Joseph Butler, C.M.G., LL.D.
President, 1914

George Herrick Duggan, D.Sc., LL.D.
President, 1916

Colonel John Stoughton Dennis, C.M.G.
President, 1917

Henry Hague Vaughan (1868), mechanical and industrial engineer, was born at Forest Hill, England, and educated at King's College, London, afterwards serving three years with Nasmyth, Wilson and Company of Patricroft, England, as an apprentice. He was with a number of railroads in the United States before becoming assistant to the vice-president of the Canadian Pacific Railway, Montreal, in 1905, where he had general charge of the design and construction of locomotives and car equipment, the maintenance of equipment east of Fort William, and the operation of the Angus shops. In 1915 Mr. Vaughan became president of the Montreal Ammunition Company, and subsequently vice-president of the Dominion Copper Products Company. In 1916 he was appointed vice-president of the Dominion Bridge Company, leaving in 1920 to engage in consulting practice. He was a vice-president of the Society in 1910-1912.

Reuben Wells Leonard (1860-1930), railway, hydro-electric and mining engineer, was born at Brantford, Ont., and educated at the Royal Military College, Kingston, obtaining his early engineering experience with the Canadian Pacific Railway. In 1892-1893 he was on the construction of the first hydro-electric power development at Niagara Falls, subsequently becoming chief engineer of two railways, then entering the mining field as engineer for the Lake Superior Corporation. In 1902 Colonel Leonard became engineer of the hydro-electric developments at De Cew falls, then at Kakabeka falls and returned to mining work in 1906 as promoter and president of the Coniagas Mines. He was appointed chairman of the National Transcontinental Railway Commission in 1911, served as a director of a number of companies, was a governor of the University of Toronto and of Queen's University, and in 1916 created the Leonard Foundation, establishing scholarships in schools and colleges of the Dominion. He was one of the original members of the

Society, served on Council for three years, and was a vice-president in 1910. In 1929 he received the Sir John Kennedy Medal.

Robert Alexander Ross (1865-1936), outstanding mechanical and electrical consulting engineer, was born at Woodstock, Ont. and educated at the University of Toronto, graduating in 1890. He was with the Canadian General Electric Company until 1893, then chief electrical and mechanical engineer of the Royal Electric Company, Montreal. In 1896 he commenced his consulting practice in Montreal, and was responsible for the design of important electrical and power installations. He acted as consultant to many of the larger cities in Canada, and carried out work in China, India, the Straits Settlements, Russia, Finland, Scotland, Australia, the West Indies and the United States. He was a member of the Administrative Commission of Montreal for three years and in 1921 received the honorary degree of D.Sc. (Toronto). Dr. Ross was a member of several famous commissions and boards. He served on Council for eight years, as vice-president from 1914 to 1916 and in 1934 received the Sir John Kennedy Medal.

John Morrice Roger Fairbairn (1873), chief engineer of the Canadian Pacific Railway, was born at Peterborough, Ont., and graduated from

Robert Alexander Ross, E.E., D.Sc.
President, 1920

John Morrice Roger Fairbairn, D.Sc.
President, 1921

the University of Toronto. For some years he was with the Department of the Interior, Department of Railways and Canals, the Department of Militia and Defence, and then for a short time in private practice. Since 1901 he has been associated with the Canadian Pacific Railway, becoming principal assistant engineer in 1910, afterwards engineer, maintenance of way, and later assistant chief engineer. Mr. Fairbairn was appointed to his present position in 1918, and received the degree of D.Sc. from the University of Toronto in 1921. He has served as a member of the Council and a vice-president of The Institute.

John G. Sullivan (1863), railway and canal engineer, was born at Bushnell's Basin, New York, and graduated from Cornell University in 1888. He commenced his engineering work with the Great Northern Railway and came to Canada as assistant engineer for the Alberta Railway and Coal Company in 1893. From 1898 until 1905 he was on railway construction, latterly as division engineer on the Canadian Pacific Railway. From 1905 to 1907 Mr. Sullivan was assistant and acting chief engineer of the Panama canal. In 1908 he became assistant chief engineer for the eastern lines of the Canadian Pacific Railway; in 1911 chief engineer of western lines, and in 1915 chief engineer of the system. He resigned in 1918, but was retained

John G. Sullivan, C.E., LL.D.
President, 1922

Arthur T. St. Laurent, B.A., C.E.
President, 1923

as consulting engineer until 1928. Mr. Sullivan served on the Council of the Society in 1910 and 1918, and was a vice-president in 1911, 1912 and 1913. He is the recipient of the Sir John Kennedy Medal this year.

Arthur T. St. Laurent (1859-1923), public works engineer, was born at Rimouski, Que., and graduated from the Ecole Polytechnique, Montreal, in 1885. Following graduation he was engaged on harbours and railway surveys, then for two years on the Temiscouata Railway construction. In 1888 he joined the engineering branch of the Department of Public Works, and in 1890 was appointed assistant resident engineer at Winnipeg for the district of Manitoba and the Northwest Territories. In 1895 Mr. St. Laurent surveyed the Red river below Winnipeg and prepared the plans and designs of a proposed lock and movable dam. In the same year he was appointed engineer in the department, and became chief engineer in 1922. In 1909 he was a member of Council of the Society, and a vice-president during 1915, 1916 and 1917. Elected President in 1923 he died in March of the same year.

Walter Joseph Francis (1872-1924), consulting engineer, was born in Toronto and graduated from the University of Toronto in 1893. Following graduation he joined the Central Bridge Engineering Company, and

Walter Joseph Francis, B.A.Sc.
President, 1923-1924

Arthur Surveyer, B.A., B.A.Sc., C.E., D.Eng.
President, 1924-1925

subsequently the Department of Railways and Canals. In 1907 he became assistant manager and chief engineer of the Dominion Engineering and Construction Company, Montreal, also engineer to the Royal Commission on the Quebec Bridge disaster. Mr. Francis reported on various hydro-electric power propositions including that of the North Saskatchewan river at Edmonton, also on the public utilities of the city of Edmonton, and the construction of the Don siphon for main sewers, Toronto. In 1910 he formed a partnership with Frederick B. Brown. He was the first chairman of the Montreal Branch and either a councillor or vice-president from 1910 until he became president; he died during his term of office.

Arthur Surveyer (1878), consulting engineer, was born in Montreal and graduated from Laval University and the Ecole Polytechnique. He took a post-graduate course at the Ecole Speciale d'Industrie et des Mines du Hainaut, at Mons, Belgium, then joined the Public Works Department of Canada in 1904, remaining until 1911, when he entered private practice in Montreal. He was a member of the St. Lawrence River Commission, and in 1912 reported to the Federal Government on the effect of the Chicago Drainage Canal diversion. Dr. Surveyer has been employed in a consulting capacity by the Federal Government, the province of Quebec and most of the important cities in the province. He was the recipient of the degree of D.Eng. from the Rensselaer Polytechnic Institute in 1924. He served on Council from 1915 to 1921, and was then elected a vice-president, serving three years.

Major George A. Walkem, B.Sc.
President, 1926

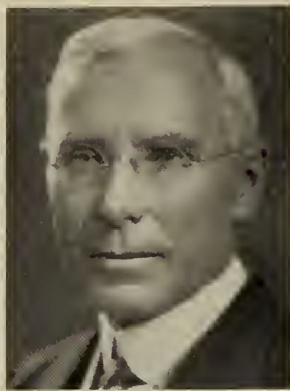
George A. Walkem (1872), managing director of the Vancouver Machinery Depot Limited, Vancouver, was born at Kingston, Ont., and graduated from McGill University in 1896. He served his apprenticeship in the Kingston Locomotive Works and Kingston Foundry; from 1901 to 1905 was works manager for the Vancouver Engineering Works, and in 1906 organized the Vancouver Machinery Depot. He rendered distinguished service during the War, his duties in Egypt and Palestine with the Railway Operation Division, R.E., including the charge of the Kantara Military Railway. Major Walkem is president of the Gulf of Georgia Towing Company and of the British Columbia Dock Company. He takes an active part in civic and public life, served as a Councillor of The Institute during 1921 and 1922, and was a vice-president in 1923 and 1924.

Albert R. Decary (1875), superintendent engineer of the province of Quebec for the Department of Public Works of Canada, was born in Montreal, and received his education at the St. Mary's College and at the Ecole Polytechnique, Montreal. In 1905 he was appointed district engineer at Quebec for the Department of Public Works of Canada, and in 1913 received the appointment which he still holds. Dr. Decary has always taken an active interest in the affairs of The Institute, having been made a councillor in 1914, and sitting on Council in that capacity until 1924, when he became vice-president. He has been a member of a number of special committees of The Institute, and when the Quebec Branch was formed in 1907 was among its principal promoters. In 1927 the degree of D.A.Sc. was conferred on him by the University of Montreal.

Albert R. Decary, D.A.Sc.
President, 1927

Julian Cleveland Smith (1878), President of the Shawinigan Water and Power Company, Montreal, was born at Elmira, N.Y., receiving his early education at Buffalo, and his engineering training at Cornell University, graduating in 1900 with the degree of M.E. He began his career as a draughtsman with Wallace C. Johnston at Niagara Falls, N.Y., and in 1902 joined the Shawinigan Water and Power Company as assistant engineer of their plant at Shawinigan Falls, Que. In 1903 he was appointed superintendent of the plant, and gradually advanced to general superintendent and chief engineer of the company. He became vice-president of the company in 1913, general manager in 1916, and president in 1933. Mr. Smith also presides over the activities of a number of subsidiary and associated companies. The degree of Doctor of Laws was conferred upon him by Queen's University in 1922.

Charles Hamilton Mitchell (1872), hydraulic engineer, soldier and educationalist, was born at Petrolia, Ont., graduating from the University of Toronto in 1892. In 1898 he received the degree of C.E., and the honorary degrees of LL.D. (Toronto) in 1919, and D.Eng. (New York) in 1922. He acted as assistant city engineer, and city engineer of Niagara Falls, N.Y., and from 1901 to 1905 was connected with the Ontario Power Company. In 1906 he travelled through Europe, studying hydro-electric power developments, then entered private consulting practice in Toronto until 1914, engaged largely on the economics and design of hydraulic and hydro-electric power works. He served overseas during the Great War for five years on the General Staff (Intelligence) in France, Belgium, Italy and England, being mentioned in despatches seven times, and receiving numerous British and foreign decorations. General Mitchell was appointed Dean of the Faculty of Applied Science and Engineering of the University of Toronto in 1919. He served on the Council of The



Brig.-Gen. Charles H. Mitchell, C.B., C.M.G., D.S.O., C.E., D.Eng.
President, 1929

Institute during 1908-1909, and as vice-president from 1920 to 1923.

Alexander Joseph Grant (1863), eminent canal engineer, was born in Banffshire, Scotland, and educated at the University of Ottawa and St. Mary's College, Montreal, beginning his professional career in 1880 on a survey for the Canadian Pacific Railway. In 1886 he entered the Department of Railways and Canals, later transferring to the engineering staff of the Soulanges canal. On its completion in 1903 he was appointed engineer in charge of the Port Colborne improvements, remaining there until 1906 when he became superintending engineer of the Trent Canal. From 1919 until he retired in 1934 Mr. Grant was responsible for the construction of the Welland Ship Canal. He assisted in the formation of the Niagara Peninsula Branch in 1919, served on Council as vice-president in 1928-1929 and in 1934 was the recipient of the Sir John Kennedy Medal.

Sam Graham Porter (1875), manager of the Department of Natural Resources of the Canadian Pacific Railway Company, Calgary, was born at Kyle, Texas, graduated from Baylor University, then from the Massachusetts Institute of Technology with the degree of S.B. in 1903. He began his career in the United States Recla-

Sam Graham Porter, S.B., M.A.
President, 1931

mation Service, and after several engineering appointments came to Canada in 1913, entering the Dominion Government service and becoming inspecting engineer in the Irrigation Office of the Department of the Interior at Calgary; later assistant chief engineer and acting commissioner of irrigation. He left the Civil Service in 1918 and joined the Canadian Pacific Railway, becoming superintendent of operation and maintenance of the southern section of the company's irrigation system. Mr. Porter organized the Lethbridge Branch in 1921, served on Council in 1921-1923, and was a vice-president in 1927-1928.

Charles Camsell (1876), geologist, mining engineer and explorer, was born at Fort Liard, N.W.T., and graduated from the University of Manitoba in 1894, later taking post-graduate courses at Queen's University, Harvard University and the Massachusetts Institute of Technology. From 1894 until his appointment as Deputy Minister of Mines in 1920, Dr. Camsell was engaged in the study of geological data and exploration. He has served as chairman of the Dominion Fuel Board, member of the National Research Council, and chairman of the Canadian National Committee of the World Power Conference. His honours include the degrees of LL.D. from Queen's Uni-

versity and the University of Alberta; his achievements as an explorer in Northern Canada merited the award of the Murchison Grant by the Royal Geographical Society; in 1931 the Institution of Mining and Metallurgy, London, presented him with its gold medal, and he was president of the Royal Society of Canada in 1930. Dr. Camsell was a member of the Council of The Institute in 1929 and 1930.

Olivier Odilon Lefebvre (1879), electrical and hydraulic engineer, was born in Bagot County, Que., and educated at the Ecole Polytechnique, Montreal, graduating in 1902. Entering the laboratories of the Department of Public Works, he afterwards became assistant to the Ottawa district engineer, and in 1912 was sent to Vancouver to survey Burrard Inlet and False Creek. He next became chief engineer of the Quebec Streams Commission, which office he retained until 1935 when he was appointed vice-chairman of the Quebec Electricity Commission. Dr. Lefebvre was responsible for projects such as the Gouin dam, the Lake Kenogami dam and the Mercier reservoir, all being designed and constructed under his supervision. In 1929 he received the Honorary Degree of Doctor of Science from the University of Montreal.

Frederick Perry Shearwood (1866), chief engineer of the Dominion Bridge Company, was born in London, England, and received his education by private tuition, proceeding in 1884 to Brazil, where he entered the service of the Sao Paulo Railway. After three years he came to Canada, and starting as a junior in the engineering department of the Dominion Bridge Company subsequently held the appointments of designing engineer and assistant chief engineer, until in 1921 he received his present appointment. A list of the important structures for whose design or erection Mr. Shearwood has been largely responsible, would be a list of the important work carried out by this company during the last thirty years. He served on Council in 1909 and in 1921-1922, as a vice-president and chairman of the Finance Committee in 1923-1925, and in 1926 as Treasurer.

Frederick Arthur Gaby (1878), hydro-electric and industrial engineer, was born at Richmond Hill, Ont., and graduated from the University of Toronto in 1903. First employed with the Canadian General Electric Co. and the Toronto-Niagara Co., he then went to the City of Winnipeg power plant at Pointe du Bois. In 1907 Dr. Gaby joined the Hydro-Electric Power Commission of Ontario, becoming chief engineer of the Commission in 1912 and later acting as chief executive officer. In 1934 he became consulting engineer with Noranda Mines Limited, then assistant to the president of the Canadian Pacific Railway Company, and is now executive vice-president of the British American Oil Company. He received the degree of D.Sc. from the University of Toronto in 1924 and is a member of many national and international societies.

Ernest Albert Cleveland (1874), Chief Commissioner of the Greater Vancouver Water District and Chairman of the Vancouver and Districts Joint Sewerage and Drainage Board, was born in New Brunswick. He became an articled pupil with Williams Brothers and Dawson in British Columbia, and in 1896 received his commissions as British Columbia Land Surveyor and Dominion Land Surveyor. He devoted some time to engineering study in Seattle and at the University of Washington, and in 1904 commenced private practice, subsequently becoming Comptroller of Water Rights for the Province of British Columbia, and consulting engineer to the Department of Lands. In 1926 he was appointed to the offices he now holds. He received the degree of LL.D. from the University of British Columbia in 1936. Dr. Cleveland was a member of The Institute Council in 1927, and chairman of the local advisory committee for The Institute's Western Professional Meeting in Vancouver in 1934.

# THE SEMICENTENNIAL PAPERS

## FIFTY YEARS OF CANADIAN ACHIEVEMENT IN ENGINEERING AND INDUSTRY

---

IN PLANNING the Semicentennial Celebrations of the Engineering Institute of Canada it was felt that the occasion might well be marked by a series of articles by members of the Institute, each dealing with the work accomplished in some one branch of engineering or industrial activity in Canada during the period which has seen the Institute's development.

The seventeen papers which follow have been written with the view of carrying out this idea. The Semicentennial Committee desires to express gratitude to the authors who have so generously responded to the committee's request and have given so freely of their time and energy in the preparation of these papers.

Besides their value as a record of achievement, the articles illustrate forcibly the many sided character of the engineer's work in Canada. Collectively they also give a general picture of the remarkable technical developments, which, during the past fifty years, have accompanied Canada's progress towards maturity as a nation.

VIAU BRIDGE, over the River des Prairies, Montreal, Que., opened November 1st, 1930. Total length 1,600 feet and width 57 feet; length of main arches: two 202 feet, two 212 feet, and one 222 feet; total length of approaches 550 feet.

# Public Works

## Under the Department of Public Works, Ottawa

*K. M. Cameron, M.E.I.C.,*
*Chief Engineer, Department of Public Works, Ottawa, Ont.*

Under the Union in 1841 of the provinces of Upper and Lower Canada the public works were carried on by Commissioners of Public Works who had charge of the canals, the works in navigable waters, the harbours, the lighthouses, beacons and buoys, the slides and booms, the roads and bridges, the public buildings and the provincial vessels. Prior to the Confederation of the provinces of Ontario, Quebec, New Brunswick and Nova Scotia in 1867, this body had disbursed on these public works some twenty million dollars.

The River St. Lawrence was usable for the largest vessels then afloat up to Quebec, but beyond that the draft of vessels was limited to 10 to 12 ft. Immediately after the union of Upper and Lower Canada, D. Thompson, civil engineer, was commissioned to examine the channel and following his report favouring a 16-ft. channel, work was commenced in 1844. Later, operations continued under the Harbour Commissioners of Montreal, the project of a 20-ft. channel being completed in 1865.

Prior to the Union in 1841, and from the Union to Confederation in 1867, the provinces had necessarily supplemented the original transportation routes, which were by the waterways, with roads to serve the needs for more rapid means of travel and communication.

The Confederation pact gave the roads, except military roads, and bridges to the provinces, and Dominion Government expenditures thereon since then have been as subsidy for road purposes paid to the provinces.

On the first day of July, 1867, the "British North America Act" came into force. An "Act Respecting the Public Works of Canada," 31 Vict., Chap. 12, was passed on December 21st, 1867, and the Public Works Department came into being, under the direction of the Minister, the Honourable William McDougall.

In addition to continuing the administration of the works which had been under the charge of the Commissioners of Public Works of the United Provinces, there were added to his care the canals, the works in navigable rivers, and the railways of the provinces of Nova Scotia and New Brunswick. The construction of lighthouses was continued under the Department of Public Works but the management of these, as of the provincial vessels, was transferred to the Department of Marine and Fisheries. The greater part of the roads and bridges and certain public buildings was transferred to the local governments, but the construction of military and interprovincial highways, and of classes of public buildings appropriate to the dominion service was reserved to the Dominion, and administered by the Public Works Department. The main additional responsibilities added were the Nova Scotia and the New Brunswick railways.

Fig. 1—The Parliament Buildings, Ottawa.

Over the period of twelve years following Confederation in 1867, several undertakings of note were accomplished. The Intercolonial Railway was constructed and opened to traffic on July 1st, 1876; the Prince Edward Island Railway was completed and opened to traffic on July 1st, 1875, and as a result of the surveys carried out of the route of a railway to be built on Canadian territory and terminating at the Pacific ocean, construction was begun in 1875 of what is now known as the Canadian Pacific Railway.

When in 1879 the Department of Public Works was divided into two departments, to the new Department of Railways and Canals were transferred the railway and the canal activities of the Department of Public Works, and under the continuing Public Works Department were the public buildings, the ports, harbours, piers, dredging, slides and booms, telegraphs, and military and interprovincial roads.

During this period, the channel of the River St. Lawrence to Montreal, which had been deepened to 20 ft. at low water with a width of 300 ft., was further improved. The Minister of Public Works entrusted this work to the Harbour Commissioners of Montreal, constituted in 1830. That body continued the deepening to 25 ft., under their chief engineer, the late Sir John Kennedy.

At Quebec, two works of major importance were carried out under the immediate direction of the Harbour Commissioners, reporting to the Minister of Public Works. The Lorne graving dock at Levis, 500 ft. long and with a depth of 25.5 ft. was constructed, funds being found by grants from the Dominion and Imperial Governments supplemented by an amount raised by the Harbour Commission. The Princess Louise wet dock and tidal harbour, at the junction of the River St. Charles and the St. Lawrence, had been decided on in 1874, and by 1882 the works enclosing the basins had largely been completed.

Noteworthy in their way are the reports by Sandford Fleming, engineer-in-chief, Canadian Pacific Railway, to the Minister of Public Works under date of April 5th, 1879; of James B. Eads, consulting engineer, of Mississippi river fame, to the Minister on Toronto Harbour, under date of March 4th, 1882; and that of the Montreal Flood Commission in 1888.[1]

The early development of the western provinces in 1882 may be judged from the extent of work carried out to that date. The Assiniboine river had been improved for navigation by the removal of boulders and the construction of wing dams, and similarly, the Red river from the United States Boundary to Lake Winnipeg.

In British Columbia, admitted to Confederation in 1871, there was undertaken the construction of a graving dock at Esquimalt, very similar to that constructed at Levis. Harbour improvements in that province up to 1882 were confined to the Skeena, the Naas, the Cowichan, the Courtenay and the Fraser rivers, and to Victoria harbour.

At the close of 1888 the project of deepening the ship channel to Montreal to 27½ ft. had been completed. At that juncture the responsibility for the channel was assumed by the Dominion from the Montreal Harbour Commissioners and successive steps in its further improvement were under the Public Works Department, under which the 27½-ft. channel was maintained as to depth, widened and straightened. In 1899 the project of a 29-ft. depth of channel, 400 to 500 ft. wide, was commenced. This had resulted from the low water years of 1895 and 1897 establishing that the 27½-ft. channel had a dependable depth of only 25 ft. 10 in. At the end of the century considerable attention was being given by the Department to the question of ice breaking in the channel.

The graving dock at Kingston, on Lake Ontario, was completed for operation in 1891, providing a repair facility for the increasing number of vessels trading from the Welland canal through Lake Ontario and the St. Lawrence river and its canal system to Montreal.

The discovery of gold in Yukon territory was followed by a rush of people to that country, and the late Louis Coste, then chief engineer, was sent by the Department, in March, 1898, to study the best means of improving the water courses of the district. Navigation by the water route from White Horse to Dawson City was the only (and still remains the principal) means of access.

The years immediately following were spent in effecting improvements to the route, and in the construction of lines of telegraphic communication with the outside, both of which activities still continue.

[1]Department of Public Works report 1889-90.

### The Twentieth Century

At the beginning of the century it is recorded that over eight hundred works of harbours and rivers, and nearly two hundred and fifty buildings were under direction of the Department; in addition there were 3,666 miles of telegraph land lines and 208 miles of submarine cables, with one hundred and eighty-five offices handling 76,410 messages in a year.

In the Maritime provinces the requirements of navigation for terminal facilities at the major ports were a function of the railways, principally the Intercolonial, the activities of the Department being devoted to the smaller ports, which, however, are of great importance to the population and the industries of that region.

While a similar expansion in the provision of small port facilities on the St. Lawrence and its main tributaries in Quebec was proceeding, the major activities were the completion of the newly adopted depth of 30 ft. at 1897 low water, and 450 ft. width for the channel to Montreal, and the hydrographic survey associated with that waterway.

The eastward movement of the western grain crop had become of moment, elevators being erected at Goderich on Lake Huron, Collingwood, Meaford, Midland and Depot Harbour on Georgian Bay, and at Coteau Landing on the St. Lawrence. These, built by private interests, had necessitated the deepening of the harbours to 20 ft., and the extension of the harbour works. Increased harbour area at Port Colborne, the Lake Erie end of the Welland canal was provided by the construction of a breakwater to enclose a sheltered area of some 438 acres.

The importance of lumbering and fishing on Lake Winnipeg resulted in the construction of harbours at Hnausa and Gimli; and plans were in preparation for the dam at St. Andrews rapids to bring navigation to Winnipeg on the Red river.

The Columbia and the Kootenay rivers were in demand as routes into the interior of Southern British Columbia, where settlement and mining development were active, and works were carried out to facilitate this commerce.

The Fraser river had from early days provided the route into the interior from the coast, and the Royal Engineers had been the first to plan and execute improvements, not only to the river channel but by the construction of the famous Cariboo Trail. The lower reach of the river, from the Gulf of Georgia to New Westminster had been

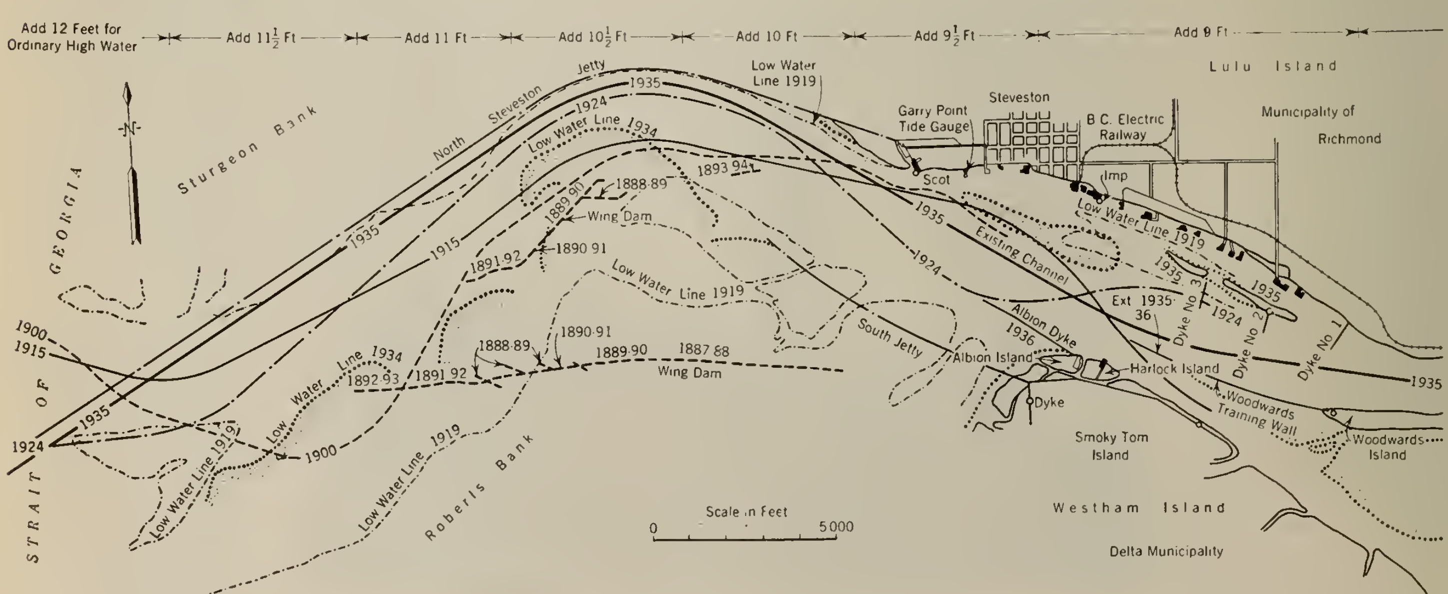

Fig. 2—The Sandheads, Fraser River, B.C.

used with difficulty by ocean vessels, and these difficulties were more pronounced as the size of ships increased with expanding trade.

This development of a stable channel in a river subject to heavy variation in flow, and meandering across some five miles of tidal flats subject to the action of an ordinary tidal range of 12 ft., has been difficult. After several unsuccessful attempts at stabilizing the channel, two reaction jetties were proposed, in 1910, springing from the mainland and extending seawards to the edge of the bank of the delta. A commencement on the north jetty was made, but for some years after the first section was built divided opinion on the future course hampered progress. Later, a plan was developed by a Board of Engineers in the Department's service, who brought to the task their experience of similar though lesser problems of like nature. Valuable geological studies were made by W. A. Johnston,* of the Geological Survey of Canada.

The work on the Fraser estuary has since then followed the plan then adopted, and a channel stable in depth and direction has resulted. As will be seen from Fig. 2, the north jetty is 25,800 ft. or 4.88 miles long, and so far, as practically a single reaction jetty, has functioned with satisfactory results. This is cited as the outstanding instance of this type of problem in Canada.

In the opening decade of the century, with a remarkable increase in population, the definite establishment of the west high among the world's producers of grain, the development of manufacturing in Canada, and the confidence in Canada's future so substantially expressed by the inflow of capital from Great Britain, an added impetus was given to the provision of adequate public works to take care of the situation.

The western railway field was served by the Canadian Pacific from 1885, but its virtual monopoly of transportation of that area was invaded by the construction of the Grand Trunk Pacific from Lake Superior to the Pacific ocean. The National Transcontinental, as a rail route to facilitate the development of Northern Ontario and Quebec and give access to a winter port on Canada's Atlantic seaboard, and the Canadian Northern, virtually a third transcontinental line, were also constructed.

The development of the Lakehead harbours on Lake Superior at Fort William and Port Arthur for transshipment of eastbound grain and reception and dispatch of westbound coal, iron, ore and manufactured products, and of the harbour of Saint John, N.B., as a winter port were the natural outcome of the railway expansion.

### Saskatchewan and Red Rivers

Notwithstanding the expansion of rail facilities in the prairie provinces, the great use and convenience the waterways had been in opening up that area led to an examination being made of the possibility of utilizing the Saskatchewan river, Lake Winnipeg and the Red river as a route for the economical handling of freight. Very complete surveys of the route from Lake Winnipeg to Edmonton, covering a distance of 941 miles, carried out from 1910 to 1915 under the Public Works Department did not indicate that the desired results could be obtained, and the project, so far as the Saskatchewan river is concerned, has remained in abeyance.

The Red river-Lake Winnipeg route into the North was however improved by the construction in 1910 of a curtain dam of the Caméré type at St. Andrews, which raises the level of the Red river by about 20 ft. at its location, some 20 miles downstream or north of Winnipeg, and by about 6 ft. at Winnipeg. It is the first of the kind to be constructed on either of the American continents, and the type was chosen so that the permanent obstruction to the flow of ice and water would be a minimum. A navigation lock permits the passage of vessels past the dam, and the supporting structure of the movable dam carries a highway floor.[2]

*His results are to be found in Memoirs 125 and 135 of the Geological Survey of Canada.

### The Georgian Bay Ship Canal

The route from Montreal to the west from earliest days followed the Ottawa river and the Mattawa to the height of land, and then Lake Nipissing and the French river to Georgian Bay. As commercial development progressed the possibilities of this as an all Canadian route for water transportation were canvassed, and several proposals were considered during the period from 1857 to 1900.[3]

The Government, in 1904, charged the Minister of Public Works with the carrying out of an examination of the route, the survey to be of such a character "that there could be projected on the plans the best location possible for a canal at least 22 ft. in depth, with a bottom width of 300 ft., from which profiles could be drawn and a correct estimate made of the amount and character of material in excavation and embankment, nature of various foundations, and final design of locks, dams, regulating works and other structures; also the right of way and definition of flooded areas."[4]

The surveys and examinations, designs, calculations and all pertinent engineering studies were under the direction of the late Arthur St. Laurent, past president of The Engineering Institute of Canada, as engineer in charge, reporting to the chief engineer of the Department, with C. R. Coutlee and S. J. Chapleau as district engineers.

The extent of the project may be gauged from the fact that the length of the route investigated, from Bout de l'Ile, at the foot of Montreal island, to the western end, the mouth of the French river at Georgian Bay, is 451 miles.

The report of the Board of Engineers, dated January 20th, 1909, advised the Minister of Public Works that a 22-ft. waterway for the largest lake boats (600 ft. by 60 ft. by 20 ft. draft) could be established for $100,000,000, with an annual maintenance cost of $900,000. It submitted plans for a canal with 27 locks varying from 5 ft. to 50 ft. lift, connecting 23 navigable pools of various lengths; the locks to be 650 ft. long, 65 ft. wide, and 22 ft. deep.

The project has not been carried out, the Government in 1912 deciding to proceed with the Welland ship canal for deep draft vessels, that work being opened to traffic in 1930.

The Georgian Bay ship canal survey, however, resulted in a very complete knowledge of the water power resources of the Ottawa river and its principal tributaries being obtained, the computed amount of power available being 1,000,000 horsepower.

### Ottawa River Storage

At the Chaudiere falls section of the Ottawa river, between Ottawa and Hull, water power leases had been granted under the Government of Canada prior to Confederation; at Confederation these fell to the lot of the Dominion to administer. In subsequent years difficulties arose over apportionment of the water available; to clarify the situation it was arranged that the lessees would build a compensating dam above the Chaudiere falls, and that the Government would construct storage and regulating dams, at the foot of Lake Timiskaming, at the foot of Quinze lake, both on the upper Ottawa, and at the outlets of Kipawa lake.[5]

On the Georgian Bay slope Lake Nipissing drains out

[2]Engineering Record, March 26th, 1910.
Engineering News, October 6th, 1910.
[3]Appendix 70, Public Works report 1867-1882.
[4]Georgian Bay Ship Canal Survey report, 1909.
[5]Ottawa River Storage report, Sessional Paper 19a, of 1911; 19 of 1912; and 19 of 1913.

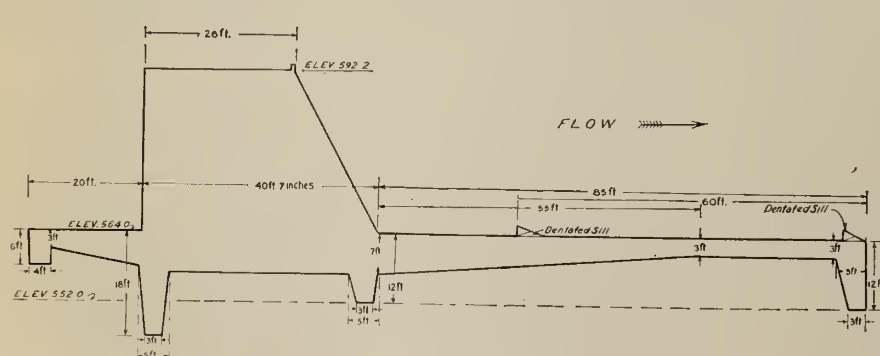
through the French river, and to benefit navigation, at the same time to do away with the annual cost of dredging in channels and at wharves, dams with Stoney sluices were constructed at the Chaudiere rapids, in the main outlet, and dams with stoplogs in the other, the outlet of the lake into the French river. The regulation of Lake Nipissing in this manner was an integral part of the Georgian Bay ship canal proposal above referred to.

The foundation conditions at the only available site for the regulating dam at the foot of Lake Timiskaming were bad, the river there following a deep cleft in the country rock, probably a fault, which had been filled with boulders of great size, and sand. Considering the class of equipment then available for construction, and the comparative inaccessibility of the site, the dam as then built, of stop log sluices on a wide concrete foundation and founded on material of the nature mentioned, was a credit to its builders. Subsequently the action of the discharge at high flows, which reaches 110,000 c.f.s., scoured out the foundation on which the concrete mattress had been laid, and in 1931 it became necessary to reconstruct the Quebec channel dam. A section of the dam as reconstructed is shown in Fig. 3; it incorporates the patented "dentated sills" of Dr. Rehbock, to overcome the scouring action, has a much heavier section, and is functioning satisfactorily.

An unexpected situation developed during the building of the Quinze and the Kipawa lake dams. Concrete was used in their construction, and all usual precautions were used to check the aggregates. When the works were nearly completed it was seen that the concrete had not developed the strength expected, and examination showed the cause to be the presence of a transparent coating of organic matter on the particles of the aggregate used. This is insoluble in water, cannot be detected by the eye, but can be removed by a 3 per cent solution of commercial caustic soda. Its presence is to be suspected in deposits of a siliceous nature, but will not be found where lime is present. That part of the structure built with aggregates so treated is sound, but the greater part built before the trouble was detected has given trouble from disintegration, and the Quinze dam will require replacement from this cause very shortly. As far as known to the author, this circumstance had not previously been experienced elsewhere.

### The Grain Export Trade

The grain trade of Canada has played an outstanding part in the development of the country. The movement of this important bulk commodity from the west has been largely by water and the provision of the necessary facilities has largely devolved on the Department of Public Works.



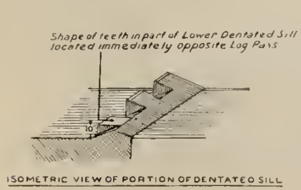


**Fig. 3—Cross Section of Dam, Temiskaming, Que.**

At Kingston, at the foot of Lake Ontario, the cargoes of lake steamers, limited in draft to 14 ft. by the Welland canal, used to be transferred to a barge fleet for passage to Montreal. In later years canal-size steamers went through to Montreal; since the completion of the Welland ship canal, upper lake freighters have access to Lake Ontario, and Kingston has again become, with Port Colborne, Buffalo and Prescott, an important grain transfer point.

The first shipment of grain from the Lakehead was in 1883. Ten thousand bushels were shipped on the steam barge *Erin*, the grain being loaded by wheelbarrows and horse carts. The schooner *Sligo*, in 1884, carried the first cargo of grain handled through a Lakehead elevator.

The elevator storage capacity at Port Arthur and Fort William has grown from one elevator of 350,000 bushels capacity in 1884, to 30 elevators in 1937, with a total capacity of 92,680,000 bushels. The grain shipped at the Lakehead during the navigation season of 1936 was 137,185,000 bushels.

## CANADIAN HARBOURS

### The Lakehead Harbours

The development of the harbours of Port Arthur and Fort William is indicated by Fig. 4. At Port Arthur the harbour has been reclaimed from the open lake by the construction of breakwaters, with the harbour area improved for ships by dredging the sheltered area thus created.[6] At Fort William, the development has followed the water course of the Kaministiquia river, which together with its branch outlet, the "Mission," have been widened to 600 ft. and deepened to 25 ft. The "McKellar" outlet has been similarly widened and deepened but the improvement extends to the outlet only, and not into the lake.

In the development to date some 49,000,000 cubic yards have been moved by dredging at prices prevailing from 9 cents per cubic yard, scow measurement, in 1907, to about 18 cents per cubic yard, situ measurement, recently; and in the rubble mound breakwater extending southwards 12,700 ft. from Bare Point at Port Arthur some 3,023,376 tons of rock have been placed as the work has progressed from 1911 to date.

### The Pacific Outlet

The first, experimental, shipment of 100,000 bushels of grain from Vancouver to Europe in 1917 demonstrating the feasibility of the Panama canal route for grain shipments, has led to increasing amounts being forwarded, and to the establishment of elevator and other facilities at Vancouver, New Westminster and Prince Rupert.

Vancouver has now a combined elevator storage capacity of 17,843,000 bushels, and shipments reached 96,869,841 bushels of all grains, in the 1932-1933 crop year.

### The Atlantic Winter Outlet

With the completion of the National Transcontinental Railway, the desire for Canadian winter ports on the Atlantic seaboard was met, in part, by the construction, under the Government Railways, of the ocean terminals at Halifax. The existence and suitability of St. John, N.B., as a winter port was recognized in the undertaking of extensive deep water piers, improvement of the entrance channel by dredging, and the construction of a graving dock, capable of accommodating the largest ships then in existence or contemplated. The wharves then existing at

[6] Breakwater Construction in Port Arthur Harbour, by F. Y. Harcourt, M.E.I.C., in The Engineering Journal, April, 1931.

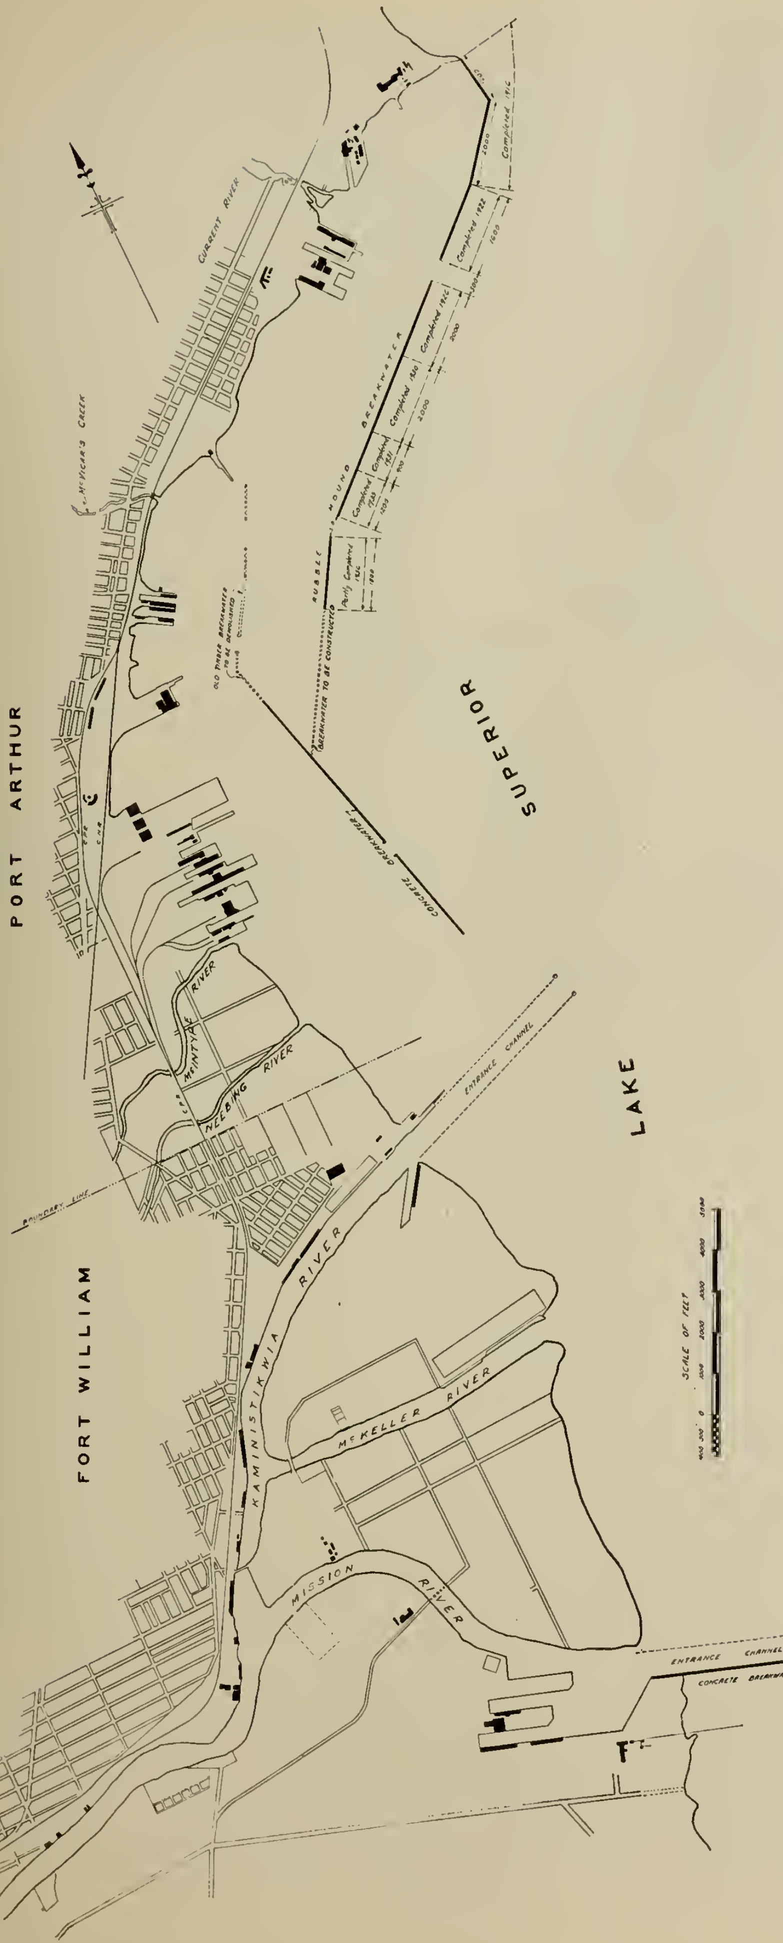

Fig. 4—Harbour at Fort William and Port Arthur, Ont., 1937.

St. John were for the greater part the property of the city, the Intercolonial Railways having provided one structure. This programme was carried out under the Department of Public Works, and, until the formation of the St. John Harbour Commission, in 1928, all Dominion Government commitments in that harbour were entrusted to the Department.

### Vancouver

On the Pacific coast the port of Vancouver served as Canada's sole outlet of major importance until the terminus of the Grand Trunk Pacific Railway was established at Prince Rupert. The importance of fostering trade with the Orient was recognized by the Government undertaking the improvement, by dredging, of the entrance to Vancouver. A large bucket ladder dredge was built in Scotland, and was employed from 1910 to 1918, in deepening to 35 ft. at low tide, from a natural controlling depth of 30 ft., and in widening to 1,200 ft. the channel entrance to the harbour; in this operation some 4,100,000 cubic yards were removed. The Department also carried out the construction of the Lapointe pier, a timber-crib structure[7] protected against the ravages of marine insects by a reinforced concrete sheathing, 18 in. thick.

### Victoria

The port of Victoria, being a port of call for the trans-Pacific liners, as well as for other ocean vessels, had been one of the earliest ports to be improved, the colonial government having commenced its development prior to the entry of the province into Confederation. The Dominion continued the improvement, which for many years consisted in deepening the harbour by dredging. To extend the deep water wharf accommodation, all of which was privately owned, the Department, in the period 1913 to 1916, constructed a rubble mound breakwater as a protection to vessels lying at the Ogden Point deep water piers, also undertaken by the Department, now the site of the grain elevator at that port, and operated by the Canadian National Railways.

### Montreal, and the Ship Channel

The improvement of the St. Lawrence River ship channel continued under the Department of Public Works until 1904, when those activities were transferred to the Marine Department, now the Department of Transport. During this period the Department constructed the Jacques-Cartier pier, completed in 1906, and a grain elevator, with wharf at section 15.

The problems of meeting the requirements for transportation facilities in Canada were very pressing; a Royal Commission on Transportation was created in 1902, and submitted its Report to the Minister in 1904-05.[8] The report presents a picture of conditions as at that time, and reflects the trend of thought on this important subject.

[7]Described by W. G. Swan in another paper of this series.

[8]Report of Royal Commission on Transportation, Sessional Paper No. 19a.

Fig. 5—Harbour at Toronto, Ont. (Heavy lines indicate work done by Public Works Dept.)

### Quebec

In Quebec harbour development of shipping requirements was met by the construction of a wharf at Pointe à Carcy, 1,460 ft. long, with an available depth of 42 ft. at low tide. This work, commenced in 1902, was carried out in five sections and completed in 1911.

### Three Rivers

The increasing importance of Three Rivers as a manufacturing centre, and as a point for trans-shipment to and from the St. Maurice valley, was met by the construction, completed in 1907, of a wharf on the St. Lawrence river with a length of 1,968 ft., and a depth at low water to accommodate ocean vessels.

The extensive territory in Quebec, south of the St. Lawrence river and dependent on Quebec harbour as a point of transfer between ship and shore was accommodated by a deep water wharf, 903 ft. long; the needs of the territory have now outgrown the capacity of the wharf and a further deep water wharf is presently under construction by the Department.

### Toronto

The industrial possibilities of Toronto harbour being recognized by the city, a scheme for improvement of the eastern portion to provide sites for industrial purposes was drawn up. Provision was made, when the Department reconstructed the western entrance to this harbour, in 1908 to 1912, that ample depth could be made available for larger ships. This was done in 1929, to coincide with the opening of the Welland ship canal, a depth of 27 ft. being provided.

Following the reconstitution of the Toronto Harbour Commission the city undertook and has carried out under that body an effective scheme of harbour improvement, the Commission developing a very complete system of wharfage on the harbour. The Dominion Government, under the Department of Public Works undertook to develop the eastern or Ashbridges Bay section of the harbour by the construction of a wharfage system, and dredging. Work continued from 1912 to 1926, and involved the building of some 16,705 lineal feet of revetment bordering a ship channel and turning basin and providing a large area with the advantages of both rail and water transportation. The Dominion Government's contribution included also a breakwater, 18,600 ft. in length from the western entrance of the harbour to the Humber river.

### Welland Ship Canal

The subsequent completion of the Welland ship canal, and increased trade by water has resulted in these facilities being fully utilized. In 1934 to 1936, under the Public Works Construction Act the Dominion constructed the Marginal Way dock, and completed section 10 of the original development (Fig. 5).

Burlington Bay, on which is situated the important manufacturing city of Hamilton, is separated from Lake Ontario by Burlington Beach, through which the Government has maintained a channel for over 100 years. This channel was deepened and widened to coincide with the Welland ship canal opening, provision being made for an ultimate depth of 27 ft. Highway traffic across the canal, probably of higher intensity than on any other route in Canada, uses the double leaf bascule bridge which replaced the earlier bridges, they in turn succeeding the original ferry.

As the completion of the Welland ship canal would allow vessels of Upper Lake capacities access to Lake Ontario and transfer their eastern transfer terminus from Port Colborne, on Lake Erie to a port on Lake Ontario level, the Department selected Prescott as the most logical place of trans-shipment and erected there a grain elevator of 5,500,000 bushels capacity, equipped for transfer of grain from Upper Lake to canal boat, or to rail. The channel from Lake Ontario to Prescott was improved to St. Lawrence Deep Waterway dimensions as a joint undertaking with the United States, each country carrying out the improvement in its own territorial waters.

The instances cited above are from the larger and better known harbours. With the development of the larger national harbours a desire developed at each centre for a means whereby those locally interested might share in the plans for its harbour, and Harbour Commissions were provided for by legislation, the financing for capital expenditures being by loans from the Dominion. In this way the activities of the Department of Public Works largely ceased at these places, except for improvement or maintenance of main entrances thereto, by breakwaters, channel piers, or dredging. By recent legislation, after the report of his study of conditions made by Sir Alexander Gibb, control of the harbours formerly financed by Dominion loans has been vested in the National Harbours Board under the Minister of Transport.

### Harbour and River Development

The requirements of the people of Canada in carrying on their business where water transportation is a factor have, however, been continuously met under the Department of Public Works, the growth in this direction being indicated in the following table, and in the graph of yearly expenditures under the Department (Fig. 6).

| | |
|---|---|
| 1882 | 199 works |
| 1892 | 387 works |
| 1902 | 571 works |
| 1912 | 1,244 works |
| 1925 | 2,221 works active |
| | 28 works abandoned |
| 1932 | 2,976 works active |
| | 281 works abandoned |
| 1934 | 3,164 works active |
| | 327 works abandoned |

Since the general conception of the prairie provinces is that of a vast field of grain it is worth noting that in 1934 there were sixty-five active works under the Harbours and Rivers division, and that eleven works of this category previously carried out had been abandoned.

### FISHERIES

The extent of the fishery resources of Canada may be judged from the facts that from Grand Manan to Labrador is a coast line of over 5,000 miles, that the Gulf of St. Lawrence is over 80,000 square miles, and the Bay of Fundy over 8,000 square miles in area, and with other waters comprise an area of fully 200,000 square miles of fishing grounds. The area of the Great Lakes in Canadian territory is some 34,000 square miles in extent; in the prairie provinces, Lakes Winnipeg, Winnipegosis, Manitoba, and Athabasca, have a combined area of 16,359 square miles, and Great Bear and Great Slave lakes, in the North West Territories, add 22,830 square miles to the list. The coast line of British Columbia is 7,180 miles in length.

In 1887 the fish catch was valued at $18,386,103, of which the prairie provinces contributed $129,084, and British Columbia $1,974,887; in 1935 the value was $34,427,864, British Columbia's fisheries accounting for $15,169,529, and the prairie provinces and Yukon for $1,756,860. In the latter year the invested capital was $43,617,888, and 82,918 persons were employed.

The value of the products of this industry exported in 1935 was $24,859,486, shipments going to 87 countries. This is exceeded only by the export fisheries trades of the United Kingdom and Norway.

From the nature of their calling fishermen are generally best served by harbours of moderate dimensions situated within reasonable distance of the fishing grounds and their homes.

### Harbour Development Problems

The engineering problems in the development of such harbours arise largely from the varying local conditions of the nature of the coast, exposure to storms, tidal or other current direction and strength, the variation in level, and winter weather conditions, especially the formation of ice, and mass ice movement. The local availability of construction materials, the prevalence, or otherwise, of teredo or limnoria in sea water, and the probable length of life to be required from the works must also be considered.

It is from the experience gained from observation during the development of the smaller harbours that there has been possible the progress made to the present day in other deep sea harbours and harbour works.

### SECONDARY HARBOURS

While we think of Halifax and Saint John as Canada's eastern winter ports, of Montreal and Quebec as eastern summer ports, and of Vancouver, Victoria and Prince Rupert as the western outlets, these are really the seaboard harbours through which our foreign commerce flows. In the collection of products for export, and in the distribution of imports from abroad, the lesser or secondary harbours play possibly an even greater part in the much larger internal trade of the country.

The development and maintenance of these secondary harbours on the sea coasts and on the shores of the Great Lakes, has been one of the main responsibilities of the Department. Ports such as Nanaimo, Powell river, Ocean Falls or Port Alberni on the Pacific coast; Liverpool, Hantsport, Bathurst or Rimouski on the Atlantic side, are only a few examples. On the Great Lakes, Cobourg and Oshawa on Lake Ontario; Port Stanley and Rondeau on Lake Erie; Goderich and Midland on Lake Huron, may also be mentioned.

During the fiscal year 1935-36 harbour and river works under the Department were completed at over seventy of these secondary points in all parts of Canada.

### Physical Characteristics

The factors influencing the location and development of harbours in Canada are many and diversified. On the Bay of Fundy the tides have a range of from 15 ft. at Yarmouth, through 27¼ ft. at Saint John, to 45½ ft. at Hopewell Cape, and 51½ ft. at Burntcoat Head. Vessels berth at high tide and lie aground during the lower portion of the tidal range, so that gridirons have been developed, in which vessels may ground much as if they were in dry-dock. These can be seen at Port Williams, an apple shipment port for the Cornwallis valley, and at Windsor, a lumber and gypsum shipping port.

**Fig. 6—Expenditures under Public Works Department 1866-1936.**

The Atlantic coast of Nova Scotia is quite different, being deeply indented and generally rocky. Harbours on this coast are generously provided by nature. The facilities provided for fishing and lumbering industries take the form of channel improvements by dredging, and the construction of piers and breakwaters. Yarmouth harbour has been greatly improved by dredging, and is the port through which much of the trade between Nova Scotia and Boston and New York is carried. The Port of Lunenburg, the centre of the salt bank fishing industry, has been similarly improved.

Conditions on the north coast of New Brunswick are largely similar to those on Prince Edward island and the Magdalen islands. The tidal range has lessened, to between 3 and 5 ft., and the shipping season is curtailed by ice in winter, whereas the outer part of the Bay of Fundy and the eastern coast of Nova Scotia are practically ice free. Characteristic of this coast, as regards harbour work, is that wide mouthed and shallow bays have been formed, generally negotiable by only the smaller classes of fishing boats. It is under these conditions that the ingenuity of the engineer finds an opportunity of trying to form a stable harbour in the midst of naturally unstable local conditions.

On the Quebec coast of the Baie des Chaleurs, westward of Gaspé harbour, the shore is generally abrupt, and of limestone or conglomerate, so that it is mainly where the rivers debouch that harbours have become established. At some points currents have moved eroded material along shore, resulting in the formation of the interesting lagoons or "barachois" found at Carleton, at Paspebiac, and at New Carlisle. That at Paspebiac has a frontage at the shore line of 6,800 ft. and projects 4,800 ft. seawards (Fig. 7). Similar conditions account for the formation of Point Pelee, on the north shore of Lake Erie.

Of another type is the bar, or island, which has been formed by the action of currents on eroded material from the Scarboro bluffs, and which encloses Toronto harbour (Fig. 5).

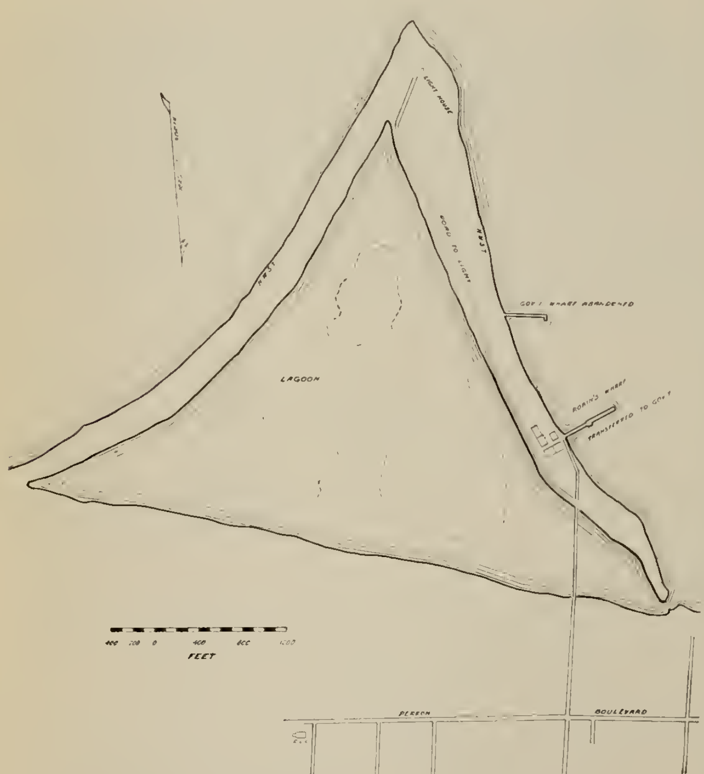

Fig. 7—Barachois at Paspebiac, Que.

If harbour accommodation is not available within the sheltered area at the mouth of a river, or that provided by some natural feature, breakwaters must be used. The rubble mound type of breakwater has been used at Port Arthur, Saint John, Victoria and elsewhere.

Stone ballasted timber-crib construction may be employed where the breakwater is to be used also as a landing wharf. Reinforced concrete cribs have been used successfully, the earliest of the type in Canada being that built in 1912, at Goderich on Lake Huron. Stable foundation conditions are necessary where that type is used, an advantage of the timber-crib or of the rubble mound types types being the flexibility which allows them to conform, with minimum subsequent repair expense, to an unstable foundation.

The most noticeable difference between the types of most harbour works on the Atlantic coast, the Great Lakes and interior lakes or waters, and those used on the Pacific arises from the absence of ice-forming winter conditions and also from the generally greater degree of shelter available on the Pacific coast. There structures are generally of timber pile construction, due to the economic accessibility of that material, although protection against teredo is necessary.

### Dredging and Dredging Plant

The steady increase in size of ships and the depth of water they require has required a great deal of dredging work by the Department. In 1892 the dredging fleet used in the improvement of Montreal harbour and the ship channel consisted of:—

Four elevator dredges,
Five tugs,
Three stone lifters,
Twelve dump scows of 80 cu. yd. capacity,
Two dump scows of 150 cu. yd. capacity,
One store ship,
One sounding scow,
Two flat scows,
Two coal barges.

At the commencement of the Great War the Department had floating plant of a value of approximately five million dollars, distributed on the Atlantic and Pacific coasts, the Great Lakes, and the interior lakes of the prairie provinces and British Columbia.

The equipment, supplemented by the use of privately owned plant used on works awarded by tender, brought about an extensive betterment in channels and harbours. All modern types of dredges, rock breakers, tugs, scows, etc. were included. The necessity for retrenchment in expenditures, together with the advanced state of the improvements at that time warranted the disposal of the major part of the fleet. Since the war the Department has maintained the more generally useful and adaptable units, and has carried out a large part of the dredging needed, by contract, after public competition.

In this way the Department, by keeping accurate record of cost of operation of its own plant, is in a position to prevent inflation of prices by private owners of plant; if necessity arises unexpectedly for dredging to be done the departmental plant can be diverted thereto without delay; if need arises for curtailment of expenditure the plant of the Department can be shut down, whereas on contract work the Department is bound to fulfil the terms of the contract. A further circumstance is that on contracts involving large quantities and extending over considerable time the contract rate cannot be altered to take advantage of any reduction in operating costs, whereas such reductions would be reflected in costs of departmental plant operations; on the other hand increases in such costs, if of any moment, may result in claims for compensation from contractors.

### PIONEER DEVELOPMENT

The development of Canada would present a vastly different picture without the adventurous, pioneering spirit which has characterized the peoples who have sought its shores. As they penetrated farther and farther into the interior their first means of transportation was by the waterways. As development continued, roads and railroads were built to provide safer and swifter transport, and the waterways became less used. But the economy of water transport remains a factor available for use as development proceeds, and to supplement other man-made means of communication and transport.
